To allow for the possibility that inputs with zero mean and unit variance are not optimal for the operations that follow instance normalization, the instance normalization operation further shifts and scales the activations using the transformation

$$y_i = \gamma \widehat{x}_i + \beta,$$

where the offset  $\beta$  and scale factor  $\gamma$  are learnable parameters that are updated during network training.

## Version History

**Introduced in R2021a**

**R2023a: Epsilon supports values less than 1e-5**

The `Epsilon` option also supports positive values less than 1e-5.

## Extended Capabilities

### **GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When at least one of the following input arguments is a `gpuArray` or a `darray` with underlying data of type `gpuArray`, this function runs on the GPU:

- `X`
- `offset`
- `scaleFactor`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

### **See Also**

# instanceNormalizationLayer

Instance normalization layer

## Description

An instance normalization layer normalizes a mini-batch of data across each channel for each observation independently. To improve the convergence of training the convolutional neural network and reduce the sensitivity to network hyperparameters, use instance normalization layers between convolutional layers and nonlinearities, such as ReLU layers.

After normalization, the layer scales the input with a learnable scale factor  $\gamma$  and shifts it by a learnable offset  $\beta$ .

## Creation

### Syntax

```
layer = instanceNormalizationLayer  
layer = instanceNormalizationLayer(Name,Value)
```

### Description

`layer = instanceNormalizationLayer` creates an instance normalization layer.

`layer = instanceNormalizationLayer(Name,Value)` creates an instance normalization layer and sets the optional `Epsilon`, “Parameters and Initialization” on page 1-1133, “Learning Rate and Regularization” on page 1-1135, and `Name` properties using one or more name-value arguments. You can specify multiple name-value arguments. Enclose each property name in quotes.

Example: `instanceNormalizationLayer('Name','instancenorm')` creates an instance normalization layer with the name 'instancenorm'

## Properties

### Instance Normalization

#### **Epsilon** — Constant to add to mini-batch variances

1e-5 (default) | positive scalar

Constant to add to the mini-batch variances, specified as a positive scalar.

The software adds this constant to the mini-batch variances before normalization to ensure numerical stability and avoid division by zero.

`Epsilon` must be greater than or equal to 1e-5.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**NumChannels — Number of input channels**

'auto' (default) | positive integer

This property is read-only.

Number of input channels, specified as one of the following:

- 'auto' — Automatically determine the number of input channels at training time.
- Positive integer — Configure the layer for the specified number of input channels. NumChannels and the number of channels in the layer input data must match. For example, if the input is an RGB image, then NumChannels must be 3. If the input is the output of a convolutional layer with 16 filters, then NumChannels must be 16.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string

**Parameters and Initialization****ScaleInitializer — Function to initialize channel scale factors**

'ones' (default) | 'narrow-normal' | function handle

Function to initialize the channel scale factors, specified as one of the following:

- 'ones' - Initialize the channel scale factors with ones.
- 'zeros' - Initialize the channel scale factors with zeros.
- 'narrow-normal' - Initialize the channel scale factors by independently sampling from a normal distribution with a mean of zero and standard deviation of 0.01.
- Function handle - Initialize the channel scale factors with a custom function. If you specify a function handle, then the function must be of the form `scale = func(sz)`, where `sz` is the size of the scale. For an example, see “Specify Custom Weight Initialization Function”.

The layer only initializes the channel scale factors when the `Scale` property is empty.

Data Types: char | string | function\_handle

**OffsetInitializer — Function to initialize channel offsets**

'zeros' (default) | 'ones' | 'narrow-normal' | function handle

Function to initialize the channel offsets, specified as one of the following:

- 'zeros' - Initialize the channel offsets with zeros.
- 'ones' - Initialize the channel offsets with ones.
- 'narrow-normal' - Initialize the channel offsets by independently sampling from a normal distribution with a mean of zero and standard deviation of 0.01.
- Function handle - Initialize the channel offsets with a custom function. If you specify a function handle, then the function must be of the form `offset = func(sz)`, where `sz` is the size of the scale. For an example, see “Specify Custom Weight Initialization Function”.

The layer only initializes the channel offsets when the `Offset` property is empty.

Data Types: char | string | function\_handle

**Scale — Channel scale factors**

[] (default) | numeric array

Channel scale factors  $\gamma$ , specified as a numeric array.

The channel scale factors are learnable parameters. When you train a network using the `trainNetwork` function or initialize a `dlnetwork` object, if `Scale` is nonempty, then the software uses the `Scale` property as the initial value. If `Scale` is empty, then the software uses the initializer specified by `ScaleInitializer`.

Depending on the type of layer input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically reshape this property to have of the following sizes:

Layer Input	Property Size
feature input	NumChannels-by-1
vector sequence input	
1-D image input	1-by-NumChannels
1-D image sequence input	
2-D image input	1-by-1-by-NumChannels
2-D image sequence input	
3-D image input	1-by-1-by-1-by-NumChannels
3-D image sequence input	

Data Types: `single` | `double`

**Offset – Channel offsets**

`[]` (default) | numeric array

Channel offsets  $\beta$ , specified as a numeric vector.

The channel offsets are learnable parameters. When you train a network using the `trainNetwork` function or initialize a `dlnetwork` object, if `Offset` is nonempty, then the software uses the `Offset` property as the initial value. If `Offset` is empty, then the software uses the initializer specified by `OffsetInitializer`.

Depending on the type of layer input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically reshape this property to have of the following sizes:

Layer Input	Property Size
feature input	NumChannels-by-1
vector sequence input	
1-D image input	1-by-NumChannels
1-D image sequence input	
2-D image input	1-by-1-by-NumChannels
2-D image sequence input	
3-D image input	1-by-1-by-1-by-NumChannels
3-D image sequence input	

Data Types: `single` | `double`

## Learning Rate and Regularization

### ScaleLearnRateFactor — Learning rate factor for scale factors

1 (default) | nonnegative scalar

Learning rate factor for the scale factors, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the scale factors in a layer. For example, if `ScaleLearnRateFactor` is 2, then the learning rate for the scale factors in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings specified with the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### OffsetLearnRateFactor — Learning rate factor for offsets

1 (default) | nonnegative scalar

Learning rate factor for the offsets, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the offsets in a layer. For example, if `OffsetLearnRateFactor` is 2, then the learning rate for the offsets in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings specified with the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### ScaleL2Factor — L<sub>2</sub> regularization factor for scale factors

1 (default) | nonnegative scalar

L<sub>2</sub> regularization factor for the scale factors, specified as a nonnegative scalar.

The software multiplies this factor by the global L<sub>2</sub> regularization factor to determine the learning rate for the scale factors in a layer. For example, if `ScaleL2Factor` is 2, then the L<sub>2</sub> regularization for the offsets in the layer is twice the global L<sub>2</sub> regularization factor. You can specify the global L<sub>2</sub> regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### OffsetL2Factor — L<sub>2</sub> regularization factor for offsets

1 (default) | nonnegative scalar

L<sub>2</sub> regularization factor for the offsets, specified as a nonnegative scalar.

The software multiplies this factor by the global L<sub>2</sub> regularization factor to determine the learning rate for the offsets in a layer. For example, if `OffsetL2Factor` is 2, then the L<sub>2</sub> regularization for the offsets in the layer is twice the global L<sub>2</sub> regularization factor. You can specify the global L<sub>2</sub> regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Layer

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For Layer array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

**NumInputs — Number of inputs**

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

**InputNames — Input names**

{'in'} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: `cell`

**NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: `double`

**OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: `cell`

## Examples

**Create Instance Normalization Layer**

Create an instance normalization layer with the name 'instancenorm'.

```
layer = instanceNormalizationLayer('Name','instancenorm')
```

```
layer =  
    InstanceNormalizationLayer with properties:
```

```
        Name: 'instancenorm'  
    NumChannels: 'auto'
```

```
    Hyperparameters
```

Epsilon: 1.0000e-05

Learnable Parameters

Offset: []

Scale: []

Show all properties

Include an instance normalization layer in a Layer array.

```
layers = [
    imageInputLayer([28 28 3])
    convolution2dLayer(5,20)
    instanceNormalizationLayer
    reluLayer
    maxPooling2dLayer(2, 'Stride', 2)
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer]
```

layers =

8x1 Layer array with layers:

1	''	Image Input	28x28x3 images with 'zerocenter' normalization
2	''	2-D Convolution	20 5x5 convolutions with stride [1 1] and padding [0 0]
3	''	Instance Normalization	Instance normalization
4	''	ReLU	ReLU
5	''	2-D Max Pooling	2x2 max pooling with stride [2 2] and padding [0 0 0 0]
6	''	Fully Connected	10 fully connected layer
7	''	Softmax	softmax
8	''	Classification Output	crossentropyex

## Algorithms

### Instance Normalization Layer

The instance normalization operation normalizes the elements  $x_i$  of the input by first calculating the mean  $\mu_I$  and variance  $\sigma_I^2$  over the spatial and time dimensions for each channel in each observation independently. Then, it calculates the normalized activations as

$$\hat{x}_i = \frac{x_i - \mu_I}{\sqrt{\sigma_I^2 + \epsilon}},$$

where  $\epsilon$  is a constant that improves numerical stability when the variance is very small.

To allow for the possibility that inputs with zero mean and unit variance are not optimal for the operations that follow instance normalization, the instance normalization operation further shifts and scales the activations using the transformation

$$y_i = \gamma \hat{x}_i + \beta,$$

where the offset  $\beta$  and scale factor  $\gamma$  are learnable parameters that are updated during network training.

## Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `InstanceNormalizationLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"CB" (channel, batch)	"CB" (channel, batch)
"SCB" (spatial, channel, batch)	"SCB" (spatial, channel, batch)
"SSCB" (spatial, spatial, channel, batch)	"SSCB" (spatial, spatial, channel, batch)
"SSSCB" (spatial, spatial, spatial, channel, batch)	"SSSCB" (spatial, spatial, spatial, channel, batch)
"CBT" (channel, batch, time)	"CBT" (channel, batch, time)
"SCBT" (spatial, channel, batch, time)	"SCBT" (spatial, channel, batch, time)
"SSCBT" (spatial, spatial, channel, batch, time)	"SSCBT" (spatial, spatial, channel, batch, time)
"SSSCBT" (spatial, spatial, spatial, channel, batch, time)	"SSSCBT" (spatial, spatial, spatial, channel, batch, time)
"CU" (channel, unspecified)	"CU" (channel, unspecified)
"SC" (spatial, channel)	"SC" (spatial, channel)
"SSC" (spatial, spatial, channel)	"SSC" (spatial, spatial, channel)
"SSSC" (spatial, spatial, spatial, channel)	"SSSC" (spatial, spatial, spatial, channel)

In `dlnetwork` objects, `InstanceNormalizationLayer` objects also support these input and output format combinations.

Input Format	Output Format
"CT" (channel, time)	"CT" (channel, time)
"SCT" (spatial, channel, time)	"SCT" (spatial, channel, time)
"SSCT" (spatial, spatial, channel, time)	"SSCT" (spatial, spatial, channel, time)
"SSSCT" (spatial, spatial, spatial, channel, time)	"SSSCT" (spatial, spatial, spatial, channel, time)

## Version History

Introduced in R2021a

### R2023a: Epsilon supports values less than 1e-5

The Epsilon option also supports positive values less than 1e-5.

### R2023a: Layer supports 1-D image sequence data

InstanceNormalizationLayer objects support normalizing 1-D image sequence data (data with one spatial and one time dimension).

## isdlarray

Check if object is dlarray

### Syntax

```
tf = isdlarray(X)
```

### Description

`tf = isdlarray(X)` returns logical 1 (true) if `X` is a `dlarray`, and logical 0 (false) otherwise. You can use this function with an `if` statement to avoid executing code that expects `dlarray` input.

### Examples

#### Check if Object is a dlarray

Create a 2-by-3-by-4 array of random values.

```
X = rand(2,3,4)
```

```
X =
```

```
X(:,:,1) =
```

```
    0.8147    0.1270    0.6324  
    0.9058    0.9134    0.0975
```

```
X(:,:,2) =
```

```
    0.2785    0.9575    0.1576  
    0.5469    0.9649    0.9706
```

```
X(:,:,3) =
```

```
    0.9572    0.8003    0.4218  
    0.4854    0.1419    0.9157
```

```
X(:,:,4) =
```

```
    0.7922    0.6557    0.8491  
    0.9595    0.0357    0.9340
```

Check if the array is a `dlarray` object.

```
isdlarray(X)
```

```
ans = logical  
     0
```

Convert the array to `dllarray`.

```
X = dllarray(X)
```

```
X =
    2x3x4 dllarray
```

```
(:,: ,1) =
```

```
    0.8147    0.1270    0.6324
    0.9058    0.9134    0.0975
```

```
(:,: ,2) =
```

```
    0.2785    0.9575    0.1576

# isequal

Check equality of deep learning layer graphs or networks

## Syntax

```
tf = isequal(net1,net2)
tf = isequal(net1,...,netN)
```

## Description

`tf = isequal(net1,net2)` checks the equality of `SeriesNetwork`, `DAGNetwork`, `LayerGraph`, or `dlnetwork` objects `net1` and `net2`.

- If both inputs are `SeriesNetwork` or `DAGNetwork` objects, or one of each, then the function returns 1 (true) when the properties and architectures match. Otherwise, the function returns 0 (false).
- If both inputs are `LayerGraph` objects, then the function returns 1 (true) when the properties and architectures match. Otherwise, the function returns 0 (false).
- If both inputs are `dlnetwork` objects, then the function returns 1 (true) when the properties and architectures match. Otherwise, the function returns 0 (false).
- For other combinations, the function returns 0 (false).

The `isequal` function can operate on arrays of networks and layer graphs. In this case, the function performs element-wise comparison.

`tf = isequal(net1,...,netN)` checks equality of the `N` networks or layer graphs `net1`, ..., `netN`.

## Examples

### Check if Layer Graphs are Equal

Create two instances of SqueezeNet layer graphs.

```
lgraph1 = squeezeNet('Weights','none');
lgraph2 = squeezeNet('Weights','none');
```

Check if the layer graphs are equal using the `isequal` function.

```
tf = isequal(lgraph1,lgraph2)
```

```
tf = logical
    1
```

### Check if Networks are Equal

Create two instances of a pretrained SqueezeNet network.

```
net1 = squeezeNet;  
net2 = squeezeNet;
```

Check if the networks are equal using the `isequal` function.

```
tf = isequal(net1,net2)  
  
tf = logical  
    1
```

## Input Arguments

### **net1, net2** — Network or layer graph

SeriesNetwork object | DAGNetwork object | dlnetwork object | LayerGraph object

Network or layer graph, specified as a SeriesNetwork, DAGNetwork, dlnetwork, or LayerGraph object.

## Version History

**Introduced in R2021a**

# isequaln

Check equality of deep learning layer graphs or networks ignoring NaN values

## Syntax

```
tf = isequaln(net1,net2)
tf = isequaln(net1,...,netN)
```

## Description

`tf = isequaln(net1,net2)` checks the equality of `SeriesNetwork`, `DAGNetwork`, `LayerGraph`, or `dlnetwork` objects `net1` and `net2`.

- If both inputs are `SeriesNetwork` or `DAGNetwork` objects, or one of each, then the function returns 1 (true) when the properties and architectures match, ignoring NaN values. Otherwise, the function returns 0 (false).
- If both inputs are `LayerGraph` objects, then the function returns 1 (true) when the properties and architectures match, ignoring NaN values. Otherwise, the function returns 0 (false).
- If both inputs are `dlnetwork` objects, then the function returns 1 (true) when the properties and architectures match, ignoring NaN values. Otherwise, the function returns 0 (false).
- For other combinations, the function returns 0 (false).

The `isequaln` function can operate on arrays of networks and layer graphs. In this case, the function performs element-wise comparison.

`tf = isequaln(net1,...,netN)` checks equality of the `N` networks or layer graphs `net1`, ..., `netN`, ignoring NaN values.

## Examples

### Check if Layer Graphs are Equal Ignoring NaN Values

Create two instances of SqueezeNet layer graphs.

```
lgraph1 = squeezeNet('Weights','none');
lgraph2 = squeezeNet('Weights','none');
```

Check if the layer graphs are equal ignoring NaN values using the `isequaln` function.

```
tf = isequaln(lgraph1,lgraph2)
```

```
tf = logical
      1
```

### Check if Networks are Equal Ignoring NaN Values

Create two instances of a pretrained SqueezeNet network.

```
net1 = squeezeNet;  
net2 = squeezeNet;
```

Check if the networks are equal ignoring NaN values using the `isequaln` function.

```
tf = isequaln(net1,net2)  
  
tf = logical  
    1
```

## Input Arguments

### **net1, net2** — Network or layer graph

SeriesNetwork object | DAGNetwork object | dlnetwork object | LayerGraph object

Network or layer graph, specified as a SeriesNetwork, DAGNetwork, dlnetwork , or LayerGraph object.

# isInNetworkDistribution

Determine whether data is within the distribution of the network

## Syntax

```
tf = isInNetworkDistribution(net,X)
tf = isInNetworkDistribution(net,X,Threshold=thr)
tf = isInNetworkDistribution(discriminator,X)
```

## Description

`tf = isInNetworkDistribution(net,X)` returns a logical array that indicates which observations in `X` are in-distribution (ID) and which observations are out-of-distribution (OOD). If an observation is ID, then the corresponding element of `tf` is 1 (true). Otherwise, the corresponding element of `tf` is 0 (false).

The function computes the distribution confidence score for each observation using the baseline method. For more information, see “Softmax-Based Methods” on page 1-1151. The function classifies any observation with a score less than or equal to the threshold as OOD. To use the default threshold value, use this syntax.

To set the threshold, use the `thr` name-value argument. Alternatively, use the `networkDistributionDiscriminator` function to create a discriminator object that automatically finds an optimal threshold and use that as the first input argument instead of `net`. You can also use the discriminator object to specify a different method to use to compute the distribution confidence scores.

`tf = isInNetworkDistribution(net,X,Threshold=thr)` also specifies a nondefault threshold value.

`tf = isInNetworkDistribution(discriminator,X)` determines which observations in `X` are ID and which observations are OOD using `discriminator`. To create a discriminator object, use the `networkDistributionDiscriminator` function. This syntax uses the threshold stored in the `Threshold` property of `discriminator`. Use this syntax to specify additional options for the software to use when it computes the distribution confidence scores and to automatically find a suitable threshold. For example, when creating a discriminator, you can specify whether to use a target true positive or false positive rate to pick the threshold. For more information, see `networkDistributionDiscriminator`.

## Examples

### Check if Data is In-Distribution

Load a pretrained classification network.

```
load("digitsClassificationMLPNet.mat")
```

Load data. Convert the data to a `dlarray` object.

```
X = digitTrain4DArrayData;  
X = dlarray(X, "SSCB");
```

Determine if the data is ID.

```
tf = isInNetworkDistribution(net,X);
```

Find the proportion of observations that the function classifies as OOD.

```
oodProportion = (sum(1-tf)/numel(tf))
```

```
oodProportion = 0.0026
```

### Specify Threshold

Load a pretrained classification network.

```
load("digitsClassificationMLPNet.mat")
```

Load data and convert the data to a `dlarray` object.

```
X = digitTrain4DArrayData;  
X = dlarray(X, "SSCB");
```

Determine if the data is ID using a threshold of 0.9.

```
tf = isInNetworkDistribution(net,X,Threshold=0.9);
```

Find the proportion of observations that the function classifies as OOD.

```
oodProportion = (sum(1-tf)/numel(tf))
```

```
oodProportion = 0
```

### Specify Additional Options Using Discriminator

Load a pretrained classification network.

```
load("digitsClassificationMLPNet.mat")
```

Load ID data. Convert the data to a `dlarray` object.

```
X = digitTrain4DArrayData;  
X = dlarray(X, "SSCB");
```

Create a discriminator using the `networkDistributionDiscriminator` function. Set the method to "odin" and the true positive goal to 0.975. The software finds the threshold that satisfies the true positive goal.

```
method = "odin";  
discriminator = networkDistributionDiscriminator(net,X,[],method, ...  
    TruePositiveGoal=0.975);
```

Determine if data is ID.

```
tf = isInNetworkDistribution(discriminator,X);
```

Find the true positive rate.

```
truePositives = sum(tf);
falseNegatives = sum(1-tf);
truePositiveRate = truePositives/(truePositives + falseNegatives)

truePositiveRate = 0.9750
```

## Input Arguments

### **net** — Neural network

`dlnetwork` object

Neural network, specified as a `dlnetwork` object with a single softmax output layer.

The software uses the baseline method to compute the distribution confidence scores. To use another method, such as ODIN or energy, specify `discriminator` as the first input argument. For more information about methods for computing distribution confidence scores, see “Distribution Confidence Scores” on page 1-1150.

For networks without a single softmax layer, create a discriminator object using the `networkDistributionDiscriminator` function with `method` set to “`hbos`” and use this object as the first input argument instead.

### **discriminator** — Distribution discriminator

`BaselineDistributionDiscriminator` object | `ODINDistributionDiscriminator` object | `EnergyDistributionDiscriminator` object | `HBOSDistributionDiscriminator` object

Distribution discriminator, specified as a `BaselineDistributionDiscriminator`, `ODINDistributionDiscriminator`, `EnergyDistributionDiscriminator`, or `HBOSDistributionDiscriminator` object. To create this object, use the `networkDistributionDiscriminator` function.

### **X** — Input data

formatted `dlarray`

Input data, specified as a formatted `dlarray`. For more information about `dlarray` formats, see the `fmt` input argument of `dlarray`.

### **thr** — Distribution threshold

0.95 (default) | scalar in the range [0, 1]

Distribution threshold, specified as a scalar in the range [0, 1]. The software uses this value to separate the ID and OOD data.

### Dependency

You can only specify this input when the first argument is `net`. If the first argument is `discriminator`, then the software uses the threshold stored in the `Threshold` property of `discriminator`. For more information, see `networkDistributionDiscriminator`.

## More About

### In-Distribution and Out-of-Distribution Data

In-distribution (ID) data refers to any data that you use to construct and train your model. Additionally, any data that is sufficiently similar to the training data is also said to be ID.

Out-of-distribution (OOD) data refers to data that is sufficiently different to the training data. For example, data collected in a different way, at a different time, under different conditions, or for a different task than the data on which the model was originally trained. Models can receive OOD data when you deploy them in an environment other than the one in which you train them. For example, suppose you train a model on clear X-ray images but then deploy the model on images taken with a lower-quality camera.

OOD data detection is important for assigning confidence to the predictions of a network. For more information, see “OOD Data Detection” on page 1-1150.

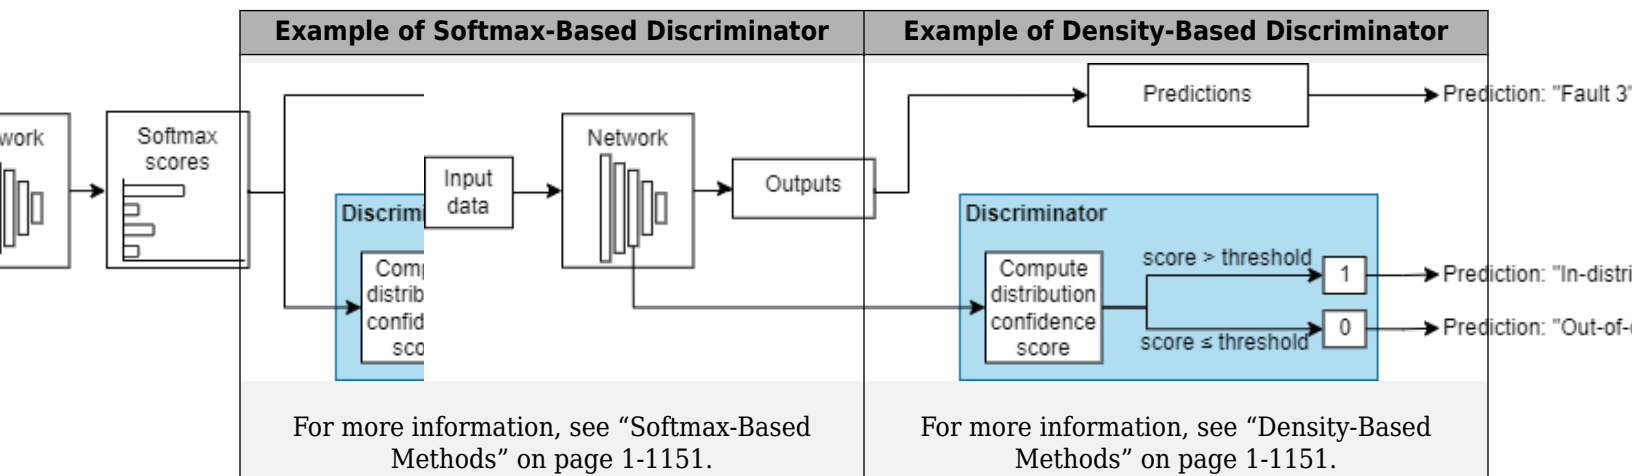

### OOD Data Detection

OOD data detection is a technique for assessing whether the inputs to a network are OOD. For methods that you apply after training, you can construct a discriminator which acts as an additional output of the trained network that classifies an observation as ID or OOD.

The discriminator works by finding a distribution confidence score for an input. You can then specify a threshold. If the score is less than or equal to that threshold, then the input is OOD. Two groups of metrics for computing distribution confidence scores are softmax-based and density-based methods. Softmax-based methods use the softmax layer to compute the scores. Density-based methods use the outputs of layers that you specify to compute the scores. For more information about how to compute distribution confidence scores, see “Distribution Confidence Scores” on page 1-1150.

These images show how a discriminator acts as an additional output of a trained neural network.

### Example Data Discriminators

### Distribution Confidence Scores

Distribution confidence scores are metrics for classifying data as ID or OOD. If an input has a score less than or equal to a threshold value, then you can classify that input as OOD. You can use different techniques for finding the distribution confidence scores.

### Softmax-Based Methods

ID data usually corresponds to a higher softmax output than OOD data[1]. Therefore, a method of defining distribution confidence scores is as a function of the softmax scores. These methods are called *softmax-based* methods. These methods only work for classification networks with a single softmax output.

Let  $a_i(X)$  be the input to the softmax layer for class  $i$ . The output of the softmax layer for class  $i$  is given by this equation:

$$P_i(X; T) = \frac{e^{a_i(X)/T}}{\sum_{j=1}^C e^{a_j(X)/T}},$$

where  $C$  is the number of classes and  $T$  is a temperature scaling. When the network predicts the class label of  $X$ , the temperature  $T$  is set to 1.

The baseline, ODIN, and energy methods each define distribution confidence scores as functions of the softmax input.

- The *baseline* method [1] uses the maximum of the unscaled output values of the softmax scores:

$$\text{confidence}(X) = \max_i P_i(X; 1).$$

- The out-of-distribution detector for neural networks (ODIN) method [2] uses the maximum of the scaled output of the softmax scores:

$$\text{confidence}(X; T) = \max_i P_i(X; T), \quad T > 0.$$

- The *energy* method [3] uses the scaled denominator of the softmax output:

$$\text{energy}(X; T) = -T \log \left( \sum_{j=1}^C e^{a_j(X)/T} \right), \quad T > 0$$

$$\text{confidence}(X; T) = -\text{energy}(X; T), \quad T > 0.$$

### Density-Based Methods

Density-based methods compute the distribution scores by describing the underlying features learned by the network as probabilistic models. Observations falling into areas of low density correspond to OOD observations.

To model the distributions of the features, you can describe the density function for each feature using a histogram. This technique is based on the histogram-based outlier score (HBOS) method [4]. This method uses a data set of ID data, such as training data, to construct histograms representing the density distributions of the ID features. This method has three stages:

- 1 Find the principal component features for which to compute the distribution confidence scores:
  - a For each specified layer, find the activations using the  $n$  data set observations. Flatten the activations across all dimensions except the batch dimension.
  - b Compute the principal components of the flattened activations matrix. Normalize the eigenvalues such that the largest eigenvalue is 1 and corresponds to the principal component that carries the greatest variance through the layer. Denote the matrix of principal components for layer  $l$  by  $Q^{(l)}$ .

The principal components are linear combinations of the activations and represent the features that the software uses to compute the distribution scores. To compute the score, the software uses only the principal components whose eigenvalues are greater than the variance cutoff value  $\sigma$ .

---

**Note** The HBOS algorithm assumes that the features are statistically independent. The principal component features are pairwise linearly independent but they can have nonlinear dependencies. To investigate feature dependencies, you can use functions such as `corr`. For an example showing how to investigate feature dependence, see “Out-of-Distribution Data Discriminator for YOLO v4 Object Detector”. If the features are not statistically independent, then the algorithm can return poor results. Using multiple layers to compute the distribution scores can increase the number of statistically dependent features.

---

- 2 For each of the principal component features with an eigenvalue greater than  $\sigma$ , construct a histogram. For each histogram:
  - a Dynamically adjusts the width of the bins to create  $\sqrt{n}$  bins of approximately equal area.
  - b Normalize the bins heights such that the largest height is 1.
- 3 Find the distribution score for an observation by summing the logarithmic height of the bin containing the observation for each of the feature histograms, over each of the layers.

Let  $f^{(l)}(X)$  denote the output of layer  $l$  for input  $X$ . Use the principal components to project the output into a lower dimensional feature space using this equation:  $\hat{f}^{(l)}(X) = (Q^{(l)})^T f^{(l)}(X)$ .

Compute the confidence score using this equation:

$$\text{HBOS}(X; \sigma) = - \sum_{l=1}^L \left( \sum_{k=1}^{N^{(l)}(\sigma)} \log(\text{hist}_k(\hat{f}_k^{(l)}(X))) \right),$$

$$\text{confidence}(X; \sigma) = - \text{HBOS}(X; \sigma),$$

where  $N^{(l)}(\sigma)$  is the number of number of principal component with an eigenvalue less than  $\sigma$  and  $L$  is the number of layers. A larger score corresponds to an observation that lies in the areas of higher density. If the observation lies outside of the range of any of the histograms, then the bin height for those histograms is 0 and the confidence score is `-Inf`.

---

**Note** The distribution scores depend on the properties of the data set used to construct the histograms [6].

---

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function runs on the GPU if its inputs meet either or both of these conditions:
  - Any values of the network learnable parameters are `darray` objects with underlying data of type `gpuArray`. To see the learnables for a network `net`, call `net.Learnables.Value`.
  - Any of the data is a `darray` object with underlying data of type `gpuArray`.

For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

## l1loss

$L_1$  loss for regression tasks

### Syntax

```
loss = l1loss(Y,targets)
loss = l1loss(Y,targets,weights)
loss = l1loss( ____,DataFormat=FMT)
loss = l1loss( ____,Name=Value)
```

### Description

The  $L_1$  loss operation computes the  $L_1$  loss given network predictions and target values. When the Reduction option is "sum" and the NormalizationFactor option is "batch-size", the computed value is known as the mean absolute error (MAE).

The `l1loss` function calculates the  $L_1$  loss using `darray` data. Using `darray` objects makes working with high dimensional data easier by allowing you to label the dimensions. For example, you can label which dimensions correspond to spatial, time, channel, and batch dimensions using the "S", "T", "C", and "B" labels, respectively. For unspecified and other dimensions, use the "U" label. For `darray` object functions that operate over particular dimensions, you can specify the dimension labels by formatting the `darray` object directly, or by using the `DataFormat` option.

`loss = l1loss(Y,targets)` computes the MAE loss for the predictions `Y` and the target values `targets`. The input `Y` must be a formatted `darray`. The output `loss` is an unformatted `darray` scalar.

`loss = l1loss(Y,targets,weights)` computes the weighted  $L_1$  loss using the weight values `weights`. The output `loss` is an unformatted `darray` scalar.

`loss = l1loss( ____,DataFormat=FMT)` computes the loss for the unformatted `darray` object `Y` and the target values with the format specified by `FMT`. Use this syntax with any of the input arguments in previous syntaxes.

`loss = l1loss( ____,Name=Value)` specifies additional options using one or more name-value arguments. For example, `l1loss(Y,targets,Reduction="none")` computes the  $L_1$  loss without reducing the output to a scalar.

### Examples

#### Mean Absolute Error Loss

Create an array of predictions for 12 observations over 10 responses.

```
numResponses = 10;
numObservations = 12;

Y = rand(numResponses,numObservations);
dLY = darray(Y,'CB');
```

View the size and format of the predictions.

```
size(dLY)
ans = 1×2
    10    12
```

```
dims(dLY)
```

```
ans =
'CB'
```

Create an array of random targets.

```
targets = rand(numResponses,numObservations);
```

View the size of the targets.

```
size(targets)
ans = 1×2
    10    12
```

Compute the mean absolute error (MAE) loss between the predictions and the targets using the `l1loss` function.

```
loss = l1loss(dLY,targets)
```

```
loss =
    1×1 dlarray
    3.1679
```

### Masked Mean Absolute Error for Padded Sequences

Create arrays of predictions and targets for 12 sequences of varying lengths over 10 responses.

```
numResponses = 10;
numObservations = 12;
maxSequenceLength = 15;

sequenceLengths = randi(maxSequenceLength,[1 numObservations]);

Y = cell(numObservations,1);
targets = cell(numObservations,1);

for i = 1:numObservations
    Y{i} = rand(numResponses,sequenceLengths(i));
    targets{i} = rand(numResponses,sequenceLengths(i));
end
```

View the cell arrays of predictions and targets.

Y

```
Y=12x1 cell array
    {10x13 double}
    {10x14 double}
    {10x2  double}
    {10x14 double}
    {10x10 double}
    {10x2  double}
    {10x5  double}
    {10x9  double}
    {10x15 double}
    {10x15 double}
    {10x3  double}
    {10x15 double}
```

targets

```
targets=12x1 cell array
    {10x13 double}
    {10x14 double}
    {10x2  double}
    {10x14 double}
    {10x10 double}
    {10x2  double}
    {10x5  double}
    {10x9  double}
    {10x15 double}
    {10x15 double}
    {10x3  double}
    {10x15 double}
```

Pad the prediction and target sequences in the second dimension using the `padsequences` function and also return the corresponding mask.

```
[Y,mask] = padsequences(Y,2);
targets = padsequences(targets,2);
```

Convert the padded sequences to `darray` with the format "CTB" (channel, time, batch). Because formatted `darray` objects automatically permute the dimensions of the underlying data, keep the order consistent by also converting the targets and mask to formatted `darray` objects with the format "CTB" (channel, batch, time).

```
dLY = darray(Y, "CTB");
targets = darray(targets, "CTB");
mask = darray(mask, "CTB");
```

View the sizes of the prediction scores, targets, and mask.

```
size(dLY)
```

```
ans = 1x3
```

```
    10    12    15
```

```
size(targets)
```

```
ans = 1×3
    10    12    15
```

```
size(mask)
```

```
ans = 1×3
    10    12    15
```

Compute the mean absolute error (MAE) between the predictions and the targets. To prevent the loss values calculated from padding from contributing to the loss, set the `Mask` option to the mask returned by the `padsequences` function.

```
loss = l1loss(dLY,targets,Mask=mask)
```

```
loss =
    1×1 darray
    32.6172
```

## Input Arguments

### Y — Predictions

`darray` | numeric array

Predictions, specified as a formatted `darray`, an unformatted `darray`, or a numeric array. When `Y` is not a formatted `darray`, you must specify the dimension format using the `DataFormat` option.

If `Y` is a numeric array, `targets` must be a `darray`.

### targets — Target responses

`darray` | numeric array

Target responses, specified as a formatted or unformatted `darray` or a numeric array.

The size of each dimension of `targets` must match the size of the corresponding dimension of `Y`.

If `targets` is a formatted `darray`, then its format must be the same as the format of `Y`, or the same as `DataFormat` if `Y` is unformatted.

If `targets` is an unformatted `darray` or a numeric array, then the function applies the format of `Y` or the value of `DataFormat` to `targets`.

---

**Tip** Formatted `darray` objects automatically permute the dimensions of the underlying data to have order "S" (spatial), "C" (channel), "B" (batch), "T" (time), then "U" (unspecified). To ensure that the dimensions of `Y` and `targets` are consistent, when `Y` is a formatted `darray`, also specify `targets` as a formatted `darray`.

---

### weights — Weights

`darray` | numeric array

Weights, specified as a formatted or unformatted `darray` or a numeric array.

If `weights` is a vector and `Y` has two or more nonsingleton dimensions, then `weights` must be a formatted `darray`, where the dimension label of the nonsingleton dimension is either "C" (channel) or "B" (batch) and has a size that matches the size of the corresponding dimension in `Y`.

If `weights` is a formatted `darray` with two or more nonsingleton dimensions, then its format must match the format of `Y`.

If `weights` is not a formatted `darray` and has two or more nonsingleton dimensions, then its size must match the size of `Y` and the function uses the same format as `Y`. Alternatively, to specify the `weights` format, use the `WeightsFormat` option.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `loss = llloss(Y, targets, Reduction="none")` specifies to compute the  $L_1$  loss without reducing the output to a scalar

### **Mask — Mask indicating which elements to include for loss computation**

`darray` | logical array | numeric array

Mask indicating which elements to include for loss computation, specified as a `darray` object, a logical array, or a numeric array with the same size as `Y`.

The function includes and excludes elements of the input data for loss computation when the corresponding value in the mask is 1 and 0, respectively.

If `Mask` is a formatted `darray` object, then its format must match that of `Y`. If `Mask` is not a formatted `darray` object, then the function uses the same format as `Y`.

If you specify the `DataFormat` option, then the function also uses the specified format for the mask.

The size of each dimension of `Mask` must match the size of the corresponding dimension in `Y`. The default value is a logical array of ones.

---

**Tip** Formatted `darray` objects automatically permute the dimensions of the underlying data to have this order: "S" (spatial), "C" (channel), "B" (batch), "T" (time), and "U" (unspecified). For example, `darray` objects automatically permute the dimensions of data with format "TSCSBS" to have format "SSSCBT".

To ensure that the dimensions of `Y` and the mask are consistent, when `Y` is a formatted `darray`, also specify the mask as a formatted `darray`.

---

### **Reduction — Mode for reducing array of loss values**

"sum" (default) | "none"

Mode for reducing the array of loss values, specified as one of the following:

- "sum" — Sum all of the elements in the array of loss values. In this case, the output `loss` is scalar.

- "none" — Do not reduce the array of loss values. In this case, the output `loss` is an unformatted `darray` object with the same size as `Y`.

### **NormalizationFactor — Divisor for normalizing reduced loss**

"batch-size" (default) | "all-elements" | "mask-included" | "none"

Divisor for normalizing the reduced loss when `Reduction` is "sum", specified as one of the following:

- "batch-size" — Normalize the loss by dividing it by the number of observations in `Y`.
- "all-elements" — Normalize the loss by dividing it by the number of elements of `Y`.
- "mask-included" — Normalize the loss by dividing the loss values by the number of included elements specified by the mask for each observation independently. To use this option, you must specify a mask using the `Mask` option.
- "none" — Do not normalize the loss.

### **DataFormat — Dimension order of unformatted data**

character vector | string scalar

Dimension order of unformatted input data, specified as a character vector or string scalar `FMT` that provides a label for each dimension of the data.

When you specify the format of a `darray` object, each character provides a label for each dimension of the data and must be one of these options:

- "S" — Spatial
- "C" — Channel
- "B" — Batch (for example, samples and observations)
- "T" — Time (for example, time steps of sequences)
- "U" — Unspecified

You can specify multiple dimensions labeled "S" or "U". You can use the labels "C", "B", and "T" at most once.

You must specify `DataFormat` when the input data is not a formatted `darray`.

Data Types: `char` | `string`

### **WeightsFormat — Dimension order of weights**

character vector | string scalar

Dimension order of the weights, specified as a character vector or string scalar that provides a label for each dimension of the weights.

When you specify the format of a `darray` object, each character provides a label for each dimension of the data and must be one of these options:

- "S" — Spatial
- "C" — Channel
- "B" — Batch (for example, samples and observations)
- "T" — Time (for example, time steps of sequences)
- "U" — Unspecified

You can specify multiple dimensions labeled "S" or "U". You can use the labels "C", "B", and "T" at most once.

You must specify `WeightsFormat` when `weights` is a numeric vector and `Y` has two or more nonsingleton dimensions.

If `weights` is not a vector, or both `weights` and `Y` are vectors, then default value of `WeightsFormat` is the same as the format of `Y`.

Data Types: `char` | `string`

## Output Arguments

### loss — L<sub>1</sub> loss

`dlarray`

L<sub>1</sub> loss, returned as an unformatted `dlarray`. The output `loss` is an unformatted `dlarray` with the same underlying data type as the input `Y`.

The size of `loss` depends on the `Reduction` option.

## Algorithms

### L1 Loss

The L<sub>1</sub> loss operation computes the L<sub>1</sub> loss given network predictions and target values. When the `Reduction` option is "sum" and the `NormalizationFactor` option is "batch-size", the computed value is known as the mean absolute error (MAE).

For each element  $Y_j$  of the input, the `l1loss` function computes the corresponding element-wise loss values using

$$\text{loss}_j = |Y_j - T_j|,$$

where  $Y_j$  is a predicted value and  $T_j$  is the corresponding target value.

To reduce the loss values to a scalar, the function then reduces the element-wise loss using the formula

$$\text{loss} = \frac{1}{N} \sum_j m_j w_j \text{loss}_j,$$

where  $N$  is the normalization factor,  $m_j$  is the mask value for element  $j$ , and  $w_j$  is the weight value for element  $j$ .

If you do not opt to reduce the loss, then the function applies the mask and the weights to the loss values directly:

$$\text{loss}_j^* = m_j w_j \text{loss}_j$$

## l2loss

$L_2$  loss for regression tasks

### Syntax

```
loss = l2loss(Y,targets)
loss = l2loss(Y,targets,weights)
loss = l2loss( ____,DataFormat=FMT)
loss = l2loss( ____,Name=Value)
```

### Description

The  $L_2$  loss operation computes the  $L_2$  loss (based on the squared  $L_2$  norm) given network predictions and target values. When the `Reduction` option is "sum" and the `NormalizationFactor` option is "batch-size", the computed value is known as the mean squared error (MSE).

The `l2loss` function calculates the  $L_2$  loss using `darray` data. Using `darray` objects makes working with high dimensional data easier by allowing you to label the dimensions. For example, you can label which dimensions correspond to spatial, time, channel, and batch dimensions using the "S", "T", "C", and "B" labels, respectively. For unspecified and other dimensions, use the "U" label. For `darray` object functions that operate over particular dimensions, you can specify the dimension labels by formatting the `darray` object directly, or by using the `DataFormat` option.

`loss = l2loss(Y,targets)` computes MSE loss for the predictions `Y` and the target values `targets`. The input `Y` must be a formatted `darray`. The output `loss` is an unformatted `darray` scalar.

`loss = l2loss(Y,targets,weights)` computes the weighted  $L_2$  loss using the weight values `weights`. The output `loss` is an unformatted `darray` scalar.

`loss = l2loss( ____,DataFormat=FMT)` computes the loss for the unformatted `darray` object `Y` and the target values with the format specified by `FMT`. Use this syntax with any of the input arguments in previous syntaxes.

`loss = l2loss( ____,Name=Value)` specifies additional options using one or more name-value arguments. For example, `l2loss(Y,targets,Reduction="none")` computes the  $L_2$  loss without reducing the output to a scalar.

### Examples

#### Mean Squared Error Loss

Create an array of predictions for 12 observations over 10 responses.

```
numResponses = 10;
numObservations = 12;
Y = rand(numResponses,numObservations);
dLY = darray(Y,'CB');
```

View the size and format of the predictions.

```
size(dLY)
ans = 1×2
    10    12
```

```
dims(dLY)
ans =
'CB'
```

Create an array of random targets.

```
targets = rand(numResponses,numObservations);
```

View the size of the targets.

```
size(targets)
ans = 1×2
    10    12
```

Compute the mean squared error (MSE) loss between the predictions and the targets using the `l2loss` function.

```
loss = l2loss(dLY,targets)
loss =
    1×1 dlarray
    1.4748
```

### Masked Mean Squared Error for Padded Sequences

Create arrays of predictions and targets for 12 sequences of varying lengths over 10 responses.

```
numResponses = 10;
numObservations = 12;
maxSequenceLength = 15;

sequenceLengths = randi(maxSequenceLength,[1 numObservations]);

Y = cell(numObservations,1);
targets = cell(numObservations,1);

for i = 1:numObservations
    Y{i} = rand(numResponses,sequenceLengths(i));
    targets{i} = rand(numResponses,sequenceLengths(i));
end
```

View the cell arrays of predictions and targets.

```
Y
```

```
Y=12x1 cell array
  {10x13 double}
  {10x14 double}
  {10x2  double}
  {10x14 double}
  {10x10 double}
  {10x2  double}
  {10x5  double}
  {10x9  double}
  {10x15 double}
  {10x15 double}
  {10x3  double}
  {10x15 double}
```

targets

```
targets=12x1 cell array
  {10x13 double}
  {10x14 double}
  {10x2  double}
  {10x14 double}
  {10x10 double}
  {10x2  double}
  {10x5  double}
  {10x9  double}
  {10x15 double}
  {10x15 double}
  {10x3  double}
  {10x15 double}
```

Pad the prediction and target sequences in the second dimension using the `padsequences` function and also return the corresponding mask.

```
[Y,mask] = padsequences(Y,2);
targets = padsequences(targets,2);
```

Convert the padded sequences to `darray` with the format "CTB" (channel, time, batch). Because formatted `darray` objects automatically permute the dimensions of the underlying data, keep the order consistent by also converting the targets and mask to formatted `darray` objects with the format "CTB" (channel, batch, time).

```
dLY = darray(Y, "CTB");
targets = darray(targets, "CTB");
mask = darray(mask, "CTB");
```

View the sizes of the prediction scores, targets, and mask.

```
size(dLY)
```

```
ans = 1x3
```

```
    10    12    15
```

```
size(targets)
```

```
ans = 1x3
```

```

    10    12    15

size(mask)
ans = 1×3

    10    12    15

```

Compute the mean squared error (MSE) between the predictions and the targets. To prevent the loss values calculated from padding from contributing to the loss, set the `Mask` option to the mask returned by the `padsequences` function.

```

loss = l2loss(dLY,targets,Mask=mask)

loss =
    1×1 dlarray

    16.3668

```

## Input Arguments

### Y — Predictions

dlarray | numeric array

Predictions, specified as a formatted `dlarray`, an unformatted `dlarray`, or a numeric array. When `Y` is not a formatted `dlarray`, you must specify the dimension format using the `DataFormat` option.

If `Y` is a numeric array, `targets` must be a `dlarray`.

### targets — Target responses

dlarray | numeric array

Target responses, specified as a formatted or unformatted `dlarray` or a numeric array.

The size of each dimension of `targets` must match the size of the corresponding dimension of `Y`.

If `targets` is a formatted `dlarray`, then its format must be the same as the format of `Y`, or the same as `DataFormat` if `Y` is unformatted.

If `targets` is an unformatted `dlarray` or a numeric array, then the function applies the format of `Y` or the value of `DataFormat` to `targets`.

---

**Tip** Formatted `dlarray` objects automatically permute the dimensions of the underlying data to have order "S" (spatial), "C" (channel), "B" (batch), "T" (time), then "U" (unspecified). To ensure that the dimensions of `Y` and `targets` are consistent, when `Y` is a formatted `dlarray`, also specify `targets` as a formatted `dlarray`.

---

### weights — Weights

dlarray | numeric array

Weights, specified as a formatted or unformatted `dlarray` or a numeric array.

If `weights` is a vector and `Y` has two or more nonsingleton dimensions, then `weights` must be a formatted `darray`, where the dimension label of the nonsingleton dimension is either "C" (channel) or "B" (batch) and has a size that matches the size of the corresponding dimension in `Y`.

If `weights` is a formatted `darray` with two or more nonsingleton dimensions, then its format must match the format of `Y`.

If `weights` is not a formatted `darray` and has two or more nonsingleton dimensions, then its size must match the size of `Y` and the function uses the same format as `Y`. Alternatively, to specify the `weights` format, use the `WeightsFormat` option.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `loss = l2loss(Y, targets, Reduction="none")` specifies to compute the  $L_2$  loss without reducing the output to a scalar

### **Mask — Mask indicating which elements to include for loss computation**

`darray` | logical array | numeric array

Mask indicating which elements to include for loss computation, specified as a `darray` object, a logical array, or a numeric array with the same size as `Y`.

The function includes and excludes elements of the input data for loss computation when the corresponding value in the mask is 1 and 0, respectively.

If `Mask` is a formatted `darray` object, then its format must match that of `Y`. If `Mask` is not a formatted `darray` object, then the function uses the same format as `Y`.

If you specify the `DataFormat` option, then the function also uses the specified format for the mask.

The size of each dimension of `Mask` must match the size of the corresponding dimension in `Y`. The default value is a logical array of ones.

---

**Tip** Formatted `darray` objects automatically permute the dimensions of the underlying data to have this order: "S" (spatial), "C" (channel), "B" (batch), "T" (time), and "U" (unspecified). For example, `darray` objects automatically permute the dimensions of data with format "TSCSBS" to have format "SSSCBT".

To ensure that the dimensions of `Y` and the mask are consistent, when `Y` is a formatted `darray`, also specify the mask as a formatted `darray`.

---

### **Reduction — Mode for reducing array of loss values**

"sum" (default) | "none"

Mode for reducing the array of loss values, specified as one of the following:

- "sum" — Sum all of the elements in the array of loss values. In this case, the output `loss` is scalar.
- "none" — Do not reduce the array of loss values. In this case, the output `loss` is an unformatted `darray` object with the same size as `Y`.

**NormalizationFactor — Divisor for normalizing reduced loss**

"batch-size" (default) | "all-elements" | "mask-included" | "none"

Divisor for normalizing the reduced loss when `Reduction` is "sum", specified as one of the following:

- "batch-size" — Normalize the loss by dividing it by the number of observations in `Y`.
- "all-elements" — Normalize the loss by dividing it by the number of elements of `Y`.
- "mask-included" — Normalize the loss by dividing the loss values by the number of included elements specified by the mask for each observation independently. To use this option, you must specify a mask using the `Mask` option.
- "none" — Do not normalize the loss.

**DataFormat — Dimension order of unformatted data**

character vector | string scalar

Dimension order of unformatted input data, specified as a character vector or string scalar `FMT` that provides a label for each dimension of the data.

When you specify the format of a `darray` object, each character provides a label for each dimension of the data and must be one of these options:

- "S" — Spatial
- "C" — Channel
- "B" — Batch (for example, samples and observations)
- "T" — Time (for example, time steps of sequences)
- "U" — Unspecified

You can specify multiple dimensions labeled "S" or "U". You can use the labels "C", "B", and "T" at most once.

You must specify `DataFormat` when the input data is not a formatted `darray`.

Data Types: `char` | `string`

**WeightsFormat — Dimension order of weights**

character vector | string scalar

Dimension order of the weights, specified as a character vector or string scalar that provides a label for each dimension of the weights.

When you specify the format of a `darray` object, each character provides a label for each dimension of the data and must be one of these options:

- "S" — Spatial
- "C" — Channel
- "B" — Batch (for example, samples and observations)
- "T" — Time (for example, time steps of sequences)
- "U" — Unspecified

You can specify multiple dimensions labeled "S" or "U". You can use the labels "C", "B", and "T" at most once.

You must specify `WeightsFormat` when `weights` is a numeric vector and `Y` has two or more nonsingleton dimensions.

If `weights` is not a vector, or both `weights` and `Y` are vectors, then default value of `WeightsFormat` is the same as the format of `Y`.

Data Types: `char` | `string`

## Output Arguments

### loss — L<sub>2</sub> loss

`dlarray`

L<sub>2</sub> loss, returned as an unformatted `dlarray`. The output `loss` is an unformatted `dlarray` with the same underlying data type as the input `Y`.

The size of `loss` depends on the `Reduction` option.

## Algorithms

### L2 Loss

The L<sub>2</sub> loss operation computes the L<sub>2</sub> loss (based on the squared L<sub>2</sub> norm) given network predictions and target values. When the `Reduction` option is "sum" and the `NormalizationFactor` option is "batch-size", the computed value is known as the mean squared error (MSE).

For each element  $Y_j$  of the input, the `l2loss` function computes the corresponding element-wise loss values using

$$\text{loss}_j = (Y_j - T_j)^2,$$

where  $Y_j$  is a predicted value and  $T_j$  is the corresponding target value.

To reduce the loss values to a scalar, the function then reduces the element-wise loss using the formula

$$\text{loss} = \frac{1}{N} \sum_j m_j w_j \text{loss}_j,$$

where  $N$  is the normalization factor,  $m_j$  is the mask value for element  $j$ , and  $w_j$  is the weight value for element  $j$ .

If you do not opt to reduce the loss, then the function applies the mask and the weights to the loss values directly:

$$\text{loss}_j^* = m_j w_j \text{loss}_j$$

## Version History

Introduced in R2021b

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When at least one of the following input arguments is a `gpuArray` or a `darray` with underlying data of type `gpuArray`, this function runs on the GPU:
  - `Y`
  - `targets`
  - `weights`
  - `Mask`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

## Layer

Network layer for deep learning

## Description

Layers that define the architecture of neural networks for deep learning.

## Creation

For a list of deep learning layers in MATLAB, see “List of Deep Learning Layers”. To specify the architecture of a neural network with all layers connected sequentially, create an array of layers directly. To specify the architecture of a network where layers can have multiple inputs or outputs, use a `LayerGraph` object.

Alternatively, you can import layers from Caffe, Keras, and ONNX using `importCaffeLayers`, `importKerasLayers`, and `importONNXLayers` respectively.

To learn how to create your own custom layers, see “Define Custom Deep Learning Layers”.

## Object Functions

`trainNetwork` Train deep learning neural network

## Examples

### Construct Network Architecture

Define a convolutional neural network architecture for classification with one convolutional layer, a ReLU layer, and a fully connected layer.

```
layers = [ ...
    imageInputLayer([28 28 3])
    convolution2dLayer([5 5],10)
    reluLayer
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer]
```

```
layers =
    6x1 Layer array with layers:
```

1	''	Image Input	28x28x3 images with 'zerocenter' normalization
2	''	2-D Convolution	10 5x5 convolutions with stride [1 1] and padding [0 0 0 0]
3	''	ReLU	ReLU
4	''	Fully Connected	10 fully connected layer
5	''	Softmax	softmax
6	''	Classification Output	crossentropyex

`layers` is a `Layer` object.

Alternatively, you can create the layers individually and then concatenate them.

```
input = imageInputLayer([28 28 3]);
conv = convolution2dLayer([5 5],10);
relu = reluLayer;
fc = fullyConnectedLayer(10);
sm = softmaxLayer;
co = classificationLayer;
```

```
layers = [ ...
    input
    conv
    relu
    fc
    sm
    co]
```

```
layers =
    6x1 Layer array with layers:
```

1	''	Image Input	28x28x3 images with 'zerocenter' normalization
2	''	2-D Convolution	10 5x5 convolutions with stride [1 1] and padding [0 0 0 0]
3	''	ReLU	ReLU
4	''	Fully Connected	10 fully connected layer
5	''	Softmax	softmax
6	''	Classification Output	crossentropyex

### Access Layers and Properties in Layer Array

Define a convolutional neural network architecture for classification with one convolutional layer, a ReLU layer, and a fully connected layer.

```
layers = [ ...
    imageInputLayer([28 28 3])
    convolution2dLayer([5 5],10)
    reluLayer
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer];
```

Display the image input layer by selecting the first layer.

```
layers(1)
```

```
ans =
    ImageInputLayer with properties:

        Name: ''
        InputSize: [28 28 3]
        SplitComplexInputs: 0

    Hyperparameters
        DataAugmentation: 'none'
        Normalization: 'zerocenter'
        NormalizationDimension: 'auto'
```

```
Mean: []
```

View the input size of the image input layer.

```
layers(1).InputSize
```

```
ans = 1×3
      28   28   3
```

Display the stride for the convolutional layer.

```
layers(2).Stride
```

```
ans = 1×2
      1   1
```

Access the bias learn rate factor for the fully connected layer.

```
layers(4).BiasLearnRateFactor
```

```
ans = 1
```

### Create Simple DAG Network

Create a simple directed acyclic graph (DAG) network for deep learning. Train the network to classify images of digits. The simple network in this example consists of:

- A main branch with layers connected sequentially.
- A *shortcut connection* containing a single 1-by-1 convolutional layer. Shortcut connections enable the parameter gradients to flow more easily from the output layer to the earlier layers of the network.

Create the main branch of the network as a layer array. The addition layer sums multiple inputs element-wise. Specify the number of inputs for the addition layer to sum. To easily add connections later, specify names for the first ReLU layer and the addition layer.

```
layers = [
    imageInputLayer([28 28 1])

    convolution2dLayer(5,16, 'Padding', 'same')
    batchNormalizationLayer
    reluLayer('Name', 'relu_1')

    convolution2dLayer(3,32, 'Padding', 'same', 'Stride', 2)
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,32, 'Padding', 'same')
    batchNormalizationLayer
    reluLayer

    additionLayer(2, 'Name', 'add')
```

```

averagePooling2dLayer(2, 'Stride', 2)
fullyConnectedLayer(10)
softmaxLayer
classificationLayer];

```

Create a layer graph from the layer array. `layerGraph` connects all the layers in `layers` sequentially. Plot the layer graph.

```

lgraph = layerGraph(layers);
figure
plot(lgraph)

```

Create the 1-by-1 convolutional layer and add it to the layer graph. Specify the number of convolutional filters and the stride so that the activation size matches the activation size of the third ReLU layer. This arrangement enables the addition layer to add the outputs of the third ReLU layer and the 1-by-1 convolutional layer. To check that the layer is in the graph, plot the layer graph.

```

skipConv = convolution2dLayer(1,32, 'Stride', 2, 'Name', 'skipConv');
lgraph = addLayers(lgraph, skipConv);
figure
plot(lgraph)

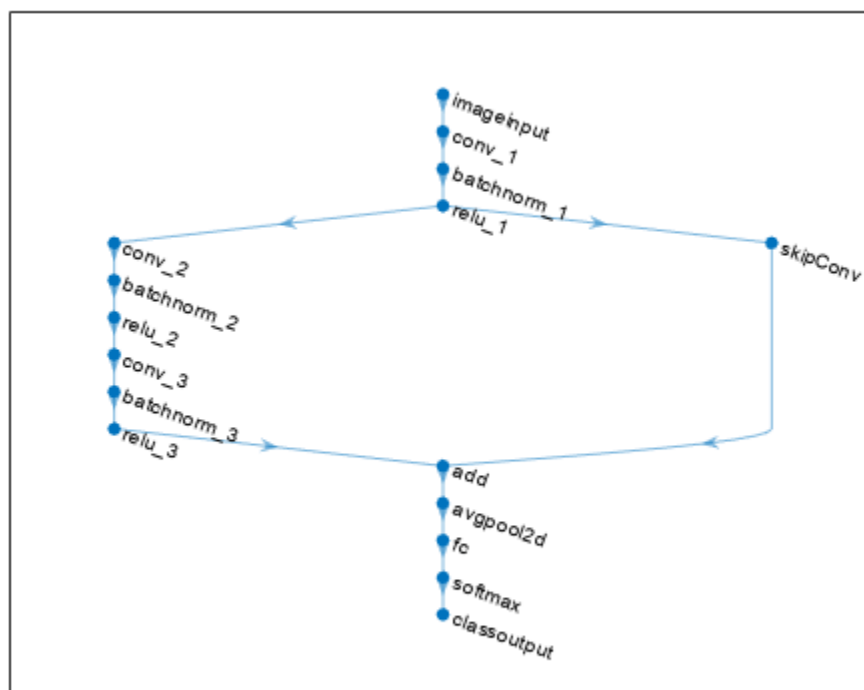

```

Create the shortcut connection from the 'relu\_1' layer to the 'add' layer. Because you specified two as the number of inputs to the addition layer when you created it, the layer has two inputs named 'in1' and 'in2'. The third ReLU layer is already connected to the 'in1' input. Connect the 'relu\_1' layer to the 'skipConv' layer and the 'skipConv' layer to the 'in2' input of the 'add' layer. The addition layer now sums the outputs of the third ReLU layer and the 'skipConv' layer. To check that the layers are connected correctly, plot the layer graph.

```
lgraph = connectLayers(lgraph, 'relu_1', 'skipConv');
lgraph = connectLayers(lgraph, 'skipConv', 'add/in2');
figure
plot(lgraph);
```

Load the training and validation data, which consists of 28-by-28 grayscale images of digits.

```
[XTrain,YTrain] = digitTrain4DArrayData;
[XValidation,YValidation] = digitTest4DArrayData;
```

Specify training options and train the network. `trainNetwork` validates the network using the validation data every `ValidationFrequency` iterations.

```
options = trainingOptions('sgdm', ...
    'MaxEpochs',8, ...
    'Shuffle','every-epoch', ...
    'ValidationData',{XValidation,YValidation}, ...
    'ValidationFrequency',30, ...
    'Verbose',false, ...
    'Plots','training-progress');
net = trainNetwork(XTrain,YTrain,lgraph,options);
```

Display the properties of the trained network. The network is a DAGNetwork object.

```
net
net =
  DAGNetwork with properties:
    Layers: [16x1 nnet.cnn.layer.Layer]
    Connections: [16x2 table]
    InputNames: {'imageinput'}
    OutputNames: {'classoutput'}
```

Classify the validation images and calculate the accuracy. The network is very accurate.

```
YPredicted = classify(net,XValidation);
accuracy = mean(YPredicted == YValidation)

accuracy = 0.9932
```

# layerGraph

Graph of network layers for deep learning

## Description

A layer graph specifies the architecture of a deep learning network with a more complex graph structure in which layers can have inputs from multiple layers and outputs to multiple layers. Networks with this structure are called directed acyclic graph (DAG) networks. After you create a `layerGraph` object, you can use the object functions to plot the graph and modify it by adding, removing, connecting, and disconnecting layers. To train the network, use the layer graph as input to the `trainNetwork` function or convert it to a `dlnetwork` and train it using a custom training loop.

## Creation

### Syntax

```
lgraph = layerGraph
lgraph = layerGraph(layers)
lgraph = layerGraph(net)
```

### Description

`lgraph = layerGraph` creates an empty layer graph that contains no layers. You can add layers to the empty graph by using the `addLayers` function.

`lgraph = layerGraph(layers)` creates a layer graph from an array of network layers and sets the `Layers` property. The layers in `lgraph` are connected in the same sequential order as in `layers`.

`lgraph = layerGraph(net)` extracts the layer graph of a `SeriesNetwork`, `DAGNetwork`, or `dlnetwork` object. For example, you can extract the layer graph of a pretrained network to perform transfer learning.

### Input Arguments

#### **net** — Deep learning network

`SeriesNetwork` object | `DAGNetwork` object | `dlnetwork` object

Deep learning network, specified as a `SeriesNetwork`, `DAGNetwork`, or `dlnetwork` object.

## Properties

### **Layers** — Network layers

Layer array

This property is read-only.

Network layers, specified as a Layer array.

**Connections — Layer connections**

table

This property is read-only.

Layer connections, specified as a table with two columns.

Each table row represents a connection in the layer graph. The first column, `Source`, specifies the source of each connection. The second column, `Destination`, specifies the destination of each connection. The connection sources and destinations are either layer names or have the form `'layerName/IOName'`, where `'IOName'` is the name of the layer input or output.

Data Types: table

**InputNames — Network input layer names**

cell array of character vectors

This property is read-only.

Network input layer names, specified as a cell array of character vectors.

Data Types: cell

**OutputNames — Network output layer names**

cell array

Network output layer names, specified as a cell array of character vectors.

Data Types: cell

**Object Functions**

<code>addLayers</code>	Add layers to layer graph or network
<code>removeLayers</code>	Remove layers from layer graph or network
<code>replaceLayer</code>	Replace layer in layer graph or network
<code>connectLayers</code>	Connect layers in layer graph or network
<code>disconnectLayers</code>	Disconnect layers in layer graph or network
<code>plot</code>	Plot neural network architecture

**Examples****Add Layers to Layer Graph**

Create an empty layer graph and an array of layers. Add the layers to the layer graph and plot the graph. `addLayers` connects the layers sequentially.

```
lgraph = layerGraph;

layers = [
    imageInputLayer([32 32 3], 'Name', 'input')
    convolution2dLayer(3,16, 'Padding', 'same', 'Name', 'conv_1')
    batchNormalizationLayer('Name', 'BN_1')
    reluLayer('Name', 'relu_1')];

lgraph = addLayers(lgraph, layers);
```

```
figure  
plot(lgraph)
```

### Create Layer Graph from an Array of Layers

Create an array of layers.

```
layers = [  
    imageInputLayer([28 28 1], 'Name', 'input')  
    convolution2dLayer(3,16, 'Padding', 'same', 'Name', 'conv_1')  
    batchNormalizationLayer('Name', 'BN_1')  
    reluLayer('Name', 'relu_1')];
```

Create a layer graph from the layer array. `layerGraph` connects all the layers in `layers` sequentially. Plot the layer graph.

```
lgraph = layerGraph(layers);  
figure  
plot(lgraph)
```

### Extract Layer Graph of DAG Network

Load a pretrained SqueezeNet network. You can use this trained network for classification and prediction.

```
net = squeezeNet;
```

To modify the network structure, first extract the structure of the DAG network by using `layerGraph`. You can then use the object functions of `LayerGraph` to modify the network architecture.

```
lgraph = layerGraph(net)
```

```
lgraph =  
  LayerGraph with properties:  
    InputNames: {'data'}  
    OutputNames: {'ClassificationLayer_predictions'}  
    Layers: [68x1 nnet.cnn.layer.Layer]  
    Connections: [75x2 table]
```

### Create Simple DAG Network

Create a simple directed acyclic graph (DAG) network for deep learning. Train the network to classify images of digits. The simple network in this example consists of:

- A main branch with layers connected sequentially.
- A *shortcut connection* containing a single 1-by-1 convolutional layer. Shortcut connections enable the parameter gradients to flow more easily from the output layer to the earlier layers of the network.

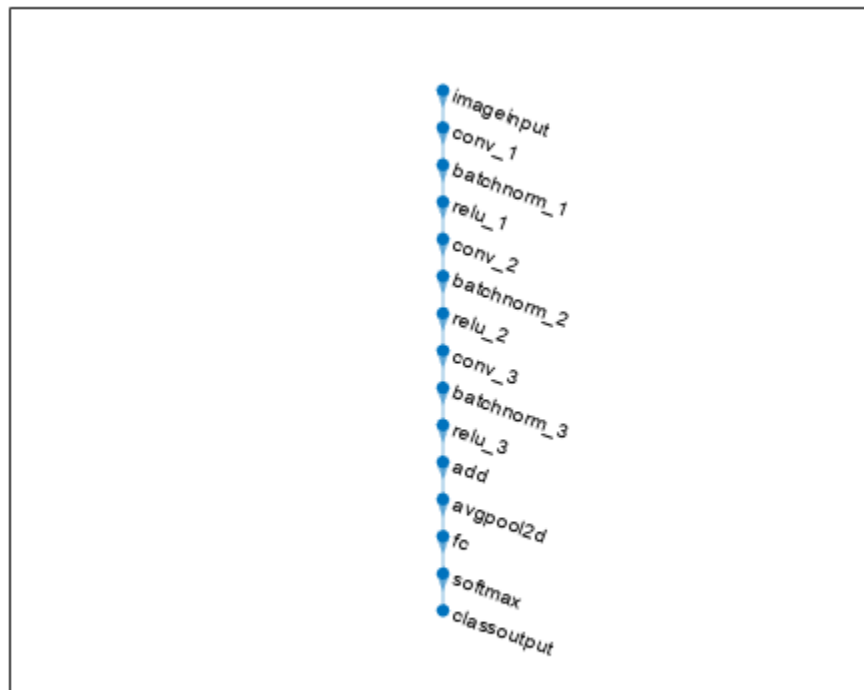

Create the main branch of the network as a layer array. The addition layer sums multiple inputs element-wise. Specify the number of inputs for the addition layer to sum. To easily add connections later, specify names for the first ReLU layer and the addition layer.

```
layers = [  
    imageInputLayer([28 28 1])  
  
    convolution2dLayer(5,16,'Padding','same')  
    batchNormalizationLayer  
    reluLayer('Name','relu_1')  
  
    convolution2dLayer(3,32,'Padding','same','Stride',2)  
    batchNormalizationLayer  
    reluLayer  
    convolution2dLayer(3,32,'Padding','same')  
    batchNormalizationLayer  
    reluLayer  
  
    additionLayer(2,'Name','add')  
  
    averagePooling2dLayer(2,'Stride',2)  
    fullyConnectedLayer(10)  
    softmaxLayer  
    classificationLayer];
```

Create a layer graph from the layer array. `layerGraph` connects all the layers in `layers` sequentially. Plot the layer graph.

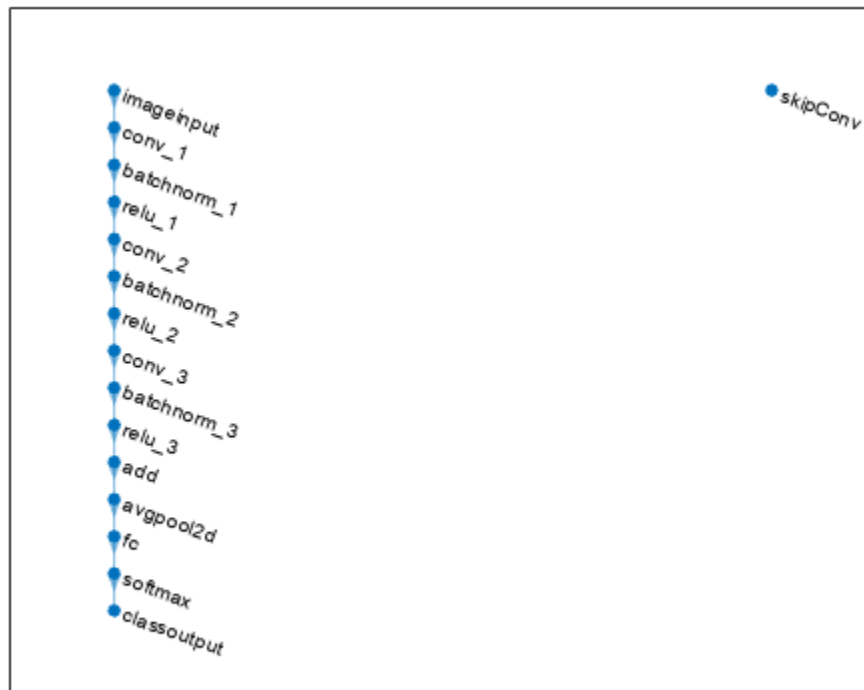

```
lgraph = layerGraph(layers);  
figure  
plot(lgraph)
```

Create the 1-by-1 convolutional layer and add it to the layer graph. Specify the number of convolutional filters and the stride so that the activation size matches the activation size of the third ReLU layer. This arrangement enables the addition layer to add the outputs of the third ReLU layer and the 1-by-1 convolutional layer. To check that the layer is in the graph, plot the layer graph.

```
skipConv = convolution2dLayer(1,32,'Stride',2,'Name','skipConv');  
lgraph = addLayers(lgraph,skipConv);  
figure  
plot(lgraph)
```

Create the shortcut connection from the 'relu\_1' layer to the 'add' layer. Because you specified two as the number of inputs to the addition layer when you created it, the layer has two inputs named 'in1' and 'in2'. The third ReLU layer is already connected to the 'in1' input. Connect the 'relu\_1' layer to the 'skipConv' layer and the 'skipConv' layer to the 'in2' input of the 'add' layer. The addition layer now sums the outputs of the third ReLU layer and the 'skipConv' layer. To check that the layers are connected correctly, plot the layer graph.

```
lgraph = connectLayers(lgraph, 'relu_1', 'skipConv');  
lgraph = connectLayers(lgraph, 'skipConv', 'add/in2');  
figure  
plot(lgraph);
```

Load the training and validation data, which consists of 28-by-28 grayscale images of digits.

```
[XTrain,YTrain] = digitTrain4DArrayData;
[XValidation,YValidation] = digitTest4DArrayData;
```

Specify training options and train the network. `trainNetwork` validates the network using the validation data every `ValidationFrequency` iterations.

```
options = trainingOptions('sgdm', ...
    'MaxEpochs',8, ...
    'Shuffle','every-epoch', ...
    'ValidationData',{XValidation,YValidation}, ...
    'ValidationFrequency',30, ...
    'Verbose',false, ...
    'Plots','training-progress');
net = trainNetwork(XTrain,YTrain,lgraph,options);
```

Display the properties of the trained network. The network is a DAGNetwork object.

```
net
```

```
net =
  DAGNetwork with properties:

    Layers: [16x1 nnet.cnn.layer.Layer]
  Connections: [16x2 table]
  InputNames: {'imageinput'}
  OutputNames: {'classoutput'}
```

Classify the validation images and calculate the accuracy. The network is very accurate.

```
YPredicted = classify(net,XValidation);
accuracy = mean(YPredicted == YValidation)

accuracy = 0.9932
```

## Limitations

- Layer graph objects contain no quantization information. Extracting the layer graph from a quantized network and then reassembling the network using `assembleNetwork` or `dlnetwork` removes quantization information from the network.

## layernorm

Normalize data across all channels for each observation independently

### Syntax

```
Y = layernorm(X,offset,scaleFactor)
Y = layernorm(X,offset,scaleFactor,'DataFormat',FMT)
Y = layernorm( ____,Name,Value)
```

### Description

The layer normalization operation normalizes the input data across all channels for each observation independently. To speed up training of recurrent and multilayer perceptron neural networks and reduce the sensitivity to network initialization, use layer normalization after the learnable operations, such as LSTM and fully connect operations.

After normalization, the operation shifts the input by a learnable offset  $\beta$  and scales it by a learnable scale factor  $\gamma$ .

The `layernorm` function applies the layer normalization operation to `darray` data. Using `darray` objects makes working with high dimensional data easier by allowing you to label the dimensions. For example, you can label which dimensions correspond to spatial, time, channel, and batch dimensions using the "S", "T", "C", and "B" labels, respectively. For unspecified and other dimensions, use the "U" label. For `darray` object functions that operate over particular dimensions, you can specify the dimension labels by formatting the `darray` object directly, or by using the `DataFormat` option.

---

**Note** To apply layer normalization within a `layerGraph` object or `Layer` array, use `layerNormalizationLayer`.

---

`Y = layernorm(X,offset,scaleFactor)` applies the layer normalization operation to the input data `X` and transforms it using the specified offset and scale factor.

The function normalizes over the 'S' (spatial), 'T' (time), 'C' (channel), and 'U' (unspecified) dimensions of `X` for each observation in the 'B' (batch) dimension, independently.

For unformatted input data, use the 'DataFormat' option.

`Y = layernorm(X,offset,scaleFactor,'DataFormat',FMT)` applies the layer normalization operation to the unformatted `darray` object `X` with the format specified by `FMT`. The output `Y` is an unformatted `darray` object with dimensions in the same order as `X`. For example, 'DataFormat', 'SSCB' specifies data for 2-D image input with the format 'SSCB' (spatial, spatial, channel, batch).

To specify the format of the scale and offset, use the 'ScaleFormat' and 'OffsetFormat' options, respectively.

`Y = layernorm( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, 'Epsilon', 1e-4 sets the epsilon value to 1e-4.

## Examples

### Apply Layer Normalization

Create a formatted `dLarray` object containing a batch of 128 sequences of length 100 with 10 channels. Specify the format 'CBT' (channel, batch, time).

```
numChannels = 10;  
miniBatchSize = 128;  
sequenceLength = 100;
```

```
X = rand(numChannels,miniBatchSize,sequenceLength);  
dLX = dLarray(X, 'CBT');
```

View the size and format of the input data.

```
size(dLX)
```

```
ans = 1×3
```

```
    10    128    100
```

```
dims(dLX)
```

```
ans =  
'CBT'
```

For per-observation channel-wise layer normalization, initialize the offset and scale with a vector of zeros and ones, respectively.

```
offset = zeros(numChannels,1);  
scaleFactor = ones(numChannels,1);
```

Apply the layer normalization operation using the `layernorm` function.

```
dLY = layernorm(dLX,offset,scaleFactor);
```

View the size and the format of the output `dLY`.

```
size(dLY)
```

```
ans = 1×3
```

```
    10    128    100
```

```
dims(dLY)
```

```
ans =  
'CBT'
```

### Apply Element-Wise Layer Normalization

To perform element-wise layer normalization, specify an offset and scale factor with the same size as a single input observation.

Create a formatted `darray` object containing a batch of 128 224-by-224 images with 3 channels. Specify the format "SSCB" (spatial, spatial, channel, batch).

```
numChannels = 3;
miniBatchSize = 128;
H = 224;
W = 224;
X = rand(H,W,numChannels,miniBatchSize);
X = darray(X, "SSCB");
```

View the size and format of the input data.

```
size(X)
```

```
ans = 1×4
      224   224     3   128
```

```
dims(X)
```

```
ans =
'SSCB'
```

For element-wise layer normalization, initialize the offset and scale with an array of zeros and ones, respectively.

```
offset = zeros(H,W,numChannels);
scaleFactor = ones(H,W,numChannels);
```

Apply the layer normalization operation using the `layernorm` function. Specify the offset and scale formats as "SSC" (spatial, spatial, channel) using the 'OffsetFormat' and 'ScaleFormat' options, respectively.

```
Y = layernorm(X,offset,scaleFactor, 'OffsetFormat', "SSC", 'ScaleFormat', "SSC");
```

View the size and the format of the output data.

```
size(Y)
```

```
ans = 1×4
      224   224     3   128
```

```
dims(Y)
```

```
ans =
'SSCB'
```

## Input Arguments

### X — Input data

`darray` | numeric array

Input data, specified as a formatted `darray`, an unformatted `darray`, or a numeric array.

If X is an unformatted `darray` or a numeric array, then you must specify the format using the `DataFormat` option. If X is a numeric array, then either `scaleFactor` or `offset` must be a `darray` object.

X must have a 'C' (channel) dimension.

### offset — Offset

`darray` | numeric array

Offset  $\beta$ , specified as a formatted `darray`, an unformatted `darray`, or a numeric array.

The size and format of the offset depends on the type of transformation.

Task	Description
Channel-wise transformation	<p>Array with one nonsingleton dimension with size matching the size of the 'C' (channel) dimension of the input X.</p> <p>For channel-wise transformation, if <code>offset</code> is a formatted <code>darray</code> object, then the nonsingleton dimension must have label 'C' (channel).</p>
Element-wise transformation	<p>Array with a 'C' (channel) dimension with the same size as the 'C' (channel) dimension of the input X and zero or the same number of 'S' (spatial), 'T' (time), and 'U' (unspecified) dimensions of the input X.</p> <p>Each dimension must have size 1 or have sizes matching the corresponding dimensions in the input X. For any repeated dimensions, for example, multiple 'S' (spatial) dimensions, the sizes must match the corresponding dimensions in X or must all be singleton.</p> <p>The software automatically expands any singleton dimensions to match the size of a single observation in the input X.</p> <p>For element-wise transformation, if <code>offset</code> is a numeric array or an unformatted <code>darray</code>, then you must specify the offset format using the '<code>OffsetFormat</code>' option.</p>

### scaleFactor — Scale factor

`darray` | numeric array

Scale factor  $\gamma$ , specified as a formatted `darray`, an unformatted `darray`, or a numeric array.

The size and format of the offset depends on the type of transformation.

Task	Description
Channel-wise transformation	<p>Array with one nonsingleton dimension with size matching the size of the 'C' (channel) dimension of the input X.</p> <p>For channel-wise transformation, if <code>scaleFactor</code> is a formatted <code>darray</code> object, then the nonsingleton dimension must have label 'C' (channel).</p>
Element-wise transformation	<p>Array with a 'C' (channel) dimension with the same size as the 'C' (channel) dimension of the input X and zero or the same number of 'S' (spatial), 'T' (time), and 'U' (unspecified) dimensions of the input X.</p> <p>Each dimension must have size 1 or have sizes matching the corresponding dimensions in the input X. For any repeated dimensions, for example, multiple 'S' (spatial) dimensions, the sizes must match the corresponding dimensions in X or must all be singleton.</p> <p>The software automatically expands any singleton dimensions to match the size of a single observation in the input X.</p> <p>For element-wise transformation, if <code>scaleFactor</code> is a numeric array or an unformatted <code>darray</code>, then you must specify the scale format using the 'ScaleFormat' option.</p>

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'Epsilon', 1e-4` sets the variance offset value to `1e-4`.

### DataFormat — Dimension order of unformatted data

character vector | string scalar

Dimension order of unformatted input data, specified as a character vector or string scalar `FMT` that provides a label for each dimension of the data.

When you specify the format of a `darray` object, each character provides a label for each dimension of the data and must be one of these options:

- "S" — Spatial

- "C" — Channel
- "B" — Batch (for example, samples and observations)
- "T" — Time (for example, time steps of sequences)
- "U" — Unspecified

You can specify multiple dimensions labeled "S" or "U". You can use the labels "C", "B", and "T" at most once.

You must specify `DataFormat` when the input data is not a formatted `darray`.

Data Types: `char` | `string`

### **Epsilon — Constant to add to mini-batch variances**

`1e-5` (default) | positive scalar

Constant to add to the mini-batch variances, specified as a positive scalar.

The software adds this constant to the mini-batch variances before normalization to ensure numerical stability and avoid division by zero.

Epsilon must be greater than or equal to `1e-5`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ScaleFormat — Dimension order of unformatted scale factor**

character vector | string scalar

Dimension order of the unformatted scale factor, specified as the comma-separated pair consisting of 'ScaleFormat' and a character vector or string scalar.

When you specify the format of a `darray` object, each character provides a label for each dimension of the data and must be one of these options:

- "S" — Spatial
- "C" — Channel
- "B" — Batch (for example, samples and observations)
- "T" — Time (for example, time steps of sequences)
- "U" — Unspecified

For layer normalization, the scale factor must have a "C" (channel) dimension. You can specify multiple dimensions labeled 'S' or 'U'. You can use the label "T" (time) at most once. The scale factor must not have a "B" (batch) dimension.

You must specify 'ScaleFormat' for element-wise normalization when `scaleFactor` is a numeric array or an unformatted `darray`.

Example: 'ScaleFormat', "SSCB"

Data Types: `char` | `string`

### **OffsetFormat — Dimension order of unformatted offset**

character vector | string scalar

Dimension order of the unformatted offset, specified as the comma-separated pair consisting of 'OffsetFormat' and a character vector or string scalar.

When you specify the format of a `darray` object, each character provides a label for each dimension of the data and must be one of these options:

- "S" — Spatial
- "C" — Channel
- "B" — Batch (for example, samples and observations)
- "T" — Time (for example, time steps of sequences)
- "U" — Unspecified

For layer normalization, the offset must have a "C" (channel) dimension. You can specify multiple dimensions labeled "S" or 'U'. You can use the label "T" (time) at most once. The offset must not have a "B" (batch) dimension.

You must specify `'OffsetFormat'` for element-wise normalization when `offset` is a numeric array or an unformatted `darray`.

Example: `'OffsetFormat', "SSCB"`

Data Types: `char | string`

### **OperationDimension — Dimension to normalize over**

`"auto" (default) | "channel-only" | "spatial-channel" | "batch-excluded"`

Dimension to normalize over, specified as one of these values:

- "auto" — For feature, sequence, 1-D image, or spatial-temporal input, normalize over the channel dimension. Otherwise, normalize over the spatial and channel dimensions.
- "channel-only" — Normalize over the channel dimension.
- "spatial-channel" — Normalize over the spatial and channel dimensions.
- "batch-excluded" — Normalize over all dimensions except for the batch dimension.

## **Output Arguments**

### **Y — Normalized data**

`darray`

Normalized data, returned as a `darray`. The output Y has the same underlying data type as the input X.

If the input data X is a formatted `darray`, Y has the same dimension labels as X. If the input data is not a formatted `darray`, Y is an unformatted `darray` with the same dimension order as the input data.

## **Algorithms**

The layer normalization operation normalizes the elements  $x_i$  of the input by first calculating the mean  $\mu_L$  and variance  $\sigma_L^2$  over the spatial, time, and channel dimensions for each observation independently. Then, it calculates the normalized activations as

$$\hat{x}_i = \frac{x_i - \mu_L}{\sqrt{\sigma_L^2 + \epsilon}}$$

where  $\epsilon$  is a constant that improves numerical stability when the variance is very small.

To allow for the possibility that inputs with zero mean and unit variance are not optimal for the operations that follow layer normalization, the layer normalization operation further shifts and scales the activations using the transformation

$$y_i = \gamma \hat{x}_i + \beta,$$

where the offset  $\beta$  and scale factor  $\gamma$  are learnable parameters that are updated during network training.

## Version History

Introduced in R2021a

### R2023a: Specify operation dimension

Specify which dimensions to normalize over using the `OperationDimension` option.

### R2023a: Epsilon supports values less than 1e-5

The `Epsilon` option also supports positive values less than 1e-5.

### R2023a: Operation normalizes over channel and spatial dimensions of 2-D and 3-D image sequence data

*Behavior changed in R2023a*

Starting in R2023a, by default, the operation normalizes 2-D and 3-D image sequence data over the channel and spatial dimensions. In previous versions, the software normalizes over all dimensions except for the batch dimension (the spatial, time, and channel dimensions). Normalization over the channel and spatial dimensions is usually better suited for these types of data. To reproduce the previous behavior, set `OperationDimension` to "batch-excluded".

### R2023a: Operation normalizes over channel dimension of 1-D image, vector sequence, and 1-D image sequence data

*Behavior changed in R2023a*

Starting in R2023a, by default, the operation normalizes 1-D image data (data with one spatial dimension and no time dimension), vector sequence (data with a time dimension and no spatial dimensions) and 1-D image sequence data (data with one spatial dimension and a time dimension) over the channel dimension. In previous versions, the software normalizes over all dimensions except for the batch dimension (the spatial, time, and channel dimensions). Normalization over the channel dimension is usually better suited for these types of data. To reproduce the previous behavior, set `OperationDimension` to "batch-excluded".

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When at least one of the following input arguments is a `gpuArray` or a `dLarray` with underlying data of type `gpuArray`, this function runs on the GPU:
  - `X`
  - `offset`
  - `scaleFactor`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# layerNormalizationLayer

Layer normalization layer

## Description

A layer normalization layer normalizes a mini-batch of data across all channels for each observation independently. To speed up training of recurrent and multilayer perceptron neural networks and reduce the sensitivity to network initialization, use layer normalization layers after the learnable layers, such as LSTM and fully connected layers.

After normalization, the layer scales the input with a learnable scale factor  $\gamma$  and shifts it by a learnable offset  $\beta$ .

## Creation

### Syntax

```
layer = layerNormalizationLayer
layer = layerNormalizationLayer(Name,Value)
```

### Description

`layer = layerNormalizationLayer` creates a layer normalization layer.

`layer = layerNormalizationLayer(Name,Value)` sets the optional `Epsilon`, “Parameters and Initialization” on page 1-1198, “Learning Rate and Regularization” on page 1-1200, and `Name` properties using one or more name-value arguments. For example, `layerNormalizationLayer('Name','layernorm')` creates a layer normalization layer with name 'layernorm'.

## Properties

### Layer Normalization

#### Epsilon — Constant to add to mini-batch variances

1e-5 (default) | positive scalar

Constant to add to the mini-batch variances, specified as a positive scalar.

The software adds this constant to the mini-batch variances before normalization to ensure numerical stability and avoid division by zero.

Epsilon must be greater than or equal to 1e-5.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### NumChannels — Number of input channels

'auto' (default) | positive integer

This property is read-only.

Number of input channels, specified as one of the following:

- 'auto' — Automatically determine the number of input channels at training time.
- Positive integer — Configure the layer for the specified number of input channels. `NumChannels` and the number of channels in the layer input data must match. For example, if the input is an RGB image, then `NumChannels` must be 3. If the input is the output of a convolutional layer with 16 filters, then `NumChannels` must be 16.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

#### **OperationDimension — Dimension to normalize over**

"auto" (default) | "channel-only" | "spatial-channel" | "batch-excluded"

Dimension to normalize over, specified as one of these values:

- "auto" — For feature, sequence, 1-D image, or spatial-temporal input, normalize over the channel dimension. Otherwise, normalize over the spatial and channel dimensions.
- "channel-only" — Normalize over the channel dimension.
- "spatial-channel" — Normalize over the spatial and channel dimensions.
- "batch-excluded" — Normalize over all dimensions except for the batch dimension.

#### **Parameters and Initialization**

##### **ScaleInitializer — Function to initialize channel scale factors**

'ones' (default) | 'narrow-normal' | function handle

Function to initialize the channel scale factors, specified as one of the following:

- 'ones' - Initialize the channel scale factors with ones.
- 'zeros' - Initialize the channel scale factors with zeros.
- 'narrow-normal' - Initialize the channel scale factors by independently sampling from a normal distribution with a mean of zero and standard deviation of 0.01.
- Function handle - Initialize the channel scale factors with a custom function. If you specify a function handle, then the function must be of the form `scale = func(sz)`, where `sz` is the size of the scale. For an example, see "Specify Custom Weight Initialization Function".

The layer only initializes the channel scale factors when the `Scale` property is empty.

Data Types: `char` | `string` | `function_handle`

##### **OffsetInitializer — Function to initialize channel offsets**

'zeros' (default) | 'ones' | 'narrow-normal' | function handle

Function to initialize the channel offsets, specified as one of the following:

- 'zeros' - Initialize the channel offsets with zeros.
- 'ones' - Initialize the channel offsets with ones.
- 'narrow-normal' - Initialize the channel offsets by independently sampling from a normal distribution with a mean of zero and standard deviation of 0.01.

- Function handle - Initialize the channel offsets with a custom function. If you specify a function handle, then the function must be of the form `offset = func(sz)`, where `sz` is the size of the scale. For an example, see “Specify Custom Weight Initialization Function”.

The layer only initializes the channel offsets when the `Offset` property is empty.

Data Types: `char` | `string` | `function_handle`

### Scale — Channel scale factors

`[]` (default) | numeric array

Channel scale factors  $\gamma$ , specified as a numeric array.

The channel scale factors are learnable parameters. When you train a network using the `trainNetwork` function or initialize a `dlnetwork` object, if `Scale` is nonempty, then the software uses the `Scale` property as the initial value. If `Scale` is empty, then the software uses the initializer specified by `ScaleInitializer`.

Depending on the type of layer input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically reshape this property to have of the following sizes:

Layer Input	Property Size
feature input	NumChannels-by-1
vector sequence input	
1-D image input	1-by-NumChannels
1-D image sequence input	
2-D image input	1-by-1-by-NumChannels
2-D image sequence input	
3-D image input	1-by-1-by-1-by-NumChannels
3-D image sequence input	

Data Types: `single` | `double`

### Offset — Channel offsets

`[]` (default) | numeric array

Channel offsets  $\beta$ , specified as a numeric vector.

The channel offsets are learnable parameters. When you train a network using the `trainNetwork` function or initialize a `dlnetwork` object, if `Offset` is nonempty, then the software uses the `Offset` property as the initial value. If `Offset` is empty, then the software uses the initializer specified by `OffsetInitializer`.

Depending on the type of layer input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically reshape this property to have of the following sizes:

Layer Input	Property Size
feature input	NumChannels-by-1
vector sequence input	
1-D image input	1-by-NumChannels

Layer Input	Property Size
1-D image sequence input	
2-D image input	1-by-1-by-NumChannels
2-D image sequence input	
3-D image input	1-by-1-by-1-by-NumChannels
3-D image sequence input	

Data Types: `single` | `double`

### Learning Rate and Regularization

#### ScaleLearnRateFactor — Learning rate factor for scale factors

1 (default) | nonnegative scalar

Learning rate factor for the scale factors, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the scale factors in a layer. For example, if `ScaleLearnRateFactor` is 2, then the learning rate for the scale factors in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings specified with the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### OffsetLearnRateFactor — Learning rate factor for offsets

1 (default) | nonnegative scalar

Learning rate factor for the offsets, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the offsets in a layer. For example, if `OffsetLearnRateFactor` is 2, then the learning rate for the offsets in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings specified with the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### ScaleL2Factor — L<sub>2</sub> regularization factor for scale factors

1 (default) | nonnegative scalar

L<sub>2</sub> regularization factor for the scale factors, specified as a nonnegative scalar.

The software multiplies this factor by the global L<sub>2</sub> regularization factor to determine the learning rate for the scale factors in a layer. For example, if `ScaleL2Factor` is 2, then the L<sub>2</sub> regularization for the offsets in the layer is twice the global L<sub>2</sub> regularization factor. You can specify the global L<sub>2</sub> regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### OffsetL2Factor — L<sub>2</sub> regularization factor for offsets

1 (default) | nonnegative scalar

L<sub>2</sub> regularization factor for the offsets, specified as a nonnegative scalar.

The software multiplies this factor by the global L<sub>2</sub> regularization factor to determine the learning rate for the offsets in a layer. For example, if `OffsetL2Factor` is 2, then the L<sub>2</sub> regularization for the

offsets in the layer is twice the global  $L_2$  regularization factor. You can specify the global  $L_2$  regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Layer

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

### InputNames — Input names

{'in'} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: `cell`

### NumOutputs — Number of outputs

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: `double`

### OutputNames — Output names

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: `cell`

## Examples

### Create Layer Normalization Layer

Create a layer normalization layer with the name 'layernorm'.

```
layer = layerNormalizationLayer('Name','layernorm')
```

```
layer =
  LayerNormalizationLayer with properties:
```

```
        Name: 'layernorm'
    NumChannels: 'auto'
```

```
Hyperparameters
```

```
    Epsilon: 1.0000e-05
OperationDimension: 'auto'
```

```
Learnable Parameters
```

```
    Offset: []
    Scale: []
```

```
Show all properties
```

Include a layer normalization layer in a Layer array.

```
layers = [
  imageInputLayer([32 32 3])
  convolution2dLayer(3,16,'Padding',1)
  layerNormalizationLayer
  reluLayer
  maxPooling2dLayer(2,'Stride',2)
  convolution2dLayer(3,32,'Padding',1)
  layerNormalizationLayer
  reluLayer
  fullyConnectedLayer(10)
  softmaxLayer
  classificationLayer]
```

```
layers =
  11x1 Layer array with layers:
```

1	''	Image Input	32x32x3 images with 'zerocenter' normalization
2	''	2-D Convolution	16 3x3 convolutions with stride [1 1] and padding [1 1]
3	''	Layer Normalization	Layer normalization
4	''	ReLU	ReLU
5	''	2-D Max Pooling	2x2 max pooling with stride [2 2] and padding [0 0 0 0]
6	''	2-D Convolution	32 3x3 convolutions with stride [1 1] and padding [1 1]
7	''	Layer Normalization	Layer normalization
8	''	ReLU	ReLU
9	''	Fully Connected	10 fully connected layer
10	''	Softmax	softmax
11	''	Classification Output	crossentropyex

## Algorithms

### Layer Normalization Layer

The layer normalization operation normalizes the elements  $x_i$  of the input by first calculating the mean  $\mu_L$  and variance  $\sigma_L^2$  over the spatial, time, and channel dimensions for each observation independently. Then, it calculates the normalized activations as

$$\widehat{x}_i = \frac{x_i - \mu_L}{\sqrt{\sigma_L^2 + \epsilon}},$$

where  $\epsilon$  is a constant that improves numerical stability when the variance is very small.

To allow for the possibility that inputs with zero mean and unit variance are not optimal for the operations that follow layer normalization, the layer normalization operation further shifts and scales the activations using the transformation

$$y_i = \gamma \widehat{x}_i + \beta,$$

where the offset  $\beta$  and scale factor  $\gamma$  are learnable parameters that are updated during network training.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `LayerNormalizationLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"CB" (channel, batch)	"CB" (channel, batch)
"SCB" (spatial, channel, batch)	"SCB" (spatial, channel, batch)
"SSCB" (spatial, spatial, channel, batch)	"SSCB" (spatial, spatial, channel, batch)
"SSSCB" (spatial, spatial, spatial, channel, batch)	"SSSCB" (spatial, spatial, spatial, channel, batch)
"CBT" (channel, batch, time)	"CBT" (channel, batch, time)
"SCBT" (spatial, channel, batch, time)	"SCBT" (spatial, channel, batch, time)
"SSCBT" (spatial, spatial, channel, batch, time)	"SSCBT" (spatial, spatial, channel, batch, time)

Input Format	Output Format
"SSSCBT" (spatial, spatial, spatial, channel, batch, time)	"SSSCBT" (spatial, spatial, spatial, channel, batch, time)
"CU" (channel, unspecified)	"CU" (channel, unspecified)
"SC" (spatial, channel)	"SC" (spatial, channel)
"SSC" (spatial, spatial, channel)	"SSC" (spatial, spatial, channel)
"SSSC" (spatial, spatial, spatial, channel)	"SSSC" (spatial, spatial, spatial, channel)

In `dlnetwork` objects, `LayerNormalizationLayer` objects also support these input and output format combinations.

Input Format	Output Format
"CT" (channel, time)	"CT" (channel, time)
"SCT" (spatial, channel, time)	"SCT" (spatial, channel, time)
"SSCT" (spatial, spatial, channel, time)	"SSCT" (spatial, spatial, channel, time)
"SSSCT" (spatial, spatial, spatial, channel, time)	"SSSCT" (spatial, spatial, spatial, channel, time)

## Version History

Introduced in R2021a

### R2023a: Specify operation dimension

Specify which dimensions to normalize over using the `OperationDimension` option.

### R2023a: Epsilon supports values less than 1e-5

The `Epsilon` option also supports positive values less than 1e-5.

### R2023a: Layer supports 1-D image sequence data

`LayerNormalizationLayer` objects support normalizing 1-D image sequence data (data with one spatial and one time dimension).

### R2023a: Layer normalizes over channel and spatial dimensions of sequence data

*Behavior changed in R2023a*

Starting in R2023a, by default, the layer normalizes sequence data over the channel and spatial dimensions. In previous versions, the software normalizes over all dimensions except for the batch dimension (the spatial, time, and channel dimensions). Normalization over the channel and spatial dimensions is usually better suited for this type of data. To reproduce the previous behavior, set `OperationDimension` to "batch-excluded".

## leakyrelu

Apply leaky rectified linear unit activation

### Syntax

```
Y = leakyrelu(X)
Y = leakyrelu(X, scaleFactor)
```

### Description

The leaky rectified linear unit (ReLU) activation operation performs a nonlinear threshold operation, where any input value less than zero is multiplied by a fixed scale factor.

This operation is equivalent to

$$f(x) = \begin{cases} x, & x \geq 0 \\ scale * x, & x < 0 \end{cases}$$

---

**Note** This function applies the leaky ReLU operation to `darray` data. If you want to apply leaky ReLU activation within a `layerGraph` object or `Layer` array, use the following layer:

- `leakyReluLayer`
- 

`Y = leakyrelu(X)` computes the leaky ReLU activation of the input `X` by applying a threshold operation. All values in `X` less than zero are multiplied by a default scale factor of `0.01`.

`Y = leakyrelu(X, scaleFactor)` specifies the scale factor for the leaky ReLU operation.

### Examples

#### Apply Leaky ReLU Operation

Create a formatted `darray` object containing a batch of 128 28-by-28 images with 3 channels. Specify the format 'SSCB' (spatial, spatial, channel, batch).

```
miniBatchSize = 128;
inputSize = [28 28];
numChannels = 3;
X = rand(inputSize(1),inputSize(2),numChannels,miniBatchSize);
X = darray(X, "SSCB");
```

View the size and format of the input data.

```
size(X)
ans = 1x4
```

```
28 28 3 128
```

```
dims(X)
```

```
ans =  
'SSCB'
```

Apply the leaky ReLU operation using the `leakyrelu` function.

```
Y = leakyrelu(X);
```

View the size and format of the output.

```
size(Y)
```

```
ans = 1×4
```

```
28 28 3 128
```

```
dims(Y)
```

```
ans =  
'SSCB'
```

### Specify Leaky ReLU Scale

Create a formatted `darray` object containing a batch of 128 28-by-28 images with 3 channels. Specify the format `'SSCB'` (spatial, spatial, channel, batch).

```
miniBatchSize = 128;  
inputSize = [28 28];  
numChannels = 3;  
X = rand(inputSize(1),inputSize(2),numChannels,miniBatchSize);  
X = darray(X,"SSCB");
```

View the size and format of the input data.

```
size(X)
```

```
ans = 1×4
```

```
28 28 3 128
```

```
dims(X)
```

```
ans =  
'SSCB'
```

Apply the leaky ReLU operation using the `leakyrelu` function and specify a scale of 0.5.

```
Y = leakyrelu(X,0.5);
```

View the size and format of the output.

```
size(Y)
```

```
ans = 1×4
      28    28     3   128
```

```
dims(Y)
```

```
ans =
'SSCB'
```

## Input Arguments

### **X — Input data**

`dlarray` object

Input data, specified as a formatted or unformatted `dlarray` object.

### **scaleFactor — Scale factor for negative inputs**

0.01 (default) | numeric scalar

Scale factor for negative inputs, specified as a numeric scalar. The default value is 0.01.

Data Types: `single` | `double`

## Output Arguments

### **Y — Leaky ReLU activations**

`dlarray`

Leaky ReLU activations, returned as a `dlarray`. The output `Y` has the same underlying data type as the input `X`.

If the input data `X` is a formatted `dlarray`, `Y` has the same dimension format as `X`. If the input data is not a formatted `dlarray`, `Y` is an unformatted `dlarray` with the same dimension order as the input data.

## Version History

**Introduced in R2019b**

## Extended Capabilities

### **GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When the input argument `X` is a `gpuArray` or a `dlarray` with underlying data of type `gpuArray`, this function runs on the GPU.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# leakyReluLayer

Leaky Rectified Linear Unit (ReLU) layer

## Description

A leaky ReLU layer performs a threshold operation, where any input value less than zero is multiplied by a fixed scalar.

This operation is equivalent to:

$$f(x) = \begin{cases} x, & x \geq 0 \\ scale * x, & x < 0 \end{cases}$$

## Creation

### Syntax

```
layer = leakyReluLayer  
layer = leakyReluLayer(scale)  
layer = leakyReluLayer( ____, 'Name', Name)
```

### Description

`layer = leakyReluLayer` returns a leaky ReLU layer.

`layer = leakyReluLayer(scale)` returns a leaky ReLU layer with a scalar multiplier for negative inputs equal to `scale`.

`layer = leakyReluLayer( ____, 'Name', Name)` returns a leaky ReLU layer and sets the optional `Name` property.

## Properties

### Leaky ReLU

#### Scale — Scalar multiplier for negative input values

0.01 (default) | numeric scalar

Scalar multiplier for negative input values, specified as a numeric scalar.

Example: 0.4

### Layer

#### Name — Layer name

'' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For Layer array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

### **NumInputs — Number of inputs**

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

### **InputNames — Input names**

{'in'} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: `cell`

### **NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: `double`

### **OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: `cell`

## **Examples**

### **Create Leaky ReLU Layer**

Create a leaky ReLU layer with the name 'leaky1' and a scalar multiplier for negative inputs equal to 0.1.

```
layer = leakyReluLayer(0.1, 'Name', 'leaky1')
```

```
layer =  
    LeakyReLULayer with properties:
```

```
        Name: 'leaky1'
```

```
        Hyperparameters
```

```
Scale: 0.1000
```

Include a leaky ReLU layer in a `Layer` array.

```
layers = [
    imageInputLayer([28 28 1])
    convolution2dLayer(3,16)
    batchNormalizationLayer
    leakyReluLayer

    maxPooling2dLayer(2, 'Stride',2)
    convolution2dLayer(3,32)
    batchNormalizationLayer
    leakyReluLayer

    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer]
```

```
layers =
    11x1 Layer array with layers:
```

1	''	Image Input	28x28x1 images with 'zerocenter' normalization
2	''	2-D Convolution	16 3x3 convolutions with stride [1 1] and padding [0 0 0 0]
3	''	Batch Normalization	Batch normalization
4	''	Leaky ReLU	Leaky ReLU with scale 0.01
5	''	2-D Max Pooling	2x2 max pooling with stride [2 2] and padding [0 0 0 0]
6	''	2-D Convolution	32 3x3 convolutions with stride [1 1] and padding [0 0 0 0]
7	''	Batch Normalization	Batch normalization
8	''	Leaky ReLU	Leaky ReLU with scale 0.01
9	''	Fully Connected	10 fully connected layer
10	''	Softmax	softmax
11	''	Classification Output	crossentropyex

## Algorithms

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

LeakyReLU objects apply an element-wise operation and supports input data of any format. The layer does not add or remove any dimensions, so it outputs data with the same format as its inputs.

# lbfgsState

State of limited-memory BFGS (L-BFGS) solver

## Description

An `lbfgsState` object stores information about steps in the L-BFGS algorithm.

The L-BFGS algorithm [1] is a quasi-Newton method that approximates the Broyden-Fletcher-Goldfarb-Shanno (BFGS) algorithm. The L-BFGS algorithm is best suited for small networks and data sets that you can process in a single batch.

Use `lbfgsState` objects in conjunction with the `lbfgsupdate` function to train a neural network using the L-BFGS algorithm.

## Creation

### Syntax

```
solverState = lbfgsState  
solverState = lbfgsState(Name=Value)
```

### Description

`solverState = lbfgsState` creates an L-BFGS state object with a history size of 10 and an initial inverse Hessian factor of 1.

`solverState = lbfgsState(Name=Value)` sets the `HistorySize` and `InitialInverseHessianFactor` properties using one or more name-value arguments.

## Properties

### L-BFGS State

#### HistorySize — Number of state updates to store

10 (default) | positive integer

Number of state updates to store, specified as a positive integer. Values between 3 and 20 suit most tasks.

The L-BFGS algorithm uses a history of gradient calculations to approximate the Hessian matrix recursively. For more information, see “Limited-Memory BFGS” on page 1-1225.

After creating the `lbfgsState` object, this property is read-only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### InitialInverseHessianFactor — Initial value that characterizes approximate inverse Hessian matrix

1 (default) | positive scalar

This property is read-only.

Initial value that characterizes the approximate inverse Hessian matrix, specified as a positive scalar.

To save memory, the L-BFGS algorithm does not store and invert the dense Hessian matrix  $B$ . Instead, the algorithm uses the approximation  $B_{k-m}^{-1} \approx \lambda_k I$ , where  $m$  is the history size, the inverse Hessian factor  $\lambda_k$  is a scalar, and  $I$  is the identity matrix, and stores the scalar inverse Hessian factor only. The algorithm updates the inverse Hessian factor at each step.

The `InitialInverseHessianFactor` property is the value of  $\lambda_0$ .

For more information, see “Limited-Memory BFGS” on page 1-1225.

After creating the `lbfgsState` object, this property is read-only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **InverseHessianFactor** – Value that characterizes approximate inverse Hessian matrix

1 (default) | positive scalar

Value that characterizes the approximate inverse Hessian matrix, specified as a positive scalar.

To save memory, the L-BFGS algorithm does not store and invert the dense Hessian matrix  $B$ . Instead, the algorithm uses the approximation  $B_{k-m}^{-1} \approx \lambda_k I$ , where  $m$  is the history size, the inverse Hessian factor  $\lambda_k$  is a scalar, and  $I$  is the identity matrix, and stores the scalar inverse Hessian factor only. The algorithm updates the inverse Hessian factor at each step.

For more information, see “Limited-Memory BFGS” on page 1-1225.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **StepHistory** – Step history

{ } (default) | cell array

Step history, specified as a cell array.

The L-BFGS algorithm uses a history of gradient calculations to approximate the Hessian matrix recursively. For more information, see “Limited-Memory BFGS” on page 1-1225.

Data Types: `cell`

### **GradientsDifferenceHistory** – Gradients difference history

{ } (default) | cell array

Gradients difference history, specified as a cell array.

The L-BFGS algorithm uses a history of gradient calculations to approximate the Hessian matrix recursively. For more information, see “Limited-Memory BFGS” on page 1-1225.

Data Types: `cell`

### **HistoryIndices** – History indices

0-by-1 vector (default) | row vector

History indices, specified as a row vector.

HistoryIndices is a 1-by-HistorySize vector, where StepHistory(i) and GradientsDifferenceHistory(i) correspond to iteration HistoryIndices(i).

For more information, see “Limited-Memory BFGS” on page 1-1225.

Data Types: double

### **Iteration Information**

#### **Loss — Loss**

[] (default) | dLarray scalar | numeric scalar

This property is read-only.

Loss, specified as a dLarray scalar, a numeric scalar, or [].

If the state object is the output of the lbfgsupdate function, then Loss is the first output of the loss function that you pass to the lbfgsupdate function. Otherwise, Loss is [].

#### **Gradients — Gradients**

[] (default) | dLarray object | numeric array | cell array | structure | table

This property is read-only.

Gradients, specified as a dLarray object, a numeric array, a cell array, a structure, a table, or [].

If the state object is the output of the lbfgsupdate function, then Gradients is the second output of the loss function that you pass to the lbfgsupdate function. Otherwise, Gradients is [].

#### **AdditionalLossFunctionOutputs — Additional loss function outputs**

1-by-0 cell array (default) | cell array

This property is read-only.

Additional loss function outputs, specified as a cell array.

If the state object is the output of the lbfgsupdate function, then AdditionalLossFunctionOutputs is a cell array containing additional outputs of the loss function that you pass to the lbfgsupdate function. Otherwise, AdditionalLossFunctionOutputs is a 1-by-0 cell array.

Data Types: cell

#### **StepNorm — Norm of step**

[] (default) | dLarray scalar | numeric scalar

This property is read-only.

Norm of the step, specified as a dLarray scalar, numeric scalar, or [].

If the state object is the output of the lbfgsupdate function, then StepNorm is the norm of the step that the lbfgsupdate function calculates. Otherwise, StepNorm is [].

#### **GradientsNorm — Norm of gradients**

[] (default) | dLarray scalar | numeric scalar

This property is read-only.

Norm of the gradients, specified as a `darray` scalar, a numeric scalar, or `[]`.

If the state object is the output of the `lbfgsupdate` function, then `GradientsNorm` is the norm of the second output of the loss function that you pass to the `lbfgsupdate` function. Otherwise, `GradientsNorm` is `[]`.

### **LineSearchStatus — Status of line search algorithm**

`""` (default) | `"completed"` | `"failed"`

This property is read-only.

Status of the line search algorithm, specified as `""`, `"completed"`, or `"failed"`.

If the state object is the output of the `lbfgsupdate` function, then `LineSearchStatus` is one of these values:

- `"completed"` — The algorithm finds a learning rate that satisfies the `LineSearchMethod` and `MaxNumLineSearchIterations` options that the `lbfgsupdate` function uses.
- `"failed"` — The algorithm fails to find a learning rate that satisfies the `LineSearchMethod` and `MaxNumLineSearchIterations` options that the `lbfgsupdate` function uses.

Otherwise, `LineSearchStatus` is `""`.

### **LineSearchMethod — Method solver uses to find suitable learning rate**

`""` (default) | `"weak-wolfe"` | `"strong-wolfe"` | `"backtracking"`

This property is read-only.

Method solver uses to find a suitable learning rate, specified as `"weak-wolfe"`, `"strong-wolfe"`, `"backtracking"`, or `[]`.

If the state object is the output of the `lbfgsupdate` function, then `LineSearchMethod` is the line search method that the `lbfgsupdate` function uses. Otherwise, `LineSearchMethod` is `""`.

### **MaxNumLineSearchIterations — Maximum number of line search iterations**

`0` (default) | nonnegative integer

This property is read-only.

Maximum number of line search iterations, specified as a nonnegative integer.

If the state object is the output of the `lbfgsupdate` function, then `MaxNumLineSearchIterations` is the maximum number of line search iterations that the `lbfgsupdate` function uses. Otherwise, `MaxNumLineSearchIterations` is `0`.

Data Types: `double`

## **Examples**

### **Create L-BFGS Solver State Object**

Create an L-BFGS solver state object.

```
solverState = lbfgsState
```

```
solverState =
  LBFGSState with properties:

    InverseHessianFactor: 1
        StepHistory: {}
  GradientsDifferenceHistory: {}
        HistoryIndices: [1x0 double]

  Iteration Information
        Loss: []
        Gradients: []
  AdditionalLossFunctionOutputs: {1x0 cell}
        GradientsNorm: []
        StepNorm: []
  LineSearchStatus: ""

  Show all properties
```

### Update Learnable Parameters in Neural Network

Load the iris flower dataset.

```
[XTrain, TTrain] = iris_dataset;
```

Convert the predictors to a `darray` object with format "CB" (channel, batch).

```
XTrain = darray(XTrain, "CB");
```

Define the network architecture.

```
numInputFeatures = size(XTrain,1);
numClasses = size(TTrain,1);
numHiddenUnits = 32;
```

```
layers = [
  featureInputLayer(numInputFeatures)
  fullyConnectedLayer(numHiddenUnits)
  reluLayer
  fullyConnectedLayer(numHiddenUnits)
  reluLayer
  fullyConnectedLayer(numClasses)
  softmaxLayer];
```

```
net = dlnetwork(layers);
```

Define the `modelLoss` function, listed in the Model Loss Function on page 1-1219 section of the example. This function takes as input a neural network, input data, and targets. The function returns the loss and the gradients of the loss with respect to the network learnable parameters.

The `lbfgsupdate` function requires a loss function with the syntax `[loss,gradients] = f(net)`. Create a variable that parameterizes the evaluated `modelLoss` function to take a single input argument.

```
lossFcn = @(net) dlfeval(@modelLoss,net,XTrain,TTrain);
```

Initialize an L-BFGS solver state object with a maximum history size of 3 and an initial inverse Hessian approximation factor of 1.1.

```
solverState = lbfgsState( ...
    HistorySize=3, ...
    InitialInverseHessianFactor=1.1);
```

Train the network for 10 epochs.

```
numEpochs = 10;
for i = 1:numEpochs
    [net, solverState] = lbfgsupdate(net, lossFcn, solverState);
end
```

### Model Loss Function

The `modelLoss` function takes as input a neural network `net`, input data `X`, and targets `T`. The function returns the loss and the gradients of the loss with respect to the network learnable parameters.

```
function [loss, gradients] = modelLoss(net, X, T)

Y = forward(net,X);
loss = crossentropy(Y,T);
gradients = dlgradient(loss,net.Learnables);

end
```

## Algorithms

### Limited-Memory BFGS

The L-BFGS algorithm [1] is a quasi-Newton method that approximates the Broyden-Fletcher-Goldfarb-Shanno (BFGS) algorithm. The L-BFGS algorithm is best suited for small networks and data sets that you can process in a single batch.

The algorithm updates learnable parameters  $W$  at iteration  $k+1$  using the update step given by

$$W_{k+1} = W_k - \eta_k B_k^{-1} \nabla J(W_k),$$

where  $W_k$  denotes the weights at iteration  $k$ ,  $\eta_k$  is the learning rate at iteration  $k$ ,  $B_k$  is an approximation of the Hessian matrix at iteration  $k$ , and  $\nabla J(W_k)$  denotes the gradients of the loss with respect to the learnable parameters at iteration  $k$ .

The L-BFGS algorithm computes the matrix-vector product  $B_k^{-1} \nabla J(W_k)$  directly. The algorithm does not require computing the inverse of  $B_k$ .

To save memory, the L-BFGS algorithm does not store and invert the dense Hessian matrix  $B$ . Instead, the algorithm uses the approximation  $B_k^{-1} \approx \lambda_k I$ , where  $m$  is the history size, the inverse Hessian factor  $\lambda_k$  is a scalar, and  $I$  is the identity matrix, and stores the scalar inverse Hessian factor only. The algorithm updates the inverse Hessian factor at each step.

To compute the matrix-vector product  $B_k^{-1} \nabla J(W_k)$  directly, the L-BFGS algorithm uses this recursive algorithm:

- 1** Set  $\mathbf{r} = B_{k-m}^{-1} \nabla J(W_k)$ , where  $m$  is the history size.
- 2** For  $i = m, \dots, 1$ :
  - a** Let  $\beta = \frac{1}{\mathbf{s}_{k-i}^\top \mathbf{y}_{k-i}} \mathbf{y}_{k-i}^\top \mathbf{r}$ , where  $\mathbf{s}_{k-i}$  and  $\mathbf{y}_{k-i}$  are the step and gradient differences for iteration  $k-i$ , respectively.
  - b** Set  $\mathbf{r} = \mathbf{r} + \mathbf{s}_{k-i}(\mathbf{a}_{k-i} - \beta)$ , where  $\mathbf{a}$  is derived from  $\mathbf{s}$ ,  $\mathbf{y}$ , and the gradients of the loss with respect to the loss function. For more information, see [1].
- 3** Return  $B_k^{-1} \nabla J(W_k) = \mathbf{r}$ .

# lbfgsupdate

Update parameters using limited-memory BFGS (L-BFGS)

## Syntax

```
[netUpdated, solverStateUpdated] = lbfgsupdate(net, lossFcn, solverState)
[parametersUpdated, solverStateUpdated] = lbfgsupdate(parameters, solverState)
```

## Description

Update the network learnable parameters in a custom training loop using the limited-memory BFGS (L-BFGS) algorithm.

The L-BFGS algorithm [1] is a quasi-Newton method that approximates the Broyden-Fletcher-Goldfarb-Shanno (BFGS) algorithm. The L-BFGS algorithm is best suited for small networks and data sets that you can process in a single batch.

---

**Note** This function applies the L-BFGS optimization algorithm to update network parameters in custom training loops that use networks defined as `dlnetwork` objects or model functions. If you want to train a network defined as a `Layer` array or as a `LayerGraph`, use the following functions:

- Create an SGDM, Adam, or RMSProp training options object using the `trainingOptions` function.
  - Use the options object with the `trainNetwork` function.
- 

`[netUpdated, solverStateUpdated] = lbfgsupdate(net, lossFcn, solverState)` updates the learnable parameters of the network `net` using the L-BFGS algorithm with the specified loss function and solver state. Use this syntax in a training loop to iteratively update a network defined as a `dlnetwork` object.

`[parametersUpdated, solverStateUpdated] = lbfgsupdate(parameters, solverState)` updates the learnable parameters in `parameters` using the L-BFGS algorithm with the specified loss function and solver state. Use this syntax in a training loop to iteratively update the learnable parameters of a network defined as a function.

## Examples

### Update Learnable Parameters in Neural Network

Load the iris flower dataset.

```
[XTrain, TTrain] = iris_dataset;
```

Convert the predictors to a `dlarray` object with format "CB" (channel, batch).

```
XTrain = dlarray(XTrain, "CB");
```

Define the network architecture.

```
numInputFeatures = size(XTrain,1);
numClasses = size(TTrain,1);
numHiddenUnits = 32;

layers = [
    featureInputLayer(numInputFeatures)
    fullyConnectedLayer(numHiddenUnits)
    reluLayer
    fullyConnectedLayer(numHiddenUnits)
    reluLayer
    fullyConnectedLayer(numClasses)
    softmaxLayer];

net = dlnetwork(layers);
```

Define the `modelLoss` function, listed in the Model Loss Function on page 1-1222 section of the example. This function takes as input a neural network, input data, and targets. The function returns the loss and the gradients of the loss with respect to the network learnable parameters.

The `lbfgsupdate` function requires a loss function with the syntax `[loss,gradients] = f(net)`. Create a variable that parameterizes the evaluated `modelLoss` function to take a single input argument.

```
lossFcn = @(net) dlfeval(@modelLoss,net,XTrain,TTrain);
```

Initialize an L-BFGS solver state object with a maximum history size of 3 and an initial inverse Hessian approximation factor of 1.1.

```
solverState = lbfgsState( ...
    HistorySize=3, ...
    InitialInverseHessianFactor=1.1);
```

Train the network for 10 epochs.

```
numEpochs = 10;
for i = 1:numEpochs
    [net, solverState] = lbfgsupdate(net,lossFcn,solverState);
end
```

### **Model Loss Function**

The `modelLoss` function takes as input a neural network `net`, input data `X`, and targets `T`. The function returns the loss and the gradients of the loss with respect to the network learnable parameters.

```
function [loss, gradients] = modelLoss(net, X, T)

Y = forward(net,X);
loss = crossentropy(Y,T);
gradients = dlgradient(loss,net.Learnables);
```

end

## Input Arguments

### net — Neural network

`dlnetwork` object

Neural network, specified as a `dlnetwork` object.

The function updates the `Learnables` property of the `dlnetwork` object. `net.Learnables` is a table with three variables:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a cell array containing a `dlarray` object.

### parameters — Learnable parameters

`dlarray` object | numeric array | cell array | structure | table

Learnable parameters, specified as a `dlarray` object, a numeric array, a cell array, a structure, or a table.

If you specify `parameters` as a table, it must contain these variables:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Parameter value, specified as a cell array containing a `dlarray` object.

You can specify `parameters` as a container of learnable parameters for your network using a cell array, structure, or table, or using nested cell arrays or structures. The learnable parameters inside the cell array, structure, or table must be `dlarray` objects or numeric values with the data type `double` or `single`.

If `parameters` is a numeric array, then `lossFcn` must not use the `dlgradient` function.

### lossFcn — Loss function

function handle | `AcceleratedFunction` object

Loss function, specified as a function handle or an `AcceleratedFunction` object with the syntax `[loss,gradients] = f(net)`, where `loss` and `gradients` correspond to the loss and gradients of the loss with respect to the learnable parameters, respectively.

To parametrize a model loss function that has a call to the `dlgradient` function, specify the loss function as `@(net) dlfeval(@modelLoss,net,arg1,...,argN)`, where `modelLoss` is a function with the syntax `[loss,gradients] = modelLoss(net,arg1,...,argN)` that returns the loss and gradients of the loss with respect to the learnable parameters in `net` given arguments `arg1,...,argN`.

If `parameters` is a numeric array, then the loss function must not use the `dlgradient` or `dlfeval` functions.

If the loss function has more than two outputs, also specify the `NumLossFunctionOutputs` argument.

Data Types: `function_handle`

**solverState — Solver state**

`lbfgsState` object | []

Solver state, specified as an `lbfgsState` object or [].

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `lbfgsupdate(net, lossFcn, solverState, LineSearchMethod="strong-wolfe")` updates the learnable parameters in `net` and searches for a learning rate that satisfies the strong Wolfe conditions.

**LineSearchMethod — Method to find suitable learning rate**

"weak-wolfe" (default) | "strong-wolfe" | "backtracking"

Method to find suitable learning rate, specified as one of these values:

- "weak-wolfe" — Search for a learning rate that satisfies the weak Wolfe conditions. This method maintains a positive definite approximation of the inverse Hessian matrix.
- "strong-wolfe" — Search for a learning rate that satisfies the strong Wolfe conditions. This method maintains a positive definite approximation of the inverse Hessian matrix.
- "backtracking" — Search for a learning rate that satisfies sufficient decrease conditions. This method does not maintain a positive definite approximation of the inverse Hessian matrix.

**MaxNumLineSearchIterations — Maximum number of line search iterations**

20 (default) | positive integer

Maximum number of line search iterations to determine learning rate, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**NumLossFunctionOutputs — Number of loss function outputs**

2 (default) | integer greater than or equal to two

Number of loss function outputs, specified as an integer greater than or equal to two. Set this option when `lossFcn` has more than two output arguments.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Output Arguments****netUpdated — Updated network**

`dlnetwork` object

Updated network, returned as a `dlnetwork` object.

The function updates the `Learnables` property of the `dlnetwork` object.

**parametersUpdated — Updated learnable parameters**

`dlarray` | numeric array | cell array | structure | table

Updated learnable parameters, returned as an object with the same type as `parameters`.

### **solverStateUpdated** — Updated solver state

`lbfgsState`

Updated solver state, returned as an `lbfgsState` state object.

## Algorithms

### Limited-Memory BFGS

The L-BFGS algorithm [1] is a quasi-Newton method that approximates the Broyden-Fletcher-Goldfarb-Shanno (BFGS) algorithm. The L-BFGS algorithm is best suited for small networks and data sets that you can process in a single batch.

The algorithm updates learnable parameters  $W$  at iteration  $k+1$  using the update step given by

$$W_{k+1} = W_k - \eta_k B_k^{-1} \nabla J(W_k),$$

where  $W_k$  denotes the weights at iteration  $k$ ,  $\eta_k$  is the learning rate at iteration  $k$ ,  $B_k$  is an approximation of the Hessian matrix at iteration  $k$ , and  $\nabla J(W_k)$  denotes the gradients of the loss with respect to the learnable parameters at iteration  $k$ .

The L-BFGS algorithm computes the matrix-vector product  $B_k^{-1} \nabla J(W_k)$  directly. The algorithm does not require computing the inverse of  $B_k$ .

To save memory, the L-BFGS algorithm does not store and invert the dense Hessian matrix  $B$ . Instead, the algorithm uses the approximation  $B_k^{-1} \approx \lambda_k I$ , where  $m$  is the history size, the inverse Hessian factor  $\lambda_k$  is a scalar, and  $I$  is the identity matrix, and stores the scalar inverse Hessian factor only. The algorithm updates the inverse Hessian factor at each step.

To compute the matrix-vector product  $B_k^{-1} \nabla J(W_k)$  directly, the L-BFGS algorithm uses this recursive algorithm:

- 1 Set  $\mathbf{r} = B_{k-m}^{-1} \nabla J(W_k)$ , where  $m$  is the history size.
- 2 For  $i = m, \dots, 1$ :
  - a Let  $\beta = \frac{1}{\mathbf{s}_{k-i}^\top \mathbf{y}_{k-i}} \mathbf{y}_{k-i}^\top \mathbf{r}$ , where  $\mathbf{s}_{k-i}$  and  $\mathbf{y}_{k-i}$  are the step and gradient differences for iteration  $k-i$ , respectively.
  - b Set  $\mathbf{r} = \mathbf{r} + \mathbf{s}_{k-i}(\mathbf{a}_{k-i} - \beta)$ , where  $\mathbf{a}$  is derived from  $\mathbf{s}$ ,  $\mathbf{y}$ , and the gradients of the loss with respect to the loss function. For more information, see [1].
- 3 Return  $B_k^{-1} \nabla J(W_k) = \mathbf{r}$ .

## Version History

Introduced in R2023a

# loadTFLiteModel

Load TensorFlow Lite model

## Syntax

```
net = loadTFLiteModel(modelFileName)
```

## Description

`net = loadTFLiteModel(modelFileName)` loads a pretrained TensorFlow Lite model file `modelFileName` and returns a `TFLiteModel` object.

Use this `TFLiteModel` object with the `predict` function in your MATLAB code to perform inference in MATLAB execution, code generation, or MATLAB Function block in Simulink models. For more information, see “Prerequisites for Deep Learning with TensorFlow Lite Models”.

To use this function, you must install the Deep Learning Toolbox Interface for TensorFlow Lite support package.

## Examples

### Perform Inference with TensorFlow Lite Model

Suppose that your current working directory contains a TensorFlow Lite Model named `mobilenet_v1_0.5_224.tflite`.

Load the model by using the `loadTFLite` function. Inspect the object this function creates.

```
net = loadTFLiteModel('mobilenet_v1_0.5_224.tflite');
disp(net)
```

```
TFLiteModel with properties:
    ModelName: 'mobilenet_v1_0.5_224.tflite'
    NumInputs: 1
    NumOutputs: 1
    InputSize: {[224 224 3]}
    OutputSize: {[1001 1]}
    NumThreads: 8
           Mean: 127.5000
    StandardDeviation: 127.5000
```

Create a MATLAB function that can perform inference using the object `net`. This function loads the Mobilenet-V1 model into a persistent network object. Then the function performs prediction by passing the network object to the `predict` function. Subsequent calls to this function reuse this the persistent object.

```
function out = tflite_predict(in)
persistent net;
if isempty(net)
    net = loadTFLiteModel('mobilenet_v1_0.5_224.tflite');
```

```
end  
out = predict(net,in);  
end
```

For an example that shows how to generate code for this function and deploy on Raspberry Pi hardware, see “Generate Code for TensorFlow Lite (TFLite) Model and Deploy on Raspberry Pi”.

---

**Note** By default, the `Mean` and `StandardDeviation` properties of a `TFLiteModel` object are both set to 127.5. To change these default values after you create the object, make assignments by using the dot notation. For example:

```
net.Mean = 0;  
net.StandardDeviation = 1;
```

If the input data is not normalized, you must set `Mean` to 0 and `StandardDeviation` to 1. Otherwise, set these properties based on how the input data is normalized.

---

## Input Arguments

**modelName** — TensorFlow Lite model file name

character vector | string scalar

Name of the TensorFlow Lite model file, specified as a character vector or a string scalar.

## Output Arguments

**net** — Object representing TensorFlow Lite model

`TFLiteModel` object

`TFLiteModel` object that represents the TensorFlow Lite model file.

## Version History

Introduced in R2022a

## Extended Capabilities

**C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

# lstm

Long short-term memory

## Syntax

```
Y = lstm(X,H0,C0,weights,recurrentWeights,bias)
[Y,hiddenState,cellState] = lstm(X,H0,C0,weights,recurrentWeights,bias)
[ ___ ] = lstm( ___, 'DataFormat', FMT)
```

## Description

The long short-term memory (LSTM) operation allows a network to learn long-term dependencies between time steps in time series and sequence data.

---

**Note** This function applies the deep learning LSTM operation to `darray` data. If you want to apply an LSTM operation within a `layerGraph` object or `Layer` array, use the following layer:

- `lstmLayer`
- 

`Y = lstm(X,H0,C0,weights,recurrentWeights,bias)` applies a long short-term memory (LSTM) calculation to input `X` using the initial hidden state `H0`, initial cell state `C0`, and parameters `weights`, `recurrentWeights`, and `bias`. The input `X` must be a formatted `darray`. The output `Y` is a formatted `darray` with the same dimension format as `X`, except for any 'S' dimensions.

The `lstm` function updates the cell and hidden states using the hyperbolic tangent function (`tanh`) as the state activation function. The `lstm` function uses the sigmoid function given by  $\sigma(x) = (1 + e^{-x})^{-1}$  as the gate activation function.

`[Y,hiddenState,cellState] = lstm(X,H0,C0,weights,recurrentWeights,bias)` also returns the hidden state and cell state after the LSTM operation.

`[ ___ ] = lstm( ___, 'DataFormat', FMT)` also specifies the dimension format `FMT` when `X` is not a formatted `darray`. The output `Y` is an unformatted `darray` with the same dimension order as `X`, except for any 'S' dimensions.

## Examples

### Apply LSTM Operation to Sequence Data

Perform an LSTM operation using three hidden units.

Create the input sequence data as 32 observations with 10 channels and a sequence length of 64

```
numFeatures = 10;
numObservations = 32;
sequenceLength = 64;
```

```
X = randn(numFeatures,numObservations,sequenceLength);  
dLX = dlarray(X,'CBT');
```

Create the initial hidden and cell states with three hidden units. Use the same initial hidden state and cell state for all observations.

```
numHiddenUnits = 3;  
H0 = zeros(numHiddenUnits,1);  
C0 = zeros(numHiddenUnits,1);
```

Create the learnable parameters for the LSTM operation.

```
weights = dlarray(randn(4*numHiddenUnits,numFeatures),'CU');  
recurrentWeights = dlarray(randn(4*numHiddenUnits,numHiddenUnits),'CU');  
bias = dlarray(randn(4*numHiddenUnits,1),'C');
```

Perform the LSTM calculation

```
[dLY,hiddenState,cellState] = lstm(dLX,H0,C0,weights,recurrentWeights,bias);
```

View the size and dimensions of dLY.

```
size(dLY)
```

```
ans = 1×3
```

```
    3    32    64
```

```
dLY.dims
```

```
ans =  
'CBT'
```

View the size of hiddenState and cellState.

```
size(hiddenState)
```

```
ans = 1×2
```

```
    3    32
```

```
size(cellState)
```

```
ans = 1×2
```

```
    3    32
```

Check that the output hiddenState is the same as the last time step of output dLY.

```
if extractdata(dLY(:,:,end)) == hiddenState  
    disp("The hidden state and the last time step are equal.");  
else  
    disp("The hidden state and the last time step are not equal.")  
end
```

The hidden state and the last time step are equal.

You can use the hidden state and cell state to keep track of the state of the LSTM operation and input further sequential data.

## Input Arguments

### **X — Input data**

`darray` | numeric array

Input data, specified as a formatted `darray`, an unformatted `darray`, or a numeric array. When `X` is not a formatted `darray`, you must specify the dimension label format using `'DataFormat', FMT`. If `X` is a numeric array, at least one of `H0`, `C0`, `weights`, `recurrentWeights`, or `bias` must be a `darray`.

`X` must contain a sequence dimension labeled "T". If `X` has any spatial dimensions labeled "S", they are flattened into the "C" channel dimension. If `X` does not have a channel dimension, then one is added. If `X` has any unspecified dimensions labeled "U", they must be singleton.

Data Types: `single` | `double`

### **H0 — Initial hidden state vector**

`darray` | numeric array

Initial hidden state vector, specified as a formatted `darray`, an unformatted `darray`, or a numeric array.

If `H0` is a formatted `darray`, it must contain a channel dimension labeled 'C' and optionally a batch dimension labeled 'B' with the same size as the 'B' dimension of `X`. If `H0` does not have a 'B' dimension, the function uses the same hidden state vector for each observation in `X`.

The size of the 'C' dimension determines the number of hidden units. The size of the 'C' dimension of `H0` must be equal to the size of the 'C' dimensions of `C0`.

If `H0` is not a formatted `darray`, the size of the first dimension determines the number of hidden units and must be the same size as the first dimension or the 'C' dimension of `C0`.

Data Types: `single` | `double`

### **C0 — Initial cell state vector**

`darray` | numeric array

Initial cell state vector, specified as a formatted `darray`, an unformatted `darray`, or a numeric array.

If `C0` is a formatted `darray`, it must contain a channel dimension labeled 'C' and optionally a batch dimension labeled 'B' with the same size as the 'B' dimension of `X`. If `C0` does not have a 'B' dimension, the function uses the same cell state vector for each observation in `X`.

The size of the 'C' dimension determines the number of hidden units. The size of the 'C' dimension of `C0` must be equal to the size of the 'C' dimensions of `H0`.

If `C0` is not a formatted `darray`, the size of the first dimension determines the number of hidden units and must be the same size as the first dimension or the 'C' dimension of `H0`.

Data Types: `single` | `double`

**weights — Weights**

dlarray | numeric array

Weights, specified as a formatted dlarray, an unformatted dlarray, or a numeric array.

Specify `weights` as a matrix of size  $4 \times \text{NumHiddenUnits}$ -by-`InputSize`, where `NumHiddenUnits` is the size of the 'C' dimension of both `C0` and `H0`, and `InputSize` is the size of the 'C' dimension of `X` multiplied by the size of each 'S' dimension of `X`, where present.

If `weights` is a formatted dlarray, it must contain a 'C' dimension of size  $4 \times \text{NumHiddenUnits}$  and a 'U' dimension of size `InputSize`.

Data Types: `single` | `double`

**recurrentWeights — Recurrent weights**

dlarray | numeric array

Recurrent weights, specified as a formatted dlarray, an unformatted dlarray, or a numeric array.

Specify `recurrentWeights` as a matrix of size  $4 \times \text{NumHiddenUnits}$ -by-`NumHiddenUnits`, where `NumHiddenUnits` is the size of the 'C' dimension of both `C0` and `H0`.

If `recurrentWeights` is a formatted dlarray, it must contain a 'C' dimension of size  $4 \times \text{NumHiddenUnits}$  and a 'U' dimension of size `NumHiddenUnits`.

Data Types: `single` | `double`

**bias — Bias**

dlarray vector | numeric vector

Bias, specified as a formatted dlarray, an unformatted dlarray, or a numeric array.

Specify `bias` as a vector of length  $4 \times \text{NumHiddenUnits}$ , where `NumHiddenUnits` is the size of the 'C' dimension of both `C0` and `H0`.

If `bias` is a formatted dlarray, the nonsingleton dimension must be labeled with 'C'.

Data Types: `single` | `double`

**FMT — Dimension order of unformatted data**

char array | string

Dimension order of unformatted input data, specified as the comma-separated pair consisting of 'DataFormat' and a character array or string `FMT` that provides a label for each dimension of the data. Each character in `FMT` must be one of the following:

- 'S' — Spatial
- 'C' — Channel
- 'B' — Batch (for example, samples and observations)
- 'T' — Time (for example, sequences)
- 'U' — Unspecified

You can specify multiple dimensions labeled 'S' or 'U'. You can use the labels 'C', 'B', and 'T' at most once.

You must specify 'DataFormat', `FMT` when the input data is not a formatted dlarray.

Example: 'DataFormat', 'SSCB'

Data Types: char | string

## Output Arguments

### Y — LSTM output

darray

LSTM output, returned as a darray. The output Y has the same underlying data type as the input X.

If the input data X is a formatted darray, Y has the same dimension format as X, except for any 'S' dimensions. If the input data is not a formatted darray, Y is an unformatted darray with the same dimension order as the input data.

The size of the 'C' dimension of Y is the same as the number of hidden units, specified by the size of the 'C' dimension of H0 or C0.

### hiddenState — Hidden state vector

darray | numeric array

Hidden state vector for each observation, returned as a darray or a numeric array with the same data type as H0.

If the input H0 is a formatted darray, then the output hiddenState is a formatted darray with the format "CB".

### cellState — Cell state vector

darray | numeric array

Cell state vector for each observation, returned as a darray or a numeric array. cellState is returned with the same data type as C0.

If the input C0 is a formatted darray, the output cellState is returned as a formatted darray with the format 'CB'.

## More About

### Long Short-Term Memory

The LSTM operation allows a network to learn long-term dependencies between time steps in time series and sequence data. For more information, see the definition of “Long Short-Term Memory Layer” on page 1-1251 on the lstmLayer reference page.

## Version History

Introduced in R2019b

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When at least one of the following input arguments is a `gpuArray` or a `dLarray` with underlying data of type `gpuArray`, this function runs on the GPU:
  - `X`
  - `H0`
  - `C0`
  - `weights`
  - `recurrentWeights`
  - `bias`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# IstmLayer

Long short-term memory (LSTM) layer for recurrent neural network (RNN)

## Description

An LSTM layer is an RNN layer that learns long-term dependencies between time steps in time series and sequence data.

The layer performs additive interactions, which can help improve gradient flow over long sequences during training.

## Creation

### Syntax

```
layer = lstmLayer(numHiddenUnits)
layer = lstmLayer(numHiddenUnits,Name,Value)
```

### Description

`layer = lstmLayer(numHiddenUnits)` creates an LSTM layer and sets the `NumHiddenUnits` property.

`layer = lstmLayer(numHiddenUnits,Name,Value)` sets additional `OutputMode`, “Activations” on page 1-1237, “State” on page 1-1237, “Parameters and Initialization” on page 1-1238, “Learning Rate and Regularization” on page 1-1240, and `Name` properties using one or more name-value pair arguments. You can specify multiple name-value pair arguments. Enclose each property name in quotes.

## Properties

### LSTM

#### **NumHiddenUnits** — Number of hidden units

positive integer

This property is read-only.

Number of hidden units (also known as the hidden size), specified as a positive integer.

The number of hidden units corresponds to the amount of information that the layer remembers between time steps (the hidden state). The hidden state can contain information from all the previous time steps, regardless of the sequence length. If the number of hidden units is too large, then the layer might overfit to the training data.

The hidden state does not limit the number of time steps that the layer processes in an iteration. To split your sequences into smaller sequences for when you use the `trainNetwork` function, use the `SequenceLength` training option.

The layer outputs data with `NumHiddenUnits` channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **OutputMode — Output mode**

`'sequence'` (default) | `'last'`

This property is read-only.

Output mode, specified as one of these values:

- `'sequence'` — Output the complete sequence.
- `'last'` — Output the last time step of the sequence.

### **HasStateInputs — Flag for state inputs to layer**

`0` (false) (default) | `1` (true)

This property is read-only.

Flag for state inputs to the layer, specified as `0` (false) or `1` (true).

If the `HasStateInputs` property is `0` (false), then the layer has one input with the name `'in'`, which corresponds to the input data. In this case, the layer uses the `HiddenState` and `CellState` properties for the layer operation.

If the `HasStateInputs` property is `1` (true), then the layer has three inputs with the names `'in'`, `'hidden'`, and `'cell'`, which correspond to the input data, hidden state, and cell state, respectively. In this case, the layer uses the values passed to these inputs for the layer operation. If `HasStateInputs` is `1` (true), then the `HiddenState` and `CellState` properties must be empty.

### **HasStateOutputs — Flag for state outputs from layer**

`0` (false) (default) | `1` (true)

This property is read-only.

Flag for state outputs from the layer, specified as `0` (false) or `1` (true).

If the `HasStateOutputs` property is `0` (false), then the layer has one output with the name `'out'`, which corresponds to the output data.

If the `HasStateOutputs` property is `1` (true), then the layer has three outputs with the names `'out'`, `'hidden'`, and `'cell'`, which correspond to the output data, hidden state, and cell state, respectively. In this case, the layer also outputs the state values that it computes.

### **InputSize — Input size**

`'auto'` (default) | positive integer

This property is read-only.

Input size, specified as a positive integer or `'auto'`. If `InputSize` is `'auto'`, then the software automatically assigns the input size at training time.

Data Types: `double` | `char`

## Activations

### StateActivationFunction — Activation function to update cell and hidden state

'tanh' (default) | 'softsign'

This property is read-only.

Activation function to update the cell and hidden state, specified as one of these values:

- 'tanh' — Use the hyperbolic tangent function (tanh).
- 'softsign' — Use the softsign function  $\text{softsign}(x) = \frac{x}{1 + |x|}$ .

The layer uses this option as the function  $\sigma_c$  in the calculations to update the cell and hidden state. For more information on how an LSTM layer uses activation functions, see “Long Short-Term Memory Layer” on page 1-1251.

### GateActivationFunction — Activation function to apply to gates

'sigmoid' (default) | 'hard-sigmoid'

This property is read-only.

Activation function to apply to the gates, specified as one of these values:

- 'sigmoid' — Use the sigmoid function  $\sigma(x) = (1 + e^{-x})^{-1}$ .
- 'hard-sigmoid' — Use the hard sigmoid function

$$\sigma(x) = \begin{cases} 0 & \text{if } x < -2.5 \\ 0.2x + 0.5 & \text{if } -2.5 \leq x \leq 2.5 \\ 1 & \text{if } x > 2.5 \end{cases}$$

The layer uses this option as the function  $\sigma_g$  in the calculations for the layer gates.

## State

### CellState — Cell state

[] (default) | numeric vector

Cell state to use in the layer operation, specified as a NumHiddenUnits-by-1 numeric vector. This value corresponds to the initial cell state when data is passed to the layer.

After you set this property manually, calls to the `resetState` function set the cell state to this value.

If `HasStateInputs` is 1 (true), then the `CellState` property must be empty.

Data Types: `single` | `double`

### HiddenState — Hidden state

[] (default) | numeric vector

Hidden state to use in the layer operation, specified as a NumHiddenUnits-by-1 numeric vector. This value corresponds to the initial hidden state when data is passed to the layer.

After you set this property manually, calls to the `resetState` function set the hidden state to this value.

If `HasStateInputs` is 1 (true), then the `HiddenState` property must be empty.

Data Types: `single` | `double`

### Parameters and Initialization

#### **InputWeightsInitializer** – Function to initialize input weights

'glorot' (default) | 'he' | 'orthogonal' | 'narrow-normal' | 'zeros' | 'ones' | function handle

Function to initialize the input weights, specified as one of the following:

- 'glorot' - Initialize the input weights with the Glorot initializer [4] (also known as Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and variance  $2/(InputSize + numOut)$ , where  $numOut = 4 * NumHiddenUnits$ .
- 'he' - Initialize the input weights with the He initializer [5]. The He initializer samples from a normal distribution with zero mean and variance  $2/InputSize$ .
- 'orthogonal' - Initialize the input weights with  $Q$ , the orthogonal matrix given by the QR decomposition of  $Z = QR$  for a random matrix  $Z$  sampled from a unit normal distribution. [6]
- 'narrow-normal' - Initialize the input weights by independently sampling from a normal distribution with zero mean and standard deviation 0.01.
- 'zeros' - Initialize the input weights with zeros.
- 'ones' - Initialize the input weights with ones.
- Function handle - Initialize the input weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the input weights.

The layer only initializes the input weights when the `InputWeights` property is empty.

Data Types: `char` | `string` | `function_handle`

#### **RecurrentWeightsInitializer** – Function to initialize recurrent weights

'orthogonal' (default) | 'glorot' | 'he' | 'narrow-normal' | 'zeros' | 'ones' | function handle

Function to initialize the recurrent weights, specified as one of the following:

- 'orthogonal' - Initialize the recurrent weights with  $Q$ , the orthogonal matrix given by the QR decomposition of  $Z = QR$  for a random matrix  $Z$  sampled from a unit normal distribution. [6]
- 'glorot' - Initialize the recurrent weights with the Glorot initializer [4] (also known as Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and variance  $2/(numIn + numOut)$ , where  $numIn = NumHiddenUnits$  and  $numOut = 4 * NumHiddenUnits$ .
- 'he' - Initialize the recurrent weights with the He initializer [5]. The He initializer samples from a normal distribution with zero mean and variance  $2/NumHiddenUnits$ .
- 'narrow-normal' - Initialize the recurrent weights by independently sampling from a normal distribution with zero mean and standard deviation 0.01.
- 'zeros' - Initialize the recurrent weights with zeros.
- 'ones' - Initialize the recurrent weights with ones.

- **Function handle** – Initialize the recurrent weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the recurrent weights.

The layer only initializes the recurrent weights when the `RecurrentWeights` property is empty.

Data Types: `char` | `string` | `function_handle`

### **BiasInitializer – Function to initialize bias**

'unit-forget-gate' (default) | 'narrow-normal' | 'ones' | function handle

Function to initialize the bias, specified as one of these values:

- 'unit-forget-gate' — Initialize the forget gate bias with ones and the remaining biases with zeros.
- 'narrow-normal' — Initialize the bias by independently sampling from a normal distribution with zero mean and a standard deviation of 0.01.
- 'ones' — Initialize the bias with ones.
- **Function handle** — Initialize the bias with a custom function. If you specify a function handle, then the function must be of the form `bias = func(sz)`, where `sz` is the size of the bias.

The layer only initializes the bias when the `Bias` property is empty.

Data Types: `char` | `string` | `function_handle`

### **InputWeights – Input weights**

[] (default) | matrix

Input weights, specified as a matrix.

The input weight matrix is a concatenation of the four input weight matrices for the components (gates) in the LSTM layer. The four matrices are concatenated vertically in the following order:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate
- 4 Output gate

The input weights are learnable parameters. When you train a neural network using the `trainNetwork` function, if `InputWeights` is nonempty, then the software uses the `InputWeights` property as the initial value. If `InputWeights` is empty, then the software uses the initializer specified by `InputWeightsInitializer`.

At training time, `InputWeights` is a `4*NumHiddenUnits-by-InputSize` matrix.

### **RecurrentWeights – Recurrent weights**

[] (default) | matrix

Recurrent weights, specified as a matrix.

The recurrent weight matrix is a concatenation of the four recurrent weight matrices for the components (gates) in the LSTM layer. The four matrices are vertically concatenated in the following order:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate
- 4 Output gate

The recurrent weights are learnable parameters. When you train an RNN using the `trainNetwork` function, if `RecurrentWeights` is nonempty, then the software uses the `RecurrentWeights` property as the initial value. If `RecurrentWeights` is empty, then the software uses the initializer specified by `RecurrentWeightsInitializer`.

At training time `RecurrentWeights` is a  $4 \times \text{NumHiddenUnits}$ -by- $\text{NumHiddenUnits}$  matrix.

### **Bias – Layer biases**

`[]` (default) | numeric vector

Layer biases, specified as a numeric vector.

The bias vector is a concatenation of the four bias vectors for the components (gates) in the layer. The layer vertically concatenates the four vectors in this order:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate
- 4 Output gate

The layer biases are learnable parameters. When you train a neural network, if `Bias` is nonempty, then `trainNetwork` uses the `Bias` property as the initial value. If `Bias` is empty, then `trainNetwork` uses the initializer specified by `BiasInitializer`.

At training time, `Bias` is a  $4 \times \text{NumHiddenUnits}$ -by-1 numeric vector.

### **Learning Rate and Regularization**

#### **InputWeightsLearnRateFactor – Learning rate factor for input weights**

1 (default) | nonnegative scalar | 1-by-4 numeric vector

Learning rate factor for the input weights, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global learning rate to determine the learning rate factor for the input weights of the layer. For example, if `InputWeightsLearnRateFactor` is 2, then the learning rate factor for the input weights of the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify with the `trainingOptions` function.

To control the value of the learning rate factor for the four individual matrices in `InputWeights`, specify a 1-by-4 vector. The entries of `InputWeightsLearnRateFactor` correspond to the learning rate factor of these components:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate

**4** Output gate

To specify the same value for all the matrices, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

**RecurrentWeightsLearnRateFactor — Learning rate factor for recurrent weights**

1 (default) | nonnegative scalar | 1-by-4 numeric vector

Learning rate factor for the recurrent weights, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global learning rate to determine the learning rate for the recurrent weights of the layer. For example, if `RecurrentWeightsLearnRateFactor` is 2, then the learning rate for the recurrent weights of the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

To control the value of the learning rate factor for the four individual matrices in `RecurrentWeights`, specify a 1-by-4 vector. The entries of `RecurrentWeightsLearnRateFactor` correspond to the learning rate factor of these components:

- 1** Input gate
- 2** Forget gate
- 3** Cell candidate
- 4** Output gate

To specify the same value for all the matrices, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

**BiasLearnRateFactor — Learning rate factor for biases**

1 (default) | nonnegative scalar | 1-by-4 numeric vector

Learning rate factor for the biases, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is 2, then the learning rate for the biases in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

To control the value of the learning rate factor for the four individual vectors in `Bias`, specify a 1-by-4 vector. The entries of `BiasLearnRateFactor` correspond to the learning rate factor of these components:

- 1** Input gate
- 2** Forget gate
- 3** Cell candidate
- 4** Output gate

To specify the same value for all the vectors, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

**InputWeightsL2Factor —  $L_2$  regularization factor for input weights**

1 (default) | nonnegative scalar | 1-by-4 numeric vector

$L_2$  regularization factor for the input weights, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization factor for the input weights of the layer. For example, if `InputWeightsL2Factor` is 2, then the  $L_2$  regularization factor for the input weights of the layer is twice the current global  $L_2$  regularization factor. The software determines the  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

To control the value of the  $L_2$  regularization factor for the four individual matrices in `InputWeights`, specify a 1-by-4 vector. The entries of `InputWeightsL2Factor` correspond to the  $L_2$  regularization factor of these components:

- 1** Input gate
- 2** Forget gate
- 3** Cell candidate
- 4** Output gate

To specify the same value for all the matrices, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

**RecurrentWeightsL2Factor —  $L_2$  regularization factor for recurrent weights**

1 (default) | nonnegative scalar | 1-by-4 numeric vector

$L_2$  regularization factor for the recurrent weights, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization factor for the recurrent weights of the layer. For example, if `RecurrentWeightsL2Factor` is 2, then the  $L_2$  regularization factor for the recurrent weights of the layer is twice the current global  $L_2$  regularization factor. The software determines the  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

To control the value of the  $L_2$  regularization factor for the four individual matrices in `RecurrentWeights`, specify a 1-by-4 vector. The entries of `RecurrentWeightsL2Factor` correspond to the  $L_2$  regularization factor of these components:

- 1** Input gate
- 2** Forget gate
- 3** Cell candidate
- 4** Output gate

To specify the same value for all the matrices, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

### **BiasL2Factor — $L_2$ regularization factor for biases**

0 (default) | nonnegative scalar | 1-by-4 numeric vector

$L_2$  regularization factor for the biases, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the biases in this layer. For example, if `BiasL2Factor` is 2, then the  $L_2$  regularization for the biases in this layer is twice the global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

To control the value of the  $L_2$  regularization factor for the four individual vectors in `Bias`, specify a 1-by-4 vector. The entries of `BiasL2Factor` correspond to the  $L_2$  regularization factor of these components:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate
- 4 Output gate

To specify the same value for all the vectors, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

## **Layer**

### **Name — Layer name**

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: char | string

### **NumInputs — Number of inputs**

1 | 3

This property is read-only.

Number of inputs to the layer.

If the `HasStateInputs` property is 0 (false), then the layer has one input with the name 'in', which corresponds to the input data. In this case, the layer uses the `HiddenState` and `CellState` properties for the layer operation.

If the `HasStateInputs` property is 1 (true), then the layer has three inputs with the names 'in', 'hidden', and 'cell', which correspond to the input data, hidden state, and cell state, respectively. In this case, the layer uses the values passed to these inputs for the layer operation. If `HasStateInputs` is 1 (true), then the `HiddenState` and `CellState` properties must be empty.

Data Types: double

**InputNames — Input names**

```
{'in'} | {'in', 'hidden', 'cell'}
```

This property is read-only.

Input names of the layer.

If the `HasStateInputs` property is `0` (`false`), then the layer has one input with the name `'in'`, which corresponds to the input data. In this case, the layer uses the `HiddenState` and `CellState` properties for the layer operation.

If the `HasStateInputs` property is `1` (`true`), then the layer has three inputs with the names `'in'`, `'hidden'`, and `'cell'`, which correspond to the input data, hidden state, and cell state, respectively. In this case, the layer uses the values passed to these inputs for the layer operation. If `HasStateInputs` is `1` (`true`), then the `HiddenState` and `CellState` properties must be empty.

**NumOutputs — Number of outputs**

```
1 | 3
```

This property is read-only.

Number of outputs to the layer.

If the `HasStateOutputs` property is `0` (`false`), then the layer has one output with the name `'out'`, which corresponds to the output data.

If the `HasStateOutputs` property is `1` (`true`), then the layer has three outputs with the names `'out'`, `'hidden'`, and `'cell'`, which correspond to the output data, hidden state, and cell state, respectively. In this case, the layer also outputs the state values that it computes.

Data Types: `double`

**OutputNames — Output names**

```
{'out'} | {'out', 'hidden', 'cell'}
```

This property is read-only.

Output names of the layer.

If the `HasStateOutputs` property is `0` (`false`), then the layer has one output with the name `'out'`, which corresponds to the output data.

If the `HasStateOutputs` property is `1` (`true`), then the layer has three outputs with the names `'out'`, `'hidden'`, and `'cell'`, which correspond to the output data, hidden state, and cell state, respectively. In this case, the layer also outputs the state values that it computes.

**Examples****Create LSTM Layer**

Create an LSTM layer with the name `'lstm1'` and 100 hidden units.

```
layer = lstmLayer(100, 'Name', 'lstm1')
```

```

layer =
  LSTMLayer with properties:
      Name: 'lstm1'
      InputNames: {'in'}
      OutputNames: {'out'}
      NumInputs: 1
      NumOutputs: 1
      HasStateInputs: 0
      HasStateOutputs: 0

  Hyperparameters
      InputSize: 'auto'
      NumHiddenUnits: 100
      OutputMode: 'sequence'
      StateActivationFunction: 'tanh'
      GateActivationFunction: 'sigmoid'

  Learnable Parameters
      InputWeights: []
      RecurrentWeights: []
      Bias: []

  State Parameters
      HiddenState: []
      CellState: []

  Show all properties

```

Include an LSTM layer in a Layer array.

```

inputSize = 12;
numHiddenUnits = 100;
numClasses = 9;

layers = [ ...
  sequenceInputLayer(inputSize)
  lstmLayer(numHiddenUnits)
  fullyConnectedLayer(numClasses)
  softmaxLayer
  classificationLayer]

layers =
  5x1 Layer array with layers:

   1  ''  Sequence Input           Sequence input with 12 dimensions
   2  ''  LSTM                     LSTM with 100 hidden units
   3  ''  Fully Connected          9 fully connected layer
   4  ''  Softmax                  softmax
   5  ''  Classification Output    crossentropyex

```

### Train Network for Sequence Classification

Train a deep learning LSTM network for sequence-to-label classification.

Load the Japanese Vowels data set as described in [1] and [2]. `XTrain` is a cell array containing 270 sequences of varying length with 12 features corresponding to LPC cepstrum coefficients. `Y` is a categorical vector of labels 1,2,...,9. The entries in `XTrain` are matrices with 12 rows (one row for each feature) and a varying number of columns (one column for each time step).

```
[XTrain,YTrain] = japaneseVowelsTrainData;
```

Visualize the first time series in a plot. Each line corresponds to a feature.

```
figure
plot(XTrain{1})
title("Training Observation 1")
numFeatures = size(XTrain{1},1);
legend("Feature " + string(1:numFeatures),'Location','northeastoutside')
```

Define the LSTM network architecture. Specify the input size as 12 (the number of features of the input data). Specify an LSTM layer to have 100 hidden units and to output the last element of the sequence. Finally, specify nine classes by including a fully connected layer of size 9, followed by a softmax layer and a classification layer.

```
inputSize = 12;
numHiddenUnits = 100;
numClasses = 9;

layers = [ ...
    sequenceInputLayer(inputSize)
    lstmLayer(numHiddenUnits,'OutputMode','last')
```

```

    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer]

layers =
    5x1 Layer array with layers:

     1 '' Sequence Input           Sequence input with 12 dimensions
     2 '' LSTM                     LSTM with 100 hidden units
     3 '' Fully Connected          9 fully connected layer
     4 '' Softmax                  softmax
     5 '' Classification Output    crossentropyex

```

Specify the training options. Specify the solver as 'adam' and 'GradientThreshold' as 1. Set the mini-batch size to 27 and set the maximum number of epochs to 70.

Because the mini-batches are small with short sequences, the CPU is better suited for training. Set 'ExecutionEnvironment' to 'cpu'. To train on a GPU, if available, set 'ExecutionEnvironment' to 'auto' (the default value).

```

maxEpochs = 70;
miniBatchSize = 27;

options = trainingOptions('adam', ...
    'ExecutionEnvironment','cpu', ...
    'MaxEpochs',maxEpochs, ...
    'MiniBatchSize',miniBatchSize, ...
    'GradientThreshold',1, ...
    'Verbose',false, ...
    'Plots','training-progress');

```

Train the LSTM network with the specified training options.

```
net = trainNetwork(XTrain,YTrain,layers,options);
```

Load the test set and classify the sequences into speakers.

```
[XTest,YTest] = japaneseVowelsTestData;
```

Classify the test data. Specify the same mini-batch size used for training.

```
YPred = classify(net,XTest,'MiniBatchSize',miniBatchSize);
```

Calculate the classification accuracy of the predictions.

```
acc = sum(YPred == YTest)./numel(YTest)
```

```
acc = 0.9432
```

## Classification LSTM Networks

To create an LSTM network for sequence-to-label classification, create a layer array containing a sequence input layer, an LSTM layer, a fully connected layer, a softmax layer, and a classification output layer.

Set the size of the sequence input layer to the number of features of the input data. Set the size of the fully connected layer to the number of classes. You do not need to specify the sequence length.

For the LSTM layer, specify the number of hidden units and the output mode 'last'.

```
numFeatures = 12;
numHiddenUnits = 100;
numClasses = 9;
layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits, 'OutputMode', 'last')
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

For an example showing how to train an LSTM network for sequence-to-label classification and classify new data, see “Sequence Classification Using Deep Learning”.

To create an LSTM network for sequence-to-sequence classification, use the same architecture as for sequence-to-label classification, but set the output mode of the LSTM layer to 'sequence'.

```
numFeatures = 12;
numHiddenUnits = 100;
numClasses = 9;
layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits, 'OutputMode', 'sequence')
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

## Regression LSTM Networks

To create an LSTM network for sequence-to-one regression, create a layer array containing a sequence input layer, an LSTM layer, a fully connected layer, and a regression output layer.

Set the size of the sequence input layer to the number of features of the input data. Set the size of the fully connected layer to the number of responses. You do not need to specify the sequence length.

For the LSTM layer, specify the number of hidden units and the output mode 'last'.

```
numFeatures = 12;
numHiddenUnits = 125;
numResponses = 1;

layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits, 'OutputMode', 'last')
    fullyConnectedLayer(numResponses)
    regressionLayer];
```

```
fullyConnectedLayer(numResponses)
regressionLayer];
```

To create an LSTM network for sequence-to-sequence regression, use the same architecture as for sequence-to-one regression, but set the output mode of the LSTM layer to 'sequence'.

```
numFeatures = 12;
numHiddenUnits = 125;
numResponses = 1;

layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits, 'OutputMode', 'sequence')
    fullyConnectedLayer(numResponses)
    regressionLayer];
```

For an example showing how to train an LSTM network for sequence-to-sequence regression and predict on new data, see “Sequence-to-Sequence Regression Using Deep Learning”.

### Deeper LSTM Networks

You can make LSTM networks deeper by inserting extra LSTM layers with the output mode 'sequence' before the LSTM layer. To prevent overfitting, you can insert dropout layers after the LSTM layers.

For sequence-to-label classification networks, the output mode of the last LSTM layer must be 'last'.

```
numFeatures = 12;
numHiddenUnits1 = 125;
numHiddenUnits2 = 100;
numClasses = 9;
layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits1, 'OutputMode', 'sequence')
    dropoutLayer(0.2)
    lstmLayer(numHiddenUnits2, 'OutputMode', 'last')
    dropoutLayer(0.2)
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

For sequence-to-sequence classification networks, the output mode of the last LSTM layer must be 'sequence'.

```
numFeatures = 12;
numHiddenUnits1 = 125;
numHiddenUnits2 = 100;
numClasses = 9;
layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits1, 'OutputMode', 'sequence')
    dropoutLayer(0.2)
    lstmLayer(numHiddenUnits2, 'OutputMode', 'sequence')
    dropoutLayer(0.2)
```

```
fullyConnectedLayer(numClasses)
softmaxLayer
classificationLayer];
```

## Algorithms

### Long Short-Term Memory Layer

An LSTM layer is an RNN layer that learns long-term dependencies between time steps in time series and sequence data.

The state of the layer consists of the *hidden state* (also known as the *output state*) and the *cell state*. The hidden state at time step  $t$  contains the output of the LSTM layer for this time step. The cell state contains information learned from the previous time steps. At each time step, the layer adds information to or removes information from the cell state. The layer controls these updates using *gates*.

These components control the cell state and hidden state of the layer.

Component	Purpose
Input gate ( $i$ )	Control level of cell state update
Forget gate ( $f$ )	Control level of cell state reset (forget)
Cell candidate ( $g$ )	Add information to cell state
Output gate ( $o$ )	Control level of cell state added to hidden state

This diagram illustrates the flow of data at time step  $t$ . This diagram shows how the gates forget, update, and output the cell and hidden states.

The learnable weights of an LSTM layer are the input weights  $W$  (InputWeights), the recurrent weights  $R$  (RecurrentWeights), and the bias  $b$  (Bias). The matrices  $W$ ,  $R$ , and  $b$  are concatenations of the input weights, the recurrent weights, and the bias of each component, respectively. The layer concatenates the matrices according to these equations:

$$W = \begin{bmatrix} W_i \\ W_f \\ W_g \\ W_o \end{bmatrix}, \quad R = \begin{bmatrix} R_i \\ R_f \\ R_g \\ R_o \end{bmatrix}, \quad b = \begin{bmatrix} b_i \\ b_f \\ b_g \\ b_o \end{bmatrix},$$

where  $i$ ,  $f$ ,  $g$ , and  $o$  denote the input gate, forget gate, cell candidate, and output gate, respectively.

The cell state at time step  $t$  is given by

$$\mathbf{c}_t = f_t \odot \mathbf{c}_{t-1} + i_t \odot g_t,$$

where  $\odot$  denotes the Hadamard product (element-wise multiplication of vectors).

The hidden state at time step  $t$  is given by

$$\mathbf{h}_t = o_t \odot \sigma_c(\mathbf{c}_t),$$

where  $\sigma_c$  denotes the state activation function. By default, the `lstmLayer` function uses the hyperbolic tangent function (`tanh`) to compute the state activation function.

These formulas describe the components at time step  $t$ .

Component	Formula
Input gate	$i_t = \sigma_g(W_i \mathbf{x}_t + R_i \mathbf{h}_{t-1} + b_i)$
Forget gate	$f_t = \sigma_g(W_f \mathbf{x}_t + R_f \mathbf{h}_{t-1} + b_f)$
Cell candidate	$g_t = \sigma_c(W_g \mathbf{x}_t + R_g \mathbf{h}_{t-1} + b_g)$
Output gate	$o_t = \sigma_g(W_o \mathbf{x}_t + R_o \mathbf{h}_{t-1} + b_o)$

In these calculations,  $\sigma_g$  denotes the gate activation function. By default, the `lstmLayer` function, uses the sigmoid function, given by  $\sigma(x) = (1 + e^{-x})^{-1}$ , to compute the gate activation function.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The formats consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `LSTMLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	OutputMode	Output Format
"CB" (channel, batch)	"sequence"	"CB" (channel, batch)
	"last"	
"CBT" (channel, batch, time)	"sequence"	"CBT" (channel, batch, time)
	"last"	"CB" (channel, batch)
"SB" (spatial, batch)	"sequence"	"CB" (channel, batch)
	"last"	

In `dlnetwork` objects, `LSTMLayer` objects also support these input and output format combinations.

Input Format	OutputMode	Output Format
"SCB" (spatial, channel, batch)	"sequence"	"CB" (channel, batch)
	"last"	
"SSCB" (spatial, spatial, channel, batch)	"sequence"	
	"last"	
"SSSCB" (spatial, spatial, spatial, channel, batch)	"sequence"	
	"last"	
"SCBT" (spatial, channel, batch, time)	"sequence"	"CBT" (channel, batch, time)
	"last"	"CB" (channel, batch)
"SSCBT" (spatial, spatial, channel, batch, time)	"sequence"	"CBT" (channel, batch, time)
	"last"	"CB" (channel, batch)
"SSSCBT" (spatial, spatial, spatial, channel, batch, time)	"sequence"	"CBT" (channel, batch, time)
	"last"	"CB" (channel, batch)
"SC" (spatial, channel)	"sequence"	"CU" (channel, unspecified)
	"last"	
"SSC" (spatial, spatial, channel)	"sequence"	
	"last"	
"SSSC" (spatial, spatial, spatial, channel)	"sequence"	
	"last"	
"CT" (channel, time)	"sequence"	"CT" (channel, time)
	"last"	"CU" (channel, unspecified)
"SCT" (spatial, channel, time)	"sequence"	"CT" (channel, time)
	"last"	"CU" (channel, unspecified)
"SSCT" (spatial, spatial, channel, time)	"sequence"	"CT" (channel, time)
	"last"	"CU" (channel, unspecified)
"SSSCT" (spatial, spatial, channel, time)	"sequence"	"CT" (channel, time)
	"last"	"CU" (channel, unspecified)
"SSB" (spatial, spatial, batch)	"sequence"	"CB" (channel, batch)
	"last"	
"SSSB" (spatial, spatial, spatial, batch)	"sequence"	
	"last"	
"BT" (batch, time)	"sequence"	"CBT" (channel, batch, time)
	"last"	"CB" (channel, batch)
"SBT" (spatial, batch, time)	"sequence"	"CBT" (channel, batch, time)
	"last"	"CB" (channel, batch)
"SSBT" (spatial, spatial, batch, time)	"sequence"	"CBT" (channel, batch, time)
	"last"	"CB" (channel, batch)

Input Format	OutputMode	Output Format
"SSSBT" (spatial, spatial, spatial, batch, time)	"sequence"	"CBT" (channel, batch, time)
	"last"	"CB" (channel, batch)

To use these input formats in `trainNetwork` workflows, convert the data to "CB" (channel, batch) or "CBT" (channel, batch, time) format using `flattenLayer`.

If the `HasStateInputs` property is 1 (true), then the layer has two additional inputs with the names "hidden" and "cell", which correspond to the hidden state and cell state, respectively. These additional inputs expect input format "CB" (channel, batch).

If the `HasStateOutputs` property is 1 (true), then the layer has two additional outputs with names "hidden" and "cell", which correspond to the hidden state and cell state, respectively. These additional outputs have output format "CB" (channel, batch).

## Version History

### Introduced in R2017b

#### **R2019a: Default input weights initialization is Glorot**

*Behavior changed in R2019a*

Starting in R2019a, the software, by default, initializes the layer input weights of this layer using the Glorot initializer. This behavior helps stabilize training and usually reduces the training time of deep neural networks.

In previous releases, the software, by default, initializes the layer input weights using the by sampling from a normal distribution with zero mean and variance 0.01. To reproduce this behavior, set the 'InputWeightsInitializer' option of the layer to 'narrow-normal'.

#### **R2019a: Default recurrent weights initialization is orthogonal**

*Behavior changed in R2019a*

Starting in R2019a, the software, by default, initializes the layer recurrent weights of this layer with  $Q$ , the orthogonal matrix given by the QR decomposition of  $Z = QR$  for a random matrix  $Z$  sampled from a unit normal distribution. This behavior helps stabilize training and usually reduces the training time of deep neural networks.

In previous releases, the software, by default, initializes the layer recurrent weights using the by sampling from a normal distribution with zero mean and variance 0.01. To reproduce this behavior, set the 'RecurrentWeightsInitializer' option of the layer to 'narrow-normal'.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

For code generation in general, the `HasStateInputs` and `HasStateOutputs` properties must be set to `0` (false).

When generating code with Intel MKL-DNN or ARM Compute Library:

- The `StateActivationFunction` property must be set to `'tanh'`.
- The `GateActivationFunction` property must be set to `'sigmoid'`.

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- For GPU code generation, the `StateActivationFunction` property must be set to `'tanh'`.
- For GPU code generation, the `GateActivationFunction` property must be set to `'sigmoid'`.
- The `HasStateInputs` and `HasStateOutputs` properties must be set to `0` (false).

# IstmProjectedLayer

Long short-term memory (LSTM) projected layer for recurrent neural network (RNN)

## Description

An LSTM projected layer is an RNN layer that learns long-term dependencies between time steps in time series and sequence data using projected learnable weights.

To compress a deep learning network, you can use *projected layers*. A projected layer is a type of deep learning layer that enables compression by reducing the number of stored learnable parameters. The layer introduces learnable projector matrices  $Q$ , replaces multiplications of the form  $Wx$ , where  $W$  is a learnable matrix, with the multiplication  $WQQ^T x$ , and stores  $Q$  and  $W' = WQ$  instead of storing  $W$ . Projecting  $x$  into a lower-dimensional space using  $Q$  typically requires less memory to store the learnable parameters and can have similarly strong prediction accuracy.

Reducing the number of learnable parameters by projecting an LSTM layer rather than reducing the number of hidden units of the LSTM layer maintains the output size of the layer and, in turn, the sizes of the downstream layers, which can result in better prediction accuracy.

## Creation

### Syntax

```
layer = lstmProjectedLayer(numHiddenUnits,outputProjectorSize,  
inputProjectorSize)  
layer = lstmProjectedLayer( __ ,Name=Value)
```

### Description

`layer = lstmProjectedLayer(numHiddenUnits,outputProjectorSize, inputProjectorSize)` creates an LSTM projected layer and sets the `NumHiddenUnits`, `OutputProjectorSize`, and `InputProjectorSize` properties.

`layer = lstmProjectedLayer( __ ,Name=Value)` sets the `OutputMode`, `HasStateInputs`, `HasStateOutputs`, “Activations” on page 1-1261, “State” on page 1-1261, “Parameters and Initialization” on page 1-1262, “Learning Rate and Regularization” on page 1-1266, and `Name` properties using one or more name-value arguments.

## Properties

### Projected LSTM

#### **NumHiddenUnits** – Number of hidden units

positive integer

This property is read-only.

Number of hidden units (also known as the hidden size), specified as a positive integer.

The number of hidden units corresponds to the amount of information that the layer remembers between time steps (the hidden state). The hidden state can contain information from all the previous time steps, regardless of the sequence length. If the number of hidden units is too large, then the layer might overfit to the training data.

The hidden state does not limit the number of time steps that the layer processes in an iteration. To split your sequences into smaller sequences for when you use the `trainNetwork` function, use the `SequenceLength` training option.

The layer outputs data with `NumHiddenUnits` channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **OutputProjectorSize** — Output projector size

positive integer

This property is read-only.

Output projector size, specified as a positive integer.

The LSTM layer operation uses four matrix multiplications of the form  $Rh_{t-1}$ , where  $R$  denotes the recurrent weights and  $h_t$  denotes the hidden state (or, equivalently, the layer output) at time step  $t$ .

The LSTM projected layer operation instead uses multiplications of the form  $RQ_oQ_o^T h_{t-1}$ , where  $Q_o$  is a `NumHiddenUnits`-by-`OutputProjectorSize` matrix known as the *output projector*. The layer uses the same projector  $Q_o$  for each of the four multiplications.

To perform the four multiplications of the form  $Rh_{t-1}$ , an LSTM layer stores four recurrent weights  $R$ , which necessitates storing  $4 * \text{NumHiddenUnits}^2$  learnable parameters. By instead storing the  $4 * \text{NumHiddenUnits}$ -by-`OutputProjectorSize` matrix  $R' = RQ_o$  and  $Q_o$ , an LSTM projected layer can perform the multiplication  $RQ_oQ_o^T h_{t-1}$  and store only  $5 * \text{NumHiddenUnits} * \text{OutputProjectorSize}$  learnable parameters.

---

**Tip** To ensure that  $RQ_oQ_o^T h_{t-1}$  requires fewer learnable parameters, set the `OutputProjectorSize` property to a value less than  $(4/5) * \text{NumHiddenUnits}$ .

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **InputProjectorSize** — Input projector size

positive integer

This property is read-only.

Input projector size, specified as a positive integer.

The LSTM layer operation uses four matrix multiplications of the form  $Wx_t$ , where  $W$  denotes the input weights and  $x_t$  denotes the layer input at time step  $t$ .

The LSTM projected layer operation instead uses multiplications of the form  $WQ_iQ_i^T x_t$ , where  $Q_i$  is an `InputSize`-by-`InputProjectorSize` matrix known as the *input projector*. The layer uses the same projector  $Q_i$  for each of the four multiplications.

To perform the four multiplications of the form  $Wx_t$ , an LSTM layer stores four weight matrices  $W$ , which necessitates storing  $4*\text{NumHiddenUnits}*InputSize$  learnable parameters. By instead storing the  $4*\text{NumHiddenUnits}$ -by-`InputProjectorSize` matrix  $W' = WQ_i$  and  $Q_i$ , an LSTM projected layer can perform the multiplication  $WQ_iQ_i^T x_t$  and store only  $(4*\text{NumHiddenUnits} + InputSize)*InputProjectorSize$  learnable parameters.

---

**Tip** To ensure that  $WQ_iQ_i^T x_t$  requires fewer learnable parameters, set the `InputProjectorSize` property to a value less than  $(4*\text{numHiddenUnits}*inputSize)/(4*\text{numHiddenUnits} + inputSize)$ .

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **OutputMode — Output mode**

`'sequence'` (default) | `'last'`

This property is read-only.

Output mode, specified as one of these values:

- `'sequence'` — Output the complete sequence.
- `'last'` — Output the last time step of the sequence.

### **HasStateInputs — Flag for state inputs to layer**

`0` (false) (default) | `1` (true)

This property is read-only.

Flag for state inputs to the layer, specified as `0` (false) or `1` (true).

If the `HasStateInputs` property is `0` (false), then the layer has one input with the name `'in'`, which corresponds to the input data. In this case, the layer uses the `HiddenState` and `CellState` properties for the layer operation.

If the `HasStateInputs` property is `1` (true), then the layer has three inputs with the names `'in'`, `'hidden'`, and `'cell'`, which correspond to the input data, hidden state, and cell state, respectively. In this case, the layer uses the values passed to these inputs for the layer operation. If `HasStateInputs` is `1` (true), then the `HiddenState` and `CellState` properties must be empty.

### **HasStateOutputs — Flag for state outputs from layer**

`0` (false) (default) | `1` (true)

This property is read-only.

Flag for state outputs from the layer, specified as `0` (false) or `1` (true).

If the `HasStateOutputs` property is `0` (false), then the layer has one output with the name `'out'`, which corresponds to the output data.

If the `HasStateOutputs` property is 1 (true), then the layer has three outputs with the names 'out', 'hidden', and 'cell', which correspond to the output data, hidden state, and cell state, respectively. In this case, the layer also outputs the state values that it computes.

### InputSize — Input size

'auto' (default) | positive integer

This property is read-only.

Input size, specified as a positive integer or 'auto'. If `InputSize` is 'auto', then the software automatically assigns the input size at training time.

Data Types: double | char

### Activations

#### StateActivationFunction — Activation function to update cell and hidden state

'tanh' (default) | 'softsign'

This property is read-only.

Activation function to update the cell and hidden state, specified as one of these values:

- 'tanh' — Use the hyperbolic tangent function (tanh).
- 'softsign' — Use the softsign function  $\text{softsign}(x) = \frac{x}{1 + |x|}$ .

The layer uses this option as the function  $\sigma_c$  in the calculations to update the cell and hidden state. For more information on how an LSTM layer uses activation functions, see “Long Short-Term Memory Layer” on page 1-1251.

#### GateActivationFunction — Activation function to apply to gates

'sigmoid' (default) | 'hard-sigmoid'

This property is read-only.

Activation function to apply to the gates, specified as one of these values:

- 'sigmoid' — Use the sigmoid function  $\sigma(x) = (1 + e^{-x})^{-1}$ .
- 'hard-sigmoid' — Use the hard sigmoid function

$$\sigma(x) = \begin{cases} 0 & \text{if } x < -2.5 \\ 0.2x + 0.5 & \text{if } -2.5 \leq x \leq 2.5 \\ 1 & \text{if } x > 2.5 \end{cases}$$

The layer uses this option as the function  $\sigma_g$  in the calculations for the layer gates.

### State

#### CellState — Cell state

[] (default) | numeric vector

Cell state to use in the layer operation, specified as a `NumHiddenUnits-by-1` numeric vector. This value corresponds to the initial cell state when data is passed to the layer.

After you set this property manually, calls to the `resetState` function set the cell state to this value.

If `HasStateInputs` is 1 (true), then the `CellState` property must be empty.

Data Types: `single` | `double`

### **HiddenState — Hidden state**

`[]` (default) | numeric vector

Hidden state to use in the layer operation, specified as a `NumHiddenUnits`-by-1 numeric vector. This value corresponds to the initial hidden state when data is passed to the layer.

After you set this property manually, calls to the `resetState` function set the hidden state to this value.

If `HasStateInputs` is 1 (true), then the `HiddenState` property must be empty.

Data Types: `single` | `double`

### **Parameters and Initialization**

#### **InputWeightsInitializer — Function to initialize input weights**

'glorot' (default) | 'he' | 'orthogonal' | 'narrow-normal' | 'zeros' | 'ones' | function handle

Function to initialize the input weights, specified as one of these values:

- 'glorot' — Initialize the input weights with the Glorot initializer [1] (also known as the Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and a variance of  $2 / (\text{InputProjectorSize} + \text{numOut})$ , where  $\text{numOut} = 4 * \text{NumHiddenUnits}$ .
- 'he' — Initialize the input weights with the He initializer [2]. The He initializer samples from a normal distribution with zero mean and a variance of  $2 / \text{InputProjectorSize}$ .
- 'orthogonal' — Initialize the input weights with  $Q$ , the orthogonal matrix in the QR decomposition of  $Z = QR$  for a random matrix  $Z$  sampled from a unit normal distribution [3].
- 'narrow-normal' — Initialize the input weights by independently sampling from a normal distribution with zero mean and a standard deviation of 0.01.
- 'zeros' — Initialize the input weights with zeros.
- 'ones' — Initialize the input weights with ones.
- Function handle — Initialize the input weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the input weights.

The layer only initializes the input weights when the `InputWeights` property is empty.

Data Types: `char` | `string` | `function_handle`

#### **RecurrentWeightsInitializer — Function to initialize recurrent weights**

'orthogonal' (default) | 'glorot' | 'he' | 'narrow-normal' | 'zeros' | 'ones' | function handle

Function to initialize the recurrent weights, specified as one of the following:

- 'orthogonal' — Initialize the recurrent weights with  $Q$ , the orthogonal matrix in the QR decomposition of  $Z = QR$  for a random matrix  $Z$  sampled from a unit normal distribution [3].

- `'glorot'` — Initialize the recurrent weights with the Glorot initializer [1] (also known as the Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and a variance of  $2/(\text{numIn} + \text{numOut})$ , where  $\text{numIn} = \text{OutputProjectorSize}$  and  $\text{numOut} = 4 * \text{NumHiddenUnits}$ .
- `'he'` — Initialize the recurrent weights with the He initializer [2]. The He initializer samples from a normal distribution with zero mean and a variance of  $2/\text{OutputProjectorSize}$ .
- `'narrow-normal'` — Initialize the recurrent weights by independently sampling from a normal distribution with zero mean and a standard deviation of 0.01.
- `'zeros'` — Initialize the recurrent weights with zeros.
- `'ones'` — Initialize the recurrent weights with ones.
- Function handle — Initialize the recurrent weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the recurrent weights.

The layer only initializes the recurrent weights when the `RecurrentWeights` property is empty.

Data Types: `char` | `string` | `function_handle`

### **InputProjectorInitializer — Function to initialize input projector**

`'orthogonal'` (default) | `'glorot'` | `'he'` | `'narrow-normal'` | `'zeros'` | `'ones'` | function handle

Function to initialize the input projector, specified as one of the following:

- `'orthogonal'` — Initialize the input projector with  $Q$ , the orthogonal matrix in the QR decomposition of  $Z = QR$  for a random matrix  $Z$  sampled from a unit normal distribution [3].
- `'glorot'` — Initialize the input projector with the Glorot initializer [1] (also known as the Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and a variance of  $2/(\text{InputSize} + \text{inputProjectorSize})$ .
- `'he'` — Initialize the input projector with the He initializer [2]. The He initializer samples from a normal distribution with zero mean and a variance of  $2/\text{InputSize}$ .
- `'narrow-normal'` — Initialize the input projector by independently sampling from a normal distribution with zero mean and a standard deviation of 0.01.
- `'zeros'` — Initialize the input weights with zeros.
- `'ones'` — Initialize the input weights with ones.
- Function handle — Initialize the input projector with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the input projector.

The layer only initializes the input projector when the `InputProjector` property is empty.

Data Types: `char` | `string` | `function_handle`

### **OutputProjectorInitializer — Function to initialize output projector**

`'orthogonal'` (default) | `'glorot'` | `'he'` | `'narrow-normal'` | `'zeros'` | `'ones'` | function handle

Function to initialize the output projector, specified as one of the following:

- `'orthogonal'` — Initialize the output projector with  $Q$ , the orthogonal matrix in the QR decomposition of  $Z = QR$  for a random matrix  $Z$  sampled from a unit normal distribution [3].

- 'glorot' — Initialize the output projector with the Glorot initializer [1] (also known as the Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and a variance of  $2/(\text{NumHiddenUnits} + \text{OutputProjectorSize})$ .
- 'he' — Initialize the output projector with the He initializer [2]. The He initializer samples from a normal distribution with zero mean and a variance of  $2/\text{NumHiddenUnits}$ .
- 'narrow-normal' — Initialize the output projector by independently sampling from a normal distribution with zero mean and a standard deviation of 0.01.
- 'zeros' — Initialize the output projector with zeros.
- 'ones' — Initialize the output projector with ones.
- Function handle — Initialize the output projector with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the output projector.

The layer only initializes the output projector when the `OutputProjector` property is empty.

Data Types: `char` | `string` | `function_handle`

### **BiasInitializer — Function to initialize bias**

'unit-forget-gate' (default) | 'narrow-normal' | 'ones' | function handle

Function to initialize the bias, specified as one of these values:

- 'unit-forget-gate' — Initialize the forget gate bias with ones and the remaining biases with zeros.
- 'narrow-normal' — Initialize the bias by independently sampling from a normal distribution with zero mean and a standard deviation of 0.01.
- 'ones' — Initialize the bias with ones.
- Function handle — Initialize the bias with a custom function. If you specify a function handle, then the function must be of the form `bias = func(sz)`, where `sz` is the size of the bias.

The layer only initializes the bias when the `Bias` property is empty.

Data Types: `char` | `string` | `function_handle`

### **InputWeights — Input weights**

[] (default) | matrix

Input weights, specified as a matrix.

The input weight matrix is a concatenation of the four input weight matrices for the components (gates) in the LSTM layer. The layer vertically concatenates the four matrices in this order:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate
- 4 Output gate

The input weights are learnable parameters. When you train a neural network using the `trainNetwork` function, if `InputWeights` is nonempty, then the software uses the `InputWeights` property as the initial value. If `InputWeights` is empty, then the software uses the initializer specified by `InputWeightsInitializer`.

At training time, `InputWeights` is a  $4 \times \text{NumHiddenUnits}$ -by-`InputProjectorSize` matrix.

### **RecurrentWeights — Recurrent weights**

`[]` (default) | matrix

Recurrent weights, specified as a matrix.

The recurrent weight matrix is a concatenation of the four recurrent weight matrices for the components (gates) in the LSTM layer. The layer vertically concatenates the four matrices in this order:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate
- 4 Output gate

The recurrent weights are learnable parameters. When you train an RNN using the `trainNetwork` function, if `RecurrentWeights` is nonempty, then the software uses the `RecurrentWeights` property as the initial value. If `RecurrentWeights` is empty, then the software uses the initializer specified by `RecurrentWeightsInitializer`.

At training time, `RecurrentWeights` is a  $4 \times \text{NumHiddenUnits}$ -by-`OutputProjectorSize` matrix.

### **InputProjector — Input projector**

`[]` (default) | matrix

Input projector, specified as a matrix.

The input projector weights are learnable parameters. When you train a network using the `trainNetwork` function, if `InputProjector` is nonempty, then the software uses the `InputProjector` property as the initial value. If `InputProjector` is empty, then the software uses the initializer specified by `InputProjectorInitializer`.

At training time, `InputProjector` is a `InputSize`-by-`InputProjectorSize` matrix.

Data Types: `single` | `double`

### **OutputProjector — Output projector**

`[]` (default) | matrix

Output projector, specified as a matrix.

The output projector weights are learnable parameters. When you train a network using the `trainNetwork` function, if `OutputProjector` is nonempty, then the software uses the `OutputProjector` property as the initial value. If `OutputProjector` is empty, then the software uses the initializer specified by `OutputProjectorInitializer`.

At training time, `OutputProjector` is a `NumHiddenUnits`-by-`OutputProjectorSize` matrix.

Data Types: `single` | `double`

### **Bias — Layer biases**

`[]` (default) | numeric vector

Layer biases, specified as a numeric vector.

The bias vector is a concatenation of the four bias vectors for the components (gates) in the layer. The layer vertically concatenates the four vectors in this order:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate
- 4 Output gate

The layer biases are learnable parameters. When you train a neural network, if `Bias` is nonempty, then `trainNetwork` uses the `Bias` property as the initial value. If `Bias` is empty, then `trainNetwork` uses the initializer specified by `BiasInitializer`.

At training time, `Bias` is a  $4 \times \text{NumHiddenUnits}$ -by-1 numeric vector.

### Learning Rate and Regularization

#### **InputWeightsLearnRateFactor** — Learning rate factor for input weights

1 (default) | nonnegative scalar | 1-by-4 numeric vector

Learning rate factor for the input weights, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global learning rate to determine the learning rate factor for the input weights of the layer. For example, if `InputWeightsLearnRateFactor` is 2, then the learning rate factor for the input weights of the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify with the `trainingOptions` function.

To control the value of the learning rate factor for the four individual matrices in `InputWeights`, specify a 1-by-4 vector. The entries of `InputWeightsLearnRateFactor` correspond to the learning rate factor of these components:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate
- 4 Output gate

To specify the same value for all the matrices, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

#### **RecurrentWeightsLearnRateFactor** — Learning rate factor for recurrent weights

1 (default) | nonnegative scalar | 1-by-4 numeric vector

Learning rate factor for the recurrent weights, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global learning rate to determine the learning rate for the recurrent weights of the layer. For example, if `RecurrentWeightsLearnRateFactor` is 2, then the learning rate for the recurrent weights of the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

To control the value of the learning rate factor for the four individual matrices in `RecurrentWeights`, specify a 1-by-4 vector. The entries of `RecurrentWeightsLearnRateFactor` correspond to the learning rate factor of these components:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate
- 4 Output gate

To specify the same value for all the matrices, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

### **InputProjectorLearnRateFactor — Learning rate factor for input projector**

1 (default) | nonnegative scalar

Learning rate factor for the input projector, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate factor for the input projector of the layer. For example, if `InputProjectorLearnRateFactor` is 2, then the learning rate factor for the input projector of the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

### **OutputProjectorLearnRateFactor — Learning rate factor for output projector**

1 (default) | nonnegative scalar

Learning rate factor for the output projector, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate factor for the output projector of the layer. For example, if `OutputProjectorLearnRateFactor` is 2, then the learning rate factor for the output projector of the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

### **BiasLearnRateFactor — Learning rate factor for biases**

1 (default) | nonnegative scalar | 1-by-4 numeric vector

Learning rate factor for the biases, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is 2, then the learning rate for the biases in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

To control the value of the learning rate factor for the four individual vectors in `Bias`, specify a 1-by-4 vector. The entries of `BiasLearnRateFactor` correspond to the learning rate factor of these components:

- 1 Input gate
- 2 Forget gate
- 3 Cell candidate

**4** Output gate

To specify the same value for all the vectors, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

**InputWeightsL2Factor —  $L_2$  regularization factor for input weights**

1 (default) | nonnegative scalar | 1-by-4 numeric vector

$L_2$  regularization factor for the input weights, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization factor for the input weights of the layer. For example, if `InputWeightsL2Factor` is 2, then the  $L_2$  regularization factor for the input weights of the layer is twice the current global  $L_2$  regularization factor. The software determines the  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

To control the value of the  $L_2$  regularization factor for the four individual matrices in `InputWeights`, specify a 1-by-4 vector. The entries of `InputWeightsL2Factor` correspond to the  $L_2$  regularization factor of these components:

- 1** Input gate
- 2** Forget gate
- 3** Cell candidate
- 4** Output gate

To specify the same value for all the matrices, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

**RecurrentWeightsL2Factor —  $L_2$  regularization factor for recurrent weights**

1 (default) | nonnegative scalar | 1-by-4 numeric vector

$L_2$  regularization factor for the recurrent weights, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization factor for the recurrent weights of the layer. For example, if `RecurrentWeightsL2Factor` is 2, then the  $L_2$  regularization factor for the recurrent weights of the layer is twice the current global  $L_2$  regularization factor. The software determines the  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

To control the value of the  $L_2$  regularization factor for the four individual matrices in `RecurrentWeights`, specify a 1-by-4 vector. The entries of `RecurrentWeightsL2Factor` correspond to the  $L_2$  regularization factor of these components:

- 1** Input gate
- 2** Forget gate
- 3** Cell candidate

**4** Output gate

To specify the same value for all the matrices, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

**InputProjectorL2Factor —  $L_2$  regularization factor for input projector**

1 (default) | nonnegative scalar

$L_2$  regularization factor for the input projector, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization factor for the input projector of the layer. For example, if `InputProjectorL2Factor` is 2, then the  $L_2$  regularization factor for the input projector of the layer is twice the current global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

**OutputProjectorL2Factor —  $L_2$  regularization factor for output projector**

1 (default) | nonnegative scalar

$L_2$  regularization factor for the output projector, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization factor for the output projector of the layer. For example, if `OutputProjectorL2Factor` is 2, then the  $L_2$  regularization factor for the output projector of the layer is twice the current global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

**BiasL2Factor —  $L_2$  regularization factor for biases**

0 (default) | nonnegative scalar | 1-by-4 numeric vector

$L_2$  regularization factor for the biases, specified as a nonnegative scalar or a 1-by-4 numeric vector.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the biases in this layer. For example, if `BiasL2Factor` is 2, then the  $L_2$  regularization for the biases in this layer is twice the global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

To control the value of the  $L_2$  regularization factor for the four individual vectors in `Bias`, specify a 1-by-4 vector. The entries of `BiasL2Factor` correspond to the  $L_2$  regularization factor of these components:

- 1** Input gate
- 2** Forget gate
- 3** Cell candidate
- 4** Output gate

To specify the same value for all the vectors, specify a nonnegative scalar.

Example: 2

Example: [1 2 1 1]

## Layer

### Name — Layer name

`''` (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name `''`.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 | 3

This property is read-only.

Number of inputs to the layer.

If the `HasStateInputs` property is `0` (`false`), then the layer has one input with the name `'in'`, which corresponds to the input data. In this case, the layer uses the `HiddenState` and `CellState` properties for the layer operation.

If the `HasStateInputs` property is `1` (`true`), then the layer has three inputs with the names `'in'`, `'hidden'`, and `'cell'`, which correspond to the input data, hidden state, and cell state, respectively. In this case, the layer uses the values passed to these inputs for the layer operation. If `HasStateInputs` is `1` (`true`), then the `HiddenState` and `CellState` properties must be empty.

Data Types: `double`

### InputNames — Input names

`{'in'}` | `{'in','hidden','cell'}`

This property is read-only.

Input names of the layer.

If the `HasStateInputs` property is `0` (`false`), then the layer has one input with the name `'in'`, which corresponds to the input data. In this case, the layer uses the `HiddenState` and `CellState` properties for the layer operation.

If the `HasStateInputs` property is `1` (`true`), then the layer has three inputs with the names `'in'`, `'hidden'`, and `'cell'`, which correspond to the input data, hidden state, and cell state, respectively. In this case, the layer uses the values passed to these inputs for the layer operation. If `HasStateInputs` is `1` (`true`), then the `HiddenState` and `CellState` properties must be empty.

### NumOutputs — Number of outputs

1 | 3

This property is read-only.

Number of outputs to the layer.

If the `HasStateOutputs` property is `0` (`false`), then the layer has one output with the name `'out'`, which corresponds to the output data.

If the `HasStateOutputs` property is 1 (true), then the layer has three outputs with the names 'out', 'hidden', and 'cell', which correspond to the output data, hidden state, and cell state, respectively. In this case, the layer also outputs the state values that it computes.

Data Types: double

### OutputNames — Output names

```
{'out'} | {'out', 'hidden', 'cell'}
```

This property is read-only.

Output names of the layer.

If the `HasStateOutputs` property is 0 (false), then the layer has one output with the name 'out', which corresponds to the output data.

If the `HasStateOutputs` property is 1 (true), then the layer has three outputs with the names 'out', 'hidden', and 'cell', which correspond to the output data, hidden state, and cell state, respectively. In this case, the layer also outputs the state values that it computes.

## Examples

### Create LSTM Projected Layer

Create an LSTM projected layer with 100 hidden units, an output projector size of 30, an input projector size of 16, and the name "lstm".

```
layer = lstmProjectedLayer(100,30,16,Name="lstm")
```

```
layer =
```

```
  LSTMProjectedLayer with properties:
```

```

        Name: 'lstm'
    InputNames: {'in'}
    OutputNames: {'out'}
        NumInputs: 1
        NumOutputs: 1
    HasStateInputs: 0
    HasStateOutputs: 0
```

```
Hyperparameters
```

```

        InputSize: 'auto'
        NumHiddenUnits: 100
    InputProjectorSize: 16
    OutputProjectorSize: 30
        OutputMode: 'sequence'
    StateActivationFunction: 'tanh'
    GateActivationFunction: 'sigmoid'
```

```
Learnable Parameters
```

```

        InputWeights: []
    RecurrentWeights: []
            Bias: []
        InputProjector: []
    OutputProjector: []
```

```
State Parameters
  HiddenState: []
  CellState: []
```

Show all properties

Include an LSTM projected layer in a layer array.

```
inputSize = 12;
numHiddenUnits = 100;
outputProjectorSize = max(1,floor(0.75*numHiddenUnits));
inputProjectorSize = max(1,floor(0.25*inputSize));

layers = [
    sequenceInputLayer(inputSize)
    lstmProjectedLayer(numHiddenUnits,outputProjectorSize,inputProjectorSize)
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer];
```

### Compare Network Projection Sizes

Compare the sizes of networks that do and do not contain projected layers.

Define an LSTM network architecture. Specify the input size as 12, which corresponds to the number of features of the input data. Configure an LSTM layer with 100 hidden units that outputs the last element of the sequence. Finally, specify nine classes by including a fully connected layer of size 9, followed by a softmax layer and a classification layer.

```
inputSize = 12;
numHiddenUnits = 100;
numClasses = 9;

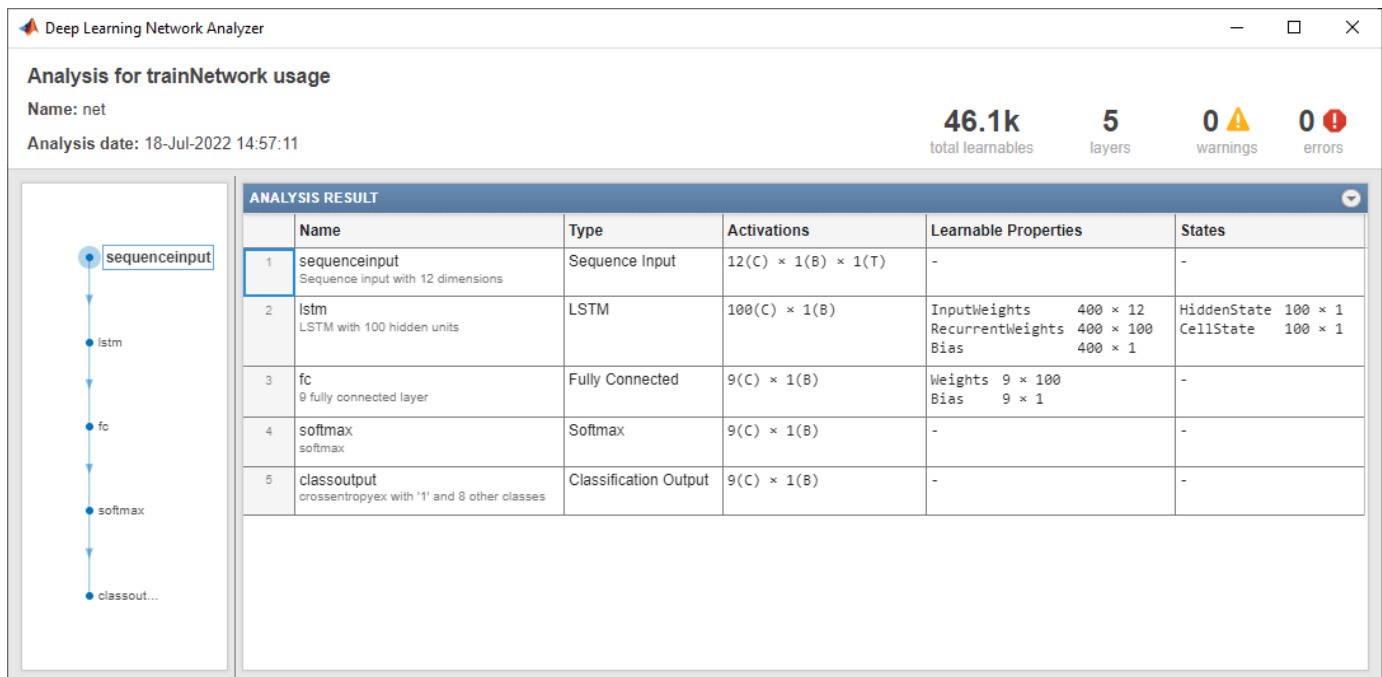

layers = [ ...
    sequenceInputLayer(inputSize)
    lstmLayer(numHiddenUnits,OutputMode="last")
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer]
```

```
layers =
  5x1 Layer array with layers:
```

1	''	Sequence Input	Sequence input with 12 dimensions
2	''	LSTM	LSTM with 100 hidden units
3	''	Fully Connected	9 fully connected layer
4	''	Softmax	softmax
5	''	Classification Output	crossentropyex

Analyze the network using the `analyzeNetwork` function. The network has approximately 46,100 learnable parameters.

```
analyzeNetwork(layers)
```

Create an identical network with an LSTM projected layer in place of the LSTM layer.

For the LSTM projected layer:

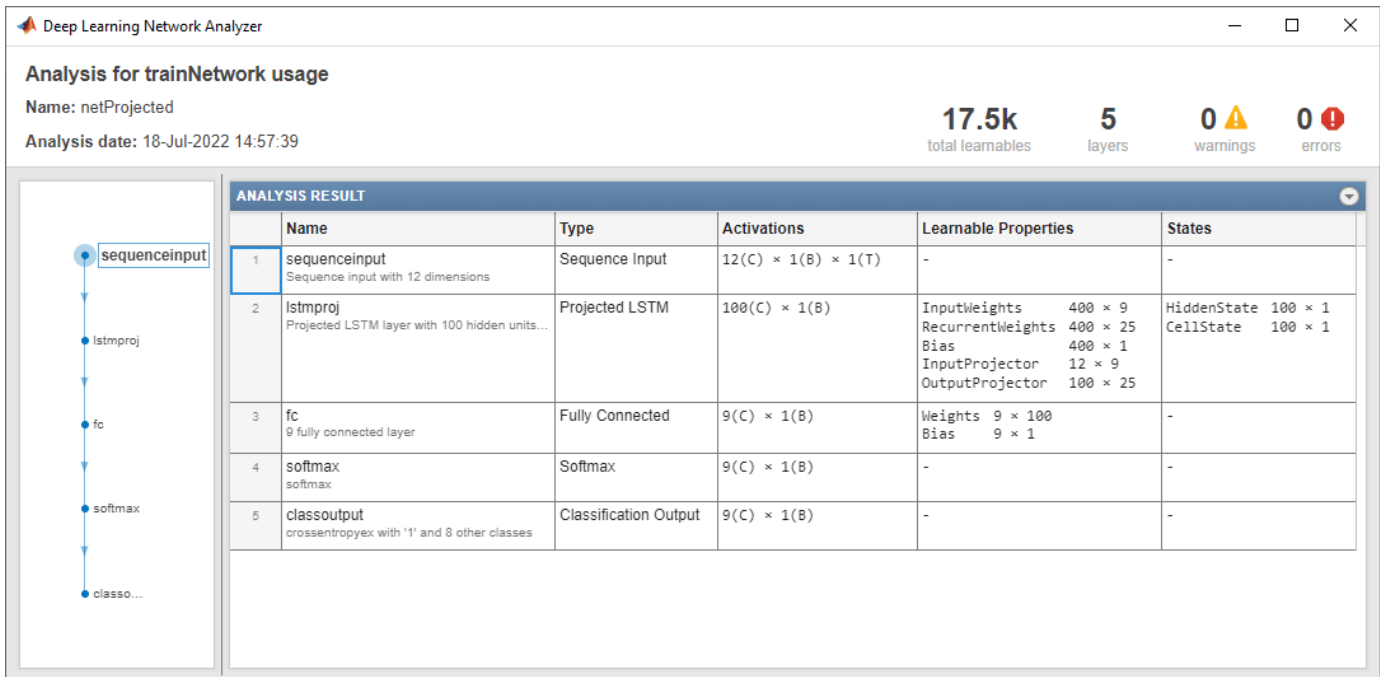

- Specify the same number of hidden units as the LSTM layer
- Specify an output projector size of 25% of the number of hidden units.
- Specify an input projector size of 75% of the input size.
- Ensure that the output and input projector sizes are positive by taking the maximum of the sizes and 1.

```
outputProjectorSize = max(1,floor(0.25*numHiddenUnits));
inputProjectorSize = max(1,floor(0.75*inputSize));
```

```
layersProjected = [ ...
    sequenceInputLayer(inputSize)
    lstmProjectedLayer(numHiddenUnits,outputProjectorSize,inputProjectorSize,OutputMode="last")
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

Analyze the network using the `analyzeNetwork` function. The network has approximately 17,500 learnable parameters, which is a reduction of more than half. The sizes of the learnable parameters of the layers following the projected layer have the same sizes as the network without the LSTM projected layer. Reducing the number of learnable parameters by projecting an LSTM layer rather than reducing the number of hidden units of the LSTM layer maintains the output size of the layer and, in turn, the sizes of the downstream layers, which can result in better prediction accuracy.

```
analyzeNetwork(layersProjected)
```

## Algorithms

### Long Short-Term Memory Layer

An LSTM layer is an RNN layer that learns long-term dependencies between time steps in time series and sequence data.

The state of the layer consists of the *hidden state* (also known as the *output state*) and the *cell state*. The hidden state at time step  $t$  contains the output of the LSTM layer for this time step. The cell state contains information learned from the previous time steps. At each time step, the layer adds information to or removes information from the cell state. The layer controls these updates using *gates*.

These components control the cell state and hidden state of the layer.

Component	Purpose
Input gate ( $i$ )	Control level of cell state update
Forget gate ( $f$ )	Control level of cell state reset (forget)
Cell candidate ( $g$ )	Add information to cell state
Output gate ( $o$ )	Control level of cell state added to hidden state

This diagram illustrates the flow of data at time step  $t$ . This diagram shows how the gates forget, update, and output the cell and hidden states.

The learnable weights of an LSTM layer are the input weights  $W$  (InputWeights), the recurrent weights  $R$  (RecurrentWeights), and the bias  $b$  (Bias). The matrices  $W$ ,  $R$ , and  $b$  are concatenations of the input weights, the recurrent weights, and the bias of each component, respectively. The layer concatenates the matrices according to these equations:

$$W = \begin{bmatrix} W_i \\ W_f \\ W_g \\ W_o \end{bmatrix}, \quad R = \begin{bmatrix} R_i \\ R_f \\ R_g \\ R_o \end{bmatrix}, \quad b = \begin{bmatrix} b_i \\ b_f \\ b_g \\ b_o \end{bmatrix},$$

where  $i$ ,  $f$ ,  $g$ , and  $o$  denote the input gate, forget gate, cell candidate, and output gate, respectively.

The cell state at time step  $t$  is given by

$$\mathbf{c}_t = f_t \odot \mathbf{c}_{t-1} + i_t \odot g_t,$$

where  $\odot$  denotes the Hadamard product (element-wise multiplication of vectors).

The hidden state at time step  $t$  is given by

$$\mathbf{h}_t = o_t \odot \sigma_c(\mathbf{c}_t),$$

where  $\sigma_c$  denotes the state activation function. By default, the `LstmLayer` function uses the hyperbolic tangent function (`tanh`) to compute the state activation function.

These formulas describe the components at time step  $t$ .

Component	Formula
Input gate	$i_t = \sigma_g(W_i \mathbf{x}_t + R_i \mathbf{h}_{t-1} + b_i)$
Forget gate	$f_t = \sigma_g(W_f \mathbf{x}_t + R_f \mathbf{h}_{t-1} + b_f)$
Cell candidate	$g_t = \sigma_c(W_g \mathbf{x}_t + R_g \mathbf{h}_{t-1} + b_g)$
Output gate	$o_t = \sigma_g(W_o \mathbf{x}_t + R_o \mathbf{h}_{t-1} + b_o)$

In these calculations,  $\sigma_g$  denotes the gate activation function. By default, the `lstmLayer` function, uses the sigmoid function, given by  $\sigma(x) = (1 + e^{-x})^{-1}$ , to compute the gate activation function.

### LSTM Projected Layer

An LSTM projected layer is an RNN layer that learns long-term dependencies between time steps in time series and sequence data using projected learnable weights.

To compress a deep learning network, you can use *projected layers*. A projected layer is a type of deep learning layer that enables compression by reducing the number of stored learnable parameters. The layer introduces learnable projector matrices  $Q$ , replaces multiplications of the form  $Wx$ , where  $W$  is a learnable matrix, with the multiplication  $WQQ^T x$ , and stores  $Q$  and  $W' = WQ$  instead of storing  $W$ . Projecting  $x$  into a lower-dimensional space using  $Q$  typically requires less memory to store the learnable parameters and can have similarly strong prediction accuracy.

Reducing the number of learnable parameters by projecting an LSTM layer rather than reducing the number of hidden units of the LSTM layer maintains the output size of the layer and, in turn, the sizes of the downstream layers, which can result in better prediction accuracy.

#### Output Projection

The LSTM layer operation uses four matrix multiplications of the form  $Rh_{t-1}$ , where  $R$  denotes the recurrent weights and  $h_t$  denotes the hidden state (or, equivalently, the layer output) at time step  $t$ .

The LSTM projected layer operation instead uses multiplications of the form  $RQ_oQ_o^T h_{t-1}$ , where  $Q_o$  is a `NumHiddenUnits-by-OutputProjectorSize` matrix known as the *output projector*. The layer uses the same projector  $Q_o$  for each of the four multiplications.

To perform the four multiplications of the form  $Rh_{t-1}$ , an LSTM layer stores four recurrent weights  $R$ , which necessitates storing  $4 * \text{NumHiddenUnits}^2$  learnable parameters. By instead storing the `4*NumHiddenUnits-by-OutputProjectorSize` matrix  $R' = RQ_o$  and  $Q_o$ , an LSTM projected layer can perform the multiplication  $RQ_oQ_o^T h_{t-1}$  and store only  $5 * \text{NumHiddenUnits} * \text{OutputProjectorSize}$  learnable parameters.

#### Input Projection

The LSTM layer operation uses four matrix multiplications of the form  $Wx_t$ , where  $W$  denotes the input weights and  $x_t$  denotes the layer input at time step  $t$ .

The LSTM projected layer operation instead uses multiplications of the form  $WQ_iQ_i^T x_t$ , where  $Q_i$  is an `InputSize-by-InputProjectorSize` matrix known as the *input projector*. The layer uses the same projector  $Q_i$  for each of the four multiplications.

To perform the four multiplications of the form  $Wx_t$ , an LSTM layer stores four weight matrices  $W$ , which necessitates storing  $4 * \text{NumHiddenUnits} * \text{InputSize}$  learnable parameters. By instead

storing the  $4 * \text{NumHiddenUnits} \text{-by-InputProjectorSize}$  matrix  $W' = WQ_i$  and  $Q_i$ , an LSTM projected layer can perform the multiplication  $WQ_i Q_i^T x_t$  and store only  $(4 * \text{NumHiddenUnits} + \text{InputSize}) * \text{InputProjectorSize}$  learnable parameters.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The formats consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `LSTMProjectedLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	OutputMode	Output Format
"CB" (channel, batch)	"sequence"	"CB" (channel, batch)
	"last"	
"CBT" (channel, batch, time)	"sequence"	"CBT" (channel, batch, time)
	"last"	"CB" (channel, batch)
"SB" (spatial, batch)	"sequence"	"CB" (channel, batch)
	"last"	

In `dlnetwork` objects, `LSTMProjectedLayer` objects also support these input and output format combinations.

Input Format	OutputMode	Output Format
"SCB" (spatial, channel, batch)	"sequence"	"CB" (channel, batch)
	"last"	
"SSCB" (spatial, spatial, channel, batch)	"sequence"	
	"last"	

Input Format	OutputMode	Output Format	
"SSSCB" (spatial, spatial, spatial, channel, batch)	"sequence"		
	"last"		
"SCBT" (spatial, channel, batch, time)	"sequence"	"CBT" (channel, batch, time)	
	"last"	"CB" (channel, batch)	
"SSCBT" (spatial, spatial, channel, batch, time)	"sequence"	"CBT" (channel, batch, time)	
	"last"	"CB" (channel, batch)	
"SSSCBT" (spatial, spatial, spatial, channel, batch, time)	"sequence"	"CBT" (channel, batch, time)	
	"last"	"CB" (channel, batch)	
"SC" (spatial, channel)	"sequence"	"CU" (channel, unspecified)	
	"last"		
"SSC" (spatial, spatial, channel)	"sequence"		
	"last"		
"SSSC" (spatial, spatial, spatial, channel)	"sequence"		
	"last"		
"CT" (channel, time)	"sequence"		"CT" (channel, time)
	"last"		"CU" (channel, unspecified)
"SCT" (spatial, channel, time)	"sequence"		"CT" (channel, time)
	"last"	"CU" (channel, unspecified)	
"SSCT" (spatial, spatial, channel, time)	"sequence"	"CT" (channel, time)	
	"last"	"CU" (channel, unspecified)	
"SSSCT" (spatial, spatial, channel, time)	"sequence"	"CT" (channel, time)	
	"last"	"CU" (channel, unspecified)	
"SSB" (spatial, spatial, batch)	"sequence"	"CB" (channel, batch)	
	"last"		
"SSSB" (spatial, spatial, spatial, batch)	"sequence"		
	"last"		
"BT" (batch, time)	"sequence"	"CBT" (channel, batch, time)	
	"last"	"CB" (channel, batch)	
"SBT" (spatial, batch, time)	"sequence"	"CBT" (channel, batch, time)	
	"last"	"CB" (channel, batch)	
"SSBT" (spatial, spatial, batch, time)	"sequence"	"CBT" (channel, batch, time)	
	"last"	"CB" (channel, batch)	
"SSSBT" (spatial, spatial, spatial, batch, time)	"sequence"	"CBT" (channel, batch, time)	
	"last"	"CB" (channel, batch)	

To use these input formats in `trainNetwork` workflows, convert the data to "CB" (channel, batch) or "CBT" (channel, batch, time) format using `flattenLayer`.

If the `HasStateInputs` property is 1 (true), then the layer has two additional inputs with the names "hidden" and "cell", which correspond to the hidden state and cell state, respectively. These additional inputs expect input format "CB" (channel, batch).

If the `HasStateOutputs` property is 1 (true), then the layer has two additional outputs with names "hidden" and "cell", which correspond to the hidden state and cell state, respectively. These additional outputs have output format "CB" (channel, batch).

# maxpool

Pool data to maximum value

## Syntax

```
Y = maxpool(X,poolsize)
[Y,indx,inputSize] = maxpool(X,poolsize)
Y = maxpool(X,'global')
___ = maxpool( ___, 'DataFormat', FMT)
___ = maxpool( ___, Name, Value)
```

## Description

The maximum pooling operation performs downsampling by dividing the input into pooling regions and computing the maximum value of each region.

The `maxpool` function applies the maximum pooling operation to `darray` data. Using `darray` objects makes working with high dimensional data easier by allowing you to label the dimensions. For example, you can label which dimensions correspond to spatial, time, channel, and batch dimensions using the "S", "T", "C", and "B" labels, respectively. For unspecified and other dimensions, use the "U" label. For `darray` object functions that operate over particular dimensions, you can specify the dimension labels by formatting the `darray` object directly, or by using the `DataFormat` option.

---

**Note** To apply maximum pooling within a `LayerGraph` object or `Layer` array, use one of the following layers:

- `maxPooling2dLayer`
  - `maxPooling3dLayer`
- 

`Y = maxpool(X,poolsize)` applies the maximum pooling operation to the formatted `darray` object `X`. The function downsamples the input by dividing it into regions defined by `poolsize` and calculating the maximum value of the data in each region. The output `Y` is a formatted `darray` with the same dimension format as `X`.

The function, by default, pools over up to three dimensions of `X` labeled 'S' (spatial). To pool over dimensions labeled 'T' (time), specify a pooling region with a 'T' dimension using the 'PoolFormat' option.

For unformatted input data, use the 'DataFormat' option.

`[Y,indx,inputSize] = maxpool(X,poolsize)` also returns the linear indices of the maximum value within each pooled region and the size of the input feature map `X` for use with the `maxunpool` function.

`Y = maxpool(X,'global')` computes the global maximum over the spatial dimensions of the input `X`. This syntax is equivalent to setting `poolsize` in the previous syntaxes to the size of the 'S' dimensions of `X`.

`___ = maxpool( ___, 'DataFormat', FMT)` applies the maximum pooling operation to the unformatted `darray` object `X` with format specified by `FMT` using any of the previous syntaxes. The output `Y` is an unformatted `darray` object with dimensions in the same order as `X`. For example, `'DataFormat', 'SSCB'` specifies data for 2-D maximum pooling with format `'SSCB'` (spatial, spatial, channel, batch).

`___ = maxpool( ___, Name, Value)` specifies options using one or more name-value pair arguments. For example, `'PoolFormat', 'T'` specifies a pooling region for 1-D pooling with format `'T'` (time).

## Examples

### Perform 2-D Maximum Pooling

Create a formatted `darray` object containing a batch of 128 28-by-28 images with 3 channels. Specify the format `'SSCB'` (spatial, spatial, channel, batch).

```
miniBatchSize = 128;  
inputSize = [28 28];  
numChannels = 3;  
X = rand(inputSize(1),inputSize(2),numChannels,miniBatchSize);  
d1X = darray(X,'SSCB');
```

View the size and format of the input data.

```
size(d1X)
```

```
ans = 1×4
```

```
    28    28     3   128
```

```
dims(d1X)
```

```
ans =  
'SSCB'
```

Apply 2-D maximum pooling with 2-by-2 pooling windows using the `maxpool` function.

```
poolSize = [2 2];  
d1Y = maxpool(d1X,poolSize);
```

View the size and format of the output.

```
size(d1Y)
```

```
ans = 1×4
```

```
    27    27     3   128
```

```
dims(d1Y)
```

```
ans =  
'SSCB'
```

## Perform 2-D Global Maximum Pooling

Create a formatted `dLarray` object containing a batch of 128 28-by-28 images with 3 channels. Specify the format 'SSCB' (spatial, spatial, channel, batch).

```
miniBatchSize = 128;
inputSize = [28 28];
numChannels = 3;
X = rand(inputSize(1),inputSize(2),numChannels,miniBatchSize);
dLX = dLarray(X, 'SSCB');
```

View the size and format of the input data.

```
size(dLX)
```

```
ans = 1×4
```

```
    28    28     3   128
```

```
dims(dLX)
```

```
ans =
'SSCB'
```

Apply 2-D global maximum pooling using the `maxpool` function by specifying the 'global' option.

```
dLY = maxpool(dLX, 'global');
```

View the size and format of the output.

```
size(dLY)
```

```
ans = 1×4
```

```
     1     1     3   128
```

```
dims(dLY)
```

```
ans =
'SSCB'
```

## Perform 1-D Maximum Pooling

Create a formatted `dLarray` object containing a batch of 128 sequences of length 100 with 12 channels. Specify the format 'CBT' (channel, batch, time).

```
miniBatchSize = 128;
sequenceLength = 100;
numChannels = 12;
X = rand(numChannels,miniBatchSize,sequenceLength);
dLX = dLarray(X, 'CBT');
```

View the size and format of the input data.

```
size(dlX)
ans = 1×3
    12    128    100
```

```
dims(dlX)
ans =
'CBT'
```

Apply 1-D maximum pooling with pooling regions of size 2 with a stride of 2 using the `maxpool` function by specifying the `'PoolFormat'` and `'Stride'` options.

```
poolSize = 2;
dlY = maxpool(dlX,poolSize,'PoolFormat','T','Stride',2);
```

View the size and format of the output.

```
size(dlY)
ans = 1×3
    12    128    50
```

```
dims(dlY)
ans =
'CBT'
```

### Unpool 2-D Maximum Pooled Data

Create a formatted `dLarray` object containing a batch of 128 28-by-28 images with 3 channels. Specify the format `'SSCB'` (spatial, spatial, channel, batch).

```
miniBatchSize = 128;
inputSize = [28 28];
numChannels = 3;
X = rand(inputSize(1),inputSize(2),numChannels,miniBatchSize);
dlX = dLarray(X,'SSCB');
```

View the size and format of the input data.

```
size(dlX)
ans = 1×4
    28    28     3   128
```

```
dims(dlX)
ans =
'SSCB'
```

Pool the data to maximum values over pooling regions of size 2 using a stride of 2.

```
[dLY,indx,dataSize] = maxpool(dlX,2,'Stride',2);
```

View the size and format of the pooled data.

```
size(dLY)
```

```
ans = 1×4
```

```
    14    14     3   128
```

```
dims(dLY)
```

```
ans =
```

```
'SSCB'
```

View the data size.

```
dataSize
```

```
dataSize = 1×4
```

```
    28    28     3   128
```

Unpool the data using the indices and data size from the maxpool operation.

```
dLY = maxunpool(dLY,indx,dataSize);
```

View the size and format of the unpooled data.

```
size(dLY)
```

```
ans = 1×4
```

```
    28    28     3   128
```

```
dims(dLY)
```

```
ans =
```

```
'SSCB'
```

### Unpool 1-D Maximum Pooled Data

Create a formatted dLarray object containing a batch of 128 sequences of length 100 with 12 channels. Specify the format 'CBT' (channel, batch, time).

```
miniBatchSize = 128;
```

```
sequenceLength = 100;
```

```
numChannels = 12;
```

```
X = rand(numChannels,miniBatchSize,sequenceLength);
```

```
dlX = dLarray(X,'CBT');
```

View the size and format of the input data.

```
size(dlX)
ans = 1×3
    12    128   100
```

```
dims(dlX)
ans =
'CBT'
```

Apply 1-D maximum pooling with pooling regions of size 2 with a stride of 2 using the `maxpool` function by specifying the `'PoolFormat'` and `'Stride'` options.

```
poolSize = 2;
[dlY,indx,dataSize] = maxpool(dlX,poolSize,'PoolFormat','T','Stride',2);
```

View the size and format of the output.

```
size(dlY)
ans = 1×3
    12    128    50
```

```
dims(dlY)
ans =
'CBT'
```

Unpool the data using the indices and data size from the `maxpool` operation.

```
dlY = maxunpool(dlY,indx,dataSize);
```

View the size and format of the unpooled data.

```
size(dlY)
ans = 1×3
    12    128   100
```

```
dims(dlY)
ans =
'CBT'
```

## Input Arguments

### X — Input data

`dlarray`

Input data, specified as a formatted or unformatted `dlarray` object.

If X is an unformatted `dlarray`, then you must specify the format using the `DataFormat` option.

The function, by default, pools over up to three dimensions of X labeled 'S' (spatial). To pool over dimensions labeled 'T' (time), specify a pooling region with a 'T' dimension using the 'PoolFormat' option.

### **poolsize — Size of pooling regions**

positive integer | vector of positive integers

Size of the pooling regions, specified as a numeric scalar or numeric vector.

To pool using a pooling region with edges of the same size, specify `poolsize` as a scalar. The pooling regions have the same size along all dimensions specified by 'PoolFormat'.

To pool using a pooling region with edges of different sizes, specify `poolsize` as a vector, where `poolsize(i)` is the size of corresponding dimension in 'PoolFormat'.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'Stride', 2 specifies the stride of the pooling regions as 2.

### **DataFormat — Dimension order of unformatted data**

character vector | string scalar

Dimension order of unformatted input data, specified as a character vector or string scalar `FMT` that provides a label for each dimension of the data.

When you specify the format of a `darray` object, each character provides a label for each dimension of the data and must be one of these options:

- "S" — Spatial
- "C" — Channel
- "B" — Batch (for example, samples and observations)
- "T" — Time (for example, time steps of sequences)
- "U" — Unspecified

You can specify multiple dimensions labeled "S" or "U". You can use the labels "C", "B", and "T" at most once.

You must specify `DataFormat` when the input data is not a formatted `darray`.

Data Types: `char` | `string`

### **PoolFormat — Dimension order of pooling region**

character vector | string scalar

Dimension order of the pooling region, specified as the comma-separated pair consisting of 'PoolFormat' and a character vector or string scalar that provides a label for each dimension of the pooling region.

The default value of 'PoolFormat' depends on the task:

Task	Default
1-D pooling	'S' (spatial)
2-D pooling	'SS' (spatial, spatial)
3-D pooling	'SSS' (spatial, spatial, spatial)

The format must have either no 'S' (spatial) dimensions, or as many 'S' (spatial) dimensions as the input data.

The function, by default, pools over up to three dimensions of X labeled 'S' (spatial). To pool over dimensions labeled 'T' (time), specify a pooling region with a 'T' dimension using the 'PoolFormat' option.

Example: 'PoolFormat', 'T'

### Stride — Step size for traversing input data

1 (default) | numeric scalar | numeric vector

Step size for traversing the input data, specified as the comma-separated pair consisting of 'Stride' and a numeric scalar or numeric vector. If you specify 'Stride' as a scalar, the same value is used for all spatial dimensions. If you specify 'Stride' as a vector of the same size as the number of spatial dimensions of the input data, the vector values are used for the corresponding spatial dimensions.

The default value of 'Stride' is 1. If 'Stride' is less than poolsize in any dimension, then the pooling regions overlap.

The Stride parameter is not supported for global pooling using the 'global' option.

Example: 'Stride', 3

Data Types: single | double

### Padding — Size of padding applied to edges of data

0 (default) | 'same' | numeric scalar | numeric vector | numeric matrix

Size of padding applied to edges of data, specified as the comma-separated pair consisting of 'Padding' and one of the following:

- 'same' — Padding size is set so that the output size is the same as the input size when the stride is 1. More generally, the output size of each spatial dimension is  $\text{ceil}(\text{inputSize}/\text{stride})$ , where inputSize is the size of the input along a spatial dimension.
- Numeric scalar — The same amount of padding is applied to both ends of all spatial dimensions.
- Numeric vector — A different amount of padding is applied along each spatial dimension. Use a vector of size d, where d is the number of spatial dimensions of the input data. The ith element of the vector specifies the size of padding applied to the start and the end along the ith spatial dimension.
- Numeric matrix — A different amount of padding is applied to the start and end of each spatial dimension. Use a matrix of size 2-by-d, where d is the number of spatial dimensions of the input data. The element (1, d) specifies the size of padding applied to the start of spatial dimension d. The element (2, d) specifies the size of padding applied to the end of spatial dimension d. For example, in 2-D, the format is [top, left; bottom, right].

The 'Padding' parameter is not supported for global pooling using the 'global' option.

Example: 'Padding', 'same'

Data Types: single | double

## Output Arguments

### Y — Pooled data

darray

Pooled data, returned as a darray with the same underlying data type as X.

If the input data X is a formatted darray, then Y has the same format as X. If the input data is not a formatted darray, then Y is an unformatted darray with the same dimension order as the input data.

### indx — Indices of maximum values

darray

Indices of maximum values in each pooled region, returned as a darray. Each value in indx represents the location of the corresponding maximum value in Y, given as a linear index of the values in X.

If X is a formatted darray, indx has the same size and format as the output Y.

If X is not a formatted darray, indx is an unformatted darray. In that case, indx is returned with the following dimension order: all 'S' dimensions, followed by 'C', 'B', and 'T' dimensions, then all 'U' dimensions. The size of indx matches the size of Y when Y is permuted to match the previously stated dimension order.

Use the indx output with the maxunpool function to unpool the output of maxpool.

indx output is not supported when using the 'global' option.

### inputSize — Size of input feature map

numeric vector

Size of the input feature map, returned as a numeric vector.

Use the inputSize output with the maxunpool function to unpool the output of maxpool.

inputSize output is not supported when using the 'global' option.

## More About

### Maximum Pooling

The maxpool function pools the input data to maximum values. For more information, see the “2-D Max Pooling Layer” on page 1-1303 section of the maxPooling2dLayer reference page.

## Version History

Introduced in R2019b

**R2020a: maxpool indices output argument changes shape and data type***Behavior changed in R2020a*

Starting in R2020a, the data type and shape of the indices output argument of the `maxpool` function are changed. The `maxpool` function outputs the indices of the maximum values as a `darray` with the same shape and format as the pooled data, instead of a numeric vector.

The indices output of `maxpool` remains compatible with the indices input of `maxunpool`. The `maxunpool` function accepts the indices of the maximum values as a `darray` with the same shape and format as the input data. To prevent errors, use only the indices output of the `maxpool` function as the indices input to the `maxunpool` function.

To reproduce the previous behavior and obtain the indices output as a numeric vector, use the following code:

```
[Y,indx,inputSize] = maxpool(Y,poolsize);  
indx = extractdata(indx);  
indx = reshape(indx,[],1);
```

**Extended Capabilities****GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When the input argument `X` is a `darray` with underlying data of type `gpuArray`, this function runs on the GPU.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# maxPooling1dLayer

1-D max pooling layer

## Description

A 1-D max pooling layer performs downsampling by dividing the input into 1-D pooling regions, then computing the maximum of each region.

The dimension that the layer pools over depends on the layer input:

- For time series and vector sequence input (data with three dimensions corresponding to the "C" (channel), "B" (batch), and "T" (time) dimensions), the layer pools over the "T" (time) dimension.
- For 1-D image input (data with three dimensions corresponding to the "S" (spatial), "C" (channel), and "B" (batch) dimensions), the layer pools over the "S" (spatial) dimension.
- For 1-D image sequence input (data with four dimensions corresponding to the "S" (spatial), "C" (channel), "B" (batch), and "T" (time) dimensions), the layer pools over the "S" (spatial) dimension.

## Creation

### Syntax

```
layer = maxPooling1dLayer(poolSize)
layer = maxPooling1dLayer(poolSize,Name=Value)
```

### Description

`layer = maxPooling1dLayer(poolSize)` creates a 1-D max pooling layer and sets the `PoolSize` property.

`layer = maxPooling1dLayer(poolSize,Name=Value)` also specifies the padding or sets the `Stride` and `Name` properties using one or more optional name-value arguments. For example, `maxPooling1dLayer(3,Padding=1,Stride=2)` creates a 1-D max pooling layer with a pool size of 3, a stride of 2, and padding of size 1 on both the left and right of the input.

### Input Arguments

#### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . ,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `maxPooling1dLayer(3,Padding=1)` creates a 1-D max pooling layer with a pool size of 3 and padding of size 1 on the left and right of the layer input.

#### Padding — Padding to apply to input

`[0 0]` (default) | "same" | nonnegative integer | vector of nonnegative integers

Padding to apply to the input, specified as one of the following:

- "same" — Apply padding such that the output size is  $\text{ceil}(\text{inputSize}/\text{stride})$ , where `inputSize` is the length of the input. When `Stride` is 1, the output is the same size as the input.
- Nonnegative integer `sz` — Add padding of size `sz` to both ends of the input.
- Vector `[l r]` of nonnegative integers — Add padding of size `l` to the left and `r` to the right of the input.

Example: `Padding=[2 1]` adds padding of size 2 to the left and size 1 to the right.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

## Properties

### Max Pooling

#### **PoolSize** — Width of pooling regions

positive integer

Width of the pooling regions, specified as a positive integer.

The width of the pooling regions `PoolSize` must be greater than or equal to the padding dimensions `PaddingSize`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **Stride** — Step size for traversing input

1 (default) | positive integer

Step size for traversing the input, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **PaddingSize** — Size of padding

`[0 0]` (default) | vector of two nonnegative integers

Size of padding to apply to each side of the input, specified as a vector `[l r]` of two nonnegative integers, where `l` is the padding applied to the left and `r` is the padding applied to the right.

When you create a layer, use the `Padding` name-value argument to specify the padding size.

Data Types: `double`

#### **PaddingMode** — Method to determine padding size

'manual' (default) | 'same'

This property is read-only.

Method to determine padding size, specified as one of the following:

- 'manual' - Pad using the integer or vector specified by `Padding`.
- 'same' - Apply padding such that the output size is  $\text{ceil}(\text{inputSize}/\text{Stride})$ , where `inputSize` is the length of the input. When `Stride` is 1, the output is the same as the input.

To specify the layer padding, use the `Padding` name-value argument.

Data Types: `char`

## Layer

### Name — Layer name

`' '` (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For Layer array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name `' '`.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

### InputNames — Input names

`{"in"}` (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: `cell`

### NumOutputs — Number of outputs

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: `double`

### OutputNames — Output names

`{'out'}` (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: `cell`

## Examples

### Create 1-D Max Pooling Layer

Create a 1-D max pooling layer with a pool size of 3.

```
layer = maxPooling1dLayer(3);
```

Include a 1-D max pooling layer in a layer array.

```
layers = [
    sequenceInputLayer(12,MinLength=40)
    convolution1dLayer(11,96)
    reluLayer
    maxPooling1dLayer(3)
    convolution1dLayer(11,96)
    reluLayer
    globalMaxPooling1dLayer
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer]
```

```
layers =
    10x1 Layer array with layers:
```

1	''	Sequence Input	Sequence input with 12 dimensions
2	''	1-D Convolution	96 11 convolutions with stride 1 and padding [0 0]
3	''	ReLU	ReLU
4	''	1-D Max Pooling	Max pooling with pool size 3, stride 1, and padding [0 0]
5	''	1-D Convolution	96 11 convolutions with stride 1 and padding [0 0]
6	''	ReLU	ReLU
7	''	1-D Global Max Pooling	1-D global max pooling
8	''	Fully Connected	10 fully connected layer
9	''	Softmax	softmax
10	''	Classification Output	crossentropyex

## Algorithms

### 1-D Max Pooling Layer

A 1-D max pooling layer performs downsampling by dividing the input into 1-D pooling regions, then computing the maximum of each region. The layer pools the input by moving the pooling regions along the input horizontally.

The dimension that the layer pools over depends on the layer input:

- For time series and vector sequence input (data with three dimensions corresponding to the "C" (channel), "B" (batch), and "T" (time) dimensions), the layer pools over the "T" (time) dimension.
- For 1-D image input (data with three dimensions corresponding to the "S" (spatial), "C" (channel), and "B" (batch) dimensions), the layer pools over the "S" (spatial) dimension.
- For 1-D image sequence input (data with four dimensions corresponding to the "S" (spatial), "C" (channel), "B" (batch), and "T" (time) dimensions), the layer pools over the "S" (spatial) dimension.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel

- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `MaxPooling1dLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"SCB" (spatial, channel, batch)	"SCB" (spatial, channel, batch)
"CBT" (channel, batch, time)	"CB" (channel, batch)
"SCBT" (spatial, channel, batch, time)	"SCBT" (spatial, channel, batch, time)
"SB" (spatial, batch)	"SB" (spatial, batch)

In `dlnetwork` objects, `MaxPooling1dLayer` objects also support these input and output format combinations.

Input Format	Output Format
"SC" (spatial, channel)	"SC" (spatial, channel)
"CT" (channel, time)	"CT" (channel, time)
"SCT" (spatial, channel, time)	"SCT" (spatial, channel, time)
"BT" (batch, time)	"BT" (batch, time)
"SBT" (spatial, batch, time)	"SBT" (spatial, batch, time)

# maxPooling2dLayer

Max pooling layer

## Description

A 2-D max pooling layer performs downsampling by dividing the input into rectangular pooling regions, then computing the maximum of each region.

## Creation

### Syntax

```
layer = maxPooling2dLayer(poolSize)
layer = maxPooling2dLayer(poolSize,Name,Value)
```

### Description

`layer = maxPooling2dLayer(poolSize)` creates a max pooling layer and sets the `PoolSize` property.

`layer = maxPooling2dLayer(poolSize,Name,Value)` sets the optional `Stride`, `Name`, and `HasUnpoolingOutputs` properties using name-value pairs. To specify input padding, use the `'Padding'` name-value pair argument. For example, `maxPooling2dLayer(2,'Stride',3)` creates a max pooling layer with pool size `[2 2]` and stride `[3 3]`. You can specify multiple name-value pairs. Enclose each property name in single quotes.

### Input Arguments

#### Name-Value Pair Arguments

Use comma-separated name-value pair arguments to specify the size of the padding to add along the edges of the layer input and to set the `Stride`, `Name`, and `HasUnpoolingOutputs` properties. Enclose names in single quotes.

Example: `maxPooling2dLayer(2,'Stride',3)` creates a max pooling layer with pool size `[2 2]` and stride `[3 3]`.

#### Padding — Input edge padding

`[0 0 0 0]` (default) | vector of nonnegative integers | `'same'`

Input edge padding, specified as the comma-separated pair consisting of `'Padding'` and one of these values:

- `'same'` — Add padding of size calculated by the software at training or prediction time so that the output has the same size as the input when the stride equals 1. If the stride is larger than 1, then the output size is `ceil(inputSize/stride)`, where `inputSize` is the height or width of the input and `stride` is the stride in the corresponding dimension. The software adds the same amount of padding to the top and bottom, and to the left and right, if possible. If the padding that must be added vertically has an odd value, then the software adds extra padding to the bottom. If

the padding that must be added horizontally has an odd value, then the software adds extra padding to the right.

- Nonnegative integer `p` — Add padding of size `p` to all the edges of the input.
- Vector `[a b]` of nonnegative integers — Add padding of size `a` to the top and bottom of the input and padding of size `b` to the left and right.
- Vector `[t b l r]` of nonnegative integers — Add padding of size `t` to the top, `b` to the bottom, `l` to the left, and `r` to the right of the input.

Example: `'Padding', 1` adds one row of padding to the top and bottom, and one column of padding to the left and right of the input.

Example: `'Padding', 'same'` adds padding so that the output has the same size as the input (if the stride equals 1).

## Properties

### Max Pooling

#### **PoolSize** — Dimensions of pooling regions

vector of two positive integers

Dimensions of the pooling regions, specified as a vector of two positive integers `[h w]`, where `h` is the height and `w` is the width. When creating the layer, you can specify `PoolSize` as a scalar to use the same value for both dimensions.

If the stride dimensions `Stride` are less than the respective pooling dimensions, then the pooling regions overlap.

The padding dimensions `PaddingSize` must be less than the pooling region dimensions `PoolSize`.

Example: `[2 1]` specifies pooling regions of height 2 and width 1.

#### **Stride** — Step size for traversing input

`[1 1]` (default) | vector of two positive integers

Step size for traversing the input vertically and horizontally, specified as a vector of two positive integers `[a b]`, where `a` is the vertical step size and `b` is the horizontal step size. When creating the layer, you can specify `Stride` as a scalar to use the same value for both dimensions.

If the stride dimensions `Stride` are less than the respective pooling dimensions, then the pooling regions overlap.

The padding dimensions `PaddingSize` must be less than the pooling region dimensions `PoolSize`.

Example: `[2 3]` specifies a vertical step size of 2 and a horizontal step size of 3.

#### **PaddingSize** — Size of padding

`[0 0 0 0]` (default) | vector of four nonnegative integers

Size of padding to apply to input borders, specified as a vector `[t b l r]` of four nonnegative integers, where `t` is the padding applied to the top, `b` is the padding applied to the bottom, `l` is the padding applied to the left, and `r` is the padding applied to the right.

When you create a layer, use the `'Padding'` name-value pair argument to specify the padding size.

Example: `[1 1 2 2]` adds one row of padding to the top and bottom, and two columns of padding to the left and right of the input.

### PaddingMode — Method to determine padding size

`'manual'` (default) | `'same'`

Method to determine padding size, specified as `'manual'` or `'same'`.

The software automatically sets the value of `PaddingMode` based on the `'Padding'` value you specify when creating a layer.

- If you set the `'Padding'` option to a scalar or a vector of nonnegative integers, then the software automatically sets `PaddingMode` to `'manual'`.
- If you set the `'Padding'` option to `'same'`, then the software automatically sets `PaddingMode` to `'same'` and calculates the size of the padding at training time so that the output has the same size as the input when the stride equals 1. If the stride is larger than 1, then the output size is  $\text{ceil}(\text{inputSize}/\text{stride})$ , where `inputSize` is the height or width of the input and `stride` is the stride in the corresponding dimension. The software adds the same amount of padding to the top and bottom, and to the left and right, if possible. If the padding that must be added vertically has an odd value, then the software adds extra padding to the bottom. If the padding that must be added horizontally has an odd value, then the software adds extra padding to the right.

### Padding — Size of padding

`[0 0]` (default) | vector of two nonnegative integers

---

**Note** `Padding` property will be removed in a future release. Use `PaddingSize` instead. When creating a layer, use the `'Padding'` name-value pair argument to specify the padding size.

---

Size of padding to apply to input borders vertically and horizontally, specified as a vector `[a b]` of two nonnegative integers, where `a` is the padding applied to the top and bottom of the input data and `b` is the padding applied to the left and right.

Example: `[1 1]` adds one row of padding to the top and bottom, and one column of padding to the left and right of the input.

### HasUnpoolingOutputs — Flag for outputs to unpooling layer

`false` (default) | `true`

Flag for outputs to unpooling layer, specified as `true` or `false`.

If the `HasUnpoolingOutputs` value equals `false`, then the max pooling layer has a single output with the name `'out'`.

To use the output of a max pooling layer as the input to a max unpooling layer, set the `HasUnpoolingOutputs` value to `true`. In this case, the max pooling layer has two additional outputs that you can connect to a max unpooling layer:

- `'indices'` — Indices of the maximum value in each pooled region.
- `'size'` — Size of the input feature map.

To enable outputs to a max unpooling layer, the pooling regions of the max pooling layer must be nonoverlapping.

For more information on how to unpool the output of a max pooling layer, see `maxUnpooling2dLayer`.

## Layer

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

### InputNames — Input names

{'in'} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: `cell`

### NumOutputs — Number of outputs

1 (default) | 3

Number of outputs of the layer.

If the `HasUnpoolingOutputs` value equals `false`, then the max pooling layer has a single output with the name 'out'.

To use the output of a max pooling layer as the input to a max unpooling layer, set the `HasUnpoolingOutputs` value to `true`. In this case, the max pooling layer has two additional outputs that you can connect to a max unpooling layer:

- 'indices' — Indices of the maximum value in each pooled region.
- 'size' — Size of the input feature map.

To enable outputs to a max unpooling layer, the pooling regions of the max pooling layer must be nonoverlapping.

For more information on how to unpool the output of a max pooling layer, see `maxUnpooling2dLayer`.

Data Types: `double`

### OutputNames — Output names

{'out'} (default) | {'out', 'indices', 'size'}

Output names of the layer.

If the `HasUnpoolingOutputs` value equals `false`, then the max pooling layer has a single output with the name `'out'`.

To use the output of a max pooling layer as the input to a max unpooling layer, set the `HasUnpoolingOutputs` value to `true`. In this case, the max pooling layer has two additional outputs that you can connect to a max unpooling layer:

- `'indices'` — Indices of the maximum value in each pooled region.
- `'size'` — Size of the input feature map.

To enable outputs to a max unpooling layer, the pooling regions of the max pooling layer must be nonoverlapping.

For more information on how to unpool the output of a max pooling layer, see `maxUnpooling2dLayer`.

Data Types: `cell`

## Examples

### Create Max Pooling Layer with Nonoverlapping Pooling Regions

Create a max pooling layer with nonoverlapping pooling regions.

```
layer = maxPooling2dLayer(2, 'Stride', 2)
```

```
layer =
  MaxPooling2DLayer with properties:
      Name: ''
      HasUnpoolingOutputs: 0
      NumOutputs: 1
      OutputNames: {'out'}

  Hyperparameters
      PoolSize: [2 2]
      Stride: [2 2]
      PaddingMode: 'manual'
      PaddingSize: [0 0 0 0]
```

The height and the width of the rectangular regions (pool size) are both 2. The pooling regions do not overlap because the step size for traversing the images vertically and horizontally (stride) is also [2 2].

Include a max pooling layer with nonoverlapping regions in a Layer array.

```
layers = [ ...
  imageInputLayer([28 28 1])
  convolution2dLayer(5,20)
  reluLayer
  maxPooling2dLayer(2, 'Stride', 2)
  fullyConnectedLayer(10)
```

```

softmaxLayer
classificationLayer]

layers =
  7x1 Layer array with layers:

   1 '' Image Input          28x28x1 images with 'zerocenter' normalization
   2 '' 2-D Convolution      20 5x5 convolutions with stride [1 1] and padding [0 0 0 0]
   3 '' ReLU                  ReLU
   4 '' 2-D Max Pooling      2x2 max pooling with stride [2 2] and padding [0 0 0 0]
   5 '' Fully Connected      10 fully connected layer
   6 '' Softmax               softmax
   7 '' Classification Output crossentropyex

```

### Create Max Pooling Layer with Overlapping Pooling Regions

Create a max pooling layer with overlapping pooling regions.

```
layer = maxPooling2dLayer([3 2], 'Stride', 2)
```

```
layer =
  MaxPooling2DLayer with properties:
```

```

      Name: ''
HasUnpoolingOutputs: 0
      NumOutputs: 1
      OutputNames: {'out'}

```

```

Hyperparameters
      PoolSize: [3 2]
      Stride: [2 2]
      PaddingMode: 'manual'
      PaddingSize: [0 0 0 0]

```

This layer creates pooling regions of size [3 2] and takes the maximum of the six elements in each region. The pooling regions overlap because there are stride dimensions `Stride` that are less than the respective pooling dimensions `PoolSize`.

Include a max pooling layer with overlapping pooling regions in a `Layer` array.

```

layers = [ ...
  imageInputLayer([28 28 1])
  convolution2dLayer(5,20)
  reluLayer
  maxPooling2dLayer([3 2], 'Stride', 2)
  fullyConnectedLayer(10)
  softmaxLayer
  classificationLayer]

```

```

layers =
  7x1 Layer array with layers:

   1 '' Image Input          28x28x1 images with 'zerocenter' normalization
   2 '' 2-D Convolution      20 5x5 convolutions with stride [1 1] and padding [0 0 0 0]
   3 '' ReLU                  ReLU

```

4	''	2-D Max Pooling	3x2 max pooling with stride [2 2] and padding [0 0 0 0]
5	''	Fully Connected	10 fully connected layer
6	''	Softmax	softmax
7	''	Classification Output	crossentropyex

## Algorithms

### 2-D Max Pooling Layer

A 2-D max pooling layer performs downsampling by dividing the input into rectangular pooling regions, then computing the maximum of each region.

The dimensions that the layer pools over depends on the layer input:

- For 2-D image input (data with four dimensions corresponding to pixels in two spatial dimensions, the channels, and the observations), the layer pools over the spatial dimensions.
- For 2-D image sequence input (data with five dimensions corresponding to the pixels in two spatial dimensions, the channels, the observations, and the time steps), the layer pools over the spatial dimensions.
- For 1-D image sequence input (data with four dimensions corresponding to the pixels in one spatial dimension, the channels, the observations, and the time steps), the layer pools over the spatial and time dimensions.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `MaxPooling2DLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"SSCB" (spatial, spatial, channel, batch)	"SSCB" (spatial, spatial, channel, batch)
"SCBT" (spatial, channel, batch, time)	"SCBT" (spatial, channel, batch, time)
"SSCBT" (spatial, spatial, channel, batch, time)	"SSCBT" (spatial, spatial, channel, batch, time)
"SSB" (spatial, spatial, batch)	"SSB" (spatial, spatial, batch)

In `dlnetwork` objects, `MaxPooling2DLayer` objects also support these input and output format combinations.

Input Format	Output Format
"SSC" (spatial, spatial, channel)	"SSC" (spatial, spatial, channel)
"SCT" (spatial, channel, time)	"SCT" (spatial, channel, time)
"SSCT" (spatial, spatial, channel, time)	"SSCT" (spatial, spatial, channel, time)
"SBT" (spatial, batch, time)	"SBT" (spatial, batch, time)
"SSBT" (spatial, spatial, batch, time)	"SSBT" (spatial, spatial, batch, time)

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

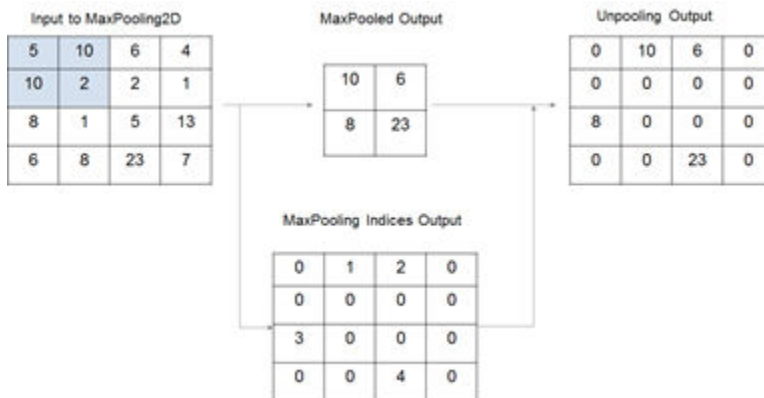

Usage notes and limitations:

If equal max values exists along the off-diagonal in a kernel window, implementation differences for the `maxPooling2dLayer` might cause minor numerical mismatch between MATLAB and the generated code. This issue also causes mismatch in the indices of the maximum value in each pooled region.

For example, consider the following input to `maxPooling2dLayer`. The output from MATLAB is shown.

For the same input, the output from the generated code is shown.

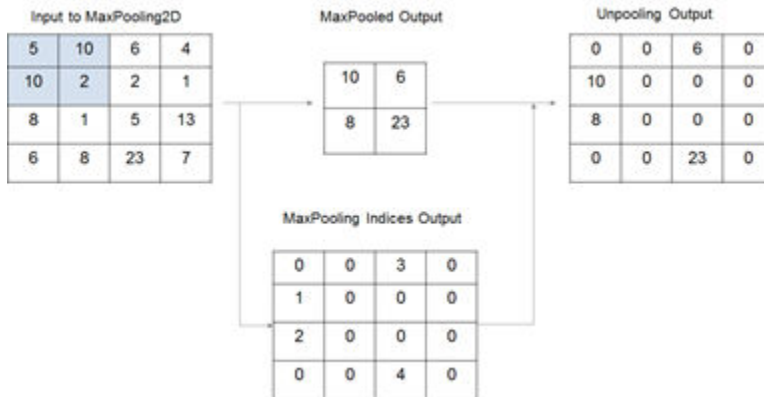

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

If equal max values exists along the off-diagonal in a kernel window, implementation differences for the `maxPooling2dLayer` might cause minor numerical mismatch between MATLAB and the generated code. This issue also causes mismatch in the indices of the maximum value in each pooled region.

For example, consider the following input to `maxPooling2dLayer`. The output from MATLAB is shown.

For the same input, the output from the generated code is shown.

# maxPooling3dLayer

3-D max pooling layer

## Description

A 3-D max pooling layer performs downsampling by dividing three-dimensional input into cuboidal pooling regions, then computing the maximum of each region.

The dimensions that the layer pools over depends on the layer input:

- For 3-D image input (data with five dimensions corresponding to pixels in three spatial dimensions, the channels, and the observations), the layer pools over the spatial dimensions.
- For 3-D image sequence input (data with six dimensions corresponding to the pixels in three spatial dimensions, the channels, the observations, and the time steps), the layer pools over the spatial dimensions.
- For 2-D image sequence input (data with five dimensions corresponding to the pixels in two spatial dimensions, the channels, the observations, and the time steps), the layer pools over the spatial and time dimensions.

## Creation

### Syntax

```
layer = maxPooling3dLayer(poolSize)  
layer = maxPooling3dLayer(poolSize,Name,Value)
```

### Description

`layer = maxPooling3dLayer(poolSize)` creates a 3-D max pooling layer and sets the `PoolSize` property.

`layer = maxPooling3dLayer(poolSize,Name,Value)` sets the optional `Stride` and `Name` properties using name-value pairs. To specify input padding, use the `'Padding'` name-value pair argument. For example, `maxPooling3dLayer(2, 'Stride', 3)` creates a 3-D max pooling layer with pool size `[2 2 2]` and stride `[3 3 3]`. You can specify multiple name-value pairs. Enclose each property name in single quotes.

### Input Arguments

#### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example: `maxPooling3dLayer(2, 'Stride', 3)` creates a 3-D max pooling layer with pool size `[2 2 2]` and stride `[3 3 3]`.

**Padding — Input edge padding**

0 (default) | array of nonnegative integers | 'same'

Input edge padding, specified as the comma-separated pair consisting of 'Padding' and one of these values:

- 'same' — Add padding of size calculated by the software at training or prediction time so that the output has the same size as the input when the stride equals 1. If the stride is larger than 1, then the output size is  $\text{ceil}(\text{inputSize}/\text{stride})$ , where `inputSize` is the height, width, or depth of the input and `stride` is the stride in the corresponding dimension. The software adds the same amount of padding to the top and bottom, to the left and right, and to the front and back, if possible. If the padding in a given dimension has an odd value, then the software adds the extra padding to the input as postpadding. In other words, the software adds extra vertical padding to the bottom, extra horizontal padding to the right, and extra depth padding to the back of the input.
- Nonnegative integer `p` — Add padding of size `p` to all the edges of the input.
- Three-element vector [`a b c`] of nonnegative integers — Add padding of size `a` to the top and bottom, padding of size `b` to the left and right, and padding of size `c` to the front and back of the input.
- 2-by-3 matrix [`t l f; b r k`] of nonnegative integers — Add padding of size `t` to the top, `b` to the bottom, `l` to the left, `r` to the right, `f` to the front, and `k` to the back of the input. In other words, the top row specifies the prepadding and the second row defines the postpadding in the three dimensions.

Example: 'Padding', 1 adds one row of padding to the top and bottom, one column of padding to the left and right, and one plane of padding to the front and back of the input.

Example: 'Padding', 'same' adds padding so that the output has the same size as the input (if the stride equals 1).

**Properties****Max Pooling****PoolSize — Dimensions of pooling regions**

vector of three positive integers

Dimensions of the pooling regions, specified as a vector of three positive integers [`h w d`], where `h` is the height, `w` is the width, and `d` is the depth. When creating the layer, you can specify `PoolSize` as a scalar to use the same value for all three dimensions.

If the stride dimensions `Stride` are less than the respective pooling dimensions, then the pooling regions overlap.

The padding dimensions `PaddingSize` must be less than the pooling region dimensions `PoolSize`.

Example: [2 1 1] specifies pooling regions of height 2, width 1, and depth 1.

**Stride — Step size for traversing input**

[1 1 1] (default) | vector of three positive integers

Step size for traversing the input in three dimensions, specified as a vector [`a b c`] of three positive integers, where `a` is the vertical step size, `b` is the horizontal step size, and `c` is the step size along the

depth direction. When creating the layer, you can specify `Stride` as a scalar to use the same value for step sizes in all three directions.

If the stride dimensions `Stride` are less than the respective pooling dimensions, then the pooling regions overlap.

The padding dimensions `PaddingSize` must be less than the pooling region dimensions `PoolSize`.

Example: `[2 3 1]` specifies a vertical step size of 2, a horizontal step size of 3, and a step size along the depth of 1.

### **PaddingSize — Size of padding**

`[0 0 0;0 0 0]` (default) | 2-by-3 matrix of nonnegative integers

Size of padding to apply to input borders, specified as 2-by-3 matrix `[t l f;b r k]` of nonnegative integers, where `t` and `b` are the padding applied to the top and bottom in the vertical direction, `l` and `r` are the padding applied to the left and right in the horizontal direction, and `f` and `k` are the padding applied to the front and back along the depth. In other words, the top row specifies the prepadding and the second row defines the postpadding in the three dimensions.

When you create a layer, use the 'Padding' name-value pair argument to specify the padding size.

Example: `[1 2 4;1 2 4]` adds one row of padding to the top and bottom, two columns of padding to the left and right, and four planes of padding to the front and back of the input.

### **PaddingMode — Method to determine padding size**

'manual' (default) | 'same'

Method to determine padding size, specified as 'manual' or 'same'.

The software automatically sets the value of `PaddingMode` based on the 'Padding' value you specify when creating a layer.

- If you set the 'Padding' option to a scalar or a vector of nonnegative integers, then the software automatically sets `PaddingMode` to 'manual'.
- If you set the 'Padding' option to 'same', then the software automatically sets `PaddingMode` to 'same' and calculates the size of the padding at training time so that the output has the same size as the input when the stride equals 1. If the stride is larger than 1, then the output size is  $\text{ceil}(\text{inputSize}/\text{stride})$ , where `inputSize` is the height, width, or depth of the input and `stride` is the stride in the corresponding dimension. The software adds the same amount of padding to the top and bottom, to the left and right, and to the front and back, if possible. If the padding in a given dimension has an odd value, then the software adds the extra padding to the input as postpadding. In other words, the software adds extra vertical padding to the bottom, extra horizontal padding to the right, and extra depth padding to the back of the input.

## **Layer**

### **Name — Layer name**

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

**NumInputs — Number of inputs**

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: double

**InputNames — Input names**

{"in"} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: cell

**NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: double

**OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

**Examples****Create Max Pooling 3-D Layer with Nonoverlapping Pooling Regions**

Create a max pooling 3-D layer with nonoverlapping pooling regions.

```
layer = maxPooling3dLayer(2,'Stride',2)
```

```
layer =  
  MaxPooling3DLayer with properties:
```

```
    Name: ''  
  NumOutputs: 1  
 OutputNames: {'out'}
```

```
Hyperparameters  
  PoolSize: [2 2 2]  
   Stride: [2 2 2]  
 PaddingMode: 'manual'  
 PaddingSize: [2x3 double]
```

The height, width, and depth of the cuboidal regions (pool size) are 2. The step size for traversing the images (stride) is 2 in all dimensions. The pooling regions do not overlap because the stride is greater than or equal to the corresponding pool size in all dimensions.

Include a max pooling layer with nonoverlapping regions in a Layer array.

```
layers = [ ...
    image3dInputLayer([28 28 28 3])
    convolution3dLayer(5,20)
    reluLayer
    maxPooling3dLayer(2, 'Stride', 2)
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer]

layers =
    7x1 Layer array with layers:

     1  ''  3-D Image Input           28x28x28x3 images with 'zerocenter' normalization
     2  ''  3-D Convolution           20 5x5x5 convolutions with stride [1 1 1] and padding [0

### Create Max Pooling 3-D Layer with Overlapping Pooling Regions

Create a max pooling 3-D layer with overlapping pooling regions and padding for the top and bottom of the input.

```
layer = maxPooling3dLayer([3 2 2], 'Stride', 2, 'Padding', [1 0 0])
```

```
layer =
    MaxPooling3DLayer with properties:

        Name: ''
        NumOutputs: 1
        OutputNames: {'out'}

    Hyperparameters
        PoolSize: [3 2 2]
        Stride: [2 2 2]
        PaddingMode: 'manual'
        PaddingSize: [2x3 double]
```

This layer creates pooling regions of size 3-by-2-by-2 and takes the maximum of the twelve elements in each region. The stride is 2 in all dimensions. The pooling regions overlap because there are stride dimensions `Stride` that are less than the respective pooling dimensions `PoolSize`.

## Algorithms

### 3-D Max Pooling Layer

A 3-D max pooling layer extends the functionality of a max pooling layer to a third dimension, depth. A max pooling layer performs down-sampling by dividing the input into rectangular or cuboidal pooling regions, and computing the maximum of each region. To learn more, see the “2-D Max Pooling Layer” on page 1-1303 section of the `maxPooling2dLayer` reference page.

The dimensions that the layer pools over depends on the layer input:

- For 3-D image input (data with five dimensions corresponding to pixels in three spatial dimensions, the channels, and the observations), the layer pools over the spatial dimensions.
- For 3-D image sequence input (data with six dimensions corresponding to the pixels in three spatial dimensions, the channels, the observations, and the time steps), the layer pools over the spatial dimensions.
- For 2-D image sequence input (data with five dimensions corresponding to the pixels in two spatial dimensions, the channels, the observations, and the time steps), the layer pools over the spatial and time dimensions.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `MaxPooling3DLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"SSSCB" (spatial, spatial, spatial, channel, batch)	"SSSCB" (spatial, spatial, spatial, channel, batch)
"SSCBT" (spatial, spatial, channel, batch, time)	"SSCBT" (spatial, spatial, channel, batch, time)

Input Format	Output Format
"SSSCBT" (spatial, spatial, spatial, channel, batch, time)	"SSSCBT" (spatial, spatial, spatial, channel, batch, time)
"SSSB" (spatial, spatial, spatial, batch)	"SSSB" (spatial, spatial, spatial, batch)

In `dl` network objects, `MaxPooling3dLayer` objects also support these input and output format combinations.

Input Format	Output Format
"SSSC" (spatial, spatial, spatial, channel)	"SSSC" (spatial, spatial, spatial, channel)
"SSCT" (spatial, spatial, channel, time)	"SSCT" (spatial, spatial, channel, time)
"SSSCT" (spatial, spatial, spatial, channel, time)	"SSSCT" (spatial, spatial, spatial, channel, time)
"SSBT" (spatial, spatial, batch, time)	"SSBT" (spatial, spatial, batch, time)
"SSSBT" (spatial, spatial, spatial, batch, time)	"SSSBT" (spatial, spatial, spatial, batch, time)

## maxunpool

Unpool the output of a maximum pooling operation

### Syntax

```
Y = maxunpool(X,indx,outputSize)
Y = maxunpool(X,indx,outputSize,'DataFormat',FMT)
```

### Description

The maximum unpooling operation unpools the output of a maximum pooling operation by upsampling and padding with zeros.

The `maxunpool` function applies the maximum unpooling operation to `darray` data. Using `darray` objects makes working with high dimensional data easier by allowing you to label the dimensions. For example, you can label which dimensions correspond to spatial, time, channel, and batch dimensions using the "S", "T", "C", and "B" labels, respectively. For unspecified and other dimensions, use the "U" label. For `darray` object functions that operate over particular dimensions, you can specify the dimension labels by formatting the `darray` object directly, or by using the `DataFormat` option.

---

**Note** To apply maximum unpooling within a `layerGraph` object or `Layer` array, use `maxUnpooling2dLayer`.

---

`Y = maxunpool(X,indx,outputSize)` upsamples the spatial or time dimensions of input data `X` to match the size `outputSize`. The data is padded with zeros between the locations of maximum values specified by `indx`. The input `X` is a formatted `darray` with dimension labels. The output `Y` is a formatted `darray` with the same dimension format as `X`.

`Y = maxunpool(X,indx,outputSize,'DataFormat',FMT)` also specifies the dimension format `FMT` when `X` is not a formatted `darray`. The output `Y` is an unformatted `darray` with the same dimension order as `X`.

### Examples

#### Unpool 2-D Maximum Pooled Data

Create a formatted `darray` object containing a batch of 128 28-by-28 images with 3 channels. Specify the format 'SSCB' (spatial, spatial, channel, batch).

```
miniBatchSize = 128;
inputSize = [28 28];
numChannels = 3;
X = rand(inputSize(1),inputSize(2),numChannels,miniBatchSize);
dIX = darray(X,'SSCB');
```

View the size and format of the input data.

```
size(dIX)
```

```
ans = 1×4
      28    28     3   128
```

```
dims(d1X)
```

```
ans =
'SSCB'
```

Pool the data to maximum values over pooling regions of size 2 using a stride of 2.

```
[d1Y,indx,dataSize] = maxpool(d1X,2,'Stride',2);
```

View the size and format of the pooled data.

```
size(d1Y)
```

```
ans = 1×4
      14    14     3   128
```

```
dims(d1Y)
```

```
ans =
'SSCB'
```

View the data size.

```
dataSize
```

```
dataSize = 1×4
      28    28     3   128
```

Unpool the data using the indices and data size from the maxpool operation.

```
d1Y = maxunpool(d1Y,indx,dataSize);
```

View the size and format of the unpooled data.

```
size(d1Y)
```

```
ans = 1×4
      28    28     3   128
```

```
dims(d1Y)
```

```
ans =
'SSCB'
```

### Unpool 1-D Maximum Pooled Data

Create a formatted `dLarray` object containing a batch of 128 sequences of length 100 with 12 channels. Specify the format 'CBT' (channel, batch, time).

```
miniBatchSize = 128;  
sequenceLength = 100;  
numChannels = 12;  
X = rand(numChannels,miniBatchSize,sequenceLength);  
dLX = dLarray(X, 'CBT');
```

View the size and format of the input data.

```
size(dLX)  
  
ans = 1×3  
  
    12    128    100
```

```
dims(dLX)
```

```
ans =  
'CBT'
```

Apply 1-D maximum pooling with pooling regions of size 2 with a stride of 2 using the `maxpool` function by specifying the 'PoolFormat' and 'Stride' options.

```
poolSize = 2;  
[dLY,indx,dataSize] = maxpool(dLX,poolSize,'PoolFormat','T','Stride',2);
```

View the size and format of the output.

```
size(dLY)  
  
ans = 1×3  
  
    12    128     50
```

```
dims(dLY)
```

```
ans =  
'CBT'
```

Unpool the data using the indices and data size from the `maxpool` operation.

```
dLY = maxunpool(dLY,indx,dataSize);
```

View the size and format of the unpooled data.

```
size(dLY)  
  
ans = 1×3  
  
    12    128    100
```

```
dims(dLY)
```

```
ans =
'CBT'
```

## Input Arguments

### X — Input data

`darray`

Input data, specified as a formatted or unformatted `darray` object.

If X is an unformatted `darray`, then you must specify the format using the `'DataFormat'` option.

The function, unpools the 'S' (spatial) and 'T' dimensions of the data to have sizes given by `outputSize`.

### indx — Indices of maximum values

`darray`

Indices of maximum values in each pooled region, specified as a `darray`.

Use the indices output of the `maxpool` function as the `indx` input to `maxunpool`.

### outputSize — Size of output feature map

numeric array

Size of the output feature map, specified as a numeric array.

Use the size output of the `maxpool` function as the `outputSize` input to `maxunpool`.

### FMT — Dimension order of unformatted data

char array | string

Dimension order of unformatted input data, specified as the comma-separated pair consisting of `'DataFormat'` and a character array or string FMT that provides a label for each dimension of the data. Each character in FMT must be one of the following:

- 'S' — Spatial
- 'C' — Channel
- 'B' — Batch (for example, samples and observations)
- 'T' — Time (for example, sequences)
- 'U' — Unspecified

You can specify multiple dimensions labeled 'S' or 'U'. You can use the labels 'C', 'B', and 'T' at most once.

You must specify `'DataFormat'`, FMT when the input data is not a formatted `darray`.

Example: `'DataFormat', 'SSCB'`

Data Types: char | string

## Output Arguments

### **Y — Unpooled data**

`darray`

Unpooled data, returned as a `darray`. The output Y has the same underlying data type as the input X.

If the input data X is a formatted `darray`, then Y has the same dimension format as X. If the input data is not a formatted `darray`, then Y is an unformatted `darray` with the same dimension order as the input data.

## Version History

**Introduced in R2019b**

## Extended Capabilities

### **GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When the input argument X is a `darray` with underlying data of type `gpuArray`, this function runs on the GPU.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# maxUnpooling2dLayer

Max unpooling layer

## Description

A 2-D max unpooling layer unpools the output of a 2-D max pooling layer.

## Creation

### Syntax

```
layer = maxUnpooling2dLayer
layer = maxUnpooling2dLayer('Name',name)
```

### Description

`layer = maxUnpooling2dLayer` creates a max unpooling layer.

`layer = maxUnpooling2dLayer('Name',name)` sets the `Name` property. To create a network containing a max unpooling layer you must specify a layer name.

## Properties

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

### NumInputs — Number of inputs

3 (default)

Number of inputs of the layer.

There are three inputs to this layer:

- `'in'` — Input feature map to unpool.
- `'indices'` — Indices of the maximum value in each pooled region. This is output by the max pooling layer.
- `'size'` — Output size of unpooled feature map. This is output by the max pooling layer.

Use the input names when connecting or disconnecting the max unpooling layer to other layers using `connectLayers` or `disconnectLayers`, respectively.

Data Types: `double`

**InputNames — Input names**`{'in','indices','size'}` (default)

Input names of the layer.

There are three inputs to this layer:

- `'in'` — Input feature map to unpool.
- `'indices'` — Indices of the maximum value in each pooled region. This is output by the max pooling layer.
- `'size'` — Output size of unpooled feature map. This is output by the max pooling layer.

Use the input names when connecting or disconnecting the max unpooling layer to other layers using `connectLayers` or `disconnectLayers`, respectively.

Data Types: `cell`

**NumOutputs — Number of outputs**`1` (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: `double`

**OutputNames — Output names**`{'out'}` (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: `cell`

## Examples

**Create Max Unpooling Layer**

Create a max unpooling layer that unpools the output of a max pooling layer.

```
layer = maxUnpooling2dLayer
```

```
layer =  
    MaxUnpooling2DLayer with properties:  
        Name: ''  
        NumInputs: 3  
        InputNames: {'in' 'indices' 'size'}
```

## Unpool Max Pooling Layer

Create a max pooling layer, and set the 'HasUnpoolingOutputs' property as true. This property gives the max pooling layer two additional outputs, 'indices' and 'size', which enables unpooling the layer. Also create a max unpooling layer.

```
layers = [
    maxPooling2dLayer(2, 'Stride', 2, 'Name', 'mpool', 'HasUnpoolingOutputs', true)
    maxUnpooling2dLayer('Name', 'unpool');
]

layers =
    2x1 Layer array with layers:

     1  'mpool'    2-D Max Pooling    2x2 max pooling with stride [2  2] and padding [0  0  0
     2  'unpool'  2-D Max Unpooling    2-D Max Unpooling
```

Sequentially connect layers by adding them to a layerGraph. This step connects the 'out' output of the max pooling layer to the 'in' input of the max unpooling layer.

```
lgraph = layerGraph(layers)

lgraph =
    LayerGraph with properties:

        InputNames: {1x0 cell}
        OutputNames: {1x0 cell}
        Layers: [2x1 nnet.cnn.layer.Layer]
        Connections: [1x2 table]
```

Unpool the output of the max pooling layer, by connecting the max pooling layer outputs to the max unpooling layer inputs.

```
lgraph = connectLayers(lgraph, 'mpool/indices', 'unpool/indices');
lgraph = connectLayers(lgraph, 'mpool/size', 'unpool/size');
```

## Version History

**Introduced in R2017b**

### Extended Capabilities

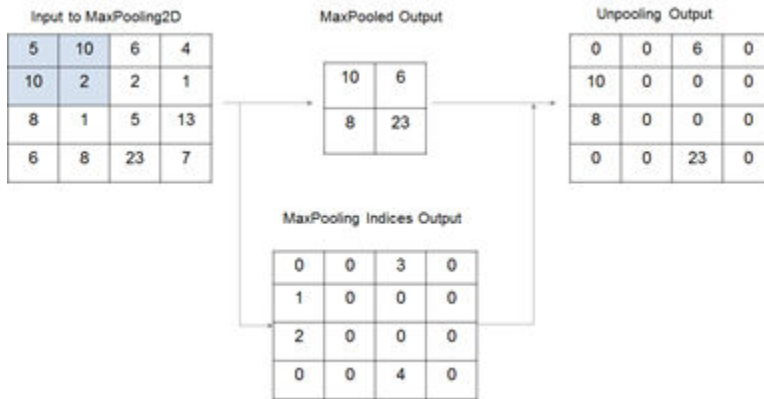

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

If equal max values exists along the off-diagonal in a kernel window, implementation differences for the maxPooling2dLayer might cause minor numerical mismatch between MATLAB and the generated code. This issue also causes mismatch in the indices of the maximum value in each pooled region.

For example, consider the following input to maxPooling2dLayer. The output from MATLAB is shown.

For the same input, the output from the generated code is shown.

**GPU Code Generation**

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

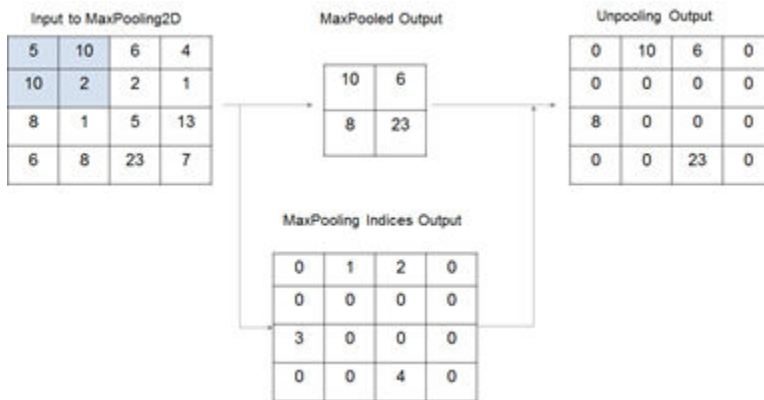

Usage notes and limitations:

If equal max values exists along the off-diagonal in a kernel window, implementation differences for the `maxPooling2dLayer` might cause minor numerical mismatch between MATLAB and the generated code. This issue also causes mismatch in the indices of the maximum value in each pooled region.

For example, consider the following input to `maxPooling2dLayer`. The output from MATLAB is shown.

For the same input, the output from the generated code is shown.

# minibatchqueue

Create mini-batches for deep learning

## Description

Use a `minibatchqueue` object to create, preprocess, and manage mini-batches of data for training using custom training loops.

A `minibatchqueue` object iterates over a datastore to provide data in a suitable format for training using custom training loops. The object prepares a queue of mini-batches that are preprocessed on demand. Use a `minibatchqueue` object to automatically convert your data to `dlarray` or `gpuArray`, convert data to a different precision, or apply a custom function to preprocess your data. You can prepare your data in parallel in the background.

During training, you can manage your data using the `minibatchqueue` object. You can shuffle the data at the start of each training epoch using the `shuffle` function and collect data from the queue for each training iteration using the `next` function. You can check if any data is left in the queue using the `hasdata` function, and reset the queue when it is empty.

## Creation

### Syntax

```
mbq = minibatchqueue(ds)
mbq = minibatchqueue(ds,numOutputs)
mbq = minibatchqueue( ___,Name,Value)
```

### Description

`mbq = minibatchqueue(ds)` creates a `minibatchqueue` object from the input datastore `ds`. The mini-batches in `mbq` have the same number of variables as the results of `read` on the input datastore.

`mbq = minibatchqueue(ds,numOutputs)` creates a `minibatchqueue` object from the input datastore `ds` and sets the number of variables in each mini-batch. Use this syntax when you use `MiniBatchFcn` to specify a mini-batch preprocessing function that has a different number of outputs than the number of variables of the input datastore `ds`.

`mbq = minibatchqueue( ___,Name,Value)` sets one or more properties using name-value options. For example, `minibatchqueue(ds, "MiniBatchSize",64, "PartialMiniBatches", "discard")` sets the size of the returned mini-batches to 64 and discards any mini-batches with fewer than 64 observations.

### Input Arguments

#### **ds** — Input datastore

datastore | custom datastore

Input datastore, specified as a MATLAB datastore or a custom datastore.

For more information about datastores for deep learning, see “Datastores for Deep Learning”.

### **numOutputs — Number of mini-batch variables**

positive integer

Number of mini-batch variables, specified as a positive integer. By default, the number of mini-batch variables is equal to the number of variables of the input datastore.

You can determine the number of variables of the input datastore by examining the output of `read(ds)`. If your datastore returns a table, the number of variables is the number of variables of the table. If your datastore returns a cell array, the number of variables is the size of the second dimension of the cell array.

If you use the `MiniBatchFcn` name-value argument to specify a mini-batch preprocessing function that returns a different number of variables than the input datastore, you must set `numOutputs` to match the number of outputs of the function.

Example: 2

## **Properties**

### **MiniBatchSize — Size of mini-batches**

128 (default) | positive integer

This property is read-only.

Size of mini-batches returned by the `next` function, specified as a positive integer. The default value is 128.

Example: 256

### **PartialMiniBatch — Return or discard incomplete mini-batches**

"return" (default) | "discard"

Return or discard incomplete mini-batches, specified as "return" or "discard".

If the total number of observations is not exactly divisible by `MiniBatchSize`, the final mini-batch returned by the `next` function can have fewer than `MiniBatchSize` observations. This property specifies how any partial mini-batches are treated, using the following options:

- "return" — A mini-batch can contain fewer than `MiniBatchSize` observations. All data is returned.

"discard" — All mini-batches must contain exactly `MiniBatchSize` observations. Some data can be discarded from the queue if there is not enough for a complete mini-batch.

Set `PartialMiniBatch` to "discard" if you require that all of your mini-batches are the same size.

Example: "discard"

Data Types: char | string

### **MiniBatchFcn — Mini-batch preprocessing function**

"collate" (default) | function handle

This property is read-only.

Mini-batch preprocessing function, specified as "collate" or a function handle.

The default value of `MiniBatchFcn` is "collate". This function concatenates the mini-batch variables into arrays.

Use a function handle to a custom function to preprocess mini-batches for custom training. Doing so is recommended for one-hot encoding classification labels, padding sequence data, calculating average images, and so on. You must specify a custom function if your data consists of cell arrays containing arrays of different sizes.

If you specify a custom mini-batch preprocessing function, the function must concatenate each batch of output variables into an array after preprocessing and return each variable as a separate function output. The function must accept at least as many inputs as the number of variables of the underlying datastore. The inputs are passed to the custom function as  $N$ -by-1 cell arrays, where  $N$  is the number of observations in the mini-batch. The function can return as many variables as required. If the function specified by `MiniBatchFcn` returns a different number of outputs than inputs, specify `numOutputs` as the number of outputs of the function.

The following actions are not recommended inside the custom function. To reproduce the desired behavior, instead, set the corresponding property when you create the `minibatchqueue` object.

Action	Recommended Property
Cast variable to different data type.	<code>OutputCast</code>
Move data to GPU.	<code>OutputEnvironment</code>
Convert data to <code>darray</code> .	<code>OutputAsDarray</code>
Apply data format to <code>darray</code> variable.	<code>MiniBatchFormat</code>

Example: `@myCustomFunction`

Data Types: `char` | `string` | `function_handle`

### **DispatchInBackground — Preprocess mini-batches in the background in a parallel pool**

`false` or `0` (default) | `true` or `1`

Preprocess mini-batches in the background in a parallel pool, specified as a numeric or logical `1` (`true`) or `0` (`false`).

Using this option requires Parallel Computing Toolbox. The input datastore `ds` must be subsettable or partitionable. To use this option, custom datastores should implement the `matlab.io.datastore.Subsettable` class.

Use this option when your mini-batches require heavy preprocessing. This option uses a parallel pool to prepare mini-batches in the background while you use mini-batches during training.

Workers in the pool process mini-batches by applying the function specified by `MiniBatchFcn`. Further processing, including applying the effects of the `OutputCast`, `OutputEnvironment`, `OutputAsDarray`, and `MiniBatchFormat`, does not occur on the workers.

When `DispatchInBackground` is set to `true`, the software opens a local parallel pool using the current settings, if a local pool is not currently open. Non-local pools are not supported. The pool opens the first time you call `next`.

Example: `true`

Data Types: `logical`

### **OutputCast — Data type of each mini-batch variable**

`'single'` (default) | `'double'` | `'int8'` | `'int16'` | `'int32'` | `'int64'` | `'uint8'` | `'uint16'` | `'uint32'` | `'uint64'` | `'logical'` | `'char'` | cell array

This property is read-only.

Data type of each mini-batch variable, specified as `'single'`, `'double'`, `'int8'`, `'int16'`, `'int32'`, `'int64'`, `'uint8'`, `'uint16'`, `'uint32'`, `'uint64'`, `'logical'`, or `'char'`, or a cell array of these values, or an empty vector.

If you specify `OutputCast` as an empty vector, the data type of each mini-batch variable is unchanged. To specify a different data type for each mini-batch variable, specify a cell array containing an entry for each mini-batch variable. The order of the elements of this cell array must match the order in which the mini-batch variables are returned. This order is the same order in which the variables are returned from the function specified by `MiniBatchFcn`. If you do not specify a custom function for `MiniBatchFcn`, it is the same order in which the variables are returned by the underlying datastore.

You must make sure that the value of `OutputCast` does not conflict with the values of the `OutputAsDlarray` or `OutputEnvironment` properties. If you specify `OutputAsDlarray` as `true` or `1`, check that the data type specified by `OutputCast` is supported by `dlarray`. If you specify `OutputEnvironment` as `"gpu"` or `"auto"` and a supported GPU is available, check that the data type specified by `OutputCast` is supported by `gpuArray`.

Example: `{'single','single','logical'}`

Data Types: `char` | `string`

### **OutputAsDlarray — Flag to convert mini-batch variable to dlarray**

`true` or `1` (default) | `false` or `0` | vector of logical values

This property is read-only.

Flag to convert mini-batch variable to `dlarray`, specified as a numeric or logical `1` (`true`) or `0` (`false`) or as a vector of numeric or logical values.

To specify a different value for each output, specify a vector containing an entry for each mini-batch variable. The order of the elements of this vector must match the order in which the mini-batch variable are returned. This order is the same order in which the variables are returned from the function specified by `MiniBatchFcn`. If you do not specify a custom function for `MiniBatchFcn`, it is the same order in which the variables are returned by the underlying datastore.

Variables that are converted to `dlarray` have the underlying data type specified by the `OutputCast` property.

Example: `[1,1,0]`

Data Types: `logical`

### **MiniBatchFormat — Data format of mini-batch variables**

`' '` (default) | character vector | cell array

This property is read-only.

Data format of mini-batch variables, specified as a character vector or a cell array of character vectors.

The mini-batch format is applied to `darray` variables only. Non-`darray` mini-batch variables must have a `MiniBatchFormat` of `''`.

To avoid an error when you have a mix of `darray` and non-`darray` variables, you must specify a value for each output by providing a cell array containing an entry for each mini-batch variable. The order of the elements of this cell array must match the order in which the mini-batch variables are returned. This is the same order in which the variables are returned from the function specified by `MiniBatchFcn`. If you do not specify a custom function for `MiniBatchFcn`, it is the same order in which the variables are returned by the underlying datastore.

Example: `{'SSCB', ''}`

Data Types: `char` | `string`

### **OutputEnvironment — Hardware resource for mini-batch variables**

`'auto'` (default) | `'gpu'` | `'cpu'` | cell array

Hardware resource for mini-batch variables returned using the `next` function, specified as one of the following values:

- `'auto'` — Return mini-batch variables on the GPU if one is available. Otherwise, return mini-batch variables on the CPU.
- `'gpu'` — Return mini-batch variables on the GPU.
- `'cpu'` — Return mini-batch variables on the CPU

To return only specific variables on the GPU, specify `OutputEnvironment` as a cell array containing an entry for each mini-batch variable. The order of the elements of this cell array must match the order the mini-batch variable are returned. This order is the same order as the variables are returned from the function specified by `MiniBatchFcn`. If you do not specify a custom `MiniBatchFcn`, it is the same order as the variables are returned by the underlying datastore.

Using a GPU requires Parallel Computing Toolbox. To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). If you choose the `'gpu'` option and Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.

Example: `{'gpu', 'cpu'}`

Data Types: `char` | `string`

### **Object Functions**

<code>hasdata</code>	Determine if <code>minibatchqueue</code> can return mini-batch
<code>next</code>	Obtain next mini-batch of data from <code>minibatchqueue</code>
<code>partition</code>	Partition <code>minibatchqueue</code>
<code>reset</code>	Reset <code>minibatchqueue</code> to start of data
<code>shuffle</code>	Shuffle data in <code>minibatchqueue</code>

### **Examples**

## Prepare Mini-Batches for Custom Training Loop

Use a `minibatchqueue` object to automatically prepare mini-batches of images and classification labels for training in a custom training loop.

Create a datastore. Calling `read` on `auimds` produces a table with two variables: `input`, containing the image data, and `response`, containing the corresponding classification labels.

```
auimds = augmentedImageDatastore([100 100],digitDatastore);
A = read(auimds);
head(A,2)
```

```
ans =
      input      response
-----
{100x100 uint8}      0
{100x100 uint8}      0
```

Create a `minibatchqueue` object from `auimds`. Set the `MiniBatchSize` property to 256.

The `minibatchqueue` object has two output variables: the images and classification labels from the `input` and `response` variables of `auimds`, respectively. Set the `minibatchqueue` object to return the images as a formatted `darray` on the GPU. The images are single-channel black-and-white images. Add a singleton channel dimension by applying the format `'SSBC'` to the batch. Return the labels as a non-`darray` on the CPU.

```
mbq = minibatchqueue(auimds,...
    'MiniBatchSize',256,...
    'OutputAsDlarray',[1,0],...
    'MiniBatchFormat',{'SSBC',''},...
    'OutputEnvironment',{'gpu','cpu'})
```

Use the next function to obtain mini-batches from `mbq`.

```
[X,Y] = next(mbq);
```

## Create Mini-Batches Using Custom Preprocessing Function and Background Dispatch

Preprocess data using a `minibatchqueue` with a custom mini-batch preprocessing function. The custom function rescales the incoming image data between 0 and 1 and calculates the average image.

Unzip the data and create a datastore.

```
unzip("MerchData.zip");
imds = imageDatastore("MerchData", ...
    IncludeSubfolders=true, ...
    LabelSource="foldernames");
```

Create a `minibatchqueue`.

- Set the number of outputs to 2, to match the number of outputs of the function.
- Set the mini-batch size.

- Preprocesses the data using the custom function `preprocessMiniBatch` defined at the end of this example. The custom function concatenates the image data into a numeric array, rescales the image between 0 and 1, and calculates the average of the batch of images. The function returns the rescaled batch of images and the average image.
- Apply the preprocessing function in the background using a parallel pool by setting the `DispatchInBackground` property to `true`. Setting `DispatchInBackground` to `true` requires Parallel Computing Toolbox™.
- Do not convert the mini-batch output variables to a `dlarray`.

```
mbq = minibatchqueue(imds,2,...  
    MiniBatchSize=16,...  
    MiniBatchFcn=@preprocessMiniBatch,...  
    DispatchInBackground=true,...  
    OutputAsDlarray=false)
```

```
mbq =  
minibatchqueue with 2 outputs and properties:
```

```
Mini-batch creation:  
    MiniBatchSize: 16  
    PartialMiniBatch: 'return'  
    MiniBatchFcn: @preprocessMiniBatch  
    DispatchInBackground: 1
```

```
Outputs:  
    OutputCast: {'single' 'single'}  
    OutputAsDlarray: [0 0]  
    MiniBatchFormat: {'' ''}  
    OutputEnvironment: {'auto' 'auto'}
```

If you are using `DispatchInBackground` and a parallel pool is not already open, a local parallel pool will automatically open when data is read from the mini-batch queue. If your preprocessing function is supported for a thread-based environment, open a thread-based parallel pool for reduced memory usage, faster scheduling, and lower data transfer costs. For more information, see “Choose Between Thread-Based and Process-Based Environments” (Parallel Computing Toolbox).

```
parpool("Threads");
```

```
Starting parallel pool (parpool) using the 'Threads' profile ...  
Connected to parallel pool with 20 workers.
```

Obtain a mini-batch and display the average of the images in the mini-batch. A thread worker applies the preprocessing function.

```
[X,averageImage] = next(mbq);  
imshow(averageImage)
```

```
function [X,averageImage] = preprocessMiniBatch(XCell)
    X = cat(4,XCell{:});

    X = rescale(X,InputMin=0,InputMax=255);
    averageImage = mean(X,4);
end
```

### Use minibatchqueue in Custom Training Loop

Train a network using `minibatchqueue` to manage the processing of mini-batches.

#### Load Training Data

Load the digits training data and store the data in a datastore. Create a datastore for the images and one for the labels using `arrayDatastore`. Then, combine the datastores to produce a single datastore to use with `minibatchqueue`.

```
[XTrain,YTrain] = digitTrain4DArrayData;
dsX = arrayDatastore(XTrain,IterationDimension=4);
dsY = arrayDatastore(YTrain);
```

```
dsTrain = combine(dsX,dsY);
```

Determine the number of unique classes in the label data.

```
classes = categories(YTrain);
numClasses = numel(classes);
```

#### Define Network

Define the network and specify the average image value using the `Mean` option in the image input layer.

```
layers = [  
    imageInputLayer([28 28 1],Mean=mean(XTrain,4))  
    convolution2dLayer(5,20)  
    reluLayer  
    convolution2dLayer(3,20,Padding=1)  
    reluLayer  
    convolution2dLayer(3,20,Padding=1)  
    reluLayer  
    fullyConnectedLayer(numClasses)  
    softmaxLayer];  
lgraph = layerGraph(layers);
```

Create a `dlnetwork` object from the layer graph.

```
net = dlnetwork(lgraph);
```

### Define Model Loss Function

Create the helper function `modelLoss`, listed at the end of the example. The function takes as input a `dlnetwork` object `net` and a mini-batch of input data `X` with corresponding labels `Y`, and returns the loss and the gradients of the loss with respect to the learnable parameters in `net`.

### Specify Training Options

Specify the options to use during training.

```
numEpochs = 10;  
miniBatchSize = 128;
```

Visualize the training progress in a plot.

```
plots = "training-progress";
```

### Create the minibatchqueue

Use `minibatchqueue` to process and manage the mini-batches of images. For each mini-batch:

- Discard partial mini-batches.
- Use the custom mini-batch preprocessing function `preprocessMiniBatch` (defined at the end of this example) to one-hot encode the class labels.
- Format the image data with the dimension labels 'SSCB' (spatial, spatial, channel, batch). By default, the `minibatchqueue` object converts the data to `dlarray` objects with underlying data type `single`. Do not add a format to the class labels.
- Train on a GPU if one is available. By default, the `minibatchqueue` object converts each output to a `gpuArray` if a GPU is available. Using a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox).

```
mbq = minibatchqueue(dsTrain,...  
    MiniBatchSize=miniBatchSize,...  
    PartialMiniBatch="discard",...  
    MiniBatchFcn=@preprocessMiniBatch,...  
    MiniBatchFormat=["SSCB",""]);
```

## Train Network

Train the model using a custom training loop. For each epoch, shuffle the data and loop over mini-batches while data is still available in the minibatchqueue. Update the network parameters using the adamupdate function. At the end of each epoch, display the training progress.

Initialize the average gradients and squared average gradients.

```
averageGrad = [];
averageSqGrad = [];
```

Calculate the total number of iterations for the training progress monitor.

```
numObservationsTrain = numel(YTrain);
numIterationsPerEpoch = ceil(numObservationsTrain / miniBatchSize);
numIterations = numEpochs * numIterationsPerEpoch;
```

Initialize the TrainingProgressMonitor object. Because the timer starts when you create the monitor object, make sure that you create the object close to the training loop.

```
if plots == "training-progress"
    monitor = trainingProgressMonitor(Metrics="Loss",Info="Epoch",XLabel="Iteration");
end
```

Train the network.

```
iteration = 0;
epoch = 0;
```

```
while epoch < numEpochs && ~monitor.Stop
    epoch = epoch + 1;

    % Shuffle data.
    shuffle (mbq);

    while hasdata(mbq) && ~monitor.Stop
        iteration = iteration + 1;

        % Read mini-batch of data.
        [X,Y] = next(mbq);

        % Evaluate the model loss and gradients using dlfeval and the
        % modelLoss helper function.
        [loss,grad] = dlfeval(@modelLoss,net,X,Y);

        % Update the network parameters using the Adam optimizer.
        [net,averageGrad,averageSqGrad] = adamupdate(net,grad,averageGrad,averageSqGrad,iteration);

        % Update the training progress monitor.
        if plots == "training-progress"
            recordMetrics(monitor,iteration,Loss=loss);
            updateInfo(monitor,Epoch=epoch + " of " + numEpochs);
            monitor.Progress = 100 * iteration/numIterations;
        end
    end
end
end
```

### Model Loss Function

The `modelLoss` helper function takes as input a `dlnetwork` object `net` and a mini-batch of input data `X` with corresponding labels `Y`, and returns the loss and the gradients of the loss with respect to the learnable parameters in `net`. To compute the gradients automatically, use the `dlgradient` function.

```
function [loss,gradients] = modelLoss(net,X,Y)
    YPred = forward(net,X);
    loss = crossentropy(YPred,Y);
    gradients = dlgradient(loss,net.Learnables);
```

```
end
```

### Mini-Batch Preprocessing Function

The `preprocessMiniBatch` function preprocesses the data using the following steps:

- 1 Extract the image data from the incoming cell array and concatenate the data into a numeric array. Concatenating the image data over the fourth dimension adds a third dimension to each image, to be used as a singleton channel dimension.
- 2 Extract the label data from the incoming cell array and concatenate along the second dimension into a categorical array.
- 3 One-hot encode the categorical labels into numeric arrays. Encoding into the first dimension produces an encoded array that matches the shape of the network output.

```
function [X,Y] = preprocessMiniBatch(XCell,YCell)
    % Extract image data from the cell array and concatenate over fourth
    % dimension to add a third singleton dimension, as the channel
    % dimension.
    X = cat(4,XCell{:});
```

```
% Extract label data from cell and concatenate.  
Y = cat(2,YCell{:});  
  
% One-hot encode labels.  
Y = onehotencode(Y,1);
```

```
end
```

## mobilenetv2

MobileNet-v2 convolutional neural network

### Syntax

```
net = mobilenetv2
net = mobilenetv2('Weights','imagenet')

lgraph = mobilenetv2('Weights','none')
```

### Description

MobileNet-v2 is a convolutional neural network that is 53 layers deep. You can load a pretrained version of the network trained on more than a million images from the ImageNet database [1]. The pretrained network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. The network has an image input size of 224-by-224. For more pretrained networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the MobileNet-v2 model. Follow the steps of “Classify Image Using GoogLeNet” and replace GoogLeNet with MobileNet-v2.

To retrain the network on a new classification task, follow the steps of “Train Deep Learning Network to Classify New Images” and load MobileNet-v2 instead of GoogLeNet.

`net = mobilenetv2` returns a MobileNet-v2 network trained on the ImageNet data set.

This function requires the Deep Learning Toolbox Model *for MobileNet-v2 Network* support package. If this support package is not installed, then the function provides a download link.

`net = mobilenetv2('Weights','imagenet')` returns a MobileNet-v2 network trained on the ImageNet data set. This syntax is equivalent to `net = mobilenetv2`.

`lgraph = mobilenetv2('Weights','none')` returns the untrained MobileNet-v2 network architecture. The untrained model does not require the support package.

### Examples

#### Download MobileNet-v2 Support Package

Download and install the Deep Learning Toolbox Model *for MobileNet-v2 Network* support package.

Type `mobilenetv2` at the command line.

```
mobilenetv2
```

If the Deep Learning Toolbox Model *for MobileNet-v2 Network* support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**. Check that the installation is successful by

typing `mobilenetv2` at the command line. If the required support package is installed, then the function returns a `DAGNetwork` object.

```
mobilenetv2
```

```
ans =
```

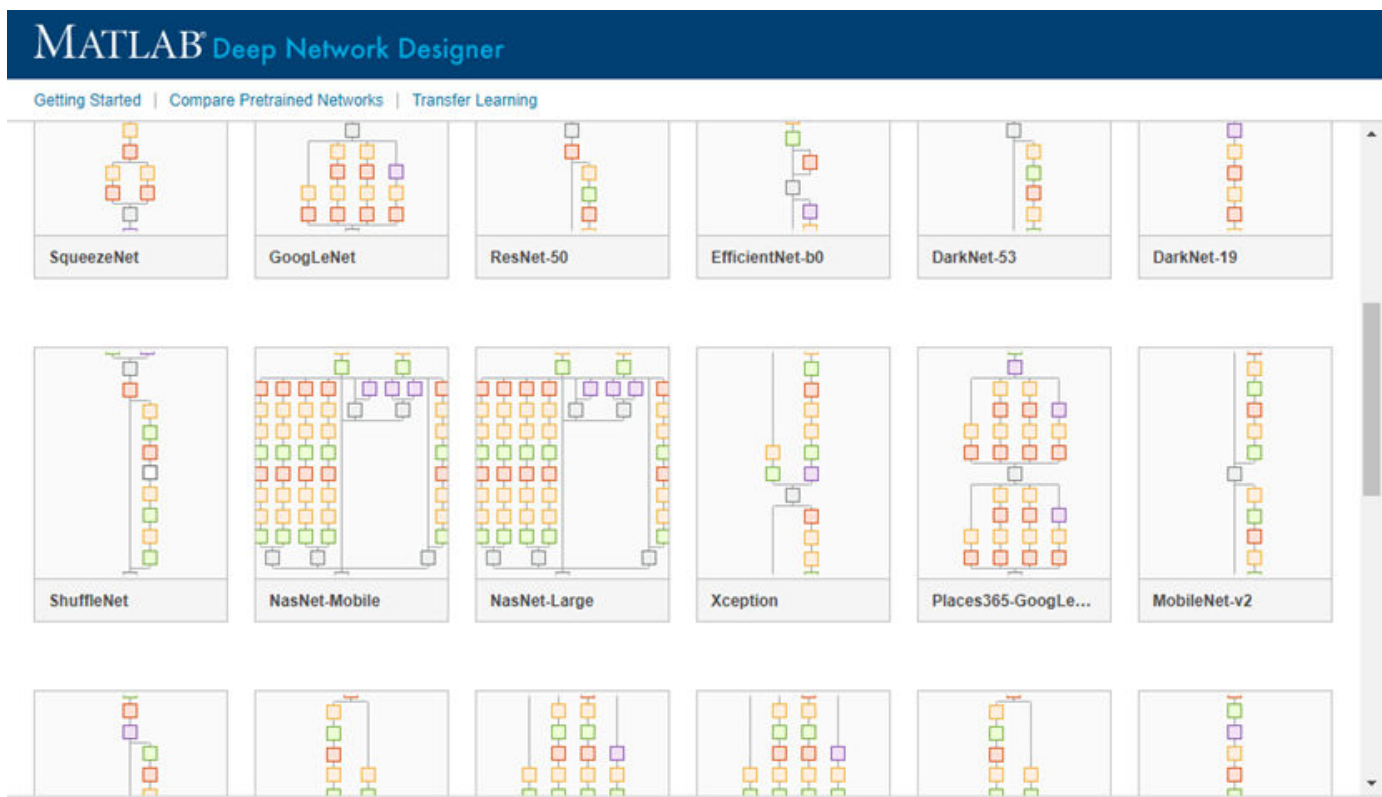

```
DAGNetwork with properties:
```

```
Layers: [155x1 nnet.cnn.layer.Layer]
Connections: [164x2 table]
```

Visualize the network using Deep Network Designer.

```
deepNetworkDesigner(mobilenetv2)
```

Explore other pretrained neural networks in Deep Network Designer by clicking **New**.

If you need to download a neural network, pause on the desired neural network and click **Install** to open the Add-On Explorer.

## Output Arguments

**net** — Pretrained MobileNet-v2 convolutional neural network

`DAGNetwork` object

Pretrained MobileNet-v2 convolutional neural network, returned as a `DAGNetwork` object.

## **lgraph — Untrained MobileNet-v2 convolutional neural network architecture**

LayerGraph object

Untrained MobileNet-v2 convolutional neural network architecture, returned as a LayerGraph object.

## **Version History**

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

For code generation, you can load the network by using the syntax `net = mobilenetv2` or by passing the `mobilenetv2` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('mobilenetv2')`

For more information, see "Load Pretrained Networks for Code Generation" (MATLAB Coder).

The syntax `mobilenetv2('Weights', 'none')` is not supported for code generation.

### **GPU Code Generation**

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- For code generation, you can load the network by using the syntax `net = mobilenetv2` or by passing the `mobilenetv2` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('mobilenetv2')`

For more information, see "Load Pretrained Networks for Code Generation" (GPU Coder).

- The syntax `mobilenetv2('Weights', 'none')` is not supported for GPU code generation.

## mse

Half mean squared error

### Syntax

```
loss = mse(Y,targets)
loss = mse(Y,targets,'DataFormat',FMT)
```

### Description

The half mean squared error operation computes the half mean squared error loss between network predictions and target values for regression tasks.

The loss is calculated using the following formula

$$\text{loss} = \frac{1}{2N} \sum_{i=1}^M (X_i - T_i)^2$$

where  $X_i$  is the network prediction,  $T_i$  is the target value,  $M$  is the total number of responses in  $X$  (across all observations), and  $N$  is the total number of observations in  $X$ .

---

**Note** This function computes the half mean squared error loss between predictions and targets stored as `dlarray` data. If you want to calculate the half mean squared error loss within a `layerGraph` object or `Layer` array for use with `trainNetwork`, use the following layer:

- `regressionLayer`
- 

`loss = mse(Y,targets)` computes the half mean squared error loss between the predictions `Y` and the target values `targets` for regression problems. The input `Y` must be a formatted `dlarray`. The output `loss` is an unformatted `dlarray` scalar.

`loss = mse(Y,targets,'DataFormat',FMT)` also specifies the dimension format `FMT` when `Y` is not a formatted `dlarray`.

## Examples

### Find Half Mean Squared Error Between Predicted and Target Values

The half mean squared error evaluates how well the network predictions correspond to the target values.

Create the input predictions as a single observation of random values with a height and width of six and a single channel.

```
height = 6;
width = 6;
```

```

channels = 1;
observations = 1;

Y = rand(height,width,channels,observations);
Y = darray(Y, 'SSCB')

```

Create the target values as a numeric array with the same dimension order as the input data `Y`.

```
targets = ones(height,width,channels,observations);
```

Compute the half mean squared error between the predictions and the targets.

```
loss = mse(Y,targets)
```

```
loss =
```

```
    1x1 darray
```

```
    5.2061
```

## Input Arguments

### Y — Predictions

`darray` | numeric array

Predictions, specified as a formatted `darray`, an unformatted `darray`, or a numeric array. When `Y` is not a formatted `darray`, you must specify the dimension format using the `DataFormat` option.

If `Y` is a numeric array, `targets` must be a `darray`.

### targets — Target responses

`darray` | numeric array

Target responses, specified as a formatted or unformatted `darray` or a numeric array.

The size of each dimension of `targets` must match the size of the corresponding dimension of `Y`.

If `targets` is a formatted `darray`, then its format must be the same as the format of `Y`, or the same as `DataFormat` if `Y` is unformatted.

If `targets` is an unformatted `darray` or a numeric array, then the function applies the format of `Y` or the value of `DataFormat` to `targets`.

---

**Tip** Formatted `darray` objects automatically permute the dimensions of the underlying data to have order "S" (spatial), "C" (channel), "B" (batch), "T" (time), then "U" (unspecified). To ensure that the dimensions of `Y` and `targets` are consistent, when `Y` is a formatted `darray`, also specify `targets` as a formatted `darray`.

---

### FMT — Dimension order of unformatted data

char array | string

Dimension order of unformatted input data, specified as the comma-separated pair consisting of 'DataFormat' and a character array or string `FMT` that provides a label for each dimension of the data. Each character in `FMT` must be one of the following:

- 'S' — Spatial
- 'C' — Channel
- 'B' — Batch (for example, samples and observations)
- 'T' — Time (for example, sequences)
- 'U' — Unspecified

You can specify multiple dimensions labeled 'S' or 'U'. You can use the labels 'C', 'B', and 'T' at most once.

You must specify 'DataFormat', FMT when the input data is not a formatted d`larray`.

Example: 'DataFormat', 'SSCB'

Data Types: char | string

## Output Arguments

### Loss — Half mean squared error loss

d`larray` scalar

Half mean squared error loss, returned as an unformatted d`larray` scalar. The output `loss` has the same underlying data type as the input `Y`.

## More About

### Half Mean Squared Error Loss

The `mse` function computes the half-mean-squared-error loss for regression problems. For more information, see the definition of “Regression Output Layer” on page 1-1503 on the `RegressionOutputLayer` reference page.

## Version History

Introduced in R2019b

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When at least one of the following input arguments is a `gpuArray` or a d`larray` with underlying data of type `gpuArray`, this function runs on the GPU:
  - `Y`
  - `targets`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# multiplicationLayer

Multiplication layer

## Description

A multiplication layer multiplies inputs from multiple neural network layers element-wise.

Specify the number of inputs to the layer when you create it. The inputs to the layer have the names 'in1', 'in2', ..., 'inN', where N is the number of inputs. Use the input names when connecting or disconnecting the layer by using `connectLayers` or `disconnectLayers`, respectively. The size of the inputs to the multiplication layer must be either same across all dimensions or same across at least one dimension with other dimensions as singleton dimensions.

## Creation

### Syntax

```
layer = multiplicationLayer(numInputs)
layer = multiplicationLayer(numInputs, 'Name', name)
```

### Description

`layer = multiplicationLayer(numInputs)` creates a multiplication layer that multiplies `numInputs` inputs element-wise. This function also sets the `NumInputs` property.

`layer = multiplicationLayer(numInputs, 'Name', name)` also sets the `Name` property.

## Properties

### NumInputs — Number of inputs

positive integer

Number of inputs to the layer, specified as a positive integer greater than or equal to 2.

The inputs have the names 'in1', 'in2', ..., 'inN', where N is `NumInputs`. For example, if `NumInputs` is 3, then the inputs have the names 'in1', 'in2', and 'in3'. Use the input names when connecting or disconnecting the layer using the `connectLayers` or `disconnectLayers` functions.

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: char | string

**InputNames — Input Names**

{'in1', 'in2', ..., 'inN'} (default)

Input names, specified as {'in1', 'in2', ..., 'inN'}, where N is the number of inputs of the layer.

Data Types: cell

**NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: double

**OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

**Examples****Create and Connect Multiplication Layer**

Create a multiplication layer with two inputs and the name 'mul\_1'.

```
mul = multiplicationLayer(2, 'Name', 'mul_1')
```

```
mul =
```

```
  MultiplicationLayer with properties:
```

```
      Name: 'mul_1'
    NumInputs: 2
  InputNames: {'in1' 'in2'}
```

```
  Learnable Parameters
  No properties.
```

```
  State Parameters
  No properties.
```

```
  Show all properties
```

Create two ReLU layers and connect them to the multiplication layer. The multiplication layer multiplies the outputs from the ReLU layers.

```
relu_1 = reluLayer('Name', 'relu_1');
relu_2 = reluLayer('Name', 'relu_2');
```

```
lgraph = layerGraph();
lgraph = addLayers(lgraph, relu_1);
```

```
lgraph = addLayers(lgraph,relu_2);  
lgraph = addLayers(lgraph,mul);  
  
lgraph = connectLayers(lgraph,'relu_1','mul_1/in1');  
lgraph = connectLayers(lgraph,'relu_2','mul_1/in2');  
  
plot(lgraph);
```

## Algorithms

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the

images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `MultiplicationLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Each input must have data of the same format.

Input Format	Output Format
"CB" (channel, batch)	"CB" (channel, batch)
"SCB" (spatial, channel, batch)	"SCB" (spatial, channel, batch)
"SSCB" (spatial, spatial, channel, batch)	"SSCB" (spatial, spatial, channel, batch)
"SSSCB" (spatial, spatial, spatial, channel, batch)	"SSSCB" (spatial, spatial, spatial, channel, batch)
"CBT" (channel, batch, time)	"CBT" (channel, batch, time)
"SCBT" (spatial, channel, batch, time)	"SCBT" (spatial, channel, batch, time)
"SSCBT" (spatial, spatial, channel, batch, time)	"SSCBT" (spatial, spatial, channel, batch, time)
"SSSCBT" (spatial, spatial, spatial, channel, batch, time)	"SSSCBT" (spatial, spatial, spatial, channel, batch, time)
"CU" (channel, unspecified)	"CU" (channel, unspecified)
"SC" (spatial, channel)	"SC" (spatial, channel)
"SSC" (spatial, spatial, channel)	"SSC" (spatial, spatial, channel)
"SSSC" (spatial, spatial, spatial, channel)	"SSSC" (spatial, spatial, spatial, channel)
"BU" (batch, unspecified)	"BU" (batch, unspecified)

In `dlnetwork` objects, `MultiplicationLayer` objects also support these input and output format combinations.

Input Format	Output Format
"CT" (channel, time)	"CT" (channel, time)
"SCT" (spatial, channel, time)	"SCT" (spatial, channel, time)
"SSCT" (spatial, spatial, channel, time)	"SSCT" (spatial, spatial, channel, time)
"SSSCT" (spatial, spatial, spatial, channel, time)	"SSSCT" (spatial, spatial, spatial, channel, time)

# nasnetlarge

Pretrained NASNet-Large convolutional neural network

## Syntax

```
net = nasnetlarge
```

## Description

NASNet-Large is a convolutional neural network that is trained on more than a million images from the ImageNet database [1]. The network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. The network has an image input size of 331-by-331. For more pretrained networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the NASNet-Large model. Follow the steps of “Classify Image Using GoogLeNet” and replace GoogLeNet with NASNet-Large.

To retrain the network on a new classification task, follow the steps of “Train Deep Learning Network to Classify New Images” and load NASNet-Large instead of GoogLeNet.

`net = nasnetlarge` returns a pretrained NASNet-Large convolutional neural network.

This function requires the *Deep Learning Toolbox Model for NASNet-Large Network* support package. If this support package is not installed, then the function provides a download link.

## Examples

### Download NASNet-Large Support Package

Download and install the *Deep Learning Toolbox Model for NASNet-Large Network* support package.

Type `nasnetlarge` at the command line.

```
nasnetlarge
```

If the *Deep Learning Toolbox Model for NASNet-Large Network* support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**. Check that the installation is successful by typing `nasnetlarge` at the command line. If the required support package is installed, then the function returns a `DAGNetwork` object.

```
nasnetlarge
```

```
ans =
```

```
DAGNetwork with properties:
```

```
    Layers: [1244x1 nnet.cnn.layer.Layer]
Connections: [1463x2 table]
```

Visualize the network using Deep Network Designer.

```
deepNetworkDesigner(nasnetLarge)
```

Explore other pretrained neural networks in Deep Network Designer by clicking **New**.

If you need to download a neural network, pause on the desired neural network and click **Install** to open the Add-On Explorer.

## Transfer Learning with NASNet-Large

You can use transfer learning to retrain the network to classify a new set of images.

Open the example "Train Deep Learning Network to Classify New Images". The original example uses the GoogLeNet pretrained network. To perform transfer learning using a different network, load your desired pretrained network and follow the steps in the example.

Load the NASNet-Large network instead of GoogLeNet.

```
net = nasnetLarge
```

Follow the remaining steps in the example to retrain your network. You must replace the last learnable layer and the classification layer in your network with new layers for training. The example shows you how to find which layers to replace.

## Output Arguments

### **net** — Pretrained NASNet-Large convolutional neural network

DAGNetwork object

Pretrained NASNet-Large convolutional neural network, returned as a DAGNetwork object.

## Version History

Introduced in R2019a

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

For code generation, you can load the network by using the syntax `net = nasnetlarge` or by passing the `nasnetlarge` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('nasnetlarge')`

For more information, see "Load Pretrained Networks for Code Generation" (MATLAB Coder).

### **GPU Code Generation**

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

For code generation, you can load the network by using the syntax `net = nasnetlarge` or by passing the `nasnetlarge` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('nasnetlarge')`

For more information, see "Load Pretrained Networks for Code Generation" (GPU Coder).

# nasnetmobile

Pretrained NASNet-Mobile convolutional neural network

## Syntax

```
net = nasnetmobile
```

## Description

NASNet-Mobile is a convolutional neural network that is trained on more than a million images from the ImageNet database [1]. The network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. The network has an image input size of 224-by-224. For more pretrained networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the NASNet-Mobile model. Follow the steps of “Classify Image Using GoogLeNet” and replace GoogLeNet with NASNet-Mobile.

To retrain the network on a new classification task, follow the steps of “Train Deep Learning Network to Classify New Images” and load NASNet-Mobile instead of GoogLeNet.

`net = nasnetmobile` returns a pretrained NASNet-Mobile convolutional neural network.

This function requires the *Deep Learning Toolbox Model for NASNet-Mobile Network* support package. If this support package is not installed, then the function provides a download link.

## Examples

### Download NASNet-Mobile Support Package

Download and install the *Deep Learning Toolbox Model for NASNet-Mobile Network* support package.

# networkDataLayout

Deep learning network data layout for learnable parameter initialization

## Description

Network data layout objects represent the data size and `dLarray` format information of input data for parameter initialization.

You can use `networkDataLayout` objects to initialize `dLnetwork` objects and custom layer learnable parameters using its size and format information as an alternative to using example data.

## Creation

### Syntax

```
layout = networkDataLayout(sz)
layout = networkDataLayout(sz,fmt)
```

### Description

`layout = networkDataLayout(sz)` creates an unformatted network data layout object and sets the `Size` property.

`layout = networkDataLayout(sz,fmt)` creates a formatted network data layout object and sets the `Size` and `Format` properties.

## Properties

### Size — Size

row vector

Size, specified as a row vector of two or more nonnegative integers or NaN values, where `sz(i)` denotes the size of dimension `i` and NaN values correspond to unknown dimension sizes.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Format — Data format

' ' (default) | string scalar | character vector

Data format, specified as a string scalar or a character vector. Each character in the string must be one of the following dimension labels:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time

- "U" — Unspecified

You can specify any number of "S" and "U" labels. You can specify at most one of each of the "C", "B", and "T" labels.

Data Types: string | char

## Object Functions

`finddim` Find dimensions with specified label

## Examples

### Create Unformatted Network Data Layout Object

Create an unformatted `networkDataLayout` object representing data of size [28 28 1].

```
layout = networkDataLayout([28 28 1])  
  
layout =  
    networkDataLayout with properties:  
  
        Size: [28 28 1]  
        Format: ''
```

### Create Formatted Network Data Layout Object

Create a formatted `networkDataLayout` object representing a batch of 2-D RGB images of size [227 227], where the batch size is unknown.

```
layout = networkDataLayout([227 227 3 NaN], "SSCB")  
  
layout =  
    networkDataLayout with properties:  
  
        Size: [227 227 3 NaN]  
        Format: 'SSCB'
```

### Initialize Network using Network Data Layout Objects

Create an uninitialized `dlnetwork` object that has two unconnected inputs.

```
layers = [  
    convolution2dLayer(5,16,Name="conv")  
    batchNormalizationLayer  
    reluLayer  
    fullyConnectedLayer(50)  
    flattenLayer  
    concatenationLayer(1,2,Name="cat")
```

```
    fullyConnectedLayer(10)
    softmaxLayer];
```

```
net = dlnetwork(layers,Initialize=false);
```

View the input names of the network.

```
net.InputNames
```

```
ans = 1x2 cell
    {'conv'}    {'cat/in2'}
```

Create network data layout objects that represent input data for the inputs. For the first input, specify a batch of 28-by-28 grayscale images. For the second input specify a batch of single-channel feature data.

```
layout1 = networkDataLayout([28 28 1 NaN], "SSCB");
layout2 = networkDataLayout([1 NaN], "CB");
```

Initialize the network using the network data layout objects.

```
net = initialize(net,layout1,layout2)
```

```
net =
  dlnetwork with properties:
    Layers: [8x1 nnet.cnn.layer.Layer]
    Connections: [7x2 table]
    Learnables: [8x3 table]
    State: [2x3 table]
    InputNames: {'conv' 'cat/in2'}
    OutputNames: {'softmax'}
    Initialized: 1
```

View summary with summary.

## Find Dimensions of Network Data Layout Object

Create a formatted network data layout object representing 2-D image sequences. Specify the format "SSCBT" (spatial, spatial, channel, batch, time).

```
layout = networkDataLayout([227 227 3 NaN 100], "SSCBT");
```

Find the dimensions with the label "S".

```
dim = finddim(layout, "S")
```

```
dim = 1x2
    1    2
```

# networkDistributionDiscriminator

Deep learning distribution discriminator

## Syntax

```
discriminator = networkDistributionDiscriminator(net,XID,XOOD,method)
discriminator = networkDistributionDiscriminator(net,XID,[],method)
discriminator = networkDistributionDiscriminator(net,[],XOOD,method)
discriminator = networkDistributionDiscriminator( ____,Name=Value)
```

## Description

`discriminator = networkDistributionDiscriminator(net,XID,XOOD,method)` returns a distribution discriminator using the method specified by `method`.

You can use the discriminator to classify observations as in-distribution (ID) and out-of-distribution (OOD). OOD data refers to data that is sufficiently different from the data you use to train the network, which can cause the network to behave unexpectedly. For more information, see “In-Distribution and Out-of-Distribution Data” on page 1-1369.

The `networkDistributionDiscriminator` function first finds distribution confidence scores using the method you specify in `method`. The function then finds a threshold that best separates the ID and OOD distribution confidence scores. You can classify any observation with a score below the threshold as OOD. For more information about how the function computes the threshold, see “Algorithms” on page 1-1372. You can find the threshold using a set of ID data, a set of OOD data, or both.

To determine whether new data is ID or OOD, pass `discriminator` as an input to the `isInNetworkDistribution` function.

To find the distribution confidence scores, pass `discriminator` as an input to the `distributionScores` function. For more information about distribution confidence scores, see “Distribution Confidence Scores” on page 1-1370.

`discriminator = networkDistributionDiscriminator(net,XID,[],method)` returns a distribution discriminator using only the ID data. The `Threshold` property of `discriminator` contains the threshold such that the discriminator attains a true positive rate greater than the value of the `TruePositiveGoal` name-value argument. For more information, see “Algorithms” on page 1-1372.

`discriminator = networkDistributionDiscriminator(net,[],XOOD,method)` returns a distribution discriminator using only the OOD data. The `Threshold` property of `discriminator` contains the threshold such that the discriminator attains a false positive rate less than the value of the `FalsePositiveGoal` name-value argument. For more information, see “Algorithms” on page 1-1372.

`discriminator = networkDistributionDiscriminator( ____,Name=Value)` returns a discriminator with additional options specified by one or more name-value arguments.

## Examples

### Create Distribution Discriminator Using In- and Out-of-Distribution Data

Load a pretrained classification network.

```
load("digitsClassificationMLPNet.mat");
```

Load ID data. Convert the data to a `dLarray` object.

```
XID = digitTrain4DArrayData;  
XID = dLarray(XID, "SSCB");
```

Modify the ID training data to create an OOD set.

```
XOOD = XID*0.3 + 0.1;
```

Create a discriminator. The function finds the threshold that best separates the two distributions of data by maximizing the true positive rate and minimizing the false positive rate.

```
method = "baseline";  
discriminator = networkDistributionDiscriminator(net,XID,XOOD,method)
```

```
discriminator =  
  BaselineDistributionDiscriminator with properties:  
  
    Method: "baseline"  
   Network: [1x1 dlnetwork]  
  Threshold: 0.9743
```

### Create Distribution Discriminator Using Only In-Distribution Data

Load a pretrained classification network.

```
load("digitsClassificationMLPNet.mat");
```

Load ID data. Convert the data to a `dLarray` object.

```
XID = digitTrain4DArrayData;  
XID = dLarray(XID, "SSCB");
```

Create a discriminator using only the ID data. Set the method to "energy" with a temperature of 10. Specify the true positive goal as 0.975. To specify the true positive goal, you must specify ID data and not specify the false positive goal.

```
method = "energy";  
discriminator = networkDistributionDiscriminator(net,XID,[],method, ...  
    Temperature=10, ...  
    TruePositiveGoal=0.975)
```

```
discriminator =  
  EnergyDistributionDiscriminator with properties:  
  
    Method: "energy"
```

```

    Network: [1x1 dlnetwork]
    Temperature: 10
    Threshold: 23.5541

```

### Create Distribution Discriminator Using Only Out-of-Distribution Data

Load a pretrained classification network.

```
load("digitsClassificationMLPNet.mat");
```

Create OOD data. In this example, the OOD data is 1000 images of random noise. Each image is 28-by-28 pixels, the same size as the input to the network. Convert the data to a `darray` object.

```
X00D = rand([28 28 1 1000]);
X00D = darray(X00D,"SSCB");
```

Create a discriminator. Specify the false positive goal as 0.025. To specify the false positive goal, you must specify OOD data and not specify the true positive goal.

```
method = "baseline";
discriminator = networkDistributionDiscriminator(net,[],X00D,method, ...
    FalsePositiveGoal=0.025)
```

```
discriminator =
    BaselineDistributionDiscriminator with properties:

        Method: "baseline"
        Network: [1x1 dlnetwork]
        Threshold: 0.9998
```

### Create Distribution Discriminator for Regression Network

Load a pretrained regression network.

```
load("digitsRegressionMLPNet.mat")
```

Load ID data. Convert the data to a `darray` object.

```
XID = digitTrain4DArrayData;
XID = darray(XID,"SSCB");
```

Modify the ID training data to create an OOD set.

```
X00D = XID*0.3 + 0.1;
```

Create a discriminator. For regression tasks, set the method to "hbos". When using the HBOS method, you can specify additional options. Set the variance cutoff to 0.0001 and use the penultimate layer to compute the HBOS distribution scores.

```
method = "hbos";
discriminator = networkDistributionDiscriminator(net,XID,X00D,method, ...
```

```
VarianceCutoff=0.0001, ...
LayerNames="relu_2")

discriminator =
  HBOSDistributionDiscriminator with properties:

    Method: "hbos"
    Network: [1x1 dlnetwork]
    LayerNames: "relu_2"
    VarianceCutoff: 1.0000e-04
    Threshold: -54.0601
```

### Assess Performance of Distribution Discriminator

Load a pretrained classification network.

```
load('digitsClassificationMLPNet.mat');
```

Load ID data. Convert the data to a `darray` object and count the number of observations.

```
XID = digitTrain4DArrayData;
XID = darray(XID,"SSCB");
numObservations = size(XID,4);
```

Modify the ID training data to create an OOD set.

```
X00D = XID*0.3 + 0.1;
```

Create a discriminator. The function finds the threshold that best separates the two distributions of data.

```
method = "baseline";
discriminator = networkDistributionDiscriminator(net,XID,X00D,method);
```

Test the discriminator on the ID and OOD data using the `isInNetworkDistribution` function. The `isInNetworkDistribution` function returns a logical array indicating which observations are ID and which observations are OOD.

```
tfID = isInNetworkDistribution(discriminator,XID);
tf00D = isInNetworkDistribution(discriminator,X00D);
```

Calculate the accuracy for the ID and OOD observations.

```
accuracyID = sum(tfID == 1)/numel(tfID)
accuracyID = 0.9856
accuracy00D = sum(tf00D == 0)/numel(tf00D)
accuracy00D = 0.9402
```

Plot the confusion chart for the ID and OOD data.

```
trueDataLabels = [
    repmat("In-Distribution",numObservations), ...
```

```

    repelem("Out-of-Distribution",numObservations)];

predDataLabelsID = repelem("Out-of-Distribution",numObservations);
predDataLabelsID(tfID == 1) = "In-Distribution";

predDataLabelsOOD = repelem("Out-of-Distribution",numObservations);
predDataLabelsOOD(tfOOD == 1) = "In-Distribution";

predDataLabels = [predDataLabelsID,predDataLabelsOOD];

confusionchart(trueDataLabels,predDataLabels)

```

Use the `distributionScores` function to find the distribution scores for the ID and OOD data.

```

scoresID = distributionScores(discriminator,XID);
scoresOOD = distributionScores(discriminator,XOOD);
scores = [scoresID',scoresOOD'];

```

Use `rocmetrics` to plot a ROC curve to show how well the model is at separating the data into ID and OOD.

```

rocObj = rocmetrics(trueDataLabels,scores,"In-Distribution");
plot(rocObj)

```

## Input Arguments

### **net** — Neural network

`dlnetwork` object

Neural network, specified as a `dlnetwork` object.

### **XID** — In-distribution data

formatted `dlarray` object | []

In-distribution (ID) data, specified as a formatted `dlarray` object or []. For more information about `dlarray` formats, see the `fmt` input argument of `dlarray`.

At least one of the `XID` and `XOOD` input arguments must be nonempty.

For more information about ID and OOD data, see “In-Distribution and Out-of-Distribution Data” on page 1-1369.

### **XOOD** — Out-of-distribution data

formatted `dlarray` object | []

Out-of-distribution (OOD) data, specified as a formatted `dlarray` object or []. For more information about `dlarray` formats, see the `fmt` input argument of `dlarray`.

At least one of the `XID` and `XOOD` input arguments must be nonempty.

For more information about ID and OOD data, see “In-Distribution and Out-of-Distribution Data” on page 1-1369.

### method — Method for computing distribution confidence scores

"baseline" | "odin" | "energy" | "hbos"

Method for computing the distribution confidence scores, specified as one of these values:

- "baseline" — Use maximum softmax activations as the distribution confidence scores [1]. This method creates a `BaselineDistributionDiscriminator` object.
- "odin" — Use rescaled softmax activations as distribution confidence scores (also known as the ODIN method) [2]. Set the scale by specifying the `Temperature` name-value argument. This method creates an `ODINDistributionDiscriminator` object.
- "energy" — Use scaled, energy-based distribution confidence scores [3]. Set the scale by specifying the `Temperature` name-value argument. This method creates an `EnergyDistributionDiscriminator` object.
- "hbos" — Use histogram-based outlier scores (also known as the HBOS method) [4] as distribution confidence scores. The function computes the scores by constructing histograms for the principal component features for each layer that you specify in the `LayerNames` name-value argument. Use the `VarianceCutoff` name-value argument to control the number of principal component features the software uses. To use this method, `XID` must be nonempty. This method creates a `HBOSDistributionDiscriminator` object.

For more information about each method, see “Distribution Confidence Scores” on page 1-1370.

---

**Note** Specifying method as "baseline", "odin", or "energy" is valid only for single-output networks with a softmax layer as the final layer. For example, specifying `net` as a single-output classification network. You can specify method as "hbos" for any network.

---

Data Types: `char` | `string`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `TruePositiveGoal=0.99, Temperature=10`

### TruePositiveGoal — True positive goal

0.95 (default) | scalar in the range [0, 1]

True positive goal, specified as a scalar in the range [0, 1]. The software returns the threshold that correctly classifies at least this proportion of the ID data as ID.

### Dependency

If you specify a true positive goal, then `XID` must be nonempty and you cannot specify `FalsePositiveGoal`. If you specify a nonempty `XOOD` value, then the software uses only `XID` to compute the threshold.

If you do not specify the `TruePositiveGoal` and `FalsePositiveGoal` name-value arguments and provide nonempty `XID` and `XOOD` values, then the function does not use the default values and instead optimizes over the true positive rate and false positive rate to find the optimal threshold. For more information, see “Algorithms” on page 1-1372.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **FalsePositiveGoal — False positive goal**

`0.05` (default) | scalar in the range `[0, 1]`

False positive goal, specified as a scalar in the range `[0, 1]`. The software returns the threshold that incorrectly classifies at most this proportion of the OOD data as ID.

#### **Dependency**

If you specify a false positive goal, then `XOOD` must be nonempty and you must not specify `TruePositiveGoal`. If you specify a nonempty `XID` value, then the software uses only `XOOD` to compute the threshold.

If you do not specify the `TruePositiveGoal` and `FalsePositiveGoal` name-value arguments and provide nonempty `XID` and `XOOD` values, then the function does not use the default values and instead optimizes over the true positive rate and false positive rate to find the optimal threshold. For more information, see “Algorithms” on page 1-1372.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Temperature — Temperature scaling**

`1` (default) | positive scalar

Temperature scaling for the ODIN and energy methods, specified as a positive scalar. The temperature controls the scaling of the softmax scores when the function computes the distribution confidence scores. For more information, see “Distribution Confidence Scores” on page 1-1370.

#### **Dependency**

To enable this input, specify `method` as “`odin`” or “`energy`”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **LayerNames — Layer names**

string scalar | character vector | string array | cell array of character vectors

Layer names for the HBOS method, specified as a string scalar, character vector, string array, or cell array of character vectors. The default value is the first layer specified in the `OutputNames` property of `net`.

The software computes the distribution confidence scores using the principal components from all of the specified layers. For more information, see “Density-Based Methods” on page 1-1371.

---

**Note** To compute the histograms, the software must first compute the principal component features for each layer. Computing the principal components can be slow for layers with a large output size and can cause you to run out of memory. If you run out of memory, try specifying layers with a smaller output size. For more information, see “Density-Based Methods” on page 1-1371.

---

**Dependency**

To enable this input, specify method as "hbos".

Data Types: char | string | cell

**VarianceCutoff — Variance cutoff**

1e-3 (default) | scalar in the range [0, 1]

Variance cutoff for the HBOS method, specified as a scalar in the range [0, 1].

The variance cutoff controls the number of principal component features that the software uses to compute the distribution confidence scores. Using a greater number of features takes more computation time. The closer the VarianceCutoff value is to 1, the fewer principal components the software uses to compute the scores. For more information, see “Density-Based Methods” on page 1-1371.

**Dependency**

To enable this input, specify method as "hbos".

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Output Arguments****discriminator — Distribution discriminator**

BaselineDistributionDiscriminator object | ODINDistributionDiscriminator object | EnergyDistributionDiscriminator object | HBOSDistributionDiscriminator object

Distribution discriminator, returned as a BaselineDistributionDiscriminator, ODINDistributionDiscriminator, EnergyDistributionDiscriminator, or HBOSDistributionDiscriminator object.

The function returns this output as a BaselineDistributionDiscriminator, ODINDistributionDiscriminator, EnergyDistributionDiscriminator, or HBOSDistributionDiscriminator object when you specify method as "baseline", "odin", "energy", or "hbos", respectively.

The Threshold property of discriminator contains the threshold for separating the ID and OOD data. To access the threshold value, call discriminator.Threshold.

**More About****In-Distribution and Out-of-Distribution Data**

In-distribution (ID) data refers to any data that you use to construct and train your model. Additionally, any data that is sufficiently similar to the training data is also said to be ID.

Out-of-distribution (OOD) data refers to data that is sufficiently different to the training data. For example, data collected in a different way, at a different time, under different conditions, or for a different task than the data on which the model was originally trained. Models can receive OOD data when you deploy them in an environment other than the one in which you train them. For example, suppose you train a model on clear X-ray images but then deploy the model on images taken with a lower-quality camera.

OOD data detection is important for assigning confidence to the predictions of a network. For more information, see “OOD Data Detection” on page 1-1370.

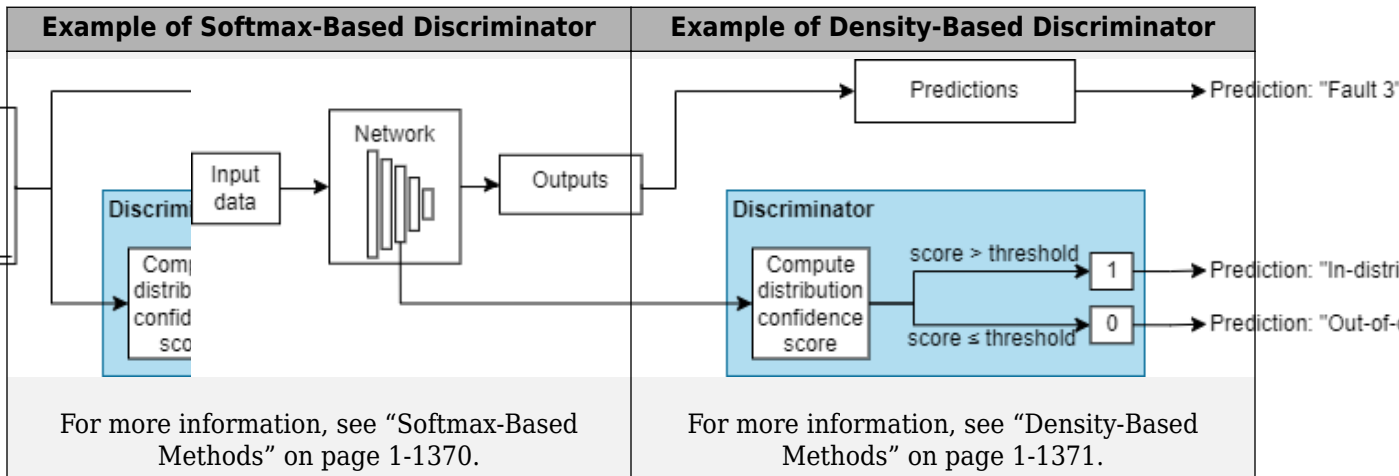

**OOD Data Detection**

OOD data detection is a technique for assessing whether the inputs to a network are OOD. For methods that you apply after training, you can construct a discriminator which acts as an additional output of the trained network that classifies an observation as ID or OOD.

The discriminator works by finding a distribution confidence score for an input. You can then specify a threshold. If the score is less than or equal to that threshold, then the input is OOD. Two groups of metrics for computing distribution confidence scores are softmax-based and density-based methods. Softmax-based methods use the softmax layer to compute the scores. Density-based methods use the outputs of layers that you specify to compute the scores. For more information about how to compute distribution confidence scores, see “Distribution Confidence Scores” on page 1-1370.

These images show how a discriminator acts as an additional output of a trained neural network.

**Example Data Discriminators**

**Distribution Confidence Scores**

Distribution confidence scores are metrics for classifying data as ID or OOD. If an input has a score less than or equal to a threshold value, then you can classify that input as OOD. You can use different techniques for finding the distribution confidence scores.

**Softmax-Based Methods**

ID data usually corresponds to a higher softmax output than OOD data[1]. Therefore, a method of defining distribution confidence scores is as a function of the softmax scores. These methods are called *softmax-based* methods. These methods only work for classification networks with a single softmax output.

Let  $a_i(X)$  be the input to the softmax layer for class  $i$ . The output of the softmax layer for class  $i$  is given by this equation:

$$P_i(X; T) = \frac{e^{a_i(X)/T}}{\sum_{j=1}^C e^{a_j(X)/T}}$$

where  $C$  is the number of classes and  $T$  is a temperature scaling. When the network predicts the class label of  $X$ , the temperature  $T$  is set to 1.

The baseline, ODIN, and energy methods each define distribution confidence scores as functions of the softmax input.

- The *baseline* method [1] uses the maximum of the unscaled output values of the softmax scores:

$$\text{confidence}(X) = \max_i P_i(X; 1).$$

- The out-of-distribution detector for neural networks (ODIN) method [2] uses the maximum of the scaled output of the softmax scores:

$$\text{confidence}(X; T) = \max_i P_i(X; T), \quad T > 0.$$

- The *energy* method [3] uses the scaled denominator of the softmax output:

$$\text{energy}(X; T) = -T \log \left( \sum_{j=1}^C e^{a_j(X)/T} \right), \quad T > 0$$

$$\text{confidence}(X; T) = -\text{energy}(X; T), \quad T > 0.$$

### Density-Based Methods

Density-based methods compute the distribution scores by describing the underlying features learned by the network as probabilistic models. Observations falling into areas of low density correspond to OOD observations.

To model the distributions of the features, you can describe the density function for each feature using a histogram. This technique is based on the histogram-based outlier score (HBOS) method [4]. This method uses a data set of ID data, such as training data, to construct histograms representing the density distributions of the ID features. This method has three stages:

- 1 Find the principal component features for which to compute the distribution confidence scores:
  - a For each specified layer, find the activations using the  $n$  data set observations. Flatten the activations across all dimensions except the batch dimension.
  - b Compute the principal components of the flattened activations matrix. Normalize the eigenvalues such that the largest eigenvalue is 1 and corresponds to the principal component that carries the greatest variance through the layer. Denote the matrix of principal components for layer  $l$  by  $Q^{(l)}$ .

The principal components are linear combinations of the activations and represent the features that the software uses to compute the distribution scores. To compute the score, the software uses only the principal components whose eigenvalues are greater than the variance cutoff value  $\sigma$ .

---

**Note** The HBOS algorithm assumes that the features are statistically independent. The principal component features are pairwise linearly independent but they can have nonlinear dependencies. To investigate feature dependencies, you can use functions such as `corr`. For an example showing how to investigate feature dependence, see “Out-of-Distribution Data Discriminator for YOLO v4 Object Detector”. If the features are not statistically independent, then the algorithm can return poor results. Using multiple layers to compute the distribution scores can increase the number of statistically dependent features.

---

- 2 For each of the principal component features with an eigenvalue greater than  $\sigma$ , construct a histogram. For each histogram:
  - a Dynamically adjusts the width of the bins to create  $\sqrt{n}$  bins of approximately equal area.
  - b Normalize the bins heights such that the largest height is 1.
- 3 Find the distribution score for an observation by summing the logarithmic height of the bin containing the observation for each of the feature histograms, over each of the layers.

Let  $f^{(l)}(X)$  denote the output of layer  $l$  for input  $X$ . Use the principal components to project the output into a lower dimensional feature space using this equation:  $\hat{f}^{(l)}(X) = (Q^{(l)})^T f^{(l)}(X)$ .

Compute the confidence score using this equation:

$$\text{HBOS}(X; \sigma) = - \sum_{l=1}^L \left( \sum_{k=1}^{N^{(l)}(\sigma)} \log(\text{hist}_k(\hat{f}_k^{(l)}(X))) \right),$$

$$\text{confidence}(X; \sigma) = - \text{HBOS}(X; \sigma),$$

where  $N^{(l)}(\sigma)$  is the number of number of principal component with an eigenvalue less than  $\sigma$  and  $L$  is the number of layers. A larger score corresponds to an observation that lies in the areas of higher density. If the observation lies outside of the range of any of the histograms, then the bin height for those histograms is 0 and the confidence score is `-Inf`.

---

**Note** The distribution scores depend on the properties of the data set used to construct the histograms [6].

---

## Algorithms

The function creates a discriminator using the trained network. The discriminator behaves as an additional output of the network and classifies an observation as ID or OOD using a threshold. For more information, see “OOD Data Detection” on page 1-1370.

To compute the distribution threshold, the function first computes the distribution confidence scores using the method that you specify in the `method` input argument. For more information, see “Distribution Confidence Scores” on page 1-1370. The software then finds the threshold that best separates the scores of the ID and OOD data. To find the threshold, the software optimizes over these values:

- True positive goal — Number of ID observations that the discriminator correctly classifies as ID. To optimize for this value, the ID data `XID` must be nonempty and you must specify `TruePositiveGoal`. If you specify `TruePositiveGoal` as `p`, then the software finds the threshold above which the proportion of ID confidence scores is `p`. This process is equivalent to finding the 100(1-`p`)-th percentile for the ID confidence scores.
- False positive goal — Number of OOD observations that the discriminator incorrectly classifies as ID. To optimize for this value, the OOD data `XOOD` must be nonempty and you must specify `FalsePositiveGoal`. If you specify `FalsePositiveGoal` as `p`, then the software finds the threshold above which the proportion of OOD confidence scores is `p`. This process is equivalent to finding the 100`p`-th percentile for the OOD confidence scores.

If you provide ID and OOD data and do not specify `TruePositiveGoal` or `FalsePositiveGoal`, then the software finds the threshold that maximizes the balanced accuracy  $\frac{1}{2}(TPR + (1 - FPR))$ . If you provide only ID data, then the software optimizes using only `TruePositiveGoal`, whose default is  $0.95$ . If you provide only OOD data, then the software optimizes using only `FalsePositiveGoal`, whose default is  $0.05$ .

This figure illustrates the different thresholds that the software chooses if you optimize over both the true positive rate and false positive rate, just the true positive rate, or just the false positive rate.

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function runs on the GPU if its inputs meet either or both of these conditions:
  - Any values of the network learnable parameters are `darray` objects with underlying data of type `gpuArray`. To see the learnables for a network `net`, call `net.Learnables.Value`.
  - Any of the data is a `darray` object with underlying data of type `gpuArray`.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# neuronPCA

Principal component analysis of neuron activations

## Description

The `compressNetworkUsingProjection` function uses principal component analysis (PCA) to identify the subspace of learnable parameters that result in the highest variance in neuron activations by analyzing the network activations using a data set representative of the training data. The PCA step can be computationally intensive. If you expect to compress the same network multiple times (for example, when exploring different levels of compression), then you can perform the PCA step up front using a `neuronPCA` object.

Forward passes of a projected deep neural network are typically faster when you deploy the network to embedded hardware using library-free C or C++ code generation.

If you prune or quantize your network, then use compression using projection after pruning and before quantization. Network compression using projection supports projecting LSTM layers only.

## Creation

### Syntax

```
npca = neuronPCA(net,mbq)
npca = neuronPCA(net,X1,...,XN)
npca = neuronPCA( ___,LayerNames=names)
npca = neuronPCA( ___,VerbosityLevel=level)
```

### Description

`npca = neuronPCA(net,mbq)` computes the principal component analysis of the neuron activations in `net` using the data in the mini-batch queue `mbq`. The software analyzes the input and output activations of the projectable layers in `net`. This function requires the Deep Learning Toolbox Model Quantization Library support package. This support package is a free add-on that you can download using the Add-On Explorer. Alternatively, see Deep Learning Toolbox Model Quantization Library.

`npca = neuronPCA(net,X1,...,XN)` computes the principal component analysis of the neuron activations using the data in the `darray` objects `X1,...,XN`, where `N` is the number of network inputs.

`npca = neuronPCA( ___,LayerNames=names)` specifies which layers to analyze and sets the `LayerNames` property.

`npca = neuronPCA( ___,VerbosityLevel=level)` specifies the amount of information displayed in the command window.

## Input Arguments

### **net** — Neural network

initialized `dlnetwork` object

Neural network, specified as an initialized `dlnetwork` object.

### **mbq** — Mini-batch queue

`minibatchqueue` object

Mini-batch queue that outputs data for each input of the network, specified as a `minibatchqueue` object.

The PCA step typically works best when using the full training set. However, any dataset that is representative of the training data distribution suffices. The input data must contain two or more observations and sequences must contain two or more time steps.

---

**Note** Do not pad sequence as this can negatively impact the analysis. Instead, truncate mini-batches of data to have the same length or use mini-batches of size 1.

---

### **X1, . . . , XN** — Input data

formatted `dlarray`

Input data, specified as a formatted `dlarray`.

For more information about `dlarray` formats, see the `fmt` input argument of `dlarray`.

The PCA step typically works best when using the full training set. However, any dataset that is representative of the training data distribution suffices. The input data must contain two or more observations and sequences must contain two or more time steps.

---

**Note** Do not pad sequence as this can negatively impact the analysis. Instead, truncate mini-batches of data to have the same length or use mini-batches of size 1.

---

### **level** — Verbosity level

"summary" (default) | "steps" | "iterations" | "off"

Verbosity level, specified as one of these values:

- "summary" — Display a summary of the neuron PCA algorithm.
- "steps" — Display information about the steps of the neuron PCA algorithm.
- "iterations" — Display information about the iterations of the neuron PCA algorithm.
- "off" — Do not display information.

## Properties

### **LayerNames** — Names of layers to analyze

string array | cell array of character vectors | character vector

Names of layers to analyze, specified as a string array, cell array of character vectors, or a character vector containing a single layer name.

The software, by default, analyzes all the layers in the network that support projection. Network compression using projection supports projecting LSTM layers only.

Data Types: `string` | `cell`

### **InputEigenvalues — Eigenvalues of activations input to projectable layers**

cell array

Eigenvalues of activations input to projectable layers, specified as a cell array. Each element contains the input eigenvalues for the corresponding projectable layer in `LayerNames`.

Data Types: `cell`

### **InputEigenvectors — Eigenvectors of activations input to projectable layers**

cell array

Eigenvectors of activations input to projectable layers, specified as a cell array. Each element contains the input eigenvectors for the corresponding projectable layer in `LayerNames`.

Data Types: `cell`

### **OutputEigenvalues — Eigenvalues of activations output by projectable layers**

cell array

Eigenvalues of activations output by projectable layers, specified as a cell array. Each element contains the output eigenvalues for the corresponding projectable layer in `LayerNames`.

Data Types: `cell`

### **OutputEigenvectors — Eigenvectors of activations output by projectable layers**

cell array

Eigenvectors of activations output by projectable layers, specified as a cell array. Each element contains the output eigenvectors for the corresponding projectable layer in `LayerNames`.

Data Types: `cell`

## **Examples**

### **Analyze Neuron Activations for Compression Using Projection**

Load the pretrained network in `dlnetJapaneseVowels` and the training data.

```
load dlnetJapaneseVowels
XTrain = japaneseVowelsTrainData;
```

Create a mini-batch queue containing the training data. To create a mini-batch queue from in-memory data, convert the sequences to an array datastore.

```
adsXTrain = arrayDatastore(XTrain,OutputType="same");
```

Create the `minibatchqueue` object.

- Specify a mini-batch size of 16.
- Preprocess the mini-batches using the `preprocessMiniBatchPredictors` function, listed in the Mini-Batch Predictors Preprocessing Function section of the example.
- Specify that the output data has format "CTB" (channel, time, batch).

```
miniBatchSize = 16;
```

```
mbqTrain = minibatchqueue(adsXTrain, ...  
    MiniBatchSize=miniBatchSize, ...  
    MiniBatchFcn=@preprocessMiniBatchPredictors, ...  
    MiniBatchFormat="CTB");
```

Create the `neuronPCA` object.

```
npca = neuronPCA(net,mbqTrain);
```

```
neuronPCA analyzed 1 layers: "lstm"
```

View the properties of the `neuronPCA` object.

```
npca
```

```
npca =  
    neuronPCA with properties:  
  
        LayerNames: "lstm"  
    InputEigenvalues: {[12×1 double]}  
    InputEigenvectors: {[12×12 double]}  
    OutputEigenvalues: {[100×1 double]}  
    OutputEigenvectors: {[100×100 double]}
```

### Mini-Batch Predictors Preprocessing Function

The `preprocessMiniBatchPredictors` function preprocesses a mini-batch of predictors by extracting the sequence data from the input cell array and truncating them along the second dimension so that they have the same length.

**Note:** Do not pad sequence data when doing the PCA step for projection as this can negatively impact the analysis. Instead, truncate mini-batches of data to have the same length or use mini-batches of size 1.

```
function X = preprocessMiniBatchPredictors(dataX)
```

```
X = padsequences(dataX,2,Length="shortest");
```

```
end
```

## Version History

Introduced in R2022b

### Extended Capabilities

#### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function runs on the GPU if any of these conditions are met:
  - Any of the values of the network learnable parameters inside `net.Learnables.Value` are `dLarray` objects with underlying data of type `gpuArray`
  - The input argument `mbq` outputs `dLarray` objects with underlying data of type `gpuArray`
  - The input arguments `X1, . . . , XN` are `dLarray` objects with underlying data of type `gpuArray`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

## next

Obtain next mini-batch of data from minibatchqueue

### Syntax

```
[x1,...,xN] = next(mbq)
```

### Description

[x1,...,xN] = next(mbq) returns a mini-batch of data prepared using the minibatchqueue object mbq. The function returns as many variables as the number of outputs of mbq.

### Examples

#### Obtain Mini-Batch

Create a minibatchqueue object and obtain a mini-batch.

Create a minibatchqueue object from a datastore. Set the MiniBatchSize property to 2.

```
auimds = augmentedImageDatastore([100 100],digitDatastore);  
mbq = minibatchqueue(auimds,'MiniBatchSize',2,'MiniBatchFormat',{'SSBC','BC'})
```

mbq =  
minibatchqueue with 2 outputs and properties:

```
Mini-batch creation:  
    MiniBatchSize: 2  
    PartialMiniBatch: 'return'  
    MiniBatchFcn: 'collate'  
    DispatchInBackground: 0  
  
Outputs:  
    OutputCast: {'single' 'single'}  
    OutputAsDlarray: [1 1]  
    MiniBatchFormat: {'SSBC' 'BC'}  
    OutputEnvironment: {'auto' 'auto'}
```

Use next to obtain a mini-batch. mbq has two outputs.

```
[X,Y] = next(mbq);
```

X is a mini-batch containing two images from the datastore. Y contains the classification labels of those images. Check the size and data format of the mini-batch variables.

```
size(X)  
dims(X)  
size(Y)  
dims(Y)  
  
ans = 1x4  
    100    100     1     2
```

```
ans = 'SSCB'  
ans = 1×2  
      1      2  
ans = 'CB'
```

## Input Arguments

### **mbq** — Mini-batch queue

minibatchqueue object

Mini-batch queue, specified as a minibatchqueue object.

## Output Arguments

### **[x1, ..., xN]** — Mini-batch

numeric array | cell array

Mini-batch, returned as a numeric array or cell array.

The number and type of variables returned by `next` depends on the configuration of `mbq`. The function returns as many variables as the number of outputs of `mbq`.

## occlusionSensitivity

Explain network predictions by occluding the inputs

### Syntax

```
scoreMap = occlusionSensitivity(net,X,label)
activationMap = occlusionSensitivity(net,X,layer,channel)
___ = occlusionSensitivity(___ ,Name,Value)
```

### Description

`scoreMap = occlusionSensitivity(net,X,label)` computes a map of the change in classification score for the classes specified by `label` when parts of the input data `X` are occluded with a mask. The change in classification score is relative to the original data without occlusion. The occluding mask is moved across the input data, giving a change in classification score for each mask location. Use an occlusion sensitivity map to identify the parts of your input data that most impact the classification score. Areas in the map with higher positive values correspond to regions of input data that contribute positively to the specified classification label. The network must contain a `classificationLayer`.

`activationMap = occlusionSensitivity(net,X,layer,channel)` computes a map of the change in total activation for the specified layer and channel when parts of the input data `X` are occluded with a mask. The change in activation score is relative to the original data without occlusion. Areas in the map with higher positive values correspond to regions of input data that contribute positively to the specified channel activation, obtained by summing over all spatial dimensions for that channel. The total activation fulfills the role of the class score for classification tasks and generalizes the occlusion sensitivity technique to nonclassification tasks.

Use this syntax to compute the occlusion sensitivity map for nonclassification tasks, such as regression, or for use with a network containing a custom classification layer.

`___ = occlusionSensitivity(___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, `'Stride',50` sets the stride of the occluding mask to 50 pixels.

### Examples

#### Visualize Which Parts of an Image Influence Classification Score

Import the pretrained network GoogLeNet.

```
net = googlenet;
```

Import the image and resize to match the input size for the network.

```
X = imread("sherlock.jpg");
inputSize = net.Layers(1).InputSize(1:2);
X = imresize(X,inputSize);
```

Display the image.

```
imshow(X)
```

Classify the image to get the class label.

```
label = classify(net,X)
```

```
label = categorical  
       golden retriever
```

Use `occlusionSensitivity` to determine which parts of the image positively influence the classification result.

```
scoreMap = occlusionSensitivity(net,X,label);
```

Plot the result over the original image with transparency to see which areas of the image affect the classification score.

```
figure  
imshow(X)  
hold on  
imagesc(scoreMap,'AlphaData',0.5);  
colormap jet
```

The red parts of the map show the areas which have a positive contribution to the specified label. The dog's left eye and ear strongly influence the network's prediction of golden retriever.

You can get similar results using the gradient class activation mapping (Grad-CAM) technique. Grad-CAM uses the gradient of the classification score with respect to the last convolutional layer in a network in order to understand which parts of the image are most important for classification. For an example, see “Grad-CAM Reveals the Why Behind Deep Learning Decisions”.

## Input Arguments

### **net** — Trained network

SeriesNetwork object | DAGNetwork object

Trained network, specified as a SeriesNetwork object or a DAGNetwork object. You can get a trained network by importing a pretrained network or by training your own network using the `trainNetwork` function. For more information about pretrained networks, see “Pretrained Deep Neural Networks”.

`net` must contain a single input layer. The input layer must be an `imageInputLayer`.

### **X** — Observation to occlude

numeric array

Observation to occlude, specified as a numeric array. You can calculate the occlusion sensitivity map of one observation at a time. For example, specify a single image to understand which parts of that image affect classification results.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **label** — Class label used to calculate change in classification score

categorical array | character array | string array

Class label used to calculate change in classification score, specified as a categorical, a character array, or a string array.

If you specify `label` as a vector, the software calculates the change in classification score for each class label independently. In that case, `scoreMap(:, :, i)` corresponds to the occlusion sensitivity map for the *i*th element in `label`.

Data Types: `char` | `string` | `categorical`

### **layer** — Layer used to calculate change in activation

`character vector` | `string scalar`

Layer used to calculate change in activation, specified as a character vector or a string scalar. Specify `layer` as the name of the layer in `net` for which you want to compute the change in activations.

Data Types: `char` | `string`

### **channel** — Channel used to calculate change in activation

`numeric index` | `vector of numeric indices`

Channel used to calculate change in activation, specified as scalar or vector of channel indices. The possible choices for `channel` depend on the selected layer. For example, for convolutional layers, the `NumFilters` property specifies the number of output channels. You can use `analyzeNetwork` to inspect the network and find out the number of output channels for each layer.

If `channel` is specified as a vector, the change in total activation for each specified channel is calculated independently. In that case, `activationMap(:, :, i)` corresponds to the occlusion sensitivity map for the *i*th element in `channel`.

The function computes the change in total activation due to occlusion. The total activation is computed by summing over all spatial dimensions of the activation of that channel. The occlusion sensitivity map corresponds to the difference between the total activation of the original data with no occlusion and the total activation for the occluded data. Areas in the map with higher positive values correspond to regions of input data that contribute positively to the specified channel activation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'MaskSize', 75, 'OutputUpsampling', 'nearest'` uses an occluding mask with size 75 pixels along each side, and uses nearest-neighbor interpolation to upsample the output to the same size as the input data

### **MaskSize** — Size of occluding mask

`'auto'` (default) | `vector` | `scalar`

Size of occluding mask, specified as the comma-separated pair consisting of `'MaskSize'` and one of the following.

- `'auto'` — Use a mask size of 20% of the input size, rounded to the nearest integer.

- A vector of the form `[h w]`— Use a rectangular mask with height `h` and width `w`.
- A scalar — Use a square mask with height and width equal to the specified value.

Example: `'MaskSize',[50 60]`

### **Stride — Step size for traversing mask across input data**

`'auto'` (default) | vector | scalar

Step size for traversing the mask across the input data, specified as the comma-separated pair consisting of `'Stride'` and one of the following.

- `'auto'` — Use a stride of 10% of the input size, rounded to the nearest integer.
- A vector of the form `[a b]`— Use a vertical stride of `a` and a horizontal stride of `b`.
- A scalar — Use a stride of the specified value in both the vertical and horizontal directions.

Example: `'Stride',30`

### **MaskValue — Replacement value of occluded region**

`'auto'` (default) | scalar | vector

Replacement value of occluded region, specified as the comma-separated pair consisting of `'MaskValue'` and one of the following.

- `'auto'` — Replace occluded pixels with the channel-wise mean of the input data.
- A scalar — Replace occluded pixels with the specified value.
- A vector — Replace occluded pixels with the value specified for each channel. The vector must contain the same number of elements as the number of output channels of the layer.

Example: `'MaskValue',0.5`

### **OutputUpsampling — Output upsampling method**

`'bicubic'` (default) | `'nearest'` | `'none'`

Output upsampling method, specified as the comma-separated pair consisting of `'OutputUpsampling'` and one of the following.

- `'bicubic'` — Use bicubic interpolation to produce a smooth map the same size as the input data.
- `'nearest'` — Use nearest-neighbor interpolation expand the map to the same size as the input data. The map indicates the resolution of the occlusion computation with respect to the size of the input data.
- `'none'` — Use no upsampling. The map can be smaller than the input data.

If `'OutputUpsampling'` is `'bicubic'` or `'nearest'`, the computed map is upsampled to the size of the input data using the `imresize` function.

Example: `'OutputUpsampling','nearest'`

### **MaskClipping — Edge handling of the occluding mask**

`'on'` (default) | `'off'`

Edge handling of the occluding mask, specified as the comma-separated pair consisting of `'MaskClipping'` and one of the following.

- 'on' — Place the center of the first mask at the top-left corner of the input data. Masks at the edges of the data are not full size.
- 'off' — Place the top-left corner of the first mask at the top-left corner of the input data. Masks are always full size. If the values of the `MaskSize` and `Stride` options mean that some masks extend past the boundaries of the data, those masks are excluded.

For non-image input data, you can ensure you always occlude the same amount of input data using the option `'MaskClipping', 'off'`. For example, for word embeddings data, you can ensure the same number of words are occluded at each point.

Example: `'MaskClipping', 'off'`

### **MiniBatchSize — Size of mini-batch**

128 (default) | positive integer

Size of the mini-batch to use to compute the map of change in classification score, specified as the comma-separated pair consisting of `'MiniBatchSize'` and a positive integer.

A mini-batch is a subset of the set of occluded images as the mask is moved across the input image. All occluded images are used to calculate the map; the mini-batch determines the number of images that are passed to the network at once. Larger mini-batch sizes lead to faster computation, at the cost of more memory.

Example: `'MiniBatchSize', 256`

### **ExecutionEnvironment — Hardware resource**

'auto' (default) | 'cpu' | 'gpu'

Hardware resource for computing map, specified as the comma-separated pair consisting of `'ExecutionEnvironment'` and one of the following.

- 'auto' — Use a GPU if one is available. Otherwise, use the CPU.
- 'cpu' — Use the CPU.
- 'gpu' — Use the GPU.

The GPU option requires Parallel Computing Toolbox. To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). If you choose the `'ExecutionEnvironment', 'gpu'` option and Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.

Example: `'ExecutionEnvironment', 'gpu'`

## **Output Arguments**

### **scoreMap — Map of change of classification score**

numeric matrix | numeric array

Map of change of classification score, returned as a numeric matrix or a numeric array. The change in classification score is calculated relative to the original input data without occlusion. Areas in the map with higher positive values correspond to regions of input data that contribute positively to the specified classification label.

If `label` is specified as a vector, the change in classification score for each class label is calculated independently. In that case, `scoreMap(:, :, i)` corresponds to the occlusion sensitivity map for the `i`th element in `label`.

### **activationMap — Map of change of total activation**

numeric matrix | numeric array

Map of change of total activation, returned as a numeric matrix or a numeric array.

The function computes the change in total activation due to occlusion. The total activation is computed by summing over all spatial dimensions of the activation of that channel. The occlusion sensitivity map corresponds to the difference between the total activation of the original data with no occlusion and the total activation for the occluded data. Areas in the map with higher positive values correspond to regions of input data that contribute positively to the specified channel activation.

If `channels` is specified as a vector, the change in total activation for each specified channel is calculated independently. In that case, `activationMap(:, :, i)` corresponds to the occlusion sensitivity map for the `i`th element in `channel`.

# ODINDistributionDiscriminator

ODIN distribution discriminator

## Description

The `ODINDistributionDiscriminator` is a distribution discriminator that uses the out-of-distribution detector for neural networks (ODIN) method to compute distribution confidence scores. The object contains a threshold that you can use to separate observations into in-distribution (ID) and out-of-distribution (OOD) data sets.

## Creation

Create an `ODINDistributionDiscriminator` object using the `networkDistributionDiscriminator` function and setting the method input argument to "odin".

---

**Note** The object type depends on the method you specify when you use the `networkDistributionDiscriminator` function. The method determines how the software computes the distribution confidence scores. You can set the method argument to either "baseline", "odin", "energy", or "hbos". For more information, see “Distribution Confidence Scores” on page 1-1391.

---

## Properties

### Method — Method for computing distribution confidence scores

"odin"

This property is read-only.

Method for computing the distribution confidence scores, returned as "odin". For more information, see “Distribution Confidence Scores” on page 1-1391.

### Network — Deep learning network

`dlnetwork` object

This property is read-only.

Deep learning network, returned as a `dlnetwork` object.

### Temperature — Temperature scaling

positive scalar

This property is read-only.

Temperature scaling, returned as a positive scalar. The temperature controls the scaling of the softmax scores when the software computes the distribution confidence scores. For more information, see “Distribution Confidence Scores” on page 1-1391.

Example: 1000

**Threshold – Distribution threshold**

positive scalar

This property is read-only.

Distribution threshold, returned as a positive scalar. The threshold separates the ID and OOD data using the distribution confidence scores.

Example: 1.2

**Object Functions**

`isInNetworkDistribution` Determine whether data is within the distribution of the network  
`distributionScores` Distribution confidence scores

**Examples****Create Distribution Discriminator Using ODIN Method**

Load a pretrained classification network.

```
load("digitsClassificationMLPNet.mat");
```

Load ID data. Convert the data to a `darray` object.

```
XID = digitTrain4DArrayData;  
XID = darray(XID, "SSCB");
```

Modify the ID training data to create an OOD set.

```
X00D = XID.*0.3 + 0.1;
```

Create a discriminator using the ODIN method. Set the temperature scaling to 1000.

```
method="odin";  
discriminator = networkDistributionDiscriminator(net,XID,X00D,method, ...  
    Temperature=1000)
```

```
discriminator =  
    ODINDistributionDiscriminator with properties:
```

```
    Method: "odin"  
    Network: [1x1 dlnetwork]  
    Temperature: 1000  
    Threshold: 0.1009
```

Assess the performance of the discriminator on the OOD data.

```
tf = isInNetworkDistribution(discriminator,X00D);  
accuracy = sum(tf == 0)/numel(tf)
```

```
accuracy = 0.9074
```

## More About

### In-Distribution and Out-of-Distribution Data

In-distribution (ID) data refers to any data that you use to construct and train your model. Additionally, any data that is sufficiently similar to the training data is also said to be ID.

Out-of-distribution (OOD) data refers to data that is sufficiently different to the training data. For example, data collected in a different way, at a different time, under different conditions, or for a different task than the data on which the model was originally trained. Models can receive OOD data when you deploy them in an environment other than the one in which you train them. For example, suppose you train a model on clear X-ray images but then deploy the model on images taken with a lower-quality camera.

OOD data detection is important for assigning confidence to the predictions of a network. For more information, see “OOD Data Detection” on page 1-1391.

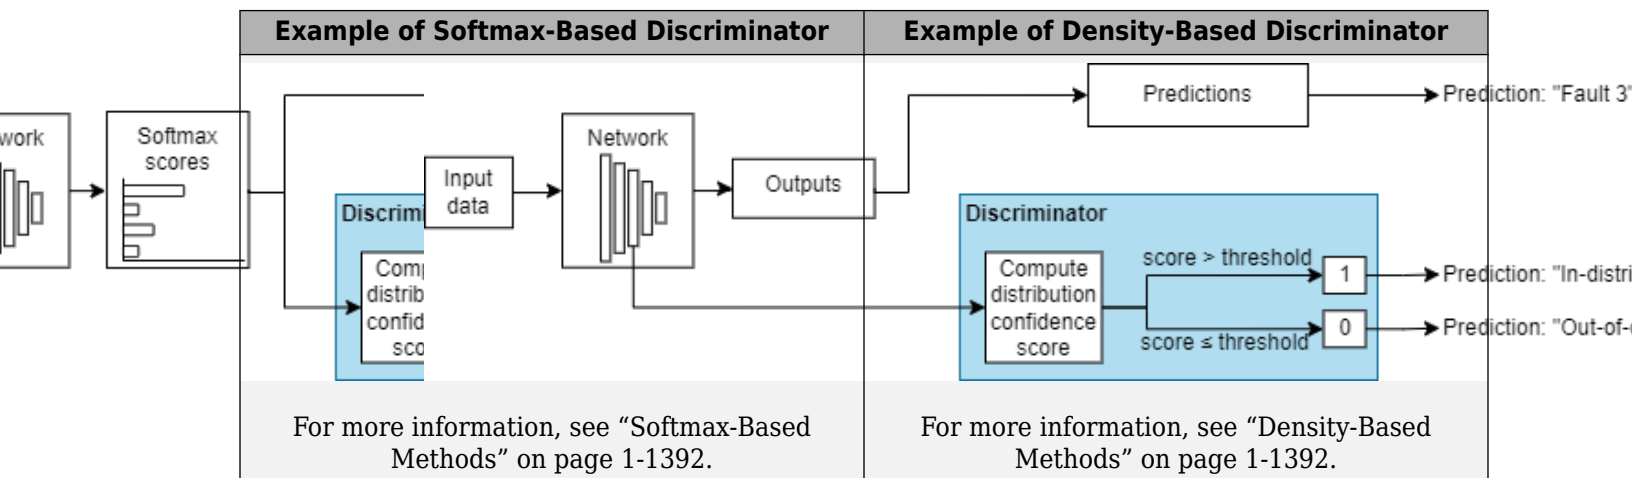

### OOD Data Detection

OOD data detection is a technique for assessing whether the inputs to a network are OOD. For methods that you apply after training, you can construct a discriminator which acts as an additional output of the trained network that classifies an observation as ID or OOD.

The discriminator works by finding a distribution confidence score for an input. You can then specify a threshold. If the score is less than or equal to that threshold, then the input is OOD. Two groups of metrics for computing distribution confidence scores are softmax-based and density-based methods. Softmax-based methods use the softmax layer to compute the scores. Density-based methods use the outputs of layers that you specify to compute the scores. For more information about how to compute distribution confidence scores, see “Distribution Confidence Scores” on page 1-1391.

These images show how a discriminator acts as an additional output of a trained neural network.

### Example Data Discriminators

### Distribution Confidence Scores

Distribution confidence scores are metrics for classifying data as ID or OOD. If an input has a score less than or equal to a threshold value, then you can classify that input as OOD. You can use different techniques for finding the distribution confidence scores.

### Softmax-Based Methods

ID data usually corresponds to a higher softmax output than OOD data[1]. Therefore, a method of defining distribution confidence scores is as a function of the softmax scores. These methods are called *softmax-based* methods. These methods only work for classification networks with a single softmax output.

Let  $a_i(X)$  be the input to the softmax layer for class  $i$ . The output of the softmax layer for class  $i$  is given by this equation:

$$P_i(X; T) = \frac{e^{a_i(X)/T}}{\sum_{j=1}^C e^{a_j(X)/T}},$$

where  $C$  is the number of classes and  $T$  is a temperature scaling. When the network predicts the class label of  $X$ , the temperature  $T$  is set to 1.

The baseline, ODIN, and energy methods each define distribution confidence scores as functions of the softmax input.

- The *baseline* method [1] uses the maximum of the unscaled output values of the softmax scores:

$$\text{confidence}(X) = \max_i P_i(X; 1).$$

- The out-of-distribution detector for neural networks (ODIN) method [2] uses the maximum of the scaled output of the softmax scores:

$$\text{confidence}(X; T) = \max_i P_i(X; T), \quad T > 0.$$

- The *energy* method [3] uses the scaled denominator of the softmax output:

$$\text{energy}(X; T) = -T \log \left( \sum_{j=1}^C e^{a_j(X)/T} \right), \quad T > 0$$

$$\text{confidence}(X; T) = -\text{energy}(X; T), \quad T > 0.$$

### Density-Based Methods

Density-based methods compute the distribution scores by describing the underlying features learned by the network as probabilistic models. Observations falling into areas of low density correspond to OOD observations.

To model the distributions of the features, you can describe the density function for each feature using a histogram. This technique is based on the histogram-based outlier score (HBOS) method [4]. This method uses a data set of ID data, such as training data, to construct histograms representing the density distributions of the ID features. This method has three stages:

- 1 Find the principal component features for which to compute the distribution confidence scores:
  - a For each specified layer, find the activations using the  $n$  data set observations. Flatten the activations across all dimensions except the batch dimension.
  - b Compute the principal components of the flattened activations matrix. Normalize the eigenvalues such that the largest eigenvalue is 1 and corresponds to the principal component that carries the greatest variance through the layer. Denote the matrix of principal components for layer  $l$  by  $Q^{(l)}$ .

The principal components are linear combinations of the activations and represent the features that the software uses to compute the distribution scores. To compute the score, the software uses only the principal components whose eigenvalues are greater than the variance cutoff value  $\sigma$ .

---

**Note** The HBOS algorithm assumes that the features are statistically independent. The principal component features are pairwise linearly independent but they can have nonlinear dependencies. To investigate feature dependencies, you can use functions such as `corr`. For an example showing how to investigate feature dependence, see “Out-of-Distribution Data Discriminator for YOLO v4 Object Detector”. If the features are not statistically independent, then the algorithm can return poor results. Using multiple layers to compute the distribution scores can increase the number of statistically dependent features.

---

- 2 For each of the principal component features with an eigenvalue greater than  $\sigma$ , construct a histogram. For each histogram:
  - a Dynamically adjusts the width of the bins to create  $\sqrt{n}$  bins of approximately equal area.
  - b Normalize the bins heights such that the largest height is 1.
- 3 Find the distribution score for an observation by summing the logarithmic height of the bin containing the observation for each of the feature histograms, over each of the layers.

Let  $f^{(l)}(X)$  denote the output of layer  $l$  for input  $X$ . Use the principal components to project the output into a lower dimensional feature space using this equation:  $\hat{f}^{(l)}(X) = (Q^{(l)})^T f^{(l)}(X)$ .

Compute the confidence score using this equation:

$$\text{HBOS}(X; \sigma) = - \sum_{l=1}^L \left( \sum_{k=1}^{N^{(l)}(\sigma)} \log(\text{hist}_k(\hat{f}_k^{(l)}(X))) \right),$$

$$\text{confidence}(X; \sigma) = - \text{HBOS}(X; \sigma),$$

where  $N^{(l)}(\sigma)$  is the number of number of principal component with an eigenvalue less than  $\sigma$  and  $L$  is the number of layers. A larger score corresponds to an observation that lies in the areas of higher density. If the observation lies outside of the range of any of the histograms, then the bin height for those histograms is 0 and the confidence score is `-Inf`.

---

**Note** The distribution scores depend on the properties of the data set used to construct the histograms [6].

---

# onehotdecode

Decode probability vectors into class labels

## Syntax

```
A = onehotdecode(B, classes, featureDim)
A = onehotdecode(B, classes, featureDim, typename)
```

## Description

`A = onehotdecode(B, classes, featureDim)` decodes each probability vector in `B` to the most probable class label from the labels specified by `classes`. `featureDim` specifies the dimension along which the probability vectors are defined. The function decodes the probability vectors into class labels by matching the position of the highest value in the vector with the class label in the corresponding position in `classes`. Each probability vector in `A` is replaced with the value of `classes` that corresponds to the highest value in the probability vector.

`A = onehotdecode(B, classes, featureDim, typename)` decodes each probability vector in `B` to the most probable class label and returns the result with data type `typename`. Use this syntax to obtain decoded class labels with a specific data type.

## Examples

### Encode and Decode Labels

Use the `onehotencode` and `onehotdecode` functions to encode a set of labels into probability vectors and decode them back into labels.

Create a vector of categorical labels.

```
colorsOriginal = ["red" "blue" "red" "green" "yellow" "blue"];
colorsOriginal = categorical(colorsOriginal)
```

```
colorsOriginal = 1x6 categorical
    red    blue    red    green    yellow    blue
```

Determine the classes in the categorical vector.

```
classes = categories(colorsOriginal);
```

One-hot encode the labels into probability vectors by using the `onehotencode` function. Encode the probability vectors into the first dimension.

```
colorsEncoded = onehotencode(colorsOriginal, 1)
```

```
colorsEncoded = 4x6
    0    1    0    0    0    1
    0    0    0    1    0    0
    1    0    1    0    0    0
```

```
0 0 0 0 1 0
```

Use `onehotdecode` to decode the probability vectors.

```
colorsDecoded = onehotdecode(colorsEncoded, classes, 1)
```

```
colorsDecoded = 1x6 categorical
    red    blue    red    green    yellow    blue
```

The decoded labels match the original labels.

### Decode Probability Vectors into Most Probable Classes

Use `onehotdecode` to decode a set of probability vectors into the most probable class for each observation.

Create a set of 10 random probability vectors. The vectors express the probability that an observation belongs to one of five classes.

```
numObs = 10;
numClasses = 5;

prob = rand(numObs, numClasses);

tot = sum(prob, 2);
prob = prob./tot;
```

Define the set of five classes.

```
classes = ["Red" "Yellow" "Green" "Blue" "Purple"];
```

Decode the probabilities into the most probable classes. The probability vectors are encoded into the second dimension, so specify the dimension containing encoded probabilities as 2. Obtain the most probable classes as a vector of strings.

```
result = onehotdecode(prob, classes, 2, "string")
```

```
result = 10x1 string
    "Red"
    "Yellow"
    "Yellow"
    "Green"
    "Yellow"
    "Blue"
    "Green"
    "Yellow"
    "Red"
    "Red"
```

## Input Arguments

### **B — Probability vectors**

numeric array

Probability vectors to decode, specified as a numeric array.

Values in **B** must be between 0 and 1. If a probability vector in **B** contains NaN values, the function decodes that observation to the class with the largest probability that is not NaN. If an observation contains only NaN values, the function decodes that observation to the first class label in **classes**.

Data Types: `single` | `double`

### **classes — Classes**

cell array | string vector | numeric vector | character array

Classes, specified as a cell array of character vectors, a string vector, a numeric vector, or a two-dimensional character array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `string` | `cell` | `char`

### **featureDim — Dimension containing probability vectors**

positive integer

Dimension containing probability vectors, specified as a positive integer.

Use `featureDim` to specify the dimension in **B** that contains the probability vectors. The function replaces each vector in **B** along the specified dimension with the element of **classes** in the same position as the highest value along the vector.

The dimension of **B** specified by `featureDim` must have length equal to the number of classes specified by **classes**.

### **typename — Data type of decoded labels**

'categorical' (default) | character vector | string scalar

Data type of decoded labels, specified as a character vector or a string scalar.

Valid values of `typename` are 'categorical', 'string', and numeric types such as 'single' and 'int64'. If you specify a numeric type, **classes** must be a numeric vector.

Example: 'double'

Data Types: `char` | `string`

## Output Arguments

### **A — Decoded class labels**

categorical array (default) | string array | numeric array

Decoded class labels, returned as a categorical array, a string array, or a numeric array.

# onehotencode

Encode data labels into one-hot vectors

## Syntax

```
B = onehotencode(A,featureDim)
tblB = onehotencode(tblA)
___ = onehotencode( ___,typename)
___ = onehotencode( ___, 'ClassNames',classes)
```

## Description

`B = onehotencode(A, featureDim)` encodes data labels in categorical array `A` into a one-hot encoded array `B`. The function replaces each element of `A` with a numeric vector of length equal to the number of unique classes in `A` along the dimension specified by `featureDim`. The vector contains a 1 in the position corresponding to the class of the label in `A`, and a 0 in every other position. Any `<undefined>` values are encoded to NaN values.

`tblB = onehotencode(tblA)` encodes categorical data labels in table `tblA` into a table of one-hot encoded numeric values. The function replaces the single variable of `tblA` with as many variables as the number of unique classes in `tblA`. Each row in `tblB` contains a 1 in the variable corresponding to the class of the label in `tblA`, and a 0 in all other variables.

`___ = onehotencode( ___, typename)` encodes the labels into numeric values of data type `typename`. Use this syntax with any of the input and output arguments in previous syntaxes.

`___ = onehotencode( ___, 'ClassNames', classes)` also specifies the names of the classes to use for encoding. Use this syntax when `A` or `tblA` does not contain categorical values, when you want to exclude any class labels from being encoded, or when you want to encode the vector elements in a specific order. Any label in `A` or `tblA` of a class that does not exist in `classes` is encoded to a vector of NaN values.

## Examples

### One-Hot Encode a Vector of Labels

Encode a categorical vector of class labels into one-hot vectors representing the labels.

Create a column vector of labels, where each row of the vector represents a single observation. Convert the labels to a categorical array.

```
labels = ["red"; "blue"; "red"; "green"; "yellow"; "blue"];
labels = categorical(labels);
```

View the order of the categories.

```
categories(labels)
```

```
ans = 4x1 cell
    {'blue' }
```

```
{'green' }  
{'red'   }  
{'yellow'}
```

Encode the labels into one-hot vectors. Expand the labels into vectors in the second dimension to encode the classes.

```
labels = onehotencode(labels,2)
```

```
labels = 6x4
```

```
0  0  1  0  
1  0  0  0  
0  0  1  0  
0  1  0  0  
0  0  0  1  
1  0  0  0
```

Each observation in `labels` is now a row vector with a 1 in the position corresponding to the category of the class label and 0 in all other positions. The function encodes the labels in the same order as the categories, such that a 1 in position 1 represents the first category in the list, in this case, 'blue'.

### One-Hot Encode Table

One-hot encode a table of categorical values.

Create a table of categorical data labels. Each row in the table holds a single observation.

```
color = ["blue"; "red"; "blue"; "green"; "yellow"; "red"];  
color = categorical(color);  
color = table (color);
```

One-hot encode the table of class labels.

```
color = onehotencode(color)
```

```
color=6x4 table  
  blue  green  red  yellow  
-----  
  1      0      0      0  
  0      0      1      0  
  1      0      0      0  
  0      1      0      0  
  0      0      0      1  
  0      0      1      0
```

Each column of the table represents a class. The function encodes the data labels with a 1 in the column of the corresponding class, and 0 everywhere else.

### One-Hot Encode Subset of Classes

If not all classes in the data are relevant, encode the data labels using only a subset of the classes.

Create a row vector of data labels, where each column of the vector represents a single observation

```
pets = ["dog" "fish" "cat" "dog" "cat" "bird"];
```

Define the list of classes to encode. These classes are a subset of those present in the observations.

```
animalClasses = ["bird"; "cat"; "dog"];
```

One-hot encode the observations into the first dimension. Specify the classes to encode.

```
encPets = onehotencode(pets,1,"ClassNames",animalClasses)
```

```
encPets = 3×6
```

```

0 NaN 0 0 0 1
0 NaN 1 0 1 0
1 NaN 0 1 0 0
```

Observations of a class not present in the list of classes to encode are encoded to a vector of NaN values.

### One-Hot Encode Image for Semantic Segmentation

Use onehotencode to encode a matrix of class labels, such as a semantic segmentation of an image.

Define a simple 15-by-15 pixel segmentation matrix of class labels.

```
A = "blue";
B = "green";
C = "black";
```

```
A = repmat(A,8,15);
B = repmat(B,7,5);
C = repmat(C,7,5);
```

```
seg = [A;B C B];
```

Convert the segmentation matrix into a categorical array.

```
seg = categorical(seg);
```

One-hot encode the segmentation matrix into an array of type single. Expand the encoded labels into the third dimension.

```
encSeg = onehotencode(seg,3,"single");
```

Check the size of the encoded segmentation.

```
size(encSeg)
```

```
ans = 1×3
```

```
15 15 3
```

The three possible classes of the pixels in the segmentation matrix are encoded as vectors in the third dimension.

### One-Hot Encode Table with Several Variables

If your data is a table that contains several types of class variables, you can encode each variable separately.

Create a table of observations of several types of categorical data.

```
color = ["blue"; "red"; "blue"; "green"; "yellow"; "red"];
color = categorical(color);

pets = ["dog"; "fish"; "cat"; "dog"; "cat"; "bird"];
pets = categorical(pets);

location = ["USA"; "CAN"; "CAN"; "USA"; "AUS"; "USA"];
location = categorical(location);

data = table(color,pets,location)
```

```
data=6x3 table
   color    pets    location
   -----
   blue     dog     USA
   red      fish    CAN
   blue     cat     CAN
   green    dog     USA
   yellow   cat     AUS
   red      bird    USA
```

Use a for-loop to one-hot encode each table variable and append it to a new table containing the encoded data.

```
encData = table();

for i=1:width(data)
    encData = [encData onehotencode(data(:,i))];
end
```

```
encData
```

```
encData=6x11 table
   blue    green    red    yellow    bird    cat    dog    fish    AUS    CAN    USA
   -----
   1       0       0       0       0       0       1       0       0       0       1
   0       0       1       0       0       0       0       1       0       1       0
   1       0       0       0       0       1       0       0       0       1       0
   0       1       0       0       0       0       1       0       0       0       1
```

```

0      0      0      1      0      1      0      0      1      0      0
0      0      1      0      1      0      0      0      0      0      1

```

Each row of `encData` encodes the three different categorical classes for each observation.

## Input Arguments

### A — Array of data labels

categorical array | numeric array | string array

Array of data labels to encode, specified as a categorical array, a numeric array, or a string array.

- If `A` is a categorical array, the elements of the one-hot encoded vectors match the same order in `categories(A)`.
- If `A` is not a categorical array, you must specify the classes to encode using the `'ClassNames'` name-value argument. The function encodes the vectors in the order that the classes appear in `classes`.
- If `A` contains undefined values or values not present in `classes`, the function encodes those values as a vector of NaN values. `typename` must be `'double'` or `'single'`.

Data Types: categorical | numeric | string

### tblA — Table of data labels

table

Table of data labels to encode, specified as a table. The table must contain a single variable and one row for each observation. Each entry must contain a categorical scalar, a numeric scalar, or a string scalar.

- If `tblA` contains categorical values, the elements of the one-hot encoded vectors match the order of the categories; for example, the same order as `categories(tbl(1,n))`.
- If `tblA` does not contain categorical values, you must specify the classes to encode using the `'ClassNames'` name-value argument. The function encodes the vectors in the order that the classes appear in `classes`.
- If `tblA` contains undefined values or values not present in `classes`, the function encodes those values as NaN values. `typename` must be `'double'` or `'single'`.

Data Types: table

### featureDim — Dimension to expand

positive integer

Dimension to expand to encode the labels, specified as a positive integer.

`featureDim` must specify a singleton dimension of `A`, or be larger than `n` where `n` is the number of dimensions of `A`.

### typename — Data type of encoded labels

`'double'` (default) | character vector | string scalar

Data type of the encoded labels, specified as a character vector or a string scalar.

- If the classification label input is a categorical array, a numeric array, or a string array, then the encoded labels are returned as an array of data type `typename`.
- If the classification label input is a table, then the encoded labels are returned as a table where each entry has data type `typename`.

Valid values of `typename` are floating point, signed and unsigned integer, and logical types.

Example: `'int64'`

Data Types: `char` | `string`

### **classes** — Classes to encode

`cell array` | `string vector` | `numeric vector` | `character array`

Classes to encode, specified as a cell array of character vectors, a string vector, a numeric vector, or a two-dimensional character array.

- If the input `A` or `tblA` does not contain categorical values, then you must specify `classes`. You can also use the `classes` argument to exclude any class labels from being encoded, or to encode the vector elements in a specific order.
- If `A` or `tblA` contains undefined values or values not present in `classes`, the function encodes those values to a vector of NaN values. `typename` must be `'double'` or `'single'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `string` | `cell`

## **Output Arguments**

### **B** — Encoded labels

`numeric array`

Encoded labels, returned as a numeric array.

### **tblB** — Encoded labels

`table`

Encoded labels, returned as a table.

Each row of `tblB` contains the one-hot encoded label for a single observation, in the same order as in `tblA`. Each row contains a 1 in the variable corresponding to the class of the label in `tblA`, and a 0 in all other variables.

# padsequences

Pad or truncate sequence data to same length

## Syntax

```
XPad = padsequences(X, paddingDim)
[XPad, mask] = padsequences(X, paddingDim)
[ ___ ] = padsequences(X, paddingDim, Name, Value)
```

## Description

`XPad = padsequences(X, paddingDim)` pads the sequences in the cell array `X` along the dimension specified by `paddingDim`. The function adds padding at the end of each sequence to match the size of the longest sequence in `X`. The padded sequences are concatenated and the function returns `XPad` as an array.

`[XPad, mask] = padsequences(X, paddingDim)` additionally returns a logical array representing the positions of original sequence data in `XPad`. The position of values of `true` or `1` in `mask` correspond to the positions of original sequence data in `XPad`; values of `false` or `0` correspond to padded values.

`[ ___ ] = padsequences(X, paddingDim, Name, Value)` specifies options using one or more name-value arguments in addition to the input and output arguments in previous syntaxes. For example, `'PaddingValue', 'left'` adds padding to the beginning of the original sequence.

## Examples

### Pad Sequence Data to Same Length

Pad sequence data ready for training.

Load the sequence data.

```
s = japaneseVowelsTrainData;
```

The preprocessed data contains 270 observations each with 12 sequence features. The length of the observations varies between 7 and 26 time steps.

Pad the data with zeros to the same length as the longest sequence. The function applies on the right side of the data. Specify the dimension containing the time steps as the padding dimension. For this example, the dimension is 2.

```
sPad = padsequences(s, 2);
```

Examine the size of the padded sequences.

```
size(sPad)
```

```
ans = 1×3
```

12 26 270

### Pad or Truncate Both Sides of Sequence Data

Use `padsequences` to extend or cut each sequence to a fixed length by adding or removing data at both ends of the sequence, depending on the length of the original sequence.

Load the sequence data.

```
s = japaneseVowelsTrainData;
```

The preprocessed data contains 270 observations each with 12 sequence features. The length of the observations varies between 7 and 26 time steps.

Process the data so that each sequence is exactly 14 time steps. For shorter sequences, padding is required, while longer sequences need to be truncated. Pad or truncate at both sides of the data. For the padded sequences, apply symmetric padding so that the padded values are mirror reflections of the original sequence values.

```
[sPad,mask] = padsequences(s,2,'Length',14,'Direction','both','PaddingValue','symmetric');
```

Compare some of the padded sequences with the original sequence. Each observation contains 12 features so extract a single feature to compare.

Extract the first feature of the 74th observation. This sequence is shorter than 14 time steps.

```
s{74}(1,:)
```

```
ans = 1×9
```

```
0.6691 0.5291 0.3820 0.3107 0.2546 0.1942 0.0931 -0.0179 -0.1081
```

```
sPad(1,:,74)
```

```
ans = 1×14
```

```
0.5291 0.6691 0.6691 0.5291 0.3820 0.3107 0.2546 0.1942 0.0931 -0.0179 -0.1081 0.1081 0.0179 0.1942
```

```
mask(1,:,74)
```

```
ans = 1×14 logical array
```

```
0 0 1 1 1 1 1 1 1 1 1 0 0 0
```

The function centers the sequence and pads at both ends by reflecting the values at the ends of the sequence. The mask shows the location of the original sequence values.

Extract the first feature of the 28th observation. This sequence is longer than 14 time steps.

```
s{28}(1,:)
```

```
ans = 1×16
```

```

    1.1178    1.0772    1.2365    1.4858    1.6191    1.4893    1.2791    1.4692    1.5592    1.5112
sPad(1,:,28)
ans = 1×14
    1.0772    1.2365    1.4858    1.6191    1.4893    1.2791    1.4692    1.5592    1.5112    1.5112
mask(1,:,28)
ans = 1×14 logical array
     1     1     1     1     1     1     1     1     1     1     1     1     1     1

```

The function centers the sequence and truncates at both ends. The mask shows that all data in the resulting sequence is part of the original sequence.

### Pad Mini-Batches of Sequences for Custom Training Loop

Use the `padsequences` function in conjunction with `minibatchqueue` to prepare and preprocess sequence data ready for training using a custom training loop.

The example uses the human activity recognition training data. The data contains six time series of sensor data obtained from a smartphone worn on the body. Each sequence has three features and varies in length. The three features correspond to the accelerometer readings in three different directions.

Load the training data. Combine the data and labels into a single datastore.

```

s = load("HumanActivityTrain.mat");
dsXTrain = arrayDatastore(s.XTrain,'OutputType','same');
dsYTrain = arrayDatastore(s.YTrain,'OutputType','same');
dsTrain = combine(dsXTrain,dsYTrain);

```

Use `minibatchqueue` to process the mini-batches of sequence data. Define a custom mini-batch preprocessing function `preprocessMiniBatch` (defined at the end of this example) to pad the sequence data and labels, and one-hot encode the label sequences. To also return the mask of the padded data, specify three output variables for the `minibatchqueue` object.

```

miniBatchSize = 2;
mbq = minibatchqueue(dsTrain,3,...
    'MiniBatchSize',miniBatchSize,...
    'MiniBatchFcn', @preprocessMiniBatch);

```

Check the size of the mini-batches.

```

[X,Y,mask] = next(mbq);
size(X)
ans = 1×3

```

```
3      64480      2

size(mask)
ans = 1×3

3      64480      2
```

Each mini-batch has two observations. The function pads the sequences to the same size as the longest sequence in the mini-batch. The mask is the same size as the padded sequences, and shows the location of the original data values in the padded sequence data.

```
size(Y)
ans = 1×3

5      64480      2
```

The padded labels are one-hot encoded into numeric data ready for training.

```
function [xPad,yPad,mask] = preprocessMiniBatch(X,Y)
    [xPad,mask] = padsequences(X,2);
    yPad = padsequences(Y,2);
    yPad = onehotencode(yPad,1);
end
```

## Input Arguments

### **X — Sequences to pad**

cell vector

Sequences to pad, specified as a cell vector of numeric or categorical arrays.

Data Types: `cell`

### **paddingDim — Dimension along which to pad**

positive integer

Dimension along which to pad input sequence data, specified as a positive integer.

Example: 2

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `padsequences(X, 'Length', 'shortest', 'Direction', 'both')` truncates the sequences at each end, to match the length of the shortest input sequence.

**Length — Length of padded sequences**`'longest' (default) | 'shortest' | positive integer`

Length of padded sequences, specified as one of the following:

- `'longest'` — Pad each input sequence to the same length as the longest input sequence.
- `'shortest'` — Truncate each input sequence to the same length as the shortest input sequence.
- Positive integer — Pad or truncate each input sequence to the specified length.

Example: `padsequences(X, 'Length', 'shortest')`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string`

**Direction — Direction of padding or truncation**`'right' (default) | 'left' | 'both'`

Direction of padding or truncation, specified as one of the following:

- `'right'` — Pad or truncate at the end of each original sequence.
- `'left'` — Pad or truncate at the beginning of each original sequence.
- `'both'` — Pad or truncate at the beginning and end of each original sequence. Half the required padding or truncation is applied to each end of the sequence.

Example: `padsequences(X, 'Direction', 'both')`

Data Types: `char | string`

**PaddingValue — Value used to pad input**`'auto' (default) | 'symmetric' | numeric scalar | categorical scalar`

Value used to pad input, specified as one of the following:

- `'auto'` — Determine the padding value automatically depending on the data type of the input sequences. Numeric sequences are padded with 0. Categorical sequences are padded with `<undefined>`.
- `'symmetric'` — Pad each sequence with a mirror reflection of itself.
- Numeric scalar — Pad each sequence with the specified numeric value.
- Categorical scalar — Pad each sequence with the specified categorical value.

Example: `padsequences(X, 'PaddingValue', 'symmetric')`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | categorical`

**UniformOutput — Flag to return padded data as uniform array**`true or 1 (default) | false or 0`

Flag to return padded data as a uniform array, specified as a numeric or logical 1 (`true`) or 0 (`false`). When you set the value to 0, `XPad` is returned as a cell vector with the same size and underlying data type as the input `X`.

Example: `padsequences(X, 'UniformOutput', 0)`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`

## Output Arguments

### **XPad — Padded sequence data**

numeric array | categorical array | cell vector

Padded sequence data, returned as a numeric array, categorical array, or a cell vector of numeric or categorical arrays.

If you set the `UniformOutput` name-value option to `true` or `1`, the function concatenates the padded sequences over the last dimension. The last dimension of `XPad` has the same size as the number of sequences in input `X`. `XPad` is an array with  $N + 1$  dimensions, where  $N$  is the number of dimensions of the sequence arrays in `X`. `XPad` has the same data type as the arrays in input `X`.

If you set the `UniformOutput` name-value option to `false` or `0`, the function returns the padded sequences as a cell vector with the same size and underlying data type as the input `X`.

### **mask — Position of original sequence data**

logical array | cell vector

Position of original sequence data in the padded sequences, returned as a logical array or as a cell vector of logical arrays.

`mask` has the same size and data type as `XPad`. Values of `1` in `mask` correspond to positions of original sequence values in `XPad`. Values of `0` correspond to padded values.

Use `mask` to excluded padded values from loss calculations using the `"Mask"` name-value option in the `crossentropy` function.

# partition

Partition minibatchqueue

## Syntax

```
submbq = partition(mbq,numParts,indx)
```

## Description

`submbq = partition(mbq,numParts,indx)` partitions the minibatchqueue object `mbq` into `numParts` parts and returns the partition corresponding to the index `indx`. The properties of `submbq` are the same as the properties of `mbq`.

The output minibatchqueue object has access only to the partition of data it is given when it is created. Using `reset` with `submbq` resets the minibatchqueue object to the start of the data partition. Using `shuffle` with `submbq` shuffles only the partitioned data. If you want to shuffle the data across multiple partitions, you must shuffle the original minibatchqueue object and then re-partition.

## Examples

### Partition minibatchqueue

Use the partition function to divide a minibatchqueue object into three parts.

Create a minibatchqueue object from a datastore.

```
ds = digitDatastore;
mbq = minibatchqueue(ds)
```

`mbq =`  
minibatchqueue with 1 output and properties:

```
Mini-batch creation:
  MiniBatchSize: 128
  PartialMiniBatch: 'return'
  MiniBatchFcn: 'collate'
  DispatchInBackground: 0
```

```
Outputs:
  OutputCast: {'single'}
  OutputAsDlarray: 1
  MiniBatchFormat: {''}
  OutputEnvironment: {'auto'}
```

Partition the minibatchqueue object into three parts and return the first partition.

```
sub1 = partition(mbq,3,1)
```

`sub1 =`  
minibatchqueue with 1 output and properties:

```
Mini-batch creation:
  MiniBatchSize: 128
  PartialMiniBatch: 'return'
  MiniBatchFcn: 'collate'
  DispatchInBackground: 0

Outputs:
  OutputCast: {'single'}
  OutputAsDlarray: 1
  MiniBatchFormat: {''}
  OutputEnvironment: {'auto'}
```

sub1 contains approximately the first third of the data in mbq.

### Partition minibatchqueue in Parallel

Use the `partition` function to divide a `minibatchqueue` object into three parts.

Create a `minibatchqueue` object from a datastore.

```
ds = digitDatastore;
mbq = minibatchqueue(ds)

mbq =
minibatchqueue with 1 output and properties:
```

```
Mini-batch creation:
  MiniBatchSize: 128
  PartialMiniBatch: 'return'
  MiniBatchFcn: 'collate'
  DispatchInBackground: 0

Outputs:
  OutputCast: {'single'}
  OutputAsDlarray: 1
  MiniBatchFormat: {''}
  OutputEnvironment: {'auto'}
```

Partition the `minibatchqueue` object into three parts on three workers in a parallel pool. Iterate over the data on each worker.

```
numWorkers = 3;
p = parpool("Processes",numWorkers);
parfor i=1:3
    submbq = partition(mbq,3,i);
    while hasdata(submbq)
        data = next(submbq);
    end
end
```

Each worker has access to a subset of the data in the original `minibatchqueue` object.

## Input Arguments

### **mbq** — Mini-batch queue

`minibatchqueue` object

Mini-batch queue, specified as a `minibatchqueue` object.

### **numParts** — Number of partitions

numeric scalar

Number of partitions, specified as a numeric scalar.

### **indx** — Partition index

numeric scalar

Partition index, specified as a numeric scalar.

## Output Arguments

### **submbq** — Output minibatchqueue

`minibatchqueue`

Output `minibatchqueue`, specified as a `minibatchqueue` object. `submbq` contains a subset of the data in `mbq`. The properties of `submbq` are the same as the properties of `mbq`.

# ONNXParameters

Parameters of imported ONNX network for deep learning

## Description

`ONNXParameters` contains the parameters (such as weights and bias) of an imported ONNX (Open Neural Network Exchange) network. Use `ONNXParameters` to perform tasks such as transfer learning.

## Creation

Create an `ONNXParameters` object by using `importONNXFunction`.

## Properties

### **Learnables — Parameters updated during network training**

structure

Parameters updated during network training, specified as a structure. For example, the weights of convolution and fully connected layers are parameters that the network learns during training. To prevent `Learnables` parameters from being updated during training, convert them to `Nonlearnables` by using `freezeParameters`. Convert frozen parameters back to `Learnables` by using `unfreezeParameters`.

Add a new parameter to `params.Learnables` by using `addParameter`. Remove a parameter from `params.Learnables` by using `removeParameter`.

Access the fields of the structure `Learnables` by using dot notation. For example, `params.Learnables.conv1_W` could display the weights of the first convolution layer. Initialize the weights for transfer learning by entering `params.Learnables.conv1_W = rand([1000,4096])`. For more details about assigning a new value and parameter naming, see “Tips” on page 1-1422.

### **Nonlearnables — Parameters unchanged during network training**

structure

Parameters unchanged during network training, specified as a structure. For example, padding and stride are parameters that stay constant during training.

Add a new parameter to `params.Nonlearnables` by using `addParameter`. Remove a parameter from `params.Nonlearnables` by using `removeParameter`.

Access the fields of the structure `Nonlearnables` by using dot notation. For example, `params.Nonlearnables.conv1_Padding` could display the padding of the first convolution layer. For more details about parameter naming, see “Tips” on page 1-1422.

### **State — Network state**

structure

Network state, specified as a structure. The network `State` contains information remembered by the network between iterations and updated across multiple training batches. For example, the states of LSTM and batch normalization layers are `State` parameters.

Add a new parameter to `params.State` by using `addParameter`. Remove a parameter from `params.State` by using `removeParameter`.

Access the fields of the structure `State` by using dot notation. For example, `params.State.bn1_var` could display the variance of the first batch normalization layer. For more details about parameter naming, see “Tips” on page 1-1422.

### **NumDimensions — Number of dimensions for every parameter**

structure

This property is read-only.

Number of dimensions for every parameter, specified as a structure. `NumDimensions` includes trailing singleton dimensions.

Access the fields of the structure `NumDimensions` by using dot notation. For example, `params.NumDimensions.conv1_W` could display the number of dimensions for the weights parameter of the first convolution layer.

### **NetworkFunctionName — Name of model function**

character vector | string scalar

This property is read-only.

Name of the model function, specified as a character vector or string scalar. The property `NetworkFunctionName` contains the name of the function `NetworkFunctionName`, which you specify in `importONNXFunction`. The function `NetworkFunctionName` contains the architecture of the imported ONNX network.

Example: 'shufflenetFcn'

## **Object Functions**

<code>addParameter</code>	Add parameter to ONNXParameters object
<code>freezeParameters</code>	Convert learnable network parameters in ONNXParameters to nonlearnable
<code>removeParameter</code>	Remove parameter from ONNXParameters object
<code>unfreezeParameters</code>	Convert nonlearnable network parameters in ONNXParameters to learnable

## **Examples**

### **Train Imported ONNX Function Using Custom Training Loop**

Import the `squeezenet` convolution neural network as a function and fine-tune the pretrained network with transfer learning to perform classification on a new collection of images.

This example uses several helper functions. To view the code for these functions, see `Helper Functions` on page 1-1420.

Unzip and load the new images as an image datastore. `imageDatastore` automatically labels the images based on folder names and stores the data as an `ImageDatastore` object. An image

datastore enables you to store large image data, including data that does not fit in memory, and efficiently read batches of images during training of a convolutional neural network. Specify the mini-batch size.

```
unzip("MerchData.zip");
miniBatchSize = 8;
imds = imageDatastore("MerchData", ...
    IncludeSubfolders=true, ...
    LabelSource="foldernames", ...
    ReadSize=miniBatchSize);
```

This data set is small, containing 75 training images. Display some sample images.

```
numImages = numel(imds.Labels);
idx = randperm(numImages,16);
figure
for i = 1:16
    subplot(4,4,i)
    I = readimage(imds,idx(i));
    imshow(I)
end
```

Extract the training set and one-hot encode the categorical classification labels.

```
XTrain = readall(imds);
XTrain = single(cat(4,XTrain{:}));
YTrain_categ = categorical(imds.Labels);
YTrain = onehotencode(YTrain_categ,2)';
```

Determine the number of classes in the data.

```
classes = categories(YTrain_categ);
numClasses = numel(classes)
```

```
numClasses = 5
```

`squeezenet` is a convolutional neural network that is trained on more than a million images from the ImageNet database. As a result, the network has learned rich feature representations for a wide range of images. The network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals.

Import the pretrained `squeezenet` network as a function.

```
squeezenetONNX()
params = importONNXFunction("squeezenet.onnx", "squeezenetFcn")
```

Function containing the imported ONNX network architecture was saved to the file `squeezenetFcn.m`. To learn how to use this function, type: `help squeezenetFcn`.

```
params =
  ONNXParameters with properties:

      Learnables: [1x1 struct]
    Nonlearnables: [1x1 struct]
           State: [1x1 struct]
    NumDimensions: [1x1 struct]
NetworkFunctionName: 'squeezenetFcn'
```

`params` is an `ONNXParameters` object that contains the network parameters. `squeezenetFcn` is a model function that contains the network architecture. `importONNXFunction` saves `squeezenetFcn` in the current folder.

Calculate the classification accuracy of the pretrained network on the new training set.

```
accuracyBeforeTraining = getNetworkAccuracy(XTrain,YTrain,params);
fprintf("%.2f accuracy before transfer learning\n",accuracyBeforeTraining);
```

```
0.01 accuracy before transfer learning
```

The accuracy is very low.

Display the learnable parameters of the network by typing `params.Learnables`. These parameters, such as the weights (W) and bias (B) of convolution and fully connected layers, are updated by the network during training. Nonlearnable parameters remain constant during training.

The last two learnable parameters of the pretrained network are configured for 1000 classes.

```
conv10_W: [1x1x512x1000 dlarray]
```

```
conv10_B: [1000x1 dlarray]
```

The parameters `conv10_W` and `conv10_B` must be fine-tuned for the new classification problem. Transfer the parameters to classify five classes by initializing the parameters.

```
params.Learnables.conv10_W = rand(1,1,512,5);  
params.Learnables.conv10_B = rand(5,1);
```

Freeze all the parameters of the network to convert them to nonlearnable parameters. Because you do not need to compute the gradients of the frozen layers, freezing the weights of many initial layers can significantly speed up network training.

```
params = freezeParameters(params, "all");
```

Unfreeze the last two parameters of the network to convert them to learnable parameters.

```
params = unfreezeParameters(params, "conv10_W");  
params = unfreezeParameters(params, "conv10_B");
```

The network is ready for training. Specify the training options.

```
velocity = [];  
numEpochs = 5;  
miniBatchSize = 16;  
initialLearnRate = 0.01;  
momentum = 0.9;  
decay = 0.01;
```

Calculate the total number of iterations for the training progress monitor.

```
numObservations = size(YTrain,2);  
numIterationsPerEpoch = floor(numObservations./miniBatchSize);  
numIterations = numEpochs*numIterationsPerEpoch;
```

Initialize the `TrainingProgressMonitor` object. Because the timer starts when you create the monitor object, make sure that you create the object immediately after the training loop.

```
monitor = trainingProgressMonitor(Metrics="Loss",Info="Epoch",XLabel="Iteration");
```

Train the network.

```
epoch = 0;  
iteration = 0;  
executionEnvironment = "cpu"; % Change to "gpu" to train on a GPU.
```

```
% Loop over epochs.
```

```
while epoch < numEpochs && ~monitor.Stop
```

```
    epoch = epoch + 1;
```

```
    % Shuffle data.
```

```
    idx = randperm(numObservations);  
    XTrain = XTrain(:,:,,idx);  
    YTrain = YTrain(:,idx);
```

```
    % Loop over mini-batches.
```

```
    i = 0;  
    while i < numIterationsPerEpoch && ~monitor.Stop  
        i = i + 1;  
        iteration = iteration + 1;
```

```

% Read mini-batch of data.
idx = (i-1)*miniBatchSize+1:i*miniBatchSize;
X = XTrain(:,:,,idx);
Y = YTrain(:,idx);

% If training on a GPU, then convert data to gpuArray.
if (executionEnvironment == "auto" && canUseGPU) || executionEnvironment == "gpu"
    X = gpuArray(X);
end

% Evaluate the model gradients and loss using dlfeval and the
% modelGradients function.
[gradients,loss,state] = dlfeval(@modelGradients,X,Y,params);
params.State = state;

% Determine the learning rate for the time-based decay learning rate schedule.
learnRate = initialLearnRate/(1 + decay*iteration);

% Update the network parameters using the SGDM optimizer.
[params.Learnables,velocity] = sgdmupdate(params.Learnables,gradients,velocity);

% Update the training progress monitor.
recordMetrics(monitor,iteration,Loss=loss);
updateInfo(monitor,Epoch=epoch);
monitor.Progress = 100 * iteration/numIterations;
end
end

```

Calculate the classification accuracy of the network after fine-tuning.

```
accuracyAfterTraining = getNetworkAccuracy(XTrain,YTrain,params);  
fprintf("%.2f accuracy after transfer learning\n",accuracyAfterTraining);
```

```
1.00 accuracy after transfer learning
```

## Helper Functions

This section provides the code of the helper functions used in this example.

The `getNetworkAccuracy` function evaluates the network performance by calculating the classification accuracy.

```
function accuracy = getNetworkAccuracy(X,Y,onnxParams)  
  
N = size(X,4);  
Ypred = squeezeNetFcn(X,onnxParams,Training=false);  
  
[~,YIdx] = max(Y,[],1);  
[~,YpredIdx] = max(Ypred,[],1);  
numIncorrect = sum(abs(YIdx-YpredIdx) > 0);  
accuracy = 1 - numIncorrect/N;
```

```
end
```

The `modelGradients` function calculates the loss and gradients.

```
function [grad, loss, state] = modelGradients(X,Y,onnxParams)  
  
[y,state] = squeezeNetFcn(X,onnxParams,Training=true);  
loss = crossentropy(y,Y,DataFormat="CB");  
grad = dlgradient(loss,onnxParams.Learnables);
```

```
end
```

The `squeezeNetONNX` function generates an ONNX model of the `squeezeNet` network.

```
function squeezeNetONNX()  
  
exportONNXNetwork(squeezeNet, "squeezeNet.onnx");
```

```
end
```

## Move Parameters Mislabeled by ONNX Functional Importer

Import a network saved in the ONNX format as a function, and move the mislabeled parameters by using `freeze` or `unfreeze`.

Import the pretrained `simplenet.onnx` network as a function. `simplenet` is a simple convolutional neural network trained on digit image data. For more information on how to create `simplenet`, see “Create Simple Image Classification Network”.

Import `simplenet.onnx` using `importONNXFunction`, which returns an `ONNXParameters` object that contains the network parameters. The function also creates a new model function in the current folder that contains the network architecture. Specify the name of the model function as `simplenetFcn`.

```
params = importONNXFunction('simplenet.onnx', 'simplenetFcn');
```

A function containing the imported ONNX network has been saved to the file `simplenetFcn.m`. To learn how to use this function, type: `help simplenetFcn`.

`importONNXFunction` labels the parameters of the imported network as `Learnables` (parameters that are updated during training) or `Nonlearnables` (parameters that remain unchanged during training). The labeling is not always accurate. A recommended practice is to check if the parameters are assigned to the correct structure `params.Learnables` or `params.Nonlearnables`. Display the learnable and nonlearnable parameters of the imported network.

```
params.Learnables
```

```
ans = struct with fields:
    imageinput_Mean: [1x1 dlarray]
        conv_W: [5x5x1x20 dlarray]
        conv_B: [20x1 dlarray]
    batchnorm_scale: [20x1 dlarray]
        batchnorm_B: [20x1 dlarray]
        fc_W: [24x24x20x10 dlarray]
        fc_B: [10x1 dlarray]
```

```
params.Nonlearnables
```

```
ans = struct with fields:
    ConvStride1004: [2x1 dlarray]
    ConvDilationFactor1005: [2x1 dlarray]
    ConvPadding1006: [4x1 dlarray]
    ConvStride1007: [2x1 dlarray]
    ConvDilationFactor1008: [2x1 dlarray]
    ConvPadding1009: [4x1 dlarray]
```

Note that `params.Learnables` contains the parameter `imageinput_Mean`, which should remain unchanged during training (see the `Mean` property of `imageInputLayer`). Convert `imageinput_Mean` to a nonlearnable parameter. The `freezeParameters` function removes the parameter `imageinput_Mean` from `params.Learnables` and adds it to `params.Nonlearnables` sequentially.

```
params = freezeParameters(params, 'imageinput_Mean');
```

Display the updated learnable and nonlearnable parameters.

```
params.Learnables
```

```
ans = struct with fields:
    conv_W: [5x5x1x20 dlarray]
    conv_B: [20x1 dlarray]
    batchnorm_scale: [20x1 dlarray]
    batchnorm_B: [20x1 dlarray]
    fc_W: [24x24x20x10 dlarray]
    fc_B: [10x1 dlarray]
```

```
params.Nonlearnables
```

```
ans = struct with fields:
    ConvStride1004: [2x1 dlarray]
```

```
ConvDilationFactor1005: [2×1 dlarray]
  ConvPadding1006: [4×1 dlarray]
  ConvStride1007: [2×1 dlarray]
ConvDilationFactor1008: [2×1 dlarray]
  ConvPadding1009: [4×1 dlarray]
imageinput_Mean: [1×1 dlarray]
```

## Tips

- The following rules apply when you assign a new value to a `params.Learnables` parameter:
  - The software automatically converts the new value to a `dlarray`.
  - The new value must be compatible with the existing value of `params.NumDimensions`.
- `importONNXFunction` derives the field names of the structures `Learnables`, `Nonlearnables`, and `State` from the names in the imported ONNX model file. The field names might differ between imported networks.

# partitionByIndex

Partition augmentedImageDatastore according to indices

## Syntax

```
auimds2 = partitionByIndex(auimds,ind)
```

## Description

`auimds2 = partitionByIndex(auimds,ind)` partitions a subset of observations in an augmented image datastore, `auimds`, into a new datastore, `auimds2`. The desired observations are specified by indices, `ind`.

## Input Arguments

### **auimds** – Augmented image datastore

augmentedImageDatastore

Augmented image datastore, specified as an augmentedImageDatastore object.

### **ind** – Indices

vector of positive integers

Indices of observations, specified as a vector of positive integers.

## Output Arguments

### **auimds2** – Output datastore

augmentedImageDatastore object

Output datastore, returned as an augmentedImageDatastore object containing a subset of files from `auimds`.

# PlaceholderLayer

Layer replacing an unsupported Keras or ONNX layer

## Description

PlaceholderLayer is a layer that `importKerasLayers` and `importONNXLayers` insert into a layer array or layer graph in place of an unsupported Keras or ONNX layer.

## Creation

Importing layers from a Keras or ONNX network that has layers that are not supported by Deep Learning Toolbox creates PlaceholderLayer objects.

## Properties

### Name — Layer name

character vector | string scalar

Layer name, specified as a character vector or a string scalar.

Data Types: char | string

### Description — Layer description

character vector | string scalar

Layer description, specified as a character vector or a string scalar.

Data Types: char | string

### Type — Layer type

character vector | string scalar

Layer type, specified as a character vector or a string scalar.

Data Types: char | string

### KerasConfiguration — Keras configuration of layer

structure

Keras configuration of a layer, specified as a structure. The fields of the structure depend on the layer type.

---

**Note** This property only exists if the layer was created when importing a Keras network.

---

Data Types: struct

### ONNXNode — ONNX configuration of layer

structure

ONNX configuration of a layer, specified as a structure. The fields of the structure depend on the layer type.

---

**Note** This property only exists if the layer was created when importing an ONNX network.

---

Data Types: struct

### Weights — Imported weights

structure

Imported weights, specified as a structure.

Data Types: struct

## Examples

### Find and Explore Placeholder Layers

Specify the Keras network file to import layers from.

```
modelfile = 'digitsDAGnetwithnoise.h5';
```

Import the network architecture. The network includes some layer types that are not supported by Deep Learning Toolbox. The `importKerasLayers` function replaces each unsupported layer with a placeholder layer and returns a warning message.

```
lgraph = importKerasLayers(modelfile)
```

Warning: Unable to import some Keras layers, because they are not supported by the Deep Learning

```
lgraph =
  LayerGraph with properties:
    InputNames: {'input_1'}
    OutputNames: {'ClassificationLayer_activation_1'}
    Layers: [15x1 nnet.cnn.layer.Layer]
    Connections: [15x2 table]
```

Display the imported layers of the network. Two placeholder layers replace the Gaussian noise layers in the Keras network.

```
lgraph.Layers
```

```
ans =
  15x1 Layer array with layers:
    1 'input_1'           Image Input           28x28x1 images
    2 'conv2d_1'         2-D Convolution      20 7x7 convolutions with s
    3 'conv2d_1_relu'    ReLU                  ReLU
    4 'conv2d_2'         2-D Convolution      20 3x3 convolutions with s
    5 'conv2d_2_relu'    ReLU                  ReLU
    6 'gaussian_noise_1' PLACEHOLDER LAYER    Placeholder for 'GaussianN
    7 'gaussian_noise_2' PLACEHOLDER LAYER    Placeholder for 'GaussianN
```

```

8 'max_pooling2d_1'      2-D Max Pooling      2x2 max pooling with stride
9 'max_pooling2d_2'      2-D Max Pooling      2x2 max pooling with stride
10 'flatten_1'          Keras Flatten         Flatten activations into 1
11 'flatten_2'          Keras Flatten         Flatten activations into 1
12 'concatenate_1'      Depth concatenation    Depth concatenation of 2 in
13 'dense_1'            Fully Connected       10 fully connected layer
14 'activation_1'       Softmax               softmax
15 'ClassificationLayer_activation_1' Classification Output  crossentropyex

```

Find the placeholder layers using `findPlaceholderLayers`. The output argument contains the two placeholder layers that `importKerasLayers` inserted in place of the Gaussian noise layers of the Keras network.

```
placeholders = findPlaceholderLayers(lgraph)
```

```
placeholders =
    2x1 PlaceholderLayer array with layers:
```

```

1 'gaussian_noise_1'  PLACEHOLDER LAYER  Placeholder for 'GaussianNoise' Keras layer
2 'gaussian_noise_2'  PLACEHOLDER LAYER  Placeholder for 'GaussianNoise' Keras layer

```

Specify a name for each placeholder layer.

```
gaussian1 = placeholders(1);
gaussian2 = placeholders(2);
```

Display the configuration of each placeholder layer.

```
gaussian1.KerasConfiguration
```

```
ans = struct with fields:
    trainable: 1
    name: 'gaussian_noise_1'
    stddev: 1.5000
```

```
gaussian2.KerasConfiguration
```

```
ans = struct with fields:
    trainable: 1
    name: 'gaussian_noise_2'
    stddev: 0.7000
```

## Assemble Network from Pretrained Keras Layers

This example shows how to import the layers from a pretrained Keras network, replace the unsupported layers with custom layers, and assemble the layers into a network ready for prediction.

### Import Keras Network

Import the layers from a Keras network model. The network in `'digitsDAGnetwithnoise.h5'` classifies images of digits.

```
filename = 'digitsDAGnetwithnoise.h5';
lgraph = importKerasLayers(filename, 'ImportWeights', true);
```

Warning: Unable to import some Keras layers, because they are not supported by the Deep Learning

The Keras network contains some layers that are not supported by Deep Learning Toolbox. The `importKerasLayers` function displays a warning and replaces the unsupported layers with placeholder layers.

Plot the layer graph using `plot`.

```
figure
plot(lgraph)
title("Imported Network")
```

### Replace Placeholder Layers

To replace the placeholder layers, first identify the names of the layers to replace. Find the placeholder layers using `findPlaceholderLayers`.

```
placeholderLayers = findPlaceholderLayers(lgraph)
```

```
placeholderLayers =
    2x1 PlaceholderLayer array with layers:
```

1	'gaussian_noise_1'	PLACEHOLDER LAYER	Placeholder for 'GaussianNoise' Keras layer
2	'gaussian_noise_2'	PLACEHOLDER LAYER	Placeholder for 'GaussianNoise' Keras layer

Display the Keras configurations of these layers.

```
placeholderLayers.KerasConfiguration
```

```
ans = struct with fields:
    trainable: 1
    name: 'gaussian_noise_1'
    stddev: 1.5000
```

```
ans = struct with fields:
    trainable: 1
    name: 'gaussian_noise_2'
    stddev: 0.7000
```

Create two Gaussian noise layers with the same configurations as the imported Keras layers using the helper `gaussianNoiseLayer` function.

```
gnLayer1 = gaussianNoiseLayer(1.5, 'new_gaussian_noise_1');
gnLayer2 = gaussianNoiseLayer(0.7, 'new_gaussian_noise_2');
```

Replace the placeholder layers with the custom layers using `replaceLayer`.

```
lgraph = replaceLayer(lgraph, 'gaussian_noise_1', gnLayer1);
lgraph = replaceLayer(lgraph, 'gaussian_noise_2', gnLayer2);
```

Plot the updated layer graph using `plot`.

```
figure
plot(lgraph)
title("Network with Replaced Layers")
```

## Specify Class Names

If the imported classification layer does not contain the classes, then you must specify these before prediction. If you do not specify the classes, then the software automatically sets the classes to 1, 2, ..., N, where N is the number of classes.

Find the index of the classification layer by viewing the Layers property of the layer graph.

```
lgraph.Layers
```

```
ans =
  15x1 Layer array with layers:

     1  'input_1'           Image Input           28x28x1 images
     2  'conv2d_1'         2-D Convolution      20 7x7x1 convolutions with
     3  'conv2d_1_relu'    ReLU                  ReLU
     4  'conv2d_2'         2-D Convolution      20 3x3x1 convolutions with
     5  'conv2d_2_relu'    ReLU                  ReLU
     6  'new_gaussian_noise_1' Gaussian Noise        Gaussian noise with standa
     7  'new_gaussian_noise_2' Gaussian Noise        Gaussian noise with standa
     8  'max_pooling2d_1'  2-D Max Pooling      2x2 max pooling with stride
     9  'max_pooling2d_2'  2-D Max Pooling      2x2 max pooling with stride
    10  'flatten_1'        Keras Flatten         Flatten activations into 1
    11  'flatten_2'        Keras Flatten         Flatten activations into 1
    12  'concatenate_1'    Depth concatenation    Depth concatenation of 2 in
    13  'dense_1'          Fully Connected       10 fully connected layer
    14  'activation_1'     Softmax               softmax
    15  'ClassificationLayer_activation_1' Classification Output  crossentropyex
```

The classification layer has the name 'ClassificationLayer\_activation\_1'. View the classification layer and check the Classes property.

```
cLayer = lgraph.Layers(end)
```

```
cLayer =
  ClassificationOutputLayer with properties:

      Name: 'ClassificationLayer_activation_1'
      Classes: 'auto'
      ClassWeights: 'none'
      OutputSize: 'auto'

  Hyperparameters
      LossFunction: 'crossentropyex'
```

Because the Classes property of the layer is 'auto', you must specify the classes manually. Set the classes to 0, 1, ..., 9, and then replace the imported classification layer with the new one.

```
cLayer.Classes = string(0:9)
```

```
cLayer =
  ClassificationOutputLayer with properties:

      Name: 'ClassificationLayer_activation_1'
      Classes: [0 1 2 3 4 5 6 7 8 9]
      ClassWeights: 'none'
      OutputSize: 10
```

```
Hyperparameters  
LossFunction: 'crossentropyex'
```

```
lgraph = replaceLayer(lgraph, 'ClassificationLayer_activation_1', cLayer);
```

## Assemble Network

Assemble the layer graph using `assembleNetwork`. The function returns a `DAGNetwork` object that is ready to use for prediction.

```
net = assembleNetwork(lgraph)
```

```
net =
```

```
DAGNetwork with properties:
```

```
Layers: [15x1 nnet.cnn.layer.Layer]  
Connections: [15x2 table]  
InputNames: {'input_1'}  
OutputNames: {'ClassificationLayer_activation_1'}
```

# plot

Plot neural network architecture

## Syntax

```
plot(lgraph)
plot(net)
```

## Description

`plot(lgraph)` plots a diagram of the layer graph `lgraph`. The `plot` function labels each layer by its name and displays all layer connections.

---

**Tip** To create an interactive network visualization and analyze the network architecture, use `deepNetworkDesigner(lgraph)`. For more information, see **Deep Network Designer**.

---

`plot(net)` plots a diagram of the network `net`.

## Examples

### Plot Layer Graph

Create a layer graph from an array of layers. Connect the 'relu\_1' layer to the 'add' layer.

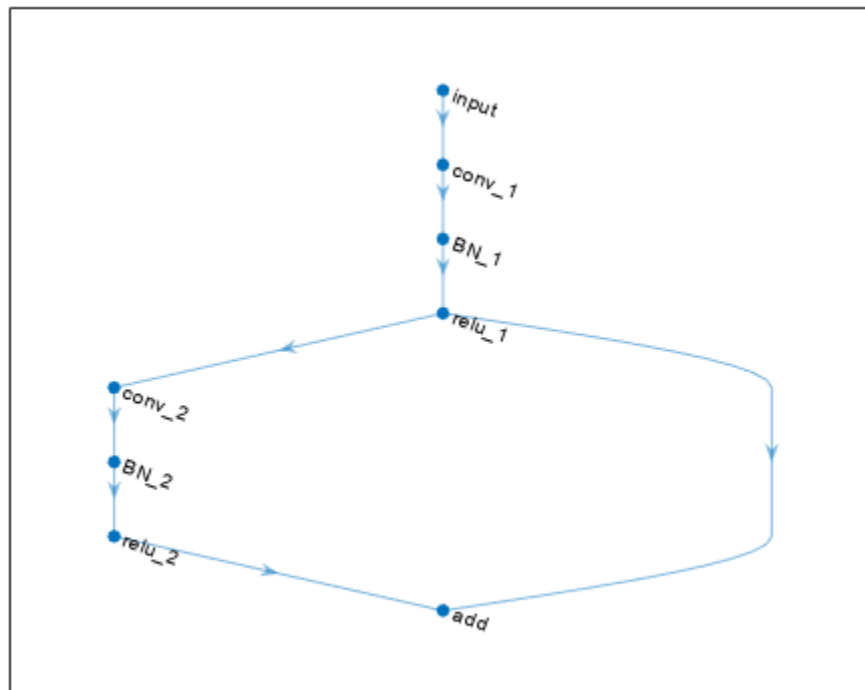

```
layers = [
    imageInputLayer([32 32 3], 'Name', 'input')
    convolution2dLayer(3,16, 'Padding', 'same', 'Name', 'conv_1')
    batchNormalizationLayer('Name', 'BN_1')
    reluLayer('Name', 'relu_1')

    convolution2dLayer(3,16, 'Padding', 'same', 'Stride', 2, 'Name', 'conv_2')
    batchNormalizationLayer('Name', 'BN_2')
    reluLayer('Name', 'relu_2')
    additionLayer(2, 'Name', 'add')];

lgraph = layerGraph(layers);
lgraph = connectLayers(lgraph, 'relu_1', 'add/in2');
```

Plot the layer graph.

```
figure
plot(lgraph);
```

### Plot DAG Network

Load a pretrained GoogLeNet convolutional neural network as a DAGNetwork object. If the Deep Learning Toolbox™ Model for GoogLeNet Network support package is not installed, then the software provides a download link.

```
net = googlenet
```

```
net =
```

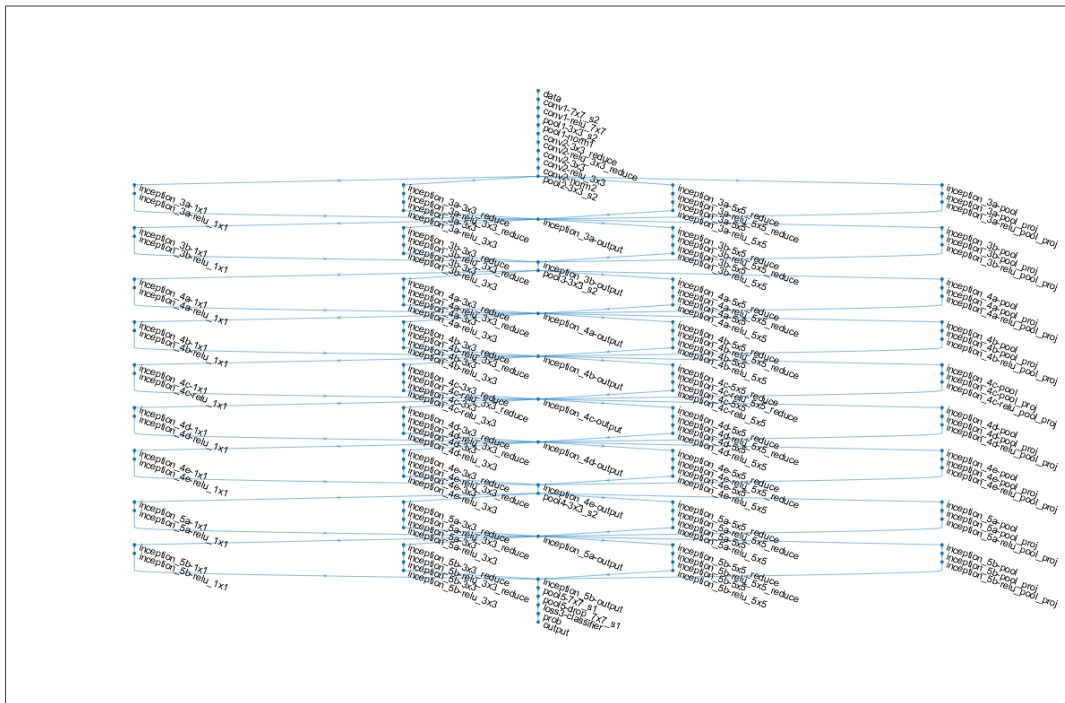

```
DAGNetwork with properties:
```

```
Layers: [144×1 nnet.cnn.layer.Layer]
```

```
Connections: [170×2 table]
```

Plot the network.

```
figure('Units','normalized','Position',[0.1 0.1 0.8 0.8]);
plot(net)
```

## Plot Series Network

Load a pretrained AlexNet convolutional neural network as a SeriesNetwork object. If the Deep Learning Toolbox™ Model for AlexNet Network support package is not installed, then the software provides a download link.

```
net = alexnet
```

```
net =  
SeriesNetwork with properties:
```

```
Layers: [25x1 nnet.cnn.layer.Layer]  
InputNames: {'data'}  
OutputNames: {'output'}
```

Plot the network.

```
plot(net)
```

## Input Arguments

### `lgraph` — Layer graph

LayerGraph object

Layer graph, specified as a LayerGraph object. To create a layer graph, use `layerGraph`.

### `net` — Deep learning network

SeriesNetwork object | DAGNetwork object | `dlnetwork` object

Deep learning network, specified as a SeriesNetwork, DAGNetwork, or `dlnetwork` object.

## Version History

Introduced in R2017b

### See Also

## plot

Plot receiver operating characteristic (ROC) curves and other performance curves

### Syntax

```
plot(rocObj)
plot(ax, rocObj)
plot( ____, Name=Value)
curveObj = plot( ____)
[curveObj, graphicsObjs] = plot( ____)
```

### Description

`plot(rocObj)` creates a receiver operating characteristic (ROC) curve on page 1-1446, which is a plot of the true positive rate (TPR) versus the false positive rate (FPR), for each class in the `ClassNames` property of the `rocmetrics` object `rocObj`. The function marks the model operating point on page 1-1624 for each curve, and displays the value of the area under the ROC curve (AUC on page 1-1446) and the class name for the curve in the legend.

`plot(ax, rocObj)` creates the plot on the axes specified by `ax` instead of the current axes.

`plot( ____, Name=Value)` specifies additional options using one or more name-value arguments in addition to any of the input argument combinations in the previous syntaxes. For example, `AverageROCType="macro", ClassNames=[]` computes the average performance metrics using the macro-averaging method and plots the average ROC curve only.

`curveObj = plot( ____)` returns a `ROCCurve` object for each performance curve.

`[curveObj, graphicsObjs] = plot( ____)` also returns graphics objects for the model operating points and diagonal line.

### Examples

#### Plot ROC Curve

Load a sample of predicted classification scores and true labels for a classification problem.

```
load('flowersDataResponses.mat')
```

`trueLabels` is the true labels for an image classification problem and `scores` is the softmax prediction scores. `scores` is an N-by-K array where N is the number of observations and K is the number of classes.

```
trueLabels = flowersData.trueLabels;
scores = flowersData.scores;
```

Load the class names. The column order of `scores` follows the class order stored in `classNames`.

```
classNames = flowersData.classNames;
```

Create a `rocmetrics` object by using the true labels in `trueLabels` and the classification scores in `scores`. Specify the column order of scores using `classNames`.

```
rocObj = rocmetrics(trueLabels,scores,classNames);
```

`rocObj` is a `rocmetrics` object that stores the AUC values and performance metrics for each class in the `AUC` and `Metrics` properties. Display the `AUC` property.

```
rocObj.AUC
```

```
ans = 1x5 single row vector
```

```
    0.9781    0.9889    0.9728    0.9809    0.9732
```

Plot the ROC curve for each class.

```
plot(rocObj)
```

The filled circle markers indicate the model operating points. The legend displays the class name and AUC value for each curve.

Plot the macro average ROC curve.

```
plot(rocObj,AverageROCType=["macro"],ClassNames=[])
```

### Plot Precision-Recall Curve and Detection Error Tradeoff (DET) Graph

Create a `rocmetrics` object and plot performance curves by using the `plot` function. Specify the `XAxisMetric` and `YAxisMetric` name-value arguments of the `plot` function to plot different types of performance curves other than the ROC curve. If you specify new metrics when you call the `plot` function, the function computes the new metrics and then uses them to plot the curve.

Load a sample of true labels and the prediction scores for a classification problem. For this example, there are five classes: daisy, dandelion, roses, sunflowers, and tulips. The class names are stored in `classNames`. The scores are the softmax prediction scores generated using the `predict` function. `scores` is an N-by-K array where N is the number of observations and K is the number of classes. The column order of `scores` follows the class order stored in `classNames`.

```
load('flowersDataResponses.mat')

scores = flowersData.scores;
trueLabels = flowersData.trueLabels;

classNames = flowersData.classNames;
```

Create a `rocmetrics` object. The `rocmetrics` function computes the FPR and TPR at different thresholds.

```
rocObj = rocmetrics(trueLabels,scores,classNames);
```

Plot the precision-recall curve for the first class. Specify the y-axis metric as precision (or positive predictive value) and the x-axis metric as recall (or true positive rate). The `plot` function computes the new metric values and plots the curve. Compute the area under the precision-recall curve using the trapezoidal method of the `trapz` function, and display the value in the legend.

```
curveObj = plot(rocObj,ClassNames=classNames(1), ...
    YAxisMetric="PositivePredictiveValue",XAxisMetric="TruePositiveRate");
xyData = rmmissing([curveObj.XData curveObj.YData]);
auc = trapz(xyData(:,1),xyData(:,2));
legend(join([string(classNames(1)) " (AUC = " string(auc) ")"],""), ...
    Location="southwest")
title("Precision-Recall Curve")
```

Plot the detection error tradeoff (DET) graph for the first class. Specify the y-axis metric as the false negative rate and the x-axis metric as the false positive rate. Use a log scale for the x-axis and y-axis.

```
f = figure;
plot(rocObj,ClassNames=classNames(1), ...
    YAxisMetric="FalseNegativeRate",XAxisMetric="FalsePositiveRate")
f.CurrentAxes.XScale = "log";
f.CurrentAxes.YScale = "log";
title("DET Graph")
```

### Plot Confidence Intervals

Compute the confidence intervals for FPR and TPR for fixed threshold values by using bootstrap samples, and plot the confidence intervals for TPR on the ROC curve by using the `plot` function. This examples requires Statistics and Machine Learning Toolbox™.

Load a sample of true labels and the prediction scores for a classification problem. For this example, there are five classes: daisy, dandelion, roses, sunflowers, and tulips. The class names are stored in `classNames`. The scores are the softmax prediction scores generated using the `predict` function. `scores` is an N-by-K array where N is the number of observations and K is the number of classes. The column order of `scores` follows the class order stored in `classNames`.

```
load('flowersDataResponses.mat')

scores = flowersData.scores;
trueLabels = flowersData.trueLabels;

classNames = flowersData.classNames;
```

Create a `rocmetrics` object by using the true labels in `trueLabels` and the classification scores in `scores`. Specify the column order of scores using `classNames`. Specify `NumBootstraps` as 100 to use 100 bootstrap samples to compute the confidence intervals.

```
rocObj = rocmetrics(trueLabels,scores,classNames,NumBootstraps=100);
```

Plot the ROC curve and the confidence intervals for TPR. Specify `ShowConfidenceIntervals=true` to show the confidence intervals.

```
plot(rocObj,ShowConfidenceIntervals=true)
```

The shaded area around each curve indicates the confidence intervals. `rocmetrics` computes the ROC curves using the scores. The confidence intervals represent the estimates of uncertainty for the curve.

Specify one class to plot by using the `ClassNames` name-value argument.

```
plot(rocObj,ShowConfidenceIntervals=true,ClassNames="daisy")
```

## Input Arguments

### **rocObj** — Object evaluating classification performance

rocmetrics object

Object evaluating classification performance, specified as a rocmetrics object.

### **ax** — Target axes

Axes object

Target axes, specified as an Axes object.

If you do not specify the axes and the current axes are Cartesian, then `plot` uses the current axes (`gca`). For more information on creating an Axes object, see `axes` and `gca`.

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `YAxisMetric="PositivePredictiveValue", XAxisMetric="TruePositiveRate"` plots the precision (positive predictive value) versus the recall (true positive rate), which represents a precision-recall curve.

**AverageROCType — Method for averaging ROC curves**

"none" (default) | "micro" | "macro" | "weighted" | string array | cell array of character vectors

Method for averaging ROC curves, specified as "none", "micro", "macro", "weighted", a string array of method names, or a cell array of method names.

- If you specify "none" (default), the `plot` function does not create the average ROC curve. The `AverageROCType` value must be "none" if `plot` creates performance curves other than a ROC curve.
- If you specify multiple methods as a string array or a cell array of character vectors, then the `plot` function plots multiple average ROC curves using the specified methods.
- If you specify one or more averaging methods and specify `ClassNames=[]`, then the `plot` function plots only the average ROC curves.

`plot` computes the averages of performance metrics for a multiclass classification problem, and plots the average ROC curves using these methods:

- "micro" (micro-averaging) — `plot` finds the average performance metrics by treating all one-versus-all on page 1-1446 binary classification problems as one binary classification problem. The function computes the confusion matrix components for the combined binary classification problem, and then computes the average FPR and TPR using the values of the confusion matrix.
- "macro" (macro-averaging) — `plot` computes the average values for FPR and TPR by averaging the values of all one-versus-all binary classification problems.
- "weighted" (weighted macro-averaging) — `plot` computes the weighted average values for FPR and TPR using the macro-averaging method and using the prior class probabilities (the `Prior` property of `rocObj`) as weights.

The algorithm type determines the length of the vectors in the `XData`, `YData`, and `Thresholds` properties of a `ROCCurve` object, returned by `plot`, for the average ROC curve. For more details, see "Average of Performance Metrics".

Example: `AverageROCType="macro"`

Example: `AverageROCType=["micro","macro"]`

Data Types: `char` | `string`

**ClassNames — Class labels to plot**

`rocObj.ClassNames` (default) | categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to plot, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. The values and data types in `ClassNames` must match those of the class names in the `ClassNames` property of `rocObj`. (The software treats character or string arrays as cell arrays of character vectors.)

- If you specify multiple class labels, the `plot` function plots a ROC curve for each class.
- If you specify `ClassNames=[]` and specify one or more averaging methods using `AverageROCType`, then the `plot` function plots only the average ROC curves.

Example: `ClassNames=["red","blue"]`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

**ShowConfidenceIntervals — Flag to show confidence intervals of y-axis metric**

false or 0 (default) | true or 1

Flag to show the confidence intervals of the y-axis metric (`YAxisMetric`), specified as logical 0 (false) or 1 (true).

The `ShowConfidenceIntervals` value can be true only if the `Metrics` property of `rocObj` contains the confidence intervals for the y-axis metric.

Example: `ShowConfidenceIntervals=true`

Using confidence intervals requires Statistics and Machine Learning Toolbox.

Data Types: logical

**ShowDiagonalLine — Flag to show diagonal line**

true or 1 | false or 0

Flag to show the diagonal line that extends from  $[0, 0]$  to  $[1, 1]$ , specified as logical 1 (true) or 0 (false).

The default value is true if you plot a ROC curve or an average ROC curve, and false otherwise.

In the ROC curve plot, the diagonal line represents a random classifier, and the line passing through  $[0, 0]$ ,  $[0, 1]$ , and  $[1, 1]$  represents a perfect classifier.

Example: `ShowDiagonalLine=false`

Data Types: logical

**ShowModelOperatingPoint — Flag to show model operating point**

true or 1 | false or 0

Flag to show the model operating point on page 1-1624, specified as logical 1 (true) or 0 (false).

The default value is true for a ROC curve, and false for an average ROC curve. The `ShowModelOperatingPoint` value must be false for performance curves other than ROC.

Example: `ShowModelOperatingPoint=false`

Data Types: logical

**XAxisMetric — Metric for x-axis**

"FalsePositiveRate" (default) | name of performance metric | function handle

Metric for the x-axis, specified as a character vector or string scalar of the built-in metric name or a custom metric name, or a function handle (`@metricName`).

- Built-in metrics — Specify one of the following built-in metric names by using a character vector or string scalar.

Name	Description
"TruePositives" or "tp"	Number of true positives (TP)
"FalseNegatives" or "fn"	Number of false negatives (FN)
"FalsePositives" or "fp"	Number of false positives (FP)

Name	Description
"TrueNegatives" or "tn"	Number of true negatives (TN)
"SumOfTrueAndFalsePositives" or "tp+fp"	Sum of TP and FP
"RateOfPositivePredictions" or "rpp"	Rate of positive predictions (RPP), $(TP+FP)/(TP+FN+FP+TN)$
"RateOfNegativePredictions" or "rnp"	Rate of negative predictions (RNP), $(TN+FN)/(TP+FN+FP+TN)$
"Accuracy" or "accu"	Accuracy, $(TP+TN)/(TP+FN+FP+TN)$
"TruePositiveRate" or "tpr"	True positive rate (TPR), also known as recall or sensitivity, $TP/(TP+FN)$
"FalseNegativeRate", "fnr", or "miss"	False negative rate (FNR), or miss rate, $FN/(TP+FN)$
"FalsePositiveRate" or "fpr"	False positive rate (FPR), also known as fallout or 1-specificity, $FP/(TN+FP)$
"TrueNegativeRate", "tnr", or "spec"	True negative rate (TNR), or specificity, $TN/(TN+FP)$
"PositivePredictiveValue", "ppv", or "prec"	Positive predictive value (PPV), or precision, $TP/(TP+FP)$
"NegativePredictiveValue" or "npv"	Negative predictive value (NPV), $TN/(TN+FN)$
"ExpectedCost" or "ecost"	<p>Expected cost, <math>(TP*cost(P P)+FN*cost(N P)+FP*cost(P N)+TN*cost(N N))/(TP+FN+FP+TN)</math>, where <math>cost</math> is a 2-by-2 misclassification cost matrix containing <math>[0, cost(N P); cost(P N), 0]</math>. <math>cost(N P)</math> is the cost of misclassifying a positive class (P) as a negative class (N), and <math>cost(P N)</math> is the cost of misclassifying a negative class as a positive class.</p> <p>The software converts the K-by-K matrix specified by the <code>Cost</code> name-value argument of <code>rocmetrics</code> to a 2-by-2 matrix for each one-versus-all binary problem. For details, see "Misclassification Cost Matrix".</p>

The software computes the scale vector using the prior class probabilities (`Prior`) and the number of classes in `Labels`, and then scales the performance metrics according to this scale vector. For details, see "Performance Metrics".

- Custom metric stored in the `Metrics` property — Specify the name of a custom metric stored in the `Metrics` property of the input object `rocObj`. The `rocmetrics` function names a custom metric "CustomMetricN", where N is the number that refers to the custom metric. For example, specify `XAxisMetric="CustomMetric1"` to use the first custom metric in `Metrics` as a metric for the x-axis.
- Custom metric — Specify a new custom metric by using a function handle. A custom function that returns a performance metric must have this form:

```
metric = customMetric(C,scale,cost)
```

- The output argument `metric` is a scalar value.
- A custom metric is a function of the confusion matrix (`C`), scale vector (`scale`), and cost matrix (`cost`). The software finds these input values for each one-versus-all binary problem. For details, see “Performance Metrics”.
  - `C` is a 2-by-2 confusion matrix consisting of [TP, FN; FP, TN].
  - `scale` is a 2-by-1 scale vector.
  - `cost` is a 2-by-2 misclassification cost matrix.

The `plot` function names a custom metric “Custom Metric” for the axis label.

The software does not support cross-validation for a custom metric. Instead, you can specify to use bootstrap when you create a `rocmetrics` object.

If you specify a new metric instead of one in the `Metrics` property of the input object `rocObj`, the `plot` function computes and plots the metric values. If you compute confidence intervals when you create `rocObj`, the `plot` function also computes confidence intervals for the new metric.

The `plot` function ignores NaNs in the performance metric values. Note that the positive predictive value (PPV) is NaN for the reject-all threshold for which  $TP = FP = 0$ , and the negative predictive value (NPV) is NaN for the accept-all threshold for which  $TN = FN = 0$ . For more details, see “Thresholds, Fixed Metric, and Fixed Metric Values”.

Example: `XAxisMetric="FalseNegativeRate"`

Data Types: `char` | `string` | `function_handle`

### **YAxisMetric — Metric for y-axis**

`"TruePositiveRate"` (default) | name of performance metric | function handle

Metric for the y-axis, specified as a character vector or string scalar of the built-in metric name or custom metric name, or a function handle (`@metricName`). For details, see `XAxisMetric`.

Example: `YAxisMetric="FalseNegativeRate"`

Data Types: `char` | `string` | `function_handle`

## **Output Arguments**

### **curveObj — Object for performance curve**

`ROCCurve` object | array of `ROCCurve` objects

Object for the performance curve, returned as a `ROCCurve` object or an array of `ROCCurve` objects. `plot` returns a `ROCCurve` object for each performance curve.

Use `curveObj` to query and modify properties of the plot after creating it. For a list of properties, see `ROCCurve` Properties.

### **graphicsObjs — Graphics objects**

graphics array

Graphics objects for the model operating points and diagonal line, returned as a graphics array containing `Scatter` and `Line` objects.

`graphicsObjs` contains a `Scatter` object for each model operating point (if `ShowModelOperatingPoint=true`) and a `Line` object for the diagonal line (if

ShowDiagonalLine=true). Use `graphicsObjs` to query and modify properties of the model operating points and diagonal line after creating the plot. For a list of properties, see Scatter Properties and Line Properties.

## More About

### Receiver Operating Characteristic (ROC) Curve

A ROC curve shows the true positive rate versus the false positive rate for different thresholds of classification scores.

The true positive rate and the false positive rate are defined as follows:

- True positive rate (TPR), also known as recall or sensitivity —  $TP / (TP + FN)$ , where TP is the number of true positives and FN is the number of false negatives
- False positive rate (FPR), also known as fallout or 1-specificity —  $FP / (TN + FP)$ , where FP is the number of false positives and TN is the number of true negatives

Each point on a ROC curve corresponds to a pair of TPR and FPR values for a specific threshold value. You can find different pairs of TPR and FPR values by varying the threshold value, and then create a ROC curve using the pairs. For each class, `rocmetrics` uses all distinct adjusted score on page 1-1447 values as threshold values to create a ROC curve.

For a multiclass classification problem, `rocmetrics` formulates a set of one-versus-all on page 1-1446 binary classification problems to have one binary problem for each class, and finds a ROC curve for each class using the corresponding binary problem. Each binary problem assumes one class as positive and the rest as negative.

For a binary classification problem, if you specify the classification scores as a matrix, `rocmetrics` formulates two one-versus-all binary classification problems. Each of these problems treats one class as a positive class and the other class as a negative class, and `rocmetrics` finds two ROC curves. Use one of the curves to evaluate the binary classification problem.

For more details, see “ROC Curve and Performance Metrics”.

### Area Under ROC Curve (AUC)

The area under a ROC curve (AUC) corresponds to the integral of a ROC curve (TPR values) with respect to FPR from  $FPR = 0$  to  $FPR = 1$ .

The AUC provides an aggregate performance measure across all possible thresholds. The AUC values are in the range 0 to 1, and larger AUC values indicate better classifier performance.

### One-Versus-All (OVA) Coding Design

The one-versus-all (OVA) coding design reduces a multiclass classification problem to a set of binary classification problems. In this coding design, each binary classification treats one class as positive and the rest of the classes as negative. `rocmetrics` uses the OVA coding design for multiclass classification and evaluates the performance on each class by using the binary classification that the class is positive.

For example, the OVA coding design for three classes formulates three binary classifications:

	Binary 1	Binary 2	Binary 3
Class 1	1	-1	-1
Class 2	-1	1	-1
Class 3	-1	-1	1

Each row corresponds to a class, and each column corresponds to a binary classification problem. The first binary classification assumes that class 1 is a positive class and the rest of the classes are negative. `rocmetrics` evaluates the performance on the first class by using the first binary classification problem.

## Algorithms

### Adjusted Scores for Multiclass Classification Problem

For each class, `rocmetrics` adjusts the classification scores (input argument `Scores` of `rocmetrics`) relative to the scores for the rest of the classes if you specify `Scores` as a matrix. Specifically, the adjusted score for a class given an observation is the difference between the score for the class and the maximum value of the scores for the rest of the classes.

For example, if you have  $[s_1, s_2, s_3]$  in a row of `Scores` for a classification problem with three classes, the adjusted score values are  $[s_1 - \max(s_2, s_3), s_2 - \max(s_1, s_3), s_3 - \max(s_1, s_2)]$ .

`rocmetrics` computes the performance metrics using the adjusted score values for each class.

For a binary classification problem, you can specify `Scores` as a two-column matrix or a column vector. Using a two-column matrix is a simpler option because the `predict` function of a classification object returns classification scores as a matrix, which you can pass to `rocmetrics`. If you pass scores in a two-column matrix, `rocmetrics` adjusts scores in the same way that it adjusts scores for multiclass classification, and it computes performance metrics for both classes. You can use the metric values for one of the two classes to evaluate the binary classification problem. The metric values for a class returned by `rocmetrics` when you pass a two-column matrix are equivalent to the metric values returned by `rocmetrics` when you specify classification scores for the class as a column vector.

## predict

Predict responses using trained deep learning neural network

### Syntax

```
Y = predict(net,images)
Y = predict(net,sequences)
Y = predict(net,features)

Y = predict(net,X1,...,XN)
Y = predict(net,mixed)

[Y1,...,YM] = predict( ___ )

___ = predict( ___ ,Name=Value)
```

### Description

You can make predictions using a trained neural network for deep learning on either a CPU or GPU. Using a GPU requires a Parallel Computing Toolbox license and a supported GPU device. For information about supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). Specify the hardware requirements using the `ExecutionEnvironment` name-value argument.

Use this function to predict responses using a trained `SeriesNetwork` or `DAGNetwork` object. For information on predicting responses using a `dlnetwork` object, see `predict`.

`Y = predict(net,images)` predicts the responses of the specified images using the trained network `net`.

`Y = predict(net,sequences)` predicts the responses of the specified sequences using the trained network `net`.

`Y = predict(net,features)` predicts the responses of the specified feature data using the trained network `net`.

`Y = predict(net,X1,...,XN)` predicts the responses for the data in the numeric or cell arrays `X1, ..., XN` for the multi-input network `net`. The input `Xi` corresponds to the network input `net.InputNames(i)`.

`Y = predict(net,mixed)` predicts the responses using the trained network `net` with multiple inputs of mixed data types.

`[Y1,...,YM] = predict( ___ )` predicts responses for the `M` outputs of a multi-output network using any of the previous input arguments. The output `Yj` corresponds to the network output `net.OutputNames(j)`. To return categorical outputs for the classification output layers, set the `ReturnCategorical` option to `1` (true).

`___ = predict( ___ ,Name=Value)` predicts the responses with additional options specified by one or more name-value arguments.

**Tip**

- Use the `predict` function to predict responses using a regression network or to classify data using a multi-output network. To classify data using a single-output classification network, use the `classify` function.
- When you make predictions with sequences of different lengths, the mini-batch size can impact the amount of padding added to the input data, which can result in different predicted values. Try using different values to see which works best with your network. To specify mini-batch size and padding options, use the `MiniBatchSize` and `SequenceLength` options, respectively.
- For predicting responses using `dlnetwork` objects, see `predict`.

**Examples****Predict Numeric Responses Using Trained Convolutional Neural Network**

Load the pretrained network `digitsRegressionNet`. This network is a regression convolutional neural network that predicts the angle of rotation of handwritten digits.

```
load digitsRegressionNet
```

View the network layers. The output layer of the network is a regression layer.

```
layers = net.Layers
```

```
layers =
```

```
18x1 Layer array with layers:
```

1	'imageinput'	Image Input	28x28x1 images with 'zerocenter' normalization
2	'conv_1'	2-D Convolution	8 3x3x1 convolutions with stride [1 1] and padding [1 1]
3	'batchnorm_1'	Batch Normalization	Batch normalization with 8 channels
4	'relu_1'	ReLU	ReLU
5	'avgpool2d_1'	2-D Average Pooling	2x2 average pooling with stride [2 2] and padding [1 1]
6	'conv_2'	2-D Convolution	16 3x3x8 convolutions with stride [1 1] and padding [1 1]
7	'batchnorm_2'	Batch Normalization	Batch normalization with 16 channels
8	'relu_2'	ReLU	ReLU
9	'avgpool2d_2'	2-D Average Pooling	2x2 average pooling with stride [2 2] and padding [1 1]
10	'conv_3'	2-D Convolution	32 3x3x16 convolutions with stride [1 1] and padding [1 1]
11	'batchnorm_3'	Batch Normalization	Batch normalization with 32 channels
12	'relu_3'	ReLU	ReLU
13	'conv_4'	2-D Convolution	32 3x3x32 convolutions with stride [1 1] and padding [1 1]
14	'batchnorm_4'	Batch Normalization	Batch normalization with 32 channels
15	'relu_4'	ReLU	ReLU
16	'dropout'	Dropout	20% dropout
17	'fc'	Fully Connected	1 fully connected layer
18	'regressionoutput'	Regression Output	mean-squared-error with response 'Response'

Load the test images.

```
XTest = digitTest4DArrayData;
```

Predict the responses of the input data using the `predict` function.

```
YTest = predict(net,XTest);
```

View some of the test images at random with their predictions.

```

numPlots = 9;
idx = randperm(size(XTest,4),numPlots);

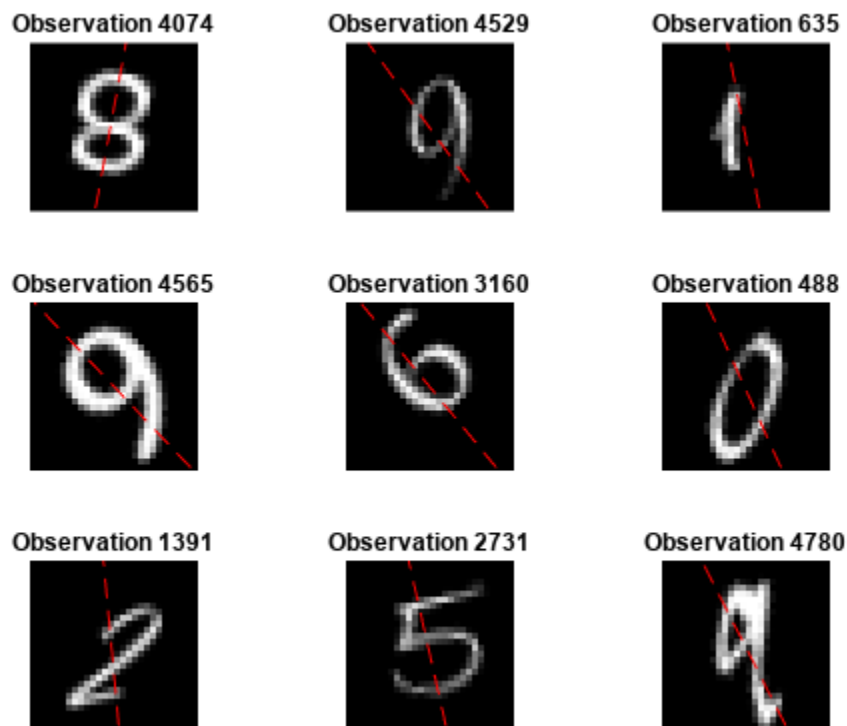

sz = size(XTest,1);
offset = sz/2;

figure
tiledlayout("flow")

for i = 1:numPlots
    nexttile
    imshow(XTest(:,:,,idx(i)))
    title("Observation " + idx(i))

    hold on
    plot(offset*[1-tand(YTest(idx(i))) 1+tand(YTest(idx(i)))],[sz 0],"r--")
    hold off
end

```

### Predict Numeric Responses of Sequences Using Trained LSTM Network

Load the pretrained network `freqNet`. This network is an LSTM regression neural network that predicts the frequency of waveforms.

```
load freqNet
```

View the network layers. The output layer of the network is a regression layer.

```
net.Layers
```

```
ans =
  4x1 Layer array with layers:

    1 'sequenceinput'    Sequence Input    Sequence input with 3 dimensions
    2 'lstm'             LSTM             LSTM with 100 hidden units
    3 'fc'              Fully Connected  1 fully connected layer
    4 'regressionoutput' Regression Output mean-squared-error with response 'Response'
```

Load the test sequences.

```
load WaveformData
```

```
X = data;
```

Predict the responses of the input data using the `predict` function. Because the network was trained using sequences truncated to the shortest sequence length of each mini-batch, also truncate the test sequences by setting the `SequenceLength` option to "shortest".

```
Y = predict(net,X,SequenceLength="shortest");
```

Visualize the first few predictions in a plot.

```
figure
tiledlayout(2,2)
for i = 1:4
    nexttile
    stackedplot(X{i}',DisplayLabels="Channel " + (1:3))

    xlabel("Time Step")
    title("Predicted Frequency: " + string(Y(i)))
end
```

## Input Arguments

### **net** — Trained network

SeriesNetwork object | DAGNetwork object

Trained network, specified as a `SeriesNetwork` or a `DAGNetwork` object. You can get a trained network by importing a pretrained network (for example, by using the `googlenet` function) or by training your own network using `trainNetwork`.

For information on predicting responses using `dlnetwork` objects, see `predict`.

### **images** — Image data

datastore | numeric array | table

Image data, specified as one of the following.

Data Type		Description	Example Usage
Datastore	ImageDatastore	Datastore of images saved on disk	Make predictions with images saved on disk, where the images are the same size.  When the images are different sizes, use an <b>AugmentedImageDatastore</b> object.
	AugmentedImageDatastore	Datastore that applies random affine geometric transformations, including resizing, rotation, reflection, shear, and translation	Make predictions with images saved on disk, where the images are different sizes.
	TransformedDatastore	Datastore that transforms batches of data read from an underlying datastore using a custom transformation function	<ul style="list-style-type: none"> <li>Transform datastores with outputs not supported by <b>predict</b>.</li> <li>Apply custom transformations to datastore output.</li> </ul>
	CombinedDatastore	Datastore that reads from two or more underlying datastores	<ul style="list-style-type: none"> <li>Make predictions using networks with multiple inputs.</li> <li>Combine predictors from different data sources.</li> </ul>
	Custom mini-batch datastore	Custom datastore that returns mini-batches of data	Make predictions using data in a format that other datastores do not support.  For details, see “Develop Custom Mini-Batch Datastore”.
Numeric array		Images specified as a numeric array	Make predictions using data that fits in memory and does not require additional processing like resizing.
Table		Images specified as a table	Make predictions using data stored in a table.

When you use a datastore with networks with multiple inputs, the datastore must be a **TransformedDatastore** or **CombinedDatastore** object.

**Tip** For sequences of images, for example, video data, use the `sequences` input argument.

**Datstore**

Datstores read mini-batches of images and responses. Use datstores when you have data that does not fit in memory or when you want to resize the input data.

These datstores are directly compatible with `predict` for image data.:

- `ImageDatastore`
- `AugmentedImageDatastore`
- `CombinedDatstore`
- `TransformedDatstore`
- Custom mini-batch datstore. For details, see “Develop Custom Mini-Batch Datstore”.

Note that `ImageDatastore` objects allow for batch reading of JPG or PNG image files using prefetching. If you use a custom function for reading the images, then `ImageDatastore` objects do not prefetch.

**Tip** Use `augmentedImageDatastore` for efficient preprocessing of images for deep learning, including image resizing.

Do not use the `readFcn` option of the `imageDatstore` function for preprocessing or resizing, as this option is usually significantly slower.

You can use other built-in datstores for making predictions by using the `transform` and `combine` functions. These functions can convert the data read from datstores to the format required by `classify`.

The required format of the datstore output depends on the network architecture.

Network Architecture	Datstore Output	Example Output
Single input	<p>Table or cell array, where the first column specifies the predictors.</p> <p>Table elements must be scalars, row vectors, or 1-by-1 cell arrays containing a numeric array.</p> <p>Custom datstores must output tables.</p>	<pre>data = read(ds) data =     4x1 table            Predictors     _____     {224x224x3 double}     {224x224x3 double}     {224x224x3 double}     {224x224x3 double}</pre>

Network Architecture	Datastore Output	Example Output
		<pre>data = read(ds)  data =      4×1 cell array      {224×224×3 double}     {224×224×3 double}     {224×224×3 double}     {224×224×3 double}</pre>
Multiple input	<p>Cell array with at least <code>numInputs</code> columns, where <code>numInputs</code> is the number of network inputs.</p> <p>The first <code>numInputs</code> columns specify the predictors for each input.</p> <p>The order of inputs is given by the <code>InputNames</code> property of the network.</p>	<pre>data = read(ds)  data =      4×2 cell array      {224×224×3 double} {128×128×3 do     {224×224×3 double} {128×128×3 do     {224×224×3 double} {128×128×3 do     {224×224×3 double} {128×128×3 do</pre>

The format of the predictors depends on the type of data.

Data	Format
2-D images	<i>h-by-w-by-c</i> numeric array, where <i>h</i> , <i>w</i> , and <i>c</i> are the height, width, and number of channels of the images, respectively
3-D images	<i>h-by-w-by-d-by-c</i> numeric array, where <i>h</i> , <i>w</i> , <i>d</i> , and <i>c</i> are the height, width, depth, and number of channels of the images, respectively

For more information, see “Datastores for Deep Learning”.

### Numeric Array

For data that fits in memory and does not require additional processing like augmentation, you can specify a data set of images as a numeric array.

The size and shape of the numeric array depends on the type of image data.

Data	Format
2-D images	<i>h-by-w-by-c-by-N</i> numeric array, where <i>h</i> , <i>w</i> , and <i>c</i> are the height, width, and number of channels of the images, respectively, and <i>N</i> is the number of images

Data	Format
3-D images	<i>h-by-w-by-d-by-c-by-N</i> numeric array, where <i>h</i> , <i>w</i> , <i>d</i> , and <i>c</i> are the height, width, depth, and number of channels of the images, respectively, and <i>N</i> is the number of images

**Table**

As an alternative to datastores or numeric arrays, you can also specify images in a table.

When you specify images in a table, each row in the table corresponds to an observation.

For image input, the predictors must be in the first column of the table, specified as one of the following:

- Absolute or relative file path to an image, specified as a character vector
- 1-by-1 cell array containing a *h-by-w-by-c* numeric array representing a 2-D image, where *h*, *w*, and *c* correspond to the height, width, and number of channels of the image, respectively

---

**Tip** To input complex-valued data into a neural network, the `SplitComplexInputs` option of the input layer must be 1.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `table`

Complex Number Support: Yes

**sequences — Sequence or time series data**

`datastore` | cell array of numeric arrays | numeric array

Sequence or time series data, specified as one of the following.

Data Type	Description	Example Usage
Datastore	<code>TransformedDatastore</code>	<ul style="list-style-type: none"> <li>• Transform datastores with outputs not supported by <code>predict</code>.</li> <li>• Apply custom transformations to datastore output.</li> </ul>
	<code>CombinedDatastore</code>	<ul style="list-style-type: none"> <li>• Make predictions using networks with multiple inputs.</li> <li>• Combine predictors from different data sources.</li> </ul>

Data Type		Description	Example Usage
	Custom mini-batch datastore	Custom datastore that returns mini-batches of data	Make predictions using data in a format that other datastores do not support.  For details, see “Develop Custom Mini-Batch Datastore”.
Numeric or cell array		A single sequence specified as a numeric array or a data set of sequences specified as cell array of numeric arrays	Make predictions using data that fits in memory and does not require additional processing like custom transformations.

### Datastore

Datastores read mini-batches of sequences and responses. Use datastores when you have data that does not fit in memory or when you want to apply transformations to the data.

These datastores are directly compatible with `predict` for sequence data:

- `CombinedDatastore`
- `TransformedDatastore`
- Custom mini-batch datastore. For details, see “Develop Custom Mini-Batch Datastore”.

You can use other built-in datastores for making predictions by using the `transform` and `combine` functions. These functions can convert the data read from datastores to the table or cell array format required by `predict`. For example, you can transform and combine data read from in-memory arrays and CSV files using an `ArrayDatastore` and an `TabularTextDatastore` object, respectively.

The datastore must return data in a table or cell array. Custom mini-batch datastores must output tables.

Datastore Output	Example Output
Table	<pre>data = read(ds)  data =      4x2 table      Predictors     _____     {12x50 double}     {12x50 double}     {12x50 double}     {12x50 double}</pre>

Datastore Output	Example Output
Cell array	<pre>data = read(ds)  data =      4×2 cell array      {12×50 double}     {12×50 double}     {12×50 double}     {12×50 double}</pre>

The format of the predictors depends on the type of data.

Data	Format of Predictors
Vector sequence	$c$ -by- $s$ matrix, where $c$ is the number of features of the sequence and $s$ is the sequence length
1-D image sequence	$h$ -by- $c$ -by- $s$ array, where $h$ and $c$ correspond to the height and number of channels of the image, respectively, and $s$ is the sequence length.  Each sequence in the mini-batch must have the same sequence length.
2-D image sequence	$h$ -by- $w$ -by- $c$ -by- $s$ array, where $h$ , $w$ , and $c$ correspond to the height, width, and number of channels of the image, respectively, and $s$ is the sequence length.  Each sequence in the mini-batch must have the same sequence length.
3-D image sequence	$h$ -by- $w$ -by- $d$ -by- $c$ -by- $s$ array, where $h$ , $w$ , $d$ , and $c$ correspond to the height, width, depth, and number of channels of the image, respectively, and $s$ is the sequence length.  Each sequence in the mini-batch must have the same sequence length.

For predictors returned in tables, the elements must contain a numeric scalar, a numeric row vector, or a 1-by-1 cell array containing a numeric array.

For more information, see “Datastores for Deep Learning”.

### Numeric or Cell Array

For data that fits in memory and does not require additional processing like custom transformations, you can specify a single sequence as a numeric array or a data set of sequences as a cell array of numeric arrays.

For cell array input, the cell array must be an  $N$ -by-1 cell array of numeric arrays, where  $N$  is the number of observations. The size and shape of the numeric array representing a sequence depends on the type of sequence data.

Input	Description
Vector sequences	$c$ -by- $s$ matrices, where $c$ is the number of features of the sequences and $s$ is the sequence length
1-D image sequences	$h$ -by- $c$ -by- $s$ arrays, where $h$ and $c$ correspond to the height and number of channels of the images, respectively, and $s$ is the sequence length
2-D image sequences	$h$ -by- $w$ -by- $c$ -by- $s$ arrays, where $h$ , $w$ , and $c$ correspond to the height, width, and number of channels of the images, respectively, and $s$ is the sequence length
3-D image sequences	$h$ -by- $w$ -by- $d$ -by- $c$ -by- $s$ , where $h$ , $w$ , $d$ , and $c$ correspond to the height, width, depth, and number of channels of the 3-D images, respectively, and $s$ is the sequence length

**Tip** To input complex-valued data into a neural network, the `SplitComplexInputs` option of the input layer must be 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `cell`

Complex Number Support: Yes

### features — Feature data

`datastore` | numeric array | table

Feature data, specified as one of the following.

Data Type	Description	Example Usage
Datastore	<code>TransformedDatastore</code>	<ul style="list-style-type: none"> <li>Transform datastores with outputs not supported by <code>predict</code>.</li> <li>Apply custom transformations to datastore output.</li> </ul>
	<code>CombinedDatastore</code>	<ul style="list-style-type: none"> <li>Make predictions using networks with multiple inputs.</li> <li>Combine predictors from different data sources.</li> </ul>

Data Type		Description	Example Usage
	Custom mini-batch datastore	Custom datastore that returns mini-batches of data	Make predictions using data in a format that other datastores do not support.  For details, see “Develop Custom Mini-Batch Datastore”.
Table		Feature data specified as a table	Make predictions using data stored in a table.
Numeric array		Feature data specified as numeric array	Make predictions using data that fits in memory and does not require additional processing like custom transformations.

**Datastore**

Datastores read mini-batches of feature data and responses. Use datastores when you have data that does not fit in memory or when you want to apply transformations to the data.

These datastores are directly compatible with `predict` for feature data:

- `CombinedDatastore`
- `TransformedDatastore`
- Custom mini-batch datastore. For details, see “Develop Custom Mini-Batch Datastore”.

You can use other built-in datastores for making predictions by using the `transform` and `combine` functions. These functions can convert the data read from datastores to the table or cell array format required by `predict`. For more information, see “Datastores for Deep Learning”.

For networks with multiple inputs, the datastore must be a `TransformedDatastore` or `CombinedDatastore` object.

The datastore must return data in a table or a cell array. Custom mini-batch datastores must output tables. The format of the datastore output depends on the network architecture.

Network Architecture	Datastore Output	Example Output
Single input layer	<p>Table or cell array with at least one column, where the first column specifies the predictors.</p> <p>Table elements must be scalars, row vectors, or 1-by-1 cell arrays containing a numeric array.</p> <p>Custom mini-batch datastores must output tables.</p>	<p>Table for network with one input:</p> <pre>data = read(ds) data =     4x2 table         Predictors     _____     {24x1 double}     {24x1 double}     {24x1 double}     {24x1 double}</pre> <p>Cell array for network with one input:</p> <pre>data = read(ds) data =     4x1 cell array         {24x1 double}         {24x1 double}         {24x1 double}         {24x1 double}</pre>
Multiple input layers	<p>Cell array with at least <code>numInputs</code> columns, where <code>numInputs</code> is the number of network inputs.</p> <p>The first <code>numInputs</code> columns specify the predictors for each input.</p> <p>The order of inputs is given by the <code>InputNames</code> property of the network.</p>	<p>Cell array for network with two inputs:</p> <pre>data = read(ds) data =     4x3 cell array         {24x1 double}  {28x1 double}         {24x1 double}  {28x1 double}         {24x1 double}  {28x1 double}         {24x1 double}  {28x1 double}</pre>

The predictors must be  $c$ -by-1 column vectors, where  $c$  is the number of features.

For more information, see “Datastores for Deep Learning”.

### Table

For feature data that fits in memory and does not require additional processing like custom transformations, you can specify feature data and responses as a table.

Each row in the table corresponds to an observation. The arrangement of predictors in the table columns depends on the type of task.

Task	Predictors
Feature classification	Features specified in one or more columns as scalars.

**Numeric Array**

For feature data that fits in memory and does not require additional processing like custom transformations, you can specify feature data as a numeric array.

The numeric array must be an  $N$ -by-`numFeatures` numeric array, where  $N$  is the number of observations and `numFeatures` is the number of features of the input data.

---

**Tip** To input complex-valued data into a neural network, the `SplitComplexInputs` option of the input layer must be 1.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `table`  
 Complex Number Support: Yes

**X1, . . . , XN — Numeric or cell arrays for networks with multiple inputs**

`numeric array` | `cell array`

Numeric or cell arrays for networks with multiple inputs.

For image, sequence, and feature predictor input, the format of the predictors must match the formats described in the `images`, `sequences`, or `features` argument descriptions, respectively.

For an example showing how to train a network with multiple inputs, see “Train Network on Image and Feature Data”.

To input complex-valued data into a neural network, the `SplitComplexInputs` option of the input layer must be 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `cell`  
 Complex Number Support: Yes

**mixed — Mixed data**

`TransformedDatastore` | `CombinedDatastore` | `custom mini-batch datastore`

Mixed data, specified as one of the following.

Data Type	Description	Example Usage
TransformedDatastore	Datastore that transforms batches of data read from an underlying datastore using a custom transformation function	<ul style="list-style-type: none"> <li>• Make predictions using networks with multiple inputs.</li> <li>• Transform outputs of datastores not supported by <code>predict</code> so they have the required format.</li> <li>• Apply custom transformations to datastore output.</li> </ul>
CombinedDatastore	Datastore that reads from two or more underlying datastores	<ul style="list-style-type: none"> <li>• Make predictions using networks with multiple inputs.</li> <li>• Combine predictors from different data sources.</li> </ul>
Custom mini-batch datastore	Custom datastore that returns mini-batches of data	<p>Make predictions using data in a format that other datastores do not support.</p> <p>For details, see “Develop Custom Mini-Batch Datastore”.</p>

You can use other built-in datastores for making predictions by using the `transform` and `combine` functions. These functions can convert the data read from datastores to the table or cell array format required by `predict`. For more information, see “Datastores for Deep Learning”.

The datastore must return data in a table or a cell array. Custom mini-batch datastores must output tables. The format of the datastore output depends on the network architecture.

Datastore Output	Example Output
<p>Cell array with <code>numInputs</code> columns, where <code>numInputs</code> is the number of network inputs.</p> <p>The order of inputs is given by the <code>InputNames</code> property of the network.</p>	<pre>data = read(ds)  data =      4×3 cell array      {24×1 double}    {28×1 double}     {24×1 double}    {28×1 double}     {24×1 double}    {28×1 double}     {24×1 double}    {28×1 double}</pre>

For image, sequence, and feature predictor input, the format of the predictors must match the formats described in the `images`, `sequences`, or `features` argument descriptions, respectively.

For an example showing how to train a network with multiple inputs, see “Train Network on Image and Feature Data”.

---

**Tip** To convert a numeric array to a datastore, use `arrayDatastore`.

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `MiniBatchSize=256` specifies the mini-batch size as 256.

### MiniBatchSize — Size of mini-batches

128 (default) | positive integer

Size of mini-batches to use for prediction, specified as a positive integer. Larger mini-batch sizes require more memory, but can lead to faster predictions.

When you make predictions with sequences of different lengths, the mini-batch size can impact the amount of padding added to the input data, which can result in different predicted values. Try using different values to see which works best with your network. To specify mini-batch size and padding options, use the `MiniBatchSize` and `SequenceLength` options, respectively.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Acceleration — Performance optimization

"auto" (default) | "mex" | "none"

Performance optimization, specified as one of the following:

- "auto" — Automatically apply a number of optimizations suitable for the input network and hardware resources.
- "mex" — Compile and execute a MEX function. This option is available only when you use a GPU. Using a GPU requires a Parallel Computing Toolbox license and a supported GPU device. For information about supported devices, see "GPU Computing Requirements" (Parallel Computing Toolbox). If Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.
- "none" — Disable all acceleration.

If `Acceleration` is "auto", then MATLAB applies a number of compatible optimizations and does not generate a MEX function.

The "auto" and "mex" options can offer performance benefits at the expense of an increased initial run time. Subsequent calls with compatible parameters are faster. Use performance optimization when you plan to call the function multiple times using new input data.

The "mex" option generates and executes a MEX function based on the network and parameters used in the function call. You can have several MEX functions associated with a single network at one time. Clearing the network variable also clears any MEX functions associated with that network.

The "mex" option supports networks that contain the layers listed on the "Supported Layers" (GPU Coder) page, except for `sequenceInputLayer` objects.

The "mex" option is available when you use a single GPU.

To use the "mex" option, you must have a C/C++ compiler installed and the GPU Coder Interface for Deep Learning support package. Install the support package using the Add-On Explorer in MATLAB. For setup instructions, see "MEX Setup" (GPU Coder). GPU Coder is not required.

For quantized networks, the "mex" option requires a CUDA enabled NVIDIA GPU with compute capability 6.1, 6.3, or higher.

MATLAB Compiler does not support deploying networks when you use the "mex" option.

### **ExecutionEnvironment — Hardware resource**

"auto" (default) | "gpu" | "cpu" | "multi-gpu" | "parallel"

Hardware resource, specified as one of the following:

- "auto" — Use a GPU if one is available; otherwise, use the CPU.
- "gpu" — Use the GPU. Using a GPU requires a Parallel Computing Toolbox license and a supported GPU device. For information about supported devices, see "GPU Computing Requirements" (Parallel Computing Toolbox). If Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.
- "cpu" — Use the CPU.
- "multi-gpu" — Use multiple GPUs on one machine, using a local parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts a parallel pool with pool size equal to the number of available GPUs.
- "parallel" — Use a local or remote parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts one using the default cluster profile. If the pool has access to GPUs, then only workers with a unique GPU perform computation. If the pool does not have GPUs, then computation takes place on all available CPU workers instead.

For more information on when to use the different execution environments, see "Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud".

The "gpu", "multi-gpu", and "parallel" options require Parallel Computing Toolbox. To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see "GPU Computing Requirements" (Parallel Computing Toolbox). If you choose one of these options and Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.

To make predictions in parallel with networks with recurrent layers (by setting ExecutionEnvironment to either "multi-gpu" or "parallel"), the SequenceLength option must be "shortest" or "longest".

Networks with custom layers that contain State parameters do not support making predictions in parallel.

### **ReturnCategorical — Option to return categorical labels**

0 (false) (default) | 1 (true)

Option to return categorical labels, specified as 0 (false) or 1 (true).

If ReturnCategorical is 1 (true), then the function returns categorical labels for classification output layers. Otherwise, the function returns the prediction scores for classification output layers.

### **SequenceLength — Option to pad or truncate sequences**

"longest" (default) | "shortest" | positive integer

Option to pad, truncate, or split input sequences, specified as one of the following:

- "longest" — Pad sequences in each mini-batch to have the same length as the longest sequence. This option does not discard any data, though padding can introduce noise to the neural network.
- "shortest" — Truncate sequences in each mini-batch to have the same length as the shortest sequence. This option ensures that no padding is added, at the cost of discarding data.
- Positive integer — For each mini-batch, pad the sequences to the length of the longest sequence in the mini-batch, and then split the sequences into smaller sequences of the specified length. If splitting occurs, then the software creates extra mini-batches. If the specified sequence length does not evenly divide the sequence lengths of the data, then the mini-batches containing the ends of those sequences have length shorter than the specified sequence length. Use this option if the full sequences do not fit in memory. Alternatively, try reducing the number of sequences per mini-batch by setting the `MiniBatchSize` option to a lower value.

To learn more about the effect of padding, truncating, and splitting the input sequences, see "Sequence Padding, Truncation, and Splitting".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### **SequencePaddingDirection — Direction of padding or truncation**

"right" (default) | "left"

Direction of padding or truncation, specified as one of the following:

- "right" — Pad or truncate sequences on the right. The sequences start at the same time step and the software truncates or adds padding to the end of the sequences.
- "left" — Pad or truncate sequences on the left. The software truncates or adds padding to the start of the sequences so that the sequences end at the same time step.

Because recurrent layers process sequence data one time step at a time, when the recurrent layer `OutputMode` property is 'last', any padding in the final time steps can negatively influence the layer output. To pad or truncate sequence data on the left, set the `SequencePaddingDirection` option to "left".

For sequence-to-sequence neural networks (when the `OutputMode` property is 'sequence' for each recurrent layer), any padding in the first time steps can negatively influence the predictions for the earlier time steps. To pad or truncate sequence data on the right, set the `SequencePaddingDirection` option to "right".

To learn more about the effect of padding, truncating, and splitting the input sequences, see "Sequence Padding, Truncation, and Splitting".

### **SequencePaddingValue — Value to pad sequences**

0 (default) | scalar

Value by which to pad input sequences, specified as a scalar.

The option is valid only when `SequenceLength` is "longest" or a positive integer. Do not pad sequences with NaN, because doing so can propagate errors throughout the neural network.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### Y — Predicted responses

numeric array | categorical array | cell array

Predicted responses, returned as a numeric array, a categorical array, or a cell array. The format of Y depends on the type of problem.

The following table describes the format for regression problems.

Task	Format
2-D image regression	<ul style="list-style-type: none"> <li><math>N</math>-by-<math>R</math> matrix, where <math>N</math> is the number of images and <math>R</math> is the number of responses</li> <li><math>h</math>-by-<math>w</math>-by-<math>c</math>-by-<math>N</math> numeric array, where <math>h</math>, <math>w</math>, and <math>c</math> are the height, width, and number of channels of the images, respectively, and <math>N</math> is the number of images</li> </ul>
3-D image regression	<ul style="list-style-type: none"> <li><math>N</math>-by-<math>R</math> matrix, where <math>N</math> is the number of images and <math>R</math> is the number of responses</li> <li><math>h</math>-by-<math>w</math>-by-<math>d</math>-by-<math>c</math>-by-<math>N</math> numeric array, where <math>h</math>, <math>w</math>, <math>d</math>, and <math>c</math> are the height, width, depth, and number of channels of the images, respectively, and <math>N</math> is the number of images</li> </ul>
Sequence-to-one regression	$N$ -by- $R$ matrix, where $N$ is the number of sequences and $R$ is the number of responses
Sequence-to-sequence regression	<p><math>N</math>-by-1 cell array of numeric sequences, where <math>N</math> is the number of sequences. The sequences are matrices with <math>R</math> rows, where <math>R</math> is the number of responses. Each sequence has the same number of time steps as the corresponding input sequence after the <code>SequenceLength</code> option is applied to each mini-batch independently.</p> <p>For sequence-to-sequence regression tasks with one observation, sequences can be a matrix. In this case, Y is a matrix of responses.</p>
Feature regression	$N$ -by- $R$ matrix, where $N$ is the number of observations and $R$ is the number of responses

For sequence-to-sequence regression problems with one observation, sequences can be a matrix. In this case, Y is a matrix of responses.

If `ReturnCategorical` is 0 (false) and the output layer of the network is a classification layer, then Y is the predicted classification scores. This table describes the format of the scores for classification tasks.

Task	Format
Image classification	$N$ -by- $K$ matrix, where $N$ is the number of observations and $K$ is the number of classes
Sequence-to-label classification	

Task	Format
Feature classification	
Sequence-to-sequence classification	<i>N</i> -by-1 cell array of matrices, where <i>N</i> is the number of observations. The sequences are matrices with <i>K</i> rows, where <i>K</i> is the number of classes. Each sequence has the same number of time steps as the corresponding input sequence after the <code>SequenceLength</code> option is applied to each mini-batch independently.

If `ReturnCategorical` is 1 (true), and the output layer of the network is a classification layer, then *Y* is a categorical vector or a cell array of categorical vectors. This table describes the format of the labels for classification tasks.

Task	Format
Image or feature classification	<i>N</i> -by-1 categorical vector of labels, where <i>N</i> is the number of observations
Sequence-to-label classification	
Sequence-to-sequence classification	<p><i>N</i>-by-1 cell array of categorical sequences of labels, where <i>N</i> is the number of observations. Each sequence has the same number of time steps as the corresponding input sequence after the <code>SequenceLength</code> option is applied to each mini-batch independently.</p> <p>For sequence-to-sequence classification tasks with one observation, sequences can be a matrix. In this case, <i>Y</i> is a categorical sequence of labels.</p>

***Y*<sub>1</sub>, . . . , *Y*<sub>*M*</sub> — Predicted scores or responses of networks with multiple outputs**

numeric array | categorical array | cell array

Predicted scores or responses of networks with multiple outputs, returned as numeric arrays, categorical arrays, or cell arrays.

Each output *Y*<sub>*j*</sub> corresponds to the network output `net.OutputNames(j)` and has format as described in the *Y* output argument.

## Algorithms

### Floating-Point Arithmetic

When you train a neural network using the `trainNetwork` function, or when you use prediction or validation functions with `DAGNetwork` and `SeriesNetwork` objects, the software performs these computations using single-precision, floating-point arithmetic. Functions for training, prediction, and validation include `trainNetwork`, `predict`, `classify`, and `activations`. The software uses single-precision arithmetic when you train neural networks using both CPUs and GPUs.

### Reproducibility

To provide the best performance, deep learning using a GPU in MATLAB is not guaranteed to be deterministic. Depending on your network architecture, under some conditions you might get

different results when using a GPU to train two identical networks or make two predictions using the same network and data.

## Alternatives

For networks with a single classification layer only, you can compute the predicted classes and the predicted scores from a trained network using the `classify` function.

To compute the activations from a network layer, use the `activations` function.

For recurrent networks such as LSTM networks, you can make predictions and update the network state using `classifyAndUpdateState` and `predictAndUpdateState`.

## Version History

### Introduced in R2016a

### **R2022b: Prediction functions pad mini-batches to length of longest sequence before splitting when you specify `SequenceLength` option as an integer**

Starting in R2022b, when you make predictions with sequence data using the `predict`, `classify`, `predictAndUpdateState`, `classifyAndUpdateState`, and `activations` functions and the `SequenceLength` option is an integer, the software pads sequences to the length of the longest sequence in each mini-batch and then splits the sequences into mini-batches with the specified sequence length. If `SequenceLength` does not evenly divide the sequence length of the mini-batch, then the last split mini-batch has a length shorter than `SequenceLength`. This behavior prevents time steps that contain only padding values from influencing predictions.

In previous releases, the software pads mini-batches of sequences to have a length matching the nearest multiple of `SequenceLength` that is greater than or equal to the mini-batch length and then splits the data. To reproduce this behavior, manually pad the input data such that the mini-batches have the length of the appropriate multiple of `SequenceLength`. For sequence-to-sequence workflows, you may also need to manually remove time steps of the output that correspond to padding values.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- C++ code generation supports the following syntaxes:
  - `Y = predict(net, images)`, where `images` is a numeric array
  - `Y = predict(net, sequences)`, where `sequences` is a cell array
  - `Y = predict(net, features)`, where `features` is a numeric array
  - `[Y1, ..., YM] = predict(__)` using any of the previous syntaxes
  - `__ = predict(__, Name=Value)` using any of the previous syntaxes
- For numeric inputs, the input must not have a variable size. The size must be fixed at code generation time.
- For vector sequence inputs, the number of features must be a constant during code generation. The sequence length can be variable sized.
- For image sequence inputs, the height, width, and the number of channels must be a constant during code generation.
- Only the `MiniBatchSize`, `ReturnCategorical`, `SequenceLength`, `SequencePaddingDirection`, and `SequencePaddingValue` name-value pair arguments are supported for code generation. All name-value pairs must be compile-time constants.
- Only the "longest" and "shortest" options of the `SequenceLength` name-value pair is supported for code generation.
- If `ReturnCategorical` is 1 (true) and you use a GCC C/C++ compiler version 8.2 or above, you might get a `-Wstringop-overflow` warning.
- Code generation for Intel MKL-DNN target does not support the combination of `SequenceLength="longest"`, `SequencePaddingDirection="left"`, and `SequencePaddingValue=0` name-value arguments.

For more information about generating code for deep learning neural networks, see "Workflow for Deep Learning Code Generation with MATLAB Coder" (MATLAB Coder).

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- GPU code generation supports the following syntaxes:
  - `Y = predict(net, images)`, where `images` is a numeric array
  - `Y = predict(net, sequences)`, where `sequences` is a cell array or numeric array
  - `Y = predict(net, features)`, where `features` is a numeric array
  - `[Y1, ..., YM] = predict(__)` using any of the previous syntaxes
  - `__ = predict(__, Name=Value)` using any of the previous syntaxes
- For numeric inputs, the input must not have variable size. The size must be fixed at code generation time.
- GPU code generation does not support `gpuArray` inputs to the `predict` function.
- The `cuDNN` library supports vector and 2-D image sequences. The `TensorRT` library support only vector input sequences. The `ARM Compute Library for GPU` does not support recurrent networks.
- For vector sequence inputs, the number of features must be a constant during code generation. The sequence length can be variable sized.

- For image sequence inputs, the height, width, and the number of channels must be a constant during code generation.
- Only the `MiniBatchSize`, `ReturnCategorical`, `SequenceLength`, `SequencePaddingDirection`, and `SequencePaddingValue` name-value pair arguments are supported for code generation. All name-value pairs must be compile-time constants.
- Only the "longest" and "shortest" option of the `SequenceLength` name-value pair is supported for code generation.
- GPU code generation for the `predict` function supports inputs that are defined as half-precision floating point data types. For more information, see `half`.
- If `ReturnCategorical` is set to 1 (true) and you use a GCC C/C++ compiler version 8.2 or above, you might get a `-Wstringop-overflow` warning.

### Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run computations in parallel, set the `ExecutionEnvironment` option to "multi-gpu" or "parallel".

For details, see "Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud".

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

- The `ExecutionEnvironment` option must be "auto" or "gpu" when the input data is:
  - A `gpuArray`
  - A cell array containing `gpuArray` objects
  - A table containing `gpuArray` objects
  - A datastore that outputs cell arrays containing `gpuArray` objects
  - A datastore that outputs tables containing `gpuArray` objects

For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

## predictAndUpdateState

Predict responses using a trained recurrent neural network and update the network state

### Syntax

```
[updatedNet,Y] = predictAndUpdateState(recNet,sequences)
[updatedNet,Y] = predictAndUpdateState(recNet,X1,...,XN)
[updatedNet,Y] = predictAndUpdateState(recNet,mixed)
[updatedNet,Y1,...,YM] = predictAndUpdateState( ___ )
[ ___ ] = predictAndUpdateState( ___ ,Name=Value)
```

### Description

You can make predictions using a trained deep learning network on either a CPU or GPU. Using a GPU requires a Parallel Computing Toolbox license and a supported GPU device. For information about supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). Specify the hardware requirements using the `ExecutionEnvironment` name-value argument.

`[updatedNet,Y] = predictAndUpdateState(recNet,sequences)` predicts responses for data in `sequences` using the trained recurrent neural network `recNet` and updates the network state.

This function supports recurrent neural networks only. The input `recNet` must have at least one recurrent layer such as an LSTM layer or a custom layer with state parameters.

`[updatedNet,Y] = predictAndUpdateState(recNet,X1,...,XN)` predicts the responses for the data in the numeric or cell arrays `X1, ..., XN` for the multi-input network `recNet`. The input `Xi` corresponds to the network input `recNet.InputNames(i)`.

`[updatedNet,Y] = predictAndUpdateState(recNet,mixed)` makes predictions using the multi-input network `recNet` with data of mixed data types.

`[updatedNet,Y1,...,YM] = predictAndUpdateState( ___ )` predicts responses for the `M` outputs of a multi-output network using any of the previous input arguments. The output `Yj` corresponds to the network output `recNet.OutputNames(j)`. To return categorical outputs for the classification output layers, set the `ReturnCategorical` option to `1` (true).

`[ ___ ] = predictAndUpdateState( ___ ,Name=Value)` makes predictions with additional options specified by one or more name-value arguments using any of the previous syntaxes. For example, `MiniBatchSize=27` makes predictions using mini-batches of size 27.

---

**Tip** When you make predictions with sequences of different lengths, the mini-batch size can impact the amount of padding added to the input data, which can result in different predicted values. Try using different values to see which works best with your network. To specify mini-batch size and padding options, use the `MiniBatchSize` and `SequenceLength` options, respectively.

---

### Examples

## Predict and Update Network State

Predict responses using a trained recurrent neural network and update the network state.

Load `JapaneseVowelsNet`, a pretrained long short-term memory (LSTM) network trained on the Japanese Vowels data set as described in [1] and [2]. This network was trained on the sequences sorted by sequence length with a mini-batch size of 27.

Load `JapaneseVowelsNet`

View the network architecture.

```
net.Layers
```

```
ans =
    5x1 Layer array with layers:

         1  'sequenceinput'  Sequence Input           Sequence input with 12 dimensions
         2  'lstm'           LSTM                     LSTM with 100 hidden units
         3  'fc'             Fully Connected         9 fully connected layer
         4  'softmax'        Softmax                  softmax
         5  'classoutput'   Classification Output   crossentropyex with '1' and 8 other classes
```

Load the test data.

```
[XTest,TTest] = japaneseVowelsTestData;
```

Loop over the time steps in a sequence. Predict the scores of each time step and update the network state.

```
X = XTest{94};
numTimeSteps = size(X,2);
for i = 1:numTimeSteps
    v = X(:,i);
    [net,score] = predictAndUpdateState(net,v);
    scores(:,i) = score;
end
```

Plot the prediction scores. The plot shows how the prediction scores change between time steps.

```
classNames = string(net.Layers(end).Classes);
figure
lines = plot(scores');
xlim([1 numTimeSteps])
legend("Class " + classNames,Location="northwest")
xlabel("Time Step")
ylabel("Score")
title("Prediction Scores Over Time Steps")
```

Highlight the prediction scores over time steps for the correct class.

```
trueLabel = TTest(94)

trueLabel = categorical
           3

lines(trueLabel).LineWidth = 3;
```

Display the final time step prediction in a bar chart.

```
figure
bar(score)
title("Final Prediction Scores")
xlabel("Class")
ylabel("Score")
```

## Input Arguments

### **recNet** — Trained recurrent neural network

SeriesNetwork object | DAGNetwork object

Trained recurrent neural network, specified as a `SeriesNetwork` or a `DAGNetwork` object. You can get a trained network by importing a pretrained network or by training your own network using the `trainNetwork` function.

`recNet` is a recurrent neural network. It must have at least one recurrent layer (for example, an LSTM network).

### **sequences** — Sequence or time series data

cell array of numeric arrays | numeric array | datastore

Sequence or time series data, specified as an  $N$ -by-1 cell array of numeric arrays, where  $N$  is the number of observations, a numeric array representing a single sequence, or a datastore.

For cell array or numeric array input, the dimensions of the numeric arrays containing the sequences depend on the type of data.

Input	Description
Vector sequences	$c$ -by- $s$ matrices, where $c$ is the number of features of the sequences and $s$ is the sequence length.
1-D image sequences	$h$ -by- $c$ -by- $s$ arrays, where $h$ and $c$ correspond to the height and number of channels of the images, respectively, and $s$ is the sequence length.
2-D image sequences	$h$ -by- $w$ -by- $c$ -by- $s$ arrays, where $h$ , $w$ , and $c$ correspond to the height, width, and number of channels of the images, respectively, and $s$ is the sequence length.
3-D image sequences	$h$ -by- $w$ -by- $d$ -by- $c$ -by- $s$ , where $h$ , $w$ , $d$ , and $c$ correspond to the height, width, depth, and number of channels of the 3-D images, respectively, and $s$ is the sequence length.

For datastore input, the datastore must return data as a cell array of sequences or a table whose first column contains sequences. The dimensions of the sequence data must correspond to the table above.

**Tip** To input complex-valued data into a neural network, the `SplitComplexInputs` option of the input layer must be 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `cell`

Complex Number Support: Yes

**X1, . . . , XN — Numeric or cell arrays for networks with multiple inputs**

numeric array | cell array

Numeric or cell arrays for networks with multiple inputs.

For sequence predictor input, the input must be a numeric array representing a single sequence or a cell array of sequences, where the format of the predictors match the formats described in the `sequences` argument description. For image and feature predictor input, the input must be a numeric array and the format of the predictors must match the one of the following:

Data	Format
2-D images	$h$ -by- $w$ -by- $c$ numeric array, where $h$ , $w$ , and $c$ are the height, width, and number of channels of the images, respectively.
3-D images	$h$ -by- $w$ -by- $d$ -by- $c$ numeric array, where $h$ , $w$ , $d$ , and $c$ are the height, width, depth, and number of channels of the images, respectively.
Feature data	$c$ -by-1 column vectors, where $c$ is the number of features.

For an example showing how to train a network with multiple inputs, see “Train Network on Image and Feature Data”.

---

**Tip** To input complex-valued data into a network, the `SplitComplexInputs` option of the input layer must be 1.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `cell`

Complex Number Support: Yes

### **mixed** – Mixed data

`TransformedDatastore` | `CombinedDatastore` | custom mini-batch datastore

Mixed data, specified as one of the following.

Data Type	Description	Example Usage
<code>TransformedDatastore</code>	Datastore that transforms batches of data read from an underlying datastore using a custom transformation function	<ul style="list-style-type: none"> <li>• Make predictions using networks with multiple inputs.</li> <li>• Transform outputs of datastores not supported by <code>predictAndUpdateState</code> so they have the required format.</li> <li>• Apply custom transformations to datastore output.</li> </ul>
<code>CombinedDatastore</code>	Datastore that reads from two or more underlying datastores	<ul style="list-style-type: none"> <li>• Make predictions using networks with multiple inputs.</li> <li>• Combine predictors from different data sources.</li> </ul>
Custom mini-batch datastore	Custom datastore that returns mini-batches of data	<p>Make predictions using data in a format that other datastores do not support.</p> <p>For details, see “Develop Custom Mini-Batch Datastore”.</p>

You can use other built-in datastores for making predictions by using the `transform` and `combine` functions. These functions can convert the data read from datastores to the table or cell array format required by `predictAndUpdateState`. For more information, see “Datastores for Deep Learning”.

The datastore must return data in a table or a cell array. Custom mini-batch datastores must output tables. The format of the datastore output depends on the network architecture.

Datastore Output	Example Output
<p>Cell array with <code>numInputs</code> columns, where <code>numInputs</code> is the number of network inputs.</p> <p>The order of inputs is given by the <code>InputNames</code> property of the network.</p>	<pre>data = read(ds) data =     4x3 cell array     {12x50 double}    {28x1 double}     {12x50 double}    {28x1 double}     {12x50 double}    {28x1 double}     {12x50 double}    {28x1 double}</pre>

For sequence predictor input, the input must be a numeric array representing a single sequence or a cell array of sequences, where the format of the predictors match the formats described in the `sequences` argument description. For image and feature predictor input, the input must be a numeric array and the format of the predictors must match the one of the following:

Data	Format
2-D images	<i>h</i> -by- <i>w</i> -by- <i>c</i> numeric array, where <i>h</i> , <i>w</i> , and <i>c</i> are the height, width, and number of channels of the images, respectively.
3-D images	<i>h</i> -by- <i>w</i> -by- <i>d</i> -by- <i>c</i> numeric array, where <i>h</i> , <i>w</i> , <i>d</i> , and <i>c</i> are the height, width, depth, and number of channels of the images, respectively.
Feature data	<i>c</i> -by-1 column vectors, where <i>c</i> is the number of features.

For an example showing how to train a network with multiple inputs, see “Train Network on Image and Feature Data”.

---

**Tip** To convert a numeric array to a datastore, use `ArrayDatastore`.

---

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[updatedNet,Y] = predictAndUpdateState(recNet,C,MiniBatchSize=27)` makes predictions using mini-batches of size 27.

### MiniBatchSize — Size of mini-batches

128 (default) | positive integer

Size of mini-batches to use for prediction, specified as a positive integer. Larger mini-batch sizes require more memory, but can lead to faster predictions.

When you make predictions with sequences of different lengths, the mini-batch size can impact the amount of padding added to the input data, which can result in different predicted values. Try using

different values to see which works best with your network. To specify mini-batch size and padding options, use the `MiniBatchSize` and `SequenceLength` options, respectively.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Acceleration — Performance optimization**

`"auto"` (default) | `"none"`

Performance optimization, specified as one of the following:

- `"auto"` — Automatically apply a number of optimizations suitable for the input network and hardware resources.
- `"none"` — Disable all acceleration.

Using the `Acceleration` option `"auto"` can offer performance benefits, but at the expense of an increased initial run time. Subsequent calls with compatible parameters are faster. Use performance optimization when you plan to call the function multiple times using new input data.

### **ExecutionEnvironment — Hardware resource**

`"auto"` (default) | `"gpu"` | `"cpu"`

Hardware resource, specified as one of the following:

- `"auto"` — Use a GPU if one is available; otherwise, use the CPU.
- `"gpu"` — Use the GPU. Using a GPU requires a Parallel Computing Toolbox license and a supported GPU device. For information about supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). If Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.
- `"cpu"` — Use the CPU.

### **ReturnCategorical — Option to return categorical labels**

`0` (false) (default) | `1` (true)

Option to return categorical labels, specified as `0` (false) or `1` (true).

If `ReturnCategorical` is `1` (true), then the function returns categorical labels for classification output layers. Otherwise, the function returns the prediction scores for classification output layers.

### **SequenceLength — Option to pad or truncate sequences**

`"longest"` (default) | `"shortest"` | positive integer

Option to pad, truncate, or split input sequences, specified as one of the following:

- `"longest"` — Pad sequences in each mini-batch to have the same length as the longest sequence. This option does not discard any data, though padding can introduce noise to the neural network.
- `"shortest"` — Truncate sequences in each mini-batch to have the same length as the shortest sequence. This option ensures that no padding is added, at the cost of discarding data.
- Positive integer — For each mini-batch, pad the sequences to the length of the longest sequence in the mini-batch, and then split the sequences into smaller sequences of the specified length. If splitting occurs, then the software creates extra mini-batches. If the specified sequence length does not evenly divide the sequence lengths of the data, then the mini-batches containing the ends those sequences have length shorter than the specified sequence length. Use this option if the full sequences do not fit in memory. Alternatively, try reducing the number of sequences per mini-batch by setting the `MiniBatchSize` option to a lower value.

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### **SequencePaddingDirection — Direction of padding or truncation**

`"right"` (default) | `"left"`

Direction of padding or truncation, specified as one of the following:

- `"right"` — Pad or truncate sequences on the right. The sequences start at the same time step and the software truncates or adds padding to the end of the sequences.
- `"left"` — Pad or truncate sequences on the left. The software truncates or adds padding to the start of the sequences so that the sequences end at the same time step.

Because recurrent layers process sequence data one time step at a time, when the recurrent layer `OutputMode` property is `'last'`, any padding in the final time steps can negatively influence the layer output. To pad or truncate sequence data on the left, set the `SequencePaddingDirection` option to `"left"`.

For sequence-to-sequence neural networks (when the `OutputMode` property is `'sequence'` for each recurrent layer), any padding in the first time steps can negatively influence the predictions for the earlier time steps. To pad or truncate sequence data on the right, set the `SequencePaddingDirection` option to `"right"`.

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

### **SequencePaddingValue — Value to pad sequences**

`0` (default) | scalar

Value by which to pad input sequences, specified as a scalar.

The option is valid only when `SequenceLength` is `"longest"` or a positive integer. Do not pad sequences with NaN, because doing so can propagate errors throughout the neural network.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Output Arguments**

### **updatedNet — Updated network**

`SeriesNetwork` object | `DAGNetwork` object

Updated network. `updatedNet` is the same type of network as the input network.

### **Y — Predicted scores or responses**

numeric array | categorical array | cell array

Predicted scores or responses, returned as a numeric array, categorical array, or a cell array. The format of Y depends on the type of problem.

The following table describes the format for classification tasks.

<b>Task</b>	<b>ReturnCategorical</b>	<b>Format</b>
Sequence-to-label classification	0 (false)	$N$ -by- $K$ matrix, where $N$ is the number of observations, and $K$ is the number of classes
	1 (true)	$N$ -by-1 categorical vector, where $N$ is the number of observations
Sequence-to-sequence classification	0 (false)	$N$ -by-1 cell array of matrices, where $N$ is the number of observations. The sequences are matrices with $K$ rows, where $K$ is the number of classes. Each sequence has the same number of time steps as the corresponding input sequence after the <code>SequenceLength</code> option is applied to each mini-batch independently.
	1 (true)	$N$ -by-1 cell array of categorical sequences, where $N$ is the number of observations. The categorical sequences are categorical vectors with the same number of time steps as the corresponding input sequence after the <code>SequenceLength</code> option is applied to each mini-batch independently.

For sequence-to-sequence classification tasks with one observation, `sequences` can be a matrix. In this case, the format of `Y` depends on the `ReturnCategorical` option:

- If `ReturnCategorical` is 0 (false), then `Y` is a  $K$ -by- $S$  matrix scores, where  $K$  is the number of classes, and  $S$  is the total number of time steps in the corresponding input sequence.
- If `ReturnCategorical` is 1 (true), then `Y` is a  $1$ -by- $S$  categorical vector, where  $S$  is the total number of time steps in the corresponding input sequence.

The following table describes the format for regression tasks.

<b>Task</b>	<b>Format</b>
Sequence-to-one regression	$N$ -by- $R$ matrix, where $N$ is the number of observations and $R$ is the number of responses.

Task	Format
Sequence-to-sequence regression	<p><math>N</math>-by-1 cell array of numeric sequences, where <math>N</math> is the number of observations. The sequences are matrices with <math>R</math> rows, where <math>R</math> is the number of responses. Each sequence has the same number of time steps as the corresponding input sequence after applying the <code>SequenceLength</code> option to each mini-batch independently.</p> <p>For sequence-to-sequence problems with one observation, <code>sequences</code> can be a matrix. In this case, <math>Y</math> is a matrix of responses.</p>

### $Y_1, \dots, Y_M$ — Predicted scores or responses of networks with multiple outputs

numeric array | categorical array | cell array

Predicted scores or responses of networks with multiple outputs, returned as numeric arrays, categorical arrays, or cell arrays.

Each output  $Y_j$  corresponds to the network output `recNet.OutputNames(j)` and has format as described in the  $Y$  output argument.

## Algorithms

### Floating-Point Arithmetic

When you train a neural network using the `trainNetwork` function, or when you use prediction or validation functions with `DAGNetwork` and `SeriesNetwork` objects, the software performs these computations using single-precision, floating-point arithmetic. Functions for training, prediction, and validation include `trainNetwork`, `predict`, `classify`, and `activations`. The software uses single-precision arithmetic when you train neural networks using both CPUs and GPUs.

### Reproducibility

To provide the best performance, deep learning using a GPU in MATLAB is not guaranteed to be deterministic. Depending on your network architecture, under some conditions you might get different results when using a GPU to train two identical networks or make two predictions using the same network and data.

## Alternatives

For recurrent neural networks with a single classification layer only, you can compute the predicted classes and scores and update the network state using the `classifyAndUpdateState` function.

To compute the activations of a network layer, use the `activations` function. The `activations` function does not update the network state.

To make predictions without updating the network state, use the `classify` function or the `predict` function.

## Version History

Introduced in R2017b

### R2022b: Prediction functions pad mini-batches to length of longest sequence before splitting when you specify SequenceLength option as an integer

Starting in R2022b, when you make predictions with sequence data using the `predict`, `classify`, `predictAndUpdateState`, `classifyAndUpdateState`, and `activations` functions and the `SequenceLength` option is an integer, the software pads sequences to the length of the longest sequence in each mini-batch and then splits the sequences into mini-batches with the specified sequence length. If `SequenceLength` does not evenly divide the sequence length of the mini-batch, then the last split mini-batch has a length shorter than `SequenceLength`. This behavior prevents time steps that contain only padding values from influencing predictions.

In previous releases, the software pads mini-batches of sequences to have a length matching the nearest multiple of `SequenceLength` that is greater than or equal to the mini-batch length and then splits the data. To reproduce this behavior, manually pad the input data such that the mini-batches have the length of the appropriate multiple of `SequenceLength`. For sequence-to-sequence workflows, you may also need to manually remove time steps of the output that correspond to padding values.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- C++ code generation supports the following syntaxes:
  - `[updatedNet,Y] = predictAndUpdateState(recNet,sequences)`, where `sequences` is cell array.
  - `[updatedNet,Y] = predictAndUpdateState(recNet,sequences,Name=Value)`
- For vector sequence inputs, the number of features must be a constant during code generation. The sequence length can be variable sized.
- For image sequence inputs, the height, width, and the number of channels must be a constant during code generation.
- Only the `MiniBatchSize`, `SequenceLength`, `SequencePaddingDirection`, and `SequencePaddingValue` name-value arguments are supported for code generation. All name-value arguments must be compile-time constants.
- Only the "longest" and "shortest" options of the `SequenceLength` name-value argument is supported for code generation.

- Code generation for Intel MKL-DNN target does not support the combination of `SequenceLength="longest"`, `SequencePaddingDirection="left"`, and `SequencePaddingValue=0` name-value arguments.

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- GPU code generation supports the following syntaxes:
  - `[updatedNet,Y] = predictAndUpdateState(recNet,sequences)`, where `sequences` is cell array or numeric array.
  - `[updatedNet,Y] = predictAndUpdateState(recNet,sequences,Name=Value)`
- GPU code generation for the `predictAndUpdateState` function is only supported for recurrent neural networks targeting cuDNN and TensorRT libraries.
- GPU code generation does not support `gpuArray` inputs to the `predictAndUpdateState` function.
- For vector sequence inputs, the number of features must be a constant during code generation. The sequence length can be variable sized.
- For image sequence inputs, the height, width, and the number of channels must be a constant during code generation.
- Only the `MiniBatchSize`, `SequenceLength`, `SequencePaddingDirection`, and `SequencePaddingValue` name-value arguments are supported for code generation. All name-value pairs must be compile-time constants.
- Only the "longest" and "shortest" options of the `SequenceLength` name-value argument is supported for code generation.

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

- The `ExecutionEnvironment` option must be "auto" or "gpu" when the input data is:
  - A `gpuArray`
  - A cell array containing `gpuArray` objects
  - A table containing `gpuArray` objects
  - A datastore that outputs cell arrays containing `gpuArray` objects
  - A datastore that outputs tables containing `gpuArray` objects

For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

## read

Read data from augmentedImageDatastore

### Syntax

```
data = read(auimds)
[data,info] = read(auimds)
```

### Description

`data = read(auimds)` returns a batch of data from an augmented image datastore, `auimds`. Subsequent calls to the `read` function continue reading from the endpoint of the previous call.

`[data,info] = read(auimds)` also returns information about the extracted data, including metadata, in `info`.

### Input Arguments

#### **auimds** — Augmented image datastore

augmentedImageDatastore

Augmented image datastore, specified as an `augmentedImageDatastore` object. The datastore specifies a `MiniBatchSize` number of observations in each batch, and a `numObservations` total number of observations.

### Output Arguments

#### **data** — Output data

table

Output data, returned as a table. When the datastore `auimds` reads a full batch of data, the table has `MiniBatchSize` rows. For the last batch of data in the datastore, if `numObservations` is not cleanly divisible by `MiniBatchSize`, then `read` returns a partial batch containing all of the remaining observations.

The first column of the table, "input", returns the data for each image. The table has a second column, "response", when `auimds` reads data of these types:

- Image files containing labeled image data, when the file names are specified by an image datastore
- A numeric array containing categorical labels or numeric responses
- A table that includes one or more responses

#### **info** — Information about read data

structure array

Information about read data, returned as a structure array. The structure array can contain these fields.

Field Name	Description
Filename	Cell array of character vectors. Each element is a fully resolved path containing the path string, name of the file, and file extension for the corresponding image. This field is present when <code>auimds</code> reads data from files specified by an image datastore.
FileSize	Numeric vector. Each element is the total file size, in bytes, of the corresponding image. For MAT-files, <code>FileSize</code> is the total number of key-value pairs in the file. This field is present when <code>auimds</code> reads data from files specified by an image datastore.
Label	Categorical vector. Each element is the category label of the corresponding image. This field is present when <code>auimds</code> reads labeled data from files specified by an image datastore.
MiniBatchIndices	Numeric vector. Each element is the index of the input image in the array. This field is present when <code>auimds</code> reads data from numeric arrays.

## Version History

Introduced in R2018a

### See Also

`read (Datastore)` | `readByIndex` | `readall`

## readByIndex

Read data specified by index from `augmentedImageDatastore`

### Syntax

```
data = readByIndex(auimds,ind)
[data,info] = readByIndex(auimds,ind)
```

### Description

`data = readByIndex(auimds,ind)` returns a subset of observations from an augmented image datastore, `auimds`. The desired observations are specified by indices, `ind`.

`[data,info] = readByIndex(auimds,ind)` also returns information about the observations, including metadata, in `info`.

### Input Arguments

#### **auimds** — Augmented image datastore

`augmentedImageDatastore`

Augmented image datastore, specified as an `augmentedImageDatastore` object.

#### **ind** — Indices

vector of positive integers

Indices of observations, specified as a vector of positive integers.

### Output Arguments

#### **data** — Observations from datastore

table

Observations from the datastore, returned as a table with `length(ind)` number of rows.

#### **info** — Information about read data

structure array

Information about read data, returned as a structure array with the following fields.

Field Name	Description
MiniBatchIndices	Numeric vector of indices.

## Version History

Introduced in R2018a

## recordMetrics

**Package:** experiments

Record metric values in experiment results table and training plot

### Syntax

```
recordMetrics(monitor, step, metricName=metricValue)
recordMetrics(monitor,
step, metricName1=metricValue1, ..., metricNameN=metricValueN)
recordMetrics(monitor, step, metricStructure)
```

### Description

`recordMetrics(monitor, step, metricName=metricValue)` records the specified metric value for a trial in the **Experiment Manager** results table and training plot.

`recordMetrics(monitor, step, metricName1=metricValue1, ..., metricNameN=metricValueN)` records multiple metric values for a trial.

`recordMetrics(monitor, step, metricStructure)` records the metric values specified by the structure `metricStructure`.

### Examples

#### Track Progress, Display Information and Record Metric Values, and Produce Training Plots

Use an `experiments.Monitor` object to track the progress of the training, display information and metric values in the experiment results table, and produce training plots for custom training experiments.

Before starting the training, specify the names of the information and metric columns of the Experiment Manager results table.

```
monitor.Info = ["GradientDecayFactor", "SquaredGradientDecayFactor"];
monitor.Metrics = ["TrainingLoss", "ValidationLoss"];
```

Specify the horizontal axis label for the training plot. Group the training and validation loss in the same subplot.

```
monitor.XLabel = "Iteration";
groupSubPlot(monitor, "Loss", ["TrainingLoss", "ValidationLoss"]);
```

Update the values of the gradient decay factor and the squared gradient decay factor for the trial in the results table.

```
updateInfo(monitor, ...
    GradientDecayFactor=gradientDecayFactor, ...
    SquaredGradientDecayFactor=squaredGradientDecayFactor);
```

After each iteration of the custom training loop, record the value of training and validation loss for the trial in the results table and the training plot.

```
recordMetrics(monitor, iteration, ...
    TrainingLoss=trainingLoss, ...
    ValidationLoss=validationLoss);
```

Update the training progress for the trial based on the fraction of iterations completed.

```
monitor.Progress = 100 * (iteration/numIterations);
```

### Specify Metric Values by Using Structure

Use a structure to record metric values in the results table and the training plot.

```
structure.TrainingLoss = trainingLoss;
structure.ValidationLoss = validationLoss;
recordMetrics(monitor, iteration, structure);
```

## Input Arguments

### monitor — Experiment monitor

experiments.Monitor object

Experiment monitor for the trial, specified as an `experiments.Monitor` object. When you run a custom training experiment, Experiment Manager passes this object as the second input argument of the training function.

### step — Custom training loop step

numeric scalar | `dlarray`

Custom training loop step, such as the iteration or epoch number, specified as a numeric scalar or `dlarray` object. Experiment Manager uses this value as the x-coordinate in the training plot.

### metricName — Metric name

string | character vector

Metric name, specified as a string or character vector. This name must be an element of the `Metrics` property of the `experiments.Monitor` object `monitor`.

Data Types: `char` | `string`

### metricValue — Metric value

numeric scalar | `dlarray`

Metric value, specified as a numeric scalar or `dlarray` object. Experiment Manager uses this value as the y-coordinate in the training plot.

### metricStructure — Metric names and values

structure

Metric names and values, specified as a structure. Names must be elements of the `Metrics` property of the `experiments.Monitor` object `monitor` and can appear in any order in the structure.

Example: `struct(TrainingLoss=trainingLoss, ValidationLoss=validationLoss)`

Data Types: `struct`

## Tips

- Both information and metric columns display values in the results table for your experiment. Additionally, the training plot shows a record of the metric values. Use information columns for text and for numerical values that you want to display in the results table but not in the training plot.
- Use the `groupSubPlot` function to define your training subplots before calling the function `recordMetrics`.

## Version History

Introduced in R2021a

# recordMetrics

**Package:** deep

Record metric values for custom training loops

## Syntax

```
recordMetrics(monitor, step, metricName=metricValue)
recordMetrics(monitor,
step, metricName1=metricValue1, ..., metricNameN=metricValueN)
recordMetrics(monitor, step, metricStructure)
```

## Description

`recordMetrics(monitor, step, metricName=metricValue)` records the specified metric value in the training plot and the `MetricData` property of the `TrainingProgressMonitor` object `monitor`.

`recordMetrics(monitor, step, metricName1=metricValue1, ..., metricNameN=metricValueN)` records multiple metric values.

`recordMetrics(monitor, step, metricStructure)` records the metric values specified by the structure `metricStructure`.

## Examples

### Track Progress and Produce Training Plots

Use a `TrainingProgressMonitor` object to track training progress and produce training plots for custom training loops.

Create a `TrainingProgressMonitor` object. The monitor automatically tracks the start time and the elapsed time. The timer starts when you create the object.

---

**Tip** To ensure that the elapsed time accurately reflects the training time, make sure you create the `TrainingProgressMonitor` object close to the start of your custom training loop.

---

```
monitor = trainingProgressMonitor;
```

Before you start the training, specify names for the information and metric values.

```
monitor.Info = ["LearningRate", "Epoch", "Iteration"];
monitor.Metrics = ["TrainingLoss", "ValidationLoss", "TrainingAccuracy", "ValidationAccuracy"];
```

Specify the horizontal axis label for the training plot. Group the training and validation loss in the same subplot, and group the training and validation accuracy in the same plot.

```
monitor.XLabel = "Iteration";  
groupSubPlot(monitor, "Loss", ["TrainingLoss", "ValidationLoss"]);  
groupSubPlot(monitor, "Accuracy", ["TrainingAccuracy", "ValidationAccuracy"]);
```

During training:

- Evaluate the **Stop** property at the start of each step in your custom training loop. When you click the **Stop** button in the Training Progress window, the **Stop** property changes to 1. Training stops if your training loop exits when the **Stop** property is 1.
- Update the information values. The updated values appear in the Training Progress window.
- Record the metric values. The recorded values appear in the training plot.
- Update the training progress percentage based on the fraction of iterations completed.

---

**Note** The following example code is a template. You must edit this training loop to compute your metric and information values. For a complete example that you can run in MATLAB, see “Monitor Custom Training Loop Progress During Training”.

---

```
epoch = 0;  
iteration = 0;  
  
monitor.Status = "Running";  
  
while epoch < maxEpochs && ~monitor.Stop  
    epoch = epoch + 1;  
  
    while hasData(mbq) && ~monitor.Stop  
        iteration = iteration + 1;  
  
        % Add code to calculate metric and information values.  
        % lossTrain = ...  
  
        updateInfo(monitor, ...  
            LearningRate=learnRate, ...  
            Epoch=string(epoch) + " of " + string(maxEpochs), ...  
            Iteration=string(iteration) + " of " + string(numIterations));  
  
        recordMetrics(monitor, iteration, ...  
            TrainingLoss=lossTrain, ...  
            TrainingAccuracy=accuracyTrain, ...  
            ValidationLoss=lossValidation, ...  
            ValidationAccuracy=accuracyValidation);  
  
        monitor.Progress = 100*iteration/numIterations;  
    end  
end
```

The Training Progress window shows animated plots of the metrics, and the information values, training progress bar, and elapsed time.

- The training plots update each time you call `recordMetrics`.
- The values under **Information** update each time you call `updateInfo`.
- The elapsed time updates each time you call `recordMetrics` or `updateInfo`, and when you update the property.

## Specify Metric Values by Using Structure

Use a structure to record metric values.

```
structure.TrainingLoss = trainingLoss;
structure.ValidationLoss = validationLoss;
recordMetrics(monitor, iteration, structure);
```

## Input Arguments

### monitor — Training progress monitor

TrainingProgressMonitor object

Training progress monitor, specified as a TrainingProgressMonitor object.

### step — Custom training loop step

numeric scalar | dlarray object

Custom training loop step, such as the iteration or epoch number, specified as a numeric scalar or dlarray object. The software uses this value as the x-coordinate in the training plot.

### metricName — Metric name

string scalar | character vector

Metric name, specified as a string scalar or character vector. This input must be an element of the Metrics property of monitor.

Data Types: char | string | cell

**metricValue — Metric value**

numeric scalar | dIarray object

Metric value, specified as a numeric scalar or dIarray object. The software uses this value as the y-coordinate in the training plot.

**metricStructure — Metric names and values**

structure

Metric names and values, specified as a structure. Names must be elements of the `Metrics` property of `monitor` and can appear in any order in the structure.

Example: `struct(TrainingLoss=trainingLoss,ValidationLoss=validationLoss)`

Data Types: struct

**Tips**

- The information values appear in the Training Progress window and the training plot shows a record of the metric values. Use information values for text and for numerical values that you want to display in the training window but not in the training plot.
- Use the `groupSubPlot` function to group multiple metrics in a single training subplot.

# regressionLayer

Regression output layer

## Syntax

```
layer = regressionLayer
layer = regressionLayer(Name,Value)
```

## Description

A regression layer computes the half-mean-squared-error loss for regression tasks.

`layer = regressionLayer` returns a regression output layer for a neural network as a `RegressionOutputLayer` object.

Predict responses of a trained regression network using `predict`. Normalizing the responses often helps stabilizing and speeding up training of neural networks for regression. For more information, see “Train Convolutional Neural Network for Regression”.

`layer = regressionLayer(Name,Value)` sets the optional `Name` and `ResponseNames` properties using name-value pairs. For example, `regressionLayer('Name','output')` creates a regression layer with the name 'output'. Enclose each property name in single quotes.

## Examples

### Create Regression Output Layer

Create a regression output layer with the name 'rouput'.

```
layer = regressionLayer('Name','rouput')
```

```
layer =
  RegressionOutputLayer with properties:
```

```
    Name: 'rouput'
  ResponseNames: {}
```

```
Hyperparameters
  LossFunction: 'mean-squared-error'
```

The default loss function for regression is mean-squared-error.

Include a regression output layer in a Layer array.

```
layers = [ ...
  imageInputLayer([28 28 1])
  convolution2dLayer(12,25)
  reluLayer
  fullyConnectedLayer(1)
  regressionLayer]
```

```
layers =  
    5x1 Layer array with layers:  
  
    1 '' Image Input      28x28x1 images with 'zerocenter' normalization  
    2 '' 2-D Convolution  25 12x12 convolutions with stride [1 1] and padding [0 0 0  
    3 '' ReLU             ReLU  
    4 '' Fully Connected  1 fully connected layer  
    5 '' Regression Output mean-squared-error
```

## Input Arguments

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `regressionLayer('Name','output')` creates a regression layer with the name 'output'

### Name — Layer name

'' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ''.

Data Types: `char` | `string`

### ResponseNames — Names of responses

{ } (default) | cell array of character vectors | string array

Names of the responses, specified a cell array of character vectors or a string array. At training time, the software automatically sets the response names according to the training data. The default is {}.

Data Types: `cell`

## Output Arguments

### layer — Regression output layer

`RegressionOutputLayer` object

Regression output layer, returned as a `RegressionOutputLayer` object.

## More About

### Regression Output Layer

A regression layer computes the half-mean-squared-error loss for regression tasks. For typical regression problems, a regression layer must follow the final fully connected layer.

For a single observation, the mean-squared-error is given by:

$$\text{MSE} = \sum_{i=1}^R \frac{(t_i - y_i)^2}{R},$$

where  $R$  is the number of responses,  $t_i$  is the target output, and  $y_i$  is the network's prediction for response  $i$ .

For image and sequence-to-one regression networks, the loss function of the regression layer is the half-mean-squared-error of the predicted responses, not normalized by  $R$ :

$$\text{loss} = \frac{1}{2} \sum_{i=1}^R (t_i - y_i)^2.$$

For image-to-image regression networks, the loss function of the regression layer is the half-mean-squared-error of the predicted responses for each pixel, not normalized by  $R$ :

$$\text{loss} = \frac{1}{2} \sum_{p=1}^{HWC} (t_p - y_p)^2,$$

where  $H$ ,  $W$ , and  $C$  denote the height, width, and number of channels of the output respectively, and  $p$  indexes into each element (pixel) of  $t$  and  $y$  linearly.

For sequence-to-sequence regression networks, the loss function of the regression layer is the half-mean-squared-error of the predicted responses for each time step, not normalized by  $R$ :

$$\text{loss} = \frac{1}{2S} \sum_{i=1}^S \sum_{j=1}^R (t_{ij} - y_{ij})^2,$$

where  $S$  is the sequence length.

When training, the software calculates the mean loss over the observations in the mini-batch.

# RegressionOutputLayer

Regression output layer

## Description

A regression layer computes the half-mean-squared-error loss for regression tasks.

## Creation

Create a regression output layer using `regressionLayer`.

## Properties

### Regression Output

#### ResponseNames — Names of responses

`{}` (default) | cell array of character vectors | string array

Names of the responses, specified a cell array of character vectors or a string array. At training time, the software automatically sets the response names according to the training data. The default is `{}`.

Data Types: `cell`

#### LossFunction — Loss function for training

`'mean-squared-error'`

Loss function the software uses for training, specified as `'mean-squared-error'`.

### Layer

#### Name — Layer name

`''` (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name `''`.

Data Types: `char` | `string`

#### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

#### InputNames — Input names

`{"in"}` (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: cell

### **NumOutputs — Number of outputs**

0 (default)

Number of outputs of the layer. The layer has no outputs.

Data Types: double

### **OutputNames — Output names**

{ } (default)

Output names of the layer. The layer has no outputs.

Data Types: cell

## **Examples**

### **Create Regression Output Layer**

Create a regression output layer with the name 'routput'.

```
layer = regressionLayer('Name','routput')
```

```
layer =  
  RegressionOutputLayer with properties:  
      Name: 'routput'  
  ResponseNames: {}  
  
  Hyperparameters  
    LossFunction: 'mean-squared-error'
```

The default loss function for regression is mean-squared-error.

Include a regression output layer in a Layer array.

```
layers = [ ...  
  imageInputLayer([28 28 1])  
  convolution2dLayer(12,25)  
  reluLayer  
  fullyConnectedLayer(1)  
  regressionLayer]  
  
layers =  
  5x1 Layer array with layers:  
  
  1 '' Image Input 28x28x1 images with 'zerocenter' normalization  
  2 '' 2-D Convolution 25 12x12 convolutions with stride [1 1] and padding [0 0 0]  
  3 '' ReLU ReLU  
  4 '' Fully Connected 1 fully connected layer  
  5 '' Regression Output mean-squared-error
```

## More About

### Regression Output Layer

A regression layer computes the half-mean-squared-error loss for regression tasks. For typical regression problems, a regression layer must follow the final fully connected layer.

For a single observation, the mean-squared-error is given by:

$$\text{MSE} = \sum_{i=1}^R \frac{(t_i - y_i)^2}{R},$$

where  $R$  is the number of responses,  $t_i$  is the target output, and  $y_i$  is the network's prediction for response  $i$ .

For image and sequence-to-one regression networks, the loss function of the regression layer is the half-mean-squared-error of the predicted responses, not normalized by  $R$ :

$$\text{loss} = \frac{1}{2} \sum_{i=1}^R (t_i - y_i)^2.$$

For image-to-image regression networks, the loss function of the regression layer is the half-mean-squared-error of the predicted responses for each pixel, not normalized by  $R$ :

$$\text{loss} = \frac{1}{2} \sum_{p=1}^{HWC} (t_p - y_p)^2,$$

where  $H$ ,  $W$ , and  $C$  denote the height, width, and number of channels of the output respectively, and  $p$  indexes into each element (pixel) of  $t$  and  $y$  linearly.

For sequence-to-sequence regression networks, the loss function of the regression layer is the half-mean-squared-error of the predicted responses for each time step, not normalized by  $R$ :

$$\text{loss} = \frac{1}{2S} \sum_{i=1}^S \sum_{j=1}^R (t_{ij} - y_{ij})^2,$$

where  $S$  is the sequence length.

When training, the software calculates the mean loss over the observations in the mini-batch.

## reset

Reset minibatchqueue to start of data

### Syntax

```
reset(mbq)
```

### Description

reset(mbq) resets mbq back to the start of the underlying datastore.

### Examples

#### Reset minibatchqueue and Obtain More Mini-Batches

You can call next on a minibatchqueue object until all data is returned. When you reach the end of the data, use reset to reset the minibatchqueue object and continue obtaining mini-batches with next.

Create a minibatchqueue object from a datastore.

```
ds = digitDatastore;
mbq = minibatchqueue(ds, 'MinibatchSize', 256)
```

```
mbq =
minibatchqueue with 1 output and properties:
```

```
Mini-batch creation:
    MiniBatchSize: 256
    PartialMiniBatch: 'return'
    MiniBatchFcn: 'collate'
    DispatchInBackground: 0
```

```
Outputs:
    OutputCast: {'single'}
    OutputAsDlarray: 1
    MiniBatchFormat: {''}
    OutputEnvironment: {'auto'}
```

Iterate over all data in the minibatchqueue object. Use hasdata to check if data is still available.

```
while hasdata(mbq)
    [~,] = next(mbq);
end
```

When hasdata returns 0 (false), you cannot collect a mini-batch using next.

```
hasdata(mbq)
```

```
ans =
    0
```

```
X = next(mbq);
```

```
Error using minibatchqueue/next (line 353)
```

```
Unable to provide a mini-batch because end of data reached. Use reset or shuffle to continue generating data.
```

Reset the minibatchqueue object. Now, `hasdata` returns `1 (true)`, and you can continue to obtain data using `next`.

```
reset(mbq);  
hasdata(mbq)
```

```
ans =  
     1
```

```
X = next(mbq);
```

## Input Arguments

### **mbq** — Mini-batch queue

minibatchqueue object

Mini-batch queue, specified as a minibatchqueue object.

## Version History

**Introduced in R2020b**

## Syntax

```
qDetails = quantizationDetails(net)
```

## Description

`qDetails = quantizationDetails(net)` returns a 1-by-1 structure array containing the quantization details for your neural network. The data is returned as a structure with the fields:

- `IsQuantized` — Returns 1 (true) if the network is quantized; otherwise, returns 0 (false)
- `TargetLibrary` — Target library for code generation
- `QuantizedLayerNames` — List of quantized layers
- `QuantizedLearnables` — Quantized network learnable parameters

## Examples

### Show Quantization Details

This example shows how to display the quantization details for a neural network.

Load the pretrained network. `net` is a SqueezeNet convolutional neural network that has been retrained using transfer learning to classify images in the `MerchData` data set.

```
load squeezeNetMerch
net

net =
  DAGNetwork with properties:

    Layers: [68x1 nnet.cnn.layer.Layer]
  Connections: [75x2 table]
    InputNames: {'data'}
    OutputNames: {'new_classoutput'}
```

Use the `quantizationDetails` function to see that the network is not quantized.

```
qDetails_original = quantizationDetails(net)

qDetails_original = struct with fields:
    IsQuantized: 0
    TargetLibrary: ""
  QuantizedLayerNames: [0x0 string]
  QuantizedLearnables: [0x3 table]
```

The `IsQuantized` field returns 0 (false) because the original network uses the single-precision floating-point data type.

Unzip and load the `MerchData` images as an image datastore. Define an `augmentedImageDatastore` object to resize the data for the network, and split the data into calibration and validation data sets to use for quantization.

```
unzip('MerchData.zip');
imds = imageDatastore('MerchData', ...
    'IncludeSubfolders',true, ...
    'LabelSource','foldernames');
[calData, valData] = splitEachLabel(imds, 0.7, 'randomized');
aug_calData = augmentedImageDatastore([227 227], calData);
aug_valData = augmentedImageDatastore([227 227], valData);
```

Create a `dlquantizer` object and specify the network to quantize. Set the execution environment to MATLAB.

```
quantObj = dlquantizer(net,'ExecutionEnvironment','MATLAB');
```

Use the `calibrate` function to exercise the network with sample inputs and collect range information.

```
calResults = calibrate(quantObj,aug_calData);
```

Use the `quantize` method to quantize the network object and return a simulatable quantized network.

```
qNet = quantize(quantObj)
```

```
qNet =
Quantized DAGNetwork with properties:

    Layers: [68x1 nnet.cnn.layer.Layer]
Connections: [75x2 table]
  InputNames: {'data'}
OutputNames: {'new_classoutput'}
```

Use the `quantizationDetails` method to extract quantization details.

Use the `quantizationDetails` method to extract the quantization details.

```
qDetails = quantizationDetails(qNet)

qDetails = struct with fields:
    IsQuantized: 1
    TargetLibrary: "none"
    QuantizedLayerNames: [26x1 string]
    QuantizedLearnables: [52x3 table]
```

Inspect the `QuantizedLayerNames` field to see a list of the quantized layers.

```
qDetails.QuantizedLayerNames
```

```
ans = 26x1 string
    "conv1"
    "fire2-squeeze1x1"
    "fire2-expand1x1"
```

```

"fire2-expand3x3"
"fire3-squeeze1x1"
"fire3-expand1x1"
"fire3-expand3x3"
"fire4-squeeze1x1"
"fire4-expand1x1"
"fire4-expand3x3"
"fire5-squeeze1x1"
"fire5-expand1x1"
"fire5-expand3x3"
"fire6-squeeze1x1"
"fire6-expand1x1"
"fire6-expand3x3"
"fire7-squeeze1x1"
"fire7-expand1x1"
"fire7-expand3x3"
"fire8-squeeze1x1"
"fire8-expand1x1"
"fire8-expand3x3"
"fire9-squeeze1x1"
"fire9-expand1x1"
"fire9-expand3x3"
"new_conv"

```

Inspect the `QuantizedLearnables` field to see the quantized values for learnable parameters in the network.

`qDetails.QuantizedLearnables`

:	:	:

## Input Arguments

**net** — Neural network

dlnetwork object | DAGNetwork object | SeriesNetwork object

Quantized neural network specified as a `dlnetwork`, `SeriesNetwork`, or a `DAGNetwork` object.

## Version History

Introduced in R2022a

### R2023a: Display quantization details of quantized `dlnetwork` objects

The `quantizationDetails` function now supports quantized `dlnetwork` objects.

## resetState

Reset state parameters of neural network

### Syntax

```
netUpdated = resetState(net)
```

### Description

`netUpdated = resetState(net)` resets the state parameters of a neural network. Use this function to reset the state of a recurrent neural network such as an LSTM network.

### Examples

#### Reset Network State

Reset the network state between sequence predictions.

Load `JapaneseVowelsNet`, a pretrained long short-term memory (LSTM) network trained on the Japanese Vowels data set as described in [1] and [2]. This network was trained on the sequences sorted by sequence length with a mini-batch size of 27.

```
load JapaneseVowelsNet
```

View the network architecture.

```
net.Layers
```

```
ans =
    5x1 Layer array with layers:
         1 'sequenceinput'  Sequence Input           Sequence input with 12 dimensions
         2 'lstm'          LSTM                    LSTM with 100 hidden units
         3 'fc'            Fully Connected        9 fully connected layer
         4 'softmax'       Softmax                 softmax
         5 'classoutput'   Classification Output   crossentropyex with '1' and 8 other classes
```

Load the test data.

```
[XTest,YTest] = japaneseVowelsTestData;
```

Classify a sequence and update the network state. For reproducibility, set `rng` to `'shuffle'`.

```
rng('shuffle')
X = XTest{94};
[net,label] = classifyAndUpdateState(net,X);
label
```

```
label = categorical
      3
```

Classify another sequence using the updated network.

```
X = XTest{1};  
label = classify(net,X)  
  
label = categorical  
      7
```

Compare the final prediction with the true label.

```
trueLabel = YTest(1)  
  
trueLabel = categorical  
          1
```

The updated state of the network may have negatively influenced the classification. Reset the network state and predict on the sequence again.

```
net = resetState(net);  
label = classify(net,XTest{1})  
  
label = categorical  
      1
```

## Input Arguments

### **net** — Neural network

SeriesNetwork object | DAGNetwork object | dlnetwork object

Neural network, specified as a SeriesNetwork, DAGNetwork, or dlnetwork object.

The `resetState` function only has an effect if `net` has state parameters (for example, a network with at least one recurrent layer such as an LSTM layer). If the input network does not have state parameters, then the function has no effect and returns the input network.

## Output Arguments

### **netUpdated** — Updated network

SeriesNetwork object | DAGNetwork object | dlnetwork object

Updated network, returned as a network of the same type as the input network.

The `resetState` function only has an effect if `net` has state parameters (for example, a network with at least one recurrent layer such as an LSTM layer). If the input network does not have state parameters, then the function has no effect and returns the input network.

## Version History

**Introduced in R2017b**

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Code generation for Intel MKL-DNN target does not support the combination of 'SequenceLength', 'longest', 'SequencePaddingDirection', 'left', and 'SequencePaddingValue', 0 name-value arguments.

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- GPU code generation for the `resetState` function is only supported for recurrent neural networks targeting cuDNN and TensorRT libraries.

## rmspropupdate

Update parameters using root mean squared propagation (RMSProp)

### Syntax

```
[netUpdated, averageSqGrad] = rmspropupdate(net, grad, averageSqGrad)
[params, averageSqGrad] = rmspropupdate(params, grad, averageSqGrad)
[ ___ ] = rmspropupdate( ___ learnRate, sqGradDecay, epsilon)
```

### Description

Update the network learnable parameters in a custom training loop using the root mean squared propagation (RMSProp) algorithm.

---

**Note** This function applies the RMSProp optimization algorithm to update network parameters in custom training loops that use networks defined as `dlnetwork` objects or model functions. If you want to train a network defined as a `Layer` array or as a `LayerGraph`, use the following functions:

- Create a `TrainingOptionsRMSProp` object using the `trainingOptions` function.
  - Use the `TrainingOptionsRMSProp` object with the `trainNetwork` function.
- 

`[netUpdated, averageSqGrad] = rmspropupdate(net, grad, averageSqGrad)` updates the learnable parameters of the network `net` using the RMSProp algorithm. Use this syntax in a training loop to iteratively update a network defined as a `dlnetwork` object.

`[params, averageSqGrad] = rmspropupdate(params, grad, averageSqGrad)` updates the learnable parameters in `params` using the RMSProp algorithm. Use this syntax in a training loop to iteratively update the learnable parameters of a network defined using functions.

`[ ___ ] = rmspropupdate( ___ learnRate, sqGradDecay, epsilon)` also specifies values to use for the global learning rate, square gradient decay, and small constant `epsilon`, in addition to the input arguments in previous syntaxes.

### Examples

#### Update Learnable Parameters Using rmspropupdate

Perform a single root mean squared propagation update step with a global learning rate of `0.05` and squared gradient decay factor of `0.95`.

Create the parameters and parameter gradients as numeric arrays.

```
params = rand(3,3,4);
grad = ones(3,3,4);
```

Initialize the average squared gradient for the first iteration.

```
averageSqGrad = [];
```

Specify custom values for the global learning rate and squared gradient decay factor.

```
learnRate = 0.05;
sqGradDecay = 0.95;
```

Update the learnable parameters using `rmspropupdate`.

```
[params,averageSqGrad] = rmspropupdate(params,grad,averageSqGrad,learnRate,sqGradDecay);
```

## Train a Network Using `rmspropupdate`

Use `rmspropupdate` to train a network using the root mean squared propagation (RMSProp) algorithm.

### Load Training Data

Load the digits training data.

```
[XTrain,TTrain] = digitTrain4DArrayData;
classes = categories(TTrain);
numClasses = numel(classes);
```

### Define the Network

Define the network architecture and specify the average image value using the `Mean` option in the image input layer.

```
layers = [
    imageInputLayer([28 28 1], 'Mean', mean(XTrain,4))
    convolution2dLayer(5,20)
    reluLayer
    convolution2dLayer(3,20, 'Padding',1)
    reluLayer
    convolution2dLayer(3,20, 'Padding',1)
    reluLayer
    fullyConnectedLayer(numClasses)
    softmaxLayer];
```

Create a `dlnetwork` object from the layer array.

```
net = dlnetwork(layers);
```

### Define Model Loss Function

Create the helper function `modelLoss`, listed at the end of the example. The function takes a `dlnetwork` object and a mini-batch of input data with corresponding labels, and returns the loss and the gradients of the loss with respect to the learnable parameters.

### Specify Training Options

Specify the options to use during training.

```
miniBatchSize = 128;
numEpochs = 20;
numObservations = numel(TTrain);
numIterationsPerEpoch = floor(numObservations./miniBatchSize);
```

## Train Network

Initialize the squared average gradients.

```
averageSqGrad = [];
```

Calculate the total number of iterations for the training progress monitor.

```
numIterations = numEpochs * numIterationsPerEpoch;
```

Initialize the `TrainingProgressMonitor` object. Because the timer starts when you create the monitor object, make sure that you create the object close to the training loop.

```
monitor = trainingProgressMonitor(Metrics="Loss",Info="Epoch",XLabel="Iteration");
```

Train the model using a custom training loop. For each epoch, shuffle the data and loop over mini-batches of data. Update the network parameters using the `rmspropupdate` function. At the end of each iteration, display the training progress.

Train on a GPU, if one is available. Using a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox).

Train the network.

```
iteration = 0;  
epoch = 0;
```

```
while epoch < numEpochs && ~monitor.Stop  
    epoch = epoch + 1;  
  
    % Shuffle data.  
    idx = randperm(numel(TTrain));  
    XTrain = XTrain(:,:,,idx);  
    TTrain = TTrain(idx);  
  
    i = 0;  
    while i < numIterationsPerEpoch && ~monitor.Stop  
        i = i + 1;  
        iteration = iteration + 1;  
  
        % Read mini-batch of data and convert the labels to dummy  
        % variables.  
        idx = (i-1)*miniBatchSize+1:i*miniBatchSize;  
        X = XTrain(:,:,,idx);  
  
        T = zeros(numClasses,miniBatchSize,"single");  
        for c = 1:numClasses  
            T(c,TTrain(idx)==classes(c)) = 1;  
        end  
  
        % Convert mini-batch of data to a dlarray.  
        X = dlarray(single(X),"SSCB");  
  
        % If training on a GPU, then convert data to a gpuArray.  
        if canUseGPU  
            X = gpuArray(X);  
        end
```

```

% Evaluate the model loss and gradients using dlfeval and the
% modelLoss function.
[loss,gradients] = dlfeval(@modelLoss,net,X,T);

% Update the network parameters using the RMSProp optimizer.
[net,averageSqGrad] = rmspropupdate(net,gradients,averageSqGrad);

% Update the training progress monitor.
recordMetrics(monitor,iteration,Loss=loss);
updateInfo(monitor,Epoch=epoch + " of " + numEpochs);
monitor.Progress = 100 * iteration/numIterations;
end
end

```

### Test the Network

Test the classification accuracy of the model by comparing the predictions on a test set with the true labels.

```
[XTest,TTest] = digitTest4DArrayData;
```

Convert the data to a `dlarray` with dimension format "SSCB". For GPU prediction, also convert the data to a `gpuArray`.

```

XTest = dlarray(XTest,"SSCB");
if canUseGPU
    XTest = gpuArray(XTest);
end

```

To classify images using a `dlnetwork` object, use the `predict` function and find the classes with the highest scores.

```
YTest = predict(net,XTest);  
[~,idx] = max(extractdata(YTest),[],1);  
YTest = classes(idx);
```

Evaluate the classification accuracy.

```
accuracy = mean(YTest==TTest)
```

```
accuracy = 0.9926
```

### Model Loss Function

The helper function `modelLoss` takes a `dlnetwork` object `net` and a mini-batch of input data `X` with corresponding labels `T`, and returns the loss and the gradients of the loss with respect to the learnable parameters in `net`. To compute the gradients automatically, use the `dlgradient` function.

```
function [loss,gradients] = modelLoss(net,X,T)  
  
Y = forward(net,X);  
  
loss = crossentropy(Y,T);  
  
gradients = dlgradient(loss,net.Learnables);  
  
end
```

## Input Arguments

### **net** — Network

`dlnetwork` object

Network, specified as a `dlnetwork` object.

The function updates the `Learnables` property of the `dlnetwork` object. `net.Learnables` is a table with three variables:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of parameter, specified as a cell array containing a `dlarray`.

The input argument `grad` must be a table of the same form as `net.Learnables`.

### **params** — Network learnable parameters

`dlarray` | numeric array | cell array | structure | table

Network learnable parameters, specified as a `dlarray`, a numeric array, a cell array, a structure, or a table.

If you specify `params` as a table, it must contain the following three variables.

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of parameter, specified as a cell array containing a `dlarray`.

You can specify `params` as a container of learnable parameters for your network using a cell array, structure, or table, or nested cell arrays or structures. The learnable parameters inside the cell array, structure, or table must be `darray` or numeric values of data type `double` or `single`.

The input argument `grad` must be provided with exactly the same data type, ordering, and fields (for structures) or variables (for tables) as `params`.

Data Types: `single` | `double` | `struct` | `table` | `cell`

### **grad — Gradients of loss**

`darray` | numeric array | cell array | structure | table

Gradients of the loss, specified as a `darray`, a numeric array, a cell array, a structure, or a table.

The exact form of `grad` depends on the input network or learnable parameters. The following table shows the required format for `grad` for possible inputs to `rmspropupdate`.

<b>Input</b>	<b>Learnable Parameters</b>	<b>Gradients</b>
<code>net</code>	Table <code>net.Learnables</code> containing <code>Layer</code> , <code>Parameter</code> , and <code>Value</code> variables. The <code>Value</code> variable consists of cell arrays that contain each learnable parameter as a <code>darray</code> .	Table with the same data type, variables, and ordering as <code>net.Learnables</code> . <code>grad</code> must have a <code>Value</code> variable consisting of cell arrays that contain the gradient of each learnable parameter.
<code>params</code>	<code>darray</code>	<code>darray</code> with the same data type and ordering as <code>params</code>
	Numeric array	Numeric array with the same data type and ordering as <code>params</code>
	Cell array	Cell array with the same data types, structure, and ordering as <code>params</code>
	Structure	Structure with the same data types, fields, and ordering as <code>params</code>
	Table with <code>Layer</code> , <code>Parameter</code> , and <code>Value</code> variables. The <code>Value</code> variable must consist of cell arrays that contain each learnable parameter as a <code>darray</code> .	Table with the same data types, variables, and ordering as <code>params</code> . <code>grad</code> must have a <code>Value</code> variable consisting of cell arrays that contain the gradient of each learnable parameter.

You can obtain `grad` from a call to `dlfeval` that evaluates a function that contains a call to `dlgradient`. For more information, see “Use Automatic Differentiation In Deep Learning Toolbox”.

### **averageSqGrad — Moving average of squared parameter gradients**

`[]` | `darray` | numeric array | cell array | structure | table

Moving average of squared parameter gradients, specified as an empty array, a `darray`, a numeric array, a cell array, a structure, or a table.

The exact form of `averageSqGrad` depends on the input network or learnable parameters. The following table shows the required format for `averageSqGrad` for possible inputs to `rmspropupdate`.

Input	Learnable Parameters	Average Squared Gradients
<code>net</code>	Table <code>net.Learnables</code> containing <code>Layer</code> , <code>Parameter</code> , and <code>Value</code> variables. The <code>Value</code> variable consists of cell arrays that contain each learnable parameter as a <code>dlarray</code> .	Table with the same data type, variables, and ordering as <code>net.Learnables</code> . <code>averageSqGrad</code> must have a <code>Value</code> variable consisting of cell arrays that contain the average squared gradient of each learnable parameter.
<code>params</code>	<code>dlarray</code>	<code>dlarray</code> with the same data type and ordering as <code>params</code>
	Numeric array	Numeric array with the same data type and ordering as <code>params</code>
	Cell array	Cell array with the same data types, structure, and ordering as <code>params</code>
	Structure	Structure with the same data types, fields, and ordering as <code>params</code>
	Table with <code>Layer</code> , <code>Parameter</code> , and <code>Value</code> variables. The <code>Value</code> variable must consist of cell arrays that contain each learnable parameter as a <code>dlarray</code> .	Table with the same data types, variables, and ordering as <code>params</code> . <code>averageSqGrad</code> must have a <code>Value</code> variable consisting of cell arrays that contain the average squared gradient of each learnable parameter.

If you specify `averageSqGrad` as an empty array, the function assumes no previous gradients and runs in the same way as for the first update in a series of iterations. To update the learnable parameters iteratively, use the `averageSqGrad` output of a previous call to `rmspropupdate` as the `averageSqGrad` input.

**LearnRate – Global learning rate**

0.001 (default) | positive scalar

Global learning rate, specified as a positive scalar. The default value of `LearnRate` is 0.001.

If you specify the network parameters as a `dlnetwork`, the learning rate for each parameter is the global learning rate multiplied by the corresponding learning rate factor property defined in the network layers.

**sqGradDecay – Squared gradient decay factor**

0.9 (default) | positive scalar between 0 and 1.

Squared gradient decay factor, specified as a positive scalar between 0 and 1. The default value of `sqGradDecay` is 0.9.

### **epsilon — Small constant**

1e-8 (default) | positive scalar

Small constant for preventing divide-by-zero errors, specified as a positive scalar. The default value of `epsilon` is 1e-8.

## **Output Arguments**

### **netUpdated — Updated network**

`dlnetwork` object

Updated network, returned as a `dlnetwork` object.

The function updates the `Learnables` property of the `dlnetwork` object.

### **params — Updated network learnable parameters**

`dlarray` | numeric array | cell array | structure | table

Updated network learnable parameters, returned as a `dlarray`, a numeric array, a cell array, a structure, or a table with a `Value` variable containing the updated learnable parameters of the network.

### **averageSqGrad — Updated moving average of squared parameter gradients**

`dlarray` | numeric array | cell array | structure | table

Updated moving average of squared parameter gradients, returned as a `dlarray`, a numeric array, a cell array, a structure, or a table.

## **More About**

### **RMSProp**

The function uses the root mean squared propagation algorithm to update the learnable parameters. For more information, see the definition of the RMSProp algorithm under “Stochastic Gradient Descent” on page 1-1782 on the `trainingOptions` reference page.

## **Version History**

### **Introduced in R2019b**

#### **R2020a: rmspropupdate squared gradient decay factor default is 0.9**

*Behavior changed in R2020a*

Starting in R2020a, the default value of the squared gradient decay factor in `rmspropupdate` is 0.9. In previous versions, the default value was 0.999. To reproduce the previous default behavior, use one of the following syntaxes:

```
[net,averageSqGrad] = rmspropupdate(net,grad,averageSqGrad,0.001,0.999)
[params,averageSqGrad] = rmspropupdate(params,grad,averageSqGrad,0.001,0.999)
```

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When at least one of the following input arguments is a `gpuArray` or a `dlarray` with underlying data of type `gpuArray`, this function runs on the GPU.
  - `grad`
  - `averageSqGrad`
  - `params`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# relu

Apply rectified linear unit activation

## Syntax

$Y = \text{relu}(X)$

## Description

The rectified linear unit (ReLU) activation operation performs a nonlinear threshold operation, where any input value less than zero is set to zero.

This operation is equivalent to

$$f(x) = \begin{cases} x, & x > 0 \\ 0, & x \leq 0. \end{cases}$$

---

**Note** This function applies the ReLU operation to `darray` data. If you want to apply the ReLU activation within a `layerGraph` object or `Layer` array, use the following layer:

- `reluLayer`
- 

$Y = \text{relu}(X)$  computes the ReLU activation of the input  $X$  by applying a threshold operation. All values in  $X$  that are less than zero are set to zero.

## Examples

### Apply ReLU Operation

Create a formatted `darray` object containing a batch of 128 28-by-28 images with 3 channels. Specify the format 'SSCB' (spatial, spatial, channel, batch).

```
miniBatchSize = 128;
inputSize = [28 28];
numChannels = 3;
X = rand(inputSize(1),inputSize(2),numChannels,miniBatchSize);
X = darray(X,"SSCB");
```

View the size and format of the input data.

```
size(X)
```

```
ans = 1x4
```

```
    28    28     3   128
```

```
dims(X)
```

```
ans =  
'SSCB'
```

Apply the ReLU operation using the `relu` function.

```
Y = relu(X);
```

View the size and format of the output.

```
size(Y)
```

```
ans = 1×4
```

```
    28    28     3   128
```

```
dims(Y)
```

```
ans =  
'SSCB'
```

## Input Arguments

### **X** — Input data

`darray` object

Input data, specified as a formatted or unformatted `darray` object.

## Output Arguments

### **Y** — ReLU activations

`darray`

ReLU activations, returned as a `darray`. The output `Y` has the same underlying data type as the input `X`.

If the input data `X` is a formatted `darray`, `Y` has the same dimension format as `X`. If the input data is not a formatted `darray`, `Y` is an unformatted `darray` with the same dimension order as the input data.

## Version History

**Introduced in R2019b**

## Extended Capabilities

### **GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When the input argument `X` is a `darray` with underlying data of type `gpuArray`, this function runs on the GPU.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# reluLayer

Rectified Linear Unit (ReLU) layer

## Description

A ReLU layer performs a threshold operation to each element of the input, where any value less than zero is set to zero.

This operation is equivalent to

$$f(x) = \begin{cases} x, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

## Creation

### Syntax

```
layer = reluLayer  
layer = reluLayer('Name', Name)
```

### Description

`layer = reluLayer` creates a ReLU layer.

`layer = reluLayer('Name', Name)` creates a ReLU layer and sets the optional `Name` property using a name-value pair. For example, `reluLayer('Name', 'relu1')` creates a ReLU layer with the name 'relu1'.

## Properties

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

**InputNames — Input names**

{"in"} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: cell

**NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: double

**OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

**Examples****Create ReLU Layer**

Create a ReLU layer with the name 'relu1'.

```
layer = reluLayer('Name','relu1')
```

```
layer =  
    ReLULayer with properties:
```

```
    Name: 'relu1'
```

Include a ReLU layer in a Layer array.

```
layers = [ ...  
    imageInputLayer([28 28 1])  
    convolution2dLayer(5,20)  
    reluLayer  
    maxPooling2dLayer(2,'Stride',2)  
    fullyConnectedLayer(10)  
    softmaxLayer  
    classificationLayer]
```

```
layers =  
    7x1 Layer array with layers:
```

```
    1 '' Image Input          28x28x1 images with 'zerocenter' normalization  
    2 '' 2-D Convolution     20 5x5 convolutions with stride [1 1] and padding [0 0 0 0]
```

```
3 '' ReLU ReLU
4 '' 2-D Max Pooling 2x2 max pooling with stride [2 2] and padding [0 0 0 0]
5 '' Fully Connected 10 fully connected layer
6 '' Softmax softmax
7 '' Classification Output crossentropyex
```

## More About

### ReLU Layer

A ReLU layer performs a threshold operation to each element of the input, where any value less than zero is set to zero.

Convolutional and batch normalization layers are usually followed by a nonlinear activation function such as a rectified linear unit (ReLU), specified by a ReLU layer. A ReLU layer performs a threshold operation to each element, where any input value less than zero is set to zero, that is,

$$f(x) = \begin{cases} x, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

The ReLU layer does not change the size of its input.

There are other nonlinear activation layers that perform different operations and can improve the network accuracy for some applications. For a list of activation layers, see “Activation Layers”.

## Version History

## removeLayers

**Package:** `nnet.cnn`

Remove layers from layer graph or network

### Syntax

```
lgraphUpdated = removeLayers(lgraph, layerNames)
netUpdated = removeLayers(net, layerNames)
```

### Description

`lgraphUpdated = removeLayers(lgraph, layerNames)` removes the layers specified by `layerNames` from the layer graph `lgraph`. The function also removes any connections to the removed layers.

`netUpdated = removeLayers(net, layerNames)` removes the layers specified by `layerNames` from the `dlnetwork` object `net`. The function also removes any connections to the removed layers.

### Examples

#### Remove Layer from Layer Graph

Create a layer graph from an array of layers.

```
layers = [
    imageInputLayer([28 28 1], 'Name', 'input')
    convolution2dLayer(3, 16, 'Padding', 'same', 'Name', 'conv_1')
    batchNormalizationLayer('Name', 'BN_1')
    reluLayer('Name', 'relu_1')];

lgraph = layerGraph(layers);
figure
plot(lgraph)
```

Remove the 'BN\_1' layer and its connections.

```
lgraph = removeLayers(lgraph, 'BN_1');  
figure  
plot(lgraph)
```

## Input Arguments

### **lgraph** — Layer graph

LayerGraph object

Layer graph, specified as a LayerGraph object. To create a layer graph, use `layerGraph`.

### **net** — Neural network

dlnetwork object

Neural network, specified as a dlnetwork object.

### **layerNames** — Names of layers to remove

character vector | cell array of character vectors | string array

Names of layers to remove, specified as a character vector, a cell array of character vectors, or a string array.

To remove a single layer from the layer graph, specify the name of the layer.

To remove multiple layers, specify the layer names in an array, where each element of the array is a layer name.

Example: 'conv1'

Example: {'conv1', 'add1'}

## Output Arguments

### **lgraphUpdated** — Updated layer graph

LayerGraph object

Updated layer graph, returned as a LayerGraph object.

### **netUpdated** — Updated network

dlnetwork object

Updated network, returned as an uninitialized dlnetwork object.

To initialize the learnable parameters of a dlnetwork object, use the `initialize` function.

The `removeLayers` function does not preserve quantization information. If the input network is a quantized network, then the output network does not contain quantization information.

## Version History

**Introduced in R2017b**

## removeParameter

Remove parameter from ONNXParameters object

### Syntax

```
params = removeParameter(params,name)
```

### Description

`params = removeParameter(params,name)` removes the parameter specified by name from the ONNXParameters object `params`.

### Examples

#### Remove Parameters from Imported ONNX Model Function

Import a network saved in the ONNX format as a function and modify the network parameters.

Import the pretrained `simplenet3fc.onnx` network as a function. `simplenet3fc` is a simple convolutional neural network trained on digit image data. For more information on how to create a network similar to `simplenet3fc`, see “Create Simple Image Classification Network”.

Import `simplenet3fc.onnx` using `importONNXFunction`, which returns an `ONNXParameters` object that contains the network parameters. The function also creates a new model function in the current folder that contains the network architecture. Specify the name of the model function as `simplenetFcn`.

```
params = importONNXFunction('simplenet3fc.onnx','simplenetFcn');
```

A function containing the imported ONNX network has been saved to the file `simplenetFcn.m`. To learn how to use this function, type: `help simplenetFcn`.

Display the parameters that are updated during training (`params.Learnables`) and the parameters that remain unchanged during training (`params.Nonlearnables`).

```
params.Learnables
```

```
ans = struct with fields:
    imageinput_Mean: [1×1 dlarray]
        conv_W: [5×5×1×20 dlarray]
        conv_B: [20×1 dlarray]
    batchnorm_scale: [20×1 dlarray]
        batchnorm_B: [20×1 dlarray]
        fc_1_W: [24×24×20×20 dlarray]
        fc_1_B: [20×1 dlarray]
        fc_2_W: [1×1×20×20 dlarray]
        fc_2_B: [20×1 dlarray]
        fc_3_W: [1×1×20×10 dlarray]
        fc_3_B: [10×1 dlarray]
```

```
params.Nonlearnables
```

```
ans = struct with fields:
    ConvStride1004: [2×1 dlarray]
    ConvDilationFactor1005: [2×1 dlarray]
    ConvPadding1006: [4×1 dlarray]
    ConvStride1007: [2×1 dlarray]
    ConvDilationFactor1008: [2×1 dlarray]
    ConvPadding1009: [4×1 dlarray]
    ConvStride1010: [2×1 dlarray]
    ConvDilationFactor1011: [2×1 dlarray]
    ConvPadding1012: [4×1 dlarray]
    ConvStride1013: [2×1 dlarray]
    ConvDilationFactor1014: [2×1 dlarray]
    ConvPadding1015: [4×1 dlarray]
```

The network has parameters that represent three fully connected layers. To see the parameters of the convolutional layers `fc_1`, `fc_2`, and `fc_3`, open the model function `simplenetFcn`.

open `simplenetFcn`

Scroll down to the layer definitions in the function `simplenetFcn`. The code below shows the definitions for layers `fc_1`, `fc_2`, and `fc_3`.

```
% Conv:
[weights, bias, stride, dilationFactor, padding, dataFormat, NumDims.fc_1] = prepareConvArgs(Var...
Vars.fc_1 = dlconv(Vars.relu1001, weights, bias, 'Stride', stride, 'DilationFactor', dilationFactor...

% Conv:
[weights, bias, stride, dilationFactor, padding, dataFormat, NumDims.fc_2] = prepareConvArgs(Var...
Vars.fc_2 = dlconv(Vars.fc_1, weights, bias, 'Stride', stride, 'DilationFactor', dilationFactor, ...

% Conv:
[weights, bias, stride, dilationFactor, padding, dataFormat, NumDims.fc_3] = prepareConvArgs(Var...
Vars.fc_3 = dlconv(Vars.fc_2, weights, bias, 'Stride', stride, 'DilationFactor', dilationFactor, ...
```

You can remove the parameters of the fully connected layer `fc_2` to reduce computational complexity. Check the output dimensions of the previous layer and the input dimensions of the subsequent layer before removing a middle layer from `params`. In this case, the output size of the previous layer `fc_1` is 20, and the input size of the subsequent layer `fc_3` is also 20.

Remove the parameters of layer `fc_2` by using `removeParameter`.

```
params = removeParameter(params, 'fc_2_B');
params = removeParameter(params, 'fc_2_W');
params = removeParameter(params, 'ConvStride1010');
params = removeParameter(params, 'ConvDilationFactor1011');
params = removeParameter(params, 'ConvPadding1012');
```

Display the updated learnable and nonlearnable parameters.

```
params.Learnables
```

```
ans = struct with fields:
    imageinput_Mean: [1×1 dlarray]
    conv_W: [5×5×1×20 dlarray]
    conv_B: [20×1 dlarray]
```

```
batchnorm_scale: [20×1 darray]
batchnorm_B: [20×1 darray]
fc_1_W: [24×24×20×20 darray]
fc_1_B: [20×1 darray]
fc_3_W: [1×1×20×10 darray]
fc_3_B: [10×1 darray]
```

`params.Nonlearnables`

```
ans = struct with fields:
    ConvStride1004: [2×1 darray]
    ConvDilationFactor1005: [2×1 darray]
    ConvPadding1006: [4×1 darray]
    ConvStride1007: [2×1 darray]
    ConvDilationFactor1008: [2×1 darray]
    ConvPadding1009: [4×1 darray]
    ConvStride1013: [2×1 darray]
    ConvDilationFactor1014: [2×1 darray]
    ConvPadding1015: [4×1 darray]
```

Modify the architecture of the model function to reflect the changes in `params` so you can use the network for prediction with the new parameters or retrain the network. Open the model function `simplenetFcn`. Then, remove the fully connected layer `fc_2`, and change the input data of the convolution operation `dlconv` for layer `fc_3` to `Vars.fc_1`.

open `simplenetFcn`

The code below shows layers `fc_1` and `fc_3`.

```
% Conv:
[weights, bias, stride, dilationFactor, padding, dataFormat, NumDims.fc_1] = prepareConvArgs(Vars
Vars.fc_1 = dlconv(Vars.relu1001, weights, bias, 'Stride', stride, 'DilationFactor', dilationFactor);

% Conv:
[weights, bias, stride, dilationFactor, padding, dataFormat, NumDims.fc_3] = prepareConvArgs(Vars
Vars.fc_3 = dlconv(Vars.fc_1, weights, bias, 'Stride', stride, 'DilationFactor', dilationFactor);
```

## Input Arguments

### **params** — Network parameters

ONNXParameters object

Network parameters, specified as an ONNXParameters object. `params` contains the network parameters of the imported ONNX model.

### **name** — Name of parameter

character vector | string scalar

Name of the parameter, specified as a character vector or string scalar.

Example: 'conv2\_W'

Example: 'conv2\_Padding'

## Output Arguments

### **params — Network parameters**

ONNXParameters object

Network parameters, returned as an ONNXParameters object. params contains the network parameters updated by removeParameter.

## Version History

**Introduced in R2020b**

# replaceLayer

**Package:** `nnet.cnn`

Replace layer in layer graph or network

## Syntax

```
lgraphUpdated = replaceLayer(lgraph, layerName, larray)
netUpdated = replaceLayer(net, layerName, larray)
___ = replaceLayer( ___, 'ReconnectBy', mode)
```

## Description

`lgraphUpdated = replaceLayer(lgraph, layerName, larray)` replaces the layer `layerName` in the layer graph `lgraph` with the layers in `larray`.

`replaceLayer` connects the layers in `larray` sequentially and connects `larray` into the layer graph.

`netUpdated = replaceLayer(net, layerName, larray)` replaces the layer `layerName` in the `dlnetwork` object `net` with the layers in `larray`.

`replaceLayer` connects the layers in `larray` sequentially and connects `larray` into the network.

`___ = replaceLayer( ___, 'ReconnectBy', mode)` additionally specifies the method of reconnecting layers.

## Examples

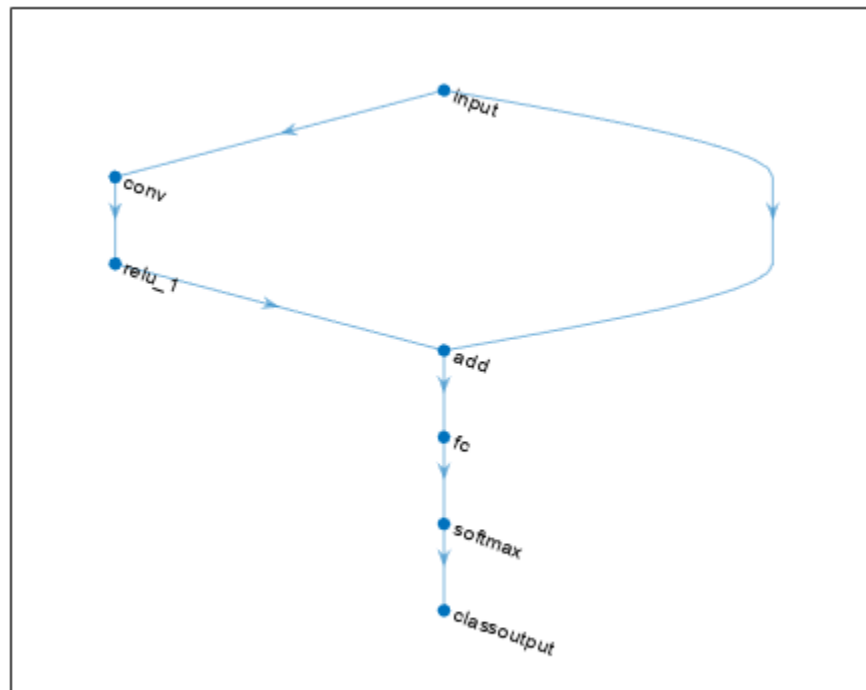

### Replace Layer in Layer Graph

Define a simple network architecture and plot it.

```
layers = [
    imageInputLayer([28 28 1], 'Name', 'input')
    convolution2dLayer(3, 16, 'Padding', 'same')
    reluLayer('Name', 'relu_1')
    additionLayer(2, 'Name', 'add')
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer];

lgraph = layerGraph(layers);
lgraph = connectLayers(lgraph, 'input', 'add/in2');

figure
plot(lgraph)
```

Replace the ReLU layer in the network with a batch normalization layer followed by a leaky ReLU layer.

```
layers = [  
    batchNormalizationLayer  
    leakyReluLayer(0.1)];  
lgraph = replaceLayer(lgraph, 'relu_1', layers);  
plot(lgraph)
```

### Assemble Network from Pretrained Keras Layers

This example shows how to import the layers from a pretrained Keras network, replace the unsupported layers with custom layers, and assemble the layers into a network ready for prediction.

#### Import Keras Network

Import the layers from a Keras network model. The network in 'digitsDAGnetwithnoise.h5' classifies images of digits.

```
filename = 'digitsDAGnetwithnoise.h5';
lgraph = importKerasLayers(filename, 'ImportWeights', true);
```

Warning: Unable to import some Keras layers, because they are not supported by the Deep Learning

The Keras network contains some layers that are not supported by Deep Learning Toolbox. The `importKerasLayers` function displays a warning and replaces the unsupported layers with placeholder layers.

Plot the layer graph using `plot`.

```
figure
plot(lgraph)
title("Imported Network")
```

## Replace Placeholder Layers

To replace the placeholder layers, first identify the names of the layers to replace. Find the placeholder layers using `findPlaceholderLayers`.

```
placeholderLayers = findPlaceholderLayers(lgraph)
```

```
placeholderLayers =  
  2x1 PlaceholderLayer array with layers:
```

1	'gaussian_noise_1'	PLACEHOLDER LAYER	Placeholder for 'GaussianNoise' Keras layer
2	'gaussian_noise_2'	PLACEHOLDER LAYER	Placeholder for 'GaussianNoise' Keras layer

Display the Keras configurations of these layers.

```
placeholderLayers.KerasConfiguration
```

```
ans = struct with fields:  
  trainable: 1  
  name: 'gaussian_noise_1'  
  stddev: 1.5000
```

```
ans = struct with fields:  
  trainable: 1  
  name: 'gaussian_noise_2'  
  stddev: 0.7000
```

Create two Gaussian noise layers with the same configurations as the imported Keras layers using the helper `gaussianNoiseLayer` function.

```
gnLayer1 = gaussianNoiseLayer(1.5, 'new_gaussian_noise_1');
gnLayer2 = gaussianNoiseLayer(0.7, 'new_gaussian_noise_2');
```

Replace the placeholder layers with the custom layers using `replaceLayer`.

```
lgraph = replaceLayer(lgraph, 'gaussian_noise_1', gnLayer1);
lgraph = replaceLayer(lgraph, 'gaussian_noise_2', gnLayer2);
```

Plot the updated layer graph using `plot`.

```
figure
plot(lgraph)
title("Network with Replaced Layers")
```

### Specify Class Names

If the imported classification layer does not contain the classes, then you must specify these before prediction. If you do not specify the classes, then the software automatically sets the classes to 1, 2, ..., N, where N is the number of classes.

Find the index of the classification layer by viewing the `Layers` property of the layer graph.

```
lgraph.Layers
```

```
ans =
    15x1 Layer array with layers:
```

1	'input_1'	Image Input	28x28x1 images
2	'conv2d_1'	2-D Convolution	20 7x7x1 convolutions with
3	'conv2d_1_relu'	ReLU	ReLU
4	'conv2d_2'	2-D Convolution	20 3x3x1 convolutions with
5	'conv2d_2_relu'	ReLU	ReLU
6	'new_gaussian_noise_1'	Gaussian Noise	Gaussian noise with standa
7	'new_gaussian_noise_2'	Gaussian Noise	Gaussian noise with standa
8	'max_pooling2d_1'	2-D Max Pooling	2x2 max pooling with stride
9	'max_pooling2d_2'	2-D Max Pooling	2x2 max pooling with stride
10	'flatten_1'	Keras Flatten	Flatten activations into 1
11	'flatten_2'	Keras Flatten	Flatten activations into 1
12	'concatenate_1'	Depth concatenation	Depth concatenation of 2 in
13	'dense_1'	Fully Connected	10 fully connected layer
14	'activation_1'	Softmax	softmax
15	'ClassificationLayer_activation_1'	Classification Output	crossentropyex

The classification layer has the name 'ClassificationLayer\_activation\_1'. View the classification layer and check the `Classes` property.

```
cLayer = lgraph.Layers(end)
```

```
cLayer =
```

```
ClassificationOutputLayer with properties:
```

```
    Name: 'ClassificationLayer_activation_1'
    Classes: 'auto'
    ClassWeights: 'none'
    OutputSize: 'auto'
```

```
Hyperparameters
```

```
LossFunction: 'crossentropyex'
```

Because the `Classes` property of the layer is 'auto', you must specify the classes manually. Set the classes to 0, 1, ..., 9, and then replace the imported classification layer with the new one.

```
cLayer.Classes = string(0:9)
```

```
cLayer =
```

```
ClassificationOutputLayer with properties:
```

```
    Name: 'ClassificationLayer_activation_1'
    Classes: [0 1 2 3 4 5 6 7 8 9]
    ClassWeights: 'none'
    OutputSize: 10
```

```
Hyperparameters
```

```
LossFunction: 'crossentropyex'
```

```
lgraph = replaceLayer(lgraph, 'ClassificationLayer_activation_1', cLayer);
```

### Assemble Network

Assemble the layer graph using `assembleNetwork`. The function returns a `DAGNetwork` object that is ready to use for prediction.

```
net = assembleNetwork(lgraph)
```

```
net =  
  DAGNetwork with properties:  
  
    Layers: [15x1 nnet.cnn.layer.Layer]  
  Connections: [15x2 table]  
  InputNames: {'input_1'}  
  OutputNames: {'ClassificationLayer_activation_1'}
```

## Input Arguments

### **lgraph** — Layer graph

LayerGraph object

Layer graph, specified as a LayerGraph object. To create a layer graph, use `layerGraph`.

### **net** — Neural network

dlnetwork object

Neural network, specified as a dlnetwork object.

### **layerName** — Name of layer to replace

string scalar | character vector

Name of the layer to replace, specified as a string scalar or a character vector.

### **larray** — Network layers

Layer array

Network layers, specified as a Layer array.

For a list of built-in layers, see “List of Deep Learning Layers”.

### **mode** — Method to reconnect layers

'name' (default) | 'order'

Method to reconnect layers specified as one of the following:

- 'name' - Reconnect `larray` using the input and output names of the replaced layer. For each layer connected to an input of the replaced layer, reconnect the layer to the input of the same input name of `larray(1)`. For each layer connected to an output of the replaced layer, reconnect the layer to the output of the same output name of `larray(end)`.
- 'order' - Reconnect `larray` using the order of the input names of `larray(1)` and the output names of `larray(end)`. Reconnect the layer connected to the *i*th input of the replaced layer to the *i*th input of `larray(1)`. Reconnect the layer connected to the *j*th output of the replaced layer to the *j*th output of `larray(end)`.

Data Types: char | string

## Output Arguments

### **lgraphUpdated** — Updated layer graph

LayerGraph object

Updated layer graph, returned as a LayerGraph object.

**netUpdated — Updated network**`dlnetwork` object

Updated network, returned as an uninitialized `dlnetwork` object.

To initialize the learnable parameters of a `dlnetwork` object, use the `initialize` function.

The `replaceLayer` function does not preserve quantization information. If the input network is a quantized network, then the output network does not contain quantization information.

## Version History

**Introduced in R2018b**

## resnet18

ResNet-18 convolutional neural network

### Syntax

```
net = resnet18
net = resnet18('Weights','imagenet')

lgraph = resnet18('Weights','none')
```

### Description

ResNet-18 is a convolutional neural network that is 18 layers deep. You can load a pretrained version of the network trained on more than a million images from the ImageNet database [1]. The pretrained network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. The network has an image input size of 224-by-224. For more pretrained networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the ResNet-18 model. Follow the steps of “Classify Image Using GoogLeNet” and replace GoogLeNet with ResNet-18.

To retrain the network on a new classification task, follow the steps of “Train Deep Learning Network to Classify New Images” and load ResNet-18 instead of GoogLeNet.

---

**Tip** To create an untrained residual network suitable for image classification tasks, use `resnetLayers`.

---

`net = resnet18` returns a ResNet-18 network trained on the ImageNet data set.

This function requires the Deep Learning Toolbox Model *for ResNet-18 Network* support package. If this support package is not installed, then the function provides a download link.

`net = resnet18('Weights','imagenet')` returns a ResNet-18 network trained on the ImageNet data set. This syntax is equivalent to `net = resnet18`.

`lgraph = resnet18('Weights','none')` returns the untrained ResNet-18 network architecture. The untrained model does not require the support package.

### Examples

#### Download ResNet-18 Support Package

Download and install the Deep Learning Toolbox Model *for ResNet-18 Network* support package.

Type `resnet18` at the command line.

```
resnet18
```

If the Deep Learning Toolbox Model for *ResNet-18 Network* support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**. Check that the installation is successful by typing `resnet18` at the command line. If the required support package is installed, then the function returns a DAGNetwork object.

```
resnet18
```

```
ans =
```

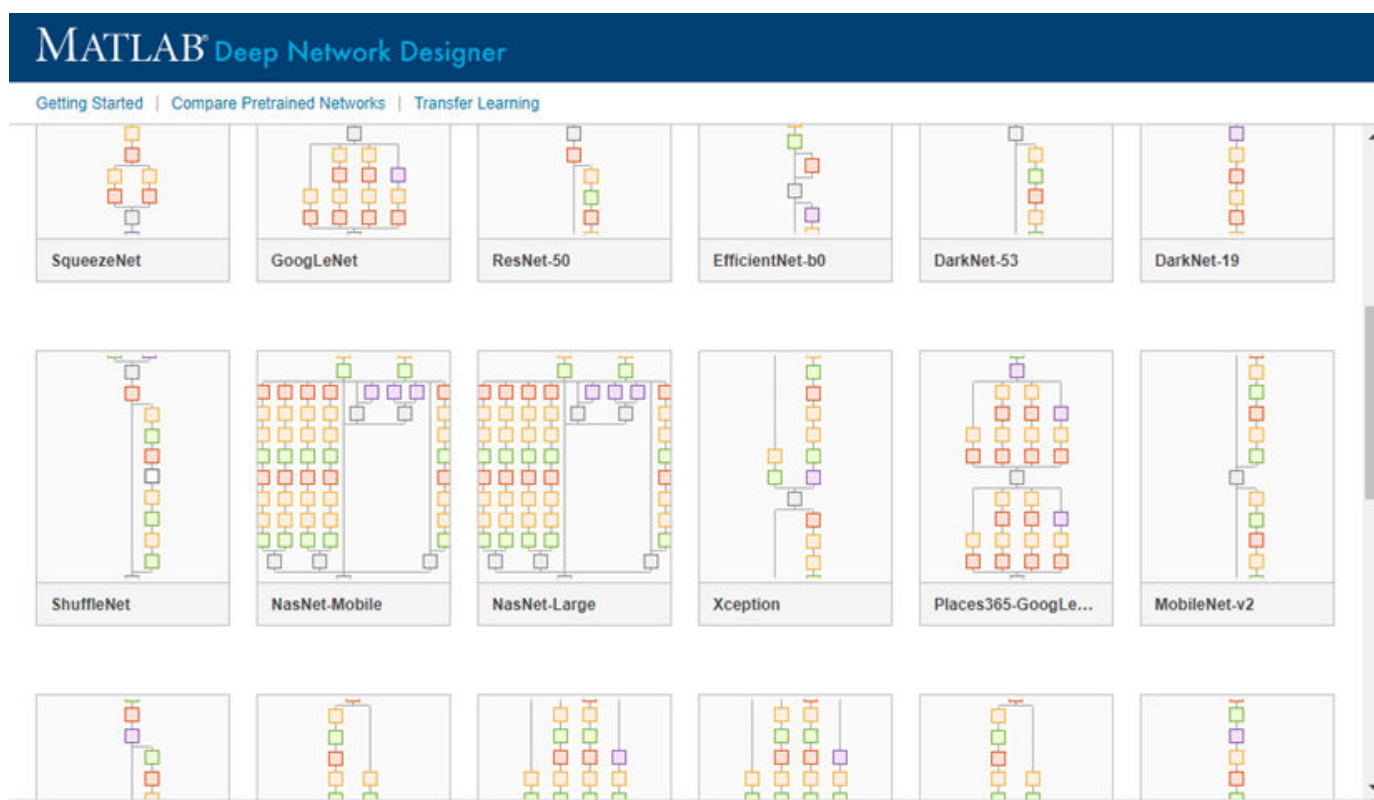

```
DAGNetwork with properties:
```

```
    Layers: [72x1 nnet.cnn.layer.Layer]  
    Connections: [79x2 table]
```

Visualize the network using Deep Network Designer.

```
deepNetworkDesigner(resnet18)
```

Explore other pretrained neural networks in Deep Network Designer by clicking **New**.

If you need to download a neural network, pause on the desired neural network and click **Install** to open the Add-On Explorer.

### Classify Image Using ResNet-18

Load a pretrained ResNet-18 model.

```
net = resnet18;
```

Read a test image using `imread`.

```
I = imread("peppers.png");  
imshow(I)
```

The pretrained model requires the image size to be the same as the input size of the network. Determine the input size of the network using the `InputSize` property of the first layer of the network.

```
sz = net.Layers(1).InputSize
```

```
sz = 1×3
```

```
    224    224     3
```

Resize the image to the input size of the network.

```
I = imresize(I,sz(1:2));
```

Classify the image using `classify`.

```
label = classify(net,I)
```

```
label = categorical  
    bell pepper
```

Show the image and classification result together.

```
imshow(I)  
title(label)
```

### **Interactive Transfer Learning Using ResNet-18**

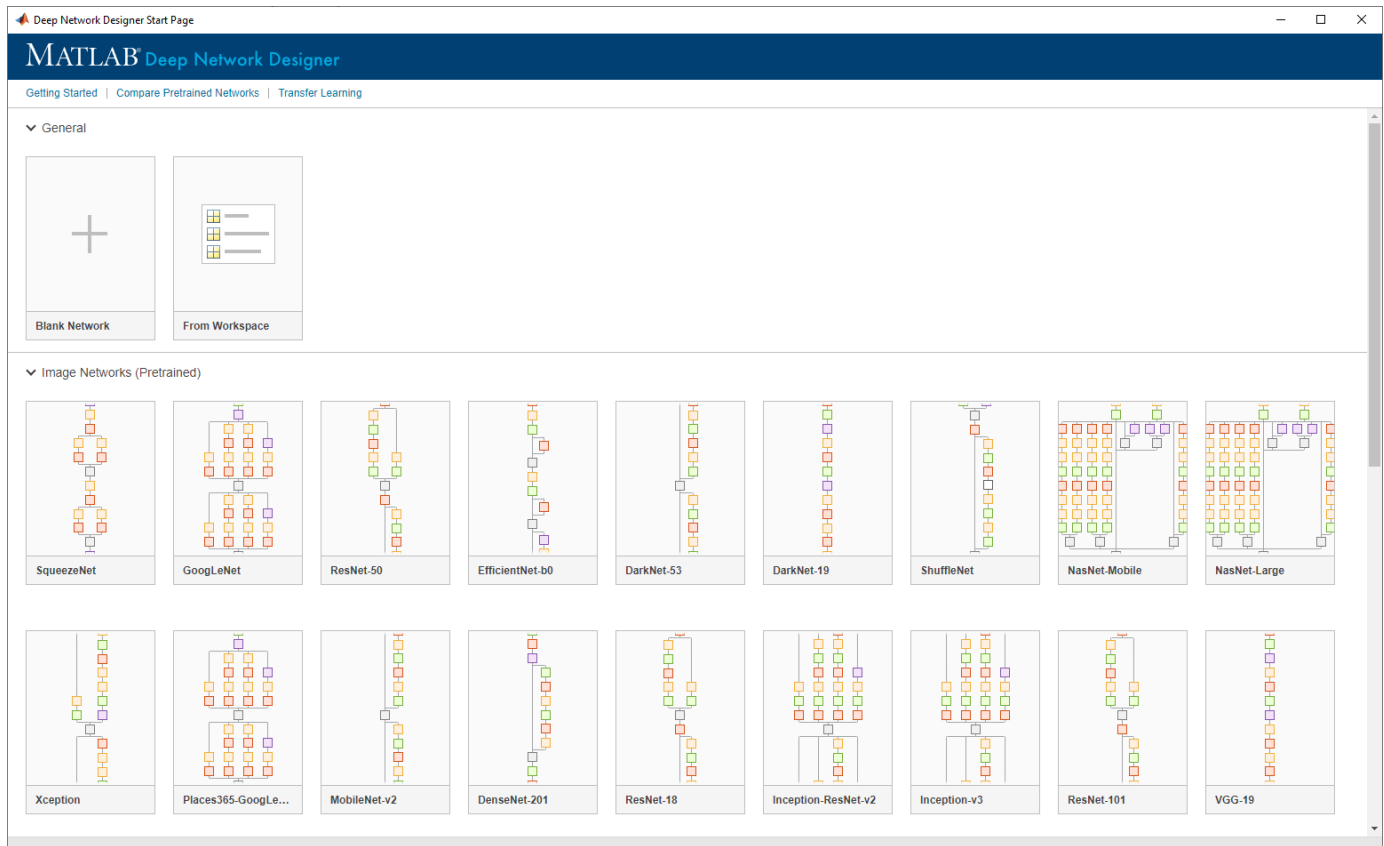

In the workspace, extract the MathWorks Merch data set.

```
unzip("MerchData.zip");
```

Open Deep Network Designer to see available pretrained networks.

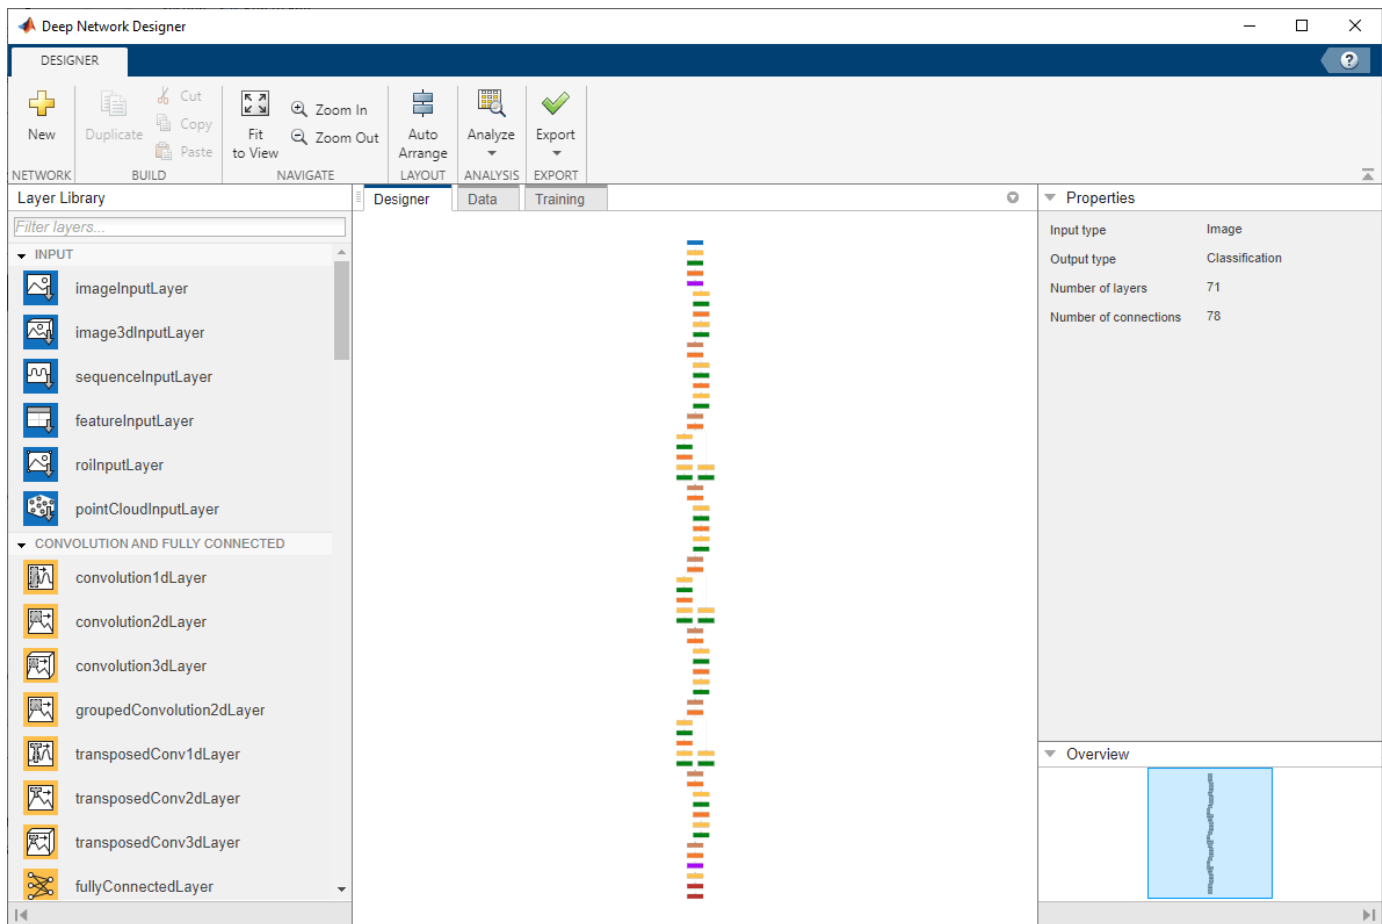

```
deepNetworkDesigner
```

# 1 Deep Learning Functions

Select ResNet-18 and click **Open**. If Deep Learning Toolbox™ Model for ResNet-18 Network is not installed, then the software opens the **Add-On Explorer**.

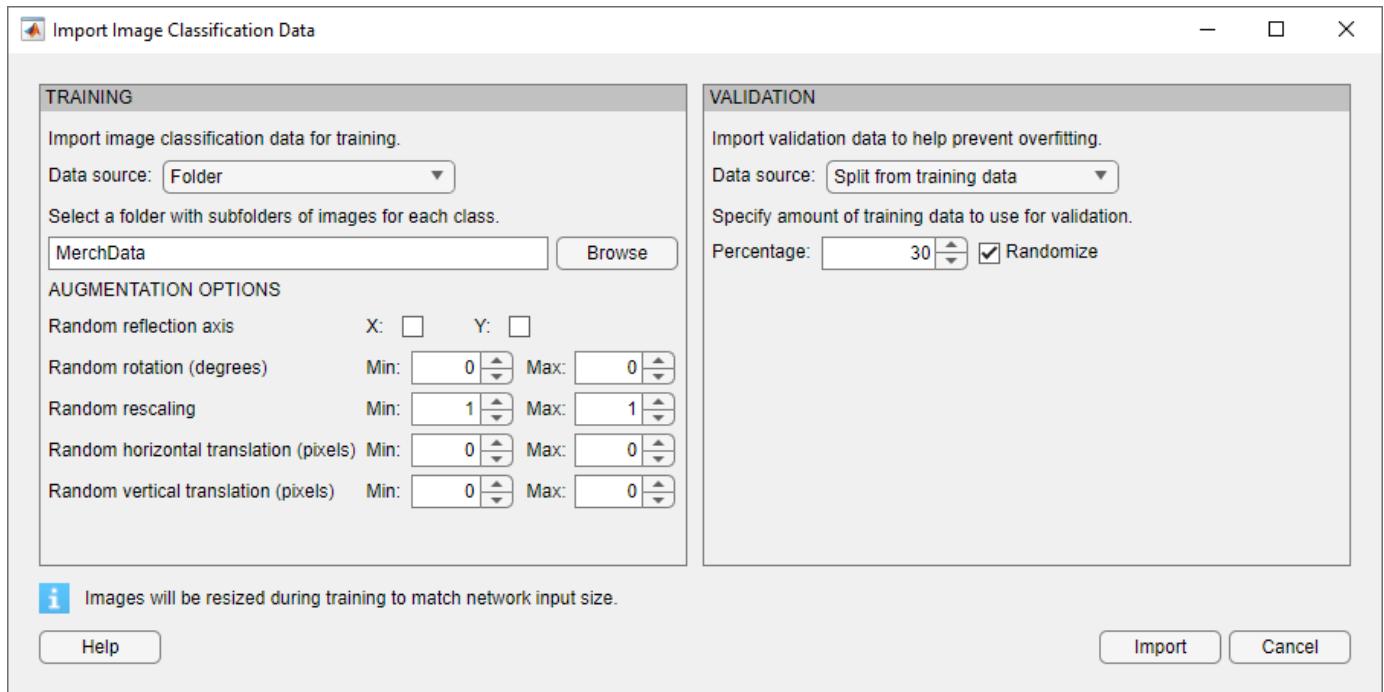

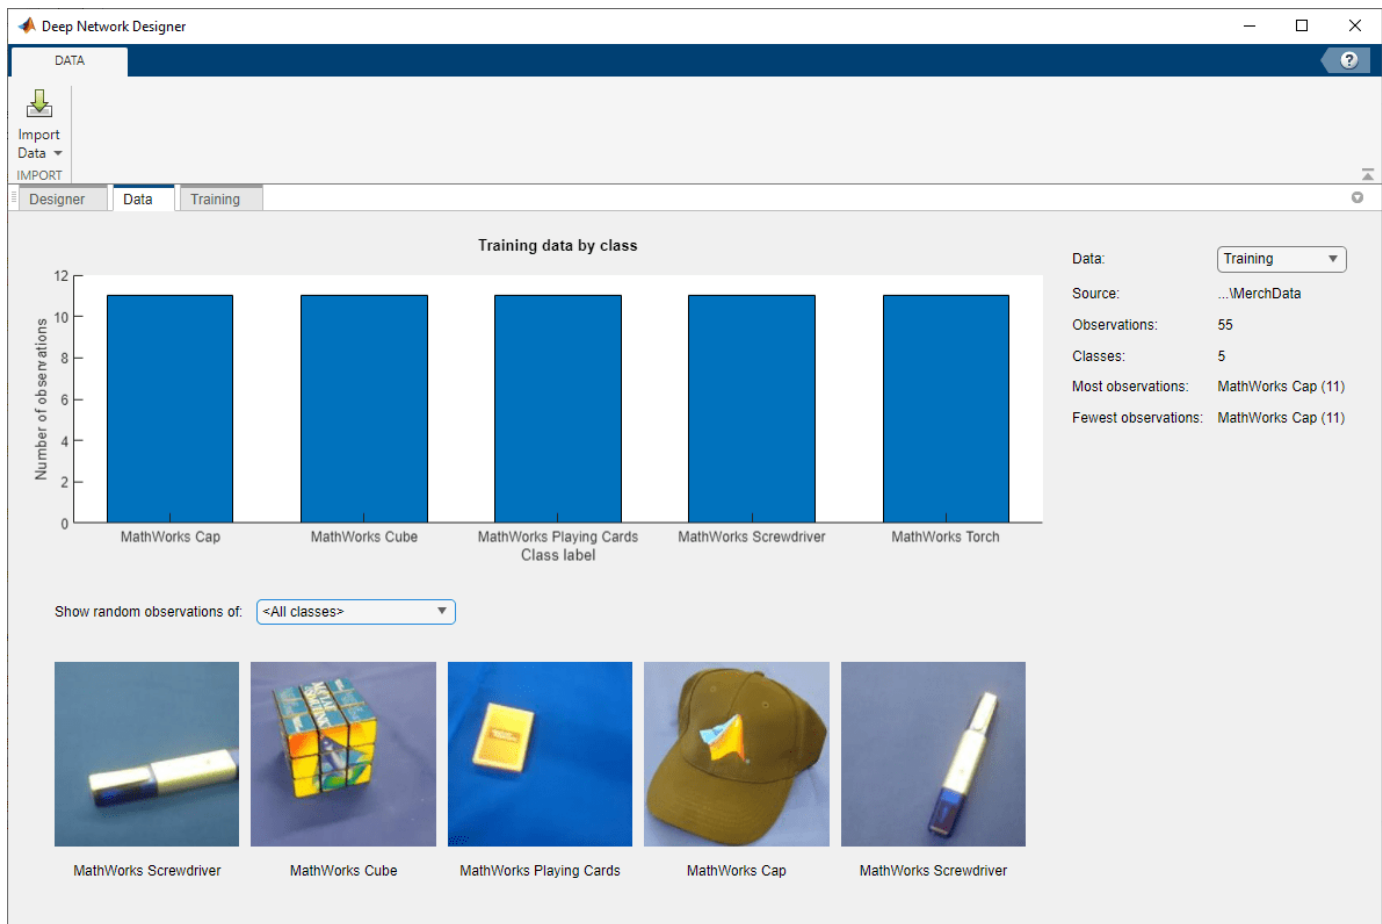

To load the data into Deep Network Designer, on the **Data** tab, click **Import Data > Import Image Classification Data**. In the **Data source** list, select **Folder**. Click **Browse** and select the extracted MerchData folder.

Divide the data into training and validation data sets. Use 70% of the images for training and 30% for validation. Select **Randomize** to randomly assign the specified proportion of images to the validation and training sets.

Click **Import** to import the data into Deep Network Designer.

The app shows a summary of the imported data.

To retrain the pretrained network to classify new images, replace the last fully connected layer and the final classification layer with new layers adapted to the new data set.

In the **Designer** pane, scroll to the end of the network and then zoom in. Drag a new `fullyConnectedLayer` onto the canvas. Change **OutputSize** to the number of classes in the new data, in this example, 5.

To make learning faster in the new layers than in the transferred layers, set `WeightLearnRateFactor` and `BiasLearnRateFactor` to 10. Delete the last fully connected layer ('`fc1000`') and connect your new layer instead.

The diagram shows a vertical flow of three layers: a fully connected layer (fc), a softmax layer (prob), and a classification layer (classoutput). The properties panel for the selected 'fullyConnectedLayer' is as follows:

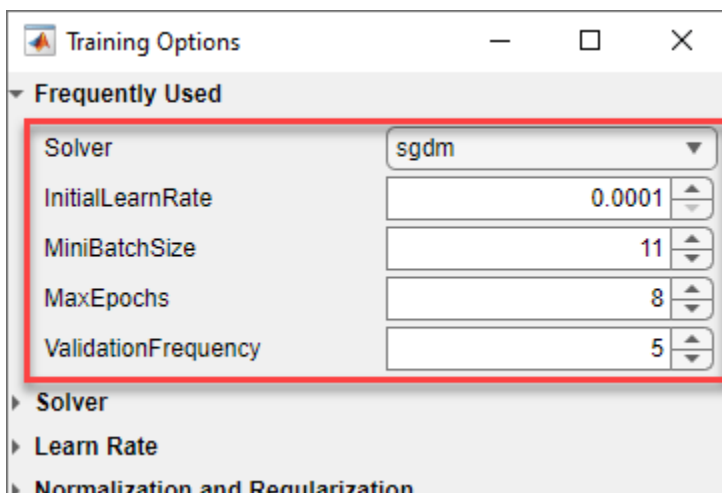

Property	Value
Name	fc
InputSize	auto
OutputSize	5
Weights	[]
Bias	[]
WeightLearnRateFactor	10
WeightL2Factor	1
BiasLearnRateFactor	10

Replace the output layer. Drag a new classificationLayer onto the canvas. Delete the original output layer ('ClassificationLayer\_predictions') and connect your new layer instead.

The diagram shows the same vertical flow of layers, but the classification layer (classoutput) is now highlighted in blue. The properties panel for the selected 'classificationLayer' is as follows:

Property	Value
Name	classoutput
Classes	auto
ClassWeights	none
OutputSize	auto
LossFunction	crossentropyex

Specify training options. Select the **Training** tab and click **Training Options**. Set **Solver** to `sgdm`, **InitialLearnRate** to `0.0001`, **MiniBatchSize** to `11`, **MaxEpochs** to `8`, and **ValidationFrequency** to `5`.

To train the network with the specified training options, click **OK** and then click **Train**.

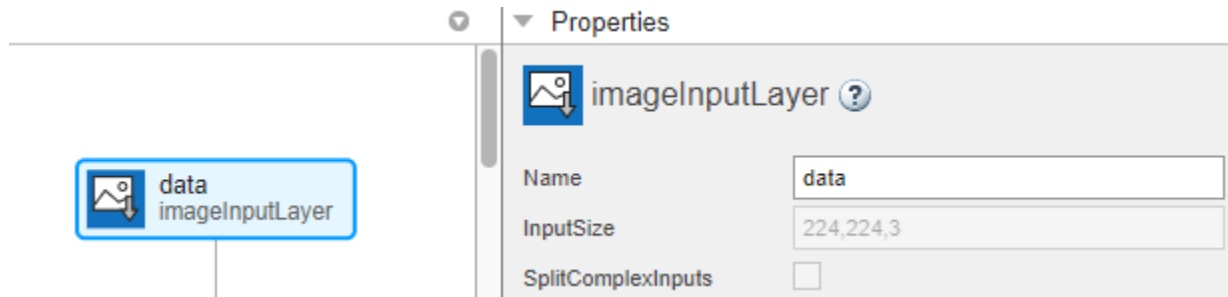

To export the network architecture with the trained weights, on the **Training** tab, select **Export > Export Trained Network and Results**. Deep Network Designer exports the trained network as the variable `trainedNetwork_1`.

Load a new image to classify using the trained network.

```
I = imread("MerchDataTest.jpg");
```

Deep Network Designer resizes the images during training to match the network input size. To view the network input size, go to the **Designer** pane and select the `imageInputLayer` (first layer). This network has an input size of 224-by-224.

Resize the test image to match the network input size.

```
I = imresize(I,[224 224]);
```

Classify the test image using the trained network.

```
YPred = classify(trainedNetwork_1,I);  
imshow(I)  
title("Predicted Class: " + string(YPred));
```

## Programmatic Transfer Learning Using ResNet-18

Load the pretrained ResNet-18 neural network and find the input size.

```
net = resnet18;  
inputSize = net.Layers(1).InputSize;
```

Extract the MathWorks Merch data set. Load the new images as an image datastore.

```
unzip("MerchData.zip");
imds = imageDatastore("MerchData", ...
    IncludeSubfolders=true, ...
    LabelSource="foldernames");
```

```
numClasses = numel(categories(imds.Labels));
```

Divide the data into training and validation data sets. Specify "randomized" to randomly assign the specified proportion of images to the validation and training sets.

```
[imdsTrain,imdsValidation] = splitEachLabel(imds,0.7,"randomized");
```

Use an augmented image datastore to automatically resize the training images to match the input size of the network.

```
augimdsTrain = augmentedImageDatastore(inputSize(1:2),imdsTrain);
augimdsValidation = augmentedImageDatastore(inputSize(1:2),imdsValidation);
```

To retrain the pretrained network to classify new images, replace the last fully connected layer and the final classification layer with new layers adapted to the new data set. First, extract the layer graph from the trained network.

```
lgraph = layerGraph(net);
```

Replace the fully connected layer with a new fully connected layer that has number of outputs equal to the number of classes. To make learning faster in the new layers than in the transferred layers, increase the `WeightLearnRateFactor` and `BiasLearnRateFactor` values of the fully connected layer.

```
newLearnableLayer = fullyConnectedLayer(numClasses, ...
    WeightLearnRateFactor=10, ...
    BiasLearnRateFactor=10);
```

```
lgraph = replaceLayer(lgraph,"fc1000",newLearnableLayer);
```

The classification layer specifies the output classes of the network. Replace the classification layer with a new layer without class labels. `trainNetwork` automatically sets the output classes of the layer at training time.

```
newClassLayer = classificationLayer;
lgraph = replaceLayer(lgraph,"ClassificationLayer_predictions",newClassLayer);
```

Specify the training options. To slow down learning in the transferred layers, set the initial learning rate to a small value.

```
options = trainingOptions("sgdm", ...
    InitialLearnRate=0.0001, ...
    MiniBatchSize=11, ...
    MaxEpochs=8, ...
    ValidationData=augimdsValidation, ...
    ValidationFrequency=5, ...
    Verbose=false, ...
    Plots="training-progress");
```

Train the network.

```
trainedNetwork = trainNetwork(augimdsTrain,lgraph,options);
```

Load a new image to classify using the trained network.

```
I = imread("MerchDataTest.jpg");
I = imresize(I,inputSize(1:2));
```

Classify the test image.

```
YPred = classify(trainedNetwork,I);
imshow(I)
title("Predicted class: " + string(YPred));
```

Predicted class: MathWorks Cube

## Output Arguments

**net** — Pretrained ResNet-18 convolutional neural network

DAGNetwork object

Pretrained ResNet-18 convolutional neural network, returned as a DAGNetwork object.

**lgraph** — Untrained ResNet-18 convolutional neural network architecture

LayerGraph object

Untrained ResNet-18 convolutional neural network architecture, returned as a LayerGraph object.

## Version History

Introduced in R2018a

# resnet50

ResNet-50 convolutional neural network

## Syntax

```
net = resnet50
net = resnet50('Weights','imagenet')

lgraph = resnet50('Weights','none')
```

## Description

ResNet-50 is a convolutional neural network that is 50 layers deep. You can load a pretrained version of the neural network trained on more than a million images from the ImageNet database [1]. The pretrained neural network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the neural network has learned rich feature representations for a wide range of images. The neural network has an image input size of 224-by-224. For more pretrained neural networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the ResNet-50 model. Follow the steps of “Classify Image Using GoogLeNet” and replace GoogLeNet with ResNet-50.

To retrain the neural network on a new classification task, follow the steps of “Train Deep Learning Network to Classify New Images” and load ResNet-50 instead of GoogLeNet.

---

**Tip** To create an untrained residual neural network suitable for image classification tasks, use `resnetLayers`.

---

`net = resnet50` returns a ResNet-50 neural network trained on the ImageNet data set.

This function requires the Deep Learning Toolbox Model *for ResNet-50 Network* support package. If this support package is not installed, then the function provides a download link.

`net = resnet50('Weights','imagenet')` returns a ResNet-50 neural network trained on the ImageNet data set. This syntax is equivalent to `net = resnet50`.

`lgraph = resnet50('Weights','none')` returns the untrained ResNet-50 neural network architecture. The untrained model does not require the support package.

## Examples

### Download ResNet-50 Support Package

Download and install the Deep Learning Toolbox Model *for ResNet-50 Network* support package.

Type `resnet50` at the command line.

```
resnet50
```

If the Deep Learning Toolbox Model for *ResNet-50 Network* support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**. Check that the installation is successful by typing `resnet50` at the command line. If the required support package is installed, then the function returns a DAGNetwork object.

```
resnet50
```

```
ans =
```

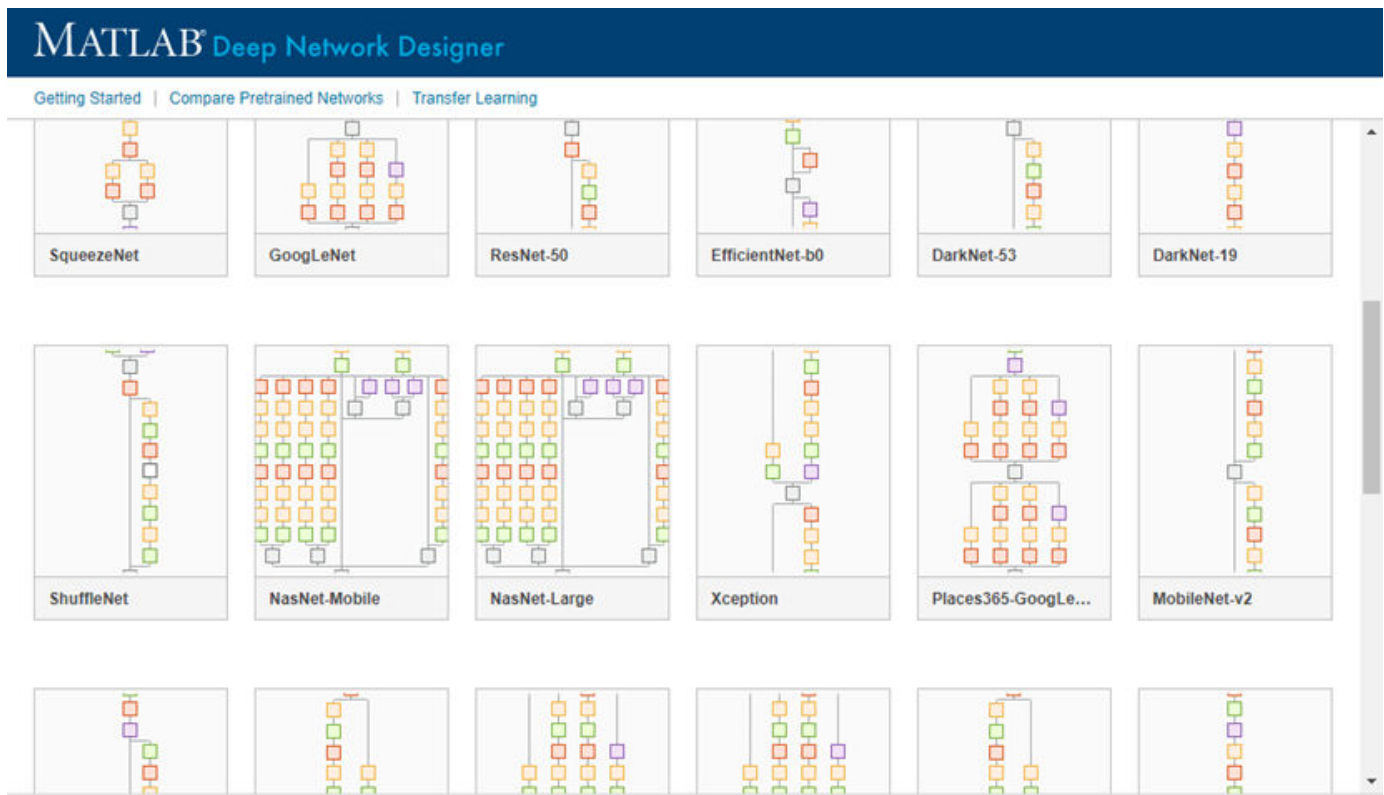

```
DAGNetwork with properties:

# resnetLayers

Create 2-D residual network

## Syntax

```
lgraph = resnetLayers(inputSize,numClasses)
lgraph = resnetLayers( ____,Name=Value)
```

## Description

`lgraph = resnetLayers(inputSize,numClasses)` creates a 2-D residual network with an image input size specified by `inputSize` and a number of classes specified by `numClasses`. A residual network consists of stacks of blocks. Each block contains deep learning layers. The network includes an image classification layer, suitable for predicting the categorical label of an input image.

To create a 3-D residual network, use `resnet3dLayers`.

`lgraph = resnetLayers( ____,Name=Value)` creates a residual network using one or more name-value arguments using any of the input arguments in the previous syntax. For example, `InitialNumFilters=32` specifies 32 filters in the initial convolutional layer.

## Examples

### Residual Network with Bottleneck

Create a residual network with a bottleneck architecture.

```
imageSize = [224 224 3];
numClasses = 10;

lgraph = resnetLayers(imageSize,numClasses)

lgraph =
  LayerGraph with properties:
    InputNames: {'input'}
    OutputNames: {'output'}
    Layers: [177x1 nnet.cnn.layer.Layer]
    Connections: [192x2 table]
```

Analyze the network.

```
analyzeNetwork(lgraph)
```

This network is equivalent to a ResNet-50 residual network.

### Residual Network with Custom Stack Depth

Create a ResNet-101 network using a custom stack depth.

```
imageSize = [224 224 3];
numClasses = 10;

stackDepth = [3 4 23 3];
numFilters = [64 128 256 512];

lgraph = resnetLayers(imageSize,numClasses, ...
    StackDepth=stackDepth, ...
    NumFilters=numFilters)

lgraph =
    LayerGraph with properties:

        InputNames: {'input'}
        OutputNames: {'output'}
        Layers: [347x1 nnet.cnn.layer.Layer]
        Connections: [379x2 table]
```

Analyze the network.

```
analyzeNetwork(lgraph)
```

### Train Residual Network

Create and train a residual network to classify images.

Load the digits data as in-memory numeric arrays using the `digitTrain4DArrayData` and `digitTest4DArrayData` functions.

```
[XTrain,YTrain] = digitTrain4DArrayData;
[XTest,YTest] = digitTest4DArrayData;
```

Define the residual network. The digits data contains 28-by-28 pixel images, therefore, construct a residual network with smaller filters.

```
imageSize = [28 28 1];
numClasses = 10;

lgraph = resnetLayers(imageSize,numClasses, ...
    InitialStride=1, ...
    InitialFilterSize=3, ...
    InitialNumFilters=16, ...
    StackDepth=[4 3 2], ...
    NumFilters=[16 32 64]);
```

Set the options to the default settings for the stochastic gradient descent with momentum. Set the maximum number of epochs at 5, and start the training with an initial learning rate of 0.1.

```
options = trainingOptions("sgdm", ...
    MaxEpochs=5, ...
    InitialLearnRate=0.1, ...
```

```
Verbose=false, ...
Plots="training-progress");
```

Train the network.

```
net = trainNetwork(XTrain,YTrain,lgraph,options);
```

Test the performance of the network by evaluating the prediction accuracy of the test data. Use the `classify` function to predict the class label of each test image.

```
YPred = classify(net,XTest);
```

Calculate the accuracy. The accuracy is the fraction of labels that the network predicts correctly.

```
accuracy = sum(YPred == YTest)/numel(YTest)
```

```
accuracy = 0.9956
```

## Convert Residual Network to dlnetwork Object

To train a residual network using a custom training loop, first convert it to a `dlnetwork` object.

Create a residual network.

```
lgraph = resnetLayers([224 224 3],5);
```

Remove the classification layer.

```
lgraph = removeLayers(lgraph,"output");
```

Replace the input layer with a new input layer that has `Normalization` set to "none". To use an input layer with zero-center or z-score normalization, you must specify an `imageInputLayer` with nonempty value for the `Mean` property. For example, `Mean=sum(XTrain,4)`, where `XTrain` is a 4-D array containing your input data.

```
newInputLayer = imageInputLayer([224 224 3],Normalization="none");  
lgraph = replaceLayer(lgraph,"input",newInputLayer);
```

Convert to a `dlnetwork`.

```
dlnet = dlnetwork(lgraph)
```

```
dlnet =  
  dlnetwork with properties:
```

```
    Layers: [176x1 nnet.cnn.layer.Layer]  
 Connections: [191x2 table]  
 Learnables: [214x3 table]  
    State: [106x3 table]  
 InputNames: {'imageinput'}  
 OutputNames: {'softmax'}  
 Initialized: 1
```

```
View summary with summary.
```

## Input Arguments

### **inputSize** — Network input image size

2-element vector | 3-element vector

Network input image size, specified as one of the following:

- 2-element vector in the form  $[height, width]$ .
- 3-element vector in the form  $[height, width, depth]$ , where *depth* is the number of channels. Set *depth* to 3 for RGB images and to 1 for grayscale images. For multispectral and hyperspectral images, set *depth* to the number of channels.

The *height* and *width* values must be greater than or equal to  $initialStride * poolingStride * 2^D$ , where *D* is the number of downsampling blocks. Set the initial stride using the `InitialStride` argument. The pooling stride is 1 when the `InitialPoolingLayer` is set to "none", and 2 otherwise.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **numClasses** — Number of classes

integer greater than 1

Number of classes in the image classification network, specified as an integer greater than 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Name-Value Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `InitialFilterSize=[5,5],InitialNumFilters=32,BottleneckType="none"` specifies an initial filter size of 5-by-5 pixels, 32 initial filters, and a network architecture without bottleneck components.

## Initial Layers

### InitialFilterSize — Filter size in first convolutional layer

7 (default) | positive integer | 2-element vector of positive integers

Filter size in the first convolutional layer, specified as one of the following:

- Positive integer. The filter has equal height and width. For example, specifying 5 yields a filter of height 5 and width 5.
- 2-element vector in the form `[height, width]`. For example, specifying an initial filter size of `[1 5]` yields a filter of height 1 and width 5.

Example: `InitialFilterSize=[5,5]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### InitialNumFilters — Number of filters in first convolutional layer

64 (default) | positive integer

Number of filters in the first convolutional layer, specified as a positive integer. The number of initial filters determines the number of channels (feature maps) in the output of the first convolutional layer in the residual network.

Example: `InitialNumFilters=32`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### InitialStride — Stride in first convolutional layer

2 (default) | positive integer | 2-element vector of positive integers

Stride in the first convolutional layer, specified as a:

- Positive integer. The stride has equal height and width. For example, specifying 3 yields a stride of height 3 and width 3.
- 2-element vector in the form `[height, width]`. For example, specifying an initial stride of `[1 2]` yields a stride of height 1 and width 2.

The stride defines the step size for traversing the input vertically and horizontally.

Example: `InitialStride=[3,3]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### InitialPoolingLayer — First pooling layer

"max" (default) | "average" | "none"

First pooling layer before the initial residual block, specified as one of the following:

- "max" — Use a max pooling layer before the initial residual block. For more information, see `maxPooling2dLayer`.
- "average" — Use an average pooling layer before the initial residual block. For more information, see `averagePooling2dLayer`.

- "none"— Do not use a pooling layer before the initial residual block.

Example: `InitialPoolingLayer="average"`

Data Types: `char` | `string`

### **Network Architecture**

#### **ResidualBlockType — Residual block type**

`"batchnorm-before-add"` (default) | `"batchnorm-after-add"`

Residual block type, specified as one of the following:

- `"batchnorm-before-add"` — Add the batch normalization layer before the addition layer in the residual blocks [1].
- `"batchnorm-after-add"` — Add the batch normalization layer after the addition layer in the residual blocks [2].

The `ResidualBlockType` argument specifies the location of the batch normalization layer in the standard and downsampling residual blocks. For more information, see “More About” on page 1-1576.

Example: `ResidualBlockType="batchnorm-after-add"`

Data Types: `char` | `string`

#### **BottleneckType — Block bottleneck type**

`"downsample-first-conv"` (default) | `"none"`

Block bottleneck type, specified as one of the following:

- `"downsample-first-conv"` — Use bottleneck residual blocks that perform downsampling in the first convolutional layer of the downsampling residual blocks, using a stride of 2. A bottleneck residual block consists of three convolutional layers: a 1-by-1 layer for downsampling the channel dimension, a 3-by-3 convolutional layer, and a 1-by-1 layer for upsampling the channel dimension.

The number of filters in the final convolutional layer is four times that in the first two convolutional layers. For more information, see “NumFilters” on page 1-0 .

- `"none"` — Do not use bottleneck residual blocks. The residual blocks consist of two 3-by-3 convolutional layers.

A bottleneck block performs a 1-by-1 convolution before the 3-by-3 convolution to reduce the number of channels by a factor of four. Networks with and without bottleneck blocks will have a similar level of computational complexity, but the total number of features propagating in the residual connections is four times larger when you use bottleneck units. Therefore, using a bottleneck increases the efficiency of the network [1]. For more information on the layers in each residual block, see “More About” on page 1-1576.

Example: `BottleneckType="none"`

Data Types: `char` | `string`

#### **StackDepth — Number of residual blocks in each stack**

`[3 4 6 3]` (default) | vector of positive integers

Number of residual blocks in each stack, specified as a vector of positive integers. For example, if the stack depth is [3 4 6 3], the network has four stacks, with three blocks, four blocks, six blocks, and three blocks.

Specify the number of filters in the convolutional layers of each stack using the `NumFilters` argument. The `StackDepth` value must have the same number of elements as the `NumFilters` value.

Example: `StackDepth=[9 12 69 9]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NumFilters — Number of filters in convolutional layers of each stack**

[64 128 256 512] (default) | vector of positive integers

Number of filters in the convolutional layers of each stack, specified as a vector of positive integers.

- When you set `BottleneckType` to "downsample-first-conv", the first two convolutional layers in each block of each stack have the same number of filters, set by the `NumFilters` value. The final convolutional layer has four times the number of filters in the first two convolutional layers.

For example, suppose you set `NumFilters` to [4 5] and `BottleneckType` to "downsample-first-conv". In the first stack, the first two convolutional layers in each block have 4 filters and the final convolutional layer in each block has 16 filters. In the second stack, the first two convolutional layers in each block have 5 filters and the final convolutional layer has 20 filters.

- When you set `BottleneckType` to "none", the convolutional layers in each stack have the same number of filters, set by the `NumFilters` value.

The `NumFilters` value must have the same number of elements as the `StackDepth` value.

The `NumFilters` value determines the layers on the residual connection in the initial residual block. There is a convolutional layer on the residual connection if one of the following conditions is met:

- `BottleneckType`="downsample-first-conv"(default) and `InitialNumFilters` is not equal to four times the first element of `NumFilters`.
- `BottleneckType`="none" and `InitialNumFilters` is not equal to the first element of `NumFilters`.

For more information about the layers in each residual block, see "More About" on page 1-1576.

Example: `NumFilters=[32 64 126 256]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Normalization — Data normalization**

"zerocenter" (default) | "zscore"

Data normalization to apply every time data is forward-propagated through the input layer, specified as one of the following:

- "zerocenter" — Subtract the mean. The mean is calculated at training time.
- "zscore" — Subtract the mean and divide by the standard deviation. The mean and standard deviation are calculated at training time.

Example: `Normalization="zscore"`

Data Types: `char` | `string`

## Output Arguments

### **lgraph** — Residual network

LayerGraph object

Residual network, returned as a `layerGraph` object.

## More About

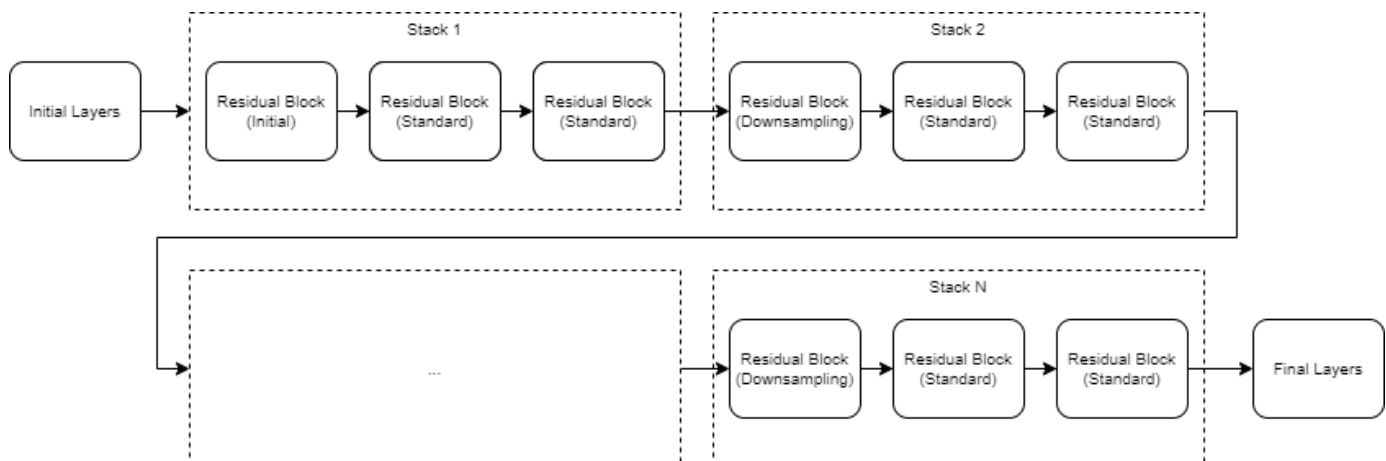

### Residual Network

Residual networks (ResNets) are a type of deep network consisting of building blocks that have *residual connections* (also known as *skip* or *shortcut* connections). These connections allow the input to skip the convolutional units of the main branch, thus providing a simpler path through the network. By allowing the parameter gradients to flow more easily from the output layer to the earlier layers of the network, residual connections help mitigate the problem of vanishing gradients during early training.

The structure of a residual network is flexible. The key component is the inclusion of the residual connections within *residual blocks*. A group of residual blocks is called a *stack*. A ResNet architecture consists of initial layers, followed by stacks containing residual blocks, and then the final layers. A network has three types of residual blocks:

- Initial residual block — This block occurs at the start of the first stack. The layers in the residual connection of the initial residual block determine if the block preserves the activation sizes or performs downsampling.
- Standard residual block — This block occurs multiple times in each stack, after the first downsampling residual block. The standard residual block preserves the activation sizes.
- Downsampling residual block — This block occurs once, at the start of each stack. The first convolutional unit in the downsampling block downsamples the spatial dimensions by a factor of two.

A typical stack has a downsampling residual block, followed by  $m$  standard residual blocks, where  $m$  is greater than or equal to one. The first stack is the only stack that begins with an initial residual block.

The initial, standard, and downsampling residual blocks can be *bottleneck* or nonbottleneck blocks. Bottleneck blocks perform a 1-by-1 convolution before the 3-by-3 convolution, to reduce the number of channels by a factor of four. Networks with and without bottleneck blocks have a similar level of computational complexity, but the total number of features propagating in the residual connections is four times larger when you use the bottleneck units. Therefore, using bottleneck blocks increases the efficiency of the network.

The layers inside each block are determined by the type of block and the options you set.

--------------------	---	---	--	--	---	---

		to "batchnorm-before-add", the residual connection will also have a batch normalization layer.	ResidualBlock Type argument.		contains a convolution2dLayer with [1,1] filter and [2,2] stride.  The downsampling block halves the height and width of the input, and increases the number of channels.	
--	--	--	---------------------------------	--	---	--

The convolution and fully connected layer weights are initialized using the He weight initialization method [3]. For more information, see `convolution2dLayer`.

## Tips

- When working with small images, set the `InitialPoolingLayer` option to "none" to remove the initial pooling layer and reduce the amount of downsampling.
- Residual networks are usually named ResNet- $X$ , where  $X$  is the *depth* of the network. The depth of a network is defined as the largest number of sequential convolutional or fully connected layers on a path from the input layer to the output layer. You can use the following formula to compute the depth of your network:

$$\text{depth} = \begin{cases} 1 + 2 \sum_{i=1}^N s_i + 1 & \text{If no bottleneck} \\ 1 + 3 \sum_{i=1}^N s_i + 1 & \text{If bottleneck} \end{cases},$$

where  $s_i$  is the depth of stack  $i$ .

Networks with the same depth can have different network architectures. For example, you can create a ResNet-14 architecture with or without a bottleneck:

```
resnet14Bottleneck = resnetLayers([224 224 3],10, ...
StackDepth=[2 2], ...
NumFilters=[64 128]);
```

```
resnet14NoBottleneck = resnetLayers([224 224 3],10, ...
BottleneckType="none", ...
StackDepth=[2 2 2], ...
NumFilters=[64 128 256]);
```

The relationship between bottleneck and nonbottleneck architectures also means that a network with a bottleneck will have a different depth than a network without a bottleneck.

```
resnet50Bottleneck = resnetLayers([224 224 3],10);
```

```
resnet34NoBottleneck = resnetLayers([224 224 3],10, ...
BottleneckType="none");
```

## Extended Capabilities

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

You can use the residual network for code generation. First, create the network using the `resnetLayers` function. Then, use the `trainNetwork` function to train the network. After training and evaluating the network, you can generate code for the `DAGNetwork` object by using GPU Coder™.

## resnet3dLayers

Create 3-D residual network

### Syntax

```
lgraph = resnet3dLayers(inputSize,numClasses)
lgraph = resnet3dLayers( ____,Name=Value)
```

### Description

`lgraph = resnet3dLayers(inputSize,numClasses)` creates a 3-D residual network with an image input size specified by `inputSize` and a number of classes specified by `numClasses`. A residual network consists of stacks of blocks. Each block contains deep learning layers. The network includes an image classification layer, suitable for predicting the categorical label of an input image.

To create a 2-D residual network, use `resnetLayers`.

`lgraph = resnet3dLayers( ____,Name=Value)` creates a residual network using one or more name-value arguments using any of the input arguments in the previous syntax. For example, `InitialNumFilters=32` specifies 32 filters in the initial convolutional layer.

### Examples

#### 3-D Residual Network with Bottleneck

Create a 3-D residual network with a bottleneck architecture.

```
imageSize = [224 224 64 3];
numClasses = 10;

lgraph = resnet3dLayers(imageSize,numClasses)

lgraph =
    LayerGraph with properties:
        InputNames: {'input'}
        OutputNames: {'output'}
        Layers: [177x1 nnet.cnn.layer.Layer]
        Connections: [192x2 table]
```

Analyze the network.

```
analyzeNetwork(lgraph)
```

This network is equivalent to a 3-D ResNet-50 residual network.

### 3-D Residual Network with Custom Stack Depth

Create a 3-D ResNet-101 network using a custom stack depth.

```
imageSize = [224 224 64 3];
numClasses = 10;

stackDepth = [3 4 23 3];
numFilters = [64 128 256 512];

lgraph = resnet3dLayers(imageSize,numClasses, ...
    StackDepth=stackDepth, ...
    NumFilters=numFilters)

lgraph =
    LayerGraph with properties:

        InputNames: {'input'}
        OutputNames: {'output'}
        Layers: [347x1 nnet.cnn.layer.Layer]
        Connections: [379x2 table]
```

Analyze the network.

```
analyzeNetwork(lgraph)
```

## Input Arguments

### inputSize — Network input image size

3-element vector | 4-element vector

Network input image size, specified as one of the following:

- 3-element vector in the form [*height*, *width*, *depth*]
- 4-element vector in the form [*height*, *width*, *depth*, *channel*] where *channel* denotes the number of image channels.

The *height*, *width*, and *depth* values must be greater than or equal to  $initialStride * poolingStride * 2^D$ , where  $D$  is the number of downsampling blocks. Set the initial stride using the `InitialStride` argument. The pooling stride is 1 when the `InitialPoolingLayer` is set to "none", and 2 otherwise.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### numClasses — Number of classes

integer greater than 1

Number of classes in the image classification network, specified as an integer greater than 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `InitialFilterSize=[5,5,5],InitialNumFilters=32,BottleneckType="none"` specifies an initial filter size of 5-by-5-by-5 pixels, 32 initial filters, and a network architecture without bottleneck components.

## Initial Layers

### **InitialFilterSize** — Filter size in first convolutional layer

7 (default) | positive integer | 3-element vector of positive integers

Filter size in the first convolutional layer, specified as one of the following:

- Positive integer. The filter has equal height, width, and depth. For example, specifying 5 yields a filter of height 5, width 5, and depth 5.
- 3-element vector in the form `[height, width, depth]`. For example, specifying an initial filter size of `[1 5 2]` yields a filter of height 1, width 5, and depth 2.

Example: `InitialFilterSize=[5,5,5]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **InitialNumFilters** — Number of filters in first convolutional layer

64 (default) | positive integer

Number of filters in the first convolutional layer, specified as a positive integer. The number of initial filters determines the number of channels (feature maps) in the output of the first convolutional layer in the residual network.

Example: `InitialNumFilters=32`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **InitialStride** — Stride in first convolutional layer

2 (default) | positive integer | 3-element vector of positive integers

Stride in the first convolutional layer, specified as a:

- Positive integer. The stride has equal height, width, and depth. For example, specifying 3 yields a stride of height 3, width 3, and depth 3.
- 3-element vector in the form `[height, width, depth]`. For example, specifying an initial stride of `[1 2 2]` yields a stride of height 1, width 2, and depth 2.

The stride defines the step size for traversing the input in three dimensions.

Example: `InitialStride=[3,3,3]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **InitialPoolingLayer** — First pooling layer

"max" (default) | "average" | "none"

First pooling layer before the initial residual block, specified as one of the following:

- "max" — Use a max pooling layer before the initial residual block. For more information, see `maxPooling3dLayer`.
- "average" — Use an average pooling layer before the initial residual block. For more information, see `globalAveragePooling3dLayer`.
- "none"— Do not use a pooling layer before the initial residual block.

Example: `InitialPoolingLayer="average"`

Data Types: `char` | `string`

## Network Architecture

### ResidualBlockType — Residual block type

"batchnorm-before-add" (default) | "batchnorm-after-add"

Residual block type, specified as one of the following:

- "batchnorm-before-add" — Add the batch normalization layer before the addition layer in the residual blocks [1].
- "batchnorm-after-add" — Add the batch normalization layer after the addition layer in the residual blocks [2].

The `ResidualBlockType` argument specifies the location of the batch normalization layer in the standard and downsampling residual blocks. For more information, see "More About" on page 1-1589.

Example: `ResidualBlockType="batchnorm-after-add"`

Data Types: `char` | `string`

### BottleneckType — Block bottleneck type

"downsample-first-conv" (default) | "none"

Block bottleneck type, specified as one of the following:

- "downsample-first-conv" — Use bottleneck residual blocks that perform downsampling in the first convolutional layer of the downsampling residual blocks, using a stride of 2. A bottleneck residual block consists of three convolutional layers: a 1-by-1-by-1 layer for downsampling the channel dimension, a 3-by-3-by-3 convolutional layer, and a 1-by-1-by-1 layer for upsampling the channel dimension.

The number of filters in the final convolutional layer is four times that in the first two convolutional layers. For more information, see "NumFilters" on page 1-0 .

- "none" — Do not use bottleneck residual blocks. The residual blocks consist of two 3-by-3-by-3 convolutional layers.

A bottleneck block performs a 1-by-1-by-1 convolution before the 3-by-3-by-3 convolution to reduce the number of channels by a factor of four. Networks with and without bottleneck blocks will have a similar level of computational complexity, but the total number of features propagating in the residual connections is four times larger when you use bottleneck units. Therefore, using a bottleneck increases the efficiency of the network [1]. For more information on the layers in each residual block, see "More About" on page 1-1589.

Example: `BottleneckType="none"`

Data Types: `char` | `string`

**StackDepth — Number of residual blocks in each stack**`[3 4 6 3]` (default) | vector of positive integers

Number of residual blocks in each stack, specified as a vector of positive integers. For example, if the stack depth is `[3 4 6 3]`, the network has four stacks, with three blocks, four blocks, six blocks, and three blocks.

Specify the number of filters in the convolutional layers of each stack using the `NumFilters` argument. The `StackDepth` value must have the same number of elements as the `NumFilters` value.

Example: `StackDepth=[9 12 69 9]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**NumFilters — Number of filters in convolutional layers of each stack**`[64 128 256 512]` (default) | vector of positive integers

Number of filters in the convolutional layers of each stack, specified as a vector of positive integers.

- When you set `BottleneckType` to "downsample-first-conv", the first two convolutional layers in each block of each stack have the same number of filters, set by the `NumFilters` value. The final convolutional layer has four times the number of filters in the first two convolutional layers.

For example, suppose you set `NumFilters` to `[4 5]` and `BottleneckType` to "downsample-first-conv". In the first stack, the first two convolutional layers in each block have 4 filters and the final convolutional layer in each block has 16 filters. In the second stack, the first two convolutional layers in each block have 5 filters and the final convolutional layer has 20 filters.

- When you set `BottleneckType` to "none", the convolutional layers in each stack have the same number of filters, set by the `NumFilters` value.

The `NumFilters` value must have the same number of elements as the `StackDepth` value.

The `NumFilters` value determines the layers on the residual connection in the initial residual block. There is a convolutional layer on the residual connection if one of the following conditions is met:

- `BottleneckType`="downsample-first-conv"(default) and `InitialNumFilters` is not equal to four times the first element of `NumFilters`.
- `BottleneckType`="none" and `InitialNumFilters` is not equal to the first element of `NumFilters`.

For more information about the layers in each residual block, see "More About" on page 1-1589.

Example: `NumFilters=[32 64 126 256]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Normalization — Data normalization**`"zerocenter"` (default) | `"zscore"`

Data normalization to apply every time data is forward-propagated through the input layer, specified as one of the following:

- "zerocenter" — Subtract the mean. The mean is calculated at training time.

- "zscore" — Subtract the mean and divide by the standard deviation. The mean and standard deviation are calculated at training time.

Example: Normalization="zscore"

Data Types: char | string

## Output Arguments

### lgraph — 3-D residual network

layerGraph object

3-D residual network, returned as a layerGraph object.

## More About

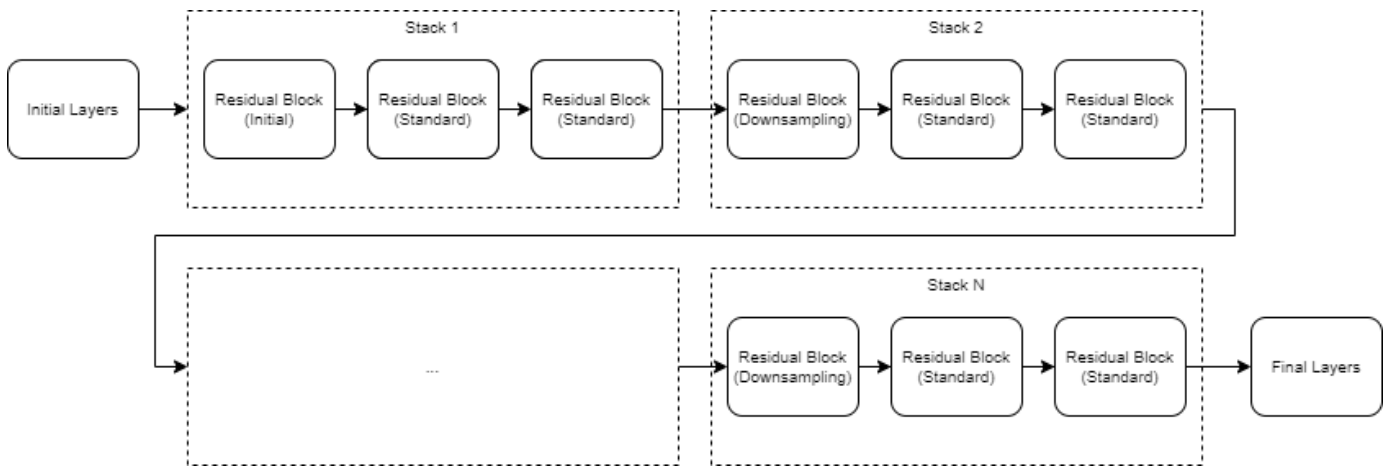

### Residual Network

Residual networks (ResNets) are a type of deep network consisting of building blocks that have *residual connections* (also known as *skip* or *shortcut* connections). These connections allow the input to skip the convolutional units of the main branch, thus providing a simpler path through the network. By allowing the parameter gradients to flow more easily from the output layer to the earlier layers of the network, residual connections help mitigate the problem of vanishing gradients during early training.

The structure of a residual network is flexible. The key component is the inclusion of the residual connections within *residual blocks*. A group of residual blocks is called a *stack*. A ResNet architecture consists of initial layers, followed by stacks containing residual blocks, and then the final layers. A network has three types of residual blocks:

- Initial residual block — This block occurs at the start of the first stack. The layers in the residual connection of the initial residual block determine if the block preserves the activation sizes or performs downsampling.
- Standard residual block — This block occurs multiple times in each stack, after the first downsampling residual block. The standard residual block preserves the activation sizes.
- Downsampling residual block — This block occurs once, at the start of each stack. The first convolutional unit in the downsampling block downsamples the spatial dimensions by a factor of two.

A typical stack has a downsampling residual block, followed by  $m$  standard residual blocks, where  $m$  is greater than or equal to one. The first stack is the only stack that begins with an initial residual block.

The initial, standard, and downsampling residual blocks can be *bottleneck* or nonbottleneck blocks. Bottleneck blocks perform a 1-by-1-by-1 convolution before the 3-by-3-by-3 convolution, to reduce the number of channels by a factor of four. Networks with and without bottleneck blocks have a similar level of computational complexity, but the total number of features propagating in the residual connections is four times larger when you use the bottleneck units. Therefore, using bottleneck blocks increases the efficiency of the network.

The layers inside each block are determined by the type of block and the options you set.

-------------------------------------	---	--	--	--	--	---

		Type is set to "batchnorm-before-add", the residual connection will also have a batch normalization layer.	the addition layer. Set the position of the addition layer using the ResidualBlock Type argument.		branch contains a convolution3dLayer with [1,1,1] filter and [2,2,2] stride.  The downsampling block halves the height and width of the input, and increases the number of channels.	
--	--	--	--	--	--	--

The convolution and fully connected layer weights are initialized using the He weight initialization method [3]. For more information, see `convolution3dLayer`.

## Tips

- When working with small images, set the `InitialPoolingLayer` option to "none" to remove the initial pooling layer and reduce the amount of downsampling.
- Residual networks are usually named ResNet- $X$ , where  $X$  is the *depth* of the network. The depth of a network is defined as the largest number of sequential convolutional or fully connected layers on a path from the input layer to the output layer. You can use the following formula to compute the depth of your network:

$$\text{depth} = \begin{cases} 1 + 2 \sum_{i=1}^N s_i + 1 & \text{If no bottleneck} \\ 1 + 3 \sum_{i=1}^N s_i + 1 & \text{If bottleneck} \end{cases},$$

where  $s_i$  is the depth of stack  $i$ .

Networks with the same depth can have different network architectures. For example, you can create a 3-D ResNet-14 architecture with or without a bottleneck:

```
resnet14Bottleneck = resnet3dLayers([224 224 64 3],10, ...
StackDepth=[2 2], ...
NumFilters=[64 128]);
```

```
resnet14NoBottleneck = resnet3dLayers([224 224 64 3],10, ...
BottleneckType="none", ...
StackDepth=[2 2 2], ...
NumFilters=[64 128 256]);
```

The relationship between bottleneck and nonbottleneck architectures also means that a network with a bottleneck will have a different depth than a network without a bottleneck.

```
resnet50Bottleneck = resnet3dLayers([224 224 64 3],10);
```

```
resnet34NoBottleneck = resnet3dLayers([224 224 64 3],10, ...
BottleneckType="none");
```

## Version History

Introduced in R2021b

## Extended Capabilities

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

You can use the residual network for code generation. First, create the network using the `resnet3dLayers` function. Then, use the `trainNetwork` function to train the network. After training and evaluating the network, you can generate code for the `DAGNetwork` object by using GPU Coder™.

# ROCCurve Properties

Receiver operating characteristic (ROC) curve appearance and behavior

## Description

ROCCurve properties control the appearance and behavior of a ROCCurve object, which the `plot` function of a `rocmetrics` object returns for each receiver operating characteristic (ROC) curve or other performance curve.

By changing property values, you can modify certain aspects of the ROC curve. Use dot notation to query and set properties; for example:

```
rocObj = rocmetrics(Lables, Scores, ClassNames);
curveObj = plot(rocObj);
c = curveObj(1).Color;
curveObj(1).Color = "red";
```

## Properties

### ROC Curve Data

#### XAxisMetric — Performance metric for x-axis

name of performance metric

This property is read-only.

Performance metric for the x-axis, stored in `XData`, specified as a string scalar of the performance metric name.

The `XAxisMetric` name-value argument of the `plot` function sets this property. The default value of this argument is `"FalsePositiveRate"`.

For details about built-in and custom metric names, see the `XAxisMetric` name-value argument of the `plot` function.

#### XData — x-axis values

numeric vector

This property is read-only.

x-axis values for `XAxisMetric`, specified as a numeric vector.

Data Types: `double`

#### YAxisMetric — Performance metric for y-axis

name of performance metric

This property is read-only.

Performance metric for the y-axis, stored in `YData`, specified as a string scalar of the performance metric name.

The `YAxisMetric` name-value argument of the `plot` function sets this property. The default value of this argument is `"TruePositiveRate"`.

For details about built-in and custom metric names, see the `XAxisMetric` name-value argument of the `plot` function.

### **YData — y-axis values**

numeric vector

This property is read-only.

y-axis values for `YAxisMetric`, specified as a numeric vector.

Data Types: `double`

### **Thresholds — Thresholds on classification scores**

numeric vector

This property is read-only.

Thresholds on classification scores at which the software finds each of the performance metric values (`XData` and `YData`), specified as a numeric vector.

Data Types: `double`

### **ROC Curve Options**

#### **ShowConfidenceIntervals — Flag to show confidence intervals**

`true` or `1` | `false` or `0`

Flag to show the confidence intervals for the y-axis metric (`YAxisMetric`), specified as logical `1` (`true`) or `0` (`false`).

The `ShowConfidenceIntervals` name-value argument of the `plot` function sets this property. The default value of the argument is `false`.

The `ShowConfidenceIntervals` value can be `true` only if the `Metrics` property of the `rocmetrics` object contains the confidence intervals for the y-axis metric.

Using confidence intervals requires Statistics and Machine Learning Toolbox.

### **Color**

#### **Color — Color of line and confidence interval shading**

RGB triplet | hexadecimal color code | `'r'` | `'g'` | `'b'` | ...

Color of the line and confidence interval shading, specified as an RGB triplet, hexadecimal color code, color name, or short name.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
"red"	"r"	[1 0 0]	"#FF0000"	
"green"	"g"	[0 1 0]	"#00FF00"	
"blue"	"b"	[0 0 1]	"#0000FF"	
"cyan"	"c"	[0 1 1]	"#00FFFF"	
"magenta"	"m"	[1 0 1]	"#FF00FF"	
"yellow"	"y"	[1 1 0]	"#FFFF00"	
"black"	"k"	[0 0 0]	"#000000"	
"white"	"w"	[1 1 1]	"#FFFFFF"	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	"#0072BD"	
[0.8500 0.3250 0.0980]	"#D95319"	
[0.9290 0.6940 0.1250]	"#EDB120"	
[0.4940 0.1840 0.5560]	"#7E2F8E"	
[0.4660 0.6740 0.1880]	"#77AC30"	
[0.3010 0.7450 0.9330]	"#4DBEEE"	
[0.6350 0.0780 0.1840]	"#A2142F"	

Example: 'blue'

Example: [0 0 1]

Example: '#0000FF'

### ColorMode — Mode for setting Color

'auto' (default) | 'manual'

Mode for setting the Color property, specified as one of these values:

- 'auto' — The software controls the value of the Color property by selecting a color from the ColorOrder property of the axes.
- 'manual' — You control the value of the Color property manually by setting the value of the Color property directly on the object.

If you change the value of the Color property manually, the software changes the value of the ColorMode property to 'manual'.

### Line

#### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the options in this table.

Line Style	Description	Resulting Line
"_"	Solid line	
"_ _"	Dashed line	
":"	Dotted line	
"- ."	Dash-dotted line	
"none"	No line	No line

### LineStyleMode — Mode for setting LineStyle

'auto' (default) | 'manual'

Mode for setting the LineStyle property, specified as one of these values:

- 'auto' — The software controls the value of the LineStyle property by selecting a line style from the LineStyleOrder property of the axes.
- 'manual' — You control the value of the LineStyle property manually by setting the value of the LineStyle property directly on the object.

If you change the value of the LineStyle property manually, the software changes the value of the LineStyleMode property to 'manual'.

### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in points, where 1 point = 1/72 of an inch. If the line has markers, then the line width also affects the marker edges.

The line width cannot be thinner than the width of a pixel. If you set the line width to a value that is less than the width of a pixel on your system, the line is displayed one pixel wide.

### SeriesIndex — Series index

whole number

Series index, specified as a whole number greater than or equal to 0. This property is useful for reassigning the colors, line styles, or markers of several ROCCurve objects so that they match each other. By default, the SeriesIndex property of a ROCCurve object is a number that corresponds to its order of creation, starting at 1.

The software uses the number to calculate indices for assigning color, line style, or markers when you call plotting functions. The indices refer to the rows of the arrays stored in the ColorOrder and LineStyleOrder properties of the axes.

The software automatically updates the color, line style, or markers of the ROCCurve object when you change its SeriesIndex, or when you change the ColorOrder or LineStyleOrder properties of the axes. However, the following conditions must be true for the changes to have any effect:

- At least one of these properties of the ROCCurve object is set to 'auto': ColorMode, LineStyleMode, or MarkerMode.

- The SeriesIndex property of the ROCCurve object is greater than 0.
- The NextSeriesIndex property of the axes object is greater than 0.

### Markers

#### Marker — Marker symbol

'none' | 'o' | '+' | '\*' | '.' | ...

Marker symbol, specified as one of the values in this table. By default, the object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

Marker	Description	Resulting Marker
"o"	Circle	○
"+"	Plus sign	+
"*"	Asterisk	*
"."	Point	•
"x"	Cross	×
"_"	Horizontal line	—
" "	Vertical line	
"square"	Square	□
"diamond"	Diamond	◇
"^"	Upward-pointing triangle	△
"v"	Downward-pointing triangle	▽
">"	Right-pointing triangle	▷
"<"	Left-pointing triangle	◁
"pentagram"	Pentagram	☆
"hexagram"	Hexagram	☆
"none"	No markers	Not applicable

#### MarkerMode — Mode for setting Marker

'auto' (default) | 'manual'

Mode for setting the Marker property, specified as one of these values:

- 'auto' — The software controls the value of the object's Marker property.
- 'manual' — You control the value of the Marker property manually by setting the value of the Marker property directly on the object.

If you change the value of the `Marker` property manually, the software changes the value of the `MarkerMode` property to `'manual'`.

### Legend

#### **DisplayName** — Text used in legend

character vector

Text used in the legend, specified as a character vector.

The default value of `DisplayName` is the name of the class for which the curve describes the performance. If the curve is a ROC curve, then `DisplayName` also contains the area under the ROC curve (AUC) value.

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property.

If you interactively edit the character vector in an existing legend, then the software updates the `DisplayName` property to the edited character vector.

#### **Annotation** — Control for legend

Annotation object

Control for including the `ROCCurve` object in the legend or excluding the object from the legend, specified as an Annotation object. Set the underlying `IconDisplayStyle` property to one of these values:

- `'on'` — Include the `ROCCurve` object in the legend (default).
- `'off'` — Do not include the `ROCCurve` object in the legend.

For example, to exclude the `ROCCurve` object `curveObj` from the legend, set the `IconDisplayStyle` property to `'off'`.

```
curveObj.Annotation.LegendInformation.IconDisplayStyle = 'off';
```

Alternatively, you can control the items in a legend using the `legend` function. Specify the first input argument as a vector of the graphics objects to include. If you do not specify an existing graphics object in the first input argument, then it does not appear in the legend. However, graphics objects added to the axes after the legend is created do appear in the legend. Consider creating the legend after creating all the plots to avoid extra items.

### Interactivity

#### **Visible** — State of visibility for object

`'on'` (default) | on/off logical value

State of visibility for an object, specified as `'on'` or `'off'`, or as numeric or logical `1` (`true`) or `0` (`false`). A value of `'on'` is equivalent to `true`, and `'off'` is equivalent to `false`. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

- 'on' — Display the object.
- 'off' — Hide the object without deleting it. You still can access the properties of an invisible object.

### DataTipTemplate — Data tip content

DataTipTemplate object

Data tip content, specified as a DataTipTemplate object. You can control the content that appears in a data tip by modifying the properties of the underlying DataTipTemplate object. For a list of properties, see DataTipTemplate.

For an example of modifying data tips, see “Create Custom Data Tips”.

---

**Note** The DataTipTemplate object is not returned by findobj or findall, and it is not copied by copyobj.

---

### Selected — Selection state of object

'off' (default) | on/off logical value

Selection state of an object, specified as 'on' or 'off', or as numeric or logical 1 (true) or 0 (false). A value of 'on' is equivalent to true, and 'off' is equivalent to false. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type matlab.lang.OnOffSwitchState.

- 'on' — The object is selected. If you click the object when editing the plot, the software sets the object's Selected property to 'on'. If the SelectionHighlight property is also set to 'on', the software displays selection handles around the object.
- 'off' — The object is not selected.

### SelectionHighlight — Display of selection handles

'on' (default) | on/off logical value

Display of selection handles when an object is selected, specified as 'on' or 'off', or as numeric or logical 1 (true) or 0 (false). A value of 'on' is equivalent to true, and 'off' is equivalent to false. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type matlab.lang.OnOffSwitchState.

- 'on' — Display selection handles around the object when the Selected property is set to 'on'.
- 'off' — Do not display selection handles around the object, even when the Selected property is set to 'on'.

### Callback Execution Control

#### PickableParts — Ability to capture mouse clicks

'visible' (default) | 'all' | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Capture mouse clicks when they are visible. The Visible property must be set to 'on' and you must click a part of the ROCCurve object that has a defined color. You cannot click a part that has an associated color property set to 'none'. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the ROCCurve object responds to the click or if an ancestor does.

- 'all' — Capture mouse clicks regardless of visibility. The `Visible` property can be set to 'on' or 'off' and you can click a part of the `ROCCurve` object that has no color. The `HitTest` property determines if the `ROCCurve` object responds to the click or if an ancestor does.
- 'none' — Mouse clicks cannot be captured. Clicking the `ROCCurve` object passes the click to the object below it in the current view of the figure window. The `HitTest` property has no effect.

**HitTest — Response to captured mouse clicks**

'on' (default) | on/off logical value

Response to captured mouse clicks, specified as 'on' or 'off', or as numeric or logical 1 (true) or 0 (false). A value of 'on' is equivalent to true, and 'off' is equivalent to false. Thus, you can use the value of this property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

- 'on' — Create a data tip at a data point of the `ROCCurve` object.
- 'off' — Trigger the callbacks for the nearest ancestor of the `ROCCurve` object that has one of these:
  - `HitTest` property set to 'on'
  - `PickableParts` property set to a value that enables the ancestor to capture mouse clicks

---

**Note** The `PickableParts` property determines if the `ROCCurve` object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

**Parent/Child****Parent — Parent**

Axes object

Parent, specified as an Axes object.

**Children — Children**

empty `GraphicsPlaceholder` array | `DataTip` object array

Children, specified as an empty `GraphicsPlaceholder` array or a `DataTip` object array. Use this property to view a list of data tips plotted on the performance curve.

You cannot add or remove children using the `Children` property. To add a child to this list, set the `Parent` property of the `DataTip` object to the `ROCCurve` object.

**HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of the object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The object handle is always visible.
- 'off' — The object handle is invisible at all times. This option is useful for preventing unintended changes by another function. Set `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.

- `'callback'` — The object handle is visible from callbacks or functions invoked by callbacks, but not from functions invoked from the command line. This option blocks access to the object at the command line, but permits callback functions to access the object.

If the object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return the object. Examples of such functions include the `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close` functions.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

### Identifier

#### Type — Type of graphics object

`'roccurve'`

This property is read-only.

Type of graphics object, specified as `'roccurve'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

#### Tag — Object identifier

`''` (default) | character vector | string scalar

Object identifier, specified as a character vector or string scalar. You can specify a unique `Tag` value to serve as an identifier for an object. When you need to access the object elsewhere in your code, you can use the `findobj` function to search for the object based on the `Tag` value.

#### UserData — User data

`[]` (default) | array

User data, specified as any MATLAB array. For example, you can specify a scalar, vector, matrix, cell array, character array, table, or structure. Use this property to store arbitrary data on an object.

If you are working in App Designer, create public or private properties in the app to share data instead of using the `UserData` property. For more information, see “Share Data Within App Designer Apps”.

“ROC Curve and Performance Metrics”

“Compare Deep Learning Models Using ROC Curves”

## rocmetrics

Receiver operating characteristic (ROC) curve and performance metrics for binary and multiclass classifiers

### Description

Create a `rocmetrics` object to evaluate the performance of a classification model using receiver operating characteristic (ROC) curves on page 1-1623 or other performance metrics. `rocmetrics` supports both binary and multiclass problems.

For each class, `rocmetrics` computes performance metrics for a one-versus-all on page 1-1624 ROC curve. You can compute metrics for an average ROC curve by using the `average` function. After computing metrics for ROC curves, you can plot them by using the `plot` function.

By default, `rocmetrics` computes the false positive rates (FPR) and the true positive rates (TPR) to obtain a ROC curve and the area under the ROC curve (AUC) on page 1-1624. You can compute additional metrics by specifying the `AdditionalMetrics` name-value argument when you create an object or by calling the `addMetrics` function after you create an object. A `rocmetrics` object stores the computed metrics and AUC values in the `Metrics` and `AUC` properties, respectively.

`rocmetrics` computes pointwise confidence intervals for the performance metrics when you set the `NumBootstraps` value to a positive integer or when you specify cross-validated data for the true class labels (`Labels`), classification scores (`Scores`), and observation weights (`Weights`). For details, see “Pointwise Confidence Intervals”. Using confidence intervals requires Statistics and Machine Learning Toolbox.

### Creation

#### Syntax

```
rocObj = rocmetrics(Labels,Scores,ClassNames)
```

```
rocObj = rocmetrics(Labels,Scores,ClassNames,Name=Value)
```

#### Description

`rocObj = rocmetrics(Labels,Scores,ClassNames)` creates a `rocmetrics` object using the true class labels in `Labels` and the classification scores in `Scores`. Specify `Labels` as a vector of length `n`, and specify `Scores` as a matrix of size `n`-by-`K`, where `n` is the number of observations, and `K` is the number of classes. `ClassNames` specifies the column order in `Scores`.

The `Metrics` and `AUC` properties contain the performance metrics and AUC value for each class for which you specify `Scores` and `ClassNames`.

If you specify cross-validated data in `Labels` and `Scores` as cell arrays, then `rocmetrics` computes confidence intervals for the performance metrics. Using cross-validated data requires Statistics and Machine Learning Toolbox.

`rocObj = rocmetrics(Labels, Scores, ClassNames, Name=Value)` specifies additional options using one or more name-value arguments. For example, `Prior="uniform"` sets all class probabilities to be equal.

## Input Arguments

### Labels — True class labels

numeric vector | logical vector | categorical vector | character array | string array | cell array

True class labels, specified as a numeric vector, logical vector, categorical vector, character array, string array, or cell array of character vectors. You can also specify `Labels` as a cell array of one of these types for cross-validated data.

- For data that is not cross-validated, the length of `Labels` and the number of rows in `Scores` must be equal.
- For cross-validated data, you must specify `Labels`, `Scores`, and `Weights` as cell arrays with the same number of elements. `rocmetrics` treats an element in the cell arrays as data from one cross-validation fold and computes pointwise confidence intervals for the performance metrics. The length of `Labels{i}` and the number of rows in `Scores{i}` must be equal. Using cross-validated data requires Statistics and Machine Learning Toolbox.

Each row of `Labels` or `Labels{i}` represents the true label of one observation.

This argument sets the `Labels` property.

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

### Scores — Classification scores

numeric matrix | cell array of numeric matrices

Classification scores, specified as a numeric matrix or a cell array of numeric matrices.

Each row of the matrix in `Scores` contains the classification scores of one observation for all classes specified in `ClassNames`. The column order of `Scores` must match the class order in `ClassNames`.

- For a matrix input, `Score(j,k)` is the classification score of observation `j` for class `ClassNames(k)`. For example, `predict` returns predicted class scores as an  $n$ -by- $K$  matrix, where  $n$  is the number of observations and  $K$  is the number classes. Pass the output to `rocmetrics`.

The number of rows in `Scores` and the length of `Labels` must be equal. `rocmetrics` adjusts scores for each class relative to the scores for the rest of the classes. For details, see “Adjusted Scores for Multiclass Classification Problem” on page 1-1625.

- For a vector input, `Score(j)` is the classification score of observation `j` for the class specified in `ClassNames`.
  - `ClassNames` must contain only one class.
  - `Prior` must be a two-element vector with `Prior(1)` representing the prior probability for the specified class.
  - `Cost` must be a 2-by-2 matrix containing  $[\text{Cost}(P|P), \text{Cost}(N|P); \text{Cost}(P|N), \text{Cost}(N|N)]$ , where `P` is a positive class (the class for which you specify classification scores), and `N` is a negative class.
  - The length of `Scores` and the length of `Labels` must be equal.

If you want to display the model operating point when you plot the ROC curve using the `plot` function, the values in `Score(j)` must be the posterior probability. This restriction applies only to a vector input.

- For cross-validated data, you must specify `Labels`, `Scores`, and `Weights` as cell arrays with the same number of elements. `rocmetrics` treats an element in the cell arrays as data from one cross-validation fold and computes pointwise confidence intervals for the performance metrics. `Score{i}(j,k)` is the classification score of observation `j` in element `i` for class `ClassNames(k)`. The number of rows in `Scores{i}` and the length of `Labels{i}` must be equal. Using cross-validated data requires Statistics and Machine Learning Toolbox.

For more information, see “Classification Score Input for `rocmetrics`”.

This argument sets the `Scores` property.

Data Types: `single` | `double` | `cell`

### **ClassNames — Class names**

numeric vector | logical vector | categorical vector | character array | string array | cell array of character vectors

Class names, specified as a numeric vector, logical vector, categorical vector, character array, string array, or cell array of character vectors. `ClassNames` must have the same data type as the true labels in `Labels`. The values in `ClassNames` must appear in `Labels`.

- If you specify classification scores for only one class in `Scores`, `ClassNames` specifies only the name of this class.
- Otherwise, `ClassNames` specifies the order of the classes in `Scores`, `Cost`, and `Prior`.

This argument sets the `ClassNames` property.

Data Types: `single` | `double` | `logical` | `cell` | `categorical`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `FixedMetric="FalsePositiveRate", FixedMetricValues=0:0.01:1` holds the FPR values fixed at `0:0.01:1`.

### **Performance Metrics**

#### **AdditionalMetrics — Additional model performance metrics**

`[]` (default) | character vector | string array | function handle | cell array

Additional model performance metrics to compute, specified as a character vector or string scalar of the built-in metric name, string array of names, function handle (`@metricName`), or cell array of names or function handles. A `rocmetrics` object always computes the false positive rates (FPR) and the true positive rates (TPR) to obtain a ROC curve. Therefore, you do not have to specify to compute FPR and TPR.

- Built-in metrics — Specify one of the following built-in metric names by using a character vector or string scalar. You can specify more than one by using a string array.

Name	Description
"TruePositives" or "tp"	Number of true positives (TP)
"FalseNegatives" or "fn"	Number of false negatives (FN)
"FalsePositives" or "fp"	Number of false positives (FP)
"TrueNegatives" or "tn"	Number of true negatives (TN)
"SumOfTrueAndFalsePositives" or "tp+fp"	Sum of TP and FP
"RateOfPositivePredictions" or "rpp"	Rate of positive predictions (RPP), $(TP+FP)/(TP+FN+FP+TN)$
"RateOfNegativePredictions" or "rnp"	Rate of negative predictions (RNP), $(TN+FN)/(TP+FN+FP+TN)$
"Accuracy" or "accu"	Accuracy, $(TP+TN)/(TP+FN+FP+TN)$
"FalseNegativeRate", "fnr", or "miss"	False negative rate (FNR), or miss rate, $FN/(TP+FN)$
"TrueNegativeRate", "tnr", or "spec"	True negative rate (TNR), or specificity, $TN/(TN+FP)$
"PositivePredictiveValue", "ppv", or "prec"	Positive predictive value (PPV), or precision, $TP/(TP+FP)$
"NegativePredictiveValue" or "npv"	Negative predictive value (NPV), $TN/(TN+FN)$
"ExpectedCost" or "ecost"	<p>Expected cost, <math>(TP*cost(P P)+FN*cost(N P)+FP*cost(P N)+TN*cost(N N))/(TP+FN+FP+TN)</math>, where <i>cost</i> is a 2-by-2 misclassification cost matrix containing <math>[0, cost(N P); cost(P N), 0]</math>. <i>cost(N P)</i> is the cost of misclassifying a positive class (P) as a negative class (N), and <i>cost(P N)</i> is the cost of misclassifying a negative class as a positive class.</p> <p>The software converts the K-by-K matrix specified by the <i>Cost</i> name-value argument of <i>rocmetrics</i> to a 2-by-2 matrix for each one-versus-all binary problem. For details, see "Misclassification Cost Matrix".</p>

The software computes the scale vector using the prior class probabilities (*Prior*) and the number of classes in *Labels*, and then scales the performance metrics according to this scale vector. For details, see "Performance Metrics".

- Custom metric — Specify a custom metric by using a function handle. A custom function that returns a performance metric must have this form:

```
metric = customMetric(C, scale, cost)
```

- The output argument *metric* is a scalar value.
- A custom metric is a function of the confusion matrix (*C*), scale vector (*scale*), and cost matrix (*cost*). The software finds these input values for each one-versus-all binary problem. For details, see "Performance Metrics".
- *C* is a 2-by-2 confusion matrix consisting of  $[TP, FN; FP, TN]$ .

- `scale` is a 2-by-1 scale vector.
- `cost` is a 2-by-2 misclassification cost matrix.

The software does not support cross-validation for a custom metric. Instead, you can specify to use bootstrap when you create a `rocmetrics` object.

Note that the positive predictive value (PPV) is NaN for the reject-all threshold for which  $TP = FP = 0$ , and the negative predictive value (NPV) is NaN for the accept-all threshold for which  $TN = FN = 0$ . For more details, see “Thresholds, Fixed Metric, and Fixed Metric Values”.

Example: `AdditionalMetrics=["Accuracy","PositivePredictiveValue"]`

Example: `AdditionalMetrics={"Accuracy",@m1,@m2}` specifies the accuracy metric and the custom metrics `m1` and `m2` as additional metrics. `rocmetrics` stores the custom metric values as variables named `CustomMetric1` and `CustomMetric2` in the `Metrics` property.

Data Types: `char` | `string` | `cell` | `function_handle`

### **FixedMetric — Fixed metric**

"Thresholds" (default) | "FalsePositiveRate" | "TruePositiveRate" | metric specified by `AdditionalMetrics`

Fixed metric, specified as "Thresholds", "FalsePositiveRate" (or "fpr"), "TruePositiveRate" (or "tpr"), or a metric specified by the `AdditionalMetrics` name-value argument. To hold a custom metric fixed, specify `FixedMetric` as "CustomMetricN", where N is the number that refers to the custom metric. For example, specify "CustomMetric1" to use the first custom metric specified by `AdditionalMetrics` as the fixed metric.

`rocmetrics` finds the ROC curves and other metric values that correspond to the fixed values (`FixedMetricValues`) of the fixed metric (`FixedMetric`), and stores the values in the `Metrics` property as a table. For more details, see “Thresholds, Fixed Metric, and Fixed Metric Values”.

If `rocmetrics` computes confidence intervals, it uses one of two methods for the computation, depending on the `FixedMetric` value:

- If `FixedMetric` is "Thresholds" (default), `rocmetrics` uses threshold averaging.
- If `FixedMetric` is a nondefault value, `rocmetrics` uses vertical averaging.

For details, see “Pointwise Confidence Intervals”.

Using confidence intervals requires Statistics and Machine Learning Toolbox.

Example: `FixedMetric="TruePositiveRate"`

Data Types: `char` | `string`

### **FixedMetricValues — Values for fixed metric**

"all" (default) | numeric vector

Values for the fixed metric (`FixedMetric`), specified as "all" or a numeric vector.

`rocmetrics` finds the ROC curves and other metric values that correspond to the fixed values (`FixedMetricValues`) of the fixed metric (`FixedMetric`), and stores the values in the `Metrics` property as a table.

The default `FixedMetric` value is "Thresholds", and the default `FixedMetricValues` value is "all". For each class, `rocmetrics` uses all distinct adjusted score values on page 1-1625 as

threshold values and computes the performance metrics using the threshold values. Depending on the `UseNearestNeighbor` setting, `rocmetrics` uses the exact threshold values corresponding to the fixed values or the nearest threshold values. For more details, see “Thresholds, Fixed Metric, and Fixed Metric Values”.

If `rocmetrics` computes confidence intervals, it holds `FixedMetric` fixed at `FixedMetricValues`.

- `FixedMetric` value is "Thresholds", and `FixedMetricValues` is "all" — `rocmetrics` computes confidence intervals at the values corresponding to all distinct threshold values.
- `FixedMetric` value is a performance metric, and `FixedMetricValues` is "all" — `rocmetrics` finds the metric values corresponding to all distinct threshold values, and computes confidence intervals at the values corresponding to the metric values.

For details, see “Pointwise Confidence Intervals”. Using confidence intervals requires Statistics and Machine Learning Toolbox.

Example: `FixedMetricValues=0:0.01:1`

Data Types: `single` | `double`

### **NaNFlag — NaN condition**

"omitnan" (default) | "includenan"

NaN condition, specified as "omitnan" or "includenan".

- "omitnan" — `rocmetrics` ignores all NaN score values in the input `Scores` and the corresponding values in `Labels` and `Weights`.
- "includenan" — `rocmetrics` uses the NaN score values in the input `Scores` for the calculation. The function adds the observations with NaN scores to false classification counts in the respective class. That is, the function counts observations with NaN scores from the positive class as false negative (FN), and counts observations with NaN scores from the negative class as false positive (FP).

For more details, see “NaN Score Values”.

Example: `NaNFlag="includenan"`

Data Types: `char` | `string`

### **UseNearestNeighbor — Indicator to use nearest metric values**

false or 0 | true or 1

Indicator to use the nearest metric values, specified as logical 0 (false) or 1 (true).

- logical 0 (false) — `rocmetrics` uses the exact threshold values corresponding to the specified fixed metric values in `FixedMetricValues` for `FixedMetric`.
- logical 1 (true) — Among the adjusted input scores on page 1-1625, `rocmetrics` finds a value that is the nearest to the threshold value corresponding to each specified fixed metric value.

For more details, see “Thresholds, Fixed Metric, and Fixed Metric Values”.

The `UseNearestNeighbor` value must be false if `rocmetrics` computes confidence intervals. Otherwise, the default value is true.

Using confidence intervals requires Statistics and Machine Learning Toolbox.

Example: `UseNearestNeighbor=false`

Data Types: `logical`

### **Options for Classification Model**

#### **Cost — Misclassification cost**

square matrix

Misclassification cost, specified as a  $K$ -by- $K$  square matrix  $C$ , where  $K$  is the number of unique classes in `Labels`.  $C(i, j)$  is the cost of classifying a point into class  $j$  if its true class is  $i$  (that is, the rows correspond to the true class and the columns correspond to the predicted class). `ClassNames` specifies the order of the classes.

`rocmetrics` converts the  $K$ -by- $K$  matrix to a 2-by-2 matrix for each one-versus-all binary problem. For details, see “Misclassification Cost Matrix”.

If you specify classification scores for only one class in `Scores`, the `Cost` value must be a 2-by-2 matrix containing  $[0, \text{cost}(N|P); \text{cost}(P|N), 0]$ , where  $P$  is a positive class (the class for which you specify classification scores), and  $N$  is a negative class.  $\text{cost}(N|P)$  is the cost of misclassifying a positive class as a negative class, and  $\text{cost}(P|N)$  is the cost of misclassifying a negative class as a positive class.

The default value is  $C(i, j)=1$  if  $i \neq j$ , and  $C(i, j)=0$  if  $i=j$ . The diagonal entries of a cost matrix must be zero.

This argument sets the `Cost` property.

Example: `Cost=[0 2;1 0]`

Data Types: `single` | `double`

#### **Prior — Prior class probabilities**

"empirical" (default) | "uniform" | vector of scalar values

Prior class probabilities, specified as one of the following:

- "empirical" determines class probabilities from class frequencies in the true class labels `Labels`. If you pass observation weights (`Weights`), `rocmetrics` also uses the weights to compute the class probabilities.
- "uniform" sets all class probabilities to be equal.
- Vector of scalar values, with one scalar value for each class. `ClassNames` specifies the order of the classes.

If you specify classification scores for only one class in `Scores`, the `Prior` value must be a two-element vector with `Prior(1)` representing the prior probability for the specified class.

This argument sets the `Prior` property.

Example: `Prior="uniform"`

Data Types: `single` | `double` | `char` | `string`

#### **Weights — Observation weights**

numeric vector of positive values | cell array containing numeric vectors of positive values

Observation weights, specified as a numeric vector of positive values or a cell array containing numeric vectors of positive values.

- For data that is not cross-validated, specify `Weights` as a numeric vector that has the same length as `Labels`.
- For cross-validated data, you must specify `Labels`, `Scores`, and `Weights` as cell arrays with the same number of elements. `rocmetrics` treats an element in the cell arrays as data from one cross-validation fold and computes pointwise confidence intervals for the performance metrics. The length of `Weights{i}` and the length of `Labels{i}` must be equal. Using cross-validated data requires Statistics and Machine Learning Toolbox.

`rocmetrics` weighs the observations in `Labels` and `Scores` with the corresponding values in `Weights`. If you set the `NumBootstraps` value to a positive integer, `rocmetrics` draws samples with replacement, using the weights as multinomial sampling probabilities. Using the `NumBootstraps` name-value argument requires Statistics and Machine Learning Toolbox.

By default, `Weights` is a vector of ones or a cell array containing vectors of ones.

This argument sets the `Weights` property.

Data Types: `single` | `double` | `cell`

### Options for Confidence Intervals

#### Alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the pointwise confidence intervals, specified as a scalar in the range (0,1).

If you specify `Alpha` as  $\alpha$ , then `rocmetrics` computes  $100 \times (1 - \alpha)\%$  pointwise confidence intervals for the performance metrics.

This argument is related to computing confidence intervals. Therefore, it is valid only when you specify cross-validated data for `Labels`, `Scores`, and `Weights`, or when you set the `NumBootstraps` value to a positive integer.

This option requires Statistics and Machine Learning Toolbox.

Example: `Alpha=0.01` specifies 99% confidence intervals.

Data Types: `single` | `double`

#### BootstrapOptions — Bootstrap options for parallel computation

`statset("rocmetrics")` (default) | structure

Bootstrap options for parallel computation, specified as a structure.

You can specify options for computing bootstrap iterations in parallel and setting random numbers during the bootstrap sampling. Create the `BootstrapOptions` structure with `statset`. This table lists the option fields and their values.

Field Name	Field Value	Default
<code>UseParallel</code>	Set this value to <code>true</code> to compute bootstrap iterations in parallel.	<code>false</code>

Field Name	Field Value	Default
UseSubstreams	Set this value to true to run computations in parallel in a reproducible manner.  To compute reproducibly, set Streams to a type that allows substreams: "mlfg6331_64" or "mrg32k3a".	false
Streams	Specify this value as a RandStream object or cell array of such objects. Use a single object except when the UseParallel value is true and the UseSubstreams value is false. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify Streams, then rocmetrics uses the default stream or streams.

This argument is valid only when you specify NumBootstraps as a positive integer to compute confidence intervals using bootstrapping.

This option requires Statistics and Machine Learning Toolbox, and parallel computation requires Parallel Computing Toolbox.

Example: `BootstrapOptions=statset(UseParallel=true)`

Data Types: struct

**BootstrapType – Bootstrap confidence interval type**

"bca" (default) | "corrected percentile" | "normal" | "percentile" | "student"

Bootstrap confidence interval type, specified as one of the values in this table.

Value	Description
"bca"	Bias corrected and accelerated percentile method [8][9]. This method involves a $z_0$ factor computed using the proportion of bootstrap values that are less than the original sample value. To produce reasonable results when the sample is lumpy, the software computes $z_0$ by including half of the bootstrap values that are the same as the original sample value.
"corrected percentile" or "cper"	Bias corrected percentile method [10]
"normal" or "norm"	Normal approximated interval with bootstrapped bias and standard error [11]
"percentile" or "per"	Basic percentile method
"student" or "stud"	Studentized confidence interval [8]

This argument is valid only when you specify NumBootstraps as a positive integer to compute confidence intervals using bootstrapping.

This option requires Statistics and Machine Learning Toolbox.

Example: `BootstrapType="student"`

Data Types: `char` | `string`

### **NumBootstraps — Number of bootstrap samples to draw**

0 (default) | nonnegative integer scalar

Number of bootstrap samples to draw for computing pointwise confidence intervals, specified as a nonnegative integer scalar.

If you specify `NumBootstraps` as a positive integer, then `rocmetrics` uses `NumBootstraps` bootstrap samples. To create each bootstrap sample, the function randomly selects `n` out of the `n` rows of input data with replacement. The default value 0 implies that `rocmetrics` does not use bootstrapping.

`rocmetrics` computes confidence intervals by using either cross-validated data or bootstrap samples. Therefore, if you specify cross-validated data for `Labels`, `Scores`, and `Weights`, then `NumBootstraps` must be 0.

For details, see “Pointwise Confidence Intervals”.

This option requires Statistics and Machine Learning Toolbox.

Example: `NumBootstraps=500`

Data Types: `single` | `double`

### **NumBootstrapsStudentizedSE — Number of bootstrap samples to draw for studentized standard error estimate**

100 (default) | positive integer scalar

Number of bootstrap samples to draw for the studentized standard error estimate, specified as a positive integer scalar.

This argument is valid only when you specify `NumBootstraps` as a positive integer and `BootstrapType` as `"student"` to compute studentized bootstrap confidence intervals. `rocmetrics` estimates the studentized standard error estimate by using `NumBootstrapsStudentizedSE` bootstrap data samples.

This option requires Statistics and Machine Learning Toolbox.

Example: `NumBootstrapsStudentizedSE=500`

Data Types: `single` | `double`

## **Properties**

### **Performance Metrics**

#### **AUC — Area under ROC curve**

numeric vector | numeric matrix

This property is read-only.

Area under the ROC curve (AUC) on page 1-1624, specified as a numeric vector or matrix.

`rocmetrics` computes the AUC for each one-versus-all ROC curve (that is, for each class). The column order of the AUC property value matches the class order in `ClassNames`.

For a binary problem where you specify `Scores` as a two-column matrix, this property is a 1-by-2 vector containing identical AUC values. The AUC values are identical because the overall model performance on one class is identical to the performance on the other class for a binary problem.

If `rocmetrics` computes confidence intervals for AUC, the AUC property value is a matrix in which the first row corresponds to the AUC values, and the second and third rows correspond to the lower and upper bounds, respectively. `rocmetrics` computes confidence intervals for AUC if the function also computes confidence intervals for the performance metrics and you set `FixedMetric` to "Thresholds" (default), "FalsePositiveRate", or "TruePositiveRate". Using confidence intervals requires Statistics and Machine Learning Toolbox.

Data Types: `single` | `double`

### **Metrics — Performance metrics**

table

This property is read-only.

Performance metrics, specified as a table.

The table contains performance metric values for all classes, vertically concatenated according to the class order in `ClassNames`. The table has a row for each unique threshold value for each class. `rocmetrics` determines the threshold values to use based on the value of `FixedMetric`, `FixedMetricValues`, and `UseNearestNeighbor`. For details, see "Thresholds, Fixed Metric, and Fixed Metric Values".

The number of rows for each class in the table is the number of unique threshold values.

Each row of the table contains these variables: `ClassName`, `Threshold`, `FalsePositiveRate`, and `TruePositiveRate`, as well as a variable for each additional metric specified in `AdditionalMetrics`. If you specify a custom metric, `rocmetrics` names the metric "CustomMetricN", where N is the number that refers to the custom metric. For example, "CustomMetric1" corresponds to the first custom metric specified by `AdditionalMetrics`.

Each variable in the `Metrics` table contains a vector or a three-column matrix.

- If `rocmetrics` does not compute confidence intervals, each variable contains a vector.
- If `rocmetrics` computes confidence intervals, both `ClassName` and the variable for `FixedMetric` (`Threshold`, `FalsePositiveRate`, `TruePositiveRate`, or an additional metric) contain a vector, and the other variables contain a three-column matrix. The first column of the matrix corresponds to the metric values, and the second and third columns correspond to the lower and upper bounds, respectively.

Using confidence intervals requires Statistics and Machine Learning Toolbox.

Data Types: `table`

### **Classification Model Properties**

You can specify the following properties when creating a `rocmetrics` object.

#### **ClassNames — Class names**

numeric vector | logical vector | categorical vector | cell array of character vectors

This property is read-only.

Class names, specified as a numeric vector, logical vector, categorical vector, or cell array of character vectors.

For details, see the input argument `ClassNames`, which sets this property. (The software treats character or string arrays as cell arrays of character vectors.)

Data Types: `single` | `double` | `logical` | `cell` | `categorical`

### **Cost — Misclassification cost**

square matrix

This property is read-only.

Misclassification cost, specified as a square matrix.

For details, see the `Cost` name-value argument, which sets this property.

Data Types: `single` | `double`

### **Labels — True class labels**

numeric vector | logical vector | categorical vector | cell array

This property is read-only.

True class labels, specified as a numeric vector, logical vector, categorical vector, cell array of character vectors, or cell array of one of these types for cross-validated data.

For details, see the input argument `Labels`, which sets this property. (The software treats character or string arrays as cell arrays of character vectors.)

Data Types: `single` | `double` | `logical` | `cell` | `categorical`

### **Prior — Prior class probabilities**

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector.

For details, see the `Prior` name-value argument, which sets this property. If you specify this argument as a character vector or string scalar ("`empirical`" or "`uniform`"), `rocmetrics` computes the prior probabilities and stores the `Prior` property as a numeric vector.

Data Types: `single` | `double`

### **Scores — Classification scores**

numeric matrix | cell array of numeric matrices

This property is read-only.

Classification scores, specified as a numeric matrix or a cell array of numeric matrices.

For details, see the input argument `Scores`, which sets this property.

Data Types: `single` | `double` | `cell`

**Weights – Observation weights**

numeric vector of positive values | cell array containing numeric vectors of positive values

This property is read-only.

Observation weights, specified as a numeric vector of positive values or a cell array containing numeric vectors of positive values.

For details, see the `Weights` name-value argument, which sets this property.

Data Types: `single` | `double` | `cell`

**Object Functions**

`addMetrics` Compute additional classification performance metrics  
`average` Compute performance metrics for average receiver operating characteristic (ROC) curve in multiclass problem  
`plot` Plot receiver operating characteristic (ROC) curves and other performance curves

**Examples****Plot ROC Curve**

Load a sample of predicted classification scores and true labels for a classification problem.

```
load('flowersDataResponses.mat')
```

`trueLabels` is the true labels for an image classification problem and `scores` is the softmax prediction scores. `scores` is an N-by-K array where N is the number of observations and K is the number of classes.

```
trueLabels = flowersData.trueLabels;  
scores = flowersData.scores;
```

Load the class names. The column order of `scores` follows the class order stored in `classNames`.

```
classNames = flowersData.classNames;
```

Create a `rocmetrics` object by using the true labels in `trueLabels` and the classification scores in `scores`. Specify the column order of `scores` using `classNames`.

```
rocObj = rocmetrics(trueLabels,scores,classNames);
```

`rocObj` is a `rocmetrics` object that stores the AUC values and performance metrics for each class in the `AUC` and `Metrics` properties. Display the `AUC` property.

```
rocObj.AUC
```

```
ans = 1x5 single row vector
```

```
    0.9781    0.9889    0.9728    0.9809    0.9732
```

Plot the ROC curve for each class.

```
plot(rocObj)
```

The filled circle markers indicate the model operating points. The legend displays the class name and AUC value for each curve.

Plot the macro average ROC curve.

```
plot(rocObj, AverageROCType=["macro"], ClassNames=[])
```

### Compute Confidence Intervals Using Bootstrapping

Compute the confidence intervals for FPR and TPR for fixed threshold values by using bootstrap samples, and plot the confidence intervals for TPR on the ROC curve by using the `plot` function. This examples requires Statistics and Machine Learning Toolbox™.

Load a sample of true labels and the prediction scores for a classification problem. For this example, there are five classes: daisy, dandelion, roses, sunflowers, and tulips. The class names are stored in `classNames`. The scores are the softmax prediction scores generated using the `predict` function. `scores` is an N-by-K array where N is the number of observations and K is the number of classes. The column order of `scores` follows the class order stored in `classNames`.

```
load('flowersDataResponses.mat')

scores = flowersData.scores;
trueLabels = flowersData.trueLabels;
predLabels = flowersData.predictedLabels;

classNames = flowersData.classNames;
```

Create a `rocmetrics` object by using the true labels in `trueLabels` and the classification scores in `scores`. Specify the column order of `scores` using `classNames`. Specify `NumBootstraps` as 100 to use 100 bootstrap samples to compute the confidence intervals.

```
rocObj = rocmetrics(trueLabels,scores,classNames,NumBootstraps=100);
```

Find the rows for the second class in the table of the `Metrics` property, and display the first eight rows.

```
idx = rocObj.Metrics.ClassName ==classNames(2);
head(rocObj.Metrics(idx,:))
```

ClassName	Threshold	FalsePositiveRate			TruePositiveRate		
dandelion	1	0	0	0	0	0	0
dandelion	1	0	0	0	0.23889	0.17858	0.31326
dandelion	1	0	0	0	0.26111	0.20107	0.34007
dandelion	1	0	0	0	0.27222	0.21829	0.35778
dandelion	1	0	0	0	0.28889	0.22739	0.36583
dandelion	1	0	0	0	0.29444	0.23682	0.41685
dandelion	1	0	0	0	0.3	0.24296	0.42567
dandelion	1	0	0	0	0.31111	0.24964	0.42614

Each row of the table contains the metric value and its confidence intervals for FPR and TPR for a fixed threshold value. The `Threshold` variable is a column vector, and the `FalsePositiveRate` and `TruePositiveRate` variables are three-column matrices. The first column of the matrices corresponds to the metric values, and the second and third columns correspond to the lower and upper bounds, respectively.

Plot the ROC curve and the confidence intervals for TPR. Specify `ShowConfidenceIntervals=true` to show the confidence intervals.

```
plot(rocObj,ShowConfidenceIntervals=true)
```

The shaded area around the ROC curve indicates the confidence intervals. The confidence intervals represent the uncertainty of the curve due to the variance in the data set for the trained model.

Specify one class to plot by using the `ClassNames` name-value argument.

```
plot(rocObj, ShowConfidenceIntervals=true, ClassNames="daisy")
```

## More About

### Receiver Operating Characteristic (ROC) Curve

A ROC curve shows the true positive rate versus the false positive rate for different thresholds of classification scores.

The true positive rate and the false positive rate are defined as follows:

- True positive rate (TPR), also known as recall or sensitivity —  $TP / (TP + FN)$ , where TP is the number of true positives and FN is the number of false negatives
- False positive rate (FPR), also known as fallout or 1-specificity —  $FP / (TN + FP)$ , where FP is the number of false positives and TN is the number of true negatives

Each point on a ROC curve corresponds to a pair of TPR and FPR values for a specific threshold value. You can find different pairs of TPR and FPR values by varying the threshold value, and then create a ROC curve using the pairs. For each class, `rocmetrics` uses all distinct adjusted score on page 1-1625 values as threshold values to create a ROC curve.

For a multiclass classification problem, `rocmetrics` formulates a set of one-versus-all on page 1-1624 binary classification problems to have one binary problem for each class, and finds a ROC curve for each class using the corresponding binary problem. Each binary problem assumes one class as positive and the rest as negative.

For a binary classification problem, if you specify the classification scores as a matrix, `rocmetrics` formulates two one-versus-all binary classification problems. Each of these problems treats one class as a positive class and the other class as a negative class, and `rocmetrics` finds two ROC curves. Use one of the curves to evaluate the binary classification problem.

For more details, see “ROC Curve and Performance Metrics”.

### Area Under ROC Curve (AUC)

The area under a ROC curve (AUC) corresponds to the integral of a ROC curve (TPR values) with respect to FPR from  $FPR = 0$  to  $FPR = 1$ .

The AUC provides an aggregate performance measure across all possible thresholds. The AUC values are in the range 0 to 1, and larger AUC values indicate better classifier performance.

### One-Versus-All (OVA) Coding Design

The one-versus-all (OVA) coding design reduces a multiclass classification problem to a set of binary classification problems. In this coding design, each binary classification treats one class as positive and the rest of the classes as negative. `rocmetrics` uses the OVA coding design for multiclass classification and evaluates the performance on each class by using the binary classification that the class is positive.

For example, the OVA coding design for three classes formulates three binary classifications:

	Binary 1	Binary 2	Binary 3
Class 1	1	-1	-1
Class 2	-1	1	-1
Class 3	-1	-1	1

Each row corresponds to a class, and each column corresponds to a binary classification problem. The first binary classification assumes that class 1 is a positive class and the rest of the classes are negative. `rocmetrics` evaluates the performance on the first class by using the first binary classification problem.

### Model Operating Point

The model operating point represents the FPR and TPR corresponding to the typical threshold value.

The typical threshold value depends on the input format of the `Scores` argument (classification scores) specified when you create a `rocmetrics` object:

- If you specify `Scores` as a matrix, `rocmetrics` assumes that the values in `Scores` are the scores for a multiclass classification problem and uses adjusted score on page 1-1625 values. A multiclass classification model classifies an observation into a class that yields the largest score, which corresponds to a nonnegative score in the adjusted scores. Therefore, the threshold value is 0.
- If you specify `Scores` as a column vector, `rocmetrics` assumes that the values in `Scores` are posterior probabilities of the class specified in `ClassNames`. A binary classification model classifies an observation into a class that yields a higher posterior probability, that is, a posterior probability greater than 0.5. Therefore, the threshold value is 0.5.

For a binary classification problem, you can specify `Scores` as a two-column matrix or a column vector. However, if the classification scores are not posterior probabilities, you must specify `Scores` as a matrix. A binary classifier classifies an observation into a class that yields a larger score, which

is equivalent to a class that yields a nonnegative adjusted score. Therefore, if you specify `Scores` as a matrix for a binary classifier, `rocmetrics` can find a correct model operating point using the same scheme that it applies to a multiclass classifier. If you specify classification scores that are not posterior probabilities as a vector, `rocmetrics` cannot identify a correct model operating point because it always uses 0.5 as a threshold for the model operating point.

The `plot` function displays a filled circle marker at the model operating point for each ROC curve (see `ShowModelOperatingPoint`). The function chooses a point corresponding to the typical threshold value. If the curve does not have a data point for the typical threshold value, the function finds a point that has the smallest threshold value greater than the typical threshold. The point on the curve indicates identical performance to the performance of the typical threshold value.

## Algorithms

### Adjusted Scores for Multiclass Classification Problem

For each class, `rocmetrics` adjusts the classification scores (input argument `Scores` of `rocmetrics`) relative to the scores for the rest of the classes if you specify `Scores` as a matrix. Specifically, the adjusted score for a class given an observation is the difference between the score for the class and the maximum value of the scores for the rest of the classes.

For example, if you have  $[s_1, s_2, s_3]$  in a row of `Scores` for a classification problem with three classes, the adjusted score values are  $[s_1 - \max(s_2, s_3), s_2 - \max(s_1, s_3), s_3 - \max(s_1, s_2)]$ .

`rocmetrics` computes the performance metrics using the adjusted score values for each class.

For a binary classification problem, you can specify `Scores` as a two-column matrix or a column vector. Using a two-column matrix is a simpler option because the `predict` function of a classification object returns classification scores as a matrix, which you can pass to `rocmetrics`. If you pass scores in a two-column matrix, `rocmetrics` adjusts scores in the same way that it adjusts scores for multiclass classification, and it computes performance metrics for both classes. You can use the metric values for one of the two classes to evaluate the binary classification problem. The metric values for a class returned by `rocmetrics` when you pass a two-column matrix are equivalent to the metric values returned by `rocmetrics` when you specify classification scores for the class as a column vector.

# selfAttentionLayer

Self-attention layer

## Description

A self-attention layer computes single-head or multihead self-attention of its input.

The layer:

- 1 Computes the queries, keys, and values from the input
- 2 Computes the scaled dot-product attention across heads using the queries, keys, and values
- 3 Merges the results from the heads
- 4 Performs a linear transformation on the merged result

## Creation

### Syntax

```
layer = selfAttentionLayer(numHeads, numKeyChannels)
layer = selfAttentionLayer(numHeads, numKeyChannels, Name=Value)
```

### Description

`layer = selfAttentionLayer(numHeads, numKeyChannels)` creates a self-attention layer and sets the `NumHeads` and `NumKeyChannels` properties.

`layer = selfAttentionLayer(numHeads, numKeyChannels, Name=Value)` sets the optional `NumValueChannels`, `OutputSize`, `HasPaddingMaskInput`, `AttentionMask`, `DropoutProbability`, `HasScoresOutput`, “Parameters and Initialization” on page 1-1629, “Learning Rate and Regularization” on page 1-1631, and `Name` properties.

## Properties

### Self-Attention

#### **NumHeads** — Number of attention heads

positive integer

This property is read-only.

Number of attention heads, specified as a positive integer that evenly divides `NumKeyChannels`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **NumKeyChannels** — Number of channels for keys and queries

positive integer

This property is read-only.

Number of channels for the keys and queries, specified as a positive integer that is divisible by `NumHeads`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### **NumValueChannels — Number of channels for values**

`"auto"` (default) | positive integer

Number of channels for the values, specified as one of these values:

- `"auto"` — Use `NumKeyChannels`.
- Positive integer — Use the specified number of channels. This value must be divisible by `NumHeads`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### **OutputSize — Number of channels of layer output**

`"auto"` (default) | positive integer

Number of channels of the layer output, specified as one of these values:

- `"auto"` — Use the number of channels in the layer input.
- Positive integer — Use the specified number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### **HasPaddingMaskInput — Flag indicating whether layer has mask input**

`0` (`false`) (default) | `1` (`true`)

Flag indicating whether the layer has an input that represents the padding mask, specified as `0` (`false`) or `1` (`true`).

If the `HasPaddingMaskInput` property is `0` (`false`), then the layer has one input with the name `'in'`, which corresponds to the input data. In this case, the layer treats all elements as data.

If the `HasPaddingMaskInput` property is `1` (`true`), then the layer has two inputs with the names `'in'` and `'mask'`, which correspond to the input data and the mask, respectively. In this case, the padding mask is an array of ones and zeros. The layer prevents or allows attention to elements in the key-value pairs when the corresponding element in the mask is zero or one, respectively.

### **AttentionMask — Mask preventing attention to elements in key-value pairs**

`"none"` (default) | `"causal"`

Mask preventing attention to elements in key-value pairs, specified as one of these values:

- `"none"` — Do not prevent attention to elements based on their positions. If `HasPaddingMaskInput` is `1` (`true`), then the layer prevents attention to padding elements only.
- `"causal"` — Prevent elements in position `M` from attending to elements in position `N`, where `N` is greater than `M`. Use this option for auto-regressive models.

### **DropoutProbability — Dropout probability for attention scores**

`0` (default) | scalar in the range `[0, 1)`

Dropout probability for attention scores, specified as a scalar in the range [0, 1).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### HasScoresOutput — Flag indicating whether layer has scores output

0 (false) (default) | 1 (true)

Flag indicating whether the layer has an output that represents the attention scores, specified as one of these values:

- 0 (false) — The layer does not have an output that represents the attention scores.
- 1 (true) — The layer has an output with the name "scores" that represents the attention scores.

### InputSize — Number of input channels

"auto" (default) | positive integer

This property is read-only.

Number of input channels, specified as one of these values:

- "auto" — Automatically determine the number of input channels when you initialize the network
- Positive integer — Configure the layer for the specified number of input channels. `InputSize` and the number of channels in the layer input data must match.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

## Parameters and Initialization

### WeightsInitializer — Function to initialize weights

"glorot" (default) | "he" | "narrow-normal" | "zeros" | "ones" | function handle

Function to initialize the query, key, value, and output weights, specified as one of these values:

- "glorot" - Initialize the weights with the Glorot initializer (also known as Xavier initializer) [2]. The Glorot initializer independently samples from a uniform distribution with zero mean and a variance of  $2 / (\text{numIn} + \text{numOut})$ . The values of `numIn` and `numOut` depend on the weight matrix:

Weight	numIn	numOut
Query	InputSize	NumKeyChannels
Key	InputSize	NumKeyChannels
Value	InputSize	NumValueChannels
Output	NumValueChannels	OutputSize

- "he" - Initialize the weights with the He initializer [3]. The He initializer samples from a normal distribution with zero mean and a variance of  $2 / \text{numIn}$ . The values of `numIn` and `numOut` depend on the weight matrix:

Weight	numIn	numOut
Query	InputSize	NumKeyChannels
Key	InputSize	NumKeyChannels

Weight	numIn	numOut
Value	InputSize	NumValueChannels
Output	NumValueChannels	OutputSize

- "narrow-normal" — Initialize the weights by independently sampling from a normal distribution with zero mean and a standard deviation of 0.01.
- "zeros" — Initialize the weights with zeros.
- "ones" — Initialize the weights with ones.
- Function handle — Initialize the weights with a custom function. If you specify a function handle, then the function must have the form `weights = func(sz)`, where `sz` is the size of the weights. For an example, see "Specify Custom Weight Initialization Function".

The layer only initializes the weights when the corresponding weights property is empty.

Data Types: `char` | `string` | `function_handle`

### **BiasInitializer** — Function to initialize biases

"zeros" (default) | "narrow-normal" | "ones" | function handle

Function to initialize the query, key, value, and output biases, specified as one of these values:

- "zeros" — Initialize the biases with zeros.
- "ones" — Initialize the biases with ones.
- "narrow-normal" — Initialize the biases by independently sampling from a normal distribution with zero mean and a standard deviation of 0.01.
- Function handle — Initialize the biases with a custom function. If you specify a function handle, then the function must have the form `bias = func(sz)`, where `sz` is the size of the biases.

The layer only initializes the biases when the corresponding bias property is empty.

Data Types: `char` | `string` | `function_handle`

### **QueryWeights** — Query weights

[] (default) | matrix

Query weights, specified as a `NumKeyChannels`-by-`numInputChannels` matrix or [], where `numInputChannels` is the number of channels in the layer input.

Data Types: `single` | `double`

### **KeyWeights** — Key weights

[] (default) | matrix

Key weights, specified as a `NumKeyChannels`-by-`numInputChannels` matrix or [], where `numInputChannels` is the number of channels in the layer input.

Data Types: `single` | `double`

### **ValueWeights** — Value weights

[] (default) | matrix

Value weights, specified as a `NumValueChannels`-by-`numInputChannels` matrix or [], where `numInputChannels` is the number of channels in the layer input.

Data Types: `single` | `double`

### **OutputWeights — Output weights**

`[]` (default) | matrix

Output weights, specified as an `OutputSize`-by-`NumValueChannels` matrix or `[]`.

Data Types: `single` | `double`

### **QueryBias — Query biases**

`[]` (default) | vector

Query biases, specified as a `NumKeyChannels`-by-1 vector or `[]`.

Data Types: `single` | `double`

### **KeyBias — Key biases**

`[]` (default) | vector

Key biases, specified as a `NumKeyChannels`-by-1 vector or `[]`.

Data Types: `single` | `double`

### **ValueBias — Value biases**

`[]` (default) | vector

Value biases, specified as a `NumValueChannels`-by-1 vector or `[]`.

Data Types: `single` | `double`

### **OutputBias — Output biases**

`[]` (default) | vector

Output biases, specified as an `OutputSize`-by-1 vector or `[]`.

Data Types: `single` | `double`

## **Learning Rate and Regularization**

### **WeightLearnRateFactor — Learning rate factor for weights**

1 (default) | nonnegative scalar

Learning rate factor for the query, key, value, and output weights, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the weights in this layer. For example, if `WeightLearnRateFactor` is 2, then the learning rate for the weights in this layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **BiasLearnRateFactor — Learning rate factor for biases**

1 (default) | nonnegative scalar

Learning rate factor for the query, key, value, and output biases, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is 2, then the learning rate for the biases

in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **WeightL2Factor — $L_2$ regularization factor for weights**

1 (default) | nonnegative scalar

$L_2$  regularization factor for the query, key, value, and output weights, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the weights in this layer. For example, if `WeightL2Factor` is 2, then the  $L_2$  regularization for the weights in this layer is twice the global  $L_2$  regularization factor. You can specify the global  $L_2$  regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **BiasL2Factor — $L_2$ regularization factor for biases**

0 (default) | nonnegative scalar

$L_2$  regularization factor for the query, key, value, and output biases, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the biases in this layer. For example, if `BiasL2Factor` is 2, then the  $L_2$  regularization for the biases in this layer is twice the global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Layer**

### **Name — Layer name**

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

### **NumInputs — Number of inputs**

1 | 2

This property is read-only.

Number of inputs to the layer.

If the `HasPaddingMaskInput` property is 0 (`false`), then the layer has one input with the name 'in', which corresponds to the input data. In this case, the layer treats all elements as data.

If the `HasPaddingMaskInput` property is 1 (`true`), then the layer has two inputs with the names 'in' and 'mask', which correspond to the input data and the mask, respectively. In this case, the padding mask is an array of ones and zeros. The layer prevents or allows attention to elements in the key-value pairs when the corresponding element in the mask is zero or one, respectively.

Data Types: double

### InputNames — Input names

`{'in'} | {'in', 'mask'}`

This property is read-only.

Input names of the layer.

If the `HasPaddingMaskInput` property is `0` (`false`), then the layer has one input with the name `'in'`, which corresponds to the input data. In this case, the layer treats all elements as data.

If the `HasPaddingMaskInput` property is `1` (`true`), then the layer has two inputs with the names `'in'` and `'mask'`, which correspond to the input data and the mask, respectively. In this case, the padding mask is an array of ones and zeros. The layer prevents or allows attention to elements in the key-value pairs when the corresponding element in the mask is zero or one, respectively.

### NumOutputs — Number of outputs

`1 | 2`

This property is read-only.

Number of outputs of the layer.

If the `HasScoresOutput` property is `0` (`false`), then the layer has one output with the name `'out'`, which corresponds to the output data.

If the `HasScoresOutput` property is `1` (`true`), then the layer has two outputs with the names `'out'` and `'scores'`, which correspond to the output data and the attention scores, respectively.

Data Types: double

### OutputNames — Output names

`{'out'} | {'out', 'scores'}`

This property is read-only.

Output names of the layer.

If the `HasScoresOutput` property is `0` (`false`), then the layer has one output with the name `'out'`, which corresponds to the output data.

If the `HasScoresOutput` property is `1` (`true`), then the layer has two outputs with the names `'out'` and `'scores'`, which correspond to the output data and the attention scores, respectively.

## Examples

### Create Self-Attention Layer

Create a self-attention layer with eight heads and 256 key and query channels.

```
layer = selfAttentionLayer(8,256)
layer =
  SelfAttentionLayer with properties:
```

```
        Name: ''
        AttentionMask: 'none'
HasPaddingMaskInput: 0
HasScoresOutput: 0

Hyperparameters
    InputSize: 'auto'
    NumHeads: 8
    NumKeyChannels: 256
    NumValueChannels: 'auto'
    OutputSize: 'auto'
    DropoutProbability: 0

Learnable Parameters
    QueryWeights: []
    KeyWeights: []
    ValueWeights: []
    OutputWeights: []
    QueryBias: []
    KeyBias: []
    ValueBias: []
    OutputBias: []

Show all properties
```

Include a self-attention layer in a layer array.

```
layers = [
    sequenceInputLayer(12)
    selfAttentionLayer(4,12)
    layerNormalization
    fullyConnectedLayer(9)
    softmaxLayer];
```

# sequenceFoldingLayer

Sequence folding layer

## Description

A sequence folding layer converts a batch of image sequences to a batch of images. Use a sequence folding layer to perform convolution operations on time steps of image sequences independently.

To use a sequence folding layer, you must connect the `miniBatchSize` output to the `miniBatchSize` input of the corresponding sequence unfolding layer. For an example, see “Create Network for Video Classification” on page 1-1637.

## Creation

### Syntax

```
layer = sequenceFoldingLayer  
layer = sequenceFoldingLayer('Name',Name)
```

### Description

`layer = sequenceFoldingLayer` creates a sequence folding layer.

`layer = sequenceFoldingLayer('Name',Name)` creates a sequence folding layer and sets the optional `Name` property using a name-value pair. For example, `sequenceFoldingLayer('Name','fold1')` creates a sequence folding layer with the name 'fold1'. Enclose the property name in single quotes.

## Properties

### Name — Layer name

'' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ''.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

**InputNames – Input names**

```
{"in"} (default)
```

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: `cell`

**NumOutputs – Number of outputs**

```
2 (default)
```

Number of outputs of the layer.

The layer has two outputs:

- 'out' - Output feature map corresponding to reshaped input.
- 'miniBatchSize' - Size of the mini-batch passed into the layer. This output must be connected to the 'miniBatchSize' input of the corresponding sequence unfolding layer.

Data Types: `double`

**OutputNames – Output names**

```
{'out', 'miniBatchSize'} (default)
```

Output names of the layer.

The layer has two outputs:

- 'out' - Output feature map corresponding to reshaped input.
- 'miniBatchSize' - Size of the mini-batch passed into the layer. This output must be connected to the 'miniBatchSize' input of the corresponding sequence unfolding layer.

Data Types: `cell`

**Examples****Create Sequence Folding Layer**

Create a sequence folding layer with name the 'fold1'.

```
layer = sequenceFoldingLayer('Name', 'fold1')
```

```
layer =
```

```
SequenceFoldingLayer with properties:
```

```
    Name: 'fold1'
 NumOutputs: 2
 OutputNames: {'out' 'miniBatchSize'}
```

## Create Network for Video Classification

Create a deep learning network for data containing sequences of images, such as video and medical image data.

- To input sequences of images into a network, use a sequence input layer.
- To apply convolutional operations independently to each time step, first convert the sequences of images to an array of images using a sequence folding layer.
- To restore the sequence structure after performing these operations, convert this array of images back to image sequences using a sequence unfolding layer.
- To convert images to feature vectors, use a flatten layer.

You can then input vector sequences into LSTM and BiLSTM layers.

## Define Network Architecture

Create a classification LSTM network that classifies sequences of 28-by-28 grayscale images into 10 classes.

Define the following network architecture:

- A sequence input layer with an input size of [28 28 1].
- A convolution, batch normalization, and ReLU layer block with 20 5-by-5 filters.
- An LSTM layer with 200 hidden units that outputs the last time step only.
- A fully connected layer of size 10 (the number of classes) followed by a softmax layer and a classification layer.

To perform the convolutional operations on each time step independently, include a sequence folding layer before the convolutional layers. LSTM layers expect vector sequence input. To restore the sequence structure and reshape the output of the convolutional layers to sequences of feature vectors, insert a sequence unfolding layer and a flatten layer between the convolutional layers and the LSTM layer.

```
inputSize = [28 28 1];
filterSize = 5;
numFilters = 20;
numHiddenUnits = 200;
numClasses = 10;

layers = [ ...
    sequenceInputLayer(inputSize, 'Name', 'input')

    sequenceFoldingLayer('Name', 'fold')

    convolution2dLayer(filterSize, numFilters, 'Name', 'conv')
    batchNormalizationLayer('Name', 'bn')
    reluLayer('Name', 'relu')

    sequenceUnfoldingLayer('Name', 'unfold')
    flattenLayer('Name', 'flatten')

    lstmLayer(numHiddenUnits, 'OutputMode', 'last', 'Name', 'lstm')

    fullyConnectedLayer(numClasses, 'Name', 'fc')
```

```
softmaxLayer('Name','softmax')
classificationLayer('Name','classification')];
```

Convert the layers to a layer graph and connect the `miniBatchSize` output of the sequence folding layer to the corresponding input of the sequence unfolding layer.

```
lgraph = layerGraph(layers);
lgraph = connectLayers(lgraph,'fold/miniBatchSize','unfold/miniBatchSize');
```

View the final network architecture using the `plot` function.

```
figure
plot(lgraph)
```

# sequenceInputLayer

Sequence input layer

## Description

A sequence input layer inputs sequence data to a neural network.

## Creation

### Syntax

```
layer = sequenceInputLayer(inputSize)
layer = sequenceInputLayer(inputSize,Name,Value)
```

### Description

`layer = sequenceInputLayer(inputSize)` creates a sequence input layer and sets the `InputSize` property.

`layer = sequenceInputLayer(inputSize,Name,Value)` sets the optional `MinLength`, `Normalization`, `Mean`, and `Name` properties using name-value pairs. You can specify multiple name-value pairs. Enclose each property name in single quotes.

## Properties

### Sequence Input

#### InputSize — Size of input

positive integer | vector of positive integers

Size of the input, specified as a positive integer or a vector of positive integers.

- For vector sequence input, `InputSize` is a scalar corresponding to the number of features.
- For 1-D image sequence input, `InputSize` is vector of two elements `[h c]`, where `h` is the image height and `c` is the number of channels of the image.
- For 2-D image sequence input, `InputSize` is vector of three elements `[h w c]`, where `h` is the image height, `w` is the image width, and `c` is the number of channels of the image.
- For 3-D image sequence input, `InputSize` is vector of four elements `[h w d c]`, where `h` is the image height, `w` is the image width, `d` is the image depth, and `c` is the number of channels of the image.

To specify the minimum sequence length of the input data, use the `MinLength` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### MinLength — Minimum sequence length of input data

1 (default) | positive integer

Minimum sequence length of input data, specified as a positive integer. When training or making predictions with the network, if the input data has fewer than `MinLength` time steps, then the software throws an error.

When you create a network that downsamples data in the time dimension, you must take care that the network supports your training data and any data for prediction. Some deep learning layers require that the input has a minimum sequence length. For example, a 1-D convolution layer requires that the input has at least as many time steps as the filter size.

As time series of sequence data propagates through a network, the sequence length can change. For example, downsampling operations such as 1-D convolutions can output data with fewer time steps than its input. This means that downsampling operations can cause later layers in the network to throw an error because the data has a shorter sequence length than the minimum length required by the layer.

When you train or assemble a network, the software automatically checks that sequences of length 1 can propagate through the network. Some networks might not support sequences of length 1, but can successfully propagate sequences of longer lengths. To check that a network supports propagating your training and expected prediction data, set the `MinLength` property to a value less than or equal to the minimum length of your data and the expected minimum length of your prediction data.

---

**Tip** To prevent convolution and pooling layers from changing the size of the data, set the `Padding` option of the layer to "same" or "causal".

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **Normalization — Data normalization**

'none' (default) | 'zerocenter' | 'zscore' | 'rescale-symmetric' | 'rescale-zero-one' | function handle

Data normalization to apply every time data is forward propagated through the input layer, specified as one of the following:

- 'zerocenter' — Subtract the mean specified by `Mean`.
- 'zscore' — Subtract the mean specified by `Mean` and divide by `StandardDeviation`.
- 'rescale-symmetric' — Rescale the input to be in the range [-1, 1] using the minimum and maximum values specified by `Min` and `Max`, respectively.
- 'rescale-zero-one' — Rescale the input to be in the range [0, 1] using the minimum and maximum values specified by `Min` and `Max`, respectively.
- 'none' — Do not normalize the input data.
- function handle — Normalize the data using the specified function. The function must be of the form  $Y = \text{func}(X)$ , where  $X$  is the input data and the output  $Y$  is the normalized data.

---

**Tip** The software, by default, automatically calculates the normalization statistics when using the `trainNetwork` function. To save time when training, specify the required statistics for normalization and set the `ResetInputNormalization` option in `trainingOptions` to 0 (false).

---

The software applies normalization to all input elements, including padding values.

Data Types: `char` | `string` | `function_handle`

**NormalizationDimension — Normalization dimension**

'auto' (default) | 'channel' | 'element' | 'all'

Normalization dimension, specified as one of the following:

- 'auto' - If the training option is `false` and you specify any of the normalization statistics (`Mean`, `StandardDeviation`, `Min`, or `Max`), then normalize over the dimensions matching the statistics. Otherwise, recalculate the statistics at training time and apply channel-wise normalization.
- 'channel' - Channel-wise normalization.
- 'element' - Element-wise normalization.
- 'all' - Normalize all values using scalar statistics.

Data Types: `char` | `string`**Mean — Mean for zero-center and z-score normalization**

[] (default) | numeric array | numeric scalar

Mean for zero-center and z-score normalization, specified as a numeric array, or empty.

- For vector sequence input, `Mean` must be a `InputSize`-by-1 vector of means per channel, a numeric scalar, or [].
- For 2-D image sequence input, `Mean` must be a numeric array of the same size as `InputSize`, a 1-by-1-by-`InputSize(3)` array of means per channel, a numeric scalar, or [].
- For 3-D image sequence input, `Mean` must be a numeric array of the same size as `InputSize`, a 1-by-1-by-1-by-`InputSize(4)` array of means per channel, a numeric scalar, or [].

If you specify the `Mean` property, then `Normalization` must be 'zerocenter' or 'zscore'. If `Mean` is [], then the `trainNetwork` function calculates the mean and ignores padding values. To train a `dlnetwork` object using a custom training loop or assemble a network without training it using the `assembleNetwork` function, you must set the `Mean` property to a numeric scalar or a numeric array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**StandardDeviation — Standard deviation**

[] (default) | numeric array | numeric scalar

Standard deviation used for z-score normalization, specified as a numeric array, a numeric scalar, or empty.

- For vector sequence input, `StandardDeviation` must be a `InputSize`-by-1 vector of standard deviations per channel, a numeric scalar, or [].
- For 2-D image sequence input, `StandardDeviation` must be a numeric array of the same size as `InputSize`, a 1-by-1-by-`InputSize(3)` array of standard deviations per channel, a numeric scalar, or [].
- For 3-D image sequence input, `StandardDeviation` must be a numeric array of the same size as `InputSize`, a 1-by-1-by-1-by-`InputSize(4)` array of standard deviations per channel, or a numeric scalar.

If you specify the `StandardDeviation` property, then `Normalization` must be 'zscore'. If `StandardDeviation` is [], then the `trainNetwork` function calculates the mean and ignores padding values. To train a `dlnetwork` object using a custom training loop or assemble a network

without training it using the `assembleNetwork` function, you must set the `StandardDeviation` property to a numeric scalar or a numeric array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Min — Minimum value for rescaling**

`[]` (default) | numeric array | numeric scalar

Minimum value for rescaling, specified as a numeric array, or empty.

- For vector sequence input, `Min` must be a `InputSize`-by-1 vector of means per channel or a numeric scalar.
- For 2-D image sequence input, `Min` must be a numeric array of the same size as `InputSize`, a 1-by-1-by-`InputSize(3)` array of minima per channel, or a numeric scalar.
- For 3-D image sequence input, `Min` must be a numeric array of the same size as `InputSize`, a 1-by-1-by-1-by-`InputSize(4)` array of minima per channel, or a numeric scalar.

If you specify the `Min` property, then `Normalization` must be `'rescale-symmetric'` or `'rescale-zero-one'`. If `Min` is `[]`, then the `trainNetwork` function calculates the minima and ignores padding values. To train a `dlnetwork` object using a custom training loop or assemble a network without training it using the `assembleNetwork` function, you must set the `Min` property to a numeric scalar or a numeric array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Max — Maximum value for rescaling**

`[]` (default) | numeric array | numeric scalar

Maximum value for rescaling, specified as a numeric array, or empty.

- For vector sequence input, `Max` must be a `InputSize`-by-1 vector of means per channel or a numeric scalar.
- For 2-D image sequence input, `Max` must be a numeric array of the same size as `InputSize`, a 1-by-1-by-`InputSize(3)` array of maxima per channel, a numeric scalar, or `[]`.
- For 3-D image sequence input, `Max` must be a numeric array of the same size as `InputSize`, a 1-by-1-by-1-by-`InputSize(4)` array of maxima per channel, a numeric scalar, or `[]`.

If you specify the `Max` property, then `Normalization` must be `'rescale-symmetric'` or `'rescale-zero-one'`. If `Max` is `[]`, then the `trainNetwork` function calculates the maxima and ignores padding values. To train a `dlnetwork` object using a custom training loop or assemble a network without training it using the `assembleNetwork` function, you must set the `Max` property to a numeric scalar or a numeric array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **SplitComplexInputs — Flag to split input data into real and imaginary components**

`0` (`false`) (default) | `1` (`true`)

This property is read-only.

Flag to split input data into real and imaginary components specified as one of these values:

- `0` (`false`) - Do not split input data.
- `1` (`true`) - Split data into real and imaginary components.

When `SplitComplexInputs` is 1, then the layer outputs twice as many channels as the input data. For example, if the input data is complex-values with `numChannels` channels, then the layer outputs data with  $2 * \text{numChannels}$  channels, where channels 1 through `numChannels` contain the real components of the input data and `numChannels+1` through  $2 * \text{numChannels}$  contain the imaginary components of the input data. If the input data is real, then channels `numChannels+1` through  $2 * \text{numChannels}$  are all zero.

To input complex-valued data into a neural network, the `SplitComplexInputs` option of the input layer must be 1.

For an example showing how to train a network with complex-valued data, see “Train Network with Complex-Valued Data”.

## Layer

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For Layer array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

### NumInputs — Number of inputs

0 (default)

This property is read-only.

Number of inputs of the layer. The layer has no inputs.

Data Types: `double`

### InputNames — Input names

{ } (default)

This property is read-only.

Input names of the layer. The layer has no inputs.

Data Types: `cell`

### NumOutputs — Number of outputs

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: `double`

### OutputNames — Output names

{ 'out' } (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

## Examples

### Create Sequence Input Layer

Create a sequence input layer with the name 'seq1' and an input size of 12.

```
layer = sequenceInputLayer(12, 'Name', 'seq1')
```

```
layer =  
  SequenceInputLayer with properties:  
      Name: 'seq1'  
      InputSize: 12  
      MinLength: 1  
      SplitComplexInputs: 0  
  
  Hyperparameters  
      Normalization: 'none'  
      NormalizationDimension: 'auto'
```

Include a sequence input layer in a Layer array.

```
inputSize = 12;  
numHiddenUnits = 100;  
numClasses = 9;  
  
layers = [ ...  
  sequenceInputLayer(inputSize)  
  lstmLayer(numHiddenUnits, 'OutputMode', 'last')  
  fullyConnectedLayer(numClasses)  
  softmaxLayer  
  classificationLayer]
```

```
layers =  
  5x1 Layer array with layers:  
  
  1  ''  Sequence Input           Sequence input with 12 dimensions  
  2  ''  LSTM                   LSTM with 100 hidden units  
  3  ''  Fully Connected        9 fully connected layer  
  4  ''  Softmax                 softmax  
  5  ''  Classification Output   crossentropyex
```

### Create Sequence Input Layer for Image Sequences

Create a sequence input layer for sequences of 224-224 RGB images with the name 'seq1'.

```
layer = sequenceInputLayer([224 224 3], 'Name', 'seq1')
```

```
layer =  
  SequenceInputLayer with properties:
```

```
        Name: 'seq1'  
        InputSize: [224 224 3]  
        MinLength: 1  
        SplitComplexInputs: 0  
  
Hyperparameters  
    Normalization: 'none'  
    NormalizationDimension: 'auto'
```

## Train Network for Sequence Classification

Train a deep learning LSTM network for sequence-to-label classification.

Load the Japanese Vowels data set as described in [1] and [2]. `XTrain` is a cell array containing 270 sequences of varying length with 12 features corresponding to LPC cepstrum coefficients. `Y` is a categorical vector of labels 1,2,...,9. The entries in `XTrain` are matrices with 12 rows (one row for each feature) and a varying number of columns (one column for each time step).

```
[XTrain,YTrain] = japaneseVowelsTrainData;
```

Visualize the first time series in a plot. Each line corresponds to a feature.

```
figure  
plot(XTrain{1})  
title("Training Observation 1")  
numFeatures = size(XTrain{1},1);  
legend("Feature " + string(1:numFeatures), 'Location', 'northeastoutside')
```

Define the LSTM network architecture. Specify the input size as 12 (the number of features of the input data). Specify an LSTM layer to have 100 hidden units and to output the last element of the sequence. Finally, specify nine classes by including a fully connected layer of size 9, followed by a softmax layer and a classification layer.

```
inputSize = 12;
numHiddenUnits = 100;
numClasses = 9;

layers = [ ...
    sequenceInputLayer(inputSize)
    lstmLayer(numHiddenUnits, 'OutputMode', 'last')
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer]
```

```
layers =
    5x1 Layer array with layers:
```

1	''	Sequence Input	Sequence input with 12 dimensions
2	''	LSTM	LSTM with 100 hidden units
3	''	Fully Connected	9 fully connected layer
4	''	Softmax	softmax
5	''	Classification Output	crossentropyex

Specify the training options. Specify the solver as 'adam' and 'GradientThreshold' as 1. Set the mini-batch size to 27 and set the maximum number of epochs to 70.

Because the mini-batches are small with short sequences, the CPU is better suited for training. Set 'ExecutionEnvironment' to 'cpu'. To train on a GPU, if available, set 'ExecutionEnvironment' to 'auto' (the default value).

```
maxEpochs = 70;
miniBatchSize = 27;

options = trainingOptions('adam', ...
    'ExecutionEnvironment','cpu', ...
    'MaxEpochs',maxEpochs, ...
    'MiniBatchSize',miniBatchSize, ...
    'GradientThreshold',1, ...
    'Verbose',false, ...
    'Plots','training-progress');
```

Train the LSTM network with the specified training options.

```
net = trainNetwork(XTrain,YTrain,layers,options);
```

Load the test set and classify the sequences into speakers.

```
[XTest,YTest] = japaneseVowelsTestData;
```

Classify the test data. Specify the same mini-batch size used for training.

```
YPred = classify(net,XTest,'MiniBatchSize',miniBatchSize);
```

Calculate the classification accuracy of the predictions.

```
acc = sum(YPred == YTest)./numel(YTest)
```

```
acc = 0.9432
```

### **Classification LSTM Networks**

To create an LSTM network for sequence-to-label classification, create a layer array containing a sequence input layer, an LSTM layer, a fully connected layer, a softmax layer, and a classification output layer.

Set the size of the sequence input layer to the number of features of the input data. Set the size of the fully connected layer to the number of classes. You do not need to specify the sequence length.

For the LSTM layer, specify the number of hidden units and the output mode 'last'.

```
numFeatures = 12;  
numHiddenUnits = 100;  
numClasses = 9;  
layers = [ ...  
    sequenceInputLayer(numFeatures)  
    lstmLayer(numHiddenUnits,'OutputMode','last')  
    fullyConnectedLayer(numClasses)  
    softmaxLayer  
    classificationLayer];
```

For an example showing how to train an LSTM network for sequence-to-label classification and classify new data, see “Sequence Classification Using Deep Learning”.

To create an LSTM network for sequence-to-sequence classification, use the same architecture as for sequence-to-label classification, but set the output mode of the LSTM layer to 'sequence'.

```
numFeatures = 12;  
numHiddenUnits = 100;  
numClasses = 9;  
layers = [ ...  
    sequenceInputLayer(numFeatures)  
    lstmLayer(numHiddenUnits,'OutputMode','sequence')  
    fullyConnectedLayer(numClasses)  
    softmaxLayer  
    classificationLayer];
```

### **Regression LSTM Networks**

To create an LSTM network for sequence-to-one regression, create a layer array containing a sequence input layer, an LSTM layer, a fully connected layer, and a regression output layer.

Set the size of the sequence input layer to the number of features of the input data. Set the size of the fully connected layer to the number of responses. You do not need to specify the sequence length.

For the LSTM layer, specify the number of hidden units and the output mode 'last'.

```
numFeatures = 12;
numHiddenUnits = 125;
numResponses = 1;

layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits, 'OutputMode', 'last')
    fullyConnectedLayer(numResponses)
    regressionLayer];
```

To create an LSTM network for sequence-to-sequence regression, use the same architecture as for sequence-to-one regression, but set the output mode of the LSTM layer to 'sequence'.

```
numFeatures = 12;
numHiddenUnits = 125;
numResponses = 1;

layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits, 'OutputMode', 'sequence')
    fullyConnectedLayer(numResponses)
    regressionLayer];
```

For an example showing how to train an LSTM network for sequence-to-sequence regression and predict on new data, see “Sequence-to-Sequence Regression Using Deep Learning”.

## Deeper LSTM Networks

You can make LSTM networks deeper by inserting extra LSTM layers with the output mode 'sequence' before the LSTM layer. To prevent overfitting, you can insert dropout layers after the LSTM layers.

For sequence-to-label classification networks, the output mode of the last LSTM layer must be 'last'.

```
numFeatures = 12;
numHiddenUnits1 = 125;
numHiddenUnits2 = 100;
numClasses = 9;
layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits1, 'OutputMode', 'sequence')
    dropoutLayer(0.2)
    lstmLayer(numHiddenUnits2, 'OutputMode', 'last')
    dropoutLayer(0.2)
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

For sequence-to-sequence classification networks, the output mode of the last LSTM layer must be 'sequence'.

```
numFeatures = 12;
numHiddenUnits1 = 125;
numHiddenUnits2 = 100;
```

```
numClasses = 9;
layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits1, 'OutputMode', 'sequence')
    dropoutLayer(0.2)
    lstmLayer(numHiddenUnits2, 'OutputMode', 'sequence')
    dropoutLayer(0.2)
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

### Create Network for Video Classification

Create a deep learning network for data containing sequences of images, such as video and medical image data.

- To input sequences of images into a network, use a sequence input layer.
- To apply convolutional operations independently to each time step, first convert the sequences of images to an array of images using a sequence folding layer.
- To restore the sequence structure after performing these operations, convert this array of images back to image sequences using a sequence unfolding layer.
- To convert images to feature vectors, use a flatten layer.

You can then input vector sequences into LSTM and BiLSTM layers.

### Define Network Architecture

Create a classification LSTM network that classifies sequences of 28-by-28 grayscale images into 10 classes.

Define the following network architecture:

- A sequence input layer with an input size of [28 28 1].
- A convolution, batch normalization, and ReLU layer block with 20 5-by-5 filters.
- An LSTM layer with 200 hidden units that outputs the last time step only.
- A fully connected layer of size 10 (the number of classes) followed by a softmax layer and a classification layer.

To perform the convolutional operations on each time step independently, include a sequence folding layer before the convolutional layers. LSTM layers expect vector sequence input. To restore the sequence structure and reshape the output of the convolutional layers to sequences of feature vectors, insert a sequence unfolding layer and a flatten layer between the convolutional layers and the LSTM layer.

```
inputSize = [28 28 1];
filterSize = 5;
numFilters = 20;
numHiddenUnits = 200;
numClasses = 10;

layers = [ ...
```

```
sequenceInputLayer(inputSize, 'Name', 'input')

sequenceFoldingLayer('Name', 'fold')

convolution2dLayer(filterSize, numFilters, 'Name', 'conv')
batchNormalizationLayer('Name', 'bn')
reluLayer('Name', 'relu')

sequenceUnfoldingLayer('Name', 'unfold')
flattenLayer('Name', 'flatten')

lstmLayer(numHiddenUnits, 'OutputMode', 'last', 'Name', 'lstm')

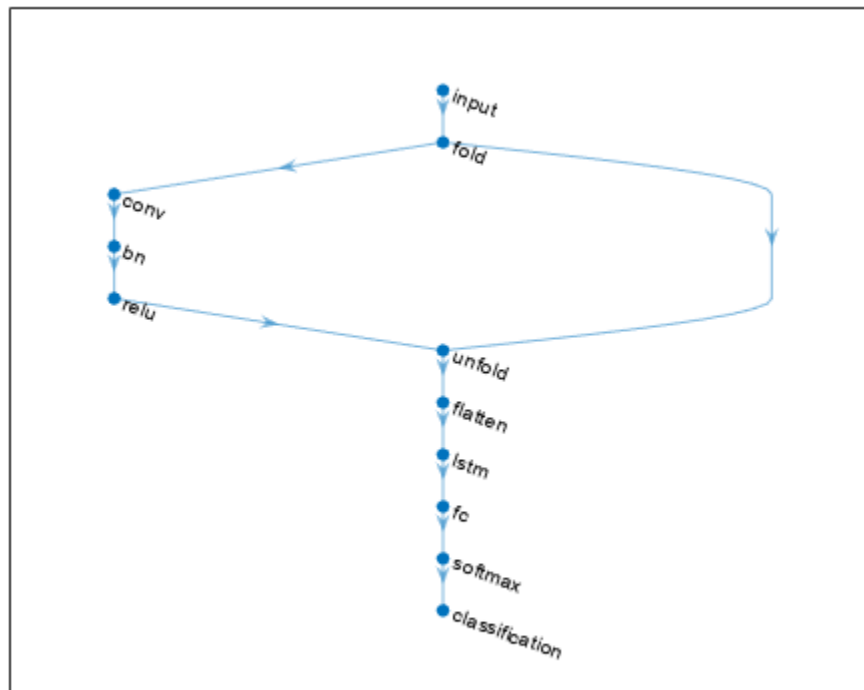

fullyConnectedLayer(numClasses, 'Name', 'fc')
softmaxLayer('Name', 'softmax')
classificationLayer('Name', 'classification')];
```

Convert the layers to a layer graph and connect the `miniBatchSize` output of the sequence folding layer to the corresponding input of the sequence unfolding layer.

```
lgraph = layerGraph(layers);
lgraph = connectLayers(lgraph, 'fold/miniBatchSize', 'unfold/miniBatchSize');
```

View the final network architecture using the `plot` function.

```
figure
plot(lgraph)
```

## Version History

Introduced in R2017b

### **R2019b: sequenceInputLayer, by default, uses channel-wise normalization for zero-center normalization**

*Behavior change in future release*

Starting in R2019b, `sequenceInputLayer`, by default, uses channel-wise normalization for zero-center normalization. In previous versions, this layer uses element-wise normalization. To reproduce this behavior, set the `NormalizationDimension` option of this layer to 'element'.

### **R2020a: trainNetwork ignores padding values when calculating normalization statistics**

*Behavior changed in R2020a*

Starting in R2020a, `trainNetwork` ignores padding values when calculating normalization statistics. This means that the `Normalization` option in the `sequenceInputLayer` now makes training invariant to data operations, for example, 'zerocenter' normalization now implies that the training results are invariant to the mean of the data.

If you train on padded sequences, then the calculated normalization factors may be different in earlier versions and can produce different results.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

- For vector sequence inputs, the number of features must be a constant during code generation.
- For code generation, the input data must contain either zero or two spatial dimensions.
- Code generation does not support 'Normalization' specified using a function handle.
- Code generation does not support complex input and does not support 'SplitComplexInputs' option.

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

To generate CUDA or C++ code by using GPU Coder, you must first construct and train a deep neural network. Once the network is trained and evaluated, you can configure the code generator to generate code and deploy the convolutional neural network on platforms that use NVIDIA or ARM GPU processors. For more information, see “Deep Learning with GPU Coder” (GPU Coder).

For this layer, you can generate code that takes advantage of the NVIDIA CUDA deep neural network library (cuDNN), or the NVIDIA TensorRT high performance inference library.

- The cuDNN library supports vector and 2-D image sequences. The TensorRT library support only vector input sequences.
- For vector sequence inputs, the number of features must be a constant during code generation.
- For image sequence inputs, the height, width, and the number of channels must be a constant during code generation.
- Code generation does not support 'Normalization' specified using a function handle.
- Code generation does not support complex input and does not support 'SplitComplexInputs' option.

# sequenceUnfoldingLayer

Sequence unfolding layer

## Description

A sequence unfolding layer restores the sequence structure of the input data after sequence folding.

To use a sequence unfolding layer, you must connect the `miniBatchSize` output of the corresponding sequence folding layer to the `miniBatchSize` input of the sequence unfolding layer. For an example, see “Create Network for Video Classification” on page 1-1658.

## Creation

### Syntax

```
layer = sequenceUnfoldingLayer
layer = sequenceUnfoldingLayer('Name',Name)
```

### Description

`layer = sequenceUnfoldingLayer` creates a sequence unfolding layer.

`layer = sequenceUnfoldingLayer('Name',Name)` creates a sequence unfolding layer and sets the optional `Name` property using a name-value pair. For example, `sequenceUnfoldingLayer('Name','unfold1')` creates a sequence unfolding layer with the name `'unfold1'`. Enclose the property name in single quotes.

## Properties

### Name — Layer name

`''` (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name `''`.

Data Types: `char` | `string`

### NumInputs — Number of inputs

2 (default)

Number of inputs of the layer.

This layer has two inputs:

- `'in'` - Input feature map.

- 'miniBatchSize' - Size of the mini-batch from the corresponding sequence folding layer. This output must be connected to the 'miniBatchSize' output of the corresponding sequence folding layer.

Data Types: double

**InputNames — Input names**

{'in', 'miniBatchSize'} (default)

Input names of the layer.

This layer has two inputs:

- 'in' - Input feature map.
- 'miniBatchSize' - Size of the mini-batch from the corresponding sequence folding layer. This output must be connected to the 'miniBatchSize' output of the corresponding sequence folding layer.

Data Types: cell

**NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: double

**OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

## Examples

**Create Sequence Unfolding Layer**

Create a sequence unfolding layer with the name 'unfold1'.

```
layer = sequenceUnfoldingLayer('Name', 'unfold1')
```

```
layer =  
    SequenceUnfoldingLayer with properties:  
        Name: 'unfold1'  
        NumInputs: 2  
        InputNames: {'in' 'miniBatchSize'}
```

## Create Network for Video Classification

Create a deep learning network for data containing sequences of images, such as video and medical image data.

- To input sequences of images into a network, use a sequence input layer.
- To apply convolutional operations independently to each time step, first convert the sequences of images to an array of images using a sequence folding layer.
- To restore the sequence structure after performing these operations, convert this array of images back to image sequences using a sequence unfolding layer.
- To convert images to feature vectors, use a flatten layer.

You can then input vector sequences into LSTM and BiLSTM layers.

## Define Network Architecture

Create a classification LSTM network that classifies sequences of 28-by-28 grayscale images into 10 classes.

Define the following network architecture:

- A sequence input layer with an input size of [28 28 1].
- A convolution, batch normalization, and ReLU layer block with 20 5-by-5 filters.
- An LSTM layer with 200 hidden units that outputs the last time step only.
- A fully connected layer of size 10 (the number of classes) followed by a softmax layer and a classification layer.

To perform the convolutional operations on each time step independently, include a sequence folding layer before the convolutional layers. LSTM layers expect vector sequence input. To restore the sequence structure and reshape the output of the convolutional layers to sequences of feature vectors, insert a sequence unfolding layer and a flatten layer between the convolutional layers and the LSTM layer.

```
inputSize = [28 28 1];
filterSize = 5;
numFilters = 20;
numHiddenUnits = 200;
numClasses = 10;

layers = [ ...
    sequenceInputLayer(inputSize, 'Name', 'input')

    sequenceFoldingLayer('Name', 'fold')

    convolution2dLayer(filterSize, numFilters, 'Name', 'conv')
    batchNormalizationLayer('Name', 'bn')
    reluLayer('Name', 'relu')

    sequenceUnfoldingLayer('Name', 'unfold')
    flattenLayer('Name', 'flatten')

    lstmLayer(numHiddenUnits, 'OutputMode', 'last', 'Name', 'lstm')

    fullyConnectedLayer(numClasses, 'Name', 'fc')
```

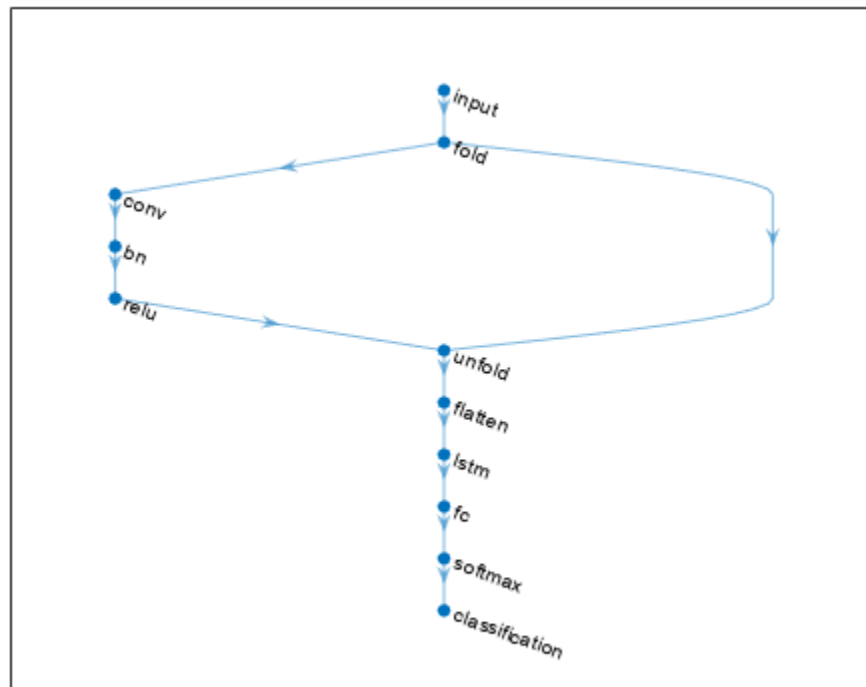

```
softmaxLayer('Name','softmax')  
classificationLayer('Name','classification')];
```

Convert the layers to a layer graph and connect the `miniBatchSize` output of the sequence folding layer to the corresponding input of the sequence unfolding layer.

```
lgraph = layerGraph(layers);  
lgraph = connectLayers(lgraph,'fold/miniBatchSize','unfold/miniBatchSize');
```

View the final network architecture using the `plot` function.

```
figure  
plot(lgraph)
```

# SeriesNetwork

Series network for deep learning

## Description

A series network is a neural network for deep learning with layers arranged one after the other. It has a single input layer and a single output layer.

## Creation

There are several ways to create a `SeriesNetwork` object:

- Load a pretrained network using `alexnet`, `darknet19`, `vgg16`, or `vgg19`. For an example, see “Load Pretrained AlexNet Convolutional Neural Network” on page 1-1663.
- Train or fine-tune a network using `trainNetwork`. For an example, see “Train Network for Image Classification” on page 1-1664.
- Import a pretrained network from TensorFlow-Keras, Caffe, or the ONNX (Open Neural Network Exchange) model format.
  - For a Keras model, use `importKerasNetwork`. For an example, see “Import and Plot Keras Network” on page 1-983.
  - For a Caffe model, use `importCaffeNetwork`. For an example, see “Import Caffe Network” on page 1-960.
  - For an ONNX model, use `importONNXNetwork`. For an example, see “Import ONNX Network as DAGNetwork” on page 1-1061.
- Assemble a deep learning network from pretrained layers using the `assembleNetwork` function.

---

**Note** To learn about other pretrained networks, such as `googlenet` and `resnet50`, see “Pretrained Deep Neural Networks”.

---

## Properties

### Layers — Network layers

Layer array

This property is read-only.

Network layers, specified as a Layer array.

### InputNames — Network input layer names

cell array of character vectors

This property is read-only.

Network input layer names, specified as a cell array of character vectors.

Data Types: cell

### OutputNames — Network output layer names

cell array

Network output layer names, specified as a cell array of character vectors.

Data Types: cell

## Object Functions

activations	Compute deep learning network layer activations
classify	Classify data using trained deep learning neural network
predict	Predict responses using trained deep learning neural network
predictAndUpdateState	Predict responses using a trained recurrent neural network and update the network state
classifyAndUpdateState	Classify data using a trained recurrent neural network and update the network state
resetState	Reset state parameters of neural network
plot	Plot neural network architecture

## Examples

### Load Pretrained AlexNet Convolutional Neural Network

Load a pretrained AlexNet convolutional neural network and examine the layers and classes.

Load the pretrained AlexNet network using `alexnet`. The output `net` is a `SeriesNetwork` object.

```
net = alexnet
```

```
net =
  SeriesNetwork with properties:
    Layers: [25x1 nnet.cnn.layer.Layer]
```

Using the `Layers` property, view the network architecture. The network comprises of 25 layers. There are 8 layers with learnable weights: 5 convolutional layers, and 3 fully connected layers.

```
net.Layers
```

```
ans =
  25x1 Layer array with layers:

   1 'data'      Image Input          227x227x3 images with 'zerocenter' normalizati

```

You can view the names of the classes learned by the network by viewing the `Classes` property of the classification output layer (the final layer). View the first 10 classes by selecting the first 10 elements.

```
net.Layers(end).Classes(1:10)
```

```
ans = 10x1 categorical array
    tench
  goldfish
 great white shark
  tiger shark
 hammerhead
 electric ray
  stingray
    cock
    hen
  ostrich
```

## Import Layers from Caffe Network

Specify the example file `'digitsnet.prototxt'` to import.

```
protofile = 'digitsnet.prototxt';
```

Import the network layers.

```
layers = importCaffeLayers(protofile)
```

```
layers =
    1x7 Layer array with layers:
     1 'testdata' Image Input      28x28x1 images
     2 'conv1'    Convolution   20 5x5x1 convolutions with stride [1 1] and padding [0 0]
     3 'relu1'    ReLU          ReLU
     4 'pool1'    Max Pooling   2x2 max pooling with stride [2 2] and padding [0 0]
     5 'ip1'      Fully Connected 10 fully connected layer
     6 'loss'     Softmax       softmax
     7 'output'   Classification Output crossentropyex with 'class1', 'class2', and 8 other classes
```

## Train Network for Image Classification

Load the data as an ImageDatastore object.

```
digitDatasetPath = fullfile(matlabroot,'toolbox','nnet', ...
    'nndemos','nndatasets','DigitDataset');
imds = imageDatastore(digitDatasetPath, ...
    'IncludeSubfolders',true, ...
    'LabelSource','foldernames');
```

The datastore contains 10,000 synthetic images of digits from 0 to 9. The images are generated by applying random transformations to digit images created with different fonts. Each digit image is 28-by-28 pixels. The datastore contains an equal number of images per category.

Display some of the images in the datastore.

```
figure
numImages = 10000;
perm = randperm(numImages,20);
for i = 1:20
    subplot(4,5,i);
    imshow(imds.Files{perm(i)});
    drawnow;
end
```

Divide the datastore so that each category in the training set has 750 images and the testing set has the remaining images from each label.

```
numTrainingFiles = 750;
[imdsTrain,imdsTest] = splitEachLabel(imds,numTrainingFiles,'randomize');
```

`splitEachLabel` splits the image files in `digitData` into two new datastores, `imdsTrain` and `imdsTest`.

Define the convolutional neural network architecture.

```
layers = [ ...
    imageInputLayer([28 28 1])
    convolution2dLayer(5,20)
    reluLayer
    maxPooling2dLayer(2,'Stride',2)
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer];
```

Set the options to the default settings for the stochastic gradient descent with momentum. Set the maximum number of epochs at 20, and start the training with an initial learning rate of 0.0001.

```
options = trainingOptions('sgdm', ...
    'MaxEpochs',20,...
    'InitialLearnRate',1e-4, ...
    'Verbose',false, ...
    'Plots','training-progress');
```

Train the network.

```
net = trainNetwork(imdsTrain,layers,options);
```

Run the trained network on the test set, which was not used to train the network, and predict the image labels (digits).

```
YPred = classify(net, imdsTest);
YTest = imdsTest.Labels;
```

Calculate the accuracy. The accuracy is the ratio of the number of true labels in the test data matching the classifications from `classify` to the number of images in the test data.

```
accuracy = sum(YPred == YTest)/numel(YTest)
accuracy = 0.9416
```

## Version History

# setL2Factor

**Package:** `nnet.cnn.layer`

Set L2 regularization factor of layer learnable parameter

## Syntax

```
layerUpdated = setL2Factor(layer, parameterName, factor)
layerUpdated = setL2Factor(layer, parameterPath, factor)

netUpdated = setL2Factor(net, layerName, parameterName, factor)
netUpdated = setL2Factor(net, parameterPath, factor)
```

## Description

`layerUpdated = setL2Factor(layer, parameterName, factor)` sets the L2 regularization factor of the parameter with the name `parameterName` in `layer` to `factor`.

For built-in layers, you can set the L2 regularization factor directly by using the corresponding property. For example, for a `convolution2dLayer` layer, the syntax `layer = setL2Factor(layer, 'Weights', factor)` is equivalent to `layer.WeightL2Factor = factor`.

`layerUpdated = setL2Factor(layer, parameterPath, factor)` sets the L2 regularization factor of the parameter specified by the path `parameterPath`. Use this syntax when the parameter is in a `dlnetwork` object in a custom layer.

`netUpdated = setL2Factor(net, layerName, parameterName, factor)` sets the L2 regularization factor of the parameter with the name `parameterName` in the layer with name `layerName` for the specified `dlnetwork` object.

`netUpdated = setL2Factor(net, parameterPath, factor)` sets the L2 regularization factor of the parameter specified by the path `parameterPath`. Use this syntax when the parameter is in a nested layer.

## Examples

### Set and Get L2 Regularization Factor of Learnable Parameter

Set and get the L2 regularization factor of a learnable parameter of a layer.

Create a layer array containing the custom layer `preluLayer`, attached to this is example as a supporting file. To access this layer, open this example as a live script.

Create a layer array including a custom layer `preluLayer`.

```
layers = [ ...
    imageInputLayer([28 28 1])
    convolution2dLayer(5,20)
    batchNormalizationLayer
```

```
preluLayer
fullyConnectedLayer(10)
softmaxLayer
classificationLayer];
```

Set the L2 regularization factor of the Alpha learnable parameter of the preluLayer to 2.

```
layers(4) = setL2Factor(layers(4), "Alpha", 2);
```

View the updated L2 regularization factor.

```
factor = getL2Factor(layers(4), "Alpha")
```

```
factor = 2
```

### Set and Get L2 Regularization Factor of Nested Layer Learnable Parameter

Set and get the L2 regularization factor of a learnable parameter of a nested layer.

Create a residual block layer using the custom layer residualBlockLayer attached to this example as a supporting file. To access this file, open this example as a Live Script.

```
numFilters = 64;
layer = residualBlockLayer(numFilters)
```

```
layer =
  residualBlockLayer with properties:
```

```
    Name: ''
```

```
    Learnable Parameters
      Network: [1x1 dlnetwork]
```

```
    State Parameters
      Network: [1x1 dlnetwork]
```

```
Show all properties
```

View the layers of the nested network.

```
layer.Network.Layers
```

```
ans =
  7x1 Layer array with layers:
```

1	'conv_1'	2-D Convolution	64 3x3 convolutions with stride [1 1] and padding
2	'batchnorm_1'	Batch Normalization	Batch normalization
3	'relu_1'	ReLU	ReLU
4	'conv_2'	2-D Convolution	64 3x3 convolutions with stride [1 1] and padding
5	'batchnorm_2'	Batch Normalization	Batch normalization
6	'add'	Addition	Element-wise addition of 2 inputs
7	'relu_2'	ReLU	ReLU

Set the L2 regularization factor of the learnable parameter 'Weights' of the layer 'conv\_1' to 2 using the setL2Factor function.

```
factor = 2;
layer = setL2Factor(layer, 'Network/conv_1/Weights', factor);
```

Get the updated L2 regularization factor using the `getL2Factor` function.

```
factor = getL2Factor(layer, 'Network/conv_1/Weights')
factor = 2
```

### Set and Get L2 Regularization Factor of `dlnetwork` Learnable Parameter

Set and get the L2 regularization factor of a learnable parameter of a `dlnetwork` object.

Create a `dlnetwork` object.

```
layers = [
    imageInputLayer([28 28 1], 'Normalization', 'none', 'Name', 'in')
    convolution2dLayer(5, 20, 'Name', 'conv')
    batchNormalizationLayer('Name', 'bn')
    reluLayer('Name', 'relu')
    fullyConnectedLayer(10, 'Name', 'fc')
    softmaxLayer('Name', 'sm')];
```

```
lgraph = layerGraph(layers);
```

```
dlnet = dlnetwork(lgraph);
```

Set the L2 regularization factor of the 'Weights' learnable parameter of the convolution layer to 2 using the `setL2Factor` function.

```
factor = 2;
dlnet = setL2Factor(dlnet, 'conv', 'Weights', factor);
```

Get the updated L2 regularization factor using the `getL2Factor` function.

```
factor = getL2Factor(dlnet, 'conv', 'Weights')
factor = 2
```

### Set and Get L2 Regularization Factor of Nested `dlnetwork` Learnable Parameter

Set and get the L2 regularization factor of a learnable parameter of a nested layer in a `dlnetwork` object.

Create a `dlnetwork` object containing the custom layer `residualBlockLayer` attached to this example as a supporting file. To access this file, open this example as a Live Script.

```
inputSize = [224 224 3];
numFilters = 32;
numClasses = 5;

layers = [
    imageInputLayer(inputSize, 'Normalization', 'none', 'Name', 'in')
```

```

convolution2dLayer(7,numFilters,'Stride',2,'Padding','same','Name','conv')
groupNormalizationLayer('all-channels','Name','gn')
reluLayer('Name','relu')
maxPooling2dLayer(3,'Stride',2,'Name','max')
residualBlockLayer(numFilters,'Name','res1')
residualBlockLayer(numFilters,'Name','res2')
residualBlockLayer(2*numFilters,'Stride',2,'IncludeSkipConvolution',true,'Name','res3')
residualBlockLayer(2*numFilters,'Name','res4')
residualBlockLayer(4*numFilters,'Stride',2,'IncludeSkipConvolution',true,'Name','res5')
residualBlockLayer(4*numFilters,'Name','res6')
globalAveragePooling2dLayer('Name','gap')
fullyConnectedLayer(numClasses,'Name','fc')
softmaxLayer('Name','sm')];

```

```
dlnet = dlnetwork(layers);
```

The `Learnables` property of the `dlnetwork` object is a table that contains the learnable parameters of the network. The table includes parameters of nested layers in separate rows. View the learnable parameters of the layer "res1".

```

learnables = dlnet.Learnables;
idx = learnables.Layer == "res1";
learnables(idx,:)

```

ans=8×3 table

Layer	Parameter	Value
"res1"	"Network/conv_1/Weights"	{3x3x32x32 dlarray}
"res1"	"Network/conv_1/Bias"	{1x1x32 dlarray}
"res1"	"Network/batchnorm_1/Offset"	{1x1x32 dlarray}
"res1"	"Network/batchnorm_1/Scale"	{1x1x32 dlarray}
"res1"	"Network/conv_2/Weights"	{3x3x32x32 dlarray}
"res1"	"Network/conv_2/Bias"	{1x1x32 dlarray}
"res1"	"Network/batchnorm_2/Offset"	{1x1x32 dlarray}
"res1"	"Network/batchnorm_2/Scale"	{1x1x32 dlarray}

For the layer "res1", set the L2 regularization factor of the learnable parameter 'Weights' of the layer 'conv\_1' to 2 using the `setL2Factor` function.

```

factor = 2;
dlnet = setL2Factor(dlnet,'res1/Network/conv_1/Weights',factor);

```

Get the updated L2 regularization factor using the `getL2Factor` function.

```

factor = getL2Factor(dlnet,'res1/Network/conv_1/Weights')
factor = 2

```

## Input Arguments

### layer — Input layer

scalar Layer object

Input layer, specified as a scalar Layer object.

**parameterName — Parameter name**

character vector | string scalar

Parameter name, specified as a character vector or a string scalar.

**factor — L2 regularization factor**

nonnegative scalar

L2 regularization factor for the parameter, specified as a nonnegative scalar.

The software multiplies this factor with the global L2 regularization factor to determine the L2 regularization factor for the specified parameter. For example, if `factor` is 2, then the L2 regularization for the specified parameter is twice the global L2 regularization factor. You can specify the global L2 regularization factor using the `trainingOptions` function.

Example: 2

**parameterPath — Path to parameter in nested layer**

string scalar | character vector

Path to parameter in nested layer, specified as a string scalar or a character vector. A nested layer is a custom layer that itself defines a layer graph as a learnable parameter.

If the input to `setL2Factor` is a nested layer, then the parameter path has the form "propertyName/layerName/parameterName", where:

- `propertyName` is the name of the property containing a `dlnetwork` object
- `layerName` is the name of the layer in the `dlnetwork` object
- `parameterName` is the name of the parameter

If there are multiple levels of nested layers, then specify each level using the form "propertyName1/layerName1/.../propertyNameN/layerNameN/parameterName", where `propertyName1` and `layerName1` correspond to the layer in the input to the `setL2Factor` function, and the subsequent parts correspond to the deeper levels.

Example: For layer input to `setL2Factor`, the path "Network/conv1/Weights" specifies the "Weights" parameter of the layer with name "conv1" in the `dlnetwork` object given by `layer.Network`.

If the input to `setL2Factor` is a `dlnetwork` object and the desired parameter is in a nested layer, then the parameter path has the form "layerName1/propertyName/layerName/parameterName", where:

- `layerName1` is the name of the layer in the input `dlnetwork` object
- `propertyName` is the property of the layer containing a `dlnetwork` object
- `layerName` is the name of the layer in the `dlnetwork` object
- `parameterName` is the name of the parameter

If there are multiple levels of nested layers, then specify each level using the form "layerName1/propertyName1/.../layerNameN/propertyNameN/layerName/parameterName", where `layerName1` and `propertyName1` correspond to the layer in the input to the `setL2Factor` function, and the subsequent parts correspond to the deeper levels.

Example: For `dlnetwork` input to `setL2Factor`, the path `"res1/Network/conv1/Weights"` specifies the `"Weights"` parameter of the layer with name `"conv1"` in the `dlnetwork` object given by `layer.Network`, where `layer` is the layer with name `"res1"` in the input network `net`.

Data Types: `char` | `string`

**net — Neural network**

`dlnetwork` object

Neural network, specified as a `dlnetwork` object.

**layerName — Layer name**

`string scalar` | `character vector`

Layer name, specified as a `string scalar` or a `character vector`.

Data Types: `char` | `string`

**Output Arguments****layerUpdated — Updated layer**

`Layer` object

Updated layer, returned as a `Layer`.

**netUpdated — Updated network**

`dlnetwork` object

Updated network, returned as a `dlnetwork`.

# setLearnRateFactor

**Package:** `nnet.cnn.layer`

Set learn rate factor of layer learnable parameter

## Syntax

```
layerUpdated = setLearnRateFactor(layer, parameterName, factor)
layerUpdated = setLearnRateFactor(layer, parameterPath, factor)

netUpdated = setLearnRateFactor(net, layerName, parameterName, factor)
netUpdated = setLearnRateFactor(net, parameterPath, factor)
```

## Description

`layerUpdated = setLearnRateFactor(layer, parameterName, factor)` sets the learn rate factor of the parameter with the name `parameterName` in `layer` to `factor`.

For built-in layers, you can set the learn rate factor directly by using the corresponding property. For example, for a `convolution2dLayer` layer, the syntax `layer = setLearnRateFactor(layer, 'Weights', factor)` is equivalent to `layer.WeightLearnRateFactor = factor`.

`layerUpdated = setLearnRateFactor(layer, parameterPath, factor)` sets the learn rate factor of the parameter specified by the path `parameterPath`. Use this syntax when the parameter is in a `dlnetwork` object in a custom layer.

`netUpdated = setLearnRateFactor(net, layerName, parameterName, factor)` sets the learn rate factor of the parameter with the name `parameterName` in the layer with name `layerName` for the specified `dlnetwork` object.

`netUpdated = setLearnRateFactor(net, parameterPath, factor)` sets the learn rate factor of the parameter specified by the path `parameterPath`. Use this syntax when the parameter is in a nested layer.

## Examples

### Set and Get Learning Rate Factor of Learnable Parameter

Set and get the learning rate factor of a learnable parameter of a custom PReLU layer.

Create a layer array containing the custom layer `preluLayer`, attached to this is example as a supporting file. To access this layer, open this example as a live script.

```
layers = [ ...
    imageInputLayer([28 28 1])
    convolution2dLayer(5,20)
    batchNormalizationLayer
    preluLayer
```

```
fullyConnectedLayer(10)
softmaxLayer
classificationLayer];
```

Set the learn rate factor of the Alpha learnable parameter of the preLU layer to 2.

```
layers(4) = setLearnRateFactor(layers(4), "Alpha", 2);
```

View the updated learn rate factor.

```
factor = getLearnRateFactor(layers(4), "Alpha")
```

```
factor = 2
```

### Set and Get Learning Rate Factor of Nested Layer Learnable Parameter

Set and get the learning rate factor of a learnable parameter of a nested layer.

Create a residual block layer using the custom layer `residualBlockLayer` attached to this example as a supporting file. To access this file, open this example as a Live Script.

```
numFilters = 64;
layer = residualBlockLayer(numFilters)
```

```
layer =
  residualBlockLayer with properties:
```

```
    Name: ''
```

```
  Learnable Parameters
    Network: [1x1 dlnetwork]
```

```
  State Parameters
    Network: [1x1 dlnetwork]
```

```
  Show all properties
```

View the layers of the nested network.

```
layer.Network.Layers
```

```
ans =
  7x1 Layer array with layers:
```

1	'conv_1'	2-D Convolution	64 3x3 convolutions with stride [1 1] and padding
2	'batchnorm_1'	Batch Normalization	Batch normalization
3	'relu_1'	ReLU	ReLU
4	'conv_2'	2-D Convolution	64 3x3 convolutions with stride [1 1] and padding
5	'batchnorm_2'	Batch Normalization	Batch normalization
6	'add'	Addition	Element-wise addition of 2 inputs
7	'relu_2'	ReLU	ReLU

Set the learning rate factor of the learnable parameter 'Weights' of the layer 'conv\_1' to 2 using the `setLearnRateFactor` function.

```
factor = 2;
layer = setLearnRateFactor(layer, 'Network/conv_1/Weights', factor);
```

Get the updated learning rate factor using the `getLearnRateFactor` function.

```
factor = getLearnRateFactor(layer, 'Network/conv_1/Weights')
factor = 2
```

### Set and Get Learn Rate Factor of dlnetwork Learnable Parameter

Set and get the learning rate factor of a learnable parameter of a `dlnetwork` object.

Create a `dlnetwork` object.

```
layers = [
    imageInputLayer([28 28 1], 'Normalization', 'none', 'Name', 'in')
    convolution2dLayer(5, 20, 'Name', 'conv')
    batchNormalizationLayer('Name', 'bn')
    reluLayer('Name', 'relu')
    fullyConnectedLayer(10, 'Name', 'fc')
    softmaxLayer('Name', 'sm')];
```

```
lgraph = layerGraph(layers);
```

```
dlnet = dlnetwork(lgraph);
```

Set the learn rate factor of the 'Weights' learnable parameter of the convolution layer to 2 using the `setLearnRateFactor` function.

```
factor = 2;
dlnet = setLearnRateFactor(dlnet, 'conv', 'Weights', factor);
```

Get the updated learn rate factor using the `getLearnRateFactor` function.

```
factor = getLearnRateFactor(dlnet, 'conv', 'Weights')
factor = 2
```

### Set and Get Learning Rate Factor of Nested dlnetwork Learnable Parameter

Set and get the learning rate factor of a learnable parameter of a nested layer in a `dlnetwork` object.

Create a `dlnetwork` object containing the custom layer `residualBlockLayer` attached to this example as a supporting file. To access this file, open this example as a Live Script.

```
inputSize = [224 224 3];
numFilters = 32;
numClasses = 5;

layers = [
    imageInputLayer(inputSize, 'Normalization', 'none', 'Name', 'in')
```

```

convolution2dLayer(7,numFilters,'Stride',2,'Padding','same','Name','conv')
groupNormalizationLayer('all-channels','Name','gn')
reluLayer('Name','relu')
maxPooling2dLayer(3,'Stride',2,'Name','max')
residualBlockLayer(numFilters,'Name','res1')
residualBlockLayer(numFilters,'Name','res2')
residualBlockLayer(2*numFilters,'Stride',2,'IncludeSkipConvolution',true,'Name','res3')
residualBlockLayer(2*numFilters,'Name','res4')
residualBlockLayer(4*numFilters,'Stride',2,'IncludeSkipConvolution',true,'Name','res5')
residualBlockLayer(4*numFilters,'Name','res6')
globalAveragePooling2dLayer('Name','gap')
fullyConnectedLayer(numClasses,'Name','fc')
softmaxLayer('Name','sm']);

```

```
dlnet = dlnetwork(layers);
```

View the layers of the nested network in the layer 'res1'.

```
dlnet.Layers(6).Network.Layers
```

```
ans =
```

```
7x1 Layer array with layers:
```

1	'conv_1'	2-D Convolution	32 3x3x32 convolutions with stride [1 1] and padding
2	'batchnorm_1'	Batch Normalization	Batch normalization with 32 channels
3	'relu_1'	ReLU	ReLU
4	'conv_2'	2-D Convolution	32 3x3x32 convolutions with stride [1 1] and padding
5	'batchnorm_2'	Batch Normalization	Batch normalization with 32 channels
6	'add'	Addition	Element-wise addition of 2 inputs
7	'relu_2'	ReLU	ReLU

Set the learning rate factor of the learnable parameter 'Weights' of the layer 'conv\_1' to 2 using the `setLearnRateFactor` function.

```
factor = 2;
dlnet = setLearnRateFactor(dlnet,'res1/Network/conv_1/Weights',factor);
```

Get the updated learning rate factor using the `getLearnRateFactor` function.

```
factor = getLearnRateFactor(dlnet,'res1/Network/conv_1/Weights')
factor = 2
```

### Freeze Learnable Parameters of `dlnetwork` Object

Load a pretrained network.

```
net = squeezeNet;
```

Convert the network to a layer graph, remove the output layer, and convert it to a `dlnetwork` object.

```
lgraph = layerGraph(net);
lgraph = removeLayers(lgraph,'ClassificationLayer_predictions');
dlnet = dlnetwork(lgraph);
```

The `Learnables` property of the `dlnetwork` object is a table that contains the learnable parameters of the network. The table includes parameters of nested layers in separate rows. View the first few rows of the learnables table.

```
learnables = dlnet.Learnables;
head(learnables)
```

Layer	Parameter	Value
"conv1"	"Weights"	{3x3x3x64 dlarray}
"conv1"	"Bias"	{1x1x64 dlarray}
"fire2-squeeze1x1"	"Weights"	{1x1x64x16 dlarray}
"fire2-squeeze1x1"	"Bias"	{1x1x16 dlarray}
"fire2-expand1x1"	"Weights"	{1x1x16x64 dlarray}
"fire2-expand1x1"	"Bias"	{1x1x64 dlarray}
"fire2-expand3x3"	"Weights"	{3x3x16x64 dlarray}
"fire2-expand3x3"	"Bias"	{1x1x64 dlarray}

To freeze the learnable parameters of the network, loop over the learnable parameters and set the learn rate to 0 using the `setLearnRateFactor` function.

```
factor = 0;

numLearnables = size(learnables,1);
for i = 1:numLearnables
    layerName = learnables.Layer(i);
    parameterName = learnables.Parameter(i);

    dlnet = setLearnRateFactor(dlnet,layerName,parameterName,factor);
end
```

To use the updated learn rate factors when training, you must pass the `dlnetwork` object to the update function in the custom training loop. For example, use the command

```
[dlnet,velocity] = sgdupdate(dlnet,gradients,velocity);
```

## Input Arguments

### layer — Input layer

scalar Layer object

Input layer, specified as a scalar Layer object.

### parameterName — Parameter name

character vector | string scalar

Parameter name, specified as a character vector or a string scalar.

### factor — Learning rate factor

nonnegative scalar

Learning rate factor for the parameter, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the specified parameter. For example, if `factor` is 2, then the learning rate for the specified parameter is

twice the current global learning rate. The software determines the global learning rate based on the settings specified with the `trainingOptions` function.

Example: 2

### **parameterPath** — Path to parameter in nested layer

string scalar | character vector

Path to parameter in nested layer, specified as a string scalar or a character vector. A nested layer is a custom layer that itself defines a layer graph as a learnable parameter.

If the input to `setLearnRateFactor` is a nested layer, then the parameter path has the form "propertyName/layerName/parameterName", where:

- `propertyName` is the name of the property containing a `dlnetwork` object
- `layerName` is the name of the layer in the `dlnetwork` object
- `parameterName` is the name of the parameter

If there are multiple levels of nested layers, then specify each level using the form "propertyName1/layerName1/.../propertyNameN/layerNameN/parameterName", where `propertyName1` and `layerName1` correspond to the layer in the input to the `setLearnRateFactor` function, and the subsequent parts correspond to the deeper levels.

Example: For layer input to `setLearnRateFactor`, the path "Network/conv1/Weights" specifies the "Weights" parameter of the layer with name "conv1" in the `dlnetwork` object given by `layer.Network`.

If the input to `setLearnRateFactor` is a `dlnetwork` object and the desired parameter is in a nested layer, then the parameter path has the form "layerName1/propertyName/layerName/parameterName", where:

- `layerName1` is the name of the layer in the input `dlnetwork` object
- `propertyName` is the property of the layer containing a `dlnetwork` object
- `layerName` is the name of the layer in the `dlnetwork` object
- `parameterName` is the name of the parameter

If there are multiple levels of nested layers, then specify each level using the form "layerName1/propertyName1/.../layerNameN/propertyNameN/layerName/parameterName", where `layerName1` and `propertyName1` correspond to the layer in the input to the `setLearnRateFactor` function, and the subsequent parts correspond to the deeper levels.

Example: For `dlnetwork` input to `setLearnRateFactor`, the path "res1/Network/conv1/Weights" specifies the "Weights" parameter of the layer with name "conv1" in the `dlnetwork` object given by `layer.Network`, where `layer` is the layer with name "res1" in the input network `net`.

Data Types: char | string

### **net** — Neural network

`dlnetwork` object

Neural network, specified as a `dlnetwork` object.

### **layerName** — Layer name

string scalar | character vector

Layer name, specified as a string scalar or a character vector.

Data Types: `char` | `string`

## Output Arguments

### **layerUpdated** — Updated layer

Layer object

Updated layer, returned as a Layer.

### **netUpdated** — Updated network

`dlnetwork` object

Updated network, returned as a `dlnetwork`.

## Version History

**Introduced in R2017b**

## sgdmupdate

Update parameters using stochastic gradient descent with momentum (SGDM)

### Syntax

```
[netUpdated,vel] = sgdmupdate(net,grad,vel)
[params,vel] = sgdmupdate(params,grad,vel)
[___] = sgdmupdate(___ learnRate,momentum)
```

### Description

Update the network learnable parameters in a custom training loop using the stochastic gradient descent with momentum (SGDM) algorithm.

---

**Note** This function applies the SGDM optimization algorithm to update network parameters in custom training loops that use networks defined as `dlnetwork` objects or model functions. If you want to train a network defined as a `Layer` array or as a `LayerGraph`, use the following functions:

- Create a `TrainingOptionsSGDM` object using the `trainingOptions` function.
  - Use the `TrainingOptionsSGDM` object with the `trainNetwork` function.
- 

`[netUpdated,vel] = sgdmupdate(net,grad,vel)` updates the learnable parameters of the network `net` using the SGDM algorithm. Use this syntax in a training loop to iteratively update a network defined as a `dlnetwork` object.

`[params,vel] = sgdmupdate(params,grad,vel)` updates the learnable parameters in `params` using the SGDM algorithm. Use this syntax in a training loop to iteratively update the learnable parameters of a network defined using functions.

`[___] = sgdmupdate(___ learnRate,momentum)` also specifies values to use for the global learning rate and momentum, in addition to the input arguments in previous syntaxes.

### Examples

#### Update Learnable Parameters Using sgdmupdate

Perform a single SGDM update step with a global learning rate of `0.05` and momentum of `0.95`.

Create the parameters and parameter gradients as numeric arrays.

```
params = rand(3,3,4);
grad = ones(3,3,4);
```

Initialize the parameter velocities for the first iteration.

```
vel = [];
```

Specify custom values for the global learning rate and momentum.

```
learnRate = 0.05;
momentum = 0.95;
```

Update the learnable parameters using `sgdmupdate`.

```
[params,vel] = sgdmupdate(params,grad,vel,learnRate,momentum);
```

## Train Network Using `sgdmupdate`

Use `sgdmupdate` to train a network using the SGDM algorithm.

### Load Training Data

Load the digits training data.

```
[XTrain,TTrain] = digitTrain4DArrayData;
classes = categories(TTrain);
numClasses = numel(classes);
```

### Define Network

Define the network architecture and specify the average image value using the `Mean` option in the image input layer.

```
layers = [
    imageInputLayer([28 28 1], 'Mean', mean(XTrain,4))
    convolution2dLayer(5,20)
    reluLayer
    convolution2dLayer(3,20, 'Padding',1)
    reluLayer
    convolution2dLayer(3,20, 'Padding',1)
    reluLayer
    fullyConnectedLayer(numClasses)
    softmaxLayer];
```

Create a `dlnetwork` object from the layer array.

```
net = dlnetwork(layers);
```

### Define Model Loss Function

Create the helper function `modelLoss`, listed at the end of the example. The function takes a `dlnetwork` object and a mini-batch of input data with corresponding labels, and returns the loss and the gradients of the loss with respect to the learnable parameters.

### Specify Training Options

Specify the options to use during training.

```
miniBatchSize = 128;
numEpochs = 20;
numObservations = numel(TTrain);
numIterationsPerEpoch = floor(numObservations./miniBatchSize);
```

## Train Network

Initialize the velocity parameter.

```
vel = [];
```

Calculate the total number of iterations for the training progress monitor.

```
numIterations = numEpochs * numIterationsPerEpoch;
```

Initialize the `TrainingProgressMonitor` object. Because the timer starts when you create the monitor object, make sure that you create the object close to the training loop.

```
monitor = trainingProgressMonitor(Metrics="Loss", Info="Epoch", XLabel="Iteration");
```

Train the model using a custom training loop. For each epoch, shuffle the data and loop over mini-batches of data. Update the network parameters using the `sgdmupdate` function. At the end of each iteration, display the training progress.

Train on a GPU, if one is available. Using a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox).

```
iteration = 0;
```

```
epoch = 0;
```

```
while epoch < numEpochs && ~monitor.Stop
    epoch = epoch + 1;

    % Shuffle data.
    idx = randperm(numel(TTrain));
    XTrain = XTrain(:,:,,idx);
    TTrain = TTrain(idx);

    i = 0;
    while i < numIterationsPerEpoch && ~monitor.Stop
        i = i + 1;
        iteration = iteration + 1;

        % Read mini-batch of data and convert the labels to dummy
        % variables.
        idx = (i-1)*miniBatchSize+1:i*miniBatchSize;
        X = XTrain(:,:,,idx);

        T = zeros(numClasses, miniBatchSize,"single");
        for c = 1:numClasses
            T(c,TTrain(idx)==classes(c)) = 1;
        end

        % Convert mini-batch of data to a darray.
        X = darray(single(X),"SSCB");

        % If training on a GPU, then convert data to a gpuArray.
        if canUseGPU
            X = gpuArray(X);
        end

        % Evaluate the model loss and gradients using dlfeval and the
```

```

% modelLoss function.
[loss,gradients] = dlfeval(@modelLoss,net,X,T);

% Update the network parameters using the SGDM optimizer.
[net,vel] = sgdmupdate(net,gradients,vel);

% Update the training progress monitor.
recordMetrics(monitor,iteration,Loss=loss);
updateInfo(monitor,Epoch=epoch + " of " + numEpochs);
monitor.Progress = 100 * iteration/numIterations;
end
end

```

## Test the Network

Test the classification accuracy of the model by comparing the predictions on a test set with the true labels.

```
[XTest,TTest] = digitTest4DArrayData;
```

Convert the data to a `dlarray` with the dimension format "SSCB" (spatial, spatial, channel, batch). For GPU prediction, also convert the data to a `gpuArray`.

```

XTest = dlarray(XTest,"SSCB");
if canUseGPU
    XTest = gpuArray(XTest);
end

```

To classify images using a `dlnetwork` object, use the `predict` function and find the classes with the highest scores.

```

YTest = predict(net,XTest);
[~,idx] = max(extractdata(YTest),[],1);
YTest = classes(idx);

```

Evaluate the classification accuracy.

```
accuracy = mean(YTest==TTest)
accuracy = 0.9910
```

### Model Loss Function

The `modelLoss` function takes a `dlnetwork` object `net` and a mini-batch of input data `X` with corresponding labels `T`, and returns the loss and the gradients of the loss with respect to the learnable parameters in `net`. To compute the gradients automatically, use the `dlgradient` function.

```
function [loss,gradients] = modelLoss(net,X,T)
Y = forward(net,X);
loss = crossentropy(Y,T);
gradients = dlgradient(loss,net.Learnables);
end
```

### Input Arguments

#### **net** — Network

`dlnetwork` object

Network, specified as a `dlnetwork` object.

The function updates the `Learnables` property of the `dlnetwork` object. `net.Learnables` is a table with three variables:

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of parameter, specified as a cell array containing a `dlarray`.

The input argument `grad` must be a table of the same form as `net.Learnables`.

#### **params** — Network learnable parameters

`dlarray` | numeric array | cell array | structure | table

Network learnable parameters, specified as a `dlarray`, a numeric array, a cell array, a structure, or a table.

If you specify `params` as a table, it must contain the following three variables.

- `Layer` — Layer name, specified as a string scalar.
- `Parameter` — Parameter name, specified as a string scalar.
- `Value` — Value of parameter, specified as a cell array containing a `dlarray`.

You can specify `params` as a container of learnable parameters for your network using a cell array, structure, or table, or nested cell arrays or structures. The learnable parameters inside the cell array, structure, or table must be `dlarray` or numeric values of data type `double` or `single`.

The input argument `grad` must be provided with exactly the same data type, ordering, and fields (for structures) or variables (for tables) as `params`.

Data Types: `single` | `double` | `struct` | `table` | `cell`

### **grad** — Gradients of the loss

`dlarray` | numeric array | cell array | structure | table

Gradients of the loss, specified as a `dlarray`, a numeric array, a cell array, a structure, or a table.

The exact form of `grad` depends on the input network or learnable parameters. The following table shows the required format for `grad` for possible inputs to `sgdmupdate`.

<b>Input</b>	<b>Learnable Parameters</b>	<b>Gradients</b>
<code>net</code>	Table <code>net.Learnables</code> containing <code>Layer</code> , <code>Parameter</code> , and <code>Value</code> variables. The <code>Value</code> variable consists of cell arrays that contain each learnable parameter as a <code>dlarray</code> .	Table with the same data type, variables, and ordering as <code>net.Learnables</code> . <code>grad</code> must have a <code>Value</code> variable consisting of cell arrays that contain the gradient of each learnable parameter.
<code>params</code>	<code>dlarray</code>	<code>dlarray</code> with the same data type and ordering as <code>params</code>
	Numeric array	Numeric array with the same data type and ordering as <code>params</code>
	Cell array	Cell array with the same data types, structure, and ordering as <code>params</code>
	Structure	Structure with the same data types, fields, and ordering as <code>params</code>
	Table with <code>Layer</code> , <code>Parameter</code> , and <code>Value</code> variables. The <code>Value</code> variable must consist of cell arrays that contain each learnable parameter as a <code>dlarray</code> .	Table with the same data types, variables, and ordering as <code>params</code> . <code>grad</code> must have a <code>Value</code> variable consisting of cell arrays that contain the gradient of each learnable parameter.

You can obtain `grad` from a call to `dlfeval` that evaluates a function that contains a call to `dlgradient`. For more information, see “Use Automatic Differentiation In Deep Learning Toolbox”.

### **vel** — Parameter velocities

`[]` | `dlarray` | numeric array | cell array | structure | table

Parameter velocities, specified as an empty array, a `dlarray`, a numeric array, a cell array, a structure, or a table.

The exact form of `vel` depends on the input network or learnable parameters. The following table shows the required format for `vel` for possible inputs to `sgdmupdate`.

Input	Learnable Parameters	Velocities
net	Table net.Learnables containing Layer, Parameter, and Value variables. The Value variable consists of cell arrays that contain each learnable parameter as a dlarray.	Table with the same data type, variables, and ordering as net.Learnables. vel must have a Value variable consisting of cell arrays that contain the velocity of each learnable parameter.
params	dlarray	dlarray with the same data type and ordering as params
	Numeric array	Numeric array with the same data type and ordering as params
	Cell array	Cell array with the same data types, structure, and ordering as params
	Structure	Structure with the same data types, fields, and ordering as params
	Table with Layer, Parameter, and Value variables. The Value variable must consist of cell arrays that contain each learnable parameter as a dlarray.	Table with the same data types, variables, and ordering as params. vel must have a Value variable consisting of cell arrays that contain the velocity of each learnable parameter.

If you specify `vel` as an empty array, the function assumes no previous velocities and runs in the same way as for the first update in a series of iterations. To update the learnable parameters iteratively, use the `vel` output of a previous call to `sgdupdate` as the `vel` input.

### LearnRate — Global learning rate

0.01 (default) | positive scalar

Learning rate, specified as a positive scalar. The default value of `LearnRate` is 0.01.

If you specify the network parameters as a `dlnetwork` object, the learning rate for each parameter is the global learning rate multiplied by the corresponding learning rate factor property defined in the network layers.

### momentum — Momentum

0.9 (default) | positive scalar between 0 and 1

Momentum, specified as a positive scalar between 0 and 1. The default value of `momentum` is 0.9.

## Output Arguments

### netUpdated — Updated network

dlnetwork object

Updated network, returned as a `dlnetwork` object.

The function updates the `Learnables` property of the `dlnetwork` object.

### **params — Updated network learnable parameters**

`dlarray` | numeric array | cell array | structure | table

Updated network learnable parameters, returned as a `dlarray`, a numeric array, a cell array, a structure, or a table with a `Value` variable containing the updated learnable parameters of the network.

### **vel — Updated parameter velocities**

`dlarray` | numeric array | cell array | structure | table

Updated parameter velocities, returned as a `dlarray`, a numeric array, a cell array, a structure, or a table.

## **More About**

### **Stochastic Gradient Descent with Momentum**

The function uses the stochastic gradient descent with momentum algorithm to update the learnable parameters. For more information, see the definition of the stochastic gradient descent with momentum algorithm under “Stochastic Gradient Descent” on page 1-1782 on the `trainingOptions` reference page.

## **Version History**

**Introduced in R2019b**

## **Extended Capabilities**

### **GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When at least one of the following input arguments is a `gpuArray` or a `dlarray` with underlying data of type `gpuArray`, this function runs on the GPU.
  - `grad`
  - `params`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

### Syntax

```
auimds2 = shuffle(auimds)
```

### Description

`auimds2 = shuffle(auimds)` returns an `augmentedImageDatastore` object containing a random ordering of the data from augmented image datastore `auimds`.

### Input Arguments

**auimds** — Augmented image datastore

`augmentedImageDatastore`

Augmented image datastore, specified as an `augmentedImageDatastore` object.

### Output Arguments

**auimds2** — Output datastore

`augmentedImageDatastore` object

Output datastore, returned as an `augmentedImageDatastore` object containing randomly ordered files from `auimds`.

## Version History

Introduced in R2018a

`read` | `readByIndex` | `readall`

# shuffle

Shuffle data in minibatchqueue

## Syntax

```
shuffle(mbq)
```

## Description

`shuffle(mbq)` resets the data held in `mbq` and shuffles it into a random order. After shuffling, the next function returns different mini-batches. Use this syntax to reset and shuffle your data after each training epoch in a custom training loop.

## Examples

### Differences Between shuffle and reset

The `shuffle` function resets and shuffles the `minibatchqueue` object so that you can obtain data from it in a random order. By contrast, the `reset` function resets the `minibatchqueue` object to the start of the underlying datastore.

Create a `minibatchqueue` object from a datastore.

```
ds = digitDatastore;
mbq = minibatchqueue(ds, 'MinibatchSize', 256)
```

`mbq` =  
minibatchqueue with 1 output and properties:

```
Mini-batch creation:
    MiniBatchSize: 256
    PartialMiniBatch: 'return'
    MiniBatchFcn: 'collate'
    DispatchInBackground: 0
```

```
Outputs:
    OutputCast: {'single'}
    OutputAsDlarray: 1
    MiniBatchFormat: {''}
    OutputEnvironment: {'auto'}
```

Obtain the first mini-batch of data.

```
X1 = next(mbq);
```

Iterate over the rest of the data in the `minibatchqueue` object. Use `hasdata` to check if data is still available.

```
while hasdata(mbq)
    next(mbq);
end
```

Shuffle the `minibatchqueue` object and obtain the first mini-batch after the queue is shuffled.

```
shuffle(mbq);  
X2 = next(mbq);
```

Iterate over the remaining data again.

```
while hasdata(mbq)  
    next(mbq);  
end
```

Reset the `minibatchqueue` object and obtain the first mini-batch after the queue is reset.

```
reset(mbq);  
X3 = next(mbq);
```

Check whether the mini-batches obtained after resetting or shuffling the `minibatchqueue` object are the same as the first mini-batch after the `minibatchqueue` object is created.

```
isequal(X1,X2)  
isequal(X1,X3)
```

```
ans =  
    0  
ans =  
    1
```

The `reset` function returns the `minibatchqueue` object to the start of the underlying data, so that the `next` function returns mini-batches in the same order each time. By contrast, the `shuffle` function shuffles the underlying data and produces randomized mini-batches.

## Input Arguments

### **mbq** — Mini-batch queue

`minibatchqueue` object

Mini-batch queue, specified as a `minibatchqueue` object.

## Version History

**Introduced in R2020b**

# shufflenet

Pretrained ShuffleNet convolutional neural network

## Syntax

```
net = shufflenet
```

## Description

ShuffleNet is a convolutional neural network that is trained on more than a million images from the ImageNet database [1]. The network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. The network has an image input size of 224-by-224. For more pretrained networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the ShuffleNet model. Follow the steps of “Classify Image Using GoogLeNet” and replace GoogLeNet with ShuffleNet.

To retrain the network on a new classification task, follow the steps of “Train Deep Learning Network to Classify New Images” and load ShuffleNet instead of GoogLeNet.

`net = shufflenet` returns a pretrained ShuffleNet convolutional neural network.

This function requires the *Deep Learning Toolbox Model for ShuffleNet Network* support package. If this support package is not installed, then the function provides a download link.

## Examples

### Download ShuffleNet Support Package

Download and install the *Deep Learning Toolbox Model for ShuffleNet Network* support package.

Type `shufflenet` at the command line.

```
shufflenet
```

If the *Deep Learning Toolbox Model for ShuffleNet Network* support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**. Check that the installation is successful by typing `shufflenet` at the command line. If the required support package is installed, then the function returns a `DAGNetwork` object.

```
shufflenet
```

```
ans =
```

```
DAGNetwork with properties:
```

```
    Layers: [173x1 nnet.cnn.layer.Layer]
 Connections: [188x2 table]
```

Visualize the network using Deep Network Designer.

```
deepNetworkDesigner(shufflenet)
```

Explore other pretrained neural networks in Deep Network Designer by clicking **New**.

If you need to download a neural network, pause on the desired neural network and click **Install** to open the Add-On Explorer.

## Transfer Learning with ShuffleNet

You can use transfer learning to retrain the network to classify a new set of images.

Open the example "Train Deep Learning Network to Classify New Images". The original example uses the GoogLeNet pretrained network. To perform transfer learning using a different network, load your desired pretrained network and follow the steps in the example.

Load the ShuffleNet network instead of GoogLeNet.

```
net = shufflenet
```

Follow the remaining steps in the example to retrain your network. You must replace the last learnable layer and the classification layer in your network with new layers for training. The example shows you how to find which layers to replace.

## Output Arguments

### **net** — Pretrained ShuffleNet convolutional neural network

DAGNetwork object

Pretrained ShuffleNet convolutional neural network, returned as a DAGNetwork object.

## Version History

Introduced in R2019a

## sigmoid

Apply sigmoid activation

### Syntax

```
Y = sigmoid(X)
```

### Description

The sigmoid activation operation applies the sigmoid function to the input data.

This operation is equivalent to

$$f(x) = \frac{1}{1 + e^{-x}}$$

---

**Note** This function applies the sigmoid operation to `dlarray` data. If you want to apply sigmoid within a `layerGraph` object or `Layer` array, use the following layer:

- `sigmoidLayer`
- 

`Y = sigmoid(X)` computes the sigmoid activation of the input `X` by applying the sigmoid transfer function. All values in `Y` are between 0 and 1.

### Examples

#### Apply Sigmoid Activation

Use the `sigmoid` function to set all values in the input data to a value between 0 and 1.

Create the input data as a single observation of random values with a height and width of seven and 32 channels.

```
height = 7;  
width = 7;  
channels = 32;  
observations = 1;  
  
X = randn(height,width,channels,observations);  
X = dlarray(X, 'SSCB');
```

Compute the sigmoid activation.

```
Y = sigmoid(X);
```

All values in  $Y$  now range between 0 and 1.

## Input Arguments

### **X** — Input data

`dlarray`

Input data, specified as a formatted `dlarray`, an unformatted `dlarray`, or a numeric array.

Data Types: `single` | `double`

## Output Arguments

### **Y** — Sigmoid activations

`dlarray`

Sigmoid activations, returned as a `dlarray`. All values in  $Y$  are between 0 and 1. The output  $Y$  has the same underlying data type as the input  $X$ .

If the input data  $X$  is a formatted `dlarray`,  $Y$  has the same dimension format as  $X$ . If the input data is not a formatted `dlarray`,  $Y$  is an unformatted `dlarray` with the same dimension order as the input data.

## Version History

Introduced in R2019b

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

### **GPU Code Generation**

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

### **GPU Arrays**

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- When the input argument  $X$  is a `dlarray` with underlying data of type `gpuArray`, this function runs on the GPU.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# sigmoidLayer

Sigmoid layer

## Description

A sigmoid layer applies a sigmoid function to the input such that the output is bounded in the interval (0,1).

---

**Tip** To use the sigmoid layer for binary or multilabel classification problems, create a custom binary cross-entropy loss output layer or use a custom training loop.

---

## Creation

### Syntax

```
layer = sigmoidLayer
layer = sigmoidLayer('Name',Name)
```

### Description

`layer = sigmoidLayer` creates a sigmoid layer.

`layer = sigmoidLayer('Name',Name)` creates a sigmoid layer and sets the optional `Name` property using a name-value pair argument. For example, `sigmoidLayer('Name','sig1')` creates a sigmoid layer with the name `'sig1'`. Enclose the property name in single quotes.

## Properties

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name `' '`.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

### InputNames — Input names

{"in"} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: cell

**NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: double

**OutputNames — Output names**

{ 'out' } (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

## Examples

**Create Sigmoid Layer**

Create a sigmoid layer with the name 'sig1'.

```
layer = sigmoidLayer('Name', 'sig1')
```

```
layer =  
  SigmoidLayer with properties:
```

```
  Name: 'sig1'
```

```
  Learnable Parameters  
  No properties.
```

```
  State Parameters  
  No properties.
```

```
  Show all properties
```

## Algorithms

**Sigmoid Layer**

A sigmoid layer applies a sigmoid function to the input such that the output is bounded in the interval (0,1).

This operation is equivalent to

$$f(x) = \frac{1}{1 + e^{-x}}.$$

A multilabel classification problem can be thought of as a binary classification problem, where each class is considered independently of other classes as either present or not present. Solving this type of problem requires the sigmoid activation function, where for any sample  $x_n$  the posterior probability of class  $C_k$  is

$$P(C_k|x_n) = \frac{1}{1 + e^{-a_k}}.$$

The value  $a_k$  is the weighted sum of all the units that are connected to class  $k$ . Performing multilabel classification requires a sigmoid layer followed by a custom binary cross-entropy loss layer.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

`SigmoidLayer` objects apply an element-wise operation and supports input data of any format. The layer does not add or remove any dimensions, so it outputs data with the same format as its inputs.

## Version History

# softmax

Apply softmax activation to channel dimension

## Syntax

```
Y = softmax(X)
Y = softmax(X, 'DataFormat', FMT)
```

## Description

The softmax activation operation applies the softmax function to the channel dimension of the input data.

The softmax function normalizes the value of the input data across the channel dimension such that it sums to one. You can regard the output of the softmax function as a probability distribution.

---

**Note** This function applies the softmax operation to `darray` data. If you want to apply softmax within a `layerGraph` object or `Layer` array, use the following layer:

- `softmaxLayer`
- 

`Y = softmax(X)` computes the softmax activation of the input `X` by applying the softmax transfer function to the channel dimension of the input data. All values in `Y` are between 0 and 1, and sum to 1. The input `X` must be a formatted `darray`. The output `Y` is a formatted `darray` with the same dimension format as `X`.

`Y = softmax(X, 'DataFormat', FMT)` also specifies dimension format `FMT` when `X` is not a formatted `darray`. The output `Y` is an unformatted `darray` with the same dimension order as `X`.

## Examples

### Apply Softmax Activation

Use the `softmax` function to set all values in the input data to values between 0 and 1 that sum to 1 over all channels.

Create the input classification data as two observations of random variables. The data can be in any of 10 categories.

```
numCategories = 10;
observations = 2;

X = rand(numCategories, observations);
X = darray(X, 'CB');
```

Compute the softmax activation.

```
Y = softmax(X)
totalProb = sum(Y,1)

Y =
    10(C) x 2(B) darray

    0.1151    0.0578
    0.1261    0.1303
    0.0579    0.1285
    0.1270    0.0802
    0.0959    0.1099
    0.0562    0.0569
    0.0673    0.0753
    0.0880    0.1233
    0.1328    0.1090
    0.1337    0.1288
totalProb =
    1(C) x 2(B) darray

    1.0000    1.0000
```

All values in Y range between 0 and 1. The values over all channels sum to 1 for each observation.

## Input Arguments

### X — Input data

darray

Input data, specified as a formatted darray or an unformatted darray. When X is not a formatted darray, you must specify the dimension label format using 'DataFormat', FMT.

X must contain a 'C' channel dimension.

Data Types: single | double

### FMT — Dimension order of unformatted data

char array | string

Dimension order of unformatted input data, specified as the comma-separated pair consisting of 'DataFormat' and a character array or string FMT that provides a label for each dimension of the data. Each character in FMT must be one of the following:

- 'S' — Spatial
- 'C' — Channel
- 'B' — Batch (for example, samples and observations)
- 'T' — Time (for example, sequences)
- 'U' — Unspecified

You can specify multiple dimensions labeled 'S' or 'U'. You can use the labels 'C', 'B', and 'T' at most once.

You must specify 'DataFormat', FMT when the input data is not a formatted darray.

Example: 'DataFormat', 'SSCB'

Data Types: `char` | `string`

## Output Arguments

### Y — Softmax activations

`darray`

Softmax activations, returned as a `darray`. All values in Y are between 0 and 1. The output Y has the same underlying data type as the input X.

If the input data X is a formatted `darray`, Y has the same dimension format as X. If the input data is not a formatted `darray`, Y is an unformatted `darray` with the same dimension order as the input data.

## More About

### Softmax Activation

The `softmax` function normalizes the input across the channel dimension, such that it sums to one. For more information, see the definition of “Softmax Layer” on page 1-1709 on the `softmaxLayer` reference page.

# softmaxLayer

Softmax layer

## Description

A softmax layer applies a softmax function to the input.

## Creation

### Syntax

```
layer = softmaxLayer
layer = softmaxLayer('Name',Name)
```

### Description

`layer = softmaxLayer` creates a softmax layer.

`layer = softmaxLayer('Name',Name)` creates a softmax layer and sets the optional `Name` property using a name-value pair. For example, `softmaxLayer('Name','sm1')` creates a softmax layer with the name 'sm1'. Enclose the property name in single quotes.

## Properties

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlNetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

### InputNames — Input names

{"in"} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: cell

### **NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: double

### **OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

## **Examples**

### **Create Softmax Layer**

Create a softmax layer with the name 'sm1'.

```
layer = softmaxLayer('Name','sm1')
```

```
layer =  
    SoftmaxLayer with properties:
```

```
    Name: 'sm1'
```

Include a softmax layer in a Layer array.

```
layers = [ ...

    convolution2dLayer(5,20)  
    reluLayer  
    maxPooling2dLayer(2,'Stride',2)  
    fullyConnectedLayer(10)  
    softmaxLayer  
    classificationLayer]
```

```
layers =  
    7x1 Layer array with layers:
```

1	''	Image Input	28x28x1 images with 'zerocenter' normalization
2	''	2-D Convolution	20 5x5 convolutions with stride [1 1] and padding [0 0 0 0]
3	''	ReLU	ReLU
4	''	2-D Max Pooling	2x2 max pooling with stride [2 2] and padding [0 0 0 0]
5	''	Fully Connected	10 fully connected layer
6	''	Softmax	softmax
7	''	Classification Output	crossentropyex

## Algorithms

### Softmax Layer

A softmax layer applies a softmax function to the input.

For classification problems, a softmax layer and then a classification layer usually follow the final fully connected layer.

The output unit activation function is the softmax function:

$$y_r(x) = \frac{\exp(a_r(x))}{\sum_{j=1}^k \exp(a_j(x))},$$

where  $0 \leq y_r \leq 1$  and  $\sum_{j=1}^k y_j = 1$ .

The softmax function is the output unit activation function after the last fully connected layer for multi-class classification problems:

$$P(c_r|x, \theta) = \frac{P(x, \theta|c_r)P(c_r)}{\sum_{j=1}^k P(x, \theta|c_j)P(c_j)} = \frac{\exp(a_r(x, \theta))}{\sum_{j=1}^k \exp(a_j(x, \theta))},$$

where  $0 \leq P(c_r|x, \theta) \leq 1$  and  $\sum_{j=1}^k P(c_j|x, \theta) = 1$ . Moreover,  $a_r = \ln(P(x, \theta|c_r)P(c_r))$ ,  $P(x, \theta|c_r)$  is the conditional probability of the sample given class  $r$ , and  $P(c_r)$  is the class prior probability.

The softmax function is also known as the *normalized exponential* and can be considered the multi-class generalization of the logistic sigmoid function [1].

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `SoftmaxLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"CB" (channel, batch)	"CB" (channel, batch)
"SCB" (spatial, channel, batch)	"SCB" (spatial, channel, batch)
"SSCB" (spatial, spatial, channel, batch)	"SSCB" (spatial, spatial, channel, batch)
"SSSCB" (spatial, spatial, spatial, channel, batch)	"SSSCB" (spatial, spatial, spatial, channel, batch)
"CBT" (channel, batch, time)	"CBT" (channel, batch, time)
"SCBT" (spatial, channel, batch, time)	"SCBT" (spatial, channel, batch, time)
"SSCBT" (spatial, spatial, channel, batch, time)	"SSCBT" (spatial, spatial, channel, batch, time)
"SSSCBT" (spatial, spatial, spatial, channel, batch, time)	"SSSCBT" (spatial, spatial, spatial, channel, batch, time)
"CU" (channel, unspecified)	"CU" (channel, unspecified)
"SC" (spatial, channel)	"SC" (spatial, channel)
"SSC" (spatial, spatial, channel)	"SSC" (spatial, spatial, channel)
"SSSC" (spatial, spatial, spatial, channel)	"SSSC" (spatial, spatial, spatial, channel)

In `dlnetwork` objects, `SoftmaxLayer` objects also support these input and output format combinations.

Input Format	Output Format
"CT" (channel, time)	"CT" (channel, time)
"SCT" (spatial, channel, time)	"SCT" (spatial, channel, time)
"SSCT" (spatial, spatial, channel, time)	"SSCT" (spatial, spatial, channel, time)
"SSSCT" (spatial, spatial, spatial, channel, time)	"SSSCT" (spatial, spatial, spatial, channel, time)

## sortClasses

**Package:** `mlearnlib.graphics.chart`

Sort classes of confusion matrix chart

### Syntax

```
sortClasses(cm,order)
```

### Description

`sortClasses(cm,order)` sorts the classes of the confusion matrix chart `cm` in the order specified by `order`. You can sort the classes in their natural order, by the values along the diagonal of the confusion matrix, or in fixed order that you specify.

### Examples

#### Sort Classes in a Fixed Order

Load a sample of predicted and true labels for a classification problem. `trueLabels` are the true labels for an image classification problem and `predictedLabels` are the predictions of a convolutional neural network. Create a confusion matrix chart.

```
load('Cifar10Labels.mat','trueLabels','predictedLabels');
figure
cm = confusionchart(trueLabels,predictedLabels);
```

True Class	airplane	923	4	21	8	4	1	5	5	23	6
	automobile	5	972	2					1	5	15
	bird	26	2	892	30	13	8	17	5	4	3
	cat	12	4	32	826	24	48	30	12	5	7
	deer	5	1	28	24	898	13	14	14	2	1
	dog	7	2	28	111	18	801	13	17		3
	frog	5		16	27	3	4	943	1	1	
	horse	9	1	14	13	22	17	3	915	2	4
	ship	37	10	4	4		1	2	1	931	10
	truck	20	39	3	3			2	1	9	923
		airplane	automobile	bird	cat	deer	dog	frog	horse	ship	truck
		Predicted Class									

Reorder the classes of the confusion matrix chart so that the classes are in a fixed order.

```
sortClasses(cm, ...
  ["cat" "dog" "horse" "deer" "bird" "frog", ...
  "airplane" "ship" "automobile" "truck"])
```

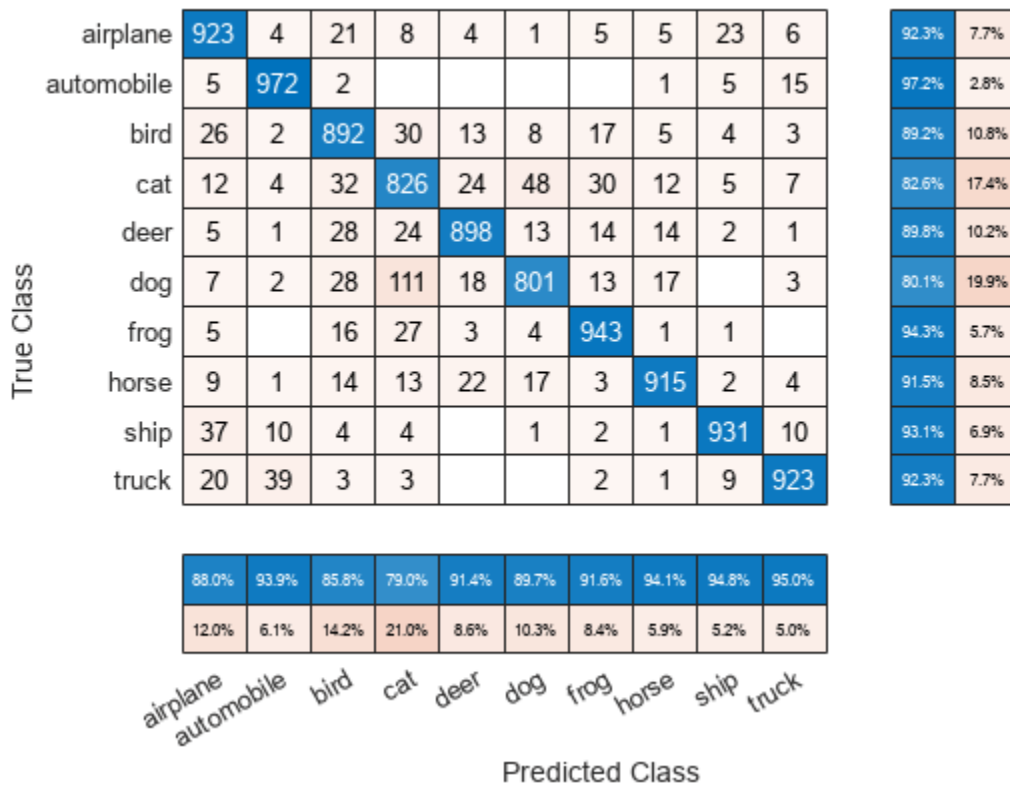

cat	826	48	12	24	32	30	12	5	4	7
dog	111	801	17	18	28	13	7		2	3
horse	13	17	915	22	14	3	9	2	1	4
deer	24	13	14	898	28	14	5	2	1	1
bird	30	8	5	13	892	17	26	4	2	3
frog	27	4	1	3	16	943	5	1		
airplane	8	1	5	4	21	5	923	23	4	6
ship	4	1	1		4	2	37	931	10	10
automobile			1		2		5	5	972	15
truck	3		1		3	2	20	9	39	923

Predicted Class

### Sort Classes by Precision or Recall

Load a sample of predicted and true labels for a classification problem. `trueLabels` are the true labels for an image classification problem and `predictedLabels` are the predictions of a convolutional neural network. Create a confusion matrix chart with column and row summaries

```
load('Cifar10Labels.mat', 'trueLabels', 'predictedLabels');
figure
cm = confusionchart(trueLabels, predictedLabels, ...
  'ColumnSummary', 'column-normalized', ...
  'RowSummary', 'row-normalized');
```

To sort the classes of the confusion matrix by class-wise recall (true positive rate), normalize the cell values across each row, that is, by the number of observations that have the same true class. Sort the classes by the corresponding diagonal cell values and reset the normalization of the cell values. The classes are now sorted such that the percentages in the blue cells in the row summaries to the right are decreasing.

```
cm.Normalization = 'row-normalized';
sortClasses(cm, 'descending-diagonal');
cm.Normalization = 'absolute';
```

True Class	automobile	972		5	5	15	1		2			97.2%	2.8%								
	frog		943	1	5		1	3	16	27	4	94.3%	5.7%								
	ship	10	2	931	37	10	1		4	4	1	93.1%	6.9%								
	airplane	4	5	23	923	6	5	4	21	8	1	92.3%	7.7%								
	truck	39	2	9	20	923	1		3	3		92.3%	7.7%								
	horse	1	3	2	9	4	915	22	14	13	17	91.5%	8.5%								
	deer	1	14	2	5	1	14	898	28	24	13	89.8%	10.2%								
	bird	2	17	4	26	3	5	13	892	30	8	89.2%	10.8%								
	cat	4	30	5	12	7	12	24	32	826	48	82.6%	17.4%								
	dog	2	13		7	3	17	18	28	111	801	80.1%	19.9%								
												93.9%	91.6%	94.8%	88.0%	95.0%	94.1%	91.4%	85.8%	79.0%	89.7%
												6.1%	8.4%	5.2%	12.0%	5.0%	5.9%	8.6%	14.2%	21.0%	10.3%
												automobile	frog	ship	airplane	truck	horse	deer	bird	cat	dog
												Predicted Class									

To sort the classes by class-wise precision (positive predictive value), normalize the cell values across each column, that is, by the number of observations that have the same predicted class. Sort the classes by the corresponding diagonal cell values and reset the normalization of the cell values. The classes are now sorted such that the percentages in the blue cells in the column summaries at the bottom are decreasing.

```
cm.Normalization = 'column-normalized';
sortClasses(cm, 'descending-diagonal');
cm.Normalization = 'absolute';
```

## Input Arguments

### cm — Confusion matrix chart

ConfusionMatrixChart object

Confusion matrix chart, specified as a ConfusionMatrixChart object. To create a confusion matrix chart, use confusionchart,

### order — Order in which to sort classes

'auto' | 'ascending-diagonal' | 'descending-diagonal' | array

Order in which to sort the classes of the confusion matrix chart, specified as one of these values:

- 'auto' — Sorts the classes into their natural order as defined by the sort function. For example, if the class labels of the confusion matrix chart are a string vector, then sort alphabetically. If the class labels are an ordinal categorical vector, then use the order of the class labels.
- 'ascending-diagonal' — Sort the classes so that the values along the diagonal of the confusion matrix increase from top left to bottom right.
- 'descending-diagonal' — Sort the classes so that the values along the diagonal of the confusion matrix decrease from top left to bottom right.
- 'cluster' (Requires Statistics and Machine Learning Toolbox) — Sort the classes to cluster similar classes. You can customize clustering by using the pdist, linkage, and optimalleaforder functions. For details, see “Sort Classes to Cluster Similar Classes” (Statistics and Machine Learning Toolbox).

- **Array** — Sort the classes in a unique order specified by a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. The array must be a permutation of the `ClassLabels` property of the confusion matrix chart.

Example: `sortClasses(cm, 'ascending-diagonal')`

Example: `sortClasses(cm, ["owl", "cat", "toad"])`

## Version History

## squeezenet

SqueezeNet convolutional neural network

### Syntax

```
net = squeezenet
net = squeezenet('Weights','imagenet')
```

```
lgraph = squeezenet('Weights','none')
```

### Description

SqueezeNet is a convolutional neural network that is 18 layers deep. You can load a pretrained version of the network trained on more than a million images from the ImageNet database [1]. The pretrained network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. This function returns a SqueezeNet v1.1 network, which has similar accuracy to SqueezeNet v1.0 but requires fewer floating-point operations per prediction [3]. The network has an image input size of 227-by-227. For more pretrained networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the SqueezeNet network. For an example, see “Classify Image Using SqueezeNet” on page 1-1734.

You can retrain a SqueezeNet network to perform a new task using transfer learning. For an example, see “Interactive Transfer Learning Using SqueezeNet” on page 1-1719.

`net = squeezenet` returns a SqueezeNet network trained on the ImageNet data set.

`net = squeezenet('Weights','imagenet')` returns a SqueezeNet network trained on the ImageNet data set. This syntax is equivalent to `net = squeezenet`.

`lgraph = squeezenet('Weights','none')` returns the untrained SqueezeNet network architecture.

### Examples

#### Load SqueezeNet Network

Load a pretrained SqueezeNet network.

```
net = squeezenet
```

```
net =
```

```
  DAGNetwork with properties:
```

```
    Layers: [68x1 nnet.cnn.layer.Layer]
 Connections: [75x2 table]
```

This function returns a DAGNetwork object.

SqueezeNet is included within Deep Learning Toolbox. To load other networks, use functions such as `googlenet` to get links to download pretrained networks from the Add-On Explorer.

### Interactive Transfer Learning Using SqueezeNet

This example shows how to fine-tune a pretrained SqueezeNet network to classify a new collection of images. This process is called transfer learning and is usually much faster and easier than training a new network, because you can apply learned features to a new task using a smaller number of training images. To prepare a network for transfer learning interactively, use Deep Network Designer.

#### Extract Data

In the workspace, extract the MathWorks Merch data set. This is a small data set containing 75 images of MathWorks merchandise, belonging to five different classes (*cap*, *cube*, *playing cards*, *screwdriver*, and *torch*).

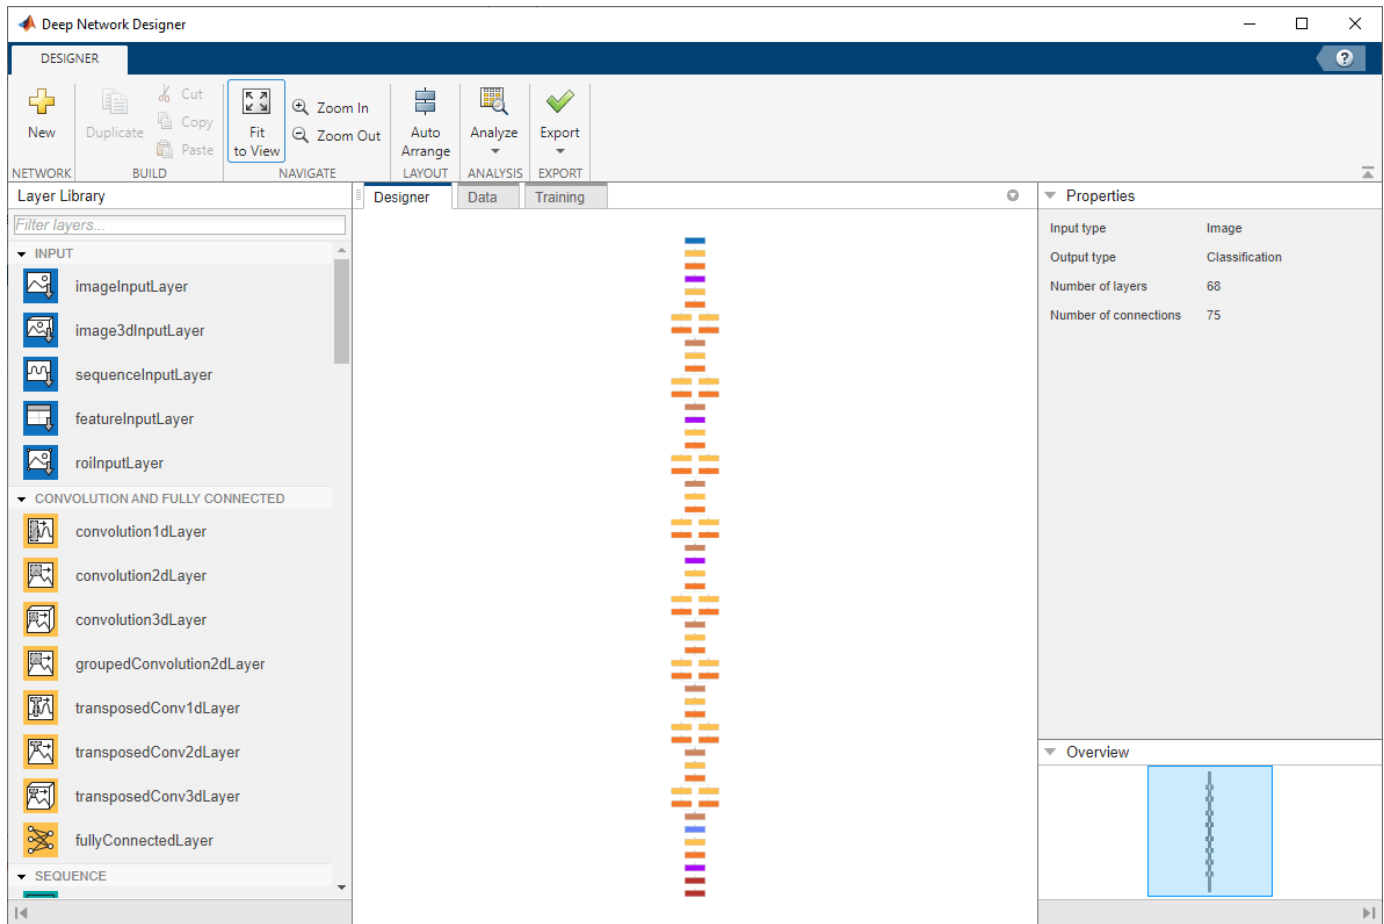

```
unzip("MerchData.zip");
```

#### Open SqueezeNet in Deep Network Designer

Open Deep Network Designer with SqueezeNet.

```
deepNetworkDesigner(squeezeNet);
```

Deep Network Designer displays a zoomed-out view of the whole network in the **Designer** pane.

Explore the network plot. To zoom in with the mouse, use **Ctrl+scroll wheel**. To pan, use the arrow keys, or hold down the scroll wheel and drag the mouse. Select a layer to view its properties. Deselect all layers to view the network summary in the **Properties** pane.

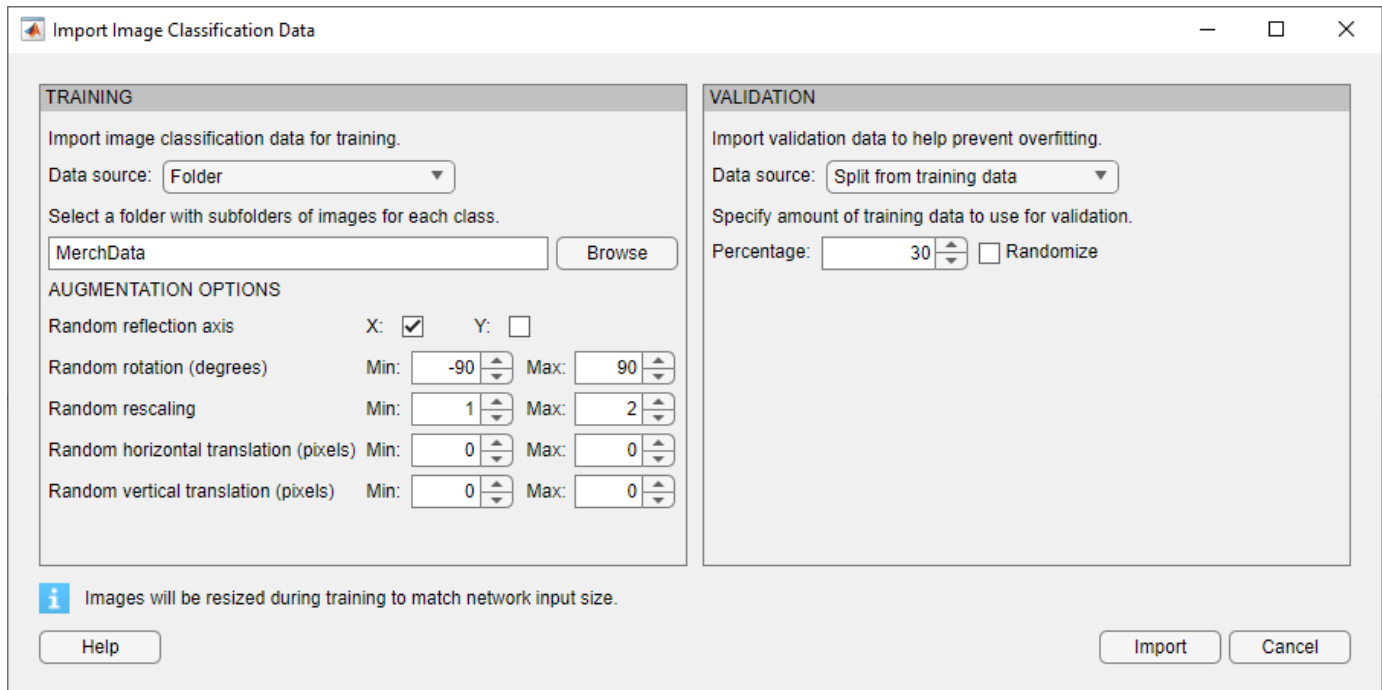

## Import Data

To load the data into Deep Network Designer, on the **Data** tab, click **Import Data > Import Image Classification Data**.

In the **Data source** list, select **Folder**. Click **Browse** and select the extracted MerchData folder.

Divide the data into 70% training data and 30% validation data.

Specify augmentation operations to perform on the training images. For this example, apply a random reflection in the x-axis, a random rotation from the range  $[-90,90]$  degrees, and a random rescaling from the range  $[1,2]$ . Data augmentation helps prevent the network from overfitting and memorizing the exact details of the training images.

Click **Import** to import the data into Deep Network Designer.

### Visualize Data

Using Deep Network Designer, you can visually inspect the distribution of the training and validation data in the **Data** tab. You can also view random observations and their labels as a simple check before training. You can see that, in this example, there are five classes in the data set.

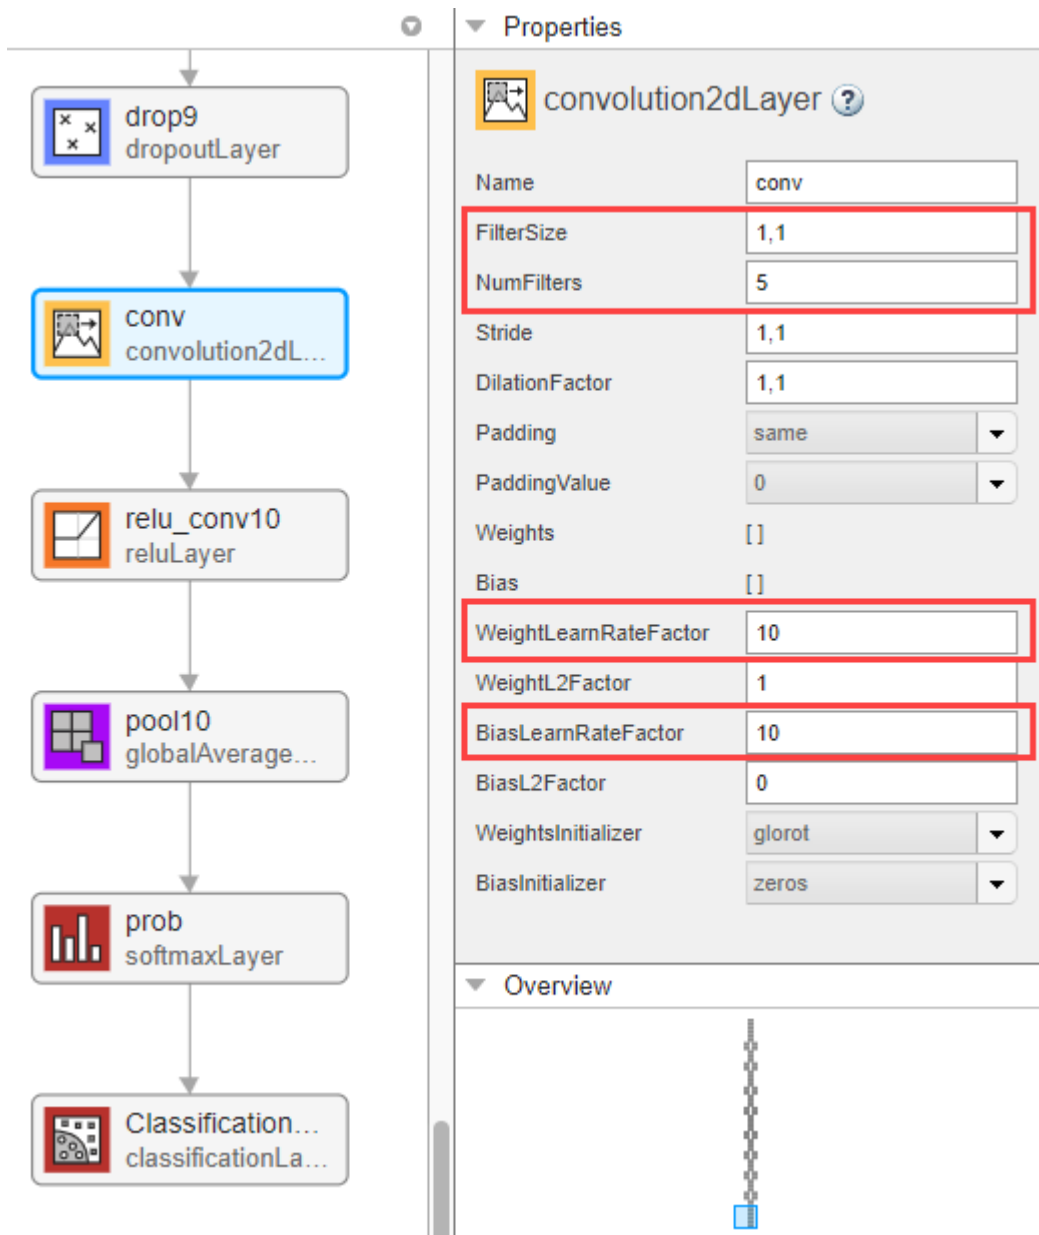

### Edit Network for Transfer Learning

The convolutional layers of the network extract image features that the last learnable layer and the final classification layer use to classify the input image. These two layers, 'conv10' and 'ClassificationLayer\_predictions' in SqueezeNet, contain information on how to combine the features that the network extracts into class probabilities, a loss value, and predicted labels. To retrain a pretrained network to classify new images, replace these two layers with new layers adapted to the new data set.

In most networks, the last layer with learnable weights is a fully connected layer. In some networks, such as SqueezeNet, the last learnable layer is the final convolutional layer instead. In this case, replace the convolutional layer with a new convolutional layer with the number of filters equal to the number of classes.

In the **Designer** pane, drag a new `convolution2dLayer` onto the canvas. To match the original convolutional layer, set `FilterSize` to 1, 1. Change `NumFilters` to the number of classes in the new data, in this example, 5.

Change the learning rates so that learning is faster in the new layer than in the transferred layers by setting `WeightLearnRateFactor` and `BiasLearnRateFactor` to 10. Delete the last 2-D convolutional layer and connect your new layer instead.

Replace the output layer. Scroll to the end of the **Layer Library** and drag a new **classificationLayer** onto the canvas. Delete the original output layer and connect your new layer instead.

### Check Network

To make sure your edited network is ready for training, click **Analyze**, and ensure the Deep Learning Network Analyzer reports zero errors.

Deep Learning Network Analyzer

## Train Network

Specify training options. Select the **Training** tab and click **Training Options**.

- Set the initial learn rate to a small value to slow down learning in the transferred layers.
- Specify the validation frequency so that the accuracy on the validation data is calculated once every epoch.
- Specify a small number of epochs. An epoch is a full training cycle on the entire training data set. For transfer learning, you do not need to train for as many epochs.
- Specify the mini-batch size, that is, how many images to use in each iteration. To ensure the whole data set is used during each epoch, set the mini-batch size to evenly divide the number of training samples.

For this example, set **InitialLearnRate** to 0.0001, **MaxEpochs** to 8, and **ValidationFrequency** to 5. As there are 55 observations, set **MiniBatchSize** to 11.

To train the network with the specified training options, click **OK** and then click **Train**.

Deep Network Designer allows you to visualize and monitor training progress. You can then edit the training options and retrain the network, if required.

### Export Results and Generate MATLAB Code

To export the network architecture with the trained weights, on the **Training** tab, select **Export > Export Trained Network and Results**. Deep Network Designer exports the trained network as the variable `trainedNetwork_1` and the training info as the variable `trainInfoStruct_1`.

```
trainInfoStruct_1
```

```

trainInfoStruct_1 = struct with fields:
    TrainingLoss: [1×40 double]
    TrainingAccuracy: [1×40 double]
    ValidationLoss: [3.3420 NaN NaN NaN 2.1187 NaN NaN NaN NaN 1.4291 NaN NaN NaN NaN 0
    ValidationAccuracy: [20 NaN NaN NaN 30 NaN NaN NaN NaN 55.0000 NaN NaN NaN NaN 65 NaN NaN
    BaseLearnRate: [1×40 double]
    FinalValidationLoss: 0.3749
    FinalValidationAccuracy: 95

```

You can also generate MATLAB code, which recreates the network and the training options used. On the **Training** tab, select **Export > Generate Code for Training**. Examine the MATLAB code to learn how to programmatically prepare the data for training, create the network architecture, and train the network.

### Classify New Image

Load a new image to classify using the trained network.

```
I = imread("MerchDataTest.jpg");
```

Deep Network Designer resizes the images during training to match the network input size. To view the network input size, go to the **Designer** pane and select the `imageInputLayer` (first layer). This network has an input size of 227-by-227.

The screenshot shows the Deep Network Designer interface. On the left, a network diagram displays two layers: 'data imageInputLayer' and 'conv1 convolution2dL...'. On the right, the 'Properties' pane for the selected 'imageInputLayer' is shown. The 'InputSize' property is highlighted with a red box and is set to '227,227,3'. Other properties include 'Name' (data), 'Normalization' (zerocenter), 'NormalizationDimension' (auto), 'Mean' ([1×1×3 single]), and 'StandardDeviation' ([]).

Resize the test image to match the network input size.

```
I = imresize(I, [227 227]);
```

Classify the test image using the trained network.

```

[YPred,probs] = classify(trainedNetwork_1,I);
imshow(I)
label = YPred;
title(string(label) + ", " + num2str(100*max(probs),3) + "%");

```

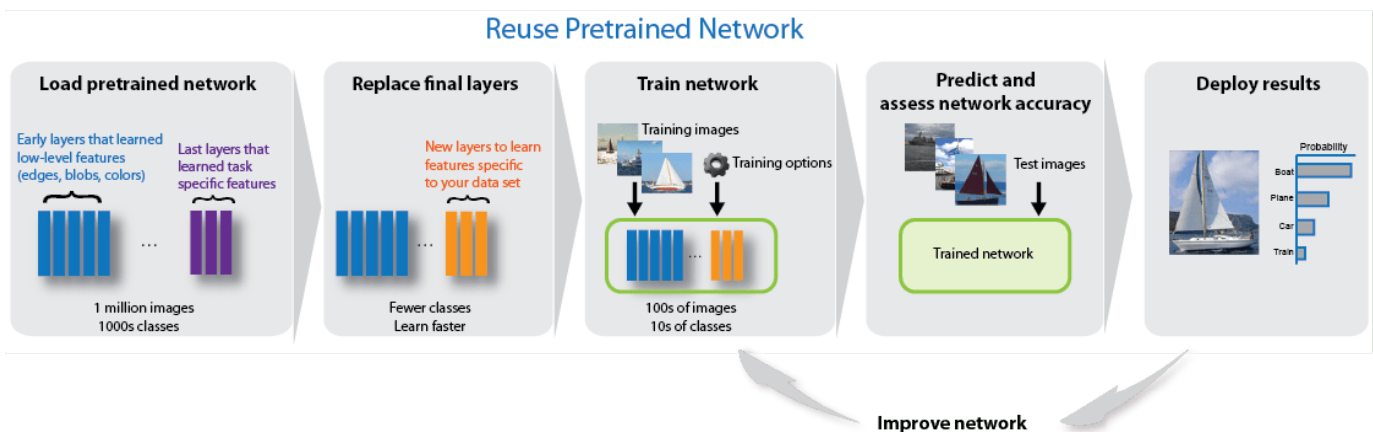

### Programmatic Transfer Learning Using SqueezeNet

This example shows how to fine-tune a pretrained SqueezeNet convolutional neural network to perform classification on a new collection of images.

SqueezeNet has been trained on over a million images and can classify images into 1000 object categories (such as keyboard, coffee mug, pencil, and many animals). The network has learned rich feature representations for a wide range of images. The network takes an image as input and outputs a label for the object in the image together with the probabilities for each of the object categories.

Transfer learning is commonly used in deep learning applications. You can take a pretrained network and use it as a starting point to learn a new task. Fine-tuning a network with transfer learning is usually much faster and easier than training a network with randomly initialized weights from scratch. You can quickly transfer learned features to a new task using a smaller number of training images.

## Load Data

Unzip and load the new images as an image datastore. `imageDatastore` automatically labels the images based on folder names and stores the data as an `ImageDatastore` object. An image datastore enables you to store large image data, including data that does not fit in memory, and efficiently read batches of images during training of a convolutional neural network.

```
unzip('MerchData.zip');
imds = imageDatastore('MerchData', ...
    'IncludeSubfolders',true, ...
    'LabelSource','foldernames');
```

Divide the data into training and validation data sets. Use 70% of the images for training and 30% for validation. `splitEachLabel` splits the `images` datastore into two new datastores.

```
[imdsTrain,imdsValidation] = splitEachLabel(imds,0.7,'randomized');
```

This very small data set now contains 55 training images and 20 validation images. Display some sample images.

```
numTrainImages = numel(imdsTrain.Labels);
idx = randperm(numTrainImages,16);

I = imtile(imds, 'Frames', idx);

figure
imshow(I)
```

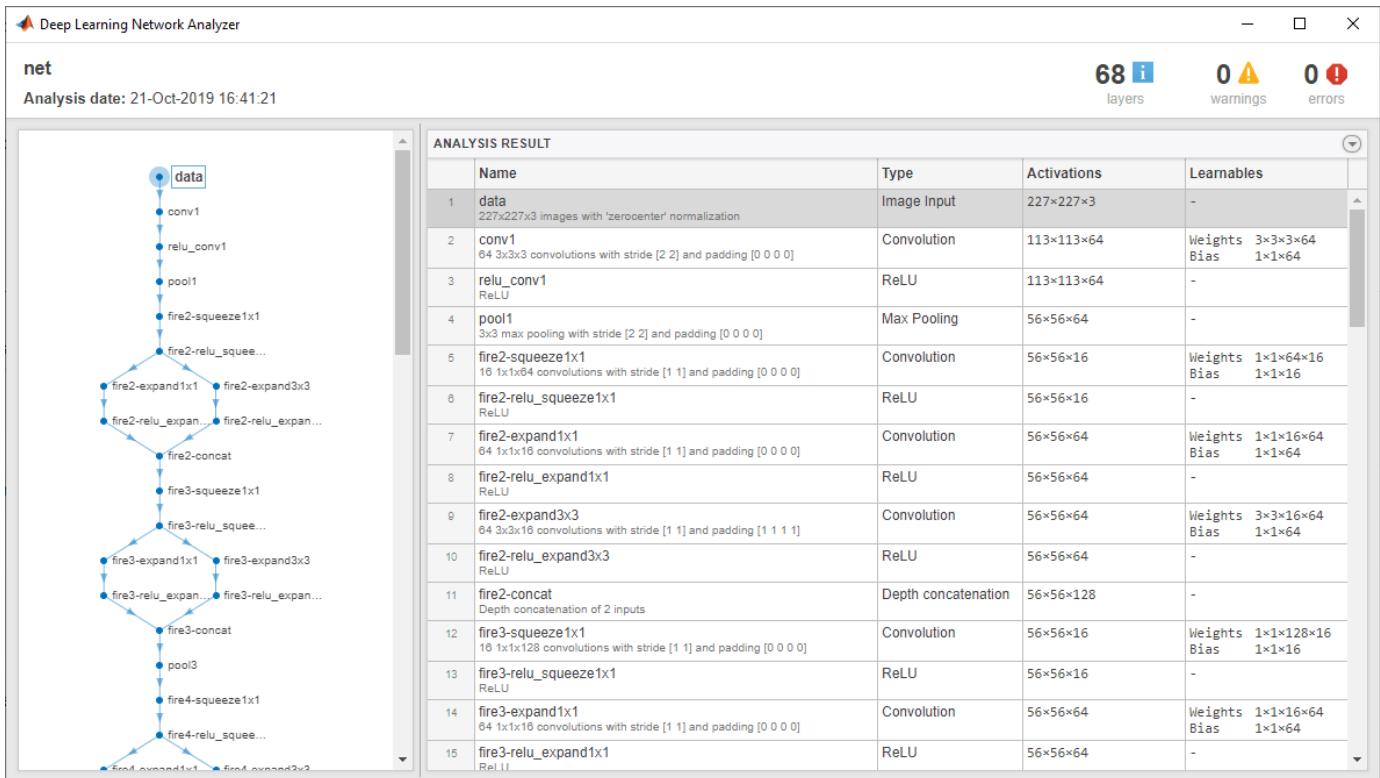

## Load Pretrained Network

Load the pretrained SqueezeNet neural network.

```
net = squeezeNet;
```

Use `analyzeNetwork` to display an interactive visualization of the network architecture and detailed information about the network layers.

```
analyzeNetwork(net)
```

The first layer, the image input layer, requires input images of size 227-by-227-by-3, where 3 is the number of color channels.

```
inputSize = net.Layers(1).InputSize
```

```
inputSize = 1x3
```

```
227 227 3
```

## Replace Final Layers

The convolutional layers of the network extract image features that the last learnable layer and the final classification layer use to classify the input image. These two layers, 'conv10' and 'ClassificationLayer\_predictions' in SqueezeNet, contain information on how to combine the features that the network extracts into class probabilities, a loss value, and predicted labels. To retrain a pretrained network to classify new images, replace these two layers with new layers adapted to the new data set.

Extract the layer graph from the trained network.

```
lgraph = layerGraph(net);
```

Find the names of the two layers to replace. You can do this manually or you can use the supporting function `findLayersToReplace` to find these layers automatically.

```
[learnableLayer,classLayer] = findLayersToReplace(lgraph);
```

```
ans =  
1x2 Layer array with layers:
```

```

1 'conv10'                2-D Convolution          1000 1x1x512 convolutions w
2 'ClassificationLayer_predictions'  Classification Output    crossentropyex with 'tench'

```

In most networks, the last layer with learnable weights is a fully connected layer. In some networks, such as SqueezeNet, the last learnable layer is a 1-by-1 convolutional layer instead. In this case, replace the convolutional layer with a new convolutional layer with the number of filters equal to the number of classes. To learn faster in the new layers than in the transferred layers, increase the `WeightLearnRateFactor` and `BiasLearnRateFactor` values of the convolutional layer.

```

numClasses = numel(categories(imdsTrain.Labels))

numClasses = 5

newConvLayer = convolution2dLayer([1, 1],numClasses,'WeightLearnRateFactor',10,'BiasLearnRateFactor',10);
lgraph = replaceLayer(lgraph,'conv10',newConvLayer);

```

The classification layer specifies the output classes of the network. Replace the classification layer with a new one without class labels. `trainNetwork` automatically sets the output classes of the layer at training time.

```

newClassificationLayer = classificationLayer('Name','new_classoutput');
lgraph = replaceLayer(lgraph,'ClassificationLayer_predictions',newClassificationLayer);

```

### Train Network

The network requires input images of size 227-by-227-by-3, but the images in the image datastore have different sizes. Use an augmented image datastore to automatically resize the training images. Specify additional augmentation operations to perform on the training images: randomly flip the training images along the vertical axis, and randomly translate them up to 30 pixels horizontally and vertically. Data augmentation helps prevent the network from overfitting and memorizing the exact details of the training images.

```

pixelRange = [-30 30];
imageAugmenter = imageDataAugmenter( ...
    'RandXReflection',true, ...
    'RandXTranslation',pixelRange, ...
    'RandYTranslation',pixelRange);
augImdsTrain = augmentedImageDatastore(inputSize(1:2),imdsTrain, ...
    'DataAugmentation',imageAugmenter);

```

To automatically resize the validation images without performing further data augmentation, use an augmented image datastore without specifying any additional preprocessing operations.

```

augImdsValidation = augmentedImageDatastore(inputSize(1:2),imdsValidation);

```

Specify the training options. For transfer learning, keep the features from the early layers of the pretrained network (the transferred layer weights). To slow down learning in the transferred layers, set the initial learning rate to a small value. In the previous step, you increased the learning rate factors for the convolutional layer to speed up learning in the new final layers. This combination of learning rate settings results in fast learning only in the new layers and slower learning in the other layers. When performing transfer learning, you do not need to train for as many epochs. An epoch is a full training cycle on the entire training data set. Specify the mini-batch size to be 11 so that in each epoch you consider all of the data. The software validates the network every `ValidationFrequency` iterations during training.

```

options = trainingOptions('sgdm', ...
    'MiniBatchSize',11, ...

```

```

'MaxEpochs',7, ...
'InitialLearnRate',2e-4, ...
'Shuffle','every-epoch', ...
'ValidationData',augimdsValidation, ...
'ValidationFrequency',3, ...
'Verbose',false, ...
'Plots','training-progress');

```

Train the network that consists of the transferred and new layers. By default, `trainNetwork` uses a GPU if one is available. This requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). Otherwise, `trainNetwork` uses a CPU. You can also specify the execution environment by using the 'ExecutionEnvironment' name-value pair argument of `trainingOptions`.

```
netTransfer = trainNetwork(augimdsTrain,lgraph,options);
```

### Classify Validation Images

Classify the validation images using the fine-tuned network.

```
[YPred,scores] = classify(netTransfer,augimdsValidation);
```

Display four sample validation images with their predicted labels.

```
idx = randperm(numel(imdsValidation.Files),4);  
figure  
for i = 1:4  
    subplot(2,2,i)  
    I = readimage(imdsValidation,idx(i));  
    imshow(I)  
    label = YPred(idx(i));  
    title(string(label));  
end
```

**MathWorks Playing Cards**

**MathWorks Playing Cards**

**MathWorks Cube**

**MathWorks Cube**

Calculate the classification accuracy on the validation set. Accuracy is the fraction of labels that the network predicts correctly.

```
YValidation = imdsValidation.Labels;  
accuracy = mean(YPred == YValidation)
```

```
accuracy = 1
```

For tips on improving classification accuracy, see “Deep Learning Tips and Tricks”.

### **Classify Image Using SqueezeNet**

Read, resize, and classify an image using SqueezeNet.

First, load a pretrained SqueezeNet model.

```
net = squeezenet;
```

Read the image using `imread`.

```
I = imread('peppers.png');  
figure  
imshow(I)
```

The pretrained model requires the image size to be the same as the input size of the network. Determine the input size of the network using the `InputSize` property of the first layer of the network.

```
sz = net.Layers(1).InputSize
```

```
sz = 1×3
```

```
227 227 3
```

Resize the image to the input size of the network.

```
I = imresize(I,sz(1:2));  
figure  
imshow(I)
```

Classify the image using `classify`.

```
label = classify(net,I)  
  
label = categorical  
      bell pepper
```

Show the image and classification result together.

```
figure  
imshow(I)  
title(label)
```

bell pepper

## Feature Extraction Using SqueezeNet

This example shows how to extract learned image features from a pretrained convolutional neural network and use those features to train an image classifier.

Feature extraction is the easiest and fastest way to use the representational power of pretrained deep networks. For example, you can train a support vector machine (SVM) using `fitcecoc` (Statistics and Machine Learning Toolbox™) on the extracted features. Because feature extraction requires only a single pass through the data, it is a good starting point if you do not have a GPU to accelerate network training with.

### Load Data

Unzip and load the sample images as an image datastore. `imageDatastore` automatically labels the images based on folder names and stores the data as an `ImageDatastore` object. An image datastore lets you store large image data, including data that does not fit in memory. Split the data into 70% training and 30% test data.

```
unzip("MerchData.zip");

imds = imageDatastore("MerchData", ...
    IncludeSubfolders=true, ...
    LabelSource="foldernames");

[imdsTrain,imdsTest] = splitEachLabel(imds,0.7,"randomized");
```

This very small data set now has 55 training images and 20 validation images. Display some sample images.

```
numImagesTrain = numel(imdsTrain.Labels);
idx = randperm(numImagesTrain,16);
```

```
I = imtile(imds,"Frames",idx);  
  
figure  
imshow(I)
```

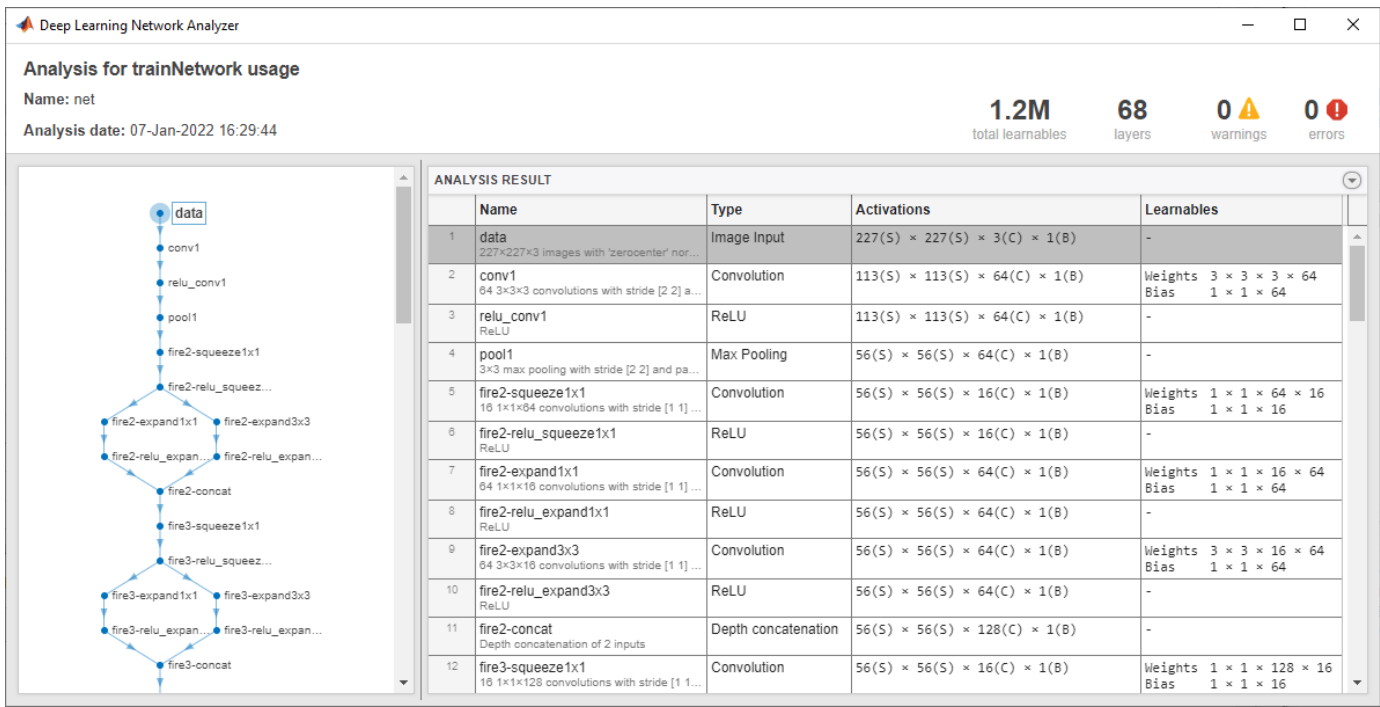

### Load Pretrained Network

Load a pretrained SqueezeNet network. SqueezeNet is trained on more than a million images and can classify images into 1000 object categories, for example, keyboard, mouse, pencil, and many animals. As a result, the model has learned rich feature representations for a wide range of images.

```
net = squeezeNet;
```

Analyze the network architecture.

```
analyzeNetwork(net)
```

The first layer, the image input layer, requires input images of size 227-by-227-by-3, where 3 is the number of color channels.

```
inputSize = net.Layers(1).InputSize
```

```
inputSize = 1x3
```

```
    227    227    3
```

### Extract Image Features

The network constructs a hierarchical representation of input images. Deeper layers contain higher level features, constructed using the lower level features of earlier layers. To get the feature representations of the training and test images, use `activations` on the global average pooling layer "pool10". To get a lower level representation of the images, use an earlier layer in the network.

The network requires input images of size 227-by-227-by-3, but the images in the image datastores have different sizes. To automatically resize the training and test images before inputting them to the network, create augmented image datastores, specify the desired image size, and use these datastores as input arguments to `activations`.

```
augImdsTrain = augmentedImageDatastore(inputSize(1:2), imdsTrain);  
augImdsTest = augmentedImageDatastore(inputSize(1:2), imdsTest);
```

```
layer = "pool10";  
featuresTrain = activations(net, augImdsTrain, layer, OutputAs="rows");  
featuresTest = activations(net, augImdsTest, layer, OutputAs="rows");
```

Extract the class labels from the training and test data.

```
TTrain = imdsTrain.Labels;  
TTest = imdsTest.Labels;
```

### **Fit Image Classifier**

Use the features extracted from the training images as predictor variables and fit a multiclass support vector machine (SVM) using `fitcecoc` (Statistics and Machine Learning Toolbox).

```
mdl = fitcecoc(featuresTrain,TTrain);
```

### **Classify Test Images**

Classify the test images using the trained SVM model and the features extracted from the test images.

```
YPred = predict(mdl,featuresTest);
```

Display four sample test images with their predicted labels.

```
idx = [1 5 10 15];  
figure  
for i = 1:numel(idx)  
    subplot(2,2,i)  
    I = readimage(imdsTest,idx(i));  
    label = YPred(idx(i));  
  
    imshow(I)  
    title(label)  
end
```

**MathWorks Cap****MathWorks Cube****MathWorks Playing Cards****MathWorks Screwdriver**

Calculate the classification accuracy on the test set. Accuracy is the fraction of labels that the network predicts correctly.

```
accuracy = mean(YPred == TTest)
```

```
accuracy = 0.9500
```

This SVM has high accuracy. If the accuracy is not high enough using feature extraction, then try transfer learning instead.

## Output Arguments

**net** — Pretrained SqueezeNet convolutional neural network

DAGNetwork object

Pretrained SqueezeNet convolutional neural network, returned as a DAGNetwork object.

**lgraph** — Untrained SqueezeNet convolutional neural network architecture

LayerGraph object

Untrained SqueezeNet convolutional neural network architecture, returned as a LayerGraph object.

## Version History

Introduced in R2018a

## References

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

For code generation, load the network by passing the `squeezenet` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('squeezenet')`.

For more information, see "Load Pretrained Networks for Code Generation" (MATLAB Coder).

The syntax `squeezenet('Weights','none')` is not supported for code generation.

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- For code generation, you can load the network by using the syntax `net = squeezenet` or by passing the `squeezenet` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('squeezenet')`.

For more information, see "Load Pretrained Networks for Code Generation" (GPU Coder).

- The syntax `squeezenet('Weights','none')` is not supported for GPU code generation.

# stripdims

Remove darray data format

## Syntax

```
Y = stripdims(X)
```

## Description

`Y = stripdims(X)` returns the darray `X` without any dimension labels. `Y` is an unformatted darray.

## Examples

### Remove Data Format from darray

Create a formatted darray.

```
d1X = darray(randn(3,2,1,2), 'SSTU')
```

```
d1X =
    3(S) x 2(S) x 1(T) x 2(U) darray
```

```
(:,:,1,1) =
```

```
    0.5377    0.8622
    1.8339    0.3188
   -2.2588   -1.3077
```

```
(:,:,1,2) =
```

```
   -0.4336    2.7694
    0.3426   -1.3499
    3.5784    3.0349
```

Create an array that is the same as `d1X` but has no dimension labels.

```
y = stripdims(d1X)
```

```
y =
    3x2x1x2 darray
```

```
(:,:,1,1) =
```

```
    0.5377    0.8622
    1.8339    0.3188
   -2.2588   -1.3077
```

```
(:, :, 1, 2) =  
-0.4336    2.7694  
 0.3426   -1.3499  
 3.5784    3.0349
```

## Input Arguments

### **X** — Input data

`dLarray` object

Input data, specified as a formatted or unformatted `dLarray` object.

## Output Arguments

### **Y** — Unformatted `dLarray`

unformatted `dLarray` object

Unformatted `dLarray`, returned as an unformatted `dLarray` object that is the same as the input array `X`, but without any dimension labels. If `X` is unformatted, then `Y = X`.

## Tips

- Use `stripdims` to ensure that a `dLarray` behaves like a numeric array of the same size, without any special behavior due to dimension labels.
- `ndims(X)` can decrease after a `stripdims` call because the function removes trailing singleton dimensions.

```
X = dLarray(ones(3,2), 'SCB');  
ndims(X)
```

```
ans =
```

```
3
```

```
X = stripdims(X);  
ndims(X)
```

```
ans =
```

```
2
```

## summary

Print network summary

### Syntax

```
summary(net)
```

### Description

`summary(net)` prints a summary of the `dlnetwork` object `net`. The summary shows whether the network is initialized, the total number of learnable parameters, and information about the network inputs.

Network input summaries require or input layers or an initialized network. Network learnable parameter summaries require an initialized network.

### Examples

#### Print Network Summary

Load the `dlnetwork` object `net` from the `dlnetDigits` MAT file.

```
load dlnetDigits
```

Print the network summary using the `summary` function.

```
summary(net)

    Initialized: true

    Number of learnables: 84k

    Inputs:
      1 'in' 28x28x1 images
```

### Input Arguments

#### **net** — Neural network

`dlnetwork` object

Neural network, specified as a `dlnetwork` object.

# swishLayer

Swish layer

## Description

A swish activation layer applies the swish function on the layer inputs.

The swish operation is given by  $f(x) = \frac{x}{1 + e^{-x}}$ .

## Creation

### Syntax

```
layer = swishLayer  
layer = swishLayer('Name',Name)
```

### Description

`layer = swishLayer` creates a swish layer.

`layer = swishLayer('Name',Name)` creates a swish layer and sets the optional `Name` property using a name-value argument. For example, `swishLayer('Name','swish1')` creates a swish layer with the name 'swish1'.

## Properties

### Name — Layer name

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

### InputNames — Input names

{"in"} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: cell

### **NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: double

### **OutputNames — Output names**

{ 'out' } (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

## **Examples**

### **Create Swish Layer**

Create a swish layer with the name 'swish1'.

```
layer = swishLayer('Name','swish1')
```

```
layer =  
  SwishLayer with properties:
```

```
  Name: 'swish1'
```

```
  Learnable Parameters  
  No properties.
```

```
  State Parameters  
  No properties.
```

```
  Show all properties
```

Include a swish layer in a Layer array.

```
layers = [ ...  
  imageInputLayer([28 28 1])  
  convolution2dLayer(5,20)  
  batchNormalizationLayer  
  swishLayer  
  maxPooling2dLayer(2,'Stride',2)  
  fullyConnectedLayer(10)  
  softmaxLayer  
  classificationLayer]
```

```
layers =  
  8x1 Layer array with layers:
```

1	''	Image Input	28x28x1 images with 'zerocenter' normalization
2	''	2-D Convolution	20 5x5 convolutions with stride [1 1] and padding [0 0 0 0]
3	''	Batch Normalization	Batch normalization
4	''	Swish	Swish
5	''	2-D Max Pooling	2x2 max pooling with stride [2 2] and padding [0 0 0 0]
6	''	Fully Connected	10 fully connected layer
7	''	Softmax	softmax
8	''	Classification Output	crossentropyex

## Algorithms

### Swish Layer

A swish activation layer applies the swish function on the layer inputs. The swish operation is given by  $f(x) = \frac{x}{1 + e^{-x}}$ . The swish layer does not change the size of its input.

Activation layers such as swish layers improve the training accuracy for some applications and usually follow convolution and normalization layers. Other nonlinear activation layers perform different operations. For a list of activation layers, see "Activation Layers".

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

`SwishLayer` objects apply an element-wise operation and supports input data of any format. The layer and does not add or remove any dimensions, so it outputs data with the same format as its inputs.

# **tanhLayer**

Hyperbolic tangent (tanh) layer

## **Description**

A hyperbolic tangent (tanh) activation layer applies the tanh function on the layer inputs.

## **Creation**

### **Syntax**

```
layer = tanhLayer  
layer = tanhLayer('Name',Name)
```

### **Description**

`layer = tanhLayer` creates a hyperbolic tangent layer.

`layer = tanhLayer('Name',Name)` additionally specifies the optional `Name` property. For example, `tanhLayer('Name','tanh1')` creates a tanh layer with the name `'tanh1'`.

## **Properties**

### **Name — Layer name**

`''` (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name `''`.

Data Types: `char` | `string`

### **NumInputs — Number of inputs**

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

### **InputNames — Input names**

`{"in"}` (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: `cell`

**NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: double

**OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

**Examples****Create Hyperbolic Tangent Layer**

# taylorPrunableNetwork

Network that can be pruned by using first-order Taylor approximation

## Description

A `TaylorPrunableNetwork` object enables support for pruning of filters in convolution layers by using first-order Taylor approximation. To prune filters in a `dlnetwork` object, first convert it to a `TaylorPrunableNetwork` object and then use the associated object functions.

To prune a deep neural network, you require the Deep Learning Toolbox Model Quantization Library support package. This support package is a free add-on that you can download using the Add-On Explorer. Alternatively, see Deep Learning Toolbox Model Quantization Library.

## Creation

### Syntax

```
prunableNet = taylorPrunableNetwork(net)
prunableNet = taylorPrunableNetwork(layers)
```

### Description

`prunableNet = taylorPrunableNetwork(net)` converts a `dlnetwork` object `net` to a `TaylorPrunableNetwork` object. The latter is a different representation of the same network that is suitable for pruning by using the Taylor pruning algorithm. If the input network cannot be pruned, this function produces an error.

`prunableNet = taylorPrunableNetwork(layers)` converts the network layers specified in `layers` to a `TaylorPrunableNetwork` object that is suitable for pruning by using the Taylor pruning algorithm. The input `layers` must be a `LayerGraph` object or a `Layer` array that can be converted to a `dlnetwork` object.

### Input Arguments

#### **net** — Neural network

`dlnetwork` object

Neural network, specified as a `dlnetwork` object.

#### **layers** — Network layers

`LayerGraph` object | `Layer` array

Network layers, specified as a `layerGraph` object or as a `Layer` array.

## Properties

#### **Learnables** — Network learnable parameters

table

Network learnable parameters, specified as a table with three columns:

- `Layer` - Layer name, specified as a string scalar.
- `Parameter` - Parameter name, specified as a string scalar.
- `Value` - Value of parameter, specified as a `darray` object.

The network learnable parameters contain the features learned by the network. For example, the weights of convolution and fully connected layers.

Data Types: `table`

### **State — Network state**

`table`

Network state, specified as a table.

The network state is a table with three columns:

- `Layer` - Layer name, specified as a string scalar.
- `Parameter` - State parameter name, specified as a string scalar.
- `Value` - Value of state parameter, specified as a `darray` object.

Layer states contain information calculated during the layer operation to be retained for use in subsequent forward passes of the layer. For example, the cell state and hidden state of LSTM layers, or running statistics in batch normalization layers.

For recurrent layers, such as LSTM layers, with the `HasStateInputs` property set to 1 (true), the state table does not contain entries for the states of that layer.

During training or inference, you can update the network state using the output of the `forward` and `predict` functions.

Data Types: `table`

### **InputNames — Network input layer names**

`cell array of character vectors`

This property is read-only.

Network input layer names, specified as a cell array of character vectors.

Data Types: `cell`

### **OutputNames — Names of layers that return network outputs**

`cell array of character vectors | string array`

Names of layers that return network outputs, specified as a cell array of character vectors or a string array.

If you do not specify the output names, then the software sets the `OutputNames` property to the layers with disconnected outputs. If a layer has multiple outputs, then the disconnected outputs are specified as `'layerName/outputName'`.

The `predict` and `forward` functions, by default, return the data output by the layers given by the `OutputNames` property.

Data Types: cell | string

### **NumPrunables** — Number of convolution layer filters that are suitable for pruning

nonnegative integer

Number of convolution layer filters in the network that are suitable for pruning by using first-order Taylor approximation, specified as a nonnegative integer.

## **Object Functions**

forward	Compute deep learning network output for training
predict	Compute deep learning network output for inference
updatePrunables	Remove filters from prunable layers based on importance scores
updateScore	Compute and accumulate Taylor-based importance scores for pruning
dlnetwork	Deep learning network for custom training loops

## **Examples**

### **Prune dlnetwork Object to Compress the Model**

This example shows how to prune a dlnetwork object by using a custom pruning loop.

#### **Load dlnetwork Object**

Load a trained dlnetwork object and the corresponding classes.

```
s = load("digitsCustom.mat");  
dlnet_1 = s.dlnet;  
classes = s.classes;
```

Inspect the layers of the dlnetwork object. The network has three convolution layers at locations 2, 5, and 8 of the Layer array.

```
layers_1 = dlnet_1.Layers
```

```
layers_1 =
```

```
12x1 Layer array with layers:
```

1	'input'	Image Input	28x28x1 images with 'zerocenter' normalization
2	'conv1'	2-D Convolution	20 5x5x1 convolutions with stride [1 1] and padding
3	'bn1'	Batch Normalization	Batch normalization with 20 channels
4	'relu1'	ReLU	ReLU
5	'conv2'	2-D Convolution	20 3x3x20 convolutions with stride [1 1] and padding
6	'bn2'	Batch Normalization	Batch normalization with 20 channels
7	'relu2'	ReLU	ReLU
8	'conv3'	2-D Convolution	20 3x3x20 convolutions with stride [1 1] and padding
9	'bn3'	Batch Normalization	Batch normalization with 20 channels
10	'relu3'	ReLU	ReLU
11	'fc'	Fully Connected	10 fully connected layer
12	'softmax'	Softmax	softmax

#### **Load Data for Prediction**

Load the digits data for prediction.

```
dataFolder = fullfile(toolboxdir("nnet"), "ndemos", "nndatasets", "DigitDataset");
```

```

imds = imageDatastore(dataFolder, ...
    IncludeSubfolders=true, ...
    LabelSource="foldernames");

```

Partition the data into pruning and validation sets. Set aside 10% of the data for validation using the `splitEachLabel` function.

```

[imdsPrune,imdsValidation] = splitEachLabel(imds,0.9,"randomize");

```

The network used in this example requires input images of size 28-by-28-by-1. To automatically resize the images, use augmented image datastores.

```

inputSize = [28 28 1];
augimdsPrune = augmentedImageDatastore(inputSize(1:2),imdsPrune);
augimdsValidation = augmentedImageDatastore(inputSize(1:2),imdsValidation);

```

### Prune dlnetwork Object

Convert the `dlnetwork` object to a representation that is suitable for pruning by using the `taylorPrunableNetwork` function. This function returns a `TaylorPrunableNetwork` object that has the `NumPrunables` property set to 48. This indicates that 48 filters in the original model are suitable for pruning by using the Taylor pruning algorithm.

```

prunableNet_1 = taylorPrunableNetwork(dlnet_1)

```

```

prunableNet_1 =
    TaylorPrunableNetwork with properties:

        Learnables: [14x3 table]
           State: [6x3 table]
    InputNames: {'input'}
    OutputNames: {'softmax'}
    NumPrunables: 48

```

Create a `minibatchqueue` object that processes and manages mini-batches of images during pruning. For each mini-batch:

- Use the custom mini-batch preprocessing function `preprocessMiniBatch` (defined at the end of this example) to convert the labels to one-hot encoded variables.
- Format the image data with the dimension labels "SSCB" (spatial, spatial, channel, batch). By default, the `minibatchqueue` object converts the data to `dlarray` objects with underlying type `single`. Do not format the class labels.
- Train on a GPU if one is available. By default, the `minibatchqueue` object converts each output to a `gpuArray` if a GPU is available. Using a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see "GPU Computing Requirements" (Parallel Computing Toolbox).

```

miniBatchSize = 128;
imds.ReadSize = miniBatchSize;

mbq = minibatchqueue(augimdsPrune, ...
    MiniBatchSize=miniBatchSize, ...
    MiniBatchFcn=@preprocessMiniBatch, ...
    MiniBatchFormat=["SSCB" ""]);

```

Calculate Taylor-based importance scores of the prunable filters in the network by looping over the mini-batches of data. For each mini-batch:

- Calculate pruning activations and pruning gradients by using the `modelLoss` function defined at the end of this example
- Update importance scores of the prunable filters by using the `updateScore` function

```
while hasdata(mbq)
    [X,T] = next(mbq);
    [~,pruningActivations,pruningGradients] = dlfeval(@modelLoss,prunableNet_1,X,T);
    prunableNet_1 = updateScore(prunableNet_1,pruningActivations,pruningGradients);
end
```

Finally, remove filters with the lowest importance scores to create a new `TaylorPrunableNetwork` object by using the `updatePrunables` function. By default, a single call to this function removes 8 filters. Observe that the new network `prunableNet_2` has 40 prunable filters remaining.

```
prunableNet_2 = updatePrunables(prunableNet_1)
```

```
prunableNet_2 =
    TaylorPrunableNetwork with properties:
```

```
    Learnables: [14x3 table]
        State: [6x3 table]
    InputNames: {'input'}
    OutputNames: {'softmax'}
    NumPrunables: 40
```

To further compress the model, run the custom pruning loop and update prunables again.

### Extract Pruned `dlnetwork` Object

Use the `dlnetwork` function to extract the pruned `dlnetwork` object from the pruned `TaylorPrunableNetwork` object. You can now use this compressed `dlnetwork` object to perform inference.

```
dlnet_2 = dlnetwork(prunableNet_2);
```

Compare the convolution layers of the original and the pruned `dlnetwork` objects. Observe that the three convolution layers in the pruned network have fewer filters. These counts agree with the fact that, by default, a single call to the `updatePrunables` function removes 8 filters from the network.

```
conv_layers_1 = dlnet_1.Layers([2 5 8])
```

```
conv_layers_1 =
    3x1 Convolution2DLayer array with layers:
```

```
    1 'conv1' 2-D Convolution 20 5x5x1 convolutions with stride [1 1] and padding [0 0]
    2 'conv2' 2-D Convolution 20 3x3x20 convolutions with stride [1 1] and padding [1 1]
    3 'conv3' 2-D Convolution 20 3x3x20 convolutions with stride [1 1] and padding [1 1]
```

```
conv_layers_2 = dlnet_2.Layers([2 5 8])
```

```
conv_layers_2 =
    3x1 Convolution2DLayer array with layers:
```

```
    1 'conv1' 2-D Convolution 17 5x5x1 convolutions with stride [1 1] and padding [0 0]
```

```

2 'conv2' 2-D Convolution 18 3x3x17 convolutions with stride [1 1] and padding [1 1]
3 'conv3' 2-D Convolution 17 3x3x18 convolutions with stride [1 1] and padding [1 1]

```

## Supporting Functions

### Model Loss Function

The `modelLoss` function takes a `TaylorPrunableNetwork` object `net`, a mini-batch of input data `X` with corresponding targets `T` and returns activations in `net` and the gradients of the loss with respect to the activations in `net`. To compute the gradients automatically, this function uses the `dlgradient` function.

```

function [loss, pruningActivations, pruningGradients] = modelLoss(net,X,T)

% Calculate network output for training.
[out, ~, pruningActivations] = forward(net,X);

% Calculate loss.
loss = crossentropy(out,T);

% Compute pruning gradients.
pruningGradients = dlgradient(loss,pruningActivations);
end

```

### Mini Batch Preprocessing Function

The `preprocessMiniBatch` function preprocesses a mini-batch of predictors and labels using the following steps:

- 1 Preprocess the images using the `preprocessMiniBatchPredictors` function.
- 2 Extract the label data from the incoming cell array and concatenate into a categorical array along the second dimension.
- 3 One-hot encode the categorical labels into numeric arrays. Encoding into the first dimension produces an encoded array that matches the shape of the network output.

```

function [X,T] = preprocessMiniBatch(dataX,dataT)

% Preprocess predictors.
X = preprocessMiniBatchPredictors(dataX);

% Extract label data from cell and concatenate.
T = cat(2,dataT{1:end});

% One-hot encode labels.
T = onehotencode(T,1);

end

```

### Mini-Batch Predictors Preprocessing Function

The `preprocessMiniBatchPredictors` function preprocesses a mini-batch of predictors by extracting the image data from the input cell array and concatenating into a numeric array. For grayscale input, concatenating over the fourth dimension adds a third dimension to each image, to use as a singleton channel dimension.

```

function X = preprocessMiniBatchPredictors(dataX)

```

```
% Concatenate.  
X = cat(4,dataX{1:end});  
  
% Normalize the images.  
X = X/255;  
  
end
```

## More About

### Layers Supported for Pruning

The Taylor pruning algorithm prunes filters from `convolution2dLayer` objects. Pruning convolutional filters can also reduce the number of learnable parameters in downstream layers, for example:

- `batchNormalizationLayer`
- `fullyConnectedLayer`
- `groupedConvolution2dLayer`
- `transposedConv2dLayer`

### Effect of Network Architecture on Pruning

For certain network architectures, data dependency between the prunable layers and other layers in the network might prevent pruning of filters. These are some example architectures that exhibit this behavior:

- Your network has a `convolution2dLayer`, a `groupNormalizationLayer` and another `convolution2dLayer` connected in sequence. The presence of the group normalization layer prevents pruning of filters of the first convolution layer, because doing so changes the shape of the input channels of the group normalization layer.
- Your network has a 2-D convolution layer, a softmax layer, and an output layer connected in sequence. This architecture prevents pruning of filters of the convolution layer because doing so changes the output size of the network.

## Algorithms

For an individual input data point in the pruning dataset, you use the `forward` function to calculate the output of the deep learning network and the activations of the prunable filters. Then you calculate the gradients of the loss with respect to these activations using automatic differentiation. You then pass the network, the activations, and the gradients to the `updateScore` function. For each prunable filter in the network, the `updateScore` function calculates the change in loss that occurs if that filter is pruned from the network (up to first-order Taylor approximation). Based on this change, the function associates an importance score with that filter and updates the `TaylorPrunableNetwork` object [1].

Inside the custom pruning loop, you accumulate importance scores for the prunable filters over all mini-batches of the pruning dataset. Then you pass the network object to the `updatePrunables` function. This function prunes the filters that have the lowest importance scores and hence have the smallest effect on the accuracy of the network output. The number of filters that a single call to the `updatePrunables` function prunes is determined by the optional name-value argument `MaxToPrune`, that has a default value of 8.

All these steps complete a single pruning iteration. To further compress your model, repeat these steps multiple times over a loop.

## Version History

Introduced in R2022a

## trainingOptions

Options for training deep learning neural network

### Syntax

```
options = trainingOptions(solverName)
options = trainingOptions(solverName,Name=Value)
```

### Description

`options = trainingOptions(solverName)` returns training options for the optimizer specified by `solverName`. To train a neural network, use the training options as an input argument to the `trainNetwork` function.

`options = trainingOptions(solverName,Name=Value)` returns training options with additional options specified by one or more name-value arguments.

### Examples

#### Specify Training Options

Create a set of options for training a network using stochastic gradient descent with momentum. Reduce the learning rate by a factor of 0.2 every 5 epochs. Set the maximum number of epochs for training to 20, and use a mini-batch with 64 observations at each iteration. Turn on the training progress plot.

```
options = trainingOptions("sgdm", ...
    LearnRateSchedule="piecewise", ...
    LearnRateDropFactor=0.2, ...
    LearnRateDropPeriod=5, ...
    MaxEpochs=20, ...
    MiniBatchSize=64, ...
    Plots="training-progress")

options =
    TrainingOptionsSGDM with properties:

        Momentum: 0.9000
        InitialLearnRate: 0.0100
        LearnRateSchedule: 'piecewise'
        LearnRateDropFactor: 0.2000
        LearnRateDropPeriod: 5
        L2Regularization: 1.0000e-04
        GradientThresholdMethod: 'l2norm'
        GradientThreshold: Inf
        MaxEpochs: 20
        MiniBatchSize: 64
        Verbose: 1
        VerboseFrequency: 50
        ValidationData: []
```

```

ValidationFrequency: 50
ValidationPatience: Inf
    Shuffle: 'once'
CheckpointPath: ''
CheckpointFrequency: 1
CheckpointFrequencyUnit: 'epoch'
ExecutionEnvironment: 'auto'
WorkerLoad: []
OutputFcn: []
    Plots: 'training-progress'
SequenceLength: 'longest'
SequencePaddingValue: 0
SequencePaddingDirection: 'right'
DispatchInBackground: 0
ResetInputNormalization: 1
BatchNormalizationStatistics: 'population'
OutputNetwork: 'last-iteration'

```

## Monitor Deep Learning Training Progress

This example shows how to monitor the training process of deep learning networks.

When you train networks for deep learning, it is often useful to monitor the training progress. By plotting various metrics during training, you can learn how the training is progressing. For example, you can determine if and how quickly the network accuracy is improving, and whether the network is starting to overfit the training data.

This example shows how to monitor training progress for networks trained using the `trainNetwork` function. For networks trained using a custom training loop, use a `trainingProgressMonitor` object to plot metrics during training. For more information, see “Monitor Custom Training Loop Progress”.

When you set the `Plots` training option to “training-progress” in `trainingOptions` and start network training, `trainNetwork` creates a figure and displays training metrics at every iteration. Each iteration is an estimation of the gradient and an update of the network parameters. If you specify validation data in `trainingOptions`, then the figure shows validation metrics each time `trainNetwork` validates the network. The figure plots the following:

- **Training accuracy** — Classification accuracy on each individual mini-batch.
- **Smoothed training accuracy** — Smoothed training accuracy, obtained by applying a smoothing algorithm to the training accuracy. It is less noisy than the unsmoothed accuracy, making it easier to spot trends.
- **Validation accuracy** — Classification accuracy on the entire validation set (specified using `trainingOptions`).
- **Training loss, smoothed training loss, and validation loss** — The loss on each mini-batch, its smoothed version, and the loss on the validation set, respectively. If the final layer of your network is a `classificationLayer`, then the loss function is the cross entropy loss. For more information about loss functions for classification and regression problems, see “Output Layers”.

For regression networks, the figure plots the root mean square error (RMSE) instead of the accuracy.

The figure marks each training **Epoch** using a shaded background. An epoch is a full pass through the entire data set.

During training, you can stop training and return the current state of the network by clicking the stop button in the top-right corner. For example, you might want to stop training when the accuracy of the network reaches a plateau and it is clear that the accuracy is no longer improving. After you click the stop button, it can take a while for the training to complete. Once training is complete, `trainNetwork` returns the trained network.

When training finishes, view the **Results** showing the finalized validation accuracy and the reason that training finished. If the `OutputNetwork` training option is "last-iteration" (default), the finalized metrics correspond to the last training iteration. If the `OutputNetwork` training option is "best-validation-loss", the finalized metrics correspond to the iteration with the lowest validation loss. The iteration from which the final validation metrics are calculated is labeled **Final** in the plots.

If your network contains batch normalization layers, then the final validation metrics can be different to the validation metrics evaluated during training. This is because the mean and variance statistics used for batch normalization can be different after training completes. For example, if the `BatchNormalizationStatistics` training option is "population", then after training, the software finalizes the batch normalization statistics by passing through the training data once more and uses the resulting mean and variance. If the `BatchNormalizationStatistics` training option is "moving", then the software approximates the statistics during training using a running estimate and uses the latest values of the statistics.

On the right, view information about the training time and settings. To learn more about training options, see "Set Up Parameters and Train Convolutional Neural Network".

To save the training progress plot, click **Export Training Plot** in the training window. You can save the plot as a PNG, JPEG, TIFF, or PDF file. You can also save the individual plots of loss, accuracy, and root mean squared error using the axes toolbar.

## Plot Training Progress During Training

Train a network and plot the training progress during training.

Load the training data, which contains 5000 images of digits. Set aside 1000 of the images for network validation.

```
[XTrain,YTrain] = digitTrain4DArrayData;
```

```
idx = randperm(size(XTrain,4),1000);
XValidation = XTrain(:,:,,idx);
XTrain(:,:,,idx) = [];
YValidation = YTrain(idx);
YTrain(idx) = [];
```

Construct a network to classify the digit image data.

```
layers = [
    imageInputLayer([28 28 1])
    convolution2dLayer(3,8,Padding="same")
    batchNormalizationLayer
    reluLayer
    maxPooling2dLayer(2,Stride=2)
    convolution2dLayer(3,16,Padding="same")
    batchNormalizationLayer
    reluLayer
    maxPooling2dLayer(2,Stride=2)
    convolution2dLayer(3,32,Padding="same")
```

```
batchNormalizationLayer  
reluLayer  
fullyConnectedLayer(10)  
softmaxLayer  
classificationLayer];
```

Specify options for network training. To validate the network at regular intervals during training, specify validation data. Choose the `ValidationFrequency` value so that the network is validated about once per epoch. To plot training progress during training, set the `Plots` training option to "training-progress".

```
options = trainingOptions("sgdm", ...  
    MaxEpochs=8, ...  
    ValidationData={XValidation,YValidation}, ...  
    ValidationFrequency=30, ...  
    Verbose=false, ...  
    Plots="training-progress");
```

Train the network.

```
net = trainNetwork(XTrain,YTrain,layers,options);
```

## Input Arguments

### `solverName` — Solver for training neural network

`'sgdm' | 'rmsprop' | 'adam'`

Solver for training neural network, specified as one of the following:

- 'sgdm' — Use the stochastic gradient descent with momentum (SGDM) optimizer. You can specify the momentum value using the `Momentum` training option.
- 'rmsprop' — Use the RMSProp optimizer. You can specify the decay rate of the squared gradient moving average using the `SquaredGradientDecayFactor` training option.
- 'adam' — Use the Adam optimizer. You can specify the decay rates of the gradient and squared gradient moving averages using the `GradientDecayFactor` and `SquaredGradientDecayFactor` training options, respectively.

For more information about the different solvers, see “Stochastic Gradient Descent” on page 1-1782.

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example:

`InitialLearnRate=0.03,L2Regularization=0.0005,LearnRateSchedule="piecewise"` specifies the initial learning rate as 0.03 and the  $L_2$  regularization factor as 0.0005, and instructs the software to drop the learning rate every given number of epochs by multiplying with a certain factor.

## Plots and Display

### Plots — Plots to display during neural network training

'none' (default) | 'training-progress'

Plots to display during neural network training, specified as one of the following:

- 'none' — Do not display plots during training.
- 'training-progress' — Plot training progress. The plot shows mini-batch loss and accuracy, validation loss and accuracy, and additional information on the training progress. The plot has a stop button  in the top-right corner. Click the button to stop training and return the current state of the neural network. You can save the training plot as an image or PDF by clicking **Export Training Plot**. For more information on the training progress plot, see “Monitor Deep Learning Training Progress”.

### Verbose — Indicator to display training progress information

1 (true) (default) | 0 (false)

Indicator to display training progress information in the command window, specified as 1 (true) or 0 (false).

The verbose output displays the following information:

**Classification Neural Networks**

<b>Field</b>	<b>Description</b>
Epoch	Epoch number. An epoch corresponds to a full pass of the data.
Iteration	Iteration number. An iteration corresponds to a mini-batch.
Time Elapsed	Time elapsed in hours, minutes, and seconds.
Mini-batch Accuracy	Classification accuracy on the mini-batch.
Validation Accuracy	Classification accuracy on the validation data. If you do not specify validation data, then the function does not display this field.
Mini-batch Loss	Loss on the mini-batch. If the output layer is a <code>ClassificationOutputLayer</code> object, then the loss is the cross entropy loss for multi-class classification problems with mutually exclusive classes.
Validation Loss	Loss on the validation data. If the output layer is a <code>ClassificationOutputLayer</code> object, then the loss is the cross entropy loss for multi-class classification problems with mutually exclusive classes. If you do not specify validation data, then the function does not display this field.
Base Learning Rate	Base learning rate. The software multiplies the learn rate factors of the layers by this value.

**Regression Neural Networks**

Field	Description
Epoch	Epoch number. An epoch corresponds to a full pass of the data.
Iteration	Iteration number. An iteration corresponds to a mini-batch.
Time Elapsed	Time elapsed in hours, minutes, and seconds.
Mini-batch RMSE	Root-mean-squared-error (RMSE) on the mini-batch.
Validation RMSE	RMSE on the validation data. If you do not specify validation data, then the software does not display this field.
Mini-batch Loss	Loss on the mini-batch. If the output layer is a <code>RegressionOutputLayer</code> object, then the loss is the half-mean-squared-error.
Validation Loss	Loss on the validation data. If the output layer is a <code>RegressionOutputLayer</code> object, then the loss is the half-mean-squared-error. If you do not specify validation data, then the software does not display this field.
Base Learning Rate	Base learning rate. The software multiplies the learn rate factors of the layers by this value.

When training stops, the verbose output displays the reason for stopping.

To specify validation data, use the `ValidationData` training option.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**VerboseFrequency — Frequency of verbose printing**

50 (default) | positive integer

Frequency of verbose printing, which is the number of iterations between printing to the command window, specified as a positive integer. This option only has an effect when the `Verbose` training option is 1 (true).

If you validate the neural network during training, then `trainNetwork` also prints to the command window every time validation occurs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Mini-Batch Options****MaxEpochs — Maximum number of epochs**

30 (default) | positive integer

Maximum number of epochs to use for training, specified as a positive integer.

An iteration is one step taken in the gradient descent algorithm towards minimizing the loss function using a mini-batch. An epoch is the full pass of the training algorithm over the entire training set.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **MiniBatchSize — Size of mini-batch**

128 (default) | positive integer

Size of the mini-batch to use for each training iteration, specified as a positive integer. A mini-batch is a subset of the training set that is used to evaluate the gradient of the loss function and update the weights.

If the mini-batch size does not evenly divide the number of training samples, then `trainNetwork` discards the training data that does not fit into the final complete mini-batch of each epoch.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Shuffle — Option for data shuffling**

'once' (default) | 'never' | 'every-epoch'

Option for data shuffling, specified as one of the following:

- 'once' — Shuffle the training and validation data once before training.
- 'never' — Do not shuffle the data.
- 'every-epoch' — Shuffle the training data before each training epoch, and shuffle the validation data before each neural network validation. If the mini-batch size does not evenly divide the number of training samples, then `trainNetwork` discards the training data that does not fit into the final complete mini-batch of each epoch. To avoid discarding the same data every epoch, set the `Shuffle` training option to 'every-epoch'.

## **Validation**

### **ValidationData — Data to use for validation during training**

[] (default) | datastore | table | cell array

Data to use for validation during training, specified as [], a datastore, a table, or a cell array containing the validation predictors and responses.

You can specify validation predictors and responses using the same formats supported by the `trainNetwork` function. You can specify the validation data as a datastore, table, or the cell array {`predictors`, `responses`}, where `predictors` contains the validation predictors and `responses` contains the validation responses.

For more information, see the `images`, `sequences`, and `features` input arguments of the `trainNetwork` function.

During training, `trainNetwork` calculates the validation accuracy and validation loss on the validation data. To specify the validation frequency, use the `ValidationFrequency` training option. You can also use the validation data to stop training automatically when the validation loss stops decreasing. To turn on automatic validation stopping, use the `ValidationPatience` training option.

If your neural network has layers that behave differently during prediction than during training (for example, dropout layers), then the validation accuracy can be higher than the training (mini-batch) accuracy.

The validation data is shuffled according to the `Shuffle` training option. If `Shuffle` is 'every-epoch', then the validation data is shuffled before each neural network validation.

If `ValidationData` is `[]`, then the software does not validate the neural network during training.

**ValidationFrequency — Frequency of neural network validation**

50 (default) | positive integer

Frequency of neural network validation in number of iterations, specified as a positive integer.

The `ValidationFrequency` value is the number of iterations between evaluations of validation metrics. To specify validation data, use the `ValidationData` training option.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ValidationPatience — Patience of validation stopping**

Inf (default) | positive integer

Patience of validation stopping of neural network training, specified as a positive integer or `Inf`.

`ValidationPatience` specifies the number of times that the loss on the validation set can be larger than or equal to the previously smallest loss before neural network training stops. If `ValidationPatience` is `Inf`, then the values of the validation loss do not cause training to stop early.

The returned neural network depends on the `OutputNetwork` training option. To return the neural network with the lowest validation loss, set the `OutputNetwork` training option to `"best-validation-loss"`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**OutputNetwork — Neural network to return when training completes**

'last-iteration' (default) | 'best-validation-loss'

Neural network to return when training completes, specified as one of the following:

- `'last-iteration'` - Return the neural network corresponding to the last training iteration.
- `'best-validation-loss'` - Return the neural network corresponding to the training iteration with the lowest validation loss. To use this option, you must specify the `ValidationData` training option.

**Solver Options****InitialLearnRate — Initial learning rate**

positive scalar

Initial learning rate used for training, specified as a positive scalar.

The default value is `0.01` for the `'sgdm'` solver and `0.001` for the `'rmsprop'` and `'adam'` solvers.

If the learning rate is too low, then training can take a long time. If the learning rate is too high, then training might reach a suboptimal result or diverge.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**LearnRateSchedule — Option for dropping learning rate during training**

'none' (default) | 'piecewise'

Option for dropping the learning rate during training, specified as of the following:

- 'none' — The learning rate remains constant throughout training.
- 'piecewise' — The software updates the learning rate every certain number of epochs by multiplying with a certain factor. Use the `LearnRateDropFactor` training option to specify the value of this factor. Use the `LearnRateDropPeriod` training option to specify the number of epochs between multiplications.

### **LearnRateDropPeriod — Number of epochs for dropping the learning rate**

10 (default) | positive integer

Number of epochs for dropping the learning rate, specified as a positive integer. This option is valid only when the `LearnRateSchedule` training option is 'piecewise'.

The software multiplies the global learning rate with the drop factor every time the specified number of epochs passes. Specify the drop factor using the `LearnRateDropFactor` training option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **LearnRateDropFactor — Factor for dropping the learning rate**

0.1 (default) | scalar from 0 to 1

Factor for dropping the learning rate, specified as a scalar from 0 to 1. This option is valid only when the `LearnRateSchedule` training option is 'piecewise'.

`LearnRateDropFactor` is a multiplicative factor to apply to the learning rate every time a certain number of epochs passes. Specify the number of epochs using the `LearnRateDropPeriod` training option.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **L2Regularization — Factor for L<sub>2</sub> regularization**

0.0001 (default) | nonnegative scalar

Factor for L<sub>2</sub> regularization (weight decay), specified as a nonnegative scalar. For more information, see “L2 Regularization” on page 1-1785.

You can specify a multiplier for the L<sub>2</sub> regularization for neural network layers with learnable parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Momentum — Contribution of previous step**

0.9 (default) | scalar from 0 to 1

Contribution of the parameter update step of the previous iteration to the current iteration of stochastic gradient descent with momentum, specified as a scalar from 0 to 1.

A value of 0 means no contribution from the previous step, whereas a value of 1 means maximal contribution from the previous step. The default value works well for most tasks.

To specify the `Momentum` training option, `solverName` must be 'sgdm'.

For more information, see “Stochastic Gradient Descent with Momentum” on page 1-1783.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**GradientDecayFactor — Decay rate of gradient moving average**

0.9 (default) | nonnegative scalar less than 1

Decay rate of gradient moving average for the Adam solver, specified as a nonnegative scalar less than 1. The gradient decay rate is denoted by  $\beta_1$  in the “Adam” on page 1-1784 section.

To specify the GradientDecayFactor training option, solverName must be 'adam'.

The default value works well for most tasks.

For more information, see “Adam” on page 1-1784.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**SquaredGradientDecayFactor — Decay rate of squared gradient moving average**

nonnegative scalar less than 1

Decay rate of squared gradient moving average for the Adam and RMSProp solvers, specified as a nonnegative scalar less than 1. The squared gradient decay rate is denoted by  $\beta_2$  in [4].

To specify the SquaredGradientDecayFactor training option, solverName must be 'adam' or 'rmsprop'.

Typical values of the decay rate are 0.9, 0.99, and 0.999, corresponding to averaging lengths of 10, 100, and 1000 parameter updates, respectively.

The default value is 0.999 for the Adam solver. The default value is 0.9 for the RMSProp solver.

For more information, see “Adam” on page 1-1784 and “RMSProp” on page 1-1783.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Epsilon — Denominator offset**

1e-8 (default) | positive scalar

Denominator offset for Adam and RMSProp solvers, specified as a positive scalar.

The solver adds the offset to the denominator in the neural network parameter updates to avoid division by zero. The default value works well for most tasks.

To specify the Epsilon training option, solverName must be 'adam' or 'rmsprop'.

For more information, see “Adam” on page 1-1784 and “RMSProp” on page 1-1783.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**ResetInputNormalization — Option to reset input layer normalization**

1 (true) (default) | 0 (false)

Option to reset input layer normalization, specified as one of the following:

- 1 (true) — Reset the input layer normalization statistics and recalculate them at training time.
- 0 (false) — Calculate normalization statistics at training time when they are empty.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### BatchNormalizationStatistics — Mode to evaluate statistics in batch normalization layers

'population' (default) | 'moving'

Mode to evaluate the statistics in batch normalization layers, specified as one of the following:

- 'population' - Use the population statistics. After training, the software finalizes the statistics by passing through the training data once more and uses the resulting mean and variance.
- 'moving' - Approximate the statistics during training using a running estimate given by update steps

$$\mu^* = \lambda_\mu \widehat{\mu} + (1 - \lambda_\mu)\mu$$

$$\sigma^{2*} = \lambda_{\sigma^2} \widehat{\sigma^2} + (1 - \lambda_{\sigma^2})\sigma^2$$

where  $\mu^*$  and  $\sigma^{2*}$  denote the updated mean and variance, respectively,  $\lambda_\mu$  and  $\lambda_{\sigma^2}$  denote the mean and variance decay values, respectively,  $\widehat{\mu}$  and  $\widehat{\sigma^2}$  denote the mean and variance of the layer input, respectively, and  $\mu$  and  $\sigma^2$  denote the latest values of the moving mean and variance values, respectively. After training, the software uses the most recent value of the moving mean and variance statistics. This option supports CPU and single GPU training only.

### Gradient Clipping

#### GradientThreshold — Gradient threshold

Inf (default) | positive scalar

Gradient threshold, specified as Inf or a positive scalar. If the gradient exceeds the value of GradientThreshold, then the gradient is clipped according to the GradientThresholdMethod training option.

For more information, see Gradient Clipping on page 1-1784.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### GradientThresholdMethod — Gradient threshold method

'l2norm' (default) | 'global-l2norm' | 'absolute-value'

Gradient threshold method used to clip gradient values that exceed the gradient threshold, specified as one of the following:

- 'l2norm' — If the  $L_2$  norm of the gradient of a learnable parameter is larger than GradientThreshold, then scale the gradient so that the  $L_2$  norm equals GradientThreshold.
- 'global-l2norm' — If the global  $L_2$  norm,  $L$ , is larger than GradientThreshold, then scale all gradients by a factor of GradientThreshold/ $L$ . The global  $L_2$  norm considers all learnable parameters.
- 'absolute-value' — If the absolute value of an individual partial derivative in the gradient of a learnable parameter is larger than GradientThreshold, then scale the partial derivative to have magnitude equal to GradientThreshold and retain the sign of the partial derivative.

For more information, see Gradient Clipping on page 1-1784.

## Sequence Options

### SequenceLength — Option to pad or truncate sequences

"longest" (default) | "shortest" | positive integer

Option to pad, truncate, or split input sequences, specified as one of the following:

- "longest" — Pad sequences in each mini-batch to have the same length as the longest sequence. This option does not discard any data, though padding can introduce noise to the neural network.
- "shortest" — Truncate sequences in each mini-batch to have the same length as the shortest sequence. This option ensures that no padding is added, at the cost of discarding data.
- Positive integer — For each mini-batch, pad the sequences to the length of the longest sequence in the mini-batch, and then split the sequences into smaller sequences of the specified length. If splitting occurs, then the software creates extra mini-batches. If the specified sequence length does not evenly divide the sequence lengths of the data, then the mini-batches containing the ends of those sequences have length shorter than the specified sequence length. Use this option if the full sequences do not fit in memory. Alternatively, try reducing the number of sequences per mini-batch by setting the `MiniBatchSize` option to a lower value.

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### SequencePaddingDirection — Direction of padding or truncation

"right" (default) | "left"

Direction of padding or truncation, specified as one of the following:

- "right" — Pad or truncate sequences on the right. The sequences start at the same time step and the software truncates or adds padding to the end of the sequences.
- "left" — Pad or truncate sequences on the left. The software truncates or adds padding to the start of the sequences so that the sequences end at the same time step.

Because recurrent layers process sequence data one time step at a time, when the recurrent layer `OutputMode` property is 'last', any padding in the final time steps can negatively influence the layer output. To pad or truncate sequence data on the left, set the `SequencePaddingDirection` option to "left".

For sequence-to-sequence neural networks (when the `OutputMode` property is 'sequence' for each recurrent layer), any padding in the first time steps can negatively influence the predictions for the earlier time steps. To pad or truncate sequence data on the right, set the `SequencePaddingDirection` option to "right".

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

### SequencePaddingValue — Value to pad sequences

0 (default) | scalar

Value by which to pad input sequences, specified as a scalar.

The option is valid only when `SequenceLength` is "longest" or a positive integer. Do not pad sequences with NaN, because doing so can propagate errors throughout the neural network.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Hardware Options

### ExecutionEnvironment — Hardware resource for training neural network

`'auto'` (default) | `'cpu'` | `'gpu'` | `'multi-gpu'` | `'parallel'`

Hardware resource for training neural network, specified as one of the following:

- `'auto'` — Use a GPU if one is available. Otherwise, use the CPU.
- `'cpu'` — Use the CPU.
- `'gpu'` — Use the GPU.
- `'multi-gpu'` — Use multiple GPUs on one machine, using a local parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts a parallel pool with pool size equal to the number of available GPUs.
- `'parallel'` — Use a local or remote parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts one using the default cluster profile. If the pool has access to GPUs, then only workers with a unique GPU perform training computation. If the pool does not have GPUs, then training takes place on all available CPU workers instead.

For more information on when to use the different execution environments, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud”.

`'gpu'`, `'multi-gpu'`, and `'parallel'` options require Parallel Computing Toolbox. To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). If you choose one of these options and Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.

To see an improvement in performance when training in parallel, try scaling up the `MiniBatchSize` and `InitialLearnRate` training options by the number of GPUs.

The `'multi-gpu'` and `'parallel'` options do not support neural networks containing custom layers with state parameters or built-in layers that are stateful at training time. For example:

- recurrent layers such as `LSTMlayer`, `BiLSTMlayer`, or `GRUlayer` objects when the `SequenceLength` training option is a positive integer
- `BatchNormalizationLayer` objects when the `BatchNormalizationStatistics` training option is set to `'moving'`

### WorkerLoad — Parallel worker load division

scalar from 0 to 1 | positive integer | numeric vector

Parallel worker load division between GPUs or CPUs, specified as one of the following:

- Scalar from 0 to 1 — Fraction of workers on each machine to use for neural network training computation. If you train the neural network using data in a mini-batch datastore with background dispatch enabled, then the remaining workers fetch and preprocess data in the background.
- Positive integer — Number of workers on each machine to use for neural network training computation. If you train the neural network using data in a mini-batch datastore with background dispatch enabled, then the remaining workers fetch and preprocess data in the background.
- Numeric vector — Neural network training load for each worker in the parallel pool. For a vector  $W$ , worker  $i$  gets a fraction  $W(i)/\text{sum}(W)$  of the work (number of examples per mini-batch). If you

train a neural network using data in a mini-batch datastore with background dispatch enabled, then you can assign a worker load of 0 to use that worker for fetching data in the background. The specified vector must contain one value per worker in the parallel pool.

If the parallel pool has access to GPUs, then workers without a unique GPU are never used for training computation. The default for pools with GPUs is to use all workers with a unique GPU for training computation, and the remaining workers for background dispatch. If the pool does not have access to GPUs and CPUs are used for training, then the default is to use one worker per machine for background data dispatch.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DispatchInBackground — Flag to enable background dispatch**

0 (false) (default) | 1 (true)

Flag to enable background dispatch (asynchronous prefetch queuing) to read training data from datastores, specified as 0 (false) or 1 (true). Background dispatch requires Parallel Computing Toolbox.

`DispatchInBackground` is only supported for datastores that are partitionable. For more information, see “Use Datastore for Parallel Training and Background Dispatching”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Checkpoints**

#### **CheckpointPath — Path for saving checkpoint neural networks**

"" (default) | character vector

Path for saving the checkpoint neural networks, specified as a character vector or string scalar.

- If you do not specify a path (that is, you use the default ""), then the software does not save any checkpoint neural networks.
- If you specify a path, then `trainNetwork` saves checkpoint neural networks to this path and assigns a unique name to each neural network. You can then load any checkpoint neural network and resume training from that neural network.

If the folder does not exist, then you must first create it before specifying the path for saving the checkpoint neural networks. If the path you specify does not exist, then `trainingOptions` returns an error.

The `CheckpointFrequency` and `CheckpointFrequencyUnit` options specify the frequency of saving checkpoint neural networks.

For more information about saving neural network checkpoints, see “Save Checkpoint Networks and Resume Training”.

Data Types: `char` | `string`

#### **CheckpointFrequency — Frequency of saving checkpoint neural networks**

1 (default) | positive integer

Frequency of saving checkpoint neural networks, specified as a positive integer.

If `CheckpointFrequencyUnit` is 'epoch', then the software saves checkpoint neural networks every `CheckpointFrequency` epochs.

If `CheckpointFrequencyUnit` is `'iteration'`, then the software saves checkpoint neural networks every `CheckpointFrequency` iterations.

This option only has an effect when `CheckpointPath` is nonempty.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CheckpointFrequencyUnit — Checkpoint frequency unit**

`'epoch'` (default) | `'iteration'`

Checkpoint frequency unit, specified as `'epoch'` or `'iteration'`.

If `CheckpointFrequencyUnit` is `'epoch'`, then the software saves checkpoint neural networks every `CheckpointFrequency` epochs.

If `CheckpointFrequencyUnit` is `'iteration'`, then the software saves checkpoint neural networks every `CheckpointFrequency` iterations.

This option only has an effect when `CheckpointPath` is nonempty.

### **OutputFcn — Output functions**

function handle | cell array of function handles

Output functions to call during training, specified as a function handle or cell array of function handles. `trainNetwork` calls the specified functions once before the start of training, after each iteration, and once after training has finished. `trainNetwork` passes a structure containing information in the following fields:

Field	Description
Epoch	Current epoch number
Iteration	Current iteration number
TimeSinceStart	Time in seconds since the start of training
TrainingLoss	Current mini-batch loss
ValidationLoss	Loss on the validation data
BaseLearnRate	Current base learning rate
TrainingAccuracy	Accuracy on the current mini-batch (classification neural networks)
TrainingRMSE	RMSE on the current mini-batch (regression neural networks)
ValidationAccuracy	Accuracy on the validation data (classification neural networks)
ValidationRMSE	RMSE on the validation data (regression neural networks)
State	Current training state, with a possible value of <code>"start"</code> , <code>"iteration"</code> , or <code>"done"</code> .

If a field is not calculated or relevant for a certain call to the output functions, then that field contains an empty array.

You can use output functions to display or plot progress information, or to stop training. To stop training early, make your output function return `1` (true). If any output function returns `1` (true), then

training finishes and `trainNetwork` returns the latest neural network. For an example showing how to use output functions, see “Customize Output During Deep Learning Network Training”.

Data Types: `function_handle` | `cell`

## Output Arguments

### options — Training options

`TrainingOptionsSGDM` | `TrainingOptionsRMSProp` | `TrainingOptionsADAM`

Training options, returned as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object. To train a neural network, use the training options as an input argument to the `trainNetwork` function.

If `solverName` is 'sgdm', 'rmsprop', or 'adam', then the training options are returned as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object, respectively.

You can edit training option properties of `TrainingOptionsSGDM`, `TrainingOptionsADAM`, and `TrainingOptionsRMSProp` objects directly. For example, to change the mini-batch size after using the `trainingOptions` function, you can edit the `MiniBatchSize` property directly:

```
options = trainingOptions('sgdm');  
options.MiniBatchSize = 64;
```

## Tips

- For most deep learning tasks, you can use a pretrained neural network and adapt it to your own data. For an example showing how to use transfer learning to retrain a convolutional neural network to classify a new set of images, see “Train Deep Learning Network to Classify New Images”. Alternatively, you can create and train neural networks from scratch using `layerGraph` objects with the `trainNetwork` and `trainingOptions` functions.

If the `trainingOptions` function does not provide the training options that you need for your task, then you can create a custom training loop using automatic differentiation. To learn more, see “Define Deep Learning Network for Custom Training Loops”.

## Algorithms

### Initial Weights and Biases

For convolutional and fully connected layers, the initialization for the weights and biases are given by the `WeightsInitializer` and `BiasInitializer` properties of the layers, respectively. For examples showing how to change the initialization for the weights and biases, see “Specify Initial Weights and Biases in Convolutional Layer” on page 1-412 and “Specify Initial Weights and Biases in Fully Connected Layer” on page 1-766.

### Stochastic Gradient Descent

The standard gradient descent algorithm updates the network parameters (weights and biases) to minimize the loss function by taking small steps at each iteration in the direction of the negative gradient of the loss,

$$\theta_{t+1} = \theta_t - \alpha \nabla E(\theta_t),$$

where  $\ell$  is the iteration number,  $\alpha > 0$  is the learning rate,  $\theta$  is the parameter vector, and  $E(\theta)$  is the loss function. In the standard gradient descent algorithm, the gradient of the loss function,  $\nabla E(\theta)$ , is evaluated using the entire training set, and the standard gradient descent algorithm uses the entire data set at once.

By contrast, at each iteration the *stochastic* gradient descent algorithm evaluates the gradient and updates the parameters using a subset of the training data. A different subset, called a mini-batch, is used at each iteration. The full pass of the training algorithm over the entire training set using mini-batches is one *epoch*. Stochastic gradient descent is stochastic because the parameter updates computed using a mini-batch is a noisy estimate of the parameter update that would result from using the full data set. You can specify the mini-batch size and the maximum number of epochs by using the `MiniBatchSize` and `MaxEpochs` training options, respectively.

### Stochastic Gradient Descent with Momentum

The stochastic gradient descent algorithm can oscillate along the path of steepest descent towards the optimum. Adding a momentum term to the parameter update is one way to reduce this oscillation [2]. The stochastic gradient descent with momentum (SGDM) update is

$$\theta_{\ell+1} = \theta_{\ell} - \alpha \nabla E(\theta_{\ell}) + \gamma(\theta_{\ell} - \theta_{\ell-1}),$$

where  $\gamma$  determines the contribution of the previous gradient step to the current iteration. You can specify this value using the `Momentum` training option. To train a neural network using the stochastic gradient descent with momentum algorithm, specify 'sgdm' as the first input argument to `trainingOptions`. To specify the initial value of the learning rate  $\alpha$ , use the `InitialLearnRate` training option. You can also specify different learning rates for different layers and parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

### RMSProp

Stochastic gradient descent with momentum uses a single learning rate for all the parameters. Other optimization algorithms seek to improve network training by using learning rates that differ by parameter and can automatically adapt to the loss function being optimized. RMSProp (root mean square propagation) is one such algorithm. It keeps a moving average of the element-wise squares of the parameter gradients,

$$v_{\ell} = \beta_2 v_{\ell-1} + (1 - \beta_2) [\nabla E(\theta_{\ell})]^2$$

$\beta_2$  is the decay rate of the moving average. Common values of the decay rate are 0.9, 0.99, and 0.999. The corresponding averaging lengths of the squared gradients equal  $1/(1-\beta_2)$ , that is, 10, 100, and 1000 parameter updates, respectively. You can specify  $\beta_2$  by using the `SquaredGradientDecayFactor` training options. The RMSProp algorithm uses this moving average to normalize the updates of each parameter individually,

$$\theta_{\ell+1} = \theta_{\ell} - \frac{\alpha \nabla E(\theta_{\ell})}{\sqrt{v_{\ell} + \epsilon}}$$

where the division is performed element-wise. Using RMSProp effectively decreases the learning rates of parameters with large gradients and increases the learning rates of parameters with small gradients.  $\epsilon$  is a small constant added to avoid division by zero. You can specify  $\epsilon$  by using the `Epsilon` training option, but the default value usually works well. To use RMSProp to train a neural network, specify 'rmsprop' as the first input to `trainingOptions`.

## Adam

Adam (derived from *adaptive moment estimation*) [4] uses a parameter update that is similar to RMSProp, but with an added momentum term. It keeps an element-wise moving average of both the parameter gradients and their squared values,

$$m_\ell = \beta_1 m_{\ell-1} + (1 - \beta_1) \nabla E(\theta_\ell)$$

$$v_\ell = \beta_2 v_{\ell-1} + (1 - \beta_2) [\nabla E(\theta_\ell)]^2$$

You can specify the  $\beta_1$  and  $\beta_2$  decay rates using the `GradientDecayFactor` and `SquaredGradientDecayFactor` training options, respectively. Adam uses the moving averages to update the network parameters as

$$\theta_{\ell+1} = \theta_\ell - \frac{\alpha m_\ell}{\sqrt{v_\ell} + \epsilon}$$

If gradients over many iterations are similar, then using a moving average of the gradient enables the parameter updates to pick up momentum in a certain direction. If the gradients contain mostly noise, then the moving average of the gradient becomes smaller, and so the parameter updates become smaller too. You can specify  $\epsilon$  by using the `Epsilon` training option. The default value usually works well, but for certain problems a value as large as 1 works better. To use Adam to train a neural network, specify 'adam' as the first input to `trainingOptions`. The full Adam update also includes a mechanism to correct a bias that appears in the beginning of training. For more information, see [4].

Specify the learning rate  $\alpha$  for all optimization algorithms using the `InitialLearnRate` training option. The effect of the learning rate is different for the different optimization algorithms, so the optimal learning rates are also different in general. You can also specify learning rates that differ by layers and by parameter. For more information, see "Set Up Parameters in Convolutional and Fully Connected Layers".

## Gradient Clipping

If the gradients increase in magnitude exponentially, then the training is unstable and can diverge within a few iterations. This "gradient explosion" is indicated by a training loss that goes to NaN or Inf. Gradient clipping helps prevent gradient explosion by stabilizing the training at higher learning rates and in the presence of outliers [3]. Gradient clipping enables networks to be trained faster, and does not usually impact the accuracy of the learned task.

There are two types of gradient clipping.

- Norm-based gradient clipping rescales the gradient based on a threshold, and does not change the direction of the gradient. The 'l2norm' and 'global-l2norm' values of `GradientThresholdMethod` are norm-based gradient clipping methods.
- Value-based gradient clipping clips any partial derivative greater than the threshold, which can result in the gradient arbitrarily changing direction. Value-based gradient clipping can have unpredictable behavior, but sufficiently small changes do not cause the network to diverge. The 'absolute-value' value of `GradientThresholdMethod` is a value-based gradient clipping method.

## L<sub>2</sub> Regularization

Adding a regularization term for the weights to the loss function  $E(\theta)$  is one way to reduce overfitting [1], [2]. The regularization term is also called *weight decay*. The loss function with the regularization term takes the form

$$E_R(\theta) = E(\theta) + \lambda\Omega(w),$$

where  $w$  is the weight vector,  $\lambda$  is the regularization factor (coefficient), and the regularization function  $\Omega(w)$  is

$$\Omega(w) = \frac{1}{2}w^T w.$$

Note that the biases are not regularized [2]. You can specify the regularization factor  $\lambda$  by using the `L2Regularization` training option. You can also specify different regularization factors for different layers and parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

The loss function that the software uses for network training includes the regularization term. However, the loss value displayed in the command window and training progress plot during training is the loss on the data only and does not include the regularization term.

## Version History

### Introduced in R2016a

#### **R2022b: `trainNetwork` pads mini-batches to length of longest sequence before splitting when you specify `SequenceLength` training option as an integer**

Starting in R2022b, when you train a neural network with sequence data using the `trainNetwork` function and the `SequenceLength` option is an integer, the software pads sequences to the length of the longest sequence in each mini-batch and then splits the sequences into mini-batches with the specified sequence length. If `SequenceLength` does not evenly divide the sequence length of the mini-batch, then the last split mini-batch has a length shorter than `SequenceLength`. This behavior prevents the neural network training on time steps that contain only padding values.

In previous releases, the software pads mini-batches of sequences to have a length matching the nearest multiple of `SequenceLength` that is greater than or equal to the mini-batch length and then splits the data. To reproduce this behavior, use a custom training loop and implement this behavior when you preprocess mini-batches of data.

#### **R2018b: `ValidationPatience` training option default is `Inf`**

*Behavior changed in R2018b*

Starting in R2018b, the default value of the `ValidationPatience` training option is `Inf`, which means that automatic stopping via validation is turned off. This behavior prevents the training from stopping before sufficiently learning from the data.

In previous versions, the default value is 5. To reproduce this behavior, set the `ValidationPatience` option to 5.

#### **R2018b: Different file name for checkpoint networks**

*Behavior changed in R2018b*

Starting in R2018b, when saving checkpoint networks, the software assigns file names beginning with `net_checkpoint_`. In previous versions, the software assigns file names beginning with `convnet_checkpoint_`.

If you have code that saves and loads checkpoint networks, then update your code to load files with the new name.

# TrainingOptionsADAM

Training options for Adam optimizer

## Description

Training options for Adam (adaptive moment estimation) optimizer, including learning rate information,  $L_2$  regularization factor, and mini-batch size.

## Creation

Create a TrainingOptionsADAM object using trainingOptions and specifying 'adam' as the first input argument.

## Properties

### Plots and Display

#### Plots — Plots to display during neural network training

'none' (default) | 'training-progress'

Plots to display during neural network training, specified as one of the following:

- 'none' — Do not display plots during training.
- 'training-progress' — Plot training progress. The plot shows mini-batch loss and accuracy, validation loss and accuracy, and additional information on the training progress. The plot has a stop button  in the top-right corner. Click the button to stop training and return the current state of the neural network. You can save the training plot as an image or PDF by clicking **Export Training Plot**. For more information on the training progress plot, see “Monitor Deep Learning Training Progress”.

#### Verbose — Indicator to display training progress information

1 (true) (default) | 0 (false)

Indicator to display training progress information in the command window, specified as 1 (true) or 0 (false).

The verbose output displays the following information:

**Classification Neural Networks**

<b>Field</b>	<b>Description</b>
Epoch	Epoch number. An epoch corresponds to a full pass of the data.
Iteration	Iteration number. An iteration corresponds to a mini-batch.
Time Elapsed	Time elapsed in hours, minutes, and seconds.
Mini-batch Accuracy	Classification accuracy on the mini-batch.
Validation Accuracy	Classification accuracy on the validation data. If you do not specify validation data, then the function does not display this field.
Mini-batch Loss	Loss on the mini-batch. If the output layer is a <code>ClassificationOutputLayer</code> object, then the loss is the cross entropy loss for multi-class classification problems with mutually exclusive classes.
Validation Loss	Loss on the validation data. If the output layer is a <code>ClassificationOutputLayer</code> object, then the loss is the cross entropy loss for multi-class classification problems with mutually exclusive classes. If you do not specify validation data, then the function does not display this field.
Base Learning Rate	Base learning rate. The software multiplies the learn rate factors of the layers by this value.

## Regression Neural Networks

Field	Description
Epoch	Epoch number. An epoch corresponds to a full pass of the data.
Iteration	Iteration number. An iteration corresponds to a mini-batch.
Time Elapsed	Time elapsed in hours, minutes, and seconds.
Mini-batch RMSE	Root-mean-squared-error (RMSE) on the mini-batch.
Validation RMSE	RMSE on the validation data. If you do not specify validation data, then the software does not display this field.
Mini-batch Loss	Loss on the mini-batch. If the output layer is a <code>RegressionOutputLayer</code> object, then the loss is the half-mean-squared-error.
Validation Loss	Loss on the validation data. If the output layer is a <code>RegressionOutputLayer</code> object, then the loss is the half-mean-squared-error. If you do not specify validation data, then the software does not display this field.
Base Learning Rate	Base learning rate. The software multiplies the learn rate factors of the layers by this value.

When training stops, the verbose output displays the reason for stopping.

To specify validation data, use the `ValidationData` training option.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### VerboseFrequency — Frequency of verbose printing

50 (default) | positive integer

Frequency of verbose printing, which is the number of iterations between printing to the command window, specified as a positive integer. This option only has an effect when the `Verbose` training option is 1 (true).

If you validate the neural network during training, then `trainNetwork` also prints to the command window every time validation occurs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Mini-Batch Options

#### MaxEpochs — Maximum number of epochs

30 (default) | positive integer

Maximum number of epochs to use for training, specified as a positive integer.

An iteration is one step taken in the gradient descent algorithm towards minimizing the loss function using a mini-batch. An epoch is the full pass of the training algorithm over the entire training set.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **MiniBatchSize — Size of mini-batch**

128 (default) | positive integer

Size of the mini-batch to use for each training iteration, specified as a positive integer. A mini-batch is a subset of the training set that is used to evaluate the gradient of the loss function and update the weights.

If the mini-batch size does not evenly divide the number of training samples, then `trainNetwork` discards the training data that does not fit into the final complete mini-batch of each epoch.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Shuffle — Option for data shuffling**

'once' (default) | 'never' | 'every-epoch'

Option for data shuffling, specified as one of the following:

- 'once' — Shuffle the training and validation data once before training.
- 'never' — Do not shuffle the data.
- 'every-epoch' — Shuffle the training data before each training epoch, and shuffle the validation data before each neural network validation. If the mini-batch size does not evenly divide the number of training samples, then `trainNetwork` discards the training data that does not fit into the final complete mini-batch of each epoch. To avoid discarding the same data every epoch, set the `Shuffle` training option to 'every-epoch'.

## **Validation**

### **ValidationData — Data to use for validation during training**

[] (default) | datastore | table | cell array

Data to use for validation during training, specified as [], a datastore, a table, or a cell array containing the validation predictors and responses.

You can specify validation predictors and responses using the same formats supported by the `trainNetwork` function. You can specify the validation data as a datastore, table, or the cell array `{predictors, responses}`, where `predictors` contains the validation predictors and `responses` contains the validation responses.

For more information, see the `images`, `sequences`, and `features` input arguments of the `trainNetwork` function.

During training, `trainNetwork` calculates the validation accuracy and validation loss on the validation data. To specify the validation frequency, use the `ValidationFrequency` training option. You can also use the validation data to stop training automatically when the validation loss stops decreasing. To turn on automatic validation stopping, use the `ValidationPatience` training option.

If your neural network has layers that behave differently during prediction than during training (for example, dropout layers), then the validation accuracy can be higher than the training (mini-batch) accuracy.

The validation data is shuffled according to the `Shuffle` training option. If `Shuffle` is 'every-epoch', then the validation data is shuffled before each neural network validation.

If `ValidationData` is `[]`, then the software does not validate the neural network during training.

### **ValidationFrequency — Frequency of neural network validation**

50 (default) | positive integer

Frequency of neural network validation in number of iterations, specified as a positive integer.

The `ValidationFrequency` value is the number of iterations between evaluations of validation metrics. To specify validation data, use the `ValidationData` training option.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ValidationPatience — Patience of validation stopping**

Inf (default) | positive integer

Patience of validation stopping of neural network training, specified as a positive integer or `Inf`.

`ValidationPatience` specifies the number of times that the loss on the validation set can be larger than or equal to the previously smallest loss before neural network training stops. If `ValidationPatience` is `Inf`, then the values of the validation loss do not cause training to stop early.

The returned neural network depends on the `OutputNetwork` training option. To return the neural network with the lowest validation loss, set the `OutputNetwork` training option to `"best-validation-loss"`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **OutputNetwork — Neural network to return when training completes**

'last-iteration' (default) | 'best-validation-loss'

Neural network to return when training completes, specified as one of the following:

- `'last-iteration'` - Return the neural network corresponding to the last training iteration.
- `'best-validation-loss'` - Return the neural network corresponding to the training iteration with the lowest validation loss. To use this option, you must specify the `ValidationData` training option.

## **Solver Options**

### **InitialLearnRate — Initial learning rate**

0.001 (default) | positive scalar

Initial learning rate used for training, specified as a positive scalar.

If the learning rate is too low, then training can take a long time. If the learning rate is too high, then training might reach a suboptimal result or diverge.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **LearnRateScheduleSettings — Settings for learning rate schedule**

structure

This property is read-only.

Settings for the learning rate schedule, specified as a structure. `LearnRateScheduleSettings` has the field `Method`, which specifies the type of method for adjusting the learning rate. The possible methods are:

- 'none' — The learning rate is constant throughout training.
- 'piecewise' — The learning rate drops periodically during training.

If `Method` is 'piecewise', then `LearnRateScheduleSettings` contains two more fields:

- `DropRateFactor` — The multiplicative factor by which the learning rate drops during training
- `DropPeriod` — The number of epochs that passes between adjustments to the learning rate during training

Specify the settings for the learning schedule rate using `trainingOptions`.

Data Types: `struct`

### **L2Regularization — Factor for L<sub>2</sub> regularization**

0.0001 (default) | nonnegative scalar

Factor for L<sub>2</sub> regularization (weight decay), specified as a nonnegative scalar. For more information, see “L2 Regularization” on page 1-1800.

You can specify a multiplier for the L<sub>2</sub> regularization for neural network layers with learnable parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **GradientDecayFactor — Decay rate of gradient moving average**

0.9 (default) | nonnegative scalar less than 1

Decay rate of gradient moving average for the Adam solver, specified as a nonnegative scalar less than 1. The gradient decay rate is denoted by  $\beta_1$  in the “Adam” on page 1-1799 section.

The default value works well for most tasks.

For more information, see “Adam” on page 1-1799.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **SquaredGradientDecayFactor — Decay rate of squared gradient moving average**

0.999 (default) | nonnegative scalar less than 1

Decay rate of squared gradient moving average for the Adam solver, specified as a nonnegative scalar less than 1. The squared gradient decay rate is denoted by  $\beta_2$  in the “Adam” on page 1-1799 section.

Typical values of the decay rate are 0.9, 0.99, and 0.999, corresponding to averaging lengths of 10, 100, and 1000 parameter updates, respectively.

For more information, see “Adam” on page 1-1799.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Epsilon — Denominator offset**

1e-8 (default) | positive scalar

Denominator offset for Adam solver, specified as a positive scalar.

The solver adds the offset to the denominator in the neural network parameter updates to avoid division by zero. The default value works well for most tasks.

For more information, see “Adam” on page 1-1799.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **ResetInputNormalization — Option to reset input layer normalization**

1 (true) (default) | 0 (false)

Option to reset input layer normalization, specified as one of the following:

- 1 (true) — Reset the input layer normalization statistics and recalculate them at training time.
- 0 (false) — Calculate normalization statistics at training time when they are empty.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **BatchNormalizationStatistics — Mode to evaluate statistics in batch normalization layers**

'population' (default) | 'moving'

Mode to evaluate the statistics in batch normalization layers, specified as one of the following:

- 'population' - Use the population statistics. After training, the software finalizes the statistics by passing through the training data once more and uses the resulting mean and variance.
- 'moving' - Approximate the statistics during training using a running estimate given by update steps

$$\mu^* = \lambda_\mu \widehat{\mu} + (1 - \lambda_\mu)\mu$$

$$\sigma^{2*} = \lambda_{\sigma^2} \widehat{\sigma^2} + (1 - \lambda_{\sigma^2})\sigma^2$$

where  $\mu^*$  and  $\sigma^{2*}$  denote the updated mean and variance, respectively,  $\lambda_\mu$  and  $\lambda_{\sigma^2}$  denote the mean and variance decay values, respectively,  $\widehat{\mu}$  and  $\widehat{\sigma^2}$  denote the mean and variance of the layer input, respectively, and  $\mu$  and  $\sigma^2$  denote the latest values of the moving mean and variance values, respectively. After training, the software uses the most recent value of the moving mean and variance statistics. This option supports CPU and single GPU training only.

## **Gradient Clipping**

### **GradientThreshold — Gradient threshold**

Inf (default) | positive scalar

Gradient threshold, specified as Inf or a positive scalar. If the gradient exceeds the value of GradientThreshold, then the gradient is clipped according to the GradientThresholdMethod training option.

For more information, see Gradient Clipping on page 1-1800.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**GradientThresholdMethod — Gradient threshold method**`'l2norm'` (default) | `'global-l2norm'` | `'absolute-value'`

Gradient threshold method used to clip gradient values that exceed the gradient threshold, specified as one of the following:

- `'l2norm'` — If the  $L_2$  norm of the gradient of a learnable parameter is larger than `GradientThreshold`, then scale the gradient so that the  $L_2$  norm equals `GradientThreshold`.
- `'global-l2norm'` — If the global  $L_2$  norm,  $L$ , is larger than `GradientThreshold`, then scale all gradients by a factor of `GradientThreshold/L`. The global  $L_2$  norm considers all learnable parameters.
- `'absolute-value'` — If the absolute value of an individual partial derivative in the gradient of a learnable parameter is larger than `GradientThreshold`, then scale the partial derivative to have magnitude equal to `GradientThreshold` and retain the sign of the partial derivative.

For more information, see Gradient Clipping on page 1-1800.

**Sequence Options****SequenceLength — Option to pad or truncate sequences**`"longest"` (default) | `"shortest"` | positive integer

Option to pad, truncate, or split input sequences, specified as one of the following:

- `"longest"` — Pad sequences in each mini-batch to have the same length as the longest sequence. This option does not discard any data, though padding can introduce noise to the neural network.
- `"shortest"` — Truncate sequences in each mini-batch to have the same length as the shortest sequence. This option ensures that no padding is added, at the cost of discarding data.
- Positive integer — For each mini-batch, pad the sequences to the length of the longest sequence in the mini-batch, and then split the sequences into smaller sequences of the specified length. If splitting occurs, then the software creates extra mini-batches. If the specified sequence length does not evenly divide the sequence lengths of the data, then the mini-batches containing the ends of those sequences have length shorter than the specified sequence length. Use this option if the full sequences do not fit in memory. Alternatively, try reducing the number of sequences per mini-batch by setting the `MiniBatchSize` option to a lower value.

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

**SequencePaddingDirection — Direction of padding or truncation**`"right"` (default) | `"left"`

Direction of padding or truncation, specified as one of the following:

- `"right"` — Pad or truncate sequences on the right. The sequences start at the same time step and the software truncates or adds padding to the end of the sequences.
- `"left"` — Pad or truncate sequences on the left. The software truncates or adds padding to the start of the sequences so that the sequences end at the same time step.

Because recurrent layers process sequence data one time step at a time, when the recurrent layer `OutputMode` property is `'last'`, any padding in the final time steps can negatively influence the

layer output. To pad or truncate sequence data on the left, set the `SequencePaddingDirection` option to "left".

For sequence-to-sequence neural networks (when the `OutputMode` property is 'sequence' for each recurrent layer), any padding in the first time steps can negatively influence the predictions for the earlier time steps. To pad or truncate sequence data on the right, set the `SequencePaddingDirection` option to "right".

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

### **SequencePaddingValue — Value to pad sequences**

0 (default) | scalar

Value by which to pad input sequences, specified as a scalar.

The option is valid only when `SequenceLength` is "longest" or a positive integer. Do not pad sequences with NaN, because doing so can propagate errors throughout the neural network.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## **Hardware Options**

### **ExecutionEnvironment — Hardware resource for training neural network**

'auto' (default) | 'cpu' | 'gpu' | 'multi-gpu' | 'parallel'

Hardware resource for training neural network, specified as one of the following:

- 'auto' — Use a GPU if one is available. Otherwise, use the CPU.
- 'cpu' — Use the CPU.
- 'gpu' — Use the GPU.
- 'multi-gpu' — Use multiple GPUs on one machine, using a local parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts a parallel pool with pool size equal to the number of available GPUs.
- 'parallel' — Use a local or remote parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts one using the default cluster profile. If the pool has access to GPUs, then only workers with a unique GPU perform training computation. If the pool does not have GPUs, then training takes place on all available CPU workers instead.

For more information on when to use the different execution environments, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud”.

'gpu', 'multi-gpu', and 'parallel' options require Parallel Computing Toolbox. To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). If you choose one of these options and Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.

To see an improvement in performance when training in parallel, try scaling up the `MiniBatchSize` and `InitialLearnRate` training options by the number of GPUs.

The 'multi-gpu' and 'parallel' options do not support neural networks containing custom layers with state parameters or built-in layers that are stateful at training time. For example:

- recurrent layers such as `LSTMLayer`, `BiLSTMLayer`, or `GRULayer` objects when the `SequenceLength` training option is a positive integer
- `BatchNormalizationLayer` objects when the `BatchNormalizationStatistics` training option is set to `'moving'`

**WorkerLoad — Parallel worker load division**

scalar from 0 to 1 | positive integer | numeric vector

Parallel worker load division between GPUs or CPUs, specified as one of the following:

- Scalar from 0 to 1 — Fraction of workers on each machine to use for neural network training computation. If you train the neural network using data in a mini-batch datastore with background dispatch enabled, then the remaining workers fetch and preprocess data in the background.
- Positive integer — Number of workers on each machine to use for neural network training computation. If you train the neural network using data in a mini-batch datastore with background dispatch enabled, then the remaining workers fetch and preprocess data in the background.
- Numeric vector — Neural network training load for each worker in the parallel pool. For a vector  $W$ , worker  $i$  gets a fraction  $W(i)/\text{sum}(W)$  of the work (number of examples per mini-batch). If you train a neural network using data in a mini-batch datastore with background dispatch enabled, then you can assign a worker load of 0 to use that worker for fetching data in the background. The specified vector must contain one value per worker in the parallel pool.

If the parallel pool has access to GPUs, then workers without a unique GPU are never used for training computation. The default for pools with GPUs is to use all workers with a unique GPU for training computation, and the remaining workers for background dispatch. If the pool does not have access to GPUs and CPUs are used for training, then the default is to use one worker per machine for background data dispatch.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**DispatchInBackground — Flag to enable background dispatch**

0 (false) (default) | 1 (true)

Flag to enable background dispatch (asynchronous prefetch queuing) to read training data from datastores, specified as 0 (false) or 1 (true). Background dispatch requires Parallel Computing Toolbox.

`DispatchInBackground` is only supported for datastores that are partitionable. For more information, see “Use Datastore for Parallel Training and Background Dispatching”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Checkpoints****CheckpointPath — Path for saving checkpoint neural networks**

"" (default) | character vector

Path for saving the checkpoint neural networks, specified as a character vector or string scalar.

- If you do not specify a path (that is, you use the default `""`), then the software does not save any checkpoint neural networks.
- If you specify a path, then `trainNetwork` saves checkpoint neural networks to this path and assigns a unique name to each neural network. You can then load any checkpoint neural network and resume training from that neural network.

If the folder does not exist, then you must first create it before specifying the path for saving the checkpoint neural networks. If the path you specify does not exist, then `trainingOptions` returns an error.

The `CheckpointFrequency` and `CheckpointFrequencyUnit` options specify the frequency of saving checkpoint neural networks.

For more information about saving neural network checkpoints, see “Save Checkpoint Networks and Resume Training”.

Data Types: `char` | `string`

### **CheckpointFrequency — Frequency of saving checkpoint neural networks**

1 (default) | positive integer

Frequency of saving checkpoint neural networks, specified as a positive integer.

If `CheckpointFrequencyUnit` is `'epoch'`, then the software saves checkpoint neural networks every `CheckpointFrequency` epochs.

If `CheckpointFrequencyUnit` is `'iteration'`, then the software saves checkpoint neural networks every `CheckpointFrequency` iterations.

This option only has an effect when `CheckpointPath` is nonempty.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CheckpointFrequencyUnit — Checkpoint frequency unit**

`'epoch'` (default) | `'iteration'`

Checkpoint frequency unit, specified as `'epoch'` or `'iteration'`.

If `CheckpointFrequencyUnit` is `'epoch'`, then the software saves checkpoint neural networks every `CheckpointFrequency` epochs.

If `CheckpointFrequencyUnit` is `'iteration'`, then the software saves checkpoint neural networks every `CheckpointFrequency` iterations.

This option only has an effect when `CheckpointPath` is nonempty.

### **OutputFcn — Output functions**

function handle | cell array of function handles

Output functions to call during training, specified as a function handle or cell array of function handles. `trainNetwork` calls the specified functions once before the start of training, after each iteration, and once after training has finished. `trainNetwork` passes a structure containing information in the following fields:

Field	Description
Epoch	Current epoch number
Iteration	Current iteration number
TimeSinceStart	Time in seconds since the start of training
TrainingLoss	Current mini-batch loss

Field	Description
ValidationLoss	Loss on the validation data
BaseLearnRate	Current base learning rate
TrainingAccuracy	Accuracy on the current mini-batch (classification neural networks)
TrainingRMSE	RMSE on the current mini-batch (regression neural networks)
ValidationAccuracy	Accuracy on the validation data (classification neural networks)
ValidationRMSE	RMSE on the validation data (regression neural networks)
State	Current training state, with a possible value of "start", "iteration", or "done".

If a field is not calculated or relevant for a certain call to the output functions, then that field contains an empty array.

You can use output functions to display or plot progress information, or to stop training. To stop training early, make your output function return 1 (true). If any output function returns 1 (true), then training finishes and `trainNetwork` returns the latest neural network. For an example showing how to use output functions, see “Customize Output During Deep Learning Network Training”.

Data Types: `function_handle` | `cell`

## Examples

### Create Training Options for the Adam Optimizer

Create a set of options for training a neural network using the Adam optimizer. Set the maximum number of epochs for training to 20, and use a mini-batch with 64 observations at each iteration. Specify the learning rate and the decay rate of the moving average of the squared gradient. Turn on the training progress plot.

```
options = trainingOptions("adam", ...
    InitialLearnRate=3e-4, ...
    SquaredGradientDecayFactor=0.99, ...
    MaxEpochs=20, ...
    MiniBatchSize=64, ...
    Plots="training-progress")

options =
    TrainingOptionsADAM with properties:

        GradientDecayFactor: 0.9000
    SquaredGradientDecayFactor: 0.9900
            Epsilon: 1.0000e-08
        InitialLearnRate: 3.0000e-04
        LearnRateSchedule: 'none'
    LearnRateDropFactor: 0.1000
    LearnRateDropPeriod: 10
        L2Regularization: 1.0000e-04
    GradientThresholdMethod: 'l2norm'
```

```

GradientThreshold: Inf
  MaxEpochs: 20
  MiniBatchSize: 64
  Verbose: 1
  VerboseFrequency: 50
  ValidationData: []
ValidationFrequency: 50
ValidationPatience: Inf
  Shuffle: 'once'
  CheckpointPath: ''
  CheckpointFrequency: 1
CheckpointFrequencyUnit: 'epoch'
ExecutionEnvironment: 'auto'
  WorkerLoad: []
  OutputFcn: []
  Plots: 'training-progress'
  SequenceLength: 'longest'
  SequencePaddingValue: 0
SequencePaddingDirection: 'right'
DispatchInBackground: 0
ResetInputNormalization: 1
BatchNormalizationStatistics: 'population'
OutputNetwork: 'last-iteration'

```

## Algorithms

### Adam

Adam (derived from *adaptive moment estimation*) [1] uses a parameter update that is similar to RMSProp, but with an added momentum term. It keeps an element-wise moving average of both the parameter gradients and their squared values,

$$m_\ell = \beta_1 m_{\ell-1} + (1 - \beta_1) \nabla E(\theta_\ell)$$

$$v_\ell = \beta_2 v_{\ell-1} + (1 - \beta_2) [\nabla E(\theta_\ell)]^2$$

You can specify the  $\beta_1$  and  $\beta_2$  decay rates using the `GradientDecayFactor` and `SquaredGradientDecayFactor` training options, respectively. Adam uses the moving averages to update the network parameters as

$$\theta_{\ell+1} = \theta_\ell - \frac{\alpha m_\ell}{\sqrt{|v_\ell|} + \epsilon}$$

If gradients over many iterations are similar, then using a moving average of the gradient enables the parameter updates to pick up momentum in a certain direction. If the gradients contain mostly noise, then the moving average of the gradient becomes smaller, and so the parameter updates become smaller too. You can specify  $\epsilon$  by using the `Epsilon` training option. The default value usually works well, but for certain problems a value as large as 1 works better. To use Adam to train a neural network, specify 'adam' as the first input to `trainingOptions`. The full Adam update also includes a mechanism to correct a bias that appears in the beginning of training. For more information, see [1].

Specify the learning rate  $\alpha$  for all optimization algorithms using the `InitialLearnRate` training option. The effect of the learning rate is different for the different optimization algorithms, so the

optimal learning rates are also different in general. You can also specify learning rates that differ by layers and by parameter. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

## **L<sub>2</sub> Regularization**

Adding a regularization term for the weights to the loss function  $E(\theta)$  is one way to reduce overfitting [1], [2]. The regularization term is also called *weight decay*. The loss function with the regularization term takes the form

$$E_R(\theta) = E(\theta) + \lambda\Omega(w),$$

where  $w$  is the weight vector,  $\lambda$  is the regularization factor (coefficient), and the regularization function  $\Omega(w)$  is

$$\Omega(w) = \frac{1}{2}w^T w.$$

Note that the biases are not regularized [2]. You can specify the regularization factor  $\lambda$  by using the `L2Regularization` training option. You can also specify different regularization factors for different layers and parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

The loss function that the software uses for network training includes the regularization term. However, the loss value displayed in the command window and training progress plot during training is the loss on the data only and does not include the regularization term.

## **Gradient Clipping**

If the gradients increase in magnitude exponentially, then the training is unstable and can diverge within a few iterations. This “gradient explosion” is indicated by a training loss that goes to NaN or Inf. Gradient clipping helps prevent gradient explosion by stabilizing the training at higher learning rates and in the presence of outliers [3]. Gradient clipping enables networks to be trained faster, and does not usually impact the accuracy of the learned task.

There are two types of gradient clipping.

- Norm-based gradient clipping rescales the gradient based on a threshold, and does not change the direction of the gradient. The `'l2norm'` and `'global-l2norm'` values of `GradientThresholdMethod` are norm-based gradient clipping methods.
- Value-based gradient clipping clips any partial derivative greater than the threshold, which can result in the gradient arbitrarily changing direction. Value-based gradient clipping can have unpredictable behavior, but sufficiently small changes do not cause the network to diverge. The `'absolute-value'` value of `GradientThresholdMethod` is a value-based gradient clipping method.

## **Version History**

**Introduced in R2018a**

**R2022b: `trainNetwork` pads mini-batches to length of longest sequence before splitting when you specify `SequenceLength` training option as an integer**

Starting in R2022b, when you train a neural network with sequence data using the `trainNetwork` function and the `SequenceLength` option is an integer, the software pads sequences to the length of the longest sequence in each mini-batch and then splits the sequences into mini-batches with the specified sequence length. If `SequenceLength` does not evenly divide the sequence length of the mini-batch, then the last split mini-batch has a length shorter than `SequenceLength`. This behavior prevents the neural network training on time steps that contain only padding values.

In previous releases, the software pads mini-batches of sequences to have a length matching the nearest multiple of `SequenceLength` that is greater than or equal to the mini-batch length and then splits the data. To reproduce this behavior, use a custom training loop and implement this behavior when you preprocess mini-batches of data.

### **R2018b: ValidationPatience training option default is Inf**

*Behavior changed in R2018b*

Starting in R2018b, the default value of the `ValidationPatience` training option is `Inf`, which means that automatic stopping via validation is turned off. This behavior prevents the training from stopping before sufficiently learning from the data.

In previous versions, the default value is 5. To reproduce this behavior, set the `ValidationPatience` option to 5.

# TrainingOptionsRMSProp

Training options for RMSProp optimizer

## Description

Training options for RMSProp (root mean square propagation) optimizer, including learning rate information,  $L_2$  regularization factor, and mini-batch size.

## Creation

Create a TrainingOptionsRMSProp object using `trainingOptions` and specifying 'rmsprop' as the first input argument.

## Properties

### Plots and Display

#### Plots — Plots to display during neural network training

'none' (default) | 'training-progress'

Plots to display during neural network training, specified as one of the following:

- 'none' — Do not display plots during training.
- 'training-progress' — Plot training progress. The plot shows mini-batch loss and accuracy, validation loss and accuracy, and additional information on the training progress. The plot has a stop button  in the top-right corner. Click the button to stop training and return the current state of the neural network. You can save the training plot as an image or PDF by clicking **Export Training Plot**. For more information on the training progress plot, see “Monitor Deep Learning Training Progress”.

#### Verbose — Indicator to display training progress information

1 (true) (default) | 0 (false)

Indicator to display training progress information in the command window, specified as 1 (true) or 0 (false).

The verbose output displays the following information:

**Classification Neural Networks**

<b>Field</b>	<b>Description</b>
Epoch	Epoch number. An epoch corresponds to a full pass of the data.
Iteration	Iteration number. An iteration corresponds to a mini-batch.
Time Elapsed	Time elapsed in hours, minutes, and seconds.
Mini-batch Accuracy	Classification accuracy on the mini-batch.
Validation Accuracy	Classification accuracy on the validation data. If you do not specify validation data, then the function does not display this field.
Mini-batch Loss	Loss on the mini-batch. If the output layer is a <code>ClassificationOutputLayer</code> object, then the loss is the cross entropy loss for multi-class classification problems with mutually exclusive classes.
Validation Loss	Loss on the validation data. If the output layer is a <code>ClassificationOutputLayer</code> object, then the loss is the cross entropy loss for multi-class classification problems with mutually exclusive classes. If you do not specify validation data, then the function does not display this field.
Base Learning Rate	Base learning rate. The software multiplies the learn rate factors of the layers by this value.

## Regression Neural Networks

Field	Description
Epoch	Epoch number. An epoch corresponds to a full pass of the data.
Iteration	Iteration number. An iteration corresponds to a mini-batch.
Time Elapsed	Time elapsed in hours, minutes, and seconds.
Mini-batch RMSE	Root-mean-squared-error (RMSE) on the mini-batch.
Validation RMSE	RMSE on the validation data. If you do not specify validation data, then the software does not display this field.
Mini-batch Loss	Loss on the mini-batch. If the output layer is a <code>RegressionOutputLayer</code> object, then the loss is the half-mean-squared-error.
Validation Loss	Loss on the validation data. If the output layer is a <code>RegressionOutputLayer</code> object, then the loss is the half-mean-squared-error. If you do not specify validation data, then the software does not display this field.
Base Learning Rate	Base learning rate. The software multiplies the learn rate factors of the layers by this value.

When training stops, the verbose output displays the reason for stopping.

To specify validation data, use the `ValidationData` training option.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### VerboseFrequency — Frequency of verbose printing

50 (default) | positive integer

Frequency of verbose printing, which is the number of iterations between printing to the command window, specified as a positive integer. This option only has an effect when the `Verbose` training option is 1 (true).

If you validate the neural network during training, then `trainNetwork` also prints to the command window every time validation occurs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Mini-Batch Options

#### MaxEpochs — Maximum number of epochs

30 (default) | positive integer

Maximum number of epochs to use for training, specified as a positive integer.

An iteration is one step taken in the gradient descent algorithm towards minimizing the loss function using a mini-batch. An epoch is the full pass of the training algorithm over the entire training set.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **MiniBatchSize — Size of mini-batch**

128 (default) | positive integer

Size of the mini-batch to use for each training iteration, specified as a positive integer. A mini-batch is a subset of the training set that is used to evaluate the gradient of the loss function and update the weights.

If the mini-batch size does not evenly divide the number of training samples, then `trainNetwork` discards the training data that does not fit into the final complete mini-batch of each epoch.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Shuffle — Option for data shuffling**

'once' (default) | 'never' | 'every-epoch'

Option for data shuffling, specified as one of the following:

- 'once' — Shuffle the training and validation data once before training.
- 'never' — Do not shuffle the data.
- 'every-epoch' — Shuffle the training data before each training epoch, and shuffle the validation data before each neural network validation. If the mini-batch size does not evenly divide the number of training samples, then `trainNetwork` discards the training data that does not fit into the final complete mini-batch of each epoch. To avoid discarding the same data every epoch, set the `Shuffle` training option to 'every-epoch'.

## **Validation**

### **ValidationData — Data to use for validation during training**

[] (default) | datastore | table | cell array

Data to use for validation during training, specified as [], a datastore, a table, or a cell array containing the validation predictors and responses.

You can specify validation predictors and responses using the same formats supported by the `trainNetwork` function. You can specify the validation data as a datastore, table, or the cell array {`predictors`, `responses`}, where `predictors` contains the validation predictors and `responses` contains the validation responses.

For more information, see the `images`, `sequences`, and `features` input arguments of the `trainNetwork` function.

During training, `trainNetwork` calculates the validation accuracy and validation loss on the validation data. To specify the validation frequency, use the `ValidationFrequency` training option. You can also use the validation data to stop training automatically when the validation loss stops decreasing. To turn on automatic validation stopping, use the `ValidationPatience` training option.

If your neural network has layers that behave differently during prediction than during training (for example, dropout layers), then the validation accuracy can be higher than the training (mini-batch) accuracy.

The validation data is shuffled according to the `Shuffle` training option. If `Shuffle` is 'every-epoch', then the validation data is shuffled before each neural network validation.

If `ValidationData` is `[]`, then the software does not validate the neural network during training.

**ValidationFrequency — Frequency of neural network validation**

50 (default) | positive integer

Frequency of neural network validation in number of iterations, specified as a positive integer.

The `ValidationFrequency` value is the number of iterations between evaluations of validation metrics. To specify validation data, use the `ValidationData` training option.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ValidationPatience — Patience of validation stopping**

Inf (default) | positive integer

Patience of validation stopping of neural network training, specified as a positive integer or `Inf`.

`ValidationPatience` specifies the number of times that the loss on the validation set can be larger than or equal to the previously smallest loss before neural network training stops. If `ValidationPatience` is `Inf`, then the values of the validation loss do not cause training to stop early.

The returned neural network depends on the `OutputNetwork` training option. To return the neural network with the lowest validation loss, set the `OutputNetwork` training option to `"best-validation-loss"`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**OutputNetwork — Neural network to return when training completes**

'last-iteration' (default) | 'best-validation-loss'

Neural network to return when training completes, specified as one of the following:

- `'last-iteration'` - Return the neural network corresponding to the last training iteration.
- `'best-validation-loss'` - Return the neural network corresponding to the training iteration with the lowest validation loss. To use this option, you must specify the `ValidationData` training option.

**Solver Options****InitialLearnRate — Initial learning rate**

0.001 (default) | positive scalar

Initial learning rate used for training, specified as a positive scalar.

If the learning rate is too low, then training can take a long time. If the learning rate is too high, then training might reach a suboptimal result or diverge.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**LearnRateScheduleSettings — Settings for learning rate schedule**

structure

This property is read-only.

Settings for the learning rate schedule, specified as a structure. `LearnRateScheduleSettings` has the field `Method`, which specifies the type of method for adjusting the learning rate. The possible methods are:

- 'none' — The learning rate is constant throughout training.
- 'piecewise' — The learning rate drops periodically during training.

If `Method` is 'piecewise', then `LearnRateScheduleSettings` contains two more fields:

- `DropRateFactor` — The multiplicative factor by which the learning rate drops during training
- `DropPeriod` — The number of epochs that passes between adjustments to the learning rate during training

Specify the settings for the learning schedule rate using `trainingOptions`.

Data Types: `struct`

### **L2Regularization — Factor for L<sub>2</sub> regularization**

0.0001 (default) | nonnegative scalar

Factor for L<sub>2</sub> regularization (weight decay), specified as a nonnegative scalar. For more information, see “L2 Regularization” on page 1-1814.

You can specify a multiplier for the L<sub>2</sub> regularization for neural network layers with learnable parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **SquaredGradientDecayFactor — Decay rate of squared gradient moving average**

0.9 (default) | nonnegative scalar less than 1

Decay rate of squared gradient moving average for the RMSProp solver, specified as a nonnegative scalar less than 1.

Typical values of the decay rate are 0.9, 0.99, and 0.999, corresponding to averaging lengths of 10, 100, and 1000 parameter updates, respectively.

For more information, see “RMSProp” on page 1-1814.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Epsilon — Denominator offset**

1e-8 (default) | positive scalar

Denominator offset for the RMSProp solver, specified as a positive scalar.

The solver adds the offset to the denominator in the neural network parameter updates to avoid division by zero. The default value works well for most tasks.

For more information about the different solvers, see “RMSProp” on page 1-1814.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ResetInputNormalization — Option to reset input layer normalization**

1 (true) (default) | 0 (false)

Option to reset input layer normalization, specified as one of the following:

- 1 (true) — Reset the input layer normalization statistics and recalculate them at training time.
- 0 (false) — Calculate normalization statistics at training time when they are empty.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **BatchNormalizationStatistics — Mode to evaluate statistics in batch normalization layers**

'population' (default) | 'moving'

Mode to evaluate the statistics in batch normalization layers, specified as one of the following:

- 'population' - Use the population statistics. After training, the software finalizes the statistics by passing through the training data once more and uses the resulting mean and variance.
- 'moving' - Approximate the statistics during training using a running estimate given by update steps

$$\mu^* = \lambda_{\mu} \widehat{\mu} + (1 - \lambda_{\mu}) \mu$$

$$\sigma^{2*} = \lambda_{\sigma^2} \widehat{\sigma^2} + (1 - \lambda_{\sigma^2}) \sigma^2$$

where  $\mu^*$  and  $\sigma^{2*}$  denote the updated mean and variance, respectively,  $\lambda_{\mu}$  and  $\lambda_{\sigma^2}$  denote the mean and variance decay values, respectively,  $\widehat{\mu}$  and  $\widehat{\sigma^2}$  denote the mean and variance of the layer input, respectively, and  $\mu$  and  $\sigma^2$  denote the latest values of the moving mean and variance values, respectively. After training, the software uses the most recent value of the moving mean and variance statistics. This option supports CPU and single GPU training only.

## **Gradient Clipping**

### **GradientThreshold — Gradient threshold**

Inf (default) | positive scalar

Gradient threshold, specified as Inf or a positive scalar. If the gradient exceeds the value of GradientThreshold, then the gradient is clipped according to the GradientThresholdMethod training option.

For more information, see Gradient Clipping on page 1-1815.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **GradientThresholdMethod — Gradient threshold method**

'l2norm' (default) | 'global-l2norm' | 'absolute-value'

Gradient threshold method used to clip gradient values that exceed the gradient threshold, specified as one of the following:

- 'l2norm' — If the  $L_2$  norm of the gradient of a learnable parameter is larger than GradientThreshold, then scale the gradient so that the  $L_2$  norm equals GradientThreshold.
- 'global-l2norm' — If the global  $L_2$  norm,  $L$ , is larger than GradientThreshold, then scale all gradients by a factor of GradientThreshold/ $L$ . The global  $L_2$  norm considers all learnable parameters.

- `'absolute-value'` — If the absolute value of an individual partial derivative in the gradient of a learnable parameter is larger than `GradientThreshold`, then scale the partial derivative to have magnitude equal to `GradientThreshold` and retain the sign of the partial derivative.

For more information, see Gradient Clipping on page 1-1815.

## Sequence Options

### SequenceLength — Option to pad or truncate sequences

`"longest"` (default) | `"shortest"` | positive integer

Option to pad, truncate, or split input sequences, specified as one of the following:

- `"longest"` — Pad sequences in each mini-batch to have the same length as the longest sequence. This option does not discard any data, though padding can introduce noise to the neural network.
- `"shortest"` — Truncate sequences in each mini-batch to have the same length as the shortest sequence. This option ensures that no padding is added, at the cost of discarding data.
- Positive integer — For each mini-batch, pad the sequences to the length of the longest sequence in the mini-batch, and then split the sequences into smaller sequences of the specified length. If splitting occurs, then the software creates extra mini-batches. If the specified sequence length does not evenly divide the sequence lengths of the data, then the mini-batches containing the ends those sequences have length shorter than the specified sequence length. Use this option if the full sequences do not fit in memory. Alternatively, try reducing the number of sequences per mini-batch by setting the `MiniBatchSize` option to a lower value.

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### SequencePaddingDirection — Direction of padding or truncation

`"right"` (default) | `"left"`

Direction of padding or truncation, specified as one of the following:

- `"right"` — Pad or truncate sequences on the right. The sequences start at the same time step and the software truncates or adds padding to the end of the sequences.
- `"left"` — Pad or truncate sequences on the left. The software truncates or adds padding to the start of the sequences so that the sequences end at the same time step.

Because recurrent layers process sequence data one time step at a time, when the recurrent layer `OutputMode` property is `'last'`, any padding in the final time steps can negatively influence the layer output. To pad or truncate sequence data on the left, set the `SequencePaddingDirection` option to `"left"`.

For sequence-to-sequence neural networks (when the `OutputMode` property is `'sequence'` for each recurrent layer), any padding in the first time steps can negatively influence the predictions for the earlier time steps. To pad or truncate sequence data on the right, set the `SequencePaddingDirection` option to `"right"`.

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

**SequencePaddingValue — Value to pad sequences**`0 (default) | scalar`

Value by which to pad input sequences, specified as a scalar.

The option is valid only when `SequenceLength` is "longest" or a positive integer. Do not pad sequences with NaN, because doing so can propagate errors throughout the neural network.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**Hardware Options****ExecutionEnvironment — Hardware resource for training neural network**`'auto' (default) | 'cpu' | 'gpu' | 'multi-gpu' | 'parallel'`

Hardware resource for training neural network, specified as one of the following:

- `'auto'` — Use a GPU if one is available. Otherwise, use the CPU.
- `'cpu'` — Use the CPU.
- `'gpu'` — Use the GPU.
- `'multi-gpu'` — Use multiple GPUs on one machine, using a local parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts a parallel pool with pool size equal to the number of available GPUs.
- `'parallel'` — Use a local or remote parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts one using the default cluster profile. If the pool has access to GPUs, then only workers with a unique GPU perform training computation. If the pool does not have GPUs, then training takes place on all available CPU workers instead.

For more information on when to use the different execution environments, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud”.

`'gpu'`, `'multi-gpu'`, and `'parallel'` options require Parallel Computing Toolbox. To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). If you choose one of these options and Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.

To see an improvement in performance when training in parallel, try scaling up the `MiniBatchSize` and `InitialLearnRate` training options by the number of GPUs.

The `'multi-gpu'` and `'parallel'` options do not support neural networks containing custom layers with state parameters or built-in layers that are stateful at training time. For example:

- recurrent layers such as `LSTMlayer`, `BiLSTMlayer`, or `GRUlayer` objects when the `SequenceLength` training option is a positive integer
- `BatchNormalizationLayer` objects when the `BatchNormalizationStatistics` training option is set to `'moving'`

**WorkerLoad — Parallel worker load division**`scalar from 0 to 1 | positive integer | numeric vector`

Parallel worker load division between GPUs or CPUs, specified as one of the following:

- Scalar from 0 to 1 — Fraction of workers on each machine to use for neural network training computation. If you train the neural network using data in a mini-batch datastore with background dispatch enabled, then the remaining workers fetch and preprocess data in the background.
- Positive integer — Number of workers on each machine to use for neural network training computation. If you train the neural network using data in a mini-batch datastore with background dispatch enabled, then the remaining workers fetch and preprocess data in the background.
- Numeric vector — Neural network training load for each worker in the parallel pool. For a vector  $W$ , worker  $i$  gets a fraction  $W(i) / \text{sum}(W)$  of the work (number of examples per mini-batch). If you train a neural network using data in a mini-batch datastore with background dispatch enabled, then you can assign a worker load of 0 to use that worker for fetching data in the background. The specified vector must contain one value per worker in the parallel pool.

If the parallel pool has access to GPUs, then workers without a unique GPU are never used for training computation. The default for pools with GPUs is to use all workers with a unique GPU for training computation, and the remaining workers for background dispatch. If the pool does not have access to GPUs and CPUs are used for training, then the default is to use one worker per machine for background data dispatch.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DispatchInBackground — Flag to enable background dispatch**

0 (false) (default) | 1 (true)

Flag to enable background dispatch (asynchronous prefetch queuing) to read training data from datastores, specified as 0 (false) or 1 (true). Background dispatch requires Parallel Computing Toolbox.

`DispatchInBackground` is only supported for datastores that are partitionable. For more information, see “Use Datastore for Parallel Training and Background Dispatching”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Checkpoints**

### **CheckpointPath — Path for saving checkpoint neural networks**

"" (default) | character vector

Path for saving the checkpoint neural networks, specified as a character vector or string scalar.

- If you do not specify a path (that is, you use the default ""), then the software does not save any checkpoint neural networks.
- If you specify a path, then `trainNetwork` saves checkpoint neural networks to this path and assigns a unique name to each neural network. You can then load any checkpoint neural network and resume training from that neural network.

If the folder does not exist, then you must first create it before specifying the path for saving the checkpoint neural networks. If the path you specify does not exist, then `trainingOptions` returns an error.

The `CheckpointFrequency` and `CheckpointFrequencyUnit` options specify the frequency of saving checkpoint neural networks.

For more information about saving neural network checkpoints, see “Save Checkpoint Networks and Resume Training”.

Data Types: char | string

**CheckpointFrequency — Frequency of saving checkpoint neural networks**

1 (default) | positive integer

Frequency of saving checkpoint neural networks, specified as a positive integer.

If CheckpointFrequencyUnit is 'epoch', then the software saves checkpoint neural networks every CheckpointFrequency epochs.

If CheckpointFrequencyUnit is 'iteration', then the software saves checkpoint neural networks every CheckpointFrequency iterations.

This option only has an effect when CheckpointPath is nonempty.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**CheckpointFrequencyUnit — Checkpoint frequency unit**

'epoch' (default) | 'iteration'

Checkpoint frequency unit, specified as 'epoch' or 'iteration'.

If CheckpointFrequencyUnit is 'epoch', then the software saves checkpoint neural networks every CheckpointFrequency epochs.

If CheckpointFrequencyUnit is 'iteration', then the software saves checkpoint neural networks every CheckpointFrequency iterations.

This option only has an effect when CheckpointPath is nonempty.

**OutputFcn — Output functions**

function handle | cell array of function handles

Output functions to call during training, specified as a function handle or cell array of function handles. `trainNetwork` calls the specified functions once before the start of training, after each iteration, and once after training has finished. `trainNetwork` passes a structure containing information in the following fields:

Field	Description
Epoch	Current epoch number
Iteration	Current iteration number
TimeSinceStart	Time in seconds since the start of training
TrainingLoss	Current mini-batch loss
ValidationLoss	Loss on the validation data
BaseLearnRate	Current base learning rate
TrainingAccuracy	Accuracy on the current mini-batch (classification neural networks)
TrainingRMSE	RMSE on the current mini-batch (regression neural networks)
ValidationAccuracy	Accuracy on the validation data (classification neural networks)

Field	Description
ValidationRMSE	RMSE on the validation data (regression neural networks)
State	Current training state, with a possible value of "start", "iteration", or "done".

If a field is not calculated or relevant for a certain call to the output functions, then that field contains an empty array.

You can use output functions to display or plot progress information, or to stop training. To stop training early, make your output function return 1 (true). If any output function returns 1 (true), then training finishes and `trainNetwork` returns the latest neural network. For an example showing how to use output functions, see “Customize Output During Deep Learning Network Training”.

Data Types: `function_handle` | `cell`

## Examples

### Create Training Options for the RMSProp Optimizer

Create a set of options for training a neural network using the RMSProp optimizer. Set the maximum number of epochs for training to 20, and use a mini-batch with 64 observations at each iteration. Specify the learning rate and the decay rate of the moving average of the squared gradient. Turn on the training progress plot.

```
options = trainingOptions("rmsprop", ...
    InitialLearnRate=3e-4, ...
    SquaredGradientDecayFactor=0.99, ...
    MaxEpochs=20, ...
    MiniBatchSize=64, ...
    Plots="training-progress")
```

```
options =
  TrainingOptionsRMSProp with properties:

    SquaredGradientDecayFactor: 0.9900
              Epsilon: 1.0000e-08
      InitialLearnRate: 3.0000e-04
    LearnRateSchedule: 'none'
    LearnRateDropFactor: 0.1000
    LearnRateDropPeriod: 10
      L2Regularization: 1.0000e-04
    GradientThresholdMethod: 'l2norm'
      GradientThreshold: Inf
              MaxEpochs: 20
      MiniBatchSize: 64
              Verbose: 1
    VerboseFrequency: 50
      ValidationData: []
    ValidationFrequency: 50
    ValidationPatience: Inf
              Shuffle: 'once'
      CheckpointPath: ''
    CheckpointFrequency: 1
    CheckpointFrequencyUnit: 'epoch'
```

```
ExecutionEnvironment: 'auto'  
  WorkerLoad: []  
  OutputFcn: []  
    Plots: 'training-progress'  
  SequenceLength: 'longest'  
  SequencePaddingValue: 0  
  SequencePaddingDirection: 'right'  
  DispatchInBackground: 0  
  ResetInputNormalization: 1  
  BatchNormalizationStatistics: 'population'  
  OutputNetwork: 'last-iteration'
```

## Algorithms

### RMSProp

Stochastic gradient descent with momentum uses a single learning rate for all the parameters. Other optimization algorithms seek to improve network training by using learning rates that differ by parameter and can automatically adapt to the loss function being optimized. RMSProp (root mean square propagation) is one such algorithm. It keeps a moving average of the element-wise squares of the parameter gradients,

$$v_t = \beta_2 v_{t-1} + (1 - \beta_2) [\nabla E(\theta_t)]^2$$

$\beta_2$  is the decay rate of the moving average. Common values of the decay rate are 0.9, 0.99, and 0.999. The corresponding averaging lengths of the squared gradients equal  $1/(1-\beta_2)$ , that is, 10, 100, and 1000 parameter updates, respectively. You can specify  $\beta_2$  by using the `SquaredGradientDecayFactor` training options. The RMSProp algorithm uses this moving average to normalize the updates of each parameter individually,

$$\theta_{t+1} = \theta_t - \frac{\alpha \nabla E(\theta_t)}{\sqrt{v_t} + \epsilon}$$

where the division is performed element-wise. Using RMSProp effectively decreases the learning rates of parameters with large gradients and increases the learning rates of parameters with small gradients.  $\epsilon$  is a small constant added to avoid division by zero. You can specify  $\epsilon$  by using the `Epsilon` training option, but the default value usually works well. To use RMSProp to train a neural network, specify `'rmsprop'` as the first input to `trainingOptions`.

### L<sub>2</sub> Regularization

Adding a regularization term for the weights to the loss function  $E(\theta)$  is one way to reduce overfitting [1], [2]. The regularization term is also called *weight decay*. The loss function with the regularization term takes the form

$$E_R(\theta) = E(\theta) + \lambda \Omega(w),$$

where  $w$  is the weight vector,  $\lambda$  is the regularization factor (coefficient), and the regularization function  $\Omega(w)$  is

$$\Omega(w) = \frac{1}{2} w^T w.$$

Note that the biases are not regularized [2]. You can specify the regularization factor  $\lambda$  by using the `L2Regularization` training option. You can also specify different regularization factors for different layers and parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

The loss function that the software uses for network training includes the regularization term. However, the loss value displayed in the command window and training progress plot during training is the loss on the data only and does not include the regularization term.

### Gradient Clipping

If the gradients increase in magnitude exponentially, then the training is unstable and can diverge within a few iterations. This "gradient explosion" is indicated by a training loss that goes to NaN or Inf. Gradient clipping helps prevent gradient explosion by stabilizing the training at higher learning rates and in the presence of outliers [3]. Gradient clipping enables networks to be trained faster, and does not usually impact the accuracy of the learned task.

There are two types of gradient clipping.

- Norm-based gradient clipping rescales the gradient based on a threshold, and does not change the direction of the gradient. The `'l2norm'` and `'global-l2norm'` values of `GradientThresholdMethod` are norm-based gradient clipping methods.
- Value-based gradient clipping clips any partial derivative greater than the threshold, which can result in the gradient arbitrarily changing direction. Value-based gradient clipping can have unpredictable behavior, but sufficiently small changes do not cause the network to diverge. The `'absolute-value'` value of `GradientThresholdMethod` is a value-based gradient clipping method.

## Version History

### Introduced in R2018a

#### **R2022b: `trainNetwork` pads mini-batches to length of longest sequence before splitting when you specify `SequenceLength` training option as an integer**

Starting in R2022b, when you train a neural network with sequence data using the `trainNetwork` function and the `SequenceLength` option is an integer, the software pads sequences to the length of the longest sequence in each mini-batch and then splits the sequences into mini-batches with the specified sequence length. If `SequenceLength` does not evenly divide the sequence length of the mini-batch, then the last split mini-batch has a length shorter than `SequenceLength`. This behavior prevents the neural network training on time steps that contain only padding values.

In previous releases, the software pads mini-batches of sequences to have a length matching the nearest multiple of `SequenceLength` that is greater than or equal to the mini-batch length and then splits the data. To reproduce this behavior, use a custom training loop and implement this behavior when you preprocess mini-batches of data.

#### **R2018b: `ValidationPatience` training option default is Inf**

*Behavior changed in R2018b*

Starting in R2018b, the default value of the `ValidationPatience` training option is `Inf`, which means that automatic stopping via validation is turned off. This behavior prevents the training from stopping before sufficiently learning from the data.

In previous versions, the default value is 5. To reproduce this behavior, set the `ValidationPatience` option to 5.

# TrainingOptionsSGDM

Training options for stochastic gradient descent with momentum

## Description

Training options for stochastic gradient descent with momentum, including learning rate information,  $L_2$  regularization factor, and mini-batch size.

## Creation

Create a TrainingOptionsSGDM object using trainingOptions and specifying 'sgdm' as the first input argument.

## Properties

### Plots and Display

#### Plots — Plots to display during neural network training

'none' (default) | 'training-progress'

Plots to display during neural network training, specified as one of the following:

- 'none' — Do not display plots during training.
- 'training-progress' — Plot training progress. The plot shows mini-batch loss and accuracy, validation loss and accuracy, and additional information on the training progress. The plot has a stop button  in the top-right corner. Click the button to stop training and return the current state of the neural network. You can save the training plot as an image or PDF by clicking **Export Training Plot**. For more information on the training progress plot, see “Monitor Deep Learning Training Progress”.

#### Verbose — Indicator to display training progress information

1 (true) (default) | 0 (false)

Indicator to display training progress information in the command window, specified as 1 (true) or 0 (false).

The verbose output displays the following information:

**Classification Neural Networks**

<b>Field</b>	<b>Description</b>
Epoch	Epoch number. An epoch corresponds to a full pass of the data.
Iteration	Iteration number. An iteration corresponds to a mini-batch.
Time Elapsed	Time elapsed in hours, minutes, and seconds.
Mini-batch Accuracy	Classification accuracy on the mini-batch.
Validation Accuracy	Classification accuracy on the validation data. If you do not specify validation data, then the function does not display this field.
Mini-batch Loss	Loss on the mini-batch. If the output layer is a <code>ClassificationOutputLayer</code> object, then the loss is the cross entropy loss for multi-class classification problems with mutually exclusive classes.
Validation Loss	Loss on the validation data. If the output layer is a <code>ClassificationOutputLayer</code> object, then the loss is the cross entropy loss for multi-class classification problems with mutually exclusive classes. If you do not specify validation data, then the function does not display this field.
Base Learning Rate	Base learning rate. The software multiplies the learn rate factors of the layers by this value.

## Regression Neural Networks

Field	Description
Epoch	Epoch number. An epoch corresponds to a full pass of the data.
Iteration	Iteration number. An iteration corresponds to a mini-batch.
Time Elapsed	Time elapsed in hours, minutes, and seconds.
Mini-batch RMSE	Root-mean-squared-error (RMSE) on the mini-batch.
Validation RMSE	RMSE on the validation data. If you do not specify validation data, then the software does not display this field.
Mini-batch Loss	Loss on the mini-batch. If the output layer is a <code>RegressionOutputLayer</code> object, then the loss is the half-mean-squared-error.
Validation Loss	Loss on the validation data. If the output layer is a <code>RegressionOutputLayer</code> object, then the loss is the half-mean-squared-error. If you do not specify validation data, then the software does not display this field.
Base Learning Rate	Base learning rate. The software multiplies the learn rate factors of the layers by this value.

When training stops, the verbose output displays the reason for stopping.

To specify validation data, use the `ValidationData` training option.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### VerboseFrequency — Frequency of verbose printing

50 (default) | positive integer

Frequency of verbose printing, which is the number of iterations between printing to the command window, specified as a positive integer. This option only has an effect when the `Verbose` training option is 1 (true).

If you validate the neural network during training, then `trainNetwork` also prints to the command window every time validation occurs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Mini-Batch Options

#### MaxEpochs — Maximum number of epochs

30 (default) | positive integer

Maximum number of epochs to use for training, specified as a positive integer.

An iteration is one step taken in the gradient descent algorithm towards minimizing the loss function using a mini-batch. An epoch is the full pass of the training algorithm over the entire training set.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **MiniBatchSize — Size of mini-batch**

128 (default) | positive integer

Size of the mini-batch to use for each training iteration, specified as a positive integer. A mini-batch is a subset of the training set that is used to evaluate the gradient of the loss function and update the weights.

If the mini-batch size does not evenly divide the number of training samples, then `trainNetwork` discards the training data that does not fit into the final complete mini-batch of each epoch.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Shuffle — Option for data shuffling**

'once' (default) | 'never' | 'every-epoch'

Option for data shuffling, specified as one of the following:

- 'once' — Shuffle the training and validation data once before training.
- 'never' — Do not shuffle the data.
- 'every-epoch' — Shuffle the training data before each training epoch, and shuffle the validation data before each neural network validation. If the mini-batch size does not evenly divide the number of training samples, then `trainNetwork` discards the training data that does not fit into the final complete mini-batch of each epoch. To avoid discarding the same data every epoch, set the `Shuffle` training option to 'every-epoch'.

## **Validation**

### **ValidationData — Data to use for validation during training**

[] (default) | datastore | table | cell array

Data to use for validation during training, specified as [], a datastore, a table, or a cell array containing the validation predictors and responses.

You can specify validation predictors and responses using the same formats supported by the `trainNetwork` function. You can specify the validation data as a datastore, table, or the cell array `{predictors, responses}`, where `predictors` contains the validation predictors and `responses` contains the validation responses.

For more information, see the `images`, `sequences`, and `features` input arguments of the `trainNetwork` function.

During training, `trainNetwork` calculates the validation accuracy and validation loss on the validation data. To specify the validation frequency, use the `ValidationFrequency` training option. You can also use the validation data to stop training automatically when the validation loss stops decreasing. To turn on automatic validation stopping, use the `ValidationPatience` training option.

If your neural network has layers that behave differently during prediction than during training (for example, dropout layers), then the validation accuracy can be higher than the training (mini-batch) accuracy.

The validation data is shuffled according to the `Shuffle` training option. If `Shuffle` is 'every-epoch', then the validation data is shuffled before each neural network validation.

If `ValidationData` is `[]`, then the software does not validate the neural network during training.

### **ValidationFrequency — Frequency of neural network validation**

50 (default) | positive integer

Frequency of neural network validation in number of iterations, specified as a positive integer.

The `ValidationFrequency` value is the number of iterations between evaluations of validation metrics. To specify validation data, use the `ValidationData` training option.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ValidationPatience — Patience of validation stopping**

Inf (default) | positive integer

Patience of validation stopping of neural network training, specified as a positive integer or `Inf`.

`ValidationPatience` specifies the number of times that the loss on the validation set can be larger than or equal to the previously smallest loss before neural network training stops. If `ValidationPatience` is `Inf`, then the values of the validation loss do not cause training to stop early.

The returned neural network depends on the `OutputNetwork` training option. To return the neural network with the lowest validation loss, set the `OutputNetwork` training option to `"best-validation-loss"`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **OutputNetwork — Neural network to return when training completes**

'last-iteration' (default) | 'best-validation-loss'

Neural network to return when training completes, specified as one of the following:

- `'last-iteration'` - Return the neural network corresponding to the last training iteration.
- `'best-validation-loss'` - Return the neural network corresponding to the training iteration with the lowest validation loss. To use this option, you must specify the `ValidationData` training option.

## **Solver Options**

### **InitialLearnRate — Initial learning rate**

0.01 (default) | positive scalar

Initial learning rate used for training, specified as a positive scalar.

If the learning rate is too low, then training can take a long time. If the learning rate is too high, then training might reach a suboptimal result or diverge.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **LearnRateScheduleSettings — Settings for learning rate schedule**

structure

This property is read-only.

Settings for the learning rate schedule, specified as a structure. `LearnRateScheduleSettings` has the field `Method`, which specifies the type of method for adjusting the learning rate. The possible methods are:

- `'none'` — The learning rate is constant throughout training.
- `'piecewise'` — The learning rate drops periodically during training.

If `Method` is `'piecewise'`, then `LearnRateScheduleSettings` contains two more fields:

- `DropRateFactor` — The multiplicative factor by which the learning rate drops during training
- `DropPeriod` — The number of epochs that passes between adjustments to the learning rate during training

Specify the settings for the learning schedule rate using `trainingOptions`.

Data Types: `struct`

### **L2Regularization — Factor for L<sub>2</sub> regularization**

`0.0001` (default) | nonnegative scalar

Factor for L<sub>2</sub> regularization (weight decay), specified as a nonnegative scalar. For more information, see “L2 Regularization” on page 1-1829.

You can specify a multiplier for the L<sub>2</sub> regularization for neural network layers with learnable parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Momentum — Contribution of previous step**

`0.9` (default) | scalar from 0 to 1

Contribution of the parameter update step of the previous iteration to the current iteration of stochastic gradient descent with momentum, specified as a scalar from 0 to 1.

A value of 0 means no contribution from the previous step, whereas a value of 1 means maximal contribution from the previous step. The default value works well for most tasks.

For more information, see “Stochastic Gradient Descent with Momentum” on page 1-1829.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ResetInputNormalization — Option to reset input layer normalization**

`1` (true) (default) | `0` (false)

Option to reset input layer normalization, specified as one of the following:

- `1` (true) — Reset the input layer normalization statistics and recalculate them at training time.
- `0` (false) — Calculate normalization statistics at training time when they are empty.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **BatchNormalizationStatistics — Mode to evaluate statistics in batch normalization layers**

`'population'` (default) | `'moving'`

Mode to evaluate the statistics in batch normalization layers, specified as one of the following:

- 'population' - Use the population statistics. After training, the software finalizes the statistics by passing through the training data once more and uses the resulting mean and variance.
- 'moving' - Approximate the statistics during training using a running estimate given by update steps

$$\mu^* = \lambda_\mu \widehat{\mu} + (1 - \lambda_\mu)\mu$$

$$\sigma^{2*} = \lambda_\sigma 2\widehat{\sigma^2} + (1 - \lambda_\sigma)\sigma^2$$

where  $\mu^*$  and  $\sigma^{2*}$  denote the updated mean and variance, respectively,  $\lambda_\mu$  and  $\lambda_\sigma$  denote the mean and variance decay values, respectively,  $\widehat{\mu}$  and  $\widehat{\sigma^2}$  denote the mean and variance of the layer input, respectively, and  $\mu$  and  $\sigma^2$  denote the latest values of the moving mean and variance values, respectively. After training, the software uses the most recent value of the moving mean and variance statistics. This option supports CPU and single GPU training only.

## Gradient Clipping

### GradientThreshold — Gradient threshold

Inf (default) | positive scalar

Gradient threshold, specified as Inf or a positive scalar. If the gradient exceeds the value of GradientThreshold, then the gradient is clipped according to the GradientThresholdMethod training option.

For more information, see Gradient Clipping on page 1-1829.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### GradientThresholdMethod — Gradient threshold method

'l2norm' (default) | 'global-l2norm' | 'absolute-value'

Gradient threshold method used to clip gradient values that exceed the gradient threshold, specified as one of the following:

- 'l2norm' — If the  $L_2$  norm of the gradient of a learnable parameter is larger than GradientThreshold, then scale the gradient so that the  $L_2$  norm equals GradientThreshold.
- 'global-l2norm' — If the global  $L_2$  norm,  $L$ , is larger than GradientThreshold, then scale all gradients by a factor of GradientThreshold/ $L$ . The global  $L_2$  norm considers all learnable parameters.
- 'absolute-value' — If the absolute value of an individual partial derivative in the gradient of a learnable parameter is larger than GradientThreshold, then scale the partial derivative to have magnitude equal to GradientThreshold and retain the sign of the partial derivative.

For more information, see Gradient Clipping on page 1-1829.

## Sequence Options

### SequenceLength — Option to pad or truncate sequences

"longest" (default) | "shortest" | positive integer

Option to pad, truncate, or split input sequences, specified as one of the following:

- `"longest"` — Pad sequences in each mini-batch to have the same length as the longest sequence. This option does not discard any data, though padding can introduce noise to the neural network.
- `"shortest"` — Truncate sequences in each mini-batch to have the same length as the shortest sequence. This option ensures that no padding is added, at the cost of discarding data.
- Positive integer — For each mini-batch, pad the sequences to the length of the longest sequence in the mini-batch, and then split the sequences into smaller sequences of the specified length. If splitting occurs, then the software creates extra mini-batches. If the specified sequence length does not evenly divide the sequence lengths of the data, then the mini-batches containing the ends of those sequences have length shorter than the specified sequence length. Use this option if the full sequences do not fit in memory. Alternatively, try reducing the number of sequences per mini-batch by setting the `MiniBatchSize` option to a lower value.

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### **SequencePaddingDirection — Direction of padding or truncation**

`"right"` (default) | `"left"`

Direction of padding or truncation, specified as one of the following:

- `"right"` — Pad or truncate sequences on the right. The sequences start at the same time step and the software truncates or adds padding to the end of the sequences.
- `"left"` — Pad or truncate sequences on the left. The software truncates or adds padding to the start of the sequences so that the sequences end at the same time step.

Because recurrent layers process sequence data one time step at a time, when the recurrent layer `OutputMode` property is `'last'`, any padding in the final time steps can negatively influence the layer output. To pad or truncate sequence data on the left, set the `SequencePaddingDirection` option to `"left"`.

For sequence-to-sequence neural networks (when the `OutputMode` property is `'sequence'` for each recurrent layer), any padding in the first time steps can negatively influence the predictions for the earlier time steps. To pad or truncate sequence data on the right, set the `SequencePaddingDirection` option to `"right"`.

To learn more about the effect of padding, truncating, and splitting the input sequences, see “Sequence Padding, Truncation, and Splitting”.

### **SequencePaddingValue — Value to pad sequences**

`0` (default) | scalar

Value by which to pad input sequences, specified as a scalar.

The option is valid only when `SequenceLength` is `"longest"` or a positive integer. Do not pad sequences with NaN, because doing so can propagate errors throughout the neural network.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Hardware Options**

#### **ExecutionEnvironment — Hardware resource for training neural network**

`'auto'` (default) | `'cpu'` | `'gpu'` | `'multi-gpu'` | `'parallel'`

Hardware resource for training neural network, specified as one of the following:

- 'auto' — Use a GPU if one is available. Otherwise, use the CPU.
- 'cpu' — Use the CPU.
- 'gpu' — Use the GPU.
- 'multi-gpu' — Use multiple GPUs on one machine, using a local parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts a parallel pool with pool size equal to the number of available GPUs.
- 'parallel' — Use a local or remote parallel pool based on your default cluster profile. If there is no current parallel pool, the software starts one using the default cluster profile. If the pool has access to GPUs, then only workers with a unique GPU perform training computation. If the pool does not have GPUs, then training takes place on all available CPU workers instead.

For more information on when to use the different execution environments, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud”.

'gpu', 'multi-gpu', and 'parallel' options require Parallel Computing Toolbox. To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). If you choose one of these options and Parallel Computing Toolbox or a suitable GPU is not available, then the software returns an error.

To see an improvement in performance when training in parallel, try scaling up the `MiniBatchSize` and `InitialLearnRate` training options by the number of GPUs.

The 'multi-gpu' and 'parallel' options do not support neural networks containing custom layers with state parameters or built-in layers that are stateful at training time. For example:

- recurrent layers such as `LSTMLayer`, `BiLSTMLayer`, or `GRULayer` objects when the `SequenceLength` training option is a positive integer
- `BatchNormalizationLayer` objects when the `BatchNormalizationStatistics` training option is set to 'moving'

#### **WorkerLoad — Parallel worker load division**

scalar from 0 to 1 | positive integer | numeric vector

Parallel worker load division between GPUs or CPUs, specified as one of the following:

- Scalar from 0 to 1 — Fraction of workers on each machine to use for neural network training computation. If you train the neural network using data in a mini-batch datastore with background dispatch enabled, then the remaining workers fetch and preprocess data in the background.
- Positive integer — Number of workers on each machine to use for neural network training computation. If you train the neural network using data in a mini-batch datastore with background dispatch enabled, then the remaining workers fetch and preprocess data in the background.
- Numeric vector — Neural network training load for each worker in the parallel pool. For a vector  $W$ , worker  $i$  gets a fraction  $W(i)/\text{sum}(W)$  of the work (number of examples per mini-batch). If you train a neural network using data in a mini-batch datastore with background dispatch enabled, then you can assign a worker load of 0 to use that worker for fetching data in the background. The specified vector must contain one value per worker in the parallel pool.

If the parallel pool has access to GPUs, then workers without a unique GPU are never used for training computation. The default for pools with GPUs is to use all workers with a unique GPU for training computation, and the remaining workers for background dispatch. If the pool does not have

access to GPUs and CPUs are used for training, then the default is to use one worker per machine for background data dispatch.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DispatchInBackground — Flag to enable background dispatch**

`0` (false) (default) | `1` (true)

Flag to enable background dispatch (asynchronous prefetch queuing) to read training data from datastores, specified as `0` (false) or `1` (true). Background dispatch requires Parallel Computing Toolbox.

`DispatchInBackground` is only supported for datastores that are partitionable. For more information, see “Use Datastore for Parallel Training and Background Dispatching”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Checkpoints**

### **CheckpointPath — Path for saving checkpoint neural networks**

`''` (default) | character vector

Path for saving the checkpoint neural networks, specified as a character vector or string scalar.

- If you do not specify a path (that is, you use the default `''`), then the software does not save any checkpoint neural networks.
- If you specify a path, then `trainNetwork` saves checkpoint neural networks to this path and assigns a unique name to each neural network. You can then load any checkpoint neural network and resume training from that neural network.

If the folder does not exist, then you must first create it before specifying the path for saving the checkpoint neural networks. If the path you specify does not exist, then `trainingOptions` returns an error.

The `CheckpointFrequency` and `CheckpointFrequencyUnit` options specify the frequency of saving checkpoint neural networks.

For more information about saving neural network checkpoints, see “Save Checkpoint Networks and Resume Training”.

Data Types: `char` | `string`

### **CheckpointFrequency — Frequency of saving checkpoint neural networks**

`1` (default) | positive integer

Frequency of saving checkpoint neural networks, specified as a positive integer.

If `CheckpointFrequencyUnit` is `'epoch'`, then the software saves checkpoint neural networks every `CheckpointFrequency` epochs.

If `CheckpointFrequencyUnit` is `'iteration'`, then the software saves checkpoint neural networks every `CheckpointFrequency` iterations.

This option only has an effect when `CheckpointPath` is nonempty.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**CheckpointFrequencyUnit — Checkpoint frequency unit**

'epoch' (default) | 'iteration'

Checkpoint frequency unit, specified as 'epoch' or 'iteration'.

If CheckpointFrequencyUnit is 'epoch', then the software saves checkpoint neural networks every CheckpointFrequency epochs.

If CheckpointFrequencyUnit is 'iteration', then the software saves checkpoint neural networks every CheckpointFrequency iterations.

This option only has an effect when CheckpointPath is nonempty.

**OutputFcn — Output functions**

function handle | cell array of function handles

Output functions to call during training, specified as a function handle or cell array of function handles. `trainNetwork` calls the specified functions once before the start of training, after each iteration, and once after training has finished. `trainNetwork` passes a structure containing information in the following fields:

Field	Description
Epoch	Current epoch number
Iteration	Current iteration number
TimeSinceStart	Time in seconds since the start of training
TrainingLoss	Current mini-batch loss
ValidationLoss	Loss on the validation data
BaseLearnRate	Current base learning rate
TrainingAccuracy	Accuracy on the current mini-batch (classification neural networks)
TrainingRMSE	RMSE on the current mini-batch (regression neural networks)
ValidationAccuracy	Accuracy on the validation data (classification neural networks)
ValidationRMSE	RMSE on the validation data (regression neural networks)
State	Current training state, with a possible value of "start", "iteration", or "done".

If a field is not calculated or relevant for a certain call to the output functions, then that field contains an empty array.

You can use output functions to display or plot progress information, or to stop training. To stop training early, make your output function return 1 (true). If any output function returns 1 (true), then training finishes and `trainNetwork` returns the latest neural network. For an example showing how to use output functions, see “Customize Output During Deep Learning Network Training”.

Data Types: `function_handle` | `cell`

## Examples

### Specify Training Options

Create a set of options for training a network using stochastic gradient descent with momentum. Reduce the learning rate by a factor of 0.2 every 5 epochs. Set the maximum number of epochs for training to 20, and use a mini-batch with 64 observations at each iteration. Turn on the training progress plot.

```
options = trainingOptions("sgdm", ...  
    LearnRateSchedule="piecewise", ...  
    LearnRateDropFactor=0.2, ...  
    LearnRateDropPeriod=5, ...  
    MaxEpochs=20, ...  
    MiniBatchSize=64, ...  
    Plots="training-progress")
```

```
options =  
    TrainingOptionsSGDM with properties:  
  
        Momentum: 0.9000  
        InitialLearnRate: 0.0100  
        LearnRateSchedule: 'piecewise'  
        LearnRateDropFactor: 0.2000  
        LearnRateDropPeriod: 5  
        L2Regularization: 1.0000e-04  
        GradientThresholdMethod: 'l2norm'  
        GradientThreshold: Inf  
        MaxEpochs: 20  
        MiniBatchSize: 64  
        Verbose: 1  
        VerboseFrequency: 50  
        ValidationData: []  
        ValidationFrequency: 50  
        ValidationPatience: Inf  
        Shuffle: 'once'  
        CheckpointPath: ''  
        CheckpointFrequency: 1  
        CheckpointFrequencyUnit: 'epoch'  
        ExecutionEnvironment: 'auto'  
        WorkerLoad: []  
        OutputFcn: []  
        Plots: 'training-progress'  
        SequenceLength: 'longest'  
        SequencePaddingValue: 0  
        SequencePaddingDirection: 'right'  
        DispatchInBackground: 0  
        ResetInputNormalization: 1  
        BatchNormalizationStatistics: 'population'  
        OutputNetwork: 'last-iteration'
```

## Algorithms

### Stochastic Gradient Descent with Momentum

The stochastic gradient descent algorithm can oscillate along the path of steepest descent towards the optimum. Adding a momentum term to the parameter update is one way to reduce this oscillation [2]. The stochastic gradient descent with momentum (SGDM) update is

$$\theta_{\ell+1} = \theta_{\ell} - \alpha \nabla E(\theta_{\ell}) + \gamma(\theta_{\ell} - \theta_{\ell-1}),$$

where  $\gamma$  determines the contribution of the previous gradient step to the current iteration. You can specify this value using the `Momentum` training option. To train a neural network using the stochastic gradient descent with momentum algorithm, specify `'sgdm'` as the first input argument to `trainingOptions`. To specify the initial value of the learning rate  $\alpha$ , use the `InitialLearnRate` training option. You can also specify different learning rates for different layers and parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

### L<sub>2</sub> Regularization

Adding a regularization term for the weights to the loss function  $E(\theta)$  is one way to reduce overfitting [1], [2]. The regularization term is also called *weight decay*. The loss function with the regularization term takes the form

$$E_R(\theta) = E(\theta) + \lambda \Omega(w),$$

where  $w$  is the weight vector,  $\lambda$  is the regularization factor (coefficient), and the regularization function  $\Omega(w)$  is

$$\Omega(w) = \frac{1}{2} w^T w.$$

Note that the biases are not regularized [2]. You can specify the regularization factor  $\lambda$  by using the `L2Regularization` training option. You can also specify different regularization factors for different layers and parameters. For more information, see “Set Up Parameters in Convolutional and Fully Connected Layers”.

The loss function that the software uses for network training includes the regularization term. However, the loss value displayed in the command window and training progress plot during training is the loss on the data only and does not include the regularization term.

### Gradient Clipping

If the gradients increase in magnitude exponentially, then the training is unstable and can diverge within a few iterations. This “gradient explosion” is indicated by a training loss that goes to `NaN` or `Inf`. Gradient clipping helps prevent gradient explosion by stabilizing the training at higher learning rates and in the presence of outliers [3]. Gradient clipping enables networks to be trained faster, and does not usually impact the accuracy of the learned task.

There are two types of gradient clipping.

- Norm-based gradient clipping rescales the gradient based on a threshold, and does not change the direction of the gradient. The `'l2norm'` and `'global-l2norm'` values of `GradientThresholdMethod` are norm-based gradient clipping methods.
- Value-based gradient clipping clips any partial derivative greater than the threshold, which can result in the gradient arbitrarily changing direction. Value-based gradient clipping can have

unpredictable behavior, but sufficiently small changes do not cause the network to diverge. The 'absolute-value' value of `GradientThresholdMethod` is a value-based gradient clipping method.

## Version History

### Introduced in R2016a

#### **R2022b: `trainNetwork` pads mini-batches to length of longest sequence before splitting when you specify `SequenceLength` training option as an integer**

Starting in R2022b, when you train a neural network with sequence data using the `trainNetwork` function and the `SequenceLength` option is an integer, the software pads sequences to the length of the longest sequence in each mini-batch and then splits the sequences into mini-batches with the specified sequence length. If `SequenceLength` does not evenly divide the sequence length of the mini-batch, then the last split mini-batch has a length shorter than `SequenceLength`. This behavior prevents the neural network training on time steps that contain only padding values.

In previous releases, the software pads mini-batches of sequences to have a length matching the nearest multiple of `SequenceLength` that is greater than or equal to the mini-batch length and then splits the data. To reproduce this behavior, use a custom training loop and implement this behavior when you preprocess mini-batches of data.

#### **R2018b: `ValidationPatience` training option default is `Inf`**

*Behavior changed in R2018b*

Starting in R2018b, the default value of the `ValidationPatience` training option is `Inf`, which means that automatic stopping via validation is turned off. This behavior prevents the training from stopping before sufficiently learning from the data.

In previous versions, the default value is 5. To reproduce this behavior, set the `ValidationPatience` option to 5.

# trainingProgressMonitor

Monitor and plot training progress for deep learning custom training loops

## Description

Use a TrainingProgressMonitor object to track training progress when using a custom training loop.

You can use a TrainingProgressMonitor object to:

- Create animated custom metric plots and record custom metrics during training.
- Display and record training information during training.
- Stop training early.
- Track training progress with a progress bar.
- Track elapsed time.

This image shows an example of the Training Progress window during training. For more information about configuring the Training Progress window and an example showing how to generate this figure, see “Monitor Custom Training Loop Progress”.

## Creation

### Syntax

```
monitor = trainingProgressMonitor  
monitor = trainingProgressMonitor(Name=Value)
```

### Description

`monitor = trainingProgressMonitor` creates a `TrainingProgressMonitor` object that you can use to track the training progress and create training plots.

`monitor = trainingProgressMonitor(Name=Value)` sets the `Metrics`, `Info`, `Visible`, `Progress`, `Status`, and `XLabel` properties using one or more name-value arguments.

### Properties

#### Metrics — Metric names

"" (default) | string scalar | character vector | string array | cell array of character vectors

Metric names, specified as a string scalar, character vector, string array, or cell array of character vectors. Valid names begin with a letter, and contain letters, digits, and underscores. Each metric appears in its own training subplot. To plot more than one metric in a single subplot, use the `groupSubPlot` function.

Example: `["TrainingLoss", "ValidationLoss"];`

Data Types: `char` | `string` | `cell`

#### Info — Information names

"" (default) | string scalar | character vector | string array | cell array of character vectors

Information names, specified as a string scalar, character vector, string array, or cell array of character vectors. Valid names begin with a letter, and contain letters, digits, and underscores. These names appear in the Training Progress window but do not appear as training plots.

Example: `["GradientDecayFactor", "SquaredGradientDecayFactor"];`

Data Types: `char` | `string` | `cell`

#### Stop — Request to stop training

false or 0 (default) | true or 1

This property is read-only.

Request to stop training, specified as a numeric or logical 0 (false) or 1 (true). The value of this property changes to 1 when you click the **Stop** button in the Training Progress window. The **Stop** button only appears if you set the `Visible` property to 'on' or 1 (true).

Data Types: `logical`

#### Visible — State of visibility

'on' (default) | on/off logical value

State of visibility, specified as 'on' or 'off', or as numeric or logical 1 (true) or 0 (false). A value of 'on' is equivalent to true, and 'off' is equivalent to false. Thus, you can use the value of this

property as a logical value. The value is stored as an on/off logical value of type `matlab.lang.OnOffSwitchState`.

- 'on' — Display the Training Progress window.
- 'off' — Hide the Training Progress window without deleting it. You still can access the properties of an invisible object.

Example: 'off'

### **Progress — Training progress percentage**

0 (default) | scalar in the range [0, 100] | d`l`array object in the range [0, 100]

Training progress percentage, specified as a scalar or d`l`array object in the range [0, 100].

Example: 17;

### **XLabel — Horizontal axis label**

"" (default) | string scalar | character vector

Horizontal axis label in the training plot, specified as a string scalar or character vector.

Example: "Iteration";

Data Types: char | string | cell

### **Status — Training status**

"" (default) | string scalar | character vector

Training status, specified as a string scalar or character vector.

Example: "Running";

Data Types: char | string | cell

### **MetricData — Metric values**

structure

This property is read-only.

Metric values, specified as a structure. Use the `Metrics` property to specify the field names for the structure. Each field contains a matrix with two columns. The first column contains the custom training loop step values and the second column contains the metric values recorded by the `recordMetrics` function.

Data Types: struct

### **InfoData — Information values**

structure

This property is read-only.

Information values, specified as a structure. Use the `Info` property to specify the field names for the structure. Each field is a column vector that contains the values updated by the `updateInfo` function.

Data Types: struct

## Object Functions

groupSubPlot	Group metrics in training plot
recordMetrics	Record metric values for custom training loops
updateInfo	Update information values for custom training loops

## Examples

### Track Progress and Produce Training Plots

Use a `TrainingProgressMonitor` object to track training progress and produce training plots for custom training loops.

Create a `TrainingProgressMonitor` object. The monitor automatically tracks the start time and the elapsed time. The timer starts when you create the object.

---

**Tip** To ensure that the elapsed time accurately reflects the training time, make sure you create the `TrainingProgressMonitor` object close to the start of your custom training loop.

---

```
monitor = trainingProgressMonitor;
```

Before you start the training, specify names for the information and metric values.

```
monitor.Info = ["LearningRate", "Epoch", "Iteration"];  
monitor.Metrics = ["TrainingLoss", "ValidationLoss", "TrainingAccuracy", "ValidationAccuracy"];
```

Specify the horizontal axis label for the training plot. Group the training and validation loss in the same subplot, and group the training and validation accuracy in the same plot.

```
monitor.XLabel = "Iteration";  
groupSubPlot(monitor, "Loss", ["TrainingLoss", "ValidationLoss"]);  
groupSubPlot(monitor, "Accuracy", ["TrainingAccuracy", "ValidationAccuracy"]);
```

During training:

- Evaluate the `Stop` property at the start of each step in your custom training loop. When you click the **Stop** button in the Training Progress window, the `Stop` property changes to 1. Training stops if your training loop exits when the `Stop` property is 1.
- Update the information values. The updated values appear in the Training Progress window.
- Record the metric values. The recorded values appear in the training plot.
- Update the training progress percentage based on the fraction of iterations completed.

---

**Note** The following example code is a template. You must edit this training loop to compute your metric and information values. For a complete example that you can run in MATLAB, see “Monitor Custom Training Loop Progress During Training”.

---

```
epoch = 0;  
iteration = 0;  
  
monitor.Status = "Running";
```

```

while epoch < maxEpochs && ~monitor.Stop
    epoch = epoch + 1;

    while hasData(mbq) && ~monitor.Stop
        iteration = iteration + 1;

        % Add code to calculate metric and information values.
        % lossTrain = ...

        updateInfo(monitor, ...
            LearningRate=learnRate, ...
            Epoch=string(epoch) + " of " + string(maxEpochs), ...
            Iteration=string(iteration) + " of " + string(numIterations));

        recordMetrics(monitor, iteration, ...
            TrainingLoss=lossTrain, ...
            TrainingAccuracy=accuracyTrain, ...
            ValidationLoss=lossValidation, ...
            ValidationAccuracy=accuracyValidation);

        monitor.Progress = 100*iteration/numIterations;
    end
end

```

The Training Progress window shows animated plots of the metrics, and the information values, training progress bar, and elapsed time.

- The training plots update each time you call `recordMetrics`.
- The values under **Information** update each time you call `updateInfo`.
- The elapsed time updates each time you call `recordMetrics` or `updateInfo`, and when you update the property.

### Prepare Plotting Code for Custom Training Experiment

A `TrainingProgressMonitor` object has the same properties and object functions as an `experiments.Monitor` object. Therefore, you can easily adapt your plotting code for use in an **Experiment Manager** setup script.

How you monitor training depends on where you are training.

- If you are using a custom training loop script, you must create and manage a `TrainingProgressMonitor` object yourself.
- If you are using a custom training experiment, **Experiment Manager** creates an `experiments.Monitor` object for each trial of your experiment. By default, **Experiment Manager** saves the `experiments.Monitor` object as the variable `monitor`.

In **Experiment Manager**, you can use the `experiments.Monitor` object in place of the `TrainingProgressMonitor` object in your custom training loop code.

For example, suppose your training script creates a `TrainingProgressMonitor` object to track and plot training and validation loss.

```
monitor = trainingProgressMonitor( ...
    Metrics=["TrainingLoss","ValidationLoss"], ...
    XLabel="Iteration");

groupSubPlot(monitor,"Loss",["TrainingLoss","ValidationLoss"]);
```

```
iteration = 1;
recordMetrics(monitor, iteration, TrainingLoss=loss, ValidationLoss=lossVal);
```

To adapt this code for use in **Experiment Manager** with an `experiments.Monitor` object:

- Convert any code that sets properties using `Name=Value` syntax to use dot notation.
- Delete the call to `trainingProgressMonitor`. This is because **Experiment Manager** creates a monitor for you.

Use the adapted code inside your **Experiment Manager** setup function.

```
% Inside custom training experiment setup function
```

```
monitor.Metrics=["TrainingLoss", "ValidationLoss"];
monitor.XLabel = "Iteration";

groupSubPlot(monitor, "Loss", ["TrainingLoss", "ValidationLoss"]);

iteration = 1;
recordMetrics(monitor, iteration, TrainingLoss=loss, ValidationLoss=lossVal);
```

---

**Note** **Experiment Manager** accesses the monitor object as the second input argument of the training function. You must check that the second input argument matches the variable name of your monitor object. For more information, see “Configure Custom Training Experiment” on page 1-54.

---

## Tips

- The information values appear in the Training Progress window and the training plot shows a record of the metric values. Use information values for text and for numerical values that you want to display in the training window but not in the training plot.
- When you click the **Stop** button in the Training Progress window, the `Stop` property is set to 1 (`true`). This stops training if your training loop exits when the `Stop` property is 1. For example, to enable early stopping, include the following code in your custom training loop.

```
while numEpochs < maxEpochs && ~monitor.Stop
% Custom training loop code.
end
```

- The elapsed time updates each time you call `recordMetrics` or `updateInfo`, and when you update the `Progress` property.

## Version History

Introduced in R2022b

“Train Network Using Custom Training Loop”

“Detect Issues During Deep Neural Network Training”

## trainNetwork

Train deep learning neural network

### Syntax

```
net = trainNetwork(images, layers, options)
net = trainNetwork(images, responses, layers, options)

net = trainNetwork(sequences, layers, options)
net = trainNetwork(sequences, responses, layers, options)

net = trainNetwork(features, layers, options)
net = trainNetwork(features, responses, layers, options)

net = trainNetwork(mixed, layers, options)

[net, info] = trainNetwork( __ )
```

### Description

For classification and regression tasks, you can train various types of neural networks using the `trainNetwork` function.

For example, you can train:

- a convolutional neural network (ConvNet, CNN) for image data
- a recurrent neural network (RNN) such as a long short-term memory (LSTM) or a gated recurrent unit (GRU) neural network for sequence and time-series data
- a multilayer perceptron (MLP) neural network for numeric feature data

You can train on either a CPU or a GPU. For image classification and image regression, you can train a single neural network in parallel using multiple GPUs or a local or remote parallel pool. Training on a GPU or in parallel requires Parallel Computing Toolbox. To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox). To specify training options, including options for the execution environment, use the `trainingOptions` function.

When training a neural network, you can specify the predictors and responses as a single input or in two separate inputs.

`net = trainNetwork(images, layers, options)` trains the neural network specified by `layers` for image classification and regression tasks using the images and responses specified by `images` and the training options defined by `options`.

`net = trainNetwork(images, responses, layers, options)` trains using the images specified by `images` and responses specified by `responses`.

`net = trainNetwork(sequences, layers, options)` trains a neural network for sequence or time-series classification and regression tasks (for example, an LSTM or GRU neural network) using the sequences and responses specified by `sequences`.

`net = trainNetwork(sequences, responses, layers, options)` trains using the sequences specified by `sequences` and responses specified by `responses`.

`net = trainNetwork(features, layers, options)` trains a neural network for feature classification or regression tasks (for example, a multilayer perceptron (MLP) neural network) using the feature data and responses specified by `features`.

`net = trainNetwork(features, responses, layers, options)` trains using the feature data specified by `features` and responses specified by `responses`.

`net = trainNetwork(mixed, layers, options)` trains a neural network with multiple inputs with mixed data types with the data and responses specified by `mixed`.

`[net, info] = trainNetwork( ___ )` also returns information on the training using any of the previous syntaxes.

## Examples

### Train Network for Image Classification

Load the data as an `ImageDatastore` object.

```
digitDatasetPath = fullfile(matlabroot, 'toolbox', 'nnet', ...
    'nndemos', 'nndatasets', 'DigitDataset');
imds = imageDatastore(digitDatasetPath, ...
    'IncludeSubfolders', true, ...
    'LabelSource', 'foldernames');
```

The datastore contains 10,000 synthetic images of digits from 0 to 9. The images are generated by applying random transformations to digit images created with different fonts. Each digit image is 28-by-28 pixels. The datastore contains an equal number of images per category.

Display some of the images in the datastore.

```
figure
numImages = 10000;
perm = randperm(numImages, 20);
for i = 1:20
    subplot(4, 5, i);
    imshow(imds.Files{perm(i)});
    drawnow;
end
```

Divide the datastore so that each category in the training set has 750 images and the testing set has the remaining images from each label.

```
numTrainingFiles = 750;
[imdsTrain,imdsTest] = splitEachLabel(imds,numTrainingFiles,'randomize');
```

`splitEachLabel` splits the image files in `digitData` into two new datastores, `imdsTrain` and `imdsTest`.

Define the convolutional neural network architecture.

```
layers = [ ...
    imageInputLayer([28 28 1])
    convolution2dLayer(5,20)
    reluLayer
    maxPooling2dLayer(2,'Stride',2)
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer];
```

Set the options to the default settings for the stochastic gradient descent with momentum. Set the maximum number of epochs at 20, and start the training with an initial learning rate of 0.0001.

```
options = trainingOptions('sgdm', ...
    'MaxEpochs',20,...
    'InitialLearnRate',1e-4, ...
    'Verbose',false, ...
    'Plots','training-progress');
```

Train the network.

```
net = trainNetwork(imdsTrain, layers, options);
```

Run the trained network on the test set, which was not used to train the network, and predict the image labels (digits).

```
YPred = classify(net, imdsTest);
YTest = imdsTest.Labels;
```

Calculate the accuracy. The accuracy is the ratio of the number of true labels in the test data matching the classifications from `classify` to the number of images in the test data.

```
accuracy = sum(YPred == YTest)/numel(YTest)
```

```
accuracy = 0.9416
```

## Train Network with Augmented Images

Train a convolutional neural network using augmented image data. Data augmentation helps prevent the network from overfitting and memorizing the exact details of the training images.

Load the sample data, which consists of synthetic images of handwritten digits.

```
[XTrain,YTrain] = digitTrain4DArrayData;
```

`digitTrain4DArrayData` loads the digit training set as 4-D array data. `XTrain` is a 28-by-28-by-1-by-5000 array, where:

- 28 is the height and width of the images.
- 1 is the number of channels.
- 5000 is the number of synthetic images of handwritten digits.

`YTrain` is a categorical vector containing the labels for each observation.

Set aside 1000 of the images for network validation.

```
idx = randperm(size(XTrain,4),1000);  
XValidation = XTrain(:,:,,idx);  
XTrain(:,:,,idx) = [];  
YValidation = YTrain(idx);  
YTrain(idx) = [];
```

Create an `imageDataAugmenter` object that specifies preprocessing options for image augmentation, such as resizing, rotation, translation, and reflection. Randomly translate the images up to three pixels horizontally and vertically, and rotate the images with an angle up to 20 degrees.

```
imageAugmenter = imageDataAugmenter( ...  
    'RandRotation',[-20,20], ...  
    'RandXTranslation',[-3 3], ...  
    'RandYTranslation',[-3 3])
```

```
imageAugmenter =  
    imageDataAugmenter with properties:
```

```
    FillValue: 0  
    RandXReflection: 0  
    RandYReflection: 0  
    RandRotation: [-20 20]  
    RandScale: [1 1]  
    RandXScale: [1 1]  
    RandYScale: [1 1]  
    RandXShear: [0 0]  
    RandYShear: [0 0]  
    RandXTranslation: [-3 3]  
    RandYTranslation: [-3 3]
```

Create an `augmentedImageDatastore` object to use for network training and specify the image output size. During training, the datastore performs image augmentation and resizes the images. The datastore augments the images without saving any images to memory. `trainNetwork` updates the network parameters and then discards the augmented images.

```
imageSize = [28 28 1];  
augimds = augmentedImageDatastore(imageSize,XTrain,YTrain,'DataAugmentation',imageAugmenter);
```

Specify the convolutional neural network architecture.

```
layers = [  
    imageInputLayer(imageSize)  
  
    convolution2dLayer(3,8,'Padding','same')  
    batchNormalizationLayer  
    reluLayer  
  
    maxPooling2dLayer(2,'Stride',2)  
  
    convolution2dLayer(3,16,'Padding','same')  
    batchNormalizationLayer  
    reluLayer  
  
    maxPooling2dLayer(2,'Stride',2)  
  
    convolution2dLayer(3,32,'Padding','same')  
    batchNormalizationLayer  
    reluLayer  
  
    fullyConnectedLayer(10)  
    softmaxLayer  
    classificationLayer];
```

Specify training options for stochastic gradient descent with momentum.

```
opts = trainingOptions('sgdm', ...  
    'MaxEpochs',15, ...  
    'Shuffle','every-epoch', ...  
    'Plots','training-progress', ...  
    'Verbose',false, ...  
    'ValidationData',{XValidation,YValidation});
```

Train the network. Because the validation images are not augmented, the validation accuracy is higher than the training accuracy.

```
net = trainNetwork(augimds,layers,opts);
```

## Train Network for Image Regression

Load the sample data, which consists of synthetic images of handwritten digits. The third output contains the corresponding angles in degrees by which each image has been rotated.

Load the training images as 4-D arrays using `digitTrain4DArrayData`. The output `XTrain` is a 28-by-28-by-1-by-5000 array, where:

- 28 is the height and width of the images.
- 1 is the number of channels.
- 5000 is the number of synthetic images of handwritten digits.

`YTrain` contains the rotation angles in degrees.

```
[XTrain,~,YTrain] = digitTrain4DArrayData;
```

Display 20 random training images using `imshow`.

```
figure
numTrainImages = numel(YTrain);
idx = randperm(numTrainImages,20);
for i = 1:numel(idx)
    subplot(4,5,i)
    imshow(XTrain(:,:,:,idx(i)))
    drawnow;
end
```

Specify the convolutional neural network architecture. For regression problems, include a regression layer at the end of the network.

```
layers = [ ...  
    imageInputLayer([28 28 1])  
    convolution2dLayer(12,25)  
    reluLayer  
    fullyConnectedLayer(1)  
    regressionLayer];
```

Specify the network training options. Set the initial learn rate to 0.001.

```
options = trainingOptions('sgdm', ...  
    'InitialLearnRate',0.001, ...  
    'Verbose',false, ...  
    'Plots','training-progress');
```

Train the network.

```
net = trainNetwork(XTrain,YTrain,layers,options);
```

Test the performance of the network by evaluating the prediction accuracy of the test data. Use `predict` to predict the angles of rotation of the validation images.

```
[XTest,~ ,YTest] = digitTest4DArrayData;
YPred = predict(net,XTest);
```

Evaluate the performance of the model by calculating the root-mean-square error (RMSE) of the predicted and actual angles of rotation.

```
rmse = sqrt(mean((YTest - YPred).^2))
```

```
rmse = single
      6.0339
```

### Train Network for Sequence Classification

Train a deep learning LSTM network for sequence-to-label classification.

Load the Japanese Vowels data set as described in [1] and [2]. `XTrain` is a cell array containing 270 sequences of varying length with 12 features corresponding to LPC cepstrum coefficients. `Y` is a categorical vector of labels 1,2,...,9. The entries in `XTrain` are matrices with 12 rows (one row for each feature) and a varying number of columns (one column for each time step).

```
[XTrain,YTrain] = japaneseVowelsTrainData;
```

Visualize the first time series in a plot. Each line corresponds to a feature.

```
figure
plot(XTrain{1}')
title("Training Observation 1")
numFeatures = size(XTrain{1},1);
legend("Feature " + string(1:numFeatures),'Location','northeastoutside')
```

Define the LSTM network architecture. Specify the input size as 12 (the number of features of the input data). Specify an LSTM layer to have 100 hidden units and to output the last element of the sequence. Finally, specify nine classes by including a fully connected layer of size 9, followed by a softmax layer and a classification layer.

```
inputSize = 12;
numHiddenUnits = 100;
numClasses = 9;

layers = [ ...
    sequenceInputLayer(inputSize)
    lstmLayer(numHiddenUnits,'OutputMode','last')
```

```
fullyConnectedLayer(numClasses)
softmaxLayer
classificationLayer]

layers =
  5x1 Layer array with layers:

   1 '' Sequence Input           Sequence input with 12 dimensions
   2 '' LSTM                     LSTM with 100 hidden units
   3 '' Fully Connected          9 fully connected layer
   4 '' Softmax                  softmax
   5 '' Classification Output    crossentropyex
```

Specify the training options. Specify the solver as 'adam' and 'GradientThreshold' as 1. Set the mini-batch size to 27 and set the maximum number of epochs to 70.

Because the mini-batches are small with short sequences, the CPU is better suited for training. Set 'ExecutionEnvironment' to 'cpu'. To train on a GPU, if available, set 'ExecutionEnvironment' to 'auto' (the default value).

```
maxEpochs = 70;
miniBatchSize = 27;

options = trainingOptions('adam', ...
    'ExecutionEnvironment','cpu', ...
    'MaxEpochs',maxEpochs, ...
    'MiniBatchSize',miniBatchSize, ...
    'GradientThreshold',1, ...
    'Verbose',false, ...
    'Plots','training-progress');
```

Train the LSTM network with the specified training options.

```
net = trainNetwork(XTrain,YTrain,layers,options);
```

Load the test set and classify the sequences into speakers.

```
[XTest,YTest] = japaneseVowelsTestData;
```

Classify the test data. Specify the same mini-batch size used for training.

```
YPred = classify(net,XTest,'MiniBatchSize',miniBatchSize);
```

Calculate the classification accuracy of the predictions.

```
acc = sum(YPred == YTest)./numel(YTest)
```

```
acc = 0.9432
```

### Train Network with Numeric Features

If you have a data set of numeric features (for example a collection of numeric data without spatial or time dimensions), then you can train a deep learning network using a feature input layer.

Read the transmission casing data from the CSV file "transmissionCasingData.csv".

```
filename = "transmissionCasingData.csv";
tbl = readtable(filename, 'TextType', 'String');
```

Convert the labels for prediction to categorical using the `convertvars` function.

```
labelName = "GearToothCondition";
tbl = convertvars(tbl, labelName, 'categorical');
```

To train a network using categorical features, you must first convert the categorical features to numeric. First, convert the categorical predictors to categorical using the `convertvars` function by specifying a string array containing the names of all the categorical input variables. In this data set, there are two categorical features with names "SensorCondition" and "ShaftCondition".

```
categoricalInputNames = ["SensorCondition" "ShaftCondition"];
tbl = convertvars(tbl, categoricalInputNames, 'categorical');
```

Loop over the categorical input variables. For each variable:

- Convert the categorical values to one-hot encoded vectors using the `onehotencode` function.
- Add the one-hot vectors to the table using the `addvars` function. Specify to insert the vectors after the column containing the corresponding categorical data.
- Remove the corresponding column containing the categorical data.

```
for i = 1:numel(categoricalInputNames)
    name = categoricalInputNames(i);
    oh = onehotencode(tbl(:,name));
    tbl = addvars(tbl, oh, 'After', name);
    tbl(:,name) = [];
end
```

`end`

Split the vectors into separate columns using the `splitvars` function.

```
tbl = splitvars(tbl);
```

View the first few rows of the table. Notice that the categorical predictors have been split into multiple columns with the categorical values as the variable names.

```
head(tbl)
```

SigMean	SigMedian	SigRMS	SigVar	SigPeak	SigPeak2Peak	SigSkewness	SigKurtosis
-0.94876	-0.9722	1.3726	0.98387	0.81571	3.6314	-0.041525	2.7187
-0.97537	-0.98958	1.3937	0.99105	0.81571	3.6314	-0.023777	2.7187
1.0502	1.0267	1.4449	0.98491	2.8157	3.6314	-0.04162	2.7187
1.0227	1.0045	1.4288	0.99553	2.8157	3.6314	-0.016356	2.7187
1.0123	1.0024	1.4202	0.99233	2.8157	3.6314	-0.014701	2.7187
1.0275	1.0102	1.4338	1.0001	2.8157	3.6314	-0.02659	2.7187
1.0464	1.0275	1.4477	1.0011	2.8157	3.6314	-0.042849	2.7187
1.0459	1.0257	1.4402	0.98047	2.8157	3.6314	-0.035405	2.7187

View the class names of the data set.

```
classNames = categories(tbl{:,labelName})
```

```
classNames = 2x1 cell
    {'No Tooth Fault'}
```

```
{'Tooth Fault' }
```

Next, partition the data set into training and test partitions. Set aside 15% of the data for testing.

Determine the number of observations for each partition.

```
numObservations = size(tbl,1);
numObservationsTrain = floor(0.85*numObservations);
numObservationsTest = numObservations - numObservationsTrain;
```

Create an array of random indices corresponding to the observations and partition it using the partition sizes.

```
idx = randperm(numObservations);
idxTrain = idx(1:numObservationsTrain);
idxTest = idx(numObservationsTrain+1:end);
```

Partition the table of data into training and testing partitions using the indices.

```
tblTrain = tbl(idxTrain,:);
tblTest = tbl(idxTest,:);
```

Define a network with a feature input layer and specify the number of features. Also, configure the input layer to normalize the data using Z-score normalization.

```
numFeatures = size(tbl,2) - 1;
numClasses = numel(classNames);

layers = [
    featureInputLayer(numFeatures,'Normalization','zscore')
    fullyConnectedLayer(50)
    batchNormalizationLayer
    reluLayer
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

Specify the training options.

```
miniBatchSize = 16;

options = trainingOptions('adam', ...
    'MiniBatchSize',miniBatchSize, ...
    'Shuffle','every-epoch', ...
    'Plots','training-progress', ...
    'Verbose',false);
```

Train the network using the architecture defined by `layers`, the training data, and the training options.

```
net = trainNetwork(tblTrain,layers,options);
```

Predict the labels of the test data using the trained network and calculate the accuracy. The accuracy is the proportion of the labels that the network predicts correctly.

```
YPred = classify(net,tblTest,'MiniBatchSize',miniBatchSize);
YTest = tblTest(:,labelName);
```

```
accuracy = sum(YPred == YTest)/numel(YTest)
```

```
accuracy = 0.9688
```

## Input Arguments

### images — Image data

datastore | numeric array | table

Image data, specified as one of the following:

Data Type		Description	Example Usage
Datastore	ImageDatastore	Datastore of images saved on disk.	<p>Train image classification neural network with images saved on disk, where the images are the same size.</p> <p>When the images are different sizes, use an <b>AugmentedImageDatastore</b> object.</p> <p><b>ImageDatastore</b> objects support image classification tasks only. To use image datastores for regression neural networks, create a transformed or combined datastore that contains the images and responses using the <b>transform</b> and <b>combine</b> functions, respectively.</p>
	AugmentedImageDatastore	Datastore that applies random affine geometric transformations, including resizing, rotation, reflection, shear, and translation.	<ul style="list-style-type: none"> <li>• Train image classification neural network with images saved on disk, where the images are different sizes.</li> <li>• Train image classification neural network and generate new data using augmentations.</li> </ul>

Data Type		Description	Example Usage
	TransformedDatastore	Datastore that transforms batches of data read from an underlying datastore using a custom transformation function.	<ul style="list-style-type: none"> <li>• Train image regression neural network.</li> <li>• Train neural networks with multiple inputs.</li> <li>• Transform datastores with outputs not supported by <code>trainNetwork</code>.</li> <li>• Apply custom transformations to datastore output.</li> </ul>
	CombinedDatastore	Datastore that reads from two or more underlying datastores.	<ul style="list-style-type: none"> <li>• Train image regression neural network.</li> <li>• Train neural networks with multiple inputs.</li> <li>• Combine predictors and responses from different data sources.</li> </ul>
	PixelLabelImageDatastore	Datastore that applies identical affine geometric transformations to images and corresponding pixel labels.	Train neural network for semantic segmentation.
	RandomPatchExtractionDatastore	Datastore that extracts pairs of random patches from images or pixel label images and optionally applies identical random affine geometric transformations to the pairs.	Train neural network for object detection.
	DenoisingImageDatastore	Datastore that applies randomly generated Gaussian noise.	Train neural network for image denoising.

Data Type		Description	Example Usage
	Custom mini-batch datastore	Custom datastore that returns mini-batches of data.	Train neural network using data in a format that other datastores do not support.  For details, see “Develop Custom Mini-Batch Datastore”.
Numeric array		Images specified as numeric array. If you specify images as a numeric array, then you must also specify the <code>responses</code> argument.	Train neural network using data that fits in memory and does not require additional processing like augmentation.
Table		Images specified as a table. If you specify images as a table, then you can also specify which columns contain the responses using the <code>responses</code> argument.	Train neural network using data stored in a table.

For neural networks with multiple inputs, the datastore must be a `TransformedDatastore` or `CombinedDatastore` object.

---

**Tip** For sequences of images, for example video data, use the `sequences` input argument.

---

### Datastore

Datastores read mini-batches of images and responses. Datastores are best suited when you have data that does not fit in memory or when you want to apply augmentations or transformations to the data.

The list below lists the datastores that are directly compatible with `trainNetwork` for image data.

- `ImageDatastore`
- `AugmentedImageDatastore`
- `CombinedDatastore`
- `TransformedDatastore`
- `PixelLabelImageDatastore`
- `RandomPatchExtractionDatastore`
- `DenoisingImageDatastore`
- Custom mini-batch datastore. For details, see “Develop Custom Mini-Batch Datastore”.

For example, you can create an image datastore using the `imageDatastore` function and use the names of the folders containing the images as labels by setting the `'LabelSource'` option to `'foldernames'`. Alternatively, you can specify the labels manually using the `Labels` property of the image datastore.

Note that `ImageDatastore` objects allow for batch reading of JPG or PNG image files using prefetching. If you use a custom function for reading the images, then `ImageDatastore` objects do not prefetch.

**Tip** Use `augmentedImageDatastore` for efficient preprocessing of images for deep learning, including image resizing.

Do not use the `readFcn` option of the `imageDatastore` function for preprocessing or resizing, as this option is usually significantly slower.

You can use other built-in datastores for training deep learning neural networks by using the `transform` and `combine` functions. These functions can convert the data read from datastores to the format required by `trainNetwork`.

For neural networks with multiple inputs, the datastore must be a `TransformedDatastore` or `CombinedDatastore` object.

The required format of the datastore output depends on the neural network architecture.

Neural Network Architecture	Datastore Output	Example Output										
Single input layer	Table or cell array with two columns.  The first and second columns specify the predictors and responses, respectively.  Table elements must be scalars, row vectors, or 1-by-1 cell arrays containing a numeric array.  Custom mini-batch datastores must output tables.	Table for neural network with one input and one output:  <code>data = read(ds)</code>  <code>data =</code>  4×2 table  <table style="margin-left: 40px; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center; border-bottom: 1px solid black;">Predictors</th> <th style="text-align: center; border-bottom: 1px solid black;">Response</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">{224×224×3 double}</td> <td style="text-align: center;">2</td> </tr> <tr> <td style="text-align: center;">{224×224×3 double}</td> <td style="text-align: center;">7</td> </tr> <tr> <td style="text-align: center;">{224×224×3 double}</td> <td style="text-align: center;">9</td> </tr> <tr> <td style="text-align: center;">{224×224×3 double}</td> <td style="text-align: center;">9</td> </tr> </tbody> </table>	Predictors	Response	{224×224×3 double}	2	{224×224×3 double}	7	{224×224×3 double}	9	{224×224×3 double}	9
	Predictors	Response										
{224×224×3 double}	2											
{224×224×3 double}	7											
{224×224×3 double}	9											
{224×224×3 double}	9											
	Cell array for neural network with one input and one output:  <code>data = read(ds)</code>  <code>data =</code>  4×2 cell array  <table style="margin-left: 40px; border-collapse: collapse;"> <tbody> <tr> <td style="text-align: center;">{224×224×3 double}</td> <td style="text-align: center;">{[2]}</td> </tr> <tr> <td style="text-align: center;">{224×224×3 double}</td> <td style="text-align: center;">{[7]}</td> </tr> <tr> <td style="text-align: center;">{224×224×3 double}</td> <td style="text-align: center;">{[9]}</td> </tr> <tr> <td style="text-align: center;">{224×224×3 double}</td> <td style="text-align: center;">{[9]}</td> </tr> </tbody> </table>	{224×224×3 double}	{[2]}	{224×224×3 double}	{[7]}	{224×224×3 double}	{[9]}	{224×224×3 double}	{[9]}			
{224×224×3 double}	{[2]}											
{224×224×3 double}	{[7]}											
{224×224×3 double}	{[9]}											
{224×224×3 double}	{[9]}											

Neural Network Architecture	Datastore Output	Example Output
Multiple input layers	<p>Cell array with (<code>numInputs</code> + 1) columns, where <code>numInputs</code> is the number of neural network inputs.</p> <p>The first <code>numInputs</code> columns specify the predictors for each input and the last column specifies the responses.</p> <p>The order of inputs is given by the <code>InputNames</code> property of the layer graph <code>layers</code>.</p>	<p>Cell array for neural network with two inputs and one output.</p> <pre>data = read(ds)  data =      4×3 cell array      {224×224×3 double}    {128×128×3 do     {224×224×3 double}    {128×128×3 do     {224×224×3 double}    {128×128×3 do     {224×224×3 double}    {128×128×3 do</pre>

The format of the predictors depends on the type of data.

Data	Format
2-D images	<i>h-by-w-by-c</i> numeric array, where <i>h</i> , <i>w</i> , and <i>c</i> are the height, width, and number of channels of the images, respectively.
3-D images	<i>h-by-w-by-d-by-c</i> numeric array, where <i>h</i> , <i>w</i> , <i>d</i> , and <i>c</i> are the height, width, depth, and number of channels of the images, respectively.

For predictors returned in tables, the elements must contain a numeric scalar, a numeric row vector, or a 1-by-1 cell array containing the numeric array.

The format of the responses depends on the type of task.

Task	Response Format
Image classification	Categorical scalar
Image regression	<ul style="list-style-type: none"> <li>Numeric scalar</li> <li>Numeric vector</li> <li>3-D numeric array representing a 2-D image</li> <li>4-D numeric array representing a 3-D image</li> </ul>

For responses returned in tables, the elements must be a categorical scalar, a numeric scalar, a numeric row vector, or a 1-by-1 cell array containing a numeric array.

For more information, see “Datastores for Deep Learning”.

### Numeric Array

For data that fits in memory and does not require additional processing like augmentation, you can specify a data set of images as a numeric array. If you specify images as a numeric array, then you must also specify the `responses` argument.

The size and shape of the numeric array depends on the type of image data.

Data	Format
2-D images	$h$ -by- $w$ -by- $c$ -by- $N$ numeric array, where $h$ , $w$ , and $c$ are the height, width, and number of channels of the images, respectively, and $N$ is the number of images.
3-D images	$h$ -by- $w$ -by- $d$ -by- $c$ -by- $N$ numeric array, where $h$ , $w$ , $d$ , and $c$ are the height, width, depth, and number of channels of the images, respectively, and $N$ is the number of images.

**Table**

As an alternative to datastores or numeric arrays, you can also specify images and responses in a table. If you specify images as a table, then you can also specify which columns contain the responses using the `responses` argument.

When specifying images and responses in a table, each row in the table corresponds to an observation.

For image input, the predictors must be in the first column of the table, specified as one of the following:

- Absolute or relative file path to an image, specified as a character vector
- 1-by-1 cell array containing a  $h$ -by- $w$ -by- $c$  numeric array representing a 2-D image, where  $h$ ,  $w$ , and  $c$  correspond to the height, width, and number of channels of the image, respectively.

The format of the responses depends on the type of task.

Task	Response Format
Image classification	Categorical scalar
Image regression	<ul style="list-style-type: none"> <li>• Numeric scalar</li> <li>• Two or more columns of scalar values</li> <li>• 1-by-1 cell array containing a <math>h</math>-by-<math>w</math>-by-<math>c</math> numeric array representing a 2-D image</li> <li>• 1-by-1 cell array containing a <math>h</math>-by-<math>w</math>-by-<math>d</math>-by-<math>c</math> numeric array representing a 3-D image</li> </ul>

For neural networks with image input, if you do not specify `responses`, then the function, by default, uses the first column of `tbl` for the predictors and the subsequent columns as responses.

**Tip**

- If the predictors or the responses contains NaNs, then they are propagated through the neural network during training. In these cases, the training usually fails to converge.
- For regression tasks, normalizing the responses often helps to stabilize and speed up training of neural networks for regression. For more information, see “Train Convolutional Neural Network for Regression”.
- To input complex-valued data into a neural network, the `SplitComplexInputs` option of the input layer must be 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | table

Complex Number Support: Yes

### sequences — Sequence or time series data

datastore | cell array of numeric arrays | numeric array

Sequence or time series data, specified as one of the following:

Data Type		Description	Example Usage
Datastore	TransformedDatastore	Datastore that transforms batches of data read from an underlying datastore using a custom transformation function.	<ul style="list-style-type: none"> <li>Transform datastores with outputs not supported by <code>trainNetwork</code>.</li> <li>Apply custom transformations to datastore output.</li> </ul>
	CombinedDatastore	Datastore that reads from two or more underlying datastores.	Combine predictors and responses from different data sources.
	Custom mini-batch datastore	Custom datastore that returns mini-batches of data.	<p>Train neural network using data in a format that other datastores do not support.</p> <p>For details, see “Develop Custom Mini-Batch Datastore”.</p>
Numeric or cell array		A single sequence specified as a numeric array or a data set of sequences specified as cell array of numeric arrays. If you specify sequences as a numeric or cell array, then you must also specify the responses argument.	Train neural network using data that fits in memory and does not require additional processing like custom transformations.

### Datastore

Datastores read mini-batches of sequences and responses. Datastores are best suited when you have data that does not fit in memory or when you want to apply transformations to the data.

The list below lists the datastores that are directly compatible with `trainNetwork` for sequence data.

- `CombinedDatastore`
- `TransformedDatastore`

- Custom mini-batch datastore. For details, see “Develop Custom Mini-Batch Datastore”.

You can use other built-in datastores for training deep learning neural networks by using the `transform` and `combine` functions. These functions can convert the data read from datastores to the table or cell array format required by `trainNetwork`. For example, you can transform and combine data read from in-memory arrays and CSV files using `ArrayDatastore` and `TabularTextDatastore` objects, respectively.

The datastore must return data in a table or cell array. Custom mini-batch datastores must output tables.

Datastore Output	Example Output
Table	<pre>data = read(ds)  data =      4x2 table        Predictors      Response       _____      _____     {12x50 double}         2     {12x50 double}         7     {12x50 double}         9     {12x50 double}         9</pre>
Cell array	<pre>data = read(ds)  data =      4x2 cell array      {12x50 double}    {[2]}     {12x50 double}    {[7]}     {12x50 double}    {[9]}     {12x50 double}    {[9]}</pre>

The format of the predictors depend on the type of data.

Data	Format of Predictors
Vector sequence	<i>c</i> -by- <i>s</i> matrix, where <i>c</i> is the number of features of the sequence and <i>s</i> is the sequence length.
1-D image sequence	<p><i>h</i>-by-<i>c</i>-by-<i>s</i> array, where <i>h</i> and <i>c</i> correspond to the height and number of channels of the image, respectively, and <i>s</i> is the sequence length.</p> <p>Each sequence in the mini-batch must have the same sequence length.</p>

<b>Data</b>	<b>Format of Predictors</b>
2-D image sequence	<p><math>h</math>-by-<math>w</math>-by-<math>c</math>-by-<math>s</math> array, where <math>h</math>, <math>w</math>, and <math>c</math> correspond to the height, width, and number of channels of the image, respectively, and <math>s</math> is the sequence length.</p> <p>Each sequence in the mini-batch must have the same sequence length.</p>
3-D image sequence	<p><math>h</math>-by-<math>w</math>-by-<math>d</math>-by-<math>c</math>-by-<math>s</math> array, where <math>h</math>, <math>w</math>, <math>d</math>, and <math>c</math> correspond to the height, width, depth, and number of channels of the image, respectively, and <math>s</math> is the sequence length.</p> <p>Each sequence in the mini-batch must have the same sequence length.</p>

For predictors returned in tables, the elements must contain a numeric scalar, a numeric row vector, or a 1-by-1 cell array containing a numeric array.

The format of the responses depends on the type of task.

<b>Task</b>	<b>Format of Responses</b>
Sequence-to-label classification	Categorical scalar
Sequence-to-one regression	Scalar
Sequence-to-vector regression	Numeric row vector
Sequence-to-sequence classification	<ul style="list-style-type: none"> <li>1-by-<math>s</math> sequence of categorical labels, where <math>s</math> is the sequence length of the corresponding predictor sequence.</li> <li><math>h</math>-by-<math>w</math>-by-<math>s</math> sequence of categorical labels, where <math>h</math>, <math>w</math>, and <math>s</math> are the height, width, and sequence length of the corresponding predictor sequence, respectively.</li> <li><math>h</math>-by-<math>w</math>-by-<math>d</math>-by-<math>s</math> sequence of categorical labels, where <math>h</math>, <math>w</math>, <math>d</math>, and <math>s</math> are the height, width, depth, and sequence length of the corresponding predictor sequence, respectively.</li> </ul> <p>Each sequence in the mini-batch must have the same sequence length.</p>

Task	Format of Responses
Sequence-to-sequence regression	<ul style="list-style-type: none"> <li>• <math>R</math>-by-<math>s</math> matrix, where <math>R</math> is the number of responses and <math>s</math> is the sequence length of the corresponding predictor sequence.</li> <li>• <math>h</math>-by-<math>w</math>-by-<math>R</math>-by-<math>s</math> sequence of numeric responses, where <math>R</math> is the number of responses, and <math>h</math>, <math>w</math>, and <math>s</math> are the height, width, and sequence length of the corresponding predictor sequence, respectively.</li> <li>• <math>h</math>-by-<math>w</math>-by-<math>d</math>-by-<math>R</math>-by-<math>s</math> sequence of numeric responses, where <math>R</math> is the number of responses, and <math>h</math>, <math>w</math>, <math>d</math>, and <math>s</math> are the height, width, depth, and sequence length of the corresponding predictor sequence, respectively.</li> </ul> <p>Each sequence in the mini-batch must have the same sequence length.</p>

For responses returned in tables, the elements must be a categorical scalar, a numeric scalar, a numeric row vector, or a 1-by-1 cell array containing a numeric array.

For more information, see “Datastores for Deep Learning”.

**Numeric or Cell Array**

For data that fits in memory and does not require additional processing like custom transformations, you can specify a single sequence as a numeric array or a data set of sequences as a cell array of numeric arrays. If you specify sequences as a cell or numeric array, then you must also specify the `responses` argument.

For cell array input, the cell array must be an  $N$ -by-1 cell array of numeric arrays, where  $N$  is the number of observations. The size and shape of the numeric array representing a sequence depends on the type of sequence data.

Input	Description
Vector sequences	$c$ -by- $s$ matrices, where $c$ is the number of features of the sequences and $s$ is the sequence length.
1-D image sequences	$h$ -by- $c$ -by- $s$ arrays, where $h$ and $c$ correspond to the height and number of channels of the images, respectively, and $s$ is the sequence length.
2-D image sequences	$h$ -by- $w$ -by- $c$ -by- $s$ arrays, where $h$ , $w$ , and $c$ correspond to the height, width, and number of channels of the images, respectively, and $s$ is the sequence length.

Input	Description
3-D image sequences	$h$ -by- $w$ -by- $d$ -by- $c$ -by- $s$ , where $h$ , $w$ , $d$ , and $c$ correspond to the height, width, depth, and number of channels of the 3-D images, respectively, and $s$ is the sequence length.

The `trainNetwork` function supports neural networks with at most one sequence input layer.

### Tip

- If the predictors or the responses contains NaNs, then they are propagated through the neural network during training. In these cases, the training usually fails to converge.
- For regression tasks, normalizing the responses often helps to stabilize and speed up training. For more information, see “Train Convolutional Neural Network for Regression”.
- To input complex-valued data into a neural network, the `SplitComplexInputs` option of the input layer must be 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `cell`

Complex Number Support: Yes

### features – Feature data

`datastore` | numeric array | table

Feature data, specified as one of the following:

Data Type	Description	Example Usage
Datastore	<code>TransformedDatastore</code>	<ul style="list-style-type: none"> <li>• Train neural networks with multiple inputs.</li> <li>• Transform datastores with outputs not supported by <code>trainNetwork</code>.</li> <li>• Apply custom transformations to datastore output.</li> </ul>
	<code>CombinedDatastore</code>	<ul style="list-style-type: none"> <li>• Train neural networks with multiple inputs.</li> <li>• Combine predictors and responses from different data sources.</li> </ul>

Data Type		Description	Example Usage
	Custom mini-batch datastore	Custom datastore that returns mini-batches of data.	Train neural network using data in a format that other datastores do not support.  For details, see “Develop Custom Mini-Batch Datastore”.
Table		Feature data specified as a table. If you specify features as a table, then you can also specify which columns contain the responses using the <code>responses</code> argument.	Train neural network using data stored in a table.
Numeric array		Feature data specified as numeric array. If you specify features as a numeric array, then you must also specify the <code>responses</code> argument.	Train neural network using data that fits in memory and does not require additional processing like custom transformations.

**Datastore**

Datastores read mini-batches of feature data and responses. Datastores are best suited when you have data that does not fit in memory or when you want to apply transformations to the data.

The list below lists the datastores that are directly compatible with `trainNetwork` for feature data.

- `CombinedDatastore`
- `TransformedDatastore`
- Custom mini-batch datastore. For details, see “Develop Custom Mini-Batch Datastore”.

You can use other built-in datastores for training deep learning neural networks by using the `transform` and `combine` functions. These functions can convert the data read from datastores to the table or cell array format required by `trainNetwork`. For more information, see “Datastores for Deep Learning”.

For neural networks with multiple inputs, the datastore must be a `TransformedDatastore` or `CombinedDatastore` object.

The datastore must return data in a table or a cell array. Custom mini-batch datastores must output tables. The format of the datastore output depends on the neural network architecture.

Neural Network Architecture	Datastore Output	Example Output																		
Single input layer	<p>Table or cell array with two columns.</p> <p>The first and second columns specify the predictors and responses, respectively.</p> <p>Table elements must be scalars, row vectors, or 1-by-1 cell arrays containing a numeric array.</p> <p>Custom mini-batch datastores must output tables.</p>	<p>Table for neural network with one input and one output:</p> <pre>data = read(ds) data =</pre> <pre>4x2 table</pre> <table border="1"> <thead> <tr> <th>Predictors</th> <th>Response</th> </tr> </thead> <tbody> <tr> <td>{24x1 double}</td> <td>2</td> </tr> <tr> <td>{24x1 double}</td> <td>7</td> </tr> <tr> <td>{24x1 double}</td> <td>9</td> </tr> <tr> <td>{24x1 double}</td> <td>9</td> </tr> </tbody> </table> <p>Cell array for neural network with one input and one output:</p> <pre>data = read(ds) data =</pre> <pre>4x2 cell array</pre> <table border="1"> <tbody> <tr> <td>{24x1 double}</td> <td>{[2]}</td> </tr> <tr> <td>{24x1 double}</td> <td>{[7]}</td> </tr> <tr> <td>{24x1 double}</td> <td>{[9]}</td> </tr> <tr> <td>{24x1 double}</td> <td>{[9]}</td> </tr> </tbody> </table>	Predictors	Response	{24x1 double}	2	{24x1 double}	7	{24x1 double}	9	{24x1 double}	9	{24x1 double}	{[2]}	{24x1 double}	{[7]}	{24x1 double}	{[9]}	{24x1 double}	{[9]}
Predictors	Response																			
{24x1 double}	2																			
{24x1 double}	7																			
{24x1 double}	9																			
{24x1 double}	9																			
{24x1 double}	{[2]}																			
{24x1 double}	{[7]}																			
{24x1 double}	{[9]}																			
{24x1 double}	{[9]}																			
Multiple input layers	<p>Cell array with (numInputs + 1) columns, where numInputs is the number of neural network inputs.</p> <p>The first numInputs columns specify the predictors for each input and the last column specifies the responses.</p> <p>The order of inputs is given by the InputNames property of the layer graph layers.</p>	<p>Cell array for neural network with two inputs and one output:</p> <pre>data = read(ds) data =</pre> <pre>4x3 cell array</pre> <table border="1"> <tbody> <tr> <td>{24x1 double}</td> <td>{28x1 double}</td> <td>{}</td> </tr> <tr> <td>{24x1 double}</td> <td>{28x1 double}</td> <td>{}</td> </tr> <tr> <td>{24x1 double}</td> <td>{28x1 double}</td> <td>{}</td> </tr> <tr> <td>{24x1 double}</td> <td>{28x1 double}</td> <td>{}</td> </tr> </tbody> </table>	{24x1 double}	{28x1 double}	{}	{24x1 double}	{28x1 double}	{}	{24x1 double}	{28x1 double}	{}	{24x1 double}	{28x1 double}	{}						
{24x1 double}	{28x1 double}	{}																		
{24x1 double}	{28x1 double}	{}																		
{24x1 double}	{28x1 double}	{}																		
{24x1 double}	{28x1 double}	{}																		

The predictors must be  $c$ -by-1 column vectors, where  $c$  is the number of features.

The format of the responses depends on the type of task.

Task	Format of Responses
Classification	Categorical scalar
Regression	<ul style="list-style-type: none"> <li>Scalar</li> <li>Numeric vector</li> </ul>

For more information, see “Datastores for Deep Learning”.

### Table

For feature data that fits in memory and does not require additional processing like custom transformations, you can specify feature data and responses as a table.

Each row in the table corresponds to an observation. The arrangement of predictors and responses in the table columns depends on the type of task.

Task	Predictors	Responses
Feature classification	Features specified in one or more columns as scalars.  If you do not specify the <code>responses</code> argument, then the predictors must be in the first <code>numFeatures</code> columns of the table, where <code>numFeatures</code> is the number of features of the input data.	Categorical label
Feature regression		One or more columns of scalar values

For classification neural networks with feature input, if you do not specify the `responses` argument, then the function, by default, uses the first (`numColumns` - 1) columns of `tbl` for the predictors and the last column for the labels, where `numFeatures` is the number of features in the input data.

For regression neural networks with feature input, if you do not specify the `responseNames` argument, then the function, by default, uses the first `numFeatures` columns for the predictors and the subsequent columns for the responses, where `numFeatures` is the number of features in the input data.

### Numeric Array

For feature data that fits in memory and does not require additional processing like custom transformations, you can specify feature data as a numeric array. If you specify feature data as a numeric array, then you must also specify the `responses` argument.

The numeric array must be an  $N$ -by-`numFeatures` numeric array, where  $N$  is the number of observations and `numFeatures` is the number of features of the input data.

### Tip

- Normalizing the responses often helps to stabilize and speed up training of neural networks for regression. For more information, see “Train Convolutional Neural Network for Regression”.
- Responses must not contain NaNs. If the predictor data contains NaNs, then they are propagated through the training. However, in most cases, the training fails to converge.
- To input complex-valued data into a neural network, the `SplitComplexInputs` option of the input layer must be 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `table`

Complex Number Support: Yes

### **mixed** — Mixed data

datastore

Mixed data and responses, specified as one of the following:

Data Type	Description	Example Usage
TransformedDatastore	Datastore that transforms batches of data read from an underlying datastore using a custom transformation function.	<ul style="list-style-type: none"> <li>Train neural networks with multiple inputs.</li> <li>Transform outputs of datastores not supported by <code>trainNetwork</code> to have the required format.</li> <li>Apply custom transformations to datastore output.</li> </ul>
CombinedDatastore	Datastore that reads from two or more underlying datastores.	<ul style="list-style-type: none"> <li>Train neural networks with multiple inputs.</li> <li>Combine predictors and responses from different data sources.</li> </ul>
Custom mini-batch datastore	Custom datastore that returns mini-batches of data.	<p>Train neural network using data in a format that other datastores do not support.</p> <p>For details, see “Develop Custom Mini-Batch Datastore”.</p>

You can use other built-in datastores for training deep learning neural networks by using the `transform` and `combine` functions. These functions can convert the data read from datastores to the table or cell array format required by `trainNetwork`. For more information, see “Datastores for Deep Learning”.

The datastore must return data in a table or a cell array. Custom mini-batch datastores must output tables. The format of the datastore output depends on the neural network architecture.

Datastore Output	Example Output
<p>Cell array with <math>(\text{numInputs} + 1)</math> columns, where <code>numInputs</code> is the number of neural network inputs.</p> <p>The first <code>numInputs</code> columns specify the predictors for each input and the last column specifies the responses.</p> <p>The order of inputs is given by the <code>InputNames</code> property of the layer graph <code>layers</code>.</p>	<pre>data = read(ds) data =     4x3 cell array     {24x1 double}    {28x1 double}    {[2]}     {24x1 double}    {28x1 double}    {[2]}     {24x1 double}    {28x1 double}    {[9]}     {24x1 double}    {28x1 double}    {[9]}</pre>

For image, sequence, and feature predictor input, the format of the predictors must match the formats described in the `images`, `sequences`, or `features` argument descriptions, respectively.

Similarly, the format of the responses must match the formats described in the `images`, `sequences`, or `features` argument descriptions that corresponds to the type of task.

The `trainNetwork` function supports neural networks with at most one sequence input layer.

For an example showing how to train a neural network with multiple inputs, see “Train Network on Image and Feature Data”.

---

**Tip**

- To convert a numeric array to a datastore, use `ArrayDatastore`.
  - When combining layers in a neural network with mixed types of data, you may need to reformat the data before passing it to a combination layer (such as a concatenation or an addition layer). To reformat the data, you can use a `flatten` layer to flatten the spatial dimensions into the channel dimension, or create a `FunctionLayer` object or custom layer that reformats and reshapes.
- 

**responses — Responses**

categorical vector | numeric array | cell array of sequences | character vector | cell array of character vectors | string array

Responses.

When the input data is a numeric array or a cell array, specify the responses as one of the following.

- categorical vector of labels
- numeric array of numeric responses
- cell array of categorical or numeric sequences

When the input data is a table, you can optionally specify which columns of the table contains the responses as one of the following:

- character vector
- cell array of character vectors
- string array

When the input data is a numeric array or a cell array, then the format of the responses depends on the type of task.

Task		Format
Classification	Image classification	<i>N</i> -by-1 categorical vector of labels, where <i>N</i> is the number of observations.
	Feature classification	
	Sequence-to-label classification	

Task	Format	
	Sequence-to-sequence classification	<p><math>N</math>-by-1 cell array of categorical sequences of labels, where <math>N</math> is the number of observations. Each sequence must have the same number of time steps as the corresponding predictor sequence.</p> <p>For sequence-to-sequence classification tasks with one observation, sequences can also be a vector. In this case, responses must be a categorical row-vector of labels.</p>
Regression	2-D image regression	<ul style="list-style-type: none"> <li>• <math>N</math>-by-<math>R</math> matrix, where <math>N</math> is the number of images and <math>R</math> is the number of responses.</li> <li>• <math>h</math>-by-<math>w</math>-by-<math>c</math>-by-<math>N</math> numeric array, where <math>h</math>, <math>w</math>, and <math>c</math> are the height, width, and number of channels of the images, respectively, and <math>N</math> is the number of images.</li> </ul>
	3-D image regression	<ul style="list-style-type: none"> <li>• <math>N</math>-by-<math>R</math> matrix, where <math>N</math> is the number of images and <math>R</math> is the number of responses.</li> <li>• <math>h</math>-by-<math>w</math>-by-<math>d</math>-by-<math>c</math>-by-<math>N</math> numeric array, where <math>h</math>, <math>w</math>, <math>d</math>, and <math>c</math> are the height, width, depth, and number of channels of the images, respectively, and <math>N</math> is the number of images.</li> </ul>
	Feature regression	$N$ -by- $R$ matrix, where $N$ is the number of observations and $R$ is the number of responses.
	Sequence-to-one regression	$N$ -by- $R$ matrix, where $N$ is the number of sequences and $R$ is the number of responses.

Task		Format
	Sequence-to-sequence regression	<p><math>N</math>-by-1 cell array of numeric sequences, where <math>N</math> is the number of sequences, with sequences given by one of the following:</p> <ul style="list-style-type: none"> <li>• <math>R</math>-by-<math>s</math> matrix, where <math>R</math> is the number of responses and <math>s</math> is the sequence length of the corresponding predictor sequence.</li> <li>• <math>h</math>-by-<math>w</math>-by-<math>R</math>-by-<math>s</math> array, where <math>h</math> and <math>w</math> are the height and width of the output, respectively, <math>R</math> is the number of responses, and <math>s</math> is the sequence length of the corresponding predictor sequence.</li> <li>• <math>h</math>-by-<math>w</math>-by-<math>d</math>-by-<math>R</math>-by-<math>s</math> array, where <math>h</math>, <math>w</math>, and <math>d</math> are the height, width, and depth of the output, respectively, <math>R</math> is the number of responses, and <math>s</math> is the sequence length of the corresponding predictor sequence.</li> </ul> <p>For sequence-to-sequence regression tasks with one observation, sequences can be a numeric array. In this case, responses must be a numeric array of responses.</p>

---

**Tip** Normalizing the responses often helps to stabilize and speed up training of neural networks for regression. For more information, see “Train Convolutional Neural Network for Regression”.

---

---

**Tip** Responses must not contain NaNs. If the predictor data contains NaNs, then they are propagated through the training. However, in most cases, the training fails to converge.

---

### Layers — Neural network layers

Layer array | LayerGraph object

Neural network layers, specified as a Layer array or a LayerGraph object.

To create a neural network with all layers connected sequentially, you can use a Layer array as the input argument. In this case, the returned neural network is a SeriesNetwork object.

A directed acyclic graph (DAG) neural network has a complex structure in which layers can have multiple inputs and outputs. To create a DAG neural network, specify the neural network architecture as a `LayerGraph` object and then use that layer graph as the input argument to `trainNetwork`.

The `trainNetwork` function supports neural networks with at most one sequence input layer.

For a list of built-in layers, see “List of Deep Learning Layers”.

### options — Training options

`TrainingOptionsSGDM` | `TrainingOptionsRMSProp` | `TrainingOptionsADAM`

Training options, specified as a `TrainingOptionsSGDM`, `TrainingOptionsRMSProp`, or `TrainingOptionsADAM` object returned by the `trainingOptions` function.

## Output Arguments

### net — Trained neural network

`SeriesNetwork` object | `DAGNetwork` object

Trained neural network, returned as a `SeriesNetwork` object or a `DAGNetwork` object.

If you train the neural network using a `Layer` array, then `net` is a `SeriesNetwork` object. If you train the neural network using a `LayerGraph` object, then `net` is a `DAGNetwork` object.

### info — Training information

structure

Training information, returned as a structure, where each field is a scalar or a numeric vector with one element per training iteration.

For classification tasks, `info` contains the following fields:

- `TrainingLoss` — Loss function values
- `TrainingAccuracy` — Training accuracies
- `ValidationLoss` — Loss function values
- `ValidationAccuracy` — Validation accuracies
- `BaseLearnRate` — Learning rates
- `FinalValidationLoss` — Validation loss of returned neural network
- `FinalValidationAccuracy` — Validation accuracy of returned neural network
- `OutputNetworkIteration` — Iteration number of returned neural network

For regression tasks, `info` contains the following fields:

- `TrainingLoss` — Loss function values
- `TrainingRMSE` — Training RMSE values
- `ValidationLoss` — Loss function values
- `ValidationRMSE` — Validation RMSE values
- `BaseLearnRate` — Learning rates

- `FinalValidationLoss` — Validation loss of returned neural network
- `FinalValidationRMSE` — Validation RMSE of returned neural network
- `OutputNetworkIteration` — Iteration number of returned neural network

The structure only contains the fields `ValidationLoss`, `ValidationAccuracy`, `ValidationRMSE`, `FinalValidationLoss`, `FinalValidationAccuracy`, and `FinalValidationRMSE` when `options` specifies validation data. The `ValidationFrequency` training option determines which iterations the software calculates validation metrics. The final validation metrics are scalar. The other fields of the structure are row vectors, where each element corresponds to a training iteration. For iterations when the software does not calculate validation metrics, the corresponding values in the structure are NaN.

For neural networks containing batch normalization layers, if the `BatchNormalizationStatistics` training option is 'population' then the final validation metrics are often different from the validation metrics evaluated during training. This is because batch normalization layers in the final neural network perform different operations than during training. For more information, see `batchNormalizationLayer`.

## More About

### Save Checkpoint Neural Networks and Resume Training

Deep Learning Toolbox enables you to save neural networks as `.mat` files during training. This periodic saving is especially useful when you have a large neural network or a large data set, and training takes a long time. If the training is interrupted for some reason, you can resume training from the last saved checkpoint neural network. If you want `trainNetwork` to save checkpoint neural networks, then you must specify the name of the path by using the `CheckpointPath` option of `trainingOptions`. If the path that you specify does not exist, then `trainingOptions` returns an error.

`trainNetwork` automatically assigns unique names to checkpoint neural network files. In the example name, `net_checkpoint__351__2018_04_12__18_09_52.mat`, 351 is the iteration number, 2018\_04\_12 is the date, and 18\_09\_52 is the time at which `trainNetwork` saves the neural network. You can load a checkpoint neural network file by double-clicking it or using the `load` command at the command line. For example:

```
load net_checkpoint__351__2018_04_12__18_09_52.mat
```

You can then resume training by using the layers of the neural network as an input argument to `trainNetwork`. For example:

```
trainNetwork(XTrain,TTrain,net.Layers,options)
```

You must manually specify the training options and the input data, because the checkpoint neural network does not contain this information. For an example, see “Resume Training from Checkpoint Network”.

### Floating-Point Arithmetic

When you train a neural network using the `trainNetwork` function, or when you use prediction or validation functions with `DAGNetwork` and `SeriesNetwork` objects, the software performs these computations using single-precision, floating-point arithmetic. Functions for training, prediction, and validation include `trainNetwork`, `predict`, `classify`, and `activations`. The software uses single-precision arithmetic when you train neural networks using both CPUs and GPUs.

## Reproducibility

To provide the best performance, deep learning using a GPU in MATLAB is not guaranteed to be deterministic. Depending on your network architecture, under some conditions you might get different results when using a GPU to train two identical networks or make two predictions using the same network and data.

## Version History

### Introduced in R2016a

#### **R2022b: trainNetwork pads mini-batches to length of longest sequence before splitting when you specify SequenceLength training option as an integer**

Starting in R2022b, when you train a neural network with sequence data using the `trainNetwork` function and the `SequenceLength` option is an integer, the software pads sequences to the length of the longest sequence in each mini-batch and then splits the sequences into mini-batches with the specified sequence length. If `SequenceLength` does not evenly divide the sequence length of the mini-batch, then the last split mini-batch has a length shorter than `SequenceLength`. This behavior prevents the neural network training on time steps that contain only padding values.

In previous releases, the software pads mini-batches of sequences to have a length matching the nearest multiple of `SequenceLength` that is greater than or equal to the mini-batch length and then splits the data. To reproduce this behavior, use a custom training loop and implement this behavior when you preprocess mini-batches of data.

#### **R2021a: Support for specifying tables of MAT file paths will be removed**

*Warns starting in R2021a*

When specifying sequence data for the `trainNetwork` function, support for specifying tables of MAT file paths will be removed in a future release.

To train neural networks with sequences that do not fit in memory, use a datastore. You can use any datastore to read your data and then use the `transform` function to transform the datastore output to the format the `trainNetwork` function requires. For example, you can read data using a `FileDatastore` or `TabularTextDatastore` object then transform the output using the `transform` function.

#### **R2021b: trainNetwork automatically stops training when loss is NaN**

*Behavior changed in R2021b*

When you train a neural network using the `trainNetwork` function, training automatically stops when the loss is NaN. Usually, a loss value of NaN introduces NaN values to the neural network learnable parameters, which in turn can cause the neural network to fail to train or to make valid predictions. This change helps identify issues with the neural network before training completes.

In previous releases, the neural network continues to train when the loss is NaN.

## Extended Capabilities

### Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run computation in parallel, set the 'ExecutionEnvironment' option to 'multi-gpu' or 'parallel'.

Use `trainingOptions` to set the 'ExecutionEnvironment' and supply the options to `trainNetwork`. If you do not set 'ExecutionEnvironment', then `trainNetwork` runs on a GPU if available.

For details, see “Scale Up Deep Learning in Parallel, on GPUs, and in the Cloud”.

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

- To prevent out-of-memory errors, recommended practice is not to move large sets of training data onto the GPU. Instead, train your neural network on a GPU by using `trainingOptions` to set the 'ExecutionEnvironment' to "auto" or "gpu" and supply the options to `trainNetwork`.
- The `ExecutionEnvironment` option must be "auto" or "gpu" when the input data is:
  - A `gpuArray`
  - A cell array containing `gpuArray` objects
  - A table containing `gpuArray` objects
  - A datastore that outputs cell arrays containing `gpuArray` objects
  - A datastore that outputs tables containing `gpuArray` objects

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

# transposedConv1dLayer

Transposed 1-D convolution layer

## Syntax

```
layer = transposedConv1dLayer(filterSize,numFilters)
layer = transposedConv1dLayer(filterSize,numFilters,Name=Value)
```

## Description

A transposed 1-D convolution layer upsamples one-dimensional feature maps.

This layer is sometimes incorrectly known as a "deconvolution" or "deconv" layer. This layer is the transpose of convolution and does not perform deconvolution.

`layer = transposedConv1dLayer(filterSize,numFilters)` returns a 1-D transposed convolution layer and sets the `FilterSize` and `NumFilters` properties.

`layer = transposedConv1dLayer(filterSize,numFilters,Name=Value)` returns a 1-D transposed convolutional layer and specifies additional options using one or more name-value arguments.

## Examples

### Create 1-D Transposed Convolutional Layer

Create a 1-D transposed convolutional layer with 96 filters of length 11 and a stride of 4.

```
layer = transposedConv1dLayer(11,96,Stride=4)
```

```
layer =
  TransposedConvolution1dLayer with properties:
```

```
    Name: ''
```

```
Hyperparameters
```

```
  FilterSize: 11
  NumChannels: 'auto'
  NumFilters: 96
  Stride: 4
  CroppingMode: 'manual'
  CroppingSize: [0 0]
```

```
Learnable Parameters
```

```
  Weights: []
  Bias: []
```

```
Show all properties
```

## Input Arguments

### **filterSize** — Length of filters

positive integer

Length of the filters, specified as a positive integer. The filter size defines the size of the local regions to which the neurons connect in the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **numFilters** — Number of filters

positive integer

Number of filters, specified as a positive integer. This number corresponds to the number of neurons in the layer that connect to the same region in the input. This parameter determines the number of channels (feature maps) in the output of the layer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `transposedConv1dLayer(11,96,Stride=4)` creates a 1-D transposed convolutional layer with 96 filters of length 11 and a stride of 4.

### **Transposed Convolution**

#### **Stride** — Upsampling factor

1 (default) | positive integer

Upsampling factor of the input, specified as a positive integer that corresponds to the horizontal stride.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **Cropping** — Output size reduction

0 (default) | "same" | nonnegative integer | vector of two nonnegative integers

Output size reduction, specified as one of the following:

- "same" — Set the cropping so that the output size equals `inputSize.*Stride`, where `inputSize` is the length of the layer input. If `Cropping` is "same", then the software automatically sets the `CroppingMode` property of the layer to 'same'.

The software trims an equal amount from the left and right, when possible. If the horizontal crop amount has an odd value, then the software trims an extra column from the right.

- A positive integer — Crop the specified amount of data from the left and right edges.
- A vector of nonnegative integers [`l` `r`] — Crop `l` and `r` from the left and right, respectively.

If you set the `Cropping` option to a numeric value, then the software automatically sets the `CroppingMode` property of the layer to 'manual'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

**NumChannels — Number of input channels**

"auto" (default) | positive integer

Number of input channels, specified as one of the following:

- "auto" — Automatically determine the number of input channels at training time.
- Positive integer — Configure the layer for the specified number of input channels. NumChannels and the number of channels in the layer input data must match. For example, if the input is an RGB image, then NumChannels must be 3. If the input is the output of a convolutional layer with 16 filters, then NumChannels must be 16.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string

**Parameters and Initialization****WeightsInitializer — Function to initialize weights**

'glorot' (default) | 'he' | 'narrow-normal' | 'zeros' | 'ones' | function handle

Function to initialize the weights, specified as one of the following:

- 'glorot' — Initialize the weights with the Glorot initializer [1] (also known as the Xavier initializer). The Glorot initializer independently samples from a uniform distribution with a mean of zero and a variance of  $2/(\text{numIn} + \text{numOut})$ , where  $\text{numIn} = \text{FilterSize} * \text{NumChannels}$  and  $\text{numOut} = \text{FilterSize} * \text{NumFilters}$ .
- 'he' - Initialize the weights with the He initializer [2]. The He initializer samples from a normal distribution with a mean of zero and a variance of  $2/\text{numIn}$ , where  $\text{numIn} = \text{FilterSize} * \text{NumChannels}$ .
- 'narrow-normal' — Initialize the weights by independently sampling from a normal distribution with a mean of zero and a standard deviation of 0.01.
- 'zeros' — Initialize the weights with zeros.
- 'ones' — Initialize the weights with ones.
- Function handle — Initialize the weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the weights. For an example, see "Specify Custom Weight Initialization Function".

The layer only initializes the weights when the `Weights` property is empty.

Data Types: char | string | function\_handle

**BiasInitializer — Function to initialize biases**

'zeros' (default) | 'narrow-normal' | 'ones' | function handle

Function to initialize the biases, specified as one of the following:

- 'zeros' — Initialize the biases with zeros.
- 'ones' — Initialize the biases with ones.
- 'narrow-normal' — Initialize the biases by independently sampling from a normal distribution with a mean of zero and a standard deviation of 0.01.
- Function handle — Initialize the biases with a custom function. If you specify a function handle, then the function must be of the form `bias = func(sz)`, where `sz` is the size of the biases.

The layer only initializes the biases when the `Bias` property is empty.

Data Types: `char` | `string` | `function_handle`

### **Weights — Layer weights**

`[]` (default) | numeric array

Layer weights for the transposed convolution operation, specified as a `FilterSize-by-NumFilters-by-NumChannels` numeric array or `[]`.

The layer weights are learnable parameters. You can specify the initial value for the weights directly using the `Weights` property of the layer. When you train a network, if the `Weights` property of the layer is nonempty, then `trainNetwork` uses the `Weights` property as the initial value. If the `Weights` property is empty, then `trainNetwork` uses the initializer specified by the `WeightsInitializer` property of the layer.

Data Types: `single` | `double`

### **Bias — Layer biases**

`[]` (default) | numeric array

Layer biases for the transposed convolutional operation, specified as a `1-by-NumFilters` numeric array or `[]`.

The layer biases are learnable parameters. When you train a neural network, if `Bias` is nonempty, then `trainNetwork` uses the `Bias` property as the initial value. If `Bias` is empty, then `trainNetwork` uses the initializer specified by `BiasInitializer`.

Data Types: `single` | `double`

### **Learning Rate and Regularization**

#### **WeightLearnRateFactor — Learning rate factor for weights**

1 (default) | nonnegative scalar

Learning rate factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the weights in this layer. For example, if `WeightLearnRateFactor` is 2, then the learning rate for the weights in this layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **BiasLearnRateFactor — Learning rate factor for biases**

1 (default) | nonnegative scalar

Learning rate factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is 2, then the learning rate for the biases in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **WeightL2Factor — $L_2$ regularization factor for weights**

1 (default) | nonnegative scalar

$L_2$  regularization factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the weights in this layer. For example, if `WeightL2Factor` is 2, then the  $L_2$  regularization for the weights in this layer is twice the global  $L_2$  regularization factor. You can specify the global  $L_2$  regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **BiasL2Factor — $L_2$ regularization factor for biases**

0 (default) | nonnegative scalar

$L_2$  regularization factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the biases in this layer. For example, if `BiasL2Factor` is 2, then the  $L_2$  regularization for the biases in this layer is twice the global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Layer**

### **Name — Layer name**

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

## **Output Arguments**

### **layer — Transposed 1-D convolution layer**

`TransposedConvolution1DLayer` object

Transposed 1-D convolution layer, returned as a `TransposedConvolution1DLayer` object.

## **Algorithms**

### **1-D Transposed Convolutional Layer**

A transposed 1-D convolution layer upsamples one-dimensional feature maps.

The *standard* convolution operation *downsamples* the input by applying sliding convolutional filters to the input. By flattening the input and output, you can express the convolution operation as  $Y = CX + B$  for the convolution matrix  $C$  and bias vector  $B$  that can be derived from the layer weights and biases.

Similarly, the *transposed* convolution operation *upsamples* the input by applying sliding convolutional filters to the input. To upsample the input instead of downsampling using sliding filters, the layer zero-pads each edge of the input with padding that has the size of the corresponding filter edge size minus 1.

By flattening the input and output, the transposed convolution operation is equivalent to  $Y = C^T X + B$ , where  $C$  and  $B$  denote the convolution matrix and bias vector for standard convolution derived from the layer weights and biases, respectively. This operation is equivalent to the backward function of a standard convolution layer.

A 1-D transposed convolution layer upsamples a single dimension only. The dimension that the layer upsamples depends on the layer input:

- For time series and vector sequence input (data with three dimensions corresponding to the channels, observations, and time steps), the layer upsamples the time dimension.
- For 1-D image input (data with three dimensions corresponding to the spatial pixels, channels, and observations), the layer upsamples the spatial dimension.
- For 1-D image sequence input (data with four dimensions corresponding to the spatial pixels, channels, observations, and time steps), the layer upsamples the spatial dimension.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `TransposedConvolution1DLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"SCB" (spatial, channel, batch)	"SCB" (spatial, channel, batch)
"CBT" (channel, batch, time)	"CBT" (channel, batch, time)
"SCBT" (spatial, channel, batch, time)	"SCBT" (spatial, channel, batch, time)

In `dlnetwork` objects, `TransposedConvolution1DLayer` objects also support these input and output format combinations.

Input Format	Output Format
"SC" (spatial, channel)	"SC" (spatial, channel)
"CT" (channel, time)	"CT" (channel, time)
"SCT" (spatial, channel, time)	"SCT" (spatial, channel, time)

# transposedConv2dLayer

Transposed 2-D convolution layer

## Syntax

```
layer = transposedConv2dLayer(filterSize,numFilters)
layer = transposedConv2dLayer(filterSize,numFilters,Name,Value)
```

## Description

A transposed 2-D convolution layer upsamples two-dimensional feature maps.

This layer is sometimes incorrectly known as a "deconvolution" or "deconv" layer. This layer performs the transpose of convolution and does not perform deconvolution.

`layer = transposedConv2dLayer(filterSize,numFilters)` returns a 2-D transposed convolution layer and sets the `FilterSize` and `NumFilters` properties.

`layer = transposedConv2dLayer(filterSize,numFilters,Name,Value)` returns a 2-D transposed convolutional layer and specifies additional options using one or more name-value pair arguments.

## Examples

### Create Transposed Convolutional Layer

Create a transposed convolutional layer with 96 filters, each with a height and width of 11. Use a stride of 4 in the horizontal and vertical directions.

```
layer = transposedConv2dLayer(11,96,'Stride',4);
```

## Input Arguments

### **filterSize** — Height and width of filters

positive integer | vector of two positive integers

Height and width of the filters, specified as a positive integer or a vector of two positive integers [h w], where h is the height and w is the width. The filter size defines the size of the local regions to which the neurons connect in the input.

If `filterSize` is a positive integer, then the software uses the same value for both dimensions.

Example: [5 6] specifies filters of height and width of 5 and 6, respectively.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **numFilters** — Number of filters

positive integer

Number of filters, specified as a positive integer. This number corresponds to the number of neurons in the layer that connect to the same region in the input. This parameter determines the number of channels (feature maps) in the output of the layer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `transposedConv2dLayer(11,96,'Stride',4)` creates a 2-D transposed convolutional layer with 96 filters of size 11 and a stride of 4.

### Transposed Convolution

#### Stride — Up-sampling factor

1 (default) | vector of two positive integers | positive integer

Up-sampling factor of the input, specified as one of the following:

- A vector of two positive integers [`a b`], where `a` is the vertical stride and `b` is the horizontal stride.
- A positive integer that corresponds to both the vertical and horizontal stride.

Example: `'Stride',[2 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### Cropping — Output size reduction

0 (default) | "same" | nonnegative integer | vector of two nonnegative integers

Output size reduction, specified as one of the following:

- "same" - Set the cropping so that the output size equals `inputSize.*Stride`, where `inputSize` is the height and width of the layer input. If you set the `Cropping` option to "same", then the software automatically sets the `CroppingMode` property of the layer to 'same'.

The software trims an equal amount from the top and bottom, and the left and right, if possible. If the vertical crop amount has an odd value, then the software trims an extra row from the bottom. If the horizontal crop amount has an odd value, then the software trims an extra column from the right.

- A positive integer - Crop the specified amount of data from all the edges.
- A vector of nonnegative integers [`a b`] - Crop `a` from the top and bottom and crop `b` from the left and right.
- A vector [`t b l r`] - Crop `t`, `b`, `l`, `r` from the top, bottom, left, and right of the input, respectively.

If you set the `Cropping` option to a numeric value, then the software automatically sets the `CroppingMode` property of the layer to 'manual'.

Example: `[1 2]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### **NumChannels — Number of input channels**

`"auto"` (default) | positive integer

Number of input channels, specified as one of the following:

- `"auto"` — Automatically determine the number of input channels at training time.
- Positive integer — Configure the layer for the specified number of input channels. `NumChannels` and the number of channels in the layer input data must match. For example, if the input is an RGB image, then `NumChannels` must be 3. If the input is the output of a convolutional layer with 16 filters, then `NumChannels` must be 16.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### **Parameters and Initialization**

#### **WeightsInitializer — Function to initialize weights**

`'glorot'` (default) | `'he'` | `'narrow-normal'` | `'zeros'` | `'ones'` | function handle

Function to initialize the weights, specified as one of the following:

- `'glorot'` - Initialize the weights with the Glorot initializer [1] (also known as Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and variance  $2/(\text{numIn} + \text{numOut})$ , where  $\text{numIn} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{NumChannels}$  and  $\text{numOut} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{NumFilters}$ .
- `'he'` - Initialize the weights with the He initializer [2]. The He initializer samples from a normal distribution with zero mean and variance  $2/\text{numIn}$ , where  $\text{numIn} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{NumChannels}$ .
- `'narrow-normal'` - Initialize the weights by independently sampling from a normal distribution with zero mean and standard deviation 0.01.
- `'zeros'` - Initialize the weights with zeros.
- `'ones'` - Initialize the weights with ones.
- Function handle - Initialize the weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the weights. For an example, see “Specify Custom Weight Initialization Function”.

The layer only initializes the weights when the `Weights` property is empty.

Data Types: `char` | `string` | `function_handle`

#### **BiasInitializer — Function to initialize biases**

`'zeros'` (default) | `'narrow-normal'` | `'ones'` | function handle

Function to initialize the biases, specified as one of the following:

- `'zeros'` — Initialize the biases with zeros.
- `'ones'` — Initialize the biases with ones.
- `'narrow-normal'` — Initialize the biases by independently sampling from a normal distribution with a mean of zero and a standard deviation of 0.01.

- **Function handle** — Initialize the biases with a custom function. If you specify a function handle, then the function must be of the form `bias = func(sz)`, where `sz` is the size of the biases.

The layer only initializes the biases when the `Bias` property is empty.

Data Types: `char` | `string` | `function_handle`

### **Weights — Layer weights**

`[]` (default) | numeric array

Layer weights for the transposed convolution operation, specified as a `filterSize(1)`-by-`filterSize(2)`-by-`numFilters`-by-`NumChannels` numeric array or `[]`.

The layer weights are learnable parameters. You can specify the initial value for the weights directly using the `Weights` property of the layer. When you train a network, if the `Weights` property of the layer is nonempty, then `trainNetwork` uses the `Weights` property as the initial value. If the `Weights` property is empty, then `trainNetwork` uses the initializer specified by the `WeightsInitializer` property of the layer.

Data Types: `single` | `double`

### **Bias — Layer biases**

`[]` (default) | numeric array

Layer biases for the transposed convolutional operation, specified as a 1-by-1-by-`numFilters` numeric array or `[]`.

The layer biases are learnable parameters. When you train a neural network, if `Bias` is nonempty, then `trainNetwork` uses the `Bias` property as the initial value. If `Bias` is empty, then `trainNetwork` uses the initializer specified by `BiasInitializer`.

Data Types: `single` | `double`

## **Learning Rate and Regularization**

### **WeightLearnRateFactor — Learning rate factor for weights**

1 (default) | nonnegative scalar

Learning rate factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the weights in this layer. For example, if `WeightLearnRateFactor` is 2, then the learning rate for the weights in this layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **BiasLearnRateFactor — Learning rate factor for biases**

1 (default) | nonnegative scalar

Learning rate factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is 2, then the learning rate for the biases in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **WeightL2Factor — $L_2$ regularization factor for weights**

1 (default) | nonnegative scalar

$L_2$  regularization factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the weights in this layer. For example, if `WeightL2Factor` is 2, then the  $L_2$  regularization for the weights in this layer is twice the global  $L_2$  regularization factor. You can specify the global  $L_2$  regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **BiasL2Factor — $L_2$ regularization factor for biases**

0 (default) | nonnegative scalar

$L_2$  regularization factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the biases in this layer. For example, if `BiasL2Factor` is 2, then the  $L_2$  regularization for the biases in this layer is twice the global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Layer**

### **Name — Layer name**

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

## **Output Arguments**

### **layer — Transposed 2-D convolution layer**

`TransposedConvolution2DLayer` object

Transposed 2-D convolution layer, returned as a `TransposedConvolution2DLayer` object.

## **Algorithms**

### **2-D Transposed Convolutional Layer**

A transposed 2-D convolution layer upsamples two-dimensional feature maps.

The *standard* convolution operation *downsamples* the input by applying sliding convolutional filters to the input. By flattening the input and output, you can express the convolution operation as  $Y = CX + B$  for the convolution matrix  $C$  and bias vector  $B$  that can be derived from the layer weights and biases.

Similarly, the *transposed* convolution operation *upsamples* the input by applying sliding convolutional filters to the input. To upsample the input instead of downsampling using sliding filters, the layer zero-pads each edge of the input with padding that has the size of the corresponding filter edge size minus 1.

By flattening the input and output, the transposed convolution operation is equivalent to  $Y = C^T X + B$ , where  $C$  and  $B$  denote the convolution matrix and bias vector for standard convolution derived from the layer weights and biases, respectively. This operation is equivalent to the backward function of a standard convolution layer.

This image shows a 3-by-3 filter upsampling 2-by-2 input. The lower map represents the input and the upper map represents the output. <sup>2</sup>

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

<sup>2</sup> Image credit: Convolution arithmetic (License)

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `TransposedConvolution2DLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"SSCB" (spatial, spatial, channel, batch)	"SSCB" (spatial, spatial, channel, batch)
"SSC" (spatial, spatial, channel)	"SSC" (spatial, spatial, channel)

In `dlnetwork` objects, `TransposedConvolution2DLayer` objects also support these input and output format combinations.

Input Format	Output Format
"SSCBT" (spatial, spatial, channel, batch, time)	"SSCBT" (spatial, spatial, channel, batch, time)
"SSCT" (spatial, spatial, channel, time)	"SSCT" (spatial, spatial, channel, time)

## Version History

### Introduced in R2017b

#### R2019a: Default weights initialization is Glorot

*Behavior changed in R2019a*

Starting in R2019a, the software, by default, initializes the layer weights of this layer using the Glorot initializer. This behavior helps stabilize training and usually reduces the training time of deep networks.

In previous releases, the software, by default, initializes the layer weights by sampling from a normal distribution with zero mean and variance 0.01. To reproduce this behavior, set the `'WeightsInitializer'` option of the layer to `'narrow-normal'`.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Code generation does not support asymmetric cropping of the input. For example, specifying a vector [t b l r] for the 'Cropping' parameter to crop the top, bottom, left, and right of the input is not supported.

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

```

## Input Arguments

### **filterSize — Height, width, and depth of filters**

positive integer | vector of three positive integers

Height, width, and depth of the filters, specified as a positive integer or a vector of three positive integers [h w d], where h is the height, w is the width, and d is the depth. The filter size defines the size of the local regions to which the neurons connect in the input.

If `filterSize` is a scalar, then the software uses the same value for all three dimensions.

Example: [5 6 7] specifies filters with a height, width, and depth of 5, 6, and 7 respectively.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **numFilters — Number of filters**

positive integer

Number of filters, specified as a positive integer. This number corresponds to the number of neurons in the layer that connect to the same region in the input. This parameter determines the number of channels (feature maps) in the output of the layer.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `transposedConv3dLayer(11,96,'Stride',4)` creates a 3-D transposed convolutional layer with 96 filters of size 11 and a stride of 4.

### **Transposed Convolution**

#### **Stride — Step size for traversing input**

[1 1 1] (default) | vector of three positive integers

Step size for traversing the input in three dimensions, specified as a vector [a b c] of three positive integers, where a is the vertical step size, b is the horizontal step size, and c is the step size along the depth. When creating the layer, you can specify `Stride` as a scalar to use the same value for step sizes in all three directions.

Example: [2 3 1] specifies a vertical step size of 2, a horizontal step size of 3, and a step size along the depth of 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### **Cropping — Output size reduction**

0 (default) | "same" | vector of nonnegative integers | matrix of nonnegative integers

Output size reduction, specified as one of the following:

- 'same' - Set the cropping so that the output size equals `inputSize.*Stride`, where `inputSize` is the height, width, and depth of the layer input. If you set the `Cropping` option to "same", then the software automatically sets the `CroppingMode` property of the layer to 'same'.

The software trims an equal amount from the top and bottom, the left and right, and the front and back, if possible. If the vertical crop amount has an odd value, then the software trims an extra row from the bottom. If the horizontal crop amount has an odd value, then the software trims an extra column from the right. If the depth crop amount has an odd value, then the software trims an extra plane from the back.

- A positive integer - Crop the specified amount of data from all the edges.
- A vector of nonnegative integers [a b c] - Crop a from the top and bottom, crop b from the left and right, and crop c from the front and back.
- a matrix of nonnegative integers [t l f; b r bk] of nonnegative integers — Crop t, l, f, b, r, bk from the top, left, front, bottom, right, and back of the input, respectively.

If you set the **Cropping** option to a numeric value, then the software automatically sets the **CroppingMode** property of the layer to 'manual'.

Example: [1 2 2]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string

### **NumChannels — Number of input channels**

"auto" (default) | positive integer

Number of input channels, specified as one of the following:

- "auto" — Automatically determine the number of input channels at training time.
- Positive integer — Configure the layer for the specified number of input channels. **NumChannels** and the number of channels in the layer input data must match. For example, if the input is an RGB image, then **NumChannels** must be 3. If the input is the output of a convolutional layer with 16 filters, then **NumChannels** must be 16.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string

### **Parameters and Initialization**

#### **WeightsInitializer — Function to initialize weights**

'glorot' (default) | 'he' | 'narrow-normal' | 'zeros' | 'ones' | function handle

Function to initialize the weights, specified as one of the following:

- 'glorot' - Initialize the weights with the Glorot initializer [1] (also known as Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and variance  $2/(\text{numIn} + \text{numOut})$ , where  $\text{numIn} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{FilterSize}(3) * \text{NumChannels}$  and  $\text{numOut} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{FilterSize}(3) * \text{NumFilters}$ .
- 'he' - Initialize the weights with the He initializer [2]. The He initializer samples from a normal distribution with zero mean and variance  $2/\text{numIn}$ , where  $\text{numIn} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{FilterSize}(3) * \text{NumChannels}$ .
- 'narrow-normal' - Initialize the weights by independently sampling from a normal distribution with zero mean and standard deviation 0.01.
- 'zeros' - Initialize the weights with zeros.
- 'ones' - Initialize the weights with ones.

- Function handle - Initialize the weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the weights. For an example, see “Specify Custom Weight Initialization Function”.

The layer only initializes the weights when the `Weights` property is empty.

Data Types: `char` | `string` | `function_handle`

### **BiasInitializer — Function to initialize biases**

'zeros' (default) | 'narrow-normal' | 'ones' | function handle

Function to initialize the biases, specified as one of the following:

- 'zeros' — Initialize the biases with zeros.
- 'ones' — Initialize the biases with ones.
- 'narrow-normal' — Initialize the biases by independently sampling from a normal distribution with a mean of zero and a standard deviation of 0.01.
- Function handle — Initialize the biases with a custom function. If you specify a function handle, then the function must be of the form `bias = func(sz)`, where `sz` is the size of the biases.

The layer only initializes the biases when the `Bias` property is empty.

Data Types: `char` | `string` | `function_handle`

### **Weights — Layer weights**

[] (default) | numeric array

Layer weights for the transposed convolution operation, specified as a `FilterSize(1)`-by-`FilterSize(2)`-by-`FilterSize(3)`-by-`numFilters`-by-`NumChannels` numeric array or [].

The layer weights are learnable parameters. You can specify the initial value for the weights directly using the `Weights` property of the layer. When you train a network, if the `Weights` property of the layer is nonempty, then `trainNetwork` uses the `Weights` property as the initial value. If the `Weights` property is empty, then `trainNetwork` uses the initializer specified by the `WeightsInitializer` property of the layer.

Data Types: `single` | `double`

### **Bias — Layer biases**

[] (default) | numeric array

Layer biases for the transposed convolutional operation, specified as a 1-by-1-by-1-by-`numFilters` numeric array or [].

The layer biases are learnable parameters. When you train a neural network, if `Bias` is nonempty, then `trainNetwork` uses the `Bias` property as the initial value. If `Bias` is empty, then `trainNetwork` uses the initializer specified by `BiasInitializer`.

Data Types: `single` | `double`

### **Learning Rate and Regularization**

#### **WeightLearnRateFactor — Learning rate factor for weights**

1 (default) | nonnegative scalar

Learning rate factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the weights in this layer. For example, if `WeightLearnRateFactor` is 2, then the learning rate for the weights in this layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **BiasLearnRateFactor — Learning rate factor for biases**

1 (default) | nonnegative scalar

Learning rate factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is 2, then the learning rate for the biases in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **WeightL2Factor — $L_2$ regularization factor for weights**

1 (default) | nonnegative scalar

$L_2$  regularization factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the weights in this layer. For example, if `WeightL2Factor` is 2, then the  $L_2$  regularization for the weights in this layer is twice the global  $L_2$  regularization factor. You can specify the global  $L_2$  regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **BiasL2Factor — $L_2$ regularization factor for biases**

0 (default) | nonnegative scalar

$L_2$  regularization factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the biases in this layer. For example, if `BiasL2Factor` is 2, then the  $L_2$  regularization for the biases in this layer is twice the global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Layer**

### **Name — Layer name**

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

## Output Arguments

### Layer — Transposed 3-D convolution layer

TransposedConvolution3DLayer object

Transposed 3-D convolution layer, returned as a TransposedConvolution3dLayer object.

## Algorithms

### 3-D Transposed Convolutional Layer

A transposed 3-D convolution layer upsamples three-dimensional feature maps.

The *standard* convolution operation *downsamples* the input by applying sliding convolutional filters to the input. By flattening the input and output, you can express the convolution operation as  $Y = CX + B$  for the convolution matrix  $C$  and bias vector  $B$  that can be derived from the layer weights and biases.

Similarly, the *transposed* convolution operation *upsamples* the input by applying sliding convolutional filters to the input. To upsample the input instead of downsampling using sliding filters, the layer zero-pads each edge of the input with padding that has the size of the corresponding filter edge size minus 1.

By flattening the input and output, the transposed convolution operation is equivalent to  $Y = C^T X + B$ , where  $C$  and  $B$  denote the convolution matrix and bias vector for standard convolution derived from the layer weights and biases, respectively. This operation is equivalent to the backward function of a standard convolution layer.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `TransposedConvolution3DLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the

Formattable property set to 0 (false), then the layer receives an unformatted d`l`array object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"SSSCB" (spatial, spatial, spatial, channel, batch)	"SSSCB" (spatial, spatial, spatial, channel, batch)
"SSSC" (spatial, spatial, spatial, channel)	"SSSC" (spatial, spatial, spatial, channel)

In d`l`network objects, TransposedConvolution3DLayer objects also support these input and output format combinations.

Input Format	Output Format
"SSSCBT" (spatial, spatial, spatial, channel, batch, time)	"SSSCBT" (spatial, spatial, spatial, channel, batch, time)
"SSSCT" (spatial, spatial, spatial, channel, time)	"SSSCT" (spatial, spatial, spatial, channel, time)

# TransposedConvolution1DLayer

Transposed 1-D convolution layer

## Description

A transposed 1-D convolution layer upsamples one-dimensional feature maps.

This layer is sometimes incorrectly known as a "deconvolution" or "deconv" layer. This layer performs the transpose of convolution and does not perform deconvolution.

## Creation

Create a transposed convolution 1-D output layer using `transposedConv1dLayer`.

## Properties

### Transposed Convolution

#### FilterSize — Length of filters

positive integer

Length of the filters, specified as a positive integer. The filter size defines the size of the local regions to which the neurons connect in the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### NumFilters — Number of filters

positive integer

This property is read-only.

Number of filters, specified as a positive integer. This number corresponds to the number of neurons in the layer that connect to the same region in the input. This parameter determines the number of channels (feature maps) in the layer output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### Stride — Step size for traversing input

1 (default) | positive integer

Step size for traversing the input, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### CroppingMode — Method to determine cropping size

'manual' (default) | 'same'

Method to determine cropping size, specified as 'manual' or 'same'.

The software automatically sets the value of `CroppingMode` based on the `Cropping` value you specify when creating the layer.

- If you set the `Cropping` option to a numeric value, then the software automatically sets the `CroppingMode` property of the layer to `'manual'`.
- If you set the `Cropping` option to `'same'`, then the software automatically sets the `CroppingMode` property of the layer to `'same'` and set the cropping so that the output size equals `inputSize.*Stride`, where `inputSize` is the length of the layer input.

To specify the cropping size, use the `Cropping` option of `transposedConv1dLayer`.

### **NumChannels — Number of input channels**

`'auto'` (default) | positive integer

This property is read-only.

Number of input channels, specified as one of the following:

- `'auto'` — Automatically determine the number of input channels at training time.
- Positive integer — Configure the layer for the specified number of input channels. `NumChannels` and the number of channels in the layer input data must match. For example, if the input is an RGB image, then `NumChannels` must be 3. If the input is the output of a convolutional layer with 16 filters, then `NumChannels` must be 16.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### **Parameters and Initialization**

#### **WeightsInitializer — Function to initialize weights**

`'glorot'` (default) | `'he'` | `'narrow-normal'` | `'zeros'` | `'ones'` | function handle

Function to initialize the weights, specified as one of the following:

- `'glorot'` — Initialize the weights with the Glorot initializer [1] (also known as the Xavier initializer). The Glorot initializer independently samples from a uniform distribution with a mean of zero and a variance of  $2/(\text{numIn} + \text{numOut})$ , where  $\text{numIn} = \text{FilterSize} * \text{NumChannels}$  and  $\text{numOut} = \text{FilterSize} * \text{NumFilters}$ .
- `'he'` - Initialize the weights with the He initializer [2]. The He initializer samples from a normal distribution with a mean of zero and a variance of  $2/\text{numIn}$ , where  $\text{numIn} = \text{FilterSize} * \text{NumChannels}$ .
- `'narrow-normal'` — Initialize the weights by independently sampling from a normal distribution with a mean of zero and a standard deviation of 0.01.
- `'zeros'` — Initialize the weights with zeros.
- `'ones'` — Initialize the weights with ones.
- Function handle — Initialize the weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the weights. For an example, see “Specify Custom Weight Initialization Function”.

The layer only initializes the weights when the `Weights` property is empty.

Data Types: `char` | `string` | `function_handle`

**BiasInitializer — Function to initialize biases**

'zeros' (default) | 'narrow-normal' | 'ones' | function handle

Function to initialize the biases, specified as one of the following:

- 'zeros' — Initialize the biases with zeros.
- 'ones' — Initialize the biases with ones.
- 'narrow-normal' — Initialize the biases by independently sampling from a normal distribution with a mean of zero and a standard deviation of 0.01.
- Function handle — Initialize the biases with a custom function. If you specify a function handle, then the function must be of the form `bias = func(sz)`, where `sz` is the size of the biases.

The layer only initializes the biases when the `Bias` property is empty.

Data Types: char | string | function\_handle

**Weights — Layer weights**

[] (default) | numeric array

Layer weights for the transposed convolution operation, specified as a `FilterSize-by-NumFilters-by-NumChannels` numeric array or [].

The layer weights are learnable parameters. You can specify the initial value for the weights directly using the `Weights` property of the layer. When you train a network, if the `Weights` property of the layer is nonempty, then `trainNetwork` uses the `Weights` property as the initial value. If the `Weights` property is empty, then `trainNetwork` uses the initializer specified by the `WeightsInitializer` property of the layer.

Data Types: single | double

**Bias — Layer biases**

[] (default) | numeric array

Layer biases for the transposed convolutional operation, specified as a `1-by-NumFilters` numeric array or [].

The layer biases are learnable parameters. When you train a neural network, if `Bias` is nonempty, then `trainNetwork` uses the `Bias` property as the initial value. If `Bias` is empty, then `trainNetwork` uses the initializer specified by `BiasInitializer`.

Data Types: single | double

**Learning Rate and Regularization****WeightLearnRateFactor — Learning rate factor for weights**

1 (default) | nonnegative scalar

Learning rate factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the weights in this layer. For example, if `WeightLearnRateFactor` is 2, then the learning rate for the weights in this layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**BiasLearnRateFactor — Learning rate factor for biases**

1 (default) | nonnegative scalar

Learning rate factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is 2, then the learning rate for the biases in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**WeightL2Factor —  $L_2$  regularization factor for weights**

1 (default) | nonnegative scalar

$L_2$  regularization factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the weights in this layer. For example, if `WeightL2Factor` is 2, then the  $L_2$  regularization for the weights in this layer is twice the global  $L_2$  regularization factor. You can specify the global  $L_2$  regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**BiasL2Factor —  $L_2$  regularization factor for biases**

0 (default) | nonnegative scalar

$L_2$  regularization factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the biases in this layer. For example, if `BiasL2Factor` is 2, then the  $L_2$  regularization for the biases in this layer is twice the global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**Layer****Name — Layer name**

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`**NumInputs — Number of inputs**

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

**InputNames — Input names**

{"in"} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: cell

**NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: double

**OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

## Algorithms

### 1-D Transposed Convolutional Layer

A transposed 1-D convolution layer upsamples one-dimensional feature maps.

The *standard* convolution operation *downsamples* the input by applying sliding convolutional filters to the input. By flattening the input and output, you can express the convolution operation as  $Y = CX + B$  for the convolution matrix  $C$  and bias vector  $B$  that can be derived from the layer weights and biases.

Similarly, the *transposed* convolution operation *upsamples* the input by applying sliding convolutional filters to the input. To upsample the input instead of downsampling using sliding filters, the layer zero-pads each edge of the input with padding that has the size of the corresponding filter edge size minus 1.

By flattening the input and output, the transposed convolution operation is equivalent to  $Y = C^T X + B$ , where  $C$  and  $B$  denote the convolution matrix and bias vector for standard convolution derived from the layer weights and biases, respectively. This operation is equivalent to the backward function of a standard convolution layer.

A 1-D transposed convolution layer upsamples a single dimension only. The dimension that the layer upsamples depends on the layer input:

- For time series and vector sequence input (data with three dimensions corresponding to the channels, observations, and time steps), the layer upsamples the time dimension.
- For 1-D image input (data with three dimensions corresponding to the spatial pixels, channels, and observations), the layer upsamples the spatial dimension.
- For 1-D image sequence input (data with four dimensions corresponding to the spatial pixels, channels, observations, and time steps), the layer upsamples the spatial dimension.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `TransposedConvolution1DLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"SCB" (spatial, channel, batch)	"SCB" (spatial, channel, batch)
"CBT" (channel, batch, time)	"CBT" (channel, batch, time)
"SCBT" (spatial, channel, batch, time)	"SCBT" (spatial, channel, batch, time)

In `dlnetwork` objects, `TransposedConvolution1DLayer` objects also support these input and output format combinations.

Input Format	Output Format
"SC" (spatial, channel)	"SC" (spatial, channel)
"CT" (channel, time)	"CT" (channel, time)
"SCT" (spatial, channel, time)	"SCT" (spatial, channel, time)

# TransposedConvolution2DLayer

Transposed 2-D convolution layer

## Description

A transposed 2-D convolution layer upsamples two-dimensional feature maps.

This layer is sometimes incorrectly known as a "deconvolution" or "deconv" layer. This layer is the transpose of convolution and does not perform deconvolution.

## Creation

Create a transposed convolution 2-D layer using `transposedConv2dLayer`.

## Properties

### Transposed Convolution

#### FilterSize — Height and width of filters

vector of two positive integers

Height and width of the filters, specified as a vector of two positive integers  $[h \ w]$ , where  $h$  is the height and  $w$  is the width. `FilterSize` defines the size of the local regions to which the neurons connect in the input.

If you set `FilterSize` using an input argument, then you can specify `FilterSize` as scalar to use the same value for both dimensions.

Example: `[5 5]` specifies filters of height 5 and width 5.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### NumFilters — Number of filters

positive integer

This property is read-only.

Number of filters, specified as a positive integer. This number corresponds to the number of neurons in the layer that connect to the same region in the input. This parameter determines the number of channels (feature maps) in the layer output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### Stride — Step size for traversing input

`[1 1]` (default) | vector of two positive integers

Step size for traversing the input vertically and horizontally, specified as a vector  $[a \ b]$  of two positive integers, where  $a$  is the vertical step size and  $b$  is the horizontal step size. When creating the layer, you can specify `Stride` as a scalar to use the same value for both step sizes.

Example: `[2 3]` specifies a vertical step size of 2 and a horizontal step size of 3.

### **CroppingMode — Method to determine cropping size**

`'manual'` (default) | `'same'`

Method to determine cropping size, specified as `'manual'` or `same`.

The software automatically sets the value of `CroppingMode` based on the `'Cropping'` value you specify when creating the layer.

- If you set the `Cropping` option to a numeric value, then the software automatically sets the `CroppingMode` property of the layer to `'manual'`.
- If you set the `'Cropping'` option to `'same'`, then the software automatically sets the `CroppingMode` property of the layer to `'same'` and set the cropping so that the output size equals `inputSize .* Stride`, where `inputSize` is the height and width of the layer input.

To specify the cropping size, use the `'Cropping'` option of `transposedConv2dLayer`.

### **CroppingSize — Output size reduction**

`[0 0 0 0]` (default) | vector of four nonnegative integers

Output size reduction, specified as a vector of four nonnegative integers `[t b l r]`, where `t`, `b`, `l`, `r` are the amounts to crop from the top, bottom, left, and right, respectively.

To specify the cropping size manually, use the `'Cropping'` option of `transposedConv2dLayer`.

Example: `[0 1 0 1]`

### **Cropping — Output size reduction**

`[0 0]` (default) | vector of two nonnegative integers

---

**Note** `Cropping` property will be removed in a future release. Use `CroppingSize` instead. To specify the cropping size manually, use the `'Cropping'` option of `transposedConv2dLayer`.

---

Output size reduction, specified as a vector of two nonnegative integers `[a b]`, where `a` corresponds to the cropping from the top and bottom and `b` corresponds to the cropping from the left and right.

To specify the cropping size manually, use the `'Cropping'` option of `transposedConv2dLayer`.

Example: `[0 1]`

### **NumChannels — Number of input channels**

`'auto'` (default) | positive integer

This property is read-only.

Number of input channels, specified as one of the following:

- `'auto'` — Automatically determine the number of input channels at training time.
- Positive integer — Configure the layer for the specified number of input channels. `NumChannels` and the number of channels in the layer input data must match. For example, if the input is an RGB image, then `NumChannels` must be 3. If the input is the output of a convolutional layer with 16 filters, then `NumChannels` must be 16.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### Parameters and Initialization

#### WeightsInitializer — Function to initialize weights

`'glorot'` (default) | `'he'` | `'narrow-normal'` | `'zeros'` | `'ones'` | function handle

Function to initialize the weights, specified as one of the following:

- `'glorot'` - Initialize the weights with the Glorot initializer [1] (also known as Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and variance  $2/(\text{numIn} + \text{numOut})$ , where  $\text{numIn} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{NumChannels}$  and  $\text{numOut} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{NumFilters}$ .
- `'he'` - Initialize the weights with the He initializer [2]. The He initializer samples from a normal distribution with zero mean and variance  $2/\text{numIn}$ , where  $\text{numIn} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{NumChannels}$ .
- `'narrow-normal'` - Initialize the weights by independently sampling from a normal distribution with zero mean and standard deviation 0.01.
- `'zeros'` - Initialize the weights with zeros.
- `'ones'` - Initialize the weights with ones.
- Function handle - Initialize the weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the weights. For an example, see “Specify Custom Weight Initialization Function”.

The layer only initializes the weights when the `Weights` property is empty.

Data Types: `char` | `string` | `function_handle`

#### BiasInitializer — Function to initialize biases

`'zeros'` (default) | `'narrow-normal'` | `'ones'` | function handle

Function to initialize the biases, specified as one of the following:

- `'zeros'` — Initialize the biases with zeros.
- `'ones'` — Initialize the biases with ones.
- `'narrow-normal'` — Initialize the biases by independently sampling from a normal distribution with a mean of zero and a standard deviation of 0.01.
- Function handle — Initialize the biases with a custom function. If you specify a function handle, then the function must be of the form `bias = func(sz)`, where `sz` is the size of the biases.

The layer only initializes the biases when the `Bias` property is empty.

Data Types: `char` | `string` | `function_handle`

#### Weights — Layer weights

`[]` (default) | numeric array

Layer weights for the convolutional layer, specified as a `FilterSize(1)`-by-`FilterSize(2)`-by-`NumFilters`-by-`NumChannels` array.

The layer weights are learnable parameters. You can specify the initial value for the weights directly using the `Weights` property of the layer. When you train a network, if the `Weights` property of the

layer is nonempty, then `trainNetwork` uses the `Weights` property as the initial value. If the `Weights` property is empty, then `trainNetwork` uses the initializer specified by the `WeightsInitializer` property of the layer.

Data Types: `single` | `double`

### **Bias — Layer biases**

`[]` (default) | numeric array

Layer biases for the convolutional layer, specified as a numeric array.

The layer biases are learnable parameters. When you train a neural network, if `Bias` is nonempty, then `trainNetwork` uses the `Bias` property as the initial value. If `Bias` is empty, then `trainNetwork` uses the initializer specified by `BiasInitializer`.

At training time, `Bias` is a 1-by-1-by-`NumFilters` array.

Data Types: `single` | `double`

### **Learning Rate and Regularization**

#### **WeightLearnRateFactor — Learning rate factor for weights**

1 (default) | nonnegative scalar

Learning rate factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the weights in this layer. For example, if `WeightLearnRateFactor` is 2, then the learning rate for the weights in this layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **BiasLearnRateFactor — Learning rate factor for biases**

1 (default) | nonnegative scalar

Learning rate factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is 2, then the learning rate for the biases in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **WeightL2Factor — $L_2$ regularization factor for weights**

1 (default) | nonnegative scalar

$L_2$  regularization factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the weights in this layer. For example, if `WeightL2Factor` is 2, then the  $L_2$  regularization for the weights in this layer is twice the global  $L_2$  regularization factor. You can specify the global  $L_2$  regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**BiasL2Factor —  $L_2$  regularization factor for biases**

0 (default) | nonnegative scalar

$L_2$  regularization factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the biases in this layer. For example, if `BiasL2Factor` is 2, then the  $L_2$  regularization for the biases in this layer is twice the global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Layer****Name — Layer name**

' ' (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name ' '.

Data Types: `char` | `string`

**NumInputs — Number of inputs**

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

**InputNames — Input names**

{"in"} (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: `cell`

**NumOutputs — Number of outputs**

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: `double`

**OutputNames — Output names**

{'out'} (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: cell

## Examples

### Create Transposed Convolutional Layer

Create a transposed convolutional layer with 96 filters, each with a height and width of 11. Use a stride of 4 in the horizontal and vertical directions.

```
layer = transposedConv2dLayer(11,96, 'Stride',4);
```

## Algorithms

### 2-D Transposed Convolutional Layer

A transposed 2-D convolution layer upsamples two-dimensional feature maps.

The *standard* convolution operation *downsamples* the input by applying sliding convolutional filters to the input. By flattening the input and output, you can express the convolution operation as  $Y = CX + B$  for the convolution matrix  $C$  and bias vector  $B$  that can be derived from the layer weights and biases.

Similarly, the *transposed* convolution operation *upsamples* the input by applying sliding convolutional filters to the input. To upsample the input instead of downsampling using sliding filters, the layer zero-pads each edge of the input with padding that has the size of the corresponding filter edge size minus 1.

By flattening the input and output, the transposed convolution operation is equivalent to  $Y = C^T X + B$ , where  $C$  and  $B$  denote the convolution matrix and bias vector for standard convolution derived from the layer weights and biases, respectively. This operation is equivalent to the backward function of a standard convolution layer.

This image shows a 3-by-3 filter upsampling 2-by-2 input. The lower map represents the input and the upper map represents the output.<sup>3</sup>

---

<sup>3</sup> Image credit: Convolution arithmetic (License)

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The format consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `TransposedConvolution2DLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"SSCB" (spatial, spatial, channel, batch)	"SSCB" (spatial, spatial, channel, batch)
"SSC" (spatial, spatial, channel)	"SSC" (spatial, spatial, channel)

In `dlnetwork` objects, `TransposedConvolution2DLayer` objects also support these input and output format combinations.

Input Format	Output Format
"SSCBT" (spatial, spatial, channel, batch, time)	"SSCBT" (spatial, spatial, channel, batch, time)
"SSCT" (spatial, spatial, channel, time)	"SSCT" (spatial, spatial, channel, time)

## Version History

### Introduced in R2017b

#### R2019a: Default weights initialization is Glorot

*Behavior changed in R2019a*

Starting in R2019a, the software, by default, initializes the layer weights of this layer using the Glorot initializer. This behavior helps stabilize training and usually reduces the training time of deep networks.

In previous releases, the software, by default, initializes the layer weights by sampling from a normal distribution with zero mean and variance 0.01. To reproduce this behavior, set the 'WeightsInitializer' option of the layer to 'narrow-normal'.

#### R2019a: Cropping property of TransposedConvolution2DLayer will be removed

*Not recommended starting in R2019a*

Cropping property of `TransposedConvolution2DLayer` will be removed, use `CroppingSize` instead. To update your code, replace all instances of the `Cropping` property with `CroppingSize`.

# TransposedConvolution3dLayer

Transposed 3-D convolution layer

## Description

A transposed 3-D convolution layer upsamples three-dimensional feature maps.

This layer is sometimes incorrectly known as a "deconvolution" or "deconv" layer. This layer is the transpose of convolution and does not perform deconvolution.

## Creation

Create a transposed convolution 3-D layer using `transposedConv3dLayer`.

## Properties

### Transposed Convolution

#### **FilterSize** — Height, width, and depth of filters

vector of three positive integers

Height, width, and depth of the filters, specified as a vector `[h w d]` of three positive integers, where `h` is the height, `w` is the width, and `d` is the depth. `FilterSize` defines the size of the local regions to which the neurons connect in the input.

When creating the layer, you can specify `FilterSize` as a scalar to use the same value for the height, width, and depth.

Example: `[5 5 5]` specifies filters with a height, width, and depth of 5.

#### **NumFilters** — Number of filters

positive integer

This property is read-only.

Number of filters, specified as a positive integer. This number corresponds to the number of neurons in the layer that connect to the same region in the input. This parameter determines the number of channels (feature maps) in the layer output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **Stride** — Step size for traversing input

`[1 1 1]` (default) | vector of three positive integers

Step size for traversing the input in three dimensions, specified as a vector `[a b c]` of three positive integers, where `a` is the vertical step size, `b` is the horizontal step size, and `c` is the step size along the depth. When creating the layer, you can specify `Stride` as a scalar to use the same value for step sizes in all three directions.

Example: [2 3 1] specifies a vertical step size of 2, a horizontal step size of 3, and a step size along the depth of 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **CroppingMode — Method to determine cropping size**

'manual' (default) | 'same'

Method to determine cropping size, specified as 'manual' or 'same'.

The software automatically sets the value of `CroppingMode` based on the 'Cropping' value you specify when creating the layer.

- If you set the `Cropping` option to a numeric value, then the software automatically sets the `CroppingMode` property of the layer to 'manual'.
- If you set the 'Cropping' option to 'same', then the software automatically sets the `CroppingMode` property of the layer to 'same' and set the cropping so that the output size equals `inputSize .* Stride`, where `inputSize` is the height, width, and depth of the layer input.

To specify the cropping size, use the 'Cropping' option of `transposedConv3dLayer`.

### **CroppingSize — Output size reduction**

[0 0 0;0 0 0] (default) | matrix of nonnegative integers

Output size reduction, specified as a matrix of nonnegative integers [t l f; b r bk], t, l, f, b, r, bk are the amounts to crop from the top, left, front, bottom, right, and back of the input, respectively.

To specify the cropping size manually, use the 'Cropping' option of `transposedConv2dLayer`.

Example: [0 1 0 1 0 1]

### **NumChannels — Number of input channels**

'auto' (default) | positive integer

This property is read-only.

Number of input channels, specified as one of the following:

- 'auto' — Automatically determine the number of input channels at training time.
- Positive integer — Configure the layer for the specified number of input channels. `NumChannels` and the number of channels in the layer input data must match. For example, if the input is an RGB image, then `NumChannels` must be 3. If the input is the output of a convolutional layer with 16 filters, then `NumChannels` must be 16.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string

## **Parameters and Initialization**

### **WeightsInitializer — Function to initialize weights**

'glorot' (default) | 'he' | 'narrow-normal' | 'zeros' | 'ones' | function handle

Function to initialize the weights, specified as one of the following:

- 'glorot' - Initialize the weights with the Glorot initializer [1] (also known as Xavier initializer). The Glorot initializer independently samples from a uniform distribution with zero mean and variance  $2/(\text{numIn} + \text{numOut})$ , where  $\text{numIn} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{FilterSize}(3) * \text{NumChannels}$  and  $\text{numOut} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{FilterSize}(3) * \text{NumFilters}$ .
- 'he' - Initialize the weights with the He initializer [2]. The He initializer samples from a normal distribution with zero mean and variance  $2/\text{numIn}$ , where  $\text{numIn} = \text{FilterSize}(1) * \text{FilterSize}(2) * \text{FilterSize}(3) * \text{NumChannels}$ .
- 'narrow-normal' - Initialize the weights by independently sampling from a normal distribution with zero mean and standard deviation 0.01.
- 'zeros' - Initialize the weights with zeros.
- 'ones' - Initialize the weights with ones.
- Function handle - Initialize the weights with a custom function. If you specify a function handle, then the function must be of the form `weights = func(sz)`, where `sz` is the size of the weights. For an example, see "Specify Custom Weight Initialization Function".

The layer only initializes the weights when the `Weights` property is empty.

Data Types: `char` | `string` | `function_handle`

### **BiasInitializer — Function to initialize biases**

'zeros' (default) | 'narrow-normal' | 'ones' | function handle

Function to initialize the biases, specified as one of the following:

- 'zeros' — Initialize the biases with zeros.
- 'ones' — Initialize the biases with ones.
- 'narrow-normal' — Initialize the biases by independently sampling from a normal distribution with a mean of zero and a standard deviation of 0.01.
- Function handle — Initialize the biases with a custom function. If you specify a function handle, then the function must be of the form `bias = func(sz)`, where `sz` is the size of the biases.

The layer only initializes the biases when the `Bias` property is empty.

Data Types: `char` | `string` | `function_handle`

### **Weights — Layer weights**

[] (default) | numeric array

Layer weights for the transposed convolutional layer, specified as a numeric array.

The layer weights are learnable parameters. You can specify the initial value for the weights directly using the `Weights` property of the layer. When you train a network, if the `Weights` property of the layer is nonempty, then `trainNetwork` uses the `Weights` property as the initial value. If the `Weights` property is empty, then `trainNetwork` uses the initializer specified by the `WeightsInitializer` property of the layer.

At training time, `Weights` is a `FilterSize(1)`-by-`FilterSize(2)`-by-`FilterSize(3)`-by-`NumFilters`-by-`NumChannels` array.

Data Types: `single` | `double`

**Bias — Layer biases**

[] (default) | numeric array

Layer biases for the transposed convolutional layer, specified as a numeric array.

The layer biases are learnable parameters. When you train a neural network, if `Bias` is nonempty, then `trainNetwork` uses the `Bias` property as the initial value. If `Bias` is empty, then `trainNetwork` uses the initializer specified by `BiasInitializer`.

At training time, `Bias` is a 1-by-1-by-1-by-NumFilters array.

Data Types: `single` | `double`

**Learning Rate and Regularization****WeightLearnRateFactor — Learning rate factor for weights**

1 (default) | nonnegative scalar

Learning rate factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the weights in this layer. For example, if `WeightLearnRateFactor` is 2, then the learning rate for the weights in this layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**BiasLearnRateFactor — Learning rate factor for biases**

1 (default) | nonnegative scalar

Learning rate factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global learning rate to determine the learning rate for the biases in this layer. For example, if `BiasLearnRateFactor` is 2, then the learning rate for the biases in the layer is twice the current global learning rate. The software determines the global learning rate based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**WeightL2Factor —  $L_2$  regularization factor for weights**

1 (default) | nonnegative scalar

$L_2$  regularization factor for the weights, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the weights in this layer. For example, if `WeightL2Factor` is 2, then the  $L_2$  regularization for the weights in this layer is twice the global  $L_2$  regularization factor. You can specify the global  $L_2$  regularization factor using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**BiasL2Factor —  $L_2$  regularization factor for biases**

0 (default) | nonnegative scalar

$L_2$  regularization factor for the biases, specified as a nonnegative scalar.

The software multiplies this factor by the global  $L_2$  regularization factor to determine the  $L_2$  regularization for the biases in this layer. For example, if `BiasL2Factor` is 2, then the  $L_2$

regularization for the biases in this layer is twice the global  $L_2$  regularization factor. The software determines the global  $L_2$  regularization factor based on the settings you specify using the `trainingOptions` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Layer

### Name — Layer name

`''` (default) | character vector | string scalar

Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with the name `''`.

Data Types: `char` | `string`

### NumInputs — Number of inputs

1 (default)

This property is read-only.

Number of inputs of the layer. This layer accepts a single input only.

Data Types: `double`

### InputNames — Input names

`{"in"}` (default)

This property is read-only.

Input names of the layer. This layer accepts a single input only.

Data Types: `cell`

### NumOutputs — Number of outputs

1 (default)

This property is read-only.

Number of outputs of the layer. This layer has a single output only.

Data Types: `double`

### OutputNames — Output names

`{'out'}` (default)

This property is read-only.

Output names of the layer. This layer has a single output only.

Data Types: `cell`

## Examples

## Create Transposed 3-D Convolutional Layer

Create a transposed 3-D convolutional layer with 32 filters, each with a height, width, and depth of 11. Use a stride of 4 in the horizontal and vertical directions and 2 along the depth.

```
layer = transposedConv3dLayer(11,32,'Stride',[4 4 2])
```

```
layer =
  TransposedConvolution3DLayer with properties:

    Name: ''

  Hyperparameters
    FilterSize: [11 11 11]
    NumChannels: 'auto'
    NumFilters: 32
    Stride: [4 4 2]
    CroppingMode: 'manual'
    CroppingSize: [2x3 double]

  Learnable Parameters
    Weights: []
    Bias: []

  Show all properties
```

## Algorithms

### 3-D Transposed Convolutional Layer

A transposed 3-D convolution layer upsamples three-dimensional feature maps.

The *standard* convolution operation *downsamples* the input by applying sliding convolutional filters to the input. By flattening the input and output, you can express the convolution operation as  $Y = CX + B$  for the convolution matrix  $C$  and bias vector  $B$  that can be derived from the layer weights and biases.

Similarly, the *transposed* convolution operation *upsamples* the input by applying sliding convolutional filters to the input. To upsample the input instead of downsampling using sliding filters, the layer zero-pads each edge of the input with padding that has the size of the corresponding filter edge size minus 1.

By flattening the input and output, the transposed convolution operation is equivalent to  $Y = C^T X + B$ , where  $C$  and  $B$  denote the convolution matrix and bias vector for standard convolution derived from the layer weights and biases, respectively. This operation is equivalent to the backward function of a standard convolution layer.

### Layer Input and Output Formats

Layers in a layer array or layer graph pass data to subsequent layers as formatted `darray` objects. The format of a `darray` object is a string of characters, in which each character describes the corresponding dimension of the data. The formats consists of one or more of these characters:

- "S" — Spatial
- "C" — Channel
- "B" — Batch
- "T" — Time
- "U" — Unspecified

For example, 2-D image data represented as a 4-D array, where the first two dimensions correspond to the spatial dimensions of the images, the third dimension corresponds to the channels of the images, and the fourth dimension corresponds to the batch dimension, can be described as having the format "SSCB" (spatial, spatial, channel, batch).

You can interact with these `darray` objects in automatic differentiation workflows such as developing a custom layer, using a `functionLayer` object, or using the `forward` and `predict` functions with `dlnetwork` objects.

This table shows the supported input formats of `TransposedConvolution3DLayer` objects and the corresponding output format. If the output of the layer is passed to a custom layer that does not inherit from the `nnet.layer.Formattable` class, or a `FunctionLayer` object with the `Formattable` property set to `0` (false), then the layer receives an unformatted `darray` object with dimensions ordered corresponding to the formats in this table.

Input Format	Output Format
"SSSCB" (spatial, spatial, spatial, channel, batch)	"SSSCB" (spatial, spatial, spatial, channel, batch)
"SSSC" (spatial, spatial, spatial, channel)	"SSSC" (spatial, spatial, spatial, channel)

In `dlnetwork` objects, `TransposedConvolution3DLayer` objects also support these input and output format combinations.

Input Format	Output Format
"SSSCBT" (spatial, spatial, spatial, channel, batch, time)	"SSSCBT" (spatial, spatial, spatial, channel, batch, time)
"SSSCT" (spatial, spatial, spatial, channel, time)	"SSSCT" (spatial, spatial, spatial, channel, time)

## unfreezeParameters

Convert nonlearnable network parameters in `ONNXParameters` to learnable

### Syntax

```
params = unfreezeParameters(params, names)
```

### Description

`params = unfreezeParameters(params, names)` unfreezes the network parameters specified by `names` in the `ONNXParameters` object `params`. The function moves the specified parameters from `params.Nonlearnables` in the input argument `params` to `params.Learnables` in the output argument `params`.

### Examples

#### Train Imported ONNX Function Using Custom Training Loop

Import the `squeezenet` convolution neural network as a function and fine-tune the pretrained network with transfer learning to perform classification on a new collection of images.

This example uses several helper functions. To view the code for these functions, see `Helper Functions` on page 1-1926.

Unzip and load the new images as an image datastore. `imageDatastore` automatically labels the images based on folder names and stores the data as an `ImageDatastore` object. An image datastore enables you to store large image data, including data that does not fit in memory, and efficiently read batches of images during training of a convolutional neural network. Specify the mini-batch size.

```
unzip("MerchData.zip");
miniBatchSize = 8;
imds = imageDatastore("MerchData", ...
    IncludeSubfolders=true, ...
    LabelSource="foldernames", ...
    ReadSize=miniBatchSize);
```

This data set is small, containing 75 training images. Display some sample images.

```
numImages = numel(imds.Labels);
idx = randperm(numImages,16);
figure
for i = 1:16
    subplot(4,4,i)
    I = readimage(imds,idx(i));
    imshow(I)
end
```

Extract the training set and one-hot encode the categorical classification labels.

```
XTrain = readall(imds);
XTrain = single(cat(4,XTrain{:}));
YTrain_categ = categorical(imds.Labels);
YTrain = onehotencode(YTrain_categ,2)';
```

Determine the number of classes in the data.

```
classes = categories(YTrain_categ);
numClasses = numel(classes)
```

```
numClasses = 5
```

`squeezenet` is a convolutional neural network that is trained on more than a million images from the ImageNet database. As a result, the network has learned rich feature representations for a wide range of images. The network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals.

Import the pretrained `squeezenet` network as a function.

```
squeezenetONNX()
params = importONNXFunction("squeezenet.onnx", "squeezenetFcn")
```

Function containing the imported ONNX network architecture was saved to the file `squeezenetFcn.m`. To learn how to use this function, type: `help squeezenetFcn`.

```
params =  
    ONNXParameters with properties:  
  
        Learnables: [1x1 struct]  
        Nonlearnables: [1x1 struct]  
        State: [1x1 struct]  
        NumDimensions: [1x1 struct]  
        NetworkFunctionName: 'squeezenetFcn'
```

`params` is an `ONNXParameters` object that contains the network parameters. `squeezenetFcn` is a model function that contains the network architecture. `importONNXFunction` saves `squeezenetFcn` in the current folder.

Calculate the classification accuracy of the pretrained network on the new training set.

```
accuracyBeforeTraining = getNetworkAccuracy(XTrain,YTrain,params);  
fprintf("%.2f accuracy before transfer learning\n",accuracyBeforeTraining);
```

```
0.01 accuracy before transfer learning
```

The accuracy is very low.

Display the learnable parameters of the network by typing `params.Learnables`. These parameters, such as the weights (**W**) and bias (**B**) of convolution and fully connected layers, are updated by the network during training. Nonlearnable parameters remain constant during training.

The last two learnable parameters of the pretrained network are configured for 1000 classes.

```
conv10_W: [1x1x512x1000 dlarray]
```

```
conv10_B: [1000x1 dlarray]
```

The parameters `conv10_W` and `conv10_B` must be fine-tuned for the new classification problem. Transfer the parameters to classify five classes by initializing the parameters.

```
params.Learnables.conv10_W = rand(1,1,512,5);  
params.Learnables.conv10_B = rand(5,1);
```

Freeze all the parameters of the network to convert them to nonlearnable parameters. Because you do not need to compute the gradients of the frozen layers, freezing the weights of many initial layers can significantly speed up network training.

```
params = freezeParameters(params,"all");
```

Unfreeze the last two parameters of the network to convert them to learnable parameters.

```
params = unfreezeParameters(params,"conv10_W");  
params = unfreezeParameters(params,"conv10_B");
```

The network is ready for training. Specify the training options.

```
velocity = [];  
numEpochs = 5;  
miniBatchSize = 16;
```

```

initialLearnRate = 0.01;
momentum = 0.9;
decay = 0.01;

```

Calculate the total number of iterations for the training progress monitor.

```

numObservations = size(YTrain,2);
numIterationsPerEpoch = floor(numObservations./miniBatchSize);
numIterations = numEpochs*numIterationsPerEpoch;

```

Initialize the `TrainingProgressMonitor` object. Because the timer starts when you create the monitor object, make sure that you create the object immediately after the training loop.

```

monitor = trainingProgressMonitor(Metrics="Loss",Info="Epoch",XLabel="Iteration");

```

Train the network.

```

epoch = 0;
iteration = 0;
executionEnvironment = "cpu"; % Change to "gpu" to train on a GPU.

% Loop over epochs.
while epoch < numEpochs && ~monitor.Stop

    epoch = epoch + 1;

    % Shuffle data.
    idx = randperm(numObservations);
    XTrain = XTrain(:,:,,idx);
    YTrain = YTrain(:,idx);

    % Loop over mini-batches.
    i = 0;
    while i < numIterationsPerEpoch && ~monitor.Stop
        i = i + 1;
        iteration = iteration + 1;

        % Read mini-batch of data.
        idx = (i-1)*miniBatchSize+1:i*miniBatchSize;
        X = XTrain(:,:,,idx);
        Y = YTrain(:,idx);

        % If training on a GPU, then convert data to gpuArray.
        if (executionEnvironment == "auto" && canUseGPU) || executionEnvironment == "gpu"
            X = gpuArray(X);
        end

        % Evaluate the model gradients and loss using dlfeval and the
        % modelGradients function.
        [gradients,loss,state] = dlfeval(@modelGradients,X,Y,params);
        params.State = state;

        % Determine the learning rate for the time-based decay learning rate schedule.
        learnRate = initialLearnRate/(1 + decay*iteration);

        % Update the network parameters using the SGDM optimizer.
        [params.Learnables,velocity] = sgdmupdate(params.Learnables,gradients,velocity);
    end
end

```

```

% Update the training progress monitor.
recordMetrics(monitor,iteration,Loss=loss);
updateInfo(monitor,Epoch=epoch);
monitor.Progress = 100 * iteration/numIterations;
end
end

```

Calculate the classification accuracy of the network after fine-tuning.

```

accuracyAfterTraining = getNetworkAccuracy(XTrain,YTrain,params);
fprintf("%.2f accuracy after transfer learning\n",accuracyAfterTraining);

```

```

1.00 accuracy after transfer learning

```

### Helper Functions

This section provides the code of the helper functions used in this example.

The `getNetworkAccuracy` function evaluates the network performance by calculating the classification accuracy.

```

function accuracy = getNetworkAccuracy(X,Y,onnxParams)

N = size(X,4);
Ypred = squeezeNetFcn(X,onnxParams,Training=false);

[~,YIdx] = max(Y,[],1);
[~,YpredIdx] = max(Ypred,[],1);
numIncorrect = sum(abs(YIdx-YpredIdx) > 0);
accuracy = 1 - numIncorrect/N;

```

```
end
```

The `modelGradients` function calculates the loss and gradients.

```
function [grad, loss, state] = modelGradients(X,Y,onnxParams)

[y,state] = squeezeNetFcn(X,onnxParams,Training=true);
loss = crossentropy(y,Y,DataFormat="CB");
grad = dlgradient(loss,onnxParams.Learnables);
```

```
end
```

The `squeezeNetONNX` function generates an ONNX model of the squeezeNet network.

```
function squeezeNetONNX()

exportONNXNetwork(squeezeNet, "squeezeNet.onnx");
```

```
end
```

## Input Arguments

### params — Network parameters

ONNXParameters object

Network parameters, specified as an ONNXParameters object. `params` contains the network parameters of the imported ONNX model.

### names — Names of parameters to unfreeze

'all' | string array

Names of the parameters to unfreeze, specified as 'all' or a string array. Unfreeze all nonlearnable parameters by setting names to 'all'. Unfreeze `k` nonlearnable parameters by defining the parameter names in the 1-by-`k` string array `names`.

Example: ["gpu\_0\_sl\_pred\_b\_0", "gpu\_0\_sl\_pred\_w\_0"]

Data Types: char | string

## Output Arguments

### params — Network parameters

ONNXParameters object

Network parameters, returned as an ONNXParameters object. `params` contains the network parameters updated by `unfreezeParameters`.

## Version History

Introduced in R2020b

## See Also

# TFLiteModel

TensorFlow Lite model

## Description

A `TFLiteModel` object enables support for simulation and code generation for deep learning inference by using TensorFlow Lite models

Use a `TFLiteModel` object with the `predict` function in your MATLAB code to perform inference in MATLAB execution, code generation, or MATLAB Function block in Simulink models. For more information, see “Prerequisites for Deep Learning with TensorFlow Lite Models”.

To use this object, you must install the Deep Learning Toolbox Interface for TensorFlow Lite support package.

## Creation

To create a `TFLiteModel` object from a pretrained TensorFlow Lite model file, use the `loadTFLiteModel` function.

## Properties

### **ModelName** — Name of the TensorFlow Lite model file

character vector

Name of the TensorFlow Lite model file, specified as a character vector.

### **NumInputs** — Number of inputs of the TensorFlow Lite model

numeric scalar

Number of inputs the TensorFlow Lite model accepts, specified as a integer-valued numeric scalar.

### **NumOutputs** — Number of outputs of the TensorFlow Lite model

numeric scalar

Number of outputs the TensorFlow Lite model produces, specified as a integer-valued numeric scalar.

### **InputSize** — Size of inputs of the TensorFlow model

cell array containing numeric arrays

Size of inputs of the TensorFlow model, specified as a cell array containing numeric arrays.

### **OutputSize** — Size of outputs of the TensorFlow model

cell array containing numeric arrays

Size of outputs of the TensorFlow model, specified as a cell array containing numeric arrays.

### **NumThreads** — Number of computational threads used for inference computation

numeric scalar

Number of computational threads used for running inference with the TensorFlow Lite model, specified as an integer-valued numeric scalar.

The default value of this property is equal to the value returned by the `maxNumCompThreads` function.

### Mean — Mean for input data normalization

127.5 (default) | double scalar

Mean value to which the input data is normalized, specified as a double scalar. If the input data is not normalized, you must set this property to 0. Otherwise, set this property based on how the input data is normalized.

### StandardDeviation — Standard deviation for input data normalization

127.5 (default) | double scalar

Standard deviation to which the input data is normalized, specified as a double scalar. If the input data is not normalized, you must set this property to 1. Otherwise, set this property based on how the input data is normalized.

## Object Functions

`predict` Compute deep learning network output for inference by using a TensorFlow Lite model

## Examples

### Perform Inference with TensorFlow Lite Model

Suppose that your current working directory contains a TensorFlow Lite Model named `mobilenet_v1_0.5_224.tflite`.

Load the model by using the `loadTFLite` function. Inspect the object this function creates.

```
net = loadTFLiteModel('mobilenet_v1_0.5_224.tflite');
disp(net)
```

```
TFLiteModel with properties:
    ModelName: 'mobilenet_v1_0.5_224.tflite'
    NumInputs: 1
    NumOutputs: 1
    InputSize: {[224 224 3]}
    OutputSize: {[1001 1]}
    NumThreads: 8
            Mean: 127.5000
    StandardDeviation: 127.5000
```

Create a MATLAB function that can perform inference using the object `net`. This function loads the Mobilenet-V1 model into a persistent network object. Then the function performs prediction by passing the network object to the `predict` function. Subsequent calls to this function reuse this the persistent object.

```
function out = tflite_predict(in)
persistent net;
if isempty(net)
    net = loadTFLiteModel('mobilenet_v1_0.5_224.tflite');
```

```
end  
out = predict(net,in);  
end
```

For an example that shows how to generate code for this function and deploy on Raspberry Pi hardware, see “Generate Code for TensorFlow Lite (TFLite) Model and Deploy on Raspberry Pi”.

## Version History

Introduced in R2022a

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- If code generation target is the host computer, the default value of the NumThreads property is equal to the value returned by the maxNumCompThreads function.
- If code generation target is a non-host hardware board, the default value of the NumThreads property is -1. To optimize performance, in your entry-point function, set this property based on the number of threads available on your hardware board.

# predict

Compute deep learning network output for inference by using a TensorFlow Lite model

## Syntax

```
Y = predict(net,X)
[Y1,...,YN] = predict(net,X)
___ = predict( ___,Name=Value)
```

## Description

`Y = predict(net,X)` returns the network output `Y` during inference given the input data `X` and the network `net` with a single input and a single output.

To use this function, you must install the Deep Learning Toolbox Interface for TensorFlow Lite support package.

`[Y1,...,YN] = predict(net,X)` returns the `N` outputs `Y1`, ..., `YN` during inference for networks that have `N` outputs.

`___ = predict( ___,Name=Value)` provides you options to control the data type (`int8/uint8` vs `single`) of inputs and outputs when `net` is a quantized model. There is an additional option to enable or disable the execution of `predict` on Windows platform for quantized models. All these name-value arguments are ignored if `net` is not a quantized model.

---

**Tip** For prediction with `SeriesNetwork` and `DAGNetwork` objects, see `predict`.

---

## Examples

### Perform Inference with TensorFlow Lite Model

Suppose that your current working directory contains a TensorFlow Lite Model named `mobilenet_v1_0.5_224.tflite`.

Load the model by using the `loadTFLite` function. Inspect the object this function creates.

```
net = loadTFLiteModel('mobilenet_v1_0.5_224.tflite');
disp(net)
```

```
TFLiteModel with properties:
    ModelName: 'mobilenet_v1_0.5_224.tflite'
    NumInputs: 1
    NumOutputs: 1
    InputSize: {[224 224 3]}
    OutputSize: {[1001 1]}
    NumThreads: 8
             Mean: 127.5000
    StandardDeviation: 127.5000
```

Create a MATLAB function that can perform inference using the object `net`. This function loads the Mobilenet-V1 model into a persistent network object. Then the function performs prediction by passing the network object to the `predict` function. Subsequent calls to this function reuse this the persistent object.

```
function out = tflite_predict(in)
persistent net;
if isempty(net)
    net = loadTFLiteModel('mobilenet_v1_0.5_224.tflite');
end
out = predict(net,in);
end
```

For an example that shows how to generate code for this function and deploy on Raspberry Pi hardware, see “Generate Code for TensorFlow Lite (TFLite) Model and Deploy on Raspberry Pi”.

## Input Arguments

### **net** — Object representing TensorFlow Lite model

TFLiteModel object

TFLiteModel object that represents the TensorFlow Lite model file.

### **X** — Input to the network

single | double | int8 | uint8

Image or sequence input to the network, specified as a numeric array.

- For image classification networks, the input must be of shape (H,W,C,N), where H is height, W is width, C is channel, and N is batch size.
- For recurrent neural networks, the input must be of shape (D, N, S), where D is channel or feature dimension, N is batch size, and S is timestamp or sequence length.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `Y = predict(net,X,QuantizeInputs = true)`

### **QuantizeInputs** — Whether to convert inputs to a quantized model to int8/uint8 values

false (default) | true

Whether to convert inputs to a quantized model to int8/uint8 values before performing inference computation, specified as one of the values in this table.

Value	Description
false	This value is the default value.  The <code>predict</code> function directly uses the inputs that you provide.

Value	Description
true	The <code>predict</code> function quantizes inputs to the type expected by the <code>InputType</code> property of the model before performing inference computation.

This option only applies to quantized TFLite models and is ignored if the model is not quantized. For quantized TFLite models, you must set `QuantizeInputs` to `true` if input to the network is `single` or `double`.

For code generation workflows, you must specify this option as a constant.

Data Types: `logical`

### **DequantizeOutputs – Whether to convert outputs of a quantized model to single values**

`false` (default) | `true`

Whether to convert outputs of a quantized model to single data type before returning them, specified as one of the values in this table.

Value	Description
false	This value is the default value.  The <code>predict</code> function returns <code>int8/uint8</code> values.
true	The <code>predict</code> function converts outputs to single data type before returning them.

This option only applies to quantized TFLite models and is ignored if the model is not quantized.

For code generation workflows, you must specify this option as a constant.

Data Types: `logical`

### **EnableINT8InferenceOnWindows – Whether to allow predict to run on Windows platform for quantized models**

`false` (default) | `true`

Whether to allow `predict` to run on Windows platform for quantized models, specified as one of the values in this table.

Value	Description
false	This value is the default value.  Running the <code>predict</code> function with a quantized model produces an error on Windows platform. This default behavior allows you to detect existing issues with TFLite library v2.8.0 for quantized models on Windows platform.
true	Running the <code>predict</code> function with a quantized model on Windows platform bypasses the default error and executes to completion.

This option only applies to quantized TFLite models and is ignored if the model is not quantized. This option is also ignored on Linux platform or in embedded deployment workflows.

For code generation workflows, you must specify this option as a constant.

Data Types: `logical`

## Output Arguments

### Y — Output data

`single | int8 | uint8`

Output data, specified as a numeric array.

When performing inference with quantized TensorFlow Lite models, the output data is normalized in one of these ways:

- Signed 8-bit integer type outputs are normalized as  $\text{output}[i] = (\text{prediction}[i] + 128) / 256.0$ .
- Unsigned 8-bit integer type outputs are normalized as  $\text{output}[i] = \text{prediction}[i] / 255.0$ .

## Version History

Introduced in R2022a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

For code generation workflows, you must specify `QuantizeInputs`, `DequantizeOutputs` and `EnableINT8InferenceOnWindows` options as constant.

# updateInfo

**Package:** experiments

Update information columns in experiment results table

## Syntax

```
updateInfo(monitor, infoName=infoValue)
updateInfo(monitor, infoName1=infoValue1, ..., infoNameN=infoValueN)
updateInfo(monitor, infoStructure)
```

## Description

`updateInfo(monitor, infoName=infoValue)` updates the specified information column for a trial in the **Experiment Manager** results table.

`updateInfo(monitor, infoName1=infoValue1, ..., infoNameN=infoValueN)` updates multiple information columns for a trial.

`updateInfo(monitor, infoStructure)` updates the information columns using the values specified by the structure `infoStructure`.

## Examples

### Track Progress, Display Information and Record Metric Values, and Produce Training Plots

Use an `experiments.Monitor` object to track the progress of the training, display information and metric values in the experiment results table, and produce training plots for custom training experiments.

Before starting the training, specify the names of the information and metric columns of the Experiment Manager results table.

```
monitor.Info = ["GradientDecayFactor", "SquaredGradientDecayFactor"];
monitor.Metrics = ["TrainingLoss", "ValidationLoss"];
```

Specify the horizontal axis label for the training plot. Group the training and validation loss in the same subplot.

```
monitor.XLabel = "Iteration";
groupSubPlot(monitor, "Loss", ["TrainingLoss", "ValidationLoss"]);
```

Update the values of the gradient decay factor and the squared gradient decay factor for the trial in the results table.

```
updateInfo(monitor, ...
    GradientDecayFactor=gradientDecayFactor, ...
    SquaredGradientDecayFactor=squaredGradientDecayFactor);
```

After each iteration of the custom training loop, record the value of training and validation loss for the trial in the results table and the training plot.

```
recordMetrics(monitor, iteration, ...  
    TrainingLoss=trainingLoss, ...  
    ValidationLoss=validationLoss);
```

Update the training progress for the trial based on the fraction of iterations completed.

```
monitor.Progress = 100 * (iteration/numIterations);
```

### Specify Information Values by Using Structure

Use a structure to update values of information columns in the results table.

```
structure.GradientDecayFactor = gradientDecayFactor;  
structure.SquaredGradientDecayFactor = squaredGradientDecayFactor;  
updateInfo(monitor, structure);
```

## Input Arguments

### **monitor** — Experiment monitor

`experiments.Monitor` object

Experiment monitor for the trial, specified as an `experiments.Monitor` object. When you run a custom training experiment, Experiment Manager passes this object as the second input argument of the training function.

### **infoName** — Information column name

string | character vector

Information column name, specified as a string or character vector. This name must be an element of the `Info` property of the `experiments.Monitor` object `monitor`.

Data Types: `char` | `string`

### **infoValue** — Information column value

numeric scalar | string | character vector | `dlarray`

Information column value, specified as a numeric scalar, string, character vector, or `dlarray` object.

### **infoStructure** — Information column names and values

structure

Information column names and values, specified as a structure. Names must be elements of the `Info` property of the `experiments.Monitor` object `monitor` and can appear in any order in the structure.

Example:

```
struct(GradientDecayFactor=gradientDecayFactor, SquaredGradientDecayFactor=squ  
aredGradientDecayFactor)
```

Data Types: `struct`

## Tips

- Both information and metric columns display values in the results table for your experiment. Additionally, the training plot shows a record of the metric values. Use information columns for

text and for numerical values that you want to display in the results table but not in the training plot.

## **Version History**

**Introduced in R2021a**

### **See Also**

#### **Apps**

**Experiment Manager**

`experiments.Monitor`

#### **Functions**

`groupSubPlot` | `recordMetrics` | `struct`

## updateInfo

**Package:** deep

Update information values for custom training loops

### Syntax

```
updateInfo(monitor,infoName=infoValue)
updateInfo(monitor,infoName1=infoValue1,...,infoNameN=infoValueN)
updateInfo(monitor,infoStructure)
```

### Description

`updateInfo(monitor,infoName=infoValue)` updates the specified information in the Training Progress window and saves the values in the `InfoData` property of the `TrainingProgressMonitor` object `monitor`.

`updateInfo(monitor,infoName1=infoValue1,...,infoNameN=infoValueN)` updates multiple information values.

`updateInfo(monitor,infoStructure)` updates the information using the values specified by the structure `infoStructure`.

### Examples

#### Track Progress and Produce Training Plots

Use a `TrainingProgressMonitor` object to track training progress and produce training plots for custom training loops.

Create a `TrainingProgressMonitor` object. The monitor automatically tracks the start time and the elapsed time. The timer starts when you create the object.

---

**Tip** To ensure that the elapsed time accurately reflects the training time, make sure you create the `TrainingProgressMonitor` object close to the start of your custom training loop.

---

```
monitor = trainingProgressMonitor;
```

Before you start the training, specify names for the information and metric values.

```
monitor.Info = ["LearningRate","Epoch","Iteration"];
monitor.Metrics = ["TrainingLoss","ValidationLoss","TrainingAccuracy","ValidationAccuracy"];
```

Specify the horizontal axis label for the training plot. Group the training and validation loss in the same subplot, and group the training and validation accuracy in the same plot.

```
monitor.XLabel = "Iteration";
groupSubPlot(monitor,"Loss",["TrainingLoss","ValidationLoss"]);
groupSubPlot(monitor,"Accuracy",["TrainingAccuracy","ValidationAccuracy"]);
```

During training:

- Evaluate the **Stop** property at the start of each step in your custom training loop. When you click the **Stop** button in the Training Progress window, the **Stop** property changes to 1. Training stops if your training loop exits when the **Stop** property is 1.
- Update the information values. The updated values appear in the Training Progress window.
- Record the metric values. The recorded values appear in the training plot.
- Update the training progress percentage based on the fraction of iterations completed.

---

**Note** The following example code is a template. You must edit this training loop to compute your metric and information values. For a complete example that you can run in MATLAB, see “Monitor Custom Training Loop Progress During Training”.

---

```
epoch = 0;
iteration = 0;

monitor.Status = "Running";

while epoch < maxEpochs && ~monitor.Stop
    epoch = epoch + 1;

    while hasData(mbq) && ~monitor.Stop
        iteration = iteration + 1;

        % Add code to calculate metric and information values.
        % lossTrain = ...

        updateInfo(monitor, ...
            LearningRate=learnRate, ...
            Epoch=string(epoch) + " of " + string(maxEpochs), ...
            Iteration=string(iteration) + " of " + string(numIterations));

        recordMetrics(monitor, iteration, ...
            TrainingLoss=lossTrain, ...
            TrainingAccuracy=accuracyTrain, ...
            ValidationLoss=lossValidation, ...
            ValidationAccuracy=accuracyValidation);

        monitor.Progress = 100*iteration/numIterations;
    end
end
```

The Training Progress window shows animated plots of the metrics, and the information values, training progress bar, and elapsed time.

- The training plots update each time you call `recordMetrics`.
- The values under **Information** update each time you call `updateInfo`.
- The elapsed time updates each time you call `recordMetrics` or `updateInfo`, and when you update the property.

### Specify Information Values by Using Structure

Use a structure to update the information values.

```
structure.GradientDecayFactor = gradientDecayFactor;
structure.SquaredGradientDecayFactor = squaredGradientDecayFactor;
updateInfo(monitor, structure);
```

### Input Arguments

#### monitor — Training progress monitor

TrainingProgressMonitor object

Training progress monitor, specified as a TrainingProgressMonitor object.

#### infoName — Information name

string scalar | character vector

Information name, specified as a string scalar or character vector. This name must be an element of the Info property of monitor.

Data Types: char | string | cell

#### infoValue — Information value

numeric scalar | string scalar | character vector | dIarray object

Information value, specified as a numeric scalar, string scalar, character vector, or dIarray object.

## **infoStructure — Information names and values**

structure

Information names and values, specified as a structure. Names must be elements of the `Info` property of `monitor` and can appear in any order in the structure.

Example:

```
struct(GradientDecayFactor=gradientDecayFactor,SquaredGradientDecayFactor=squaredGradientDecayFactor)
```

Data Types: `struct`

## **Tips**

- The information values appear in the Training Progress window and the training plot shows a record of the metric values. Use information values for text and for numerical values that you want to display in the training window but not in the training plot.

## **Version History**

**Introduced in R2022b**

## **See Also**

## updatePrunables

**Package:** `deep.prune`

Remove filters from prunable layers based on importance scores

### Syntax

```
prunableNet_new = updatePrunables(prunableNet)
prunableNet_new = updatePrunables(prunableNet,MaxToPrune=maxToPrune)
```

### Description

`prunableNet_new = updatePrunables(prunableNet)` removes up to 8 prunable filters from the convolution layers of `prunableNet` and returns an updated `TaylorPrunableNetwork` object. This function removes filters that have the lowest Taylor-based importance scores.

To prune a deep neural network, you require the Deep Learning Toolbox Model Quantization Library support package. This support package is a free add-on that you can download using the Add-On Explorer. Alternatively, see [Deep Learning Toolbox Model Quantization Library](#).

`prunableNet_new = updatePrunables(prunableNet,MaxToPrune=maxToPrune)` removes up to `maxToPrune` prunable filters from the convolution layers of `prunableNet` and returns an updated `TaylorPrunableNetwork` object.

### Examples

#### Prune dlnetwork Object to Compress the Model

This example shows how to prune a `dlnetwork` object by using a custom pruning loop.

#### Load dlnetwork Object

Load a trained `dlnetwork` object and the corresponding classes.

```
s = load("digitsCustom.mat");
dlnet_1 = s.dlnet;
classes = s.classes;
```

Inspect the layers of the `dlnetwork` object. The network has three convolution layers at locations 2, 5, and 8 of the `Layer` array.

```
layers_1 = dlnet_1.Layers
```

```
layers_1 =
    12x1 Layer array with layers:
```

1	'input'	Image Input	28x28x1 images with 'zerocenter' normalization
2	'conv1'	2-D Convolution	20 5x5x1 convolutions with stride [1 1] and padding
3	'bn1'	Batch Normalization	Batch normalization with 20 channels
4	'relu1'	ReLU	ReLU

5	'conv2'	2-D Convolution	20 3x3x20 convolutions with stride [1 1] and padding
6	'bn2'	Batch Normalization	Batch normalization with 20 channels
7	'relu2'	ReLU	ReLU
8	'conv3'	2-D Convolution	20 3x3x20 convolutions with stride [1 1] and padding
9	'bn3'	Batch Normalization	Batch normalization with 20 channels
10	'relu3'	ReLU	ReLU
11	'fc'	Fully Connected	10 fully connected layer
12	'softmax'	Softmax	softmax

### Load Data for Prediction

Load the digits data for prediction.

```
dataFolder = fullfile(toolboxdir("nnet"), "nndemos", "nndatasets", "DigitDataset");

imds = imageDatastore(dataFolder, ...
    IncludeSubfolders=true, ...
    LabelSource="foldernames");
```

Partition the data into pruning and validation sets. Set aside 10% of the data for validation using the `splitEachLabel` function.

```
[imdsPrune, imdsValidation] = splitEachLabel(imds, 0.9, "randomize");
```

The network used in this example requires input images of size 28-by-28-by-1. To automatically resize the images, use augmented image datastores.

```
inputSize = [28 28 1];
augimdsPrune = augmentedImageDatastore(inputSize(1:2), imdsPrune);
augimdsValidation = augmentedImageDatastore(inputSize(1:2), imdsValidation);
```

### Prune dlNetwork Object

Convert the `dlNetwork` object to a representation that is suitable for pruning by using the `taylorPrunableNetwork` function. This function returns a `TaylorPrunableNetwork` object that has the `NumPrunables` property set to 48. This indicates that 48 filters in the original model are suitable for pruning by using the Taylor pruning algorithm.

```
prunableNet_1 = taylorPrunableNetwork(dlnet_1)
```

```
prunableNet_1 =
    TaylorPrunableNetwork with properties:
```

```
    Learnables: [14x3 table]
    State: [6x3 table]
    InputNames: {'input'}
    OutputNames: {'softmax'}
    NumPrunables: 48
```

Create a `minibatchqueue` object that processes and manages mini-batches of images during pruning. For each mini-batch:

- Use the custom mini-batch preprocessing function `preprocessMiniBatch` (defined at the end of this example) to convert the labels to one-hot encoded variables.
- Format the image data with the dimension labels "SSCB" (spatial, spatial, channel, batch). By default, the `minibatchqueue` object converts the data to `dlarray` objects with underlying type `single`. Do not format the class labels.

- Train on a GPU if one is available. By default, the `minibatchqueue` object converts each output to a `gpuArray` if a GPU is available. Using a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox).

```
miniBatchSize = 128;
imds.ReadSize = miniBatchSize;

mbq = minibatchqueue(augimdsPrune, ...
    MiniBatchSize=miniBatchSize, ...
    MiniBatchFcn=@preprocessMiniBatch, ...
    MiniBatchFormat=["SSCB" ""]);
```

Calculate Taylor-based importance scores of the prunable filters in the network by looping over the mini-batches of data. For each mini-batch:

- Calculate pruning activations and pruning gradients by using the `modelLoss` function defined at the end of this example
- Update importance scores of the prunable filters by using the `updateScore` function

```
while hasdata(mbq)
    [X,T] = next(mbq);
    [~,pruningActivations,pruningGradients] = dlfeval(@modelLoss,prunableNet_1,X,T);
    prunableNet_1 = updateScore(prunableNet_1,pruningActivations,pruningGradients);
end
```

Finally, remove filters with the lowest importance scores to create a new `TaylorPrunableNetwork` object by using the `updatePrunables` function. By default, a single call to this function removes 8 filters. Observe that the new network `prunableNet_2` has 40 prunable filters remaining.

```
prunableNet_2 = updatePrunables(prunableNet_1)

prunableNet_2 =
    TaylorPrunableNetwork with properties:

        Learnables: [14x3 table]
           State: [6x3 table]
    InputNames: {'input'}
    OutputNames: {'softmax'}
    NumPrunables: 40
```

To further compress the model, run the custom pruning loop and update prunables again.

### Extract Pruned `dlnetwork` Object

Use the `dlnetwork` function to extract the pruned `dlnetwork` object from the pruned `TaylorPrunableNetwork` object. You can now use this compressed `dlnetwork` object to perform inference.

```
dlnet_2 = dlnetwork(prunableNet_2);
```

Compare the convolution layers of the original and the pruned `dlnetwork` objects. Observe that the three convolution layers in the pruned network have fewer filters. These counts agree with the fact that, by default, a single call to the `updatePrunables` function removes 8 filters from the network.

```
conv_layers_1 = dlnet_1.Layers([2 5 8])
```

```

conv_layers_1 =
  3x1 Convolution2DLayer array with layers:

      1  'conv1'  2-D Convolution  20 5x5x1 convolutions with stride [1 1] and padding [0 0]
      2  'conv2'  2-D Convolution  20 3x3x20 convolutions with stride [1 1] and padding [1 1]
      3  'conv3'  2-D Convolution  20 3x3x20 convolutions with stride [1 1] and padding [1 1]

conv_layers_2 = dlnet_2.Layers([2 5 8])

conv_layers_2 =
  3x1 Convolution2DLayer array with layers:

      1  'conv1'  2-D Convolution  17 5x5x1 convolutions with stride [1 1] and padding [0 0]
      2  'conv2'  2-D Convolution  18 3x3x17 convolutions with stride [1 1] and padding [1 1]
      3  'conv3'  2-D Convolution  17 3x3x18 convolutions with stride [1 1] and padding [1 1]

```

## Supporting Functions

### Model Loss Function

The `modelLoss` function takes a `TaylorPrunableNetwork` object `net`, a mini-batch of input data `X` with corresponding targets `T` and returns activations in `net` and the gradients of the loss with respect to the activations in `net`. To compute the gradients automatically, this function uses the `dlgradient` function.

```

function [loss, pruningActivations, pruningGradients] = modelLoss(net,X,T)

% Calculate network output for training.
[out, ~, pruningActivations] = forward(net,X);

% Calculate loss.
loss = crossentropy(out,T);

% Compute pruning gradients.
pruningGradients = dlgradient(loss,pruningActivations);
end

```

### Mini Batch Preprocessing Function

The `preprocessMiniBatch` function preprocesses a mini-batch of predictors and labels using the following steps:

- 1 Preprocess the images using the `preprocessMiniBatchPredictors` function.
- 2 Extract the label data from the incoming cell array and concatenate into a categorical array along the second dimension.
- 3 One-hot encode the categorical labels into numeric arrays. Encoding into the first dimension produces an encoded array that matches the shape of the network output.

```

function [X,T] = preprocessMiniBatch(dataX,dataT)

% Preprocess predictors.
X = preprocessMiniBatchPredictors(dataX);

% Extract label data from cell and concatenate.
T = cat(2,dataT{1:end});

% One-hot encode labels.

```

```
T = onehotencode(T,1);
```

```
end
```

### Mini-Batch Predictors Preprocessing Function

The `preprocessMiniBatchPredictors` function preprocesses a mini-batch of predictors by extracting the image data from the input cell array and concatenating into a numeric array. For grayscale input, concatenating over the fourth dimension adds a third dimension to each image, to use as a singleton channel dimension.

```
function X = preprocessMiniBatchPredictors(dataX)
```

```
% Concatenate.
```

```
X = cat(4,dataX{1:end});
```

```
% Normalize the images.
```

```
X = X/255;
```

```
end
```

## Input Arguments

### **prunableNet** — Network for pruning by using first-order Taylor approximation

TaylorPrunableNetwork object

Network for pruning by using first-order Taylor approximation, specified as a TaylorPrunableNetwork object.

### **maxToPrune** — Maximum number of filters to be pruned

8 (default) | numeric scalar

Maximum number of filters to be pruned, specified as a numeric integer-valued scalar

## Output Arguments

### **prunableNet\_new** — Pruned network

TaylorPrunableNetwork object

Network object from which filters with low Taylor-based importance scores have been removed, specified as a TaylorPrunableNetwork object.

## Version History

Introduced in R2022a

## See Also

[taylorPrunableNetwork](#) | [updateScore](#) | [dlnetwork](#) | [forward](#) | [predict](#)

## Topics

“Prune Filters in a Detection Network Using Taylor Scores”

# updateScore

**Package:** deep.prune

Compute and accumulate Taylor-based importance scores for pruning

## Syntax

```
prunableNet_new = updateScore(prunableNet,pruningActivations,
pruningGradients)
```

## Description

`prunableNet_new = updateScore(prunableNet,pruningActivations, pruningGradients)` computes and accumulates Taylor-based importance scores of convolution filters in prunable layers. This function returns another `TaylorPrunableNetwork` object whose state contains these updated scores.

To get robust estimates of the importance scores of the convolution filters in your network, execute `updateScore` several times on the same prunable network for different mini-batches of data.

To prune a deep neural network, you require the Deep Learning Toolbox Model Quantization Library support package. This support package is a free add-on that you can download using the Add-On Explorer. Alternatively, see [Deep Learning Toolbox Model Quantization Library](#).

## Examples

### Prune dlnetwork Object to Compress the Model

This example shows how to prune a `dlnetwork` object by using a custom pruning loop.

#### Load dlnetwork Object

Load a trained `dlnetwork` object and the corresponding classes.

```
s = load("digitsCustom.mat");
dlnet_1 = s.dlnet;
classes = s.classes;
```

Inspect the layers of the `dlnetwork` object. The network has three convolution layers at locations 2, 5, and 8 of the `Layer` array.

```
layers_1 = dlnet_1.Layers
```

```
layers_1 =
    12x1 Layer array with layers:
```

1	'input'	Image Input	28x28x1 images with 'zerocenter' normalization
2	'conv1'	2-D Convolution	20 5x5x1 convolutions with stride [1 1] and padding
3	'bn1'	Batch Normalization	Batch normalization with 20 channels
4	'relu1'	ReLU	ReLU

```

5 'conv2'      2-D Convolution      20 3x3x20 convolutions with stride [1 1] and padding
6 'bn2'       Batch Normalization  Batch normalization with 20 channels
7 'relu2'     ReLU                  ReLU
8 'conv3'     2-D Convolution      20 3x3x20 convolutions with stride [1 1] and padding
9 'bn3'       Batch Normalization  Batch normalization with 20 channels
10 'relu3'    ReLU                  ReLU
11 'fc'       Fully Connected     10 fully connected layer
12 'softmax'  Softmax              softmax

```

### Load Data for Prediction

Load the digits data for prediction.

```

dataFolder = fullfile(toolboxdir("nnet"), "nndemos", "nndatasets", "DigitDataset");

imds = imageDatastore(dataFolder, ...
    IncludeSubfolders=true, ...
    LabelSource="foldernames");

```

Partition the data into pruning and validation sets. Set aside 10% of the data for validation using the `splitEachLabel` function.

```
[imdsPrune, imdsValidation] = splitEachLabel(imds, 0.9, "randomize");
```

The network used in this example requires input images of size 28-by-28-by-1. To automatically resize the images, use augmented image datastores.

```

inputSize = [28 28 1];
augimdsPrune = augmentedImageDatastore(inputSize(1:2), imdsPrune);
augimdsValidation = augmentedImageDatastore(inputSize(1:2), imdsValidation);

```

### Prune dlnetwork Object

Convert the `dlnetwork` object to a representation that is suitable for pruning by using the `taylorPrunableNetwork` function. This function returns a `TaylorPrunableNetwork` object that has the `NumPrunables` property set to 48. This indicates that 48 filters in the original model are suitable for pruning by using the Taylor pruning algorithm.

```
prunableNet_1 = taylorPrunableNetwork(dlnet_1)
```

```
prunableNet_1 =
TaylorPrunableNetwork with properties:
```

```

Learnables: [14x3 table]
State: [6x3 table]
InputNames: {'input'}
OutputNames: {'softmax'}
NumPrunables: 48

```

Create a `minibatchqueue` object that processes and manages mini-batches of images during pruning. For each mini-batch:

- Use the custom mini-batch preprocessing function `preprocessMiniBatch` (defined at the end of this example) to convert the labels to one-hot encoded variables.
- Format the image data with the dimension labels "SSCB" (spatial, spatial, channel, batch). By default, the `minibatchqueue` object converts the data to `dlarray` objects with underlying type `single`. Do not format the class labels.

- Train on a GPU if one is available. By default, the `minibatchqueue` object converts each output to a `gpuArray` if a GPU is available. Using a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see “GPU Computing Requirements” (Parallel Computing Toolbox).

```
miniBatchSize = 128;
imds.ReadSize = miniBatchSize;

mbq = minibatchqueue(augimdsPrune, ...
    MiniBatchSize=miniBatchSize, ...
    MiniBatchFcn=@preprocessMiniBatch, ...
    MiniBatchFormat=["SSCB" ""]);
```

Calculate Taylor-based importance scores of the prunable filters in the network by looping over the mini-batches of data. For each mini-batch:

- Calculate pruning activations and pruning gradients by using the `modelLoss` function defined at the end of this example
- Update importance scores of the prunable filters by using the `updateScore` function

```
while hasdata(mbq)
    [X,T] = next(mbq);
    [~,pruningActivations,pruningGradients] = dlfeval(@modelLoss,prunableNet_1,X,T);
    prunableNet_1 = updateScore(prunableNet_1,pruningActivations,pruningGradients);
end
```

Finally, remove filters with the lowest importance scores to create a new `TaylorPrunableNetwork` object by using the `updatePrunables` function. By default, a single call to this function removes 8 filters. Observe that the new network `prunableNet_2` has 40 prunable filters remaining.

```
prunableNet_2 = updatePrunables(prunableNet_1)
```

```
prunableNet_2 =
    TaylorPrunableNetwork with properties:

        Learnables: [14x3 table]
           State: [6x3 table]
    InputNames: {'input'}
    OutputNames: {'softmax'}
    NumPrunables: 40
```

To further compress the model, run the custom pruning loop and update prunables again.

### Extract Pruned `dlnetwork` Object

Use the `dlnetwork` function to extract the pruned `dlnetwork` object from the pruned `TaylorPrunableNetwork` object. You can now use this compressed `dlnetwork` object to perform inference.

```
dlnet_2 = dlnetwork(prunableNet_2);
```

Compare the convolution layers of the original and the pruned `dlnetwork` objects. Observe that the three convolution layers in the pruned network have fewer filters. These counts agree with the fact that, by default, a single call to the `updatePrunables` function removes 8 filters from the network.

```
conv_layers_1 = dlnet_1.Layers([2 5 8])
```

```
conv_layers_1 =  
  3x1 Convolution2DLayer array with layers:  
  
    1  'conv1'  2-D Convolution  20 5x5x1 convolutions with stride [1 1] and padding [0 0  
    2  'conv2'  2-D Convolution  20 3x3x20 convolutions with stride [1 1] and padding [1 1  
    3  'conv3'  2-D Convolution  20 3x3x20 convolutions with stride [1 1] and padding [1 1  
  
conv_layers_2 = dlnet_2.Layers([2 5 8])  
  
conv_layers_2 =  
  3x1 Convolution2DLayer array with layers:  
  
    1  'conv1'  2-D Convolution  17 5x5x1 convolutions with stride [1 1] and padding [0 0  
    2  'conv2'  2-D Convolution  18 3x3x17 convolutions with stride [1 1] and padding [1 1  
    3  'conv3'  2-D Convolution  17 3x3x18 convolutions with stride [1 1] and padding [1 1
```

## Supporting Functions

### Model Loss Function

The `modelLoss` function takes a `TaylorPrunableNetwork` object `net`, a mini-batch of input data `X` with corresponding targets `T` and returns activations in `net` and the gradients of the loss with respect to the activations in `net`. To compute the gradients automatically, this function uses the `dlgradient` function.

```
function [loss, pruningActivations, pruningGradients] = modelLoss(net,X,T)  
  
% Calculate network output for training.  
[out, ~, pruningActivations] = forward(net,X);  
  
% Calculate loss.  
loss = crossentropy(out,T);  
  
% Compute pruning gradients.  
pruningGradients = dlgradient(loss,pruningActivations);  
end
```

### Mini Batch Preprocessing Function

The `preprocessMiniBatch` function preprocesses a mini-batch of predictors and labels using the following steps:

- 1 Preprocess the images using the `preprocessMiniBatchPredictors` function.
- 2 Extract the label data from the incoming cell array and concatenate into a categorical array along the second dimension.
- 3 One-hot encode the categorical labels into numeric arrays. Encoding into the first dimension produces an encoded array that matches the shape of the network output.

```
function [X,T] = preprocessMiniBatch(dataX,dataT)  
  
% Preprocess predictors.  
X = preprocessMiniBatchPredictors(dataX);  
  
% Extract label data from cell and concatenate.  
T = cat(2,dataT{1:end});  
  
% One-hot encode labels.
```

```
T = onehotencode(T,1);
```

```
end
```

### Mini-Batch Predictors Preprocessing Function

The `preprocessMiniBatchPredictors` function preprocesses a mini-batch of predictors by extracting the image data from the input cell array and concatenating into a numeric array. For grayscale input, concatenating over the fourth dimension adds a third dimension to each image, to use as a singleton channel dimension.

```
function X = preprocessMiniBatchPredictors(dataX)
```

```
% Concatenate.
```

```
X = cat(4,dataX{1:end});
```

```
% Normalize the images.
```

```
X = X/255;
```

```
end
```

## Input Arguments

### **prunableNet** — Network for pruning by using first-order Taylor approximation

TaylorPrunableNetwork object

Network for pruning by using first-order Taylor approximation, specified as a TaylorPrunableNetwork object.

### **pruningActivations** — Activations of the pruning layers

cell array containing darray objects

Activations of the pruning layers, specified as a cell array containing darray objects. To retrieve these values, call the `forward` function on the prunable network.

### **pruningGradients** — Gradients of loss with respect to activations

cell array containing darray objects

Gradients of loss with respect to `pruningActivations`, specified as a cell array containing darray objects. To calculate `pruningGradients`, first calculate the loss and then use the `dlgradient` function.

## Output Arguments

### **prunableNet\_new** — Updated network for pruning

TaylorPrunableNetwork object

Network object for pruning that been updated to contain the accumulated Taylor-based importance scores of the prunable filters, specified as a TaylorPrunableNetwork object.

## Version History

Introduced in R2022a

**See Also**

taylorPrunableNetwork | updatePrunables | dlnetwork | forward | predict

**Topics**

“Prune Filters in a Detection Network Using Taylor Scores”

# validate

Quantize and validate a deep neural network

## Syntax

```
valResults = validate(quantObj, valData)
valResults = validate(quantObj, valData, quantOpts)
```

## Description

`valResults = validate(quantObj, valData)` quantizes the weights, biases, and activations in the convolution layers of the network, and validates the network specified by `dlquantizer` object, `quantObj`, using the data specified by `valData`.

`valResults = validate(quantObj, valData, quantOpts)` quantizes and validates the network with additional options specified by `quantOpts`.

This function requires Deep Learning Toolbox Model Quantization Library. To learn about the products required to quantize a deep neural network, see “Quantization Workflow Prerequisites”.

## Examples

### Quantize a Neural Network for GPU Target

This example shows how to quantize learnable parameters in the convolution layers of a neural network for GPU and explore the behavior of the quantized network. In this example, you quantize the squeezenet neural network after retraining the network to classify new images according to the “Train Deep Learning Network to Classify New Images” example. In this example, the memory required for the network is reduced approximately 75% through quantization while the accuracy of the network is not affected.

Load the pretrained network. `net` is the output network of the Train Deep Learning Network to Classify New Images example.

```
load squeezeNetmerch
net

net =
  DAGNetwork with properties:

    Layers: [68x1 nnet.cnn.layer.Layer]
  Connections: [75x2 table]
    InputNames: {'data'}
    OutputNames: {'new_classoutput'}
```

Define calibration and validation data to use for quantization.

The calibration data is used to collect the dynamic ranges of the weights and biases in the convolution and fully connected layers of the network and the dynamic ranges of the activations in all

layers of the network. For the best quantization results, the calibration data must be representative of inputs to the network.

The validation data is used to test the network after quantization to understand the effects of the limited range and precision of the quantized convolution layers in the network.

In this example, use the images in the MerchData data set. Define an augmentedImageDatastore object to resize the data for the network. Then, split the data into calibration and validation data sets.

```
unzip('MerchData.zip');
imds = imageDatastore('MerchData', ...
    'IncludeSubfolders',true, ...
    'LabelSource','foldernames');
[calData, valData] = splitEachLabel(imds, 0.7, 'randomized');
aug_calData = augmentedImageDatastore([227 227], calData);
aug_valData = augmentedImageDatastore([227 227], valData);
```

Create a dlquantizer object and specify the network to quantize.

```
quantObj = dlquantizer(net);
```

Define a metric function to use to compare the behavior of the network before and after quantization. This example uses the hComputeModelAccuracy metric function.

```
function accuracy = hComputeModelAccuracy(predictionScores, net, datastore)
%% Computes model-level accuracy statistics

    % Load ground truth
    tmp = readall(datastore);
    groundTruth = tmp.response;

    % Compare with predicted label with actual ground truth
    predictionError = {};
    for idx=1:numel(groundTruth)
        [~, idy] = max(predictionScores(idx,:));
        yActual = net.Layers(end).Classes(idy);
        predictionError{end+1} = (yActual == groundTruth(idx)); %#ok
    end

    % Sum all prediction errors.
    predictionError = [predictionError{:}];
    accuracy = sum(predictionError)/numel(predictionError);
end
```

Specify the metric function in a dlquantizationOptions object.

```
quantOpts = dlquantizationOptions('MetricFcn',{@(x)hComputeModelAccuracy(x, net, aug_valData)});
```

Use the calibrate function to exercise the network with sample inputs and collect range information. The calibrate function exercises the network and collects the dynamic ranges of the weights and biases in the convolution and fully connected layers of the network and the dynamic ranges of the activations in all layers of the network. The function returns a table. Each row of the table contains range information for a learnable parameter of the optimized network.

```
calResults = calibrate(quantObj, aug_calData)
```

```
calResults=121x5 table
    Optimized Layer Name      Network Layer Name      Learnables / Activations      MinValue
```

```

_____
{'conv1_Weights'      }      {'conv1'      }      "Weights"      -0.9198
{'conv1_Bias'        }      {'conv1'      }      "Bias"         -0.0792

:

```

Use the `validate` function to quantize the learnable parameters in the convolution layers of the network and exercise the network. The function uses the metric function defined in the `dlquantizationOptions` object to compare the results of the network before and after quantization.

```
valResults = validate(quantObj, aug_valData, quantOpts)
```

```
valResults = struct with fields:
    NumSamples: 20
    MetricResults: [1x1 struct]
    Statistics: [2x2 table]
```

Examine the validation output to see the performance of the quantized network.

```
valResults.MetricResults.Result
```

```
ans=2x2 table
    NetworkImplementation    MetricOutput
    _____
    {'Floating-Point'}      1
    {'Quantized'           }      1
```

```
valResults.Statistics
```

```
ans=2x2 table
    NetworkImplementation    LearnableParameterMemory(bytes)
    _____
    {'Floating-Point'}      2.9003e+06
    {'Quantized'           }      7.3393e+05
```

In this example, the memory required for the network was reduced approximately 75% through quantization. The accuracy of the network is not affected.

The weights, biases, and activations of the convolution layers of the network specified in the `dlquantizer` object now use scaled 8-bit integer data types.

## Quantize Network for FPGA Deployment

Reduce the memory footprint of a deep neural network by quantizing the weights, biases, and activations of convolution layers to 8-bit scaled integer data types. This example shows how to use Deep Learning Toolbox Model Quantization Library and Deep Learning HDL Toolbox to deploy the `int8` network to a target FPGA board.

For this example, you need:

- Deep Learning Toolbox™
- Deep Learning HDL Toolbox™
- Deep Learning Toolbox Model Quantization Library
- Deep Learning HDL Toolbox Support Package for Xilinx FPGA and SoC Devices
- MATLAB Coder Interface for Deep Learning.

## Load Pretrained Network

Load the pretrained LogoNet network and analyze the network architecture.

```
snet = getLogoNetwork;  
deepNetworkDesigner(snet);
```

## Load Data

This example uses the `logos_dataset` data set. The data set consists of 320 images. Each image is 227-by-227 in size and has three color channels (RGB). Create an `augmentedImageDatastore` object for calibration and validation. Expedite calibration and validation by reducing the calibration data set to 20 images. The MATLAB simulation workflow has a maximum limit of five images when validating the quantized network. Reduce the validation data set sizes to five images. The FPGA validation workflow has a maximum limit of one image when validating the quantized network. Reduce the FPGA validation data set to a single image.

```
curDir = pwd;  
unzip("logos_dataset.zip");  
imageData = imageDatastore(fullfile(curDir,'logos_dataset'),...  
'IncludeSubfolders',true,'FileExtensions','.JPG','LabelSource','foldernames');  
[calibrationData, validationData] = splitEachLabel(imageData, 0.5,'randomized');  
calibrationData_reduced = calibrationData.subset(1:20);  
validationData_simulation = validationData.subset(1:5);  
validationData_FPGA = validationData.subset(1:1);
```

## Generate Calibration Result File for the Network

Create a `dlquantizer` (Deep Learning HDL Toolbox) object and specify the network to quantize. Specify the execution environment as FPGA.

```
dlQuantObj_simulation = dlquantizer(snet,'ExecutionEnvironment',"FPGA",'Simulation','on');  
dlQuantObj_FPGA = dlquantizer(snet,'ExecutionEnvironment',"FPGA");
```

Use the `calibrate` (Deep Learning HDL Toolbox) function to exercise the network with sample inputs and collect the range information. The `calibrate` function collects the dynamic ranges of the weights and biases. The `calibrate` function returns a table. Each row of the table contains range information for a learnable parameter of the quantized network.

```
calibrate(dlQuantObj_simulation,calibrationData_reduced)
```

ans=35x5 table

### Create Target Object

Create a target object with a custom name for your target device and an interface to connect your target device to the host computer. Interface options are JTAG and Ethernet. To use JTAG, install Xilinx™ Vivado™ Design Suite 2020.2. To set the Xilinx Vivado toolpath, enter:

```
% hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\n2020.2\bin\vivado.bat');
```

To create the target object, enter:

```
hTarget = dlhdl.Target('Xilinx','Interface','Ethernet');
```

Alternatively, you can also use the JTAG interface.

```
% hTarget = dlhdl.Target('Xilinx', 'Interface', 'JTAG');
```

### Create dlQuantizationOptions Object

Create a `dlquantizationOptions` object. Specify the target bitstream and target board interface. The default metric function is a Top-1 accuracy metric function.

```
options_FPGA = dlquantizationOptions('Bitstream','zcu102_int8','Target',hTarget);  
options_simulation = dlquantizationOptions;
```

To use a custom metric function, specify the metric function in the `dlquantizationOptions` object.

```
options_FPGA = dlquantizationOptions('MetricFcn',{@(x)hComputeAccuracy(x,snet,validationData_FPGA)});  
options_simulation = dlquantizationOptions('MetricFcn',{@(x)hComputeAccuracy(x,snet,validationData_simulation)});
```

### Validate Quantized Network

Use the `validate` function to quantize the learnable parameters in the convolution layers of the network. The `validate` function simulates the quantized network in MATLAB. The `validate` function uses the metric function defined in the `dlquantizationOptions` object to compare the results of the single-data-type network object to the results of the quantized network object.

```
prediction_simulation = dlQuantObj_simulation.validate(validationData_simulation,options_simulation);
```

```
Compiling leg: conv_1>>relu_4 ...  
Compiling leg: conv_1>>relu_4 ... complete.  
Compiling leg: maxpool_4 ...  
Compiling leg: maxpool_4 ... complete.  
Compiling leg: fc_1>>fc_3 ...  
Compiling leg: fc_1>>fc_3 ... complete.
```

```
prediction_simulation = struct with fields:  
    NumSamples: 5  
    MetricResults: [1x1 struct]  
    Statistics: []
```

For validation on an FPGA, the `validate` function:

- Programs the FPGA board by using the output of the `compile` method and the programming file
- Downloads the network weights and biases

- Compares the performance of the network before and after quantization

```
prediction_FPGA = dlQuantObj_FPGA.validate(validationData_FPGA,options_FPGA)
```

```

## Quantize a Neural Network for CPU Target

This example shows how to quantize and validate a neural network for a CPU target. This workflow is similar to other execution environments, but before validating you must establish a `raspi` connection and specify it as target using `dlquantizationOptions`.

First, load your network. This example uses the pretrained network `squeezenet`.

```
load squeezenetmerch
net

net =
  DAGNetwork with properties:

    Layers: [68x1 nnet.cnn.layer.Layer]
    Connections: [75x2 table]
    InputNames: {'data'}
    OutputNames: {'new_classoutput'}
```

Then define your calibration and validation data, `calDS` and `valDS` respectively.

```
unzip('MerchData.zip');
imds = imageDatastore('MerchData', ...
    'IncludeSubfolders',true, ...
    'LabelSource','foldernames');
[calData, valData] = splitEachLabel(imds, 0.7, 'randomized');
```

```
aug_calData = augmentedImageDatastore([227 227],calData);
aug_valData = augmentedImageDatastore([227 227],valData);
```

Create the dlquantizer object and specify a CPU execution environment.

```
dq = dlquantizer(net,'ExecutionEnvironment','CPU')

dq =
  dlquantizer with properties:
    NetworkObject: [1x1 DAGNetwork]
    ExecutionEnvironment: 'CPU'
```

Calibrate the network.

```
calResults = calibrate(dq,aug_calData,'UseGPU','off')
```

```
calResults=122x5 table

## Quantize YOLO v3 Object Detector

This example shows how to quantize a `yolov3objectDetector` (Computer Vision Toolbox) object using preprocessed calibration and validation data.

First, download a pretrained YOLO v3 object detector.

```
detector = downloadPretrainedNetwork();
```

This example uses a small labeled data set that contains one or two labeled instances of a vehicle. Many of these images come from the Caltech Cars 1999 and 2001 data sets, created by Pietro Perona and used with permission.

Unzip the vehicle images and load the vehicle ground truth data.

```
unzip vehicleDatasetImages.zip
data = load('vehicleDatasetGroundTruth.mat');
vehicleDataset = data.vehicleDataset;
```

Add the full path to the local vehicle data folder.

```
vehicleDataset.imageFilename = fullfile(pwd, vehicleDataset.imageFilename);
```

Create an `imageDatastore` for loading the images and a `boxLabelDatastore` (Computer Vision Toolbox) for the ground truth bounding boxes.

```
imds = imageDatastore(vehicleDataset.imageFilename);
blDs = boxLabelDatastore(vehicleDataset(:,2));
```

Use the `combine` function to combine both the datastores into a `CombinedDatastore`.

```
combinedDS = combine(imds, blDs);
```

Split the data into calibration and validation data.

```
calData = combinedDS.subset(1:32);
valData = combinedDS.subset(33:64);
```

Use the `preprocess` (Computer Vision Toolbox) method of `yoloV3ObjectDetector` (Computer Vision Toolbox) object with `transform` function to prepare the data for calibration and validation.

The `transform` function returns a `TransformedDatastore` object.

```
processedCalData = transform(calData, @(data)preprocess(detector,data));
processedValData = transform(valData, @(data)preprocess(detector,data));
```

Create the `dlquantizer` object.

```
dq = dlquantizer(detector, 'ExecutionEnvironment', 'MATLAB');
```

Calibrate the network.

```
calResults = calibrate(dq, processedCalData, 'UseGPU', 'off')
```

*calResults=135x5 table*

    detector = pretrained.detector;
end

```

## Input Arguments

### **quantObj** — Network to quantize

`dlquantizer` object

Network to quantize, specified as a `dlquantizer` object.

### **valData** — Data to use for validation of quantized network

`imageDatastore` object | `augmentedImageDatastore` object | `pixelLabelImageDatastore` object | `CombinedDatastore` object | `TransformedDatastore` object

Data to use for validation of quantized network, specified as an `imageDatastore` object, an `augmentedImageDatastore` object, a `pixelLabelImageDatastore` object, a `CombinedDatastore` object, or a `TransformedDatastore` object.

You must preprocess the data used for validation of a `yolov3objectDetector` object using the `preprocess` function. For an example of using preprocessed data for validation of a `yolov3objectDetector`, see “Quantize YOLO v3 Object Detector” on page 1-1963.

`validate` accepts a `CombinedDatastore` or `TransformedDatastore` object as input data for validating quantized `yolov3objectDetector` and `yolov4objectDetector` objects. The

CombinedDatastore and TransformedDatastore used for validation must contain an imageDatastore or augmentedImageDatastore as the first datastore and a boxLabelDatastore as the second datastore. For more information on valid datastores, see “Prepare Data for Quantizing Networks”.

**quantOpts — Options for quantizing network**

dlquantizationOptions object

Options for quantizing the network, specified as a dlquantizationOptions object.

**Output Arguments**

**valResults — Performance of quantized network**

struct

Performance of quantized network, returned as a struct. The struct contains these fields.

- NumSamples — The number of sample inputs used to validate the network, specified by valData.
- MetricResults — Struct containing results of the metric function defined in the dlquantizationOptions object. When more than one metric function is specified in the dlquantizationOptions object, MetricResults is an array of structs.

MetricResults contains these fields:

Field	Description
MetricFunction	Metric function used to determine the performance of the quantized network, specified in the dlquantizationOptions object.
Result	Table indicating the results of the metric function before and after quantization.  The first row in the table, 'Floating-Point', contains information for the original floating-point implementation. The second row, 'Quantized', contains information for the quantized implementation. The output of the metric function is displayed in the MetricOutput column.

- Statistics — Table indicating the learnable parameter memory used, in bytes, by the original floating-point implementation of the network and the quantized implementation.

When the ExecutionEnvironment for the dlquantizer object is set to FPGA, the Statistics table is a table indicating these values for the original floating-point and quantized network implementations:

- Frames per second
- Number of convolution threads
- Number of fully connected threads
- Lookup table (LUT) resource utilization percentage

- Block RAM resource utilization percentage
- DSP resource utilization percentage

## Algorithms

The `validate` function determines the default metric function to use for the validation based on the type of network that is being quantized.

Type of Network	Metric Function
Classification	Top-1 Accuracy — Accuracy of the network
Object Detection	Average Precision — Average precision over all detection results. See <code>evaluateDetectionPrecision</code> .
Regression	MSE — Mean squared error of the network
Semantic Segmentation	<code>evaluateSemanticSegmentation</code> — Evaluate semantic segmentation data set against ground truth
Single Shot Detector (SSD)	WeightedIOU — Average IoU of each class, weighted by the number of pixels in that class

When the 'Simulation' property of the `dlquantizer` object is set to 'on', the default metric function uses at most 5 files from the validation datastore. Custom metric functions, specified using a `dlquantizationOptions` object, do not have this restriction.

# verifyNetworkRobustness

Verify adversarial robustness of deep learning network

## Syntax

```
result = verifyNetworkRobustness(net,XLower,XUpper,label)
```

## Description

`result = verifyNetworkRobustness(net,XLower,XUpper,label)` verifies whether the network `net` is adversarially robust with respect to the class `label` when the input is between `XLower` and `XUpper`. For more information, see “Adversarial Examples” on page 1-1973.

A network is robust to adversarial examples for a specific input if the predicted class does not change when the input is perturbed between `XLower` and `XUpper`. For more information, see “Algorithms” on page 1-1973.

The `verifyNetworkRobustness` function requires the Deep Learning Toolbox Verification Library support package. If this support package is not installed, use the **Add-On Explorer**. To open the **Add-On Explorer**, go to the MATLAB Toolstrip and click **Add-Ons > Get Add-Ons**.

## Examples

### Verify Network Robustness

Verify the adversarial robustness of an image classification network.

Load a pretrained classification network. This network is a `dlnetwork` object that has been trained to predict the class label of images of handwritten digits.

```
load("digitsRobustClassificationMLPNet.mat");
```

Prepare the network for verification by removing the softmax layer. When you remove layers from a `dlnetwork` object, the software returns the network as an uninitialized `dlnetwork` object. To initialize the network, use the `initialize` function.

```
netRobust = removeLayers(netRobust,"softmax");
netRobust = initialize(netRobust);
```

Load the test data.

```
[XTest,TTest] = digitTest4DArrayData;
```

Select the first ten images.

```
X = XTest(:,:,,1:10);
label = TTest(1:10);
```

Convert the test data to a `dlarray` object.

```
X = dlarray(X,"SSCB");
```

Verify the network robustness to an input perturbation between -0.01 and 0.01 for each pixel. Create lower and upper bounds for the input.

```
perturbation = 0.01;  
XLower = X - perturbation;  
XUpper = X + perturbation;
```

Verify the network robustness for each test image.

```
result = verifyNetworkRobustness(netRobust,XLower,XUpper,label);  
summary(result)
```

```
verified      10  
violated      0  
unproven      0
```

### Approximate Maximum Adversarial Perturbation

Find the maximum adversarial perturbation that you can apply to an input without changing the predicted class.

Load a pretrained classification network. This network is a `dlnetwork` object that has been trained to predict the class of images of handwritten digits.

```
load("digitsRobustClassificationMLPNet.mat");
```

Prepare the network for verification by removing the softmax layer. When you remove layers from a `dlnetwork` object, the software returns the network as an uninitialized `dlnetwork` object. To initialize the network, use the `initialize` function.

```
netRobust = removeLayers(netRobust,"softmax");  
netRobust = initialize(netRobust);
```

Load the test data.

```
[XTest,TTest] = digitTest4DArrayData;
```

Select a test image.

```
idx = 3;  
X = XTest(:,:,:,idx);  
label = TTest(idx);
```

Create lower and upper bounds for a range of perturbation values.

```
perturbationRange = 0:0.005:0.05;  
  
for i = 1:numel(perturbationRange)  
XLower(:,:,:,i) = X - perturbationRange(i);  
XUpper(:,:,:,i) = X + perturbationRange(i);  
end
```

Repeat the class label for each set of bounds.

```
label = repmat(label,numel(perturbationRange),1);
```

Convert the bounds to `dLarray` objects.

```
XLower = dLarray(XLower, "SSCB");
XUpper = dLarray(XUpper, "SSCB");
```

Verify the adversarial robustness for each perturbation.

```
result = verifyNetworkRobustness(netRobust, XLower, XUpper, label);
plot(perturbationRange, result, "*")
xlabel("Perturbation")
```

Find the maximum perturbation value for which the function returns verified.

```
maxIdx = find(result=="verified",1,"last");
maxPerturbation = perturbationRange(maxIdx)

maxPerturbation = 0.0300
```

## Input Arguments

### **net** — Network

initialized `dLnetwork` object

Network, specified as an initialized `dLnetwork` object. To initialize a `dLnetwork` object, use the `initialize` function.

The function supports networks with these layers:

- `imageInputLayer` with `Normalization="none"`
- `featureInputLayer` with `Normalization="none"`
- `fullyConnectedLayer`
- `convolution2dLayer` with `Dilation` set to `[1 1]` or `1` and `PaddingValue` set to `0`
- `reluLayer`
- `tanhLayer`
- `batchNormalizationLayer`
- `averagePooling2dLayer` with `PaddingValue` set to `0`
- `globalAveragePooling2dLayer`
- `dropoutLayer`
- `sigmoidLayer`

The function does not support networks with multiple inputs and multiple outputs.

The function verifies the network using the final layer. For most applications, use the final fully connected layer for verification. If your network has a different layer as its final layer (for example, softmax), remove the layer before calling the function.

**XLower — Input lower bound**

formatted `darray` object

Input lower bound, specified as a formatted `darray` object. For more information about `darray` formats, see the `fmt` input argument of `darray`.

The lower and upper bounds, `XLower` and `XUpper`, must have the same size and format. The function computes the results across the batch ("B") dimension of the input lower and upper bounds.

**XUpper — Input upper bound**

formatted `darray` object

Input upper bound, specified as a formatted `darray` object. For more information about `darray` formats, see the `fmt` input argument of `darray`.

The lower and upper bounds, `XLower` and `XUpper`, must have the same size and format. The function computes the results across the batch ("B") dimension of the input lower and upper bounds.

**label — Class label**

numeric index | categorical

Class label, specified as a numeric index or a categorical, or a vector of these values. The length of `label` must match the size of the batch ("B") dimension of the lower and upper bounds.

The function verifies that the predicted class that the network returns matches `label` for any input in the range defined by the lower and upper bounds.

---

**Note** If you specify `label` as a categorical, then the order of the categories must match the order of the outputs in the network.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `categorical`

## Output Arguments

### result — Verification result

categorical array

Verification result, returned as a categorical array. For each set of input lower and upper bounds, the function returns the corresponding element of this array as one of these values:

- "verified" — The network is robust to adversarial inputs between the specified bounds.
- "violated" — The network is not robust to adversarial inputs between the specified bounds.
- "unproven" — Unable to prove whether the network is robust to adversarial inputs between the specified bounds.

The function computes the results across the batch ("B") dimension of the input lower and upper bounds. If you supply  $k$  upper bounds, lower bounds, and labels, then `result(k)` corresponds to the verification result for the  $k$ th input lower and upper bounds with respect to `label(k)`. For more information, see "Algorithms" on page 1-1973.

## More About

### Adversarial Examples

Neural networks can be susceptible to a phenomenon known as *adversarial examples* [1], where very small changes to an input can cause the network predictions to significantly change. For example, making a small change to an image that causes the network to misclassify it. These changes are often imperceptible to humans.

For example, this image shows that adding an imperceptible perturbation to an image of peppers means that the classification changes from "bell pepper" to "pillow".

A network is *adversarially robust* if the output of the network does not change significantly when the input is perturbed. For classification tasks, adversarial robustness means that the output of the fully connected layer with the highest value does not change, and therefore the predicted class does not change.

## Algorithms

To verify the robustness of a network for an input, the function checks that when the input is perturbed between the specified lower and upper bound, the output does not significantly change.

Let  $X$  be an input with respect to which you want to test the robustness of the network. To use the `verifyNetworkRobustness` function, you must specify a lower and upper bound for the input. For example, let  $\epsilon$  be a small perturbation. You can define a lower and upper bound for the input as  $X_{\text{lower}} = X - \epsilon$  and  $X_{\text{upper}} = X + \epsilon$ , respectively.

To verify the adversarial robustness of the network, the function checks that, for all inputs between  $X_{\text{lower}}$  and  $X_{\text{upper}}$ , no adversarial example exists. To check for adversarial examples, the function uses these steps.

- 1 Create an input set using the lower and upper input bounds.
- 2 Pass the input set through the network and return an output set. To reduce computational overhead, the function performs abstract interpretation by approximating the output of each layer using the DeepPoly [2] method.
- 3 Check if the specified label remains the same for the entire input set. Because the algorithm uses overapproximation when it computes the output set, the result can be unproven if part of the output set corresponds to an adversarial example.

If you specify multiple pairs of input lower and upper bounds, then the function verifies the robustness for each pair of input bounds.

---

**Note** Because of floating-point round-off error, the verification results might be slightly different when working with networks produced using C/C++ code generation.

---

# quantize

Quantize deep neural network

## Syntax

```
quantizedNetwork = quantize(quantObj)  
quantizedNetwork = quantize(quantObj,Name,Value)
```

## Description

`quantizedNetwork = quantize(quantObj)` quantizes a deep neural network using a calibrated `dlquantizer` object, `quantObj`. The quantized neural network object, `quantizedNetwork`, enables visibility of the quantized layers, weights, and biases of the network, as well as simulatable quantized inference behavior.

`quantizedNetwork = quantize(quantObj,Name,Value)` specifies additional options using one or more name name-value arguments.

This function requires Deep Learning Toolbox Model Quantization Library. To learn about the products required to quantize a deep neural network, see “Quantization Workflow Prerequisites”.

## Examples

### Emulate Target Agnostic Quantized Network

This example shows how to create a target agnostic, simulatable quantized deep neural network in MATLAB.

Target agnostic quantization allows you to see the effect quantization has on your neural network without target hardware or target-specific quantization schemes. Creating a target agnostic quantized network is useful if you:

- Do not have access to your target hardware.
- Want to preview whether or not your network is suitable for quantization.
- Want to find layers that are sensitive to quantization.

Quantized networks emulate quantized behavior for quantization-compatible layers. Network architecture like layers and connections are the same as the original network, but inference behavior uses limited precision types. Once you have quantized your network, you can use the `quantizationDetails` function to retrieve details on what was quantized.

Load the pretrained network. `net` is a SqueezeNet network that has been retrained using transfer learning to classify images in the `MerchData` data set.

```
load squeezeNetMerch  
net  
  
net =  
    DAGNetwork with properties:
```

```
Layers: [68x1 nnet.cnn.layer.Layer]
Connections: [75x2 table]
InputNames: {'data'}
OutputNames: {'new_classoutput'}
```

You can use the `quantizationDetails` function to see that the network is not quantized.

```
qDetailsOriginal = quantizationDetails(net)
```

```
qDetailsOriginal = struct with fields:
    IsQuantized: 0
    TargetLibrary: ""
    QuantizedLayerNames: [0x0 string]
    QuantizedLearnables: [0x3 table]
```

Unzip and load the `MerchData` images as an image datastore.

```
unzip('MerchData.zip')
imds = imageDatastore('MerchData', ...
    'IncludeSubfolders',true, ...
    'LabelSource','foldernames');
```

Define calibration and validation data to use for quantization. The output size of the images are changed for both calibration and validation data according to network requirements.

```
[calData,valData] = splitEachLabel(imds,0.7,'randomized');
augCalData = augmentedImageDatastore([227 227],calData);
augValData = augmentedImageDatastore([227 227],valData);
```

Create `dlquantizer` object and specify the network to quantize. Set the execution environment to MATLAB. How the network is quantized depends on the execution environment. The MATLAB execution environment is agnostic to the target hardware and allows you to prototype quantized behavior.

```
quantObj = dlquantizer(net,'ExecutionEnvironment','MATLAB');
```

Use the `calibrate` function to exercise the network with sample inputs and collect range information. The `calibrate` function exercises the network and collects the dynamic ranges of the weights and biases in the convolution and fully connected layers of the network and the dynamic ranges of the activations in all layers of the network. The function returns a table. Each row of the table contains range information for a learnable parameter of the optimized network.

```
calResults = calibrate(quantObj,augCalData);
```

Use the `quantize` method to quantize the network object and return a simulatable quantized network.

```
qNet = quantize(quantObj)
```

```
qNet =
Quantized DAGNetwork with properties:

    Layers: [68x1 nnet.cnn.layer.Layer]
Connections: [75x2 table]
InputNames: {'data'}
```

```
OutputNames: {'new_classoutput'}
```

Use the `quantizationDetails` method to extract quantization details.

You can use the `quantizationDetails` function to see that the network is now quantized.

```
qDetailsQuantized = quantizationDetails(qNet)
```

```
qDetailsQuantized = struct with fields:
    IsQuantized: 1
    TargetLibrary: "none"
    QuantizedLayerNames: [26x1 string]
    QuantizedLearnables: [52x3 table]
```

Make predictions using the original, single-precision floating-point network, and the quantized INT8 network.

```
predOriginal = classify(net, augValData);           % Predictions for the non-quantized network
predQuantized = classify(qNet, augValData);        % Predictions for the quantized network
```

Compute the relative accuracy of the quantized network as compared to the original network.

```
ccrQuantized = mean(predQuantized == valData.Labels)*100
ccrQuantized = 100
```

```
ccrOriginal = mean(predOriginal == valData.Labels)*100
ccrOriginal = 100
```

For this validation data set, the quantized network gives the same predictions as the floating-point network.

## Emulate GPU Target Behavior for Quantized Network

This example shows how to emulate the behavior of a quantized network for GPU deployment. Once you quantize your network for a GPU execution environment, you can emulate the GPU target behavior without the GPU hardware. Doing so allows you to examine your quantized network structure and behavior without generating code for deployment.

Emulated quantized networks are not smaller than the original network.

Load the pretrained network. `net` is a SqueezeNet convolutional neural network that has been retrained using transfer learning to classify images in the `MerchData` data set.

```
load squeezeNetMerch
lgraph = layerGraph(net);
lgraph = removeLayers(lgraph, "new_classoutput");
dlNet = dlNetwork(lgraph)

dlNet =
    dlNetwork with properties:
```

```
Layers: [67x1 nnet.cnn.layer.Layer]
Connections: [74x2 table]
Learnables: [52x3 table]
State: [0x3 table]
InputNames: {'data'}
OutputNames: {'prob'}
Initialized: 1
```

View summary with `summary`.

Define calibration and validation data to use for quantization.

Use the calibration data to collect the dynamic ranges of the weights and biases in the convolution and fully connected layers of the network and the dynamic ranges of the activations in all layers of the network. For the best quantization results, the calibration data must be representative of inputs to the network.

Use the validation data to test the network after quantization to understand the effects of the limited range and precision of the quantized convolution layers in the network.

For this example, use the images in the MerchData data set. Split the data into calibration and validation data sets.

```
unzip("MerchData.zip");
imds = imageDatastore("MerchData", ...
    IncludeSubfolders=true, ...
    LabelSource="foldernames");
classes = categories(imds.Labels);
[calData, valData] = splitEachLabel(imds, 0.7, "randomized");
```

Create a `dlquantizer` object and specify the network to quantize. How the network is quantized depends on the execution environment. Set `ExecutionEnvironment` to `GPU` to perform quantization specific to GPU target hardware.

```
quantObj = dlquantizer(dlnet, ExecutionEnvironment="GPU");
```

Use the `calibrate` function to exercise the network object with sample inputs and collect range information.

```
calResults = calibrate(quantObj, calData);
```

Use the `quantize` method to quantize the network object and return a simulatable quantized network.

```
qNet = quantize(quantObj)
```

```
qNet =
  Quantized dlnetwork with properties:

    Layers: [67x1 nnet.cnn.layer.Layer]
Connections: [74x2 table]
Learnables: [52x3 table]
State: [0x3 table]
InputNames: {'data'}
OutputNames: {'prob'}
Initialized: 1
```

View summary with `summary`.  
 Use the `quantizationDetails` function to extract quantization details.

You can use the `quantizationDetails` method to see that the network is now quantized.

```
qDetails = quantizationDetails(qNet)

qDetails = struct with fields:
    IsQuantized: 1
    TargetLibrary: "cudnn"
    QuantizedLayerNames: [55x1 string]
    QuantizedLearnables: [35x3 table]
```

The `TargetLibrary` field shows that the quantized network emulates the CUDA® Deep Neural Network library (cuDNN).

The `QuantizedLayerNames` field displays a list of layers that have been quantized.

```
qDetails.QuantizedLayerNames(1:5)

ans = 5x1 string
    "conv1"
    "relu_conv1"
    "pool1"
    "fire2-squeeze1x1"
    "fire2-relu_squeeze1x1"
```

The `QuantizedLearnables` field contains additional details on quantized network learnable parameters. In this example, the 2-D convolutional layer, `conv1`, has had the weights scaled and casted to `int8`. The bias is scaled and remains in single precision. The values of quantized learnables are returned as stored integer values.

```
qDetails.QuantizedLearnables
```

```
ans=35x3 table
      Layer      Parameter      Value
-----
"conv1"      "Weights"      {3x3x3x64  int8  }
"conv1"      "Bias"          {1x1x64    single}
"fire2-squeeze1x1"  "Weights"      {1x1x64x16 int8  }
"fire2-squeeze1x1"  "Bias"          {1x1x16    single}

      :
```

You can use the quantized network to emulate how a network quantized for GPU target hardware would perform a classification task.

Make predictions using the original, single-precision floating-point network. To accelerate the computation by compiling and executing a MEX function on the GPU, use the acceleration option "mex" of the predict function.

```
XTest = readall(valData);  
XTest = cat(4,XTest{:});  
XTest = dldarray(gpuArray(single(XTest)), "SSCB");  
TTest = valData.Labels;
```

```
YTestOriginal = predict(dlnet,XTest,Acceleration="mex");
```

Generating MEX for cudnn target.

```
YTestOriginal = onehotdecode(YTestOriginal,classes,3);
```

Make predictions using the quantized INT8 network. Use the acceleration option "mex" of the predict function. MEX acceleration is supported for quantized networks based on quantization objects with ExecutionEnvironment set to GPU.

```
YTestQuantized = predict(qNet,XTest,Acceleration="mex");
```

Generating MEX for cudnn target.

```
YTestQuantized = onehotdecode(YTestQuantized,classes,3);
```

Compute the relative accuracy of the quantized network as compared to the original network.

```
ccrOriginal = mean(squeeze(YTestOriginal) == valData.Labels)
```

```
ccrOriginal = 1
```

```
ccrQuantized = mean(squeeze(YTestQuantized) == valData.Labels)
```

```
ccrQuantized = 1
```

The quantized network shows no drop in accuracy.

## Emulate FPGA Target Behavior for Quantized Network

This example shows how to emulate the behavior of a quantized network for FPGA deployment. Once you quantize your network for an FPGA execution environment, you can emulate the FPGA target behavior without any FPGA hardware. This action allows you to examine your quantized network structure and behavior without generating code for deployment.

Load the pretrained network.

```
if ~isfile("LogoNet.mat")  
    url = "https://www.mathworks.com/supportfiles/gpuCoder/cnn_models/logo_detection/LogoNet.mat";  
    websave("LogoNet.mat",url);  
end  
data = load("LogoNet.mat");  
net = data.convnet;
```

Define calibration and validation data to use for quantization.

Use the calibration data to collect the dynamic ranges of the weights and biases in the convolution and fully connected layers, the dynamic ranges of the activations in all the layers, and the dynamic ranges of the parameters for some layers. For the best quantization results, the calibration data must be representative of inputs to the network.

Use the validation data to test the network after quantization. Test the network to determine the effects of the limited range and precision of the quantized layers and layer parameters in the network.

This example uses the images in the `logos_dataset` data set. Create an `imageDatastore` object, then split the data into calibration and validation data sets.

```
unzip("logos_dataset.zip");
imageData = imageDatastore(fullfile(pwd,"logos_dataset"),...
    IncludeSubfolders=true,FileExtensions=".JPG",LabelSource="foldernames");
[calData,valData] = splitEachLabel(imageData,0.7,"randomized");
```

Create a `dlquantizer` object and specify the network to quantize. Set the execution environment for the quantized network to FPGA.

```
quantObj = dlquantizer(net,ExecutionEnvironment="FPGA");
```

Use the `calibrate` function to exercise the network with sample inputs and collect range information.

```
calResults = calibrate(quantObj,calData,UseGPU="off");
```

Use the `quantize` function to quantize the network object and return a quantized network for simulation.

```
qNet = quantize(quantObj)
```

```
qNet =
  Quantized DAGNetwork with properties:

    Layers: [22x1 nnet.cnn.layer.Layer]
  Connections: [21x2 table]
    InputNames: {'imageinput'}
    OutputNames: {'classoutput'}
```

Use the `quantizationDetails` function to extract quantization details.

Use the `quantizationDetails` method to extract quantization details.

You can use the `quantizationDetails` function to confirm that the network is now quantized. The `TargetLibrary` field shows that the quantized network emulates an FPGA target.

```
qDetails = quantizationDetails(qNet)

qDetails = struct with fields:
    IsQuantized: 1
    TargetLibrary: "fpga"
  QuantizedLayerNames: [17x1 string]
  QuantizedLearnables: [14x3 table]
```

The `QuantizedLayerNames` field displays a list of quantized layers.

`qDetails.QuantizedLayerNames`

```
ans = 17x1 string
"conv_1"
"relu_1"
"maxpool_1"
"conv_2"
"relu_2"
"maxpool_2"
"conv_3"
"relu_3"
"maxpool_3"
"conv_4"
"relu_4"
"maxpool_4"
"fc_1"
"relu_5"
"fc_2"
"relu_6"
"fc_3"
```

The `QuantizedLearnables` field contains additional details about the quantized network learnable parameters. In this example, the 2-D convolutional layers and fully connected layers have their weights scaled and cast to `int8`. The bias is scaled and remains in `int32`. The `quantizationDetails` function returns the values of the quantized learnables as stored integer values.

`qDetails.QuantizedLearnables`

```
ans=14x3 table
   Layer      Parameter      Value
   -----      -
"conv_1"    "Weights"    {5x5x3x96      int8 }
"conv_1"    "Bias"       {1x1x96        int32}
"conv_2"    "Weights"    {3x3x96x128    int8 }
"conv_2"    "Bias"       {1x1x128       int32}
"conv_3"    "Weights"    {3x3x128x384   int8 }
"conv_3"    "Bias"       {1x1x384       int32}
"conv_4"    "Weights"    {3x3x384x128   int8 }
"conv_4"    "Bias"       {1x1x128       int32}
"fc_1"      "Weights"    {5x5x128x2048  int8 }
"fc_1"      "Bias"       {1x1x2048      int32}
"fc_2"      "Weights"    {1x1x2048x2048 int8 }
"fc_2"      "Bias"       {1x1x2048      int32}
"fc_3"      "Weights"    {1x1x2048x32   int8 }
"fc_3"      "Bias"       {1x1x32        int32}
```

You can use the quantized network to emulate a network quantized for FPGA target hardware performing a classification task.

```
ypred = qNet.classify(valData);
ccr = mean(ypred == valData.Labels)

ccr = 1
```

## Input Arguments

### **quantObj — Network to quantize**

`dlquantizer` object

`dlquantizer` object containing the network to quantize, calibrated using the `calibrate` object function. The “ExecutionEnvironment” on page 1-0 must be set to 'GPU' 'FPGA', or 'MATLAB'.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `quantizedNetwork = quantize(quantObj, 'ExponentScheme', 'Histogram')`

### **ExponentScheme — Exponent selection scheme**

'MinMax' (default) | 'Histogram'

Exponent selection scheme, specified as one of these values:

- 'MinMax' — Evaluate the exponent based on the range information in the calibration statistics and avoid overflows.
- 'Histogram' — Distribution-based scaling which evaluates the exponent to best fit the calibration data.

Example: 'ExponentScheme', 'Histogram'

## Output Arguments

### **quantizedNetwork — Quantized neural network**

`dlnetwork` object | `DAGNetwork` object | `yolov2objectDetector` object | `yolov3objectDetector` object | `yolov4objectDetector` object | `ssdobjectDetector` object

Quantized neural network, returned as a `dlnetwork`, `DAGNetwork`, `yolov2objectDetector`, `yolov3objectDetector`, `yolov4objectDetector`, or a `ssdobjectDetector` object.

## Limitations

- The `quantize` function does not support quantization of networks using `dlquantizer` objects with “ExecutionEnvironment” on page 1-0 set to 'CPU'.
- Code generation does not support quantized deep neural networks produced by the `quantize` function.

## Version History

Introduced in R2022a

**R2022a: Quantize `dlquantizer` objects calibrated in R2022a and later**

The `quantize` function supports quantization of `dlquantizer` objects that are calibrated in R2022a and later.

## **R2022b: quantize support for FPGA execution environment**

Use the `quantize` method to create a simulatable quantized network when the `ExecutionEnvironment` property of `dlquantizer` is set to `FPGA`. The simulatable quantized network enables visibility of the quantized layers, weights, and biases of the network, as well as simulatable quantized inference behavior.

## **R2023a: Quantize dlquantizer objects that specify a dlnetwork**

The `quantize` function now supports quantization of `dlnetwork` objects using a calibration `dlquantizer` object.

# vgg16

VGG-16 convolutional neural network

## Syntax

```
net = vgg16
net = vgg16('Weights','imagenet')

layers = vgg16('Weights','none')
```

## Description

VGG-16 is a convolutional neural network that is 16 layers deep. You can load a pretrained version of the network trained on more than a million images from the ImageNet database [1]. The pretrained network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. The network has an image input size of 224-by-224. For more pretrained networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the VGG-16 network. Follow the steps of “Classify Image Using GoogLeNet” and replace GoogLeNet with VGG-16.

To retrain the network on a new classification task, follow the steps of “Train Deep Learning Network to Classify New Images” and load VGG-16 instead of GoogLeNet.

`net = vgg16` returns a VGG-16 network trained on the ImageNet data set.

This function requires Deep Learning Toolbox Model *for VGG-16 Network* support package. If this support package is not installed, then the function provides a download link.

`net = vgg16('Weights','imagenet')` returns a VGG-16 network trained on the ImageNet data set. This syntax is equivalent to `net = vgg16`.

`layers = vgg16('Weights','none')` returns the untrained VGG-16 network architecture. The untrained model does not require the support package.

## Examples

### Download VGG-16 Support Package

Download and install Deep Learning Toolbox Model *for VGG-16 Network* support package.

Type `vgg16` at the command line.

```
vgg16
```

If Deep Learning Toolbox Model *for VGG-16 Network* support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**. Check that the installation is successful by typing `vgg16` at the command line.

```
vgg16
```

```
ans =
```

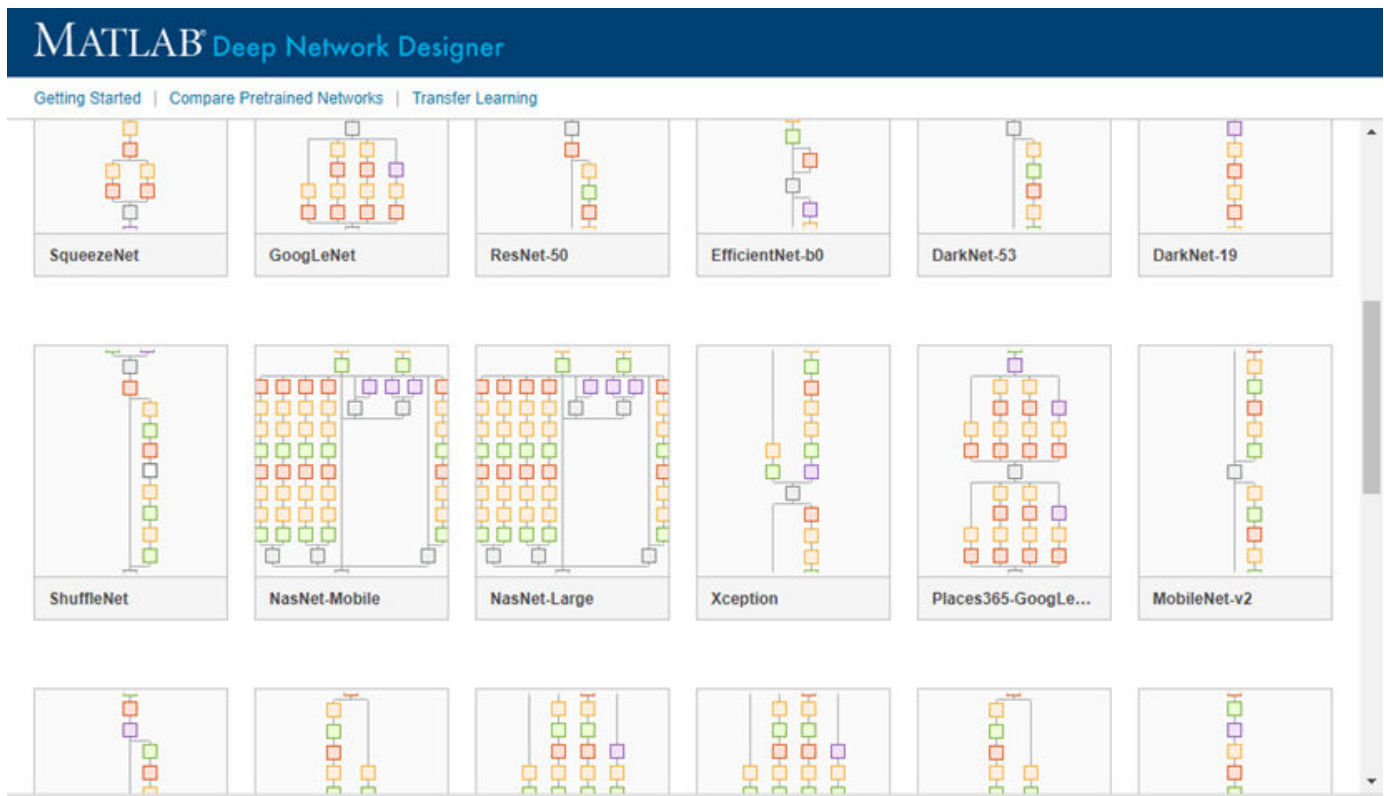

```
SeriesNetwork with properties:
```

```
Layers: [41x1 nnet.cnn.layer.Layer]
```

Visualize the network using Deep Network Designer.

```
deepNetworkDesigner(vgg16)
```

Explore other pretrained neural networks in Deep Network Designer by clicking **New**.

If you need to download a neural network, pause on the desired neural network and click **Install** to open the Add-On Explorer.

### Load Pretrained VGG-16 Convolutional Neural Network

Load a pretrained VGG-16 convolutional neural network and examine the layers and classes.

Use `vgg16` to load the pretrained VGG-16 network. The output net is a `SeriesNetwork` object.

```
net = vgg16
```

```
net =
```

```
SeriesNetwork with properties:
```

```
Layers: [41x1 nnet.cnn.layer.Layer]
```

View the network architecture using the `Layers` property. The network has 41 layers. There are 16 layers with learnable weights: 13 convolutional layers, and 3 fully connected layers.

```
net.Layers
```

```
ans =
```

```
41x1 Layer array with layers:
```

40	'prob'	Softmax	softmax
41	'output'	Classification Output	crossentropyex with 'tench' and 999 other classes

To view the names of the classes learned by the network, you can view the `Classes` property of the classification output layer (the final layer). View the first 10 classes by specifying the first 10 elements.

```
net.Layers(end).Classes(1:10)
```

```
ans = 10x1 categorical array
    tench
    goldfish
    great white shark
    tiger shark
    hammerhead
    electric ray
    stingray
    cock
    hen
    ostrich
```

## Output Arguments

### **net** — Pretrained VGG-16 convolutional neural network

SeriesNetwork object

Pretrained VGG-16 convolutional neural network returned as a SeriesNetwork object.

### **layers** — Untrained VGG-16 convolutional neural network architecture

Layer array

Untrained VGG-16 convolutional neural network architecture, returned as a Layer array.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

For code generation, you can load the network by using the syntax `net = vgg16` or by passing the `vgg16` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('vgg16')`

For more information, see "Load Pretrained Networks for Code Generation" (MATLAB Coder).

The syntax `vgg16('Weights', 'none')` is not supported for code generation.

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- For code generation, you can load the network by using the syntax `net = vgg16` or by passing the `vgg16` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('vgg16')`

For more information, see “Load Pretrained Networks for Code Generation” (GPU Coder).

- The syntax `vgg16('Weights', 'none')` is not supported for GPU code generation.

## vgg19

VGG-19 convolutional neural network

### Syntax

```
net = vgg19
net = vgg19('Weights','imagenet')

layers = vgg19('Weights','none')
```

### Description

VGG-19 is a convolutional neural network that is 19 layers deep. You can load a pretrained version of the network trained on more than a million images from the ImageNet database [1]. The pretrained network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. The network has an image input size of 224-by-224. For more pretrained networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the VGG-19 network. Follow the steps of “Classify Image Using GoogLeNet” and replace GoogLeNet with VGG-19.

To retrain the network on a new classification task, follow the steps of “Train Deep Learning Network to Classify New Images” and load VGG-19 instead of GoogLeNet.

`net = vgg19` returns a VGG-19 network trained on the ImageNet data set.

This function requires Deep Learning Toolbox Model *for VGG-19 Network* support package. If this support package is not installed, then the function provides a download link.

`net = vgg19('Weights','imagenet')` returns a VGG-19 network trained on the ImageNet data set. This syntax is equivalent to `net = vgg19`.

`layers = vgg19('Weights','none')` returns the untrained VGG-19 network architecture. The untrained model does not require the support package.

### Examples

#### Download VGG-19 Support Package

This example shows how to download and install Deep Learning Toolbox Model *for VGG-19 Network* support package.

Type `vgg19` at the command line.

```
vgg19
```

If Deep Learning Toolbox Model *for VGG-19 Network* support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the

support package, click the link, and then click **Install**. Check that the installation is successful by typing `vgg19` at the command line.

```

great white shark
  tiger shark
  hammerhead
  electric ray
  stingray
    cock
    hen
  ostrich

```

## Output Arguments

### **net** — Pretrained VGG-19 convolutional neural network

SeriesNetwork object

Pretrained VGG-19 convolutional neural network returned as a SeriesNetwork object.

### **layers** — Untrained VGG-19 convolutional neural network architecture

Layer array

Untrained VGG-19 convolutional neural network architecture, returned as a Layer array.

## Version History

Introduced in R2017a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

For code generation, you can load the network by using the syntax `net = vgg19` or by passing the `vgg19` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('vgg19')`

For more information, see “Load Pretrained Networks for Code Generation” (MATLAB Coder).

The syntax `vgg19('Weights', 'none')` is not supported for code generation.

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- For code generation, you can load the network by using the syntax `net = vgg19` or by passing the `vgg19` function to `coder.loadDeepLearningNetwork`. For example: `net = coder.loadDeepLearningNetwork('vgg19')`

For more information, see “Load Pretrained Networks for Code Generation” (GPU Coder).

- The syntax `vgg19('Weights', 'none')` is not supported for GPU code generation.

# vggish

VGGish neural network

## Syntax

```
net = vggish
```

## Description

`net = vggish` returns a pretrained VGGish model.

This function requires both Audio Toolbox and Deep Learning Toolbox.

## Examples

### Download VGGish Network

Download and unzip the Audio Toolbox™ model for VGGish.

Type `vggish` at the Command Window. If the Audio Toolbox model for VGGish is not installed, then the function provides a link to the location of the network weights. To download the model, click the link. Unzip the file to a location on the MATLAB path.

Alternatively, execute these commands to download and unzip the VGGish model to your temporary directory.

```
downloadFolder = fullfile(tempdir, 'VGGishDownload');  
loc = websave(downloadFolder, 'https://ssd.mathworks.com/supportfiles/audio/vggish.zip');  
VGGishLocation = tempdir;  
unzip(loc, VGGishLocation)  
addpath(fullfile(VGGishLocation, 'vggish'))
```

Check that the installation is successful by typing `vggish` at the Command Window. If the network is installed, then the function returns a `SeriesNetwork` object.

```
vggish
```

```
ans =  
SeriesNetwork with properties:  
  
Layers: [24x1 nnet.cnn.layer.Layer]  
InputNames: {'InputBatch'}  
OutputNames: {'regressionoutput'}
```

### Load Pretrained VGGish Network

Load a pretrained VGGish convolutional neural network and examine the layers and classes.

Use `vggish` to load the pretrained VGGish network. The output `net` is a `SeriesNetwork` object.

```
net = vggish
net =
  SeriesNetwork with properties:
    Layers: [24x1 nnet.cnn.layer.Layer]
    InputNames: {'InputBatch'}
    OutputNames: {'regressionoutput'}
```

View the network architecture using the `Layers` property. The network has 24 layers. There are nine layers with learnable weights, of which six are convolutional layers and three are fully connected layers.

```
net.Layers
```

```
ans =
  24x1 Layer array with layers:

    1  'InputBatch'      Image Input      96x64x1 images
    2  'conv1'           Convolution      64 3x3x1 convolutions with stride [1 1] and padding
    3  'relu'            ReLU
    4  'pool1'           Max Pooling      2x2 max pooling with stride [2 2] and padding
    5  'conv2'           Convolution      128 3x3x64 convolutions with stride [1 1] and padding
    6  'relu2'           ReLU
    7  'pool2'           Max Pooling      2x2 max pooling with stride [2 2] and padding
    8  'conv3_1'         Convolution      256 3x3x128 convolutions with stride [1 1] and padding
    9  'relu3_1'         ReLU
   10  'conv3_2'         Convolution      256 3x3x256 convolutions with stride [1 1] and padding
   11  'relu3_2'         ReLU
   12  'pool3'           Max Pooling      2x2 max pooling with stride [2 2] and padding
   13  'conv4_1'         Convolution      512 3x3x256 convolutions with stride [1 1] and padding
   14  'relu4_1'         ReLU
   15  'conv4_2'         Convolution      512 3x3x512 convolutions with stride [1 1] and padding
   16  'relu4_2'         ReLU
   17  'pool4'           Max Pooling      2x2 max pooling with stride [2 2] and padding
   18  'fc1_1'           Fully Connected  4096 fully connected layer
   19  'relu5_1'         ReLU
   20  'fc1_2'           Fully Connected  4096 fully connected layer
   21  'relu5_2'         ReLU
   22  'fc2'             Fully Connected  128 fully connected layer
   23  'EmbeddingBatch'  ReLU
   24  'regressionoutput' Regression Output mean-squared-error
```

Use `analyzeNetwork` to visually explore the network.

```
analyzeNetwork(net)
```

## Extract Features Using VGGish

Read in an audio signal to extract feature embeddings from it.

```
[audioIn, fs] = audioread(Ambiance-16-44p1-...);
```

Plot and listen to the audio signal.

```
t = (0:numel(audioIn)-1)/fs;
plot(t, audioIn)
xlabel("Time (s)")
ylabel("Amplitude")
axis tight
```

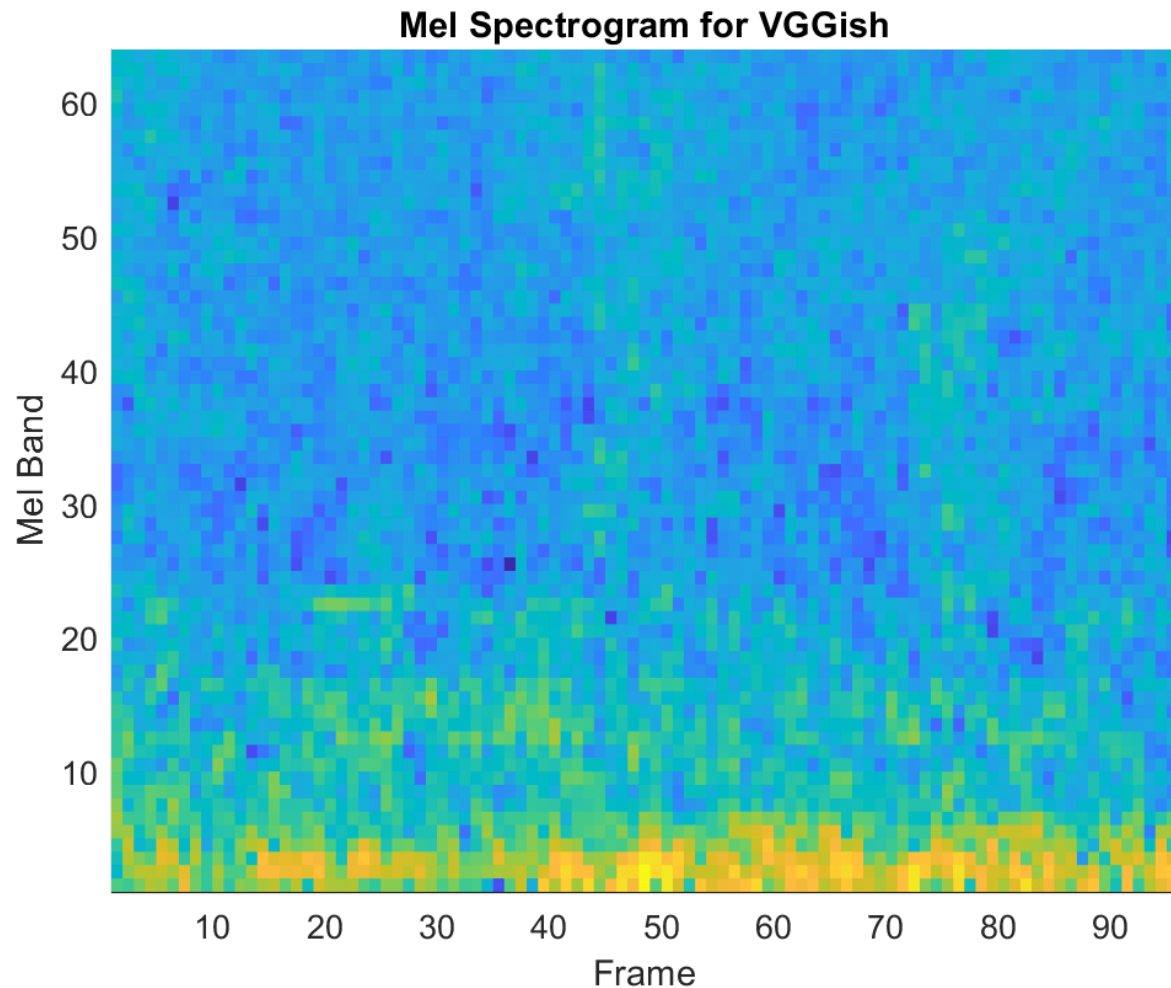

```
% To play the sound, call soundsc(audioIn,fs)
```

VGGish requires you to preprocess the audio signal to match the input format used to train the network. The preprocessing steps include resampling the audio signal and computing an array of mel spectrograms. To learn more about mel spectrograms, see `melSpectrogram` (Audio Toolbox). Use `vggishPreprocess` to preprocess the signal and extract the mel spectrograms to be passed to VGGish. Visualize one of these spectrograms chosen at random.

```
spectrograms = vggishPreprocess(audioIn,fs);  
  
arbitrarySpect = spectrograms(:,:,1,randi(size(spectrograms,4)));  
surf(arbitrarySpect,EdgeColor="none")  
view(90,-90)  
xlabel("Mel Band")  
ylabel("Frame")  
title("Mel Spectrogram for VGGish")  
axis tight
```

Create a VGGish neural network. Using the `vggish` function requires installing the pretrained VGGish network. If the network is not installed, the function provides a link to download the pretrained model.

```
net = vggish;
```

Call `predict` with the network on the preprocessed mel spectrogram images to extract feature embeddings. The feature embeddings are returned as a `numFrames`-by-128 matrix, where `numFrames` is the number of individual spectrograms and 128 is the number of elements in each feature vector.

```
features = predict(net,spectrograms);  
[numFrames,numFeatures] = size(features)
```

```
numFrames = 24
```

```
numFeatures = 128
```

Visualize the VGGish feature embeddings.

```
surf(features,EdgeColor="none")  
view([90 -90])
```

```
xlabel("Feature")  
ylabel("Frame")  
title("VGGish Feature Embeddings")  
axis tight
```

### Transfer Learning Using VGGish

In this example, you transfer the learning in the VGGish regression model to an audio classification task.

Download and unzip the environmental sound classification data set. This data set consists of recordings labeled as one of 10 different audio sound classes (ESC-10).

```
downloadFolder = matlab.internal.examples.downloadSupportFile("audio", "ESC-10.zip");  
unzip(downloadFolder, tempdir)  
dataLocation = fullfile(tempdir, "ESC-10");
```

Create an `audioDatastore` (Audio Toolbox) object to manage the data and split it into train and validation sets. Call `countEachLabel` (Audio Toolbox) to display the distribution of sound classes and the number of unique labels.

```
ads = audioDatastore(dataLocation,IncludeSubfolders=true,LabelSource="foldernames");
labelTable = countEachLabel(ads)
```

```
labelTable=10×2 table
      Label      Count
-----
chainsaw      40
clock_tick    40
crackling_fire 40
crying_baby   40
dog           40
helicopter    40
rain          40
rooster       38
sea_waves     40
sneezing      40
```

Determine the total number of classes.

```
numClasses = height(labelTable);
```

Call `splitEachLabel` (Audio Toolbox) to split the data set into train and validation sets. Inspect the distribution of labels in the training and validation sets.

```
[adsTrain, adsValidation] = splitEachLabel(ads,0.8);
```

```
countEachLabel(adsTrain)
```

```
ans=10×2 table
      Label      Count
-----
chainsaw      32
clock_tick    32
crackling_fire 32
crying_baby   32
dog           32
helicopter    32
rain          32
rooster       30
sea_waves     32
sneezing      32
```

```
countEachLabel(adsValidation)
```

```
ans=10×2 table
      Label      Count
-----
chainsaw      8
clock_tick    8
crackling_fire 8
```

```
crying_baby      8
dog              8
helicopter       8
rain             8
rooster          8
sea_waves        8
sneezing         8
```

The VGGish network expects audio to be preprocessed into log mel spectrograms. Use `vggishPreprocess` (Audio Toolbox) to extract the spectrograms from the train set. There are multiple spectrograms for each audio signal. Replicate the labels so that they are in one-to-one correspondence with the spectrograms.

```
overlapPercentage = 75 ;

trainFeatures = [];
trainLabels = [];
while hasdata(adsTrain)
    [audioIn,fileInfo] = read(adsTrain);
    features = vggishPreprocess(audioIn,fileInfo.SampleRate,OverlapPercentage=overlapPercentage)
    numSpectrograms = size(features,4);
    trainFeatures = cat(4,trainFeatures,features);
    trainLabels = cat(2,trainLabels, repelem(fileInfo.Label,numSpectrograms));
end
```

Extract spectrograms from the validation set and replicate the labels.

```
validationFeatures = [];
validationLabels = [];
segmentsPerFile = zeros(numel(adsValidation.Files), 1);
idx = 1;
while hasdata(adsValidation)
    [audioIn,fileInfo] = read(adsValidation);
    features = vggishPreprocess(audioIn,fileInfo.SampleRate,OverlapPercentage=overlapPercentage)
    numSpectrograms = size(features,4);
    validationFeatures = cat(4,validationFeatures,features);
    validationLabels = cat(2,validationLabels, repelem(fileInfo.Label,numSpectrograms));

    segmentsPerFile(idx) = numSpectrograms;
    idx = idx + 1;
end
```

Load the VGGish model and convert it to a `layerGraph` object.

```
net = vggish;

lgraph = layerGraph(net.Layers);
```

Use `removeLayers` to remove the final regression output layer from the graph. After you remove the regression layer, the new final layer of the graph is a ReLU layer named 'EmbeddingBatch'.

```
lgraph = removeLayers(lgraph,"regressionoutput");
lgraph.Layers(end)
```

```
ans =
    ReLULayer with properties:
```

Name: 'EmbeddingBatch'

Use `addLayers` to add a `fullyConnectedLayer`, a `softmaxLayer`, and a `classificationLayer` to the graph. Set the `WeightLearnRateFactor` and `BiasLearnRateFactor` of the new fully connected layer to 10 so that learning is faster in the new layer than in the transferred layers.

```
lgraph = addLayers(lgraph,[ ...
    fullyConnectedLayer(numClasses,Name="FCFinal",WeightLearnRateFactor=10,BiasLearnRateFactor=10)
    softmaxLayer(Name="softmax")
    classificationLayer(Name="classOut")]);
```

Use `connectLayers` to append the fully connected, softmax, and classification layers to the layer graph.

```
lgraph = connectLayers(lgraph,"EmbeddingBatch","FCFinal");
```

To define training options, use `trainingOptions`.

```
miniBatchSize = 128;
options = trainingOptions("adam", ...
    MaxEpochs=5, ...
    MiniBatchSize=miniBatchSize, ...
    Shuffle="every-epoch", ...
    ValidationData={validationFeatures,validationLabels}, ...
    ValidationFrequency=50, ...
    LearnRateSchedule="piecewise", ...
    LearnRateDropFactor=0.5, ...
    LearnRateDropPeriod=2, ...
    OutputNetwork="best-validation-loss", ...
    Verbose=false, ...
    Plots="training-progress");
```

To train the network, use `trainNetwork`.

```
[trainedNet, netInfo] = trainNetwork(trainFeatures,trainLabels,lgraph,options);
```

Each audio file was split into several segments to feed into the VGGish network. Combine the predictions for each file in the validation set using a majority-rule decision.

```
validationPredictions = classify(trainedNet,validationFeatures);
```

```
idx = 1;
validationPredictionsPerFile = categorical;
for ii = 1:numel(adsValidation.Files)
    validationPredictionsPerFile(ii,1) = mode(validationPredictions(idx:idx+segmentsPerFile(ii))-1);
    idx = idx + segmentsPerFile(ii);
end
```

Use confusionchart to evaluate the performance of the network on the validation set.

```
figure(Units="normalized",Position=[0.2 0.2 0.5 0.5]);
confusionchart(adsValidation.Labels,validationPredictionsPerFile, ...
    Title=sprintf("Confusion Matrix for Validation Data \nAccuracy = %0.2f %%",mean(validationPredictionsPerFile)), ...
    ColumnSummary="column-normalized", ...
    RowSummary="row-normalized")
```

**Confusion Matrix for Validation Data**

# xception

Xception convolutional neural network

## Syntax

```
net = xception
net = xception('Weights','imagenet')

lgraph = xception('Weights','none')
```

## Description

Xception is a convolutional neural network that is 71 layers deep. You can load a pretrained version of the network trained on more than a million images from the ImageNet database [1]. The pretrained network can classify images into 1000 object categories, such as keyboard, mouse, pencil, and many animals. As a result, the network has learned rich feature representations for a wide range of images. The network has an image input size of 299-by-299. For more pretrained networks in MATLAB, see “Pretrained Deep Neural Networks”.

You can use `classify` to classify new images using the Xception model. Follow the steps of “Classify Image Using GoogLeNet” and replace GoogLeNet with Xception.

To retrain the network on a new classification task, follow the steps of “Train Deep Learning Network to Classify New Images” and load Xception instead of GoogLeNet.

`net = xception` returns an Xception network trained on the ImageNet data set.

This function requires the Deep Learning Toolbox Model *for Xception Network* support package. If this support package is not installed, then the function provides a download link.

`net = xception('Weights','imagenet')` returns an Xception network trained on the ImageNet data set. This syntax is equivalent to `net = xception`.

`lgraph = xception('Weights','none')` returns the untrained Xception network architecture. The untrained model does not require the support package.

## Examples

### Download Xception Support Package

Download and install the Deep Learning Toolbox Model *for Xception Network* support package.

Type `xception` at the command line.

```
xception
```

If the Deep Learning Toolbox Model *for Xception Network* support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**. Check that the installation is successful by

typing `xception` at the command line. If the required support package is installed, then the function returns a `DAGNetwork` object.

```
xception
```

```
ans =
```

```
DAGNetwork with properties:
```

```
Layers: [171x1 nnet.cnn.layer.Layer]  
Connections: [182x2 table]
```

Visualize the network using Deep Network Designer.

```
deepNetworkDesigner(xception)
```

Explore other pretrained neural networks in Deep Network Designer by clicking **New**.

If you need to download a neural network, pause on the desired neural network and click **Install** to open the Add-On Explorer.

## Output Arguments

**net** — Pretrained Xception convolutional neural network

DAGNetwork object

Pretrained Xception convolutional neural network, returned as a `DAGNetwork` object.

**lgraph — Untrained Xception convolutional neural network architecture**

LayerGraph object

Untrained Xception convolutional neural network architecture, returned as a LayerGraph object.

**Version History**

Introduced in R2019a

# yamnet

YAMNet neural network

## Syntax

```
net = yamnet
```

## Description

`net = yamnet` returns a pretrained YAMNet model.

This function requires both Audio Toolbox and Deep Learning Toolbox.

## Examples

### Download YAMNet

Download and unzip the Audio Toolbox™ model for YAMNet.

Type `yamnet` at the Command Window. If the Audio Toolbox model for YAMNet is not installed, then the function provides a link to the location of the network weights. To download the model, click the link. Unzip the file to a location on the MATLAB path.

Alternatively, execute the following commands to download and unzip the YAMNet model to your temporary directory.

```
downloadFolder = fullfile(tempdir, 'YAMNetDownload');  
loc = websave(downloadFolder, 'https://ssd.mathworks.com/supportfiles/audio/yamnet.zip');  
YAMNetLocation = tempdir;  
unzip(loc, YAMNetLocation)  
addpath(fullfile(YAMNetLocation, 'yamnet'))
```

Check that the installation is successful by typing `yamnet` at the Command Window. If the network is installed, then the function returns a `SeriesNetwork` object.

```
yamnet
```

```
ans =  
SeriesNetwork with properties:  
  
    Layers: [86x1 nnet.cnn.layer.Layer]  
  InputNames: {'input_1'}  
 OutputNames: {'Sound'}
```

### Load Pretrained YAMNet

Load a pretrained YAMNet convolutional neural network and examine the layers and classes.

Use `yamnet` to load the pretrained YAMNet network. The output net is a `SeriesNetwork` object.

```
net = yamnet

net =
  SeriesNetwork with properties:
    Layers: [86x1 nnet.cnn.layer.Layer]
    InputNames: {'input_1'}
    OutputNames: {'Sound'}
```

View the network architecture using the `Layers` property. The network has 86 layers. There are 28 layers with learnable weights: 27 convolutional layers, and 1 fully connected layer.

```
net.Layers

ans =
  86x1 Layer array with layers:

   1  'input_1'           Image Input           96x64x1 images
   2  'conv2d'           Convolution           32 3x3x1 convolutions with stride
   3  'b'                 Batch Normalization  Batch normalization with 32 channels

78	'L131'	Batch Normalization	Batch normalization with 1024 channels
79	'activation_25'	ReLU	ReLU
80	'conv2d_13'	Convolution	1024 1x1x1024 convolutions with stride 1
81	'L132'	Batch Normalization	Batch normalization with 1024 channels
82	'activation_26'	ReLU	ReLU
83	'global_average_pooling2d'	Global Average Pooling	Global average pooling
84	'dense'	Fully Connected	521 fully connected layer
85	'softmax'	Softmax	softmax
86	'Sound'	Classification Output	crossentropyex with 'Speech' and 'Sound'

To view the names of the classes learned by the network, you can view the `Classes` property of the classification output layer (the final layer). View the first 10 classes by specifying the first 10 elements.

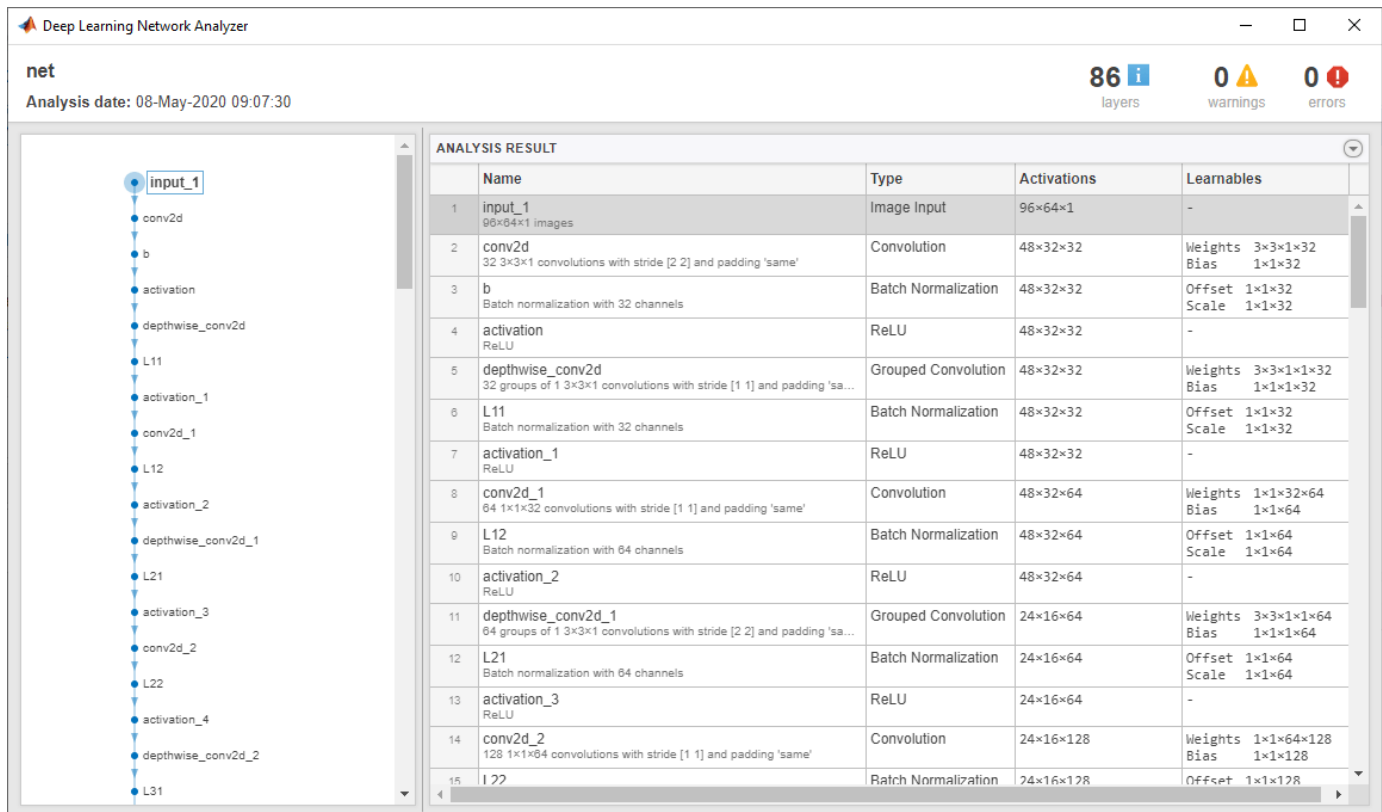

```
net.Layers(end).Classes(1:10)
```

```
ans = 10x1 categorical
    Speech
    Child speech, kid speaking
```

Conversation  
 Narration, monologue  
 Babbling  
 Speech synthesizer  
 Shout  
 Bellow  
 Whoop  
 Yell

Use analyzeNetwork to visually explore the network.

```
analyzeNetwork(net)
```

YAMNet was released with a corresponding sound class ontology, which you can explore using the `yamnetGraph` (Audio Toolbox) object.

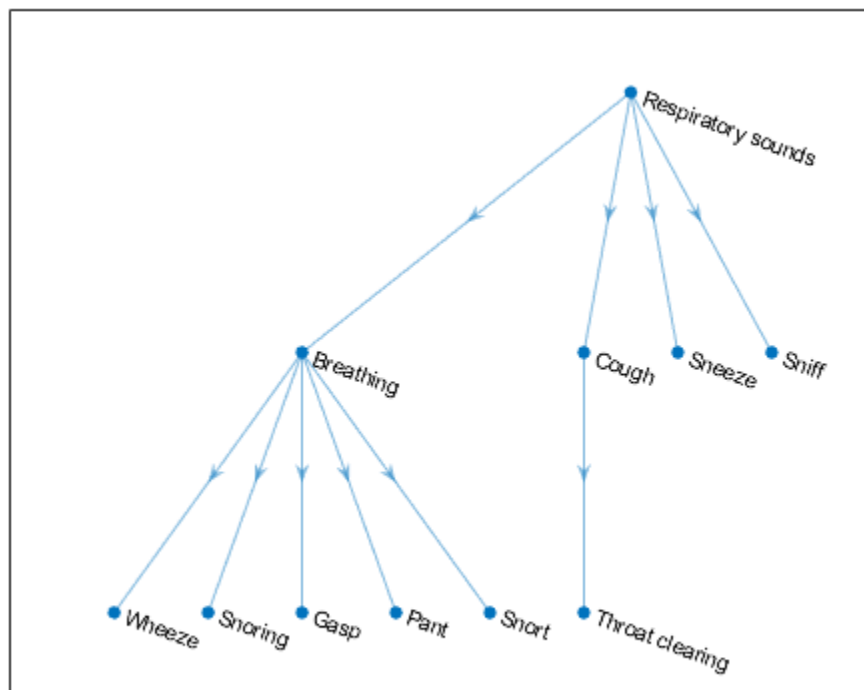

```
ygraph = yamnetGraph;  
p = plot(ygraph);  
layout(p, 'layered')
```

The ontology graph plots all 521 possible sound classes. Plot a subgraph of the sounds related to respiratory sounds.

```
allRespiratorySounds = dfsearch(ygraph, "Respiratory sounds");  
ygraphSpeech = subgraph(ygraph, allRespiratorySounds);  
plot(ygraphSpeech)
```

### Classify Sounds Using YAMNet

Read in an audio signal to classify it.

```
[audioIn,fs] = audioread(TrainWhistle-16-44...);
```

Plot and listen to the audio signal.

```
t = (0:numel(audioIn)-1)/fs;  
plot(t,audioIn)  
xlabel("Time (s)")  
ylabel("Amplitude")  
axis tight
```

```
% To play the sound, call soundsc(audioIn,fs)
```

YAMNet requires you to preprocess the audio signal to match the input format used to train the network. The preprocessing steps include resampling the audio signal and computing an array of mel spectrograms. To learn more about mel spectrograms, see `melSpectrogram` (Audio Toolbox). Use `yamnetPreprocess` to preprocess the signal and extract the mel spectrograms to be passed to YAMNet. Visualize one of these spectrograms chosen at random.

```
spectrograms = yamnetPreprocess(audioIn,fs);  
  
arbitrarySpect = spectrograms(:,:,1,randi(size(spectrograms,4)));  
surf(arbitrarySpect,EdgeColor="none")  
view([90 -90])  
xlabel("Mel Band")  
ylabel("Frame")  
title("Mel Spectrogram for YAMNet")  
axis tight
```

Create a YAMNet neural network. Using the `yamnet` function requires installing the pretrained YAMNet network. If the network is not installed, the function provides a link to download the pretrained model. Call `classify` with the network on the preprocessed mel spectrogram images.

```
net = yamnet;  
classes = classify(net,spectrograms);
```

Calling `classify` returns a label for each of the spectrogram images in the input. Classify the sound as the most frequently occurring label in the output of `classify`.

```
mySound = mode(classes)  
  
mySound = categorical  
Whistle
```

## Transfer Learning Using YAMNet

Download and unzip the air compressor data set [1] on page 1-2022. This data set consists of recordings from air compressors in a healthy state or one of 7 faulty states.

```
url = 'https://www.mathworks.com/supportfiles/audio/AirCompressorDataset/AirCompressorDataset.zip';
downloadFolder = fullfile(tempdir,'aircompressordataset');
datasetLocation = tempdir;

if ~exist(fullfile(tempdir,'AirCompressorDataSet'),'dir')
    loc = websave(downloadFolder,url);
    unzip(loc,fullfile(tempdir,'AirCompressorDataSet'))
end
```

Create an `audioDatastore` (Audio Toolbox) object to manage the data and split it into train and validation sets.

```
ads = audioDatastore(downloadFolder,'IncludeSubfolders',true,'LabelSource','foldernames');

[adsTrain,adsValidation] = splitEachLabel(ads,0.8,0.2);
```

Read an audio file from the datastore and save the sample rate for later use. Reset the datastore to return the read pointer to the beginning of the data set. Listen to the audio signal and plot the signal in the time domain.

```
[x,fileInfo] = read(adsTrain);
fs = fileInfo.SampleRate;

reset(adsTrain)

sound(x,fs)

figure
t = (0:size(x,1)-1)/fs;
plot(t,x)
xlabel('Time (s)')
title('State = ' + string(fileInfo.Label))
axis tight
```

Extract Mel spectrograms from the train set using `yamnetPreprocess`. There are multiple spectrograms for each audio signal. Replicate the labels so that they are in one-to-one correspondence with the spectrograms.

```
emptyLabelVector = adsTrain.Labels;
emptyLabelVector(:) = [];

trainFeatures = [];
trainLabels = emptyLabelVector;
while hasdata(adsTrain)
    [audioIn,fileInfo] = read(adsTrain);
    features = yamnetPreprocess(audioIn,fileInfo.SampleRate);
    numSpectrums = size(features,4);
    trainFeatures = cat(4,trainFeatures,features);
    trainLabels = cat(2,trainLabels, repmat(fileInfo.Label,1,numSpectrums));
end
```

Extract features from the validation set and replicate the labels.

```
validationFeatures = [];
validationLabels = emptyLabelVector;
while hasdata(adsValidation)
    [audioIn,fileInfo] = read(adsValidation);
    features = yamnetPreprocess(audioIn,fileInfo.SampleRate);
    numSpectrums = size(features,4);
    validationFeatures = cat(4,validationFeatures,features);
    validationLabels = cat(2,validationLabels, repmat(fileInfo.Label,1,numSpectrums));
end
```

The air compressor data set has only eight classes.

Read in YAMNet and convert it to a `layerGraph`.

If YAMNet pretrained network is not installed on your machine, execute the following commands to download and unzip the YAMNet model to your temporary directory.

```
downloadFolder = fullfile(tempdir, 'YAMNetDownload');
loc = websave(downloadFolder, 'https://ssd.mathworks.com/supportfiles/audio/yamnet.zip');
YAMNetLocation = tempdir;
unzip(loc, YAMNetLocation)
addpath(fullfile(YAMNetLocation, 'yamnet'))
```

After you read in YAMNet and convert it to a `layerGraph`, replace the final `fullyConnectedLayer` and the final `classificationLayer` to reflect the new task.

```
uniqueLabels = unique(adsTrain.Labels);
numLabels = numel(uniqueLabels);

net = yamnet;

lgraph = layerGraph(net.Layers);

newDenseLayer = fullyConnectedLayer(numLabels, "Name", "dense");
lgraph = replaceLayer(lgraph, "dense", newDenseLayer);

newClassificationLayer = classificationLayer("Name", "Sounds", "Classes", uniqueLabels);
lgraph = replaceLayer(lgraph, "Sound", newClassificationLayer);
```

To define training options, use `trainingOptions`.

```
miniBatchSize = 128;
validationFrequency = floor(numel(trainLabels)/miniBatchSize);
options = trainingOptions('adam', ...
    'InitialLearnRate', 3e-4, ...
    'MaxEpochs', 2, ...
    'MiniBatchSize', miniBatchSize, ...
    'Shuffle', 'every-epoch', ...
    'Plots', 'training-progress', ...
    'Verbose', false, ...
    'ValidationData', {single(validationFeatures), validationLabels}, ...
    'ValidationFrequency', validationFrequency);
```

To train the network, use `trainNetwork`.

```
airCompressorNet = trainNetwork(trainFeatures, trainLabels, lgraph, options);
```

Save the trained network to `airCompressorNet.mat`. You can now use this pre-trained network by loading the `airCompressorNet.mat` file.

```
save airCompressorNet.mat airCompressorNet
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `activations` and `predict` object functions are supported.
- To create a `SeriesNetwork` object for code generation, see "Load Pretrained Networks for Code Generation" (MATLAB Coder).

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- Only the `activations`, `classify`, `predict`, `predictAndUpdateState`, and `resetState` object functions are supported.
- To create a `SeriesNetwork` object for code generation, see "Load Pretrained Networks for Code Generation" (GPU Coder).

# Approximation, Clustering, and Control Functions

---

# adapt

Adapt neural network to data as it is simulated

## Syntax

```
[net,Y,E,Pf,Af,tr] = adapt(net,P,T,Pi,Ai)
```

## To Get Help

Type `help network/adapt`.

## Description

This function calculates network outputs and errors after each presentation of an input.

`[net,Y,E,Pf,Af,tr] = adapt(net,P,T,Pi,Ai)` takes

<code>net</code>	Network
<code>P</code>	Network inputs
<code>T</code>	Network targets (default = zeros)
<code>Pi</code>	Initial input delay conditions (default = zeros)
<code>Ai</code>	Initial layer delay conditions (default = zeros)

and returns the following after applying the adapt function `net.adaptFcn` with the adaption parameters `net.adaptParam`:

<code>net</code>	Updated network
<code>Y</code>	Network outputs
<code>E</code>	Network errors
<code>Pf</code>	Final input delay conditions
<code>Af</code>	Final layer delay conditions
<code>tr</code>	Training record (epoch and perf)

Note that `T` is optional and is only needed for networks that require targets. `Pi` and `Pf` are also optional and only need to be used for networks that have input or layer delays.

`adapt`'s signal arguments can have two formats: cell array or matrix.

The cell array format is easiest to describe. It is most convenient for networks with multiple inputs and outputs, and allows sequences of inputs to be presented,

<code>P</code>	<code>Ni-by-TS</code> cell array	Each element <code>P{i,ts}</code> is an <code>Ri-by-Q</code> matrix.
<code>T</code>	<code>Nt-by-TS</code> cell array	Each element <code>T{i,ts}</code> is a <code>Vi-by-Q</code> matrix.

$P_i$	$N_i$ -by-ID cell array	Each element $P_i\{i, k\}$ is an $R_i$ -by- $Q$ matrix.
$A_i$	$N_L$ -by-LD cell array	Each element $A_i\{i, k\}$ is an $S_i$ -by- $Q$ matrix.
$Y$	$N_o$ -by-TS cell array	Each element $Y\{i, ts\}$ is a $U_i$ -by- $Q$ matrix.
$E$	$N_o$ -by-TS cell array	Each element $E\{i, ts\}$ is a $U_i$ -by- $Q$ matrix.
$P_f$	$N_i$ -by-ID cell array	Each element $P_f\{i, k\}$ is an $R_i$ -by- $Q$ matrix.
$A_f$	$N_L$ -by-LD cell array	Each element $A_f\{i, k\}$ is an $S_i$ -by- $Q$ matrix.

where

$N_i$	=	<code>net.numInputs</code>
$N_L$	=	<code>net.numLayers</code>
$N_o$	=	<code>net.numOutputs</code>
ID	=	<code>net.numInputDelays</code>
LD	=	<code>net.numLayerDelays</code>
TS	=	Number of time steps
$Q$	=	Batch size
$R_i$	=	<code>net.inputs{i}.size</code>
$S_i$	=	<code>net.layers{i}.size</code>
$U_i$	=	<code>net.outputs{i}.size</code>

The columns of  $P_i$ ,  $P_f$ ,  $A_i$ , and  $A_f$  are ordered from oldest delay condition to most recent:

$P_i\{i, k\}$	=	Input $i$ at time $ts = k - ID$
$P_f\{i, k\}$	=	Input $i$ at time $ts = TS + k - ID$
$A_i\{i, k\}$	=	Layer output $i$ at time $ts = k - LD$
$A_f\{i, k\}$	=	Layer output $i$ at time $ts = TS + k - LD$

The matrix format can be used if only one time step is to be simulated ( $TS = 1$ ). It is convenient for networks with only one input and output, but can be used with networks that have more.

Each matrix argument is found by storing the elements of the corresponding cell array argument in a single matrix:

$P$	(sum of $R_i$ )-by- $Q$ matrix
$T$	(sum of $V_i$ )-by- $Q$ matrix
$P_i$	(sum of $R_i$ )-by-( $ID*Q$ ) matrix
$A_i$	(sum of $S_i$ )-by-( $LD*Q$ ) matrix
$Y$	(sum of $U_i$ )-by- $Q$ matrix
$E$	(sum of $U_i$ )-by- $Q$ matrix

Pf	(sum of Ri)-by-(ID*Q) matrix
Af	(sum of Si)-by-(LD*Q) matrix

## Examples

Here two sequences of 12 steps (where T1 is known to depend on P1) are used to define the operation of a filter.

```
p1 = {-1 0 1 0 1 1 -1 0 -1 1 0 1};
t1 = {-1 -1 1 1 1 2 0 -1 -1 0 1 1};
```

Here `linearlayer` is used to create a layer with an input range of `[-1 1]`, one neuron, input delays of 0 and 1, and a learning rate of 0.1. The linear layer is then simulated.

```
net = linearlayer([0 1],0.1);
```

Here the network adapts for one pass through the sequence.

The network's mean squared error is displayed. (Because this is the first call to `adapt`, the default `Pi` is used.)

```
[net,y,e,pf] = adapt(net,p1,t1);
mse(e)
```

Note that the errors are quite large. Here the network adapts to another 12 time steps (using the previous Pf as the new initial delay conditions).

```
p2 = {1 -1 -1 1 1 -1 0 0 0 1 -1 -1};
t2 = {2 0 -2 0 2 0 -1 0 0 1 0 -1};
[net,y,e,pf] = adapt(net,p2,t2,pf);
mse(e)
```

Here the network adapts for 100 passes through the entire sequence.

```
p3 = [p1 p2];
t3 = [t1 t2];
for i = 1:100
    [net,y,e] = adapt(net,p3,t3);
end
mse(e)
```

The error after 100 passes through the sequence is very small. The network has adapted to the relationship between the input and target signals.

## Algorithms

`adapt` calls the function indicated by `net.adaptFcn`, using the adaption parameter values indicated by `net.adaptParam`.

Given an input sequence with `TS` steps, the network is updated as follows: Each step in the sequence of inputs is presented to the network one at a time. The network's weight and bias values are updated after each step, before the next step in the sequence is presented. Thus the network is updated `TS` times.

## **Version History**

Introduced before R2006a

### **See Also**

sim | init | train | revert

## adaptwb

Adapt network with weight and bias learning rules

### Syntax

```
[net,ar,Ac] = adapt(net,Pd,T,Ai)
```

### Description

This function is normally not called directly, but instead called indirectly through the function `adapt` after setting a network's adaption function (`net.adaptFcn`) to this function.

`[net,ar,Ac] = adapt(net,Pd,T,Ai)` takes these arguments,

net	Neural network
Pd	Delayed processed input states and inputs
T	Targets
Ai	Initial layer delay states

and returns

net	Neural network after adaption
ar	Adaption record
Ac	Combined initial layer states and layer outputs

### Examples

Linear layers use this adaption function. Here a linear layer with input delays of 0 and 1, and a learning rate of 0.5, is created and adapted to produce some target data `t` when given some input data `x`. The response is then plotted, showing the network's error going down over time.

```
x = {-1 0 1 0 1 1 -1 0 -1 1 0 1};
t = {-1 -1 1 1 1 2 0 -1 -1 0 1 1};
net = linearlayer([0 1],0.5);
net.adaptFcn
[net,y,e,xf] = adapt(net,x,t);
plotresponse(t,y)
```

## Version History

Introduced in R2010b

### See Also

`adapt`

## adddelay

Add delay to neural network response

### Syntax

```
net = adddelay(net,n)
```

### Description

`net = adddelay(net,n)` takes these arguments,

net	Neural network
n	Number of delays

and returns the network with input delay connections increased, and output feedback delays decreased, by the specified number of delays `n`. The result is a network that behaves identically, except that outputs are produced `n` timesteps later.

If the number of delays `n` is not specified, a default of one delay is used.

## Examples

### Remove and Add Delay to Network

This example shows how to create, train, and simulate a time delay network in its original form, on an input time series `X` and target series `T`. Then the delay is removed and later added back. The first and third outputs will be identical, while the second result will include a new prediction for the following step.

#### Time Delay

```
[X,T] = simpleseries_dataset;  
net1 = timedelaynet(1:2,20);  
[Xs,Xi,Ai,Ts] = preparets(net1,X,T);  
net1 = train(net1,Xs,Ts,Xi);
```

## boxdist

Distance between two position vectors

### Syntax

```
d = boxdist(pos)
```

### Description

`boxdist` is a layer distance function that is used to find the distances between the layer's neurons, given their positions.

`d = boxdist(pos)` takes one argument,

<code>pos</code>	N-by-S matrix of neuron positions
------------------	-----------------------------------

and returns the S-by-S matrix of distances.

`boxdist` is most commonly used with layers whose topology function is `gridtop`.

### Examples

Here you define a random matrix of positions for 10 neurons arranged in three-dimensional space and then find their distances.

```
pos = rand(3,10);  
d = boxdist(pos)
```

### Network Use

To change a network so that a layer's topology uses `boxdist`, set `net.layers{i}.distanceFcn` to `'boxdist'`.

In either case, call `sim` to simulate the network with `boxdist`.

### Algorithms

The box distance  $D$  between two position vectors  $P_i$  and  $P_j$  from a set of  $S$  vectors is

$$D_{ij} = \max(\text{abs}(P_i - P_j))$$

## Version History

Introduced before R2006a

### See Also

`dist` | `linkdist` | `mandist` | `sim`

## bttderiv

Backpropagation through time derivative function

### Syntax

```
bttderiv('dperf_dwb',net,X,T,Xi,Ai,EW)
bttderiv('de_dwb',net,X,T,Xi,Ai,EW)
```

### Description

This function calculates derivatives using the chain rule from a network's performance back through the network, and in the case of dynamic networks, back through time.

`bttderiv('dperf_dwb',net,X,T,Xi,Ai,EW)` takes these arguments,

<code>net</code>	Neural network
<code>X</code>	Inputs, an $R \times Q$ matrix (or $N \times TS$ cell array of $R \times Q$ matrices)
<code>T</code>	Targets, an $S \times Q$ matrix (or $M \times TS$ cell array of $S \times Q$ matrices)
<code>Xi</code>	Initial input delay states (optional)
<code>Ai</code>	Initial layer delay states (optional)
<code>EW</code>	Error weights (optional)

and returns the gradient of performance with respect to the network's weights and biases, where  $R$  and  $S$  are the number of input and output elements and  $Q$  is the number of samples (and  $N$  and  $M$  are the number of input and output signals,  $R_i$  and  $S_i$  are the number of each input and outputs elements, and  $TS$  is the number of timesteps).

`bttderiv('de_dwb',net,X,T,Xi,Ai,EW)` returns the Jacobian of errors with respect to the network's weights and biases.

### Examples

Here a feedforward network is trained and both the gradient and Jacobian are calculated.

```
[x,t] = simplefit_dataset;
net = feedforwardnet(20);
net = train(net,x,t);
y = net(x);
perf = perform(net,t,y);
gwb = bttderiv('dperf_dwb',net,x,t)
jwb = bttderiv('de_dwb',net,x,t)
```

# cascadeforwardnet

Generate cascade-forward neural network

## Syntax

```
net = cascadeforwardnet(hiddenSizes,trainFcn)
```

## Description

`net = cascadeforwardnet(hiddenSizes,trainFcn)` returns a cascade-forward neural network with a hidden layer size of `hiddenSizes` and training function, specified by `trainFcn`.

Cascade-forward networks are similar to feed-forward networks, but include a connection from the input and every previous layer to following layers.

As with feed-forward networks, a two-or more layer cascade-network can learn any finite input-output relationship arbitrarily well given enough hidden neurons.

## Examples

### Construct and Train a Cascade-Forward Neural Network

This example shows how to use a cascade-forward neural network to solve a simple problem.

Load the training data.

```
[x,t] = simplefit_dataset;
```

The 1-by-94 matrix `x` contains the input values and the 1-by-94 matrix `t` contains the associated target output values.

Construct a cascade-forward network with one hidden layer of size 10.

```
net = cascadeforwardnet(10);
```

Train the network `net` using the training data.

```
net = train(net,x,t);
```

Network Diagram

View the trained network.

`view(net)`

Estimate the targets using the trained network.

```
y = net(x);
```

Assess the performance of the trained network. The default performance function is mean squared error.

```
perf = perform(net,y,t)
```

```
perf = 1.9372e-05
```

## Input Arguments

### hiddenSizes — Size of the hidden layers

10 (default) | row vector

Size of the hidden layers in the network, specified as a row vector. The length of the vector determines the number of hidden layers in the network.

Example: For example, you can specify a network with 3 hidden layers, where the first hidden layer size is 10, the second is 8, and the third is 5 as follows: [10,8,5]

The input and output sizes are set to zero. The software adjusts the sizes of these during training according to the training data.

Data Types: single | double

**trainFcn — Training function name**

'trainlm' (default) | 'trainbr' | 'trainbfg' | 'trainrp' | 'trainscg' | ...

Training function name, specified as one of the following.

Training Function	Algorithm
'trainlm'	Levenberg-Marquardt
'trainbr'	Bayesian Regularization
'trainbfg'	BFGS Quasi-Newton
'trainrp'	Resilient Backpropagation
'trainscg'	Scaled Conjugate Gradient
'traincgb'	Conjugate Gradient with Powell/Beale Restarts
'traincgf'	Fletcher-Powell Conjugate Gradient
'traincgp'	Polak-Ribière Conjugate Gradient
'trainoss'	One Step Secant
'traingdx'	Variable Learning Rate Gradient Descent
'traingdm'	Gradient Descent with Momentum
'traingd'	Gradient Descent

Example: For example, you can specify the variable learning rate gradient descent algorithm as the training algorithm as follows: 'traingdx'

For more information on the training functions, see “Train and Apply Multilayer Shallow Neural Networks” and “Choose a Multilayer Neural Network Training Function”.

Data Types: char

**Output Arguments**

**net — Cascade-forward network**

network object

Cascade-forward neural network, returned as a network object.

**Version History**

Introduced in R2010b

## catelements

Concatenate neural network data elements

### Syntax

```
catelements(x1,x2,...,xn)  
[x1; x2; ... xn]
```

### Description

`catelements(x1,x2,...,xn)` takes any number of neural network data values, and merges them along the element dimension (i.e., the matrix row dimension).

If all arguments are matrices, this operation is the same as `[x1; x2; ... xn]`.

If any argument is a cell array, then all non-cell array arguments are enclosed in cell arrays, and then the matrices in the same positions in each argument are concatenated.

### Examples

This code concatenates the elements of two matrix data values.

```
x1 = [1 2 3; 4 7 4]  
x2 = [5 8 2; 4 7 6; 2 9 1]  
y = catelements(x1,x2)
```

This code concatenates the elements of two cell array data values.

```
x1 = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}  
x2 = {[2 1 3] [4 5 6]; [2 5 4] [9 7 5]}  
y = catelements(x1,x2)
```

## Version History

**Introduced in R2010b**

### See Also

`nndata` | `numelements` | `getelements` | `setelements` | `catsignals` | `catsamples` | `cattimesteps`

# catsamples

Concatenate neural network data samples

## Syntax

```
catsamples(x1,x2,...,xn)
[x1 x2 ... xn]
catsamples(x1,x2,...,xn,'pad',v)
```

## Description

`catsamples(x1,x2,...,xn)` takes any number of neural network data values, and merges them along the samples dimension (i.e., the matrix column dimension).

If all arguments are matrices, this operation is the same as `[x1 x2 ... xn]`.

If any argument is a cell array, then all non-cell array arguments are enclosed in cell arrays, and then the matrices in the same positions in each argument are concatenated.

`catsamples(x1,x2,...,xn,'pad',v)` allows samples with varying numbers of timesteps (columns of cell arrays) to be concatenated by padding the shorter time series with the value `v`, until they are the same length as the longest series. If `v` is not specified, then the value `NaN` is used, which is often used to represent unknown or don't-care inputs or targets.

## Examples

This code concatenates the samples of two matrix data values.

```
x1 = [1 2 3; 4 7 4]
x2 = [5 8 2; 4 7 6]
y = catsamples(x1,x2)
```

This code concatenates the samples of two cell array data values.

```
x1 = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
x2 = {[2 1 3; 5 4 1] [4 5 6; 9 4 8]; [2 5 4] [9 7 5]}
y = catsamples(x1,x2)
```

Here the samples of two cell array data values, with unequal numbers of timesteps, are concatenated.

```
x1 = {1 2 3 4 5};
x2 = {10 11 12};
y = catsamples(x1,x2,'pad')
```

## Version History

# catsignals

Concatenate neural network data signals

## Syntax

```
catsignals(x1,x2,...,xn)  
{x1; x2; ...; xn}
```

## Description

`catsignals(x1,x2,...,xn)` takes any number of neural network data values, and merges them along the element dimension (i.e., the cell row dimension).

If all arguments are matrices, this operation is the same as `{x1; x2; ...; xn}`.

If any argument is a cell array, then all non-cell array arguments are enclosed in cell arrays, and the cell arrays are concatenated as `[x1; x2; ...; xn]`.

## Examples

This code concatenates the signals of two matrix data values.

```
x1 = [1 2 3; 4 7 4]  
x2 = [5 8 2; 4 7 6]  
y = catsignals(x1,x2)
```

This code concatenates the signals of two cell array data values.

```
x1 = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}  
x2 = {[2 1 3; 5 4 1] [4 5 6; 9 4 8]; [2 5 4] [9 7 5]}  
y = catsignals(x1,x2)
```

## Version History

## cattimesteps

Concatenate neural network data timesteps

### Syntax

```
cattimesteps(x1,x2,...,xn)  
{x1 x2 ... xn}
```

### Description

`cattimesteps(x1,x2,...,xn)` takes any number of neural network data values, and merges them along the element dimension (i.e., the cell column dimension).

If all arguments are matrices, this operation is the same as `{x1 x2 ... xn}`.

If any argument is a cell array, all non-cell array arguments are enclosed in cell arrays, and the cell arrays are concatenated as `[x1 x2 ... xn]`.

### Examples

This code concatenates the elements of two matrix data values.

```
x1 = [1 2 3; 4 7 4]  
x2 = [5 8 2; 4 7 6]  
y = cattimesteps(x1,x2)
```

This code concatenates the elements of two cell array data values.

```
x1 = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}  
x2 = {[2 1 3; 5 4 1] [4 5 6; 9 4 8]; [2 5 4] [9 7 5]}  
y = cattimesteps(x1,x2)
```

## Version History

**Introduced in R2010b**

# cellmat

Create cell array of matrices

## Syntax

```
cellmat(A,B,C,D,v)
```

## Description

`cellmat(A,B,C,D,v)` takes four integer values and one scalar value `v`, and returns an `A`-by-`B` cell array of `C`-by-`D` matrices of value `v`. If the value `v` is not specified, zero is used.

## Examples

Here two cell arrays of matrices are created.

```
cm1 = cellmat(2,3,5,4)
cm2 = cellmat(3,4,2,2,pi)
```

## Version History

**Introduced in R2010b**

`nndata`

## closeloop

Convert neural network open-loop feedback to closed loop

### Syntax

```
net = closeloop(net)
[net,xi,ai] = closeloop(net,xi,ai)
```

### Description

`net = closeloop(net)` takes a neural network and closes any open-loop feedback. For each feedback output `i` whose property `net.outputs{i}.feedbackMode` is 'open', it replaces its associated feedback input and their input weights with layer weight connections coming from the output. The `net.outputs{i}.feedbackMode` property is set to 'closed', and the `net.outputs{i}.feedbackInput` property is set to an empty matrix. Finally, the value of `net.outputs{i}.feedbackDelays` is added to the delays of the feedback layer weights (i.e., to the delays values of the replaced input weights).

`[net,xi,ai] = closeloop(net,xi,ai)` converts an open-loop network and its current input delay states `xi` and layer delay states `ai` to closed-loop form.

### Examples

#### Convert NARX Network to Closed-Loop Form

This example shows how to design a NARX network in open-loop form, then convert it to closed-loop form.

```
[X,T] = simplenarx_dataset;
net = narxnet(1:2,1:2,10);
[Xs,Xi,Ai,Ts] = preparets(net,X,{},T);
net = train(net,Xs,Ts,Xi,Ai);
```

## combvec

Create all combinations of vectors

### Syntax

```
A = combvec(A1,A2,...)
```

### Description

`A = combvec(A1,A2,...)` takes any number of inputs `A`, where each input `Ai` has `Ni` columns, and returns a matrix of  $(N_1*N_2*...)$  column vectors, where the columns consist of all combinations found by combining one column vector from each input `Ai`.

### Examples

#### Generate All Combinations of Vectors Using the combvec Function

This example shows how to generate a matrix that contains all combinations of two matrices, `a1` and `a2`.

Create the two input matrices, `a1` and `a2`. Then call the `combvec` function to generate all possible combinations.

```
a1 = [1 2 3; 4 5 6];  
a2 = [7 8; 9 10];  
a3 = combvec(a1,a2)
```

```
a3 =
```

```
     1     2     3     1     2     3  
     4     5     6     4     5     6  
     7     7     7     8     8     8  
     9     9     9    10    10    10
```

### Input Arguments

#### A1 — Input matrix 1

matrix

Input matrix of which you want to calculate all combinations, specified as a matrix with `N1` column vectors.

#### A2 — Input matrix 2

matrix

Input matrix of which you want to calculate all combinations, specified as a matrix with `N2` column vectors.

## Output Arguments

### **A — Output matrix**

matrix

Output matrix, returned as a matrix of  $(N1*N2*...)$  column vectors, where the columns consist of all combinations found by combining one column vector from each input  $A_i$ .

## Version History

Introduced before R2006a

## compet

Competitive transfer function

### Graph and Symbol

### Syntax

```
A = compet(N,FP)
info = compet('code')
```

### Description

`compet` is a neural transfer function. Transfer functions calculate a layer's output from its net input.

$A = \text{compet}(N, FP)$  takes  $N$  and optional function parameters,

$N$	S-by-Q matrix of net input (column) vectors
$FP$	Struct of function parameters (ignored)

and returns the S-by-Q matrix  $A$  with a 1 in each column where the same column of  $N$  has its maximum value, and 0 elsewhere.

`info = compet('code')` returns information according to the code string specified:

`compet('name')` returns the name of this function.

`compet('output',FP)` returns the [min max] output range.

`compet('active',FP)` returns the [min max] active input range.

`compet('fullderiv')` returns 1 or 0, depending on whether  $dA_{dN}$  is S-by-S-by-Q or S-by-Q.

`compet('fpnames')` returns the names of the function parameters.

`compet('fpdefaults')` returns the default function parameters.

### Examples

Here you define a net input vector  $N$ , calculate the output, and plot both with bar graphs.

```
n = [0; 1; -0.5; 0.5];
a = compet(n);
```

```
subplot(2,1,1), bar(n), ylabel('n')  
subplot(2,1,2), bar(a), ylabel('a')
```

Assign this transfer function to layer *i* of a network.

```
net.layers{i}.transferFcn = 'compet';
```

## Version History

Introduced before R2006a

### See Also

[sim](#) | [softmax](#)

## competlayer

Competitive layer

### Syntax

```
competlayer(numClasses, kohonenLR, conscienceLR)
```

### Description

Competitive layers learn to classify input vectors into a given number of classes, according to similarity between vectors, with a preference for equal numbers of vectors per class.

`competlayer(numClasses, kohonenLR, conscienceLR)` takes these arguments,

<code>numClasses</code>	Number of classes to classify inputs (default = 5)
<code>kohonenLR</code>	Learning rate for Kohonen weights (default = 0.01)
<code>conscienceLR</code>	Learning rate for conscience bias (default = 0.001)

and returns a competitive layer with `numClasses` neurons.

### Examples

#### Create and Train a Competitive Layer

This example shows how to train a competitive layer to classify 150 iris flowers into 6 classes.

```
inputs = iris_dataset;  
net = competlayer(6);  
net = train(net, inputs);
```

Network Diagram

## con2seq

Convert concurrent vectors to sequential vectors

### Syntax

```
S = con2seq(b)
S = con2seq(b,TS)
```

### Description

Deep Learning Toolbox software arranges concurrent vectors with a matrix, and sequential vectors with a cell array (where the second index is the time step).

con2seq and seq2con allow concurrent vectors to be converted to sequential vectors, and back again.

`S = con2seq(b)` takes one input,

b	R-by-TS matrix
---	----------------

and returns one output,

S	1-by-TS cell array of R-by-1 vectors
---	--------------------------------------

`S = con2seq(b,TS)` can also convert multiple batches,

b	N-by-1 cell array of matrices with M*TS columns
TS	Time steps

and returns

S	N-by-TS cell array of matrices with M columns
---	---

### Examples

Here a batch of three values is converted to a sequence.

```
p1 = [1 4 2]
p2 = con2seq(p1)
```

Here, two batches of vectors are converted to two sequences with two time steps.

```
p1 = {[1 3 4 5; 1 1 7 4]; [7 3 4 4; 6 9 4 1]}
p2 = con2seq(p1,2)
```

### Version History

Introduced before R2006a

**See Also**

seq2con | concur

## concur

Create concurrent bias vectors

### Syntax

```
concur(B,Q)
```

### Description

```
concur(B,Q)
```

B	S-by-1 bias vector (or an N1-by-1 cell array of vectors)
Q	Concurrent size

and returns an S-by-B matrix of copies of B (or an N1-by-1 cell array of matrices).

### Examples

Here `concur` creates three copies of a bias vector.

```
b = [1; 3; 2; -1];
concur(b,3)
```

### Network Use

To calculate a layer's net input, the layer's weighted inputs must be combined with its biases. The following expression calculates the net input for a layer with the `netsum` net input function, two input weights, and a bias:

```
n = netsum(z1,z2,b)
```

The above expression works if `Z1`, `Z2`, and `B` are all S-by-1 vectors. However, if the network is being simulated by `sim` (or `adapt` or `train`) in response to `Q` concurrent vectors, then `Z1` and `Z2` will be S-by-Q matrices. Before `B` can be combined with `Z1` and `Z2`, you must make `Q` copies of it.

```
n = netsum(z1,z2,concur(b,q))
```

## Version History

Introduced before R2006a

### See Also

`con2seq` | `netprod` | `netsum` | `seq2con` | `sim`

## configure

Configure network inputs and outputs to best match input and target data

### Syntax

```
net = configure(net,x,t)
net = configure(net,x)
net = configure(net,'inputs',x,i)
net = configure(net,'outputs',t,i)
```

### Description

`net = configure(net,x,t)` takes input data `x` and target data `t`, and configures the network's inputs and outputs to match.

Configuration is the process of setting network input and output sizes and ranges, input preprocessing settings and output postprocessing settings, and weight initialization settings to match input and target data.

Configuration must happen before a network's weights and biases can be initialized. Unconfigured networks are automatically configured and initialized the first time `train` is called. Alternately, a network can be configured manually either by calling this function or by setting a network's input and output sizes, ranges, processing settings, and initialization settings properties manually.

`net = configure(net,x)` configures only inputs.

`net = configure(net,'inputs',x,i)` configures the inputs specified with the index vector `i`. If `i` is not specified all inputs are configured.

`net = configure(net,'outputs',t,i)` configures the outputs specified with the index vector `i`. If `i` is not specified all targets are configured.

### Examples

#### Configure Network with configure

This example shows how to manually configure a network for a simple fitting problem instead of using the `train` function.

```
[x,t] = simplefit_dataset;
net = feedforwardnet(20);
view(net)
```

```
net = configure(net,x,t);  
view(net)
```

### Input Arguments

**net** – Network to configure

network object

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

**x** – Input data

matrix

Network inputs, specified as a matrix.

**t** – Target data

matrix

Network targets, specified as a matrix.

**i — Index vector**

vector

Indexes of the inputs or outputs you want to configure, specified as a vector.

**Output Arguments****net — Configured network**

network object

Configured network, returned as a network object.

**Version History****Introduced in R2010b****See Also**

## confusion

Classification confusion matrix

### Syntax

```
[c,cm,ind,per] = confusion(targets,outputs)
```

### Description

---

**Tip** To plot a confusion chart for a deep learning workflow, use the `confusionchart` function.

---

`[c,cm,ind,per] = confusion(targets,outputs)` takes target and output matrices, `targets` and `outputs`, and returns the confusion value, `c`, the confusion matrix, `cm`, a cell array, `ind`, that contains the sample indices of class `i` targets classified as class `j`, and a matrix of percentages, `per`, where each row summarizes four percentages associated with the `i`-th class.

### Examples

#### Generate the Confusion Matrix of the `simpleclass` Dataset Using the `confusion` Function

This example shows how to generate the confusion matrix of the `simpleclass_dataset` dataset using the `confusion` function.

Load the `simpleclass_dataset` dataset. Define a network and then train it.

```
[x,t] = simpleclass_dataset;  
net = patternnet(10);  
net = train(net,x,t);  
y = net(x);  
[c,cm,ind,per] = confusion(t,y)
```

a3 =

1	2	3	1	2	3
4	5	6	4	5	6
7	7	7	8	8	8
9	9	9	10	10	10

### Input Arguments

#### **targets** — Matrix of targets

matrix

Matrix of targets, specified as an `S`-by-`Q` matrix, where each column vector contains a single 1 value, with all other elements equal to 0. The index of the value equal to 1 indicates which of the `S` categories that vector represents.

**outputs — Matrix of outputs**

matrix

Matrix of outputs, specified as an  $S$ -by- $Q$  matrix, where each column contains values in the range  $[0, 1]$ . The index of the largest element in the column indicates which of the  $S$  categories that vector represents.

**Output Arguments****c — Confusion value**

scalar

Fraction of misclassified samples, returned as a scalar.

**cm — Confusion matrix**

matrix

Confusion matrix, returned as an  $S$ -by- $S$  confusion matrix, where  $cm(i, j)$  is the number of samples whose target is the  $i$ -th class that was classified as  $j$ .

**ind — Array of indices**

cell array

Array of indices, returned as an  $S$ -by- $S$  cell array, where  $ind\{i, j\}$  contains the indices of samples with the  $i$ -th target class, but  $j$ -th output class.

**per — Matrix of percentages**

matrix

Matrix of percentages, returned as an  $S$ -by-4 matrix, where each row summarizes four percentages associated with the  $i$ -th class:

```
per(i,1) false negative rate
         = (false negatives)/(all output negatives)
per(i,2) false positive rate
         = (false positives)/(all output positives)
per(i,3) true positive rate
         = (true positives)/(all output positives)
per(i,4) true negative rate
         = (true negatives)/(all output negatives)
```

**Version History**

Introduced in R2006a

## convwf

Convolution weight function

### Syntax

```
Z = convwf(W,P)
dim = convwf('size',S,R,FP)
dw = convwf('dw',W,P,Z,FP)
info = convwf('code')
```

### Description

Weight functions apply weights to an input to get weighted inputs.

`Z = convwf(W,P)` returns the convolution of a weight matrix `W` and an input `P`.

`dim = convwf('size',S,R,FP)` takes the layer dimension `S`, input dimension `R`, and function parameters, and returns the weight size.

`dw = convwf('dw',W,P,Z,FP)` returns the derivative of `Z` with respect to `W`.

`info = convwf('code')` returns information about this function. The following codes are defined:

'deriv'	Name of derivative function
'fullderiv'	Reduced derivative = 2, full derivative = 1, linear derivative = 0
'pfullderiv'	Input: reduced derivative = 2, full derivative = 1, linear derivative = 0
'wfullderiv'	Weight: reduced derivative = 2, full derivative = 1, linear derivative = 0
'name'	Full name
'fpnames'	Returns names of function parameters
'fpdefaults'	Returns default function parameters

### Examples

Here you define a random weight matrix `W` and input vector `P` and calculate the corresponding weighted input `Z`.

```
W = rand(4,1);
P = rand(8,1);
Z = convwf(W,P)
```

### Network Use

To change a network so an input weight uses `convwf`, set `net.inputWeights{i,j}.weightFcn` to `'convwf'`. For a layer weight, set `net.layerWeights{i,j}.weightFcn` to `'convwf'`.

In either case, call `sim` to simulate the network with `convwf`.

## **Version History**

**Introduced in R2006a**

## crossentropy

Neural network performance

### Syntax

```
perf = crossentropy(net,targets,outputs,perfWeights)
perf = crossentropy( ___,Name,Value)
```

### Description

`perf = crossentropy(net,targets,outputs,perfWeights)` calculates a network performance given targets and outputs, with optional performance weights and other parameters. The function returns a result that heavily penalizes outputs that are extremely inaccurate ( $y$  near  $1-t$ ), with very little penalty for fairly correct classifications ( $y$  near  $t$ ). Minimizing cross-entropy leads to good classifiers.

The cross-entropy for each pair of output-target elements is calculated as:  $ce = -t .* \log(y)$ .

The aggregate cross-entropy performance is the mean of the individual values:  $perf = \text{sum}(ce(:))/\text{numel}(ce)$ .

Special case ( $N = 1$ ): If an output consists of only one element, then the outputs and targets are interpreted as binary encoding. That is, there are two classes with targets of 0 and 1, whereas in 1-of- $N$  encoding, there are two or more classes. The binary cross-entropy expression is:  $ce = -t .* \log(y) - (1-t) .* \log(1-y)$ .

`perf = crossentropy( ___,Name,Value)` supports customization according to the specified name-value pair arguments.

### Examples

#### Calculate Network Performance

This example shows how to design a classification network with cross-entropy and 0.1 regularization, then calculate performance on the whole dataset.

```
[x,t] = iris_dataset;
net = patternnet(10);
net.performParam.regularization = 0.1;
net = train(net,x,t);
```

```

### **Set crossentropy as Performance Function**

This example shows how to set up the network to use the `crossentropy` during training.

```
net = feedforwardnet(10);  
net.performFcn = 'crossentropy';  
net.performParam.regularization = 0.1;  
net.performParam.normalization = 'none';
```

## **Input Arguments**

### **net — neural network**

network object

Neural network, specified as a network object.

Example: `net = feedforwardnet(10);`

### **targets — neural network target values**

matrix or cell array of numeric values

Neural network target values, specified as a matrix or cell array of numeric values. Network target values define the desired outputs, and can be specified as an  $N$ -by- $Q$  matrix of  $Q$   $N$ -element vectors, or an  $M$ -by- $TS$  cell array where each element is an  $N_i$ -by- $Q$  matrix. In each of these cases,  $N$  or  $N_i$  indicates a vector length,  $Q$  the number of samples,  $M$  the number of signals for neural networks with multiple outputs, and  $TS$  is the number of time steps for time series data. `targets` must have the same dimensions as outputs.

The target matrix columns consist of all zeros and a single 1 in the position of the class being represented by that column vector. When  $N = 1$ , the software uses cross entropy for binary encoding, otherwise it uses cross entropy for 1-of- $N$  encoding. NaN values are allowed to indicate unknown or don't-care output values. The performance of NaN target values is ignored.

Data Types: `double` | `cell`

### **outputs — neural network output values**

matrix or cell array of numeric values

Neural network output values, specified as a matrix or cell array of numeric values. Network output values can be specified as an  $N$ -by- $Q$  matrix of  $Q$   $N$ -element vectors, or an  $M$ -by- $TS$  cell array where each element is an  $N_i$ -by- $Q$  matrix. In each of these cases,  $N$  or  $N_i$  indicates a vector length,  $Q$  the number of samples,  $M$  the number of signals for neural networks with multiple outputs and  $TS$  is the number of time steps for time series data. `outputs` must have the same dimensions as `targets`.

Outputs can include NaN to indicate unknown output values, presumably produced as a result of NaN input values (also representing unknown or don't-care values). The performance of NaN output values is ignored.

General case ( $N \geq 2$ ): The columns of the output matrix represent estimates of class membership, and should sum to 1. You can use the `softmax` transfer function to produce such output values. Use `patternnet` to create networks that are already set up to use cross-entropy performance with a softmax output layer.

Data Types: `double` | `cell`

**perfWeights — performance weights**`{1}` (default) | vector or cell array of numeric values

Performance weights, specified as a vector or cell array of numeric values. Performance weights are an optional argument defining the importance of each performance value, associated with each target value, using values between 0 and 1. Performance values of 0 indicate targets to ignore, values of 1 indicate targets to be treated with normal importance. Values between 0 and 1 allow targets to be treated with relative importance.

Performance weights have many uses. They are helpful for classification problems, to indicate which classifications (or misclassifications) have relatively greater benefits (or costs). They can be useful in time series problems where obtaining a correct output on some time steps, such as the last time step, is more important than others. Performance weights can also be used to encourage a neural network to best fit samples whose targets are known most accurately, while giving less importance to targets which are known to be less accurate.

`perfWeights` can have the same dimensions as `targets` and `outputs`. Alternately, each dimension of the performance weights can either match the dimension of `targets` and `outputs`, or be 1. For instance, if `targets` is an N-by-Q matrix defining Q samples of N-element vectors, the performance weights can be N-by-Q indicating a different importance for each target value, or N-by-1 defining a different importance for each row of the targets, or 1-by-Q indicating a different importance for each sample, or be the scalar 1 (i.e. 1-by-1) indicating the same importance for all target values.

Similarly, if `outputs` and `targets` are cell arrays of matrices, the `perfWeights` can be a cell array of the same size, a row cell array (indicating the relative importance of each time step), a column cell array (indicating the relative importance of each neural network output), or a cell array of a single matrix or just the matrix (both cases indicating that all matrices have the same importance values).

For any problem, a `perfWeights` value of `{1}` (the default) or the scalar 1 indicates all performances have equal importance.

Data Types: `double` | `cell`

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'normalization', 'standard'` specifies the inputs and targets to be normalized to the range (-1,+1).

**regularization — proportion of performance attributed to weight/bias values**

0 (default) | numeric value in the range (0,1)

Proportion of performance attributed to weight/bias values, specified as a double between 0 (the default) and 1. A larger value penalizes the network for large weights, and the more likely the network function will avoid overfitting.

Example: `'regularization', 0`

Data Types: `single` | `double`

**normalization — Normalization mode for outputs, targets, and errors**`'none'` (default) | `'standard'` | `'percent'`

Normalization mode for outputs, targets, and errors, specified as 'none', 'standard', or 'percent'. 'none' performs no normalization. 'standard' results in outputs and targets being normalized to (-1, +1), and therefore errors in the range (-2, +2). 'percent' normalizes outputs and targets to (-0.5, 0.5) and errors to (-1, 1).

Example: 'normalization', 'standard'

Data Types: char

### Output Arguments

#### **perf — network performance**

double

Network performance, returned as a double in the range (0,1).

# defaultderiv

Default derivative function

## Syntax

```
defaultderiv('dperf_dwb',net,X,T,Xi,Ai,EW)
defaultderiv('de_dwb',net,X,T,Xi,Ai,EW)
```

## Description

This function chooses the recommended derivative algorithm for the type of network whose derivatives are being calculated. For static networks, `defaultderiv` calls `staticderiv`; for dynamic networks it calls `bttderiv` to calculate the gradient and `fpderiv` to calculate the Jacobian.

`defaultderiv('dperf_dwb',net,X,T,Xi,Ai,EW)` takes these arguments,

<code>net</code>	Neural network
<code>X</code>	Inputs, an R-by-Q matrix (or N-by-TS cell array of Ri-by-Q matrices)
<code>T</code>	Targets, an S-by-Q matrix (or M-by-TS cell array of Si-by-Q matrices)
<code>Xi</code>	Initial input delay states (optional)
<code>Ai</code>	Initial layer delay states (optional)
<code>EW</code>	Error weights (optional)

and returns the gradient of performance with respect to the network's weights and biases, where R and S are the number of input and output elements and Q is the number of samples (or N and M are the number of input and output signals, Ri and Si are the number of each input and outputs elements, and TS is the number of timesteps).

`defaultderiv('de_dwb',net,X,T,Xi,Ai,EW)` returns the Jacobian of errors with respect to the network's weights and biases.

## Examples

Here a feedforward network is trained and both the gradient and Jacobian are calculated.

```
[x,t] = simplefit_dataset;
net = feedforwardnet(10);
net = train(net,x,t);
y = net(x);
perf = perform(net,t,y);
dwb = defaultderiv('dperf_dwb',net,x,t)
```

## Version History

# dist

Euclidean distance weight function

## Syntax

```
Z = dist(W,P)
dim = dist('size',S,R,FP)
dw = dist('dw',W,P,Z,FP)
D = dist(pos)
info = dist(code)
```

## Description

`Z = dist(W,P)` takes an S-by-R weight matrix, `W`, and an R-by-Q matrix of Q input (column) vectors, `P`, and returns the S-by-Q matrix of vector distances, `Z`.

Weight functions apply weights to an input to get weighted inputs.

`dim = dist('size',S,R,FP)` takes the layer dimension `S`, input dimension `R`, and function parameters, `FP`, and returns the weight size [S-by-R].

`dw = dist('dw',W,P,Z,FP)` returns the derivative of `Z` with respect to `W`.

`dist` is also a layer distance function which can be used to find the distances between neurons in a layer.

`D = dist(pos)` takes N-by-S matrix of neuron positions, `pos` and returns the S-by-S matrix of distances, `D`.

`info = dist(code)` returns information about this function. For more information, see the **code** argument description.

## Examples

### Calculate the Weighted Input By Using the dist Function

This example shows how to calculate the corresponding weighted input `Z`, given a random weight matrix `W` and input vector `P`.

```
W = rand(4,3);
P = rand(3,1);
Z = dist(W,P)
```

Here you define a random matrix of positions for 10 neurons arranged in three-dimensional space and find their distances.

```
pos = rand(3,10);  
D = dist(pos)
```

## Input Arguments

### **W — Weight matrix**

matrix

Weight matrix, specified as an S-by-R matrix.

### **P — Input matrix**

matrix

Input matrix, specified as an R-by-Q matrix of Q input (column) vectors.

### **S — Layer dimension**

scalar

Layer dimension, specified as a scalar.

### **R — Input dimension**

scalar

Input dimension, specified as a scalar.

### **pos — Neuron positions**

matrix

Matrix of neuron positions, specified as an N-by-S matrix.

### **code — Information option**

'name' | 'output' | 'active' | 'fullderiv' | 'fpnames' | 'fpdefaults'

Information you want to retrieve from the function, specified as one of the following:

- 'name' returns the name of this function.
- 'deriv' returns the name of the derivative function
- 'fullderiv' returns 1 for full derivative and 0 for linear derivative.
- 'pfullderiv' returns 2 for reduced derivative, 1 for full derivative, and 0 for linear derivative.
- 'fpnames' returns the names of the function parameters.
- 'fpdefaults' returns the default function parameters.

## Output Arguments

### **Z — Vector distances**

matrix

Vector distances, returned as an S-by-Q matrix.

### **dim — Weight size**

row vector

Weight size, returned as a row vector.

**dw — Derivative of w**

cell array

Derivative of Z with respect to W, returned as a cell array.

**D — Distances**

matrix

Distances, returned as an S-by-S matrix.

**More About****Network Use**

You can create a standard network that uses `dist` by calling `newpnn` or `newgrnn`.

To change a network so an input weight uses `dist`, set `net.inputWeights{i,j}.weightFcn` to `'dist'`. For a layer weight, set `net.layerWeights{i,j}.weightFcn` to `'dist'`.

To change a network so that a layer's topology uses `dist`, set `net.layers{i}.distanceFcn` to `'dist'`.

In either case, call `sim` to simulate the network with `dist`.

See `newpnn` or `newgrnn` for simulation examples.

**Algorithms**

The Euclidean distance  $d$  between two vectors  $X$  and  $Y$  is

$$d = \text{sum}((x-y).^2).^0.5$$

**Version History**

Introduced before R2006a

**See Also**

## distdelaynet

Distributed delay network

### Syntax

```
distdelaynet(delays,hiddenSizes,trainFcn)
```

### Description

Distributed delay networks are similar to feedforward networks, except that each input and layer weights has a tap delay line associated with it. This allows the network to have a finite dynamic response to time series input data. This network is also similar to the time delay neural network (`timedelaynet`), which only has delays on the input weight.

`distdelaynet(delays,hiddenSizes,trainFcn)` takes these arguments,

<code>delays</code>	Row vector of increasing 0 or positive delays (default = 1:2)
<code>hiddenSizes</code>	Row vector of one or more hidden layer sizes (default = 10)
<code>trainFcn</code>	Training function (default = 'trainlm')

and returns a distributed delay neural network.

### Examples

#### Distributed Delay Network

This example shows how to train a distributed delay neural network to solve a simple time series problem.

```
[X,T] = simpleseries_dataset;  
net = distdelaynet({1:2,1:2},10);  
[Xs,Xi,Ai,Ts] = preparets(net,X,T);  
net = train(net,Xs,Ts,Xi,Ai);
```

## divideblock

Divide targets into three sets using blocks of indices

### Syntax

```
[trainInd,valInd,testInd] = divideblock(Q,trainRatio,valRatio,testRatio)
```

### Description

[trainInd,valInd,testInd] = divideblock(Q,trainRatio,valRatio,testRatio) separates targets into three sets: training, validation, and testing. It takes the following inputs:

Q	Number of targets to divide up.
trainRatio	Ratio of targets for training. Default = 0.7.
valRatio	Ratio of targets for validation. Default = 0.15.
testRatio	Ratio of targets for testing. Default = 0.15.

and returns

trainInd	Training indices
valInd	Validation indices
testInd	Test indices

### Examples

```
[trainInd,valInd,testInd] = divideblock(3000,0.6,0.2,0.2);
```

### Network Use

Here are the network properties that define which data division function to use, what its parameters are, and what aspects of targets are divided up, when `train` is called.

```
net.divideFcn
net.divideParam
net.divideMode
```

## Version History

Introduced in R2008a

divideind | divideint | dividerand | dividetrain

## divideind

Divide targets into three sets using specified indices

### Syntax

```
[trainInd,valInd,testInd] = divideind(Q,trainInd,valInd,testInd)
```

### Description

`[trainInd,valInd,testInd] = divideind(Q,trainInd,valInd,testInd)` separates targets into three sets: training, validation, and testing, according to indices provided. It actually returns the same indices it receives as arguments; its purpose is to allow the indices to be used for training, validation, and testing for a network to be set manually.

The indices are returned after removing any indices greater than  $Q$ . Note that some indices in the range  $1:Q$  may not be assigned to any of the three sets, and the same indices should not be used in more than one set.

### Examples

#### Divide Samples into Three Sets Using Specified Indices

This example shows how to divide samples into three sets using specified indices for a network.

Divide 20 samples into training, validation and test indices, so that only 16 are actually used.

```
[trainInd,valInd,testInd] = divideind(20,1:8,9:12,14:16)
```

This code shows you how to ensure a network performs the same kind of data division when it is trained:

```
net.divideFcn = 'divideind';  
net.divideParam.trainInd = 1:8;  
net.divideParam.valInd = 9:12;  
net.divideParam.testInd= 14:16;
```

### Input Arguments

#### **Q** — Number of targets

scalar

Number of targets to divide up, specified as a scalar.

#### **trainInd** — Training indices

vector

Training indices, specified as a 1-by- $Q$  vector.

#### **valInd** — Validation indices

vector

Validation indices, specified as a 1-by-Q vector.

**testInd — Testing indices**

vector

Testing indices, specified as a 1-by-Q vector.

**Output Arguments****trainInd — Training indices**

vector

Training indices, returned as a vector.

**valInd — Validation indices**

vector

Validation indices, returned as a vector.

**testInd — Testing indices**

vector

Testing indices, returned as a vector.

**More About****Network Use**

These are the network properties that define which data division function to use, what its parameters are, and what aspects of targets are divided up, when `train` is called.

## divideint

Divide targets into three sets using interleaved indices

### Syntax

```
[trainInd, valInd, testInd] = divideint(Q, trainRatio, valRatio, testRatio)
```

### Description

`[trainInd, valInd, testInd] = divideint(Q, trainRatio, valRatio, testRatio)` separates targets into three sets: training, validation, and testing. It takes the following inputs,

<code>Q</code>	Number of targets to divide up.
<code>trainRatio</code>	Ratio of vectors for training. Default = 0.7.
<code>valRatio</code>	Ratio of vectors for validation. Default = 0.15.
<code>testRatio</code>	Ratio of vectors for testing. Default = 0.15.

and returns

<code>trainInd</code>	Training indices
<code>valInd</code>	Validation indices
<code>testInd</code>	Test indices

### Examples

```
[trainInd, valInd, testInd] = divideint(3000, 0.6, 0.2, 0.2);
```

### Network Use

Here are the network properties that define which data division function to use, what its parameters are, and what aspects of targets are divided up, when `train` is called.

```
net.divideFcn

# dividerand

Divide targets into three sets using random indices

## Syntax

```
[trainInd,valInd,testInd] = dividerand(Q,trainRatio,valRatio,testRatio)
```

## Description

`[trainInd,valInd,testInd] = dividerand(Q,trainRatio,valRatio,testRatio)` takes the number of targets to divide up, the ratio of vectors for training, the ratio of vectors for validation, and the ratio of vectors for testing, and returns the training indices, the validation indices, and the test indices.

## Examples

### Obtain Training, Validation, and Test Indices Using 'dividerand' Function

This example shows how to obtain the training, validation, and test indices using the `dividerand` function.

Divide 3000 samples into 60% for training, 20% for validation, and 20% for testing.

```
[trainInd,valInd,testInd] = dividerand(3000,0.6,0.2,0.2)
```

## Input Arguments

### **Q** — Targets number

scalar

Number of targets to divide up, specified as a scalar.

### **trainRatio** — Training ratio

0.7 (default) | scalar

Ratio of vectors for training, specified as a scalar.

### **valRatio** — Validation ratio

0.15 (default) | scalar

Ratio of vectors for validation, specified as a scalar.

### **testRatio** — Testing ratio

0.15 (default) | scalar

Ratio of vectors for testing, specified as a scalar.

### Output Arguments

#### **trainInd** — Training indices

vector

Training indices, returned as a row vector.

#### **valInd** — Validation indices

vector

Validation indices, returned as a row vector.

#### **testInd** — Testing indices

vector

Testing indices, returned as a row vector.

### More About

#### Network Use

Here are the network properties that define which data division function to use, what its parameters are, and what aspects of targets are divided up, when `train` is called.

## dividetrain

Assign all targets to training set

### Syntax

```
[trainInd,valInd,testInd] = dividetrain(Q)
```

### Description

[trainInd,valInd,testInd] = dividetrain(Q) assigns all targets to the training set and no targets to the validation or test sets. It takes the following inputs:

Q	Number of targets to divide up.
---	---------------------------------

and returns

trainInd	Training indices equal to 1:Q
valInd	Empty validation indices, [ ]
testInd	Empty test indices, [ ]

### Examples

```
[trainInd,valInd,testInd] = dividetrain(250);
```

### Network Use

Here are the network properties that define which data division function to use, what its parameters are, and what aspects of targets are divided up, when `train` is called.

```
net.divideFcn
net.divideParam
net.divideMode
```

## Version History

**Introduced in R2010b**

## dotprod

Dot product weight function

### Syntax

```
Z = dotprod(W,P,FP)
dim = dotprod('size',S,R,FP)
dw = dotprod('dw',W,P,Z,FP)
info = dotprod('code')
```

### Description

Weight functions apply weights to an input to get weighted inputs.

$Z = \text{dotprod}(W, P, FP)$  takes these inputs,

W	S-by-R weight matrix
P	R-by-Q matrix of Q input (column) vectors
FP	Struct of function parameters (optional, ignored)

and returns the S-by-Q dot product of W and P.

$\text{dim} = \text{dotprod}('size', S, R, FP)$  takes the layer dimension S, input dimension R, and function parameters, and returns the weight size [S-by-R].

$\text{dw} = \text{dotprod}('dw', W, P, Z, FP)$  returns the derivative of Z with respect to W.

$\text{info} = \text{dotprod}('code')$  returns information about this function. The following codes are defined:

'deriv'	Name of derivative function
'pfullderiv'	Input: reduced derivative = 2, full derivative = 1, linear derivative = 0
'wfullderiv'	Weight: reduced derivative = 2, full derivative = 1, linear derivative = 0
'name'	Full name
'fpnames'	Returns names of function parameters
'fpdefaults'	Returns default function parameters

### Examples

Here you define a random weight matrix W and input vector P and calculate the corresponding weighted input Z.

```
W = rand(4,3);
P = rand(3,1);
Z = dotprod(W,P)
```

## Network Use

You can create a standard network that uses dotprod by calling `feedforwardnet`.

To change a network so an input weight uses dotprod, set `net.inputWeights{i,j}.weightFcn` to 'dotprod'. For a layer weight, set `net.layerWeights{i,j}.weightFcn` to 'dotprod'.

In either case, call `sim` to simulate the network with dotprod.

## Version History

**Introduced before R2006a**

`sim` | `dist` | `feedforwardnet` | `negdist` | `normprod`

## elliotsig

Elliot symmetric sigmoid transfer function

### Syntax

```
A = elliotsig(N)
```

### Description

Transfer functions convert a neural network layer's net input into its net output.

`A = elliotsig(N)` takes an  $S$ -by- $Q$  matrix of net input (column) vectors,  $N$ , and returns an  $S$ -by- $Q$  matrix,  $A$ , of output vectors, where each element of  $N$  is squashed from the interval  $[-\infty \infty]$  to the interval  $[-1 \ 1]$  with an "S-shaped" function.

The advantage of this transfer function over other sigmoids is that it is fast to calculate on simple computing hardware as it does not require any exponential or trigonometric functions. Its disadvantage is that it only flattens out for large inputs, so its effect is not as local as other sigmoid functions. This might result in more training iterations, or require more neurons to achieve the same accuracy.

### Examples

Calculate a layer output from a single net input vector:

```
n = [0; 1; -0.5; 0.5];  
a = elliotsig(n);
```

Plot the transfer function:

```
n = -5:0.01:5;  
plot(n, elliotsig(n))  
set(gca,'dataaspectratio',[1 1 1],'xgrid','on','ygrid','on')
```

For a network you have already defined, change the transfer function for layer  $i$ :

```
net.layers{i}.transferFcn = 'elliotsig';
```

## Version History

Introduced in R2012b

### See Also

[elliotsig](#) | [logsig](#) | [tansig](#)

# elliott2sig

Elliot 2 symmetric sigmoid transfer function

## Syntax

```
A = elliott2sig(N)
```

## Description

Transfer functions convert a neural network layer's net input into its net output. This function is a variation on the original Elliot sigmoid function. It has a steeper slope, closer to `tansig`, but is not as smooth at the center.

`A = elliott2sig(N)` takes an  $S$ -by- $Q$  matrix of  $S$   $N$ -element net input column vectors and returns an  $S$ -by- $Q$  matrix  $A$  of output vectors, where each element of  $N$  is squashed from the interval  $[-\infty \infty]$  to the interval  $[-1 \ 1]$  with an "S-shaped" function.

The advantage of this transfer function over other sigmoids is that it is fast to calculate on simple computing hardware as it does not require any exponential or trigonometric functions. Its disadvantage is that it departs from the classic sigmoid shape around zero.

## Examples

Calculate a layer output from a single net input vector:

```
n = [0; 1; -0.5; 0.5];
a = elliott2sig(n);
```

Plot the transfer function:

```
n = -5:0.01:5;
plot(n, elliott2sig(n))
set(gca,'dataaspectratio',[1 1 1],'xgrid','on','ygrid','on')
```

For a network you have already defined, change the transfer function for layer  $i$ :

```
net.layers{i}.transferFcn = 'elliott2sig';
```

## Version History

Introduced in R2012b

## See Also

`elliotsig` | `logsig` | `tansig`

## elmannet

Elman neural network

### Syntax

```
elmannet(layerdelays,hiddenSizes,trainFcn)
```

### Description

Elman networks are feedforward networks (`feedforwardnet`) with the addition of layer recurrent connections with tap delays.

With the availability of full dynamic derivative calculations (`fpderiv` and `bttderiv`), the Elman network is no longer recommended except for historical and research purposes. For more accurate learning try time delay (`timedelaynet`), layer recurrent (`layrecnet`), NARX (`narxnet`), and NAR (`narntnet`) neural networks.

Elman networks with one or more hidden layers can learn any dynamic input-output relationship arbitrarily well, given enough neurons in the hidden layers. However, Elman networks use simplified derivative calculations (using `staticderiv`, which ignores delayed connections) at the expense of less reliable learning.

`elmannet(layerdelays,hiddenSizes,trainFcn)` takes these arguments,

<code>layerdelays</code>	Row vector of increasing 0 or positive delays (default = 1:2)
<code>hiddenSizes</code>	Row vector of one or more hidden layer sizes (default = 10)
<code>trainFcn</code>	Training function (default = 'trainlm')

and returns an Elman neural network.

### Examples

#### Train Elman Neural Network

This example shows how to train an Elman neural network to solve a simple time series problem.

```
[X,T] = simpleseries_dataset;  
net = elmannet(1:2,10);  
[Xs,Xi,Ai,Ts] = preparets(net,X,T);  
net = train(net,Xs,Ts,Xi,Ai);
```

# errsurf

Error surface of single-input neuron

## Syntax

```
errsurf(P,T,WV,BV,F)
```

## Description

errsurf(P,T,WV,BV,F) takes these arguments,

P	1-by-Q matrix of input vectors
T	1-by-Q matrix of target vectors
WV	Row vector of values of W
BV	Row vector of values of B
F	Transfer function (string)

and returns a matrix of error values over WV and BV.

## Examples

```
p = [-6.0 -6.1 -4.1 -4.0 +4.0 +4.1 +6.0 +6.1];
t = [+0.0 +0.0 +.97 +.99 +.01 +.03 +1.0 +1.0];
wv = -1:.1:1; bv = -2.5:.25:2.5;
es = errsurf(p,t,wv,bv,'logsig');
plotes(wv,bv,es,[60 30])
```

## Version History

Introduced before R2006a

## See Also

## extends

Extend time series data to given number of timesteps

### Syntax

```
extends(x, ts, v)
```

### Description

`extends(x, ts, v)` takes these values,

x	Neural network time series data
ts	Number of timesteps
v	Value

and returns the time series data either extended or truncated to match the specified number of timesteps. If the value `v` is specified, then extended series are filled in with that value, otherwise they are extended with random values.

### Examples

Here, a 20-timestep series is created and then extended to 25 timesteps with the value zero.

```
x = nndata(5, 4, 20);  
y = extends(x, 25, 0)
```

# feedforwardnet

Generate feedforward neural network

## Syntax

```
net = feedforwardnet(hiddenSizes,trainFcn)
```

## Description

`net = feedforwardnet(hiddenSizes,trainFcn)` returns a feedforward neural network with a hidden layer size of `hiddenSizes` and training function, specified by `trainFcn`.

Feedforward networks consist of a series of layers. The first layer has a connection from the network input. Each subsequent layer has a connection from the previous layer. The final layer produces the network's output.

You can use feedforward networks for any kind of input to output mapping. A feedforward network with one hidden layer and enough neurons in the hidden layers can fit any finite input-output mapping problem.

Specialized versions of the feedforward network include fitting and pattern recognition networks. For more information, see the `fitnet` and `patternnet` functions.

A variation on the feedforward network is the cascade forward network, which has additional connections from the input to every layer, and from each layer to all following layers. For more information on cascade forward networks, see the `cascadeforwardnet` function.

## Examples

### Construct and Train a Feedforward Neural Network

This example shows how to use a feedforward neural network to solve a simple problem.

Load the training data.

```
[x,t] = simplefit_dataset;
```

The 1-by-94 matrix `x` contains the input values and the 1-by-94 matrix `t` contains the associated target output values.

Construct a feedforward network with one hidden layer of size 10.

```
net = feedforwardnet(10);
```

Train the network `net` using the training data.

```
net = train(net,x,t);
```

**Training Plots**

Performance      Training State  
Error Histogram      Regression

View the trained network.

`view(net)`

Estimate the targets using the trained network.

```
y = net(x);
```

Assess the performance of the trained network. The default performance function is mean squared error.

```
perf = perform(net,y,t)
```

```
perf = 1.4639e-04
```

## Input Arguments

### hiddenSizes — Size of the hidden layers

10 (default) | row vector

Size of the hidden layers in the network, specified as a row vector. The length of the vector determines the number of hidden layers in the network.

Example: For example, you can specify a network with 3 hidden layers, where the first hidden layer size is 10, the second is 8, and the third is 5 as follows: [10,8,5]

The input and output sizes are set to zero. The software adjusts the sizes of these during training according to the training data.

Data Types: single | double

**trainFcn — Training function name**

'trainlm' (default) | 'trainbr' | 'trainbfg' | 'trainrp' | 'trainscg' | ...

Training function name, specified as one of the following.

Training Function	Algorithm
'trainlm'	Levenberg-Marquardt
'trainbr'	Bayesian Regularization
'trainbfg'	BFGS Quasi-Newton
'trainrp'	Resilient Backpropagation
'trainscg'	Scaled Conjugate Gradient
'traincgb'	Conjugate Gradient with Powell/Beale Restarts
'traincgf'	Fletcher-Powell Conjugate Gradient
'traincgp'	Polak-Ribière Conjugate Gradient
'trainoss'	One Step Secant
'traingdx'	Variable Learning Rate Gradient Descent
'traingdm'	Gradient Descent with Momentum
'traingd'	Gradient Descent

Example: For example, you can specify the variable learning rate gradient descent algorithm as the training algorithm as follows: 'traingdx'

For more information on the training functions, see “Train and Apply Multilayer Shallow Neural Networks” and “Choose a Multilayer Neural Network Training Function”.

Data Types: char

**Output Arguments**

**net — Feedforward network**

network object

Feedforward neural network, returned as a network object.

**Version History**

Introduced in R2010b

## fixunknowns

Process data by marking rows with unknown values

### Syntax

```
[y,ps] = fixunknowns(X)
[y,ps] = fixunknowns(X,FP)
Y = fixunknowns('apply',X,PS)
X = fixunknowns('reverse',Y,PS)
name = fixunknowns('name')
fp = fixunknowns('pdefaults')
pd = fixunknowns('pdesc')
fixunknowns('pcheck',fp)
```

### Description

`fixunknowns` processes matrices by replacing each row containing unknown values (represented by NaN) with two rows of information.

The first row contains the original row, with NaN values replaced by the row's mean. The second row contains 1 and 0 values, indicating which values in the first row were known or unknown, respectively.

`[y,ps] = fixunknowns(X)` takes these inputs,

X	N-by-Q matrix
---	---------------

and returns

Y	M-by-Q matrix with M - N rows added
PS	Process settings that allow consistent processing of values

`[y,ps] = fixunknowns(X,FP)` takes an empty struct `FP` of parameters.

`Y = fixunknowns('apply',X,PS)` returns `Y`, given `X` and settings `PS`.

`X = fixunknowns('reverse',Y,PS)` returns `X`, given `Y` and settings `PS`.

`name = fixunknowns('name')` returns the name of this process method.

`fp = fixunknowns('pdefaults')` returns the default process parameter structure.

`pd = fixunknowns('pdesc')` returns the process parameter descriptions.

`fixunknowns('pcheck',fp)` throws an error if any parameter is illegal.

### Examples

Here is how to format a matrix with a mixture of known and unknown values in its second row:

```
x1 = [1 2 3 4; 4 NaN 6 5; NaN 2 3 NaN]
[y1,ps] = fixunknowns(x1)
```

Next, apply the same processing settings to new values:

```
x2 = [4 5 3 2; NaN 9 NaN 2; 4 9 5 2]
y2 = fixunknowns('apply',x2,ps)
```

Reverse the processing of y1 to get x1 again.

```
x1_again = fixunknowns('reverse',y1,ps)
```

## More About

### Recode Data with NaNs Using fixunknowns

If you have input data with unknown values, you can represent them with NaN values. For example, here are five 2-element vectors with unknown values in the first element of two of the vectors:

```
p1 = [1 NaN 3 2 NaN; 3 1 -1 2 4];
```

The network will not be able to process the NaN values properly. Use the function `fixunknowns` to transform each row with NaN values (in this case only the first row) into two rows that encode that same information numerically.

```
[p2,ps] = fixunknowns(p1);
```

Here is how the first row of values was recoded as two rows.

```
p2 =
     1     2     3     2     2
     1     0     1     1     0
     3     1    -1     2     4
```

The first new row is the original first row, but with the mean value for that row (in this case 2) replacing all NaN values. The elements of the second new row are now either 1, indicating the original element was a known value, or 0 indicating that it was unknown. The original second row is now the new third row. In this way both known and unknown values are encoded numerically in a way that lets the network be trained and simulated.

Whenever supplying new data to the network, you should transform the inputs in the same way, using the settings `ps` returned by `fixunknowns` when it was used to transform the training input data.

```
p2new = fixunknowns('apply',p1new,ps);
```

The function `fixunknowns` is only recommended for input processing. Unknown targets represented by NaN values can be handled directly by the toolbox learning algorithms. For instance, performance functions used by backpropagation algorithms recognize NaN values as unknown or unimportant values.

## formwb

Form bias and weights into single vector

### Syntax

```
formwb(net,b,IW,LW)
```

### Description

`formwb(net,b,IW,LW)` takes a neural network and bias `b`, input weight `IW`, and layer weight `LW` values, and combines the values into a single vector.

### Examples

Here a network is created, configured, and its weights and biases formed into a vector.

```
[x,t] = simplefit_dataset;  
net = feedforwardnet(10);  
net = configure(net,x,t);  
wb = formwb(net,net.b,net.IW,net.LW)
```

## Version History

**Introduced in R2010b**

### See Also

[getwb](#) | [setwb](#) | [separatewb](#)

## fpderiv

Forward propagation derivative function

### Syntax

```
fpderiv('dperf_dwb',net,X,T,Xi,Ai,EW)
fpderiv('de_dwb',net,X,T,Xi,Ai,EW)
```

### Description

This function calculates derivatives using the chain rule from inputs to outputs, and in the case of dynamic networks, forward through time.

`fpderiv('dperf_dwb',net,X,T,Xi,Ai,EW)` takes these arguments,

<code>net</code>	Neural network
<code>X</code>	Inputs, an R-by-Q matrix (or N-by-TS cell array of Ri-by-Q matrices)
<code>T</code>	Targets, an S-by-Q matrix (or M-by-TS cell array of Si-by-Q matrices)
<code>Xi</code>	Initial input delay states (optional)
<code>Ai</code>	Initial layer delay states (optional)
<code>EW</code>	Error weights (optional)

and returns the gradient of performance with respect to the network's weights and biases, where R and S are the number of input and output elements and Q is the number of samples (or N and M are the number of input and output signals, Ri and Si are the number of each input and outputs elements, and TS is the number of timesteps).

`fpderiv('de_dwb',net,X,T,Xi,Ai,EW)` returns the Jacobian of errors with respect to the network's weights and biases.

### Examples

Here a feedforward network is trained and both the gradient and Jacobian are calculated.

```
[x,t] = simplefit_dataset;
net = feedforwardnet(20);
net = train(net,x,t);
y = net(x);
perf = perform(net,t,y);
gwb = fpderiv('dperf_dwb',net,x,t)
jwb = fpderiv('de_dwb',net,x,t)
```

## Version History

Introduced in R2010b

**See Also**

## fromnndata

Convert data from standard neural network cell array form

### Syntax

```
fromnndata(x,toMatrix,columnSample,cellTime)
```

### Description

`fromnndata(x,toMatrix,columnSample,cellTime)` takes these arguments,

<code>net</code>	Neural network
<code>toMatrix</code>	True if result is to be in matrix form
<code>columnSample</code>	True if samples are to be represented as columns, false if rows
<code>cellTime</code>	True if time series are to be represented as a cell array, false if represented with a matrix

and returns the original data reformatted accordingly.

### Examples

Here time-series data is converted from a matrix representation to standard cell array representation, and back. The original data consists of a 5-by-6 matrix representing one time-series sample consisting of a 5-element vector over 6 timesteps arranged in a matrix with the samples as columns.

```
x = rands(5,6)
columnSamples = true; % samples are by columns.
cellTime = false; % time-steps in matrix, not cell array.
[y,wasMatrix] = tonndata(x,columnSamples,cellTime)
x2 = fromnndata(y,wasMatrix,columnSamples,cellTime)
```

Here data is defined in standard neural network data cell form. Converting this data does not change it. The data consists of three time series samples of 2-element signals over 3 timesteps.

```
x = {rands(2,3);rands(2,3);rands(2,3)}
columnSamples = true;
cellTime = true;
[y,wasMatrix] = tonndata(x)
x2 = fromnndata(y,wasMatrix,columnSamples)
```

# gadd

Generalized addition

## Syntax

```
gadd(a,b)
```

## Description

`gadd(a,b)` takes two matrices or cell arrays, and adds them in an element-wise manner.

## Examples

### Add Matrix and Cell Array Values

This example shows how to add matrix and cell array values.

```
gadd([1 2 3; 4 5 6],[10;20])
```

```
ans = 2×3
```

```
    11    12    13
    24    25    26
```

```
gadd({1 2; 3 4},{1 3; 5 2})
```

```
ans=2×2 cell array
```

```
    {[2]}    {[5]}
    {[8]}    {[6]}
```

```
gadd({1 2 3 4},{10;20;30})
```

```
ans=3×4 cell array
```

```
    {[11]}    {[12]}    {[13]}    {[14]}
    {[21]}    {[22]}    {[23]}    {[24]}
    {[31]}    {[32]}    {[33]}    {[34]}
```

## gdivide

Generalized division

### Syntax

```
gdivide(a,b)
```

### Description

`gdivide(a,b)` takes two matrices or cell arrays, and divides them in an element-wise manner.

### Examples

#### Divide Matrix and Cell Array Values

This example shows how to divide matrix and cell array values.

```
gdivide([1 2 3; 4 5 6],[10;20])
```

```
ans = 2×3
```

```
    0.1000    0.2000    0.3000  
    0.2000    0.2500    0.3000
```

```
gdivide({1 2; 3 4},{1 3; 5 2})
```

```
ans=2×2 cell array
```

```
    {[    1]}    {[0.6667]}  
    {[0.6000]}    {[    2]}
```

```
gdivide({1 2 3 4},{10;20;30})
```

```
ans=3×4 cell array
```

```
    {[0.1000]}    {[0.2000]}    {[0.3000]}    {[0.4000]}  
    {[0.0500]}    {[0.1000]}    {[0.1500]}    {[0.2000]}  
    {[0.0333]}    {[0.0667]}    {[0.1000]}    {[0.1333]}

# gensim

Generate Simulink block for shallow neural network simulation

## Syntax

```
gensim(net,st)
```

## Description

`gensim(net,st)` creates a Simulink system containing a block that simulates neural network `net` with a sampling time of `st`.

If `net` has no input or layer delays (`net.numInputDelays` and `net.numLayerDelays` are both 0), you can use `-1` for `st` to get a network that samples continuously.

`gensim` does not support deep learning networks such as convolutional or LSTM networks. For more information on code generation for deep learning, see “Code Generation”.

For more information on `gensim`, at the MATLAB command prompt, enter `help network/gensim`.

## Examples

### Generate a Simulink Block for a Feedforward Network

This example shows how to generate a Simulink block for a feedforward network.

Create a feed-forward network using the data from the simple fit data set and generate the Simulink block.

```
[x,t] = simplefit_dataset;  
net = feedforwardnet(10);  
net = train(net,x,t)  
gensim(net)
```

### Generate a Simulink Block for a NARX Network

This example shows how to generate a Simulink block for a NARX network.

Create a NARX network.

```
[x,t] = simplenarx_dataset;  
net = narxnet(1:2,1:2,20);  
view(net)  
[xs,xi,ai,ts] = preparets(net,x,{},t);  
net = train(net,xs,ts,xi,ai);  
y = net(xs,xi,ai);
```

Convert the network to closed loop.

```
net = closeloop(net);  
view(net)
```

Prepare the data and simulate the network's closed loop response.

```
[xs,xi,ai,ts] = preparets(net,x,{},t);  
y = net(xs,xi,ai);
```

Convert the network to a Simulink system with workspace input and output ports.

```
[sysName,netName] = gensim(net,'InputMode','Workspace',...  
    'OutputMode','WorkSpace','SolverMode','Discrete');
```

Initialize the delay states. Note that this is an important step to obtain the same output as in MATLAB.

```
setsiminit(sysName,netName,net,xi,ai,1);
```

Define the model input X1 in the workspace, simulate the system programmatically.

```
x1 = nndata2sim(xs,1,1);  
out = sim(sysName,'ReturnWorkspaceOutputs','on','StopTime',num2str(x1.time(end)));  
ysim = sim2nndata(out.y1);
```

## Input Arguments

### **net** — Input network

network

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

### **st** — Sample time

-1 (default) | scalar | vector

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time” (Simulink).

## Version History

Introduced before R2006a

## See Also

`preparets`

# genFunction

Generate MATLAB function for simulating shallow neural network

## Syntax

```
genFunction(net,pathname)
genFunction( ___, 'MatrixOnly', 'yes' )
genFunction( ___, 'ShowLinks', 'no' )
```

## Description

This function generates a MATLAB function for simulating a shallow neural network. `genFunction` does not support deep learning networks such as convolutional or LSTM networks. For more information on code generation for deep learning, see “Code Generation”.

`genFunction(net,pathname)` generates a complete stand-alone MATLAB function for simulating a neural network including all settings, weight and bias values, module functions, and calculations in one file. The result is a standalone MATLAB function file. You can also use this function with MATLAB Compiler and MATLAB Coder tools.

`genFunction( ___, 'MatrixOnly', 'yes' )` overrides the default cell/matrix notation and instead generates a function that uses only matrix arguments compatible with MATLAB Coder tools. For static networks, the matrix columns are interpreted as independent samples. For dynamic networks, the matrix columns are interpreted as a series of time steps. The default value is 'no'.

`genFunction( ___, 'ShowLinks', 'no' )` disables the default behavior of displaying links to generated help and source code. The default is 'yes'.

## Examples

### Create Functions from Static Neural Network

This example shows how to create a MATLAB function and a MEX-function from a static neural network.

First, train a static network and calculate its outputs for the training data.

```
[x,t] = bodyfat_dataset;
bodyfatNet = feedforwardnet(10);
bodyfatNet = train(bodyfatNet,x,t);
y = bodyfatNet(x);
```

Next, generate and test a MATLAB function. Then the new function is compiled to a shared/dynamically linked library with `mcc`.

```
genFunction(bodyfatNet, 'bodyfatFcn');
y2 = bodyfatFcn(x);
accuracy2 = max(abs(y-y2))
mcc -W lib:libBodyfat -T link:lib bodyfatFcn
```

Next, generate another version of the MATLAB function that supports only matrix arguments (no cell arrays), and test the function. Use the MATLAB Coder tool `codegen` to generate a MEX-function, which is also tested.

```
genFunction(bodyfatNet, 'bodyfatFcn', 'MatrixOnly', 'yes');
y3 = bodyfatFcn(x);
accuracy3 = max(abs(y-y3))

x1Type = coder.typeof(double(0), [13 Inf]); % Coder type of input 1
codegen bodyfatFcn.m -config:mex -o bodyfatCodeGen -args {x1Type}
y4 = bodyfatodeGen(x);
accuracy4 = max(abs(y-y4))
```

### Create Functions from Dynamic Neural Network

This example shows how to create a MATLAB function and a MEX-function from a dynamic neural network.

First, train a dynamic network and calculate its outputs for the training data.

```
[x,t] = maglev_dataset;
maglevNet = narxnet(1:2,1:2,10);
[X,Xi,Ai,T] = preparets(maglevNet,x,{},t);
maglevNet = train(maglevNet,X,T,Xi,Ai);
[y,xf,af] = maglevNet(X,Xi,Ai);
```

Next, generate and test a MATLAB function. Use the function to create a shared/dynamically linked library with `mcc`.

```
genFunction(maglevNet, 'maglevFcn');
[y2,xf,af] = maglevFcn(X,Xi,Ai);
accuracy2 = max(abs(cell2mat(y)-cell2mat(y2)))
mcc -W lib:libMaglev -T link:lib maglevFcn
```

Next, generate another version of the MATLAB function that supports only matrix arguments (no cell arrays), and test the function. Use the MATLAB Coder tool `codegen` to generate a MEX-function, which is also tested.

```
genFunction(maglevNet, 'maglevFcn', 'MatrixOnly', 'yes');
x1 = cell2mat(X(1,:)); % Convert each input to matrix
x2 = cell2mat(X(2,:));
xi1 = cell2mat(Xi(1,:)); % Convert each input state to matrix
xi2 = cell2mat(Xi(2,:));
[y3,xf1,xf2] = maglevFcn(x1,x2,xi1,xi2);
accuracy3 = max(abs(cell2mat(y)-y3))

x1Type = coder.typeof(double(0), [1 Inf]); % Coder type of input 1
x2Type = coder.typeof(double(0), [1 Inf]); % Coder type of input 2
xi1Type = coder.typeof(double(0), [1 2]); % Coder type of input 1 states
xi2Type = coder.typeof(double(0), [1 2]); % Coder type of input 2 states
codegen maglevFcn.m -config:mex -o maglevNetCodeGen -args {x1Type x2Type xi1Type xi2Type}
[y4,xf1,xf2] = maglevNetCodeGen(x1,x2,xi1,xi2);
dynamic_codegen_accuracy = max(abs(cell2mat(y)-y4))
```

## Input Arguments

### net — neural network

network object

Neural network, specified as a network object.

```
Example: net = feedforwardnet(10);
```

**pathname — location and name of generated function file**

character string

Location and name of generated function file, specified as a character string. If you do not specify a file name extension of `.m`, it is automatically appended. If you do not specify a path to the file, the default location is the current working folder.

Example: `'myFcn.m'`

Data Types: `char`

## Version History

Introduced in R2013b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can use `genFunction` in the Deep Learning Toolbox to generate a standalone MATLAB function for a trained neural network. You can generate C/C++ code from this standalone MATLAB function. To generate Simulink blocks, use the `genSim` function. See “Deploy Shallow Neural Network Functions”.

## See Also

`gensim`

### Topics

“Deploy Shallow Neural Network Functions”

## getelements

Get neural network data elements

### Syntax

```
getelements(x,ind)
```

### Description

`getelements(x,ind)` returns the elements of neural network data `x` indicated by the indices `ind`. The neural network data may be in matrix or cell array form.

If `x` is a matrix, the result is the `ind` rows of `x`.

If `x` is a cell array, the result is a cell array with as many columns as `x`, whose elements `(1,i)` are matrices containing the `ind` rows of `[x{: ,i}]`.

### Examples

This code gets elements 1 and 3 from matrix data:

```
x = [1 2 3; 4 7 4]
y = getelements(x,[1 3])
```

This code gets elements 1 and 3 from cell array data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
y = getelements(x,[1 3])
```

## Version History

**Introduced in R2010b**

# getsamples

Get neural network data samples

## Syntax

```
getsamples(x,ind)
```

## Description

`getsamples(x,ind)` returns the samples of neural network data `x` indicated by the indices `ind`. The neural network data may be in matrix or cell array form.

If `x` is a matrix, the result is the `ind` columns of `x`.

If `x` is a cell array, the result is a cell array the same size as `x`, whose elements are the `ind` columns of the matrices in `x`.

## Examples

This code gets samples 1 and 3 from matrix data:

```
x = [1 2 3; 4 7 4]
y = getsamples(x,[1 3])
```

This code gets elements 1 and 3 from cell array data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
y = getsamples(x,[1 3])
```

## Version History

Introduced in R2010b

## See Also

## getsignals

Get neural network data signals

### Syntax

```
getsignals(x,ind)
```

### Description

`getsignals(x,ind)` returns the signals of neural network data `x` indicated by the indices `ind`. The neural network data may be in matrix or cell array form.

If `x` is a matrix, `ind` may only be 1, which will return `x`, or `[]` which will return an empty matrix.

If `x` is a cell array, then the result is the rows of `x` with indices specified by `ind`.

### Examples

This code gets signal 2 from cell array data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}  
y = getsignals(x,2)
```

### Version History

## getsiminit

Get Simulink neural network block initial input and layer delays states

### Syntax

```
[xi,ai] = getsiminit(sysName,netName,net)
```

### Description

[xi,ai] = getsiminit(sysName,netName,net) takes these arguments,

sysName	The name of the Simulink system containing the neural network block
netName	The name of the Simulink neural network block
net	The original neural network

and returns,

xi	Initial input delay states
ai	Initial layer delay states

### Examples

Here a NARX network is designed. The NARX network has a standard input and an open-loop feedback output to an associated feedback input.

```
[x,t] = simplenarx_dataset;
net = narxnet(1:2,1:2,20);
view(net)
[xs,xi,ai,ts] = preparets(net,x,{},t);
net = train(net,xs,ts,xi,ai);
y = net(xs,xi,ai);
```

Now the network is converted to closed-loop, and the data is reformatted to simulate the network's closed-loop response.

```
net = closeloop(net);
view(net)
[xs,xi,ai,ts] = preparets(net,x,{},t);
y = net(xs,xi,ai);
```

Here the network is converted to a Simulink system with workspace input and output ports. Its delay states are initialized, inputs X1 defined in the workspace, and it is ready to be simulated in Simulink.

```
[sysName,netName] = gensim(net,'InputMode','Workspace',...
    'OutputMode','Workspace','SolverMode','Discrete');
setsiminit(sysName,netName,net,xi,ai,1);
x1 = nndata2sim(x,1,1);
```

Finally the initial input and layer delays are obtained from the Simulink model. (They will be identical to the values set with setsiminit.)

```
[xi,ai] = getsiminit(sysName,netName,net);
```

## **Version History**

**Introduced in R2010b**

# gettimesteps

Get neural network data timesteps

## Syntax

```
gettimesteps(x,ind)
```

## Description

`gettimesteps(x,ind)` returns the timesteps of neural network data `x` indicated by the indices `ind`. The neural network data may be in matrix or cell array form.

If `x` is a matrix, `ind` can only be 1, which will return `x`; or `[]`, which will return an empty matrix.

If `x` is a cell array, then the result is the columns of `x` with indices specified by `ind`.

## Examples

This code gets timestep 2 from cell array data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}  
y = gettimesteps(x,2)
```

## Version History

Introduced in R2010b

## getwb

Get network weight and bias values as single vector

### Syntax

```
getwb(net)
```

### Description

`getwb(net)` returns a neural network's weight and bias values as a single vector.

### Examples

Here a feedforward network is trained to fit some data, then its bias and weight values are formed into a vector.

```
[x,t] = simplefit_dataset;  
net = feedforwardnet(20);  
net = train(net,x,t);  
wb = getwb(net)
```

## Version History

Introduced in R2010b

# gmultiply

Generalized multiplication

## Syntax

```
gmultiply(a,b)
```

## Description

gmultiply(a,b) takes two matrices or cell arrays, and multiplies them in an element-wise manner.

## Examples

### Multiply Matrix and Cell Array Values

This example shows how to multiply matrix and cell array values.

```
gmultiply([1 2 3; 4 5 6],[10;20])
```

```
ans = 2×3
```

```
    10    20    30  
    80   100   120
```

```
gmultiply({1 2; 3 4},{1 3; 5 2})
```

```
ans=2×2 cell array  
    {[ 1]}    {[6]}  
    {[15]}    {[8]}
```

```
gmultiply({1 2 3 4},{10;20;30})
```

```
ans=3×4 cell array  
    {[10]}    {[20]}    {[30]}    {[ 40]}  
    {[20]}    {[40]}    {[60]}    {[ 80]}  
    {[30]}    {[60]}    {[90]}    {[120]}
```

## Version History

Introduced in R2010b

## gnegate

Generalized negation

### Syntax

```
gnegate(x)
```

### Description

gnegate(x) takes a matrix or cell array of matrices, and negates their element values.

### Examples

#### Negate a Cell Array

This example shows how to negate a cell array:

```
x = {[1 2; 3 4],[1 -3; -5 2]};  
y = gnegate(x);  
y{1}, y{2}
```

```
ans = 2×2
```

```
  -1  -2  
  -3  -4
```

```
ans = 2×2
```

```
  -1   3  
   5  -2
```

### Version History

**Introduced in R2010b**

## gpu2nndata

Reformat neural data back from GPU

### Syntax

```
X = gpu2nndata(Y,Q)
X = gpu2nndata(Y)
X = gpu2nndata(Y,Q,N,TS)
```

### Description

Training and simulation of neural networks require that matrices be transposed. But they do not require (although they are more efficient with) padding of column length so that each column is memory aligned. This function copies data back from the current GPU and reverses this transform. It can be used on data formatted with `nndata2gpu` or on the results of network simulation.

`X = gpu2nndata(Y,Q)` copies the  $QQ$ -by- $N$  gpuArray `Y` into RAM, takes the first  $Q$  rows and transposes the result to get an  $N$ -by- $Q$  matrix representing  $Q$   $N$ -element vectors.

`X = gpu2nndata(Y)` calculates  $Q$  as the index of the last row in `Y` that is not all NaN values (those rows were added to pad `Y` for efficient GPU computation by `nndata2gpu`). `Y` is then transformed as before.

`X = gpu2nndata(Y,Q,N,TS)` takes a  $QQ$ -by- $(N*TS)$  gpuArray where `N` is a vector of signal sizes,  $Q$  is the number of samples (less than or equal to the number of rows after alignment padding  $QQ$ ), and `TS` is the number of time steps.

The gpuArray `Y` is copied back into RAM, the first  $Q$  rows are taken, and then it is partitioned and transposed into an  $M$ -by-`TS` cell array, where  $M$  is the number of elements in `N`. Each `Y{i,ts}` is an  $N(i)$ -by- $Q$  matrix.

### Examples

Copy a matrix to the GPU and back:

```
x = rand(5,6)
[y,q] = nndata2gpu(x)
x2 = gpu2nndata(y,q)
```

Copy from the GPU a neural network cell array data representing four time series, each consisting of five time steps of 2-element and 3-element signals.

```
x = nndata([2;3],4,5)
[y,q,n,ts] = nndata2gpu(x)
x2 = gpu2nndata(y,q,n,ts)
```

## Version History

Introduced in R2012b

**See Also**

nndata2gpu

# gridtop

Grid layer topology function

## Syntax

```
gridtop(dimensions)
```

## Description

`pos = gridtop` calculates neuron positions for layers whose neurons are arranged in an N-dimensional grid.

`gridtop(dimensions)` takes one argument:

dimensions	Row vector of dimension sizes
------------	-------------------------------

and returns an N-by-S matrix of N coordinate vectors where N is the number of dimensions and S is the product of dimensions.

## Examples

### Display Layer with Grid Pattern

This example shows how to display a two-dimensional layer with 40 neurons arranged in an 8-by-5 grid pattern.

```
pos = gridtop([8 5]);  
plotsom(pos)
```

## Version History

Introduced before R2006a

# gsqrt

Generalized square root

## Syntax

```
gsqrt(x)
```

## Description

`gsqrt(x)` takes a matrix or cell array of matrices, and generates the element-wise square root of the matrices.

## Examples

### Compute Element-Wise Square Root

This example shows how to get the element-wise square root of a cell array:

```
gsqrt({1 2; 3 4})  
  
ans=2x2 cell array  
    {[    1]}    {[1.4142]}  
    {[1.7321]}    {[    2]}
```

## Version History

**Introduced in R2010b**

## See Also

## gsubtract

Generalized subtraction

### Syntax

```
gsubtract(a,b)
```

### Description

`gsubtract(a,b)` takes two matrices or cell arrays, and subtracts them in an element-wise manner.

### Examples

#### Subtract Matrix and Cell Array Values

This example shows how to subtract matrix and cell array values.

```
gsubtract([1 2 3; 4 5 6],[10;20])
```

```
ans = 2×3
```

```
    -9    -8    -7  
   -16   -15   -14
```

```
gsubtract({1 2; 3 4},{1 3; 5 2})
```

```
ans=2×2 cell array
```

```
    {[ 0]}    {[ -1]}  
    {[ -2]}    {[ 2]}
```

```
gsubtract({1 2 3 4},{10;20;30})
```

```
ans=3×4 cell array
```

```
    {[ -9]}    {[ -8]}    {[ -7]}    {[ -6]}  
    {[ -19]}    {[ -18]}    {[ -17]}    {[ -16]}  
    {[ -29]}    {[ -28]}    {[ -27]}    {[ -26]}
```

# hardlim

Hard-limit transfer function

## Syntax

```
A = hardlim(N)
info = hardlim('code')
```

## Description

`A = hardlim(N)` takes an  $S$ -by- $Q$  matrix of net input (column) vectors,  $N$ , and returns  $A$ , the  $S$ -by- $Q$  Boolean matrix with elements equal to 1 where the corresponding elements in  $N$  are greater than or equal to 0.

`hardlim` is a neural transfer function. Transfer functions calculate a layer's output from its net input.

Hard-Limit Transfer Function

`info = hardlim('code')` returns useful information for each code character vector:

- `hardlim('name')` returns the name of this function.
- `hardlim('output')` returns the [min max] output range.
- `hardlim('active')` returns the [min max] active input range.
- `hardlim('fullderiv')` returns 1 or 0, depending on whether `dA_dN` is  $S$ -by- $S$ -by- $Q$  or  $S$ -by- $Q$ .
- `hardlim('fpnames')` returns the names of the function parameters.
- `hardlim('fpdefaults')` returns the default function parameters.

## Examples

### Create a Plot of the `hardlim` Transfer Function

This example shows how to create a plot of the `hardlim` transfer function.

Create the input matrix,  $n$ . Then call the `hardlim` function and plot the results.

```
n = -5:0.1:5;
a = hardlim(n);
plot(n,a)
```

Assign this transfer function to layer  $i$  of a network.

```
net.layers{i}.transferFcn = 'hardlim';
```

## Input Arguments

### **N — Input matrix**

matrix

Net input column vectors, specified as an S-by-Q matrix.

## Output Arguments

### **A — Output matrix**

matrix

Output matrix, returned as an S-by-Q Boolean matrix with elements equal to 1 where the corresponding elements in N are greater than or equal to 0.

## Algorithms

$$\text{hardlim}(n) = \begin{cases} 1 & \text{if } n \geq 0 \\ 0 & \text{otherwise} \end{cases}$$

## Version History

Introduced before R2006a

## See Also

sim | hardlims

# hardlims

Symmetric hard-limit transfer function

## Graph and Symbol

Symmetric Hard-Limit Transfer Function

## Syntax

$A = \text{hardlims}(N, FP)$

## Description

`hardlims` is a neural transfer function. Transfer functions calculate a layer's output from its net input.

$A = \text{hardlims}(N, FP)$  takes  $N$  and optional function parameters,

$N$	S-by-Q matrix of net input (column) vectors
$FP$	Struct of function parameters (ignored)

and returns  $A$ , the S-by-Q +1/-1 matrix with +1s where  $N \geq 0$ .

`info = hardlims('code')` returns information according to the code string specified:

`hardlims('name')` returns the name of this function.

`hardlims('output', FP)` returns the [min max] output range.

`hardlims('active', FP)` returns the [min max] active input range.

`hardlims('fullderiv')` returns 1 or 0, depending on whether `dA_dN` is S-by-S-by-Q or S-by-Q.

`hardlims('fpnames')` returns the names of the function parameters.

`hardlims('fpdefaults')` returns the default function parameters.

## Examples

Here is how to create a plot of the `hardlims` transfer function.

```
n = -5:0.1:5;  
a = hardlims(n);  
plot(n,a)
```

Assign this transfer function to layer *i* of a network.

```
net.layers{i}.transferFcn = 'hardlims';
```

### Algorithms

`hardlims(n)` = 1 if  $n \geq 0$ , -1 otherwise.

### Version History

Introduced before R2006a

### See Also

`sim` | `hardlim`

# hextop

Hexagonal layer topology function

## Syntax

```
hextop(dimensions)
```

## Description

hextop calculates the neuron positions for layers whose neurons are arranged in an N-dimensional hexagonal pattern.

hextop(dimensions) takes one argument:

dimensions	Row vector of dimension sizes
------------	-------------------------------

and returns an N-by-S matrix of N coordinate vectors where N is the number of dimensions and S is the product of dimensions.

## Examples

### Display Layer with Hexagonal Pattern

This example shows how to display a two-dimensional layer with 40 neurons arranged in an 8-by-5 hexagonal pattern.

```
pos = hextop([8 5]);  
plotsom(pos)
```

## Version History

Introduced before R2006a

## See Also

[gridtop](#) | [randtop](#) | [tritop](#)

# ind2vec

Convert indices to vectors

## Syntax

```
vec = ind2vec(ind)
vec = ind2vec(ind,N)
```

## Description

`vec = ind2vec(ind)` takes a row vector of indices, `ind`, and returns a sparse matrix of vectors, `vec`, containing a 1 in the row of the index they represent, as indicated by `ind`.

`ind2vec` and `vec2ind` allow indices to be represented either by themselves, or as vectors containing a 1 in the row of the index they represent.

`vec = ind2vec(ind,N)` returns an N-by-M sparse matrix, where N can be equal to or greater than the maximum index.

## Examples

### Convert Indices into Vector Representation

This example shows how to convert indices to vector representation using the `ind2vec` function.

Define four indices and then convert them to vector representation.

```
ind = [1 3 2 3];
vec = ind2vec(ind)

vec =
    (1,1)      1
    (3,2)      1
    (2,3)      1
    (3,4)      1
```

### Convert a Vector to Indices and Back

This example shows how to convert a vector to indices and back, using both the `ind2vec` and `vec2ind` functions.

Define a vector with all zeros in the last row and convert it to indices.

```
vec = [0 0 1 0; 1 0 0 0; 0 1 0 0]'
[ind,n] = vec2ind(vec)

vec =
    0     1     0
    0     0     1
```

```
      1      0      0
      0      0      0
ind = 3      1      2

n =
     4
```

Convert the indices to vector, while preserving the number of rows.

```
vec2 = full(ind2vec(ind,n))
```

```
vec2 =
      0      1      0
      0      0      1
      1      0      0
      0      0      0
```

### Input Arguments

#### **ind** – Indices

row vector

Indices, specified as a row vector.

#### **N** – Number of rows

scalar

Number of rows of the output matrix, specified as a scalar.

### Output Arguments

#### **vec** – Converted vector of indices

matrix

Vector representation of the indices, returned as an N-by-M sparse matrix.

### Version History

Introduced before R2006a

# init

Initialize neural network

## Syntax

```
init_net = init(net)
```

## Description

`init_net = init(net)` returns a neural network `net` with weight and bias values updated according to the network initialization function, specified by `net.initFcn`, and the parameter values, specified by `net.initParam`.

For more information on this function, at the MATLAB command prompt, type `help network/init`.

## Examples

### Reinitialize a Perceptron with 'init' Function

This example shows how to reinitialize a perceptron network by using the `init` function.

Create a perceptron and configure it so that its input, output, weight, and bias dimensions match the input and target data.

```
x = [0 1 0 1; 0 0 1 1];  
t = [0 0 0 1];  
net = perceptron;  
net = configure(net,x,t);  
net.iw{1,1}  
net.b{1}
```

Train the perceptron to alter its weight and bias values.

```
net = train(net,x,t);  
net.iw{1,1}  
net.b{1}
```

`init` reinitializes those weight and bias values.

```
net = init(net);  
net.iw{1,1}  
net.b{1}
```

The weights and biases are zeros again, which are the initial values used by perceptron networks.

## Input Arguments

**net** — Input network

network

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

### Output Arguments

#### **init\_net** — Reinitialized network

`network`

Network after the `init` reinitialization, returned as a network object.

### Algorithms

`init` calls `net.initFcn` to initialize the weight and bias values according to the parameter values `net.initParam`.

Typically, `net.initFcn` is set to `'initlay'`, which initializes each layer's weights and biases according to its `net.layers{i}.initFcn`.

Backpropagation networks have `net.layers{i}.initFcn` set to `'initnw'`, which calculates the weight and bias values for layer `i` using the Nguyen-Widrow initialization method.

Other networks have `net.layers{i}.initFcn` set to `'initwb'`, which initializes each weight and bias with its own initialization function. The most common weight and bias initialization function is `rands`, which generates random values between -1 and 1.

### Version History

Introduced before R2006a

# initcon

Conscience bias initialization function

## Syntax

`initcon (S,PR)`

## Description

`initcon` is a bias initialization function that initializes biases for learning with the `learncon` learning function.

`initcon (S,PR)` takes two arguments,

S	Number of rows (neurons)
PR	R-by-2 matrix of $R = [Pmin \ Pmax]$ (default = [1 1])

and returns an S-by-1 bias vector.

Note that for biases, R is always 1. `initcon` could also be used to initialize weights, but it is not recommended for that purpose.

## Examples

Here initial bias values are calculated for a five-neuron layer.

```
b = initcon(5)
```

## Network Use

You can create a standard network that uses `initcon` to initialize weights by calling `competlayer`.

To prepare the bias of layer `i` of a custom network to initialize with `initcon`,

- 1 Set `net.initFcn` to 'initlay'. (`net.initParam` automatically becomes `initlay`'s default parameters.)
- 2 Set `net.layers{i}.initFcn` to 'initwb'.
- 3 Set `net.biases{i}.initFcn` to 'initcon'.

To initialize the network, call `init`.

## Algorithms

`learncon` updates biases so that each bias value  $b(i)$  is a function of the average output  $c(i)$  of the neuron `i` associated with the bias.

`initcon` gets initial bias values by assuming that each neuron has responded to equal numbers of vectors in the past.

## **Version History**

**Introduced before R2006a**

# initlay

Layer-by-layer network initialization function

## Syntax

```
net = initlay(net)
info = initlay('code')
```

## Description

`initlay` is a network initialization function that initializes each layer `i` according to its own initialization function `net.layers{i}.initFcn`.

`net = initlay(net)` takes

<code>net</code>	Neural network
------------------	----------------

and returns the network with each layer updated.

`info = initlay('code')` returns useful information for each supported `code` character vector:

<code>'pnames'</code>	Names of initialization parameters
<code>'pdefaults'</code>	Default initialization parameters

`initlay` does not have any initialization parameters.

## Network Use

You can create a standard network that uses `initlay` by calling `feedforwardnet`, `cascadeforwardnet`, and many other network functions.

To prepare a custom network to be initialized with `initlay`,

- 1 Set `net.initFcn` to `'initlay'`. This sets `net.initParam` to the empty matrix `[]`, because `initlay` has no initialization parameters.
- 2 Set each `net.layers{i}.initFcn` to a layer initialization function. (Examples of such functions are `initwb` and `initnw`.)

To initialize the network, call `init`.

## Algorithms

The weights and biases of each layer `i` are initialized according to `net.layers{i}.initFcn`.

## Version History

Introduced before R2006a

# initlvq

LVQ weight initialization function

## Syntax

```
initlvq('configure',x)
initlvq('configure',net,'IW',i,j,settings)
initlvq('configure',net,'LW',i,j,settings)
initlvq('configure',net,'b',i,)
```

## Description

`initlvq('configure',x)` takes input data `x` and returns initialization settings for an LVQ weights associated with that input.

`initlvq('configure',net,'IW',i,j,settings)` takes a network, and indices indicating an input weight to layer `i` from input `j`, and that weights settings, and returns new weight values.

`initlvq('configure',net,'LW',i,j,settings)` takes a network, and indices indicating a layer weight to layer `i` from layer `j`, and that weights settings, and returns new weight values.

`initlvq('configure',net,'b',i,)` takes a network, and an index indicating a bias for layer `i`, and returns new bias values.

## Version History

Introduced in R2010b

## See Also

`lvqnet` | `init`

## initnw

Nguyen-Widrow layer initialization function

### Syntax

```
net = initnw(net,i)
```

### Description

`initnw` is a layer initialization function that initializes a layer's weights and biases according to the Nguyen-Widrow initialization algorithm. This algorithm chooses values in order to distribute the active region of each neuron in the layer approximately evenly across the layer's input space. The values contain a degree of randomness, so they are not the same each time this function is called.

`initnw` requires that the layer it initializes have a transfer function with a finite active input range. This includes transfer functions such as `tansig` and `satlin`, but not `purelin`, whose active input range is the infinite interval  $[-\infty, \infty]$ . Transfer functions, such as `tansig`, will return their active input range as follows:

```
activeInputRange = tansig('active')
activeInputRange =
    -2     2
```

`net = initnw(net,i)` takes two arguments,

<code>net</code>	Neural network
<code>i</code>	Index of a layer

and returns the network with layer `i`'s weights and biases updated.

There is a random element to Nguyen-Widrow initialization. Unless the default random generator is set to the same seed before each call to `initnw`, it will generate different weight and bias values each time.

### Network Use

You can create a standard network that uses `initnw` by calling `feedforwardnet` or `cascadeforwardnet`.

To prepare a custom network to be initialized with `initnw`,

- 1 Set `net.initFcn` to `'initlay'`. This sets `net.initParam` to the empty matrix `[]`, because `initlay` has no initialization parameters.
- 2 Set `net.layers{i}.initFcn` to `'initnw'`.

To initialize the network, call `init`.

## Algorithms

The Nguyen-Widrow method generates initial weight and bias values for a layer so that the active regions of the layer's neurons are distributed approximately evenly over the input space.

Advantages over purely random weights and biases are

- Few neurons are wasted (because all the neurons are in the input space).
- Training works faster (because each area of the input space has neurons). The Nguyen-Widrow method can only be applied to layers
  - With a bias
  - With weights whose `weightFcn` is `dotprod`
  - With `netInputFcn` set to `netsum`
  - With `transferFcn` whose active region is finite

If these conditions are not met, then `initnw` uses `rands` to initialize the layer's weights and biases.

## Version History

Introduced before R2006a

`cascaforwardnet` | `feedforwardnet` | `init` | `initlay` | `initwb`

## initwb

By weight and bias layer initialization function

### Syntax

```
initwb(net,i)
```

### Description

`initwb` is a layer initialization function that initializes a layer's weights and biases according to their own initialization functions.

`initwb(net,i)` takes two arguments,

<code>net</code>	Neural network
<code>i</code>	Index of a layer

and returns the network with layer `i`'s weights and biases updated.

### Network Use

You can create a standard network that uses `initwb` by calling `perceptron` or `linearlayer`.

To prepare a custom network to be initialized with `initwb`,

- 1 Set `net.initFcn` to `'initlay'`. This sets `net.initParam` to the empty matrix `[]`, because `initlay` has no initialization parameters.
- 2 Set `net.layers{i}.initFcn` to `'initwb'`.
- 3 Set each `net.inputWeights{i,j}.initFcn` to a weight initialization function. Set each `net.layerWeights{i,j}.initFcn` to a weight initialization function. Set each `net.biases{i}.initFcn` to a bias initialization function. Examples of initialization functions are `rands` (for weights and biases) and `midpoint` (for weights only).

To initialize the network, call `init`.

### Algorithms

Each weight (bias) in layer `i` is set to new values calculated according to its weight (bias) initialization function.

## Version History

Introduced before R2006a

# initzero

Zero weight and bias initialization function

## Syntax

```
W = initzero(S,PR)
b = initzero(S,[1 1])
```

## Description

`W = initzero(S,PR)` takes two arguments,

S	Number of rows (neurons)
PR	R-by-2 matrix of input value ranges = [Pmin Pmax]

and returns an S-by-R weight matrix of zeros.

`b = initzero(S,[1 1])` returns an S-by-1 bias vector of zeros.

## Examples

Here initial weights and biases are calculated for a layer with two inputs ranging over [0 1] and [-2 2] and four neurons.

```
W = initzero(5,[0 1; -2 2])
b = initzero(5,[1 1])
```

## Version History

Introduced before R2006a

## See Also

initwb | initlay | init

## isconfigured

Indicate if network inputs and outputs are configured

### Syntax

```
[flag,inputflags,outputflags] = isconfigured(net)
```

### Description

[flag,inputflags,outputflags] = isconfigured(net) takes a neural network and returns three values,

flag	True if all network inputs and outputs are configured (have non-zero sizes)
inputflags	Vector of true/false values for each configured/unconfigured input
outputflags	Vector of true/false values for each configured/unconfigured output

### Examples

Here are the flags returned for a new network before and after being configured:

```
net = feedforwardnet;  
[flag,inputFlags,outputFlags] = isconfigured(net)  
[x,t] = simplefit_dataset;  
net = configure(net,x,t);  
[flag,inputFlags,outputFlags] = isconfigured(net)
```

# layrecnet

Layer recurrent neural network

## Syntax

```
layrecnet(layerDelays,hiddenSizes,trainFcn)
```

## Description

`layrecnet(layerDelays,hiddenSizes,trainFcn)` takes these arguments:

- Row vector of increasing 0 or positive delays, `layerDelays`
- Row vector of one or more hidden layer sizes, `hiddenSizes`
- Backpropagation training function, `trainFcn`

and returns a layer recurrent neural network.

Layer recurrent neural networks are similar to feedforward networks, except that each layer has a recurrent connection with a tap delay associated with it. This allows the network to have an infinite dynamic response to time series input data. This network is similar to the time delay (`timedelaynet`) and distributed delay (`distdelaynet`) neural networks, which have finite input responses.

## Examples

### Recurrent Neural Network

This example shows how to use a layer recurrent neural network to solve a simple time series problem.

```
[X,T] = simpleseries_dataset;  
net = layrecnet(1:2,10);  
[Xs,Xi,Ai,Ts] = preparets(net,X,T);  
net = train(net,Xs,Ts,Xi,Ai);
```

## Input Arguments

### layerDelays — Input delays

[1:2] (default) | row vector

Zero or positive input delays, specified as an increasing row vector.

### hiddenSizes — Hidden sizes

10 (default) | row vector

Sizes of the hidden layers, specified as a row vector of one or more elements.

### trainFcn — Training function name

'trainlm' (default) | 'trainbr' | 'trainbfg' | 'trainrp' | 'trainscg' | ...

Training function name, specified as one of the following.

<b>Training Function</b>	<b>Algorithm</b>
'trainlm'	Levenberg-Marquardt
'trainbr'	Bayesian Regularization
'trainbfg'	BFGS Quasi-Newton
'trainrp'	Resilient Backpropagation
'trainscg'	Scaled Conjugate Gradient
'traincgb'	Conjugate Gradient with Powell/Beale Restarts
'traincgf'	Fletcher-Powell Conjugate Gradient
'traincgp'	Polak-Ribière Conjugate Gradient
'trainoss'	One Step Secant
'traingdx'	Variable Learning Rate Gradient Descent
'traingdm'	Gradient Descent with Momentum
'traingd'	Gradient Descent

Example: For example, you can specify the variable learning rate gradient descent algorithm as the training algorithm as follows: 'traingdx'

For more information on the training functions, see “Train and Apply Multilayer Shallow Neural Networks” and “Choose a Multilayer Neural Network Training Function”.

Data Types: char

# learncon

Conscience bias learning function

## Syntax

```
[dB,LS] = learncon(B,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learncon('code')
```

## Description

learncon is the conscience bias learning function used to increase the net input to neurons that have the lowest average output until each neuron responds approximately an equal percentage of the time.

[dB,LS] = learncon(B,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

B	S-by-1 bias vector
P	1-by-Q ones vector
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dB	S-by-1 weight (or bias) change matrix
LS	New learning state

Learning occurs according to learncon's learning parameter, shown here with its default value.

LP.lr - 0.001	Learning rate
---------------	---------------

info = learncon('code') returns useful information for each supported *code* character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

Deep Learning Toolbox 2.0 compatibility: The `LP.lr` described above equals 1 minus the bias time constant used by `trainc` in the Deep Learning Toolbox 2.0 software.

### Examples

Here you define a random output `A` and bias vector `W` for a layer with three neurons. You also define the learning rate `LR`.

```
a = rand(3,1);  
b = rand(3,1);  
lp.lr = 0.5;
```

Because `learncon` only needs these values to calculate a bias change (see “Algorithm” below), use them to do so.

```
dW = learncon(b,[],[],[],a,[],[],[],[],[],lp,[])
```

### Network Use

To prepare the bias of layer `i` of a custom network to learn with `learncon`,

- 1 Set `net.trainFcn` to 'trainr'. (`net.trainParam` automatically becomes `trainr`'s default parameters.)
- 2 Set `net.adaptFcn` to 'trains'. (`net.adaptParam` automatically becomes `trains`'s default parameters.)
- 3 Set `net.inputWeights{i}.learnFcn` to 'learncon'
- 4 Set each `net.layerWeights{i,j}.learnFcn` to 'learncon'. (Each weight learning parameter property is automatically set to `learncon`'s default parameters.)

To train the network (or enable it to adapt),

- 1 Set `net.trainParam` (or `net.adaptParam`) properties as desired.
- 2 Call `train` (or `adapt`).

### Algorithms

`learncon` calculates the bias change `db` for a given neuron by first updating each neuron's *conscience*, i.e., the running average of its output:

$$c = (1-lr)*c + lr*a$$

The conscience is then used to compute a bias for the neuron that is greatest for smaller conscience values.

$$b = \exp(1-\log(c)) - b$$

(`learncon` recovers `C` from the bias values each time it is called.)

### Version History

Introduced before R2006a

# learnngd

Gradient descent weight and bias learning function

## Syntax

```
[dW,LS] = learnngd(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnngd('code')
```

## Description

learnngd is the gradient descent weight and bias learning function.

[dW,LS] = learnngd(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs:

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones (1,Q))
Z	S-by-Q output gradient with respect to performance x Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnngd's learning parameter, shown here with its default value.

LP.lr - 0.01	Learning rate
--------------	---------------

info = learnngd('code') returns useful information for each supported code character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random gradient  $gW$  for a weight going to a layer with three neurons from an input with two elements. Also define a learning rate of 0.5.

```
gW = rand(3,2);  
lp.lr = 0.5;
```

Because `learnngd` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnngd([],[],[],[],[],[],[],gW,[],[],lp,[])
```

## Algorithms

`learnngd` calculates the weight change  $dW$  for a given neuron from the neuron’s input  $P$  and error  $E$ , and the weight (or bias) learning rate  $LR$ , according to the gradient descent  $dw = lr * gW$ .

## Version History

Introduced before R2006a

## learngdm

Gradient descent with momentum weight and bias learning function

### Syntax

```
[dW,LS] = learngdm(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learngdm('code')
```

### Description

learngdm is the gradient descent with momentum weight and bias learning function.

[dW,LS] = learngdm(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones (1, Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learngdm's learning parameters, shown here with their default values.

LP.lr - 0.01	Learning rate
LP.mc - 0.9	Momentum constant

info = learngdm('code') returns useful information for each code character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random gradient  $G$  for a weight going to a layer with three neurons from an input with two elements. Also define a learning rate of 0.5 and momentum constant of 0.8:

```
gW = rand(3,2);  
lp.lr = 0.5;  
lp.mc = 0.8;
```

Because `learngdm` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so. Use the default initial learning state.

```
ls = [];  
[dW,ls] = learngdm([],[],[],[],[],[],[],gW,[],[],lp,ls)
```

`learngdm` returns the weight change and a new learning state.

## Algorithms

`learngdm` calculates the weight change  $dW$  for a given neuron from the neuron’s input  $P$  and error  $E$ , the weight (or bias)  $W$ , learning rate  $LR$ , and momentum constant  $MC$ , according to gradient descent with momentum:

$$dW = mc*dW_{prev} + (1-mc)*lr*gW$$

The previous weight change  $dW_{prev}$  is stored and read from the learning state  $LS$ .

## Version History

Introduced before R2006a

## learnh

Hebb weight learning rule

### Syntax

```
[dW,LS] = learnh(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnh('code')
```

### Description

learnh is the Hebb weight learning function.

[dW,LS] = learnh(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones(1,Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnh's learning parameter, shown here with its default value.

LP.lr - 0.01	Learning rate
--------------	---------------

info = learnh('code') returns useful information for each code character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input *P* and output *A* for a layer with a two-element input and three neurons. Also define the learning rate *LR*.

```
p = rand(2,1);
a = rand(3,1);
lp.lr = 0.5;
```

Because `learnh` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnh([],p,[],[],a,[],[],[],[],[],lp,[])
```

## Network Use

To prepare the weights and the bias of layer *i* of a custom network to learn with `learnh`,

- 1 Set `net.trainFcn` to 'trainr'. (`net.trainParam` automatically becomes `trainr`'s default parameters.)
- 2 Set `net.adaptFcn` to 'trains'. (`net.adaptParam` automatically becomes `trains`'s default parameters.)
- 3 Set each `net.inputWeights{i,j}.learnFcn` to 'learnh'.
- 4 Set each `net.layerWeights{i,j}.learnFcn` to 'learnh'. (Each weight learning parameter property is automatically set to `learnh`'s default parameters.)

To train the network (or enable it to adapt),

- 1 Set `net.trainParam` (or `net.adaptParam`) properties to desired values.
- 2 Call `train` (`adapt`).

## Algorithms

`learnh` calculates the weight change *dW* for a given neuron from the neuron's input *P*, output *A*, and learning rate *LR* according to the Hebb learning rule:

```
dw = lr*a*p'
```

## learnhd

Hebb with decay weight learning rule

### Syntax

```
[dW,LS] = learnhd(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnhd('code')
```

### Description

learnhd is the Hebb weight learning function.

[dW,LS] = learnhd(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones(1,Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnhd's learning parameters, shown here with default values.

LP.dr - 0.01	Decay rate
LP.lr - 0.1	Learning rate

info = learnhd('code') returns useful information for each code character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input  $P$ , output  $A$ , and weights  $W$  for a layer with a two-element input and three neurons. Also define the decay and learning rates.

```
p = rand(2,1);
a = rand(3,1);
w = rand(3,2);
lp.dr = 0.05;
lp.lr = 0.5;
```

Because `learnhd` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnhd(w,p,[],[],a,[],[],[],[],[],lp,[])
```

## Network Use

To prepare the weights and the bias of layer  $i$  of a custom network to learn with `learnhd`,

- 1 Set `net.trainFcn` to 'trainr'. (`net.trainParam` automatically becomes `trainr`'s default parameters.)
- 2 Set `net.adaptFcn` to 'trains'. (`net.adaptParam` automatically becomes `trains`'s default parameters.)
- 3 Set each `net.inputWeights{i,j}.learnFcn` to 'learnhd'.
- 4 Set each `net.layerWeights{i,j}.learnFcn` to 'learnhd'. (Each weight learning parameter property is automatically set to `learnhd`'s default parameters.)

To train the network (or enable it to adapt),

- 1 Set `net.trainParam` (or `net.adaptParam`) properties to desired values.
- 2 Call `train` (`adapt`).

## Algorithms

`learnhd` calculates the weight change  $dW$  for a given neuron from the neuron's input  $P$ , output  $A$ , decay rate  $DR$ , and learning rate  $LR$  according to the Hebb with decay learning rule:

$$dw = lr*a*p' - dr*w$$

## Version History

Introduced before R2006a

## learnis

Instar weight learning function

### Syntax

```
[dW,LS] = learnis(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnis('code')
```

### Description

learnis is the instar weight learning function.

[dW,LS] = learnis(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones(1,Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnis's learning parameter, shown here with its default value.

LP.lr - 0.01	Learning rate
--------------	---------------

info = learnis('code') returns useful information for each *code* character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input  $P$ , output  $A$ , and weight matrix  $W$  for a layer with a two-element input and three neurons. Also define the learning rate  $LR$ .

```
p = rand(2,1);
a = rand(3,1);
w = rand(3,2);
lp.lr = 0.5;
```

Because `learnis` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnis(w,p,[],[],a,[],[],[],[],[],lp,[])
```

## Network Use

To prepare the weights and the bias of layer  $i$  of a custom network so that it can learn with `learnis`,

- 1 Set `net.trainFcn` to 'trainr'. (`net.trainParam` automatically becomes `trainr`'s default parameters.)
- 2 Set `net.adaptFcn` to 'trains'. (`net.adaptParam` automatically becomes `trains`'s default parameters.)
- 3 Set each `net.inputWeights{i,j}.learnFcn` to 'learnis'.
- 4 Set each `net.layerWeights{i,j}.learnFcn` to 'learnis'. (Each weight learning parameter property is automatically set to `learnis`'s default parameters.)

To train the network (or enable it to adapt),

- 1 Set `net.trainParam` (`net.adaptParam`) properties to desired values.
- 2 Call `train` (`adapt`).

## Algorithms

`learnis` calculates the weight change  $dW$  for a given neuron from the neuron's input  $P$ , output  $A$ , and learning rate  $LR$  according to the instar learning rule:

$$dw = lr * a * (p - w)$$

## learnk

Kohonen weight learning function

### Syntax

```
[dW,LS] = learnk(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnk('code')
```

### Description

learnk is the Kohonen weight learning function.

[dW,LS] = learnk(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones(1,Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnk's learning parameter, shown here with its default value.

LP.lr - 0.01	Learning rate
--------------	---------------

info = learnk('code') returns useful information for each code character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input  $P$ , output  $A$ , and weight matrix  $W$  for a layer with a two-element input and three neurons. Also define the learning rate  $LR$ .

```
p = rand(2,1);
a = rand(3,1);
w = rand(3,2);
lp.lr = 0.5;
```

Because `learnk` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnk(w,p,[],[],a,[],[],[],[],[],lp,[])
```

## Network Use

To prepare the weights of layer  $i$  of a custom network to learn with `learnk`,

- 1 Set `net.trainFcn` to 'trainr'. (`net.trainParam` automatically becomes `trainr`'s default parameters.)
- 2 Set `net.adaptFcn` to 'trains'. (`net.adaptParam` automatically becomes `trains`'s default parameters.)
- 3 Set each `net.inputWeights{i,j}.learnFcn` to 'learnk'.
- 4 Set each `net.layerWeights{i,j}.learnFcn` to 'learnk'. (Each weight learning parameter property is automatically set to `learnk`'s default parameters.)

To train the network (or enable it to adapt),

- 1 Set `net.trainParam` (or `net.adaptParam`) properties as desired.
- 2 Call `train` (or `adapt`).

## Algorithms

`learnk` calculates the weight change  $dW$  for a given neuron from the neuron's input  $P$ , output  $A$ , and learning rate  $LR$  according to the Kohonen learning rule:

$$dw = lr*(p' - w), \text{ if } a \sim \theta; = 0, \text{ otherwise}$$

## learnlv1

LVQ1 weight learning function

### Syntax

```
[dW,LS] = learnlv1(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnlv1('code')
```

### Description

learnlv1 is the LVQ1 weight learning function.

[dW,LS] = learnlv1(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones(1,Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnlv1's learning parameter, shown here with its default value.

LP.lr - 0.01	Learning rate
--------------	---------------

info = learnlv1('code') returns useful information for each *code* character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input  $P$ , output  $A$ , weight matrix  $W$ , and output gradient  $gA$  for a layer with a two-element input and three neurons. Also define the learning rate  $LR$ .

```
p = rand(2,1);
w = rand(3,2);
a = compet(negdist(w,p));
gA = [-1;1; 1];
lp.lr = 0.5;
```

Because `learnlv1` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnlv1(w,p,[],[],a,[],[],[],gA,[],lp,[])
```

## Network Use

You can create a standard network that uses `learnlv1` with `lvqnet`. To prepare the weights of layer  $i$  of a custom network to learn with `learnlv1`,

- 1 Set `net.trainFcn` to 'trainr'. (`net.trainParam` automatically becomes `trainr`'s default parameters.)
- 2 Set `net.adaptFcn` to 'trains'. (`net.adaptParam` automatically becomes `trains`'s default parameters.)
- 3 Set each `net.inputWeights{i,j}.learnFcn` to 'learnlv1'.
- 4 Set each `net.layerWeights{i,j}.learnFcn` to 'learnlv1'. (Each weight learning parameter property is automatically set to `learnlv1`'s default parameters.)

To train the network (or enable it to adapt),

- 1 Set `net.trainParam` (or `net.adaptParam`) properties as desired.
- 2 Call `train` (or `adapt`).

## Algorithms

`learnlv1` calculates the weight change  $dW$  for a given neuron from the neuron's input  $P$ , output  $A$ , output gradient  $gA$ , and learning rate  $LR$ , according to the LVQ1 rule, given  $i$ , the index of the neuron whose output  $a(i)$  is 1:

$$dw(i,:) = +lr*(p-w(i,:)) \text{ if } gA(i) = 0; = -lr*(p-w(i,:)) \text{ if } gA(i) = -1$$

## Version History

Introduced before R2006a

## learnlv2

LVQ2.1 weight learning function

### Syntax

```
[dW,LS] = learnlv2(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnlv2('code')
```

### Description

learnlv2 is the LVQ2 weight learning function.

[dW,LS] = learnlv2(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones (1, Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R weight gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnlv2's learning parameter, shown here with its default value.

LP.lr - 0.01	Learning rate
LP.window - 0.25	Window size (0 to 1, typically 0.2 to 0.3)

info = learnlv2('code') returns useful information for each code character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a sample input  $P$ , output  $A$ , weight matrix  $W$ , and output gradient  $gA$  for a layer with a two-element input and three neurons. Also define the learning rate  $LR$ .

```
p = rand(2,1);
w = rand(3,2);
n = negdist(w,p);
a = compet(n);
gA = [-1;1; 1];
lp.lr = 0.5;
```

Because `learnlv2` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnlv2(w,p,[],n,a,[],[],[],gA,[],lp,[])
```

## Network Use

You can create a standard network that uses `learnlv2` with `lvqnet`.

To prepare the weights of layer  $i$  of a custom network to learn with `learnlv2`,

- 1 Set `net.trainFcn` to 'trainr'. (`net.trainParam` automatically becomes `trainr`'s default parameters.)
- 2 Set `net.adaptFcn` to 'trains'. (`net.adaptParam` automatically becomes `trains`'s default parameters.)
- 3 Set each `net.inputWeights{i,j}.learnFcn` to 'learnlv2'.
- 4 Set each `net.layerWeights{i,j}.learnFcn` to 'learnlv2'. (Each weight learning parameter property is automatically set to `learnlv2`'s default parameters.)

To train the network (or enable it to adapt),

- 1 Set `net.trainParam` (or `net.adaptParam`) properties as desired.
- 2 Call `train` (or `adapt`).

## Algorithms

`learnlv2` implements Learning Vector Quantization 2.1, which works as follows:

For each presentation, if the winning neuron  $i$  should not have won, and the runnerup  $j$  should have, and the distance  $d_i$  between the winning neuron and the input  $p$  is roughly equal to the distance  $d_j$  from the runnerup neuron to the input  $p$  according to the given window,

$$\min(d_i/d_j, d_j/d_i) > (1-\text{window})/(1+\text{window})$$

then move the winning neuron  $i$  weights away from the input vector, and move the runnerup neuron  $j$  weights toward the input according to

$$\begin{aligned} dw(i,:) &= -lp.lr*(p'-w(i,:)) \\ dw(j,:) &= +lp.lr*(p'-w(j,:)) \end{aligned}$$

# learnos

Outstar weight learning function

## Syntax

```
[dW,LS] = learnos(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnos('code')
```

## Description

learnos is the outstar weight learning function.

[dW,LS] = learnos(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones(1,Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R weight gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnos's learning parameter, shown here with its default value.

LP.lr - 0.01	Learning rate
--------------	---------------

info = learnos('code') returns useful information for each *code* character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input *P*, output *A*, and weight matrix *W* for a layer with a two-element input and three neurons. Also define the learning rate *LR*.

```
p = rand(2,1);  
a = rand(3,1);  
w = rand(3,2);  
lp.lr = 0.5;
```

Because `learnos` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnos(w,p,[],[],a,[],[],[],[],[],lp,[])
```

## Network Use

To prepare the weights and the bias of layer *i* of a custom network to learn with `learnos`,

- 1 Set `net.trainFcn` to 'trainr'. (`net.trainParam` automatically becomes `trainr`'s default parameters.)
- 2 Set `net.adaptFcn` to 'trains'. (`net.adaptParam` automatically becomes `trains`'s default parameters.)
- 3 Set each `net.inputWeights{i,j}.learnFcn` to 'learnos'.
- 4 Set each `net.layerWeights{i,j}.learnFcn` to 'learnos'. (Each weight learning parameter property is automatically set to `learnos`'s default parameters.)

To train the network (or enable it to adapt),

- 1 Set `net.trainParam` (or `net.adaptParam`) properties to desired values.
- 2 Call `train(adapt)`.

## Algorithms

`learnos` calculates the weight change *dW* for a given neuron from the neuron's input *P*, output *A*, and learning rate *LR* according to the outstar learning rule:

```
dw = lr*(a-w)*p'
```

# learnp

Perceptron weight and bias learning function

## Syntax

```
[dW,LS] = learnp(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnp('code')
```

## Description

learnp is the perceptron weight/bias learning function.

[dW,LS] = learnp(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or b, and S-by-1 bias vector)
P	R-by-Q input vectors (or ones (1, Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R weight gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

info = learnp('code') returns useful information for each *code* character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input P and error E for a layer with a two-element input and three neurons.

```
p = rand(2,1);
e = rand(3,1);
```

Because `learnp` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dw = learnp([],p,[],[],[],[],e,[],[],[],[],[])
```

### Algorithms

`learnp` calculates the weight change  $dw$  for a given neuron from the neuron’s input  $P$  and error  $E$  according to the perceptron learning rule:

$$\begin{aligned} dw &= 0, \text{ if } e = 0 \\ &= p', \text{ if } e = 1 \\ &= -p', \text{ if } e = -1 \end{aligned}$$

This can be summarized as

$$dw = e * p'$$

`adapt` | `learnpn` | `train`

# learnpn

Normalized perceptron weight and bias learning function

## Syntax

```
[dW,LS] = learnpn(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnpn('code')
```

## Description

Learnpn is a weight and bias learning function. It can result in faster learning than learnp when input vectors have widely varying magnitudes.

[dW,LS] = learnpn(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones (1,Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R weight gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

info = learnpn('code') returns useful information for each *code* character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input P and error E for a layer with a two-element input and three neurons.

```
p = rand(2,1);  
e = rand(3,1);
```

Because `learnpn` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnpn([],p,[],[],[],[],e,[],[],[],[],[])
```

## Limitations

Perceptrons do have one real limitation. The set of input vectors must be linearly separable if a solution is to be found. That is, if the input vectors with targets of 1 cannot be separated by a line or hyperplane from the input vectors associated with values of 0, the perceptron will never be able to classify them correctly.

## Algorithms

`learnpn` calculates the weight change  $dW$  for a given neuron from the neuron’s input  $P$  and error  $E$  according to the normalized perceptron learning rule:

```
pn = p / sqrt(1 + p(1)^2 + p(2)^2) + ... + p(R)^2)  
dw = 0, if e = 0  
     = pn', if e = 1  
     = -pn', if e = -1
```

The expression for  $dW$  can be summarized as

```
dw = e*pn'
```

## Version History

Introduced before R2006a

# learnsom

Self-organizing map weight learning function

## Syntax

```
[dW,LS] = learnsom(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnsom('code')
```

## Description

learnsom is the self-organizing map weight learning function.

[dW,LS] = learnsom(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones (1, Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R weight gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnsom's learning parameters, shown here with their default values.

LP.order_lr	0.9	Ordering phase learning rate
LP.order_steps	1000	Ordering phase steps
LP.tune_lr	0.02	Tuning phase learning rate
LP.tune_nd	1	Tuning phase neighborhood distance

info = learnsom('code') returns useful information for each code character vector:

'pnames'	Names of learning parameters
----------	------------------------------

'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input P, output A, and weight matrix W for a layer with a two-element input and six neurons. You also calculate positions and distances for the neurons, which are arranged in a 2-by-3 hexagonal pattern. Then you define the four learning parameters.

```
p = rand(2,1);
a = rand(6,1);
w = rand(6,2);
pos = hextop(2,3);
d = linkdist(pos);
lp.order_lr = 0.9;
lp.order_steps = 1000;
lp.tune_lr = 0.02;
lp.tune_nd = 1;
```

Because `learnsom` only needs these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
ls = [];
[dW,ls] = learnsom(w,p,[],[],a,[],[],[],[],d,lp,ls)
```

## Algorithms

`learnsom` calculates the weight change  $dW$  for a given neuron from the neuron’s input P, activation A2, and learning rate LR:

$$dw = lr * a2 * (p' - w)$$

where the activation A2 is found from the layer output A, neuron distances D, and the current neighborhood size ND:

$$a2(i,q) = \begin{cases} 1, & \text{if } a(i,q) = 1 \\ 0.5, & \text{if } a(j,q) = 1 \text{ and } D(i,j) \leq nd \\ 0, & \text{otherwise} \end{cases}$$

The learning rate LR and neighborhood size NS are altered through two phases: an ordering phase and a tuning phase.

The ordering phases lasts as many steps as `LP.order_steps`. During this phase LR is adjusted from `LP.order_lr` down to `LP.tune_lr`, and ND is adjusted from the maximum neuron distance down to 1. It is during this phase that neuron weights are expected to order themselves in the input space consistent with the associated neuron positions.

During the tuning phase LR decreases slowly from `LP.tune_lr`, and ND is always set to `LP.tune_nd`. During this phase the weights are expected to spread out relatively evenly over the input space while retaining their topological order, determined during the ordering phase.

## learnsomb

Batch self-organizing map weight learning function

### Syntax

```
[dW,LS] = learnsomb(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnsomb('code')
```

### Description

learnsomb is the batch self-organizing map weight learning function.

[dW,LS] = learnsomb(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs:

W	S-by-R weight matrix (or S-by-1 bias vector)
P	R-by-Q input vectors (or ones (1, Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns the following:

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to learnsomb's learning parameter, shown here with its default value:

LP.init_neighborhood	3	Initial neighborhood size
LP.steps	100	Ordering phase steps

info = learnsomb('code') returns useful information for each code character vector:

'pnames'	Returns names of learning parameters.
'pdefaults'	Returns default learning parameters.
'needg'	Returns 1 if this function uses gW or gA.

## Examples

This example defines a random input  $P$ , output  $A$ , and weight matrix  $W$  for a layer with a 2-element input and 6 neurons. This example also calculates the positions and distances for the neurons, which appear in a 2-by-3 hexagonal pattern.

```
p = rand(2,1);
a = rand(6,1);
w = rand(6,2);
pos = hextop(2,3);
d = linkdist(pos);
lp = learnsomb('pdefaults');
```

Because `learnsomb` only needs these values to calculate a weight change (see Algorithm).

```
ls = [];
[dW,ls] = learnsomb(w,p,[],[],a,[],[],[],[],d,lp,ls)
```

## Network Use

You can create a standard network that uses `learnsomb` with `selforgmap`. To prepare the weights of layer  $i$  of a custom network to learn with `learnsomb`:

- 1 Set `NET.trainFcn` to 'trainr'. (`NET.trainParam` automatically becomes `trainr`'s default parameters.)
- 2 Set `NET.adaptFcn` to 'trains'. (`NET.adaptParam` automatically becomes `trains`'s default parameters.)
- 3 Set each `NET.inputWeights{i,j}.learnFcn` to 'learnsomb'.
- 4 Set each `NET.layerWeights{i,j}.learnFcn` to 'learnsomb'. (Each weight learning parameter property is automatically set to `learnsomb`'s default parameters.)

To train the network (or enable it to adapt):

- 1 Set `NET.trainParam` (or `NET.adaptParam`) properties as desired.
- 2 Call `train` (or `adapt`).

## Algorithms

`learnsomb` calculates the weight changes so that each neuron's new weight vector is the weighted average of the input vectors that the neuron and neurons in its neighborhood responded to with an output of 1.

The ordering phase lasts as many steps as `LP.steps`.

During this phase, the neighborhood is gradually reduced from a maximum size of `LP.init_neighborhood` down to 1, where it remains from then on.

# learnwh

Widrow-Hoff weight/bias learning function

## Syntax

```
[dW,LS] = learnwh(W,P,Z,N,A,T,E,gW,gA,D,LP,LS)
info = learnwh('code')
```

## Description

learnwh is the Widrow-Hoff weight/bias learning function, and is also known as the delta or least mean squared (LMS) rule.

[dW,LS] = learnwh(W,P,Z,N,A,T,E,gW,gA,D,LP,LS) takes several inputs,

W	S-by-R weight matrix (or b, and S-by-1 bias vector)
P	R-by-Q input vectors (or ones (1,Q))
Z	S-by-Q weighted input vectors
N	S-by-Q net input vectors
A	S-by-Q output vectors
T	S-by-Q layer target vectors
E	S-by-Q layer error vectors
gW	S-by-R weight gradient with respect to performance
gA	S-by-Q output gradient with respect to performance
D	S-by-S neuron distances
LP	Learning parameters, none, LP = []
LS	Learning state, initially should be = []

and returns

dW	S-by-R weight (or bias) change matrix
LS	New learning state

Learning occurs according to the learnwh learning parameter, shown here with its default value.

LP.lr – 0.01	Learning rate
--------------	---------------

info = learnwh('code') returns useful information for each code character vector:

'pnames'	Names of learning parameters
'pdefaults'	Default learning parameters
'needg'	Returns 1 if this function uses gW or gA

## Examples

Here you define a random input  $P$  and error  $E$  for a layer with a two-element input and three neurons. You also define the learning rate  $LR$  learning parameter.

```
p = rand(2,1);  
e = rand(3,1);  
lp.lr = 0.5;
```

Because `learnwh` needs only these values to calculate a weight change (see “Algorithm” below), use them to do so.

```
dW = learnwh([],p,[],[],[],[],e,[],[],[],lp,[])
```

## Network Use

You can create a standard network that uses `learnwh` with `linearlayer`.

To prepare the weights and the bias of layer  $i$  of a custom network to learn with `learnwh`,

- 1 Set `net.trainFcn` to 'trainb'. `net.trainParam` automatically becomes `trainb`'s default parameters.
- 2 Set `net.adaptFcn` to 'trains'. `net.adaptParam` automatically becomes `trains`'s default parameters.
- 3 Set each `net.inputWeights{i,j}.learnFcn` to 'learnwh'.
- 4 Set each `net.layerWeights{i,j}.learnFcn` to 'learnwh'.
- 5 Set `net.biases{i}.learnFcn` to 'learnwh'. Each weight and bias learning parameter property is automatically set to the `learnwh` default parameters.

To train the network (or enable it to adapt),

- 1 Set `net.trainParam` (or `net.adaptParam`) properties to desired values.
- 2 Call `train` (or `adapt`).

## Algorithms

`learnwh` calculates the weight change  $dW$  for a given neuron from the neuron's input  $P$  and error  $E$ , and the weight (or bias) learning rate  $LR$ , according to the Widrow-Hoff learning rule:

```
dw = lr*e*pn'
```

## linearlayer

Create linear layer

### Syntax

```
layer = linearlayer(inputDelays,widrowHoffLR)
```

### Description

`layer = linearlayer(inputDelays,widrowHoffLR)` takes a row vector of increasing 0 or positive delays and the Widrow-Hoff learning rate, and returns a linear layer.

Linear layers are single layers of linear neurons. They are static, with input delays of 0, or dynamic, with input delays greater than 0. You can train them on simple linear time series problems, but often are used adaptively to continue learning while deployed so they can adjust to changes in the relationship between inputs and outputs while being used.

If the learning rate is too small, learning happens very slowly. However, a greater danger is that it might be too large and learning becomes unstable resulting in large changes to weight vectors and errors increasing instead of decreasing. If a data set is available which characterizes the relationship the layer is to learn, you can calculate the maximum stable learning rate with the `maxlinlr` function.

If you need a network to solve a nonlinear time series relationship, see `timedelaynet`, `narxnet`, and `narnet`.

### Examples

#### Create and Train a Linear Layer

This example shows how to create and train a linear layer.

Create a linear layer and train it on a simple time series problem.

```
x = {0 -1 1 1 0 -1 1 0 0 1};  
t = {0 -1 0 2 1 -1 0 1 0 1};  
net = linearlayer(1:2,0.01);  
[Xs,Xi,Ai,Ts] = preparets(net,x,t);  
net = train(net,Xs,Ts,Xi,Ai);
```

Network Diagram

### Training Results

`view(net)`

```
Y = net(Xs, Xi);
perf = perform(net, Ts, Y)
```

perf = 0.2396

## Input Arguments

### **inputDelays** — Input delays

row vector

Increasing 0 or positive delays, specified as a row vector.

### **widrowHoffLR** — Widrow-Hoff learning rate

0.01 (default) | scalar

Widrow-Hoff learning rate, specified as a scalar.

## Output Arguments

### **layer** — Network layer

network

Linear layer of a network, returned as a network object.

## Version History

## linkdist

Link distance function

### Syntax

```
d = linkdist(pos)
```

### Description

`linkdist` is a layer distance function used to find the distances between the layer's neurons given their positions.

`d = linkdist(pos)` takes one argument,

<code>pos</code>	N-by-S matrix of neuron positions
------------------	-----------------------------------

and returns the S-by-S matrix of distances.

### Examples

Here you define a random matrix of positions for 10 neurons arranged in three-dimensional space and find their distances.

```
pos = rand(3,10);  
D = linkdist(pos)
```

### Network Use

You can create a standard network that uses `linkdist` as a distance function by calling `selforgmap`.

To change a network so that a layer's topology uses `linkdist`, set `net.layers{i}.distanceFcn` to `'linkdist'`.

In either case, call `sim` to simulate the network with `dist`.

### Algorithms

The link distance  $D$  between two position vectors  $P_i$  and  $P_j$  from a set of  $S$  vectors is

```
Dij = 0, if i == j  
      = 1, if (sum((Pi-Pj).2)).0.5 is <= 1  
      = 2, if k exists, Dik = Dkj = 1  
      = 3, if k1, k2 exist, Dik1 = Dk1k2 = Dk2j = 1  
      = N, if k1..kN exist, Dik1 = Dk1k2 = ... = DkNj = 1  
      = S, if none of the above conditions apply
```

## **Version History**

Introduced before R2006a

## logsig

Log-sigmoid transfer function

### Syntax

```
A = logsig(N)
dA_dN = logsig('dn',N,A,FP)
info = logsig(code)
```

### Description

---

**Tip** To use a logistic sigmoid activation for deep learning, use `sigmoidLayer` or the `dLarray` method `sigmoid`.

---

`A = logsig(N)` takes a matrix of net input vectors, `N` and returns the `S`-by-`Q` matrix, `A`, of the elements of `N` squashed into  $[0, 1]$ .

Log-Sigmoid Transfer Function

`logsig` is a transfer function. Transfer functions calculate a layer's output from its net input.

`dA_dN = logsig('dn',N,A,FP)` returns the `S`-by-`Q` derivative of `A` with respect to `N`. If `A` or `FP` are not supplied or are set to `[]`, `FP` reverts to the default parameters, and `A` is calculated from `N`.

`info = logsig(code)` returns information about this function. For more information, see the **code** argument description.

### Examples

#### Create a Plot of the `logsig` Transfer Function

This example shows how to calculate and plot the log-sigmoid transfer function of an input matrix.

Create the input matrix, `n`. Then call the `logsig` function and plot the results.

```
n = -5:0.1:5;
a = logsig(n);
plot(n,a)
```

Assign this transfer function to layer `i` of a network.

```
net.layers{i}.transferFcn = 'logsig';
```

## Input Arguments

### **N** — Input matrix

matrix

Net input column vectors, specified as an S-by-Q matrix.

### **code** — Information option

'name' | 'output' | 'active' | 'fullderiv' | 'fpnames' | 'fpdefaults'

Information you want to retrieve from the function, specified as one of the following:

- 'name' returns the name of this function.
- 'output' returns the [min max] output range.
- 'active' returns the [min max] active input range.
- 'fullderiv' returns 1 or 0, depending on whether dA\_dN is S-by-S-by-Q or S-by-Q.
- 'fpnames' returns the names of the function parameters.
- 'fpdefaults' returns the default function parameters.

## Output Arguments

### **A** — Output matrix

matrix

Output vectors, returned as an S-by-Q matrix, where each element of N is squashed from the interval [-inf inf] to the interval [0 1] with an "S-shaped" function.

## Algorithms

$$\text{logsig}(n) = 1 / (1 + \exp(-n))$$

## lvqnet

Learning vector quantization neural network

### Syntax

```
lvqnet(hiddenSize,lvqLR,lvqLF)
```

### Description

LVQ (learning vector quantization) neural networks consist of two layers. The first layer maps input vectors into clusters that are found by the network during training. The second layer merges groups of first layer clusters into the classes defined by the target data.

The total number of first layer clusters is determined by the number of hidden neurons. The larger the hidden layer the more clusters the first layer can learn, and the more complex mapping of input to target classes can be made. The relative number of first layer clusters assigned to each target class are determined according to the distribution of target classes at the time of network initialization. This occurs when the network is automatically configured the first time `train` is called, or manually configured with the function `configure`, or manually initialized with the function `init` is called.

`lvqnet(hiddenSize,lvqLR,lvqLF)` takes these arguments,

<code>hiddenSize</code>	Size of hidden layer (default = 10)
<code>lvqLR</code>	LVQ learning rate (default = 0.01)
<code>lvqLF</code>	LVQ learning function (default = 'learnlv1')

and returns an LVQ neural network.

The other option for the `lvq` learning function is `learnlv2`.

### Examples

#### Train a Learning Vector Quantization Network

This example shows how to train an LVQ network to classify iris flowers.

```
[x,t] = iris_dataset;  
net = lvqnet(10);  
net.trainParam.epochs = 50;  
net = train(net,x,t);
```

# lvqoutputs

LVQ outputs processing function

## Syntax

```
[X,settings] = lvqoutputs(X)
X = lvqoutputs('apply',X,PS)
X = lvqoutputs('reverse',X,PS)
dx_dy = lvqoutputs('dx_dy',X,X,PS)
```

## Description

`[X,settings] = lvqoutputs(X)` returns its argument unchanged, but stores the ratio of target classes in the settings for use by `initlvq` to initialize weights.

`X = lvqoutputs('apply',X,PS)` returns X.

`X = lvqoutputs('reverse',X,PS)` returns X.

`dx_dy = lvqoutputs('dx_dy',X,X,PS)` returns the identity derivative.

## Version History

Introduced in R2010b

## See Also

## mae

Mean absolute error performance function

### Syntax

```
perf = mae(E,Y,X)
dPerf_dx = mae('dx',E,Y,X,perf)
info = mae('code')
```

### Description

`perf = mae(E,Y,X)` takes a matrix or cell array of error vectors, `E`, and optionally a matrix or cell array of output vectors, `Y`, a vector of all weight and bias values, `X`, and returns network performance as the mean of absolute errors, `perf`.

`dPerf_dx = mae('dx',E,Y,X,perf)` returns the derivative of `perf` with respect to `X`.

`info = mae('code')` returns useful information for each code character vector:

- `mae('name')` returns the name of this function.
- `mae('pnames')` returns the names of the training parameters.
- `mae('pdefaults')` returns the default function parameters.

### Examples

#### Calculate Network Performance with 'mae'

This example shows how to calculate the network performance as the mean of absolute errors.

Create and configure a perceptron to have one input and one neuron:

```
net = perceptron;
net = configure(net,0,0);
```

The network is given a batch of inputs `P`. The error is calculated by subtracting the output `A` from target `T`. Then the mean absolute error is calculated.

```
p = [-10 -5 0 5 10];
t = [0 0 1 1 1];
y = net(p)
e = t-y
perf = mae(e)
```

Note that `mae` can be called with only one argument because the other arguments are ignored. `mae` supports those arguments to conform to the standard performance function argument list.

## Input Arguments

### **E — Errors**

vector | matrix | cell array

Errors, specified as a vector, a matrix, or a cell array.

### **Y — Outputs**

vector | matrix | cell array

Network outputs, specified as a vector, a matrix, or a cell array.

### **X — Weight and bias**

vector

Weight and bias values, specified as a vector.

## Output Arguments

### **perf — Network performance**

scalar

Network performance as the mean of absolute errors, returned as a scalar.

### **dPerf\_dx — Derivative of network performance**

scalar

Derivative of `perf` with respect to `X`, returned as a scalar.

## More About

### **Network Use**

You can create a standard network that uses `mae` with `perceptron`.

To prepare a custom network to be trained with `mae`, set `net.performFcn` to `'mae'`. This automatically sets `net.performParam` to the empty matrix `[]`, because `mae` has no performance parameters.

In either case, calling `train` or `adapt`, results in `mae` being used to calculate performance.

## Version History

Introduced before R2006a

### **See Also**

`mse` | `perceptron`

## mandist

Manhattan distance weight function

### Syntax

```
Z = mandist(W,P)
D = mandist(pos)
```

### Description

`Z = mandist(W,P)` takes an  $S$ -by- $R$  weight matrix,  $W$ , and an  $R$ -by- $Q$  matrix of  $Q$  input (column) vectors,  $P$ , and returns the  $S$ -by- $Q$  matrix of vector distances,  $Z$ .

`mandist` is the Manhattan distance weight function. Weight functions apply weights to an input to get weighted inputs.

`mandist` is also a layer distance function, which can be used to find the distances between neurons in a layer.

`D = mandist(pos)` takes the  $N$ -by- $S$  matrix of neuron positions, `pos`, and returns the  $S$ -by- $S$  matrix of distances,  $D$ .

### Examples

#### Calculate the Weighted Input Matrix

This example shows how to calculate the weighted input matrix.

Define a random weight matrix  $W$  and input vector  $P$  and calculate the corresponding weighted input  $Z$ .

```
W = rand(4,3);
P = rand(3,1);
Z = mandist(W,P)
```

#### Find the Distances of 10 Neurons

This example shows how to calculate the distances of 10 neurons arranged in a three-dimensional space.

Define a random matrix of positions for 10 neurons arranged in three-dimensional space and then find their distances.

```
pos = rand(3,10);
D = mandist(pos)
```

## Input Arguments

### **W — Weight matrix**

matrix

Weight matrix, specified as an S-by-R matrix.

### **P — Input matrix**

matrix

Input matrix, specified as an R-by-Q matrix of Q input (column) vectors.

### **pos — Neuron positions**

row matrix

Matrix of neuron positions, specified as an N-by-S matrix.

## Output Arguments

### **Z — Vector distances**

matrix

Matrix of vector distances, returned as an S-by-Q matrix.

### **D — Distances**

matrix

Matrix of distances, returned as an S-by-S matrix.

## More About

### **Network Use**

To change a network so an input weight uses `mandist`, set `net.inputWeights{i,j}.weightFcn` to `'mandist'`. For a layer weight, set `net.layerWeights{i,j}.weightFcn` to `'mandist'`.

To change a network so a layer's topology uses `mandist`, set `net.layers{i}.distanceFcn` to `'mandist'`.

In either case, call `sim` to simulate the network with `dist`. See `newpnn` or `newgrnn` for simulation examples.

## Algorithms

The Manhattan distance  $D$  between two vectors  $X$  and  $Y$  is

$$D = \text{sum}(\text{abs}(x-y))$$

## **Version History**

**Introduced before R2006a**

### **See Also**

`dist` | `linkdist` | `sim`

# mapminmax

Process matrices by mapping row minimum and maximum values to [-1 1]

## Syntax

```
[Y,PS] = mapminmax(X,YMIN,YMAX)
[Y,PS] = mapminmax(X,FP)
Y = mapminmax('apply',X,PS)
X = mapminmax('reverse',Y,PS)
dx_dy = mapminmax('dx_dy',X,Y,PS)
```

## Description

---

**Tip** To rescale data for deep learning workflows, use the Normalization name value pair for the input layer.

---

`[Y,PS] = mapminmax(X,YMIN,YMAX)` takes a N-by-Q matrix, X and optionally a minimum and a maximum value for each row of Y, YMIN and YMAX, and returns a N-by-Q matrix, Y, and a process settings that allow consistent processing of values, PS.

`mapminmax` processes matrices by normalizing the minimum and maximum values of each row to [YMIN, YMAX].

`[Y,PS] = mapminmax(X,FP)` takes parameters as a struct: FP.ymin, FP.ymax.

`Y = mapminmax('apply',X,PS)` returns Y, given X and settings PS.

`X = mapminmax('reverse',Y,PS)` returns X, given Y and settings PS.

`dx_dy = mapminmax('dx_dy',X,Y,PS)` returns the reverse derivative.

## Examples

### Format a Matrix With the mapminmax Function

This example shows how to format a matrix so that the minimum and maximum values of each row are mapped to default interval [-1, +1].

```
x1 = [1 2 4; 1 1 1; 3 2 2; 0 0 0]
[y1,PS] = mapminmax(x1)
```

Next, apply the same processing settings to new values.

```
x2 = [5 2 3; 1 1 1; 6 7 3; 0 0 0]
y2 = mapminmax('apply',x2,PS)
```

Reverse the processing of y1 to get x1 again.

```
x1_again = mapminmax('reverse',y1,PS)
```

## Input Arguments

### **X — Input matrix**

matrix

Matrix you want to process, specified as an N-by-Q matrix.

### **YMIN — Minimum value**

-1 (default) | scalar

Minimum value for each row of the output matrix Y, specified as a scalar.

### **YMAX — Maximum value**

-1 (default) | scalar

Maximum value for each row of the output matrix Y, specified as a scalar.

## Output Arguments

### **Y — Output matrix**

matrix

Processed matrix, returned as an N-by-Q matrix.

### **PS — Process settings**

structure

Process settings that allow consistent processing of values, returned as a structure.

## More About

### **Normalize Inputs and Targets Using mapminmax**

Before training, it is often useful to scale the inputs and targets so that they always fall within a specified range. The function `mapminmax` scales inputs and targets so that they fall in the range  $[-1,1]$ . The following code illustrates how to use this function.

```
[pn,ps] = mapminmax(p);  
[tn,ts] = mapminmax(t);  
net = train(net,pn,tn);
```

The original network inputs and targets are given in the matrices `p` and `t`. The normalized inputs and targets `pn` and `tn` that are returned will all fall in the interval  $[-1,1]$ . The structures `ps` and `ts` contain the settings, in this case the minimum and maximum values of the original inputs and targets. After the network has been trained, the `ps` settings should be used to transform any future inputs that are applied to the network. They effectively become a part of the network, just like the network weights and biases.

If `mapminmax` is used to scale the targets, then the output of the network will be trained to produce outputs in the range  $[-1,1]$ . To convert these outputs back into the same units that were used for the original targets, use the settings `ts`. The following code simulates the network that was trained in the previous code, and then converts the network output back into the original units.

```
an = sim(net,pn);  
a = mapminmax('reverse',an,ts);
```

The network output `an` corresponds to the normalized targets `tn`. The unnormalized network output `a` is in the same units as the original targets `t`.

If `mapminmax` is used to preprocess the training set data, then whenever the trained network is used with new inputs they should be preprocessed with the minimum and maximums that were computed for the training set stored in the settings `ps`. The following code applies a new set of inputs to the network already trained.

```
pnewn = mapminmax('apply',pnew,ps);  
anewn = sim(net,pnewn);  
anew = mapminmax('reverse',anewn,ts);
```

For most networks, including `feedforwardnet`, these steps are done automatically, so that you only need to use the `sim` command.

## Algorithms

It is assumed that  $X$  has only finite real values, and that the elements of each row are not all equal. (If  $x_{\max}=x_{\min}$  or if either  $x_{\max}$  or  $x_{\min}$  are non-finite, then  $y=x$  and no change occurs.)

$$y = (y_{\max}-y_{\min})*(x-x_{\min})/(x_{\max}-x_{\min}) + y_{\min};$$

## Version History

Introduced in R2006a

### See Also

`fixunknowns` | `mapstd` | `processpca`

## mapstd

Process matrices by mapping each row's means to 0 and deviations to 1

### Syntax

```
[Y,PS] = mapstd(X,ymean,ystd)
[Y,PS] = mapstd(X,FP)
Y = mapstd('apply',X,PS)
X = mapstd('reverse',Y,PS)
dx_dy = mapstd('dx_dy',X,Y,PS)
```

### Description

mapstd processes matrices by transforming the mean and standard deviation of each row to ymean and ystd.

[Y,PS] = mapstd(X,ymean,ystd) takes X and optional parameters,

X	N-by-Q matrix
ymean	Mean value for each row of Y (default is 0)
ystd	Standard deviation for each row of Y (default is 1)

and returns

Y	N-by-Q matrix
PS	Process settings that allow consistent processing of values

[Y,PS] = mapstd(X,FP) takes parameters as a struct: FP.ymean, FP.ystd.

Y = mapstd('apply',X,PS) returns Y, given X and settings PS.

X = mapstd('reverse',Y,PS) returns X, given Y and settings PS.

dx\_dy = mapstd('dx\_dy',X,Y,PS) returns the reverse derivative.

### Examples

Here you format a matrix so that the minimum and maximum values of each row are mapped to default mean and STD of 0 and 1.

```
x1 = [1 2 4; 1 1 1; 3 2 2; 0 0 0]
[y1,PS] = mapstd(x1)
```

Next, apply the same processing settings to new values.

```
x2 = [5 2 3; 1 1 1; 6 7 3; 0 0 0]
y2 = mapstd('apply',x2,PS)
```

Reverse the processing of y1 to get x1 again.

```
x1_again = mapstd('reverse',y1,PS)
```

## More About

### Normalize Network Inputs and Targets Using mapstd

Another approach for scaling network inputs and targets is to normalize the mean and standard deviation of the training set. The function `mapstd` normalizes the inputs and targets so that they will have zero mean and unity standard deviation. The following code illustrates the use of `mapstd`.

```
[pn,ps] = mapstd(p);
[tn,ts] = mapstd(t);
```

The original network inputs and targets are given in the matrices `p` and `t`. The normalized inputs and targets `pn` and `tn` that are returned will have zero means and unity standard deviation. The settings structures `ps` and `ts` contain the means and standard deviations of the original inputs and original targets. After the network has been trained, you should use these settings to transform any future inputs that are applied to the network. They effectively become a part of the network, just like the network weights and biases.

If `mapstd` is used to scale the targets, then the output of the network is trained to produce outputs with zero mean and unity standard deviation. To convert these outputs back into the same units that were used for the original targets, use `ts`. The following code simulates the network that was trained in the previous code, and then converts the network output back into the original units.

```
an = sim(net,pn);
a = mapstd('reverse',an,ts);
```

The network output `an` corresponds to the normalized targets `tn`. The unnormalized network output `a` is in the same units as the original targets `t`.

If `mapstd` is used to preprocess the training set data, then whenever the trained network is used with new inputs, you should preprocess them with the means and standard deviations that were computed for the training set using `ps`. The following commands apply a new set of inputs to the network already trained:

```
pnewn = mapstd('apply',pnew,ps);
anewn = sim(net,pnewn);
anew = mapstd('reverse',anewn,ts);
```

For most networks, including `feedforwardnet`, these steps are done automatically, so that you only need to use the `sim` command.

## Algorithms

The function assumes that `X` only contains finite real values. Additionally, the result for each row depends on the elements in that row.

- If the elements of the row are not all equal, then the function transforms the mean and standard deviation of each row to `ymean` (default 0) and `ystd` (default 1).

$$y = (x - xmean) * (ystd / xstd) + ymean;$$

- If the elements of the row are all equal, then the function does not modify the data in that row (`y=x`).

# maxlinlr

Maximum learning rate for linear layer

## Syntax

```
lr = maxlinlr(P)
lr = maxlinlr(P,'bias')
```

## Description

maxlinlr is used to calculate learning rates for `linearlayer`.

`lr = maxlinlr(P)` takes one argument,

P	R-by-Q matrix of input vectors
---	--------------------------------

and returns the maximum learning rate for a linear layer without a bias that is to be trained only on the vectors in P.

`lr = maxlinlr(P,'bias')` returns the maximum learning rate for a linear layer with a bias.

## Examples

Here you define a batch of four two-element input vectors and find the maximum learning rate for a linear layer with a bias.

```
P = [1 2 -4 7; 0.1 3 10 6];
lr = maxlinlr(P,'bias')
```

## meanabs

Mean of absolute elements of matrix or matrices

### Syntax

```
[m,n] = meanabs(x)
```

### Description

[m,n] = meanabs(x) takes a matrix or cell array of matrices and returns,

m	Mean value of all absolute finite values
n	Number of finite values

If x contains no finite values, the mean returned is 0.

### Examples

```
m = meanabs([1 2;3 4])  
[m,n] = meanabs({[1 2; NaN 4], [4 5; 2 3]})
```

## Version History

Introduced in R2010b

meansqr | sumabs | sumsqr

# meansqr

Mean of squared elements of matrix or matrices

## Syntax

```
[m,n] = meansqr(x)
```

## Description

[m,n] = meansqr(x) takes a matrix or cell array of matrices and returns,

m	Mean value of all squared finite values
n	Number of finite values

If x contains no finite values, the mean returned is 0.

## Examples

```
m = meansqr([1 2;3 4])  
[m,n] = meansqr({[1 2; NaN 4], [4 5; 2 3]})
```

## Version History

Introduced in R2010b

## midpoint

Midpoint weight initialization function

### Syntax

```
W = midpoint(S,PR)
```

### Description

`midpoint` is a weight initialization function that sets weight (row) vectors to the center of the input ranges.

`W = midpoint(S,PR)` takes two arguments,

S	Number of rows (neurons)
PR	R-by-Q matrix of Q input (column) vectors with values in the ranges = [Pmin Pmax] where Q is the batch size

and returns an S-by-R matrix with rows set to  $(P_{min}+P_{max})' / 2$ .

### Examples

Here initial weight values are calculated for a five-neuron layer with input elements ranging over [0 1] and [-2 2].

```
W = midpoint(5,[0 1; -2 2])
```

### Version History

Introduced before R2006a

### See Also

`initwb` | `initlay` | `init`

# minmax

Ranges of matrix rows

## Syntax

```
pr = minmax(P)
```

## Description

`pr = minmax(P)` takes one argument,

P	R-by-Q matrix
---	---------------

and returns the R-by-2 matrix `pr` of minimum and maximum values for each row of `P`.

Alternatively, `P` can be an M-by-N cell array of matrices. Each matrix `P{i, j}` should have `Ri` rows and `Q` columns. In this case, `minmax` returns an M-by-1 cell array where the `m`th element is an `Ri`-by-2 matrix of the minimum and maximum values of elements for the matrix on the `i`th row of `P`.

## Examples

```
x = rand(4,5)
mm = minmax(x)
x = rand(1;2),3,4)
mm = minmax(x)
```

## Version History

Introduced before R2006a

## mse

Mean squared normalized error performance function

### Syntax

```
perf = mse(net,t,y,ew)
```

### Description

---

**Tip** To use mean squared error with deep learning, use `regressionLayer`, or use the `dLarray` method `mse`.

---

`perf = mse(net,t,y,ew)` takes a neural network, `net`, a matrix or cell array of targets, `t`, a matrix or cell array of outputs, `y`, and error weights, `ew`, and returns the mean squared error.

This function has two optional parameters, which are associated with networks whose `net.trainFcn` is set to this function:

- 'regularization' can be set to any value between 0 and 1. The greater the regularization value, the more squared weights and biases are included in the performance calculation relative to errors. The default is 0, corresponding to no regularization.
- 'normalization' can be set to 'none' (the default); 'standard', which normalizes errors between -2 and 2, corresponding to normalizing outputs and targets between -1 and 1; and 'percent', which normalizes errors between -1 and 1. This feature is useful for networks with multi-element outputs. It ensures that the relative accuracy of output elements with differing target value ranges are treated as equally important, instead of prioritizing the relative accuracy of the output element with the largest target value range.

You can create a standard network that uses `mse` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `mse`, set `net.performFcn` to 'mse'. This automatically sets `net.performParam` to a structure with the default optional parameter values.

`mse` is a network performance function. It measures the network's performance according to the mean of squared errors.

## Examples

### Train Neural Network Using mse Performance Function

This example shows how to train a neural network using the `mse` performance function.

Here a two-layer feedforward network is created and trained to estimate body fat percentage using the `mse` performance function and a regularization value of 0.01.

```
[x, t] = bodyfat_dataset;  
net = feedforwardnet(10);  
net.performParam.regularization = 0.01;
```

MSE is the default performance function for `feedforwardnet`.

```
net.performFcn
```

Train the network and evaluate performance.

```
net = train(net, x, t);  
y = net(x);  
perf = perform(net, t, y)
```

Alternatively, you can call `mse` directly.

```
perf = mse(net, t, y, 'regularization', 0.01)
```

## Input Arguments

### **net** — Input matrix

matrix

Network you want to calculate the performance of, specified as a `SeriesNetwork` or a `DAGNetwork` object.

### **t** — Targets

matrix | cell array

Targets, specified as a matrix or a cell array.

### **y** — Outputs

matrix | cell array

Outputs, specified as a matrix or a cell array.

### **ew** — Error weights

1 (default) | scalar

Error weights, specified as a scalar.

## Output Arguments

### **perf** — Network performance

scalar

Performance of the network as the mean squared errors.

## Version History

Introduced before R2006a

## narnet

Nonlinear autoregressive neural network

### Syntax

```
narnet(feedbackDelays,hiddenSizes,feedbackMode,trainFcn)
```

### Description

`narnet(feedbackDelays,hiddenSizes,feedbackMode,trainFcn)` takes these arguments:

- Row vector of increasing 0 or positive feedback delays, `feedbackDelays`
- Row vector of one or more hidden layer sizes, `hiddenSizes`
- Type of feedback, `feedbackMode`
- Training function, `trainFcn`

and returns a NAR neural network.

You can train NAR (nonlinear autoregressive) neural networks to predict a time series from the past values of that series.

### Examples

#### Train NAR Network and Predict on New Data

Train a nonlinear autoregressive (NAR) neural network and predict on new time series data. Predicting a sequence of values in a time series is also known as *multistep prediction*. Closed-loop networks can perform multistep predictions. When external feedback is missing, closed-loop networks can continue to predict by using internal feedback. In NAR prediction, the future values of a time series are predicted only from past values of that series.

Load the simple time series prediction data.

```
T = simplenar_dataset;
```

Create a NAR network. Define the feedback delays and size of the hidden layers.

```
net = narnet(1:2,10);
```

Prepare the time series data using `preparets`. This function automatically shifts input and target time series by the number of steps needed to fill the initial input and layer delay states.

```
[Xs,Xi,Ai,Ts] = preparets(net, {}, {}, T);
```

A recommended practice is to fully create the network in an open loop, and then transform the network to a closed loop for multistep-ahead prediction. Then, the closed-loop network can predict as many future values as you want. If you simulate the neural network in closed-loop mode only, the network can perform as many predictions as the number of time steps in the input series.

Train the NAR network. The `train` function trains the network in an open loop (series-parallel architecture), including the validation and testing steps.

```
net = train(net,Xs,Ts,Xi,Ai);
```

```

Calculate the network output  $Y$ , final input states  $X_f$ , and final layer states  $A_f$  of the open-loop network from the network input  $X_s$ , initial input states  $X_i$ , and initial layer states  $A_i$ .

```
[Y,Xf,Af] = net(Xs,Xi,Ai);
```

Calculate the network performance.

```
perf = perform(net,Ts,Y)
```

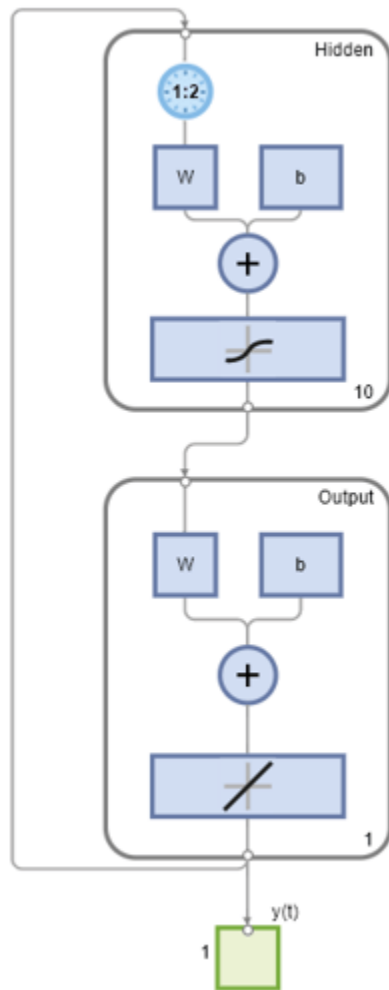

```
perf = 1.0100e-09
```

To predict the output for the next 20 time steps, first simulate the network in closed-loop mode. The final input states  $X_f$  and layer states  $A_f$  of the open-loop network  $net$  become the initial input states  $X_{ic}$  and layer states  $A_{ic}$  of the closed-loop network  $netc$ .

```
[netc,Xic,Aic] = closeloop(net,Xf,Af);
```

Display the closed-loop network. The network has only one input. In closed-loop mode, this input connects to the output. A direct delayed output connection replaces the delayed target input.

```
view(netc)
```

To simulate the network 20 time steps ahead, input an empty cell array of length 20. The network requires only the initial conditions given in  $X_{ic}$  and  $A_{ic}$ .

```
Yc = netc(cell(0,20),Xic,Aic)
```

## Input Arguments

### feedbackDelays — Feedback delays

[1:2] (default) | row vector

Zero or positive feedback delays, specified as an increasing row vector.

### hiddenSizes — Hidden sizes

10 (default) | row vector

Sizes of the hidden layers, specified as a row vector of one or more elements.

**feedbackMode — Feedback mode**

'open' (default) | 'closed' | 'none'

Type of feedback, specified as either 'open', 'closed', or 'none'.

**trainFcn — Training function name**

'trainlm' (default) | 'trainbr' | 'trainbfg' | 'trainrp' | 'trainscg' | ...

Training function name, specified as one of the following.

Training Function	Algorithm
'trainlm'	Levenberg-Marquardt
'trainbr'	Bayesian Regularization
'trainbfg'	BFGS Quasi-Newton
'trainrp'	Resilient Backpropagation
'trainscg'	Scaled Conjugate Gradient
'traincgb'	Conjugate Gradient with Powell/Beale Restarts
'traincgf'	Fletcher-Powell Conjugate Gradient
'traincgp'	Polak-Ribière Conjugate Gradient
'trainoss'	One Step Secant
'traingdx'	Variable Learning Rate Gradient Descent
'traingdm'	Gradient Descent with Momentum
'traingd'	Gradient Descent

Example: For example, you can specify the variable learning rate gradient descent algorithm as the training algorithm as follows: 'traingdx'

For more information on the training functions, see “Train and Apply Multilayer Shallow Neural Networks” and “Choose a Multilayer Neural Network Training Function”.

# narxnet

Nonlinear autoregressive neural network with external input

## Syntax

```
narxnet(inputDelays, feedbackDelays, hiddenSizes, feedbackMode, trainFcn)
```

## Description

`narxnet(inputDelays, feedbackDelays, hiddenSizes, feedbackMode, trainFcn)` takes these arguments:

- Row vector of increasing 0 or positive input delays, `inputDelays`
- Row vector of increasing 0 or positive feedback delays, `feedbackDelays`
- Row vector of one or more hidden layer sizes, `hiddenSizes`
- Type of feedback, `feedbackMode`
- Backpropagation training function, `trainFcn`

and returns a NARX neural network.

NARX (Nonlinear autoregressive with external input) networks can learn to predict one time series given past values of the same time series, the feedback input, and another time series called the external (or exogenous) time series.

## Examples

### Train NARX Network and Predict on New Data

Train a nonlinear autoregressive with external input (NARX) neural network and predict on new time series data. Predicting a sequence of values in a time series is also known as *multistep prediction*. Closed-loop networks can perform multistep predictions. When external feedback is missing, closed-loop networks can continue to predict by using internal feedback. In NARX prediction, the future values of a time series are predicted from past values of that series, the feedback input, and an external time series.

Load the simple time series prediction data.

```
[X,T] = simpleseries_dataset;
```

Partition the data into training data `XTrain` and `TTrain`, and data for prediction `XPredict`. Use `XPredict` to perform prediction after you create the closed-loop network.

```
XTrain = X(1:80);  
TTrain = T(1:80);  
XPredict = X(81:100);
```

Create a NARX network. Define the input delays, feedback delays, and size of the hidden layers.

```
net = narxnet(1:2,1:2,10);
```

Prepare the time series data using `preparets`. This function automatically shifts input and target time series by the number of steps needed to fill the initial input and layer delay states.

```
[Xs, Xi, Ai, Ts] = preparets(net, XTrain, {}, TTrain);
```

A recommended practice is to fully create the network in an open loop, and then transform the network to a closed loop for multistep-ahead prediction. Then, the closed-loop network can predict as many future values as you want. If you simulate the neural network in closed-loop mode only, the network can perform as many predictions as the number of time steps in the input series.

Train the NARX network. The `train` function trains the network in an open loop (series-parallel architecture), including the validation and testing steps.

```
net = train(net, Xs, Ts, Xi, Ai);
```

# nctool

Open Neural Net Clustering app

## Syntax

```
nctool  
nctool("close")
```

## Description

nctool opens the **Neural Net Clustering** app. For more information and an example of its usage, see “Cluster Data with a Self-Organizing Map”.

---

**Note** To interactively build, visualize, and train deep learning neural networks, use the **Deep Network Designer** app. For more information, see “Get Started with Deep Network Designer”.

---

nctool("close") closes the Neural Net Clustering app.

## Algorithms

The **Neural Net Clustering** app leads you through solving a clustering problem using a self-organizing map. The map forms a compressed representation of the inputs space, reflecting both the relative density of input vectors in that space, and a two-dimensional compressed representation of the input-space topology.

## negdist

Negative distance weight function

### Syntax

```
Z = negdist(W,P)
dim = negdist('size',S,R,FP)
dw = negdist('dz_dw',W,P,Z,FP)
```

### Description

`negdist` is a weight function. Weight functions apply weights to an input to get weighted inputs.

`Z = negdist(W,P)` takes these inputs,

W	S-by-R weight matrix
P	R-by-Q matrix of Q input (column) vectors
FP	Row cell array of function parameters (optional, ignored)

and returns the S-by-Q matrix of negative vector distances.

`dim = negdist('size',S,R,FP)` takes the layer dimension S, input dimension R, and function parameters, and returns the weight size [S-by-R].

`dw = negdist('dz_dw',W,P,Z,FP)` returns the derivative of Z with respect to W.

### Examples

Here you define a random weight matrix W and input vector P and calculate the corresponding weighted input Z.

```
W = rand(4,3);
P = rand(3,1);
Z = negdist(W,P)
```

### Network Use

You can create a standard network that uses `negdist` by calling `competlayer` or `selforgmap`.

To change a network so an input weight uses `negdist`, set `net.inputWeights{i,j}.weightFcn` to 'negdist'. For a layer weight, set `net.layerWeights{i,j}.weightFcn` to 'negdist'.

In either case, call `sim` to simulate the network with `negdist`.

### Algorithms

`negdist` returns the negative Euclidean distance:

$$z = -\sqrt{\sum(w-p)^2}$$

## **Version History**

Introduced before R2006a

### **See Also**

`competlayer` | `dist` | `dotprod` | `selforgmap` | `sim`

## netinv

Inverse transfer function

### Syntax

```
A = netinv(N,FP)
```

### Description

`netinv` is a transfer function. Transfer functions calculate a layer's output from its net input.

`A = netinv(N,FP)` takes inputs

N	S-by-Q matrix of net input (column) vectors
FP	Struct of function parameters (ignored)

and returns  $1/N$ .

`info = netinv('code')` returns information about this function. The following codes are supported:

`netinv('name')` returns the name of this function.

`netinv('output',FP)` returns the [min max] output range.

`netinv('active',FP)` returns the [min max] active input range.

`netinv('fullderiv')` returns 1 or 0, depending on whether `dA_dN` is S-by-S-by-Q or S-by-Q.

`netinv('fpnames')` returns the names of the function parameters.

`netinv('fpdefaults')` returns the default function parameters.

### Examples

Here you define 10 five-element net input vectors `N` and calculate `A`.

```
n = rand(5,10);  
a = netinv(n);
```

Assign this transfer function to layer `i` of a network.

```
net.layers{i}.transferFcn = 'netinv';
```

## Version History

Introduced in R2006a

**See Also**

tansig | logsig

## netprod

Product net input function

### Syntax

```
N = netprod({Z1,Z2,...,Zn})
info = netprod('code')
```

### Description

`netprod` is a net input function. Net input functions calculate a layer's net input by combining its weighted inputs and biases.

`N = netprod({Z1,Z2,...,Zn})` takes

$Z_i$	S-by-Q matrices in a row cell array
-------	-------------------------------------

and returns an element-wise product of  $Z_1$  to  $Z_n$ .

`info = netprod('code')` returns information about this function. The following codes are supported:

'deriv'	Name of derivative function
'fullderiv'	Full N-by-S-by-Q derivative = 1, element-wise S-by-Q derivative = 0
'name'	Full name
'fpnames'	Returns names of function parameters
'fpdefaults'	Returns default function parameters

### Examples

Here `netprod` combines two sets of weighted input vectors (user-defined).

```
Z1 = [1 2 4;3 4 1];
Z2 = [-1 2 2; -5 -6 1];
Z = {Z1,Z2};
N = netprod({Z})
```

Here `netprod` combines the same weighted inputs with a bias vector. Because  $Z_1$  and  $Z_2$  each contain three concurrent vectors, three concurrent copies of  $B$  must be created with `concur` so that all sizes match.

```
B = [0; -1];
Z = {Z1, Z2, concur(B,3)};
N = netprod(Z)
```

## Network Use

You can create a standard network that uses `netprod` by calling `newpnn` or `newgrnn`.

To change a network so that a layer uses `netprod`, set `net.layers{i}.netInputFcn` to `'netprod'`.

In either case, call `sim` to simulate the network with `netprod`. See `newpnn` or `newgrnn` for simulation examples.

## Version History

## netsum

Sum net input function

### Syntax

```
N = netsum({Z1,Z2,...,Zn},FP)
info = netsum('code')
```

### Description

`netsum` is a net input function. Net input functions calculate a layer's net input by combining its weighted inputs and biases.

`N = netsum({Z1,Z2,...,Zn},FP)` takes `Z1` to `Zn` and optional function parameters,

<code>Zi</code>	S-by-Q matrices in a row cell array
<code>FP</code>	Row cell array of function parameters (ignored)

and returns the elementwise sum of `Z1` to `Zn`.

`info = netsum('code')` returns information about this function. The following codes are supported:

`netsum('name')` returns the name of this function.

`netsum('type')` returns the type of this function.

`netsum('fpnames')` returns the names of the function parameters.

`netsum('fpdefaults')` returns default function parameter values.

`netsum('fpcheck', FP)` throws an error for illegal function parameters.

`netsum('fullderiv')` returns 0 or 1, depending on whether the derivative is S-by-Q or N-by-S-by-Q.

### Examples

Here `netsum` combines two sets of weighted input vectors and a bias. You must use `concur` to make `b` the same dimensions as `z1` and `z2`.

```
z1 = [1, 2, 4; 3, 4, 1]
z2 = [-1, 2, 2; -5, -6, 1]
b = [0; -1]
n = netsum({z1, z2, concur(b, 3)})
```

Assign this net input function to the first layer of a network.

```
net = feedforwardnet();
net.layers{1}.netInputFcn = 'netsum';
```

## network

Create custom shallow neural network

### Syntax

```
net = network
net =
network(numInputs, numLayers, biasConnect, inputConnect, layerConnect, outputConnect)
```

### To Get Help

Type `help network/network`.

---

**Tip** To learn how to create a deep learning network, see “Specify Layers of Convolutional Neural Network”.

---

### Description

`network` creates new custom networks. It is used to create networks that are then customized by functions such as `feedforwardnet` and `narxnet`.

`net = network` without arguments returns a new neural network with no inputs, layers or outputs.

`net = network(numInputs, numLayers, biasConnect, inputConnect, layerConnect, outputConnect)` takes these optional arguments (shown with default values):

<code>numInputs</code>	Number of inputs, 0
<code>numLayers</code>	Number of layers, 0
<code>biasConnect</code>	<code>numLayers</code> -by-1 Boolean vector, zeros
<code>inputConnect</code>	<code>numLayers</code> -by- <code>numInputs</code> Boolean matrix, zeros
<code>layerConnect</code>	<code>numLayers</code> -by- <code>numLayers</code> Boolean matrix, zeros
<code>outputConnect</code>	1-by- <code>numLayers</code> Boolean vector, zeros

and returns

<code>net</code>	New network with the given property values
------------------	--

### Properties

#### Architecture Properties

<code>net.numInputs</code>	0 or a positive integer	Number of inputs.
----------------------------	-------------------------	-------------------

<code>net.numLayers</code>	0 or a positive integer	Number of layers.
<code>net.biasConnect</code>	<code>numLayer</code> -by-1 Boolean vector	If <code>net.biasConnect(i)</code> is 1, then layer <code>i</code> has a bias, and <code>net.biases{i}</code> is a structure describing that bias.
<code>net.inputConnect</code>	<code>numLayer</code> -by- <code>numInputs</code> Boolean vector	If <code>net.inputConnect(i, j)</code> is 1, then layer <code>i</code> has a weight coming from input <code>j</code> , and <code>net.inputWeights{i, j}</code> is a structure describing that weight.
<code>net.layerConnect</code>	<code>numLayer</code> -by- <code>numLayers</code> Boolean vector	If <code>net.layerConnect(i, j)</code> is 1, then layer <code>i</code> has a weight coming from layer <code>j</code> , and <code>net.layerWeights{i, j}</code> is a structure describing that weight.
<code>net.outputConnect</code>	1-by- <code>numLayers</code> Boolean vector	If <code>net.outputConnect(i)</code> is 1, then the network has an output from layer <code>i</code> , and <code>net.outputs{i}</code> is a structure describing that output.
<code>net.numOutputs</code>	0 or a positive integer (read only)	Number of network outputs according to <code>net.outputConnect</code> .
<code>net.numInputDelays</code>	0 or a positive integer (read only)	Maximum input delay according to all <code>net.inputWeights{i, j}.delays</code> .
<code>net.numLayerDelays</code>	0 or a positive number (read only)	Maximum layer delay according to all <code>net.layerWeights{i, j}.delays</code> .

### Subject Structure Properties

<code>net.inputs</code>	<code>numInputs</code> -by-1 cell array	<code>net.inputs{i}</code> is a structure defining input <code>i</code> .
<code>net.layers</code>	<code>numLayers</code> -by-1 cell array	<code>net.layers{i}</code> is a structure defining layer <code>i</code> .
<code>net.biases</code>	<code>numLayers</code> -by-1 cell array	If <code>net.biasConnect(i)</code> is 1, then <code>net.biases{i}</code> is a structure defining the bias for layer <code>i</code> .
<code>net.inputWeights</code>	<code>numLayers</code> -by- <code>numInputs</code> cell array	If <code>net.inputConnect(i, j)</code> is 1, then <code>net.inputWeights{i, j}</code> is a structure defining the weight to layer <code>i</code> from input <code>j</code> .
<code>net.layerWeights</code>	<code>numLayers</code> -by- <code>numLayers</code> cell array	If <code>net.layerConnect(i, j)</code> is 1, then <code>net.layerWeights{i, j}</code> is a structure defining the weight to layer <code>i</code> from layer <code>j</code> .
<code>net.outputs</code>	1-by- <code>numLayers</code> cell array	If <code>net.outputConnect(i)</code> is 1, then <code>net.outputs{i}</code> is a structure defining the network output from layer <code>i</code> .

### Function Properties

<code>net.adaptFcn</code>	Name of a network adaption function or ''
<code>net.initFcn</code>	Name of a network initialization function or ''

<code>net.performFcn</code>	Name of a network performance function or ''
<code>net.trainFcn</code>	Name of a network training function or ''

**Parameter Properties**

<code>net.adaptParam</code>	Network adaption parameters
<code>net.initParam</code>	Network initialization parameters
<code>net.performParam</code>	Network performance parameters
<code>net.trainParam</code>	Network training parameters

**Weight and Bias Value Properties**

<code>net.IW</code>	<code>numLayers-by-numInputs</code> cell array of input weight values
<code>net.LW</code>	<code>numLayers-by-numLayers</code> cell array of layer weight values
<code>net.b</code>	<code>numLayers-by-1</code> cell array of bias values

**Other Properties**

<code>net.userData</code>	Structure you can use to store useful values
---------------------------	--

**Examples**

**Create Network with One Input and Two Layers**

This example shows how to create a network without any inputs and layers, and then set its numbers of inputs and layers to 1 and 2 respectively.

```
net = network
net.numInputs = 1
net.numLayers = 2
```

Alternatively, you can create the same network with one line of code.

```
net = network(1,2)
```

**Create Feedforward Network and View Properties**

This example shows how to create a one-input, two-layer, feedforward network. Only the first layer has a bias. An input weight connects to layer 1 from input 1. A layer weight connects to layer 2 from layer 1. Layer 2 is a network output and has a target.

```
net = network(1,2,[1;0],[1; 0],[0 0; 1 0],[0 1])
```

You can view the network subobjects with the following code.

```
net.inputs{1}
net.layers{1}, net.layers{2}
net.biases{1}
net.inputWeights{1,1}, net.layerWeights{2,1}
net.outputs{2}
```

You can alter the properties of any of the network subobjects. This code changes the transfer functions of both layers:

```
net.layers{1}.transferFcn = 'tansig';  
net.layers{2}.transferFcn = 'logsig';
```

You can view the weights for the connection from the first input to the first layer as follows. The weights for a connection from an input to a layer are stored in `net.IW`. If the values are not yet set, the result is empty.

```
net.IW{1,1}
```

You can view the weights for the connection from the first layer to the second layer as follows. Weights for a connection from a layer to a layer are stored in `net.LW`. Again, if the values are not yet set, the result is empty.

```
net.LW{2,1}
```

You can view the bias values for the first layer as follows.

```
net.b{1}
```

To change the number of elements in input 1 to 2, set each element's range:

```
net.inputs{1}.range = [0 1; -1 1];
```

After training your network, you can use `sim` to simulate the network. For example, simulate the network for a two-element input vector.

```
p = [0.5; -0.1];  
y = sim(net,p)
```

## newgrnn

Design generalized regression neural network

### Syntax

```
net = newgrnn(P,T,spread)
```

### Description

Generalized regression neural networks (grnns) are a kind of radial basis network that is often used for function approximation. grnns can be designed very quickly.

`net = newgrnn(P,T,spread)` takes three inputs,

P	R-by-Q matrix of Q input vectors
T	S-by-Q matrix of Q target class vectors
spread	Spread of radial basis functions (default = 1.0)

and returns a new generalized regression neural network.

The larger the `spread`, the smoother the function approximation. To fit data very closely, use a `spread` smaller than the typical distance between input vectors. To fit the data more smoothly, use a larger `spread`.

### Properties

`newgrnn` creates a two-layer network. The first layer has `radbas` neurons, and calculates weighted inputs with `dist` and net input with `netprod`. The second layer has `purelin` neurons, calculates weighted input with `normprod`, and net inputs with `netsum`. Only the first layer has biases.

`newgrnn` sets the first layer weights to  $P'$ , and the first layer biases are all set to  $0.8326/\text{spread}$ , resulting in radial basis functions that cross 0.5 at weighted inputs of  $\pm \text{spread}$ . The second layer weights `W2` are set to `T`.

### Examples

Here you design a radial basis network, given inputs `P` and targets `T`.

```
P = [1 2 3];  
T = [2.0 4.1 5.9];  
net = newgrnn(P,T);
```

The network is simulated for a new input.

```
P = 1.5;  
Y = sim(net,P)
```

## newlind

Design linear layer

### Syntax

```
net = newlind(P,T,Pi)
```

### Description

`net = newlind(P,T,Pi)` takes these input arguments,

P	R-by-Q matrix of Q input vectors
T	S-by-Q matrix of Q target class vectors
Pi	1-by-ID cell array of initial input delay states

where each element  $P_{i,k}$  is an  $R_i$ -by- $Q$  matrix, and the default = `[]`; and returns a linear layer designed to output  $T$  (with minimum sum square error) given input  $P$ .

`newlind(P,T,Pi)` can also solve for linear networks with input delays and multiple inputs and layers by supplying input and target data in cell array form:

P	$N_i$ -by- $TS$ cell array	Each element $P_{i,ts}$ is an $R_i$ -by- $Q$ input matrix
T	$N_t$ -by- $TS$ cell array	Each element $T_{i,ts}$ is a $V_i$ -by- $Q$ matrix
Pi	$N_i$ -by-ID cell array	Each element $P_{i,k}$ is an $R_i$ -by- $Q$ matrix, default = <code>[]</code>

and returns a linear network with  $ID$  input delays,  $N_i$  network inputs, and  $N_l$  layers, designed to output  $T$  (with minimum sum square error) given input  $P$ .

### Examples

You want a linear layer that outputs  $T$  given  $P$  for the following definitions:

```
P = [1 2 3];
T = [2.0 4.1 5.9];
```

Use `newlind` to design such a network and check its response.

```
net = newlind(P,T);
Y = sim(net,P)
```

You want another linear layer that outputs the sequence  $T$  given the sequence  $P$  and two initial input delay states  $P_i$ .

```
P = {1 2 1 3 3 2};
Pi = {1 3};
T = {5.0 6.1 4.0 6.0 6.9 8.0};
net = newlind(P,T,Pi);
Y = sim(net,P,Pi)
```

You want a linear network with two outputs Y1 and Y2 that generate sequences T1 and T2, given the sequences P1 and P2, with three initial input delay states Pi1 for input 1 and three initial delays states Pi2 for input 2.

```
P1 = {1 2 1 3 3 2}; Pi1 = {1 3 0};  
P2 = {1 2 1 1 2 1}; Pi2 = {2 1 2};  
T1 = {5.0 6.1 4.0 6.0 6.9 8.0};  
T2 = {11.0 12.1 10.1 10.9 13.0 13.0};  
net = newlind([P1; P2],[T1; T2],[Pi1; Pi2]);  
Y = sim(net,[P1; P2],[Pi1; Pi2]);  
Y1 = Y(1,:)  
Y2 = Y(2,:)
```

## Algorithms

`newlind` calculates weight  $W$  and bias  $B$  values for a linear layer from inputs  $P$  and targets  $T$  by solving this linear equation in the least squares sense:

$$[W \ b] * [P; \text{ones}] = T$$

## newpnn

Design probabilistic neural network

### Syntax

```
net = newpnn(P,T,spread)
```

### Description

Probabilistic neural networks (PNN) are a kind of radial basis network suitable for classification problems.

`net = newpnn(P,T,spread)` takes two or three arguments,

P	R-by-Q matrix of Q input vectors
T	S-by-Q matrix of Q target class vectors
spread	Spread of radial basis functions (default = 0.1)

and returns a new probabilistic neural network.

If `spread` is near zero, the network acts as a nearest neighbor classifier. As `spread` becomes larger, the designed network takes into account several nearby design vectors.

### Examples

Here a classification problem is defined with a set of inputs P and class indices Tc.

```
P = [1 2 3 4 5 6 7];
Tc = [1 2 3 2 2 3 1];
```

The class indices are converted to target vectors, and a PNN is designed and tested.

```
T = ind2vec(Tc)
net = newpnn(P,T);
Y = sim(net,P)
Yc = vec2ind(Y)
```

### Algorithms

`newpnn` creates a two-layer network. The first layer has `radbas` neurons, and calculates its weighted inputs with `dist` and its net input with `netprod`. The second layer has `compet` neurons, and calculates its weighted input with `dotprod` and its net inputs with `netsum`. Only the first layer has biases.

`newpnn` sets the first-layer weights to  $P'$ , and the first-layer biases are all set to  $0.8326/\text{spread}$ , resulting in radial basis functions that cross 0.5 at weighted inputs of  $\pm \text{spread}$ . The second-layer weights  $W2$  are set to T.

sim | ind2vec | vec2ind | newrb | newrbe | newgrnn

## newrb

Design radial basis network

### Syntax

```
net = newrb(P,T,goal,spread,MN,DF)
```

### Description

`net = newrb(P,T,goal,spread,MN,DF)` takes two of these arguments:

- `P` — R-by-Q matrix of Q input vectors
- `T` — S-by-Q matrix of Q target class vectors
- `goal` — Mean squared error goal
- `spread` — Spread of radial basis functions
- `MN` — Maximum number of neurons
- `DF` — Number of neurons to add between displays

Radial basis networks can be used to approximate functions. `newrb` adds neurons to the hidden layer of a radial basis network until it meets the specified mean squared error goal.

The larger `spread` is, the smoother the function approximation. Too large a spread means a lot of neurons are required to fit a fast-changing function. Too small a spread means many neurons are required to fit a smooth function, and the network might not generalize well. Call `newrb` with different spreads to find the best value for a given problem.

### Examples

#### Design a Radial Basis Network

This example shows how to design a radial basis network.

Design a radial basis network with inputs `P` and targets `T`.

```
P = [1 2 3];  
T = [2.0 4.1 5.9];  
net = newrb(P,T);
```

Simulate the network for a new input.

```
P = 1.5;  
Y = sim(net,P)
```

### Input Arguments

#### **P** — Input matrix

matrix

Input vectors, specified as an R-by-Q matrix.

### **T — Target class matrix**

matrix

Target class vectors, specified as an S-by-Q matrix.

### **goal — Error goal**

0.0 (default) | scalar

Mean squared error goal, specified as a scalar.

### **spread — Spread of basis functions**

1 (default) | scalar

Spread of radial basis functions, specified as a scalar.

### **MN — Neurons maximum number**

Q (default) | scalar

Maximum number of neurons, specified as a scalar.

### **DF — Neurons between displays**

25 (default) | scalar

Number of neurons to add between displays, specified as a scalar.

## **Output Arguments**

### **net — Radial basis network**

network

New radial basis network, returned as a network object

## **Algorithms**

`newrb` creates a two-layer network. The first layer has `radbases` neurons, and calculates its weighted inputs with `dist` and its net input with `netprod`. The second layer has `purelin` neurons, and calculates its weighted input with `dotprod` and its net inputs with `netsum`. Both layers have biases.

Initially the `radbases` layer has no neurons. The following steps are repeated until the network's mean squared error falls below `goal`.

- 1 The network is simulated.
- 2 The input vector with the greatest error is found.
- 3 A `radbases` neuron is added with weights equal to that vector.
- 4 The `purelin` layer weights are redesigned to minimize error.

## **Version History**

Introduced before R2006a

sim | newrbe | newgrnn | newpnn

## newrbe

Design exact radial basis network

### Syntax

```
net = newrbe(P,T,spread)
```

### Description

Radial basis networks can be used to approximate functions. `newrbe` very quickly designs a radial basis network with zero error on the design vectors.

`net = newrbe(P,T,spread)` takes two or three arguments,

P	RxQ matrix of Q R-element input vectors
T	SxQ matrix of Q S-element target class vectors
spread	Spread of radial basis functions (default = 1.0)

and returns a new exact radial basis network.

The larger the `spread` is, the smoother the function approximation will be. Too large a spread can cause numerical problems.

### Examples

Here you design a radial basis network given inputs P and targets T.

```
P = [1 2 3];
T = [2.0 4.1 5.9];
net = newrbe(P,T);
```

The network is simulated for a new input.

```
P = 1.5;
Y = sim(net,P)
```

### Algorithms

`newrbe` creates a two-layer network. The first layer has `radbas` neurons, and calculates its weighted inputs with `dist` and its net input with `netprod`. The second layer has `purelin` neurons, and calculates its weighted input with `dotprod` and its net inputs with `netsum`. Both layers have biases.

`newrbe` sets the first-layer weights to  $P'$ , and the first-layer biases are all set to  $0.8326/\text{spread}$ , resulting in radial basis functions that cross 0.5 at weighted inputs of  $\pm \text{spread}$ .

The second-layer weights  $IW\{2,1\}$  and biases  $b\{2\}$  are found by simulating the first-layer outputs  $A\{1\}$  and then solving the following linear expression:

$$[W\{2,1\} \ b\{2\}] * [A\{1\}; \text{ones}] = T$$

## nncell2mat

Combine neural network cell data into matrix

### Syntax

```
[y,i,j] nncell2mat(x)
```

### Description

[y,i,j] nncell2mat(x) takes a cell array of matrices and returns,

y	Cell array formed by concatenating matrices
i	Array of row sizes
ji	Array of column sizes

The row and column sizes returned by nncell2mat can be used to convert the returned matrix back into a cell of matrices with mat2cell.

### Examples

Here neural network data is converted to a matrix and back.

```
c = {rands(2,3) rands(2,3); rands(5,3) rands(5,3)};
[m,i,j] = nncell2mat(c)
c3 = mat2cell(m,i,j)
```

## Version History

Introduced in R2010b

### See Also

nndata | nnsz

## nncorr

Cross correlation between neural network time series

### Syntax

```
nncorr(a,b,maxlag,'flag')
```

### Description

`nncorr(a,b,maxlag,'flag')` takes these arguments,

<code>a</code>	Matrix or cell array, with columns interpreted as timesteps, and having a total number of matrix rows of <code>N</code> .
<code>b</code>	Matrix or cell array, with columns interpreted as timesteps, and having a total number of matrix rows of <code>M</code> .
<code>maxlag</code>	Maximum number of time lags
<code>flag</code>	Type of normalization (default = 'none')

and returns an `N`-by-`M` cell array where each  $\{i, j\}$  element is a  $2*\text{maxlag}+1$  length row vector formed from the correlations of `a` elements (i.e., matrix row) `i` and `b` elements (i.e., matrix column) `j`.

If `a` and `b` are specified with row vectors, the result is returned in matrix form.

The options for the normalization `flag` are:

- 'biased' — scales the raw cross-correlation by  $1/N$ .
- 'unbiased' — scales the raw correlation by  $1/(N - \text{abs}(k))$ , where `k` is the index into the result.
- 'coeff' — normalizes the sequence so that the correlations at zero lag are 1.0.
- 'none' — no scaling. This is the default.

### Examples

Here the autocorrelation of a random 1-element, 1-sample, 20-timestep signal is calculated with a maximum lag of 10.

```
a = nndata(1,1,20)
aa = nncorr(a,a,10)
```

Here the cross-correlation of the first signal with another random 2-element signal are found, with a maximum lag of 8.

```
b = nndata(2,1,20)
ab = nncorr(a,b,8)
```

## Version History

Introduced in R2010b

# nndata

Create neural network data

## Syntax

```
nndata(N,Q,TS,v)
```

## Description

`nndata(N,Q,TS,v)` takes these arguments,

N	Vector of M element sizes
Q	Number of samples
TS	Number of timesteps
v	Scalar value

and returns an M-by-TS cell array where each row *i* has N(*i*)-by-Q sized matrices of value *v*. If *v* is not specified, random values are returned.

You can access subsets of neural network data with `getelements`, `getsamples`, `gettimesteps`, and `getsignals`.

You can set subsets of neural network data with `setelements`, `setsamples`, `settimesteps`, and `setsignals`.

You can concatenate subsets of neural network data with `catelements`, `catsamples`, `cattimesteps`, and `catsignals`.

## Examples

Here four samples of five timesteps, for a 2-element signal consisting of zero values is created:

```
x = nndata(2,4,5,0)
```

To create random data with the same dimensions:

```
x = nndata(2,4,5)
```

Here static (1 timestep) data of 12 samples of 4 elements is created.

```
x = nndata(4,12)
```

## Version History

Introduced in R2010b

## nndata2gpu

Format neural data for efficient GPU training or simulation

### Syntax

```
nndata2gpu(x)
[Y,Q,N,TS] = nndata2gpu(X)
nndata2gpu(X,PRECISION)
```

### Description

nndata2gpu requires Parallel Computing Toolbox.

nndata2gpu(x) takes an N-by-Q matrix X of Q N-element column vectors, and returns it in a form for neural network training and simulation on the current GPU device.

The N-by-Q matrix becomes a QQ-by-N gpuArray where QQ is Q rounded up to the next multiple of 32. The extra rows (Q+1):QQ are filled with NaN values. The gpuArray has the same precision ('single' or 'double') as X.

[Y,Q,N,TS] = nndata2gpu(X) can also take an M-by-TS cell array of M signals over TS time steps. Each element of X{i,ts} should be an Ni-by-Q matrix of Q Ni-element vectors, representing the ith signal vector at time step ts, across all Q time series. In this case, the gpuArray Y returned is QQ-by-(sum(Ni)\*TS). Dimensions Ni, Q, and TS are also returned so they can be used with gpu2nndata to perform the reverse formatting.

nndata2gpu(X,PRECISION) specifies the default precision of the gpuArray, which can be 'double' or 'single'.

### Examples

Copy a matrix to the GPU and back:

```
x = rand(5,6)
[y,q] = nndata2gpu(x)
x2 = gpu2nndata(y,q)
```

Copy neural network cell array data, representing four time series, each consisting of five time steps of 2-element and 3-element signals:

```
x = nndata([2;3],4,5)
[y,q,n,ts] = nndata2gpu(x)
x2 = gpu2nndata(y,q,n,ts)
```

## Version History

Introduced in R2012b

**See Also**

gpu2nndata

## nndata2sim

Convert neural network data to Simulink time series

### Syntax

```
nndata2sim(x,i,q)
```

### Description

nndata2sim(x,i,q) takes these arguments,

x	Neural network data
i	Index of signal (default = 1)
q	Index of sample (default = 1)

and returns time series q of signal i as a Simulink time series structure.

### Examples

Here random neural network data is created with two signals having 4 and 3 elements respectively, over 10 timesteps. Three such series are created.

```
x = nndata([4;3],3,10);
```

Now the second signal of the first series is converted to Simulink form.

```
y_2_1 = nndata2sim(x,2,1)
```

## Version History

**Introduced in R2010b**

### See Also

nndata | sim2nndata | nnsim

## nnsizes

Number of neural data elements, samples, timesteps, and signals

### Syntax

```
[N,Q,TS,M] = nnsizes(X)
```

### Description

`[N,Q,TS,M] = nnsizes(X)` takes neural network data `x` and returns,

N	Vector containing the number of element sizes for each of M signals
Q	Number of samples
TS	Number of timesteps
M	Number of signals

If `X` is a matrix, `N` is the number of rows of `X`, `Q` is the number of columns, and both `TS` and `M` are 1.

If `X` is a cell array, `N` is an `Sx1` vector, where `M` is the number of rows in `X`, and `N(i)` is the number of rows in `X{i,1}`. `Q` is the number of columns in the matrices in `X`.

### Examples

This code gets the dimensions of matrix data:

```
x = [1 2 3; 4 7 4]
[n,q,ts,s] = nnsizes(x)
```

This code gets the dimensions of cell array data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
[n,q,ts,s] = nnsizes(x)
```

## Version History

**Introduced in R2010b**

`nndata` | `numelements` | `numsamples` | `numsignals` | `numtimesteps`

## nnstart

Open Neural Network Start app

### Syntax

```
nnstart  
nnstart("close")
```

### Description

nnstart opens a window with launch buttons for **Neural Net Fitting** app, **Neural Net Pattern Recognition** app, **Neural Net Clustering** app, and **Neural Net Time Series** app. It also provides links to lists of data sets, examples, and other useful information for getting started.

nnstart("close") closes the Neural Network Start app.

## Version History

**Introduced in R2010b**

### See Also

nctool | nftool | nprtool | ntstool

# nntool

(Removed) Open Network/Data Manager

---

**Note** nntool has been removed. Use nnstart instead. For more information, see “Compatibility Considerations”.

---

## Syntax

nntool

## Description

nntool opens the Network/Data Manager window, which allows you to import, create, use, and export neural networks and data.

## Version History

**Introduced before R2006a**

**R2022a: nntool has been removed**

*Errors starting in R2022a*

nntool has been removed. Use nnstart instead. nnstart provides graphical interfaces that allow you to design and deploy fitting, pattern recognition, clustering, and time-series neural networks.

## See Also

nnstart

## nntraintool

(Removed) Neural network training tool

---

**Note** `nntraintool` has been removed. To train a network and open the training window, use `train` instead.

---

### Syntax

```
nntraintool
nntraintool close
nntraintool('close')
```

### Description

`nntraintool` opens the neural network training GUI.

This function can be called to make the training GUI visible before training has occurred, after training if the window has been closed, or just to bring the training GUI to the front.

To access additional useful plots, related to the current or last network trained, during or after training, click their respective buttons in the training window.

`nntraintool close` or `nntraintool('close')` closes the training window.

### Version History

**Introduced in R2008a**

**R2022a: `nntraintool` has been removed**

*Errors starting in R2022a*

`nntraintool` has been removed. To train a network and open the training window, use `train` instead.

### See Also

`train`

## noloop

Remove neural network open- and closed-loop feedback

### Syntax

```
net = noloop(net)
```

### Description

`net = noloop(net)` takes a neural network and returns the network with open- and closed-loop feedback removed.

For outputs `i`, where `net.outputs{i}.feedbackMode` is 'open', the feedback mode is set to 'none', `outputs{i}.feedbackInput` is set to the empty matrix, and the associated network input is deleted.

For outputs `i`, where `net.outputs{i}.feedbackMode` is 'closed', the feedback mode is set to 'none'.

### Examples

#### Convert NARX Network to No Loop Form

This example shows how to create and train a NARX network. The NARX network has a standard input and an open-loop feedback output to an associated feedback input.

```
[X,T] = simplenarx_dataset;  
net = narxnet(1:2,1:2,20);  
[Xs,Xi,Ai,Ts] = preparets(net,X,{},T);  
net = train(net,Xs,Ts,Xi,Ai);
```

## normc

Normalize columns of matrix

### Syntax

```
normc(M)
```

### Description

`normc(M)` normalizes the columns of `M` to a length of 1.

### Examples

#### Normalize the Columns of a Matrix by Using the normc Function

This example shows how to use the `normc` function to normalize the columns of a matrix to a length of 1.

Create the matrix, `m`, of which you want to normalize the columns. Then call the `normc` function on this matrix.

```
m = [1 2; 3 4];  
normc(m)
```

```
ans =  
    0.3162    0.4472  
    0.9487    0.8944
```

### Input Arguments

#### **M** — Input matrix

matrix | cell array of matrices

Matrix of which you want to normalize the columns to a length of 1, specified as a matrix or a cell array of matrices.

### Version History

Introduced before R2006a

### See Also

`normr`

## normprod

Normalized dot product weight function

### Syntax

```
Z = normprod(W,P,FP)
dim = normprod('size',S,R,FP)
dw = normprod('dz_dw',W,P,Z,FP)
```

### Description

normprod is a weight function. Weight functions apply weights to an input to get weighted inputs.

`Z = normprod(W,P,FP)` takes these inputs,

W	S-by-R weight matrix
P	R-by-Q matrix of Q input (column) vectors
FP	Row cell array of function parameters (optional, ignored)

and returns the S-by-Q matrix of normalized dot products.

`dim = normprod('size',S,R,FP)` takes the layer dimension S, input dimension R, and function parameters, and returns the weight size [S-by-R].

`dw = normprod('dz_dw',W,P,Z,FP)` returns the derivative of Z with respect to W.

### Examples

Here you define a random weight matrix W and input vector P and calculate the corresponding weighted input Z.

```
W = rand(4,3);
P = rand(3,1);
Z = normprod(W,P)
```

### Network Use

You can create a standard network that uses normprod by calling newgrnn.

To change a network so an input weight uses normprod, set `net.inputWeights{i,j}.weightFcn` to 'normprod'. For a layer weight, set `net.layerWeights{i,j}.weightFcn` to 'normprod'.

In either case, call `sim` to simulate the network with normprod. See newgrnn for simulation examples.

### Algorithms

normprod returns the dot product normalized by the sum of the input vector elements.

$z = w*p/sum(p)$

## **Version History**

**Introduced before R2006a**

## **See Also**

dotprod

## normr

Normalize rows of matrix

### Syntax

```
normalized_M = normr(M)
```

### Description

`normalized_M = normr(M)` takes a single matrix or cell array of matrices, `M`, and returns the matrices with rows normalized to a length of one.

### Examples

#### Normalize rows of a matrix

This example shows how to use the `normr` function to normalize the rows of a matrix.

Create a 2x2 matrix and call the `normr` function to normalize its rows to a length of 1.

```
m = [1 2; 3 4];  
normr(m)  
ans =  
    0.4472    0.8944  
    0.6000    0.8000  
  
ans =  
    0.4472    0.8944  
    0.6000    0.8000
```

### Input Arguments

#### **M** — Matrix to normalize

matrix | cell array of matrices

Matrix to normalize, specified as a matrix or a cell array of matrices.

### Output Arguments

#### **normalized\_M** — Normalized matrix

matrix | cell array of matrices

Normalized matrix, returned as a matrix or a cell array of matrices.

## Version History

Introduced before R2006a

normc

## nprtool

Open Neural Net Pattern Recognition app

### Syntax

```
nprtool  
nprtool("close")
```

### Description

`nprtool` opens the **Neural Net Pattern Recognition** app. For more information and an example of its usage, see “Pattern Recognition with a Shallow Neural Network”.

---

**Note** To interactively build, visualize, and train deep learning neural networks, use the **Deep Network Designer** app. For more information, see “Get Started with Deep Network Designer”.

---

`nprtool("close")` closes the Neural Net Pattern Recognition app.

### Algorithms

The **Neural Net Pattern Recognition** app leads you through solving a pattern-recognition classification problem using a two-layer feed-forward `patternnet` network with sigmoid output neurons.

## Version History

**Introduced in R2008a**

# ntstool

Open Neural Net Time Series app

## Syntax

```
ntstool  
ntstool("close")
```

## Description

ntstool opens the **Neural Net Time Series** app and leads you through solving a fitting problem using a two-layer feed-forward network. For more information and an example of its usage, see “Shallow Neural Network Time-Series Prediction and Modeling”.

---

**Note** To interactively build, visualize, and train deep learning neural networks, use the **Deep Network Designer** app. For more information, see “Get Started with Deep Network Designer”.

---

ntstool("close") closes the Neural Net Time Series app.

## Version History

Introduced in R2010b

## num2deriv

Numeric two-point network derivative function

### Syntax

```
num2deriv('dperf_dwb',net,X,T,Xi,Ai,EW)
num2deriv('de_dwb',net,X,T,Xi,Ai,EW)
```

### Description

This function calculates derivatives using the two-point numeric derivative rule.

$$\frac{dy}{dx} = \frac{y(x + dx) - y(x)}{dx}$$

This function is much slower than the analytical (non-numerical) derivative functions, but is provided as a means of checking the analytical derivative functions. The other numerical function, `num5deriv`, is slower but more accurate.

`num2deriv('dperf_dwb',net,X,T,Xi,Ai,EW)` takes these arguments,

<code>net</code>	Neural network
<code>X</code>	Inputs, an $R \times Q$ matrix (or $N \times TS$ cell array of $R \times Q$ matrices)
<code>T</code>	Targets, an $S \times Q$ matrix (or $M \times TS$ cell array of $S \times Q$ matrices)
<code>Xi</code>	Initial input delay states (optional)
<code>Ai</code>	Initial layer delay states (optional)
<code>EW</code>	Error weights (optional)

and returns the gradient of performance with respect to the network's weights and biases, where  $R$  and  $S$  are the number of input and output elements and  $Q$  is the number of samples (and  $N$  and  $M$  are the number of input and output signals,  $R_i$  and  $S_i$  are the number of each input and outputs elements, and  $TS$  is the number of timesteps).

`num2deriv('de_dwb',net,X,T,Xi,Ai,EW)` returns the Jacobian of errors with respect to the network's weights and biases.

### Examples

Here a feedforward network is trained and both the gradient and Jacobian are calculated.

```
[x,t] = simplefit_dataset;
net = feedforwardnet(20);
net = train(net,x,t);
y = net(x);
perf = perform(net,t,y);
dwb = num2deriv('dperf_dwb',net,x,t)
```

## **Version History**

**Introduced in R2010b**

### **See Also**

bttderiv | defaultderiv | fpderiv | num5deriv | staticderiv

## num5deriv

Numeric five-point stencil neural network derivative function

### Syntax

```
num5deriv('dperf_dwb',net,X,T,Xi,Ai,EW)
num5deriv('de_dwb',net,X,T,Xi,Ai,EW)
```

### Description

This function calculates derivatives using the five-point numeric derivative rule.

$$y_1 = y(x + 2dx)$$

$$y_2 = y(x + dx)$$

$$y_3 = y(x - dx)$$

$$y_4 = y(x - 2dx)$$

$$\frac{dy}{dx} = \frac{-y_1 + 8y_2 - 8y_3 + y_4}{12dx}$$

This function is much slower than the analytical (non-numerical) derivative functions, but is provided as a means of checking the analytical derivative functions. The other numerical function, `num2deriv`, is faster but less accurate.

`num5deriv('dperf_dwb',net,X,T,Xi,Ai,EW)` takes these arguments,

<code>net</code>	Neural network
<code>X</code>	Inputs, an $R \times Q$ matrix (or $N \times TS$ cell array of $R \times Q$ matrices)
<code>T</code>	Targets, an $S \times Q$ matrix (or $M \times TS$ cell array of $S \times Q$ matrices)
<code>Xi</code>	Initial input delay states (optional)
<code>Ai</code>	Initial layer delay states (optional)
<code>EW</code>	Error weights (optional)

and returns the gradient of performance with respect to the network's weights and biases, where  $R$  and  $S$  are the number of input and output elements and  $Q$  is the number of samples (and  $N$  and  $M$  are the number of input and output signals,  $R_i$  and  $S_i$  are the number of each input and outputs elements, and  $TS$  is the number of timesteps).

`num5deriv('de_dwb',net,X,T,Xi,Ai,EW)` returns the Jacobian of errors with respect to the network's weights and biases.

### Examples

Here a feedforward network is trained and both the gradient and Jacobian are calculated.

```
[x,t] = simplefit_dataset;
net = feedforwardnet(20);
```

```
net = train(net,x,t);  
y = net(x);  
perf = perform(net,t,y);  
dwb = num5deriv('dperf_dwb',net,x,t)
```

## numelements

Number of elements in neural network data

### Syntax

```
numelements(x)
```

### Description

`numelements(x)` takes neural network data `x` in matrix or cell array form, and returns the number of elements in each signal.

If `x` is a matrix the result is the number of rows of `x`.

If `x` is a cell array the result is an `S`-by-1 vector, where `S` is the number of signals (i.e., rows of `X`), and each element `S(i)` is the number of elements in each signal `i` (i.e., rows of `x{i,1}`).

### Examples

This code calculates the number of elements represented by matrix data:

```
x = [1 2 3; 4 7 4]
n = numelements(x)
```

This code calculates the number of elements represented by cell data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
n = numelements(x)
```

## Version History

# numfinite

Number of finite values in neural network data

## Syntax

```
numfinite(x)
```

## Description

`numfinite(x)` takes a matrix or cell array of matrices and returns the number of finite elements in it.

## Examples

```
x = [1 2; 3 NaN]
n = numfinite(x)
```

```
x = {[1 2; 3 NaN] [5 NaN; NaN 8]}
n = numfinite(x)
```

## Version History

## See Also

`numnan` | `nndata` | `nnsizes`

## numnan

Number of NaN values in neural network data

### Syntax

```
numnan(x)
```

### Description

`numnan(x)` takes a matrix or cell array of matrices and returns the number of NaN elements in it.

### Examples

```
x = [1 2; 3 NaN]
n = numnan(x)
```

```
x = {[1 2; 3 NaN] [5 NaN; NaN 8]}
n = numnan(x)
```

## Version History

**Introduced in R2010b**

### See Also

`nndata` | `nnsz`

# numsamples

Number of samples in neural network data

## Syntax

```
numsamples(x)
```

## Description

`numsamples(x)` takes neural network data `x` in matrix or cell array form, and returns the number of samples.

If `x` is a matrix, the result is the number of columns of `x`.

If `x` is a cell array, the result is the number of columns of the matrices in `x`.

## Examples

This code calculates the number of samples represented by matrix data:

```
x = [1 2 3; 4 7 4]
n = numsamples(x)
```

This code calculates the number of samples represented by cell data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
n = numsamples(x)
```

## Version History

**Introduced in R2010b**

## See Also

## numsignals

Number of signals in neural network data

### Syntax

```
numsignals(x)
```

### Description

`numsignals(x)` takes neural network data `x` in matrix or cell array form, and returns the number of signals.

If `x` is a matrix, the result is 1.

If `x` is a cell array, the result is the number of rows in `x`.

### Examples

This code calculates the number of signals represented by matrix data:

```
x = [1 2 3; 4 7 4]
n = numsignals(x)
```

This code calculates the number of signals represented by cell data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
n = numsignals(x)
```

## Version History

# numtimesteps

Number of time steps in neural network data

## Syntax

```
numtimesteps(x)
```

## Description

`numtimesteps(x)` takes neural network data `x` in matrix or cell array form, and returns the number of signals.

If `x` is a matrix, the result is 1.

If `x` is a cell array, the result is the number of columns in `x`.

## Examples

This code calculates the number of time steps represented by matrix data:

```
x = [1 2 3; 4 7 4]
n = numtimesteps(x)
```

This code calculates the number of time steps represented by cell data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
n = numtimesteps(x)
```

## Version History

## openloop

Convert neural network closed-loop feedback to open loop

### Syntax

```
net = openloop(net)
[net,xi,ai] = openloop(net,xi,ai)
```

### Description

`net = openloop(net)` takes a neural network and opens any closed-loop feedback. For each feedback output `i` whose property `net.outputs{i}.feedbackMode` is 'closed', it replaces its associated feedback layer weights with a new input and input weight connections. The `net.outputs{i}.feedbackMode` property is set to 'open', and the `net.outputs{i}.feedbackInput` property is set to the index of the new input. Finally, the value of `net.outputs{i}.feedbackDelays` is subtracted from the delays of the feedback input weights (i.e., to the delays values of the replaced layer weights).

`[net,xi,ai] = openloop(net,xi,ai)` converts a closed-loop network and its current input delay states `xi` and layer delay states `ai` to open-loop form.

### Examples

#### Convert NARX Network to Open-Loop Form

This example shows how to create a NARX network in open-loop form, convert it to closed-loop form, and then convert it back.

```
[X,T] = simplenarx_dataset;
net = narxnet(1:2,1:2,10);
[Xs,Xi,Ai,Ts] = preparets(net,X,{},T);
net = train(net,Xs,Ts,Xi,Ai);
```

# patternnet

Generate pattern recognition network

## Syntax

```
net = patternnet(hiddenSizes,trainFcn,performFcn)
```

## Description

`net = patternnet(hiddenSizes,trainFcn,performFcn)` returns a pattern recognition neural network with a hidden layer size of `hiddenSizes`, a training function, specified by `trainFcn`, and a performance function, specified by `performFcn`.

Pattern recognition networks are feedforward networks that can be trained to classify inputs according to target classes. The target data for pattern recognition networks should consist of vectors of all zero values except for a 1 in element `i`, where `i` is the class they are to represent.

## Examples

### Construct and Train a Pattern Recognition Neural Network

This example shows how to design a pattern recognition network to classify iris flowers.

Load the training data.

```
[x,t] = iris_dataset;
```

Construct a pattern network with one hidden layer of size 10.

```
net = patternnet(10);
```

Train the network `net` using the training data.

```
net = train(net,x,t);
```

```

```
perf = 0.0302
```

```
classes = vec2ind(y);
```

## Input Arguments

**hiddenSizes** — Size of the hidden layers

10 (default) | row vector

Size of the hidden layers in the network, specified as a row vector. The length of the vector determines the number of hidden layers in the network.

Example: For example, you can specify a network with 3 hidden layers, where the first hidden layer size is 10, the second is 8, and the third is 5 as follows: [10,8,5]

The input and output sizes are set to zero. The software adjusts the sizes of these during training according to the training data.

Data Types: single | double

**trainFcn — Training function name**

'trainscg' (default) | 'trainbr' | 'trainbfg' | 'trainrp' | 'trainlm' | ...

Training function name, specified as one of the following.

Training Function	Algorithm
'trainlm'	Levenberg-Marquardt
'trainbr'	Bayesian Regularization
'trainbfg'	BFGS Quasi-Newton
'trainrp'	Resilient Backpropagation
'trainscg'	Scaled Conjugate Gradient
'traincgb'	Conjugate Gradient with Powell/Beale Restarts
'traincgf'	Fletcher-Powell Conjugate Gradient
'traincgp'	Polak-Ribière Conjugate Gradient
'trainoss'	One Step Secant
'traingdx'	Variable Learning Rate Gradient Descent
'traingdm'	Gradient Descent with Momentum
'traingd'	Gradient Descent

Example: For example, you can specify the variable learning rate gradient descent algorithm as the training algorithm as follows: 'traingdx'

For more information on the training functions, see “Train and Apply Multilayer Shallow Neural Networks” and “Choose a Multilayer Neural Network Training Function”.

Data Types: char

**performFcn — Performance function**

character vector

Performance function. The default value is 'crossentropy'.

This argument defines the function used to measure the network’s performance. The performance function is used to calculate network performance during training.

For a list of functions, in the MATLAB command window, type `help nnperformance`.

## Output Arguments

**net** — Pattern recognition network  
network object

Pattern recognition neural network, returned as a network object.

## Version History

Introduced in R2010b

## perceptron

Simple single-layer binary classifier

### Syntax

```
perceptron(hardlimitTF,perceptronLF)
```

### Description

---

**Note** Deep Learning Toolbox supports perceptrons for historical interest. For better results, you should instead use `patternnet`, which can solve nonlinearly separable problems. Sometimes the term “perceptrons” refers to feed-forward pattern recognition networks; but the original perceptron, described here, can solve only simple problems.

---

`perceptron(hardlimitTF,perceptronLF)` takes a hard limit transfer function, `hardlimitTF`, and a perceptron learning rule, `perceptronLF`, and returns a perceptron.

In addition to the default hard limit transfer function, perceptrons can be created with the `hardlims` transfer function. The other option for the perceptron learning rule is `learnpn`.

Perceptrons are simple single-layer binary classifiers, which divide the input space with a linear decision boundary.

Perceptrons can learn to solve a narrow range of classification problems. They were one of the first neural networks to reliably solve a given class of problem, and their advantage is a simple learning rule.

### Examples

#### Solve Simple Classification Problem Using Perceptron

This example shows how to use a perceptron to solve a simple classification logical-OR problem.

```
x = [0 0 1 1; 0 1 0 1];  
t = [0 1 1 1];  
net = perceptron;  
net = train(net,x,t);
```

## perform

Calculate network performance

### Syntax

```
perf = perform(net,t,y,ew)
```

### Description

`perf = perform(net,t,y,ew)` takes a network `net`, targets `T`, outputs `Y`, and optionally error weights `EW`, and returns network performance calculated according to the `net.performFcn` and `net.performParam` property values.

The target and output data must have the same dimensions. The error weights may be the same dimensions as the targets, in the most general case, but may also have any of its dimensions be 1. This gives the flexibility of defining error weights across any dimension desired.

### Examples

#### Calculate Network Performance with 'perform' Function

This example shows how to calculate the performance of a feed-forward network with the `perform` function.

Create a feed-forward network using the data from the simple fit data set and calculate its performance.

```
[x,t] = simplefit_dataset;  
net = feedforwardnet(20);  
net = train(net,x,t);  
y = net(x);  
perf = perform(net,t,y)
```

```
perf =  
  
    2.3654e-06
```

### Input Arguments

#### **net** — Input network

network

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

#### **t** — Network targets

matrix | cell array

Network targets, specified as a matrix or cell array.

**y — Network outputs**

matrix | cell array

Network outputs, specified as a matrix or cell array.

**ew — Error weights**

vector | matrix | cell array

Error weights, specified as a vector, matrix, or cell array.

Error weights can be defined by sample, output element, time step, or network output:

```
ew = [1.0 0.5 0.7 0.2]; % Across 4 samples
ew = [0.1; 0.5; 1.0]; % Across 3 elements
ew = {0.1 0.2 0.3 0.5 1.0}; % Across 5 timesteps
ew = {1.0; 0.5}; % Across 2 outputs
```

The error weights can also be defined across any combination, such as across two time-series (i.e., two samples) over four timesteps.

```
ew = {[0.5 0.4],[0.3 0.5],[1.0 1.0],[0.7 0.5]};
```

In the general case, error weights may have exactly the same dimensions as targets, in which case each target value will have an associated error weight.

The default error weight treats all errors the same.

```
ew = {1}
```

**Output Arguments****perf — Network performance**

scalar

Network performance, returned as a scalar.

## plotconfusion

Plot classification confusion matrix

### Syntax

```
plotconfusion(targets, outputs)
plotconfusion(targets, outputs, name)
plotconfusion(targets1, outputs1, name1, targets2, outputs2, name2, ..., targetsn, ou
tputsn, namen)
```

### Description

`plotconfusion(targets, outputs)` plots a confusion matrix for the true labels `targets` and predicted labels `outputs`. Specify the labels as categorical vectors, or in one-of-N (one-hot) form.

---

**Tip** `plotconfusion` is not recommended for categorical labels. Use `confusionchart` instead.

---

On the confusion matrix plot, the rows correspond to the predicted class (Output Class) and the columns correspond to the true class (Target Class). The diagonal cells correspond to observations that are correctly classified. The off-diagonal cells correspond to incorrectly classified observations. Both the number of observations and the percentage of the total number of observations are shown in each cell.

The column on the far right of the plot shows the percentages of all the examples predicted to belong to each class that are correctly and incorrectly classified. These metrics are often called the precision (or positive predictive value) and false discovery rate, respectively. The row at the bottom of the plot shows the percentages of all the examples belonging to each class that are correctly and incorrectly classified. These metrics are often called the recall (or true positive rate) and false negative rate, respectively. The cell in the bottom right of the plot shows the overall accuracy.

`plotconfusion(targets, outputs, name)` plots a confusion matrix and adds `name` to the beginning of the plot title.

`plotconfusion(targets1, outputs1, name1, targets2, outputs2, name2, ..., targetsn, ou tputsn, namen)` plots multiple confusion matrices in one figure and adds the name arguments to the beginnings of the titles of the corresponding plots.

### Examples

#### Plot Confusion Matrix Using Categorical Labels

Load the data consisting of synthetic images of handwritten digits. `XTrain` is a 28-by-28-by-1-by-5000 array of images and `YTrain` is a categorical vector containing the image labels.

```
[XTrain, YTrain] = digitTrain4DArrayData;
whos YTrain
```

Name	Size	Bytes	Class	Attributes
YTrain	5000x1	6062	categorical	

Define the architecture of a convolutional neural network.

```
layers = [
    imageInputLayer([28 28 1])

    convolution2dLayer(3,8,'Padding','same')
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,16,'Padding','same','Stride',2)
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,32,'Padding','same','Stride',2)
    batchNormalizationLayer
    reluLayer

    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer];
```

Specify training options and train the network.

```
options = trainingOptions('sgdm', ...
    'MaxEpochs',5, ...
    'Verbose',false, ...
    'Plots','training-progress');
net = trainNetwork(XTrain,YTrain,layers,options);
```

Load and classify test data using the trained network.

```
[XTest,YTest] = digitTest4DArrayData;
YPredicted = classify(net,XTest);
```

Plot the confusion matrix of the true test labels YTest and the predicted labels YPredicted.

```
plotconfusion(YTest,YPredicted)
```

The rows correspond to the predicted class (Output Class) and the columns correspond to the true class (Target Class). The diagonal cells correspond to observations that are correctly classified. The off-diagonal cells correspond to incorrectly classified observations. Both the number of observations and the percentage of the total number of observations are shown in each cell.

The column on the far right of the plot shows the percentages of all the examples predicted to belong to each class that are correctly and incorrectly classified. These metrics are often called the precision (or positive predictive value) and false discovery rate, respectively. The row at the bottom of the plot

shows the percentages of all the examples belonging to each class that are correctly and incorrectly classified. These metrics are often called the recall (or true positive rate) and false negative rate, respectively. The cell in the bottom right of the plot shows the overall accuracy.

Close all figures.

```
close(findall(groot, 'Type', 'figure'))
```

### Plot Confusion Matrix Using One-of-N Labels

Load sample data using the `cancer_dataset` function. `XTrain` is a 9-by-699 matrix defining nine attributes of 699 biopsies. `YTrain` is a 2-by-699 matrix where each column indicates the correct category of the corresponding observation. Each column of `YTrain` has one element that equals one in either the first or second row, corresponding to the cancer being benign or malignant, respectively. For more information on this dataset, type `help cancer_dataset` at the command line.

```
rng default
[XTrain,YTrain] = cancer_dataset;
YTrain(:,1:10)
```

```
ans = 2×10
```

```
    1    1    1    0    1    1    0    0    0    1
    0    0    0    1    0    0    1    1    1    0
```

Create a pattern recognition network and train it using the sample data.

```
net = patternnet(10);
net = train(net,XTrain,YTrain);
```

Network Diagram

Error Histogram

Confusion

Receiver Operating Characteristic

Estimate the cancer status using the trained network. Each column of the matrix `YPredicted` contains the predicted probabilities of each observation belonging to class 1 and class 2, respectively.

```
YPredicted = net(XTrain);
YPredicted(:,1:10)
```

```
ans = 2×10
```

```

0.9980  0.9979  0.9894  0.0578  0.9614  0.9960  0.0026  0.0023  0.0084  0.
0.0020  0.0021  0.0106  0.9422  0.0386  0.0040  0.9974  0.9977  0.9916  0.

```

Plot the confusion matrix. To create the plot, `plotconfusion` labels each observation according to the highest class probability.

```
plotconfusion(YTrain,YPredicted)
```

In this figure, the first two diagonal cells show the number and percentage of correct classifications by the trained network. For example, 446 biopsies are correctly classified as benign. This corresponds to 63.8% of all 699 biopsies. Similarly, 236 cases are correctly classified as malignant. This corresponds to 33.8% of all biopsies.

5 of the malignant biopsies are incorrectly classified as benign and this corresponds to 0.7% of all 699 biopsies in the data. Similarly, 12 of the benign biopsies are incorrectly classified as malignant and this corresponds to 1.7% of all data.

Out of 451 benign predictions, 98.9% are correct and 1.1% are wrong. Out of 248 malignant predictions, 95.2% are correct and 4.8% are wrong. Out of 458 benign cases, 97.4% are correctly predicted as benign and 2.6% are predicted as malignant. Out of 241 malignant cases, 97.9% are correctly classified as malignant and 2.1% are classified as benign.

Overall, 97.6% of the predictions are correct and 2.4% are wrong.

## Input Arguments

### **targets — True class labels**

categorical vector | matrix

True class labels, specified one of the following:

- A categorical vector, where each element is the class label of one observation. The `outputs` and `targets` arguments must have the same number of elements. If the categorical vectors define underlying classes, then `plotconfusion` displays all the underlying classes, even if there are no observations of some of the underlying classes. If the arguments are ordinal categorical vectors, then they must both define the same underlying categories, in the same order.
- An  $N$ -by- $M$  matrix, where  $N$  is the number of classes and  $M$  is the number of observations. Each column of the matrix must be in one-of- $N$  (one-hot) form, where a single element equal to 1 indicates the true label and all other elements equal 0.

### **outputs — Predicted class labels**

categorical vector | matrix

Predicted class labels, specified one of the following:

- A categorical vector, where each element is the class label of one observation. The `outputs` and `targets` arguments must have the same number of elements. If the categorical vectors define underlying classes, then `plotconfusion` displays all the underlying classes, even if there are no observations of some of the underlying classes. If the arguments are ordinal categorical vectors, then they must both define the same underlying categories, in the same order.
- An  $N$ -by- $M$  matrix, where  $N$  is the number of classes and  $M$  is the number of observations. Each column of the matrix can be in one-of- $N$  (one-hot) form, where a single element equal to 1 indicates the predicted label, or in the form of probabilities that sum to one.

### **name — Name of the confusion matrix**

character array

Name of the confusion matrix, specified as a character array. `plotconfusion` adds the specified name to the beginning of the plot title.

Data Types: char

## plotep

Plot weight-bias position on error surface

### Syntax

```
H = plotep(W,B,E)
H = plotep(W,B,E,H)
```

### Description

plotep is used to show network learning on a plot created by plotes.

H = plotep(W,B,E) takes these arguments,

W	Current weight value
B	Current bias value
E	Current error

and returns a cell array H, containing information for continuing the plot.

H = plotep(W,B,E,H) continues plotting using the cell array H returned by the last call to plotep.

H contains handles to dots plotted on the error surface, so they can be deleted next time; as well as points on the error contour, so they can be connected.

# ploterrcorr

Plot autocorrelation of error time series

## Syntax

```
ploterrcorr(error)  
ploterrcorr(errors, 'outputIndex', outIdx)
```

## Description

`ploterrcorr(error)` takes an error time series and plots the autocorrelation of errors across varying lags.

`ploterrcorr(errors, 'outputIndex', outIdx)` uses the optional property name/value pair to define which output error autocorrelation is plotted. The default is 1.

## Examples

### Plot Autocorrelation of Errors

Here a NARX network is used to solve a time series problem.

```
[X,T] = simplenarx_dataset;  
net = narxnet(1:2,20);  
[Xs,Xi,Ai,Ts] = preparets(net,X,{},T);  
net = train(net,Xs,Ts,Xi,Ai);
```

## ploterrhist

Plot error histogram

### Syntax

```
ploterrhist(e)  
ploterrhist(e1,'name1',e2,'name2',...)  
ploterrhist(...,'bins',bins)
```

### Description

`ploterrhist(e)` plots a histogram of error values `e`.

`ploterrhist(e1,'name1',e2,'name2',...)` takes any number of errors and names and plots each pair.

`ploterrhist(...,'bins',bins)` takes an optional property name-value pair which defines the number of bins to use in the histogram plot. The default is 20.

### Examples

#### Plot Histogram of Error Values

This example shows how to plot the histogram of error values of a trained feed-forward network.

Create a feed-forward network and train it using the data from the simple fit data set. Then plot the histogram of error values.

```
[x,t] = simplefit_dataset;  
net = feedforwardnet(20);  
net = train(net,x,t);  
y = net(x);  
e = t - y;  
ploterrhist(e,'bins',30)
```

## Input Arguments

### **e** – Errors

vector | matrix

Errors to plot, specified as a vector or a matrix.

### **'bins', bins** – Number of bins

20 (default) | integer

Number of bins to use in the histogram plot, specified as the comma-separated pair consisting of 'bins' and an integer.

## Version History

Introduced in R2010b

### See Also

## plots

Plot error surface of single-input neuron

### Syntax

```
plots(WV,BV,ES,V)
```

### Description

`plots(WV,BV,ES,V)` takes these arguments,

WV	1-by-N row vector of values of W
BV	1-by-M row vector of values of B
ES	M-by-N matrix of error vectors
V	View (default = [-37.5, 30])

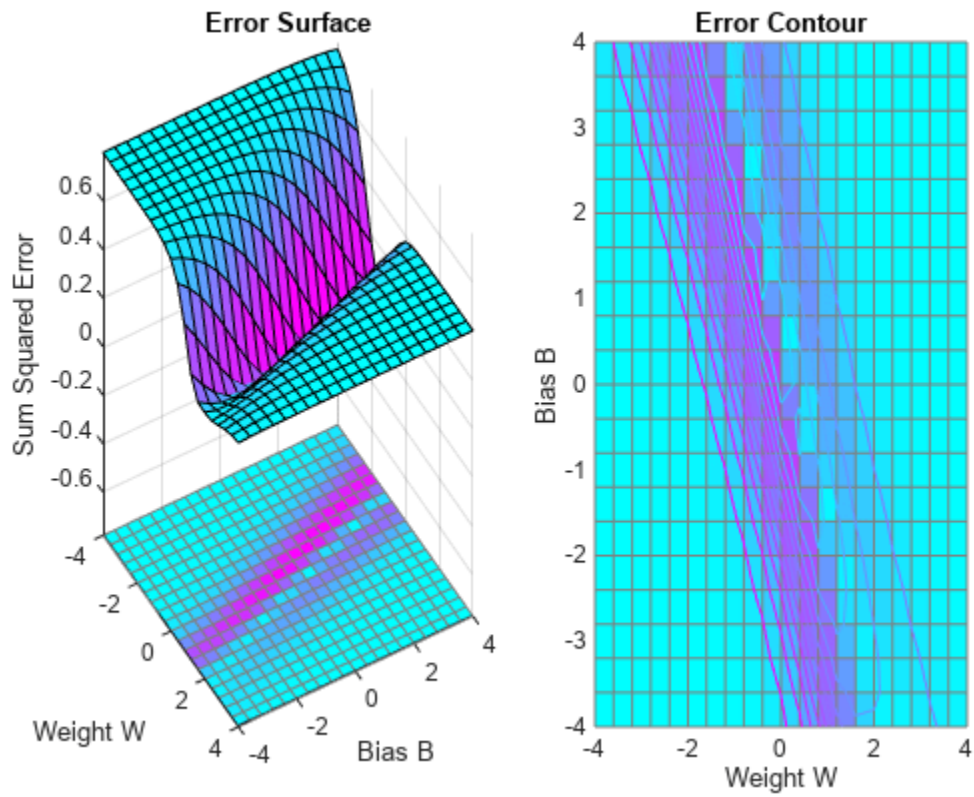

and plots the error surface with a contour underneath.

Calculate the error surface ES with `errsurf`.

### Examples

#### Plot Error Surface of Single-Input Neuron

```
p = [3 2];  
t = [0.4 0.8];  
wv = -4:0.4:4;  
bv = wv;  
ES = errsurf(p,t,wv,bv,'logsig');  
plots(wv,bv,ES,[60 30])
```

## Version History

Introduced before R2006a

## plotfit

Plot function fit

### Syntax

```
plotfit(net,inputs,targets)
plotfit(net,inputs1,targets1,name1,inputs2,targets2,name2,...)
plotfit(...,'outputIndex',outputIndex)
```

### Description

`plotfit(net,inputs,targets)` plots the output function of a network across the range of the inputs `inputs` and also plots target `targets` and output data points associated with values in `inputs`. Error bars show the difference between outputs and `targets`.

The plot appears only for networks with one input.

Only the first output/targets appear if the network has more than one output.

`plotfit(net,inputs1,targets1,name1,inputs2,targets2,name2,...)` plots multiple sets of data.

`plotfit(...,'outputIndex',outputIndex)` plots using an optional parameter that overrides the default index of the output element.

### Examples

#### Plot Output and Target Values

This example shows how to use a feed-forward network to solve a simple fitting problem.

```
[x,t] = simplefit_dataset;
net = feedforwardnet(10);
net = train(net,x,t);
```

## plotinerrcorr

Plot input to error time-series cross-correlation

### Syntax

```
plotinerrcorr(x,e)  
plotinerrcorr(...,'inputIndex',inputIndex)  
plotinerrcorr(...,'outputIndex',outputIndex)
```

### Description

`plotinerrcorr(x,e)` takes an input time series `x` and an error time series `e`, and plots the cross-correlation of inputs to errors across varying lags.

`plotinerrcorr(...,'inputIndex',inputIndex)` optionally defines which input element is being correlated and plotted. The default is 1.

`plotinerrcorr(...,'outputIndex',outputIndex)` optionally defines which error element is being correlated and plotted. The default is 1.

### Examples

#### Plot Cross-Correlation of Inputs to Errors

Here a NARX network is used to solve a time series problem.

```
[X,T] = simplenarx_dataset;  
net = narxnet(1:2,20);

## plotpc

Plot classification line on perceptron vector plot

### Syntax

```
plotpc(W,B)  
plotpc(W,B,H)
```

### Description

plotpc(W,B) takes these inputs,

W	S-by-R weight matrix (R must be 3 or less)
B	S-by-1 bias vector

and returns a handle to a plotted classification line.

plotpc(W,B,H) takes an additional input,

H	Handle to last plotted line
---	-----------------------------

and deletes the last line before plotting the new one.

This function does not change the current axis and is intended to be called after plotpv.

### Examples

#### Plot Classification Line

The code below defines and plots the inputs and targets for a perceptron:

```
p = [0 0 1 1; 0 1 0 1];  
t = [0 0 0 1];  
plotpv(p,t)
```

The following code creates a perceptron, assigns values to its weights and biases, and plots the resulting classification line.

```
net = perceptron;  
net = configure(net,p,t);  
net.iw{1,1} = [-1.2 -0.5];  
net.b{1} = 1;  
plotpc(net.iw{1,1},net.b{1})
```

## Version History

Introduced before R2006a

plotpv

## plotperform

Plot network performance

### Syntax

```
plotperform(TR)
```

### Description

`plotperform(TR)` plots error vs. epoch for the training, validation, and test performances of the training record `TR` returned by the function `train`.

### Examples

#### Plot Validation Performance of Network

This example shows how to use `plotperform` to obtain a plot of training record error values against the number of training epochs.

```
[x,t] = bodyfat_dataset;  
net = feedforwardnet(10);  
[net,tr] = train(net,x,t);
```

**Training Plots**

Performance Training State  
Error Histogram Regression

```
plotperform(tr)
```

Generally, the error reduces after more epochs of training, but might start to increase on the validation data set as the network starts overfitting the training data. In the default setup, the training stops after six consecutive increases in validation error, and the best performance is taken from the epoch with the lowest validation error.

## Input Arguments

### TR — Training record

structure

Training record (epoch and perf), returned as a structure whose fields depend on the network training function (`net.NET.trainFcn`). It can include fields such as:

- Training, data division, and performance functions and parameters
- Data division indices for training, validation and test sets
- Data division masks for training validation and test sets
- Number of epochs (`num_epochs`) and the best epoch (`best_epoch`)
- A list of training state names (`states`)
- Fields for each state name recording its value throughout training
- Performances of the best network (`best_perf`, `best_vperf`, `best_tperf`)

## **Version History**

Introduced in R2008a

## plotpv

Plot perceptron input/target vectors

### Syntax

```
plotpv(P,T)  
plotpv(P,T,V)
```

### Description

plotpv(P,T) takes these inputs,

P	R-by-Q matrix of input vectors (R must be 3 or less)
T	S-by-Q matrix of binary target vectors (S must be 3 or less)

and plots column vectors in P with markers based on T.

plotpv(P,T,V) takes an additional input,

V	Graph limits = [x_min x_max y_min y_max]
---	--

and plots the column vectors with limits set by V.

### Examples

#### Plot Inputs and Targets for Perceptron

This example shows how to define and plot the inputs and targets for a perceptron.

```
p = [0 0 1 1; 0 1 0 1];  
t = [0 0 0 1];  
plotpv(p,t)
```

## Version History

## plotregression

Plot linear regression

### Syntax

```
plotregression(targets, outputs)  
plotregression(targs1, outs1, 'name1', targs2, outs2, 'name2', ...)
```

### Description

`plotregression(targets, outputs)` plots the linear regression of targets relative to outputs.

`plotregression(targs1, outs1, 'name1', targs2, outs2, 'name2', ...)` generates multiple plots.

### Examples

#### Plot Regression

This example shows how to plot the linear regression of a feedforward net.

```
[x,t] = simplefit_dataset;  
net = feedforwardnet(10);  
net = train(net,x,t);
```

## plotresponse

Plot dynamic network time series response

### Syntax

```
plotresponse(t,y)
plotresponse(t1,'name',t2,'name2',...,y)
plotresponse(...,'outputIndex',outputIndex)
```

### Description

`plotresponse(t,y)` takes a target time series `t` and an output time series `y`, and plots them on the same axis showing the errors between them.

`plotresponse(t1,'name',t2,'name2',...,y)` takes multiple target/name pairs, typically defining training, validation and testing targets, and the output. It plots the responses with colors indicating the different target sets.

`plotresponse(...,'outputIndex',outputIndex)` optionally defines which error element is being correlated and plotted. The default is 1.

### Examples

#### Plot Target and Output Time Series Data

This example shows how to use a NARX network to solve a time series problem.

```
[X,T] = simplenarx_dataset;
net = narxnet(1:2,20);
[Xs,Xi,Ai,Ts] = preparets(net,X,{},T);
net = train(net,Xs,Ts,Xi,Ai);

# plotroc

Plot receiver operating characteristic

## Syntax

```
plotroc(targets,outputs)
plotroc(targets1,outputs2,'name1',...)
```

## Description

`plotroc(targets,outputs)` plots the receiver operating characteristic for each output class. The more each curve hugs the left and top edges of the plot, the better the classification.

---

**Tip** `plotroc` does not support categorical targets. To plot ROC metrics for categorical targets, use `rocmetrics`.

---

`plotroc(targets1,outputs2,'name1',...)` generates multiple plots.

## Examples

### Plot Receiver Operating Characteristic

This example shows how to plot the receiver operating characteristic for each output class in a pattern network.

```
load simplecluster_dataset
net = patternnet(20);
net = train(net,simpleclusterInputs,simpleclusterTargets);
```

# plotsom

Plot self-organizing map

## Syntax

```
plotsom(pos)
plotsom(W,D,ND)
```

## Description

`plotsom(pos)` takes one argument,

POS	N-by-S matrix of S N-dimension neural positions
-----	---

and plots the neuron positions with red dots, linking the neurons within a Euclidean distance of 1.

`plotsom(W,D,ND)` takes three arguments,

W	S-by-R weight matrix
D	S-by-S distance matrix
ND	Neighborhood distance (default = 1)

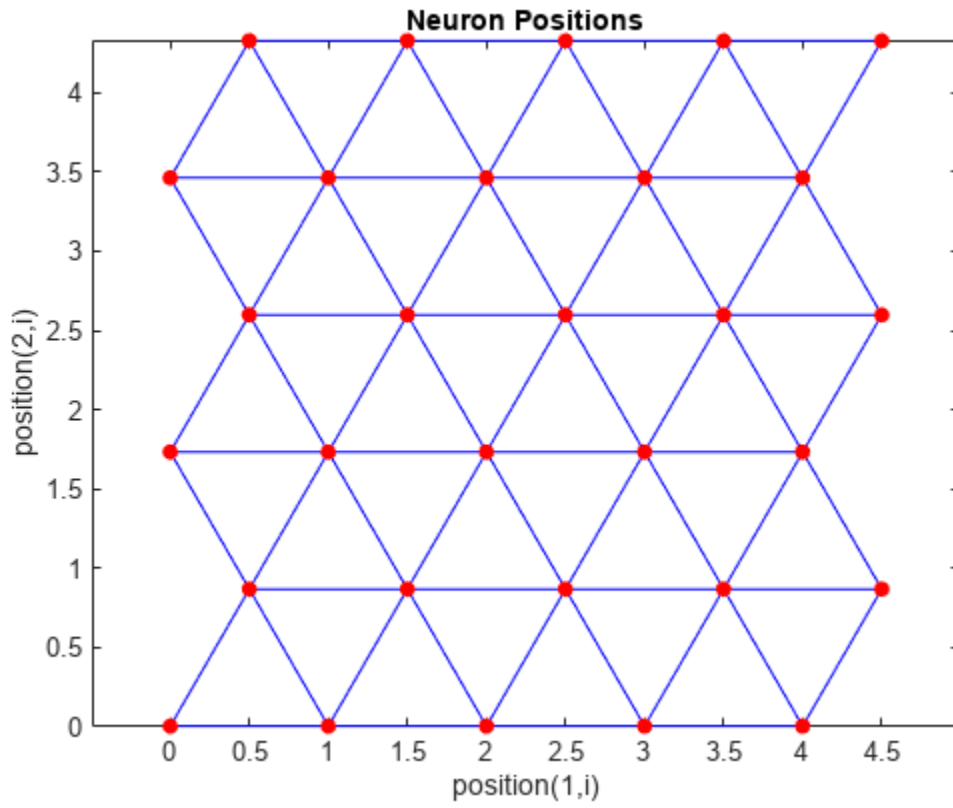

and plots the neuron's weight vectors with connections between weight vectors whose neurons are within a distance of 1.

## Examples

### Plot Self-Organizing Maps

These examples generate plots of various layer topologies.

```
pos = hextop([5 6]);
plotsom(pos)
```

```
pos = gridtop([4 5]);  
plotsom(pos)
```

```
pos = randtop([18 12]);  
plotsom(pos)
```

```
pos = gridtop([4 5 2]);  
plotsom(pos)
```

```
pos = hextop([4 4 3]);  
plotsom(pos)
```

See `plotsompos` for an example of plotting a layer's weight vectors with the input vectors they map.

## Version History

Introduced before R2006a

## See Also

`learnsom`

# plotsomhits

Plot self-organizing map sample hits

## Syntax

```
plotsomhits(net,inputs)
```

## Description

`plotsomhits(net,inputs)` plots a SOM layer, with each neuron showing the number of input vectors that it classifies. The relative number of vectors for each neuron is shown via the size of a colored patch.

This plot supports SOM networks with `hextop` and `gridtop` topologies, but not `tritop` or `randtop`.

## Examples

### Plot SOM Sample Hits

```
x = iris_dataset;  
net = selforgmap([5 5]);  
net = train(net,x);
```

# plotsomnc

Plot self-organizing map neighbor connections

## Syntax

```
plotsomnc(net)
```

## Description

`plotsomnc(net)` plots a SOM layer showing neurons as gray-blue patches and their direct neighbor relations with red lines.

This plot supports SOM networks with `hextop` and `gridtop` topologies, but not `tritop` or `randtop`.

## Examples

### Plot SOM Neighbor Connections

```
x = iris_dataset;  
net = selforgmap([8 8]);  
net = train(net,x);
```

# plotsomnd

Plot self-organizing map neighbor distances

## Syntax

```
plotsomnd(net)
```

## Description

`plotsomnd(net)` plots a SOM layer showing neurons as gray-blue patches and their direct neighbor relations with red lines. The neighbor patches are colored from black to yellow to show how close each neuron's weight vector is to its neighbors.

This plot supports SOM networks with `hextop` and `gridtop` topologies, but not `tritop` or `randtop`.

## Examples

### Plot SOM Neighbor Distances

## plotsomplanes

Plot self-organizing map weight planes

### Syntax

```
plotsomplanes(net)
```

### Description

`plotsomplanes(net)` generates a set of subplots. Each *i*th subplot shows the weights from the *i*th input to the layer's neurons, with the most negative connections shown as black, zero connections as red, and the strongest positive connections as yellow.

The plot is only shown for layers organized in one or two dimensions.

This plot supports SOM networks with `hextop` and `gridtop` topologies, but not `tritop` or `randtop`.

This function can also be called with standardized plotting function arguments used by the function `train`.

### Examples

#### Plot SOM Weight Planes

```
x = iris_dataset;  
net = selforgmap([5 5]);  
net = train(net,x);
```

# plotsompos

Plot self-organizing map weight positions

## Syntax

```
plotsompos(net)  
plotsompos(net,inputs)
```

## Description

`plotsompos(net)` plots the input vectors as green dots and shows how the SOM classifies the input space by showing blue-gray dots for each neuron's weight vector and connecting neighboring neurons with red lines.

`plotsompos(net,inputs)` plots the input data alongside the weights.

## Examples

### Plot SOM Weight Positions

```
x = iris_dataset;  
net = selforgmap([10 10]);  
net = train(net,x);
```

## plottrainstate

Plot training state values

### Syntax

```
plottrainstate(tr)
```

### Description

`plottrainstate(tr)` plots the training state from a training record `tr` returned by `train`.

### Examples

#### Plot Training State Values

This example shows how to plot training state values using `plottrainstate`.

```
[x, t] = bodyfat_dataset;  
net = feedforwardnet(10);  
[net, tr] = train(net, x, t);
```

# plotv

(To be removed) Plot vectors as lines from origin

---

**Note** `plotv` will be removed in a future release. Use `plot` instead. For information on updating your code, see “Version History”

---

## Syntax

```
plotv(M,T)
```

## Description

`plotv(M,T)` takes a matrix of column vectors, `M`, and the line plotting type, `T`, and plots the column vectors of `M`.

## Examples

### Plot Vectors Using the `plotv` Function

This example shows how to plot three 2-element vectors.

```
M = [-0.4 0.7 0.2 ;
      -0.5 0.1 0.5];
plotv(M, '-')
```

## Input Arguments

### M — Matrix to plot

matrix

Matrix of column vectors to plot, specified as a `R`-by-`Q` matrix of `Q` column vectors with `R` elements.

`R` must be 2 or greater. If `R` is greater than 2, this function only uses the first two rows of `M` for the plot.

### T — Line plotting type

character vector | string

Line style, marker, and color, specified as a character vector or string containing symbols. The symbols can appear in any order. You do not need to specify all three characteristics (line style, marker, and color). For example, if you omit the line style and specify the marker, then the plot shows only the nodes and no edges between them.

Example: `'--or'` is a red dashed line with circle markers.

Line Style	Description
-	Solid line (default)

Line Style	Description
--	Dashed line
:	Dotted line
-.	Dash-dot line

Marker	Description
o	Circle
+	Plus sign
*	Asterisk
.	Point
x	Cross
s	Square
d	Diamond
^	Upward-pointing triangle
v	Downward-pointing triangle
>	Right-pointing triangle
<	Left-pointing triangle
p	Pentagram
h	Hexagram

Color	Description
y	Yellow
m	Magenta
c	Cyan
r	Red
g	Green
b	Blue
w	White
k	Black

## Version History

Introduced before R2006a

### R2023a: To be removed

*Not recommended starting in R2023a*

`plotv` will be removed. Use `plot` instead. The `plot` function offers greater flexibility over figure properties and is consistent with other MATLAB plotting functions.

There are several differences between these functions that require updates to your code. For example, let `M` be a matrix containing three 2-element vectors.

```
M = [-0.4 0.7 0.2 ;  
     -0.5 0.1 0.5];
```

Plot the column vectors as lines from the origin.

Using plotv	Using plot
<code>plotv(M, '-')</code>	<code>origin = zeros(1,size(M,2)); plot([origin; M(1,:)],[origin; M(2,:)]);</code>

## See Also

`plot` | `plotvec` | `plotfit`

## plotvec

Plot vectors with different colors

### Syntax

```
plotvec(X,C,M)
```

### Description

`plotvec(X,C,M)` takes these inputs,

X	Matrix of (column) vectors
C	Row vector of color coordinates
M	Marker (default = '+' )

and plots each  $i$ th vector in  $X$  with a marker  $M$ , using the  $i$ th value in  $C$  as the color coordinate.

`plotvec(X)` only takes a matrix  $X$  and plots each  $i$ th vector in  $X$  with marker '+' using the index  $i$  as the color coordinate.

### Examples

#### Plot Vectors with Different Colors

This example shows how to plot four 2-element vectors.

```
x = [ 0 1 0.5 0.7 ; ...  
      -1 2 0.5 0.1];  
c = [1 2 3 4];  
plotvec(x,c)
```

## Version History

Introduced before R2006a

## plotwb

Plot Hinton diagram of weight and bias values

### Syntax

```
plotwb(net)
plotwb(IW,LW,B)
plotwb(...,'toLayers',toLayers)
plotwb(...,'fromInputs',fromInputs)
plotwb(...,'fromLayers',fromLayers)
plotwb(...,'root',root)
```

### Description

`plotwb(net)` takes a neural network and plots all its weights and biases.

`plotwb(IW,LW,B)` takes a neural networks input weights, layer weights and biases and plots them.

`plotwb(...,'toLayers',toLayers)` optionally defines which destination layers whose input weights, layer weights and biases will be plotted.

`plotwb(...,'fromInputs',fromInputs)` optionally defines which inputs will have their weights plotted.

`plotwb(...,'fromLayers',fromLayers)` optionally defines which layers will have weights coming from them plotted.

`plotwb(...,'root',root)` optionally defines the root used to scale the weight/bias patch sizes. The default is 2, which makes the 2-dimensional patch sizes scale directly with absolute weight and bias sizes. Larger values of root magnify the relative patch sizes of smaller weights and biases, making differences in smaller values easier to see.

### Examples

#### Plot Weights and Biases

Here a cascade-forward network is configured for particular data and its weights and biases are plotted in several ways.

```
[x,t] = simplefit_dataset;
net = cascadeforwardnet([15 5]);
net = configure(net,x,t);
plotwb(net)
```

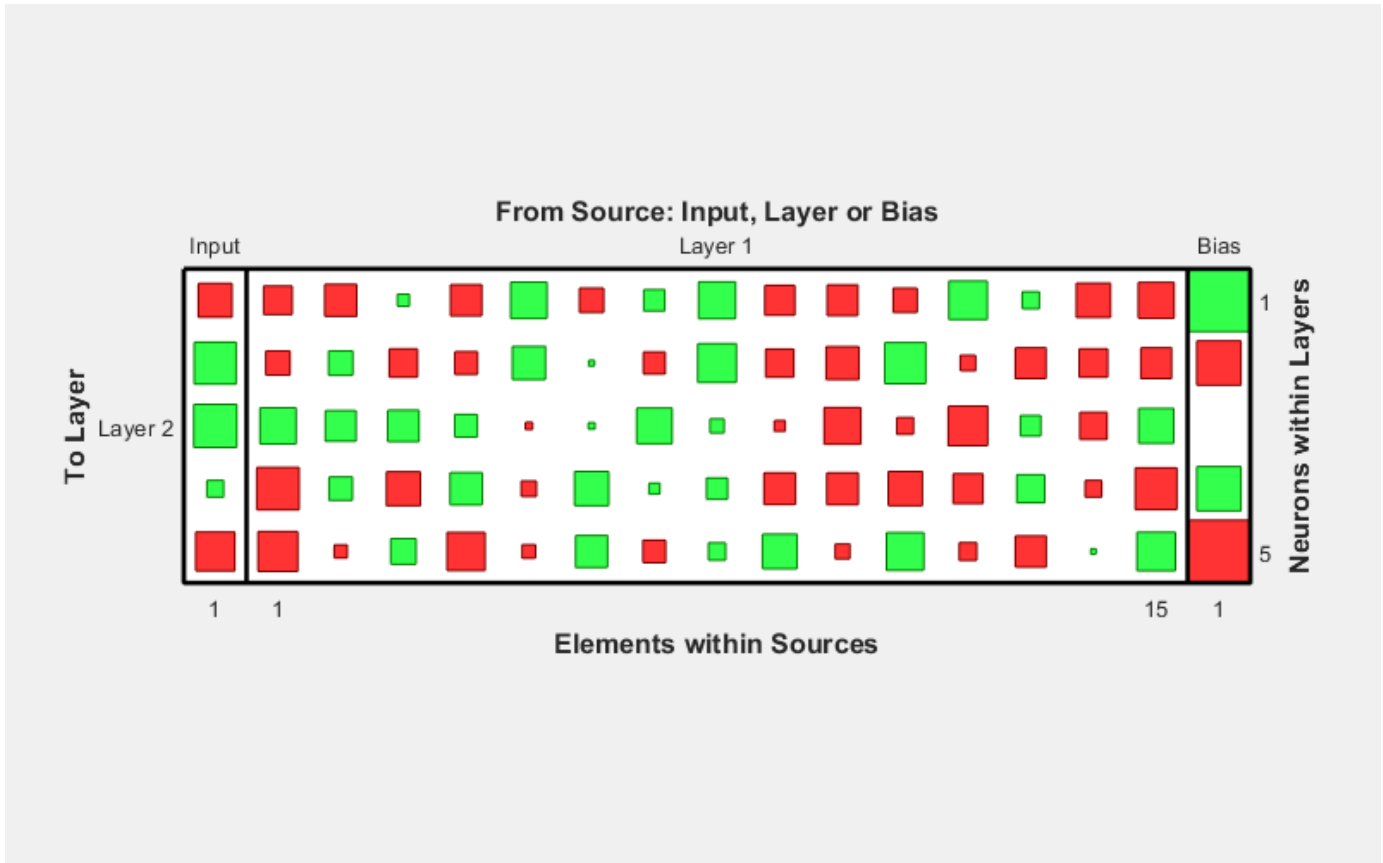

plotwb(net, 'root', 3)

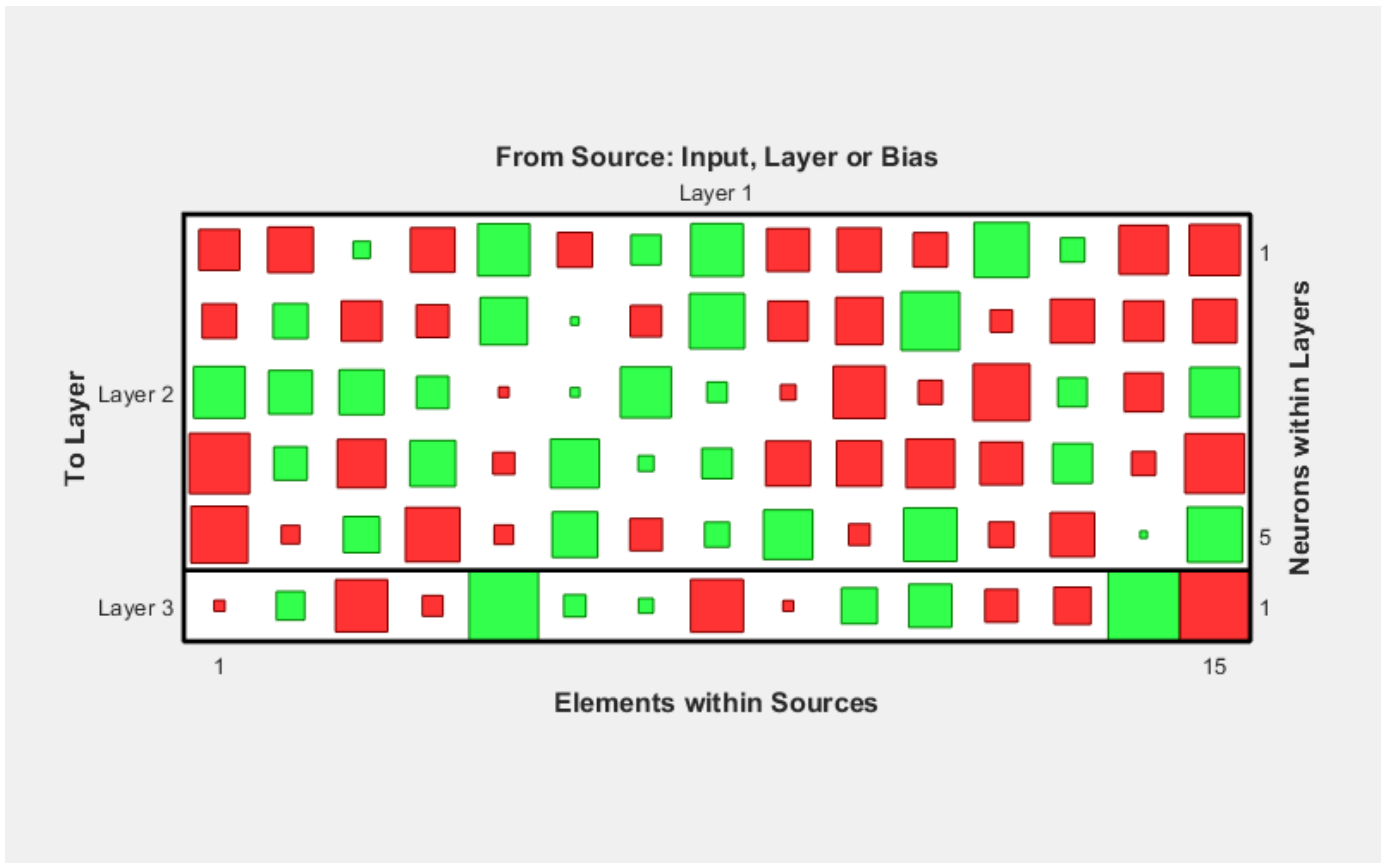

plotwb(net, 'root', 4)

```
plotwb(net, 'toLayers', 2)
```

```
plotwb(net, 'fromLayers', 1)
```

```
plotwb(net, 'toLayers', 2, 'fromInputs', 1)
```

## Version History

Introduced in R2010b

### See Also

plotsomplanes

## pnormc

Pseudonormalize columns of matrix

### Syntax

```
pnormc(X,R)
```

### Description

pnormc(X,R) takes these arguments,

X	M-by-N matrix
R	(Optional) radius to normalize columns to (default = 1)

and returns X with an additional row of elements, which results in new column vector lengths of R.

---

**Caution** For this function to work properly, the columns of X must originally have vector lengths less than R.

---

### Examples

```
x = [0.1 0.6; 0.3 0.1];  
y = pnormc(x)
```

### Version History

Introduced before R2006a

### See Also

normc | normr

## poslin

Positive linear transfer function

### Graph and Symbol

Positive Linear Transfer Function

### Syntax

```
A = poslin(N,FP)
info = poslin('code')
```

### Description

`poslin` is a neural transfer function. Transfer functions calculate a layer's output from its net input.

`A = poslin(N,FP)` takes `N` and optional function parameters,

N	S-by-Q matrix of net input (column) vectors
FP	Struct of function parameters (ignored)

and returns `A`, the S-by-Q matrix of `N`'s elements clipped to `[0, inf]`.

`info = poslin('code')` returns information about this function. The following codes are supported:

`poslin('name')` returns the name of this function.

`poslin('output',FP)` returns the `[min max]` output range.

`poslin('active',FP)` returns the `[min max]` active range.

`poslin('fullderiv')` returns 1 or 0, depending on whether `dA_dN` is S-by-S-by-Q or S-by-Q.

`poslin('fpnames')` returns the names of the function parameters.

`poslin('fpdefaults')` returns the default function parameters.

### Examples

Here is the code to create a plot of the `poslin` transfer function.

```
n = -5:0.1:5;  
a = poslin(n);  
plot(n,a)
```

Assign this transfer function to layer *i* of a network.

```
net.layers{i}.transferFcn = 'poslin';
```

## Network Use

To change a network so that a layer uses `poslin`, set `net.layers{i}.transferFcn` to `'poslin'`.

Call `sim` to simulate the network with `poslin`.

## Algorithms

The transfer function `poslin` returns the output *n* if *n* is greater than or equal to zero and 0 if *n* is less than or equal to zero.

$$\text{poslin}(n) = \begin{cases} n, & \text{if } n \geq 0 \\ 0, & \text{if } n < 0 \end{cases}$$

## Version History

Introduced before R2006a

## See Also

`sim` | `purelin` | `satlin` | `satlins`

## preparets

Prepare input and target time series data for network simulation or training

### Syntax

```
[Xs,Xi,Ai,Ts,EWs,shift] = preparets(net,Xnf,Tnf,Tf,EW)
```

### Description

`[Xs,Xi,Ai,Ts,EWs,shift] = preparets(net,Xnf,Tnf,Tf,EW)` takes these arguments:

- `net` — Neural network
- `Xnf` — Non-feedback inputs
- `Tnf` — Non-feedback targets
- `Tf` — Feedback targets
- `EW` — Error weights (optional)

and returns these arguments:

- `Xs` — Shifted inputs
- `Xi` — Initial input delay states
- `Ai` — Initial layer delay states
- `Ts` — Shifted targets
- `EWs` — Shifted error weights
- `shift` — The number of timesteps truncated from the front of `X` and `T` in order to properly fill `Xi` and `Ai`.

This function simplifies the normally complex and error prone task of reformatting input and target time series. It automatically shifts input and target time series as many steps as are needed to fill the initial input and layer delay states. If the network has open-loop feedback, then it copies feedback targets into the inputs as needed to define the open-loop inputs.

Each time a new network is designed, with different numbers of delays or feedback settings, `preparets` can reformat input and target data accordingly. Also, each time a network is transformed with `openloop`, `closeloop`, `removedelay` or `adddelay`, this function can reformat the data accordingly.

### Examples

#### Prepare Data for Open- and Closed-Loop Networks

This example shows how to prepare data for open-loop and closed-loop networks.

Create a time-delay network with 20 hidden neurons, then train and simulate it.

```
[X,T] = simpleseries_dataset;  
net = timedelaynet(1:2,20);
```

```
[Xs,Xi,Ai,Ts] = preparets(net,X,T);
net = train(net,Xs,Ts);
view(net)
```

```
Y = net(Xs,Xi,Ai);
```

Design a NARX network. The NARX network has a standard input and an open-loop feedback output to an associated feedback input.

```
[X,T] = simplenarx_dataset;
net = narxnet(1:2,1:2,20);
[Xs,Xi,Ai,Ts] = preparets(net,X,{},T);
net = train(net,Xs,Ts,Xi,Ai);
```

## Input Arguments

### net — Input network

network

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

### Xnf — Non-feedback inputs

cell array

Non-feedback input data (inputs not associated with an open loop feedback output), specified as cell array.

**Tnf — Non-feedback targets**

cell array

Target data for non-feedback outputs, specified as a cell array.

**Tf — Feedback targets**

cell array

Target data for outputs with feedback, specified as a cell array.

**EW — Error weights**

cell array

Error weights, specified as a cell array.

**Output Arguments****Xs — Shifted inputs**

cell array

Shifted inputs, returned as a cell array.

**Xi — Initial input delay states**

cell array

Initial input delay states, returned as cell array.

**Ai — Initial layer delay states**

cell array

Initial layer delay states, returned as a cell array.

**Ts — Shifted targets**

cell array

Shifted targets, returned as a cell array.

**Ews — Shifted error weights**

cell array

Shifted error weights, returned as a cell array.

**shift — Timesteps**

scalar

Number of timesteps truncated from the front of X and T in order to properly fill Xi and Ai, returned as a scalar.

**Version History****Introduced in R2010b**

## processpca

Process columns of matrix with principal component analysis

### Syntax

```
[Y,PS] = processpca(X,maxfrac)
[Y,PS] = processpca(X,FP)
Y = processpca('apply',X,PS)
X = processpca('reverse',Y,PS)
name = processpca('name')
fp = processpca('pdefaults')
names = processpca('pdesc')
processpca('pcheck',fp);
```

### Description

`processpca` processes matrices using principal component analysis so that each row is uncorrelated, the rows are in the order of the amount they contribute to total variation, and rows whose contribution to total variation are less than `maxfrac` are removed.

`[Y,PS] = processpca(X,maxfrac)` takes `X` and an optional parameter,

X	N-by-Q matrix
maxfrac	Maximum fraction of variance for removed rows (default is 0)

and returns

Y	M-by-Q matrix with N - M rows deleted
PS	Process settings that allow consistent processing of values

`[Y,PS] = processpca(X,FP)` takes parameters as a struct: `FP.maxfrac`.

`Y = processpca('apply',X,PS)` returns `Y`, given `X` and settings `PS`.

`X = processpca('reverse',Y,PS)` returns `X`, given `Y` and settings `PS`.

`name = processpca('name')` returns the name of this process method.

`fp = processpca('pdefaults')` returns default process parameter structure.

`names = processpca('pdesc')` returns the process parameter descriptions.

`processpca('pcheck',fp);` throws an error if any parameter is illegal.

### Examples

Here is how to format a matrix with an independent row, a correlated row, and a completely redundant row so that its rows are uncorrelated and the redundant row is dropped.

```
x1_independent = rand(1,5)
x1_correlated = rand(1,5) + x1_independent;
x1_redundant = x1_independent + x1_correlated
x1 = [x1_independent; x1_correlated; x1_redundant]
[y1,ps] = processpca(x1)
```

Next, apply the same processing settings to new values.

```
x2_independent = rand(1,5)
x2_correlated = rand(1,5) + x1_independent;
x2_redundant = x1_independent + x1_correlated
x2 = [x2_independent; x2_correlated; x2_redundant];
y2 = processpca('apply',x2,ps)
```

Reverse the processing of y1 to get x1 again.

```
x1_again = processpca('reverse',y1,ps)
```

## More About

### Reduce Input Dimensionality Using processpca

In some situations, the dimension of the input vector is large, but the components of the vectors are highly correlated (redundant). It is useful in this situation to reduce the dimension of the input vectors. An effective procedure for performing this operation is principal component analysis. This technique has three effects: it orthogonalizes the components of the input vectors (so that they are uncorrelated with each other), it orders the resulting orthogonal components (principal components) so that those with the largest variation come first, and it eliminates those components that contribute the least to the variation in the data set. The following code illustrates the use of `processpca`, which performs a principal-component analysis using the processing setting `maxfrac` of `0.02`.

```
[pn,ps1] = mapstd(p);
[ptrans,ps2] = processpca(pn,0.02);
```

The input vectors are first normalized, using `mapstd`, so that they have zero mean and unity variance. This is a standard procedure when using principal components. In this example, the second argument passed to `processpca` is `0.02`. This means that `processpca` eliminates those principal components that contribute less than 2% to the total variation in the data set. The matrix `ptrans` contains the transformed input vectors. The settings structure `ps2` contains the principal component transformation matrix. After the network has been trained, these settings should be used to transform any future inputs that are applied to the network. It effectively becomes a part of the network, just like the network weights and biases. If you multiply the normalized input vectors `pn` by the transformation matrix `transMat`, you obtain the transformed input vectors `ptrans`.

If `processpca` is used to preprocess the training set data, then whenever the trained network is used with new inputs, you should preprocess them with the transformation matrix that was computed for the training set, using `ps2`. The following code applies a new set of inputs to a network already trained.

```
pnewn = mapstd('apply',pnew,ps1);
pnewtrans = processpca('apply',pnewn,ps2);
a = sim(net,pnewtrans);
```

Principal component analysis is not reliably reversible. Therefore it is only recommended for input processing. Outputs require reversible processing functions.

Principal component analysis is not part of the default processing for `feedforwardnet`. You can add this with the following command:

```
net.inputs{1}.processFcns{end+1} = 'processpca';
```

## Algorithms

Values in rows whose elements are not all the same value are set to

$$y = 2*(x-\text{minx})/(\text{maxx}-\text{minx}) - 1;$$

Values in rows with all the same value are set to 0.

## Version History

Introduced in R2006a

## prune

Delete neural inputs, layers, and outputs with sizes of zero

### Syntax

```
[net,pi,pl,po] = prune(net)
```

### Description

This function removes zero-sized inputs, layers, and outputs from a network. This leaves a network which may have fewer inputs and outputs, but which implements the same operations, as zero-sized inputs and outputs do not convey any information.

One use for this simplification is to prepare a network with zero sized subobjects for Simulink, where zero sized signals are not supported.

The companion function `prunedata` can prune data to remain consistent with the transformed network.

`[net,pi,pl,po] = prune(net)` takes a neural network and returns

<code>net</code>	The same network with zero-sized subobjects removed
<code>pi</code>	Indices of pruned inputs
<code>pl</code>	Indices of pruned layers
<code>po</code>	Indices of pruned outputs

### Examples

Here a NARX dynamic network is created which has one external input and a second input which feeds back from the output.

```
net = narxnet(20);
view(net)
```

The network is then trained on a single random time-series problem with 50 timesteps. The external input happens to have no elements.

```
X = nndata(0,1,50);
T = nndata(1,1,50);
[Xs,Xi,Ai,Ts] = preparets(net,X,{},T);
net = train(net,Xs,Ts);
```

The network and data are then pruned before generating a Simulink diagram and initializing its input and layer states.

```
[net2,pi,pl,po] = prune(net);
view(net2)
[Xs2,Xi2,Ai2,Ts2] = prunedata(net,pi,pl,po,Xs,Xi,Ai,Ts);
[sysName,netName] = gensim(net2);
setsiminit(sysName,netName,net2,Xi2,Ai2);
```

## **Version History**

## prunedata

Prune data for consistency with pruned network

### Syntax

```
[Xp,Xip,Aip,Tp] = prunedata(net,pi,pl,po,X,Xi,Ai,T)
```

### Description

This function prunes data to be consistent with a network whose zero-sized inputs, layers, and outputs have been removed with `prune`.

One use for this simplification is to prepare a network with zero-sized subobjects for Simulink, where zero-sized signals are not supported.

`[Xp,Xip,Aip,Tp] = prunedata(net,pi,pl,po,X,Xi,Ai,T)` takes these arguments,

<code>net</code>	Pruned neural network
<code>pi</code>	Indices of pruned inputs
<code>pl</code>	Indices of pruned layers
<code>po</code>	Indices of pruned outputs
<code>X</code>	Input data
<code>Xi</code>	Initial input delay states
<code>Ai</code>	Initial layer delay states
<code>T</code>	Target data

and returns the pruned inputs, input and layer delay states, and targets.

### Examples

Here a NARX dynamic network is created which has one external input and a second input which feeds back from the output.

```
net = narxnet(20);
view(net)
```

The network is then trained on a single random time-series problem with 50 timesteps. The external input happens to have no elements.

```
X = nndata(0,1,50);
T = nndata(1,1,50);
[Xs,Xi,Ai,Ts] = preparets(net,X,{},T);
net = train(net,Xs,Ts);
```

The network and data are then pruned before generating a Simulink diagram and initializing its input and layer states.

```
[net2,pi,pl,po] = prune(net);
view(net2)
```

```
[Xs2,Xi2,Ai2,Ts2] = prunedata(net,pi,pl,po,Xs,Xi,Ai,Ts);  
[sysName,netName] = gensim(net2);  
setsiminit(sysName,netName,net2,Xi2,Ai2);
```

## **Version History**

## purelin

Linear transfer function

### Syntax

```
A = purelin(N)
info = purelin('code')
```

### Description

$A = \text{purelin}(N)$  takes an  $S$ -by- $Q$  matrix of net input (column) vectors,  $N$ , and returns an  $S$ -by- $Q$  matrix equal to  $N$ ,  $A$ .

Linear Transfer Function

`info = purelin('code')` returns useful information for each code character vector:

- `purelin('name')` returns the name of this function.
- `purelin('output')` returns the [min max] output range.
- `purelin('active')` returns the [min max] active input range.
- `purelin('fullderiv')` returns 1 or 0, depending on whether  $dA_{dN}$  is  $S$ -by- $S$ -by- $Q$  or  $S$ -by- $Q$ .
- `purelin('fpname')` returns the names of the function parameters.
- `purelin('fpdefaults')` returns the default function parameters.

### Examples

#### Create a purelin Transfer Function and Assign It to a Layer in a Network

This example shows how to create and plot a `purelin` transfer function and assign it to layer  $i$  in a network.

Create a plot of the `purelin` transfer function:

```
n = -5:0.1:5;
a = purelin(n);
plot(n,a)
```

Assign this transfer function to layer  $i$  in a network.

```
net.layers{i}.transferFcn = 'purelin';
```

## Input Arguments

### **N — Net inputs**

matrix

Net column vector inputs, specified as an S-by-Q matrix.

## Output Arguments

### **A — Linear transfer function**

matrix

Linear transfer function, returned as an S-by-Q matrix.

## Algorithms

$a = \text{purelin}(n) = n$

## quant

Discretize values as multiples of quantity

### Syntax

```
quant(X,Q)
```

### Description

quant(X,Q) takes two inputs,

X	Matrix, vector, or scalar
Q	Minimum value

and returns values from X rounded to nearest multiple of Q.

### Examples

```
x = [1.333 4.756 -3.897];  
y = quant(x,0.1)
```

### Version History

Introduced before R2006a

# radbas

Radial basis transfer function

## Graph and Symbol

Radial Basis Function

## Syntax

$A = \text{radbas}(N, FP)$

## Description

radbas is a neural transfer function. Transfer functions calculate a layer's output from its net input.

$A = \text{radbas}(N, FP)$  takes one or two inputs,

N	S-by-Q matrix of net input (column) vectors
FP	Struct of function parameters (ignored)

and returns A, an S-by-Q matrix of the radial basis function applied to each element of N.

## Examples

Here you create a plot of the radbas transfer function.

```
n = -5:0.1:5;
a = radbas(n);
plot(n,a)
```

Assign this transfer function to layer i of a network.

```
net.layers{i}.transferFcn = 'radbas';
```

## Algorithms

$a = \text{radbas}(n) = \exp(-n^2)$

# radbasn

Normalized radial basis transfer function

## Graph and Symbol

Radial Basis Function

## Syntax

$A = \text{radbasn}(N, FP)$

## Description

radbasn is a neural transfer function. Transfer functions calculate a layer's output from its net input. This function is equivalent to radbas, except that output vectors are normalized by dividing by the sum of the pre-normalized values.

$A = \text{radbasn}(N, FP)$  takes one or two inputs,

N	S-by-Q matrix of net input (column) vectors
FP	Struct of function parameters (ignored)

and returns A, an S-by-Q matrix of the radial basis function applied to each element of N.

## Examples

Here six random 3-element vectors are passed through the radial basis transform and normalized.

```
n = rand(3,6)
a = radbasn(n)
```

Assign this transfer function to layer i of a network.

```
net.layers{i}.transferFcn = 'radbasn';
```

## Algorithms

$$a = \text{radbasn}(n) = \frac{\exp(-n^2)}{\sum(\exp(-n^2))}$$

## **Version History**

## randnc

Normalized column weight initialization function

### Syntax

`W = randnc(S,PR)`

### Description

randnc is a weight initialization function.

`W = randnc(S,PR)` takes two inputs,

S	Number of rows (neurons)
PR	R-by-2 matrix of input value ranges = [Pmin Pmax]

and returns an S-by-R random matrix with normalized columns.

You can also call this in the form `randnc(S,R)`.

### Examples

A random matrix of four normalized three-element columns is generated:

`M = randnc(3,4)`

M =

-0.6007	-0.4715	-0.2724	0.5596
-0.7628	-0.6967	-0.9172	0.7819
-0.2395	0.5406	-0.2907	0.2747

## Version History

Introduced before R2006a

### See Also

randnr

## randnr

Normalized row weight initialization function

### Syntax

```
W = randnr(S,PR)
```

### Description

randnr is a weight initialization function.

`W = randnr(S, PR)` takes two inputs,

S	Number of rows (neurons)
PR	R-by-2 matrix of input value ranges = [Pmin Pmax]

and returns an S-by-R random matrix with normalized rows.

You can also call this in the form `randnr(S,R)`.

### Examples

A matrix of three normalized four-element rows is generated:

```
M = randnr(3,4)
```

```
M =
```

```
    0.9713    0.0800   -0.1838   -0.1282  
    0.8228    0.0338    0.1797    0.5381  
   -0.3042   -0.5725    0.5436    0.5331
```

## Version History

Introduced before R2006a

### See Also

randnc

## rands

Symmetric random weight/bias initialization function

### Syntax

```
W = rands(S,PR)
M = rands(S,R)
v = rands(S)
```

### Description

rands is a weight/bias initialization function.

`W = rands(S, PR)` takes

S	Number of neurons
PR	R-by-2 matrix of R input ranges

and returns an S-by-R weight matrix of random values between -1 and 1.

`M = rands(S, R)` returns an S-by-R matrix of random values. `v = rands(S)` returns an S-by-1 vector of random values.

### Examples

Here, three sets of random values are generated with rands.

```
rands(4,[0 1; -2 2])
rands(4)
rands(2,3)
```

### Network Use

To prepare the weights and the bias of layer `i` of a custom network to be initialized with rands,

- 1 Set `net.initFcn` to 'initlay'. (`net.initParam` automatically becomes `initlay`'s default parameters.)
- 2 Set `net.layers{i}.initFcn` to 'initwb'.
- 3 Set each `net.inputWeights{i,j}.initFcn` to 'rands'.
- 4 Set each `net.layerWeights{i,j}.initFcn` to 'rands'.
- 5 Set each `net.biases{i}.initFcn` to 'rands'.

To initialize the network, call `init`.

## Version History

Introduced before R2006a

**See Also**

## randsmall

Small random weight/bias initialization function

### Syntax

```
W = randsmall(S,PR)
M = rands(S,R)
v = rands(S)
```

### Description

randsmall is a weight/bias initialization function.

W = randsmall(S,PR) takes

S	Number of neurons
PR	R-by-2 matrix of R input ranges

and returns an S-by-R weight matrix of small random values between -0.1 and 0.1.

M = rands(S,R) returns an S-by-R matrix of random values. v = rands(S) returns an S-by-1 vector of random values.

### Examples

Here three sets of random values are generated with rands.

```
randsmall(4,[0 1; -2 2])
randsmall(4)
randsmall(2,3)
```

### Network Use

To prepare the weights and the bias of layer i of a custom network to be initialized with rands,

- 1 Set net.initFcn to 'initlay'. (net.initParam automatically becomes initlay's default parameters.)
- 2 Set net.layers{i}.initFcn to 'initwb'.
- 3 Set each net.inputWeights{i,j}.initFcn to 'randsmall'.
- 4 Set each net.layerWeights{i,j}.initFcn to 'randsmall'.
- 5 Set each net.biases{i}.initFcn to 'randsmall'.

To initialize the network, call init.

# randtop

Random layer topology function

## Syntax

```
pos = randtop(dimensions)
```

## Description

randtop calculates the neuron positions for layers whose neurons are arranged in an N-dimensional random pattern.

pos = randtop(dimensions) takes one argument:

dimensions	Row vector of dimension sizes
------------	-------------------------------

and returns an N-by-S matrix of N coordinate vectors, where N is the number of dimensions and S is the product of dimensions.

## Examples

### Display Layer with Random Pattern

This shows how to display a two-dimensional layer with neurons arranged in a random pattern.

```
pos = randtop([18 12]);  
plotsom(pos)
```

## Version History

# regression

(Not recommended) Perform linear regression of shallow network outputs on targets

---

**Note** regression is not recommended. Use `fitlm` instead. For more information, see “Compatibility Considerations”.

---

## Syntax

```
[r,m,b] = regression(t,y)
[r,m,b] = regression(t,y,'one')
```

## Description

`[r,m,b] = regression(t,y)` calculates the linear regression between each element of the network response and the corresponding target.

This function takes cell array or matrix target `t` and output `y`, each with total matrix rows of `N`, and returns the regression values, `r`, the slopes of regression fit, `m`, and the y-intercepts, `b`, for each of the `N` matrix rows.

`[r,m,b] = regression(t,y,'one')` combines all matrix rows before regressing, and returns single scalar regression, slope, and offset values.

## Examples

### Fit Regression Model and Plot Fitted Values versus Targets

This example shows how to train a feedforward network and calculate and plot the regression between its targets and outputs.

Load the training data.

```
[x,t] = simplefit_dataset;
```

The 1-by-94 matrix `x` contains the input values and the 1-by-94 matrix `t` contains the associated target output values.

Construct a feedforward neural network with one hidden layer of size 20.

```
net = feedforwardnet(20);
```

Train the network `net` using the training data.

```
net = train(net,x,t);
```

## removeconstantrows

Process matrices by removing rows with constant values

### Syntax

```
[Y,PS] = removeconstantrows(X,max_range)
[Y,PS] = removeconstantrows(X,FP)
Y = removeconstantrows('apply',X,PS)
X = removeconstantrows('reverse',Y,PS)
```

### Description

removeconstantrows processes matrices by removing rows with constant values.

[Y,PS] = removeconstantrows(X,max\_range) takes X and an optional parameter,

X	N-by-Q matrix
max_range	Maximum range of values for row to be removed (default is 0)

and returns

Y	M-by-Q matrix with N - M rows deleted
PS	Process settings that allow consistent processing of values

[Y,PS] = removeconstantrows(X,FP) takes parameters as a struct: FP.max\_range.

Y = removeconstantrows('apply',X,PS) returns Y, given X and settings PS.

X = removeconstantrows('reverse',Y,PS) returns X, given Y and settings PS.

Any NaN values in the input matrix are treated as missing data, and are not considered as unique values. So, for example, removeconstantrows removes the first row from the matrix [1 1 1 NaN; 1 1 1 2].

### Examples

Format a matrix so that the rows with constant values are removed.

```
x1 = [1 2 4; 1 1 1; 3 2 2; 0 0 0];
[y1,PS] = removeconstantrows(x1);
```

```
y1 =
     1     2     4
     3     2     2
```

```
PS =
    max_range: 0
         keep: [1 3]
        remove: [2 4]
         value: [2x1 double]
```

```
xrows: 4
yrows: 2
constants: [2x1 double]
no_change: 0
```

Next, apply the same processing settings to new values.

```
x2 = [5 2 3; 1 1 1; 6 7 3; 0 0 0];
y2 = removeconstantrows('apply',x2,PS)
```

```
5    2    3
6    7    3
```

Reverse the processing of y1 to get the original x1 matrix.

```
x1_again = removeconstantrows('reverse',y1,PS)
```

```
1    2    4
1    1    1
3    2    2
0    0    0
```

## removedelay

Remove delay to neural network's response

### Syntax

```
net = removedelay(net,n)
```

### Description

`net = removedelay(net,n)` takes these arguments,

net	Neural network
n	Number of delays

and returns the network with input delay connections decreased, and output feedback delays increased, by the specified number of delays `n`. The result is a network which behaves identically, except that outputs are produced `n` timesteps earlier.

If the number of delays `n` is not specified, a default of one delay is used.

### Examples

#### Remove and Add Delay to Network

This example shows how to create, train, and simulate a time delay network in its original form, on an input time series `X` and target series `T`. Then the delay is removed and later added back. The first and third outputs will be identical, while the second result will include a new prediction for the following step.

#### Time Delay

```
[X,T] = simpleseries_dataset;
net1 = timedelaynet(1:2,20);
[Xs,Xi,Ai,Ts] = preparets(net1,X,T);
net1 = train(net1,Xs,Ts,Xi);
```

Process matrices by removing rows with specified indices

### Syntax

```
[Y,PS] = removerows(X,'ind',ind)
[Y,PS] = removerows(X,FP)
Y = removerows('apply',X,PS)
X = removerows('reverse',Y,PS)
dx_dy = removerows('dx',X,Y,PS)
dx_dy = removerows('dx',X,[],PS)
name = removerows('name')
fp = removerows('pdefaults')
names = removerows('pdesc')
removerows('pcheck',FP)
```

### Description

removerows processes matrices by removing rows with the specified indices.

`[Y,PS] = removerows(X,'ind',ind)` takes `X` and an optional parameter,

<code>X</code>	N-by-Q matrix
<code>ind</code>	Vector of row indices to remove (default is <code>[]</code> )

and returns

<code>Y</code>	M-by-Q matrix, where <code>M == N - length(ind)</code>
<code>PS</code>	Process settings that allow consistent processing of values

`[Y,PS] = removerows(X,FP)` takes parameters as a struct: `FP.ind`.

`Y = removerows('apply',X,PS)` returns `Y`, given `X` and settings `PS`.

`X = removerows('reverse',Y,PS)` returns `X`, given `Y` and settings `PS`.

`dx_dy = removerows('dx',X,Y,PS)` returns the M-by-N-by-Q derivative of `Y` with respect to `X`.

`dx_dy = removerows('dx',X,[],PS)` returns the derivative, less efficiently.

`name = removerows('name')` returns the name of this process method.

`fp = removerows('pdefaults')` returns the default process parameter structure.

`names = removerows('pdesc')` returns the process parameter descriptions.

`removerows('pcheck',FP)` throws an error if any parameter is illegal.

## Examples

Here is how to format a matrix so that rows 2 and 4 are removed:

```
x1 = [1 2 4; 1 1 1; 3 2 2; 0 0 0]
[y1,ps] = removerows(x1,'ind',[2 4])
```

Next, apply the same processing settings to new values.

```
x2 = [5 2 3; 1 1 1; 6 7 3; 0 0 0]
y2 = removerows('apply',x2,ps)
```

Reverse the processing of y1 to get x1 again.

```
x1_again = removerows('reverse',y1,ps)
```

## Algorithms

In the reverse calculation, the unknown values of replaced rows are represented with NaN values.

## Version History

Introduced in R2006a

## See Also

## revert

Change network weights and biases to previous initialization values

### Syntax

```
net = revert (net)
```

### Description

`net = revert (net)` returns neural network `net` with weight and bias values restored to the values generated the last time the network was initialized.

If the network is altered so that it has different weight and bias connections or different input or layer sizes, then `revert` cannot set the weights and biases to their previous values and they are set to zeros instead.

### Examples

Here a perceptron is created with input size set to 2 and number of neurons to 1.

```
net = perceptron;  
net.inputs{1}.size = 2;  
net.layers{1}.size = 1;
```

The initial network has weights and biases with zero values.

```
net.iw{1,1}, net.b{1}
```

Change these values as follows:

```
net.iw{1,1} = [1 2];  
net.b{1} = 5;  
net.iw{1,1}, net.b{1}
```

You can recover the network's initial values as follows:

```
net = revert(net);  
net.iw{1,1}, net.b{1}
```

## Version History

Introduced before R2006a

### See Also

## roc

Receiver operating characteristic

### Syntax

```
[tpr,fpr,thresholds] = roc(targets,outputs)
```

### Description

`[tpr,fpr,thresholds] = roc(targets,outputs)` takes a matrix of targets and a matrix of outputs, and returns the true-positive/positive ratios, the false-positive/negative ratios and the thresholds over interval  $[0, 1]$ .

---

**Tip** `roc` does not support categorical targets. To compute ROC metrics for categorical targets, use `rocmetrics`.

---

For a single class problem, the function takes a matrix of boolean values indicating class membership and a matrix of outputs values in the range  $[0, 1]$ .

The *receiver operating characteristic* is a metric used to check the quality of classifiers. For each class of a classifier, `roc` applies threshold values across the interval  $[0, 1]$  to outputs. For each threshold, two values are calculated, the True Positive Ratio (TPR) and the False Positive Ratio (FPR). For a particular class  $i$ , TPR is the number of outputs whose actual and predicted class is class  $i$ , divided by the number of outputs whose predicted class is class  $i$ . FPR is the number of outputs whose actual class is not class  $i$ , but predicted class is class  $i$ , divided by the number of outputs whose predicted class is not class  $i$ .

You can visualize the results of this function with `plotroc`.

### Examples

#### Calculate and Plot the ROC of a Network Trained to Recognize Iris Flowers

This example shows how to calculate and plot the ROC of a network trained to recognize Iris flowers.

```
load iris_dataset
net = patternnet(20);
net = train(net,irisInputs,irisTargets);
irisOutputs = sim(net,irisInputs);
[tpr,fpr,thresholds] = roc(irisTargets,irisOutputs)
```

### Input Arguments

#### targets — Targets

matrix

Targets, specified as an  $S$ -by- $Q$  matrix, where each column vector contains a single 1 value, with all other elements 0. The index of the 1 indicates which of  $S$  categories that vector represents.

For a single class problem, this argument is specified as a 1-by- $Q$  matrix of boolean values indicating class membership.

**outputs — Outputs**

matrix

Outputs, specified as an  $S$ -by- $Q$  matrix, where each column contains values in the range  $[0, 1]$ . The index of the largest element in the column indicates which of  $S$  categories that vector presents. Alternately, 1-by- $Q$  vector, where values greater or equal to 0.5 indicate class membership, and values below 0.5, nonmembership.

**Output Arguments****tpr — True-positive ratios**

cell array

Proportion of the targets that are greater than or equal to the threshold that actually have a target value of 1, returned as a 1-by- $S$  cell array of 1-by- $N$  vectors.

For a single class problem, this output argument is returned as a 1-by- $N$  vector.

**fpr — False-positive ratios**

cell array

Proportion of the targets that are greater than or equal to the threshold that actually have a target value of zero, returned as a 1-by- $S$  cell array of 1-by- $N$  vectors.

For a single class problem, this output argument is returned as a 1-by- $N$  vector.

**thresholds — Thresholds**

cell array

Thresholds, returned as a 1-by- $S$  cell array of 1-by- $N$  vectors over interval  $[0, 1]$ .

For a single class problem, this output argument is returned as a 1-by- $N$  vector.

**Version History**

Introduced in R2008a

## sae

Sum absolute error performance function

### Syntax

```
perf = sae(net,t,y,ew)
[...] = sae(...,'regularization',regularization)
[...] = sae(...,'normalization',normalization)
[...] = sae(...,FP)
```

### Description

`sae` is a network performance function. It measures performance according to the sum of squared errors.

`perf = sae(net,t,y,ew)` takes these input arguments and optional function parameters,

<code>net</code>	Neural network
<code>t</code>	Matrix or cell array of target vectors
<code>y</code>	Matrix or cell array of output vectors
<code>ew</code>	Error weights (default = {1})

and returns the sum squared error.

This function has two optional function parameters that can be defined with parameter name/pair arguments, or as a structure `FP` argument with fields having the parameter name and assigned the parameter values:

```
[...] = sae(...,'regularization',regularization)
```

```
[...] = sae(...,'normalization',normalization)
```

```
[...] = sae(...,FP)
```

- `regularization` — can be set to any value between the default of 0 and 1. The greater the regularization value, the more squared weights and biases are taken into account in the performance calculation.
- `normalization`
  - `'none'` — performs no normalization, the default.
  - `'standard'` — normalizes outputs and targets to  $[-1, +1]$ , and therefore normalizes errors to  $[-2, +2]$ .
  - `'percent'` — normalizes outputs and targets to  $[-0.5, +0.5]$ , and therefore normalizes errors to  $[-1, +1]$ .

### Examples

Here a network is trained to fit a simple data set and its performance calculated

```
[x,t] = simplefit_dataset;  
net = fitnet(10,'trainscg');  
net.performFcn = 'sae';  
net = train(net,x,t)  
y = net(x)  
e = t-y  
perf = sae(net,t,y)
```

### **Network Use**

To prepare a custom network to be trained with `sae`, set `net.performFcn` to `'sae'`. This automatically sets `net.performParam` to the default function parameters.

Then calling `train`, `adapt` or `perform` will result in `sae` being used to calculate performance.

### **Version History**

**Introduced in R2010b**

# satlin

Saturating linear transfer function

## Graph and Symbol

$$a = \text{satlin}(n)$$

Satlin Transfer Function

## Syntax

$A = \text{satlin}(N, FP)$

## Description

`satlin` is a neural transfer function. Transfer functions calculate a layer's output from its net input.

$A = \text{satlin}(N, FP)$  takes two inputs,

N	S-by-Q matrix of net input (column) vectors
FP	Struct of function parameters (ignored)

and returns  $A$ , the S-by-Q matrix of  $N$ 's elements clipped to  $[0, 1]$ .

`info = satlin('code')` returns useful information for each supported `code` character vector:

`satlin('name')` returns the name of this function.

`satlin('output', FP)` returns the `[min max]` output range.

`satlin('active', FP)` returns the `[min max]` active input range.

`satlin('fullderiv')` returns 1 or 0, depending on whether `dA_dN` is S-by-S-by-Q or S-by-Q.

`satlin('fpnames')` returns the names of the function parameters.

`satlin('fpdefaults')` returns the default function parameters.

## Examples

Here is the code to create a plot of the `satlin` transfer function.

```
n = -5:0.1:5;  
a = satlin(n);  
plot(n,a)
```

Assign this transfer function to layer *i* of a network.

```
net.layers{i}.transferFcn = 'satlin';
```

### Algorithms

```
a = satlin(n) = 0, if n <= 0  
n, if 0 <= n <= 1  
1, if 1 <= n
```

### Version History

Introduced before R2006a

# satlins

Symmetric saturating linear transfer function

## Graph and Symbol

Satlins Transfer Function

## Syntax

$A = \text{satlins}(N, FP)$

## Description

`satlins` is a neural transfer function. Transfer functions calculate a layer's output from its net input.

$A = \text{satlins}(N, FP)$  takes  $N$  and an optional argument,

$N$	S-by-Q matrix of net input (column) vectors
$FP$	Struct of function parameters (optional, ignored)

and returns  $A$ , the S-by-Q matrix of  $N$ 's elements clipped to  $[-1, 1]$ .

`info = satlins('code')` returns useful information for each supported *code* character vector:

`satlins('name')` returns the name of this function.

`satlins('output', FP)` returns the [min max] output range.

`satlins('active', FP)` returns the [min max] active input range.

`satlins('fullderiv')` returns 1 or 0, depending on whether  $dA_{dN}$  is S-by-S-by-Q or S-by-Q.

`satlins('fpnames')` returns the names of the function parameters.

`satlins('fpdefaults')` returns the default function parameters.

## Examples

Here is the code to create a plot of the `satlins` transfer function.

```
n = -5:0.1:5;  
a = satlins(n);  
plot(n,a)
```

### Algorithms

```
satlins(n) = -1, if n <= -1  
n, if -1 <= n <= 1  
1, if 1 <= n
```

# scalprod

Scalar product weight function

## Syntax

```
Z = scalprod(W,P)
dim = scalprod('size',S,R,FP)
dw = scalprod('dw',W,P,Z,FP)
```

## Description

scalprod is the scalar product weight function. Weight functions apply weights to an input to get weighted inputs.

$Z = \text{scalprod}(W, P)$  takes these inputs,

W	1-by-1 weight matrix
P	R-by-Q matrix of Q input (column) vectors

and returns the R-by-Q scalar product of W and P defined by  $Z = w * P$ .

$\text{dim} = \text{scalprod}('size', S, R, FP)$  takes the layer dimension S, input dimension R, and function parameters, and returns the weight size [1-by-1].

$\text{dw} = \text{scalprod}('dw', W, P, Z, FP)$  returns the derivative of Z with respect to W.

## Examples

Here you define a random weight matrix W and input vector P and calculate the corresponding weighted input Z.

```
W = rand(1,1);
P = rand(3,1);
Z = scalprod(W,P)
```

## Network Use

To change a network so an input weight uses scalprod, set `net.inputWeights{i,j}.weightFcn` to 'scalprod'.

For a layer weight, set `net.layerWeights{i,j}.weightFcn` to 'scalprod'.

In either case, call `sim` to simulate the network with scalprod.

# selforgmap

Self-organizing map

## Syntax

```
selfOrgMap = selforgmap(dimensions)
selfOrgMap = selforgmap(dimensions,coverSteps,initNeighbor,topologyFcn,
distanceFcn)
```

## Description

Self-organizing maps learn to cluster data based on similarity, topology, with a preference (but no guarantee) of assigning the same number of instances to each class.

You can use self-organizing maps to cluster data and to reduce the dimensionality of data. They are inspired by the sensory and motor mappings in the mammal brain, which also appear to automatically organizing information topologically.

`selfOrgMap = selforgmap(dimensions)` takes a row vector of dimension sizes and returns a self-organizing map.

`selfOrgMap = selforgmap(dimensions,coverSteps,initNeighbor,topologyFcn,distanceFcn)` takes a row vector of dimension sizes and also a number of training steps for initial covering, an initial neighborhood size, a layer topology function, and a neuron distance function, and returns a self-organizing map.

## Examples

### Use Self-Organizing Map to Cluster Data

This example shows how to use a self-organizing map to cluster a simple set of data.

```
x = simplecluster_dataset;
net = selforgmap([8 8]);
net = train(net,x);
```

## Input Arguments

### **dimensions** — Dimension sizes

[8 8] (default) | row vector

Dimension sizes, specified as a row vector.

### **coverSteps** — Initial covering steps

100 (default) | scalar

Number of training steps for initial covering of the input space, specified as a scalar.

### **initNeighbor** — Initial neighborhood size

3 (default) | scalar

Initial neighborhood size, specified as a scalar.

**topologyFcn — Topology function**

'hextop' (default) | 'randtop' | 'gridtop' | 'tritop'

Layer topology function, specified as a topology function.

**distanceFcn — Distance function**

'linkdist' (default) | 'dist' | 'mandist'

Neuron distance function, specified as a distance function.

**Output Arguments**

**selfOrgMap — Self-organizing map**

network object

Self-organizing map, returned as a network object.

## separatwb

Separate biases and weight values from weight/bias vector

### Syntax

```
[b,IW,LW] = separatwb(net,wb)
```

### Description

[b,IW,LW] = separatwb(net,wb) takes two arguments,

net	Neural network
wb	Weight/bias vector

and returns

b	Cell array of bias vectors
IW	Cell array of input weight matrices
LW	Cell array of layer weight matrices

### Examples

Here a feedforward network is trained to fit some data, then its bias and weight values formed into a vector. The single vector is then redivided into the original biases and weights.

```
[x,t] = simplefit_dataset;
net = feedforwardnet(20);
net = train(net,x,t);
wb = formwb(net,net.b,net.iw,net.lw)
[b,iw,lw] = separatwb(net,wb)
```

## Version History

**Introduced in R2010b**

## seq2con

Convert sequential vectors to concurrent vectors

### Syntax

```
b = seq2con(s)
```

### Description

Deep Learning Toolbox software represents batches of vectors with a matrix, and sequences of vectors with multiple columns of a cell array.

`seq2con` and `con2seq` allow concurrent vectors to be converted to sequential vectors, and back again.

`b = seq2con(s)` takes one input,

s	N-by-TS cell array of matrices with M columns
---	---

and returns

b	N-by-1 cell array of matrices with M*TS columns
---	---

### Examples

Here three sequential values are converted to concurrent values.

```
p1 = {1 4 2}
p2 = seq2con(p1)
```

Here two sequences of vectors over three time steps are converted to concurrent vectors.

```
p1 = {[1; 1] [5; 4] [1; 2]; [3; 9] [4; 1] [9; 8]}
p2 = seq2con(p1)
```

## Version History

Introduced before R2006a

# setelements

Set neural network data elements

## Syntax

```
setelements(x,i,v)
```

## Description

setelements(x,i,v) takes these arguments,

x	Neural network matrix or cell array data
i	Indices
v	Neural network data to store into x

and returns the original data x with the data v stored in the elements indicated by the indices i.

## Examples

This code sets elements 1 and 3 of matrix data:

```
x = [1 2; 3 4; 7 4]
v = [10 11; 12 13];
y = setelements(x,[1 3],v)
```

This code sets elements 1 and 3 of cell array data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
v = {[20 21 22; 23 24 25] [26 27 28; 29 30 31]}
y = setelements(x,[1 3],v)
```

## Version History

**Introduced in R2010b**

## setsamples

Set neural network data samples

### Syntax

```
setsamples(x,i,v)
```

### Description

`setsamples(x,i,v)` takes these arguments,

<code>x</code>	Neural network matrix or cell array data
<code>i</code>	Indices
<code>v</code>	Neural network data to store into <code>x</code>

and returns the original data `x` with the data `v` stored in the samples indicated by the indices `i`.

### Examples

This code sets samples 1 and 3 of matrix data:

```
x = [1 2 3; 4 7 4]
v = [10 11; 12 13];
y = setsamples(x,[1 3],v)
```

This code sets samples 1 and 3 of cell array data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
v = {[20 21; 22 23] [24 25; 26 27]; [28 29] [30 31]}
y = setsamples(x,[1 3],v)
```

## Version History

**Introduced in R2010b**

# setsignals

Set neural network data signals

## Syntax

```
setsignals(x,i,v)
```

## Description

`setsignals(x,i,v)` takes these arguments,

<code>x</code>	Neural network matrix or cell array data
<code>i</code>	Indices
<code>v</code>	Neural network data to store into <code>x</code>

and returns the original data `x` with the data `v` stored in the signals indicated by the indices `i`.

## Examples

This code sets signal 2 of cell array data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}
v = {[20:22] [23:25]}
y = setsignals(x,2,v)
```

## Version History

Introduced in R2010b

## setsiminit

Set neural network Simulink block initial conditions

### Syntax

```
setsiminit(sysName,netName,net,xi,ai,Q)
```

### Description

`setsiminit(sysName,netName,net,xi,ai,Q)` takes these arguments,

<code>sysName</code>	The name of the Simulink system containing the neural network block
<code>netName</code>	The name of the Simulink neural network block
<code>net</code>	The original neural network
<code>xi</code>	Initial input delay states
<code>ai</code>	Initial layer delay states
<code>Q</code>	Sample number (default is 1)

and sets the Simulink neural network blocks initial conditions as specified.

### Examples

Here a NARX network is designed. The NARX network has a standard input and an open loop feedback output to an associated feedback input.

```
[x,t] = simplenarx_dataset;
net = narxnet(1:2,1:2,20);
view(net)
[xs,xi,ai,ts] = preparets(net,x,{},t);
net = train(net,xs,ts,xi,ai);
y = net(xs,xi,ai);
```

Now the network is converted to closed loop, and the data is reformatted to simulate the network's closed loop response.

```
net = closeloop(net);
view(net)
[xs,xi,ai,ts] = preparets(net,x,{},t);
y = net(xs,xi,ai);
```

Here the network is converted to a Simulink system with workspace input and output ports. Its delay states are initialized, inputs `X1` defined in the workspace, and it is ready to be simulated in Simulink.

```
[sysName,netName] = gensim(net,'InputMode','Workspace',...
    'OutputMode','WorkSpace','SolverMode','Discrete');
setsiminit(sysName,netName,net,xi,ai,1);
x1 = nndata2sim(x,1,1);
```

Finally the initial input and layer delays are obtained from the Simulink model. (They will be identical to the values set with `setsiminit`.)

```
[xi,ai] = getsiminit(sysName,netName,net);
```

## **Version History**

**Introduced in R2010b**

## settimesteps

Set neural network data timesteps

### Syntax

```
settimesteps(x,i,v)
```

### Description

`settimesteps(x,i,v)` takes these arguments,

<code>x</code>	Neural network matrix or cell array data
<code>i</code>	Indices
<code>v</code>	Neural network data to store into <code>x</code>

and returns the original data `x` with the data `v` stored in the timesteps indicated by the indices `i`.

### Examples

This code sets timestep 2 of cell array data:

```
x = {[1:3; 4:6] [7:9; 10:12]; [13:15] [16:18]}  
v = {[20:22; 23:25]; [25:27]}  
y = settimesteps(x,2,v)
```

## Version History

Introduced in R2010b

## setwb

Set all network weight and bias values with single vector

### Syntax

```
net = setwb(net,wb)
```

### Description

This function sets a network's weight and biases to a vector of values.

`net = setwb(net,wb)` takes the following inputs:

net	Neural network
wb	Vector of weight and bias values

### Examples

#### Set Network's Weights and Biases

This example shows how to set and view a network's weight and bias values.

Create and configure a network.

```
[x,t] = simplefit_dataset;  
net = feedforwardnet(3);  
net = configure(net,x,t);  
view(net)
```

This network has three weights and three biases in the first layer, and three weights and one bias in the second layer. So, the total number of weight and bias values in the network is 10. Set the weights and biases to random values.

```
net = setwb(net, rand(10,1));
```

View the weight and bias values

```
net.IW{1,1}
net.b{1}
```

ans =

```
0.1576
0.9706
0.9572
```

ans =

0.5469  
0.9575  
0.9649

## **Version History**

## sim

Simulate neural network

### Syntax

```
[Y,Xf,Af] = sim(net,X,Xi,Ai,T)
[Y,Xf,Af] = sim(net,{Q TS},Xi,Ai)
[Y,...] = sim(net,...,'useParallel',...)
[Y,...] = sim(net,...,'useGPU',...)
[Y,...] = sim(net,...,'showResources',...)
[Ycomposite,...] = sim(net,Xcomposite,...)
[Ygpu,...] = sim(net,Xgpu,...)
```

### To Get Help

Type `help network/sim`.

### Description

`sim` simulates neural networks.

`[Y,Xf,Af] = sim(net,X,Xi,Ai,T)` takes

<code>net</code>	Network
<code>X</code>	Network inputs
<code>Xi</code>	Initial input delay conditions (default = zeros)
<code>Ai</code>	Initial layer delay conditions (default = zeros)
<code>T</code>	Network targets (default = zeros)

and returns

<code>Y</code>	Network outputs
<code>Xf</code>	Final input delay conditions
<code>Af</code>	Final layer delay conditions

`sim` is usually called implicitly by calling the neural network as a function. For instance, these two expressions return the same result:

```
y = sim(net,x,xi,ai)
y = net(x,xi,ai)
```

Note that arguments `Xi`, `Ai`, `Xf`, and `Af` are optional and need only be used for networks that have input or layer delays.

The signal arguments can have two formats: cell array or matrix.

The cell array format is easiest to describe. It is most convenient for networks with multiple inputs and outputs, and allows sequences of inputs to be presented:

X	Ni-by-TS cell array	Each element $X\{i, ts\}$ is an $R_i$ -by- $Q$ matrix.
$X_i$	Ni-by-ID cell array	Each element $X_i\{i, k\}$ is an $R_i$ -by- $Q$ matrix.
$A_i$	Nl-by-LD cell array	Each element $A_i\{i, k\}$ is an $S_i$ -by- $Q$ matrix.
T	No-by-TS cell array	Each element $X\{i, ts\}$ is a $U_i$ -by- $Q$ matrix.
Y	No-by-TS cell array	Each element $Y\{i, ts\}$ is a $U_i$ -by- $Q$ matrix.
$X_f$	Ni-by-ID cell array	Each element $X_f\{i, k\}$ is an $R_i$ -by- $Q$ matrix.
$A_f$	Nl-by-LD cell array	Each element $A_f\{i, k\}$ is an $S_i$ -by- $Q$ matrix.

where

Ni	=	<code>net.numInputs</code>
Nl	=	<code>net.numLayers</code>
No	=	<code>net.numOutputs</code>
ID	=	<code>net.numInputDelays</code>
LD	=	<code>net.numLayerDelays</code>
TS	=	Number of time steps
Q	=	Batch size
$R_i$	=	<code>net.inputs{i}.size</code>
$S_i$	=	<code>net.layers{i}.size</code>
$U_i$	=	<code>net.outputs{i}.size</code>

The columns of  $X_i$ ,  $A_i$ ,  $X_f$ , and  $A_f$  are ordered from oldest delay condition to most recent:

$X_i\{i, k\}$	=	Input $i$ at time $ts = k - ID$
$X_f\{i, k\}$	=	Input $i$ at time $ts = TS + k - ID$
$A_i\{i, k\}$	=	Layer output $i$ at time $ts = k - LD$
$A_f\{i, k\}$	=	Layer output $i$ at time $ts = TS + k - LD$

The matrix format can be used if only one time step is to be simulated ( $TS = 1$ ). It is convenient for networks with only one input and output, but can also be used with networks that have more.

Each matrix argument is found by storing the elements of the corresponding cell array argument in a single matrix:

X	(sum of $R_i$ )-by- $Q$ matrix
$X_i$	(sum of $R_i$ )-by-( $ID*Q$ ) matrix
$A_i$	(sum of $S_i$ )-by-( $LD*Q$ ) matrix
T	(sum of $U_i$ )-by- $Q$ matrix
Y	(sum of $U_i$ )-by- $Q$ matrix
$X_f$	(sum of $R_i$ )-by-( $ID*Q$ ) matrix
$A_f$	(sum of $S_i$ )-by-( $LD*Q$ ) matrix

$[Y, X_f, A_f] = \text{sim}(\text{net}, \{Q \text{ TS}\}, X_i, A_i)$  is used for networks that do not have an input when cell array notation is used.

`[Y,...] = sim(net,...,'useParallel',...)`, `[Y,...] = sim(net,...,'useGPU',...)`, or `[Y,...] = sim(net,...,'showResources',...)` (or the network called as a function) accepts optional name/value pair arguments to control how calculations are performed. Two of these options allow training to happen faster or on larger datasets using parallel workers or GPU devices if Parallel Computing Toolbox is available. These are the optional name/value pairs:

'useParallel','no'	Calculations occur on normal MATLAB thread. This is the default 'useParallel' setting.
'useParallel','yes'	Calculations occur on parallel workers if a parallel pool is open. Otherwise calculations occur on the normal MATLAB thread.
'useGPU','no'	Calculations occur on the CPU. This is the default 'useGPU' setting.
'useGPU','yes'	Calculations occur on the current gpuDevice if it is a supported GPU (See Parallel Computing Toolbox for GPU requirements.) If the current gpuDevice is not supported, calculations remain on the CPU. If 'useParallel' is also 'yes' and a parallel pool is open, then each worker with a unique GPU uses that GPU, other workers run calculations on their respective CPU cores.
'useGPU','only'	If no parallel pool is open, then this setting is the same as 'yes'. If a parallel pool is open, then only workers with unique GPUs are used. However, if a parallel pool is open, but no supported GPUs are available, then calculations revert to performing on all worker CPUs.
'showResources','no'	Do not display computing resources used at the command line. This is the default setting.
'showResources','yes'	Show at the command line a summary of the computing resources actually used. The actual resources may differ from the requested resources, if parallel or GPU computing is requested but a parallel pool is not open or a supported GPU is not available. When parallel workers are used, each worker's computation mode is described, including workers in the pool that are not used.

`[Ycomposite,...] = sim(net,Xcomposite,...)` takes Composite data and returns Composite results. If Composite data is used, then 'useParallel' is automatically set to 'yes'.

`[Ygpu,...] = sim(net,Xgpu,...)` takes gpuArray data and returns gpuArray results. If gpuArray data is used, then 'useGPU' is automatically set to 'yes'.

## Examples

In the following examples, the `sim` function is called implicitly by calling the neural network object (`net`) as a function.

### Simulate Feedforward Networks

This example loads a dataset that maps anatomical measurements `x` to body fat percentages `t`. A feedforward network with 10 neurons is created and trained on that data, then simulated.

```
[x,t] = bodyfat_dataset;
net = feedforwardnet(10);
net = train(net,x,t);
```

### Simulate NARX Time Series Networks

This example trains an open-loop nonlinear-autoregressive network with external input, to model a levitated magnet system defined by a control current  $x$  and the magnet's vertical position response  $t$ , then simulates the network. The function `preparets` prepares the data before training and

simulation. It creates the open-loop network's combined inputs `xo`, which contains both the external input `x` and previous values of position `t`. It also prepares the delay states `xi`.

```
[x,t] = maglev_dataset;
net = narxnet(10);
[xo,xi,~,to] = preparets(net,x,{},t);
net = train(net,xo,to,xi);
y = net(xo,xi)
```

This same system can also be simulated in closed-loop form.

```
netc = closeloop(net);
view(netc)
[xc,xi,ai,tc] = preparets(netc,x,{},t);
yc = netc(xc,xi,ai);
```

### **Simulate in Parallel on a Parallel Pool**

With Parallel Computing Toolbox you can simulate and train networks faster and on larger datasets than can fit on one PC. Here training and simulation happens across parallel MATLAB workers.

```
parpool
[X,T] = vinyl_dataset;
net = feedforwardnet(10);
net = train(net,X,T,'useParallel','yes','showResources','yes');
Y = net(X,'useParallel','yes');
```

### **Simulate on GPUs**

Use Composite values to distribute the data manually, and get back the results as a Composite value. If the data is loaded as it is distributed, then while each piece of the dataset must fit in RAM, the entire dataset is limited only by the total RAM of all the workers.

```
Xc = Composite;
for i=1:numel(Xc)
    Xc{i} = X+rand(size(X))*0.1; % Use real data instead of random
end
Yc = net(Xc,'showResources','yes');
```

Networks can be simulated using the current GPU device, if it is supported by Parallel Computing Toolbox.

```
gpuDevice % Check if there is a supported GPU
Y = net(X,'useGPU','yes','showResources','yes');
```

To put the data on a GPU manually, and get the results on the GPU:

```
Xgpu = gpuArray(X);
Ygpu = net(Xgpu,'showResources','yes');
Y = gather(Ygpu);
```

To run in parallel, with workers associated with unique GPUs taking advantage of that hardware, while the rest of the workers use CPUs:

```
Y = net(X,'useParallel','yes','useGPU','yes','showResources','yes');
```

Using only workers with unique GPUs might result in higher speeds, as CPU workers might not keep up.

```
Y = net(X, 'useParallel', 'yes', 'useGPU', 'only', 'showResources', 'yes');
```

## Algorithms

`sim` uses these properties to simulate a network `net`.

```
net.numInputs, net.numLayers  
net.outputConnect, net.biasConnect  
net.inputConnect, net.layerConnect
```

These properties determine the network's weight and bias values and the number of delays associated with each weight:

```
net.IW{i,j}  
net.LW{i,j}  
net.b{i}  
net.inputWeights{i,j}.delays  
net.layerWeights{i,j}.delays
```

These function properties indicate how `sim` applies weight and bias values to inputs to get each layer's output:

```
net.inputWeights{i,j}.weightFcn  
net.layerWeights{i,j}.weightFcn  
net.layers{i}.netInputFcn  
net.layers{i}.transferFcn
```

## sim2nndata

Convert Simulink time series to neural network data

### Syntax

```
sim2nndata(x)
```

### Description

`sim2nndata(x)` takes either a column vector of values or a Simulink time series structure and converts it to a neural network data time series.

### Examples

Here a random Simulink 20-step time series is created and converted.

```
simts = rands(20,1);  
nnts = sim2nndata(simts)
```

Here a similar time series is defined with a Simulink structure and converted.

```
simts.time = 0:19  
simts.signals.values = rands(20,1);  
simts.dimensions = 1;  
nnts = sim2nndata(simts)
```

## Version History

**Introduced in R2010b**

# softmax

Soft max transfer function

## Syntax

```
A = softmax(N)
info = softmax(code)
```

## Description

---

**Tip** To use a softmax activation for deep learning, use `softmaxLayer` or the `dlarray` method `softmax`.

---

`A = softmax(N)` takes a S-by-Q matrix of net input (column) vectors, N, and returns the S-by-Q matrix, A, of the softmax competitive function applied to each column of N.

Softmax Transfer Function

`softmax` is a neural transfer function. Transfer functions calculate a layer's output from its net input.

`info = softmax(code)` returns information about this function. For more information, see the **code** argument description.

## Examples

### Create and Plot the softmax Transfer Function

This example shows how to calculate and plot the softmax transfer function of an input matrix.

Create the input matrix, n. Then call the `softmax` function and plot the results.

```
n = [0; 1; -0.5; 0.5];
a = softmax(n);
subplot(2,1,1), bar(n), ylabel('n')
subplot(2,1,2), bar(a), ylabel('a')
```

Assign this transfer function to layer i of a network.

```
net.layers{i}.transferFcn = 'softmax';
```

## Input Arguments

### **N** — Input matrix

matrix

Net input column vectors, specified as an S-by-Q matrix.

### **code** — Information option

'name' | 'output' | 'active' | 'fullderiv' | 'fpname' | 'fpdefaults'

Information you want to retrieve from the function, specified as one of the following:

- 'name' returns the name of this function.
- 'output' returns the [min max] output range.
- 'active' returns the [min max] active input range.
- 'fullderiv' returns 1 or 0, depending on whether dA\_dN is S-by-S-by-Q or S-by-Q.
- 'fpname' returns the names of the function parameters.
- 'fpdefaults' returns the default function parameters.

## Output Arguments

### **A** — Output matrix

matrix

Output matrix, returned as an S-by-Q matrix of the softmax competitive function applied to each column of N.

### **info** — Information output

string | vector | scalar

Specific information about the function, according to the option specified in the code argument, returned as either a string, a vector, or a scalar.

## Algorithms

$$a = \text{softmax}(n) = \exp(n) / \text{sum}(\exp(n))$$

## srchbac

1-D minimization using backtracking

### Syntax

```
[a,gX,perf,retcode,delta,tol] =
srchbac(net,X,Pd,Tl,Ai,Q,TS,dX,gX,perf,dperf,delta,TOL,ch_perf)
```

### Description

srchbac is a linear search routine. It searches in a given direction to locate the minimum of the performance function in that direction. It uses a technique called backtracking.

[a,gX,perf,retcode,delta,tol] = srchbac(net,X,Pd,Tl,Ai,Q,TS,dX,gX,perf,dperf,delta,TOL,ch\_perf) takes these inputs,

net	Neural network
X	Vector containing current values of weights and biases
Pd	Delayed input vectors
Tl	Layer target vectors
Ai	Initial input delay conditions
Q	Batch size
TS	Time steps
dX	Search direction vector
gX	Gradient vector
perf	Performance value at current X
dperf	Slope of performance value at current X in direction of dX
delta	Initial step size
tol	Tolerance on search
ch_perf	Change in performance on previous step

and returns

a	Step size that minimizes performance
gX	Gradient at new minimum point
perf	Performance value at new minimum point
retcode	Return code that has three elements. The first two elements correspond to the number of function evaluations in the two stages of the search. The third element is a return code. These have different meanings for different search algorithms. Some might not be used in this function.

	0 Normal
	1 Minimum step taken
	2 Maximum step taken
	3 Beta condition not met
delta	New initial step size, based on the current step size
tol	New tolerance on search

Parameters used for the backstepping algorithm are

alpha	Scale factor that determines sufficient reduction in perf
beta	Scale factor that determines sufficiently large step size
low_lim	Lower limit on change in step size
up_lim	Upper limit on change in step size
maxstep	Maximum step length
minstep	Minimum step length
scale_tol	Parameter that relates the tolerance tol to the initial step size delta, usually set to 20

The defaults for these parameters are set in the training function that calls them. See `traincgf`, `traincgb`, `traincgp`, `trainbfg`, and `trainoss`.

Dimensions for these variables are

Pd	No-by-Ni-by-TS cell array	Each element $P\{i, j, ts\}$ is a $D_{ij}$ -by- $Q$ matrix.
Tl	Nl-by-TS cell array	Each element $P\{i, ts\}$ is a $V_i$ -by- $Q$ matrix.
V	Nl-by-LD cell array	Each element $A_i\{i, k\}$ is an $S_i$ -by- $Q$ matrix.

where

Ni	=	<code>net.numInputs</code>
Nl	=	<code>net.numLayers</code>
LD	=	<code>net.numLayerDelays</code>
Ri	=	<code>net.inputs{i}.size</code>
Si	=	<code>net.layers{i}.size</code>
Vi	=	<code>net.targets{i}.size</code>
Dij	=	<code>Ri * length(net.inputWeights{i,j}.delays)</code>

## More About

### Backtracking Search

The backtracking search routine `srchbac` is best suited to use with the quasi-Newton optimization algorithms. It begins with a step multiplier of 1 and then backtracks until an acceptable reduction in the performance is obtained. On the first step it uses the value of performance at the current point and a step multiplier of 1. It also uses the value of the derivative of performance at the current point

to obtain a quadratic approximation to the performance function along the search direction. The minimum of the quadratic approximation becomes a tentative optimum point (under certain conditions) and the performance at this point is tested. If the performance is not sufficiently reduced, a cubic interpolation is obtained and the minimum of the cubic interpolation becomes the new tentative optimum point. This process is continued until a sufficient reduction in the performance is obtained.

The backtracking algorithm is described in Dennis and Schnabel. It is used as the default line search for the quasi-Newton algorithms, although it might not be the best technique for all problems.

## Algorithms

srchbac locates the minimum of the performance function in the search direction  $dX$ , using the backtracking algorithm described on page 126 and 328 of Dennis and Schnabel's book, noted below.

## srchbre

1-D interval location using Brent's method

### Syntax

```
[a,gX,perf,retcode,delta,tol] =
srchbre(net,X,Pd,Tl,Ai,Q,TS,dX,gX,perf,dperf,delta,tol,ch_perf)
```

### Description

srchbre is a linear search routine. It searches in a given direction to locate the minimum of the performance function in that direction. It uses a technique called Brent's technique.

[a,gX,perf,retcode,delta,tol] = srchbre(net,X,Pd,Tl,Ai,Q,TS,dX,gX,perf,dperf,delta,tol,ch\_perf) takes these inputs,

net	Neural network
X	Vector containing current values of weights and biases
Pd	Delayed input vectors
Tl	Layer target vectors
Ai	Initial input delay conditions
Q	Batch size
TS	Time steps
dX	Search direction vector
gX	Gradient vector
perf	Performance value at current X
dperf	Slope of performance value at current X in direction of dX
delta	Initial step size
tol	Tolerance on search
ch_perf	Change in performance on previous step

and returns

a	Step size that minimizes performance
gX	Gradient at new minimum point
perf	Performance value at new minimum point
retcode	Return code that has three elements. The first two elements correspond to the number of function evaluations in the two stages of the search. The third element is a return code. These have different meanings for different search algorithms. Some might not be used in this function.

	0 Normal
	1 Minimum step taken
	2 Maximum step taken
	3 Beta condition not met
delta	New initial step size, based on the current step size
tol	New tolerance on search

Parameters used for the Brent algorithm are

alpha	Scale factor that determines sufficient reduction in perf
beta	Scale factor that determines sufficiently large step size
bmax	Largest step size
scale_tol	Parameter that relates the tolerance tol to the initial step size delta, usually set to 20

The defaults for these parameters are set in the training function that calls them. See `traincgf`, `traincgb`, `traincgp`, `trainbfg`, and `trainoss`.

Dimensions for these variables are

Pd	No-by-Ni-by-TS cell array	Each element $P\{i, j, ts\}$ is a $D_{ij}$ -by-Q matrix.
Tl	Nl-by-TS cell array	Each element $P\{i, ts\}$ is a $V_i$ -by-Q matrix.
Ai	Nl-by-LD cell array	Each element $A_i\{i, k\}$ is an $S_i$ -by-Q matrix.

Dij	=	<code>Ri * length(net.inputWeights{i,j}.delays)</code>

## More About

### Brent's Search

Brent's search is a linear search that is a hybrid of the golden section search and a quadratic interpolation. Function comparison methods, like the golden section search, have a first-order rate of convergence, while polynomial interpolation methods have an asymptotic rate that is faster than superlinear. On the other hand, the rate of convergence for the golden section search starts when the algorithm is initialized, whereas the asymptotic behavior for the polynomial interpolation methods can take many iterations to become apparent. Brent's search attempts to combine the best features of both approaches.

For Brent's search, you begin with the same interval of uncertainty used with the golden section search, but some additional points are computed. A quadratic function is then fitted to these points and the minimum of the quadratic function is computed. If this minimum is within the appropriate interval of uncertainty, it is used in the next stage of the search and a new quadratic approximation is performed. If the minimum falls outside the known interval of uncertainty, then a step of the golden section search is performed.

See [Bren73] for a complete description of this algorithm. This algorithm has the advantage that it does not require computation of the derivative. The derivative computation requires a backpropagation through the network, which involves more computation than a forward pass. However, the algorithm can require more performance evaluations than algorithms that use derivative information.

### Algorithms

`srchbre` brackets the minimum of the performance function in the search direction  $dX$ , using Brent's algorithm, described on page 46 of Scales (see reference below). It is a hybrid algorithm based on the golden section search and the quadratic approximation.

## srchcha

1-D minimization using Charalambous' method

### Syntax

```
[a,gX,perf,retcode,delta,tol] =
srchcha(net,X,Pd,Tl,Ai,Q,TS,dX,gX,perf,dperf,delta,tol,ch_perf)
```

### Description

srchcha is a linear search routine. It searches in a given direction to locate the minimum of the performance function in that direction. It uses a technique based on Charalambous' method.

[a,gX,perf,retcode,delta,tol] = srchcha(net,X,Pd,Tl,Ai,Q,TS,dX,gX,perf,dperf,delta,tol,ch\_perf) takes these inputs,

net	Neural network
X	Vector containing current values of weights and biases
Pd	Delayed input vectors
Tl	Layer target vectors
Ai	Initial input delay conditions
Q	Batch size
TS	Time steps
dX	Search direction vector
gX	Gradient vector
perf	Performance value at current X
dperf	Slope of performance value at current X in direction of dX
delta	Initial step size
tol	Tolerance on search
ch_perf	Change in performance on previous step

and returns

a	Step size that minimizes performance
gX	Gradient at new minimum point
perf	Performance value at new minimum point
retcode	Return code that has three elements. The first two elements correspond to the number of function evaluations in the two stages of the search. The third element is a return code. These have different meanings for different search algorithms. Some might not be used in this function.

	0 Normal
	1 Minimum step taken
	2 Maximum step taken
	3 Beta condition not met
delta	New initial step size, based on the current step size
tol	New tolerance on search

Parameters used for the Charalambous algorithm are

alpha	Scale factor that determines sufficient reduction in perf
beta	Scale factor that determines sufficiently large step size
gama	Parameter to avoid small reductions in performance, usually set to 0.1
scale_tol	Parameter that relates the tolerance tol to the initial step size delta, usually set to 20

The defaults for these parameters are set in the training function that calls them. See `traincgf`, `traincgb`, `traincgp`, `trainbfg`, and `trainoss`.

Dimensions for these variables are

Pd	No-by-Ni-by-TS cell array	Each element $P\{i, j, ts\}$ is a $D_{ij}$ -by- $Q$ matrix.
Tl	Nl-by-TS cell array	Each element $P\{i, ts\}$ is a $V_i$ -by- $Q$ matrix.
Ai	Nl-by-LD cell array	Each element $A_i\{i, k\}$ is an $S_i$ -by- $Q$ matrix.

Dij	=	<code>Ri * length(net.inputWeights{i,j}.delays)</code>

## More About

### Charalambous' Search

The method of Charalambous, `srchcha`, was designed to be used in combination with a conjugate gradient algorithm for neural network training. Like `srchbre` and `srchhyb`, it is a hybrid search. It uses a cubic interpolation together with a type of sectioning.

See [Char92] for a description of Charalambous' search. This routine is used as the default search for most of the conjugate gradient algorithms because it appears to produce excellent results for many different problems. It does require the computation of the derivatives (backpropagation) in addition to the computation of performance, but it overcomes this limitation by locating the minimum with

fewer steps. This is not true for all problems, and you might want to experiment with other line searches.

## Algorithms

srchcha locates the minimum of the performance function in the search direction  $dX$ , using an algorithm based on the method described in Charalambous (see reference below).

## Version History

Introduced before R2006a

## More About

### Golden Section Search

The golden section search `srchgol` is a linear search that does not require the calculation of the slope. This routine begins by locating an interval in which the minimum of the performance function occurs. This is accomplished by evaluating the performance at a sequence of points, starting at a distance of `delta` and doubling in distance each step, along the search direction. When the performance increases between two successive iterations, a minimum has been bracketed. The next step is to reduce the size of the interval containing the minimum. Two new points are located within the initial interval. The values of the performance at these two points determine a section of the interval that can be discarded, and a new interior point is placed within the new interval. This procedure is continued until the interval of uncertainty is reduced to a width of `tol`, which is equal to `delta/scale_tol`.

See [HDB96], starting on page 12-16, for a complete description of the golden section search. Try the *Neural Network Design* demonstration `nnd12sd1` [HDB96] for an illustration of the performance of the golden section search in combination with a conjugate gradient algorithm.

### Algorithms

`srchgol` locates the minimum of the performance function in the search direction  $dX$ , using the golden section search. It is based on the algorithm as described on page 33 of Scales (see reference below).

### Version History

Introduced before R2006a

## srchhyb

1-D minimization using a hybrid bisection-cubic search

### Syntax

```
[a,gX,perf,retcode,delta,tol] =
srchhyb(net,X,Pd,Tl,Ai,Q,TS,dX,gX,perf,dperf,delta,tol,ch_perf)
```

### Description

srchhyb is a linear search routine. It searches in a given direction to locate the minimum of the performance function in that direction. It uses a technique that is a combination of a bisection and a cubic interpolation.

[a,gX,perf,retcode,delta,tol] = srchhyb(net,X,Pd,Tl,Ai,Q,TS,dX,gX,perf,dperf,delta,tol,ch\_perf) takes these inputs,

net	Neural network
X	Vector containing current values of weights and biases
Pd	Delayed input vectors
Tl	Layer target vectors
Ai	Initial input delay conditions
Q	Batch size
TS	Time steps
dX	Search direction vector
gX	Gradient vector
perf	Performance value at current X
dperf	Slope of performance value at current X in direction of dX
delta	Initial step size
tol	Tolerance on search
ch_perf	Change in performance on previous step

and returns

a	Step size that minimizes performance
gX	Gradient at new minimum point
perf	Performance value at new minimum point

retcode	Return code that has three elements. The first two elements correspond to the number of function evaluations in the two stages of the search. The third element is a return code. These have different meanings for different search algorithms. Some might not be used in this function.
	0 Normal
	1 Minimum step taken
	2 Maximum step taken
	3 Beta condition not met
delta	New initial step size, based on the current step size
tol	New tolerance on search

Parameters used for the hybrid bisection-cubic algorithm are

alpha	Scale factor that determines sufficient reduction in perf
beta	Scale factor that determines sufficiently large step size
bmax	Largest step size
scale_tol	Parameter that relates the tolerance tol to the initial step size delta, usually set to 20

The defaults for these parameters are set in the training function that calls them. See `traincgf`, `traincgb`, `traincgp`, `trainbfg`, and `trainoss`.

Dimensions for these variables are

Pd	No-by-Ni-by-TS cell array	Each element $P\{i, j, ts\}$ is a $D_{ij}$ -by- $Q$ matrix.
Tl	Nl-by-TS cell array	Each element $P\{i, ts\}$ is a $V_i$ -by- $Q$ matrix.
Ai	Nl-by-LD cell array	Each element $A_i\{i, k\}$ is an $S_i$ -by- $Q$ matrix.

where

Ni	=	<code>net.numInputs</code>
Nl	=	<code>net.numLayers</code>
LD	=	<code>net.numLayerDelays</code>
Ri	=	<code>net.inputs{i}.size</code>
Si	=	<code>net.layers{i}.size</code>
Vi	=	<code>net.targets{i}.size</code>
Dij	=	<code>Ri * length(net.inputWeights{i,j}.delays)</code>

## More About

### Hybrid Bisection Cubic Search

Like Brent's search, `srchhyb` is a hybrid algorithm. It is a combination of bisection and cubic interpolation. For the bisection algorithm, one point is located in the interval of uncertainty, and the

performance and its derivative are computed. Based on this information, half of the interval of uncertainty is discarded. In the hybrid algorithm, a cubic interpolation of the function is obtained by using the value of the performance and its derivative at the two endpoints. If the minimum of the cubic interpolation falls within the known interval of uncertainty, then it is used to reduce the interval of uncertainty. Otherwise, a step of the bisection algorithm is used.

See [Scal85] for a complete description of the hybrid bisection-cubic search. This algorithm does require derivative information, so it performs more computations at each step of the algorithm than the golden section search or Brent's algorithm.

## Algorithms

srchhyb locates the minimum of the performance function in the search direction  $dX$ , using the hybrid bisection-cubic interpolation algorithm described on page 50 of Scales (see reference below).

## **sse**

Sum squared error performance function

### **Syntax**

```
perf = sse(net,t,y,ew)
perf = sse(net,t,y,ew,Name,Value)
```

### **Description**

`perf = sse(net,t,y,ew)` takes a network `net`, targets `T`, outputs `Y`, and optionally error weights `EW`, and returns network performance calculated as the sum squared error.

`sse` is a network performance function. It measures performance according to the sum of squared errors.

`perf = sse(net,t,y,ew,Name,Value)` has two optional function parameters that set the regularization of the errors and the normalizations of the outputs and targets.

`sse` is a network performance function. It measures performance according to the sum of squared errors.

### **Examples**

#### **Calculate Network Performance with 'sse' Function**

This example shows how to calculate the performance of a feed-forward network with the `sse` function.

Create a network using the data from the simple fit data set, train it, and calculate its performance.

```
[x,t] = simplefit_dataset;
net = fitnet(10);
net.performFcn = 'sse';
net = train(net,x,t)
y = net(x)
e = t-y
perf = sse(net,t,y)
```

### **Input Arguments**

#### **net — Input network**

network

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

#### **t — Network targets**

matrix | cell array

Network targets, specified as a matrix or cell array.

### **y — Network outputs**

matrix | cell array

Network outputs, specified as a matrix or cell array.

### **ew — Network outputs**

{1} (default) | vector | matrix | cell array

Error weights, specified as a vector, matrix, or cell array.

Error weights can be defined by sample, output element, time step, or network output:

```
ew = [1.0 0.5 0.7 0.2]; % Across 4 samples
ew = [0.1; 0.5; 1.0]; % Across 3 elements
ew = {0.1 0.2 0.3 0.5 1.0}; % Across 5 timesteps
ew = {1.0; 0.5}; % Across 2 outputs
```

The error weights can also be defined across any combination, such as across two time-series (i.e., two samples) over four timesteps.

```
ew = {[0.5 0.4],[0.3 0.5],[1.0 1.0],[0.7 0.5]};
```

In the general case, error weights may have exactly the same dimensions as targets, in which case each target value will have an associated error weight.

The default error weight treats all errors the same.

```
ew = {1}
```

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'regularization',0.1

### **regularization — Proportion of performance**

0 (default) | integer between 0 and 1

Proportion of performance attributed to weight and bias values, specified as the comma-separated pair consisting of 'regularization' and an integer between 0 and 1. The larger this value is, the more the network is penalized for larger weights, and the more likely the network function avoids overfitting.

### **normalization — Output and target normalization**

'none' (default) | 'standard' | 'percent'

Output and target normalization, specified as the comma-separated pair consisting of 'normalization' and either:

- 'none' — performs no normalization.
- 'standard' — normalizes outputs and targets to [-1, +1], and therefore normalizes errors to [-2, +2].

- 'percent' — normalizes outputs and targets to  $[-0.5, +0.5]$ , and therefore normalizes errors to  $[-1, +1]$ .

### Output Arguments

#### **perf** — Network performance

scalar

Network performance calculated as the sum squared error, returned as a scalar.

### More About

#### **Network Use**

To prepare a custom network to be trained with `sse`, set `net.performFcn` to 'sse'. This automatically sets `net.performParam` to the default function parameters.

Then calling `train`, `adapt` or `perform` will result in `sse` being used to calculate performance.

# staticderiv

Static derivative function

## Syntax

```
staticderiv('dperf_dwb',net,X,T,Xi,Ai,EW)
staticderiv('de_dwb',net,X,T,Xi,Ai,EW)
```

## Description

This function calculates derivatives using the chain rule from the networks performance or outputs back to its inputs. For time series data and dynamic networks this function ignores the delay connections resulting in a approximation (which may be good or not) of the actual derivative. This function is used by Elman networks (elmnet) which is a dynamic network trained by the static derivative approximation when full derivative calculations are not available. As full derivatives are calculated by all the other derivative functions, this function is not recommended for dynamic networks except for research into training algorithms.

`staticderiv('dperf_dwb',net,X,T,Xi,Ai,EW)` takes these arguments,

<code>net</code>	Neural network
<code>X</code>	Inputs, an $R \times Q$ matrix (or $N \times TS$ cell array of $R \times Q$ matrices)
<code>T</code>	Targets, an $S \times Q$ matrix (or $M \times TS$ cell array of $S \times Q$ matrices)
<code>Xi</code>	Initial input delay states (optional)
<code>Ai</code>	Initial layer delay states (optional)
<code>EW</code>	Error weights (optional)

and returns the gradient of performance with respect to the network's weights and biases, where  $R$  and  $S$  are the number of input and output elements and  $Q$  is the number of samples (and  $N$  and  $M$  are the number of input and output signals,  $R_i$  and  $S_i$  are the number of each input and outputs elements, and  $TS$  is the number of timesteps).

`staticderiv('de_dwb',net,X,T,Xi,Ai,EW)` returns the Jacobian of errors with respect to the network's weights and biases.

## Examples

Here a feedforward network is trained and both the gradient and Jacobian are calculated.

```
[x,t] = simplefit_dataset;
net = feedforwardnet(20);
net = train(net,x,t);
y = net(x);
perf = perform(net,t,y);
gwb = staticderiv('dperf_dwb',net,x,t)
jwb = staticderiv('de_dwb',net,x,t)
```

# sumabs

Sum of absolute elements of matrix or matrices

## Syntax

```
[s,n] = sumabs(x)
```

## Description

`[s,n] = sumabs(x)` takes a matrix or cell array of matrices and returns,

s	Sum of all absolute finite values
n	Number of finite values

If `x` contains no finite values, the sum returned is 0.

## Examples

```
m = sumabs([1 2;3 4])  
[m,n] = sumabs({[1 2; NaN 4], [4 5; 2 3]})
```

## Version History

Introduced in R2010b

## See Also

## sumsqr

Sum of squared elements of matrix or matrices

### Syntax

```
[s,n] = sumsqr(x)
```

### Description

`[s,n] = sumsqr(x)` takes a matrix or cell array of matrices, `x`, and returns the sum, `s`, of all squared finite values in `x`, and the number of finite values, `n`.

If `x` does not contain finite values, the sum returned is 0.

### Examples

#### Calculate the Sum of Squared Elements Using the sumsqr Function

This example shows how to calculate the sum of squared elements of a matrix and a cell array using the `sumsqr` function.

```
m = sumsqr([1 2;3 4])
```

```
m = 30
```

```
[m,n] = sumsqr({[1 2; NaN 4], [4 5; 2 3]})
```

```
m = 75
```

```
n = 7
```

### Input Arguments

#### **x** — Input matrix

matrix | cell array of matrices

Input elements, specified as a matrix or cell array of matrices.

### Output Arguments

#### **s** — Sum of squared elements

scalar

Sum of all squared elements in `x`, returned as a scalar.

#### **n** — Number of finite values

scalar

Number of finite values in `x`, returned as a scalar.

## tansig

Hyperbolic tangent sigmoid transfer function

### Syntax

`A = tansig(N)`

### Description

---

**Tip** To use a hyperbolic tangent activation for deep learning, use the `tanhLayer` function or the `dLarray` method `tanh`.

---

`A = tansig(N)` takes a matrix of net input vectors, `N` and returns the `S`-by-`Q` matrix, `A`, of the elements of `N` squashed into `[-1 1]`.

Tan-Sigmoid Transfer Function

`tansig` is a neural transfer function. Transfer functions calculate the output of a layer from its net input.

### Examples

#### Create a Plot of the `tansig` Transfer Function

This example shows how to calculate and plot the hyperbolic tangent sigmoid transfer function of an input matrix.

Create the input matrix, `n`. Then call the `tansig` function and plot the results.

```
n = -5:0.1:5;
a = tansig(n);
plot(n,a)
```

Assign this transfer function to layer `i` of a network.

```
net.layers{i}.transferFcn = 'tansig';
```

## Input Arguments

### **N** — Input matrix

matrix

Net input column vectors, specified as an S-by-Q matrix.

## Output Arguments

### **A** — Output matrix

matrix

Output vectors, returned as an S-by-Q matrix, where each element of N is squashed from the interval  $[-\infty \infty]$  to the interval  $[-1 \ 1]$  with an "S-shaped" function.

## Algorithms

$$a = \text{tansig}(N) = 2/(1+\exp(-2*N))-1$$

This is mathematically equivalent to  $\tanh(N)$ .

## tapdelay

Shift neural network time series data for tap delay

### Syntax

```
tapdelay(x,i,ts,delays)
```

### Description

tapdelay(x,i,ts,delays) takes these arguments,

x	Neural network time series data
i	Signal index
ts	Timestep index
delays	Row vector of increasing zero or positive delays

and returns the tap delay values of signal *i* at timestep *ts* given the specified tap delays.

### Examples

Here a random signal *x* consisting of eight timesteps is defined, and a tap delay with delays of [0 1 4] is simulated at timestep 6.

```
x = num2cell(rand(1,8));  
y = tapdelay(x,1,6,[0 1 4])
```

## Version History

**Introduced in R2010b**

# timedelaynet

Time delay neural network

## Syntax

```
timedelaynet(inputDelays,hiddenSizes,trainFcn)
```

## Description

`timedelaynet(inputDelays,hiddenSizes,trainFcn)` takes these arguments:

- Row vector of increasing 0 or positive input delays, `inputDelays`
- Row vector of one or more hidden layer sizes, `hiddenSizes`
- Training function, `trainFcn`

and returns a time delay neural network.

Time delay networks are similar to feedforward networks, except that the input weight has a tap delay line associated with it. This allows the network to have a finite dynamic response to time series input data. This network is also similar to the distributed delay neural network (`distdelaynet`), which has delays on the layer weights in addition to the input weight.

## Examples

### Train Time Delay Network and Predict on New Data

This example shows how to train a time delay network.

Partition the training set. Use `Xnew` to do prediction in closed loop mode later.

```
[X,T] = simpleseries_dataset;  
Xnew = X(81:100);  
X = X(1:80);  
T = T(1:80);
```

Train a time delay network, and simulate it on the first 80 observations.

```
net = timedelaynet(1:2,10);  
[Xs,Xi,Ai,Ts] = preparets(net,X,T);  
net = train(net,Xs,Ts,Xi,Ai);
```

## Input Arguments

### inputDelays — Input delays

[1:2] (default) | row vector

Zero or positive input delays, specified as an increasing row vector.

### hiddenSizes — Hidden sizes

10 (default) | row vector

Sizes of the hidden layers, specified as a row vector of one or more elements.

### trainFcn — Training function name

'trainlm' (default) | 'trainbr' | 'trainbfg' | 'trainrp' | 'trainscg' | ...

Training function name, specified as one of the following.

Training Function	Algorithm
'trainlm'	Levenberg-Marquardt
'trainbr'	Bayesian Regularization
'trainbfg'	BFGS Quasi-Newton
'trainrp'	Resilient Backpropagation
'trainscg'	Scaled Conjugate Gradient
'traincgb'	Conjugate Gradient with Powell/Beale Restarts
'traincgf'	Fletcher-Powell Conjugate Gradient
'traincgp'	Polak-Ribière Conjugate Gradient
'trainoss'	One Step Secant
'traingdx'	Variable Learning Rate Gradient Descent
'traingdm'	Gradient Descent with Momentum
'traingd'	Gradient Descent

Example: For example, you can specify the variable learning rate gradient descent algorithm as the training algorithm as follows: 'traingdx'

For more information on the training functions, see “Train and Apply Multilayer Shallow Neural Networks” and “Choose a Multilayer Neural Network Training Function”.

Data Types: char

## tonndata

Convert data to standard neural network cell array form

### Syntax

```
[y,wasMatrix] = tonndata(x,columnSamples,cellTime)
```

### Description

[y,wasMatrix] = tonndata(x,columnSamples,cellTime) takes these arguments,

x	Matrix or cell array of matrices
columnSamples	True if original samples are oriented as columns, false if rows
cellTime	True if original samples are columns of a cell array, false if they are stored in a matrix

and returns

y	Original data transformed into standard neural network cell array form
wasMatrix	True if original data was a matrix (as opposed to cell array)

If `columnSamples` is false, then matrix `x` or matrices in cell array `x` will be transposed, so row samples will now be stored as column vectors.

If `cellTime` is false, then matrix samples will be separated into columns of a cell array so time originally represented as vectors in a matrix will now be represented as columns of a cell array.

The returned value `wasMatrix` can be used by `fromnndata` to reverse the transformation.

### Examples

Here data consisting of six timesteps of 5-element vectors, originally represented as a matrix with six columns, is converted to standard neural network representation and back.

```
x = rand(5,6)
columnSamples = true; % samples are by columns.
cellTime = false; % time-steps in matrix, not cell array.
[y,wasMatrix] = tonndata(x,columnSamples,cellTime)
x2 = fromnndata(y,wasMatrix,columnSamples,cellTime)
```

## Version History

Introduced in R2010b

# train

Train shallow neural network

## Syntax

```
trainedNet = train(net,X,T,Xi,Ai,EW)
[trainedNet,tr] = train(net,X,T,Xi,Ai,EW)
[trainedNet,tr] = train(net,X,T,Xi,Ai,EW,Name,Value)
```

## Description

This function trains a shallow neural network. For deep learning with convolutional or LSTM neural networks, see `trainNetwork` instead.

`trainedNet = train(net,X,T,Xi,Ai,EW)` trains a network `net` according to `net.trainFcn` and `net.trainParam`.

`[trainedNet,tr] = train(net,X,T,Xi,Ai,EW)` also returns a training record.

`[trainedNet,tr] = train(net,X,T,Xi,Ai,EW,Name,Value)` trains a network with additional options specified by one or more name-value pair arguments.

## Examples

### Train and Plot Networks

Here input `x` and targets `t` define a simple function that you can plot:

```
x = [0 1 2 3 4 5 6 7 8];
t = [0 0.84 0.91 0.14 -0.77 -0.96 -0.28 0.66 0.99];
plot(x,t,'o')
```

Here `feedforwardnet` creates a two-layer feed-forward network. The network has one hidden layer with ten neurons.

```
net = feedforwardnet(10);
net = configure(net,x,t);
y1 = net(x)
plot(x,t,'o',x,y1,'x')
```

The network is trained and then resimulated.

```
net = train(net,x,t);
y2 = net(x)
plot(x,t,'o',x,y1,'x',x,y2,'*')
```

### Train NARX Time Series Network

This example trains an open-loop nonlinear-autoregressive network with external input, to model a levitated magnet system defined by a control current `x` and the magnet's vertical position response `t`,

then simulates the network. The function `preparets` prepares the data before training and simulation. It creates the open-loop network's combined inputs `xo`, which contains both the external input `x` and previous values of position `t`. It also prepares the delay states `xi`.

```
[x,t] = maglev_dataset;
net = narxnet(10);
[xo,xi,~,to] = preparets(net,x,{},t);
net = train(net,xo,to,xi);
y = net(xo,xi)
```

This same system can also be simulated in closed-loop form.

```
netc = closeloop(net);
view(netc)
[xc,xi,ai,tc] = preparets(netc,x,{},t);
yc = netc(xc,xi,ai);
```

### Train a Network in Parallel on a Parallel Pool

Parallel Computing Toolbox allows Deep Learning Toolbox to simulate and train networks faster and on larger datasets than can fit on one PC. Parallel training is currently supported for backpropagation training only, not for self-organizing maps.

Here training and simulation happens across parallel MATLAB workers.

```
parpool
[X,T] = vinyl_dataset;
net = feedforwardnet(10);
net = train(net,X,T,'useParallel','yes','showResources','yes');
Y = net(X);
```

Use Composite values to distribute the data manually, and get back the results as a Composite value. If the data is loaded as it is distributed then while each piece of the dataset must fit in RAM, the entire dataset is limited only by the total RAM of all the workers.

```
[X,T] = vinyl_dataset;
Q = size(X,2);
Xc = Composite;
Tc = Composite;
numWorkers = numel(Xc);
ind = [0 ceil((1:numWorkers)*(Q/numWorkers))];
for i=1:numWorkers
    indi = (ind(i)+1):ind(i+1);
    Xc{i} = X(:,indi);
    Tc{i} = T(:,indi);
end
net = feedforwardnet;
net = configure(net,X,T);
net = train(net,Xc,Tc);
Yc = net(Xc);
```

Note in the example above the function `configure` was used to set the dimensions and processing settings of the network's inputs. This normally happens automatically when `train` is called, but when providing composite data this step must be done manually with non-Composite data.

## Train a Network on GPUs

Networks can be trained using the current GPU device, if it is supported by Parallel Computing Toolbox. GPU training is currently supported for backpropagation training only, not for self-organizing maps.

```
[X,T] = vinyl_dataset;
net = feedforwardnet(10);
net = train(net,X,T,'useGPU','yes');
y = net(X);
```

To put the data on a GPU manually:

```
[X,T] = vinyl_dataset;
Xgpu = gpuArray(X);
Tgpu = gpuArray(T);
net = configure(net,X,T);
net = train(net,Xgpu,Tgpu);
Ygpu = net(Xgpu);
Y = gather(Ygpu);
```

Note in the example above the function `configure` was used to set the dimensions and processing settings of the network's inputs. This normally happens automatically when `train` is called, but when providing `gpuArray` data this step must be done manually with non-`gpuArray` data.

To run in parallel, with workers each assigned to a different unique GPU, with extra workers running on CPU:

```
net = train(net,X,T,'useParallel','yes','useGPU','yes');
y = net(X);
```

Using only workers with unique GPUs might result in higher speed, as CPU workers might not keep up.

```
net = train(net,X,T,'useParallel','yes','useGPU','only');
Y = net(X);
```

## Train Network Using Checkpoint Saves

Here a network is trained with checkpoints saved at a rate no greater than once every two minutes.

```
[x,t] = vinyl_dataset;
net = fitnet([60 30]);
net = train(net,x,t,'CheckpointFile','MyCheckpoint','CheckpointDelay',120);
```

After a computer failure, the latest network can be recovered and used to continue training from the point of failure. The checkpoint file includes a structure variable `checkpoint`, which includes the network, training record, filename, time, and number.

```
[x,t] = vinyl_dataset;
load MyCheckpoint
net = checkpoint.net;
net = train(net,x,t,'CheckpointFile','MyCheckpoint');
```

Another use for the checkpoint feature is when you stop a parallel training session (started with the `'UseParallel'` parameter) even though the Neural Network Training Tool is not available during

parallel training. In this case, set a 'CheckpointFile', use Ctrl+C to stop training any time, then load your checkpoint file to get the network and training record.

## Input Arguments

### **net** — Input network

network object

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

### **X** — Network inputs

matrix | cell array | composite data | gpuArray

Network inputs, specified as an R-by-Q matrix or an Ni-by-TS cell array, where

- R is the input size
- Q is the batch size
- $N_i = \text{net.numInputs}$
- TS is the number of time steps

`train` arguments can have two formats: matrices, for static problems and networks with single inputs and outputs, and cell arrays for multiple timesteps and networks with multiple inputs and outputs.

- The matrix format can be used if only one time step is to be simulated ( $TS = 1$ ). It is convenient for networks with only one input and output, but can be used with networks that have more. When the network has multiple inputs, the matrix size is (sum of  $R_i$ )-by-Q.
- The cell array format is more general, and more convenient for networks with multiple inputs and outputs, allowing sequences of inputs to be presented. Each element  $X\{i, ts\}$  is an  $R_i$ -by-Q matrix, where  $R_i = \text{net.inputs}\{i\}.size$ .

If Composite data is used, then 'useParallel' is automatically set to 'yes'. The function takes Composite data and returns Composite results.

If gpuArray data is used, then 'useGPU' is automatically set to 'yes'. The function takes gpuArray data and returns gpuArray results

---

**Note** If a column of X contains at least one NaN, `train` does not use that column for training, testing, or validation.

---

### **T** — Network targets

zeros (default) | matrix | cell array | composite data | gpuArray

Network targets, specified as a U-by-Q matrix or an No-by-TS cell array, where

- U is the output size
- Q is the batch size
- $N_o = \text{net.numOutputs}$

- $TS$  is the number of time steps

`train` arguments can have two formats: matrices, for static problems and networks with single inputs and outputs, and cell arrays for multiple timesteps and networks with multiple inputs and outputs.

- The matrix format can be used if only one time step is to be simulated ( $TS = 1$ ). It is convenient for networks with only one input and output, but can be used with networks that have more. When the network has multiple inputs, the matrix size is (sum of  $U_i$ )-by- $Q$ .
- The cell array format is more general, and more convenient for networks with multiple inputs and outputs, allowing sequences of inputs to be presented. Each element  $T\{i, ts\}$  is a  $U_i$ -by- $Q$  matrix, where  $U_i = \text{net.outputs}\{i\}.\text{size}$ .

If Composite data is used, then `'useParallel'` is automatically set to `'yes'`. The function takes Composite data and returns Composite results.

If `gpuArray` data is used, then `'useGPU'` is automatically set to `'yes'`. The function takes `gpuArray` data and returns `gpuArray` results

Note that  $T$  is optional and need only be used for networks that require targets.

---

**Note** Any NaN values in the targets  $T$  are treated as missing data. If an element of  $T$  is NaN, that element is not used for training, testing, or validation.

---

### **$X_i$ – Initial input delay conditions**

zeros (default) | cell array | matrix

Initial input delay conditions, specified as an  $N_i$ -by- $ID$  cell array or an  $R$ -by- $(ID*Q)$  matrix, where

- $ID = \text{net.numInputDelays}$
- $N_i = \text{net.numInputs}$
- $R$  is the input size
- $Q$  is the batch size

For cell array input, the columns of  $X_i$  are ordered from the oldest delay condition to the most recent:  $X_i\{i, k\}$  is the input  $i$  at time  $ts = k - ID$ .

$X_i$  is also optional and need only be used for networks that have input or layer delays.

### **$A_i$ – Initial layer delay conditions**

zeros (default) | cell array | matrix

Initial layer delay conditions, specified as a  $N_l$ -by- $LD$  cell array or a (sum of  $S_i$ )-by- $(LD*Q)$  matrix, where

- $N_l = \text{net.numLayers}$
- $LD = \text{net.numLayerDelays}$
- $S_i = \text{net.layers}\{i\}.\text{size}$
- $Q$  is the batch size

For cell array input, the columns of  $A_i$  are ordered from the oldest delay condition to the most recent:  $A_i\{i, k\}$  is the layer output  $i$  at time  $ts = k - LD$ .

### **EW — Error weights**

cell array

Error weights, specified as a  $N_o$ -by- $TS$  cell array or a (sum of  $U_i$ )-by- $Q$  matrix, where

- $N_o = \text{net.numOutputs}$
- $TS$  is the number of time steps
- $U_i = \text{net.outputs}\{i\}.\text{size}$
- $Q$  is the batch size

For cell array input, each element  $EW\{i, ts\}$  is a  $U_i$ -by- $Q$  matrix, where

- $U_i = \text{net.outputs}\{i\}.\text{size}$
- $Q$  is the batch size

The error weights  $EW$  can also have a size of 1 in place of all or any of  $N_o$ ,  $TS$ ,  $U_i$  or  $Q$ . In that case,  $EW$  is automatically dimension extended to match the targets  $T$ . This allows for conveniently weighting the importance in any dimension (such as per sample) while having equal importance across another (such as time, with  $TS=1$ ). If all dimensions are 1, for instance if  $EW = \{1\}$ , then all target values are treated with the same importance. That is the default value of  $EW$ .

As noted above, the error weights  $EW$  can be of the same dimensions as the targets  $T$ , or have some dimensions set to 1. For instance if  $EW$  is 1-by- $Q$ , then target samples will have different importances, but each element in a sample will have the same importance. If  $EW$  is (sum of  $U_i$ )-by-1, then each output element has a different importance, with all samples treated with the same importance.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as  $Name_1=Value_1, \dots, Name_N=Value_N$ , where  $Name$  is the argument name and  $Value$  is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'useParallel', 'yes'`

### **useParallel — Option to specify parallel calculations**

'no' (default) | 'yes'

Option to specify parallel calculations, specified as 'yes' or 'no'.

- 'no' - Calculations occur on normal MATLAB thread. This is the default 'useParallel' setting.
- 'yes' - Calculations occur on parallel workers if a parallel pool is open. Otherwise calculations occur on the normal MATLAB thread.

### **useGPU — Option to specify GPU calculations**

'no' (default) | 'yes' | 'only'

Option to specify GPU calculations, specified as 'yes', 'no', or 'only'.

- 'no' - Calculations occur on the CPU. This is the default 'useGPU' setting.

- 'yes' - Calculations occur on the current `gpuDevice` if it is a supported GPU (See Parallel Computing Toolbox for GPU requirements.) If the current `gpuDevice` is not supported, calculations remain on the CPU. If 'useParallel' is also 'yes' and a parallel pool is open, then each worker with a unique GPU uses that GPU, other workers run calculations on their respective CPU cores.
- 'only' - If no parallel pool is open, then this setting is the same as 'yes'. If a parallel pool is open then only workers with unique GPUs are used. However, if a parallel pool is open, but no supported GPUs are available, then calculations revert to performing on all worker CPUs.

### **showResources — Option to show resources**

'no' (default) | 'yes'

Option to show resources, specified as 'yes' or 'no'.

- 'no' - Do not display computing resources used at the command line. This is the default setting.
- 'yes' - Show at the command line a summary of the computing resources actually used. The actual resources may differ from the requested resources, if parallel or GPU computing is requested but a parallel pool is not open or a supported GPU is not available. When parallel workers are used, each worker's computation mode is described, including workers in the pool that are not used.

### **reduction — Memory reduction**

1 (default) | positive integer

Memory reduction, specified as a positive integer.

For most neural networks, the default CPU training computation mode is a compiled MEX algorithm. However, for large networks the calculations might occur with a MATLAB calculation mode. This can be confirmed using 'showResources'. If MATLAB is being used and memory is an issue, setting the reduction option to a value *N* greater than 1, reduces much of the temporary storage required to train by a factor of *N*, in exchange for longer training times.

### **CheckpointFile — Checkpoint file**

' ' (default) | character vector

Checkpoint file, specified as a character vector.

The value for 'CheckpointFile' can be set to a filename to save in the current working folder, to a file path in another folder, or to an empty string to disable checkpoint saves (the default value).

### **CheckpointDelay — Checkpoint delay**

60 (default) | nonnegative integer

Checkpoint delay, specified as a nonnegative integer.

The optional parameter 'CheckpointDelay' limits how often saves happen. Limiting the frequency of checkpoints can improve efficiency by keeping the amount of time saving checkpoints low compared to the time spent in calculations. It has a default value of 60, which means that checkpoint saves do not happen more than once per minute. Set the value of 'CheckpointDelay' to 0 if you want checkpoint saves to occur only once every epoch.

## Output Arguments

### **trainedNet** — Trained network

network object

Trained network, returned as a network object.

### **tr** — Training record

structure

Training record (`epoch` and `perf`), returned as a structure whose fields depend on the network training function (`net.NET.trainFcn`). It can include fields such as:

- Training, data division, and performance functions and parameters
- Data division indices for training, validation and test sets
- Data division masks for training validation and test sets
- Number of epochs (`num_epochs`) and the best epoch (`best_epoch`)
- A list of training state names (`states`)
- Fields for each state name recording its value throughout training
- Best performances of the network, evaluated at each epoch: best performance on the training set (`best_perf`), best performance on the validation set (`best_vperf`), and best performance on the test set (`best_tperf`)

## Algorithms

`train` calls the function indicated by `net.trainFcn`, using the training parameter values indicated by `net.trainParam`.

Typically one epoch of training is defined as a single presentation of all input vectors to the network. The network is then updated according to the results of all those presentations.

Training occurs until a maximum number of epochs occurs, the performance goal is met, or any other stopping condition of the function `net.trainFcn` occurs.

Some training functions depart from this norm by presenting only one input vector (or sequence) each epoch. An input vector (or sequence) is chosen randomly for each epoch from concurrent input vectors (or sequences). `competlayer` returns networks that use `trainru`, a training function that does this.

# trainb

Batch training with weight and bias learning rules

## Syntax

```
net.trainFcn = 'trainb'
[net,tr] = train(net,...)
```

## Description

`trainb` is not called directly. Instead it is called by `train` for networks whose `net.trainFcn` property is set to `'trainb'`, thus:

`net.trainFcn = 'trainb'` sets the network `trainFcn` property.

`[net,tr] = train(net,...)` trains the network with `trainb`.

`trainb` trains a network with weight and bias learning rules with batch updates. The weights and biases are updated at the end of an entire pass through the input data.

Training occurs according to `trainb`'s training parameters, shown here with their default values:

<code>net.trainParam.epochs</code>	1000	Maximum number of epochs to train
<code>net.trainParam.goal</code>	0	Performance goal
<code>net.trainParam.max_fail</code>	6	Maximum validation failures
<code>net.trainParam.min_grad</code>	1e-6	Minimum performance gradient
<code>net.trainParam.show</code>	25	Epochs between displays (NaN for no displays)
<code>net.trainParam.showCommandLine</code>	false	Generate command-line output
<code>net.trainParam.showWindow</code>	true	Show training GUI
<code>net.trainParam.time</code>	inf	Maximum time to train in seconds

## Network Use

You can create a standard network that uses `trainb` by calling `linearlayer`.

To prepare a custom network to be trained with `trainb`,

- 1 Set `net.trainFcn` to `'trainb'`. This sets `net.trainParam` to `trainb`'s default parameters.
- 2 Set each `net.inputWeights{i,j}.learnFcn` to a learning function. Set each `net.layerWeights{i,j}.learnFcn` to a learning function. Set each `net.biases{i}.learnFcn` to a learning function. (Weight and bias learning parameters are automatically set to default values for the given learning function.)

To train the network,

- 1 Set `net.trainParam` properties to desired values.

- 2 Set weight and bias learning parameters to desired values.
- 3 Call `train`.

### Algorithms

Each weight and bias is updated according to its learning function after each epoch (one pass through the entire set of input vectors).

Training stops when any of these conditions is met:

- The maximum number of `epochs` (repetitions) is reached.
- Performance is minimized to the `goal`.
- The maximum amount of `time` is exceeded.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

# trainbfg

BFGS quasi-Newton backpropagation

## Syntax

```
net.trainFcn = 'trainbfg'
[trainedNet,tr] = train(net,...)
```

## Description

`net.trainFcn = 'trainbfg'` sets the network `trainFcn` property.

`[trainedNet,tr] = train(net,...)` trains the network with `trainbfg`.

`trainbfg` is a network training function that updates weight and bias values according to the BFGS quasi-Newton method.

Training occurs according to `trainbfg` training parameters, shown here with their default values:

- `net.trainParam.epochs` — Maximum number of epochs to train. The default value is 1000.
- `net.trainParam.showWindow` — Show training GUI. The default value is `true`.
- `net.trainParam.show` — Epochs between displays (NaN for no displays). The default value is 25.
- `net.trainParam.showCommandLine` — Generate command-line output. The default value is `false`.
- `net.trainParam.goal` — Performance goal. The default value is 0.
- `net.trainParam.time` — Maximum time to train in seconds. The default value is `inf`.
- `net.trainParam.min_grad` — Minimum performance gradient. The default value is `1e-6`.
- `net.trainParam.max_fail` — Maximum validation failures. The default value is 6.
- `net.trainParam.searchFcn` — Name of line search routine to use. The default value is `'srchbac'`.

Parameters related to line search methods (not all used for all methods):

- `net.trainParam.scal_tol` — Divide into delta to determine tolerance for linear search. The default value is 20.
- `net.trainParam.alpha` — Scale factor that determines sufficient reduction in perf. The default value is `0.001`.
- `net.trainParam.beta` — Scale factor that determines sufficiently large step size. The default value is `0.1`.
- `net.trainParam.delta` — Initial step size in interval location step. The default value is `0.01`.
- `net.trainParam.gamma` — Parameter to avoid small reductions in performance, usually set to 0.1 (see `srch_cha`). The default value is `0.1`.
- `net.trainParam.low_lim` — Lower limit on change in step size. The default value is `0.1`.
- `net.trainParam.up_lim` — Upper limit on change in step size. The default value is `0.5`.

- `net.trainParam.maxstep` — Maximum step length. The default value is 100.
- `net.trainParam.minstep` — Minimum step length. The default value is  $1.0e-6$ .
- `net.trainParam.bmax` — Maximum step size. The default value is 26.
- `net.trainParam.batch_frag` — In case of multiple batches, they are considered independent. Any nonzero value implies a fragmented batch, so the final layer's conditions of a previous trained epoch are used as initial conditions for the next epoch. The default value is 0.

## Examples

### Train Neural Network Using `trainbfg` Train Function

This example shows how to train a neural network using the `trainbfg` train function.

Here a neural network is trained to predict body fat percentages.

```
[x, t] = bodyfat_dataset;  
net = feedforwardnet(10, 'trainbfg');  
net = train(net, x, t);
```

## More About

### Network Use

You can create a standard network that uses `trainbfg` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `trainbfg`:

- 1 Set `NET.trainFcn` to `'trainbfg'`. This sets `NET.trainParam` to `trainbfg`'s default parameters.
- 2 Set `NET.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `trainbfg`.

### BFGS Quasi-Newton Backpropagation

Newton's method is an alternative to the conjugate gradient methods for fast optimization. The basic step of Newton's method is

$$\mathbf{x}_{k+1} = \mathbf{x}_k - \mathbf{A}_k^{-1} \mathbf{g}_k$$

where  $\mathbf{A}_k^{-1}$  is the Hessian matrix (second derivatives) of the performance index at the current values of the weights and biases. Newton's method often converges faster than conjugate gradient methods. Unfortunately, it is complex and expensive to compute the Hessian matrix for feedforward neural networks. There is a class of algorithms that is based on Newton's method, but which does not require calculation of second derivatives. These are called quasi-Newton (or secant) methods. They update an approximate Hessian matrix at each iteration of the algorithm. The update is computed as

a function of the gradient. The quasi-Newton method that has been most successful in published studies is the Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update. This algorithm is implemented in the `trainbfg` routine.

The BFGS algorithm is described in [DeSc83]. This algorithm requires more computation in each iteration and more storage than the conjugate gradient methods, although it generally converges in fewer iterations. The approximate Hessian must be stored, and its dimension is  $n \times n$ , where  $n$  is equal to the number of weights and biases in the network. For very large networks it might be better to use Rprop or one of the conjugate gradient algorithms. For smaller networks, however, `trainbfg` can be an efficient training function.

## Algorithms

`trainbfg` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables  $X$ . Each variable is adjusted according to the following:

$$X = X + a*dX;$$

where  $dX$  is the search direction. The parameter  $a$  is selected to minimize the performance along the search direction. The line search function `searchFcn` is used to locate the minimum point. The first search direction is the negative of the gradient of performance. In succeeding iterations the search direction is computed according to the following formula:

$$dX = -H \setminus gX;$$

where  $gX$  is the gradient and  $H$  is an approximate Hessian matrix. See page 119 of Gill, Murray, and Wright (*Practical Optimization*, 1981) for a more detailed discussion of the BFGS quasi-Newton method.

Training stops when any of these conditions occurs:

- The maximum number of `epochs` (repetitions) is reached.
- The maximum amount of `time` is exceeded.
- Performance is minimized to the `goal`.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

# trainbr

Bayesian regularization backpropagation

## Syntax

```
net.trainFcn = 'trainbr'  
[trainedNet,tr] = train(net,...)
```

## Description

`net.trainFcn = 'trainbr'` sets the network `trainFcn` property.

`[trainedNet,tr] = train(net,...)` trains the network with `trainbr`.

`trainbr` is a network training function that updates the weight and bias values according to Levenberg-Marquardt optimization. It minimizes a combination of squared errors and weights, and then determines the correct combination so as to produce a network that generalizes well. The process is called Bayesian regularization.

Training occurs according to `trainbr` training parameters, shown here with their default values:

- `net.trainParam.epochs` — Maximum number of epochs to train. The default value is 1000.
- `net.trainParam.goal` — Performance goal. The default value is 0.
- `net.trainParam.mu` — Marquardt adjustment parameter. The default value is 0.005.
- `net.trainParam.mu_dec` — Decrease factor for `mu`. The default value is 0.1.
- `net.trainParam.mu_inc` — Increase factor for `mu`. The default value is 10.
- `net.trainParam.mu_max` — Maximum value for `mu`. The default value is `1e10`.
- `net.trainParam.max_fail` — Maximum validation failures. The default value is `inf`.
- `net.trainParam.min_grad` — Minimum performance gradient. The default value is `1e-7`.
- `net.trainParam.show` — Epochs between displays (NaN for no displays). The default value is 25.
- `net.trainParam.showCommandLine` — Generate command-line output. The default value is `false`.
- `net.trainParam.showWindow` — Show training GUI. The default value is `true`.
- `net.trainParam.time` — Maximum time to train in seconds. The default value is `inf`.

Validation stops are disabled by default (`max_fail = inf`) so that training can continue until an optimal combination of errors and weights is found. However, some weight/bias minimization can still be achieved with shorter training times if validation is enabled by setting `max_fail` to 6 or some other strictly positive value.

## Examples

### Train Network with 'trainbr'

This example shows how to solve a problem consisting of inputs `p` and targets `t` by using a network. It involves fitting a noisy sine wave.

```
p = [-1:.05:1];  
t = sin(2*pi*p)+0.1*randn(size(p));
```

A feed-forward network is created with a hidden layer of 2 neurons.

```
net = feedforwardnet(2, 'trainbr');
```

Here the network is trained and tested.

```
net = train(net,p,t);  
a = net(p)
```

## Input Arguments

### **net** — Input network

matrix

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

## Output Arguments

### **trainedNet** — Trained network

network

Trained network, returned as a network object.

### **tr** — Training record

structure

Training record (`epoch` and `perf`), returned as a structure whose fields depend on the network training function (`net.NET.trainFcn`). It can include fields such as:

- Training, data division, and performance functions and parameters
- Data division indices for training, validation and test sets
- Data division masks for training validation and test sets
- Number of epochs (`num_epochs`) and the best epoch (`best_epoch`).
- A list of training state names (`states`).
- Fields for each state name recording its value throughout training
- Performances of the best network (`best_perf`, `best_vperf`, `best_tperf`)

## Limitations

This function uses the Jacobian for calculations, which assumes that performance is a mean or sum of squared errors. Therefore networks trained with this function must use either the `mse` or `sse` performance function.

## More About

### Network Use

You can create a standard network that uses `trainbr` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `trainbr`,

- 1 Set `NET.trainFcn` to `'trainbr'`. This sets `NET.trainParam` to `trainbr`'s default parameters.
- 2 Set `NET.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `trainbr`. See `feedforwardnet` and `cascadeforwardnet` for examples.

### Algorithms

`trainbr` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Bayesian regularization minimizes a linear combination of squared errors and weights. It also modifies the linear combination so that at the end of training the resulting network has good generalization qualities. See MacKay (*Neural Computation*, Vol. 4, No. 3, 1992, pp. 415 to 447) and Foresee and Hagan (*Proceedings of the International Joint Conference on Neural Networks*, June, 1997) for more detailed discussions of Bayesian regularization.

This Bayesian regularization takes place within the Levenberg-Marquardt algorithm. Backpropagation is used to calculate the Jacobian  $jX$  of performance `perf` with respect to the weight and bias variables  $X$ . Each variable is adjusted according to Levenberg-Marquardt,

$$\begin{aligned} jj &= jX * jX \\ je &= jX * E \\ dX &= -(jj+I*mu) \setminus je \end{aligned}$$

where  $E$  is all errors and  $I$  is the identity matrix.

The adaptive value  $\mu$  is increased by `mu_inc` until the change shown above results in a reduced performance value. The change is then made to the network, and  $\mu$  is decreased by `mu_dec`.

Training stops when any of these conditions occurs:

- The maximum number of `epochs` (repetitions) is reached.
- The maximum amount of `time` is exceeded.
- Performance is minimized to the `goal`.
- The performance gradient falls below `min_grad`.
- $\mu$  exceeds `mu_max`.

## trainbu

Batch unsupervised weight/bias training

### Syntax

```
net.trainFcn = 'trainbu'
[net,tr] = train(net,...)
```

### Description

`trainbu` trains a network with weight and bias learning rules with batch updates. Weights and biases updates occur at the end of an entire pass through the input data.

`trainbu` is not called directly. Instead the `train` function calls it for networks whose `NET.trainFcn` property is set to `'trainbu'`, thus:

`net.trainFcn = 'trainbu'` sets the network `trainFcn` property.

`[net,tr] = train(net,...)` trains the network with `trainbu`.

Training occurs according to `trainbu` training parameters, shown here with the following default values:

<code>net.trainParam.epochs</code>	1000	Maximum number of epochs to train
<code>net.trainParam.show</code>	25	Epochs between displays (NaN for no displays)
<code>net.trainParam.showCommandLine</code>	false	Generate command-line output
<code>net.trainParam.showWindow</code>	true	Show training GUI
<code>net.trainParam.time</code>	inf	Maximum time to train in seconds

Validation and test vectors have no impact on training for this function, but act as independent measures of network generalization.

### Network Use

You can create a standard network that uses `trainbu` by calling `selforgmap`. To prepare a custom network to be trained with `trainbu`:

- 1 Set `NET.trainFcn` to `'trainbu'`. (This option sets `NET.trainParam` to `trainbu` default parameters.)
- 2 Set each `NET.inputWeights{i,j}.learnFcn` to a learning function.
- 3 Set each `NET.layerWeights{i,j}.learnFcn` to a learning function.
- 4 Set each `NET.biases{i}.learnFcn` to a learning function. (Weight and bias learning parameters are automatically set to default values for the given learning function.)

To train the network:

- 1 Set `NET.trainParam` properties to desired values.

- 2 Set weight and bias learning parameters to desired values.
- 3 Call `train`.

See `selforgmap` for training examples.

### Algorithms

Each weight and bias updates according to its learning function after each epoch (one pass through the entire set of input vectors).

Training stops when any of these conditions is met:

- The maximum number of `epochs` (repetitions) is reached.
- Performance is minimized to the `goal`.
- The maximum amount of `time` is exceeded.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

### Version History

Introduced in R2010b

# trainc

Cyclical order weight/bias training

## Syntax

```
net.trainFcn = 'trainc'
[net,tr] = train(net,...)
```

## Description

`trainc` is not called directly. Instead it is called by `train` for networks whose `net.trainFcn` property is set to `'trainc'`, thus:

`net.trainFcn = 'trainc'` sets the network `trainFcn` property.

`[net,tr] = train(net,...)` trains the network with `trainc`.

`trainc` trains a network with weight and bias learning rules with incremental updates after each presentation of an input. Inputs are presented in cyclic order.

Training occurs according to `trainc` training parameters, shown here with their default values:

<code>net.trainParam.epochs</code>	1000	Maximum number of epochs to train
<code>net.trainParam.goal</code>	0	Performance goal
<code>net.trainParam.max_fail</code>	6	Maximum validation failures
<code>net.trainParam.show</code>	25	Epochs between displays (NaN for no displays)
<code>net.trainParam.showCommandLine</code>	false	Generate command-line output
<code>net.trainParam.showWindow</code>	true	Show training GUI
<code>net.trainParam.time</code>	inf	Maximum time to train in seconds

## Network Use

You can create a standard network that uses `trainc` by calling `competlayer`. To prepare a custom network to be trained with `trainc`,

- 1 Set `net.trainFcn` to `'trainc'`. This sets `net.trainParam` to `trainc`'s default parameters.
- 2 Set each `net.inputWeights{i,j}.learnFcn` to a learning function. Set each `net.layerWeights{i,j}.learnFcn` to a learning function. Set each `net.biases{i}.learnFcn` to a learning function. (Weight and bias learning parameters are automatically set to default values for the given learning function.)

To train the network,

- 1 Set `net.trainParam` properties to desired values.
- 2 Set weight and bias learning parameters to desired values.
- 3 Call `train`.

See `perceptron` for training examples.

### Algorithms

For each epoch, each vector (or sequence) is presented in order to the network, with the weight and bias values updated accordingly after each individual presentation.

Training stops when any of these conditions is met:

- The maximum number of epochs (repetitions) is reached.
- Performance is minimized to the goal.
- The maximum amount of time is exceeded.

# traincgb

Conjugate gradient backpropagation with Powell-Beale restarts

## Syntax

```
net.trainFcn = 'traincgb'
[net,tr] = train(net,...)
```

## Description

`traincgb` is a network training function that updates weight and bias values according to the conjugate gradient backpropagation with Powell-Beale restarts.

`net.trainFcn = 'traincgb'` sets the network `trainFcn` property.

`[net,tr] = train(net,...)` trains the network with `traincgb`.

Training occurs according to `traincgb` training parameters, shown here with their default values:

<code>net.trainParam.epochs</code>	1000	Maximum number of epochs to train
<code>net.trainParam.show</code>	25	Epochs between displays (NaN for no displays)
<code>net.trainParam.showCommandLine</code>	false	Generate command-line output
<code>net.trainParam.showWindow</code>	true	Show training GUI
<code>net.trainParam.goal</code>	0	Performance goal
<code>net.trainParam.time</code>	inf	Maximum time to train in seconds
<code>net.trainParam.min_grad</code>	1e-10	Minimum performance gradient
<code>net.trainParam.max_fail</code>	6	Maximum validation failures
<code>net.trainParam.searchFcn</code>	'srchcha'	Name of line search routine to use

Parameters related to line search methods (not all used for all methods):

<code>net.trainParam.sca1_tol</code>	20	Divide into <code>delta</code> to determine tolerance for linear search.
<code>net.trainParam.alpha</code>	0.001	Scale factor that determines sufficient reduction in <code>perf</code>
<code>net.trainParam.beta</code>	0.1	Scale factor that determines sufficiently large step size
<code>net.trainParam.delta</code>	0.01	Initial step size in interval location step
<code>net.trainParam.gama</code>	0.1	Parameter to avoid small reductions in performance, usually set to 0.1 (see <code>srch_cha</code> )
<code>net.trainParam.low_lim</code>	0.1	Lower limit on change in step size
<code>net.trainParam.up_lim</code>	0.5	Upper limit on change in step size
<code>net.trainParam.maxstep</code>	100	Maximum step length
<code>net.trainParam.minstep</code>	1.0e-6	Minimum step length

<code>net.trainParam.bmax</code>	26	Maximum step size
----------------------------------	----	-------------------

## Network Use

You can create a standard network that uses `traincgb` with `feedforwardnet` or `cascadeforwardnet`.

To prepare a custom network to be trained with `traincgb`,

- 1 Set `net.trainFcn` to `'traincgb'`. This sets `net.trainParam` to `traincgb`'s default parameters.
- 2 Set `net.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `traincgb`.

## More About

### Powell-Beale Algorithm

For all conjugate gradient algorithms, the search direction is periodically reset to the negative of the gradient. The standard reset point occurs when the number of iterations is equal to the number of network parameters (weights and biases), but there are other reset methods that can improve the efficiency of training. One such reset method was proposed by Powell [Powe77], based on an earlier version proposed by Beale [Beal72]. This technique restarts if there is very little orthogonality left between the current gradient and the previous gradient. This is tested with the following inequality:

$$|\mathbf{g}_{k-1}^T \mathbf{g}_k| \geq 0.2 \|\mathbf{g}_k\|^2$$

If this condition is satisfied, the search direction is reset to the negative of the gradient.

The `traincgb` routine has somewhat better performance than `traincgp` for some problems, although performance on any given problem is difficult to predict. The storage requirements for the Powell-Beale algorithm (six vectors) are slightly larger than for Polak-Ribière (four vectors).

## Algorithms

`traincgb` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables  $X$ . Each variable is adjusted according to the following:

$$X = X + a \cdot dX;$$

where  $dX$  is the search direction. The parameter  $a$  is selected to minimize the performance along the search direction. The line search function `searchFcn` is used to locate the minimum point. The first search direction is the negative of the gradient of performance. In succeeding iterations the search direction is computed from the new gradient and the previous search direction according to the formula

$$dX = -gX + dX_{old} \cdot Z;$$

where  $gX$  is the gradient. The parameter  $Z$  can be computed in several different ways. The Powell-Beale variation of conjugate gradient is distinguished by two features. First, the algorithm uses a test to determine when to reset the search direction to the negative of the gradient. Second, the search direction is computed from the negative gradient, the previous search direction, and the last search direction before the previous reset. See Powell, *Mathematical Programming*, Vol. 12, 1977, pp. 241 to 254, for a more detailed discussion of the algorithm.

Training stops when any of these conditions occurs:

- The maximum number of `epochs` (repetitions) is reached.
- The maximum amount of `time` is exceeded.
- Performance is minimized to the `goal`.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

## More About

### Conjugate Gradient Algorithms

All the conjugate gradient algorithms start out by searching in the steepest descent direction (negative of the gradient) on the first iteration.

$$\mathbf{p}_0 = -\mathbf{g}_0$$

A line search is then performed to determine the optimal distance to move along the current search direction:

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha_k \mathbf{p}_k$$

Then the next search direction is determined so that it is conjugate to previous search directions. The general procedure for determining the new search direction is to combine the new steepest descent direction with the previous search direction:

$$\mathbf{p}_k = -\mathbf{g}_k + \beta_k \mathbf{p}_{k-1}$$

The various versions of the conjugate gradient algorithm are distinguished by the manner in which the constant  $\beta_k$  is computed. For the Fletcher-Reeves update the procedure is

$$\beta_k = \frac{\mathbf{g}_k^T \mathbf{g}_k}{\mathbf{g}_{k-1}^T \mathbf{g}_{k-1}}$$

This is the ratio of the norm squared of the current gradient to the norm squared of the previous gradient.

See [FlRe64] or [HDB96] for a discussion of the Fletcher-Reeves conjugate gradient algorithm.

The conjugate gradient algorithms are usually much faster than variable learning rate backpropagation, and are sometimes faster than `trainrp`, although the results vary from one problem to another. The conjugate gradient algorithms require only a little more storage than the simpler algorithms. Therefore, these algorithms are good for networks with a large number of weights.

Try the *Neural Network Design* demonstration `nnd12cg` [HDB96] for an illustration of the performance of a conjugate gradient algorithm.

## Algorithms

`traincgf` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables  $X$ . Each variable is adjusted according to the following:

$$X = X + a * dX;$$

where  $dX$  is the search direction. The parameter  $a$  is selected to minimize the performance along the search direction. The line search function `searchFcn` is used to locate the minimum point. The first search direction is the negative of the gradient of performance. In succeeding iterations the search

direction is computed from the new gradient and the previous search direction, according to the formula

$$dX = -gX + dX\_old*Z;$$

where  $gX$  is the gradient. The parameter  $Z$  can be computed in several different ways. For the Fletcher-Reeves variation of conjugate gradient it is computed according to

$$Z = \text{normnew\_sqr}/\text{norm\_sqr};$$

where  $\text{norm\_sqr}$  is the norm square of the previous gradient and  $\text{normnew\_sqr}$  is the norm square of the current gradient. See page 78 of Scales (*Introduction to Non-Linear Optimization*) for a more detailed discussion of the algorithm.

Training stops when any of these conditions occurs:

- The maximum number of epochs (repetitions) is reached.
- The maximum amount of time is exceeded.
- Performance is minimized to the goal.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

## More About

### Conjugate Gradient Backpropagation with Polak-Ribière Updates

Another version of the conjugate gradient algorithm was proposed by Polak and Ribière. As with the Fletcher-Reeves algorithm, `traincgf`, the search direction at each iteration is determined by

$$\mathbf{p}_k = -\mathbf{g}_k + \beta_k \mathbf{p}_{k-1}$$

For the Polak-Ribière update, the constant  $\beta_k$  is computed by

$$\beta_k = \frac{\Delta \mathbf{g}_{k-1}^T \mathbf{g}_k}{\mathbf{g}_{k-1}^T \mathbf{g}_{k-1}}$$

This is the inner product of the previous change in the gradient with the current gradient divided by the norm squared of the previous gradient. See [FlRe64] or [HDB96] for a discussion of the Polak-Ribière conjugate gradient algorithm.

The `traincgp` routine has performance similar to `traincgf`. It is difficult to predict which algorithm will perform best on a given problem. The storage requirements for Polak-Ribière (four vectors) are slightly larger than for Fletcher-Reeves (three vectors).

## Algorithms

`traincgp` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables `X`. Each variable is adjusted according to the following:

$$X = X + a * dX;$$

where `dX` is the search direction. The parameter `a` is selected to minimize the performance along the search direction. The line search function `searchFcn` is used to locate the minimum point. The first search direction is the negative of the gradient of performance. In succeeding iterations the search direction is computed from the new gradient and the previous search direction according to the formula

$$dX = -gX + dX\_old * Z;$$

where `gX` is the gradient. The parameter `Z` can be computed in several different ways. For the Polak-Ribière variation of conjugate gradient, it is computed according to

$$Z = ((gX - gX\_old)' * gX) / norm\_sqr;$$

where `norm_sqr` is the norm square of the previous gradient, and `gX_old` is the gradient on the previous iteration. See page 78 of Scales (*Introduction to Non-Linear Optimization*, 1985) for a more detailed discussion of the algorithm.

Training stops when any of these conditions occurs:

- The maximum number of `epochs` (repetitions) is reached.
- The maximum amount of `time` is exceeded.

- Performance is minimized to the goal.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

## traingd

Gradient descent backpropagation

### Syntax

```
net.trainFcn = 'traingd'  
[trainedNet,tr] = train(net,...)
```

### Description

`net.trainFcn = 'traingd'` sets the network `trainFcn` property.

`[trainedNet,tr] = train(net,...)` trains the network with `traingd`.

`traingd` is a network training function that updates weight and bias values according to gradient descent.

Training occurs according to `traingd` training parameters, shown here with their default values:

- `net.trainParam.epochs` — Maximum number of epochs to train. The default value is 1000.
- `net.trainParam.goal` — Performance goal. The default value is 0.
- `net.trainParam.lr` — Learning rate. The default value is 0.01.
- `net.trainParam.max_fail` — Maximum validation failures. The default value is 6.
- `net.trainParam.min_grad` — Minimum performance gradient. The default value is `1e-5`.
- `net.trainParam.show` — Epochs between displays (NaN for no displays). The default value is 25.
- `net.trainParam.showCommandLine` — Generate command-line output. The default value is `false`.
- `net.trainParam.showWindow` — Show training GUI. The default value is `true`.
- `net.trainParam.time` — Maximum time to train in seconds. The default value is `inf`.

### Input Arguments

#### **net** — Input network

network object

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

### Output Arguments

#### **trainedNet** — Trained network

network object

Trained network, returned as a network object.

## **tr — Training record**

structure

Training record (`epoch` and `perf`), returned as a structure whose fields depend on the network training function (`net.NET.trainFcn`). It can include fields such as:

- Training, data division, and performance functions and parameters
- Data division indices for training, validation and test sets
- Data division masks for training validation and test sets
- Number of epochs (`num_epochs`) and the best epoch (`best_epoch`).
- A list of training state names (`states`).
- Fields for each state name recording its value throughout training
- Performances of the best network (`best_perf`, `best_vperf`, `best_tperf`)

## **More About**

### **Network Use**

You can create a standard network that uses `traingd` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `traingd`,

- 1 Set `net.trainFcn` to `'traingd'`. This sets `net.trainParam` to `traingd`'s default parameters.
- 2 Set `net.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `traingd`.

See `help feedforwardnet` and `help cascadeforwardnet` for examples.

### **Gradient Descent Backpropagation**

The batch steepest descent training function is `traingd`. The weights and biases are updated in the direction of the negative gradient of the performance function. If you want to train a network using batch steepest descent, you should set the network `trainFcn` to `traingd`, and then call the function `train`. There is only one training function associated with a given network.

There are seven training parameters associated with `traingd`:

- `epochs`
- `show`
- `goal`
- `time`
- `min_grad`
- `max_fail`
- `lr`

The learning rate `lr` is multiplied times the negative of the gradient to determine the changes to the weights and biases. The larger the learning rate, the bigger the step. If the learning rate is made too large, the algorithm becomes unstable. If the learning rate is set too small, the algorithm takes a long time to converge. See page 12-8 of [HDB96] for a discussion of the choice of learning rate.

The training status is displayed for every `show` iterations of the algorithm. (If `show` is set to `NaN`, then the training status is never displayed.) The other parameters determine when the training stops. The training stops if the number of iterations exceeds `epochs`, if the performance function drops below `goal`, if the magnitude of the gradient is less than `mingrad`, or if the training time is longer than `time seconds`. `max_fail`, which is associated with the early stopping technique, is discussed in *Improving Generalization*.

The following code creates a training set of inputs `p` and targets `t`. For batch training, all the input vectors are placed in one matrix.

```
p = [-1 -1 2 2; 0 5 0 5];  
t = [-1 -1 1 1];
```

Create the feedforward network.

```
net = feedforwardnet(3,'traingd');
```

In this simple example, turn off a feature that is introduced later.

```
net.divideFcn = '';
```

At this point, you might want to modify some of the default training parameters.

```
net.trainParam.show = 50;  
net.trainParam.lr = 0.05;  
net.trainParam.epochs = 300;  
net.trainParam.goal = 1e-5;
```

If you want to use the default training parameters, the preceding commands are not necessary.

Now you are ready to train the network.

```
[net,tr] = train(net,p,t);
```

The training record `tr` contains information about the progress of training.

Now you can simulate the trained network to obtain its response to the inputs in the training set.

```
a = net(p)  
a =  
-1.0026 -0.9962 1.0010 0.9960
```

Try the *Neural Network Design* demonstration `nnd12sd1` [HDB96] for an illustration of the performance of the batch gradient descent algorithm.

## Algorithms

`traingd` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables `X`. Each variable is adjusted according to gradient descent:

$$dX = lr * dperf/dX$$

Training stops when any of these conditions occurs:

- The maximum number of epochs (repetitions) is reached.
- The maximum amount of time is exceeded.
- Performance is minimized to the goal.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

## traingda

Gradient descent with adaptive learning rate backpropagation

### Syntax

```
net.trainFcn = 'traingda'  
[trainedNet,tr] = train(net,...)
```

### Description

`net.trainFcn = 'traingda'` sets the network `trainFcn` property.

`[trainedNet,tr] = train(net,...)` trains the network with `traingda`.

`traingda` is a network training function that updates weight and bias values according to gradient descent with adaptive learning rate.

Training occurs according to `traingda` training parameters, shown here with their default values:

- `net.trainParam.epochs` — Maximum number of epochs to train. The default value is 1000.
- `net.trainParam.goal` — Performance goal. The default value is 0.
- `net.trainParam.lr` — Learning rate. The default value is 0.01.
- `net.trainParam.lr_inc` — Ratio to increase learning rate. The default value is 1.05.
- `net.trainParam.lr_dec` — Ratio to decrease learning rate. The default value is 0.7.
- `net.trainParam.max_fail` — Maximum validation failures. The default value is 6.
- `net.trainParam.max_perf_inc` — Maximum performance increase. The default value is 1.04.
- `net.trainParam.min_grad` — Minimum performance gradient. The default value is 1e-5.
- `net.trainParam.show` — Epochs between displays (NaN for no displays). The default value is 25.
- `net.trainParam.showCommandLine` — Generate command-line output. The default value is `false`.
- `net.trainParam.showWindow` — Show training GUI. The default value is `true`.
- `net.trainParam.time` — Maximum time to train in seconds. The default value is `inf`.

### Input Arguments

#### **net** — Input network

network

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

### Output Arguments

#### **trainedNet** — Trained network

network

Trained network, returned as a `network` object..

### **tr — Training record**

structure

Training record (epoch and perf), returned as a structure whose fields depend on the network training function (`net.NET.trainFcn`). It can include fields such as:

- Training, data division, and performance functions and parameters
- Data division indices for training, validation and test sets
- Data division masks for training validation and test sets
- Number of epochs (`num_epochs`) and the best epoch (`best_epoch`).
- A list of training state names (`states`).
- Fields for each state name recording its value throughout training
- Performances of the best network (`best_perf`, `best_vperf`, `best_tperf`)

## **More About**

### **Network Use**

You can create a standard network that uses `traingda` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `traingda`,

- 1 Set `net.trainFcn` to `'traingda'`. This sets `net.trainParam` to `traingda`'s default parameters.
- 2 Set `net.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `traingda`.

See `help feedforwardnet` and `help cascadeforwardnet` for examples.

### **Gradient Descent with Adaptive Learning Rate Backpropagation**

With standard steepest descent, the learning rate is held constant throughout training. The performance of the algorithm is very sensitive to the proper setting of the learning rate. If the learning rate is set too high, the algorithm can oscillate and become unstable. If the learning rate is too small, the algorithm takes too long to converge. It is not practical to determine the optimal setting for the learning rate before training, and, in fact, the optimal learning rate changes during the training process, as the algorithm moves across the performance surface.

You can improve the performance of the steepest descent algorithm if you allow the learning rate to change during the training process. An adaptive learning rate attempts to keep the learning step size as large as possible while keeping learning stable. The learning rate is made responsive to the complexity of the local error surface.

An adaptive learning rate requires some changes in the training procedure used by `traingd`. First, the initial network output and error are calculated. At each epoch new weights and biases are calculated using the current learning rate. New outputs and errors are then calculated.

As with momentum, if the new error exceeds the old error by more than a predefined ratio, `max_perf_inc` (typically 1.04), the new weights and biases are discarded. In addition, the learning rate is decreased (typically by multiplying by `lr_dec` = 0.7). Otherwise, the new weights, etc., are

kept. If the new error is less than the old error, the learning rate is increased (typically by multiplying by `lr_inc = 1.05`).

This procedure increases the learning rate, but only to the extent that the network can learn without large error increases. Thus, a near-optimal learning rate is obtained for the local terrain. When a larger learning rate could result in stable learning, the learning rate is increased. When the learning rate is too high to guarantee a decrease in error, it is decreased until stable learning resumes.

Try the *Neural Network Design* demonstration `nnd12v1` [HDB96] for an illustration of the performance of the variable learning rate algorithm.

Backpropagation training with an adaptive learning rate is implemented with the function `traingda`, which is called just like `traingd`, except for the additional training parameters `max_perf_inc`, `lr_dec`, and `lr_inc`. Here is how it is called to train the previous two-layer network:

```
p = [-1 -1 2 2; 0 5 0 5];
t = [-1 -1 1 1];
net = feedforwardnet(3,'traingda');
net.trainParam.lr = 0.05;
net.trainParam.lr_inc = 1.05;
net = train(net,p,t);
y = net(p)
```

## Algorithms

`traingda` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `dperf` with respect to the weight and bias variables `X`. Each variable is adjusted according to gradient descent:

$$dX = lr * dperf / dX$$

At each epoch, if performance decreases toward the goal, then the learning rate is increased by the factor `lr_inc`. If performance increases by more than the factor `max_perf_inc`, the learning rate is adjusted by the factor `lr_dec` and the change that increased the performance is not made.

Training stops when any of these conditions occurs:

- The maximum number of epochs (repetitions) is reached.
- The maximum amount of time is exceeded.
- Performance is minimized to the goal.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

## traingdm

Gradient descent with momentum backpropagation

### Syntax

```
net.trainFcn = 'traingdm'
[net,tr] = train(net,...)
```

### Description

`traingdm` is a network training function that updates weight and bias values according to gradient descent with momentum.

`net.trainFcn = 'traingdm'` sets the network `trainFcn` property.

`[net,tr] = train(net,...)` trains the network with `traingdm`.

Training occurs according to `traingdm` training parameters, shown here with their default values:

<code>net.trainParam.epochs</code>	1000	Maximum number of epochs to train
<code>net.trainParam.goal</code>	0	Performance goal
<code>net.trainParam.lr</code>	0.01	Learning rate
<code>net.trainParam.max_fail</code>	6	Maximum validation failures
<code>net.trainParam.mc</code>	0.9	Momentum constant
<code>net.trainParam.min_grad</code>	1e-5	Minimum performance gradient
<code>net.trainParam.show</code>	25	Epochs between showing progress
<code>net.trainParam.showCommandLine</code>	false	Generate command-line output
<code>net.trainParam.showWindow</code>	true	Show training GUI
<code>net.trainParam.time</code>	inf	Maximum time to train in seconds

### Network Use

You can create a standard network that uses `traingdm` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `traingdm`,

- 1 Set `net.trainFcn` to `'traingdm'`. This sets `net.trainParam` to `traingdm`'s default parameters.
- 2 Set `net.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `traingdm`.

See `help feedforwardnet` and `help cascadeforwardnet` for examples.

## More About

### Gradient Descent with Momentum

In addition to `traingd`, there are three other variations of gradient descent.

Gradient descent with momentum, implemented by `traingdm`, allows a network to respond not only to the local gradient, but also to recent trends in the error surface. Acting like a lowpass filter, momentum allows the network to ignore small features in the error surface. Without momentum a network can get stuck in a shallow local minimum. With momentum a network can slide through such a minimum. See page 12-9 of [HDB96] for a discussion of momentum.

Gradient descent with momentum depends on two training parameters. The parameter `lr` indicates the learning rate, similar to the simple gradient descent. The parameter `mc` is the momentum constant that defines the amount of momentum. `mc` is set between 0 (no momentum) and values close to 1 (lots of momentum). A momentum constant of 1 results in a network that is completely insensitive to the local gradient and, therefore, does not learn properly.

```
p = [-1 -1 2 2; 0 5 0 5];
t = [-1 -1 1 1];
net = feedforwardnet(3,'traingdm');
net.trainParam.lr = 0.05;
net.trainParam.mc = 0.9;
net = train(net,p,t);
y = net(p)
```

Try the *Neural Network Design* demonstration `nnd12mo` [HDB96] for an illustration of the performance of the batch momentum algorithm.

## Algorithms

`traingdm` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables  $X$ . Each variable is adjusted according to gradient descent with momentum,

$$dX = mc*dX_{prev} + lr*(1-mc)*dperf/dX$$

where  $dX_{prev}$  is the previous change to the weight or bias.

Training stops when any of these conditions occurs:

- The maximum number of epochs (repetitions) is reached.
- The maximum amount of time is exceeded.
- Performance is minimized to the goal.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

# traingdx

Gradient descent with momentum and adaptive learning rate backpropagation

## Syntax

```
net.trainFcn = 'traingdx'  
[trainedNet,tr] = train(net,...)
```

## Description

`net.trainFcn = 'traingdx'` sets the network `trainFcn` property.

`[trainedNet,tr] = train(net,...)` trains the network with `traingdx`.

`traingdx` is a network training function that updates weight and bias values according to gradient descent momentum and an adaptive learning rate.

Training occurs according to `traingdx` training parameters, shown here with their default values:

- `net.trainParam.epochs` — Maximum number of epochs to train. The default value is 1000.
- `net.trainParam.goal` — Performance goal. The default value is 0.
- `net.trainParam.lr` — Learning rate. The default value is 0.01.
- `net.trainParam.lr_inc` — Ratio to increase learning rate. The default value is 1.05.
- `net.trainParam.lr_dec` — Ratio to decrease learning rate. The default value is 0.7.
- `net.trainParam.max_fail` — Maximum validation failures. The default value is 6.
- `net.trainParam.max_perf_inc` — Maximum performance increase. The default value is 1.04.
- `net.trainParam.mc` — Momentum constant. The default value is 0.9.
- `net.trainParam.min_grad` — Minimum performance gradient. The default value is  $1e-5$ .
- `net.trainParam.show` — Epochs between displays (NaN for no displays). The default value is 25.
- `net.trainParam.showCommandLine` — Generate command-line output. The default value is `false`.
- `net.trainParam.showWindow` — Show training GUI. The default value is `true`.
- `net.trainParam.time` — Maximum time to train in seconds. The default value is `inf`.

## Input Arguments

### **net** — Input network

matrix

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

## Output Arguments

### **trainedNet** — Trained network

network

Trained network, returned as a network object.

### **tr** — Training record

structure

Training record (epoch and perf), returned as a structure whose fields depend on the network training function (`net.NET.trainFcn`). It can include fields such as:

- Training, data division, and performance functions and parameters
- Data division indices for training, validation and test sets
- Data division masks for training validation and test sets
- Number of epochs (`num_epochs`) and the best epoch (`best_epoch`).
- A list of training state names (`states`).
- Fields for each state name recording its value throughout training
- Performances of the best network (`best_perf`, `best_vperf`, `best_tperf`)

## More About

### Network Use

You can create a standard network that uses `traingdx` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `traingdx`,

- 1 Set `net.trainFcn` to `'traingdx'`. This sets `net.trainParam` to `traingdx`'s default parameters.
- 2 Set `net.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `traingdx`.

See `help feedforwardnet` and `help cascadeforwardnet` for examples.

## Algorithms

The function `traingdx` combines adaptive learning rate with momentum training. It is invoked in the same way as `traingda`, except that it has the momentum coefficient `mc` as an additional training parameter.

`traingdx` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables  $X$ . Each variable is adjusted according to gradient descent with momentum,

$$dX = mc*dX_{prev} + lr*mc*dperf/dX$$

where `dXprev` is the previous change to the weight or bias.

For each epoch, if performance decreases toward the goal, then the learning rate is increased by the factor `lr_inc`. If performance increases by more than the factor `max_perf_inc`, the learning rate is adjusted by the factor `lr_dec` and the change that increased the performance is not made.

Training stops when any of these conditions occurs:

- The maximum number of `epochs` (repetitions) is reached.
- The maximum amount of `time` is exceeded.
- Performance is minimized to the `goal`.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

## trainlm

Levenberg-Marquardt backpropagation

### Syntax

```
net.trainFcn = 'trainlm'  
[trainedNet,tr] = train(net,...)
```

### Description

`net.trainFcn = 'trainlm'` sets the network `trainFcn` property.

`[trainedNet,tr] = train(net,...)` trains the network with `trainlm`.

`trainlm` is a network training function that updates weight and bias values according to Levenberg-Marquardt optimization.

`trainlm` is often the fastest backpropagation algorithm in the toolbox, and is highly recommended as a first-choice supervised algorithm, although it does require more memory than other algorithms.

Training occurs according to `trainlm` training parameters, shown here with their default values:

- `net.trainParam.epochs` — Maximum number of epochs to train. The default value is 1000.
- `net.trainParam.goal` — Performance goal. The default value is 0.
- `net.trainParam.max_fail` — Maximum validation failures. The default value is 6.
- `net.trainParam.min_grad` — Minimum performance gradient. The default value is  $1e-7$ .
- `net.trainParam.mu` — Initial  $\mu$ . The default value is 0.001.
- `net.trainParam.mu_dec` — Decrease factor for  $\mu$ . The default value is 0.1.
- `net.trainParam.mu_inc` — Increase factor for  $\mu$ . The default value is 10.
- `net.trainParam.mu_max` — Maximum value for  $\mu$ . The default value is  $1e10$ .
- `net.trainParam.show` — Epochs between displays (NaN for no displays). The default value is 25.
- `net.trainParam.showCommandLine` — Generate command-line output. The default value is `false`.
- `net.trainParam.showWindow` — Show training GUI. The default value is `true`.
- `net.trainParam.time` — Maximum time to train in seconds. The default value is `inf`.

Validation vectors are used to stop training early if the network performance on the validation vectors fails to improve or remains the same for `max_fail` epochs in a row. Test vectors are used as a further check that the network is generalizing well, but do not have any effect on training.

### Examples

### **Train Neural Network Using trainlm Train Function**

This example shows how to train a neural network using the `trainlm` train function.

Here a neural network is trained to predict body fat percentages.

```
[x, t] = bodyfat_dataset;  
net = feedforwardnet(10, 'trainlm');  
net = train(net, x, t);
```

## Output Arguments

### **trainedNet** — Trained network

network

Trained network, returned as a network object.

### **tr** — Training record

structure

Training record (`epoch` and `perf`), returned as a structure whose fields depend on the network training function (`net.NET.trainFcn`). It can include fields such as:

- Training, data division, and performance functions and parameters
- Data division indices for training, validation and test sets
- Data division masks for training validation and test sets
- Number of epochs (`num_epochs`) and the best epoch (`best_epoch`).
- A list of training state names (`states`).
- Fields for each state name recording its value throughout training
- Performances of the best network (`best_perf`, `best_vperf`, `best_tperf`)

## Limitations

This function uses the Jacobian for calculations, which assumes that performance is a mean or sum of squared errors. Therefore, networks trained with this function must use either the `mse` or `sse` performance function.

## More About

### Levenberg-Marquardt Algorithm

Like the quasi-Newton methods, the Levenberg-Marquardt algorithm was designed to approach second-order training speed without having to compute the Hessian matrix. When the performance function has the form of a sum of squares (as is typical in training feedforward networks), then the Hessian matrix can be approximated as

$$\mathbf{H} = \mathbf{J}^T \mathbf{J} \quad (2-1)$$

and the gradient can be computed as

$$\mathbf{g} = \mathbf{J}^T \mathbf{e} \quad (2-2)$$

where  $\mathbf{J}$  is the Jacobian matrix that contains first derivatives of the network errors with respect to the weights and biases, and  $\mathbf{e}$  is a vector of network errors. The Jacobian matrix can be computed through a standard backpropagation technique (see [HaMe94]) that is much less complex than computing the Hessian matrix.

The Levenberg-Marquardt algorithm uses this approximation to the Hessian matrix in the following Newton-like update:

$$\mathbf{x}_{k+1} = \mathbf{x}_k - [\mathbf{J}^T \mathbf{J} + \mu \mathbf{I}]^{-1} \mathbf{J}^T \mathbf{e}$$

When the scalar  $\mu$  is zero, this is just Newton's method, using the approximate Hessian matrix. When  $\mu$  is large, this becomes gradient descent with a small step size. Newton's method is faster and more accurate near an error minimum, so the aim is to shift toward Newton's method as quickly as possible. Thus,  $\mu$  is decreased after each successful step (reduction in performance function) and is increased only when a tentative step would increase the performance function. In this way, the performance function is always reduced at each iteration of the algorithm.

The original description of the Levenberg-Marquardt algorithm is given in [Marq63]. The application of Levenberg-Marquardt to neural network training is described in [HaMe94] and starting on page 12-19 of [HDB96]. This algorithm appears to be the fastest method for training moderate-sized feedforward neural networks (up to several hundred weights). It also has an efficient implementation in MATLAB® software, because the solution of the matrix equation is a built-in function, so its attributes become even more pronounced in a MATLAB environment.

Try the *Neural Network Design* demonstration `nnd12m` [HDB96] for an illustration of the performance of the batch Levenberg-Marquardt algorithm.

### Network Use

You can create a standard network that uses `trainlm` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `trainlm`,

- 1 Set `NET.trainFcn` to `trainlm`. This sets `NET.trainParam` to `trainlm`'s default parameters.
- 2 Set `NET.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `trainlm`. See `feedforwardnet` and `cascadeforwardnet` for examples.

### Algorithms

`trainlm` supports training with validation and test vectors if the network's `NET.divideFcn` property is set to a data division function. Validation vectors are used to stop training early if the network performance on the validation vectors fails to improve or remains the same for `max_fail` epochs in a row. Test vectors are used as a further check that the network is generalizing well, but do not have any effect on training.

`trainlm` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate the Jacobian  $\mathbf{jX}$  of performance `perf` with respect to the weight and bias variables  $\mathbf{X}$ . Each variable is adjusted according to Levenberg-Marquardt,

$$\begin{aligned} \mathbf{jj} &= \mathbf{jX} * \mathbf{jX} \\ \mathbf{je} &= \mathbf{jX} * \mathbf{E} \\ \mathbf{dX} &= -(\mathbf{jj} + \mathbf{I} * \mu) \setminus \mathbf{je} \end{aligned}$$

where  $\mathbf{E}$  is all errors and  $\mathbf{I}$  is the identity matrix.

The adaptive value `mu` is increased by `mu_inc` until the change above results in a reduced performance value. The change is then made to the network and `mu` is decreased by `mu_dec`.

Training stops when any of these conditions occurs:

- The maximum number of `epochs` (repetitions) is reached.
- The maximum amount of `time` is exceeded.
- Performance is minimized to the `goal`.
- The performance gradient falls below `min_grad`.
- `mu` exceeds `mu_max`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

## trainoss

One-step secant backpropagation

### Syntax

```
net.trainFcn = 'trainoss'
[net,tr] = train(net,...)
```

### Description

`trainoss` is a network training function that updates weight and bias values according to the one-step secant method.

`net.trainFcn = 'trainoss'` sets the network `trainFcn` property.

`[net,tr] = train(net,...)` trains the network with `trainoss`.

Training occurs according to `trainoss` training parameters, shown here with their default values:

<code>net.trainParam.epochs</code>	1000	Maximum number of epochs to train
<code>net.trainParam.goal</code>	0	Performance goal
<code>net.trainParam.max_fail</code>	6	Maximum validation failures
<code>net.trainParam.min_grad</code>	1e-10	Minimum performance gradient
<code>net.trainParam.searchFcn</code>	'srchbac'	Name of line search routine to use
<code>net.trainParam.show</code>	25	Epochs between displays (NaN for no displays)
<code>net.trainParam.showCommandLine</code>	false	Generate command-line output
<code>net.trainParam.showWindow</code>	true	Show training GUI
<code>net.trainParam.time</code>	inf	Maximum time to train in seconds

Parameters related to line search methods (not all used for all methods):

<code>net.trainParam.sca1_tol</code>	20	Divide into <code>delta</code> to determine tolerance for linear search.
<code>net.trainParam.alpha</code>	0.001	Scale factor that determines sufficient reduction in <code>perf</code>
<code>net.trainParam.beta</code>	0.1	Scale factor that determines sufficiently large step size
<code>net.trainParam.delta</code>	0.01	Initial step size in interval location step
<code>net.trainParam.gama</code>	0.1	Parameter to avoid small reductions in performance, usually set to 0.1 (see <code>srch_cha</code> )
<code>net.trainParam.low_lim</code>	0.1	Lower limit on change in step size
<code>net.trainParam.up_lim</code>	0.5	Upper limit on change in step size
<code>net.trainParam.maxstep</code>	100	Maximum step length
<code>net.trainParam.minstep</code>	1.0e-6	Minimum step length

<code>net.trainParam.bmax</code>	26	Maximum step size
----------------------------------	----	-------------------

## Network Use

You can create a standard network that uses `trainoss` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `trainoss`:

- 1 Set `net.trainFcn` to `'trainoss'`. This sets `net.trainParam` to `trainoss`'s default parameters.
- 2 Set `net.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `trainoss`.

## More About

### One Step Secant Method

Because the BFGS algorithm requires more storage and computation in each iteration than the conjugate gradient algorithms, there is need for a secant approximation with smaller storage and computation requirements. The one step secant (OSS) method is an attempt to bridge the gap between the conjugate gradient algorithms and the quasi-Newton (secant) algorithms. This algorithm does not store the complete Hessian matrix; it assumes that at each iteration, the previous Hessian was the identity matrix. This has the additional advantage that the new search direction can be calculated without computing a matrix inverse.

The one step secant method is described in [Batt92]. This algorithm requires less storage and computation per epoch than the BFGS algorithm. It requires slightly more storage and computation per epoch than the conjugate gradient algorithms. It can be considered a compromise between full quasi-Newton algorithms and conjugate gradient algorithms.

## Algorithms

`trainoss` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables `X`. Each variable is adjusted according to the following:

$$X = X + a*dX;$$

where `dX` is the search direction. The parameter `a` is selected to minimize the performance along the search direction. The line search function `searchFcn` is used to locate the minimum point. The first search direction is the negative of the gradient of performance. In succeeding iterations the search direction is computed from the new gradient and the previous steps and gradients, according to the following formula:

$$dX = -gX + Ac*X\_step + Bc*dgX;$$

where `gX` is the gradient, `X_step` is the change in the weights on the previous iteration, and `dgX` is the change in the gradient from the last iteration. See Battiti (*Neural Computation*, Vol. 4, 1992, pp. 141-166) for a more detailed discussion of the one-step secant algorithm.

Training stops when any of these conditions occurs:

- The maximum number of `epochs` (repetitions) is reached.
- The maximum amount of `time` is exceeded.
- Performance is minimized to the `goal`.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

## trainr

Random order incremental training with learning functions

### Syntax

```
net.trainFcn = 'trainr'
[net,tr] = train(net,...)
```

### Description

`trainr` is not called directly. Instead it is called by `train` for networks whose `net.trainFcn` property is set to `'trainr'`, thus:

`net.trainFcn = 'trainr'` sets the network `trainFcn` property.

`[net,tr] = train(net,...)` trains the network with `trainr`.

`trainr` trains a network with weight and bias learning rules with incremental updates after each presentation of an input. Inputs are presented in random order.

Training occurs according to `trainr` training parameters, shown here with their default values:

<code>net.trainParam.epochs</code>	1000	Maximum number of epochs to train
<code>net.trainParam.goal</code>	0	Performance goal
<code>net.trainParam.max_fail</code>	6	Maximum validation failures
<code>net.trainParam.show</code>	25	Epochs between displays (NaN for no displays)
<code>net.trainParam.showCommandLine</code>	false	Generate command-line output
<code>net.trainParam.showWindow</code>	true	Show training GUI
<code>net.trainParam.time</code>	inf	Maximum time to train in seconds

### Network Use

You can create a standard network that uses `trainr` by calling `competlayer` or `selforgmap`. To prepare a custom network to be trained with `trainr`,

- 1 Set `net.trainFcn` to `'trainr'`. This sets `net.trainParam` to `trainr`'s default parameters.
- 2 Set each `net.inputWeights{i,j}.learnFcn` to a learning function.
- 3 Set each `net.layerWeights{i,j}.learnFcn` to a learning function.
- 4 Set each `net.biases{i}.learnFcn` to a learning function. (Weight and bias learning parameters are automatically set to default values for the given learning function.)

To train the network,

- 1 Set `net.trainParam` properties to desired values.
- 2 Set weight and bias learning parameters to desired values.

3 Call `train`.

See `help competlayer` and `help selforgmap` for training examples.

### Algorithms

For each epoch, all training vectors (or sequences) are each presented once in a different random order, with the network and weight and bias values updated accordingly after each individual presentation.

Training stops when any of these conditions is met:

- The maximum number of `epochs` (repetitions) is reached.
- Performance is minimized to the `goal`.
- The maximum amount of `time` is exceeded.

`train`

# trainrp

Resilient backpropagation

## Syntax

```
net.trainFcn = 'trainrp'  
[trainedNet,tr] = train(net,...)
```

## Description

`net.trainFcn = 'trainrp'` sets the network `trainFcn` property.

`[trainedNet,tr] = train(net,...)` trains the network with `trainrp`.

`trainrp` is a network training function that updates weight and bias values according to the resilient backpropagation algorithm (Rprop).

Training occurs according to `trainrp` training parameters, shown here with their default values:

- `net.trainParam.epochs` — Maximum number of epochs to train. The default value is 1000.
- `net.trainParam.show` — Epochs between displays (NaN for no displays). The default value is 25.
- `net.trainParam.showCommandLine` — Generate command-line output. The default value is `false`.
- `net.trainParam.showWindow` — Show training GUI. The default value is `true`.
- `net.trainParam.goal` — Performance goal. The default value is 0.
- `net.trainParam.time` — Maximum time to train in seconds. The default value is `inf`.
- `net.trainParam.min_grad` — Minimum performance gradient. The default value is `1e-5`.
- `net.trainParam.max_fail` — Maximum validation failures. The default value is 6.
- `net.trainParam.lr` — Learning rate. The default value is `0.01`.
- `net.trainParam.delt_inc` — Increment to weight change. The default value is `1.2`.
- `net.trainParam.delt_dec` — Decrement to weight change. The default value is `0.5`.
- `net.trainParam.delta0` — Initial weight change. The default value is `0.07`.
- `net.trainParam.deltamax` — Maximum weight change. The default value is `50.0`.

## Examples

### Solve Problems with Network Trained with 'trainrp'

This example shows how to train a feed-forward network with a `trainrp` training function to solve a problem with inputs `p` and targets `t`.

Create the inputs `p` and the targets `t` that you want to solve with a network.

```
p = [0 1 2 3 4 5];  
t = [0 0 0 1 1 1];
```

Create a two-layer feed-forward network with two hidden neurons and this training function.

```
net = feedforwardnet(2, 'trainrp');
```

Train and test the network.

```
net.trainParam.epochs = 50;  
net.trainParam.show = 10;  
net.trainParam.goal = 0.1;  
net = train(net,p,t);  
a = net(p)
```

For more examples, see `help feedforwardnet` and `help cascadeforwardnet`.

### Input Arguments

#### **net** — Input network

matrix

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

### Output Arguments

#### **trainedNet** — Trained network

network

Trained network, returned as a network object.

#### **tr** — Training record

structure

Training record (epoch and perf), returned as a structure whose fields depend on the network training function (`net.NET.trainFcn`). It can include fields such as:

- Training, data division, and performance functions and parameters
- Data division indices for training, validation and test sets
- Data division masks for training validation and test sets
- Number of epochs (`num_epochs`) and the best epoch (`best_epoch`).
- A list of training state names (`states`).
- Fields for each state name recording its value throughout training
- Performances of the best network (`best_perf`, `best_vperf`, `best_tperf`)

### More About

#### **Network Use**

You can create a standard network that uses `trainrp` with `feedforwardnet` or `cascadeforwardnet`.

To prepare a custom network to be trained with `trainrp`,

- 1 Set `net.trainFcn` to `'trainrp'`. This sets `net.trainParam` to `trainrp`'s default parameters.
- 2 Set `net.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `trainrp`.

### Resilient Backpropagation

Multilayer networks typically use sigmoid transfer functions in the hidden layers. These functions are often called “squashing” functions, because they compress an infinite input range into a finite output range. Sigmoid functions are characterized by the fact that their slopes must approach zero as the input gets large. This causes a problem when you use steepest descent to train a multilayer network with sigmoid functions, because the gradient can have a very small magnitude and, therefore, cause small changes in the weights and biases, even though the weights and biases are far from their optimal values.

The purpose of the resilient backpropagation (Rprop) training algorithm is to eliminate these harmful effects of the magnitudes of the partial derivatives. Only the sign of the derivative can determine the direction of the weight update; the magnitude of the derivative has no effect on the weight update. The size of the weight change is determined by a separate update value. The update value for each weight and bias is increased by a factor `delt_inc` whenever the derivative of the performance function with respect to that weight has the same sign for two successive iterations. The update value is decreased by a factor `delt_dec` whenever the derivative with respect to that weight changes sign from the previous iteration. If the derivative is zero, the update value remains the same. Whenever the weights are oscillating, the weight change is reduced. If the weight continues to change in the same direction for several iterations, the magnitude of the weight change increases. A complete description of the Rprop algorithm is given in [RiBr93].

The following code recreates the previous network and trains it using the Rprop algorithm. The training parameters for `trainrp` are `epochs`, `show`, `goal`, `time`, `min_grad`, `max_fail`, `delt_inc`, `delt_dec`, `delta0`, and `deltamax`. The first eight parameters have been previously discussed. The last two are the initial step size and the maximum step size, respectively. The performance of Rprop is not very sensitive to the settings of the training parameters. For the example below, the training parameters are left at the default values:

```
p = [-1 -1 2 2;0 5 0 5];
t = [-1 -1 1 1];
net = feedforwardnet(3,'trainrp');
net = train(net,p,t);
y = net(p)
```

`rprop` is generally much faster than the standard steepest descent algorithm. It also has the nice property that it requires only a modest increase in memory requirements. You do need to store the update values for each weight and bias, which is equivalent to storage of the gradient.

## Algorithms

`trainrp` can train any network as long as its weight, net input, and transfer functions have derivative functions.

Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables  $X$ . Each variable is adjusted according to the following:

```
dX = deltaX.*sign(gX);
```

where the elements of `deltaX` are all initialized to `delta0`, and `gX` is the gradient. At each iteration the elements of `deltaX` are modified. If an element of `gX` changes sign from one iteration to the next, then the corresponding element of `deltaX` is decreased by `delta_dec`. If an element of `gX` maintains the same sign from one iteration to the next, then the corresponding element of `deltaX` is increased by `delta_inc`. See Riedmiller, M., and H. Braun, "A direct adaptive method for faster backpropagation learning: The RPROP algorithm," *Proceedings of the IEEE International Conference on Neural Networks*, 1993, pp. 586-591.

Training stops when any of these conditions occurs:

- The maximum number of `epochs` (repetitions) is reached.
- The maximum amount of `time` is exceeded.
- Performance is minimized to the `goal`.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

# trainru

Unsupervised random order weight/bias training

## Syntax

```
net.trainFcn = 'trainru'
[net,tr] = train(net,...)
```

## Description

`trainru` is not called directly. Instead it is called by `train` for networks whose `net.trainFcn` property is set to `'trainru'`, thus:

`net.trainFcn = 'trainru'` sets the network `trainFcn` property.

`[net,tr] = train(net,...)` trains the network with `trainru`.

`trainru` trains a network with weight and bias learning rules with incremental updates after each presentation of an input. Inputs are presented in random order.

Training occurs according to `trainru` training parameters, shown here with their default values:

<code>net.trainParam.epochs</code>	1000	Maximum number of epochs to train
<code>net.trainParam.show</code>	25	Epochs between displays (NaN for no displays)
<code>net.trainParam.showCommandLine</code>	false	Generate command-line output
<code>net.trainParam.showWindow</code>	true	Show training GUI
<code>net.trainParam.time</code>	Inf	Maximum time to train in seconds

## Network Use

To prepare a custom network to be trained with `trainru`,

- 1 Set `net.trainFcn` to `'trainru'`. This sets `net.trainParam` to `trainru`'s default parameters.
- 2 Set each `net.inputWeights{i,j}.learnFcn` to a learning function.
- 3 Set each `net.layerWeights{i,j}.learnFcn` to a learning function.
- 4 Set each `net.biases{i}.learnFcn` to a learning function. (Weight and bias learning parameters are automatically set to default values for the given learning function.)

To train the network,

- 1 Set `net.trainParam` properties to desired values.
- 2 Set weight and bias learning parameters to desired values.
- 3 Call `train`.

### **Algorithms**

For each epoch, all training vectors (or sequences) are each presented once in a different random order, with the network and weight and bias values updated accordingly after each individual presentation.

Training stops when any of these conditions is met:

- The maximum number of epochs (repetitions) is reached.

## trains

Sequential order incremental training with learning functions

### Syntax

```
net.trainFcn = 'trains'
[net,tr] = train(net,...)
```

### Description

`trains` is not called directly. Instead it is called by `train` for networks whose `net.trainFcn` property is set to `'trains'`, thus:

`net.trainFcn = 'trains'` sets the network `trainFcn` property.

`[net,tr] = train(net,...)` trains the network with `trains`.

`trains` trains a network with weight and bias learning rules with sequential updates. The sequence of inputs is presented to the network with updates occurring after each time step.

This incremental training algorithm is commonly used for adaptive applications.

Training occurs according to `trains` training parameters, shown here with their default values:

<code>net.trainParam.epochs</code>	1000	Maximum number of epochs to train
<code>net.trainParam.goal</code>	0	Performance goal
<code>net.trainParam.show</code>	25	Epochs between displays (NaN for no displays)
<code>net.trainParam.showCommandLine</code>	false	Generate command-line output
<code>net.trainParam.showWindow</code>	true	Show training GUI
<code>net.trainParam.time</code>	Inf	Maximum time to train in seconds

### Network Use

You can create a standard network that uses `trains` for adapting by calling `perceptron` or `linearlayer`.

To prepare a custom network to adapt with `trains`,

- 1 Set `net.adaptFcn` to `'trains'`. This sets `net.adaptParam` to `trains`'s default parameters.
- 2 Set each `net.inputWeights{i,j}.learnFcn` to a learning function. Set each `net.layerWeights{i,j}.learnFcn` to a learning function. Set each `net.biases{i}.learnFcn` to a learning function. (Weight and bias learning parameters are automatically set to default values for the given learning function.)

To allow the network to adapt,

- 1 Set weight and bias learning parameters to desired values.

**2** Call `adapt`.

See `help perceptron` and `help linearlayer` for adaption examples.

## **Algorithms**

Each weight and bias is updated according to its learning function after each time step in the input sequence.

# trainscg

Scaled conjugate gradient backpropagation

## Syntax

```
net.trainFcn = 'trainscg'
[trainedNet,tr] = train(net,...)
```

## Description

`net.trainFcn = 'trainscg'` sets the network `trainFcn` property.

`[trainedNet,tr] = train(net,...)` trains the network with `trainscg`.

`trainscg` is a network training function that updates weight and bias values according to the scaled conjugate gradient method.

Training occurs according to `trainscg` training parameters, shown here with their default values:

- `net.trainParam.epochs` — Maximum number of epochs to train. The default value is 1000.
- `net.trainParam.show` — Epochs between displays (NaN for no displays). The default value is 25.
- `net.trainParam.showCommandLine` — Generate command-line output. The default value is `false`.
- `net.trainParam.showWindow` — Show training GUI. The default value is `true`.
- `net.trainParam.goal` — Performance goal. The default value is 0.
- `net.trainParam.time` — Maximum time to train in seconds. The default value is `inf`.
- `net.trainParam.min_grad` — Minimum performance gradient. The default value is `1e-6`.
- `net.trainParam.max_fail` — Maximum validation failures. The default value is 6.
- `net.trainParam.mu` — Marquardt adjustment parameter. The default value is 0.005.
- `net.trainParam.sigma` — Determine change in weight for second derivative approximation. The default value is `5.0e-5`.
- `net.trainParam.lambda` — Parameter for regulating the indefiniteness of the Hessian. The default value is `5.0e-7`.

## Examples

### Train Network with 'trainscg'

This example shows how to solve a problem consisting of inputs `p` and targets `t` by using a network.

```
p = [0 1 2 3 4 5];
t = [0 0 0 1 1 1];
```

A two-layer feed-forward network with two hidden neurons and this training function is created.

```
net = feedforwardnet(2, 'trainscg');
```

Here the network is trained and tested.

```
net = train(net,p,t);  
a = net(p)
```

See `help feedforwardnet` and `help cascadeforwardnet` for other examples.

## Input Arguments

### **net** — Input network

matrix

Input network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

## Output Arguments

### **trainedNet** — Trained network

network

Trained network, returned as a network object.

### **tr** — Training record

structure

Training record (`epoch` and `perf`), returned as a structure whose fields depend on the network training function (`net.NET.trainFcn`). It can include fields such as:

- Training, data division, and performance functions and parameters
- Data division indices for training, validation and test sets
- Data division masks for training validation and test sets
- Number of epochs (`num_epochs`) and the best epoch (`best_epoch`).
- A list of training state names (`states`).
- Fields for each state name recording its value throughout training
- Performances of the best network (`best_perf`, `best_vperf`, `best_tperf`)

## More About

### Network Use

You can create a standard network that uses `trainscg` with `feedforwardnet` or `cascadeforwardnet`. To prepare a custom network to be trained with `trainscg`,

- 1 Set `net.trainFcn` to `'trainscg'`. This sets `net.trainParam` to `trainscg`'s default parameters.
- 2 Set `net.trainParam` properties to desired values.

In either case, calling `train` with the resulting network trains the network with `trainscg`.

## Algorithms

`trainscg` can train any network as long as its weight, net input, and transfer functions have derivative functions. Backpropagation is used to calculate derivatives of performance `perf` with respect to the weight and bias variables  $X$ .

The scaled conjugate gradient algorithm is based on conjugate directions, as in `traincgp`, `traincgf`, and `traincgb`, but this algorithm does not perform a line search at each iteration. See Moller (*Neural Networks*, Vol. 6, 1993, pp. 525-533) for a more detailed discussion of the scaled conjugate gradient algorithm.

Training stops when any of these conditions occurs:

- The maximum number of epochs (repetitions) is reached.
- The maximum amount of `time` is exceeded.
- Performance is minimized to the `goal`.
- The performance gradient falls below `min_grad`.
- Validation performance (validation error) has increased more than `max_fail` times since the last time it decreased (when using validation).

## tribas

Triangular basis transfer function

### Graph and Symbol

Triangular Basis Function

### Syntax

`A = tribas(N,FP)`

### Description

`tribas` is a neural transfer function. Transfer functions calculate a layer's output from its net input.

`A = tribas(N,FP)` takes `N` and optional function parameters,

<code>N</code>	S-by-Q matrix of net input (column) vectors
<code>FP</code>	Struct of function parameters (ignored)

and returns `A`, an S-by-Q matrix of the triangular basis function applied to each element of `N`.

`info = tribas('code')` can take the following forms to return specific information:

`tribas('name')` returns the name of this function.

`tribas('output',FP)` returns the [min max] output range.

`tribas('active',FP)` returns the [min max] active input range.

`tribas('fullderiv')` returns 1 or 0, depending on whether `dA_dN` is S-by-S-by-Q or S-by-Q.

`tribas('fpnames')` returns the names of the function parameters.

`tribas('fpdefaults')` returns the default function parameters.

### Examples

Here you create a plot of the `tribas` transfer function.

```
n = -5:0.1:5;  
a = tribas(n);  
plot(n,a)
```

Assign this transfer function to layer *i* of a network.

```
net.layers{i}.transferFcn = 'tribas';
```

## Algorithms

```
a = tribas(n) = 1 - abs(n), if -1 <= n <= 1  
              = 0, otherwise
```

## Version History

Introduced before R2006a

## tritop

Triangle layer topology function

### Syntax

```
pos = tritop(dimensions)
```

### Description

`tritop` calculates neuron positions for layers whose neurons are arranged in an N-dimensional triangular grid.

`pos = tritop(dimensions)` takes one argument:

<code>dimensions</code>	Row vector of dimension sizes
-------------------------	-------------------------------

and returns an N-by-S matrix of N coordinate vectors, where N is the number of dimensions and S is the product of dimensions.

### Examples

#### Display Layer with Triangular Pattern

This example shows how to display a two-dimensional layer with 40 neurons arranged in an 8-by-5 triangular grid.

```
pos = tritop([8 5]);  
plotsom(pos)
```

## Version History

Introduced in R2010b

## unconfigure

Unconfigure network inputs and outputs

### Syntax

```
unconfigure(net)
unconfigure(net, 'inputs', i)
unconfigure(net, 'outputs', i)
```

### Description

`unconfigure(net)` returns a network with its input and output sizes set to 0, its input and output processing settings and related weight initialization settings set to values consistent with zero-sized signals. The new network will be ready to be reconfigured for data of the same or different dimensions than it was previously configured for.

`unconfigure(net, 'inputs', i)` unconfigures the inputs indicated by the indices `i`. If no indices are specified, all inputs are unconfigured.

`unconfigure(net, 'outputs', i)` unconfigures the outputs indicated by the indices `i`. If no indices are specified, all outputs are unconfigured.

### Examples

#### Configure and Unconfigure Network

This example shows how to configure a network for a simple fitting problem, and then unconfigure the network.

```
[x,t] = simplefit_dataset;
net = fitnet(10);
view(net)
```

```
net = configure(net,x,t);  
view(net)
```

```
net = unconfigure(net);  
view(net)
```

## Version History

Introduced in R2010b

### See Also

`configure` | `isconfigured`

## vec2ind

Convert vectors to indices

### Syntax

```
[ind,N] = vec2ind(vec)
```

### Description

`[ind,N] = vec2ind(vec)` takes a matrix of vectors, each containing a single 1 and returns the indices of the ones, `ind`, and the number of rows in `vec`, `N`.

`ind2vec` and `vec2ind` allow indices to be represented either by themselves or as vectors containing a 1 in the row of the index they represent.

### Examples

#### Convert Three Vectors to Indices and Back

This example shows how to convert three vectors to indices and back, using both the `ind2vec` and `vec2ind` functions.

Define three vector with all zeros in the last row and convert it to indices.

```
vec = [0 0 1 0; 1 0 0 0; 0 1 0 0]'  
[ind,n] = vec2ind(vec)
```

```
vec =  
    0     1     0  
    0     0     1  
    1     0     0  
    0     0     0
```

```
ind =  
    3     1     2
```

```
n =  
    4
```

Convert the indices to vector, while preserving the number of rows.

```
vec2 = full(ind2vec(ind,n))
```

```
vec2 =  
    0     1     0  
    0     0     1
```

$$\begin{matrix} 1 & 0 & 0 \\ 0 & 0 & 0 \end{matrix}$$

## Input Arguments

### **vec** — Matrix of vectors

matrix

Vector representation of the indices, specified as a matrix of vectors, each containing a single 1.

## Output Arguments

### **ind** — Indices

row vector

Indices, returned as a row vector.

### **N** — Number of rows

scalar

Number of rows of the input matrix, returned as a scalar.

## Version History

Introduced before R2006a

# view

View shallow neural network

## Syntax

```
view(net)
```

## Description

`view(net)` opens a window that shows your shallow neural network (specified by `net`) as a graphical diagram.

---

**Tip** To visualize deep learning networks, see **Deep Network Designer**.

---

## Examples

### View Neural Network

This example shows how to view the diagram of a pattern recognition network.

```
[x,t] = iris_dataset;  
net = patternnet;  
net = configure(net,x,t);  
view(net)
```

## Input Arguments

**net** — Neural network  
network object

Neural network, specified as a network object. To create a network object, use for example, `feedforwardnet` or `narxnet`.

## Version History

Introduced in R2008a

## See Also

# Neural Net Fitting

Solve fitting problem using two-layer feed-forward networks

## Description

The **Neural Net Fitting** app lets you create, visualize, and train a two-layer feed-forward network to solve data fitting problems.

Using this app, you can:

- Import data from file, the MATLAB workspace, or use one of the example data sets.
- Split data into training, validation, and test sets.
- Define and train a neural network.
- Evaluate network performance using mean squared error and regression analysis.
- Analyze results using visualization plots, such as regression fit or histogram of errors.
- Generate MATLAB scripts to reproduce results and customize the training process.
- Generate functions suitable for deployment with MATLAB Compiler and MATLAB Coder tools, and export to Simulink for use with Simulink Coder.

---

**Note** To interactively build, visualize, and train deep learning neural networks, use the **Deep Network Designer** app. For more information, see “Get Started with Deep Network Designer”.

---

Two-layer feedforward network with sigmoid hidden neurons and linear output neurons, suitable for regression tasks.

**Model Summary**

Train a neural network to map predictors to continuous responses.

**Data**  
 Predictors: bodyfatInputs - [13x252 double]  
 Responses: bodyfatTargets - [1x252 double]  
 bodyfatInputs: double array of 252 observations with 13 features.  
 bodyfatTargets: double array of 252 observations with 1 features.

**Algorithm**  
 Data division: Random  
 Training algorithm: Levenberg-Marquardt  
 Performance: Mean squared error

**Training Results**

## Neural Net Clustering

Solve clustering problem using self-organizing map (SOM) networks

### Description

The **Neural Net Clustering** app lets you create, visualize, and train self-organizing map networks to solve clustering problems.

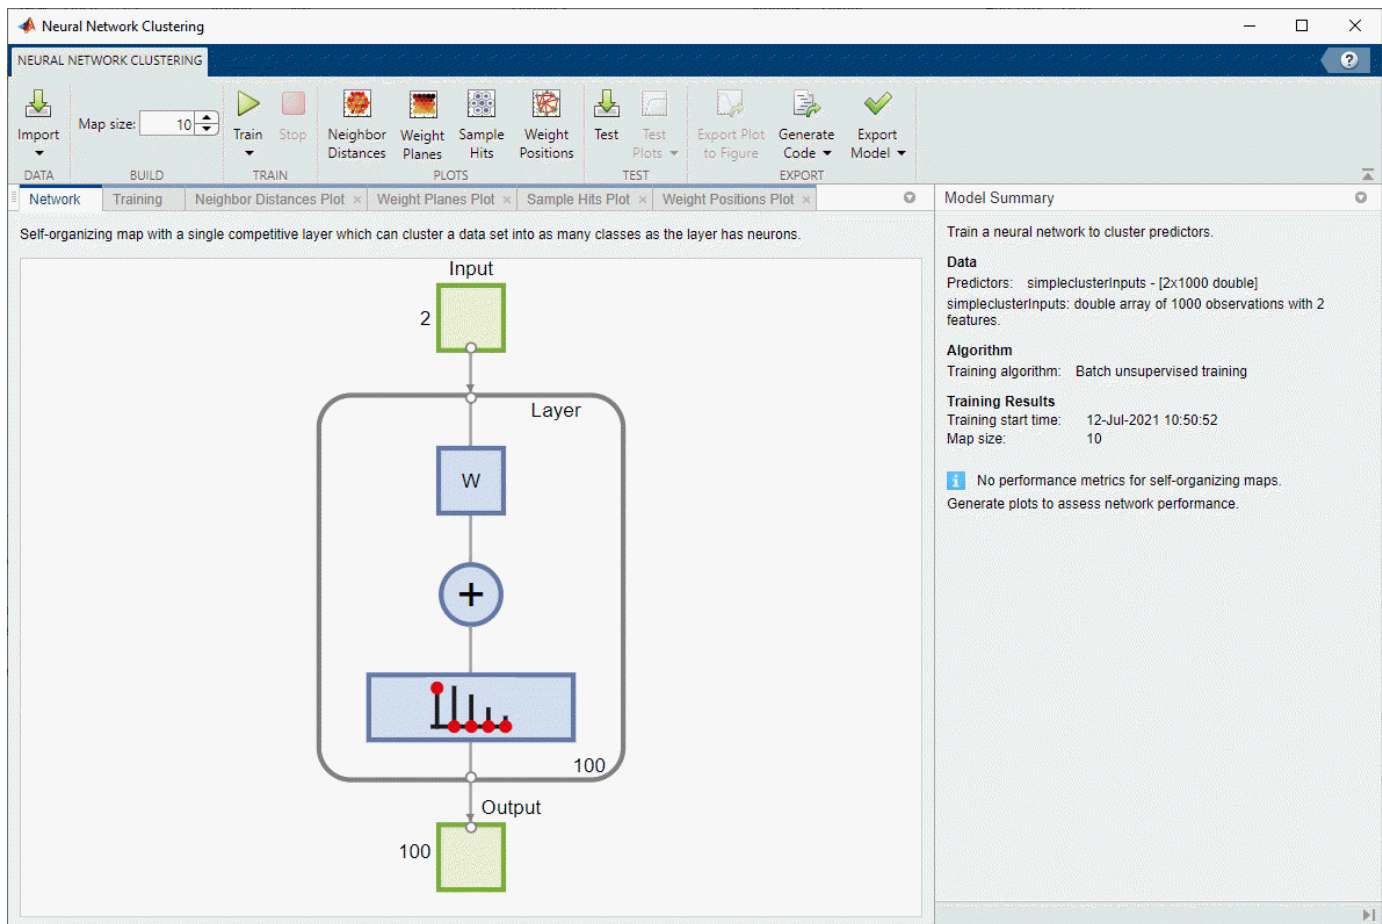

Using this app, you can:

- Import data from file, the MATLAB workspace, or use one of the example data sets.
- Define and train a neural network.
- Analyze results using visualization plots, such as neighbor distance, weight planes, sample hits, and weight position.
- Generate MATLAB scripts to reproduce results and customize the training process.
- Generate functions suitable for deployment with MATLAB Compiler and MATLAB Coder tools, and export to Simulink for use with Simulink Coder.

---

**Note** To interactively build, visualize, and train deep learning neural networks, use the **Deep Network Designer** app. For more information, see “Get Started with Deep Network Designer”.

# Neural Net Pattern Recognition

Solve pattern recognition problem using two-layer feed-forward networks

## Description

The **Neural Net Pattern Recognition** app lets you create, visualize, and train two-layer feed-forward networks to solve data classification problems.

Using this app, you can:

- Import data from file, the MATLAB workspace, or use one of the example data sets.
- Split data into training, validation, and test sets.
- Define and train a neural network.
- Evaluate network performance using cross-entropy error and misclassification error.
- Analyze results using visualization plots, such as confusion matrices and receiver operating characteristic curves.
- Generate MATLAB scripts to reproduce results and customize the training process.
- Generate functions suitable for deployment with MATLAB Compiler and MATLAB Coder tools, and export to Simulink for use with Simulink Coder.

---

**Note** To interactively build, visualize, and train deep learning neural networks, use the **Deep Network Designer** app. For more information, see “Get Started with Deep Network Designer”.

---

Two-layer feedforward network with sigmoid hidden neurons and softmax output neurons, suitable for classification tasks.

## Neural Net Time Series

Solve nonlinear time series problem using dynamic neural networks

### Description

The **Neural Net Time Series** app lets you create, visualize, and train dynamic neural networks to solve three different kinds of nonlinear time series problems.

Using this app, you can:

- Create three types of neural networks: NARX networks, NAR networks, and nonlinear input-output networks.
- Import data from file, the MATLAB workspace, or use one of the example data sets.
- Split data into training, validation, and test sets.
- Define and train a neural network.
- Evaluate network performance using mean squared error and regression analysis.
- Analyze results using visualization plots, such as autocorrelation plots or a histogram of errors.
- Generate MATLAB scripts to reproduce results and customize the training process.
- Generate functions suitable for deployment with MATLAB Compiler and MATLAB Coder tools, and export to Simulink for use with Simulink Coder.

# matlab.io.datastore.MiniBatchable class

**Package:** matlab.io.datastore

Add mini-batch support to datastore

## Description

`matlab.io.datastore.MiniBatchable` is an abstract mixin class that adds support for mini-batches to your custom datastore for use with Deep Learning Toolbox. A mini-batch datastore contains training and test data sets for use in Deep Learning Toolbox training, prediction, and classification.

To use this mixin class, you must inherit from the `matlab.io.datastore.MiniBatchable` class in addition to inheriting from the `matlab.io.Datastore` base class. Type the following syntax as the first line of your class definition file:

```
classdef MyDatastore < matlab.io.Datastore & ...
    matlab.io.datastore.MiniBatchable
    ...
end
```

To add support for mini-batches to your datastore:

- Inherit from an additional class `matlab.io.datastore.MiniBatchable`
- Define two additional properties: `MiniBatchSize` and `NumObservations`.

For more details and steps to create your custom mini-batch datastore to optimize performance during training, prediction, and classification, see “Develop Custom Mini-Batch Datastore”.

## Properties

### MiniBatchSize — Number of observations in each batch

positive integer

Number of observations that are returned in each batch, or call of the `read` function. For training, prediction, and classification, the `MiniBatchSize` property is set to the mini-batch size defined in `trainingOptions`.

#### Attributes:

Abstract	true
Access	Public

### NumObservations — Total number of observations in the datastore

positive integer

Total number of observations contained within the datastore. This number of observations is the length of one training epoch.

#### Attributes:

Abstract	true
SetAccess	Protected
ReadAccess	Public

## Attributes

Abstract	true
Sealed	false

For information on class attributes, see “Class Attributes”.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects.

## Examples

### Train Network Using Out-of-Memory Sequence Data

This example shows how to train a deep learning network on out-of-memory sequence data by transforming and combining datastores.

A transformed datastore transforms or processes data read from an underlying datastore. You can use a transformed datastore as a source of training, validation, test, and prediction data sets for deep learning applications. Use transformed datastores to read out-of-memory data or to perform specific preprocessing operations when reading batches of data. When you have separate datastores containing predictors and labels, you can combine them so you can input the data into a deep learning network.

When training the network, the software creates mini-batches of sequences of the same length by padding, truncating, or splitting the input data. For in-memory data, the `trainingOptions` function provides options to pad and truncate input sequences, however, for out-of-memory data, you must pad and truncate the sequences manually.

### Load Training Data

Load the Japanese Vowels data set as described in [1] and [2]. The zip file `japaneseVowels.zip` contains sequences of varying length. The sequences are divided into two folders, `Train` and `Test`, which contain training sequences and test sequences, respectively. In each of these folders, the sequences are divided into subfolders, which are numbered from 1 to 9. The names of these subfolders are the label names. A MAT file represents each sequence. Each sequence is a matrix with 12 rows, with one row for each feature, and a varying number of columns, with one column for each time step. The number of rows is the sequence dimension and the number of columns is the sequence length.

Unzip the sequence data.

```
filename = "japaneseVowels.zip";  
outputFolder = fullfile(tempdir,"japaneseVowels");  
unzip(filename,outputFolder);
```

For the training predictors, create a file datastore and specify the read function to be the `load` function. The `load` function, loads the data from the MAT-file into a structure array. To read files from the subfolders in the training folder, set the `'IncludeSubfolders'` option to `true`.

```
folderTrain = fullfile(outputFolder,"Train");
fdsPredictorTrain = fileDatastore(folderTrain, ...
    'ReadFcn',@load, ...
    'IncludeSubfolders',true);
```

Preview the datastore. The returned struct contains a single sequence from the first file.

```
preview(fdsPredictorTrain)

ans = struct with fields:
    X: [12x20 double]
```

For the labels, create a file datastore and specify the read function to be the `readLabel` function, defined at the end of the example. The `readLabel` function extracts the label from the subfolder name.

```
classNames = string(1:9);
fdsLabelTrain = fileDatastore(folderTrain, ...
    'ReadFcn',@(filename) readLabel(filename,classNames), ...
    'IncludeSubfolders',true);
```

Preview the datastore. The output corresponds to the label of the first file.

```
preview(fdsLabelTrain)

ans = categorical
    1
```

## Transform and Combine Datastores

To input the sequence data from the datastore of predictors to a deep learning network, the mini-batches of the sequences must have the same length. Transform the datastore using the `padSequence` function, defined at the end of the datastore, that pads or truncates the sequences to have length 20.

```
sequenceLength = 20;
tdsTrain = transform(fdsPredictorTrain,@(data) padSequence(data,sequenceLength));
```

Preview the transformed datastore. The output corresponds to the padded sequence from the first file.

```
X = preview(tdsTrain)

X = 1x1 cell array
    {12x20 double}
```

To input both the predictors and labels from both datastores into a deep learning network, combine them using the `combine` function.

```
cdsTrain = combine(tdsTrain,fdsLabelTrain);
```

Preview the combined datastore. The datastore returns a 1-by-2 cell array. The first element corresponds to the predictors. The second element corresponds to the label.

```
preview(cdsTrain)

ans = 1x2 cell array
      {12x20 double}    {[1]}
```

### Define LSTM Network Architecture

Define the LSTM network architecture. Specify the number of features of the input data as the input size. Specify an LSTM layer with 100 hidden units and to output the last element of the sequence. Finally, specify a fully connected layer with output size equal to the number of classes, followed by a softmax layer and a classification layer.

```
numFeatures = 12;
numClasses = numel(classNames);
numHiddenUnits = 100;

layers = [ ...
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits,'OutputMode','last')
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

Specify the training options. Set the solver to 'adam' and 'GradientThreshold' to 2. Set the mini-batch size to 27 and set the maximum number of epochs to 75. The datastores do not support shuffling, so set 'Shuffle' to 'never'.

Because the mini-batches are small with short sequences, the CPU is better suited for training. Set 'ExecutionEnvironment' to 'cpu'. To train on a GPU, if available, set 'ExecutionEnvironment' to 'auto' (the default value).

```
miniBatchSize = 27;

options = trainingOptions('adam', ...
    'ExecutionEnvironment','cpu', ...
    'MaxEpochs',75, ...
    'MiniBatchSize',miniBatchSize, ...
    'GradientThreshold',2, ...
    'Shuffle','never',...
    'Verbose',0, ...
    'Plots','training-progress');
```

Train the LSTM network with the specified training options.

```
net = trainNetwork(cdsTrain,layers,options);
```

## Test the Network

Create a transformed datastore containing the held-out test data using the same steps as for the training data.

```
folderTest = fullfile(outputFolder, "Test");

fdsPredictorTest = fileDatastore(folderTest, ...
    'ReadFcn', @load, ...
    'IncludeSubfolders', true);
tdsTest = transform(fdsPredictorTest, @(data) padSequence(data, sequenceLength));
```

Make predictions on the test data using the trained network.

```
YPred = classify(net, tdsTest, 'MiniBatchSize', miniBatchSize);
```

Calculate the classification accuracy on the test data. To get the labels of the test set, create a file datastore with the read function `readLabel` and specify to include subfolders. Specify that the outputs are vertically concatenateable by setting the `'UniformRead'` option to `true`.

```
fdsLabelTest = fileDatastore(folderTest, ...
    'ReadFcn', @(filename) readLabel(filename, classNames), ...
    'IncludeSubfolders', true, ...
    'UniformRead', true);
YTest = readall(fdsLabelTest);

accuracy = mean(YPred == YTest)

accuracy = 0.9351
```

## Functions

The `readLabel` function extracts the label from the specified filename over the categories in `classNames`.

```
function label = readLabel(filename,classNames)

filepath = fileparts(filename);
[~,label] = fileparts(filepath);

label = categorical(string(label),classNames);

end
```

The `padSequence` function pads or truncates the sequence in `data.X` to have the specified sequence length and returns the result in a 1-by-1 cell.

```
function sequence = padSequence(data,sequenceLength)

sequence = data.X;
[C,S] = size(sequence);

if S < sequenceLength
    padding = zeros(C,sequenceLength-S);
    sequence = [sequence padding];
else
    sequence = sequence(:,1:sequenceLength);
end

sequence = {sequence};

end
```

## Version History

### Introduced in R2018a

### **R2019a: `matlab.io.datastore.Minibatchable` is not recommended for custom image preprocessing**

*Not recommended starting in R2019a*

Starting in R2019a, `matlab.io.datastore.Minibatchable` is not recommended for custom image processing. Use the `transform` and `combine` functions with built-in datastores instead. For more information, see “Preprocess Images for Deep Learning”.

## read

**Class:** `matlab.io.datastore.MiniBatchable`

**Package:** `matlab.io.datastore`

(Not recommended) Read data from custom mini-batch datastore

---

**Note** The `read` method of `matlab.io.datastore.MiniBatchable` is not recommended. For more information, see [Compatibility Considerations](#).

---

### Syntax

```
data = read(ds)
[data,info] = read(ds)
```

### Description

`data = read(ds)` returns data from a mini-batch datastore. Subsequent calls to the `read` function continue reading from the endpoint of the previous call.

`[data,info] = read(ds)` also returns information about the extracted data in `info`, including metadata.

### Input Arguments

**mbds — Mini-batch datastore**

`datastore` | `custom MiniBatchable datastore` | ...

Mini-batch datastore, specified as a built-in datastore or custom mini-batch datastore. For more information, see “Datastores for Deep Learning”.

### Output Arguments

**data — Output data**

`table`

Output data, returned as a table with `MiniBatchSize` number of rows. For the last mini-batch of data in the datastore, if `NumObservations` is not evenly divisible by `MiniBatchSize`, then `data` should contain the remaining observations in the datastore (a partial batch smaller than `MiniBatchSize`).

The table should have two columns, with predictors in the first column and responses in the second column.

**info — Information about read data**

`structure array`

Information about read data, returned as a structure array.

## Attributes

Hidden true

To learn about attributes of methods, see Method Attributes.

## Version History

### Introduced in R2018a

#### **R2019a: read is not recommended**

*Not recommended starting in R2019a*

Before R2018a, to perform custom image preprocessing for training deep learning networks, you had to specify a custom read function using the `readFcn` property of `imageDatastore`. However, reading files using a custom read function was slow because `imageDatastore` did not prefetch files.

In R2018a, four classes including `matlab.io.datastore.MiniBatchable` were introduced as a solution to perform custom image preprocessing with support for prefetching, shuffling, and parallel training. Implementing a custom mini-batch datastore using `matlab.io.datastore.MiniBatchable` has several challenges and limitations.

- In addition to specifying the preprocessing operations, you must also define properties and methods to support reading data in batches, reading data by index, and partitioning and shuffling data.
- You must specify a value for the `NumObservations` property, but this value may be ill-defined or difficult to define in real-world applications.
- Custom mini-batch datastores are not flexible enough to support common deep learning workflows, such as deployed workflows using GPU Coder.

Starting in R2019a, built-in datastores natively support prefetch, shuffling, and parallel training when reading batches of data. The `transform` function is the preferred way to perform custom data preprocessing, or transformations. The `combine` function is the preferred way to concatenate read data from multiple datastores, including transformed datastores. Concatenated data can serve as the network inputs and expected responses for training deep learning networks. The `transform` and `combine` functions have several advantages over `matlab.io.datastore.MiniBatchable`.

- The functions enable data preprocessing and concatenation for all types of datastores, including `imageDatastore`.
- The `transform` function only requires you to define the data processing pipeline.
- When used on a deterministic datastore, the functions support `all` data types and MapReduce.
- The functions support deployed workflows.

---

**Note** The recommended solution to transform data with basic image preprocessing operations, including resizing, rotation, and reflection, is `augmentedImageDatastore`. For more information, see “Preprocess Images for Deep Learning”.

---

There are no plans to remove the `read` method of `matlab.io.datastore.MiniBatchable` at this time.

## readByIndex

**Class:** matlab.io.datastore.BackgroundDispatchable

**Package:** matlab.io.datastore

(Not recommended) Return observations specified by index from datastore

---

**Note** readByIndex is not recommended. For more information, see Compatibility Considerations.

---

### Syntax

```
[data,info] = readByIndex(ds,ind)
```

### Description

[data,info] = readByIndex(ds,ind) returns a subset of observations in a datastore, ds. The desired observations are specified by indices, ind.

### Input Arguments

**ds** — Input datastore

Datastore object

Input datastore, specified as a Datastore object.

**ind** — Indices

vector of positive integers

Indices of observations, specified as a vector of positive integers.

### Output Arguments

**data** — Observations from datastore

table

Observations from the datastore, returned as a table or an array according to the read method of the datastore. For example, when ds is a custom mini-batch datastore, then data is a table with the same format as returned by the read (MiniBatchable) method.

**info** — Information about read data

structure array

Information about read data, returned as a structure array. The structure array can contain the following fields.

Field Name	Description
Filename	Filename is a fully resolved path containing the path string, name of the file, and file extension.

Field Name	Description
FileSize	Total file size, in bytes. For MAT-files, FileSize is the total number of key-value pairs in the file.

## Attributes

## Tips

- You must implement the `readByIndex` method by deriving a subclass from the `matlab.io.datastore.BackgroundDispatchable` class.

## Version History

### Introduced in R2018a

#### **R2019a: readByIndex is not recommended**

*Not recommended starting in R2019a*

Before R2018a, to perform custom image preprocessing for training deep learning networks, you had to specify a custom read function using the `readFcn` property of `imageDatastore`. However, reading files using a custom read function was slow because `imageDatastore` did not prefetch files.

In R2018a, four classes including `matlab.io.datastore.Minibatchable` and `matlab.io.datastore.BackgroundDispatchable` were introduced as a solution to perform custom image preprocessing with support for prefetching, shuffling, and parallel training. Implementing a custom mini-batch datastore using `matlab.io.datastore.Minibatchable` has several challenges and limitations.

- In addition to specifying the preprocessing operations, you must also define properties and methods to support reading data in batches, reading data by index, and partitioning and shuffling data.
- You must specify a value for the `NumObservations` property, but this value may be ill-defined or difficult to define in real-world applications.
- Custom mini-batch datastores are not flexible enough to support common deep learning workflows, such as deployed workflows using GPU Coder.

Starting in R2019a, datastores natively support prefetch, shuffling, and parallel training when reading batches of data. The `transform` function is the preferred way to perform custom data preprocessing, or transformations. The `combine` function is the preferred way to concatenate read data from multiple datastores, including transformed datastores. Concatenated data can serve as the network inputs and expected responses for training deep learning networks. The `transform` and `combine` functions have several advantages over `matlab.io.datastore.Minibatchable` and `matlab.io.datastore.BackgroundDispatchable`.

- The functions enable data preprocessing and concatenation for all types of datastores, including `imageDatastore`.

- The `transform` function only requires you to define the data processing pipeline.
- When used on a deterministic datastore, the functions support all data types and MapReduce.
- The functions support deployed workflows.

---

**Note** The recommended solution to transform data with basic image preprocessing operations, including resizing, rotation, and reflection, is `augmentedImageDatastore`. For more information, see “Preprocess Images for Deep Learning”.

---

There are no plans to remove `matlab.io.datastore.BackgroundDispatchable` class or the `readByIndex` method at this time.

# matlab.io.datastore.PartitionableByIndex class

**Package:** matlab.io.datastore

(Not recommended) Add parallelization support to datastore

---

**Note** matlab.io.datastore.PartitionableByIndex is not recommended. For more information, see Compatibility Considerations.

---

## Description

matlab.io.datastore.PartitionableByIndex is an abstract mixin class that adds parallelization support to your custom datastore for use with Deep Learning Toolbox. This class requires Parallel Computing Toolbox.

To use this mixin class, you must inherit from the matlab.io.datastore.PartitionableByIndex class in addition to inheriting from the matlab.io.Datastore base class. Type the following syntax as the first line of your class definition file:

```
classdef MyDatastore < matlab.io.Datastore & ...
    matlab.io.datastore.PartitionableByIndex
    ...
end
```

To add support for parallel processing to your custom datastore, you must:

- Inherit from an additional class matlab.io.datastore.PartitionableByIndex
- Define the additional method: partitionByIndex

For more details and steps to create your custom datastore with parallel processing support, see “Develop Custom Mini-Batch Datastore”.

## Methods

partitionByIndex (Not recommended) Partition datastore according to indices

## Attributes

Abstract	true

## partitionByIndex

**Class:** matlab.io.datastore.PartitionableByIndex

**Package:** matlab.io.datastore

(Not recommended) Partition datastore according to indices

---

**Note** partitionByIndex is not recommended. For more information, see Compatibility Considerations.

---

### Syntax

```
ds2 = partitionByIndex(ds,ind)
```

### Description

`ds2 = partitionByIndex(ds,ind)` partitions a subset of observations in a datastore, `ds`, into a new datastore, `ds2`. The desired observations are specified by indices, `ind`.

### Input Arguments

**ds — Input datastore**

Datastore object

Input datastore, specified as a Datastore object.

**ind — Indices**

vector of positive integers

Indices of observations, specified as a vector of positive integers.

### Output Arguments

**ds2 — Partitioned datastore**

Datastore object

Partitioned datastore, returned as a Datastore object.

### Attributes

# trainAutoencoder

Train an autoencoder

## Syntax

```
autoenc = trainAutoencoder(X)
autoenc = trainAutoencoder(X,hiddenSize)
autoenc = trainAutoencoder( ____,Name,Value)
```

## Description

`autoenc = trainAutoencoder(X)` returns an autoencoder, `autoenc`, trained using the training data in `X`.

`autoenc = trainAutoencoder(X,hiddenSize)` returns an autoencoder `autoenc`, with the hidden representation size of `hiddenSize`.

`autoenc = trainAutoencoder( ____,Name,Value)` returns an autoencoder `autoenc`, for any of the above input arguments with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the sparsity proportion or the maximum number of training iterations.

## Examples

### Train Sparse Autoencoder

Load the sample data.

```
X = abalone_dataset;
```

`X` is an 8-by-4177 matrix defining eight attributes for 4177 different abalone shells: sex (M, F, and I (for infant)), length, diameter, height, whole weight, shucked weight, viscera weight, shell weight. For more information on the dataset, type `help abalone_dataset` in the command line.

Train a sparse autoencoder with default settings.

```
autoenc = trainAutoencoder(X);
```

Network Diagram

**Training Results**  
Training finished: Reached minimum gradient ✓

**Training Progress**

Unit	Initial Value	Stopped Value	Target Value
Epoch	0	721	1000
Elapsed Time	-	00:00:14	-
Performance	1.47	0.049	0

 Training: Scaled Conjugate Gradient `trainscg`  
 Performance: Mean Squared Error with L2 and Sparsity Regularizers  
 Calculations: MEX

**Training Plots**  
Performance

Reconstruct the abalone shell ring data using the trained autoencoder.

```
XReconstructed = predict(autoenc,X);
```

Compute the mean squared reconstruction error.

```
mseError = mse(X-XReconstructed)
```

```
mseError = 0.0167
```

### Train Autoencoder with Specified Options

Load the sample data.

```
X = abalone_dataset;
```

X is an 8-by-4177 matrix defining eight attributes for 4177 different abalone shells: sex (M, F, and I (for infant)), length, diameter, height, whole weight, shucked weight, viscera weight, shell weight. For more information on the dataset, type `help abalone_dataset` in the command line.

Train a sparse autoencoder with hidden size 4, 400 maximum epochs, and linear transfer function for the decoder.

```
autoenc = trainAutoencoder(X,4,'MaxEpochs',400,...  
'DecoderTransferFunction','purelin');
```

Network Diagram

Reconstruct the abalone shell ring data using the trained autoencoder.

```
XReconstructed = predict(autoenc,X);
```

Compute the mean squared reconstruction error.

```
mseError = mse(X-XReconstructed)
```

```
mseError = 0.0050
```

## Reconstruct Observations Using Sparse Autoencoder

Generate the training data.

```
rng(0,'twister'); % For reproducibility
n = 1000;
r = linspace(-10,10,n)';
x = 1 + r*5e-2 + sin(r)./r + 0.2*randn(n,1);
```

Train autoencoder using the training data.

```
hiddenSize = 25;
autoenc = trainAutoencoder(x',hiddenSize,...
    'EncoderTransferFunction','satlin',...
    'DecoderTransferFunction','purelin',...
    'L2WeightRegularization',0.01,...
    'SparsityRegularization',4,...
    'SparsityProportion',0.10);
```

Network Diagram

**Training Results**  
Training finished: Reached minimum gradient ✓

**Training Plots**  
 Performance

Generate the test data.

```
n = 1000;
r = sort(-10 + 20*rand(n,1));
xtest = 1 + r*5e-2 + sin(r)./r + 0.4*randn(n,1);
```

Predict the test data using the trained autoencoder, `autoenc`.

```
xReconstructed = predict(autoenc,xtest');
```

Plot the actual test data and the predictions.

```
figure;
plot(xtest,'r. ');
hold on
plot(xReconstructed,'go');
```

## Reconstruct Handwritten Digit Images Using Sparse Autoencoder

Load the training data.

```
XTrain = digitTrainCellArrayData;
```

The training data is a 1-by-5000 cell array, where each cell containing a 28-by-28 matrix representing a synthetic image of a handwritten digit.

Train an autoencoder with a hidden layer containing 25 neurons.

```
hiddenSize = 25;
autoenc = trainAutoencoder(XTrain,hiddenSize,...
    'L2WeightRegularization',0.004,...
    'SparsityRegularization',4,...
    'SparsityProportion',0.15);
```

Load the test data.

```
XTest = digitTestCellArrayData;
```

The test data is a 1-by-5000 cell array, with each cell containing a 28-by-28 matrix representing a synthetic image of a handwritten digit.

Reconstruct the test image data using the trained autoencoder, `autoenc`.

```
xReconstructed = predict(autoenc,XTest);
```

View the actual test data.

```
figure;  
for i = 1:20  
    subplot(4,5,i);  
    imshow(XTest{i});  
end
```

View the reconstructed test data.

```
figure;  
for i = 1:20  
    subplot(4,5,i);  
    imshow(xReconstructed{i});  
end
```

## Input Arguments

### X — Training data

matrix | cell array of image data

Training data, specified as a matrix of training samples or a cell array of image data. If X is a matrix, then each column contains a single sample. If X is a cell array of image data, then the data in each cell must have the same number of dimensions. The image data can be pixel intensity data for gray images, in which case, each cell contains an  $m$ -by- $n$  matrix. Alternatively, the image data can be RGB data, in which case, each cell contains an  $m$ -by- $n$ -3 matrix.

Data Types: `single` | `double` | `cell`

### hiddenSize — Size of hidden representation of the autoencoder

10 (default) | positive integer value

Size of hidden representation of the autoencoder, specified as a positive integer value. This number is the number of neurons in the hidden layer.

Data Types: `single` | `double`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'EncoderTransferFunction', 'satlin', 'L2WeightRegularization', 0.05 specifies the transfer function for the encoder as the positive saturating linear transfer function and the L2 weight regularization as 0.05.

**EncoderTransferFunction — Transfer function for the encoder**

'logsig' (default) | 'satlin'

Transfer function for the encoder, specified as the comma-separated pair consisting of 'EncoderTransferFunction' and one of the following.

Transfer Function Option	Definition
'logsig'	Logistic sigmoid function $f(z) = \frac{1}{1 + e^{-z}}$
'satlin'	Positive saturating linear transfer function $f(z) = \begin{cases} 0, & \text{if } z \leq 0 \\ z, & \text{if } 0 < z < 1 \\ 1, & \text{if } z \geq 1 \end{cases}$

Example: 'EncoderTransferFunction', 'satlin'

**DecoderTransferFunction — Transfer function for the decoder**

'logsig' (default) | 'satlin' | 'purelin'

Transfer function for the decoder, specified as the comma-separated pair consisting of 'DecoderTransferFunction' and one of the following.

Transfer Function Option	Definition
'logsig'	Logistic sigmoid function $f(z) = \frac{1}{1 + e^{-z}}$
'satlin'	Positive saturating linear transfer function $f(z) = \begin{cases} 0, & \text{if } z \leq 0 \\ z, & \text{if } 0 < z < 1 \\ 1, & \text{if } z \geq 1 \end{cases}$
'purelin'	Linear transfer function $f(z) = z$

Example: 'DecoderTransferFunction', 'purelin'

**MaxEpochs — Maximum number of training epochs**

1000 (default) | positive integer value

Maximum number of training epochs or iterations, specified as the comma-separated pair consisting of 'MaxEpochs' and a positive integer value.

Example: 'MaxEpochs', 1200

### **L2WeightRegularization — The coefficient for the $L_2$ weight regularizer**

0.001 (default) | a positive scalar value

The coefficient for the  $L_2$  weight regularizer on page 2-613 in the cost function (LossFunction), specified as the comma-separated pair consisting of 'L2WeightRegularization' and a positive scalar value.

Example: 'L2WeightRegularization', 0.05

### **LossFunction — Loss function to use for training**

'msesparsed' (default)

Loss function to use for training, specified as the comma-separated pair consisting of 'LossFunction' and 'msesparsed'. It corresponds to the mean squared error function adjusted for training a sparse autoencoder on page 2-613 as follows:

$$E = \frac{1}{N} \sum_{n=1}^N \sum_{k=1}^K (x_{kn} - \hat{x}_{kn})^2 + \lambda * \underbrace{\rho_{L_2}^{\text{weights}}}_{\text{regularization}} + \beta * \underbrace{\rho_{\text{sparsity}}^{\text{sparsity}}}_{\text{regularization}},$$

where  $\lambda$  is the coefficient for the  $L_2$  regularization term on page 2-613 and  $\beta$  is the coefficient for the sparsity regularization term on page 2-613. You can specify the values of  $\lambda$  and  $\beta$  by using the L2WeightRegularization and SparsityRegularization name-value pair arguments, respectively, while training an autoencoder.

### **ShowProgressWindow — Indicator to show the training window**

true (default) | false

Indicator to show the training window, specified as the comma-separated pair consisting of 'ShowProgressWindow' and either true or false.

Example: 'ShowProgressWindow', false

### **SparsityProportion — Desired proportion of training examples a neuron reacts to**

0.05 (default) | positive scalar value in the range from 0 to 1

Desired proportion of training examples a neuron reacts to, specified as the comma-separated pair consisting of 'SparsityProportion' and a positive scalar value. Sparsity proportion is a parameter of the sparsity regularizer. It controls the sparsity of the output from the hidden layer. A low value for SparsityProportion usually leads to each neuron in the hidden layer "specializing" by only giving a high output for a small number of training examples. Hence, a low sparsity proportion encourages higher degree of sparsity. See Sparse Autoencoders on page 2-613.

Example: 'SparsityProportion', 0.01 is equivalent to saying that each neuron in the hidden layer should have an average output of 0.1 over the training examples.

### **SparsityRegularization — Coefficient that controls the impact of the sparsity regularizer**

1 (default) | a positive scalar value

Coefficient that controls the impact of the sparsity regularizer on page 2-613 in the cost function, specified as the comma-separated pair consisting of 'SparsityRegularization' and a positive scalar value.

Example: 'SparsityRegularization', 1.6

**TrainingAlgorithm — The algorithm to use for training the autoencoder**`'trainscg'` (default)

The algorithm to use for training the autoencoder, specified as the comma-separated pair consisting of `'TrainingAlgorithm'` and `'trainscg'`. It stands for scaled conjugate gradient descent [1].

**ScaleData — Indicator to rescale the input data**`true` (default) | `false`

Indicator to rescale the input data, specified as the comma-separated pair consisting of `'ScaleData'` and either `true` or `false`.

Autoencoders attempt to replicate their input at their output. For it to be possible, the range of the input data must match the range of the transfer function for the decoder. `trainAutoencoder` automatically scales the training data to this range when training an autoencoder. If the data was scaled while training an autoencoder, the `predict`, `encode`, and `decode` methods also scale the data.

Example: `'ScaleData', false`

**UseGPU — Indicator to use GPU for training**`false` (default) | `true`

Indicator to use GPU for training, specified as the comma-separated pair consisting of `'UseGPU'` and either `true` or `false`.

Example: `'UseGPU', true`

**Output Arguments****autoenc — Trained autoencoder**

Autoencoder object

Trained autoencoder, returned as an `Autoencoder` object. For information on the properties and methods of this object, see `Autoencoder` class page.

**More About****Autoencoders**

An autoencoder is a neural network which is trained to replicate its input at its output. Training an autoencoder is unsupervised in the sense that no labeled data is needed. The training process is still based on the optimization of a cost function. The cost function measures the error between the input  $x$  and its reconstruction at the output  $\hat{x}$ .

An autoencoder is composed of an encoder and a decoder. The encoder and decoder can have multiple layers, but for simplicity consider that each of them has only one layer.

If the input to an autoencoder is a vector  $x \in \mathbb{R}^{D_x}$ , then the encoder maps the vector  $x$  to another vector  $z \in \mathbb{R}^{D^{(1)}}$  as follows:

$$z = h^{(1)}(W^{(1)}x + b^{(1)}),$$

where the superscript (1) indicates the first layer.  $h^{(1)}: \mathbb{R}^{D^{(1)}} \rightarrow \mathbb{R}^{D^{(1)}}$  is a transfer function for the encoder,  $W^{(1)} \in \mathbb{R}^{D^{(1)} \times D_x}$  is a weight matrix, and  $b^{(1)} \in \mathbb{R}^{D^{(1)}}$  is a bias vector. Then, the decoder maps the encoded representation  $z$  back into an estimate of the original input vector,  $x$ , as follows:

$$\hat{x} = h^{(2)}(W^{(2)}z + b^{(2)}),$$

where the superscript (2) represents the second layer.  $h^{(2)}: \mathbb{R}^{D_x} \rightarrow \mathbb{R}^{D_x}$  is the transfer function for the decoder,  $W^{(2)} \in \mathbb{R}^{D_x \times D^{(1)}}$  is a weight matrix, and  $b^{(2)} \in \mathbb{R}^{D_x}$  is a bias vector.

### Sparse Autoencoders

Encouraging sparsity of an autoencoder is possible by adding a regularizer to the cost function [2]. This regularizer is a function of the average output activation value of a neuron. The average output activation measure of a neuron  $i$  is defined as:

$$\hat{\rho}_i = \frac{1}{n} \sum_{j=1}^n z_i^{(1)}(x_j) = \frac{1}{n} \sum_{j=1}^n h(w_i^{(1)T} x_j + b_i^{(1)}),$$

where  $n$  is the total number of training examples.  $x_j$  is the  $j$ th training example,  $w_i^{(1)T}$  is the  $i$ th row of the weight matrix  $W^{(1)}$ , and  $b_i^{(1)}$  is the  $i$ th entry of the bias vector,  $b^{(1)}$ . A neuron is considered to be ‘firing’, if its output activation value is high. A low output activation value means that the neuron in the hidden layer fires in response to a small number of the training examples. Adding a term to the cost function that constrains the values of  $\hat{\rho}_i$  to be low encourages the autoencoder to learn a representation, where each neuron in the hidden layer fires to a small number of training examples. That is, each neuron specializes by responding to some feature that is only present in a small subset of the training examples.

### Sparsity Regularization

Sparsity regularizer attempts to enforce a constraint on the sparsity of the output from the hidden layer. Sparsity can be encouraged by adding a regularization term that takes a large value when the average activation value,  $\hat{\rho}_i$ , of a neuron  $i$  and its desired value,  $\rho$ , are not close in value [2]. One such sparsity regularization term can be the Kullback-Leibler divergence.

$$\Omega_{sparsity} = \sum_{i=1}^{D^{(1)}} KL(\rho \parallel \hat{\rho}_i) = \sum_{i=1}^{D^{(1)}} \rho \log\left(\frac{\rho}{\hat{\rho}_i}\right) + (1 - \rho) \log\left(\frac{1 - \rho}{1 - \hat{\rho}_i}\right)$$

Kullback-Leibler divergence is a function for measuring how different two distributions are. In this case, it takes the value zero when  $\rho$  and  $\hat{\rho}_i$  are equal to each other, and becomes larger as they diverge from each other. Minimizing the cost function forces this term to be small, hence  $\rho$  and  $\hat{\rho}_i$  to be close to each other. You can define the desired value of the average activation value using the `SparsityProportion` name-value pair argument while training an autoencoder.

### L<sub>2</sub> Regularization

When training a sparse autoencoder, it is possible to make the sparsity regulariser small by increasing the values of the weights  $w^{(l)}$  and decreasing the values of  $z^{(1)}$  [2]. Adding a regularization term on the weights to the cost function prevents it from happening. This term is called the L<sub>2</sub> regularization term and is defined by:

$$\Omega_{weights} = \frac{1}{2} \sum_{l=1}^L \sum_{j=1}^{n_l} \sum_{i=1}^{k_l} (w_{ji}^{(l)})^2,$$

where  $L$  is the number of hidden layers,  $n_l$  is the output size of layer  $l$ , and  $k_l$  is the input size of layer  $l$ . The  $L_2$  regularization term is the sum of the squared elements of the weight matrices for each layer.

### Cost Function

The cost function for training a sparse autoencoder on page 2-613 is an adjusted mean squared error function as follows:

$$E = \underbrace{\frac{1}{N} \sum_{n=1}^N \sum_{k=1}^K (x_{kn} - \hat{x}_{kn})^2}_{\text{mean squared error}} + \lambda * \underbrace{\Omega_{L_2}}_{\text{regularization}} + \beta * \underbrace{\Omega_{sparsity}}_{\text{regularization}},$$

where  $\lambda$  is the coefficient for the  $L_2$  regularization term on page 2-613 and  $\beta$  is the coefficient for the sparsity regularization term on page 2-613. You can specify the values of  $\lambda$  and  $\beta$  by using the `L2WeightRegularization` and `SparsityRegularization` name-value pair arguments, respectively, while training an autoencoder.

## Version History

Introduced in R2015b

# trainSoftmaxLayer

Train a softmax layer for classification

## Syntax

```
net = trainSoftmaxLayer(X,T)
net = trainSoftmaxLayer(X,T,Name,Value)
```

## Description

`net = trainSoftmaxLayer(X,T)` trains a softmax layer, `net`, on the input data `X` and the targets `T`.

`net = trainSoftmaxLayer(X,T,Name,Value)` trains a softmax layer, `net`, with additional options specified by one or more of the `Name, Value` pair arguments.

For example, you can specify the loss function.

## Examples

### Classify Using Softmax Layer

Load the sample data.

```
[X,T] = iris_dataset;
```

`X` is a 4x150 matrix of four attributes of iris flowers: Sepal length, sepal width, petal length, petal width.

`T` is a 3x150 matrix of associated class vectors defining which of the three classes each input is assigned to. Each row corresponds to a dummy variable representing one of the iris species (classes). In each column, a 1 in one of the three rows represents the class that particular sample (observation or example) belongs to. There is a zero in the rows for the other classes that the observation does not belong to.

Train a softmax layer using the sample data.

```
net = trainSoftmaxLayer(X,T);
```

Classify the observations into one of the three classes using the trained softmax layer.

```
Y = net(X);
```

Plot the confusion matrix using the targets and the classifications obtained from the softmax layer.

```
plotconfusion(T,Y);
```

## Input Arguments

### X — Training data

*m*-by-*n* matrix

Training data, specified as an *m*-by-*n* matrix, where *m* is the number of variables in training data, and *n* is the number of observations (examples). Hence, each column of X represents a sample.

Data Types: single | double

### T — Target data

*k*-by-*n* matrix

Target data, specified as a  $k$ -by- $n$  matrix, where  $k$  is the number of classes, and  $n$  is the number of observations. Each row is a dummy variable representing a particular class. In other words, each column represents a sample, and all entries of a column are zero except for a single one in a row. This single entry indicates the class for that sample.

Data Types: `single` | `double`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'MaxEpochs', 400, 'ShowProgressWindow', false` specifies the maximum number of iterations as 400 and hides the training window.

### MaxEpochs — Maximum number of training iterations

1000 (default) | positive integer value

Maximum number of training iterations, specified as the comma-separated pair consisting of `'MaxEpochs'` and a positive integer value.

Example: `'MaxEpochs', 500`

Data Types: `single` | `double`

### LossFunction — Loss function for the softmax layer

`'crossentropy'` (default) | `'mse'`

Loss function for the softmax layer, specified as the comma-separated pair consisting of `'LossFunction'` and either `'crossentropy'` or `'mse'`.

`mse` stands for mean squared error function, which is given by:

$$E = \frac{1}{n} \sum_{j=1}^n \sum_{i=1}^k (t_{ij} - y_{ij})^2,$$

where  $n$  is the number of training examples, and  $k$  is the number of classes.  $t_{ij}$  is the  $ij$ th entry of the target matrix,  $T$ , and  $y_{ij}$  is the  $i$ th output from the autoencoder when the input vector is  $\mathbf{x}_j$ .

The cross entropy function is given by:

$$E = \frac{1}{n} \sum_{j=1}^n \sum_{i=1}^k t_{ij} \ln y_{ij} + (1 - t_{ij}) \ln(1 - y_{ij}).$$

Example: `'LossFunction', 'mse'`

### ShowProgressWindow — Indicator to display the training window

`true` (default) | `false`

Indicator to display the training window during training, specified as the comma-separated pair consisting of `'ShowProgressWindow'` and either `true` or `false`.

Example: `'ShowProgressWindow', false`

Data Types: `logical`

### **TrainingAlgorithm — Training algorithm**

`'trainscg'` (default)

Training algorithm used to train the softmax layer, specified as the comma-separated pair consisting of `'TrainingAlgorithm'` and `'trainscg'`, which stands for scaled conjugate gradient.

Example: `'TrainingAlgorithm','trainscg'`

### **Output Arguments**

#### **net — Softmax layer for classification**

network object

Softmax layer for classification, returned as a network object. The softmax layer, `net`, is the same size as the target `T`.

### **Version History**

**Introduced in R2015b**

`trainAutoencoder` | `stack`

# Autoencoder class

Autoencoder class

## Description

An Autoencoder object contains an autoencoder network, which consists of an encoder and a decoder. The encoder maps the input to a hidden representation. The decoder attempts to map this representation back to the original input.

## Construction

`autoenc = trainAutoencoder(X)` returns an autoencoder trained using the training data in `X`.

`autoenc = trainAutoencoder(X,hiddenSize)` returns an autoencoder with the hidden representation size of `hiddenSize`.

`autoenc = trainAutoencoder( ____,Name,Value)` returns an autoencoder for any of the above input arguments with additional options specified by one or more name-value pair arguments.

## Input Arguments

### **X** — Training data

matrix | cell array of image data

Training data, specified as a matrix of training samples or a cell array of image data. If `X` is a matrix, then each column contains a single sample. If `X` is a cell array of image data, then the data in each cell must have the same number of dimensions. The image data can be pixel intensity data for gray images, in which case, each cell contains an  $m$ -by- $n$  matrix. Alternatively, the image data can be RGB data, in which case, each cell contains an  $m$ -by- $n$ -3 matrix.

Data Types: `single` | `double` | `cell`

### **hiddenSize** — Size of hidden representation of the autoencoder

10 (default) | positive integer value

Size of hidden representation of the autoencoder, specified as a positive integer value. This number is the number of neurons in the hidden layer.

Data Types: `single` | `double`

## Properties

### **HiddenSize** — Size of the hidden representation

a positive integer value

Size of the hidden representation in the hidden layer of the autoencoder, stored as a positive integer value.

Data Types: `double`

**EncoderTransferFunction — Name of the transfer function for the encoder**

string

Name of the transfer function for the encoder, stored as a string.

Data Types: char

**EncoderWeights — Weights for the encoder**

matrix

Weights for the encoder, stored as a matrix.

Data Types: double

**EncoderBiases — Bias values for the encoder**

vector

Bias values for the encoder, stored as a vector.

Data Types: double

**DecoderTransferFunction — Name of the transfer function for the decoder**

string

Name of the transfer function for the decoder, stored as a string.

Data Types: char

**DecoderWeights — Weights for the decoder**

matrix

Weights for the decoder, stored as a matrix.

Data Types: double

**DecoderBiases — Bias values for the decoder**

vector

Bias values for the decoder, stored as a vector.

Data Types: double

**TrainingParameters — Parameters that trainAutoencoder uses for training the autoencoder**

structure

Parameters that trainAutoencoder uses for training the autoencoder, stored as a structure.

Data Types: struct

**ScaleData — Indicator for data that is rescaled**

true or 1 (default) | false or 0

Indicator for data that is rescaled while passing to the autoencoder, stored as either true or false.

Autoencoders attempt to replicate their input at their output. For it to be possible, the range of the input data must match the range of the transfer function for the decoder. trainAutoencoder automatically scales the training data to this range when training an autoencoder. If the data was

scaled while training an autoencoder, the `predict`, `encode`, and `decode` methods also scale the data.

Data Types: `logical`

## Methods

<code>decode</code>	Decode encoded data
<code>encode</code>	Encode input data
<code>generateFunction</code>	Generate a MATLAB function to run the autoencoder
<code>generateSimulink</code>	Generate a Simulink model for the autoencoder
<code>network</code>	Convert <code>Autoencoder</code> object into <code>network</code> object
<code>plotWeights</code>	Plot a visualization of the weights for the encoder of an autoencoder
<code>predict</code>	Reconstruct the inputs using trained autoencoder
<code>stack</code>	Stack encoders from several autoencoders together
<code>view</code>	View autoencoder

## Copy Semantics

### Topics

Class Attributes

Property Attributes

## decode

**Class:** Autoencoder

Decode encoded data

### Syntax

```
Y = decode(autoenc,Z)
```

### Description

`Y = decode(autoenc,Z)` returns the decoded data on page 2-623 Y, using the autoencoder autoenc.

### Input Arguments

**autoenc — Trained autoencoder**

Autoencoder object

Trained autoencoder, returned by the `trainAutoencoder` function as an object of the `Autoencoder` class.

**Z — Data encoded by autoenc**

matrix

Data encoded by autoenc, specified as a matrix. Each column of Z represents an encoded sample (observation).

Data Types: `single` | `double`

### Output Arguments

**Y — Decoded data**

matrix | cell array of image data

Decoded data, returned as a matrix or a cell array of image data.

If the autoencoder autoenc was trained on a cell array of image data, then Y is also a cell array of images.

If the autoencoder autoenc was trained on a matrix, then Y is also a matrix, where each column of Y corresponds to one sample or observation.

## Examples

### Decode Encoded Data For New Images

Load the training data.

```
X = digitTrainCellArrayData;
```

X is a 1-by-5000 cell array, where each cell contains a 28-by-28 matrix representing a synthetic image of a handwritten digit.

Train an autoencoder using the training data with a hidden size of 15.

```
hiddenSize = 15;
autoenc = trainAutoencoder(X,hiddenSize);
```

Extract the encoded data for new images using the autoencoder.

```
Xnew = digitTestCellArrayData;
features = encode(autoenc,Xnew);
```

Decode the encoded data from the autoencoder.

```
Y = decode(autoenc, features);
```

Y is a 1-by-5000 cell array, where each cell contains a 28-by-28 matrix representing a synthetic image of a handwritten digit.

## Algorithms

If the input to an autoencoder is a vector  $x \in \mathbb{R}^{D_x}$ , then the encoder maps the vector  $x$  to another vector  $z \in \mathbb{R}^{D^{(1)}}$  as follows:

$$z = h^{(1)}(W^{(1)}x + b^{(1)}),$$

where the superscript (1) indicates the first layer.  $h^{(1)}: \mathbb{R}^{D^{(1)}} \rightarrow \mathbb{R}^{D^{(1)}}$  is a transfer function for the encoder,  $W^{(1)} \in \mathbb{R}^{D^{(1)} \times D_x}$  is a weight matrix, and  $b^{(1)} \in \mathbb{R}^{D^{(1)}}$  is a bias vector. Then, the decoder maps the encoded representation  $z$  back into an estimate of the original input vector,  $\hat{x}$ , as follows:

$$\hat{x} = h^{(2)}(W^{(2)}z + b^{(2)}),$$

where the superscript (2) represents the second layer.  $h^{(2)}: \mathbb{R}^{D_x} \rightarrow \mathbb{R}^{D_x}$  is the transfer function for the decoder,  $W^{(2)} \in \mathbb{R}^{D_x \times D^{(1)}}$  is a weight matrix, and  $b^{(2)} \in \mathbb{R}^{D_x}$  is a bias vector.

encode | trainAutoencoder

## encode

**Class:** Autoencoder

Encode input data

### Syntax

```
Z = encode(autoenc, Xnew)
```

### Description

`Z = encode(autoenc, Xnew)` returns the encoded data on page 2-625, `Z`, for the input data `Xnew`, using the autoencoder, `autoenc`.

### Input Arguments

**autoenc — Trained autoencoder**

Autoencoder object

Trained autoencoder, returned as an object of the `Autoencoder` class.

**Xnew — Input data**

matrix | cell array of image data | array of single image data

Input data, specified as a matrix of samples, a cell array of image data, or an array of single image data.

If the autoencoder `autoenc` was trained on a matrix, where each column represents a single sample, then `Xnew` must be a matrix, where each column represents a single sample.

If the autoencoder `autoenc` was trained on a cell array of images, then `Xnew` must either be a cell array of image data or an array of single image data.

Data Types: `single` | `double` | `cell`

### Output Arguments

**Z — Data encoded by autoenc**

matrix

Data encoded by `autoenc`, specified as a matrix. Each column of `Z` represents an encoded sample (observation).

Data Types: `single` | `double`

### Examples

## Encode Decoded Data for New Images

Load the sample data.

```
X = digitTrainCellArrayData;
```

X is a 1-by-5000 cell array, where each cell contains a 28-by-28 matrix representing a synthetic image of a handwritten digit.

Train an autoencoder with a hidden size of 50 using the training data.

```
autoenc = trainAutoencoder(X,50);
```

Encode decoded data for new image data.

```
Xnew = digitTestCellArrayData;
Z = encode(autoenc,Xnew);
```

Xnew is a 1-by-5000 cell array. Z is a 50-by-5000 matrix, where each column represents the image data of one handwritten digit in the new data Xnew.

## Algorithms

If the input to an autoencoder is a vector  $x \in \mathbb{R}^{D_x}$ , then the encoder maps the vector  $x$  to another vector  $z \in \mathbb{R}^{D^{(1)}}$  as follows:

$$z = h^{(1)}(W^{(1)}x + b^{(1)}),$$

where the superscript (1) indicates the first layer.  $h^{(1)}: \mathbb{R}^{D^{(1)}} \rightarrow \mathbb{R}^{D^{(1)}}$  is a transfer function for the encoder,  $W^{(1)} \in \mathbb{R}^{D^{(1)} \times D_x}$  is a weight matrix, and  $b^{(1)} \in \mathbb{R}^{D^{(1)}}$  is a bias vector.

# generateFunction

**Class:** Autoencoder

Generate a MATLAB function to run the autoencoder

## Syntax

```
generateFunction(autoenc)  
generateFunction(autoenc,pathname)  
generateFunction(autoenc,pathname,Name,Value)
```

## Description

`generateFunction(autoenc)` generates a complete stand-alone function in the current directory, to run the autoencoder `autoenc` on input data.

`generateFunction(autoenc,pathname)` generates a complete stand-alone function to run the autoencoder `autoenc` on input data in the location specified by `pathname`.

`generateFunction(autoenc,pathname,Name,Value)` generates a complete stand-alone function with additional options specified by the `Name,Value` pair argument.

## Input Arguments

### **autoenc** — Trained autoencoder

Autoencoder object

Trained autoencoder, returned as an object of the `Autoencoder` class.

### **pathname** — Location for generated function

string

Location for generated function, specified as a string.

Example: 'C:\MyDocuments\Autoencoders'

Data Types: char

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

### **ShowLinks** — Indicator to display the links to the generated code

false (default) | true

Indicator to display the links to the generated code in the command window, specified as the comma-separated pair consisting of 'ShowLinks' and either `true` or `false`.

Example: 'ShowLinks',true

Data Types: logical

## Examples

### Generate MATLAB Function for Running Autoencoder

Load the sample data.

```
X = iris_dataset;
```

Train an autoencoder with 4 neurons in the hidden layer.

```
autoenc = trainAutoencoder(X,4);
```

Generate the code for running the autoencoder. Show the links to the MATLAB function.

```
generateFunction(autoenc)
```

```
MATLAB function generated: neural_function.m  
To view generated function code: edit neural_function  
For examples of using function: help neural_function
```

Generate the code for the autoencoder in a specific path.

```
generateFunction(autoenc, 'H:\Documents\Autoencoder')
```

```
MATLAB function generated: H:\Documents\Autoencoder.m  
To view generated function code: edit Autoencoder  
For examples of using function: help Autoencoder
```

## Tips

- If you do not specify the path and the file name, `generateFunction`, by default, creates the code in an m-file with the name `neural_function.m`. You can change the file name after `generateFunction` generates it. Or you can specify the path and file name using the `pathname` input argument in the call to `generateFunction`.

**Class:** Autoencoder

Generate a Simulink model for the autoencoder

## Syntax

```
generateSimulink(autoenc)
```

## Description

`generateSimulink(autoenc)` creates a Simulink model for the autoencoder, `autoenc`.

## Input Arguments

**autoenc** — Trained autoencoder

Autoencoder object

Trained autoencoder, returned as an object of the Autoencoder class.

## Examples

### Generate Simulink Model for Autoencoder

Load the training data.

```
X = digitSmallCellArrayData;
```

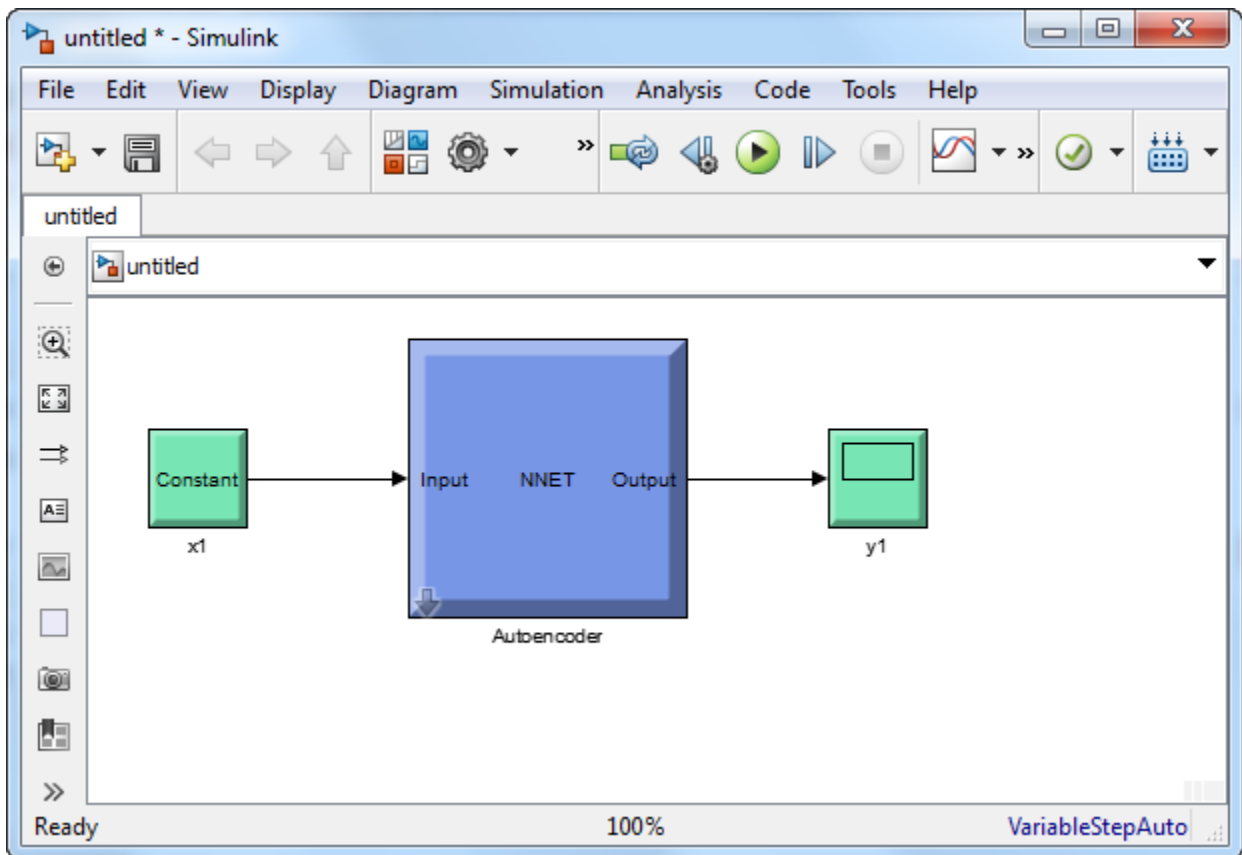

The training data is a 1-by-500 cell array, where each cell containing a 28-by-28 matrix representing a synthetic image of a handwritten digit.

Train an autoencoder with a hidden layer containing 25 neurons.

```
hiddenSize = 25;  
autoenc = trainAutoencoder(X,hiddenSize,...  
    'L2WeightRegularization',0.004,...  
    'SparsityRegularization',4,...  
    'SparsityProportion',0.15);
```

Create a Simulink model for the autoencoder, `autoenc`.

```
generateSimulink(autoenc)
```

## Version History

Introduced in R2015b

`trainAutoencoder`

## network

**Class:** Autoencoder

Convert Autoencoder object into network object

### Syntax

```
net = network(autoenc)
```

### Description

`net = network(autoenc)` returns a network object which is equivalent to the autoencoder, `autoenc`.

### Input Arguments

**autoenc — Trained autoencoder**

Autoencoder object

Trained autoencoder, returned as an object of the `Autoencoder` class.

### Output Arguments

**net — Neural network**

network object

Neural network, that is equivalent to the autoencoder `autoenc`, returned as an object of the `network` class.

### Examples

#### Create Network from Autoencoder

Load the sample data.

```
X = bodyfat_dataset;
```

`X` is a 13-by-252 matrix defining thirteen attributes of 252 different observations. For more information on the data, type `help bodyfat_dataset` in the command line.

Train an autoencoder on the attribute data.

```
autoenc = trainAutoencoder(X);
```

Network Diagram

**Training Results**  
Training finished: Reached maximum number of epochs ✓

**Training Progress**

Unit	Initial Value	Stopped Value	Target Value
Epoch	0	1000	1000
Elapsed Time	-	00:00:07	-
Performance	482	1.67	0
Gradient	1.11e+03	0.349	1e-06
Validation Checks	0	0	6

**Training Algorithms**  
Data Division: Training Only `dividetrain`  
Training: Scaled Conjugate Gradient `trainscg`  
Performance: Mean Squared Error with L2 and Sparsity Regularizers  
Calculations: MEX

**Training Plots**  
Performance

Create a network object from the autoencoder, `autoenc` .

```
net = network(autoenc);
```

Predict the attributes using the network, `net` .

```
Xpred = net(X);
```

Fit a linear regression model between the actual and estimated attributes data. Compute the estimated Pearson correlation coefficient, the slope and the intercept (bias) of the regression model, using all attribute data as one data set.

```
[C, S, B] = regression(X, Xpred, 'one')
```

```
C = 0.9997
```

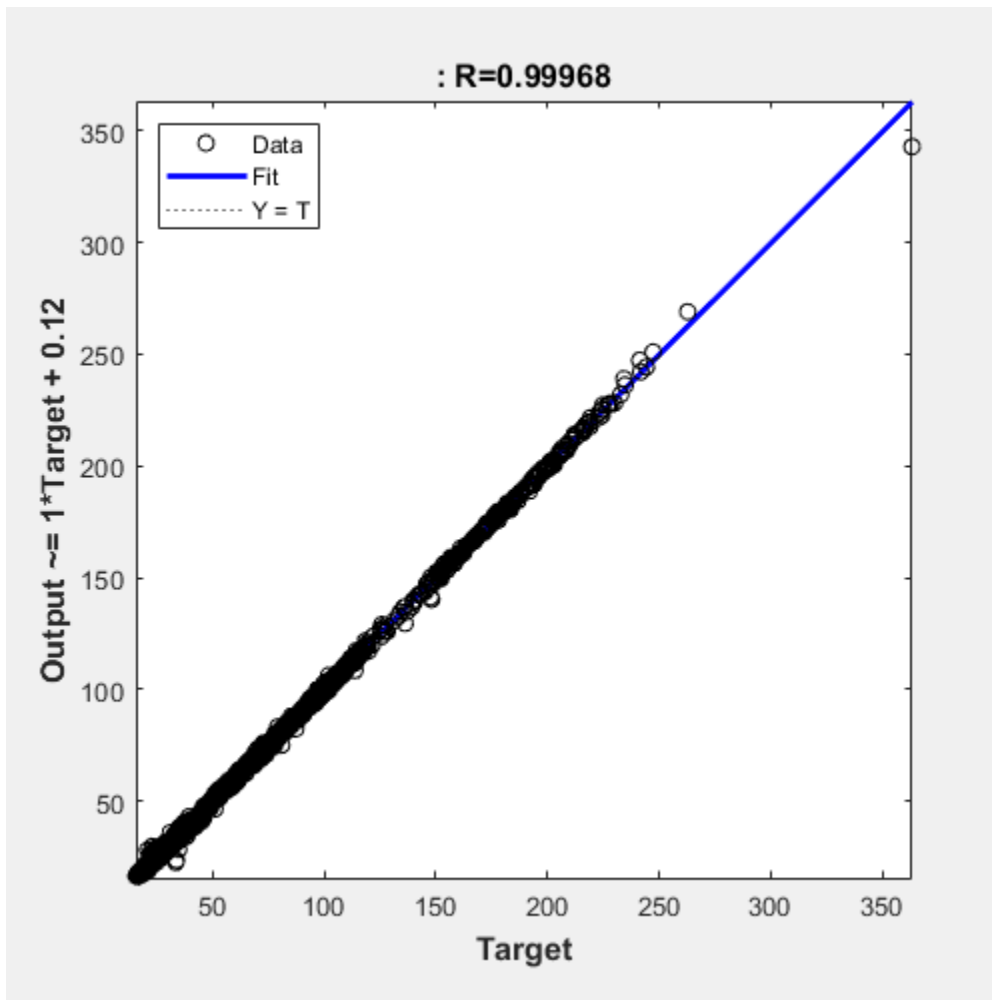

```
S = 0.9983
```

```
B = 0.1160
```

The correlation coefficient is almost 1, which indicates that the attributes data and the estimations from the neural network are highly close to each other.

Plot the actual data and the fitted line.

```
plotregression(X, Xpred);
```

The data appears to be on the fitted line, which visually supports the conclusion that the predictions are very close to the actual data.

## **Version History**

**Introduced in R2015b**

### **See Also**

`trainAutoencoder` | `Autoencoder`

## plotWeights

**Class:** Autoencoder

Plot a visualization of the weights for the encoder of an autoencoder

### Syntax

```
plotWeights(autoenc)
h = plotWeights(autoenc)
```

### Description

`plotWeights(autoenc)` visualizes the weights for the autoencoder, `autoenc`.

`h = plotWeights(autoenc)` returns a function handle `h`, for the visualization of the encoder weights for the autoencoder, `autoenc`.

### Input Arguments

**autoenc** — Trained autoencoder

Autoencoder object

Trained autoencoder, returned as an object of the `Autoencoder` class.

### Output Arguments

**h** — Image object

handle

Image object, returned as a handle.

### Examples

#### Visualize Learned Features

Load the training data.

```
X = digitTrainCellArrayData;
```

The training data is a 1-by-5000 cell array, where each cell contains a 28-by-28 matrix representing a synthetic image of a handwritten digit.

Train an autoencoder with a hidden layer of 25 neurons.

```
hiddenSize = 25;
autoenc = trainAutoencoder(X,hiddenSize, ...
    'L2WeightRegularization',0.004, ...
    'SparsityRegularization',4, ...
    'SparsityProportion',0.2);
```

Visualize the learned features.

```
plotWeights(autoenc);
```

## Tips

- `plotWeights` allows the visualization of the features that the autoencoder learns. Use it when the autoencoder is trained on image data. The visualization of the weights has the same dimensions as the images used for training.

## Version History

Introduced in R2015b

`trainAutoencoder`

## predict

**Class:** Autoencoder

Reconstruct the inputs using trained autoencoder

### Syntax

```
Y = predict(autoenc,X)
```

### Description

`Y = predict(autoenc,X)` returns the predictions `Y` for the input data `X`, using the autoencoder `autoenc`. The result `Y` is a reconstruction of `X`.

### Input Arguments

**autoenc — Trained autoencoder**

Autoencoder object

Trained autoencoder, returned as an object of the `Autoencoder` class.

**Xnew — Input data**

matrix | cell array of image data | array of single image data

Input data, specified as a matrix of samples, a cell array of image data, or an array of single image data.

If the autoencoder `autoenc` was trained on a matrix, where each column represents a single sample, then `Xnew` must be a matrix, where each column represents a single sample.

If the autoencoder `autoenc` was trained on a cell array of images, then `Xnew` must either be a cell array of image data or an array of single image data.

Data Types: `single` | `double` | `cell`

### Output Arguments

**Y — Predictions for the input data Xnew**

matrix | cell array of image data | array of single image data

Predictions for the input data `Xnew`, returned as a matrix or a cell array of image data.

- If `Xnew` is a matrix, then `Y` is also a matrix, where each column corresponds to a single sample (observation or example).
- If `Xnew` is a cell array of image data, then `Y` is also a cell array of image data, where each cell contains the data for a single image.
- If `Xnew` is an array of a single image data, then `Y` is also an array of a single image data.

## Examples

### Predict Continuous Measurements Using Trained Autoencoder

Load the training data.

```
X = iris_dataset;
```

The training data contains measurements on four attributes of iris flowers: Sepal length, sepal width, petal length, petal width.

Train an autoencoder on the training data using the positive saturating linear transfer function in the encoder and linear transfer function in the decoder.

```
autoenc = trainAutoencoder(X, 'EncoderTransferFunction', ...  
'satlin', 'DecoderTransferFunction', 'purelin');
```

**Training Plots**  
Performance

Reconstruct the measurements using the trained network, `autoenc`.

```
xReconstructed = predict(autoenc,X);
```

Plot the predicted measurement values along with the actual values in the training dataset.

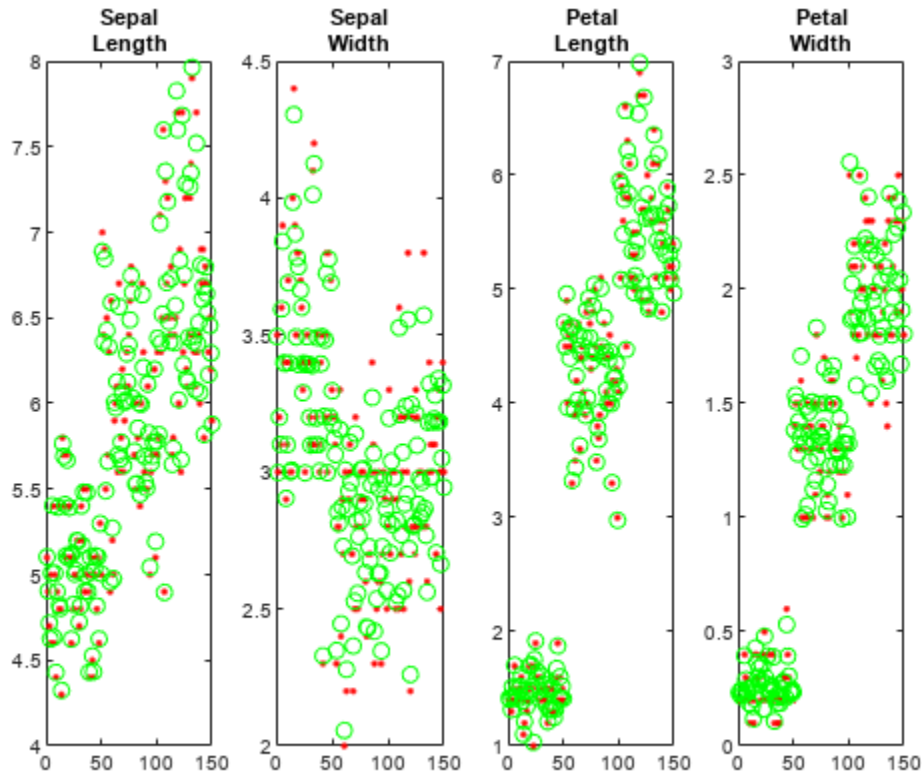

```
for i = 1:4
h(i) = subplot(1,4,i);
```

```

plot(X(i,:), 'r. ');
hold on
plot(xReconstructed(i,:), 'go');
hold off;
end
title(h(1), {'Sepal'; 'Length'});
title(h(2), {'Sepal'; 'Width'});
title(h(3), {'Petal'; 'Length'});
title(h(4), {'Petal'; 'Width'});

```

The red dots represent the training data and the green circles represent the reconstructed data.

### Reconstruct Handwritten Digit Images Using Sparse Autoencoder

Load the training data.

```
XTrain = digitTrainCellArrayData;
```

The training data is a 1-by-5000 cell array, where each cell containing a 28-by-28 matrix representing a synthetic image of a handwritten digit.

Train an autoencoder with a hidden layer containing 25 neurons.

```

hiddenSize = 25;
autoenc = trainAutoencoder(XTrain, hiddenSize, ...

```

```
'L2WeightRegularization',0.004,...  
'SparsityRegularization',4,...  
'SparsityProportion',0.15);
```

Load the test data.

```
XTest = digitTestCellArrayData;
```

The test data is a 1-by-5000 cell array, with each cell containing a 28-by-28 matrix representing a synthetic image of a handwritten digit.

Reconstruct the test image data using the trained autoencoder, autoenc.

```
xReconstructed = predict(autoenc,XTest);
```

View the actual test data.

```
figure;  
for i = 1:20  
    subplot(4,5,i);  
    imshow(XTest{i});  
end
```

View the reconstructed test data.

```
figure;  
for i = 1:20  
    subplot(4,5,i);
```

```
imshow(xReconstructed{i});  
end
```

## stack

**Class:** Autoencoder

Stack encoders from several autoencoders together

### Syntax

```
stackednet = stack(autoenc1,autoenc2,...)
stackednet = stack(autoenc1,autoenc2,...,net1)
```

### Description

`stackednet = stack(autoenc1,autoenc2,...)` returns a network object created by stacking the encoders of the autoencoders, `autoenc1`, `autoenc2`, and so on.

`stackednet = stack(autoenc1,autoenc2,...,net1)` returns a network object created by stacking the encoders of the autoencoders and the network object `net1`.

The autoencoders and the network object can be stacked only if their dimensions match.

### Input Arguments

**autoenc1 — Trained autoencoder**

Autoencoder object

Trained autoencoder, specified as an Autoencoder object.

**autoenc2 — Trained autoencoder**

Autoencoder object

Trained autoencoder, specified as an Autoencoder object.

**net1 — Trained neural network**

network object

Trained neural network, specified as a network object. `net1` can be a softmax layer, trained using the `trainSoftmaxLayer` function.

### Output Arguments

**stackednet — Stacked neural network**

network object

Stacked neural network (deep network), returned as a network object

### Examples

## Create a Stacked Network

Load the training data.

```
[X,T] = iris_dataset;
```

Train an autoencoder with a hidden layer of size 5 and a linear transfer function for the decoder. Set the L2 weight regularizer to 0.001, sparsity regularizer to 4 and sparsity proportion to 0.05.

```
hiddenSize = 5;  
autoenc = trainAutoencoder(X, hiddenSize, ...  
    'L2WeightRegularization', 0.001, ...  
    'SparsityRegularization', 4, ...  
    'SparsityProportion', 0.05, ...  
    'DecoderTransferFunction', 'purelin');
```

Network Diagram

**Training Results**

Validation Checks	0	0	6

**Training Algorithms**  
 Data Division: Training Only `dividetrain`  
 Training: Scaled Conjugate Gradient `trainscg`  
 Performance: Cross Entropy `crossentropy`  
 Calculations: MEX

Stack the encoder and the softmax layer to form a deep network.

```
stackednet = stack(autoenc, softnet);
```

View the stacked network.

```
view(stackednet);
```

## Tips

- The size of the hidden representation of one autoencoder must match the input size of the next autoencoder or network in the stack.

The first input argument of the stacked network is the input argument of the first autoencoder. The output argument from the encoder of the first autoencoder is the input of the second autoencoder in the stacked network. The output argument from the encoder of the second autoencoder is the input argument to the third autoencoder in the stacked network, and so on.

- The stacked network object `stacknet` inherits its training parameters from the final input argument `net1`.

## view

**Class:** Autoencoder

View autoencoder

### Syntax

```
view(autoenc)
```

### Description

`view(autoenc)` returns a diagram of the autoencoder, `autoenc`.

### Input Arguments

**autoenc — Trained autoencoder**

Autoencoder object

Trained autoencoder, returned as an object of the Autoencoder class.

### Examples

#### View Autoencoder

Load the training data.

```
X = iris_dataset;
```

Train an autoencoder with a hidden layer of size 5 and a linear transfer function for the decoder. Set the L2 weight regularizer to 0.001, sparsity regularizer to 4 and sparsity proportion to 0.05.

```
hiddenSize = 5;  
autoenc = trainAutoencoder(X, hiddenSize, ...  
    'L2WeightRegularization',0.001, ...

# fitnet

Function fitting neural network

## Syntax

```
net = fitnet(hiddenSizes)
net = fitnet(hiddenSizes,trainFcn)
```

## Description

`net = fitnet(hiddenSizes)` returns a function fitting neural network with a hidden layer size of `hiddenSizes`.

`net = fitnet(hiddenSizes,trainFcn)` returns a function fitting neural network with a hidden layer size of `hiddenSizes` and training function, specified by `trainFcn`.

## Examples

### Construct and Train a Function Fitting Network

Load the training data.

```
[x,t] = simplefit_dataset;
```

The 1-by-94 matrix `x` contains the input values and the 1-by-94 matrix `t` contains the associated target output values.

Construct a function fitting neural network with one hidden layer of size 10.

```
net = fitnet(10);
```

View the network.

```
view(net)
```

The sizes of the input and output are zero. The software adjusts the sizes of these during training according to the training data.

Train the network `net` using the training data.

```
net = train(net,x,t);
```

Network Diagram

**Training Results**

Training finished: Met validation criterion

Fit

View the trained network.

`view(net)`

You can see that the sizes of the input and output are 1.

Estimate the targets using the trained network.

```
y = net(x);
```

Assess the performance of the trained network. The default performance function is mean squared error.

```
perf = perform(net,y,t)
```

```
perf = 1.4639e-04
```

The default training algorithm for a function fitting network is Levenberg-Marquardt ( 'trainlm' ). Use the Bayesian regularization training algorithm and compare the performance results.

```
net = fitnet(10,'trainbr');  
net = train(net,x,t);
```

Network Diagram

### Training Results

Training finished: Reached maximum number of epochs ✔

### Training Progress

Unit	Initial Value	Stopped Value	Target Value
Epoch	0	1000	1000
Elapsed Time	-	00:00:04	-
Performance	77.6	1.77e-10	0
Gradient	144	2.1e-06	1e-07

### Training Algorithms

Data Division: Random dividerand  
 Training: Bayesian Regularization trainbr  
 Performance: Mean Squared Error mse  
 Calculations: MEX

### Training Plots

```
y = net(x);
perf = perform(net,y,t)
```

```
perf = 3.3416e-10
```

The Bayesian regularization training algorithm improves the performance of the network in terms of estimating the target values.

## Input Arguments

### **hiddenSizes** — Size of the hidden layers

10 (default) | row vector

Size of the hidden layers in the network, specified as a row vector. The length of the vector determines the number of hidden layers in the network.

Example: For example, you can specify a network with 3 hidden layers, where the first hidden layer size is 10, the second is 8, and the third is 5 as follows: [10,8,5]

The input and output sizes are set to zero. The software adjusts the sizes of these during training according to the training data.

Data Types: single | double

### **trainFcn** — Training function name

'trainlm' (default) | 'trainbr' | 'trainbfg' | 'trainrp' | 'trainscg' | ...

Training function name, specified as one of the following.

Training Function	Algorithm
'trainlm'	Levenberg-Marquardt
'trainbr'	Bayesian Regularization
'trainbfg'	BFGS Quasi-Newton
'trainrp'	Resilient Backpropagation
'trainscg'	Scaled Conjugate Gradient
'traincgb'	Conjugate Gradient with Powell/Beale Restarts
'traincgf'	Fletcher-Powell Conjugate Gradient
'traincgp'	Polak-Ribière Conjugate Gradient
'trainoss'	One Step Secant
'traingdx'	Variable Learning Rate Gradient Descent
'traingdm'	Gradient Descent with Momentum
'traingd'	Gradient Descent

Example: For example, you can specify the variable learning rate gradient descent algorithm as the training algorithm as follows: 'traingdx'

For more information on the training functions, see “Train and Apply Multilayer Shallow Neural Networks” and “Choose a Multilayer Neural Network Training Function”.

Data Types: char

## Output Arguments

### **net** — Function fitting network

network object

Function fitting network, returned as a network object.

## Tips

- Function fitting is the process of training a neural network on a set of inputs in order to produce an associated set of target outputs. After you construct the network with the desired hidden layers and the training algorithm, you must train it using a set of training data. Once the neural network has fit the data, it forms a generalization of the input-output relationship. You can then use the trained network to generate outputs for inputs it was not trained on.

# Deep Learning Blocks

---

## Image Classifier

Classify data using a trained deep learning neural network

### Libraries:

Deep Learning Toolbox / Deep Neural Networks

### Description

The Image Classifier block predicts class labels for the data at the input by using the trained network specified through the block parameter. This block allows loading of a pretrained network into the Simulink model from a MAT-file or from a MATLAB function.

### Limitations

- The Image Classifier block does not support sequence networks and multiple input and multiple output networks (MIMO).
- The Image Classifier block does not support MAT-file logging.

### Ports

#### Input

**image** — Image or feature data  
numeric array

A  $h$ -by- $w$ -by- $c$ -by- $N$  numeric array, where  $h$ ,  $w$ , and  $c$  are the height, width, and number of channels of the images, respectively, and  $N$  is the number of images.

A  $N$ -by-`numFeatures` numeric array, where  $N$  is the number of observations and `numFeatures` is the number of features of the input data.

If the array contains NaNs, then they are propagated through the network.

#### Output

**ypred** — Predicted class labels  
enumerated

Predicted class labels with the highest score, returned as a  $N$ -by-1 enumerated vector of labels, where  $N$  is the number of observations.

**scores** — Predicted class scores  
matrix

Predicted scores, returned as a  $N$ -by- $K$  matrix, where  $N$  is the number of observations, and  $K$  is the number of classes.

**labels** — Class labels for predicted scores  
matrix

Labels associated with the predicted scores, returned as a  $N$ -by- $K$  matrix, where  $N$  is the number of observations, and  $K$  is the number of classes.

## Parameters

**Network** — Source for trained network

Network from MAT-file (default) | Network from MATLAB function

Specify the source for the trained network. Select one of the following:

- **Network from MAT-file**— Import a trained network from a MAT-file containing a `SeriesNetwork`, `DAGNetwork`, or `dlnetwork` object.
- **Network from MATLAB function**— Import a pretrained network from a MATLAB function. For example, by using the `googlenet` function.

### Programmatic Use

**Block Parameter:** Network

**Type:** character vector, string

**Values:** 'Network from MAT-file' | 'Network from MATLAB function'

**Default:** 'Network from MAT-file'

**File path** — MAT-file containing trained network

untitled.mat (default) | MAT-file path or name

This parameter specifies the name of the MAT-file that contains the trained deep learning network to load. If the file is not on the MATLAB path, use the **Browse** button to locate the file.

### Dependencies

To enable this parameter, set the **Network** parameter to `Network from MAT-file`.

### Programmatic Use

**Block Parameter:** NetworkFilePath

**Type:** character vector, string

**Values:** MAT-file path or name

**Default:** 'untitled.mat'

**MATLAB function** — MATLAB function name

squeezenet (default) | MATLAB function name

This parameter specifies the name of the MATLAB function for the pretrained deep learning network. For example, use `googlenet` function to import the pretrained GoogLeNet model.

### Dependencies

To enable this parameter, set the **Network** parameter to `Network from MATLAB function`.

### Programmatic Use

**Block Parameter:** NetworkFunction

**Type:** character vector, string

**Values:** MATLAB function name

**Default:** 'squeezenet'

**Mini-batch size** — Size of mini-batches

128 (default) | positive integer

Size of mini-batches to use for prediction, specified as a positive integer. Larger mini-batch sizes require more memory, but can lead to faster predictions.

**Programmatic Use****Block Parameter:** MiniBatchSize**Type:** character vector, string**Values:** positive integer**Default:** '128'**Resize input** — Resize input dimensions

on (default) | off

Resize the data at the input port to the input size of the network.

**Programmatic Use****Block Parameter:** ResizeInput**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'on'**Classification** — Output predicted label with highest score

on (default) | off

Enable output port ypred that outputs the label with the highest score.

**Programmatic Use****Block Parameter:** Classification**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'on'**Predictions** — Output all scores and associated labels

off (default) | on

Enable output ports scores and labels that output all predicted scores and associated class labels.

**Programmatic Use****Block Parameter:** Predictions**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'

## Version History

## Extended Capabilities

**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- To generate generic C code that does not depend on third-party libraries, in the **Configuration Parameters > Code Generation** general category, set the **Language** parameter to C.
- To generate C++ code, in the **Configuration Parameters > Code Generation** general category, set the **Language** parameter to C++. To specify the target library for code generation, in the **Code Generation > Interface** category, set the **Target Library** parameter. Setting this parameter to None generates generic C++ code that does not depend on third-party libraries.
- For ERT-based targets, the **Support: variable-size signals** parameter in the **Code Generation > Interface** pane must be enabled.
- For a list of networks and layers supported for code generation, see “Networks and Layers Supported for Code Generation” (MATLAB Coder).

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The **Language** parameter in the **Configuration Parameters > Code Generation** general category must be set to C++.
- For a list of networks and layers supported for CUDA code generation, see “Supported Networks, Layers, and Classes” (GPU Coder).
- To learn more about generating code for Simulink models containing the Image Classifier block, see “Code Generation for a Deep Learning Simulink Model to Classify ECG Signals” (GPU Coder).

### See Also

Predict

## Predict

Predict responses using a trained deep learning neural network

### Libraries:

Deep Learning Toolbox / Deep Neural Networks

## Description

The Predict block predicts responses for the data at the input by using the trained network specified through the block parameter. This block allows loading of a pretrained network into the Simulink model from a MAT-file or from a MATLAB function.

---

**Note** Use the Predict block to make predictions in Simulink. To make predictions programmatically using MATLAB code, use the `classify` and `predict` functions.

---

## Ports

### Input

**input** — Image, feature, sequence, or time series data  
numeric array

The input ports of the Predict block takes the names of the input layers of the network loaded. For example, if you specify `googlenet` for `MATLAB` function, then the input port of the Predict block is labeled **data**. Based on the network loaded, the input to the predict block can be image, sequence, or time series data.

The format of the input depend on the type of data.

Data	Format of Predictors
2-D images	A $h$ -by- $w$ -by- $c$ -by- $N$ numeric array, where $h$ , $w$ , and $c$ are the height, width, and number of channels of the images, respectively, and $N$ is the number of images.
Vector sequence	$c$ -by- $s$ matrices, where $c$ is the number of features of the sequences and $s$ is the sequence length.
2-D image sequences	$h$ -by- $w$ -by- $c$ -by- $s$ arrays, where $h$ , $w$ , and $c$ correspond to the height, width, and number of channels of the images, respectively, and $s$ is the sequence length.

Data	Format of Predictors
Features	A $N$ -by- <code>numFeatures</code> numeric array, where $N$ is the number of observations and <code>numFeatures</code> is the number of features of the input data.

If the array contains NaNs, then they are propagated through the network.

## Output

**output** — Predicted scores, responses, or activations  
numeric array

The outputs port of the Predict block takes the names of the output layers of the network loaded. For example, if you specify `googlenet` for `MATLAB` function, then the output port of the Predict block is labeled **output**. Based on the network loaded, the output of the Predict block can represent predicted scores or responses.

Predicted scores or responses, returned as a  $N$ -by- $K$  array, where  $N$  is the number of observations, and  $K$  is the number of classes.

If you enable `Activations` for a network layer, the Predict block creates a new output port with the name of the selected network layer. This port outputs the activations from the selected network layer.

The activations from the network layer is returned as a numeric array. The format of output depends on the type of input data and the type of layer output.

For 2-D image output, activations is an  $h$ -by- $w$ -by- $c$ -by- $n$  array, where  $h$ ,  $w$ , and  $c$  are the height, width, and number of channels for the output of the chosen layer, respectively, and  $n$  is the number of images.

For a single time-step containing vector data, activations is a  $c$ -by- $n$  matrix, where  $n$  is the number of sequences and  $c$  is the number of features in the sequence.

For a single time-step containing 2-D image data, activations is a  $h$ -by- $w$ -by- $c$ -by- $n$  array, where  $n$  is the number of sequences,  $h$ ,  $w$ , and  $c$  are the height, width, and the number of channels of the images, respectively.

## Parameters

**Network** — Source for trained network  
Network from MAT-file (default) | Network from MATLAB function

Specify the source for the trained network. Select one of the following:

- **Network from MAT-file**— Import a trained network from a MAT-file containing a `SeriesNetwork`, `DAGNetwork`, or `dlnetwork` object.
- **Network from MATLAB function**— Import a pretrained network from a MATLAB function. For example, by using the `googlenet` function.

### Programmatic Use

**Block Parameter:** Network

**Type:** character vector, string

**Values:** 'Network from MAT-file' | 'Network from MATLAB function'

**Default:** 'Network from MAT-file'

**File path** — MAT-file containing trained network  
untitled.mat (default) | MAT-file path or name

This parameter specifies the name of the MAT-file that contains the trained deep learning network to load. If the file is not on the MATLAB path, use the **Browse** button to locate the file.

**Dependencies**

To enable this parameter, set the **Network** parameter to Network from MAT-file.

**Programmatic Use**

**Block Parameter:** NetworkFilePath

**Type:** character vector, string

**Values:** MAT-file path or name

**Default:** 'untitled.mat'

**MATLAB function** — MATLAB function name  
squeezeenet (default) | MATLAB function name

This parameter specifies the name of the MATLAB function for the pretrained deep learning network. For example, use googlenet function to import the pretrained GoogLeNet model.

**Dependencies**

To enable this parameter, set the **Network** parameter to Network from MATLAB function.

**Programmatic Use**

**Block Parameter:** NetworkFunction

**Type:** character vector, string

**Values:** MATLAB function name

**Default:** 'squeezeenet'

**Mini-batch size** — Size of mini-batches  
128 (default) | positive integer

Size of mini-batches to use for prediction, specified as a positive integer. Larger mini-batch sizes require more memory, but can lead to faster predictions.

**Programmatic Use**

**Block Parameter:** MiniBatchSize

**Type:** character vector, string

**Values:** positive integer

**Default:** '128'

**Predictions** — Output predicted scores or responses  
on (default) | off

Enable output ports that return predicted scores or responses.

**Programmatic Use**

**Block Parameter:** Predictions

**Type:** character vector, string

**Values:** 'off' | 'on'

**Default:** 'on'

**Activations** — Output network activations for a specific layer layers of the network

Use the **Activations** list to select the layer to extract features from. The selected layers appear as an output port of the Predict block.

**Programmatic Use**

**Block Parameter:** Activations

**Type:** character vector, string

**Values:** character vector in the form of `{'layerName1', layerName2', ...}'`

**Default:** ''

## Stateful Classify

Classify data using a trained deep learning recurrent neural network

### Libraries:

Deep Learning Toolbox / Deep Neural Networks

### Description

The Stateful Classify block predicts class labels for the data at the input by using the trained recurrent neural network specified through the block parameter. This block allows loading of a pretrained network into the Simulink model from a MAT-file or from a MATLAB function. This block updates the state of the network with every prediction.

To reset the state of recurrent neural network to its initial state, place the Stateful Classify block inside a Resettable Subsystem block and use the Reset control signal as trigger.

### Limitations

The Stateful Classify block does not support MAT-file logging.

### Ports

#### Input

**input** — Sequence or time series data  
numeric array

The format of the input depend on the type of data.

Input	Description
Vector sequences	$c$ -by- $s$ matrices, where $c$ is the number of features of the sequences and $s$ is the sequence length.
2-D image sequences	$h$ -by- $w$ -by- $c$ -by- $s$ arrays, where $h$ , $w$ , and $c$ correspond to the height, width, and number of channels of the images, respectively, and $s$ is the sequence length.

#### Output

**ypred** — Predicted class labels  
enumerated

Predicted class labels with the highest score, returned as a  $N$ -by-1 enumerated vector of labels, where  $N$  is the number of observations.

**scores** — Predicted class scores  
matrix

Predicted scores, returned as a  $N$ -by- $K$  matrix, where  $N$  is the number of observations, and  $K$  is the number of classes.

**labels** — Class labels for predicted scores  
matrix

Labels associated with the predicted scores, returned as a  $N$ -by- $K$  matrix, where  $N$  is the number of observations, and  $K$  is the number of classes.

## Parameters

**Network** — Source for trained recurrent neural network  
Network from MAT-file (default) | Network from MATLAB function

Specify the source for the trained recurrent neural network. The trained network must have at least one recurrent layer (for example, an LSTM network). Select one of the following:

- **Network from MAT-file**— Import a trained recurrent neural network from a MAT-file containing a `SeriesNetwork`, `DAGNetwork`, or `dlnetwork` object.
- **Network from MATLAB function**— Import a pretrained recurrent neural network from a MATLAB function.

### Programmatic Use

**Block Parameter:** Network

**Type:** character vector, string

**Values:** 'Network from MAT-file' | 'Network from MATLAB function'

**Default:** 'Network from MAT-file'

**File path** — MAT-file containing trained recurrent neural network  
untitled.mat (default) | MAT-file name

This parameter specifies the name of the MAT-file that contains the trained recurrent neural network to load. If the file is not on the MATLAB path, use the **Browse** button to locate the file.

### Dependencies

To enable this parameter, set the **Network** parameter to `Network from MAT-file`.

### Programmatic Use

**Block Parameter:** NetworkFilePath

**Type:** character vector, string

**Values:** MAT-file path or name

**Default:** 'untitled.mat'

**MATLAB function** — MATLAB function name  
untitled (default) | MATLAB function name

This parameter specifies the name of the MATLAB function for the pretrained recurrent neural network.

### Dependencies

To enable this parameter, set the **Network** parameter to `Network from MATLAB function`.

**Programmatic Use****Block Parameter:** NetworkFunction**Type:** character vector, string**Values:** MATLAB function name**Default:** 'untitled'**Sample time** — Output sample period and optional time offset

-1 (default) | scalar | vector

The **Sample time** parameter specifies when the block computes a new output value during simulation. For details, see “Specify Sample Time” (Simulink).

Specify the **Sample time** parameter as a scalar when you do not want the output to have a time offset. To add a time offset to the output, specify the **Sample time** parameter as a 1-by-2 vector where the first element is the sampling period and the second element is the offset.

By default, the **Sample time** parameter value is -1 to inherit the value.

**Programmatic Use****Block Parameter:** SampleTime**Type:** character vector**Values:** scalar | vector**Default:** '-1'**Classification** — Output predicted label with highest score

on (default) | off

Enable output port ypred that outputs the label with the highest score.

**Programmatic Use****Block Parameter:** Classification**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'on'**Predictions** — Output all scores and associated labels

off (default) | on

Enable output ports scores and labels that output all predicted scores and associated class labels.

**Programmatic Use****Block Parameter:** Predictions**Type:** character vector, string**Values:** 'off' | 'on'**Default:** 'off'

## Version History

Introduced in R2021a

## Extended Capabilities

**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- To generate generic C code that does not depend on third-party libraries, in the **Configuration Parameters > Code Generation** general category, set the **Language** parameter to C.
- To generate C++ code, in the **Configuration Parameters > Code Generation** general category, set the **Language** parameter to C++. To specify the target library for code generation, in the **Code Generation > Interface** category, set the **Target Library** parameter. Setting this parameter to None generates generic C++ code that does not depend on third-party libraries.
- For ERT-based targets, the **Support: variable-size signals** parameter in the **Code Generation > Interface** pane must be enabled.
- For a list of networks and layers supported for code generation, see “Networks and Layers Supported for Code Generation” (MATLAB Coder).

### GPU Code Generation

Generate CUDA® code for NVIDIA® GPUs using GPU Coder™.

Usage notes and limitations:

- The **Language** parameter in the **Configuration Parameters > Code Generation** general category must be set to C++.
- GPU code generation supports this block only when targeting the cuDNN library.

## Stateful Predict

Predict responses using a trained recurrent neural network

### Libraries:

Deep Learning Toolbox / Deep Neural Networks

## Description

The Stateful Predict block predicts responses for the data at the input by using the trained recurrent neural network specified through the block parameter. This block allows loading of a pretrained network into the Simulink model from a MAT-file or from a MATLAB function. This block updates the state of the network with every prediction.

To reset the state of recurrent neural network to its initial state, place the Stateful Predict block inside a Resettable Subsystem block and use the Reset control signal as trigger.

## Ports

### Input

**input** — Sequence or time series data  
numeric array

The input ports of the Stateful Predict block takes the names of the input layers of the network loaded. Based on the network loaded, the input to the predict block can be sequence or time series data.

The dimensions of the numeric arrays containing the sequences depend on the type of data.

Input	Description
Vector sequences	$c$ -by- $s$ matrices, where $c$ is the number of features of the sequences and $s$ is the sequence length.
2-D image sequences	$h$ -by- $w$ -by- $c$ -by- $s$ arrays, where $h$ , $w$ , and $c$ correspond to the height, width, and number of channels of the images, respectively, and $s$ is the sequence length.

### Output

**output** — Predicted scores or responses  
numeric array

The outputs port of the Stateful Predict block takes the names of the output layers of the network loaded. Based on the network loaded, the output of the Stateful Predict block can represent predicted scores or responses.

For sequence-to-label classification, the output is a  $N$ -by- $K$  matrix, where  $N$  is the number of observations, and  $K$  is the number of classes.

For sequence-to-sequence classification problems, the output is a  $K$ -by- $S$  matrix of scores, where  $K$  is the number of classes, and  $S$  is the total number of time steps in the corresponding input sequence.

## Parameters

**Network** — Source for trained recurrent neural network

`Network from MAT-file (default) | Network from MATLAB function`

Specify the source for the trained recurrent neural network. The trained network must have at least one recurrent layer (for example, an LSTM network). Select one of the following:

- **Network from MAT-file**— Import a trained recurrent neural network from a MAT-file containing a `SeriesNetwork`, `DAGNetwork`, or `dlnetwork` object.
- **Network from MATLAB function**— Import a pretrained recurrent neural network from a MATLAB function.

### Programmatic Use

**Block Parameter:** Network

**Type:** character vector, string

**Values:** 'Network from MAT-file' | 'Network from MATLAB function'

**Default:** 'Network from MAT-file'

**File path** — MAT-file containing trained recurrent neural network

`untitled.mat (default) | MAT-file name`

This parameter specifies the name of the MAT-file that contains the trained recurrent neural network to load. If the file is not on the MATLAB path, use the **Browse** button to locate the file.

### Dependencies

To enable this parameter, set the **Network** parameter to `Network from MAT-file`.

### Programmatic Use

**Block Parameter:** NetworkFilePath

**Type:** character vector, string

**Values:** MAT-file path or name

**Default:** 'untitled.mat'

**MATLAB function** — MATLAB function name

`untitled (default) | MATLAB function name`

This parameter specifies the name of the MATLAB function for the pretrained recurrent neural network.

### Dependencies

To enable this parameter, set the **Network** parameter to `Network from MATLAB function`.

### Programmatic Use

**Block Parameter:** NetworkFunction

**Type:** character vector, string

**Values:** MATLAB function name

**Default:** 'untitled'

**Sample time** — Output sample period and optional time offset  
-1 (default) | scalar | vector

The **Sample time** parameter specifies when the block computes a new output value during simulation. For details, see “Specify Sample Time” (Simulink).

Specify the **Sample time** parameter as a scalar when you do not want the output to have a time offset. To add a time offset to the output, specify the **Sample time** parameter as a 1-by-2 vector where the first element is the sampling period and the second element is the offset.

By default, the **Sample time** parameter value is -1 to inherit the value.

#### **Programmatic Use**

**Block Parameter:** SampleTime

**Type:** character vector

**Values:** scalar | vector

**Default:** '-1'
