totalAttribution

Compute total performance attribution by Brinson model

Syntax

```
[AggregateTotalAttribution,PeriodicTotalAttribution] = totalAttribution(
brinsonAttributionObj)
```

Description

`[AggregateTotalAttribution,PeriodicTotalAttribution] = totalAttribution(brinsonAttributionObj)` computes the total performance attribution of the portfolio, summed up for all categories, using the Brinson model.

Examples

Compute Total Performance Attribution Using `brinsonAttribution` Object

This example shows how to create a `brinsonAttribution` object and then use `totalAttribution` to compute the total performance attribution of the portfolio summed up for all categories (sectors).

Prepare Data

Create a table for the monthly prices for four assets.

```
 GM =[17.82;22.68;19.37;20.28];
 HD = [39.79;39.12;40.67;40.96];
 KO = [38.98;39.44;40.00;40.20];
 PG = [56.38;57.08;57.76;55.54];
 MonthlyPrices  = table(GM,HD,KO,PG);
```

Use `tick2ret` to define the monthly returns.

```
MonthlyReturns = tick2ret(MonthlyPrices.Variables)';
  [NumAssets,NumPeriods] = size(MonthlyReturns);
```

Define the periods.

```
Period = ones(NumAssets*NumPeriods,1);
  for k = 1:NumPeriods
      Period(k*NumAssets+1:end,1) = Period(k*NumAssets,1) + 1;
  end
```

Define the categories for the four assets.

```
Name = repmat(string(MonthlyPrices.Properties.VariableNames(:)),NumPeriods,1);
  Categories = repmat(categorical([ ...
      "Consumer Discretionary"; ...
      "Consumer Discretionary"; ...
      "Consumer Staples"; ...
      "Consumer Staples"]),NumPeriods,1);
```

Define benchmark and portfolio weights.

```
BenchmarkWeight = repmat(1./NumAssets.*ones(NumAssets, 1),NumPeriods,1);
  PortfolioWeight = repmat([1;0;1;1]./3,NumPeriods,1);
```

Create AssetTable Input

Create `AssetTable` as the input for the `brinsonAttribution` object.

```
  AssetTable = table(Period, Name, ...
      MonthlyReturns(:), Categories, PortfolioWeight, BenchmarkWeight, ...
      VariableNames=["Period","Name","Return","Category","PortfolioWeight","BenchmarkWeight"])
```

```
AssetTable=12×6 table
    Period    Name     Return             Category            PortfolioWeight    BenchmarkWeight
    ______    ____    _________    ______________________    _______________    _______________

      1       "GM"      0.27273    Consumer Discretionary        0.33333             0.25
      1       "HD"    -0.016838    Consumer Discretionary              0             0.25
      1       "KO"     0.011801    Consumer Staples              0.33333             0.25
      1       "PG"     0.012416    Consumer Staples              0.33333             0.25
      2       "GM"     -0.14594    Consumer Discretionary        0.33333             0.25
      2       "HD"     0.039622    Consumer Discretionary              0             0.25
      2       "KO"     0.014199    Consumer Staples              0.33333             0.25
      2       "PG"     0.011913    Consumer Staples              0.33333             0.25
      3       "GM"      0.04698    Consumer Discretionary        0.33333             0.25
      3       "HD"    0.0071306    Consumer Discretionary              0             0.25
      3       "KO"        0.005    Consumer Staples              0.33333             0.25
      3       "PG"    -0.038435    Consumer Staples              0.33333             0.25
```

Create brinsonAttribution Object

Use `brinsonAttribution` to create the `brinsonAttribution` object.

```
  BrinsonPAobj = brinsonAttribution(AssetTable)
```

```
BrinsonPAobj = 
  brinsonAttribution with properties:

                NumAssets: 4
       NumPortfolioAssets: 3
       NumBenchmarkAssets: 4
               NumPeriods: 3
            NumCategories: 2
                AssetName: [4x1 string]
              AssetReturn: [4x3 double]
            AssetCategory: [4x3 categorical]
     PortfolioAssetWeight: [4x3 double]
     BenchmarkAssetWeight: [4x3 double]
  PortfolioCategoryReturn: [2x3 double]
  BenchmarkCategoryReturn: [2x3 double]
  PortfolioCategoryWeight: [2x3 double]
  BenchmarkCategoryWeight: [2x3 double]
          PortfolioReturn: 0.0598
          BenchmarkReturn: 0.0540
```

```
            ActiveReturn: 0.0059
```

Compute Total Performance Attribution

Use the brinsonAttribution object with `totalAttribution` to compute the total performance attribution of the portfolio summed up for all categories.

```
[AggregateTotalAttribution, PeriodicTotalAttribution] = totalAttribution(BrinsonPAobj)
```

```
AggregateTotalAttribution=1×4 table
    Allocation    Selection    Interaction    ActiveReturn
    __________    _________    ___________    ____________

    -0.014353     0.030316      -0.010105      0.0058578  

PeriodicTotalAttribution=3×6 table

```

Input Arguments

`brinsonAttributionObj` — Brinson attribution model

object

Brinson attribution model, specified as a `brinsonAttribution` object.

Data Types: `object`

Output Arguments

`AggregateTotalAttribution` — Total attribution aggregated over all periods

table

Total attribution aggregated over all periods, returned as a table with the following columns:

- `Allocation` — Category allocation effect for the category
- `Selection` — Effect of selecting individual assets within the category
- `Interaction` — Allocation-selection interaction effect
- `ActiveReturn` — Active return compared with benchmark

`PeriodicTotalAttribution` — Total attribution for each period

table

Total attribution for each period, returned as a table with the following columns:

- `Period` — Time period numbers (1 for the first period, 2 for the second period, and so on)
- `LinkingCoefficient` — Linking coefficients used to aggregate the attribution results over all time periods

- `Allocation` — Category allocation effect for the category
- `Selection` — Effect of selecting individual assets within the category
- `Interaction` — Allocation-selection interaction effect
- `ActiveReturn` — Active return compared with benchmark

summary

Summarize performance attribution by Brinson model

Syntax

```
SummaryTable = summary(brinsonAttributionObj)
```

Description

`SummaryTable = summary(brinsonAttributionObj)` generates a table that summarizes the final results (aggregated over all time periods and categories) of the performance attribution by the Brinson model.

Examples

Generate Summary Table Using `brinsonAttribution` Object

This example shows how to create a `brinsonAttribution` object and then use `summary` to generate a table that summarizes the final results of the performance attribution by the Brinson model, aggregated over all time periods and categories (sectors).

Prepare Data

Create a table for the monthly prices for four assets.

```
 GM =[17.82;22.68;19.37;20.28];
 HD = [39.79;39.12;40.67;40.96];
 KO = [38.98;39.44;40.00;40.20];
 PG = [56.38;57.08;57.76;55.54];
 MonthlyPrices  = table(GM,HD,KO,PG);
```

Use `tick2ret` to define the monthly returns.

```
MonthlyReturns = tick2ret(MonthlyPrices.Variables)';
  [NumAssets,NumPeriods] = size(MonthlyReturns);
```

Define the periods.

```
Period = ones(NumAssets*NumPeriods,1);
  for k = 1:NumPeriods
      Period(k*NumAssets+1:end,1) = Period(k*NumAssets,1) + 1;
  end
```

Define the categories for the four assets.

```
Name = repmat(string(MonthlyPrices.Properties.VariableNames(:)),NumPeriods,1);
  Categories = repmat(categorical([ ...
      "Consumer Discretionary"; ...
      "Consumer Discretionary"; ...
      "Consumer Staples"; ...
      "Consumer Staples"]),NumPeriods,1);
```

Define benchmark and portfolio weights.

```
BenchmarkWeight = repmat(1./NumAssets.*ones(NumAssets, 1),NumPeriods,1);
  PortfolioWeight = repmat([1;0;1;1]./3,NumPeriods,1);
```

Create AssetTable Input

Create AssetTable as the input for the brinsonAttribution object.

```
  AssetTable = table(Period, Name, ...
      MonthlyReturns(:), Categories, PortfolioWeight, BenchmarkWeight, ...
      VariableNames=["Period","Name","Return","Category","PortfolioWeight","BenchmarkWeight"])
```

```
AssetTable=12×6 table
    Period    Name      Return              Category           PortfolioWeight    BenchmarkWeight
    ______    ____    _________    ______________________    _______________    _______________

      1       "GM"      0.27273    Consumer Discretionary        0.33333              0.25
      1       "HD"    -0.016838    Consumer Discretionary              0              0.25
      1       "KO"     0.011801    Consumer Staples              0.33333              0.25
      1       "PG"     0.012416    Consumer Staples              0.33333              0.25
      2       "GM"     -0.14594    Consumer Discretionary        0.33333              0.25
      2       "HD"     0.039622    Consumer Discretionary              0              0.25
      2       "KO"     0.014199    Consumer Staples              0.33333              0.25
      2       "PG"     0.011913    Consumer Staples              0.33333              0.25
      3       "GM"      0.04698    Consumer Discretionary        0.33333              0.25
      3       "HD"    0.0071306    Consumer Discretionary              0              0.25
      3       "KO"        0.005    Consumer Staples              0.33333              0.25
      3       "PG"    -0.038435    Consumer Staples              0.33333              0.25
```

Create brinsonAttribution Object

Use brinsonAttribution to create the brinsonAttribution object.

```
  BrinsonPAobj = brinsonAttribution(AssetTable)
```

```
BrinsonPAobj = 
  brinsonAttribution with properties:

                NumAssets: 4
       NumPortfolioAssets: 3
       NumBenchmarkAssets: 4
               NumPeriods: 3
            NumCategories: 2
                AssetName: [4x1 string]
              AssetReturn: [4x3 double]
            AssetCategory: [4x3 categorical]
     PortfolioAssetWeight: [4x3 double]
     BenchmarkAssetWeight: [4x3 double]
  PortfolioCategoryReturn: [2x3 double]
  BenchmarkCategoryReturn: [2x3 double]
  PortfolioCategoryWeight: [2x3 double]
  BenchmarkCategoryWeight: [2x3 double]
          PortfolioReturn: 0.0598
          BenchmarkReturn: 0.0540
             ActiveReturn: 0.0059
```

Generate Summary Table

Use the brinsonAttribution object with `summary` to generate a table that summarizes the final results of the performance attribution by the Brinson model, aggregated over all time periods and categories.

```
SummaryTable = summary(BrinsonPAobj)
```

```
SummaryTable=11×1 table
                                     Brinson Attribution Summary
                                     ___________________________

    Total Number of Assets                        4
    Number of Assets in Portfolio                 3
    Number of Assets in Benchmark                 4
    Number of Periods                             3
    Number of Categories                          2
    Portfolio Return                       0.059847
    Benchmark Return                        0.05399
    Active Return                         0.0058578
    Allocation Effect                     -0.014353
    Selection Effect                       0.030316
    Interaction Effect                    -0.010105
```

Input Arguments

`brinsonAttributionObj` — Brinson attribution model
object

Brinson attribution model, specified as a `brinsonAttribution` object.

Data Types: `object`

Output Arguments

`SummaryTable` — Metrics summarizing performance attribution by Brinson model
table

Metrics summarizing the performance attribution by the Brinson model, returned as a table where each row of the table is a calculated metric as follows:

- `Total Number of Assets` — Total for assets in the `AssetTable`
- `Number of Assets in Portfolio` — Total assets in the portfolio, as defined in `AssetTable`
- `Number of Assets in Benchmark` — The total assets in the benchmark, as defined in `AssetTable`
- `Number of Periods` — Total number of `Periods`, as defined in `AssetTable`
- `Portfolio Return` — Portfolio return, as defined in `AssetTable`
- `Benchmark Return` — Benchmark return, as defined in `AssetTable`
- `Active Return` — Calculated active return for the portfolio, as defined in `AssetTable`
- `Allocation Effect` — Allocation effect for the portfolio, as defined in `AssetTable`
- `Selection Effect` — Selection effect for the portfolio, as defined in `AssetTable`

- `Interaction Effect` — Interaction effect for the portfolio, as defined in `AssetTable`

attributionsChart

Create horizontal bar chart of performance attribution

Syntax

```
attributionsChart(BrinsonPAObj)
h = attributionsChart(ax,BrinsonPAObj)
h = attributionsChart( ___ ,Name=Value)
```

Description

`attributionsChart(BrinsonPAObj)` creates a horizontal bar chart of portfolio performance attributions by category, aggregated over all time periods using a `brinsonAttribution` object. This function decomposes active returns into category allocation, within-category selection, and allocation-selection interaction effects.

`h = attributionsChart(ax,BrinsonPAObj)` additionally returns the figure handle `h`.

`h = attributionsChart( ___ ,Name=Value)` adds optional name-value arguments.

Examples

Create Horizontal Bar Chart of Performance Attribution

This example shows how to create a `brinsonAttribution` object that you can then use with the `attributionsChart` function to generate a bar chart of performance attribution.

Prepare Data

Create a table for the monthly prices for four assets.

```
GM =[17.82;22.68;19.37;20.28];
HD = [39.79;39.12;40.67;40.96];
KO = [38.98;39.44;40.00;40.20];
PG = [56.38;57.08;57.76;55.54];
MonthlyPrices  = table(GM,HD,KO,PG);
```

Use `tick2ret` to define the monthly returns.

```
MonthlyReturns = tick2ret(MonthlyPrices.Variables)';
  [NumAssets,NumPeriods] = size(MonthlyReturns);
```

Define the periods.

```
Period = ones(NumAssets*NumPeriods,1);
  for k = 1:NumPeriods
      Period(k*NumAssets+1:end,1) = Period(k*NumAssets,1) + 1;
  end
```

Define the categories (sectors) for the four assets.

```
Name = repmat(string(MonthlyPrices.Properties.VariableNames(:)),NumPeriods,1);
  Categories = repmat(categorical([ ...
      "Consumer Discretionary"; ...
      "Consumer Discretionary"; ...
      "Consumer Staples"; ...
      "Consumer Staples"]),NumPeriods,1);
```

Define benchmark and portfolio weights.

```
BenchmarkWeight = repmat(1./NumAssets.*ones(NumAssets,1),NumPeriods,1);
  PortfolioWeight = repmat([1;0;1;1]./3,NumPeriods,1);
```

Create AssetTable Input

Create `AssetTable` as the input for the `brinsonAttribution` object.

```
AssetTable = table(Period, Name, ...
   MonthlyReturns(:), Categories, PortfolioWeight, BenchmarkWeight, ...
   VariableNames=["Period","Name","Return","Category","PortfolioWeight","BenchmarkWeight"])
```

```
AssetTable=12×6 table
    Period     Name      Return              Category            PortfolioWeight    BenchmarkWeight
    ______     ____    _________    ______________________    _______________    _______________

      1        "GM"      0.27273    Consumer Discretionary        0.33333             0.25      
      1        "HD"    -0.016838    Consumer Discretionary              0             0.25      
      1        "KO"     0.011801    Consumer Staples              0.33333             0.25      
      1        "PG"     0.012416    Consumer Staples              0.33333             0.25      
      2        "GM"     -0.14594    Consumer Discretionary        0.33333             0.25      
      2        "HD"     0.039622    Consumer Discretionary              0             0.25      
      2        "KO"     0.014199    Consumer Staples              0.33333             0.25      
      2        "PG"     0.011913    Consumer Staples              0.33333             0.25      
      3        "GM"      0.04698    Consumer Discretionary        0.33333             0.25      
      3        "HD"    0.0071306    Consumer Discretionary              0             0.25      
      3        "KO"        0.005    Consumer Staples              0.33333             0.25      
      3        "PG"    -0.038435    Consumer Staples              0.33333             0.25      
```

Create brinsonAttribution Object

Use `brinsonAttribution` to create the `brinsonAttribution` object.

```
BrinsonPAobj = brinsonAttribution(AssetTable)
```

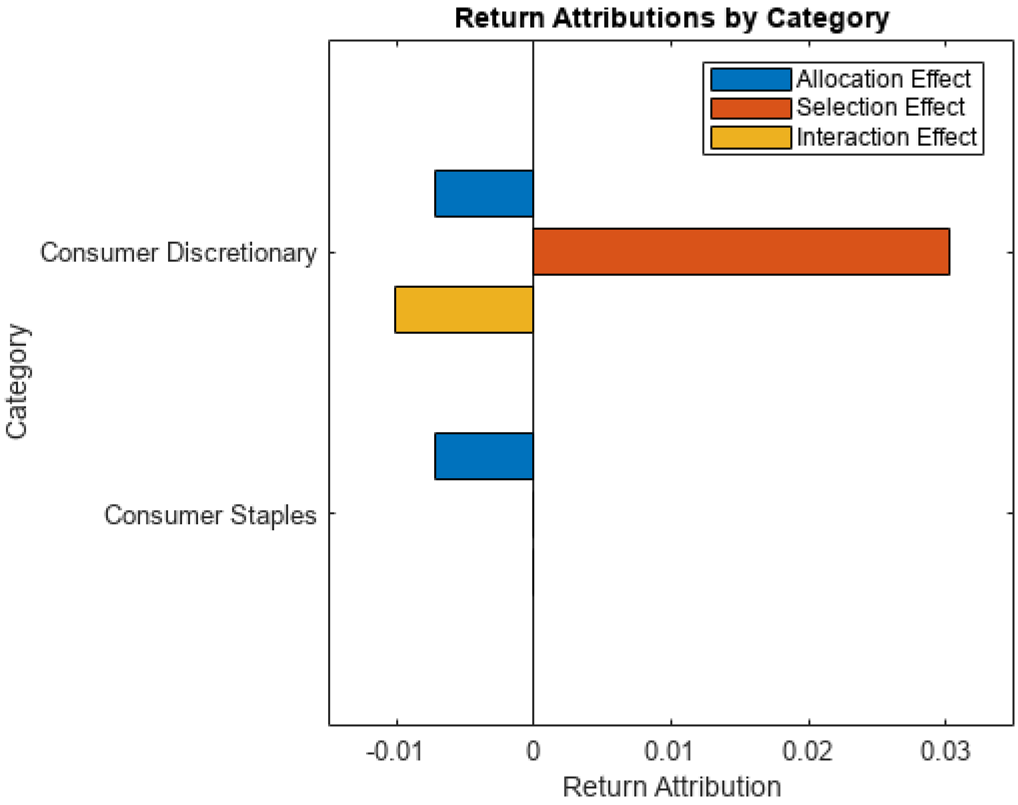
```
BrinsonPAobj = 
  brinsonAttribution with properties:

                  NumAssets: 4
         NumPortfolioAssets: 3
         NumBenchmarkAssets: 4
                 NumPeriods: 3
              NumCategories: 2
                  AssetName: [4x1 string]
                AssetReturn: [4x3 double]
              AssetCategory: [4x3 categorical]
       PortfolioAssetWeight: [4x3 double]
       BenchmarkAssetWeight: [4x3 double]
    PortfolioCategoryReturn: [2x3 double]
    BenchmarkCategoryReturn: [2x3 double]
    PortfolioCategoryWeight: [2x3 double]
    BenchmarkCategoryWeight: [2x3 double]
            PortfolioReturn: 0.0598
            BenchmarkReturn: 0.0540
               ActiveReturn: 0.0059
```

Generate Horizontal Bar Chart for Performance Attribution

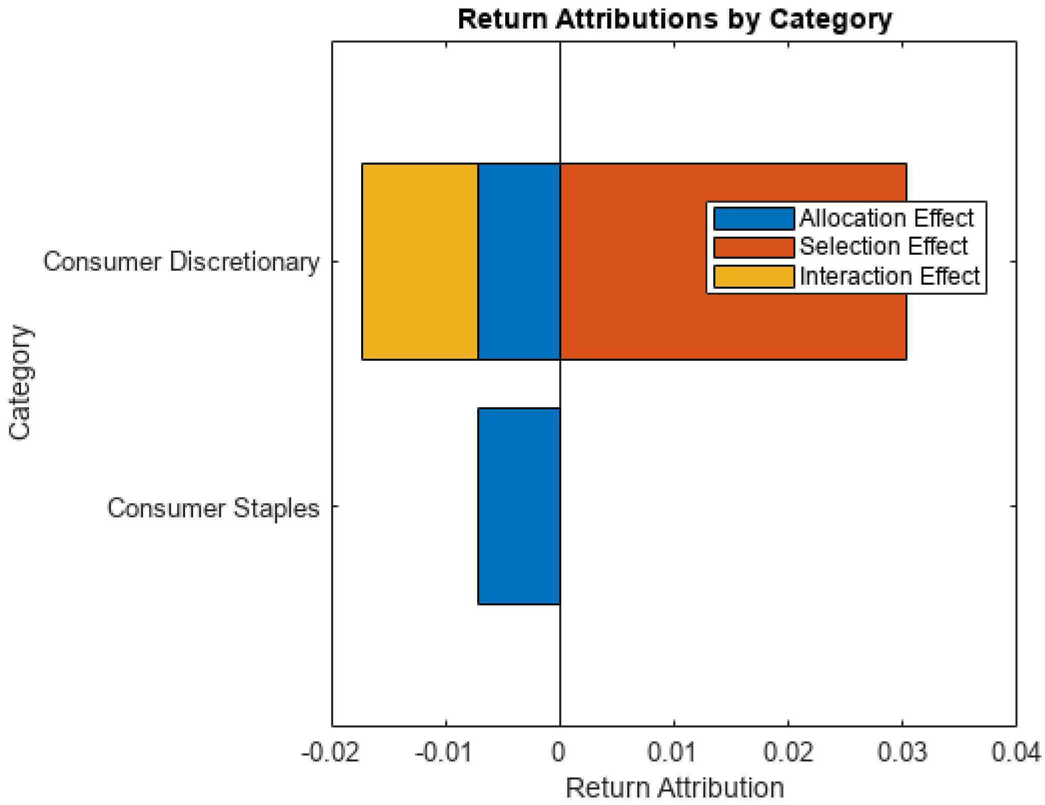
Use the `brinsonAttribution` object with `attributionsChart` to generate a horizontal bar chart of portfolio performance attributions by category, aggregated over all time periods.

```
attributionsChart(BrinsonPAobj)
```



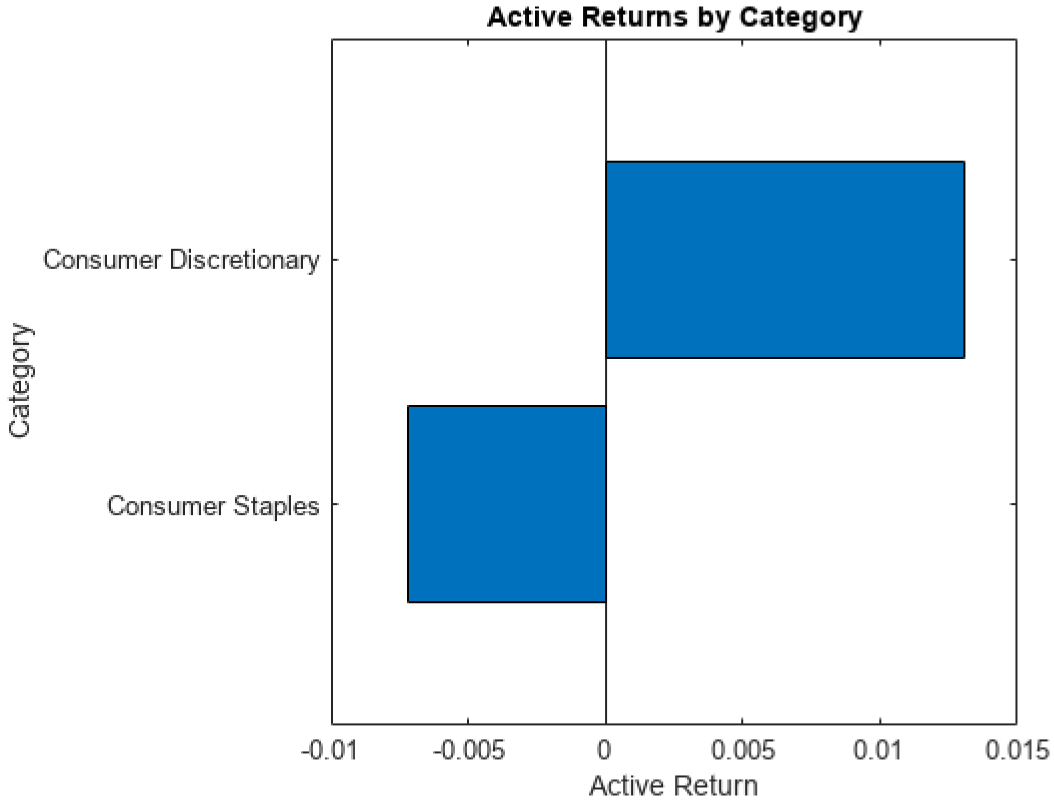
Alternatively, you can use the name-value argument for `Style` to generate a stacked horizontal bar chart of return attributions by category.

```
attributionsChart(BrinsonPAobj,Style="stacked")
```



Also, you can use the name-value argument for `Style` to generate a horizontal bar chart of active returns by category.

```
attributionsChart(BrinsonPAobj,Style="active")
```



Input Arguments

`BrinsonPAObj` — `brinsonAttribution` object to analyze performance attribution
`brinsonAttribution` object

`brinsonAttribution` object to analyze performance attribution. Use `brinsonAttribution` to create the `brinsonAttribution` object.

Data Types: `object`

`ax` — Valid axis object
`ax` object

(Optional) Valid axis object, specified as an `ax` object that you create using `axes`. `attributesChart` creates the plot on the axes specified by the optional `ax` argument instead of on the current axes (gca). The optional argument `ax` can precede any of the input argument combinations. If you do not specify an `axes` object, `attributesChart` plots into the current axes.

Data Types: `object`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `attributionsChart(BrinsonPAObj,Style="stacked")`

`Style` — Indicator to select style of attribution bar graphs

`"grouped"` (default) | character vector with value `'grouped'`, `'stacked'`, or `'active'` | string with value `"grouped"`, `"stacked"`, or `"active"`

Indicator to select style of attribution bar graphs, specified as `Style` and one of the following values:

- `"grouped"` — Plot the bar graphs for the allocation, selection, and interaction effects side-by-side.
- `"stacked"` — Stack the bar graphs for the allocation, selection, and interaction effects.
- `"active"` — Plot the bar graphs for the active returns as the sum of allocation, selection, and interaction effects.

Data Types: `char` | `string`

Output Arguments

`h` — Figure handle

handle object

Figure handle for the performance attributions chart, returned as handle object. You can use the figure handle to access and change the properties of the chart.

Version History

Introduced in R2023a

categoryReturnsChart

Create horizontal bar chart of category returns

Syntax

```
categoryReturnsChart(BrinsonPAObj)
h = categoryReturnsChart(ax,BrinsonPAObj)
```

Description

`categoryReturnsChart(BrinsonPAObj)` creates a horizontal bar chart of portfolio and benchmark category returns, aggregated over all time periods using a `brinsonAttribution` object.

`h = categoryReturnsChart(ax,BrinsonPAObj)` additionally returns the figure handle `h`.

Examples

Create Horizontal Bar Chart of Category Returns

This example shows how to create a `brinsonAttribution` object that you can then use with the `categoryReturnsChart` function to generate a bar chart of category returns.

Prepare Data

Create a table for the monthly prices for four assets.

```
 GM =[17.82;22.68;19.37;20.28];
 HD = [39.79;39.12;40.67;40.96];
 KO = [38.98;39.44;40.00;40.20];
 PG = [56.38;57.08;57.76;55.54];
 MonthlyPrices  = table(GM,HD,KO,PG);
```

Use `tick2ret` to define the monthly returns.

```
MonthlyReturns = tick2ret(MonthlyPrices.Variables)';
  [NumAssets,NumPeriods] = size(MonthlyReturns);
```

Define the periods.

```
Period = ones(NumAssets*NumPeriods,1);
  for k = 1:NumPeriods
      Period(k*NumAssets+1:end,1) = Period(k*NumAssets,1) + 1;
  end
```

Define the categories (sectors) for the four assets.

```
Name = repmat(string(MonthlyPrices.Properties.VariableNames(:)),NumPeriods,1);
  Categories = repmat(categorical([ ...
      "Consumer Discretionary"; ...
      "Consumer Discretionary"; ...
      "Consumer Staples"; ...
      "Consumer Staples"]),NumPeriods,1);
```

Define benchmark and portfolio weights.

```
BenchmarkWeight = repmat(1./NumAssets.*ones(NumAssets, 1),NumPeriods,1);
  PortfolioWeight = repmat([1;0;1;1]./3,NumPeriods,1);
```

Create AssetTable Input

Create AssetTable as the input for the brinsonAttribution object.

```
  AssetTable = table(Period, Name, ...
      MonthlyReturns(:), Categories, PortfolioWeight, BenchmarkWeight, ...
      VariableNames=["Period","Name","Return","Category","PortfolioWeight","BenchmarkWeight"])
```

```
AssetTable=12×6 table
    Period    Name      Return             Category            PortfolioWeight    BenchmarkWeight
    ______    ____    _________    ______________________    _______________    _______________

      1       "GM"      0.27273    Consumer Discretionary        0.33333              0.25
      1       "HD"    -0.016838    Consumer Discretionary              0              0.25
      1       "KO"     0.011801    Consumer Staples              0.33333              0.25
      1       "PG"     0.012416    Consumer Staples              0.33333              0.25
      2       "GM"     -0.14594    Consumer Discretionary        0.33333              0.25
      2       "HD"     0.039622    Consumer Discretionary              0              0.25
      2       "KO"     0.014199    Consumer Staples              0.33333              0.25
      2       "PG"     0.011913    Consumer Staples              0.33333              0.25
      3       "GM"      0.04698    Consumer Discretionary        0.33333              0.25
      3       "HD"    0.0071306    Consumer Discretionary              0              0.25
      3       "KO"        0.005    Consumer Staples              0.33333              0.25
      3       "PG"    -0.038435    Consumer Staples              0.33333              0.25
```

Create brinsonAttribution Object

Use brinsonAttribution to create the brinsonAttribution object.

```
  BrinsonPAobj = brinsonAttribution(AssetTable)
```

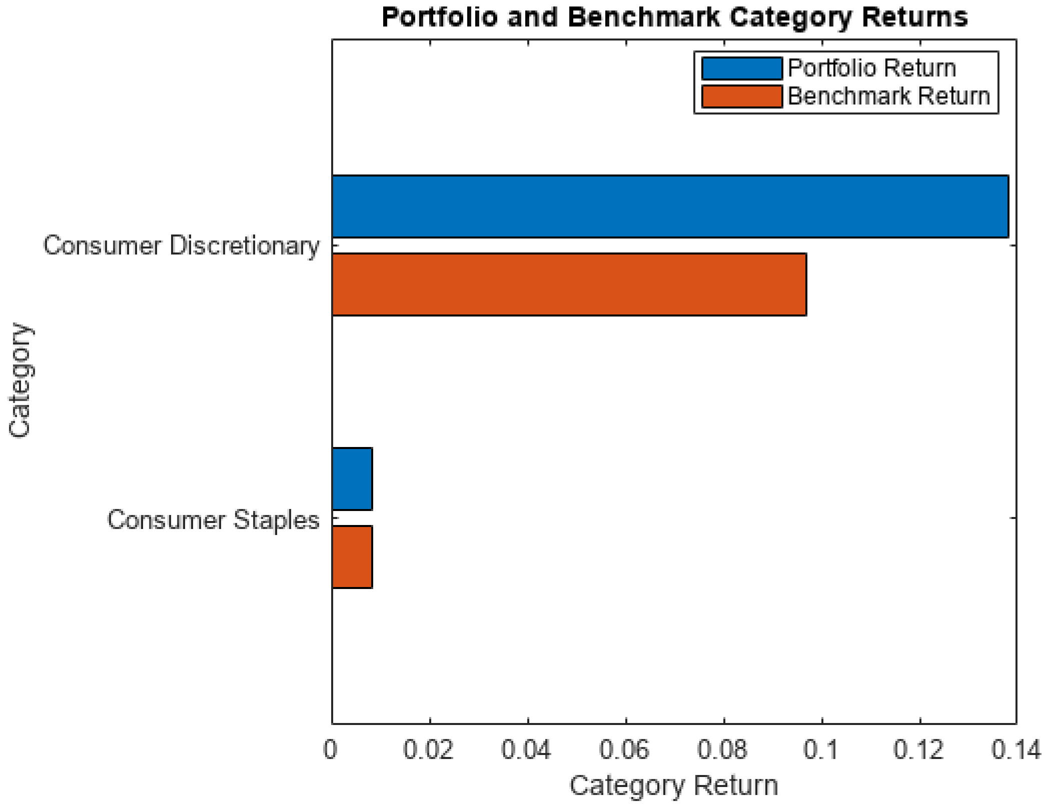
```
BrinsonPAobj = 
  brinsonAttribution with properties:

                NumAssets: 4
       NumPortfolioAssets: 3
       NumBenchmarkAssets: 4
               NumPeriods: 3
            NumCategories: 2
                AssetName: [4x1 string]
              AssetReturn: [4x3 double]
            AssetCategory: [4x3 categorical]
     PortfolioAssetWeight: [4x3 double]
     BenchmarkAssetWeight: [4x3 double]
  PortfolioCategoryReturn: [2x3 double]
  BenchmarkCategoryReturn: [2x3 double]
  PortfolioCategoryWeight: [2x3 double]
  BenchmarkCategoryWeight: [2x3 double]
          PortfolioReturn: 0.0598
          BenchmarkReturn: 0.0540
             ActiveReturn: 0.0059
```

Generate Horizontal Bar Chart for Category Returns

Use the `brinsonAttribution` object with `categoryReturnsChart` to generate a horizontal bar chart of portfolio and benchmark category returns, aggregated over all time periods.

```
categoryReturnsChart(BrinsonPAobj)
```



Input Arguments

`BrinsonPAObj` — `brinsonAttribution` object to analyze performance attribution
`brinsonAttribution` object

`brinsonAttribution` object to analyze performance attribution. Use `brinsonAttribution` to create the `brinsonAttribution` object.

Data Types: `object`

`ax` — Valid axis object
`ax` object

(Optional) Valid axis object, specified as an `ax` object that you create using `axes`. `categoryReturnsChart` creates the plot on the axes specified by the optional `ax` argument instead of on the current axes (gca). The optional argument `ax` can precede any of the input argument combinations. If you do not specify an `axes` object, `categoryReturnsChart` plots into the current axes.

Data Types: `object`

Output Arguments

h — Figure handle
handle object

Figure handle for the category returns chart, returned as handle object. You can use the figure handle to access and change the properties of the chart.

categoryWeightsChart

Create a horizontal bar chart for category weights

Syntax

```
categoryWeightsChart(BrinsonPAObj)
h = categoryWeightsChart(ax,BrinsonPAObj)
h = categoryWeightsChart(___,Name=Value)
```

Description

`categoryWeightsChart(BrinsonPAObj)` creates a horizontal bar chart of portfolio, benchmark, and active weights by category, averaged over all time periods using a `brinsonAttribution` object.

`h = categoryWeightsChart(ax,BrinsonPAObj)` additionally returns the figure handle `h`.

`h = categoryWeightsChart(___,Name=Value)` adds optional name-value arguments.

Examples

Create Horizontal Bar Chart of Category Weights

This example shows how to create a `brinsonAttribution` object that you can then use with the `categoryWeightsChart` function to generate a bar chart of category weights.

Prepare Data

Create a table for the monthly prices for four assets.

```
GM =[17.82;22.68;19.37;20.28];
HD = [39.79;39.12;40.67;40.96];
KO = [38.98;39.44;40.00;40.20];
PG = [56.38;57.08;57.76;55.54];
MonthlyPrices  = table(GM,HD,KO,PG);
```

Use `tick2ret` to define the monthly returns.

```
MonthlyReturns = tick2ret(MonthlyPrices.Variables)';
  [NumAssets,NumPeriods] = size(MonthlyReturns);
```

Define the periods.

```
Period = ones(NumAssets*NumPeriods,1);
  for k = 1:NumPeriods
      Period(k*NumAssets+1:end,1) = Period(k*NumAssets,1) + 1;
  end
```

Define the categories (sectors) for the four assets.

```
Name = repmat(string(MonthlyPrices.Properties.VariableNames(:)),NumPeriods,1);
  Categories = repmat(categorical([ ...
      "Consumer Discretionary"; ...
      "Consumer Discretionary"; ...
      "Consumer Staples"; ...
      "Consumer Staples"]),NumPeriods,1);
```

Define benchmark and portfolio weights.

```
BenchmarkWeight = repmat(1./NumAssets.*ones(NumAssets, 1),NumPeriods,1);
PortfolioWeight = repmat([1;0;1;1]./3,NumPeriods,1);
```

Create AssetTable Input

Create `AssetTable` as the input for the `brinsonAttribution` object.

```
AssetTable = table(Period, Name, ...
    MonthlyReturns(:), Categories, PortfolioWeight, BenchmarkWeight, ...
    VariableNames=["Period","Name","Return","Category","PortfolioWeight","BenchmarkWeight"])
```

```
AssetTable=12×6 table
    Period    Name      Return             Category             PortfolioWeight    BenchmarkWeight
    ______    ____    _________    ______________________    _______________    _______________

      1       "GM"      0.27273    Consumer Discretionary        0.33333             0.25      
      1       "HD"    -0.016838    Consumer Discretionary              0             0.25      
      1       "KO"     0.011801    Consumer Staples              0.33333             0.25      
      1       "PG"     0.012416    Consumer Staples              0.33333             0.25      
      2       "GM"     -0.14594    Consumer Discretionary        0.33333             0.25      
      2       "HD"     0.039622    Consumer Discretionary              0             0.25      
      2       "KO"     0.014199    Consumer Staples              0.33333             0.25      
      2       "PG"     0.011913    Consumer Staples              0.33333             0.25      
      3       "GM"      0.04698    Consumer Discretionary        0.33333             0.25      
      3       "HD"    0.0071306    Consumer Discretionary              0             0.25      
      3       "KO"        0.005    Consumer Staples              0.33333             0.25      
      3       "PG"    -0.038435    Consumer Staples              0.33333             0.25      
```

Create brinsonAttribution Object

Use `brinsonAttribution` to create the `brinsonAttribution` object.

```
BrinsonPAobj = brinsonAttribution(AssetTable)
```

```
BrinsonPAobj = 
  brinsonAttribution with properties:

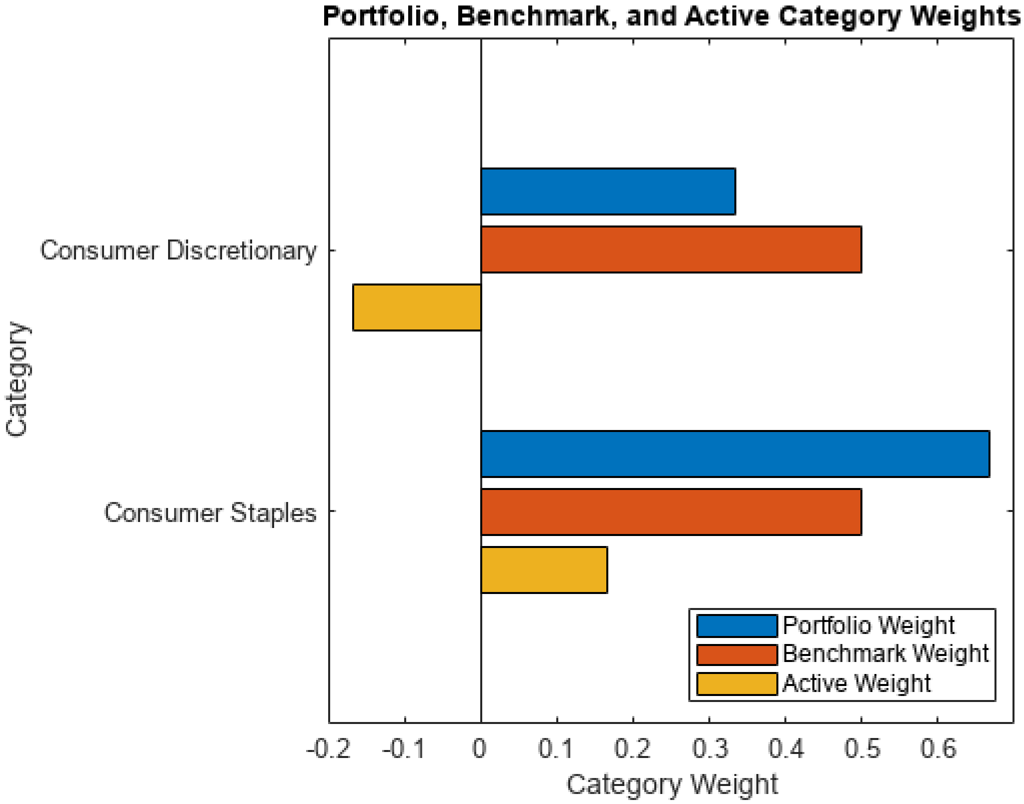
                  NumAssets: 4
         NumPortfolioAssets: 3
         NumBenchmarkAssets: 4
                 NumPeriods: 3
              NumCategories: 2
                  AssetName: [4x1 string]
                AssetReturn: [4x3 double]
              AssetCategory: [4x3 categorical]
       PortfolioAssetWeight: [4x3 double]
       BenchmarkAssetWeight: [4x3 double]
    PortfolioCategoryReturn: [2x3 double]
    BenchmarkCategoryReturn: [2x3 double]
    PortfolioCategoryWeight: [2x3 double]
    BenchmarkCategoryWeight: [2x3 double]
```

```
        PortfolioReturn: 0.0598
        BenchmarkReturn: 0.0540
           ActiveReturn: 0.0059
```

Generate Horizontal Bar Chart for Category Weights

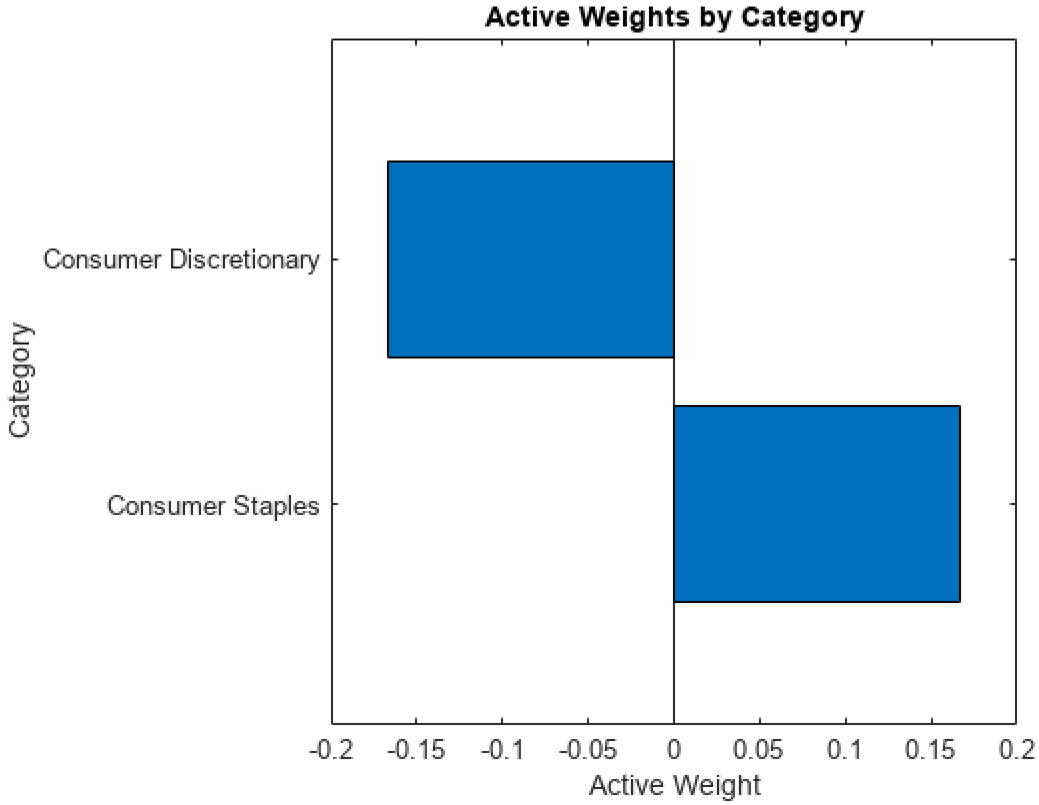
Use the `brinsonAttribution` object with `categoryWeightsChart` to generate a horizontal bar chart of portfolio, benchmark, and active weights by category, averaged over all time periods.

```
categoryWeightsChart(BrinsonPAobj)
```



Alternatively, you can use the name-value argument for `ActiveOnly` to plot only active weights by category.

```
categoryWeightsChart(BrinsonPAobj,ActiveOnly=true)
```



Input Arguments

`BrinsonPAObj` — `brinsonAttribution` object to analyze performance attribution
`brinsonAttribution` object

`brinsonAttribution` object to analyze performance attribution. Use `brinsonAttribution` to create the `brinsonAttribution` object.

Data Types: `object`

`ax` — Valid axis object
`ax` object

(Optional) Valid axis object, specified as an `ax` object that you create using `axes`. `categoryWeightsChart` creates the plot on the axes specified by the optional `ax` argument instead of on the current axes (gca). The optional argument `ax` can precede any of the input argument combinations. If you do not specify an `axes`, `categoryWeightsChart` plots into the current axes.

Data Types: `object`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `categoryWeightsChart(BrinsonPAObj,ActiveOnly=true)`

`ActiveOnly` — Indicator to plot only active weights by category

`false` (default) | logical with value `true` or `false`

Indicator to plot only active weights by category, specified as `ActiveOnly` and a logical with a value of `true` (plot active weights only) or `false` (plot portfolio, benchmark, and active weights).

Data Types: `logical`

Output Arguments

`h` — Figure handle

handle object

Figure handle for weights by category chart, returned as handle object. You can use the figure handle to access and change the properties of the chart.

Version History

Introduced in R2023a

covarianceDenoising

Estimate covariance matrix using denoising

Syntax

```
SigmaHat = covarianceDenoising(AssetReturns)
SigmaHat = covarianceDenoising(Sigma,SampleSize)
[SigmaHat,numSignalEig] = covarianceDenoising( ___ )
```

Description

`SigmaHat = covarianceDenoising(AssetReturns)` returns a covariance estimate that uses random matrix theory to denoise the empirical covariance matrix. For more information, see "Covariance Denoising" on page 15-55 and "Denoising Algorithm" on page 15-55.

In addition, you can use `covarianceShrinkage` to compute an estimate of covariance matrix using shrinkage estimation. For information on which covariance estimation method to choose, see "Comparison of Methods for Covariance Estimation" on page 4-134.

`SigmaHat = covarianceDenoising(Sigma,SampleSize)` returns a covariance estimate from an initial covariance matrix estimate (`Sigma`) and the sample size used to estimate the initial covariance (`sampleSize`).

`[SigmaHat,numSignalEig] = covarianceDenoising( ___ )` returns a covariance estimate and the number of eigenvalues that are associated with signal in combination with either of the input argument combinations in the previous syntaxes.

Examples

Perform Covariance Denoising

This example shows how to use covariance denoising to reduce noise and enhance the signal of the empirical covariance matrix. In mean-variance portfolio optimization, a noisy estimate of the covariance estimate results in unstable solutions that cause high turnover and transaction costs. Ideally, to decrease the estimation error, it is desirable to increase the sample size. Yet, there are cases where this is not possible. In extreme cases in which the number of assets is larger than the number of observations, the traditional covariance matrix results in a singular matrix. Working with a nearly singular or an ill-conditioned covariance matrix magnifies the impact of estimation errors.

Compute a portfolio efficient frontier using different covariance estimates with the same sample data.

```
% Load portfolio data with 225 assets
load port5.mat
covariance = corr2cov(stdDev_return,Correlation);
% Generate a sample with 200 observations
rng('default')
nScen = 200;
retSeries = portsim(mean_return',covariance,nScen);
```

Compute the traditional and denoised covariance estimates. Use `covarianceDenoising` to create a covariance estimate.

```
Sigma = cov(retSeries);
denoisedSigma = covarianceDenoising(retSeries);
```

Compute the condition number of both covariance estimates. The denoised covariance `denoisedSigma` has a lower condition number than the traditional covariance estimate `Sigma`.

```
conditionNum = [cond(Sigma); cond(denoisedSigma)];
condNumT = table(conditionNum,'RowNames',{'Sigma','SigmaHat'})
```

```
condNumT=2×1 table
                conditionNum
                ____________

    Sigma        2.5285e+18
    SigmaHat         1046.8
```

Use `Portfolio` to construct `Portfolio` objects that use the different `AssetCovar` values. Then use `setDefaultConstraints` to set the portfolio constraints with nonnegative weights that sum to 1 for the three portfolios: the true mean with the true covariance, the traditional covariance estimate, and the denoised estimate.

```
% Create a Portfolio object with the true parameters
p = Portfolio(AssetMean=mean_return,AssetCovar=covariance);
p = setDefaultConstraints(p);

% Create a Portfolio object with true mean and traditional covariance estimate
pTraditional = Portfolio(AssetMean=mean_return,AssetCovar=Sigma);
pTraditional = setDefaultConstraints(pTraditional);

% Create a Portfolio object with true mean and denoised covariance
pDenoised = Portfolio(AssetMean=mean_return,AssetCovar=denoisedSigma);
pDenoised = setDefaultConstraints(pDenoised);
```

Use `estimateFrontier` to estimate the efficient frontier for each of the `Portfolio` objects.

```
% Number of portfolios on the efficient frontier
nPort = 20;

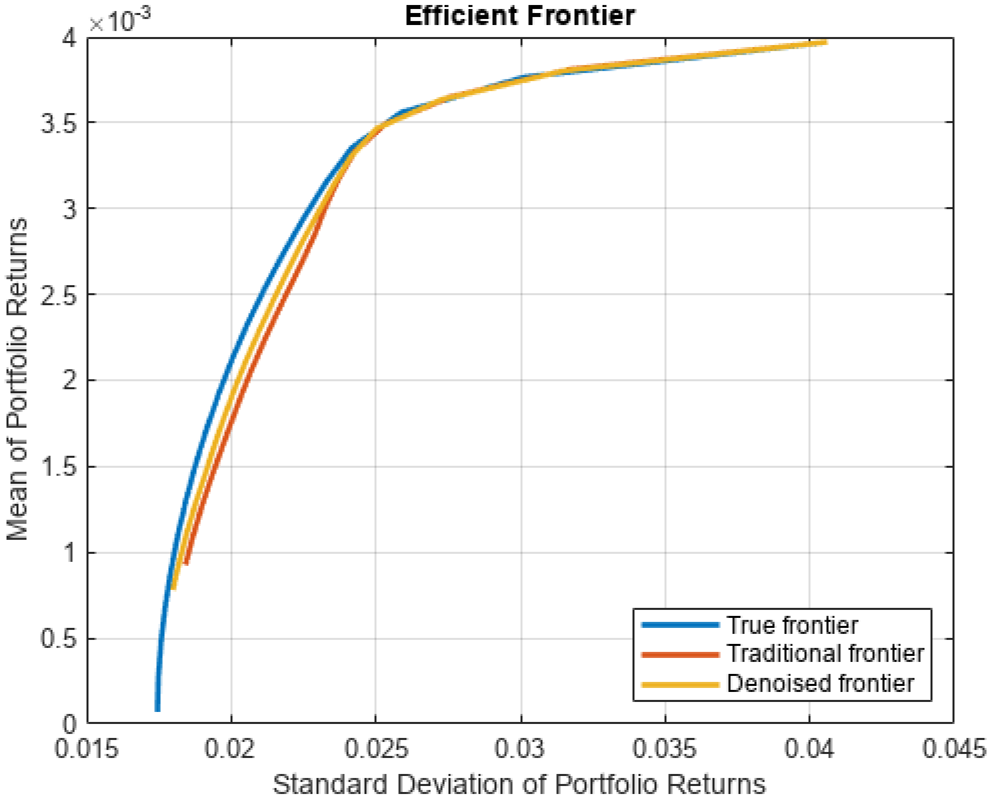
% True efficient portfolios
w = estimateFrontier(p,nPort);

% Traditional covariance efficient portfolios
wTraditional = estimateFrontier(pTraditional,nPort);

% Denoised covariance efficient portfolios
wDenoised = estimateFrontier(pDenoised,nPort);
```

Use `plotFrontier` to plot the frontier obtained from the different weights using the true parameter values.

```
figure
plotFrontier(p,w)
hold on
plotFrontier(p,wTraditional)
plotFrontier(p,wDenoised)
legend('True frontier','Traditional frontier','Denoised frontier', ...
    Location='southeast');
hold off
```



The efficient frontier obtained by denoising is closer to the true frontier than the frontier obtained using the traditional covariance estimate. This improvement shows the robustness of the denoised covariance estimate.

Sample Size Selection for Covariance Denoising

This example shows the effect of the sample size in `covarianceDenoising` to compute a denoised version of an initial covariance estimate. The `covarianceDenoising` function has two different syntaxes. This example focuses on the syntax with two inputs: a covariance estimate and the size of the sample that you use to compute the initial covariance estimate. This example demonstrates an empirical study of the effect of the sample size on the acuracy of the denoised estimate. The goal of this example is to provide insight for the choice of the sample size when this information is not available. This scenario can happen if the initial covariance estimate is stored but the information of the sample used to compute the estimate is not available.

Create Random Sample

Create a random sample using `mvnrnd`.

```
% Load data
load('port5.mat','mean_return','Correlation')

% Select the number of assets
numObservations = 300;
numAssets = 100;
mu = mean_return(1:numAssets);
C = Correlation(1:numAssets,1:numAssets);

% Generate a random sample
rng('default')
randSample = mvnrnd(mu,C,numObservations);
```

Use `corr` to compute the standard correlation estimate of the sample. This example works with the correlation matrix to remove the effect of the variance. This is useful when comparing the effect of the sample size in the denoised covariance estimate.

```
stdCorr = corr(randSample);
```

Due to numerical errors, `stdCorr` is not symmetric. Modify `stdCorr` to make it symmetric.

```
% Compute maximum absolute difference of matrix against its
% transpose
max(abs(stdCorr-stdCorr'),[],'all')
```

```
ans = 1.1102e-16
```

```
% Force correlation matrix to be symmetric
stdCorr = (stdCorr+stdCorr')/2;
```

Use `covarianceDenoising` to compute the denoised covariance estimate from `Sigma` using the correct sample size.

```
denoisedCorr = covarianceDenoising(stdCorr,numObservations);
denoisedCorr = (denoisedCorr+denoisedCorr')/2;
```

Compute Denoised Covariance for Different Sample Sizes

Compare the maximum correlation difference between the denoised covariance with the correct sample size and other sample sizes. Also, you compute the number of factors.

```
% Sample sizes to try
numSizes = 100;
sampleSizes = ceil(logspace(0,4,numSizes));

% Compute denoised correlation and store the maximum correlation
% mismatch
correlations = cell(numSizes);
numFactors = zeros(numSizes,1);
maxDiff = zeros(numSizes,1);
for i = 1:numSizes
    [correlations{i},numFactors(i)] = covarianceDenoising(stdCorr,...
        sampleSizes(i));
    maxDiff(i) = norm(correlations{i}(:)-denoisedCorr(:),inf);
end
```

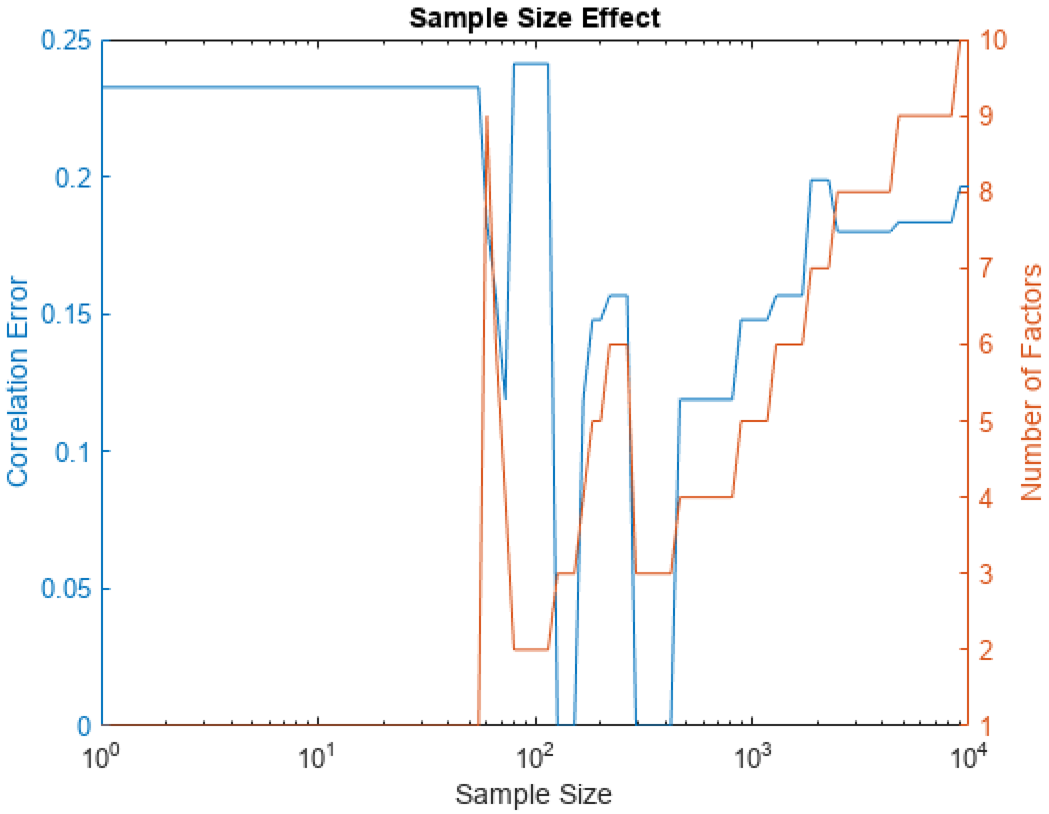
Plot the maximum error in the correlations as well as the number of factors identified for each sample size.

```
figure;

% Plot correlation error
yyaxis left
semilogx(sampleSizes,maxDiff)
hold on
ylabel("Correlation Error");

% Plot number of factors
yyaxis right
semilogx(sampleSizes,numFactors)
ylabel("Number of Factors");

% Title, labels, and legends
title("Sample Size Effect")
xlabel("Sample Size");
hold off
```



Note that when the sample size is close to the number of assets, the behavior of both the correlation error and the number of factors is erratic. Here, when the sample size is between 55 and 292, the number of factors and the correlation error jump up and down. Before 55 "observations" the number of factors is 1 because the denoising method doesn't have enough information to trust that what is being observed is signal and not noise; only the largest eigenvalue is associated with signal. Usually the largest eigenvalue is linked to the market. Meanwhile, after 292 "observations" the number of eigenvalues not associated with noise monotonically increases. This behavior happens because denoising assumes that the sample is less noisy with more observations, so identifying signal from noise is easier.

If the sample size of the initial covariance estimate is not known, it is better to choose a sample size that is far from the number of assets. For cases with less trust in the initial covariance estimate, the sample size should be smaller, below 55 in this example. If you trust the initial covariance estimate, then the sample size should be larger, above 292 in this example. The degree of trust in the initial covariance matrix can be adjusted by increasing the sample size.

Backtest to Compare Investment Strategy When Using Covariance Denoising

This example compares a minimum variance investment strategy using the traditional covariance estimate with a minimum variance strategy using covariance denoising.

Load Data

```
% Read a table of daily adjusted close prices for 2006 DJIA stocks.
T = readtable('dowPortfolio.xlsx');

% Convert the table to a timetable.
pricesTT = table2timetable(T,'RowTimes','Dates');
numAssets = size(pricesTT.Variables, 2);
```

Use the first 42 days of the `dowPortfolio.xlsx` data set to initialize the backtest strategies. The backtest is then run over the remaining data.

```
warmupPeriod = 42;
```

Compute Initial Weights

Use the `traditionalStrat` and `denoisedStrat` functions in Local Functions on page 15-53 to compute the weights.

```
% Specify no current weights (100% cash position).
w0 = zeros(1,numAssets);

% Specify warm-up partition of data set timetable.
warmupTT = pricesTT(1:warmupPeriod,:);

% Compute the initial portfolio weights for each strategy.
traditional_initial = traditionalStrat(w0,warmupTT);
shrunk_initial = denoisedStrat(w0,warmupTT);
```

Create Backtest Strategies

Create `Traditional` and `Denoising` backtest strategy objects using `backtestStrategy`.

```
% Rebalance approximately every month.
rebalFreq = 21;

% Set the rolling lookback window to be at least 2 months and at
% most 6 months.
lookback  = [42 126];

% Use a fixed transaction cost (buy and sell costs are both 0.5%
% of amount traded).
```

```
transactionsFixed = 0.005;

% Specify the strategy objects.
strat1 = backtestStrategy('Traditional', @traditionalStrat, ...
    RebalanceFrequency=rebalFreq, ...
    LookbackWindow=lookback, ...
    TransactionCosts=transactionsFixed, ...
    InitialWeights=traditional_initial);

strat2 = backtestStrategy('Denoising', @denoisedStrat, ...
    RebalanceFrequency=rebalFreq, ...
    LookbackWindow=lookback, ...
    TransactionCosts=transactionsFixed, ...
    InitialWeights=shrunk_initial);

% Aggregate the two strategy objects into an array.
strategies = [strat1, strat2];
```

Create a `backtestEngine` object then use `runBacktest` to run the backtest.

```
% Create the backtesting engine object.
backtester = backtestEngine(strategies);

% Run the backtest.
backtester = runBacktest(backtester,pricesTT,'Start',warmupPeriod);

% Generate summary table of the performance of the strategies.
summary(backtester)
```

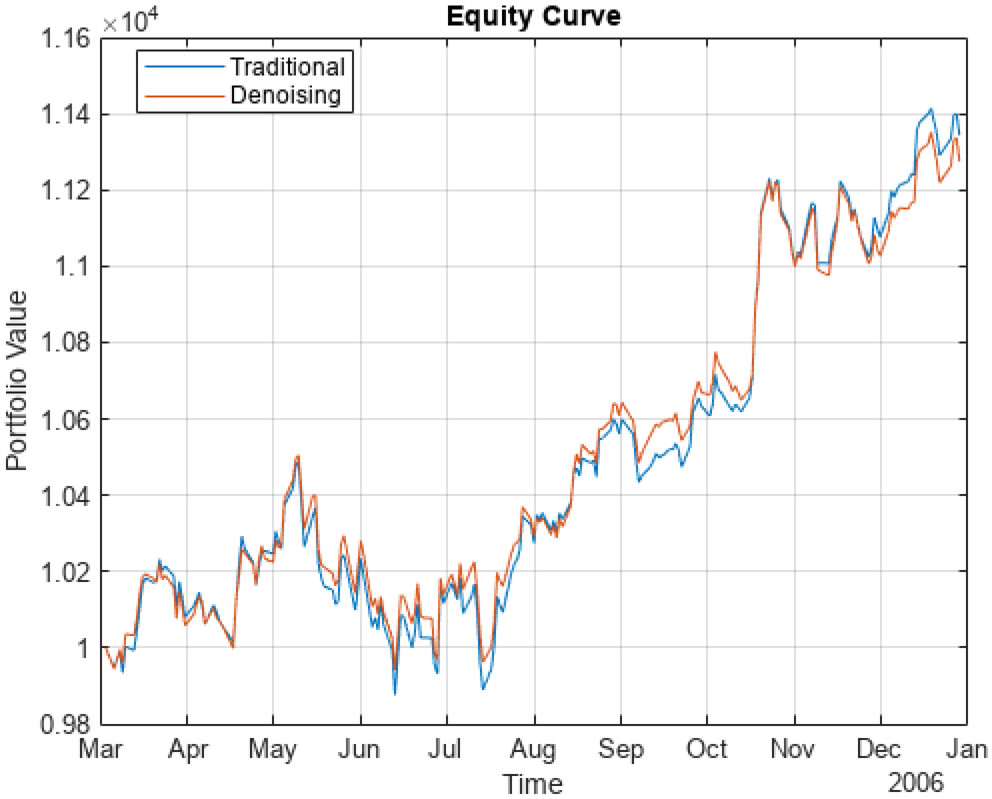
```
ans=9×2 table
                       Traditional    Denoising 
                       ___________    __________

    TotalReturn            0.13431       0.12745
    SharpeRatio            0.10807       0.10719
    Volatility           0.0057472     0.0055101
    AverageTurnover      0.0098378     0.0074213
    MaxTurnover            0.36237        0.2791
    AverageReturn        0.0006196    0.00058922
    MaxDrawdown           0.058469      0.053624
    AverageBuyCost         0.51636       0.38982
    AverageSellCost        0.51636       0.38982
```

Compare Performance of Strategies

Use `equityCurve` to plot the equity curve to compare the performance of both strategies.

```
equityCurve(backtester)
```



The maximum and average turnover are decreased using covariance denoising. Also, the covariance denoising strategy results in a decrease of buy and sell costs. In this example, not only is the turnover decreased, but also the volatility and the maximum drawdown are decreased. Therefore, in this example the denoised covariance produces more robust weights.

Local Functions

```
function new_weights = traditionalStrat(~, pricesTT)
% Function for minimum variance portfolio using traditional covariance estimate.

% Compute the returns from the prices timetable.
assetReturns = tick2ret(pricesTT);
mu = mean(assetReturns.Variables);
Sigma = cov(assetReturns.Variables,"omitrows");

% Create the portfolio problem.
p = Portfolio(AssetMean=mu,AssetCovar=Sigma);
% Specify long-only fully invested contraints.
p = setDefaultConstraints(p);

% Compute the minimum variance portfolio.
new_weights = estimateFrontierLimits(p,'min');
end

function new_weights = denoisedStrat(~, pricesTT)
% Function for minimum variance portfolio using covariance denoising.
% Compute the returns from the prices timetable.
assetReturns = tick2ret(pricesTT);
mu = mean(assetReturns.Variables);
Sigma = covarianceDenoising(assetReturns.Variables);

% Create the portfolio problem.
p = Portfolio(AssetMean=mu,AssetCovar=Sigma);
% Specify long-only fully invested contraints.
p = setDefaultConstraints(p);

% Compute the minimum variance portfolio.
new_weights = estimateFrontierLimits(p,'min');
end
```

Input Arguments

AssetReturns — Asset returns

matrix | table | timetable

Asset returns, specified as a NumObservations-by-NumAssets matrix, table, or timetable.

Note All rows (observations) with one or more NaN values are removed before computing the covariance estimate.

Data Types: double | table | timetable

Sigma — Initial covariance matrix estimate

matrix

Covariance matrix estimate, specified as a NumAssets-by-NumAssets covariance estimate matrix.

Data Types: double

SampleSize — Sample size to compute initial covariance estimate

scalar numeric

Sample size to compute the initial covariance estimate Sigma, specified as a scalar numeric value.

Data Types: double

Output Arguments

SigmaHat — Estimated covariance matrix

matrix

Estimated covariance matrix, returned as a NumAssets-by-NumAssets matrix.

numSignalEig — Number of eigenvalues associated with signal

numeric

Number of eigenvalues associated with signal, returned as a scalar numeric.

More About

Covariance Denoising

The goal of covariance denoising is to reduce the noise and enhance the signal of the empirical covariance matrix.

Covariance denoising is a common method that is used to reduce the effect of noise in the covariance approximation. Covariance denoising reduces the ill-conditioning of the traditional covariance estimate by differentiating the eigenvalues associated with noise from the eigenvalues associated with signal. Random matrix theory is used in covariance denoising to pull only the eigenvalues that are associated with noise to a common mean.

An intuitive example is when the number of variables is larger than the number of observations. In this case, the result is a noninvertible covariance matrix. Furthermore, because covariance estimation is performed using observations from random data, the estimator contains a certain amount of noise. This noise usually results in ill-conditioned covariance estimates. Working with an ill-conditioned matrix magnifies the impact of estimation errors.

Unlike shrinkage methods, denoising does not require information from the full sample. In covariance denoising using `covarianceDenoising` you only need to know the number of scenarios that were used to estimate the covariance matrix.

Algorithms

The `covarianceDenoising` function shrinks only the part of the covariance that corresponds with noise as follows:

1. Compute the correlation matrix C associated with the traditional covariance estimate Σ.
2. Compute the eigendecomposition of $C = V\Lambda V^T$.
3. Estimate the empirical distribution of the eigenvalues using kernel density estimation with `fitdist(x,'Kernal')`. For more information, see `fitdist`.
4. Fit the Marchenko-Pastur distribution to the empirical distribution by minimizing the mean squared error (MSE) between the empirical probability density function (pdf) and the fitted Marchenko-Pastur pdf. This gives the theoretical bounds λ^+ and λ^- on the eigenvalues associated with noise.
5. Let $\bar{\lambda}$ be the average of the eigenvalues smaller than λ^+. Set all eigenvalues smaller than λ^+ to $\bar{\lambda}$. These are the eigenvalues associated with noise.
6. Compute the denoised version of the correlation matrix $\widehat{C} = V\bar{\Lambda}V^T$ and rescale $\widehat{C}$ so that the main diagonal only has ones. $\widehat{C}$ is a correlation matrix.
7. Compute the denoised covariance estimate $\widehat{\Sigma}$ from $\widehat{C}$.

covarianceShrinkage

Estimate covariance matrix using shrinkage estimators

Syntax

```
SigmaHat = covarianceShrinkage(AssetReturns)
```

Description

`SigmaHat = covarianceShrinkage(AssetReturns)` returns a covariance estimate using linear shrinkage to reduce the mean squared error (MSE).

`covarianceShrinkage` computes an estimate of the covariance matrix from a sample of asset returns using the multiple of the identity shrinkage estimation method. For more information, see "Covariance Shrinkage" on page 15-62 and "covarianceShrinkage Algorithm" on page 15-63.

In addition, you can use `covarianceDenoising` to compute an estimate of covariance matrix using denoising. For information on which covariance estimation method to choosesee "Comparison of Methods for Covariance Estimation" on page 4-134.

Examples

Perform Covariance Linear Shrinkage

This example shows how to use `covarianceShrinkage` to compute covariance estimations that take into account the noise in the sample. In mean-variance portfolio optimization, a noisy estimate of the covariance estimate results in unstable solutions that cause high turnover and transaction costs. Ideally, to decrease the estimation error, it is desirable to increase the sample size. Yet, there are cases where this is not possible. In extreme cases in which the number of assets is larger than the number of observations, the traditional covariance matrix results in a singular matrix. Working with a nearly singular or an ill-conditioned covariance matrix magnifies the impact of estimation errors.

Compute a portfolio efficient frontier using different covariance estimates with the same sample data.

```
% Load portfolio data with 225 assets
load port5.mat
covariance = corr2cov(stdDev_return,Correlation);
% Generate a sample with 200 observations
rng('default')
nScen = 200;
retSeries = portsim(mean_return',covariance,nScen);
```

Compute the traditional and shrunk covariance estimates. Use `covarianceShrinkage` to reduce the effect of noise in the covariance approximation.

```
Sigma = cov(retSeries);
shrunkSigma = covarianceShrinkage(retSeries);
```

Compute the condition number of both covariance estimates. The shrunken covariance (`shrunkSigma`) has a lower condition number than the traditional covariance estimate `Sigma`.

```
conditionNum = [cond(Sigma); cond(shrunkSigma)];
condNumT = table(conditionNum,'RowNames',{'Sigma','SigmaHat'})
```

```
condNumT=2×1 table
                conditionNum
                ____________

    Sigma        2.5285e+18
    SigmaHat         5274.8
```

Use Portfolio to construct Portfolio objects that use the different AssetCovar values. Then use setDefaultConstraints to set the portfolio constraints with nonnegative weights that sum to 1 for the three portfolios: the true mean with the true covariance, the traditional covariance estimate, and the shrunk estimate.

```
% Create a Portfolio object with the true parameters
p = Portfolio(AssetMean=mean_return,AssetCovar=covariance);
p = setDefaultConstraints(p);

% Create a Portfolio object with true mean and traditional covariance estimate
pTraditional = Portfolio(AssetMean=mean_return,AssetCovar=Sigma);
pTraditional = setDefaultConstraints(pTraditional);

% Create a Portfolio object with true mean and shrunk covariance
pShrunk = Portfolio(AssetMean=mean_return,AssetCovar=shrunkSigma);
pShrunk = setDefaultConstraints(pShrunk);
```

Use estimateFrontier to estimate the efficient frontier for each of the Portfolio objects.

```
% Number of portfolios on the efficient frontier
nPort = 20;

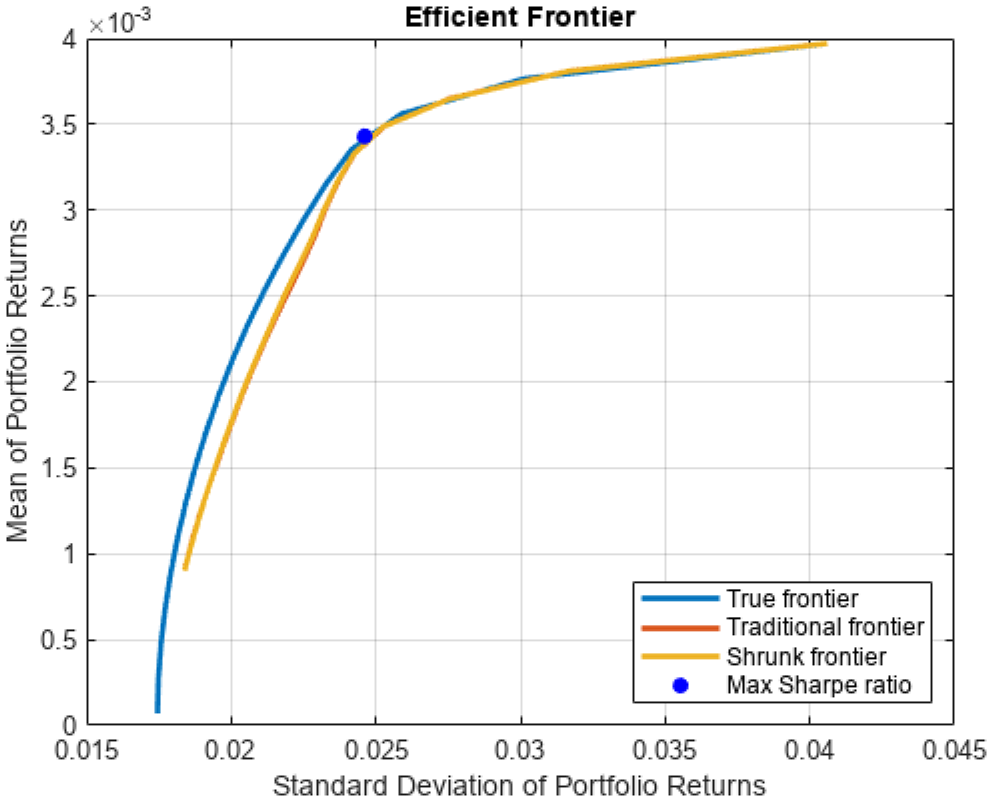
% True efficient portfolios
w = estimateFrontier(p,nPort);

% Traditional covariance efficient portfolios
wTraditional = estimateFrontier(pTraditional,nPort);

% Denoised covariance efficient portfolios
wShrunk = estimateFrontier(pShrunk,nPort);
```

Use plotFrontier to plot the frontier obtained from the different weights using the true parameter values.

```
figure
plotFrontier(p,w)
hold on
plotFrontier(p,wTraditional)
plotFrontier(p,wShrunk)
plotFrontier(p,estimateMaxSharpeRatio(p))
legend('True frontier','Traditional frontier','Shrunk frontier', ...,
'Max Sharpe ratio',Location='southeast');
hold off
```



In this example, the efficient frontiers obtained using the traditional covariance estimate and the shrunk estimate are close to each other. This means that both methods achieve similar risk and returns out-of-sample. Where the difference between these methods is more noticeable is for the portfolios to the left of the maximum Sharpe ratio portfolio. For those portfolios, the allocation computed using shrinkage has better returns out-of-sample.

Backtest to Compare Investment Strategy When Using Covariance Shrinkage

This example compares a minimum variance investment strategy using the traditional covariance estimate with a minimum variance strategy using covariance shrinkage.

Load the data.

```
% Read a table of daily adjusted close prices for 2006 DJIA stocks.
T = readtable('dowPortfolio.xlsx');

% Convert the table to a timetable.
pricesTT = table2timetable(T,'RowTimes','Dates');
numAssets = size(pricesTT.Variables, 2);
```

Use the first 42 days of the `dowPortfolio.xlsx` data set to initialize the backtest strategies. The backtest is then run over the remaining data.

```
warmupPeriod = 42;
```

Compute the initial weights. Use the `traditionalStrat` and `shrunkStrat` functions in Local Functions on page 15-61 to compute the weights.

```
% Specify no current weights (100% cash position).
w0 = zeros(1,numAssets);

% Specify warm-up partition of data set timetable.
warmupTT = pricesTT(1:warmupPeriod,:);

% Compute the initial portfolio weights for each strategy.
traditional_initial = traditionalStrat(w0,warmupTT);
shrunk_initial = shrunkStrat(w0,warmupTT);
```

Create traditional and shrinkage backtest strategy objects using `backtestStrategy`.

```
% Rebalance approximately every month.
rebalFreq = 21;

% Set the rolling lookback window to be at least 2 months and at
% most 6 months.
lookback  = [42 126];

% Use a fixed transaction cost (buy and sell costs are both 0.5%
% of amount traded).
transactionsFixed = 0.005;

% Specify the strategy objects.
strat1 = backtestStrategy('Traditional', @traditionalStrat, ...
    RebalanceFrequency=rebalFreq, ...
    LookbackWindow=lookback, ...
    TransactionCosts=transactionsFixed, ...
    InitialWeights=traditional_initial);

strat2 = backtestStrategy('Shrinkage', @shrunkStrat, ...
    RebalanceFrequency=rebalFreq, ...
    LookbackWindow=lookback, ...
    TransactionCosts=transactionsFixed, ...
    InitialWeights=shrunk_initial);

% Aggregate the two strategy objects into an array.
strategies = [strat1, strat2];
```

Create a `backtestEngine` object then use `runBacktest` to run the backtest.

```
% Create the backtesting engine object.
backtester = backtestEngine(strategies);

% Run the backtest.
backtester = runBacktest(backtester,pricesTT,'Start',warmupPeriod);

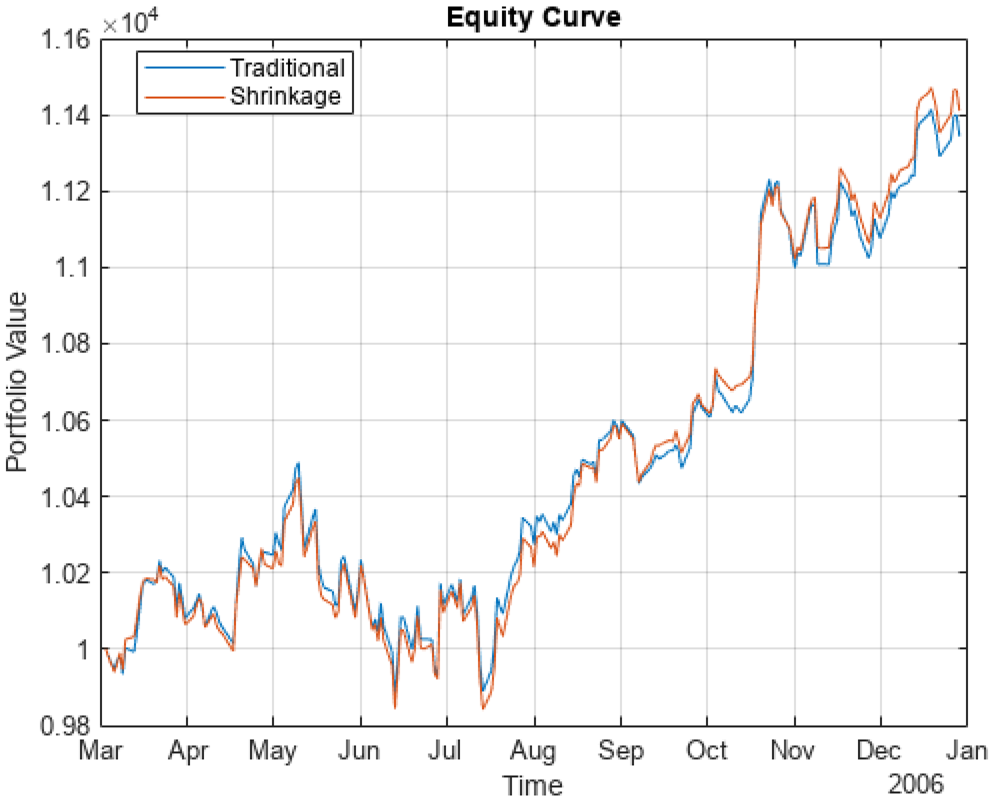
% Generate summary table of the performance of the strategies.
summary(backtester)
```

```
ans=9×2 table
                       Traditional    Shrinkage
                       ___________    _________

    TotalReturn          0.13431        0.14101
    SharpeRatio          0.10807        0.11565
    Volatility         0.0057472      0.0056077
    AverageTurnover    0.0098378      0.0077384
    MaxTurnover          0.36237        0.31835
    AverageReturn      0.0006196     0.00064699
    MaxDrawdown         0.058469       0.058133
    AverageBuyCost       0.51636        0.40533
    AverageSellCost      0.51636        0.40533
```

Use `equityCurve` to plot the equity curve to compare the performance of both strategies.

```
equityCurve(backtester)
```



The maximum and average turnover are decreased using covariance shrinkage. Also, the covariance shrinkage strategy results in a decrease of buy and sell costs. In this example, not only is the turnover decreased, but also the volatility and the maximum drawdown are decreased. Therefore, in this example the shrunk covariance produces more robust weights.

Local Functions

```
function new_weights = traditionalStrat(~, pricesTT)
% Function for minimum variance portfolio using traditional covariance estimate.

% Compute the returns from the prices timetable.
assetReturns = tick2ret(pricesTT);
mu = mean(assetReturns.Variables);
Sigma = cov(assetReturns.Variables,"omitrows");
```

```
% Create the portfolio problem.
p = Portfolio(AssetMean=mu,AssetCovar=Sigma);
% Specify long-only fully invested contraints.
p = setDefaultConstraints(p);

% Compute the minimum variance portfolio.
new_weights = estimateFrontierLimits(p,'min');
end

function new_weights = shrunkStrat(~, pricesTT)
% Function for minimum variance portfolio using covariance shrinkage.

% Compute the returns from the prices timetable.
assetReturns = tick2ret(pricesTT);
mu = mean(assetReturns.Variables);
Sigma = covarianceShrinkage(assetReturns.Variables);

% Create the portfolio problem.
p = Portfolio(AssetMean=mu,AssetCovar=Sigma);
% Specify long-only fully invested contraints.
p = setDefaultConstraints(p);

% Compute the minimum variance portfolio.
new_weights = estimateFrontierLimits(p,'min');
end
```

Input Arguments

AssetReturns — Asset returns

matrix | table | timetable

Asset returns, specified as a NumObservations-by-NumAssets matrix, table, or timetable.

Note All NumObservations with one or more NaN values are removed before computing the covariance estimate.

Data Types: double | table | timetable

Output Arguments

SigmaHat — Covariance estimate

matrix

Covariance estimate, returned as a NumAssets-by-NumAssets matrix.

More About

Covariance Shrinkage

Shrinkage estimators for covariance shrinkage are used to reduce the effect of noise in the covariance approximation.

The goal of covariance shrinkage is to pull all eigenvalues of the traditional covariance matrix towards a target.

Algorithms

The `covarianceShrikage` function applies a linear shrinkage method that shrinks the traditional covariance estimate to a multiple of the identity matrix.

$$\widehat{\Sigma} = (1 - \alpha)\Sigma + \alpha(\tau I)$$

Here, Σ is the standard covariance estimate, τ is the average sample variance, and $\alpha \in [0, 1]$ is the intensity parameter computed using

$$\alpha = \frac{\frac{1}{N}\sum_{i = 1}^{N} \text{trace}\left(\left[z_i z_i^T - \Sigma\right]^2\right)}{\text{trace}([\Sigma\text{-}\tau]^2)}$$

where z_i is the i th row of the centered sample matrix Z and N is the sample size.

bm

Brownian motion (BM) models

Description

Creates and displays Brownian motion (sometimes called *arithmetic Brownian motion* or *generalized Wiener process*) bm objects that derive from the sdeld (SDE with drift rate expressed in linear form) class.

Use bm objects to simulate sample paths of NVars state variables driven by NBrowns sources of risk over NPeriods consecutive observation periods, approximating continuous-time Brownian motion stochastic processes. This enables you to transform a vector of NBrowns uncorrelated, zero-drift, unit-variance rate Brownian components into a vector of NVars Brownian components with arbitrary drift, variance rate, and correlation structure.

Use bm to simulate any vector-valued BM process of the form:

$$dX_t = \mu(t)dt + V(t)dW_t$$

where:

- X_t is an NVars-by-1 state vector of process variables.
- μ is an NVars-by-1 drift-rate vector.
- V is an NVars-by-NBrowns instantaneous volatility rate matrix.
- dW_t is an NBrowns-by-1 vector of (possibly) correlated zero-drift/unit-variance rate Brownian components.

Creation

Syntax

```
BM = bm(Mu,Sigma)
BM = bm( ___ ,Name,Value)
```

Description

BM = bm(Mu,Sigma) creates a default BM object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time *t* and state *X(t)* and is invoked with both input arguments.

`BM = bm(___,Name,Value)` creates a `bm` object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`

The `BM` object has the following “Properties” on page 15-66:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method

Input Arguments

`Mu` — `Mu` represents the parameter μ

array or deterministic function of time | deterministic function of time and state

`Mu` represents the parameter μ, specified as an array or deterministic function of time.

If you specify `Mu` as an array, it must be an `NVars`-by-`1` column vector representing the drift rate (the expected instantaneous rate of drift, or time trend).

As a deterministic function of time, when `Mu` is called with a real-valued scalar time `t` as its only input, `Mu` must produce an `NVars`-by-`NVars` matrix. If you specify `Mu` as a function of time and state, it calculates the expected instantaneous rate of drift. This function must generate an `NVars`-by-`1` column vector when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

`Sigma` — `Sigma` represents the parameter V

array or deterministic function of time | deterministic function of time and state

`Sigma` represents the parameter *V*, specified as an array or deterministic function of time.

If you specify `Sigma` as an array, it must be an `NVars`-by-`NBrowns` matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of `Sigma` corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when Sigma is called with a real-valued scalar time t as its only input, Sigma must produce an NVars-by-NBrowns matrix. If you specify Sigma as a function of time and state, it must return an NVars-by-NBrowns matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An NVars-by-1 state vector X_t.

Although the gbm constructor enforces no restrictions on the sign of Sigma volatilities, they are specified as positive values.

Data Types: double | function_handle

Properties

StartTime — Starting time of first observation, applied to all state variables
0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a numeric.

Data Types: double

StartState — Initial values of state variables
1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, bm applies the same initial value to all state variables on all trials.

If StartState is a column vector, bm applies a unique initial value to each state variable on all trials.

If StartState is a matrix, bm applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)
NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

Simulation — User-defined simulation function or SDE simulation method
simulation by Euler approximation (simByEuler) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: `function_handle`

`Drift` — Drift rate component of continuous-time stochastic differential equations (SDEs)

value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-`1` vector-valued function accessible using the (t, X_t) interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a `drift` object are:

- `Rate`: The drift-rate function, $F(t,X_t)$
- `A`: The intercept term, $A(t,X_t)$, of $F(t,X_t)$
- `B`: The first order term, $B(t,X_t)$, of $F(t,X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: `object`

`Diffusion` — Diffusion rate component of continuous-time stochastic differential equations (SDEs)

value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects using `diffusion`:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-`1` vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the (t, X_t) interface.

The displayed parameters for a `diffusion` object are:

- `Rate`: The diffusion-rate function, $G(t,X_t)$.
- `Alpha`: The state vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$.
- `Sigma`: The volatility rate, $V(t,X_t)$, of $G(t,X_t)$.

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate` functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `object`

Object Functions

interpolate	Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simulate	Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models
simByEuler	Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simByMilstein	Simulate BM, GBM, CEV, HWV, SDEDDO, SDELD, SDEMRD sample paths by Milstein approximation

Examples

Create a bm Object

Create a univariate Brownian motion (bm) object to represent the model: $dX_t = 0.3dW_t$.

```
obj = bm(0, 0.3) % (A = Mu, Sigma)
```

```
obj = 
   Class BM: Brownian Motion
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 0
    Correlation: 1
          Drift: drift rate function F(t,X(t)) 
      Diffusion: diffusion rate function G(t,X(t)) 
     Simulation: simulation method/function simByEuler
             Mu: 0
          Sigma: 0.3
```

bm objects display the parameter A as the more familiar Mu.

The bm class also provides an overloaded Euler simulation method that improves run-time performance in certain common situations. This specialized method is invoked automatically only if *all* the following conditions are met:

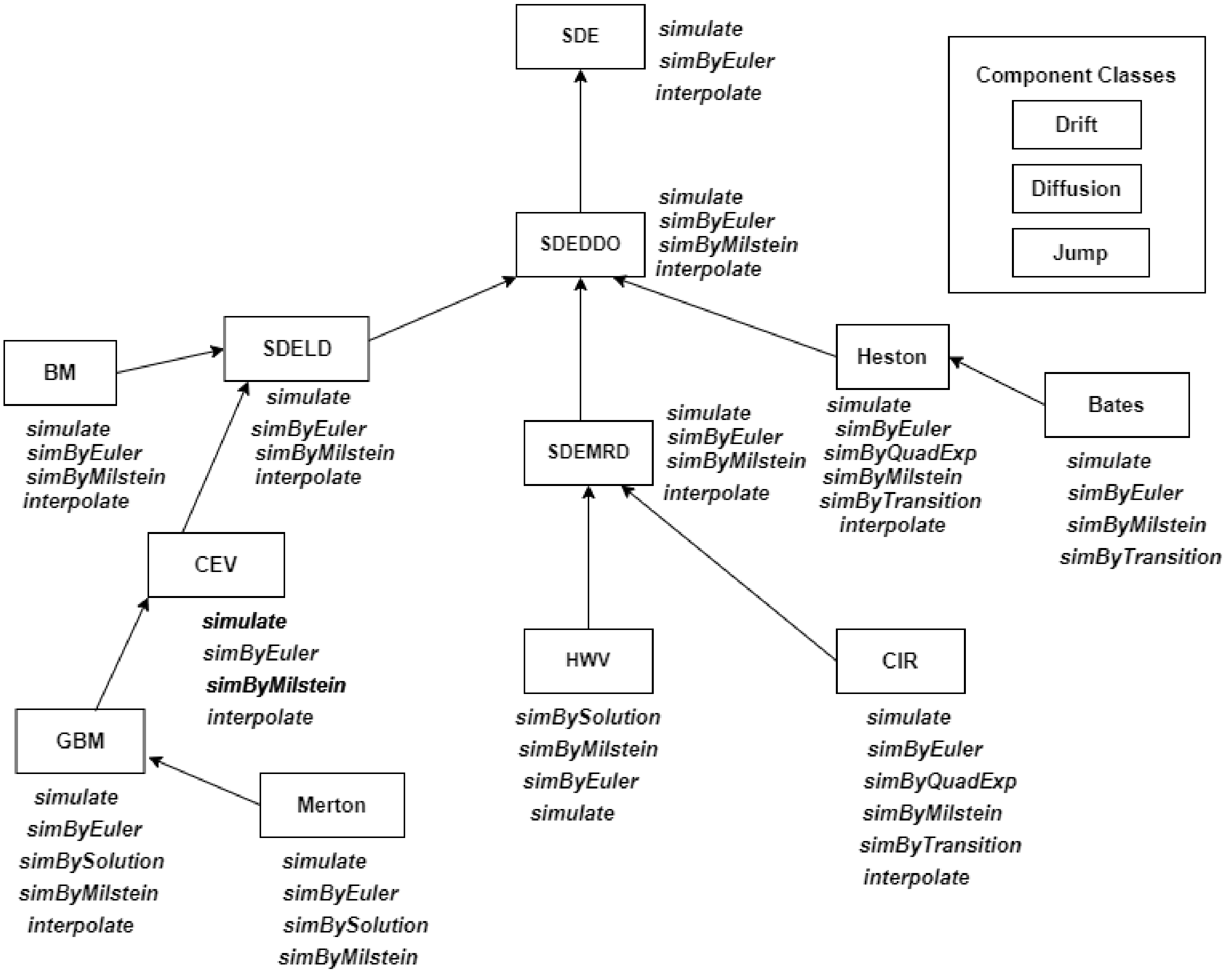
- The expected drift, or trend, rate Mu is a column vector.
- The volatility rate, Sigma, is a matrix.
- No end-of-period adjustments and/or processes are made.
- If specified, the random noise process Z is a three-dimensional array.
- If Z is unspecified, the assumed Gaussian correlation structure is a double matrix.

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time t and a state vector X_t, and return an array of appropriate dimension. Even if you originally specified an input as an array, `bm` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

cev

Constant Elasticity of Variance (CEV) model

Description

Creates and displays `cev` objects, which derive from the `sdeld` (SDE with drift rate expressed in linear form) class.

Use `cev` objects to simulate sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

This model allows you to simulate any vector-valued CEV of the form:

$$dX_t = \mu(t)X_t dt + D(t, X_t^{\alpha(t)})V(t)dW_t$$

where:

- X_t is an `NVars`-by-`1` state vector of process variables.
- μ is an `NVars`-by-`NVars` (generalized) expected instantaneous rate of return matrix.
- D is an `NVars`-by-`NVars` diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of α.
- V is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- dW_t is an `NBrowns`-by-`1` Brownian motion vector.

Creation

Syntax

```
CEV = cev(Return,Alpha,Sigma)
CEV = cev( ___ ,Name,Value)
```

Description

`CEV = cev(Return,Alpha,Sigma)` creates a default `CEV` object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time *t* and state *X(t)* and is invoked with both input arguments.

`CEV = cev( ___ ,Name,Value)` creates a `CEV` object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`

The `CEV` object has the following "Properties" on page 15-74:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Return` — Access function for the input argument `Return`, callable as a function of time and state
- `Alpha` — Access function for the input argument `Alpha`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state

Input Arguments

`Return` — Return represents the parameter μ

array or deterministic function of time or deterministic function of time and state

`Return` represents the parameter μ, specified as an array or deterministic function of time.

If you specify `Return` as an array, it must be an `NVars`-by-`NVars` matrix representing the expected (mean) instantaneous rate of return.

As a deterministic function of time, when `Return` is called with a real-valued scalar time `t` as its only input, `Return` must produce an `NVars`-by-`NVars` matrix. If you specify `Return` as a function of time and state, it must return an `NVars`-by-`NVars` matrix when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-1 state vector X_t.

Data Types: `double` | `function_handle`

`Alpha` — Return represents the parameter *D*

array or deterministic function of time or deterministic function of time and state

`Alpha` represents the parameter *D*, specified as an array or deterministic function of time.

If you specify `Alpha` as an array, it represents an `NVars`-by-`1` column vector of exponents.

As a deterministic function of time, when `Alpha` is called with a real-valued scalar time `t` as its only input, `Alpha` must produce an `NVars`-by-`1` matrix.

If you specify it as a function of time and state, `Alpha` must return an `NVars`-by-`1` column vector of exponents when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

`Sigma` — `Sigma` represents the parameter *V*
array or deterministic function of time or deterministic function of time and state

`Sigma` represents the parameter *V*, specified as an array or a deterministic function of time.

If you specify `Sigma` as an array, it must be an `NVars`-by-`NBrowns` matrix of instantaneous volatility rates. In this case, each row of `Sigma` corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when `Sigma` is called with a real-valued scalar time `t` as its only input, `Sigma` must produce an `NVars`-by-`NBrowns` matrix. If you specify `Sigma` as a function of time and state, it must return an `NVars`-by-`NBrowns` matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

Note Although `cev` does not enforce restrictions on the signs of these input arguments, each argument is specified as a positive value.

Properties

`StartTime` — Starting time of first observation, applied to all state variables
`0` (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: `double`

`StartState` — Initial values of state variables
`1` (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If `StartState` is a scalar, `cev` applies the same initial value to all state variables on all trials.

If `StartState` is a column vector, `cev` applies a unique initial value to each state variable on all trials.

If `StartState` is a matrix, `cev` applies a unique initial value to each state variable on each trial.

Data Types: `double`

`Correlation` — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)

`NBrowns`-by-`NBrowns` identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an `NBrowns`-by-`NBrowns` positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an `NBrowns`-by-`NBrowns` positive semidefinite correlation matrix. If `Correlation` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

A `Correlation` matrix represents a static condition.

As a deterministic function of time, `Correlation` allows you to specify a dynamic correlation structure.

Data Types: `double`

`Simulation` — User-defined simulation function or SDE simulation method

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: `function_handle`

`Drift` — Drift rate component of continuous-time stochastic differential equations (SDEs)

value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-`1` vector-valued function accessible using the (t, X_t) interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a `drift` object are:

- `Rate`: The drift-rate function, $F(t,X_t)$
- `A`: The intercept term, $A(t,X_t)$, of $F(t,X_t)$
- `B`: The first order term, $B(t,X_t)$, of $F(t,X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

Note You can express drift and diffusion classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components A and B as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: struct | double

Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)
value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as an object or function accessible by (t, X_t.

The diffusion rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion class allows you to create diffusion-rate objects using diffusion:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- D is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVars-by-1 vector-valued function.
- V is an NVars-by-NBrowns matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the (t, X_t) interface.

The displayed parameters for a diffusion object are:

- Rate: The diffusion-rate function, $G(t,X_t)$.
- Alpha: The state vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$.
- Sigma: The volatility rate, $V(t,X_t)$, of $G(t,X_t)$.

Alpha and Sigma enable you to query the original inputs. (The combined effect of the individual Alpha and Sigma parameters is fully encapsulated by the function stored in Rate.) The Rate functions are the calculation engines for the drift and diffusion objects, and are the only parameters required for simulation.

Note You can express drift and diffusion classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components A and B as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct` | `double`

Object Functions

interpolate — Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

simulate — Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models

simByEuler — Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

simByMilstein — Simulate BM, GBM, CEV, HWV, SDEDDO, SDELD, SDEMRD sample paths by Milstein approximation

Examples

Create a cev Object

Create a univariate `cev` object to represent the model: $dX_t = 0.25X_t + 0.3X_t^{\frac{1}{2}}dW_t$.

```
obj = cev(0.25, 0.5, 0.3) % (B = Return, Alpha, Sigma)
```

```
obj = 
   Class CEV: Constant Elasticity of Variance
   ------------------------------------------
     Dimensions: State = 1, Brownian = 1
   ------------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.25
          Alpha: 0.5
          Sigma: 0.3
```

`cev` objects display the parameter `B` as the more familiar `Return`

cir

Cox-Ingersoll-Ross (`CIR`) mean-reverting square root diffusion model

Description

Creates and displays `cir` objects, which derive from the `sdemrd` (SDE with drift rate expressed in mean-reverting form) class.

Use `cir` objects to simulate sample paths of `NVars` state variables expressed in mean-reverting drift-rate form. These state variables are driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time CIR stochastic processes with square root diffusions.

You can simulate any vector-valued CIR process of the form:

$$dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW_t$$

where:

- X_t is an `NVars`-by-`1` state vector of process variables.
- S is an `NVars`-by-`NVars` matrix of mean reversion speeds (the rate of mean reversion).
- L is an `NVars`-by-`1` vector of mean reversion levels (long-run mean or level).
- D is an `NVars`-by-`NVars` diagonal matrix, where each element along the main diagonal is the square root of the corresponding element of the state vector.
- V is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- dW_t is an `NBrowns`-by-`1` Brownian motion vector.

Creation

Syntax

```
CIR = cir(Speed,Level,Sigma)
CIR = cir( ___ ,Name,Value)
```

Description

`CIR = cir(Speed,Level,Sigma)` creates a default `CIR` object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.

- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time *t* and state *X(t)* and is invoked with both input arguments.

`CIR = cir( ___ ,Name,Value)` creates a `CIR` object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1, …,NameN,ValueN`

The `CIR` object has the following “Properties” on page 15-82:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Speed` — Access function for the input argument `Speed`, callable as a function of time and state
- `Level` — Access function for the input argument `Level`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state

Input Arguments

Speed — Speed represents the parameter *S*

array or deterministic function of time or deterministic function of time and state

`Speed` represents the parameter *S*, specified as an array or deterministic function of time.

If you specify `Speed` as an array, it must be an `NVars`-by-`NVars` matrix of mean-reversion speeds (the rate at which the state vector reverts to its long-run average `Level`).

As a deterministic function of time, when `Speed` is called with a real-valued scalar time `t` as its only input, `Speed` must produce an `NVars`-by-`NVars` matrix. If you specify `Speed` as a function of time and state, it calculates the speed of mean reversion. This function must generate an `NVars`-by-`NVars` matrix of reversion rates when called with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

`Level` — `Level` represents the parameter *L*

array or deterministic function of time or deterministic function of time and state

`Level` represents the parameter *L*, specified as an array or deterministic function of time.

If you specify `Level` as an array, it must be an `NVars`-by-`1` column vector of reversion levels.

As a deterministic function of time, when `Level` is called with a real-valued scalar time `t` as its only input, `Level` must produce an `NVars`-by-`1` column vector. If you specify `Level` as a function of time and state, it must generate an `NVars`-by-`1` column vector of reversion levels when called with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

`Sigma` — `Sigma` represents the parameter *V*

array or deterministic function of time or deterministic function of time and state

`Sigma` represents the parameter *V*, specified as an array or a deterministic function of time.

If you specify `Sigma` as an array, it must be an `NVars`-by-`NBrowns` matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of `Sigma` corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when `Sigma` is called with a real-valued scalar time `t` as its only input, `Sigma` must produce an `NVars`-by-`NBrowns` matrix. If you specify `Sigma` as a function of time and state, it must return an `NVars`-by-`NBrowns` matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

Note Although `cir` does not enforce restrictions on the signs of these input arguments, each argument is specified as a positive value.

Properties

`StartTime` — Starting time of first observation, applied to all state variables

`0` (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: `double`

`StartState` — Initial values of state variables

`1` (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, cir applies the same initial value to all state variables on all trials.

If StartState is a column vector, cir applies a unique initial value to each state variable on all trials.

If StartState is a matrix, cir applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)
NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

Simulation — User-defined simulation function or SDE simulation method
simulation by Euler approximation (simByEuler) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function_handle

Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)
value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The drift rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The drift class allows you to create drift-rate objects using drift of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- A is an NVars-by-1 vector-valued function accessible using the (t, X_t) interface.
- B is an NVars-by-NVars matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a drift object are:

- `Rate`: The drift-rate function, $F(t,X_t)$
- `A`: The intercept term, $A(t,X_t)$, of $F(t,X_t)$
- `B`: The first order term, $B(t,X_t)$, of $F(t,X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: `struct` | `double`

`Diffusion` — Diffusion rate component of continuous-time stochastic differential equations (SDEs)
value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects using `diffusion`:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-`1` vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the (t, X_t) interface.

The displayed parameters for a `diffusion` object are:

- `Rate`: The diffusion-rate function, $G(t,X_t)$.
- `Alpha`: The state vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$.
- `Sigma`: The volatility rate, $V(t,X_t)$, of $G(t,X_t)$.

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate`

functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct` | `double`

Object Functions

interpolate	Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simulate	Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models
simByEuler	Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simByTransition	Simulate CIR sample paths with transition density
simByQuadExp	Simulate Bates, Heston, and CIR sample paths by quadratic-exponential discretization scheme
simByMilstein	Simulate CIR sample paths by Milstein approximation

Examples

Create a cir Object

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift (`SDEMRD`): $dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$

where D is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model: $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$.

```
obj = cir(0.2, 0.1, 0.05)  % (Speed, Level, Sigma)
```

```
obj = 
   Class CIR: Cox-Ingersoll-Ross
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.1
          Speed: 0.2
```

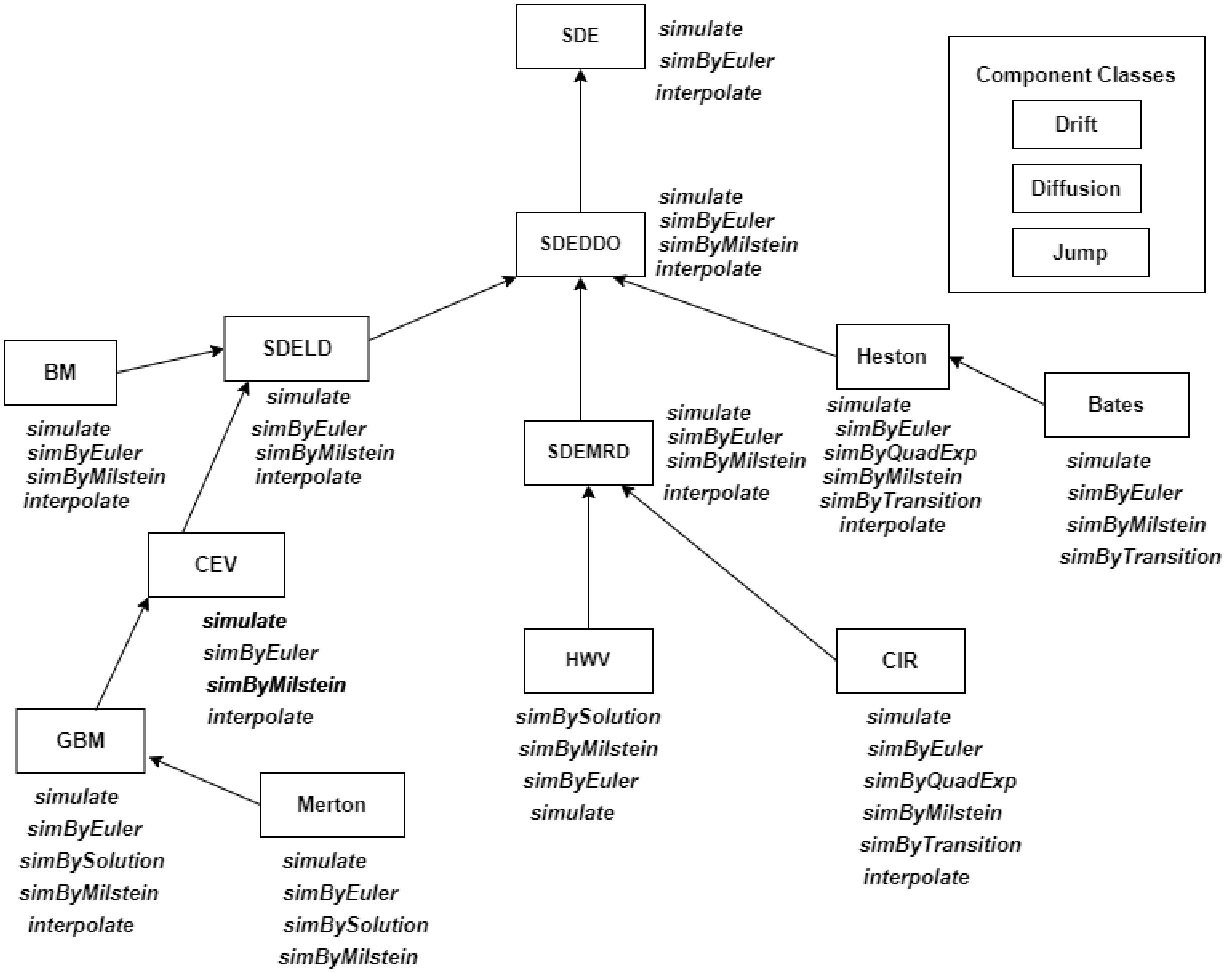
Although the last two objects are of different classes, they represent the same mathematical model. They differ in that you create the `cir` object by specifying only three input arguments. This distinction is reinforced by the fact that the `Alpha` parameter does not display – it is defined to be `1/2`.

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time t and a state vector X_t, and return an array of appropriate dimension. Even if you originally specified an input as an array, `cir` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

Version History

Introduced in R2008a

R2023a: Added `simByMilstein` method

Behavior changed in R2023a

Use the `simByMilstein` method to approximate a numerical solution of a stochastic differential equation.

diffusion

Diffusion-rate model component

Description

The `diffusion` object specifies the diffusion-rate component of continuous-time stochastic differential equations (SDEs).

The diffusion-rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion-rate specification can be any `NVars`-by-`NBrowns` matrix-valued function *G* of the general form:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t) \qquad (15\text{-}1)$$

where:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-`1` vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the (t, X_t) interface.

And a diffusion-rate specification is associated with a vector-valued SDE of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- X_t is an `NVars`-by-`1` state vector of process variables.
- dW_t is an `NBrowns`-by-`1` Brownian motion vector.
- D is an `NVars`-by-`NVars` diagonal matrix, in which each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of α.
- V is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.

The diffusion-rate specification is flexible, and provides direct parametric support for static volatilities and state vector exponents. It is also extensible, and provides indirect support for dynamic/nonlinear models via an interface. This enables you to specify virtually any diffusion-rate specification.

Creation

Syntax

`DiffusionRate = diffusion(Alpha,Sigma)`

Description

`DiffusionRate = diffusion(Alpha,Sigma)` creates default `DiffusionRate` model component.

Specify required input parameters `A` and `B` as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time *t* and state *X(t)* and is invoked with both input arguments.

The `diffusion` object that you create encapsulates the composite drift-rate specification and returns the following displayed parameters:

- `Rate` — The diffusion-rate function, *G*. `Rate` is the diffusion-rate calculation engine. It accepts the current time *t* and an `NVars`-by-`1` state vector X_t as inputs, and returns an `NVars`-by-`1` diffusion-rate vector.
- `Alpha` — Access function for the input argument `Alpha`.
- `Sigma` — Access function for the input argument `Sigma`.

Input Arguments

`Alpha` — Return represents the parameter *D*
array or deterministic function of time

`Alpha` represents the parameter *D*, specified as an array or deterministic function of time.

If you specify `Alpha` as an array, it represents an `NVars`-by-`1` column vector of exponents.

As a deterministic function of time, when `Alpha` is called with a real-valued scalar time `t` as its only input, `Alpha` must produce an `NVars`-by-`1` matrix.

If you specify it as a function of time and state, `Alpha` must return an `NVars`-by-`1` column vector of exponents when invoked with two inputs:

- A real-valued scalar observation time *t*.

- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

`Sigma` — `Sigma` represents the parameter *V*
array or deterministic function of time

`Sigma` represents the parameter *V*, specified as an array or a deterministic function of time.

If you specify `Sigma` as an array, it must be an `NVars`-by-`NBrowns` two-dimensional matrix of instantaneous volatility rates. In this case, each row of `Sigma` corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when `Sigma` is called with a real-valued scalar time `t` as its only input, `Sigma` must produce an `NVars`-by-`NBrowns` matrix. If you specify `Sigma` as a function of time and state, it must return an `NVars`-by-`NBrowns` matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

Note Although `diffusion` enforces no restrictions on the signs of these volatility parameters, each parameter is specified as a positive value.

Properties

`Rate` — Composite diffusion-rate function
value stored from diffusion-rate function (default) | function accessible by (t, X_t)

This property is read-only.

Composite diffusion-rate function, specified as: $G(t,X_t)$). The function stored in `Rate` fully encapsulates the combined effect of `Alpha` and `Sigma` where:

- `Alpha` is the state vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$.
- `Sigma` is the volatility rate, $V(t,X_t)$, of $G(t,X_t)$.

Data Types: `struct` | `double`

Examples

Create a `diffusion` Object

Create a diffusion-rate function `G`:

```
G = diffusion(1, 0.3)  % Diffusion rate function G(t,X)
```

```
G = 
   Class DIFFUSION: Diffusion Rate Specification
```

```
    ---------------------------------------------
       Rate: diffusion rate function G(t,X(t))
      Alpha: 1
      Sigma: 0.3
```

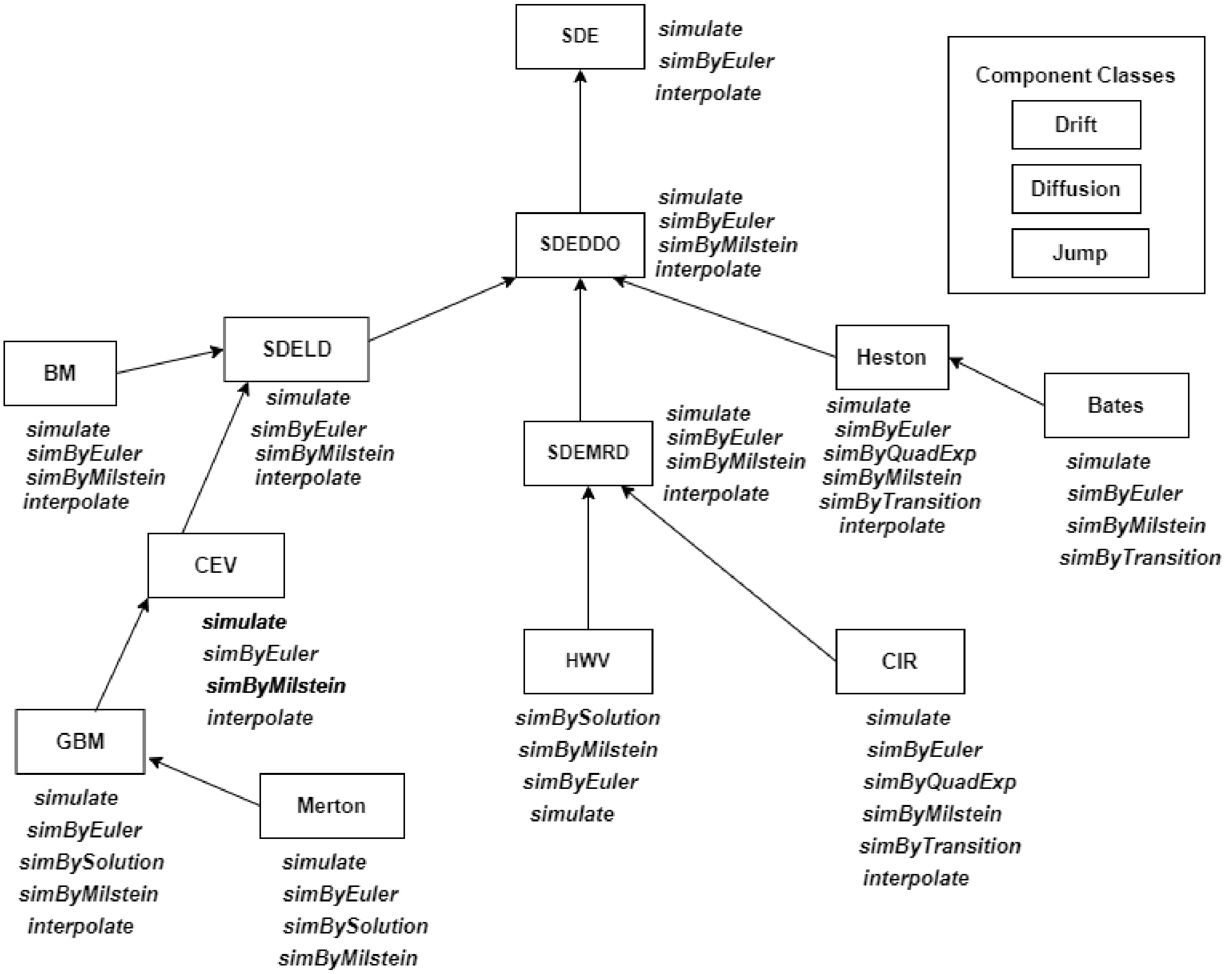
The `diffusion` object displays like a MATLAB® structure and contains supplemental information, namely, the object's class and a brief description. However, in contrast to the SDE representation, a summary of the dimensionality of the model does not appear, because the `diffusion` class creates a model component rather than a model. `G` does not contain enough information to characterize the dimensionality of a problem.

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the input arguments `Alpha` and `Sigma` as MATLAB arrays, they are associated with a specific parametric form. By contrast, when you specify either `Alpha` or `Sigma` as a function, you can customize virtually any diffusion-rate specification.

Accessing the output diffusion-rate parameters `Alpha` and `Sigma` with no inputs simply returns the original input specification. Thus, when you invoke diffusion-rate parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke diffusion-rate parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters `Alpha` and `Sigma` accept the observation time t and a state vector X_t, and return an array of appropriate dimension. Specifically, parameters `Alpha` and `Sigma` evaluate the corresponding diffusion-rate component. Even if you originally specified an input as an array, `diffusion` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

drift

Drift-rate model component

Description

The `drift` object specifies the drift-rate component of continuous-time stochastic differential equations (SDEs).

The drift-rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The drift-rate specification can be any `NVars`-by-`1` vector-valued function F of the general form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-`1` vector-valued function accessible using the (t, X_t) interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the (t, X_t) interface.

And a drift-rate specification is associated with a vector-valued SDE of the form

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- X_t is an `NVars`-by-`1` state vector of process variables.
- dW_t is an `NBrowns`-by-`1` Brownian motion vector.
- A and B are model parameters.

The drift-rate specification is flexible, and provides direct parametric support for static/linear drift models. It is also extensible, and provides indirect support for dynamic/nonlinear models via an interface. This enables you to specify virtually any drift-rate specification.

Creation

Syntax

```
DriftRate = drift(A,B)
```

Description

`DriftRate = drift(A,B)` creates a default `DriftRate` model component.

Specify required input parameters `A` and `B` as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time *t* and state *X(t)* and is invoked with both input arguments.

The `drift` object that you create encapsulates the composite drift-rate specification and returns the following displayed parameters:

- `Rate` — The drift-rate function, *F*. `Rate` is the drift-rate calculation engine. It accepts the current time *t* and an `NVars`-by-`1` state vector X_t as inputs, and returns an `NVars`-by-`1` drift-rate vector.
- `A` — Access function for the input argument `A`.
- `B` — Access function for the input argument `B`.

Input Arguments

A — A represents the parameter *A*

array or deterministic function of time

`A` represents the parameter *A*, specified as an array or deterministic function of time.

If you specify `A` as an array, it must be an `NVars`-by-`1` column vector of intercepts.

As a deterministic function of time, when `A` is called with a real-valued scalar time `t` as its only input, `A` must produce an `NVars`-by-`1` column vector. If you specify `A` as a function of time and state, it must generate an `NVars`-by-`1` column vector of intercepts when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

B — B represents the parameter *B*

array or deterministic function of time

`B` represents the parameter *B*, specified as an array or deterministic function of time.

If you specify `B` as an array, it must be an `NVars`-by-`NVars` two-dimensional matrix of state vector coefficients.

As a deterministic function of time, when `B` is called with a real-valued scalar time `t` as its only input, `B` must produce an `NVars`-by-`NVars` matrix. If you specify `B` as a function of time and state, it must generate an `NVars`-by-`NVars` matrix of state vector coefficients when invoked with two inputs:

- A real-valued scalar observation time *t*.

- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Properties

Rate — Composite drift-rate function

value stored from drift-rate function (default) | function accessible by $F(t,X_t)$

This property is read-only.

Composite drift-rate function, specified as $F(t,X_t)$. The function stored in Rate fully encapsulates the combined effect of A and B, where A and B are:

- A: The intercept term, $A(t,X_t)$, of $F(t,X_t)$
- B: The first order term, $B(t,X_t)$, of $F(t,X_t)$

Data Types: struct | double

Examples

Create a drift Object

Create a drift-rate function F:

```
F = drift(0, 0.1)   % Drift rate function F(t,X)
```

```
F = 
   Class DRIFT: Drift Rate Specification 
   ------------------------------------- 
      Rate: drift rate function F(t,X(t)) 
         A: 0
         B: 0.1
```

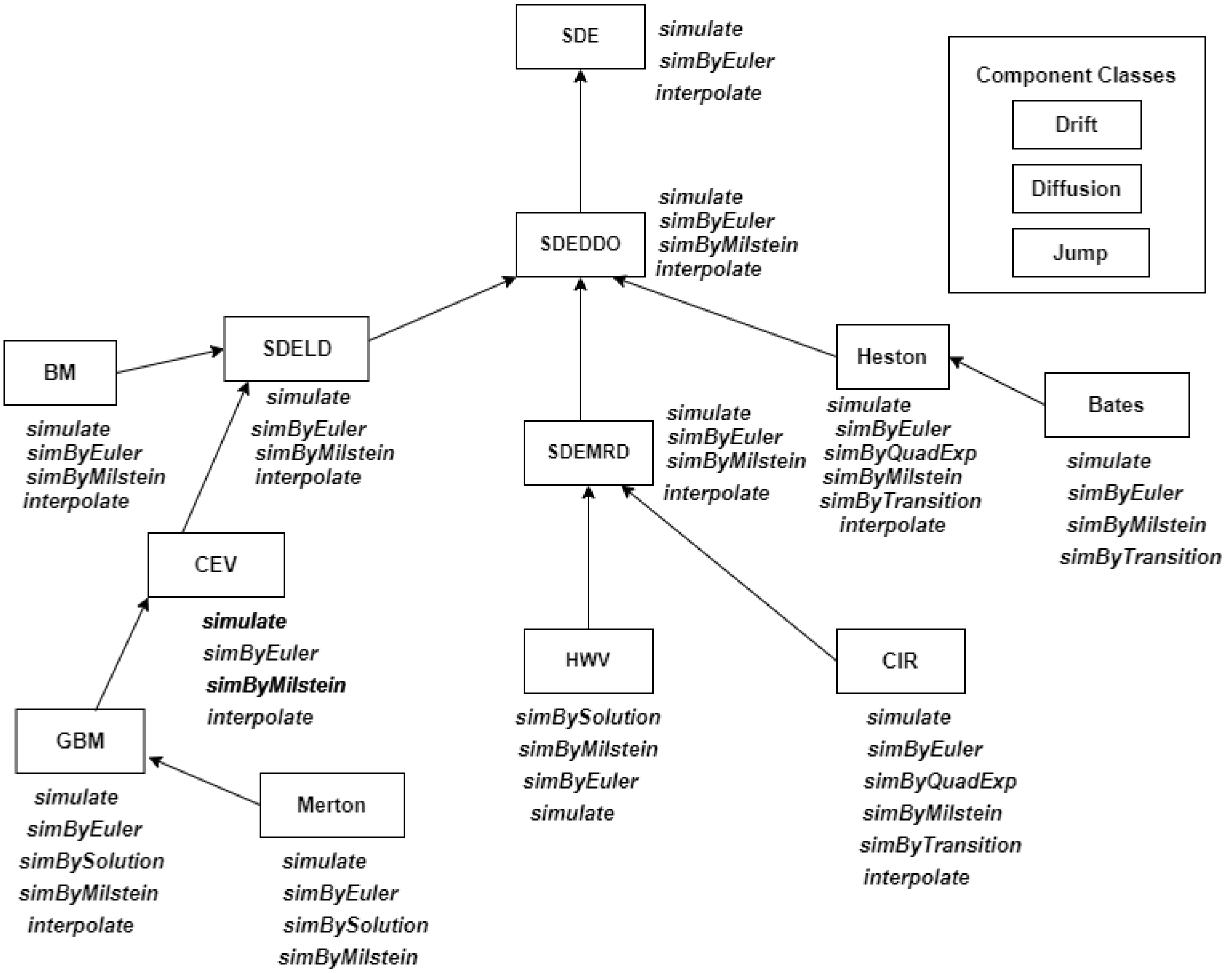
The drift object displays like a MATLAB® structure and contains supplemental information, namely, the object's class and a brief description. However, in contrast to the SDE representation, a summary of the dimensionality of the model does not appear, because the drift class creates a model component rather than a model. F does not contain enough information to characterize the dimensionality of a problem.

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the input arguments A and B as MATLAB arrays, they are associated with a linear drift parametric form. By contrast, when you specify either A or B as a function, you can customize virtually any drift-rate specification.

Accessing the output drift-rate parameters A and B with no inputs simply returns the original input specification. Thus, when you invoke drift-rate parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke drift-rate parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters A and B accept the observation time *t* and a state vector X_t, and return an array of appropriate dimension. Specifically, parameters A and B evaluate the corresponding drift-rate component. Even if you originally specified an input as an array, `drift` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

gbm

Geometric Brownian motion (GBM) model

Description

Creates and displays geometric Brownian motion models, which derive from the cev (constant elasticity of variance) class.

Geometric Brownian motion (GBM) models allow you to simulate sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time GBM stochastic processes. Specifically, this model allows the simulation of vector-valued GBM processes of the form

$$dX_t = \mu(t)X_t dt + D(t, X_t)V(t)dW_t$$

where:

- X_t is an NVars-by-1 state vector of process variables.
- μ is an NVars-by-NVars generalized expected instantaneous rate of return matrix.
- D is an NVars-by-NVars diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector X_t.
- V is an NVars-by-NBrowns instantaneous volatility rate matrix.
- dW_t is an NBrowns-by-1 Brownian motion vector.

Creation

Syntax

```
GBM = gbm(Return,Sigma)
GBM = gbm( ___ ,Name,Value)
```

Description

GBM = gbm(Return,Sigma) creates a default GBM object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time *t* and state *X(t)* and is invoked with both input arguments.

`GBM = gbm( ___ ,Name,Value)` creates a `GBM` object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`

The `GBM` object has the following “Properties” on page 15-102:

- `StartTime` — Initial observation time
- `StartState` — Initial state at `StartTime`
- `Correlation` — Access function for the `Correlation` input, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Return` — Access function for the input argument `Return`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state

Input Arguments

`Return` — `Return` represents the parameter *μ*

array or deterministic function of time or deterministic function of time and state

`Return` represents the parameter *μ*, specified as an array or deterministic function of time.

If you specify `Return` as an array, it must be an `NVars`-by-`NVars` matrix representing the expected (mean) instantaneous rate of return.

As a deterministic function of time, when `Return` is called with a real-valued scalar time `t` as its only input, `Return` must produce an `NVars`-by-`NVars` matrix. If you specify `Return` as a function of time and state, it must return an `NVars`-by-`NVars` matrix when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

`Sigma` — `Sigma` represents the parameter *V*

array or deterministic function of time or deterministic function of time and state

`Sigma` represents the parameter *V*, specified as an array or a deterministic function of time.

If you specify `Sigma` as an array, it must be an `NVars`-by-`NBrowns` matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of `Sigma` corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when Sigma is called with a real-valued scalar time t as its only input, Sigma must produce an NVars-by-NBrowns matrix. If you specify Sigma as a function of time and state, it must return an NVars-by-NBrowns matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time t.
- An NVars-by-1 state vector X_t.

Although the gbm object enforces no restrictions on the sign of Sigma volatilities, they are specified as positive values.

Data Types: double | function_handle

Properties

StartTime — Starting time of first observation, applied to all state variables

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

StartState — Initial values of state variables

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, the gbm object applies the same initial value to all state variables on all trials.

If StartState is a column vector, the gbm object applies a unique initial value to each state variable on all trials.

If StartState is a matrix, the gbm object applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

`Simulation` — User-defined simulation function or SDE simulation method

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: `function_handle`

`Drift` — Drift rate component of continuous-time stochastic differential equations (SDEs)

value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects (using `drift`) of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-`1` vector-valued function accessible using the (t, X_t) interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a `drift` object are:

- `Rate`: The drift-rate function, $F(t,X_t)$
- `A`: The intercept term, $A(t,X_t)$, of $F(t,X_t)$
- `B`: The first order term, $B(t,X_t)$, of $F(t,X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: `struct` | `double`

`Diffusion` — Diffusion rate component of continuous-time stochastic differential equations (SDEs)

value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects (using `diffusion`):

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-`1` vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the (t, X_t) interface.

The `diffusion` object's displayed parameters are:

- `Rate`: The diffusion-rate function, $G(t,X_t)$.
- `Alpha`: The state vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$.
- `Sigma`: The volatility rate, $V(t,X_t)$, of $G(t,X_t)$.

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate` functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct` | `double`

Object Functions

interpolate	Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simulate	Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models
simByEuler	Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simBySolution	Simulate approximate solution of diagonal-drift GBM processes
simByMilstein	Simulate BM, GBM, CEV, HWV, SDEDDO, SDELD, SDEMRD sample paths by Milstein approximation

Examples

Create a gbm Object

Create a univariate gbm object to represent the model: $dX_t = 0.25X_tdt + 0.3X_tdW_t$.

```
obj = gbm(0.25, 0.3)  % (B = Return, Sigma)
```

```
obj =
   Class GBM: Generalized Geometric Brownian Motion
   ------------------------------------------------
     Dimensions: State = 1, Brownian = 1
   ------------------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.25
          Sigma: 0.3
```

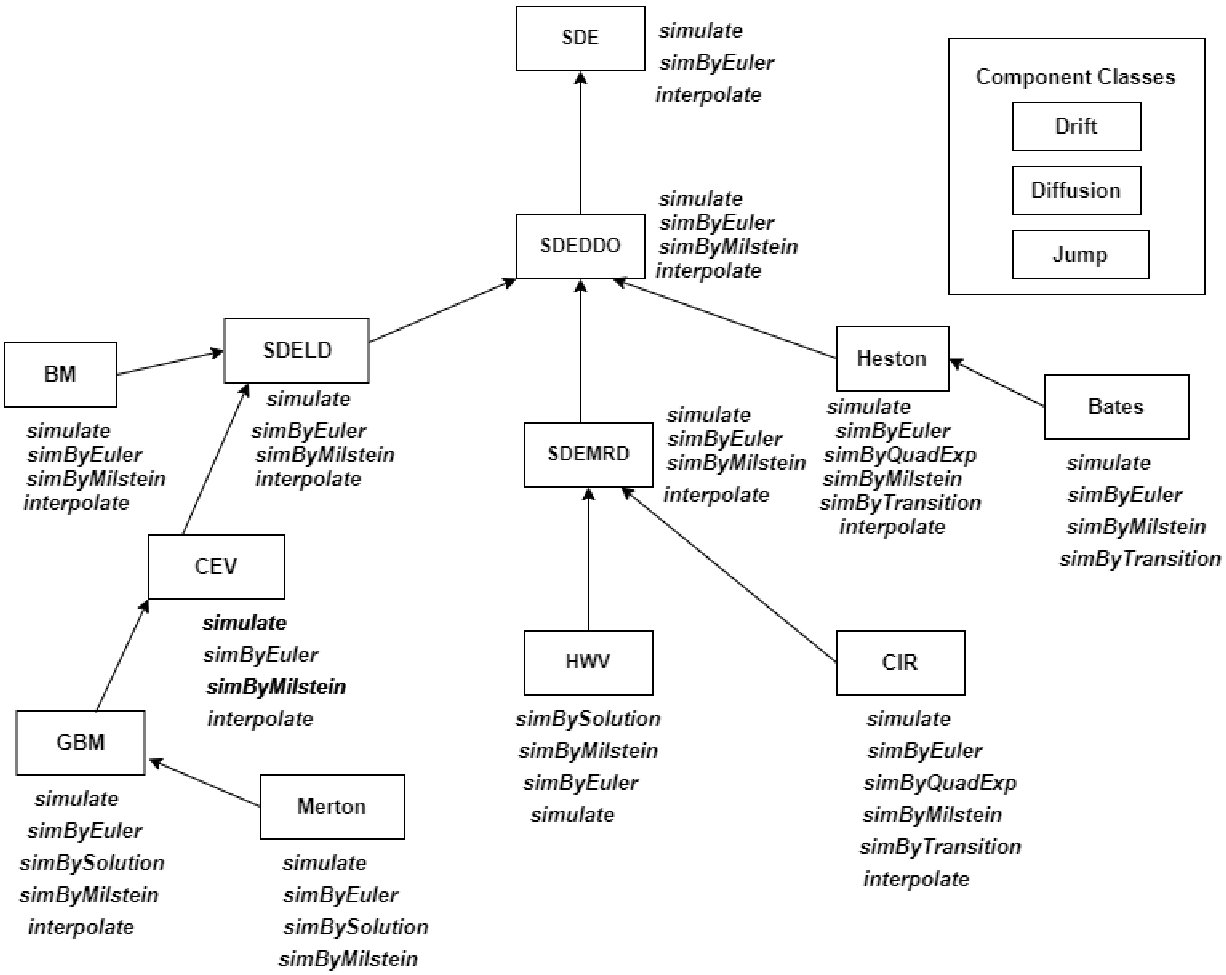
gbm objects display the parameter B as the more familiar Return

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time t and a state vector X_t, and return an array of appropriate dimension. Even if you originally specified an input as an array, `gbm` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

simBySolution

Simulate approximate solution of diagonal-drift GBM processes

Syntax

```
[Paths,Times,Z] = simBySolution(MDL,NPeriods)
[Paths,Times,Z] = simBySolution( ___ ,Name,Value)
```

Description

`[Paths,Times,Z] = simBySolution(MDL,NPeriods)` simulates approximate solution of diagonal-drift for geometric Brownian motion (GBM) processes.

`[Paths,Times,Z] = simBySolution( ___ ,Name,Value)` adds optional name-value pair arguments.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod`, `QuasiSequence` and `BrownianMotionMethod`. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Simulating Equity Markets Using GBM Simulation Functions

Use GBM simulation functions. Separable GBM models have two specific simulation functions:

- An overloaded Euler simulation function (`simulate`), designed for optimal performance.
- A `simBySolution` function that provides an approximate solution of the underlying stochastic differential equation, designed for accuracy.

Load the `Data_GlobalIdx2` data set and specify the SDE model as in “Representing Market Models Using SDE Objects” on page 14-28, and the GBM model as in “Representing Market Models Using SDELD, CEV, and GBM Objects” on page 14-30.

```
load Data_GlobalIdx2
prices  = [Dataset.TSX Dataset.CAC Dataset.DAX ...
    Dataset.NIK Dataset.FTSE Dataset.SP];

returns =  tick2ret(prices);

nVariables  = size(returns,2);
expReturn   = mean(returns);
sigma       = std(returns);
correlation = corrcoef(returns);
t           = 0;
X           = 100;
X           = X(ones(nVariables,1));

F = @(t,X) diag(expReturn)* X;
G = @(t,X) diag(X) * diag(sigma);
```

```
SDE = sde(F, G, 'Correlation', ...
    correlation, 'StartState', X);

GBM = gbm(diag(expReturn),diag(sigma), 'Correlation', ...
    correlation, 'StartState', X);
```

To illustrate the performance benefit of the overloaded Euler approximation function (`simulate`), increase the number of trials to `10000`.

```
nPeriods = 249;      % # of simulated observations
dt       =   1;      % time increment = 1 day
rng(142857,'twister')
[X,T] = simulate(GBM, nPeriods, 'DeltaTime', dt, ...
    'nTrials', 10000);

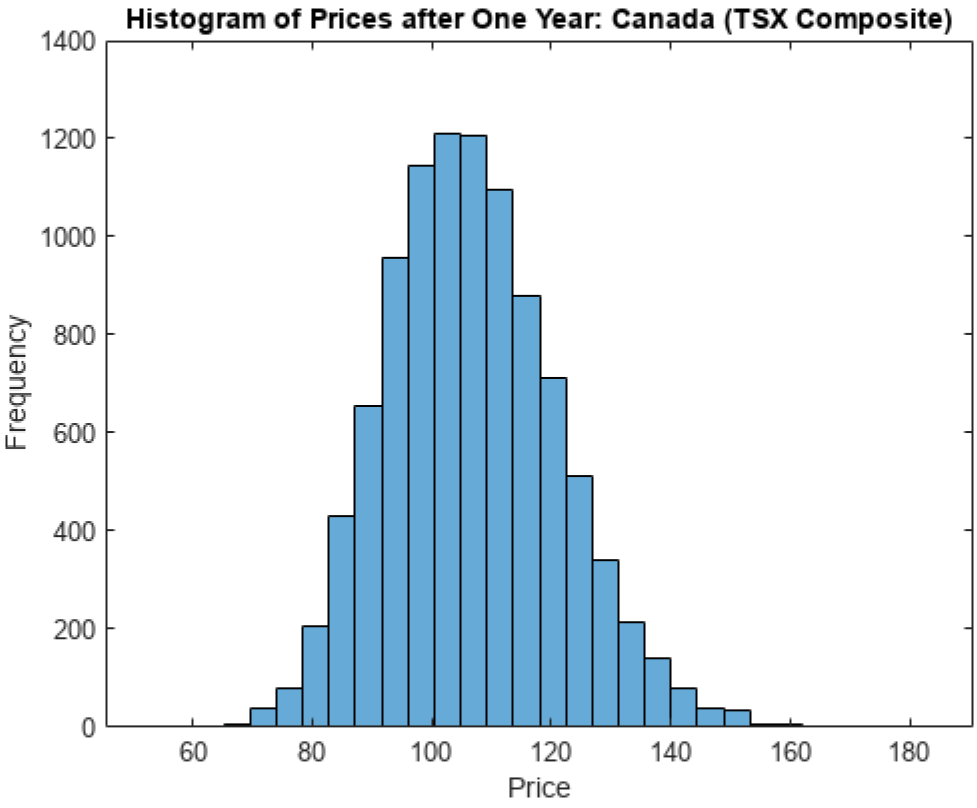
whos X

  Name        Size                     Bytes  Class     Attributes

  X         250x6x10000            120000000  double
```

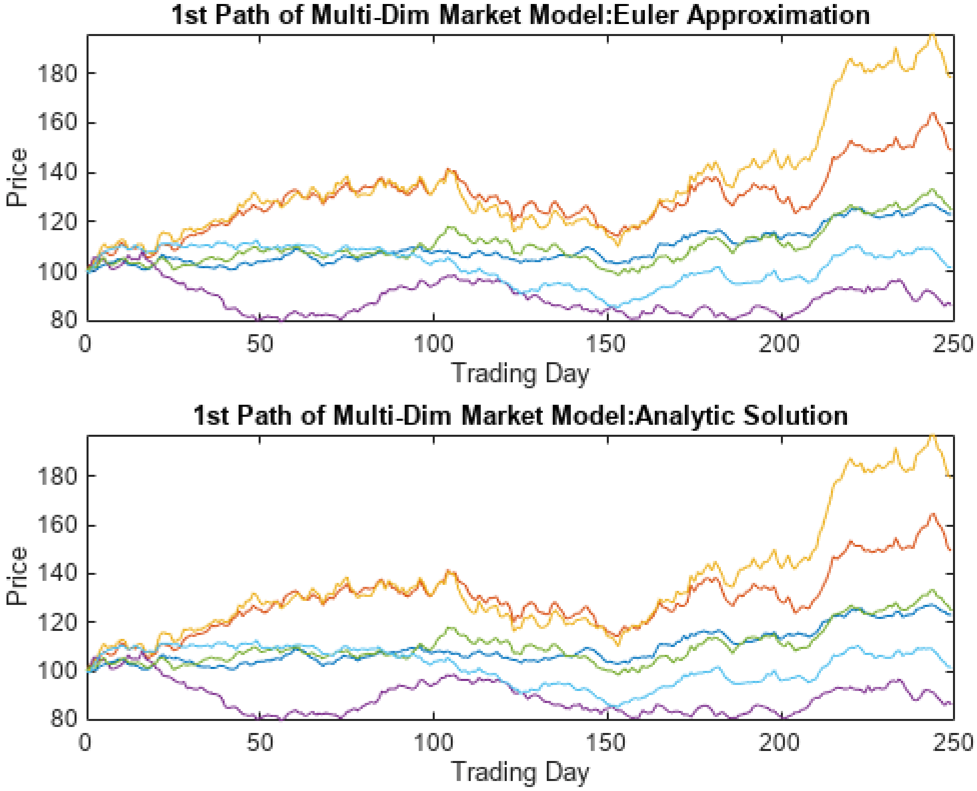
Using this sample size, examine the terminal distribution of Canada's TSX Composite to verify qualitatively the lognormal character of the data.

```
histogram(squeeze(X(end,1,:)), 30), xlabel('Price'), ylabel('Frequency')
title('Histogram of Prices after One Year: Canada (TSX Composite)')
```



Simulate 10 trials of the solution and plot the first trial:

```
rng('default')
[S,T] = simulate(SDE, nPeriods, 'DeltaTime', dt, 'nTrials', 10);
rng('default')
[X,T] = simBySolution(GBM, nPeriods,...
    'DeltaTime', dt, 'nTrials', 10);
subplot(2,1,1)
plot(T, S(:,:,1)), xlabel('Trading Day'),ylabel('Price')
title('1st Path of Multi-Dim Market Model:Euler Approximation')
subplot(2,1,2)
plot(T, X(:,:,1)), xlabel('Trading Day'),ylabel('Price')
title('1st Path of Multi-Dim Market Model:Analytic Solution')
```



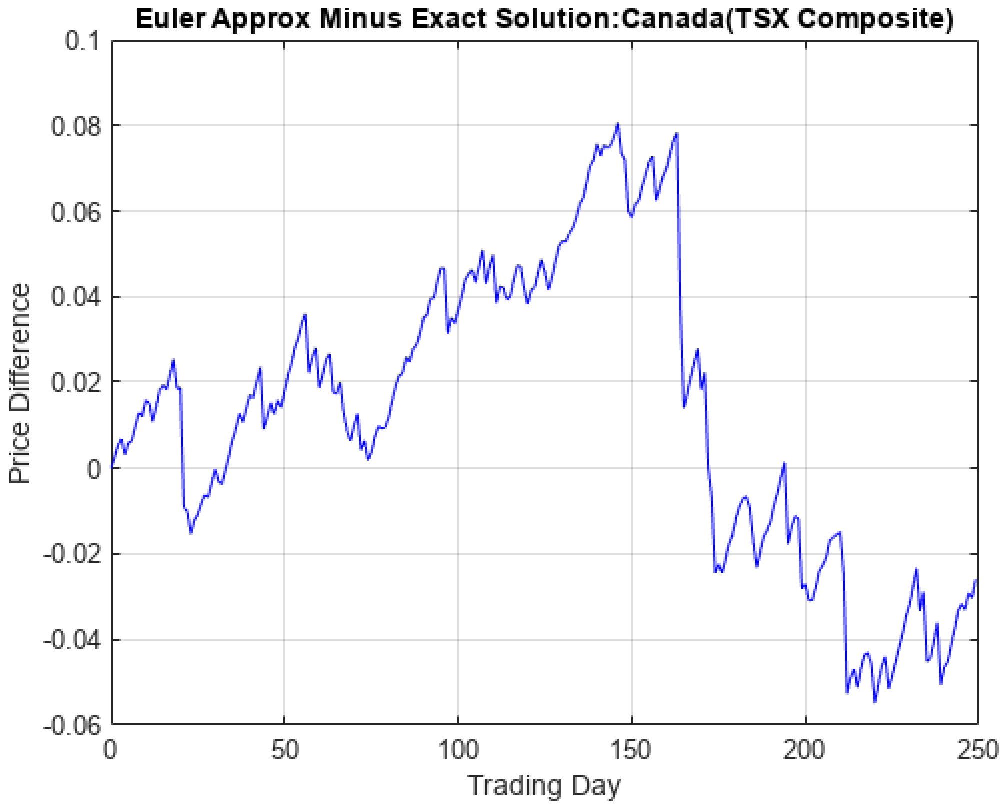
1st Path of Multi-Dim Market Model:Euler Approximation

1st Path of Multi-Dim Market Model:Analytic Solution

In this example, all parameters are constants, and `simBySolution` does indeed sample the exact solution. The details of a single index for any given trial show that the price paths of the Euler approximation and the exact solution are close, but not identical.

The following plot illustrates the difference between the two functions:

```
subplot(1,1,1)
plot(T, S(:,1,1) - X(:,1,1), 'blue'), grid('on')
xlabel('Trading Day'), ylabel('Price Difference')
title('Euler Approx Minus Exact Solution:Canada(TSX Composite)')
```



The `simByEuler` Euler approximation literally evaluates the stochastic differential equation directly from the equation of motion, for some suitable value of the `dt` time increment. This simple approximation suffers from discretization error. This error can be attributed to the discrepancy between the choice of the *dt* time increment and what in theory is a continuous-time parameter.

The discrete-time approximation improves as `DeltaTime` approaches zero. The Euler function is often the least accurate and most general method available. All models shipped in the simulation suite have the `simByEuler` function.

In contrast, the `simBySolution` function provides a more accurate description of the underlying model. This function simulates the price paths by an approximation of the closed-form solution of separable models. Specifically, it applies a Euler approach to a transformed process, which in general is not the exact solution to this `GBM` model. This is because the probability distributions of the simulated and true state vectors are identical only for piecewise constant parameters.

When all model parameters are piecewise constant over each observation period, the simulated process is exact for the observation times at which the state vector is sampled. Since all parameters are constants in this example, `simBySolution` does indeed sample the exact solution.

For an example of how to use `simBySolution` to optimize the accuracy of solutions, see “Optimizing Accuracy: About Solution Precision and Error” on page 14-65.

Simulating Equity Markets Using GBM Model with Quasi-Monte Carlo Simulation

This example shows how to use `simBySolution` with a GBM model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Load the `Data_GlobalIdx2` data set and specify the GBM model as in “Representing Market Models Using SDELD, CEV, and GBM Objects” on page 14-30.

```
load Data_GlobalIdx2
prices  = [Dataset.TSX Dataset.CAC Dataset.DAX ...
    Dataset.NIK Dataset.FTSE Dataset.SP];

returns =  tick2ret(prices);
nVariables  = size(returns,2);
expReturn   = mean(returns);
sigma       = std(returns);
correlation = corrcoef(returns);
X           = 100;
X           = X(ones(nVariables,1));

GBM = gbm(diag(expReturn),diag(sigma), 'Correlation', ...
    correlation, 'StartState', X);
```

Perform a quasi-Monte Carlo simulation by using `simBySolution` with the optional name-value arguments for `'MonteCarloMethod'`,`'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time,z] = simBySolution(GBM, 10,'ntrials',4096,'MonteCarloMethod','quasi','QuasiSequence'
```

Input Arguments

`MDL` — Geometric Brownian motion (GBM) model

`gbm` object

Geometric Brownian motion (GBM) model, specified as a `gbm` object that is created using `gbm`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Paths,Times,Z] = simBySolution(GBM,NPeriods,'DeltaTime',dt,'NTrials',10)`

NTrials — Simulated trials (sample paths) of NPERIODS observations each

1 (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of NPERIODS observations each, specified as the comma-separated pair consisting of 'NTrials' and a positive scalar integer.

Data Types: double

DeltaTimes — Positive time increments between observations

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTimes' and a scalar or a NPERIODS-by-1 column vector.

DeltaTime represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

NSteps — Number of intermediate time steps within each time increment *dt* (specified as DeltaTime)

1 (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment *dt* (specified as DeltaTime), specified as the comma-separated pair consisting of 'NSteps' and a positive scalar integer.

The simBySolution function partitions each time increment *dt* into NSteps subintervals of length *dt*/NSteps, and refines the simulation by evaluating the simulated state vector at NSteps − 1 intermediate points. Although simBySolution does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

Antithetic — Flag to indicate whether simBySolution uses antithetic sampling to generate the Gaussian random variates

False (no antithetic sampling) (default) | logical with values True or False

Flag to indicate whether simBySolution uses antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of 'Antithetic' and a scalar logical flag with a value of True or False.

When you specify True, simBySolution performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials (1,3,5,...) correspond to the primary Gaussian paths.
- Even trials (2,4,6,...) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see Z), simBySolution ignores the value of Antithetic.

Data Types: logical

MonteCarloMethod — Monte Carlo method to simulate stochastic processes

"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see Z), simBySolution ignores the value of MonteCarloMethod.

Data Types: string | char

QuasiSequence — Low discrepancy sequence to drive the stochastic processes

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note

- If MonteCarloMethod option is not specified or specified as"standard", QuasiSequence is ignored.
- If you specify an input noise process (see Z), simBySolution ignores the value of QuasiSequence.

Data Types: string | char

BrownianMotionMethod — Brownian motion construction method

"standard" (default) | string with value "brownian-bridge" or "principal-components" | character vector with value 'brownian-bridge' or 'principal-components'

Brownian motion construction method, specified as the comma-separated pair consisting of 'BrownianMotionMethod' and a string or character vector with one of the following values:

- "standard" — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- "brownian-bridge" — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- "principal-components" — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the Z input argument, BrownianMotionMethod is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the MonteCarloMethod using pseudo random numbers. However, the performance differs between the two when the MonteCarloMethod option "quasi" is introduced, with faster convergence seen for "brownian-bridge" construction option and the fastest convergence when using the "principal-components" construction option.

Data Types: string | char

Z — Direct specification of the dependent random noise process used to generate the Brownian motion vector

generates correlated Gaussian variates based on the Correlation member of the SDE object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process used to generate the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of 'Z' and a function or as an (NPERIODS * NSTEPS)-by-NBROWNS-by-NTRIALS three-dimensional array of dependent random variates.

The input argument Z allows you to directly specify the noise generation process. This process takes precedence over the Correlation parameter of the input gbm object and the value of the Antithetic input flag.

Note If you specify Z as a function, it must return an NBROWNS-by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time *t*.
- An NVARS-by-1 state vector X_t.

Data Types: double | function

StorePaths — Flag that indicates how the output array Paths is stored and returned

True (default) | logical with values True or False

Flag that indicates how the output array Paths is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar logical flag with a value of True or False.

If StorePaths is True (the default value) or is unspecified, simBySolution returns Paths as a three-dimensional time series array.

If StorePaths is False (logical 0), simBySolution returns the Paths output array as an empty matrix.

Data Types: logical

`Processes` — Sequence of end-of-period processes or state vector adjustments of the form
`simBySolution` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments of the form, specified as the comma-separated pair consisting of `'Processes'` and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simBySolution` function runs processing functions at each interpolation time. They must accept the current interpolation time t, and the current state vector X_t, and return a state vector that may be an adjustment to the input state.

`simBySolution` applies processing functions at the end of each observation period. These functions must accept the current observation time t and the current state vector X_t, and return a state vector that may be an adjustment to the input state.

The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simBySolution` tests the state vector X_t for an all-`NaN` condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be `NaN`. This test enables a user-defined `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

If you specify more than one processing function, `simBySolution` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables
array

Simulated paths of correlated state variables, returned as a `(NPERIODS + 1)`-by-`NVARS`-by-`NTRIALS` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When the input flag `StorePaths` = `False`, `simBySolution` returns `Paths` as an empty matrix.

`Times` — Observation times associated with the simulated paths
column vector

Observation times associated with the simulated paths, returned as a `(NPERIODS + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates used to generate the Brownian motion vector
array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as a `(NPERIODS * NSTEPS)`-by-`NBROWNS`-by-`NTRIALS` three-dimensional time series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

The `simBySolution` function simulates `NTRIALS` sample paths of `NVARS` correlated state variables, driven by `NBROWNS` Brownian motion sources of risk over `NPERIODS` consecutive observation periods, approximating continuous-time GBM short-rate models by an approximation of the closed-form solution.

Consider a separable, vector-valued GBM model of the form:

$$dX_t = \mu(t)X_t dt + D(t, X_t)V(t)dW_t$$

where:

- X_t is an `NVARS`-by-`1` state vector of process variables.
- μ is an `NVARS`-by-`NVARS` generalized expected instantaneous rate of return matrix.
- V is an `NVARS`-by-`NBROWNS` instantaneous volatility rate matrix.
- dW_t is an `NBROWNS`-by-`1` Brownian motion vector.

The `simBySolution` function simulates the state vector X_t using an approximation of the closed-form solution of diagonal-drift models.

When evaluating the expressions, `simBySolution` assumes that all model parameters are piecewise-constant over each simulation period.

In general, this is *not* the exact solution to the models, because the probability distributions of the simulated and true state vectors are identical *only* for piecewise-constant parameters.

When parameters are piecewise-constant over each observation period, the simulated process is exact for the observation times at which X_t is sampled.

Gaussian diffusion models, such as `hwv`, allow negative states. By default, `simBySolution` does nothing to prevent negative states, nor does it guarantee that the model be strictly mean-reverting. Thus, the model may exhibit erratic or explosive growth.

Version History

Introduced in R2008a

R2022a: Perform Quasi-Monte Carlo simulation

Behavior changed in R2022a

Perform Quasi-Monte Carlo simulation using the name-value arguments `MonteCarloMethod` and `QuasiSequence`.

R2022b: Perform Brownian bridge and principal components construction

Behavior changed in R2022b

Perform Brownian bridge and principal components construction using the name-value argument `BrownianMotionMethod`.

simBySolution

Simulate approximate solution of diagonal-drift `HWV` processes

Syntax

```
[Paths,Times,Z] = simBySolution(MDL,NPeriods)
[Paths,Times,Z] = simBySolution( ___ ,Name,Value)
```

Description

`[Paths,Times,Z] = simBySolution(MDL,NPeriods)` simulates approximate solution of diagonal-drift for Hull-White/Vasicek Gaussian Diffusion (HWV) processes.

`[Paths,Times,Z] = simBySolution( ___ ,Name,Value)` adds optional name-value pair arguments.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Use `simBySolution` with an `hwv` Object

Create an `hwv` object to represent the model:

$$dX_t = 0.2(0.1 - X_t)dt + 0.05dW_t.$$

```
hwv = hwv(0.2, 0.1, 0.05)  % (Speed, Level, Sigma)
```

```
hwv = 

   Class HWV: Hull-White/Vasicek
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.1
          Speed: 0.2
```

The `simBySolution` function simulates the state vector X_t using an approximation of the closed-form solution of diagonal drift `HWV` models. Each element of the state vector X_t is expressed as the sum of `NBrowns` correlated Gaussian random draws added to a deterministic time-variable drift.

```
NPeriods = 100
[Paths,Times,Z] = simBySolution(hwv, NPeriods,'NTrials', 10);
```

Quasi-Monte Carlo Simulation Using HWV Model

This example shows how to use `simBySolution` with a HWV model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

```
HWV = hwv(1.5,100,10,'startstate',100);
```

Perform a quasi-Monte Carlo simulation by using `simBySolution` with the optional name-value arguments for `'MonteCarloMethod'`,`'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time,z] = simBySolution(HWV, 10,'ntrials',4096,'MonteCarloMethod','quasi','QuasiSequence'
```

Input Arguments

`MDL` — Hull-White/Vasicek (HWV) model
hwv object

Hull-White/Vasicek (HWV) mode, specified as a `hwv` object that is created using `hwv`.

Data Types: `object`

`NPeriods` — Number of simulation periods
positive integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Paths,Times,Z] = simBySolution(HWV,NPeriods,'DeltaTime',dt,'NTrials',10)`

`NTrials` — Simulated trials (sample paths) of `NPeriods` observations each
1 (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of `'NTrials'` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations
1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of `'DeltaTimes'` and a scalar or a `NPeriods`-by-`1` column vector.

`DeltaTime` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps within each time increment *dt* (specified as `DeltaTime`)

`1` (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment *dt* (specified as `DeltaTime`), specified as the comma-separated pair consisting of `'NSteps'` and a positive scalar integer.

The `simBySolution` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps − 1` intermediate points. Although `simBySolution` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`Antithetic` — Flag to indicate whether `simBySolution` uses antithetic sampling to generate the Gaussian random variates

`False` (no antithetic sampling) (default) | logical with values `True` or `False`

Flag to indicate whether `simBySolution` uses antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of `'Antithetic'` and a scalar logical flag with a value of `True` or `False`.

When you specify `True`, `simBySolution` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials `(1,3,5,...)` correspond to the primary Gaussian paths.
- Even trials `(2,4,6,...)` are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see `Z`), `simBySolution` ignores the value of `Antithetic`.

Data Types: `logical`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes

`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of `'MonteCarloMethod'` and a string or character vector with one of the following values:

- `"standard"` — Monte Carlo using pseudo random numbers.
- `"quasi"` — Quasi-Monte Carlo using low-discrepancy sequences.

- "randomized-quasi" — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see Z), simBySolution ignores the value of MonteCarloMethod.

Data Types: string | char

QuasiSequence — Low discrepancy sequence to drive the stochastic processes
"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note

- If MonteCarloMethod option is not specified or specified as"standard", QuasiSequence is ignored.
- If you specify an input noise process (see Z), simBySolution ignores the value of QuasiSequence.

Data Types: string | char

BrownianMotionMethod — Brownian motion construction method
"standard" (default) | string with value "brownian-bridge" or "principal-components" | character vector with value 'brownian-bridge' or 'principal-components'

Brownian motion construction method, specified as the comma-separated pair consisting of 'BrownianMotionMethod' and a string or character vector with one of the following values:

- "standard" — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- "brownian-bridge" — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- "principal-components" — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the Z input argument, BrownianMotionMethod is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the MonteCarloMethod using pseudo random numbers. However, the performance differs between the two when the MonteCarloMethod option "quasi" is introduced, with faster convergence seen for "brownian-bridge" construction option and the fastest convergence when using the "principal-components" construction option.

Data Types: string | char

Z — Direct specification of the dependent random noise process used to generate the Brownian motion vector
generates correlated Gaussian variates based on the Correlation member of the SDE object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process used to generate the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of 'Z' and a function or as an (NPeriods * NSteps)-by-NBrowns-by-NTrials three-dimensional array of dependent random variates.

The input argument Z allows you to directly specify the noise generation process. This process takes precedence over the Correlation parameter of the input gbm object and the value of the Antithetic input flag.

Note If you specify Z as a function, it must return an NBrowns-by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time *t*.
- An NVars-by-1 state vector X_t.

Data Types: double | function

StorePaths — Flag that indicates how the output array Paths is stored and returned
True (default) | logical with values True or False

Flag that indicates how the output array Paths is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar logical flag with a value of True or False.

If StorePaths is True (the default value) or is unspecified, simBySolution returns Paths as a three-dimensional time series array.

If StorePaths is False (logical 0), simBySolution returns the Paths output array as an empty matrix.

Data Types: logical

Processes — Sequence of end-of-period processes or state vector adjustments of the form
simBySolution makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments of the form, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The simBySolution function runs processing functions at each interpolation time. They must accept the current interpolation time *t*, and the current state vector X_t, and return a state vector that may be an adjustment to the input state.

simBySolution applies processing functions at the end of each observation period. These functions must accept the current observation time *t* and the current state vector X_t, and return a state vector that may be an adjustment to the input state.

The end-of-period Processes argument allows you to terminate a given trial early. At the end of each time step, simBySolution tests the state vector X_t for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be NaN. This test enables a user-defined Processes function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

If you specify more than one processing function, simBySolution invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: cell | function

Output Arguments

Paths — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as a (NPeriods + 1)-by-NVars-by-NTrials three-dimensional time series array.

For a given trial, each row of Paths is the transpose of the state vector X_t at time *t*. When the input flag StorePaths = False, simBySolution returns Paths as an empty matrix.

Times — Observation times associated with the simulated paths

column vector

Observation times associated with the simulated paths, returned as a (NPeriods + 1)-by-1 column vector. Each element of Times is associated with the corresponding row of Paths.

Z — Dependent random variates used to generate the Brownian motion vector

array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as a (NPeriods * NSteps)-by-NBrowns-by-NTrials three-dimensional time series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

The `simBySolution` method simulates `NTrials` sample paths of `NVars` correlated state variables, driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time Hull-White/Vasicek (HWV) by an approximation of the closed-form solution.

Consider a separable, vector-valued HWV model of the form:

$$dX_t = S(t)[L(t) - X_t]dt + V(t)dW_t$$

where:

- X is an *NVars*-by-`1` state vector of process variables.
- S is an *NVars*-by-*NVars* matrix of mean reversion speeds (the rate of mean reversion).
- L is an *NVars*-by-`1` vector of mean reversion levels (long-run mean or level).
- V is an *NVars*-by-*NBrowns* instantaneous volatility rate matrix.
- W is an *NBrowns*-by-`1` Brownian motion vector.

The `simBySolution` method simulates the state vector X_t using an approximation of the closed-form solution of diagonal-drift models.

When evaluating the expressions, `simBySolution` assumes that all model parameters are piecewise-constant over each simulation period.

In general, this is *not* the exact solution to the models, because the probability distributions of the simulated and true state vectors are identical *only* for piecewise-constant parameters.

When parameters are piecewise-constant over each observation period, the simulated process is exact for the observation times at which X_t is sampled.

Gaussian diffusion models, such as `hwv`, allow negative states. By default, `simBySolution` does nothing to prevent negative states, nor does it guarantee that the model be strictly mean-reverting. Thus, the model may exhibit erratic or explosive growth.

Version History

Introduced in R2008a

R2022a: Perform Quasi-Monte Carlo simulation

Behavior changed in R2022a

Perform Quasi-Monte Carlo simulation using the name-value arguments `MonteCarloMethod` and `QuasiSequence`.

R2022b: Perform Brownian bridge and principal components construction
Behavior changed in R2022b

Perform Brownian bridge and principal components construction using the name-value argument `BrownianMotionMethod`.

heston

`Heston` model

Description

Creates and displays `heston` objects, which derive from the `sdeddo` (SDE from drift and diffusion objects).

Use `heston` objects to simulate sample paths of two state variables. Each state variable is driven by a single Brownian motion source of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic volatility processes.

Heston models are bivariate composite models. Each Heston model consists of two coupled univariate models:

- A geometric Brownian motion (`gbm`) model with a stochastic volatility function.

  $$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

  This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.
- A Cox-Ingersoll-Ross (`cir`) square root diffusion model.

  $$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

  This model describes the evolution of the variance rate of the coupled GBM price process.

Creation

Syntax

```
heston = heston(Return,Speed,Level,Volatility)
heston = heston( ___ ,Name,Value)
```

Description

`heston = heston(Return,Speed,Level,Volatility)` creates a default `heston` object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time *t* and state *X(t)* and is invoked with both input arguments.

`heston = heston( ___ ,Name,Value)` constructs a `heston` object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`

The `heston` object has the following “Properties” on page 15-130:

- `StartTime` — Initial observation time
- `StartState` — Initial state at `StartTime`
- `Correlation` — Access function for the `Correlation` input, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Return` — Access function for the input argument `Return`, callable as a function of time and state
- `Speed` — Access function for the input argument `Speed`, callable as a function of time and state
- `Level` — Access function for the input argument `Level`, callable as a function of time and state
- `Volatility` — Access function for the input argument `Volatility`, callable as a function of time and state

Input Arguments

`Return` — `Return` represents the parameter μ
array or deterministic function of time or deterministic function of time and state

`Return` represents the parameter μ, specified as an array or deterministic function of time.

If you specify `Return` as an array, it must be an `NVars`-by-`NVars` matrix representing the expected (mean) instantaneous rate of return.

As a deterministic function of time, when `Return` is called with a real-valued scalar time `t` as its only input, `Return` must produce an `NVars`-by-`NVars` matrix. If you specify `Return` as a function of time and state, it must return an `NVars`-by-`NVars` matrix when invoked with two inputs:

- A real-valued scalar observation time t.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function_handle`

`Speed` — `Return` represents the parameter S
array or deterministic function of time or deterministic function of time and state

`Speed` represents the parameter S, specified as an array or deterministic function of time.

If you specify Speed as an array, it must be an NVars-by-NVars matrix of mean-reversion speeds (the rate at which the state vector reverts to its long-run average Level).

As a deterministic function of time, when Speed is called with a real-valued scalar time t as its only input, Speed must produce an NVars-by-NVars matrix. If you specify Speed as a function of time and state, it calculates the speed of mean reversion. This function must generate an NVars-by-NVars matrix of reversion rates when called with two inputs:

- A real-valued scalar observation time t.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Level — Level represents the parameter *L*

array or deterministic function of time or deterministic function of time and state

Level represents the parameter L, specified as an array or deterministic function of time.

If you specify Level as an array, it must be an NVars-by-1 column vector of reversion levels.

As a deterministic function of time, when Level is called with a real-valued scalar time t as its only input, Level must produce an NVars-by-1 column vector. If you specify Level as a function of time and state, it must generate an NVars-by-1 column vector of reversion levels when called with two inputs:

- A real-valued scalar observation time t.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Volatility — Volatility represents the instantaneous volatility of the CIR stochastic variance model

scalar or deterministic function of time or deterministic function of time and state

Volatility (often called the *volatility of volatility* or *volatility of variance*) represents the instantaneous volatility of the CIR stochastic variance model, specified as a scalar, or deterministic function of time.

If you specifyVolatility as a scalar, it represents the instantaneous volatility of the CIR stochastic variance model.

As a deterministic function of time, when Volatility is called with a real-valued scalar time t as its only input, Volatility must produce a scalar. If you specify it as a function time and state, Volatility generates a scalar when invoked with two inputs:

- A real-valued scalar observation time t.
- A 2-by-1 state vector X_t.

Data Types: double | function_handle

Note Although heston does not enforce restrictions on the signs of any of these input arguments, each argument is specified as a positive value.

Properties

StartTime — Starting time of first observation, applied to all state variables

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

StartState — Initial values of state variables

1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, heston applies the same initial value to all state variables on all trials.

If StartState is a column vector, heston applies a unique initial value to each state variable on all trials.

If StartState is a matrix, heston applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

Simulation — User-defined simulation function or SDE simulation method

simulation by Euler approximation (simByEuler) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function_handle

Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)

value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-`1` vector-valued function accessible using the (t, X_t) interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a `drift` object are:

- `Rate`: The drift-rate function, $F(t,X_t)$
- `A`: The intercept term, $A(t,X_t)$, of $F(t,X_t)$
- `B`: The first order term, $B(t,X_t)$, of $F(t,X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: `struct` | `double`

`Diffusion` — Diffusion rate component of continuous-time stochastic differential equations (SDEs)

value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by $(t, X_t$.

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects using `diffusion`:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-`1` vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the (t, X_t) interface.

The displayed parameters for a `diffusion` object are:

- `Rate`: The diffusion-rate function, $G(t,X_t)$.
- `Alpha`: The state vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$.
- `Sigma`: The volatility rate, $V(t,X_t)$, of $G(t,X_t)$.

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate` functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct` | `double`

Object Functions

interpolate — Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

simulate — Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models

simByEuler — Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

simByQuadExp — Simulate Bates, Heston, and CIR sample paths by quadratic-exponential discretization scheme

simByTransition — Simulate Heston sample paths with transition density

simByMilstein — Simulate Heston sample paths by Milstein approximation

Examples

Create a heston Object

The Heston (`heston`) class derives directly from SDE from Drift and Diffusion (`sdeddo`). Each Heston model is a bivariate composite model, consisting of two coupled univariate models:

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

Create a `heston` object to represent the model:

$$dX_{1t} = 0.1X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

$$dX_{2t} = 0.2[0.1 - X_{2t}]dt + 0.05\sqrt{X_{2t}}dW_{2t}$$

```
obj = heston (0.1, 0.2, 0.1, 0.05)  % (Return, Speed, Level, Volatility)
```

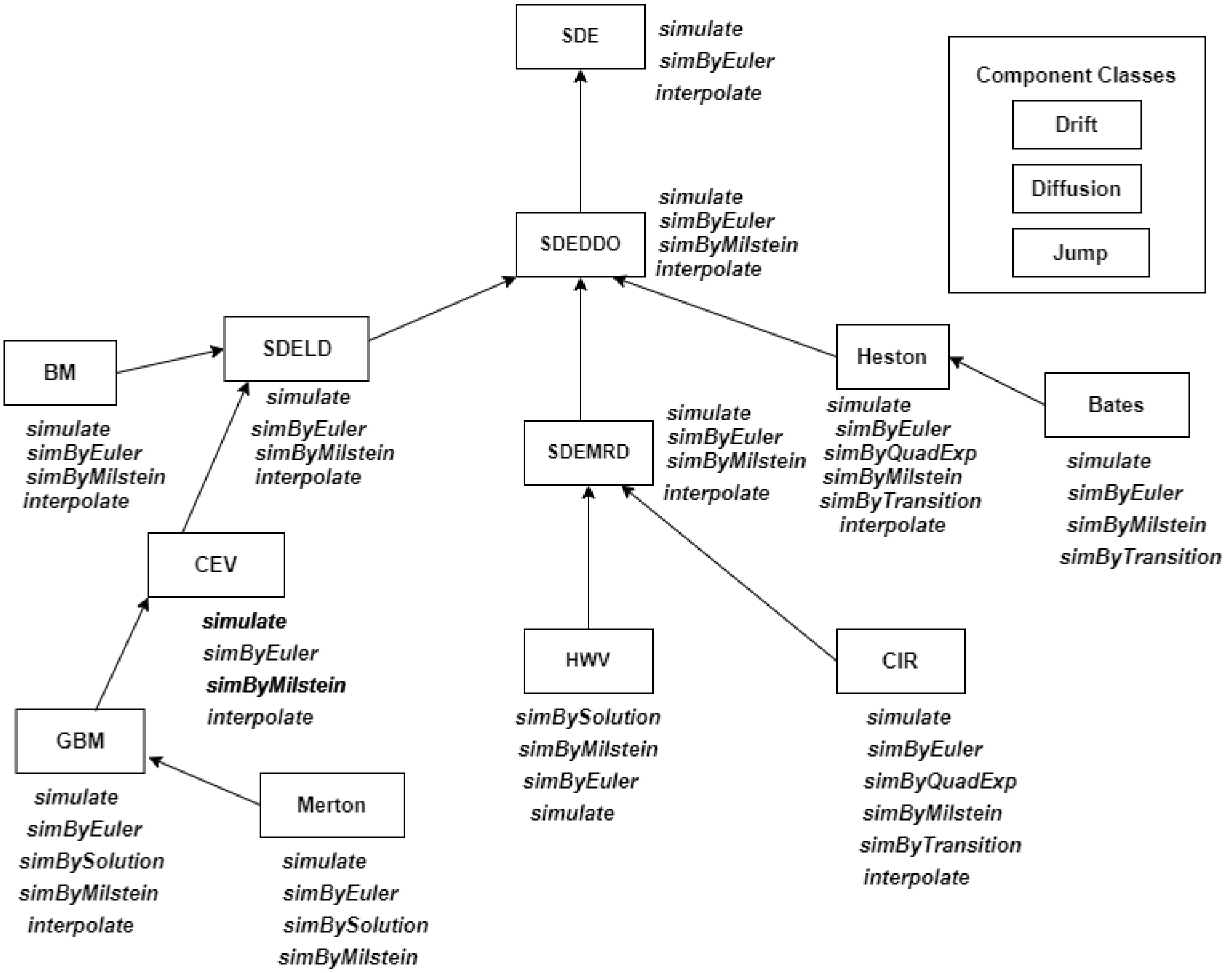
```
obj = 
   Class HESTON: Heston Bivariate Stochastic Volatility
   ----------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   ----------------------------------------------------
      StartTime: 0
     StartState: 1 (2x1 double array) 
    Correlation: 2x2 diagonal double array 
          Drift: drift rate function F(t,X(t)) 
      Diffusion: diffusion rate function G(t,X(t)) 
     Simulation: simulation method/function simByEuler
         Return: 0.1
          Speed: 0.2
          Level: 0.1
     Volatility: 0.05
```

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time t and a state vector X_t, and return an array of appropriate dimension. Even if you originally specified an input as an array, `heston` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

Version History

Introduced in R2008a

R2023a: Added `simByMilstein` method

Behavior changed in R2023a

Use the `simByMilstein` method to approximate a numerical solution of a stochastic differential equation.

hwv

Hull-White/Vasicek (HWV) Gaussian Diffusion model

Description

Create and displays hwv objects, which derive from the sdemrd (SDE with drift rate expressed in mean-reverting form) class.

Use hwv objects to simulate sample paths of NVars state variables expressed in mean-reverting drift-rate form. These state variables are driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time Hull-White/Vasicek stochastic processes with Gaussian diffusions.

This model allows you to simulate vector-valued Hull-White/Vasicek processes of the form:

$$dX_t = S(t)[L(t) - X_t]dt + V(t)dW_t \tag{15-2}$$

where:

- X_t is an NVars-by-1 state vector of process variables.
- S is an NVars-by-NVars of mean reversion speeds (the rate of mean reversion).
- L is an NVars-by-1 vector of mean reversion levels (long-run mean or level).
- V is an NVars-by-NBrowns instantaneous volatility rate matrix.
- $dW_t$is an NBrowns-by-1 Brownian motion vector.

Creation

Syntax

```
HWV = hwv(Speed,Level,Sigma)
HWV = hwv( ___ ,Name,Value)
```

Description

HWV = hwv(Speed,Level,Sigma) creates a default HWV object.

Specify required input parameters as one of the following types:

- A MATLAB array. Specifying an array indicates a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- A MATLAB function. Specifying a function provides indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported via an interface, because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed.

Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time *t* and state *X(t)* and is invoked with both input arguments.

`HWV = hwv( ___ ,Name,Value)` creates a `HWV` object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`

The `HWV` object has the following “Properties” on page 15-138:

- `StartTime` — Initial observation time
- `StartState` — Initial state at `StartTime`
- `Correlation` — Access function for the `Correlation` input, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method
- `Speed` — Access function for the input argument `Speed`, callable as a function of time and state
- `Level` — Access function for the input argument `Level`, callable as a function of time and state
- `Sigma` — Access function for the input argument `Sigma`, callable as a function of time and state

Input Arguments

Speed — Speed represents the parameter *S*

array or deterministic function of time or deterministic function of time and state

`Speed` represents the parameter *S*, specified as an array or deterministic function of time.

If you specify `Speed` as an array, it must be an `NVars`-by-`NVars` matrix of mean-reversion speeds (the rate at which the state vector reverts to its long-run average `Level`).

As a deterministic function of time, when `Speed` is called with a real-valued scalar time `t` as its only input, `Speed` must produce an `NVars`-by-`NVars` matrix. If you specify `Speed` as a function of time and state, it calculates the speed of mean reversion. This function must generate an `NVars`-by-`NVars` matrix of reversion rates when called with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-1 state vector X_t.

Data Types: `double` | `function_handle`

`Level` — Level represents the parameter *L*

array or deterministic function of time or deterministic function of time and state

`Level` represents the parameter *L*, specified as an array or deterministic function of time.

If you specify `Level` as an array, it must be an `NVars`-by-1 column vector of reversion levels.

As a deterministic function of time, when `Level` is called with a real-valued scalar time `t` as its only input, `Level` must produce an `NVars`-by-1 column vector. If you specify `Level` as a function of time and state, it must generate an NVars-by-1 column vector of reversion levels when called with two inputs:

- A real-valued scalar observation time *t*.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Sigma — Sigma represents the parameter *V*
array or deterministic function of time or deterministic function of time and state

Sigma represents the parameter *V*, specified as an array or a deterministic function of time.

If you specify Sigma as an array, it must be an NVars-by-NBrowns matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of Sigma corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when Sigma is called with a real-valued scalar time t as its only input, Sigma must produce an NVars-by-NBrowns matrix. If you specify Sigma as a function of time and state, it must return an NVars-by-NBrowns matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Note Although the hwv object does not enforce restrictions on the signs of any of these input arguments, each argument is specified as a positive value.

Properties

StartTime — Starting time of first observation, applied to all state variables
0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

StartState — Initial values of state variables
1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, the hwv object applies the same initial value to all state variables on all trials.

If StartState is a column vector, the hwv object applies a unique initial value to each state variable on all trials.

If StartState is a matrix, the hwv object applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

Simulation — User-defined simulation function or SDE simulation method

simulation by Euler approximation (simByEuler) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function_handle

Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)

value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The drift rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The drift class allows you to create drift-rate objects using drift of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- A is an NVars-by-1 vector-valued function accessible using the (t, X_t) interface.
- B is an NVars-by-NVars matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a drift object are:

- Rate: The drift-rate function, $F(t,X_t)$
- A: The intercept term, $A(t,X_t)$, of $F(t,X_t)$
- B: The first order term, $B(t,X_t)$, of $F(t,X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

Note You can express drift and diffusion classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components A and B as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: struct | double

Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)
value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The diffusion rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion class allows you to create diffusion-rate objects using diffusion:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- D is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVars-by-1 vector-valued function.
- V is an NVars-by-NBrowns matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the (t, X_t) interface.

The displayed parameters for a diffusion object are:

- Rate: The diffusion-rate function, $G(t,X_t)$.
- Alpha: The state vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$.
- Sigma: The volatility rate, $V(t,X_t)$, of $G(t,X_t)$.

Alpha and Sigma enable you to query the original inputs. (The combined effect of the individual Alpha and Sigma parameters is fully encapsulated by the function stored in Rate.) The Rate functions are the calculation engines for the drift and diffusion objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct` | `double`

Object Functions

interpolate	Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simulate	Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models
simByEuler	Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simBySolution	Simulate approximate solution of diagonal-drift HWV processes
simByMilstein	Simulate BM, GBM, CEV, HWV, SDEDDO, SDELD, SDEMRD sample paths by Milstein approximation

Examples

Create a hwv Object

The Hull-White/Vasicek (HWV) short rate class derives directly from SDE with mean-reverting drift (that is, `sdemrd`): $dX_t = S(t)[L(t) - X_t]dt + V(t)dW_t$.

Create an `hwv` object to represent the model: $dX_t = 0.2(0.1 - X_t)dt + 0.05dW_t$.

```
obj = hwv(0.2, 0.1, 0.05)  % (Speed, Level, Sigma)
```

```
obj = 
   Class HWV: Hull-White/Vasicek
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t)) 
      Diffusion: diffusion rate function G(t,X(t)) 
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.1
          Speed: 0.2
```

interpolate

Brownian interpolation of stochastic differential equations (SDEs) for `SDE`, `BM`, `GBM`, `CEV`, `CIR`, `HWV`, `Heston`, `SDEDDO`, `SDELD`, or `SDEMRD` models

Syntax

```
[XT,T] = interpolate(MDL,Times,Paths)
[XT,T] = interpolate( ___ ,Name,Value)
```

Description

`[XT,T] = interpolate(MDL,Times,Paths)` performs a Brownian interpolation into a user-specified time series array, based on a piecewise-constant Euler sampling approach.

`[XT,T] = interpolate( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Stochastic Interpolation Without Refinement

Many applications require knowledge of the state vector at intermediate sample times that are initially unavailable. One way to approximate these intermediate states is to perform a deterministic interpolation. However, deterministic interpolation techniques fail to capture the correct probability distribution at these intermediate times. Brownian (or stochastic) interpolation captures the correct joint distribution by sampling from a conditional Gaussian distribution. This sampling technique is sometimes referred to as a *Brownian Bridge*.

The default stochastic interpolation technique is designed to interpolate into an existing time series and ignore new interpolated states as additional information becomes available. This technique is the usual notion of interpolation, which is called *Interpolation without refinement*.

Alternatively, the interpolation technique may insert new interpolated states into the existing time series upon which subsequent interpolation is based, by that means refining information available at subsequent interpolation times. This technique is called *interpolation with refinement*.

Interpolation without refinement is a more traditional technique, and is most useful when the input series is closely spaced in time. In this situation, interpolation without refinement is a good technique for inferring data in the presence of missing information, but is inappropriate for extrapolation. Interpolation with refinement is more suitable when the input series is widely spaced in time, and is useful for extrapolation.

The stochastic interpolation method is available to any model. It is best illustrated, however, by way of a constant-parameter Brownian motion process. Consider a correlated, bivariate Brownian motion (`BM`) model of the form:

$$dX_{1t} = 0.3dt + 0.2dW_{1t} - 0.1dW_{2t}$$
$$dX_{2t} = 0.4dt + 0.1dW_{1t} - 0.2dW_{2t}$$
$$E[dW_{1t}dW_{2t}] = \rho dt = 0.5dt$$

1 Create a `bm` object to represent the bivariate model:

```
mu    = [0.3; 0.4];
sigma = [0.2 -0.1; 0.1 -0.2];
rho   = [1 0.5; 0.5 1];
obj   = bm(mu,sigma,'Correlation',rho);
```

2 Assuming that the drift (`Mu`) and diffusion (`Sigma`) parameters are annualized, simulate a single Monte Carlo trial of daily observations for one calendar year (250 trading days):

```
rng default                  % make output reproducible
dt    = 1/250;  % 1 trading day = 1/250 years
[X,T] = simulate(obj,250,'DeltaTime',dt);
```

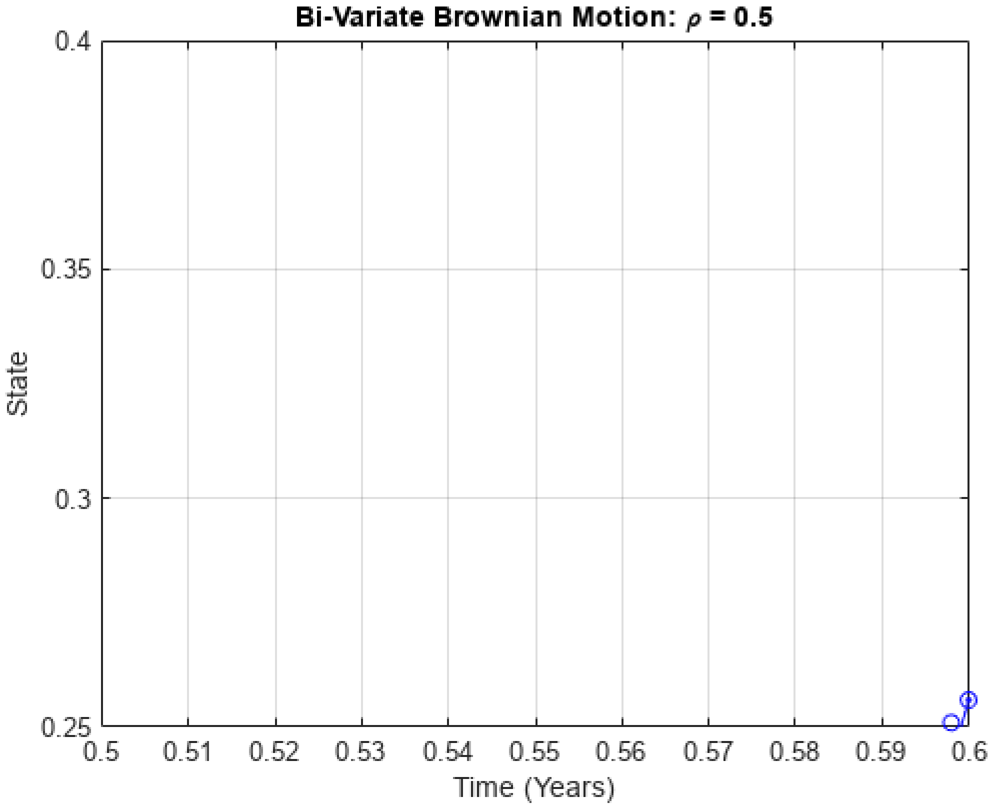
3 It is helpful to examine a small interval in detail.

   a Interpolate into the simulated time series with a Brownian bridge:

```
t = ((T(1) + dt/2):(dt/2):(T(end) - dt/2));
x = interpolate(obj,t,X,'Times',T);
```

   b Plot both the simulated and interpolated values:

```
plot(T,X(:,1),'.-r',T,X(:,2),'.-b')
grid on;
hold on;
plot(t,x(:,1),'or',t,x(:,2),'ob')
hold off;
xlabel('Time (Years)')
ylabel('State')
title('Bi-Variate Brownian Motion: \rho = 0.5')
axis([0.4999 0.6001 0.25 0.4])
```



In this plot:

- The solid red and blue dots indicate the simulated states of the bivariate model.
- The straight lines that connect the solid dots indicate intermediate states that would be obtained from a deterministic linear interpolation.
- Open circles indicate interpolated states.
- Open circles associated with every other interpolated state encircle solid dots associated with the corresponding simulated state. However, interpolated states at the midpoint of each time increment typically deviate from the straight line connecting each solid dot.

Simulation of Conditional Gaussian Distributions

You can gain additional insight into the behavior of stochastic interpolation by regarding a Brownian bridge as a Monte Carlo simulation of a conditional Gaussian distribution.

This example examines the behavior of a Brownian bridge over a single time increment.

1 Divide a single time increment of length `dt` into 10 subintervals:

```
mu    = [0.3; 0.4];
sigma = [0.2 -0.1; 0.1 -0.2];
rho   = [1 0.5; 0.5 1];
obj   = bm(mu,sigma,'Correlation',rho);

rng default; % make output reproducible
dt    = 1/250;  % 1 trading day = 1/250 years
```

```
[X,T] = simulate(obj,250,'DeltaTime',dt);

n        = 125;    % index of simulated state near middle
times    = (T(n):(dt/10):T(n + 1));
nTrials  = 25000;  % # of Trials at each time
```

2 In each subinterval, take 25000 independent draws from a Gaussian distribution, conditioned on the simulated states to the left, and right:

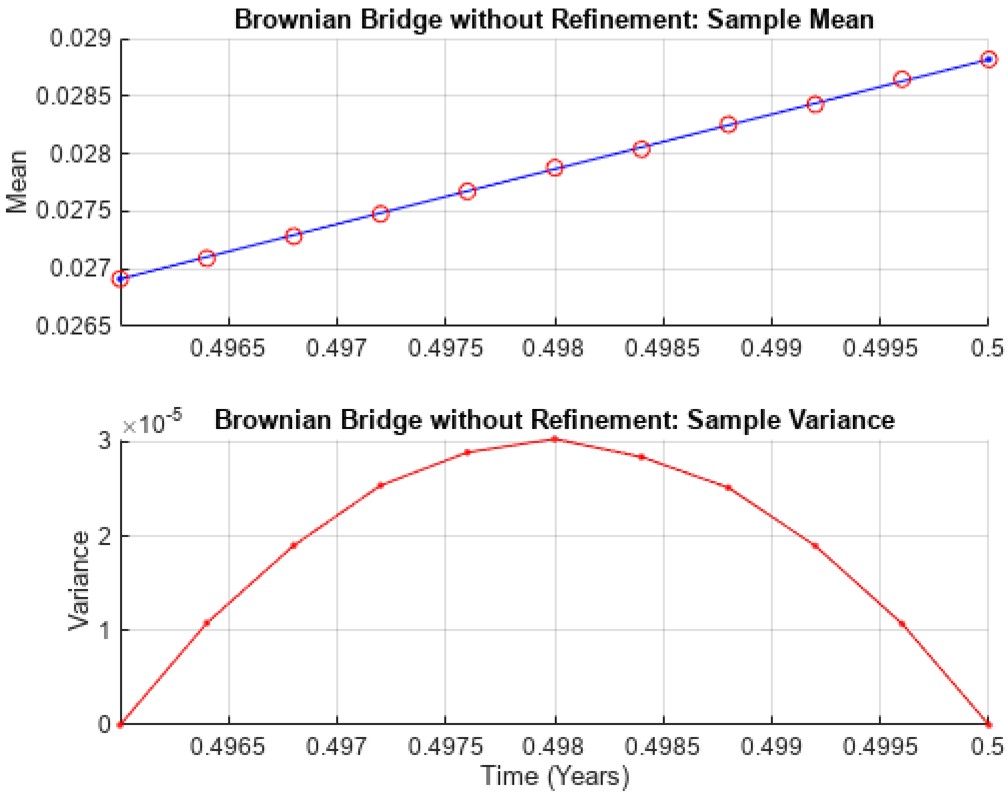
```
average  = zeros(length(times),1);
variance = zeros(length(times),1);
for i = 1:length(times)
    t = times(i);
    x = interpolate(obj,t(ones(nTrials,1)),...
        X,'Times',T);
    average(i)  = mean(x(:,1));
    variance(i) = var(x(:,1));
end
```

3 Plot the sample mean and variance of each state variable:

Note The following graph plots the sample statistics of the first state variable only, but similar results hold for any state variable.

```
subplot(2,1,1);
hold on;
grid on;
plot([T(n) T(n + 1)],[X(n,1) X(n + 1,1)],'.-b')
plot(times, average, 'or')
hold off;
title('Brownian Bridge without Refinement: Sample Mean')
ylabel('Mean')
limits = axis;
axis([T(n) T(n + 1) limits(3:4)]);

subplot(2,1,2)
hold on;
grid on;
plot(T(n),0,'.-b',T(n + 1),0,'.-b')
plot(times, variance, '.-r')
hold('off');
title('Brownian Bridge without Refinement: Sample Variance')
xlabel('Time (Years)')
ylabel('Variance')
limits = axis;
axis([T(n) T(n + 1) limits(3:4)]);
```



The Brownian interpolation within the chosen interval, *dt*, illustrates the following:

- The conditional mean of each state variable lies on a straight-line segment between the original simulated states at each endpoint.
- The conditional variance of each state variable is a quadratic function. This function attains its maximum midway between the interval endpoints, and is zero at each endpoint.
- The maximum variance, although dependent upon the actual model diffusion-rate function *G(t,X)*, is the variance of the sum of `NBrowns` correlated Gaussian variates scaled by the factor *dt/4*.

The previous plot highlights interpolation without refinement, in that none of the interpolated states take into account new information as it becomes available. If you had performed interpolation with refinement, new interpolated states would have been inserted into the time series and made available to subsequent interpolations on a trial-by-trial basis. In this case, all random draws for any given interpolation time would be identical. Also, the plot of the sample mean would exhibit greater variability, but would still cluster around the straight-line segment between the original simulated states at each endpoint. The plot of the sample variance, however, would be zero for all interpolation times, exhibiting no variability.

Input Arguments

`MDL` — Stochastic differential equation model

object

Stochastic differential equation model, specified as an `sde`, `bm`, `gbm`, `cev`, `cir`, `hwv`, `heston`, `sdeddo`, `sdeld`, or `sdemrd` object.

All `MDL` parameters are assumed piecewise constant, evaluated from the most recent observation time in `Times` that precedes a specified interpolation time in `T`. This is consistent with the Euler approach of Monte Carlo simulation.

Data Types: `object`

`Times` — Interpolation times
vector

Interpolation times, specified as a `NTimes` element vector. The length of this vector determines the number of rows in the interpolated output time series `XT`.

Data Types: `double`

`Paths` — Sample paths of correlated state variables
time series array

Sample paths of correlated state variables, specified as a `NPeriods`-by-`NVars`-by-`NTrials` time series array.

For a given trial, each row of this array is the transpose of the state vector X_t at time t. `Paths` is the initial time series array into which the `interpolate` function performs the Brownian interpolation.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[XT,T] = interpolate(MDL,T,Paths,'Times',t)`

`Times` — Observation times associated with the time series input `Paths`
zero-based, unit-increment column vector of length `NPeriods` (default) | column vector

Observation times associated with the time series input `Paths`, specified as the comma-separated pair consisting of `'Times'` and a column vector.

Data Types: `double`

`Refine` — Flag that indicates whether `interpolate` uses the interpolation times you request
`False` (`interpolate` bases the interpolation only on the state information specified in `Paths`) (default) | logical with values `True` or `False`

Flag that indicates whether `interpolate` uses the interpolation times you request (see `T`) to refine the interpolation as new information becomes available, specified as the comma-separated pair consisting of `'Refine'` and a logical with a value of `True` or `False`.

Data Types: `logical`

Processes — Sequence of background processes or state vector adjustments
interpolate makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of background processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The interpolate function runs processing functions at each interpolation time. They must accept the current interpolation time t, and the current state vector X_t, and return a state vector that may be an adjustment to the input state.

If you specify more than one processing function, interpolate invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and so on.

Data Types: cell | function

Output Arguments

XT — Interpolated state variables
array

Interpolated state variables, returned as a NTimes-by-NVars-by-NTrials time series array.

For a given trial, each row of this array is the transpose of the interpolated state vector X_t at time t. XT is the interpolated time series formed by interpolating into the input Paths time series array.

T — Interpolation times associated with the output time series XT
column vector

Interpolation times associated with the output time series XT, returned as a NTimes-by-1 column vector.

If the input interpolation time vector Times contains no missing observations (NaNs), the output of T is the same time vector as Times, but with the NaNs removed. This reduces the length of T and the number of rows of XT.

Algorithms

This function performs a Brownian interpolation into a user-specified time series array, based on a piecewise-constant Euler sampling approach.

Consider a vector-valued SDE of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- X is an *NVars*-by-1 state vector.
- F is an *NVars*-by-1 drift-rate vector-valued function.
- G is an *NVars*-by-*NBrowns* diffusion-rate matrix-valued function.

- *W* is an *NBrowns*-by-1 Brownian motion vector.

Given a user-specified time series array associated with this equation, this function performs a Brownian (stochastic) interpolation by sampling from a conditional Gaussian distribution. This sampling technique is sometimes called a *Brownian bridge*.

Note Unlike simulation methods, the interpolation function does not support user-specified noise processes.

- The interpolate function assumes that all model parameters are piecewise-constant, and evaluates them from the most recent observation time in Times that precedes a specified interpolation time in T. This is consistent with the Euler approach of Monte Carlo simulation.
- When an interpolation time falls outside the interval specified by Times, a Euler simulation extrapolates the time series by using the nearest available observation.
- The user-defined time series Paths and corresponding observation Times must be fully observed (no missing observations denoted by NaNs).
- The interpolate function assumes that the user-specified time series array Paths is associated with the sde object. For example, the Times and Paths input pair are the result of an initial course-grained simulation. However, the interpolation ignores the initial conditions of the sde object (StartTime and StartState), allowing the user-specified Times and Paths input series to take precedence.

Version History

sde

Stochastic Differential Equation (SDE) model

Description

Creates and displays general stochastic differential equation (SDE) models from user-defined drift and diffusion rate functions.

Use `sde` objects to simulate sample paths of `NVars` state variables driven by `NBROWNS` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

An `sde` object enables you to simulate any vector-valued SDE of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- X_t is an `NVars`-by-`1` state vector of process variables.
- dW_t is an `NBROWNS`-by-`1` Brownian motion vector.
- F is an `NVars`-by-`1` vector-valued drift-rate function.
- G is an `NVars`-by-`NBROWNS` matrix-valued diffusion-rate function.

Creation

Syntax

```
SDE = sde(DriftRate,DiffusionRate)
SDE = sde( ___ ,Name,Value)
```

Description

`SDE = sde(DriftRate,DiffusionRate)` creates a default `SDE` object.

`SDE = sde( ___ ,Name,Value)` creates a `SDE` object with additional options specified by one or more `Name,Value` pair arguments.

`Name` is a property name and `Value` is its corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

The `SDE` object has the following “Properties” on page 15-154:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time

- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `Simulation` — A simulation function or method

Input Arguments

`DriftRate` — `DriftRate` is a user-defined drift-rate function and represents the parameter *F*

vector or object of class `drift`

`DriftRate` is a user-defined drift-rate function and represents the parameter *F*, specified as a vector or object of class `drift`.

`DriftRate` is a function that returns an `NVars`-by-`1` drift-rate vector when called with two inputs:

- A real-valued scalar observation time t.
- An `NVars`-by-`1` state vector X_t.

Alternatively, `DriftRate` can also be an object of class `drift` that encapsulates the drift-rate specification. In this case, however, `sde` uses only the `Rate` parameter of the object. For more information on the `drift` object, see `drift`.

Data Types: `double` | `object`

`DiffusionRate` — `DiffusionRate` is a user-defined diffusion-rate function and represents the parameter *G*

matrix or object of class `diffusion`

`DiffusionRate` is a user-defined diffusion-rate function and represents the parameter *G*, specified as a matrix or object of class `diffusion`.

`DiffusionRate` is a function that returns an `NVars`-by-`NBROWNS` diffusion-rate matrix when called with two inputs:

- A real-valued scalar observation time t.
- An `NVars`-by-`1` state vector X_t.

Alternatively, `DiffusionRate` can also be an object of class `diffusion` that encapsulates the diffusion-rate specification. In this case, however, `sde` uses only the `Rate` parameter of the object. For more information on the `diffusion` object, see `diffusion`.

Data Types: `double` | `object`

Properties

`StartTime` — Starting time of first observation, applied to all state variables

`0` (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: `double`

`StartState` — Initial values of state variables

`1` (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, sde applies the same initial value to all state variables on all trials.

If StartState is a column vector, sde applies a unique initial value to each state variable on all trials.

If StartState is a matrix, sde applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)

NBROWNS-by-NBROWNS identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBROWNS-by-NBROWNS positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an NBROWNS-by-NBROWNS positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

Simulation — User-defined simulation function or SDE simulation method

simulation by Euler approximation (simByEuler) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function_handle

Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)

value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The drift rate specification supports the simulation of sample paths of NVars state variables driven by NBROWNS Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The drift class allows you to create drift-rate objects (using drift) of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- A is an NVars-by-1 vector-valued function accessible using the (t, X_t) interface.

- B is an NVars-by-NVars matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a drift object are:

- Rate: The drift-rate function, $F(t,X_t)$
- A: The intercept term, $A(t,X_t)$, of $F(t,X_t)$
- B: The first order term, $B(t,X_t)$, of $F(t,X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

When specified as MATLAB double arrays, the inputs A and B are clearly associated with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift rate specification.

Note You can express drift and diffusion classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components A and B as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: object

Diffusion — Diffusion rate component of continuous-time stochastic differential equations (SDEs)
value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The diffusion rate specification supports the simulation of sample paths of NVars state variables driven by NBROWNS Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The diffusion class allows you to create diffusion-rate objects (using diffusion):

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- D is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVars-by-1 vector-valued function.
- V is an NVars-by-NBROWNS matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the (t, X_t) interface.

The displayed parameters for a diffusion object are:

- Rate: The diffusion-rate function, $G(t,X_t)$.

- `Alpha`: The state vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$.
- `Sigma`: The volatility rate, $V(t,X_t)$, of $G(t,X_t)$.

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate` functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `object`

Object Functions

interpolate Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

simulate Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models

simByEuler Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

Examples

Create an SDE Object

Construct an `SDE` object `obj` to represent a univariate geometric Brownian Motion model of the form: $dX_t = 0.1X_tdt + 0.3X_tdW_t$.

Create drift and diffusion functions that are accessible by the common (t, X_t) interface:

```
F = @(t,X) 0.1 * X;
G = @(t,X) 0.3 * X;
```

Pass the functions to `sde` to create an object (`obj`) of class `sde`:

```
obj = sde(F, G)    % dX = F(t,X)dt + G(t,X)dW
```

```
obj = 
   Class SDE: Stochastic Differential Equation
   -------------------------------------------
     Dimensions: State = 1, Brownian = 1
   -------------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
```

obj displays like a MATLAB® structure, with the following information:

- The object's class
- A brief description of the object
- A summary of the dimensionality of the model

The object's displayed parameters are as follows:

- StartTime: The initial observation time (real-valued scalar)
- StartState: The initial state vector (NVARS-by-1 column vector)
- Correlation: The correlation structure between Brownian process
- Drift: The drift-rate function $F(t, X_t)$
- Diffusion: The diffusion-rate function $G(t, X_t)$
- Simulation: The simulation method or function.

Of these displayed parameters, only Drift and Diffusion are required inputs.

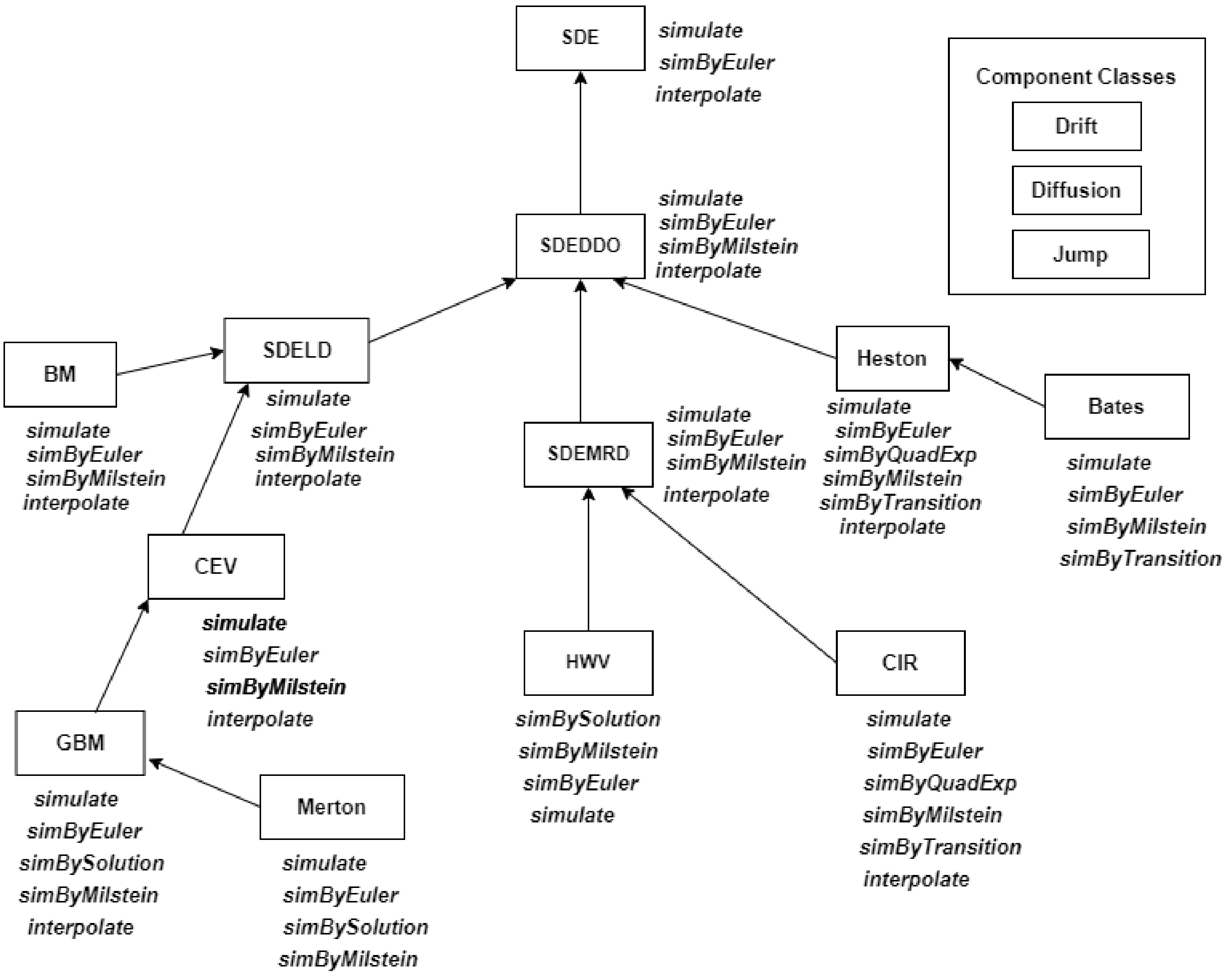
The only exception to the (t, X_t) evaluation interface is Correlation. Specifically, when you enter Correlation as a function, the SDE engine assumes that it is a deterministic function of time, $C(t)$. This restriction on Correlation as a deterministic function of time allows Cholesky factors to be computed and stored before the formal simulation. This inconsistency dramatically improves run-time performance for dynamic correlation structures. If Correlation is stochastic, you can also include it within the simulation architecture as part of a more general random number generation function.

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time t and a state vector X_t, and return an array of appropriate dimension. Even if you originally specified an input as an array, `sde` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

sdeddo

Stochastic Differential Equation (SDEDDO) model from Drift and Diffusion components

Description

Creates and displays sdeddo objects, instantiated with objects of classdrift and diffusion. These restricted sdeddo objects contain the input drift and diffusion objects; therefore, you can directly access their displayed parameters.

This abstraction also generalizes the notion of drift and diffusion-rate objects as functions that sdeddo evaluates for specific values of time t and state X_t. Like sde objects, sdeddo objects allow you to simulate sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

This method enables you to simulate any vector-valued SDEDDO of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t \tag{15-3}$$

where:

- X_t is an NVars-by-1 state vector of process variables.
- dW_t is an NBrowns-by-1 Brownian motion vector.
- F is an NVars-by-1 vector-valued drift-rate function.
- G is an NVars-by-NBrowns matrix-valued diffusion-rate function.

Creation

Syntax

```
SDEDDO = sdeddo(DriftRate,DiffusionRate)
SDEDDO = sdeddo( ___ ,Name,Value)
```

Description

SDEDDO = sdeddo(DriftRate,DiffusionRate) creates a default SDEDDO object.

SDEDDO = sdeddo(___ ,Name,Value) creates a SDEDDO object with additional options specified by one or more Name,Value pair arguments.

Name is a property name and Value is its corresponding value. Name must appear inside single quotes (''). You can specify several name-value pair arguments in any order as Name1,Value1, …,NameN,ValueN.

The SDEDDO object has the following displayed “Properties” on page 15-163:

- StartTime — Initial observation time

- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument, callable as a function of time
- `Drift` — Composite drift-rate function, callable as a function of time and state
- `Diffusion` — Composite diffusion-rate function, callable as a function of time and state
- `A` — Access function for the drift-rate property `A`, callable as a function of time and state
- `B` — Access function for the drift-rate property `B`, callable as a function of time and state
- `Alpha` — Access function for the diffusion-rate property `Alpha`, callable as a function of time and state
- `Sigma` — Access function for the diffusion-rate property `Sigma`, callable as a function of time and state
- `Simulation` — A simulation function or method

Input Arguments

`DriftRate` — `DriftRate` is a user-defined drift-rate function and represents the parameter *F*

vector or object of class `Drift`

`DriftRate` is a user-defined drift-rate function and represents the parameter *F*, specified as a vector or object of class `drift`.

`DriftRate` is a function that returns an `NVars`-by-`1` drift-rate vector when called with two inputs:

- A real-valued scalar observation time t.
- An `NVars`-by-`1` state vector X_t.

Alternatively, `DriftRate` can also be an object of class `drift` that encapsulates the drift-rate specification. In this case, however, `sde` uses only the `Rate` parameter of the object. For more information on the `drift` object, see `drift`.

Data Types: `double`

`DiffusionRate` — `DiffusionRate` is a user-defined diffusion-rate function and represents the parameter *G*

matrix or object of class `Diffusion`

`DiffusionRate` is a user-defined diffusion-rate function and represents the parameter *G*, specified as a matrix or object of class `diffusion`.

`DiffusionRate` is a function that returns an `NVars`-by-`NBrowns` diffusion-rate matrix when called with two inputs:

- A real-valued scalar observation time t.
- An `NVars`-by-`1` state vector X_t.

Alternatively, `DiffusionRate` can also be an object of class `diffusion` that encapsulates the diffusion-rate specification. In this case, however, `sde` uses only the `Rate` parameter of the object. For more information on the `diffusion` object, see `diffusion`.

Data Types: `double`

Properties

StartTime — Starting time of first observation, applied to all state variables
0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

StartState — Initial values of state variables
1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, sdeddo applies the same initial value to all state variables on all trials.

If StartState is a column vector, sdeddo applies a unique initial value to each state variable on all trials.

If StartState is a matrix, sdeddo applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)
NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

Simulation — User-defined simulation function or SDE simulation method
simulation by Euler approximation (simByEuler) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function_handle

Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)
value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `drift` class allows you to create drift-rate objects using `drift` of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- `A` is an `NVars`-by-`1` vector-valued function accessible using the (t, X_t) interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a `drift` object are:

- `Rate`: The drift-rate function, $F(t,X_t)$
- `A`: The intercept term, $A(t,X_t)$, of $F(t,X_t)$
- `B`: The first order term, $B(t,X_t)$, of $F(t,X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: `struct` | `double`

`Diffusion` — Diffusion rate component of continuous-time stochastic differential equations (SDEs)

value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by $(t, X_t$.

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects using `diffusion`:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-`1` vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the (t, X_t) interface.

The displayed parameters for a `diffusion` object are:

- `Rate`: The diffusion-rate function, $G(t,X_t)$.
- `Alpha`: The state vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$.
- `Sigma`: The volatility rate, $V(t,X_t)$, of $G(t,X_t)$.

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate` functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct` | `double`

Object Functions

interpolate	Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simulate	Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models
simByEuler	Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simByMilstein	Simulate BM, GBM, CEV, HWV, SDEDDO, SDELD, SDEMRD sample paths by Milstein approximation

Examples

Create a sdeddo Object

The `sdeddo` class derives from the base `sde` class. To use this class, you must pass drift and diffusion-rate objects to the `sdeddo` function.

Create `drift` and `diffusion` rate objects:

```
F = drift(0, 0.1);      % Drift rate function F(t,X)
G = diffusion(1, 0.3);  % Diffusion rate function G(t,X)
```

Pass the functions to the `sdeddo` function to create an object `obj` of class `sdeddo`:

```
obj = sdeddo(F, G)      % dX = F(t,X)dt + G(t,X)dW
obj =
   Class SDEDDO: SDE from Drift and Diffusion Objects
   --------------------------------------------------
     Dimensions: State = 1, Brownian = 1
   --------------------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
              A: 0
              B: 0.1
          Alpha: 1
          Sigma: 0.3
```

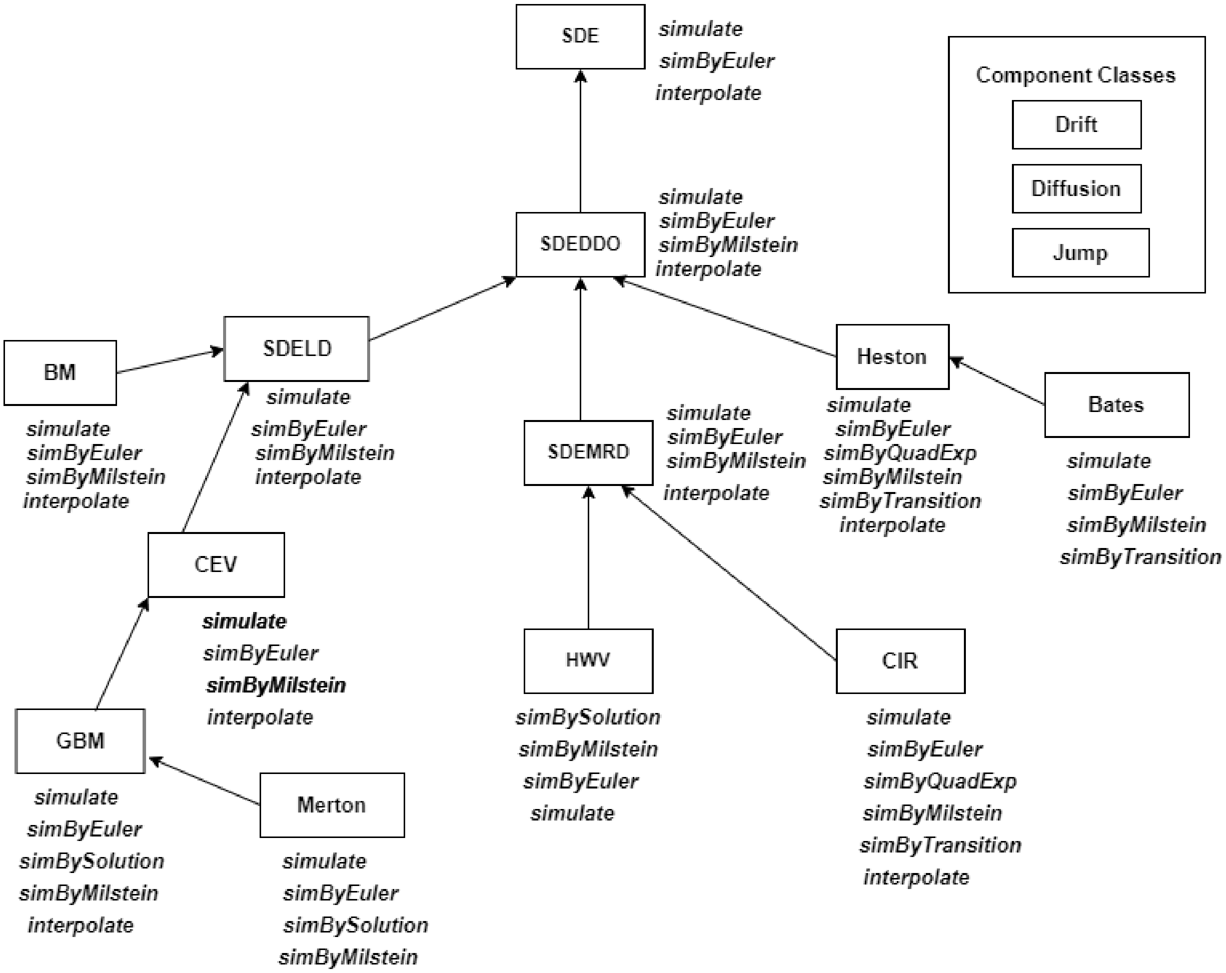
In this example, the object displays the additional parameters associated with input `drift` and `diffusion` objects.

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time t and a state vector X_t, and return an array of appropriate dimension. Even if you originally specified an input as an array, `sdeddo` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

sdeld

SDE with Linear Drift (SDELD) model

Description

Creates and displays SDE objects whose drift rate is expressed in linear drift-rate form and that derive from the sdeddo (SDE from drift and diffusion objects class).

Use sdeld objects to simulate sample paths of NVars state variables expressed in linear drift-rate form. They provide a parametric alternative to the mean-reverting drift form (see sdemrd).

These state variables are driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes with linear drift-rate functions.

The sdeld object allows you to simulate any vector-valued SDELD of the form:

$$dX_t = (A(t) + B(t)X_t)dt + D(t, X_t^{\alpha(t)})V(t)dW_t$$

where:

- X_t is an NVars-by-1 state vector of process variables.
- A is an NVars-by-1 vector.
- B is an NVars-by-NVars matrix.
- D is an NVars-by-NVars diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of α.
- V is an NVars-by-NBrowns instantaneous volatility rate matrix.
- dW_t is an NBrowns-by-1 Brownian motion vector.

Creation

Syntax

```
SDELD = sdeld(A,B,Alpha,Sigma)
SDELD = sdeld( ___ ,Name,Value)
```

Description

SDELD = sdeld(A,B,Alpha,Sigma) creates a default SDELD object.

SDELD = sdeld(___ ,Name,Value) creates a SDELD object with additional options specified by one or more Name,Value pair arguments.

Name is a property name and Value is its corresponding value. Name must appear inside single quotes (''). You can specify several name-value pair arguments in any order as Name1,Value1, …,NameN,ValueN.

The SDELD object has the following displayed "Properties" on page 15-171:

- StartTime — Initial observation time
- StartState — Initial state at time StartTime
- Correlation — Access function for the Correlation input argument, callable as a function of time
- Drift — Composite drift-rate function, callable as a function of time and state
- Diffusion — Composite diffusion-rate function, callable as a function of time and state
- A — Access function for the input argument A, callable as a function of time and state
- B — Access function for the input argument B, callable as a function of time and state
- Alpha — Access function for the input argument Alpha, callable as a function of time and state
- Sigma — Access function for the input argument Sigma, callable as a function of time and state
- Simulation — A simulation function or method

Input Arguments

A — A represents the parameter *A*

array or deterministic function of time or deterministic function of time and state

A represents the parameter *A*, specified as an array or deterministic function of time.

If you specify A as an array, it must be an NVars-by-1 column vector of intercepts.

As a deterministic function of time, when A is called with a real-valued scalar time t as its only input, A must produce an NVars-by-1 column vector. If you specify A as a function of time and state, it must generate an NVars-by-1 column vector of intercepts when invoked with two inputs:

- A real-valued scalar observation time t.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

B — B represents the parameter *B*

array or deterministic function of time or deterministic function of time and state

B represents the parameter *B*, specified as an array or deterministic function of time.

If you specify A as an array, it must be an NVars-by-NVars matrix of state vector coefficients.

As a deterministic function of time, when B is called with a real-valued scalar time t as its only input, B must produce an NVars-by-NVars matrix. If you specify B as a function of time and state, it must generate an NVars-by-NVars matrix of state vector coefficients when invoked with two inputs:

- A real-valued scalar observation time t.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Alpha — Alpha represents the parameter *D*

array or deterministic function of time or deterministic function of time and state

Alpha represents the parameter *D*, specified as an array or deterministic function of time.

If you specify Alpha as an array, it represents an NVars-by-1 column vector of exponents.

As a deterministic function of time, when Alpha is called with a real-valued scalar time t as its only input, Alpha must produce an NVars-by-1 matrix.

If you specify it as a function of time and state, Alpha must return an NVars-by-1 column vector of exponents when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Sigma — Sigma represents the parameter *V*
array or deterministic function of time or deterministic function of time and state

Sigma represents the parameter *V*, specified as an array or a deterministic function of time.

If you specify Sigma as an array, it must be an NVars-by-NBrowns matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of Sigma corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when Sigma is called with a real-valued scalar time t as its only input, Sigma must produce an NVars-by-NBrowns matrix. If you specify Sigma as a function of time and state, it must return an NVars-by-NBrowns matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An NVars-by-1 state vector X_t.

Although thegbm constructor enforces no restrictions on the sign of Sigma volatilities, they are specified as positive values.

Data Types: double | function_handle

Note Although sdeld does not enforce restrictions on the signs of Alpha or Sigma, each parameter is specified as a positive value.

Properties

StartTime — Starting time of first observation, applied to all state variables
0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

StartState — Initial values of state variables
1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, sdeld applies the same initial value to all state variables on all trials.

If StartState is a column vector, sdeld applies a unique initial value to each state variable on all trials.

If StartState is a matrix, sdeld applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)
NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

Simulation — User-defined simulation function or SDE simulation method
simulation by Euler approximation (simByEuler) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function_handle

Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)
value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by $(t, X_t$.

The drift rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The drift class allows you to create drift-rate objects using drift of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- A is an NVars-by-1 vector-valued function accessible using the (t, X_t) interface.
- B is an NVars-by-NVars matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a drift object are:

- `Rate`: The drift-rate function, *F(t,X_t)*
- `A`: The intercept term, *A(t,X_t)*, of *F(t,X_t)*
- `B`: The first order term, *B(t,X_t)*, of *F(t,X_t)*

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: `struct` | `double`

`Diffusion` — Diffusion rate component of continuous-time stochastic differential equations (SDEs)

value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects using `diffusion`:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-`1` vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the (t, X_t) interface.

The displayed parameters for a `diffusion` object are:

- `Rate`: The diffusion-rate function, *G(t,X_t)*.
- `Alpha`: The state vector exponent, which determines the format of *D(t,X_t)* of *G(t,X_t)*.
- `Sigma`: The volatility rate, *V(t,X_t)*, of *G(t,X_t)*.

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate`

functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct` | `double`

Object Functions

interpolate	Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simulate	Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models
simByEuler	Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models
simByMilstein	Simulate BM, GBM, CEV, HWV, SDEDDO, SDELD, SDEMRD sample paths by Milstein approximation

Examples

Create a sdeld Object

The `sdeld` class derives from the `sdeddo` class. These objects allow you to simulate correlated paths of `NVARS` state variables expressed in linear drift-rate form:

$$dX_t = (A(t) + B(t)X_t)dt + D(t, X_t^{\alpha(t)})V(t)dW_t.$$

```
obj = sdeld(0, 0.1, 1, 0.3) % (A, B, Alpha, Sigma)
```

```
obj = 
   Class SDELD: SDE with Linear Drift
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t)) 
      Diffusion: diffusion rate function G(t,X(t)) 
     Simulation: simulation method/function simByEuler
              A: 0
              B: 0.1
          Alpha: 1
          Sigma: 0.3
```

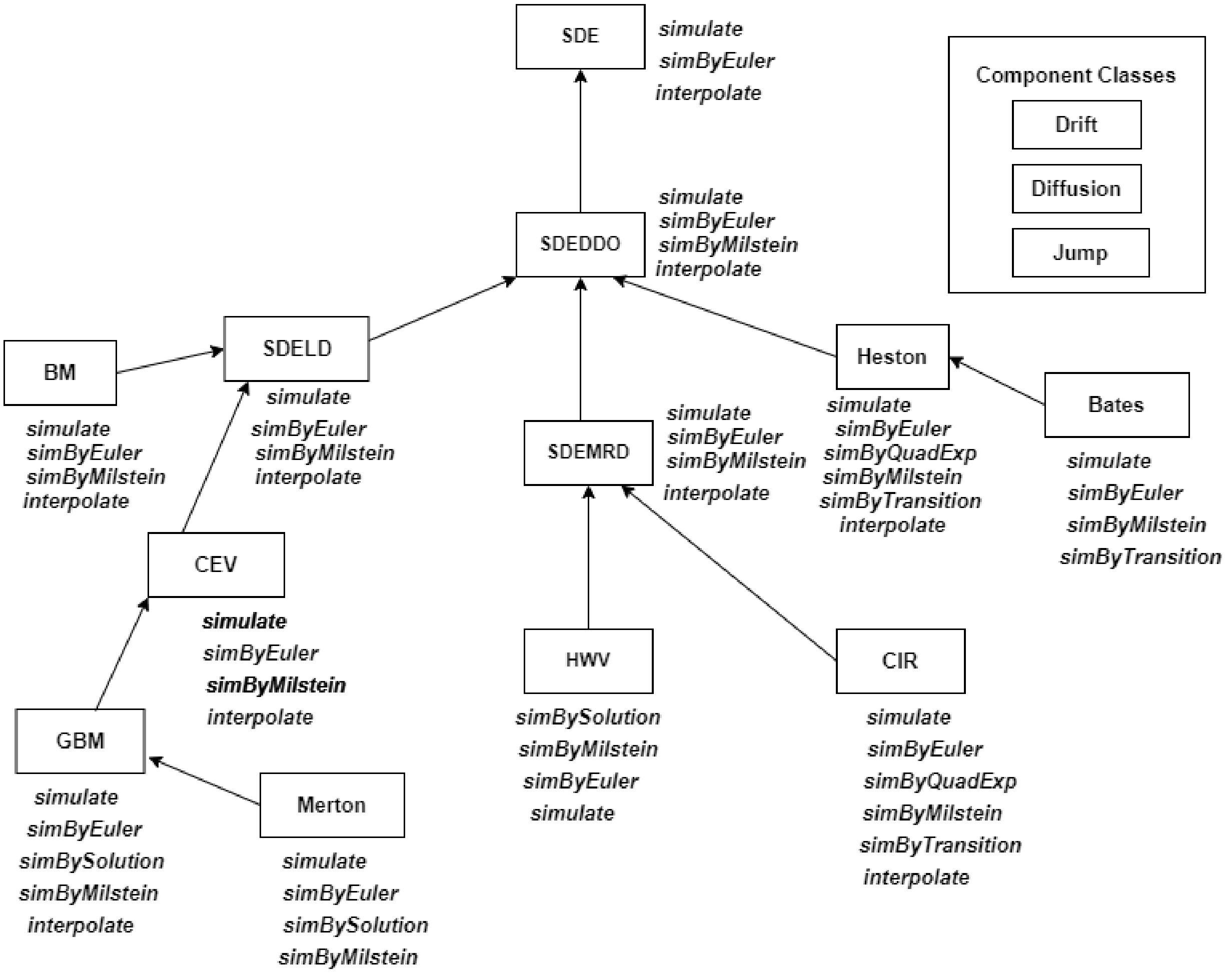
`sdeld` objects provide a parametric alternative to the mean-reverting drift form and also provide an alternative interface to the `sdeddo` parent class, because you can create an object without first having to create its drift and diffusion-rate components.

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time t and a state vector X_t, and return an array of appropriate dimension. Even if you originally specified an input as an array, `sdeld` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

sdemrd

SDE with Mean-Reverting Drift (SDEMRD) model

Description

Creates and displays SDE objects whose drift rate is expressed in mean-reverting drift-rate form and which derive from the sdeddo class (SDE from drift and diffusion objects).

Use sdemrd objects to simulate of sample paths of NVars state variables expressed in mean-reverting drift-rate form, and provide a parametric alternative to the linear drift form (see sdeld). These state variables are driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes with mean-reverting drift-rate functions.

The sdemrd object allows you to simulate any vector-valued SDEMRD of the form:

$$dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\alpha(t)})V(t)dW_t$$

where:

- X_t is an NVars-by-1 state vector of process variables.
- S is an NVars-by-NVars matrix of mean reversion speeds.
- L is an NVars-by-1 vector of mean reversion levels.
- D is an NVars-by-NVars diagonal matrix, where each element along the main diagonal is the corresponding element of the state vector raised to the corresponding power of α.
- V is an NVars-by-NBrowns instantaneous volatility rate matrix.
- dW_t is an NBrowns-by-1 Brownian motion vector.

Creation

Syntax

```
SDEMRD = sdemrd(Speed,Level,Alpha,Sigma)
SDEMRD = sdemrd(___,Name,Value)
```

Description

SDEMRD = sdemrd(Speed,Level,Alpha,Sigma) creates a default SDEMRD object.

SDEMRD = sdemrd(___,Name,Value) creates a SDEMRD object with additional options specified by one or more Name,Value pair arguments.

Name is a property name and Value is its corresponding value. Name must appear inside single quotes (''). You can specify several name-value pair arguments in any order as Name1,Value1,…,NameN,ValueN.

The SDELD object has the following displayed “Properties” on page 15-179:

- StartTime — Initial observation time
- StartState — Initial state at time StartTime
- Correlation — Access function for the Correlation input argument, callable as a function of time
- Drift — Composite drift-rate function, callable as a function of time and state
- Diffusion — Composite diffusion-rate function, callable as a function of time and state
- Speed — Access function for the input argument Speed, callable as a function of time and state
- Level — Access function for the input argument Level, callable as a function of time and state
- Alpha — Access function for the input argument Alpha, callable as a function of time and state
- Sigma — Access function for the input argument Sigma, callable as a function of time and state
- Simulation — A simulation function or method

Input Arguments

Speed — Speed represents the parameter *S*

array or deterministic function of time or deterministic function of time and state

Speed represents the parameter *S*, specified as an array or deterministic function of time.

If you specify Speed as an array, it must be an NVars-by-NVars matrix of mean-reversion speeds (the rate at which the state vector reverts to its long-run average Level).

As a deterministic function of time, when Speed is called with a real-valued scalar time t as its only input, Speed must produce an NVars-by-NVars matrix. If you specify Speed as a function of time and state, it calculates the speed of mean reversion. This function must generate an NVars-by-NVars matrix of reversion rates when called with two inputs:

- A real-valued scalar observation time t.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Level — Level represents the parameter *L*

array or deterministic function of time or deterministic function of time and state

Level represents the parameter *L*, specified as an array or deterministic function of time.

If you specify Level as an array, it must be an NVars-by-1 column vector of reversion levels.

As a deterministic function of time, when Level is called with a real-valued scalar time t as its only input, Level must produce an NVars-by-1 column vector. If you specify Level as a function of time and state, it must generate an NVars-by-1 column vector of reversion levels when called with two inputs:

- A real-valued scalar observation time t.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Alpha — Alpha represents the parameter *D*

array or deterministic function of time or deterministic function of time and state

Alpha represents the parameter *D*, specified as an array or deterministic function of time.

If you specify Alpha as an array, it represents an NVars-by-1 column vector of exponents.

As a deterministic function of time, when Alpha is called with a real-valued scalar time t as its only input, Alpha must produce an NVars-by-1 matrix.

If you specify it as a function of time and state, Alpha must return an NVars-by-1 column vector of exponents when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Sigma — Sigma represents the parameter *V*
array or deterministic function of time or deterministic function of time and state

Sigma represents the parameter *V*, specified as an array or a deterministic function of time.

If you specify Sigma as an array, it must be an NVars-by-NBrowns matrix of instantaneous volatility rates or as a deterministic function of time. In this case, each row of Sigma corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

As a deterministic function of time, when Sigma is called with a real-valued scalar time t as its only input, Sigma must produce an NVars-by-NBrowns matrix. If you specify Sigma as a function of time and state, it must return an NVars-by-NBrowns matrix of volatility rates when invoked with two inputs:

- A real-valued scalar observation time *t*.
- An NVars-by-1 state vector X_t.

Data Types: double | function_handle

Note Although sdemrd does not enforce restrictions on the signs of Alpha or Sigma, each parameter is specified as a positive value.

Properties

StartTime — Starting time of first observation, applied to all state variables
0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar

Data Types: double

StartState — Initial values of state variables
1 (default) | scalar, column vector, or matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, sdemrd applies the same initial value to all state variables on all trials.

If StartState is a column vector, sdemrd applies a unique initial value to each state variable on all trials.

If StartState is a matrix, sdemrd applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes)
NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function *C(t)* that accepts the current time *t* and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

As a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

Simulation — User-defined simulation function or SDE simulation method
simulation by Euler approximation (simByEuler) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function_handle

Drift — Drift rate component of continuous-time stochastic differential equations (SDEs)
value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The drift rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

The drift class allows you to create drift-rate objects using drift of the form:

$$F(t, X_t) = A(t) + B(t)X_t$$

where:

- A is an NVars-by-1 vector-valued function accessible using the (t, X_t) interface.
- B is an NVars-by-NVars matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a drift object are:

- `Rate`: The drift-rate function, *F(t,X_t)*
- `A`: The intercept term, *A(t,X_t)*, of *F(t,X_t)*
- `B`: The first order term, *B(t,X_t)*, of *F(t,X_t)*

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

When specified as MATLAB double arrays, the inputs `A` and `B` are clearly associated with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift rate specification.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift rate function F(t,X)`

Data Types: `struct` | `double`

`Diffusion` — Diffusion rate component of continuous-time stochastic differential equations (SDEs)
value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t.

The diffusion rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

The `diffusion` class allows you to create diffusion-rate objects using `diffusion`:

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

where:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-`1` vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the (t, X_t) interface.

The displayed parameters for a `diffusion` object are:

- `Rate`: The diffusion-rate function, *G(t,X_t)*.
- `Alpha`: The state vector exponent, which determines the format of *D(t,X_t)* of *G(t,X_t)*.
- `Sigma`: The volatility rate, *V(t,X_t)*, of *G(t,X_t)*.

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate`

functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` classes in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion rate function G(t,X)`

Data Types: `struct` | `double`

Object Functions

interpolate Brownian interpolation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

simulate Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models

simByEuler Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

simByMilstein Simulate BM, GBM, CEV, HWV, SDEDDO, SDELD, SDEMRD sample paths by Milstein approximation

Examples

Create a sdemrd Object

The `sdemrd` class derives directly from the `sdeddo` class. It provides an interface in which the drift-rate function is expressed in mean-reverting drift form: $dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\alpha(t)})V(t)dW_t$.

`sdemrd` objects provide a parametric alternative to the linear drift form by reparameterizing the general linear drift such that: $A(t) = S(t)L(t), B(t) = -S(t)$.

Create an `sdemrd` object `obj` with a square root exponent to represent the model: $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW_t$.

```
obj = sdemrd(0.2, 0.1, 0.5, 0.05)   % (Speed, Level, Alpha, Sigma)
```

```
obj = 
   Class SDEMRD: SDE with Mean-Reverting Drift
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Alpha: 0.5
          Sigma: 0.05
```

```
        Level: 0.1
        Speed: 0.2
```

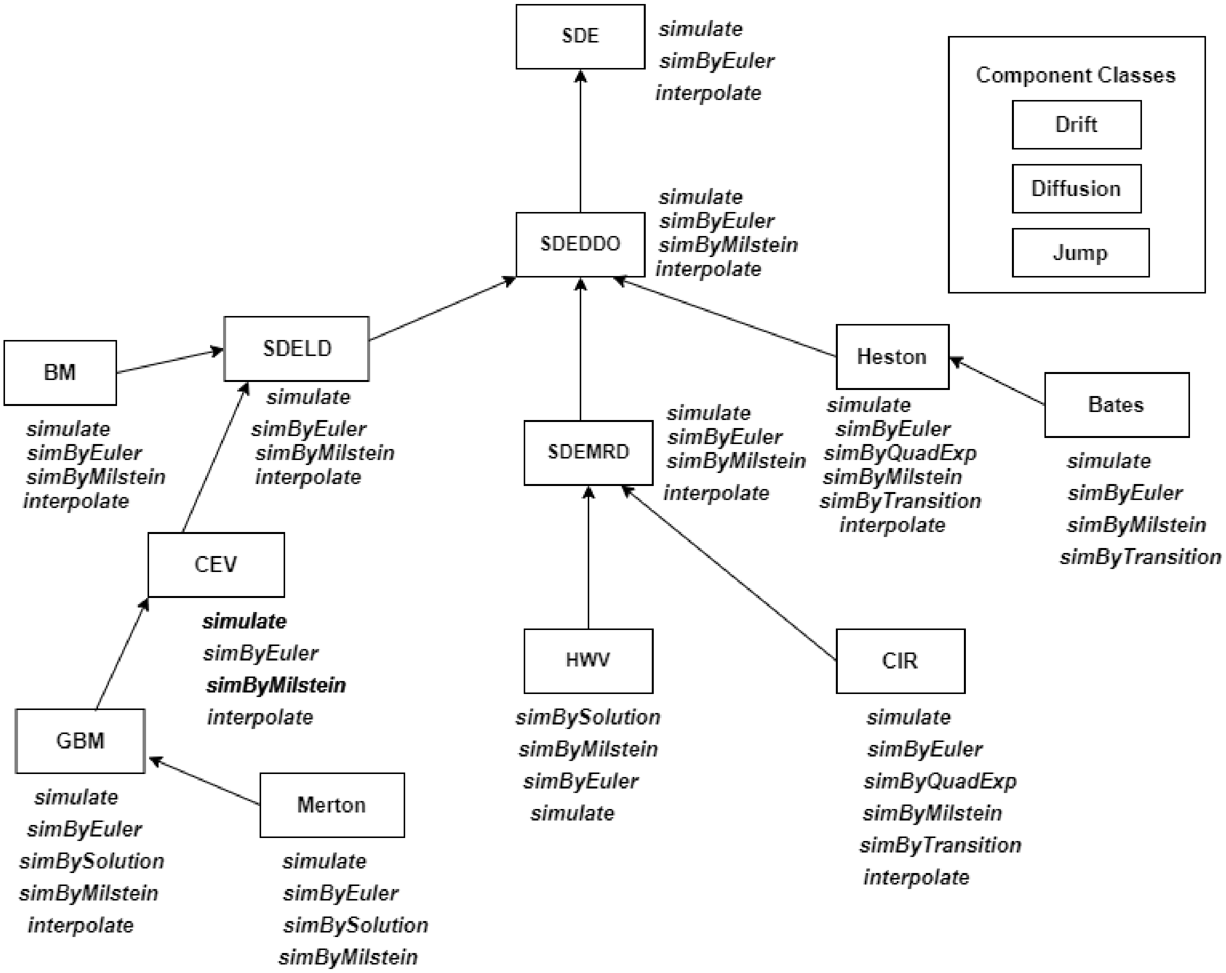
`sdemrd` objects display the familiar `Speed` and `Level` parameters instead of `A` and `B`.

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes.

The following figure illustrates the inheritance relationships.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

When you specify the required input parameters as arrays, they are associated with a specific parametric form. By contrast, when you specify either required input parameter as a function, you can customize virtually any specification.

Accessing the output parameters with no inputs simply returns the original input specification. Thus, when you invoke these parameters with no inputs, they behave like simple properties and allow you to test the data type (double vs. function, or equivalently, static vs. dynamic) of the original input specification. This is useful for validating and designing methods.

When you invoke these parameters with inputs, they behave like functions, giving the impression of dynamic behavior. The parameters accept the observation time t and a state vector X_t, and return an array of appropriate dimension. Even if you originally specified an input as an array, `sdemrd` treats it as a static function of time and state, by that means guaranteeing that all parameters are accessible by the same interface.

bates

`Bates` stochastic volatility model

Description

The `bates` function creates a `bates` object, which represents a Bates model.

The Bates model is a bivariate composite model that derives from the `heston` object. The Bates model is composed of two coupled and dissimilar univariate models, each driven by a single Brownian motion source of risk and a single compound Poisson process representing the arrivals of important events over `NPeriods` consecutive observation periods. The Bates model approximates continuous-time Bates stochastic volatility processes.

The first univariate model is a `GBM` model with a stochastic volatility function and a stochastic jump process, and usually corresponds to a price process whose variance rate is governed by the second univariate model. The second model is a Cox-Ingersoll-Ross (`CIR`) square root diffusion model that describes the evolution of the variance rate of the coupled `GBM` price process.

Bates models are bivariate composite models. Each Bates model consists of two coupled univariate models:

- A geometric Brownian motion (`gbm`) model with a stochastic volatility function and jumps.

  $$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t} + Y(t)X_{1t}dN_t$$

  This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.
- A Cox-Ingersoll-Ross (`cir`) square root diffusion model.

  $$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

  This model describes the evolution of the variance rate of the coupled Bates price process.

Creation

Syntax

```
Bates = bates(Return,Speed,Level,Volatility,JumpFreq,JumpMean,JumpVol)
Bates = bates( ___ ,Name,Value)
```

Description

`Bates = bates(Return,Speed,Level,Volatility,JumpFreq,JumpMean,JumpVol)` create a `bates` object with the default options.

Since Bates models are bivariate models composed of coupled univariate models, all required inputs correspond to scalar parameters. Specify required inputs as one of two types:

- MATLAB array. Specify an array to indicate a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- MATLAB function. Specify a function to provide indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported by an interface because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed. Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time t and state X_t and is invoked with both input arguments.

`Bates = bates(___,Name,Value)` sets “Properties” on page 15-189 using name-value pair arguments in addition to the input arguments in the preceding syntax. Enclose each property name in quotes.

The `bates` object has the following “Properties” on page 15-189:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument
- `Drift` — Composite drift-rate function
- `Diffusion` — Composite diffusion-rate function
- `Simulation` — A simulation function or method

Input Arguments

`Return` — Expected mean instantaneous rate of return of GBM price process

array | deterministic function of time | deterministic function of time and state

Expected mean instantaneous rate of return of the GBM price process, specified as an array, or a deterministic function of time.

If you specify `Return` as an array, it must be scalar.

If you specify `Return` as a deterministic function of time, you call `Return` with a real-valued scalar time `t` as its only input, it must return a scalar.

If you specify `Return` as a deterministic function of time and state, it must return a scalar when you call it with two inputs:

- A real-valued scalar observation time t
- A 2-by-1 bivariate state vector X_t

Data Types: `double` | `function_handle`

Speed — Mean-reversion speed of CIR stochastic variance process

array | deterministic function of time | deterministic function of time and state

Mean-reversion speed of the CIR stochastic variance process, specified as an array or deterministic function of time.

If you specify `Speed` as an array, it must be a scalar.

If you specify `Speed` as a deterministic function of time, you call `Speed` with a real-valued scalar time `t` as its only input, it must return a scalar.

If you specify `Speed` as a function of time and state, the function calculates the speed of mean reversion. This function must return a scalar of reversion rates when you call it with two inputs:

- A real-valued scalar observation time t
- A `2`-by-`1` bivariate state vector X_t

Note Although `bates` enforces no restrictions on `Speed`, the mean-reversion speed is nonnegative such that the underlying process reverts to some stable level.

Data Types: `double` | `function_handle`

`Level` — Reversion level or long-run average of CIR stochastic variance process

array | deterministic function of time | deterministic function of time and state

Reversion level or long-run average of the CIR stochastic variance process, specified as an array, or deterministic function of time.

If you specify `Level` as an array, it must be a scalar.

If you specify `Level` as a deterministic function of time, you call `Level` with a real-valued scalar time `t` as its only input, it must return a scalar.

If you specify `Level` as a deterministic function of time and state, it must return a scalar of reversion levels when you call it with two inputs:

- A real-valued scalar observation time t
- A `2`-by-`1` bivariate state vector X_t

Data Types: `double` | `function_handle`

`Volatility` — Instantaneous volatility CIR stochastic variance process

scalar | deterministic function of time | deterministic function of time and state

Instantaneous volatility of the CIR stochastic variance process (often called the *volatility of volatility* or *volatility of variance*), specified as a scalar, a deterministic function of time, or a deterministic function of time and state.

If you specify `Volatility` as a scalar, it represents the instantaneous volatility of the CIR stochastic variance model.

If you specify `Volatility` as a deterministic function of time, you call `Volatility` with a real-valued scalar time `t` as its only input, it must return a scalar.

If you specify `Volatility` as a deterministic function time and state, `Volatility` must return a scalar when you call it with two inputs:

- A real-valued scalar observation time t

- A 2-by-1 bivariate state vector X_t

Note Although `bates` enforces no restrictions on `Volatility`, the volatility is usually nonnegative.

Data Types: `double` | `function_handle`

`JumpFreq` — Instantaneous jump frequencies representing intensities of Poisson processes
array | deterministic function of time | deterministic function of time and state

Instantaneous jump frequencies representing the intensities (the mean number of jumps per unit time) of Poisson processes (N_t) that drive the jump simulation, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `JumpFreq` as an array, it must be a scalar.

If you specify `JumpFreq` as a deterministic function of time, you call `JumpFreq` with a real-valued scalar time `t` as its only input, it must return a scalar.

If you specify `JumpFreq` as a function of time and state, `JumpFreq` must return a scalar when you call it with two inputs:

- A real-valued scalar observation time t
- A 2-by-1 bivariate state vector X_t

Data Types: `double` | `function_handle`

`JumpMean` — Instantaneous mean of random percentage jump sizes
array | deterministic function of time | deterministic function of time and state

Instantaneous mean of random percentage jump sizes J, where log(1+J) is normally distributed with mean (log(1+`JumpMean`) - 0.5 × `JumpVol`^{2}) and standard deviation `JumpVol`, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `JumpMean` as an array, it must be a scalar.

If you specify `JumpMean` as a deterministic function of time, you call `JumpMean` with a real-valued scalar time `t` as its only input, it must return a scalar.

If you specify `JumpMean` as a function of time and state, `JumpMean` must return a scalar when you call it with two inputs:

- A real-valued scalar observation time t
- A 2-by-1 bivariate state vector X_t

Data Types: `double` | `function_handle`

`JumpVol` — Instantaneous standard deviation
array | deterministic function of time | deterministic function of time and state

Instantaneous standard deviation of log(1+J), specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `JumpVol` as an array, it must be a scalar.

If you specify JumpVol as a deterministic function of time, you call JumpVol with a real-valued scalar time t as its only input, it must return a scalar.

If you specify JumpVol as a function of time and state, JumpVol must return a scalar when you call it with two inputs:

- A real-valued scalar observation time *t*
- A 2-by-1 bivariate state vector X_t

Data Types: double | function_handle

Properties

StartTime — Starting time of first observation, applied to all state variables
0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar.

Data Types: double

StartState — Initial values of state variables
1 (default) | scalar | column vector | matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, bates applies the same initial value to all state variables on all trials.

If StartState is a bivariate column vector, bates applies a unique initial value to each state variable on all trials.

If StartState is a matrix, bates applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate Brownian motion vector (Wiener processes)
2-by-2 identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as a scalar, a 2-by-2 positive semidefinite matrix, or as a deterministic function C_t that accepts the current time *t* and returns an 2-by-2 positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

If you specify Correlation as a deterministic function of time, Correlation allows you to specify a dynamic correlation structure.

Data Types: double

Drift — Drift-rate component of continuous-time stochastic differential equations (SDEs)
value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift-rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t).

The drift rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

Use the `drift` function to create `drift` objects of the form

$$F(t, X_t) = A(t) + B(t)X_t$$

Here:

- `A` is an `NVars`-by-`1` vector-valued function accessible by the (t, X_t) interface.
- `B` is an `NVars`-by-`NVars` matrix-valued function accessible by the (t, X_t) interface.

The displayed parameters for a `drift` object follow.

- `Rate` — Drift-rate function, $F(t,X_t)$
- `A` — Intercept term, $A(t,X_t)$, of $F(t,X_t)$
- `B` — First-order term, $B(t,X_t)$, of $F(t,X_t)$

`A` and `B` enable you to query the original inputs. The function stored in `Rate` fully encapsulates the combined effect of `A` and `B`.

Specifying `AB` as MATLAB double arrays clearly associates them with a linear drift rate parametric form. However, specifying either `A` or `B` as a function allows you to customize virtually any drift-rate specification.

Note You can express `drift` and `diffusion` objects in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift-rate function F(t,X)`

Data Types: `object`

`Diffusion` — Diffusion-rate component of continuous-time stochastic differential equations (SDEs)

value stored from diffusion-rate function (default) | `diffusion` object or functions accessible by (t, X_t)

This property is read-only.

Diffusion-rate component of continuous-time stochastic differential equations (SDEs), specified as a `drift` object or function accessible by (t, X_t).

The diffusion-rate specification supports the simulation of sample paths of `NVars` state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods for approximating continuous-time stochastic processes.

Use the `diffusion` function to create `diffusion` objects of the form

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

Here:

- `D` is an `NVars`-by-`NVars` diagonal matrix-valued function.
- Each diagonal element of `D` is the corresponding element of the state vector raised to the corresponding element of an exponent `Alpha`, which is an `NVars`-by-`1` vector-valued function.
- `V` is an `NVars`-by-`NBrowns` matrix-valued volatility rate function `Sigma`.
- `Alpha` and `Sigma` are also accessible using the (t, X_t) interface.

The displayed parameters for a `diffusion` object are:

- `Rate` — Diffusion-rate function, $G(t,X_t)$
- `Alpha` — State vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$
- `Sigma` — Volatility rate, $V(t,X_t)$, of $G(t,X_t)$

`Alpha` and `Sigma` enable you to query the original inputs. (The combined effect of the individual `Alpha` and `Sigma` parameters is fully encapsulated by the function stored in `Rate`.) The `Rate` functions are the calculation engines for the `drift` and `diffusion` objects, and are the only parameters required for simulation.

Note You can express `drift` and `diffusion` objects in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components `A` and `B` as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion-rate function G(t,X)`

Data Types: `object`

`Simulation` — User-defined simulation function or SDE simulation method

simulation by Euler approximation (`simByEuler`) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: `function_handle`

Object Functions

simByEuler	Simulate Bates sample paths by Euler approximation
simByQuadExp	Simulate Bates, Heston, and CIR sample paths by quadratic-exponential discretization scheme
simulate	Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models
simByTransition	Simulate Bates sample paths with transition density
simByMilstein	Simulate Bates sample paths by Milstein approximation

Examples

Create bates Object

Bates models are bivariate composite models, composed of two coupled and dissimilar univariate models, each driven by a single Brownian motion source of risk and a single compound Poisson process representing the arrivals of important events over `NPeriods` consecutive observation periods. The simulation approximates continuous-time Bates stochastic volatility processes.

Create a `bates` object.

```
AssetPrice = 80;
            Return = 0.03;
            JumpMean = 0.02;
            JumpVol = 0.08;
            JumpFreq = 0.1;

            V0 = 0.04;
            Level = 0.05;
            Speed = 1.0;
            Volatility = 0.2;
            Rho = -0.7;
            StartState = [AssetPrice;V0];
            Correlation = [1 Rho;Rho 1];

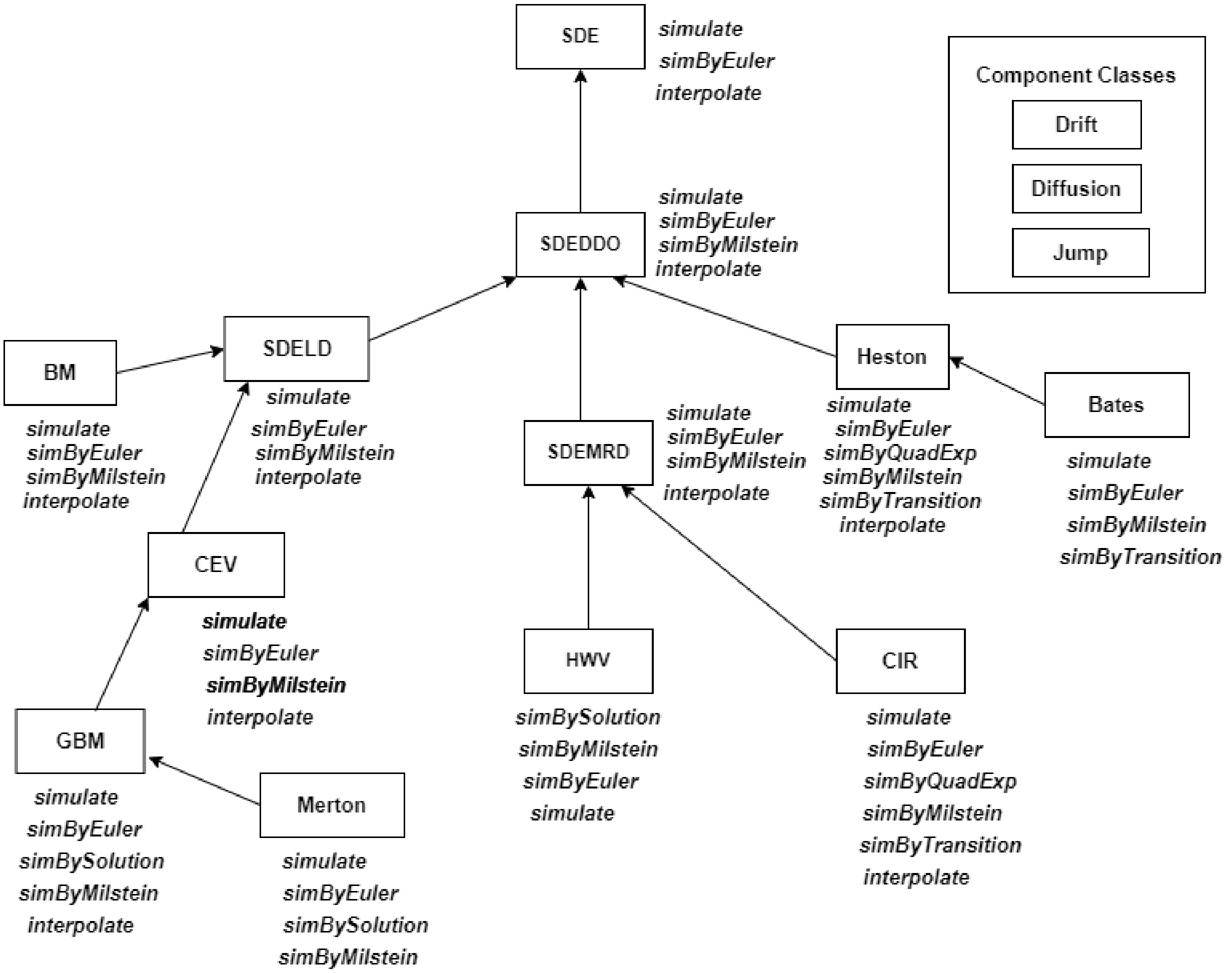
batesObj = bates(Return, Speed, Level, Volatility,...
                JumpFreq, JumpMean, JumpVol,'startstate',StartState,...
                'correlation',Correlation)
```

```
batesObj = 
   Class BATES: Bates Bivariate Stochastic Volatility
   --------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   --------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
    Correlation: 2x2 double array
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.03
          Speed: 1
          Level: 0.05
     Volatility: 0.2
       JumpFreq: 0.1
       JumpMean: 0.02
        JumpVol: 0.08
```

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes, as follows.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

The Bates model (Bates 1996) is an extension of the Heston model and adds not only stochastic volatility, but also the jump diffusion parameters as in Merton (1976) were also added to model sudden asset price movements.

Under the risk-neutral measure the model is expressed as follows

$$dS_t = (\gamma - q - \lambda_p \mu_j)S_t dt + \sqrt{\upsilon_t} S_t dW_t + J S_t dP_t$$

$$d\upsilon_t = \kappa(\theta - \upsilon_t)dt + \sigma_\upsilon \sqrt{\upsilon_t} dW_t^\upsilon$$

$$\mathrm{E}\left[dW_t dW_t^\upsilon\right] = pdt$$

$$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

Here:

$^\gamma$ is the continuous risk-free rate.

q is the continuous dividend yield.

J is the random percentage jump size conditional on the jump occurring, where

$$\ln(1 + J) \sim N(\ln(1+u_j) - \frac{\delta^2}{2}, \delta^2$$

(1+J) has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1 + J) - (\ln(1+\mu_j) - \frac{\delta^2}{2}\right]^2}{2\delta^2}\right\}$$

Here:

μ_j is the mean of J($\mu_j > -1$).

ƛ$_p$ is the annual frequency (intensity) of the Poisson process P_t (ƛ$_p \geq 0$).

υ is the initial variance of the underlying asset ($\upsilon_0 > 0$).

θ is the long-term variance level (θ > 0).

κ is the mean reversion speed for the variance (κ > 0).

σ_υ is the volatility of volatility ($\sigma_\upsilon > 0$).

p is the correlation between the Weiner processes W_t and W_t^υ ($-1 \leq p \leq 1$).

The "Feller condition" ensures positive variance: ($2\kappa\theta > \sigma_\upsilon^2$).

The stochastic volatility along with the jump help better model the asymmetric leptokurtic features, the volatility smile, and the large random fluctuations such as crashes and rallies.

Version History

Introduced in R2020a

R2023a: Added `simByMilstein` method

Behavior changed in R2023a

Use the `simByMilstein` method to approximate a numerical solution of a stochastic differential equation.

merton

Merton jump diffusion model

Description

The merton function creates a merton object, which derives from the gbm object.

The merton model, based on the Merton76 model, allows you to simulate sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk and NJumps compound Poisson processes representing the arrivals of important events over NPeriods consecutive observation periods. The simulation approximates continuous-time merton stochastic processes.

You can simulate any vector-valued merton process of the form

$$dX_t = B(t, X_t)X_t dt + D(t, X_t)V(t, x_t)dW_t + Y(t, X_t, N_t)X_t dN_t$$

Here:

- X_t is an NVars-by-1 state vector of process variables.
- $B(t,X_t)$ is an NVars-by-NVars matrix of generalized expected instantaneous rates of return.
- $D(t,X_t)$ is an NVars-by-NVars diagonal matrix in which each element along the main diagonal is the corresponding element of the state vector.
- $V(t,X_t)$ is an NVars-by-NVars matrix of instantaneous volatility rates.
- dW_t is an NBrowns-by-1 Brownian motion vector.
- $Y(t,X_t,N_t)$ is an NVars-by-NJumps matrix-valued jump size function.
- dN_t is an NJumps-by-1 counting process vector.

Creation

Syntax

```
Merton = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol)
Merton = merton( ___ ,Name,Value)
```

Description

Merton = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol) creates a default merton object. Specify required inputs as one of two types:

- MATLAB array. Specify an array to indicate a static (non-time-varying) parametric specification. This array fully captures all implementation details, which are clearly associated with a parametric form.
- MATLAB function. Specify a function to provide indirect support for virtually any static, dynamic, linear, or nonlinear model. This parameter is supported by an interface because all implementation details are hidden and fully encapsulated by the function.

Note You can specify combinations of array and function input parameters as needed. Moreover, a parameter is identified as a deterministic function of time if the function accepts a scalar time `t` as its only input argument. Otherwise, a parameter is assumed to be a function of time t and state X_t and is invoked with both input arguments.

`Merton = merton( ___ ,Name,Value)` sets "Properties" on page 15-199 using name-value pair arguments in addition to the input arguments in the preceding syntax. Enclose each property name in quotes.

The `merton` object has the following "Properties" on page 15-199:

- `StartTime` — Initial observation time
- `StartState` — Initial state at time `StartTime`
- `Correlation` — Access function for the `Correlation` input argument
- `Drift` — Composite drift-rate function
- `Diffusion` — Composite diffusion-rate function
- `Simulation` — A simulation function or method

Input Arguments

`Return` — Expected mean instantaneous rates of asset return

array | deterministic function of time | deterministic function of time and state

Expected mean instantaneous rates of asset return, denoted as $B(t,X_t)$, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `Return` as an array, it must be an `NVars`-by-`NVars` matrix representing the expected (mean) instantaneous rate of return.

If you specify Return as a deterministic function of time, when you call `Return` with a real-valued scalar time `t` as its only input, it must return an `NVars`-by-`NVars` matrix.

If you specify `Return` as a deterministic function of time and state, it must return an `NVars`-by-`NVars` matrix when you call it with two inputs:

- A real-valued scalar observation time t
- An `NVars`-by-`1` state vector X_t

Data Types: `double` | `function_handle`

`Sigma` — Instantaneous volatility rates

array | deterministic function of time | deterministic function of time and state

Instantaneous volatility rates, denoted as $V(t,X_t)$, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify `Sigma` as an array, it must be an `NVars`-by-`NBrowns` matrix of instantaneous volatility rates or a deterministic function of time. In this case, each row of `Sigma` corresponds to a particular state variable. Each column corresponds to a particular Brownian source of uncertainty, and associates the magnitude of the exposure of state variables with sources of uncertainty.

If you specify `Sigma` as a deterministic function of time, when you call `Sigma` with a real-valued scalar time `t` as its only input, it must return an `NVars`-by-`NBrowns` matrix.

If you specify Sigma as a deterministic function of time and state, it must return an NVars-by-NBrowns matrix when you call it with two inputs:

- A real-valued scalar observation time t
- An NVars-by-1 state vector X_t

Note Although merton enforces no restrictions for Sigma, volatilities are usually nonnegative.

Data Types: double | function_handle

JumpFreq — Instantaneous jump frequencies representing intensities of Poisson processes
array | deterministic function of time | deterministic function of time and state

Instantaneous jump frequencies representing the intensities (the mean number of jumps per unit time) of the Poisson processes N_t that drive the jump simulation, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify JumpFreq as an array, it must be an NJumps-by-1 vector.

If you specify JumpFreq as a deterministic function of time, when you call JumpFreq with a real-valued scalar time t as its only input, JumpFreq must produce an NJumps-by-1 vector.

If you specify JumpFreq as a deterministic function of time and state, it must return an NVars-by-NBrowns matrix when you call it with two inputs:

- A real-valued scalar observation time t
- An NVars-by-1 state vector X_t

Data Types: double | function_handle

JumpMean — Instantaneous mean of random percentage jump sizes
array | deterministic function of time | deterministic function of time and state

Instantaneous mean of random percentage jump sizes J, where log(1+J) is normally distributed with mean (log(1+JumpMean) - 0.5 × JumpVol^2) and standard deviation JumpVol, specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify JumpMean as an array, it must be an NVars-by-NJumps matrix.

If you specify JumpMean as a deterministic function of time, when you cal JumpMean with a real-valued scalar time t as its only input, it must return an NVars-by-NJumps matrix.

If you specify JumpMean as a deterministic function of time and state, it must return an NVars-by-NJumps matrix when you call it with two inputs:

- A real-valued scalar observation time t
- An NVars-by-1 state vector X_t

Data Types: double | function_handle

JumpVol — Instantaneous standard deviation
array | deterministic function of time | deterministic function of time and state

Instantaneous standard deviation of log(1+*J*), specified as an array, a deterministic function of time, or a deterministic function of time and state.

If you specify JumpVol as an array, it must be an NVars-by-NJumps matrix.

If you specify JumpVol as a deterministic function of time, when you call JumpVol with a real-valued scalar time t as its only input, it must return an NVars-by-NJumps matrix.

If you specify JumpVol as a deterministic function of time and state, it must return an NVars-by-NJumps matrix when you call it with two inputs:

- A real-valued scalar observation time *t*
- An NVars-by-1 state vector X_t

Data Types: double | function_handle

Properties

StartTime — Starting time of first observation, applied to all state variables

0 (default) | scalar

Starting time of first observation, applied to all state variables, specified as a scalar.

Data Types: double

StartState — Initial values of state variables

1 (default) | scalar | column vector | matrix

Initial values of state variables, specified as a scalar, column vector, or matrix.

If StartState is a scalar, merton applies the same initial value to all state variables on all trials.

If StartState is a column vector, merton applies a unique initial value to each state variable on all trials.

If StartState is a matrix, merton applies a unique initial value to each state variable on each trial.

Data Types: double

Correlation — Correlation between Gaussian random variates drawn to generate Brownian motion vector (Wiener processes)

NBrowns-by-NBrowns identity matrix representing independent Gaussian processes (default) | positive semidefinite matrix | deterministic function

Correlation between Gaussian random variates drawn to generate the Brownian motion vector (Wiener processes), specified as an NBrowns-by-NBrowns positive semidefinite matrix, or as a deterministic function C_t that accepts the current time *t* and returns an NBrowns-by-NBrowns positive semidefinite correlation matrix. If Correlation is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

A Correlation matrix represents a static condition.

If you specify Correlation as a deterministic function of time, you can specify a dynamic correlation structure.

Data Types: double

Drift — Drift-rate component of continuous-time stochastic differential equations (SDEs)

value stored from drift-rate function (default) | drift object or function accessible by (t, X_t)

This property is read-only.

Drift-rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t).

The drift-rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, approximating continuous-time stochastic processes.

Use the drift function to create drift objects of the form

$$F(t, X_t) = A(t) + B(t)X_t$$

Here:

- A is an NVars-by-1 vector-valued function accessible using the (t, X_t) interface.
- B is an NVars-by-NVars matrix-valued function accessible using the (t, X_t) interface.

The displayed parameters for a drift object are:

- Rate — Drift-rate function, $F(t,X_t)$
- A — Intercept term, $A(t,X_t)$, of $F(t,X_t)$
- B — First-order term, $B(t,X_t)$, of $F(t,X_t)$

A and B enable you to query the original inputs. The function stored in Rate fully encapsulates the combined effect of A and B.

Specifying AB as MATLAB double arrays clearly associates them with a linear drift rate parametric form. However, specifying either A or B as a function allows you to customize virtually any drift-rate specification.

Note You can express drift and diffusion objects in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components A and B as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `F = drift(0, 0.1) % Drift-rate function F(t,X)`

Data Types: object

Diffusion — Diffusion-rate component of continuous-time stochastic differential equations (SDEs)

value stored from diffusion-rate function (default) | diffusion object or functions accessible by (t, X_t)

This property is read-only.

Diffusion-rate component of continuous-time stochastic differential equations (SDEs), specified as a drift object or function accessible by (t, X_t).

The diffusion-rate specification supports the simulation of sample paths of NVars state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods for approximating continuous-time stochastic processes.

Use the diffusion function to create diffusion objects of the form

$$G(t, X_t) = D(t, X_t^{\alpha(t)})V(t)$$

Here:

- D is an NVars-by-NVars diagonal matrix-valued function.
- Each diagonal element of D is the corresponding element of the state vector raised to the corresponding element of an exponent Alpha, which is an NVars-by-1 vector-valued function.
- V is an NVars-by-NBrowns matrix-valued volatility rate function Sigma.
- Alpha and Sigma are also accessible using the (t, X_t) interface.

The displayed parameters for a diffusion object are:

- Rate — Diffusion-rate function, $G(t,X_t)$
- Alpha — State vector exponent, which determines the format of $D(t,X_t)$ of $G(t,X_t)$
- Sigma — Volatility rate, $V(t,X_t)$, of $G(t,X_t)$

Alpha and Sigma enable you to query the original inputs. (The combined effect of the individual Alpha and Sigma parameters is fully encapsulated by the function stored in Rate.) The Rate functions are the calculation engines for the drift and diffusion objects, and are the only parameters required for simulation.

Note You can express drift and diffusion objects in the most general form to emphasize the functional (t, X_t) interface. However, you can specify the components A and B as functions that adhere to the common (t, X_t) interface, or as MATLAB arrays of appropriate dimension.

Example: `G = diffusion(1, 0.3) % Diffusion-rate function G(t,X)`

Data Types: object

Simulation — User-defined simulation function or SDE simulation method

simulation by Euler approximation (simByEuler) (default) | function | SDE simulation method

User-defined simulation function or SDE simulation method, specified as a function or SDE simulation method.

Data Types: function_handle

Object Functions

simByEuler	Simulate Merton jump diffusion sample paths by Euler approximation
simBySolution	Simulate approximate solution of diagonal-drift Merton jump diffusion process
simByMilstein	Simulate Merton sample paths by Milstein approximation
simulate	Simulate multivariate stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, SDEMRD, Merton, or Bates models

Examples

Create merton Object

Merton jump diffusion models allow you to simulate sample paths of NVARS state variables driven by NBROWNS Brownian motion sources of risk and NJumps compound Poisson processes representing the arrivals of important events over NPeriods consecutive observation periods. The simulation approximates continuous-time merton stochastic processes.

Create a merton object.

```
AssetPrice = 80;
            Return = 0.03;
            Sigma = 0.16;
            JumpMean = 0.02;
            JumpVol = 0.08;
            JumpFreq = 2;

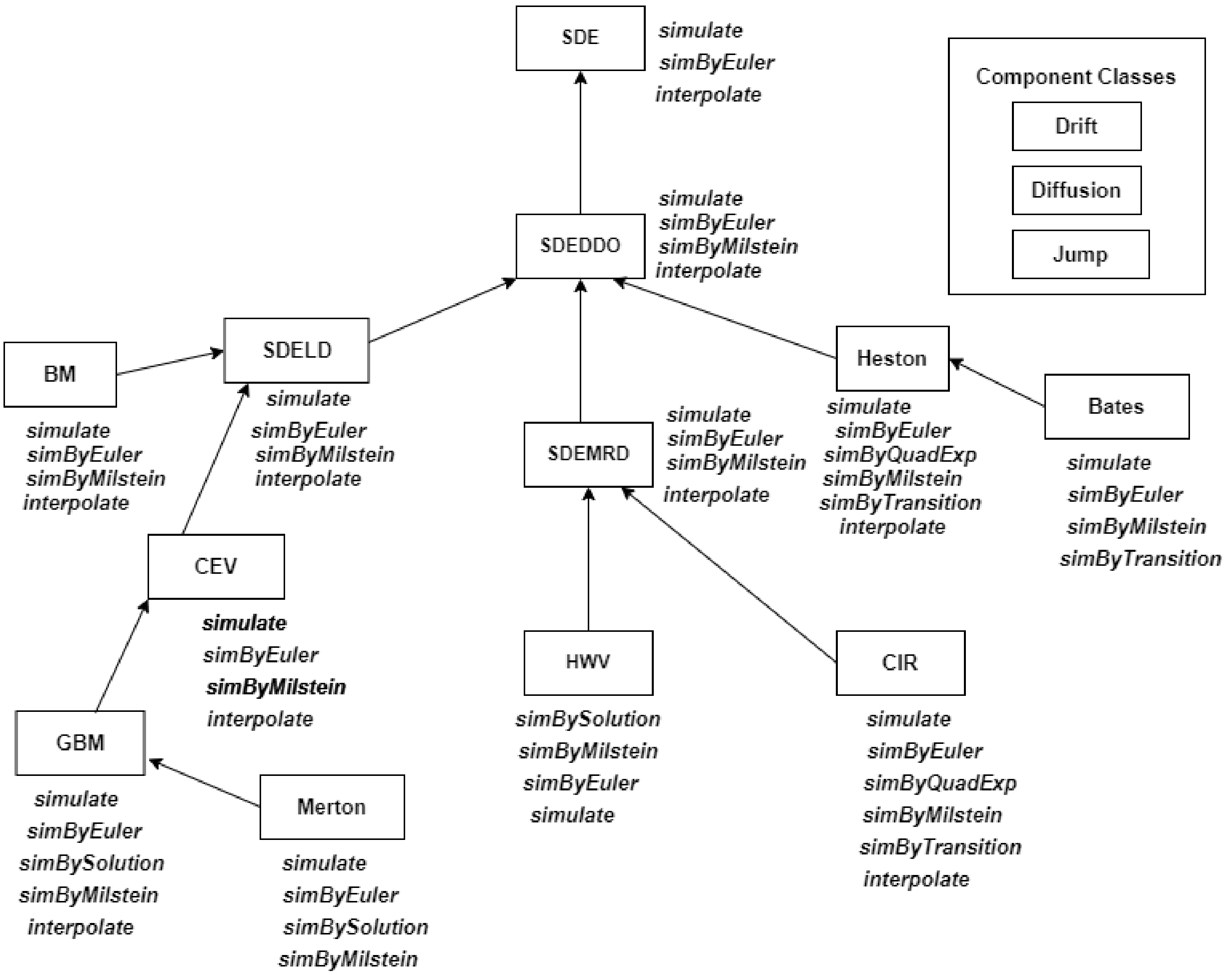
            mertonObj = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol,...
                'startstat',AssetPrice)
```

```
mertonObj = 
   Class MERTON: Merton Jump Diffusion
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 80
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.16
         Return: 0.03
       JumpFreq: 2
       JumpMean: 0.02
        JumpVol: 0.08
```

More About

Instance Hierarchy

There are inheritance relationships among the SDE classes, as follows.



For more information, see “SDE Class Hierarchy” on page 14-5.

Algorithms

The Merton jump diffusion model (Merton 1976) is an extension of the Black-Scholes model, and models sudden asset price movements (both up and down) by adding the jump diffusion parameters with the Poisson process P_t.

Under the risk-neutral measure the model is expressed as follows

$$dS_t = (\gamma - q - \lambda_p \mu_j) S_t dt + \sigma_M S_t dW_t + J S_t dP_t$$
$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

γ is the continuous risk-free rate.

q is the continuous dividend yield.

J is the random percentage jump size conditional on the jump occurring, where

$$\ln(1+J) \sim N(\ln(1+u_j) - \frac{\delta^2}{2}, \delta^2$$

(1+J) has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1+J) - (\ln(1+\mu_j) - \frac{\delta^2}{2}\right]^2}{2\delta^2}\right\}$$

Here:

μ_j is the mean of $J(\mu_j > -1)$.

λ_p is the annual frequency (intensity) of the Poisson process P_t ($\lambda_p \geq 0$).

σ_M is the volatility of the asset price ($\sigma_M > 0$).

Under this formulation, extreme events are explicitly included in the stochastic differential equation as randomly occurring discontinuous jumps in the diffusion trajectory. Therefore, the disparity between observed tail behavior of log returns and that of Brownian motion is mitigated by the inclusion of a jump mechanism.

Version History

Introduced in R2020a

R2023a: Added `simByMilstein` method

Behavior changed in R2023a

Use the `simByMilstein` method to approximate a numerical solution of a stochastic differential equation.

backtestStrategy

Create `backtestStrategy` object to define portfolio allocation strategy

Description

Create a `backtestStrategy` object which defines a portfolio allocation strategy.

Use this workflow to develop and run a backtest:

1. Define the strategy logic using a `backtestStrategy` object to specify how the strategy rebalances a portfolio of assets.
2. Use `backtestEngine` to create a `backtestEngine` object that specifies the parameters of the backtest.
3. Use `runBacktest` to run the backtest against historical asset price data and, optionally, trading signal data.
4. Use `equityCurve` to plot the equity curves of each strategy.
5. Use `summary` to summarize the backtest results in a table format.

For more detailed information on this workflow, see “Backtest Investment Strategies Using Financial Toolbox™” on page 4-231.

Creation

Syntax

```
strategy = backtestStrategy(name,rebalanceFcn)
strategy = backtestStrategy( ___ ,Name,Value)
```

Description

`strategy = backtestStrategy(name,rebalanceFcn)` creates a `backtestStrategy` object.

`strategy = backtestStrategy( ___ ,Name,Value)` sets properties on page 15-213 using name-value pair arguments and any of the arguments in the previous syntax. You can specify multiple name-value pair arguments. For example, `strat = backtestStrategy('MyStrategy',@myRebalFcn,'TransactionCost',0.005,'LookbackWindow',20)`.

Input Arguments

name — Strategy name
string

Strategy name, specified as a string.

Data Types: `string`

rebalanceFcn — Rebalance function

function handle

Rebalance function, specified as a function handle which computes new portfolio weights during the backtest. The rebalanceFcn argument implements the core logic of the trading strategy.

The signature of the rebalanceFcn depends on whether UserData and EngineDataList name-value arguments are specified for the backtestStrategy function. For an example of rebalanceFcn where UserData is specified, see “Backtest with Brinson Attribution to Evaluate Portfolio Performance” on page 4-311.

- **If UserData and EngineDataList are Empty**

  If the UserData and EngineDataList name-value arguments are empty, then the rebalanceFcn must have one of the following signatures:

  - `new_weights = rebalanceFcn(weights,assetPrices)`
  - `new_weights = rebalanceFcn(weights,assetPrices,signalData)`

  If you do *not* specify UserData, the rebalance function returns a single output argument, new_weights, which is a vector of asset weights specified as decimal percentages.

  - If the new_weights sum to 1, then the portfolio is fully invested.
  - If the new_weights sum to less than 1, then the portfolio has the remainder in cash, earning the RiskFreeRate specified in the backtestEngine object.
  - If the new_weights sum to more than 1, then there is a negative cash position (margin) and the cash borrowed accrues interest at the cash borrowing rate specified in the CashBorrowRate property of the backtestEngine object.

- **If UserData is Empty and EngineDataList is Specified**

  If the UserData name-value argument is empty and the EngineDataList name-value argument is specified, then the rebalanceFcn must have one of the following signatures:

  - `new_weights = rebalanceFcn(engineData,assetPrices)`
  - `new_weights = rebalanceFcn(engineData,assetPrices,signalData)`

- **If UserData is Specified and EngineDataList is Empty**

  If you use the name-value argument for UserData to specify a strategy-specific userData struct but do not specify the name-value argument for EngineDataList, the required syntax for rebalanceFcn must have one of the following signatures:

  - `[new_weights,userData] = rebalanceFcn(weights,assetPrices,userData)`
  - `[new_weights,userData] = rebalanceFcn(weights,assetPrices,signalData,userData)`

  If UserData is specified, then in addition to an output for new_weights, there is also an output for userData returned as a struct.

- **If Both UserData and EngineDataList are Specified**

If you use the name-value argument for UserData to specify a strategy-specific userData struct and you use the name-value argument EngineDataList to specify a backtest engine state, the required syntax for rebalanceFcn must have one of the following signatures:

- [new_weights,userData] = rebalanceFcn(engineData,assetPrices,userData)
- [new_weights,userData] = rebalanceFcn(engineData,assetPrices,signalData,userData)

If UserData is specified, then in addition to an output for new_weights, there is also an output for userData returned as a struct.

The rebalanceFcn function is called by the backtestEngine object each time the strategy must be rebalanced as specified in the RebalanceFrequency name-value argument. The backtestEngine object calls the rebalanceFcn function with the following arguments:

- weights — The current portfolio weights before rebalancing, specified as decimal percentages.
- assetPrices — A timetable containing a rolling window of adjusted asset prices.
- signalData — (Optional) A timetable containing a rolling window of signal data.

  If you provide signal data to the backtestEngine object, then the engine object passes it to the strategy rebalance function using the three input argument syntax. If do not provide signal data the backtestEngine object, then the engine object calls the rebalance function with the two input argument syntax.
- userData — (Optional) A struct to contain strategy-specific user data.

  If the UserData property is set, the userData struct is passed into rebalanceFcn.
- engineData — (Optional) A struct containing backtest state data.

  If the EngineDataList property is set, the engineData struct is passed into rebalanceFcn.

For more information on developing a rebalanceFcn function handle, see “Backtest Investment Strategies Using Financial Toolbox™” on page 4-231.

Data Types: function_handle

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: strat = backtestStrategy('MyStrategy',@myRebalFcn,'TransactionCost',0.005,'LookbackWindow',20)

RebalanceFrequency — Rebalance frequency during backtest

1 (default) | integer | duration object | calendarDuration object | vector of datetime objects

Rebalance frequency during the backtest, specified as the comma-separated pair consisting of 'RebalanceFrequency' and a scalar integer, duration orcalendarDuration object, or a vector of datetime objects.

The RebalanceFrequency specifies the schedule of dates where the strategy will rebalance its portfolio. The default is 1, meaning the strategy rebalances with each time step.

For more information, see "Defining Schedules for Backtest Strategies" on page 15-226.

Data Types: double | object | datetime

TransactionCosts — Transaction costs for trades

0 (not computed) (default) | numeric | vector | function handle

Transaction costs for trades, specified as the comma-separated pair consisting of 'TransactionCosts' and a scalar numeric, vector, or function handle. You can specify transaction costs in three ways:

- rate — A scalar decimal percentage charge to both purchases and sales of assets. For example ,if you set TransactionCosts to 0.001, then each transaction (buys and sells) would pay 0.1% in transaction fees.
- [buyRate, sellRate] — A 1-by-2 vector of decimal percentage rates that specifies separate rates for buying and selling of assets.
- computeTransactionCostsFcn — A function handle to compute customized transaction fees. If you specify a function handle, the backtestEngine object calls the TransactionCosts function to compute the fees for each rebalance. The user-defined computeTransactionCostsFcn function handle has different signatures depending on whether the optional name-value arguments UserData and EngineDataList are specified.

  - **If UserData is Empty and EngineDataList is Empty**

    When the optional name-value arguments UserData and EngineDataList are not specified, the computeTransactionCostsFcn function handle has the following signature:

    ```
    [buyCosts,sellCosts] = computeTransactionCostsFcn(deltaPositions)
    ```

    The user-defined computeTransactionCostsFcn function handle takes a single input argument, deltaPositions, which is a vector of changes in asset positions for all assets (in currency units) as a result of a rebalance. Positive elements in the deltaPositions vector indicate purchases while negative entries represent sales. The user-defined function handle must return two output arguments buyCosts and sellCosts, which contain the total costs (in currency) for the entire rebalance for each type of transaction.
  - **If UserData is Empty and EngineDataList is Specified**

    When the optional name-value argument UserData is not specified, but the optional name-value argument EngineDataList is specified, the computeTransactionCostsFcn function handle has the following signatures:

    ```
    [buyCosts,sellCosts] = computeTransactionCostsFcn(deltaPositions,engineData)
    ```
  - **If UserData is Specified and EngineDataList is Empty**

    When the optional name-value argument UserData is specified, but the optional name-value argument EngineDataList is not specified, the computeTransactionCostsFcn function handle has the following signatures:

    ```
    [buyCosts,sellCosts,userData] = computeTransactionCostsFcn(deltaPositions,userData)
    ```
  - **If Both UserData and EngineDataList are Specified**

If you use the optional name-value argument for UserData to specify a strategy-specific userData struct and the optional name-value argument EngineDataList to specify required backtest engine state data, the required syntax for the computeTransactionCostsFcn function handle must have one of the following signatures:

```
[buyCosts,sellCosts,userData] = computeTransactionCostsFcn(deltaPositions,engineData,userDa
```

If you specify the optional name-value argument UserData, then the strategy userData struct is passed to the computeTransactionCostsFcn cost function as the final input argument. The computeTransactionCostsFcn function handle can read or write any information to the userData struct. The updated userData struct is returned as the third output argument.

Data Types: double | function_handle

LookbackWindow — Lookback window

[0 Inf] (default) | 1-by-2 vector using integers | duration object | calendarDuration object

Lookback window, specified as the comma-separated pair consisting of 'LookbackWindow' and a 1-by-2 vector of integers, a duration orcalendarDurationobject.

When using a 1-by-2 vector with integers that defines the minimum and maximum size of the rolling window of data (asset prices and signal data) that you provide to the rebalanceFcn argument, you specify these limits in terms of the number of time steps. When specified as integers, the lookback window is defined in terms of rows of data from the asset (pricesTT) and signal (signalTT) timetables used in the backtest. The lookback minimum sets the minimum number of rows of asset price data that must be available to the rebalance function before a strategy rebalance can occur. The lookback maximum sets the maximum size for the rolling window of price data that is passed to the rebalance function.

For example, if the backtestEngine object is provided with daily price data, then LookbackWindow specifies the size bounds of the rolling window in days. The default is [0 Inf], meaning that all available past data is given to the rebalance function. If you specify a non-zero minimum, then the software does not call rebalanceFcn until enough time steps process to meet the minimum size.

If you specify LookbackWindow as a single scalar value, then the value is both the minimum and maximum of the LookbackWindow (that is, a fixed-sized window).

If using a duration or calendarDuration object, the lookback window minimum and maximum are defined in terms of timespans relative to the time at a rebalance. For example if the lookback minimum was set to five days (that is, days(5)), the rebalance will only occur if the backtest start time is at least five days prior to the rebalance time. Similarly, if the lookback maximum was set to six months (that is, calmonths(6)), the lookback window would contain only data that occurred at six months prior to the rebalance time or later.

Note Alternatively, the LookbackWindow can be set to a single scalar value indicating that the rolling window should be exactly that size (either in terms of rows or a time duration). The minimum and maximum size will both be set to the provided value.

Data Types: double | object

InitialWeights — Initial portfolio weights

[] (default) | vector

Initial portfolio weights, specified as the comma-separated pair consisting of `'InitialWeights'` and a vector. The `InitialWeights` vector sets the portfolio weights before the `backtestEngine` object begins the backtest. The size of the initial weights vector must match the number of assets used in the backtest.

Alternatively, you can set the `InitialWeights` name-value pair argument to empty (`[]`) to indicate the strategy will begin with no investments and in a 100% cash position. The default for `InitialWeights` is empty (`[ ]`).

Data Types: `double`

`ManagementFee` — Management fee charged as an annualized percent of the total portfolio value
`0` (default) | decimal

Management fee charged as an annualized percent of the total portfolio value, specified as the comma-separated pair consisting of `'ManagementFee'` and a numeric scalar. The management fee is the annualized fee rate paid to cover the costs of managing a strategy's portfolio. The management fee is charged based on the strategy portfolio balance at the start of each date specified by the `ManagementFeeSchedule`. The default is `0`, meaning no management fee is paid.

For more information, see “Management Fees” on page 15-227.

Data Types: `double`

`ManagementFeeSchedule` — Management fee schedule
`calyears(1)` (default) | integer | vector of datetimes | `duration` object | `calendarDuration` object

Management fee schedule, specified as the comma-separated pair consisting of `'ManagementFeeSchedule'` and a numeric scalar, a `duration` or `calendarDuration` object, or alternatively, as a vector of datetimes.

The `ManagementFeeSchedule` specifies the schedule of dates where the management fee is charged (if a `ManagementFee` is defined). The default is `calyears(1)`, meaning the management fee is charged annually.

For more information, see “Defining Schedules for Backtest Strategies” on page 15-226.

Data Types: `double` | `datetime` | `object`

`PerformanceFee` — Performance fee charged as an absolute percent of the total portfolio growth
`0` (default) | decimal

Performance fee charged as a percent of the total portfolio growth, specified as the comma-separated pair consisting of `'PerformanceFee'` and a numeric scalar. The performance fee, sometimes called an incentive fee, is a fee paid to reward a fund manager based on performance of the fund. The fee is paid periodically based on the schedule specified by the `PerformanceFeeSchedule`. The default is `0`, meaning no performance fee is paid.

For more information, see “Performance Fees” on page 15-229.

Data Types: `double`

PerformanceHurdle — Annualized hurdle rate or column in assets or signals to act as hurdle asset

0 (default) | decimal | string

Annualized hurdle rate or column in assetPrices or signalData to act as hurdle asset, specified as the comma-separated pair consisting of 'PerformanceHurdle' and a numeric scalar or a string. The PerformanceHurdle sets a minimum level of performance that a strategy must achieve before the performance fee is paid.

- If specified as a numeric scalar, the hurdle represents an annualized growth rate, for example 0.05 indicates a 5% growth rate. In this case, the performance fee is only paid if, on a performance fee date, the strategy portfolio value is greater than the high-water mark and the portfolio has produced a return greater than 5% annualized since the start of the backtest. The fee is paid only on the growth in excess of both the hurdle rate and the previous high-water mark.
- If specified as a string, the hurdle must match a column in either the assetPrices or signalData timetables of the backtest and it indicates a hurdle asset. In this case, the performance fee is paid only if the portfolio value is greater than the high-water mark and the portfolio has produced a return greater than the hurdle asset return since the start of the backtest. The performance fee is charged only on the portfolio growth in excess of both the hurdle asset growth and the previous high-water mark.

For more information, see “Performance Hurdle” on page 15-230.

Data Types: double | string

PerformanceFeeSchedule — Performance fee schedule

calyears(1) (default) | integer | vector of datetimes | duration object | calendarDuration object

Performance fee schedule, specified as the comma-separated pair consisting of 'PerformanceFeeSchedule' and a numeric scalar, a duration or calendarDuration object, or alternatively as a vector of datetimes.

PerformanceFeeSchedule specifies the schedule of dates where the performance fee is charged (if PerformanceFee is defined). The default is calyears(1), meaning the performance fee is charged annually.

For more information, see “Defining Schedules for Backtest Strategies” on page 15-226.

Data Types: double | datetime | object

UserData — Strategy-specific user data for use in rebalanceFcn

[] (default) | struct

Strategy-specific user data for use in rebalanceFcn, specified as a struct. When UserData is set to a struct, the backtestEngine provides all user-defined rebalanceFcn function handle functions with the userData struct as an additional input argument. The rebalanceFcn function handle functions can read and write to the userData struct. The rebalanceFcn function handle functions return the updated userData struct as an additional output argument.

For an example of using UserData, see “Use UserData Property to Create Stop Loss Trading Strategy” on page 15-219 and “Backtest with Brinson Attribution to Evaluate Portfolio Performance” on page 4-311.

Data Types: struct

EngineDataList — Specify set of optional backtest state data a strategy needs in rebalanceFcn

[ ] (default) | string | string array

Specify set of optional backtest state data a strategy needs in the rebalanceFcn function handle, specified as a scalar string or string array. By default, the EngineDataList property is empty, indicating that no additional engine data is required.

If a strategy requires engine data, you can specify EngineDataList as a vector of strings containing the names of the required engineData. The backtestEngine creates an engineData struct with a field corresponding to each element in the EngineDataList. Valid engineData values are:

- Weights — The current portfolio weights before rebalancing,specified as decimal percentages. This is the default first argument to the rebalance function (RebalanceFcn).
- WeightsHistory — A timetable of Weights vectors for each past date in the backtest. This timetable holds the end-of-day asset weights for each asset for each day. Future dates in the timetable contain NaN values.
- PortfolioValue — The current portfolio value at the time the rebalance function (RebalanceFcn) is called, specified as a numeric scalar. This PortfolioValue is potentially different from the "end of day" portfolio value reported by the backtestEngine at the end of the backtest. Transaction costs and other fees are paid *after* the rebalance function is called, so the PortfolioValue passed into the rebalance function by the engineData struct may be different from the final portfolio value reported for that day after the backtest completes.
- PortfolioValueHistory — A timetable of portfolio values for the backtest. The timetable contains two columns. The BeforeExpenses column holds the portfolio value for each day before any expenses (transaction costs or fees). The EndOfDay column holds the portfolio value for each day, inclusive of all transaction costs and other fees. The values in the 2nd column (EndOfDay) match the final end-of-day portfolio values reported at the end of the backtest. Future dates in the timetable contain NaN values.
- FeesHistory — A timetable of fees charged for each day in the backtest. The FeesHistory timetable has two columns: Management and Performance for the management and performance fees, respectively. The management and performance fees are defined using the ManagementFee and PerformanceFee name-value arguments. Future dates in the timetable contain NaN values.

For an example of using EngineDataList, see “Use EngineDataList Property to Enforce Trading Strategy of Whole Shares” on page 15-222.

Data Types: string

Properties

Name — Strategy name

string

Strategy name, specified as a string.

Data Types: string

RebalanceFcn — Rebalance function

function handle

Rebalance function, specified as a function handle.

Data Types: `function_handle`

`RebalanceFrequency` — Rebalance frequency during backtest
`1` (default) | numeric | `duration` object | `calendarDuration` object | vector of datetimes

Rebalance frequency during the backtest, specified as a scalar numeric, `duration` or `calendarDuration` object, or vector of datetimes.

Data Types: `double` | `object` | `datetime`

`TransactionCosts` — Transaction costs
`0` (default) | numeric | vector | function handle

Transaction costs, specified as a scalar numeric, vector, or function handle.

Data Types: `double` | `function_handle`

`LookbackWindow` — Lookback window
`[0 Inf]` (default) | numeric | vector

Lookback window, specified as a scalar numeric or vector.

Data Types: `double`

`InitialWeights` — Initial weights
`[ ]` (default) | vector

Initial weights, specified as a vector.

Data Types: `double`

`ManagementFee` — Management fee charged as an annualized percent of the total portfolio value
`0` (default) | decimal

Management fee charged as an annualized percent of the total portfolio value, specified as a numeric scalar.

Data Types: `double`

`ManagementFeeSchedule` — Management fee schedule
`calyears(1)` (default) | integer | vector of datetimes | `duration` object | `calendarDuration` object

Management fee schedule, specified as scalar numeric, a vector of datetimes, or a `duration` or `calendarDuration` object.

Data Types: `double` | `datetime` | `object`

`PerformanceFee` — Performance fee charged as an absolute percent of the total portfolio growth
`0` (default) | decimal

Performance fee charged as an absolute percent of the total portfolio growth, specified as a numeric scalar.

Data Types: `double`

`PerformanceHurdle` — Annualized hurdle rate or column in assets or signals to act as hurdle asset

`0` (default) | decimal | string

Annualized hurdle rate or column in `assetPrices` or `signalData` to act as hurdle asset, specified as a numeric scalar or a string in either `assetPrices` or `signalData` as a hurdle asset.

Data Types: `double` | `string`

`PerformanceFeeSchedule` — Performance fee schedule

`calyears(1)` (default) | decimal | vector of datetimes | `duration` object | `calendarDuration` object

Performance fee schedule, specified as a scalar numeric, vector of datetimes, or a `duration` or `calendarDuration` object.

Data Types: `datetime` | `object`

`UserData` — Strategy-specific user data for use in `rebalanceFcn`

`[]` (default) | struct

Strategy-specific user data for use in `rebalanceFcn`, specified as a struct.

Data Types: `struct`

`EngineDataList` — Specify set of optional backtest state data a strategy needs in `rebalanceFcn`

`[]` (default) | string

Specify set of optional backtest state data a strategy needs in `rebalanceFcn`, specified as a scalar string or string array.

Data Types: `string`

Examples

Create Backtesting Strategies

Define a backtest strategy by using a `backtestStrategy` object. `backtestStrategy` objects contain properties specific to a trading strategy, such as the rebalance frequency, transaction costs, and a rebalance function. The rebalance function implements the core logic of the strategy and is used by the backtesting engine during the backtest to allow the strategy to change its asset allocation and to make trades. In this example, to illustrate how to create and use backtest strategies in MATLAB®, you prepare two simple strategies for backtesting:

1. An equal weighted strategy
2. A strategy that attempts to "chase returns"

The strategy logic for these two strategies is defined in the rebalance functions on page 15-218.

Set Strategy Properties

A `backtestStrategy` object has several properties that you set using parameters for the `backtestStrategy` function.

Initial Weights

The InitialWeights property contains the asset allocation weights at the start of the backtest. The default value for InitialWeights is empty ([]), which indicates that the strategy begins the backtest uninvested, meaning that 100% of the capital is in cash earning the risk-free rate.

Set the InitialWeights to a specific asset allocation. The size of the initial weights vector must match the number of assets in the backtest.

```
% Initialize the strategies with 30 weights, since the backtest
% data comes from a year of the 30 DJIA stocks.
numAssets = 30;

% Give the initial weights for both strategies equal weighting. Weights
% must sum to 1 to be fully invested.
initialWeights = ones(1,numAssets);
initialWeights = initialWeights / sum(initialWeights);
```

Transaction Costs

The TransactionCosts property allows you to set the fees that the strategy pays for trading assets. Transaction costs are paid as a percentage of the total change in position for each asset. Specify costs in decimal percentages. For example, if TransactionCosts is set to 1% (0.01) and the strategy buys $100 worth of a stock, then the transaction costs incurred are $1.

Transaction costs are set using a 1-by-2 vector that sets separate fee rates for purchases and sales of assets. In this example, both strategies pay the same transaction costs — 25 basis points for asset purchases and 50 basis points for sales.

```
% Define the Transaction costs as [buyCosts sellCost] and specify the costs
% as decimal percentages.
tradingCosts = [0.0025 0.005];
```

You can also set the TransactionCosts property to a function handle if you need to implement arbitrarily complex transaction cost structures. For more information on creating transaction cost functions, see backtestStrategy.

Rebalance Frequency

The RebalanceFrequency property determines how often the backtesting engine rebalances and reallocates the portfolio of a strategy using the rebalance function. Set the RebalanceFrequency in terms of time steps in the backtest. For example, if the backtesting engine is testing a strategy with a set of daily price data, then set the rebalance function in days. Essentially, RebalanceFrequency represents the number of rows of price data to process between each call to the strategy rebalance function.

```
% Both strategies rebalance every 4 weeks (20 days).
rebalFreq = 20;
```

Lookback Window

Each time the backtesting engine calls a strategy rebalance function, a window of asset price data (and possibly signal data) is passed to the rebalance function. The rebalance function can then make trading and allocation decisions based on a rolling window of market data. The LookbackWindow property sets the size of these rolling windows. Set the window in terms of time steps. The window determines the number of rows of data from the asset price timetable that are passed to the rebalance function.

The LookbackWindow property can be set in two ways. For a fixed-sized rolling window of data (for example, "50 days of price history"), the LookbackWindow property is set to a single scalar value (N = 50). The software then calls the rebalance function with a price timetable containing exactly N rows of rolling price data.

Alternatively, you can define the LookbackWindow property by using a 1-by-2 vector [min max] that specifies the minimum and maximum size for an expanding window of data. In this way, you can set flexible window sizes. For example:

- [10 Inf] — At least 10 rows of data
- [0 50] — No more than 50 rows of data
- [0 Inf] — All available data (that is, no minimum, no maximum); this is the default value
- [20 20] — Exactly 20 rows of data; this is equivalent to setting LookbackWindow to the scalar value 20

The software does not call the rebalance function if the data is insufficient to create a valid rolling window, regardless of the value of the RebalanceFrequency property.

If the strategy does not require any price or signal data history, then you can indicate that the rebalance function requires no data by setting the LookbackWindow property to 0.

```
% The equal weight strategy does not require any price history data.
ewLookback = 0;

% The "chase returns" strategy bases its decisions on the trailing
% 10-day asset returns. The lookback window is set to 11 since computing 10 days
% of returns requires the close price from day 0.
chaseLookback = 11;
```

Rebalance Function

The rebalance function (rebalanceFcn) is the user-authored function that contains the logic of the strategy. The backtesting engine calls the strategy rebalance function with a fixed set of parameters and expects it to return a vector of asset weights representing the new, desired portfolio allocation after a rebalance. For more information, see the rebalance functions on page 15-218.

Create Strategies

Using the prepared strategy properties, you can create the two strategy objects.

```
% Create the equal weighted strategy. The rebalance function @equalWeights
% is defined in the Rebalance Functions section at the end of this example.
equalWeightStrategy = backtestStrategy("EqualWeight",@equalWeight, ...
    'RebalanceFrequency',rebalFreq, ...
    'TransactionCosts',tradingCosts, ...
    'LookbackWindow',ewLookback, ...
    'InitialWeights',initialWeights)
```

```
equalWeightStrategy = 
  backtestStrategy with properties:

                  Name: "EqualWeight"
          RebalanceFcn: @equalWeight
    RebalanceFrequency: 20
      TransactionCosts: [0.0025 0.0050]
        LookbackWindow: 0
```

```
            InitialWeights: [0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 0.03
             ManagementFee: 0
     ManagementFeeSchedule: 1y
            PerformanceFee: 0
    PerformanceFeeSchedule: 1y
        PerformanceHurdle: 0
                  UserData: [0x0 struct]
            EngineDataList: [0x0 string]
```

```
% Create the "chase returns" strategy.  The rebalance function
% @chaseReturns is defined in the Rebalance Functions section at the end of this example.
chaseReturnsStrategy = backtestStrategy("ChaseReturns",@chaseReturns, ...
    'RebalanceFrequency',rebalFreq, ...
    'TransactionCosts',tradingCosts, ...
    'LookbackWindow',chaseLookback, ...
    'InitialWeights',initialWeights)
```

```
chaseReturnsStrategy = 
  backtestStrategy with properties:

                      Name: "ChaseReturns"
              RebalanceFcn: @chaseReturns
        RebalanceFrequency: 20
          TransactionCosts: [0.0025 0.0050]
            LookbackWindow: 11
            InitialWeights: [0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 0.0333 0.03
             ManagementFee: 0
     ManagementFeeSchedule: 1y
            PerformanceFee: 0
    PerformanceFeeSchedule: 1y
        PerformanceHurdle: 0
                  UserData: [0x0 struct]
            EngineDataList: [0x0 string]
```

Set Up Backtesting Engine

To backtest the two strategies, use the `backtestEngine` object. The backtesting engine sets parameters of the backtest that apply to all strategies, such as the risk-free rate and initial portfolio value. For more information, see `backtestEngine`.

```
% Create an array of strategies for the backtestEngine.
strategies = [equalWeightStrategy chaseReturnsStrategy];

% Create backtesting engine to test both strategies.
backtester = backtestEngine(strategies);
```

Rebalance Functions

Strategy rebalance functions defined using the `rebalanceFcn` argument for `backtestStrategy` must adhere to a fixed API that the backtest engine expects when interacting with each strategy. Rebalance functions must implement one of the following two syntaxes:

```
function new_weights = exampleRebalanceFcn(current_weights,assetPriceTimeTable)

function new_weights = exampleRebalanceFcn(current_weights,assetPriceTimeTable,signalDataTimeTab
```

All rebalance functions take as their first input argument the current allocation weights of the portfolio. current_weights represents the asset allocation just before the rebalance occurs. During a rebalance, you can use current_weights in a variety of ways. For example, you can use current_weights to determine how far the portfolio allocation has drifted from the target allocation or to size trades during the rebalance to limit turnover.

The second and third arguments of the rebalance function syntax are the rolling windows of asset prices and optional signal data. The two tables contain the trailing N rows of the asset and signal timetables that are passed to the runBacktest function, where N is set using the LookbackWindow property of each strategy.

If optional signal data is provided to the runBacktest function, then the backtest engine passes the rolling window of signal data to each strategy that supports it.

The equalWeight strategy simply invests equally across all assets.

```
function new_weights = equalWeight(current_weights,assetPrices) %#ok<INUSD>

% Invest equally across all assets.
num_assets = numel(current_weights);
new_weights = ones(1,num_assets) / num_assets;

end
```

The chaseReturns strategy invests only in the top *X* stocks based on their rolling returns in the lookback window. This naive strategy is used simply as an illustrative example.

```
function new_weights = chaseReturns(current_weights,assetPrices)

% Set number of stocks to invest in.
numStocks = 15;

% Compute rolling returns from lookback window.
rollingReturns = assetPrices{end,:} ./ assetPrices{1,:};

% Select the X best performing stocks over the lookback window
[~,idx] = sort(rollingReturns,'descend');
bestStocksIndex = idx(1:numStocks);

% Initialize new weights to all zeros.
new_weights = zeros(size(current_weights));

% Invest equally across the top performing stocks.
new_weights(bestStocksIndex) = 1;
new_weights = new_weights / sum(new_weights);

end
```

Use UserData Property to Create Stop Loss Trading Strategy

This example shows how to use the UserData property of backtestStrategy to create a stop loss trading strategy. A stop loss strategy sets a threshold to define how much money that you are willing to lose before closing a position. For example, if you bought a stock at $100, you could set a stop loss at $95, and if the stock price falls below that point, then you sell your position. You can then set a new price that is your buy-in price to buy back into the stock.

Load Data

```
% Load equity adjusted price data and convert to timetable
T = readtable('dowPortfolio.xlsx');
pricesTT = table2timetable(T(:,[1 3:end]),'RowTimes','Dates')
```

```
pricesTT=251×30 timetable
       Dates         AA       AIG      AXP      BA        C       CAT      DD       DIS      GE
    ___________    _____    _____    _____    _____    _____    _____    _____    _____    _____

    03-Jan-2006    28.72    68.41    51.53    68.63    45.26    55.86    40.68    24.18     33.6

```

Create Backtest Stop Loss Strategy

The stop loss strategy will either be 100% invested in the stock or 100% in cash. You can use two fields in the UserData struct for backtestStrategy to set the stop loss limits:

- StopLossPercent — How much you are willing to lose before selling, as a decimal percent
- BuyInPercent — How much *further* a stock must fall after you sell it before we buy back in, as a percent

In addition, the UserData struct has the following fields:

- Asset — Ticker symbol AIG for the asset you want to trade
- StopLossPrice — Threshold to sell the asset. If the price falls below this stop loss price, sell the asset and go to cash.
- BuyInPrice — Target price to buy the asset. If the asset is at this price or lower, buy the asset.

```
stopLossStrat = backtestStrategy("StopLoss",@stopLossSingleAsset,RebalanceFrequency=1);
```

```
% Setup the initial UserData
stopLossStrat.UserData = struct(StopLossPercent=0.05,BuyInPercent=0.02,Asset="AIG",StopLossPrice=
```

The backtest strategy starts 100% in cash. Normally the BuyInPrice is set by the strategy after you sell a stock, but in this case, you can initialize the BuyInPrice to be Inf. This triggers a stock buy on the first rebalance (since any price is less than Inf). You don't need to set the StopLossPrice at this point (it is set to nan) because the strategy sets the stop loss price once a stock purchase is made.

The strategy specifies that you are only willing to lose 5% of your capital before the stop loss is triggered and you sell. Then you will buy back into the stock if it falls by an additional 2%. You can set the rebalance frequency to `1` because this type of strategy has to "rebalance" every day in order to check the price to determine if any action is needed.

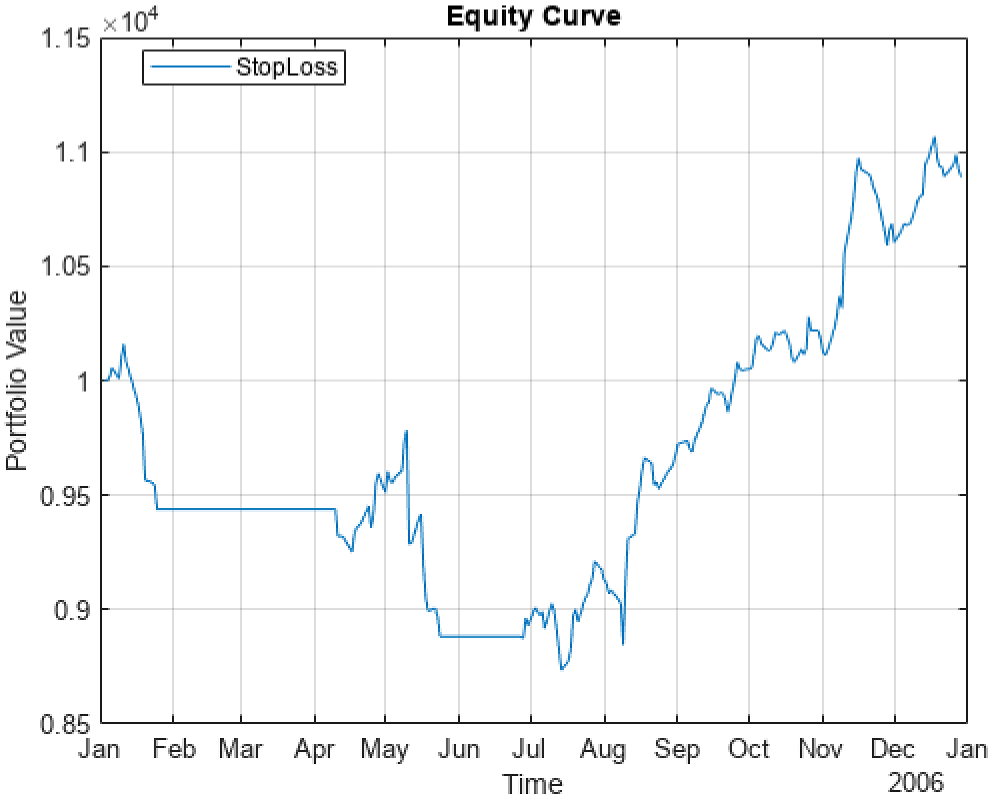
Run Backtest

Create a `backtestEngine` object and run the backtest using `runBacktest`.

```
backtester = backtestEngine(stopLossStrat);
backtester = runBacktest(backtester,pricesTT);
```

Use `equityCurve` to generate a plot the stop loss trading strategy.

```
equityCurve(backtester)
```



The flat parts of the equity curve are where the stop loss strategy has sold AIG and then later buys back into AIG.

Local Functions

```
function [new_weights,user_data] = incrementCounter(current_weights,prices,user_data)

% don't mess with the weights
new_weights = current_weights;

% increment the user data counter
user_data.Counter = user_data.Counter + 1;
```

```
end

function [new_weights,user_data] = stopLossSingleAsset(current_weights,prices,user_data)

% start with the existing weights
new_weights = current_weights;

% find column of the asset
asset = char(user_data.Asset);
assetIdx = find(strncmpi(asset,prices.Properties.VariableNames,numel(asset)));
assetPrice = prices{end,assetIdx};

% determine if we're currently invested or in cash
inCash = sum(current_weights) < 1e-5;

if inCash

    % We are in cash, see if we should buy back in
    if assetPrice <= user_data.BuyInPrice

        % Buy back in
        new_weights(assetIdx) = 1;
        % Set new stop loss price
        user_data.StopLossPrice = assetPrice * (1 - user_data.StopLossPercent);
    end

else

    % We are in the stock, see if we should sell
    if assetPrice <= user_data.StopLossPrice

        % Sell the stock
        new_weights(assetIdx) = 0;
        % Set new buy-in price
        user_data.BuyInPrice = assetPrice * (1 - user_data.BuyInPercent);
    end

end

end
```

Use EngineDataList Property to Enforce Trading Strategy of Whole Shares

This example shows how to use the `EngineDataList` property of `backtestStrategy` to enforce a trading strategy with a whole shares constraint.

Load Data

```
% Load equity adjusted price data and convert the data to timetable
T = readtable('dowPortfolio.xlsx');
pricesTT = table2timetable(T(:,[1 3:end]),'RowTimes','Dates')
```

```
pricesTT=251×30 timetable
        Dates         AA       AIG      AXP      BA        C       CAT      DD       DIS      GE
    ___________     ______   ______   ______   ______   ______   ______   ______   ______   ______

    18-Jan-2006    27.81    67.42    51.84    66.58    44.41    60.04    37.54    24.97    33.08
    19-Jan-2006    28.33    66.92    51.66    66.42    44.02    60.66    37.69       26    32.95
    20-Jan-2006    27.67    65.55    50.49    64.79    41.95    58.98    37.34    25.49     31.7
    23-Jan-2006    28.03    65.46    50.53     65.3    42.24    59.23    37.37    25.29    31.63
    24-Jan-2006    28.16    65.39    51.89    65.92    42.25    59.53    37.09    25.76    31.32
    25-Jan-2006    28.57    64.67    51.97    65.19    42.45    60.23    37.05    25.21    31.13
         ⋮
```

Create Backtest Strategies

This example runs a backtest on two equal-weighted strategies and then compares the results. The first backtest strategy uses an *exact* equal-weight rebalance function that allows fractional shares. The second backtest strategy uses a `EngineDataList` property for `PortfolioValue` to enforce a *whole shares* constraint.

Use `backtestStrategy` to create the first strategy for partial shares.

```
% Partial shares and equal weight for assets
partialRebal = @(~,prices) ones(1,width(prices)) / width(prices);
ewPartial = backtestStrategy("PartialShares",partialRebal,RebalanceFrequency=1);
```

Use `backtestStrategy` to create the second strategy for whole shares.

```
% Whole shares and equal weight for assets
ewWhole = backtestStrategy("WholeShares",@equalWeightShares,RebalanceFrequency=1,EngineDataList=
```

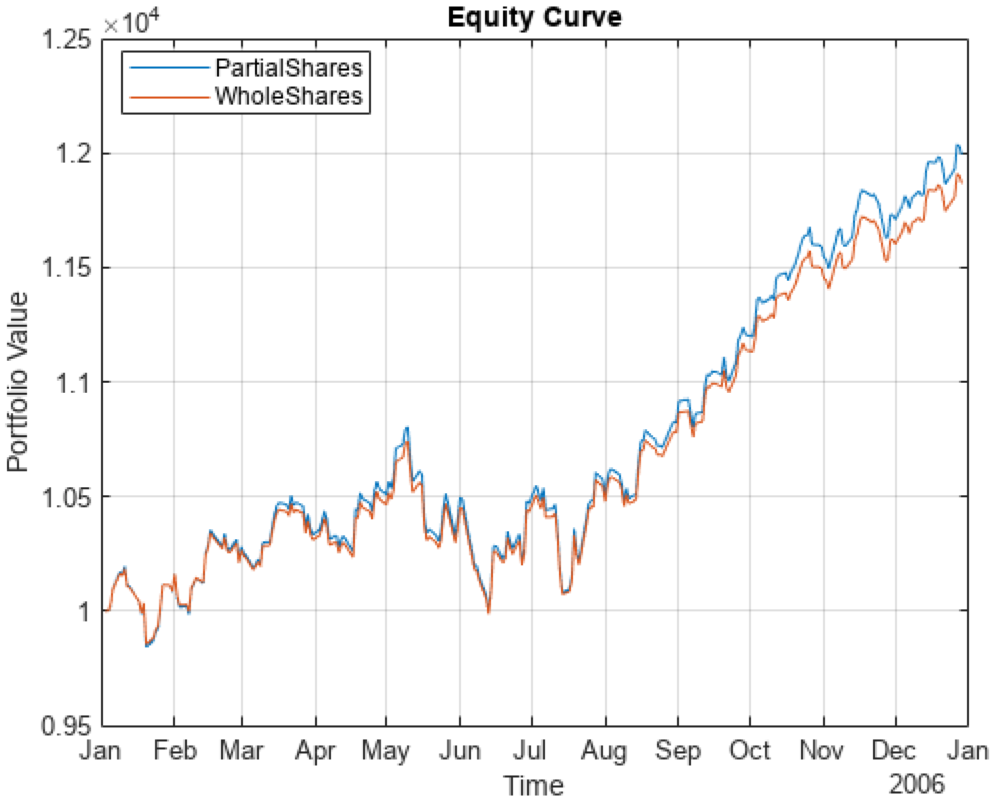
Run Backtest

Aggregate the two strategy objects, create a `backtestEngine` object, and then run the backtest using `runBacktest`.

```
strats = [ewPartial, ewWhole];
backtester = backtestEngine(strats,RiskFreeRate=0.02);
backtester = runBacktest(backtester,pricesTT);
```

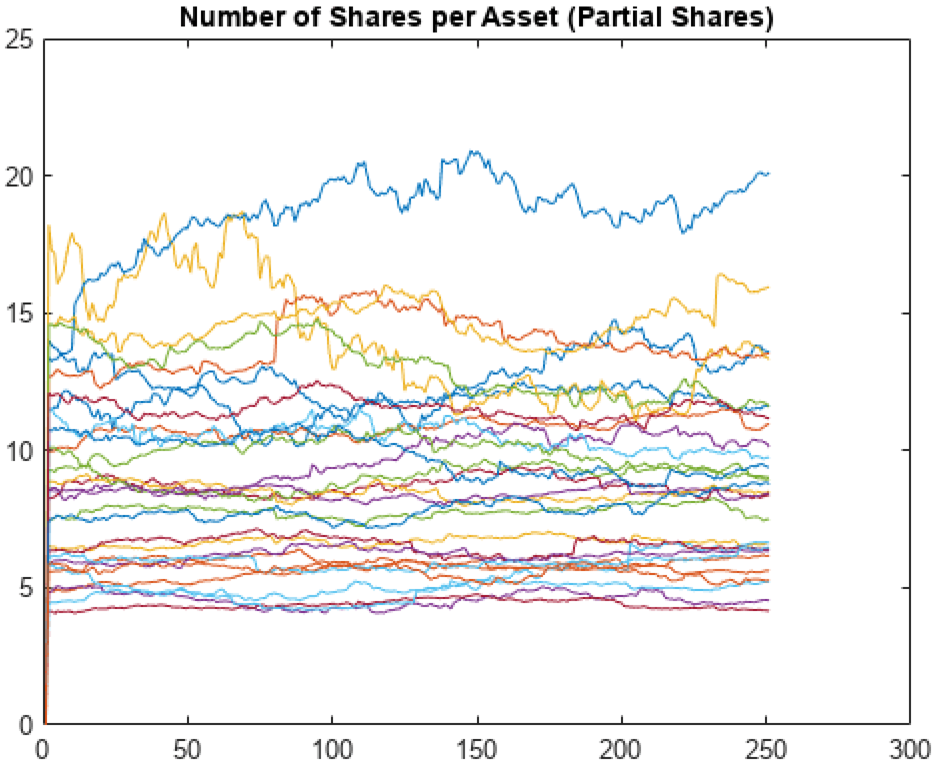
Use `equityCurve` to generate a plot for both of the trading strategies.

```
equityCurve(backtester);
```

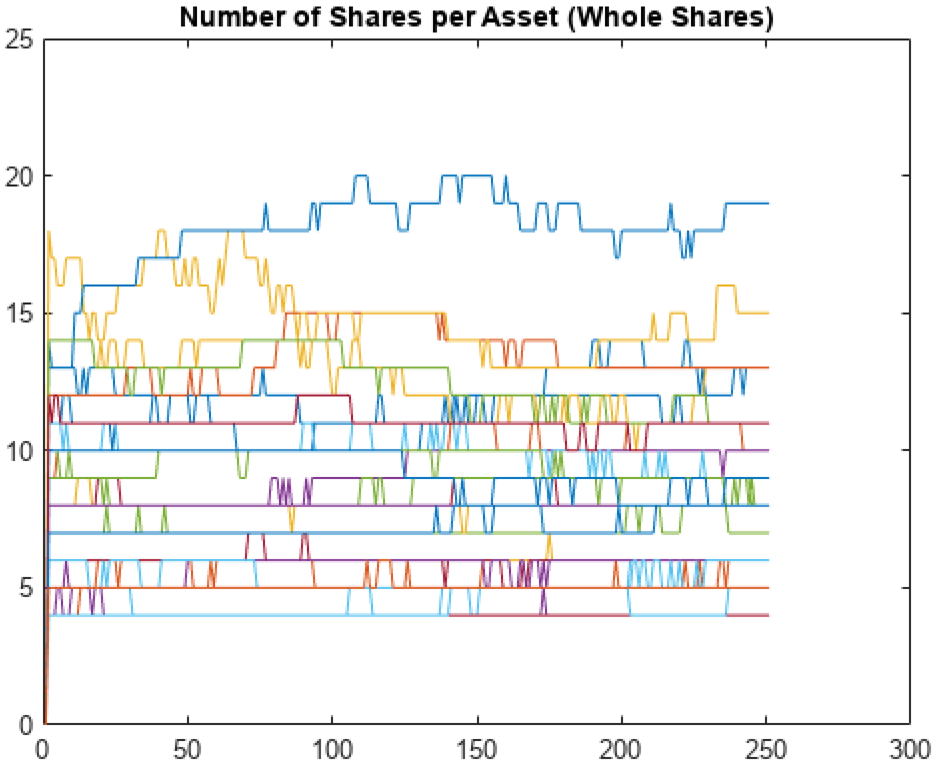


You can verify that the second strategy traded in whole shares.

```
% Plot the number of shares of each asset
plot(backtester.Positions.PartialShares{:,2:end} ./ pricesTT{:,:});
title('Number of Shares per Asset (Partial Shares)')
```



```
plot(backtester.Positions.WholeShares{:,2:end} ./ pricesTT{:,:})
title('Number of Shares per Asset (Whole Shares)')
```



Local Functions

```
function new_weights = equalWeightShares(engine_data,prices)

numAssets = width(prices);

% Dollars per asset for equal weight with partial shares
dollars_per_asset = engine_data.PortfolioValue / numAssets;
% Compute shares (partial shares first, then round down)
asset_shares = floor(dollars_per_asset ./ prices{end,:});
% Convert number of shares into dollars
asset_dollars = asset_shares .* prices{end,:};
% Convert dollars into weights
new_weights = asset_dollars / engine_data.PortfolioValue;

end
```

More About

Defining Schedules for Backtest Strategies

A backtesting schedule is a set of dates defining when specific events will occur.

The `backtestStrategy` object uses schedules in several of ways, including setting the rebalance frequency (`RebalanceFrequency`), the performance fee (`PerformanceFeeSchedule`), and the management fee (`ManagementFeeSchedule`) schedules. Schedules are specified with a syntax that supports a variety of data types, which include numeric scalars, a vector of datetimes, and duration or calendarDuration objects. The resulting schedules for the different data types are:

- Numeric — If a schedule is defined using a numeric scalar, it refers to the number of rows (of the assetPrices timetable) between each event in the schedule, starting from the backtest start date. For example, if a schedule is set to 10, then the schedule event (a rebalance date or fee payment date) occurs on every 10th row of the prices timetable while the backtest runs.
- duration or calendarDuration — If specified as a duration or calendarDuration object, the schedule specifies a duration of time between each event (rebalance date or fee payment date). The schedule is calculated starting at the backtest start date and then schedule dates are added after each step of the specified duration.
- Vector of datetimes — If the numeric or duration syntaxes are not appropriate, then you can explicitly specify schedules using a vector of datetimes.

Note For both the duration and datetime syntaxes, if a resulting schedule date is not found in the backtest data set (the assetPrices timetable), the backtestEngine either adjusts the date to the nearest valid date or else issues an error. This behavior is controlled by the DateAdjustment property of the backtestEngine object. By default, dates are adjusted to the nearest previous date. For example, if a schedule date falls on a Saturday, and is not found in the backtest data set, then the date is adjusted to the previous Friday. Alternatively, the backtestEngine DateAdjustment property allows you to adjust dates to the next valid date, or to issue an error if a date is not found by requiring exact dates.

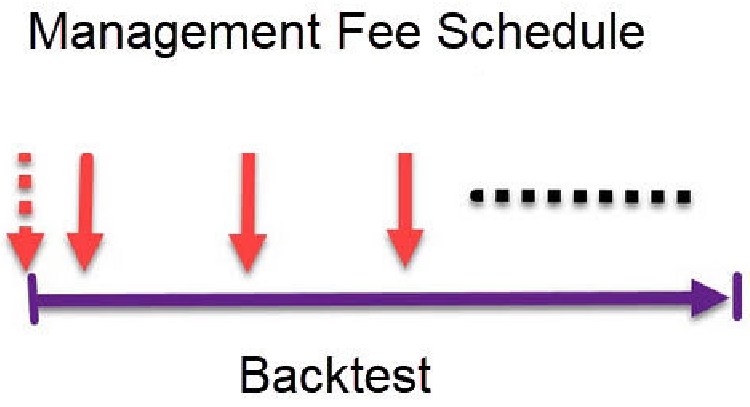
Management Fees

The management fee is the annualized rate charged on the assets under management of the strategy to pay for the fund's management costs.

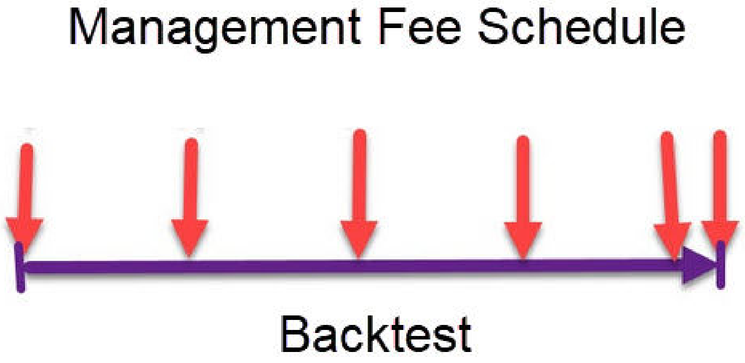
The fee is charged on each date specified by the ManagementFeeSchedule name-value argument. For more information, see “Defining Schedules for Backtest Strategies” on page 15-226.

The management fee is forward looking, meaning that a fee paid on a given date covers the management of the strategy from that date to the next management fee date. For some syntaxes of theManagementFeeSchedule, the resulting schedule does not begin and end precisely on the backtest start and end dates. In these cases, the backtest engine adds default dates to the start and end of the schedule to ensure that the entire backtest is covered by management fees. For example:

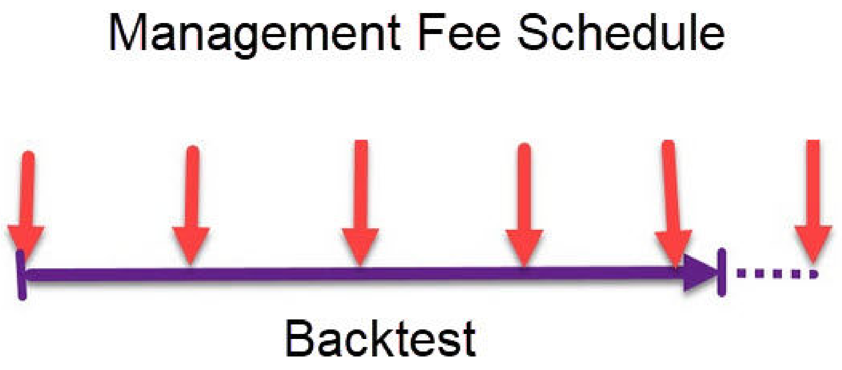
- If ManagementFeeSchedule is specified as a vector of datetimes, and the backtest start date is not included in the vector, then the start date is added to the fee schedule.



- If `ManagementFeeSchedule` is specified as a numeric scalar or a vector of datetimes, and the final specified fee date occurs before the backtest end date, then the backtest end date is added to the fee schedule.



- If `ManagementFeeSchedule` is specified as a `duration` or `calendarDuration` object, and the backtest end date is not included in the generated schedule, then a final fee date is added to the end by adding the duration object to the (previous) final fee date. This adjustment can produce a final fee date that is beyond the end of the backtest, but it results in more realistic fees paid at the final payment date.



For more information on where the resulting management fees are reported, see the `backtestEngine` object read-only property "Fees" on page 15-0 .

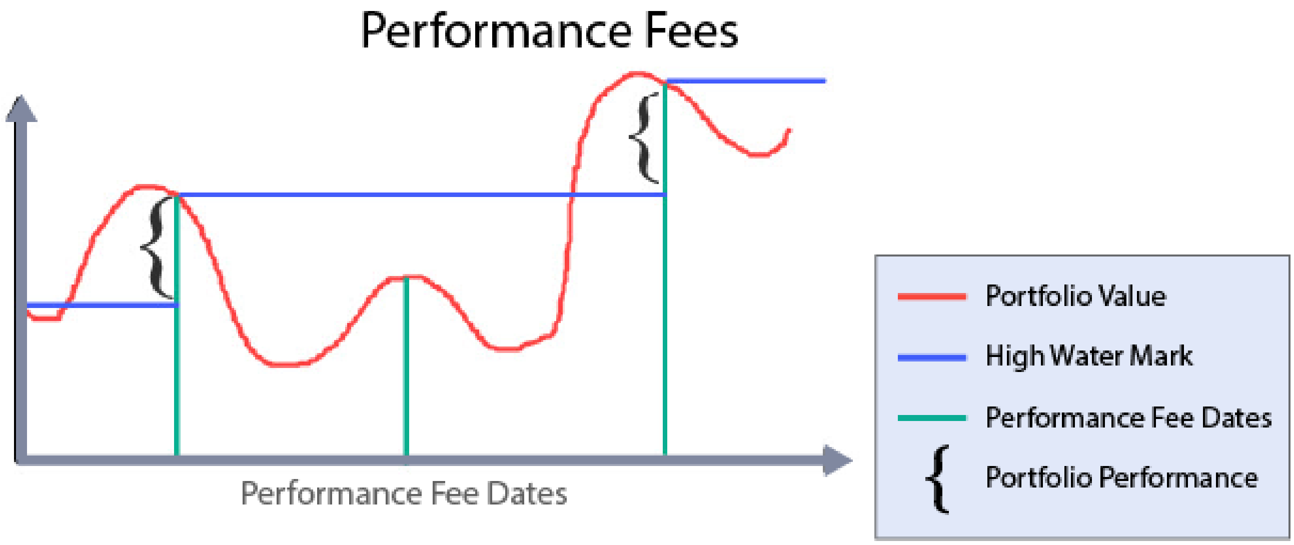
Performance Fees

A performance fee, or incentive fee, is a periodic payment that is paid by fund investors based on the fund's performance.

The performance fee can have a variety of structures, but it often is calculated as a percentage of a fund's *increase* in NAV over some tracked high-water mark. This calculation ensures the fee is paid only when the investment manager produces positive results. Performance fees in hedge funds are sometimes set at 20%, meaning if the fund NAV goes from $1M to $1.2M, a fee of $40k would be charged (20% of the $200k growth).

During the backtest, the backtest engine tracks a high-water mark. The high-water mark starts at the portfolio initial value. At each performance fee date, if the portfolio value is greater than the previous high-water mark, then the high-water mark is updated to the new portfolio value and the performance fee is paid on the growth of the portfolio. The portfolio growth is the difference between the new high-water mark and the previous one. If, on a performance fee date, the portfolio value is less than the previous high-water mark, then no fee is paid and the high-water mark is not updated.

The high-water mark is typically updated at each performance fee date and does not track maximum portfolio values between dates, as illustrated:



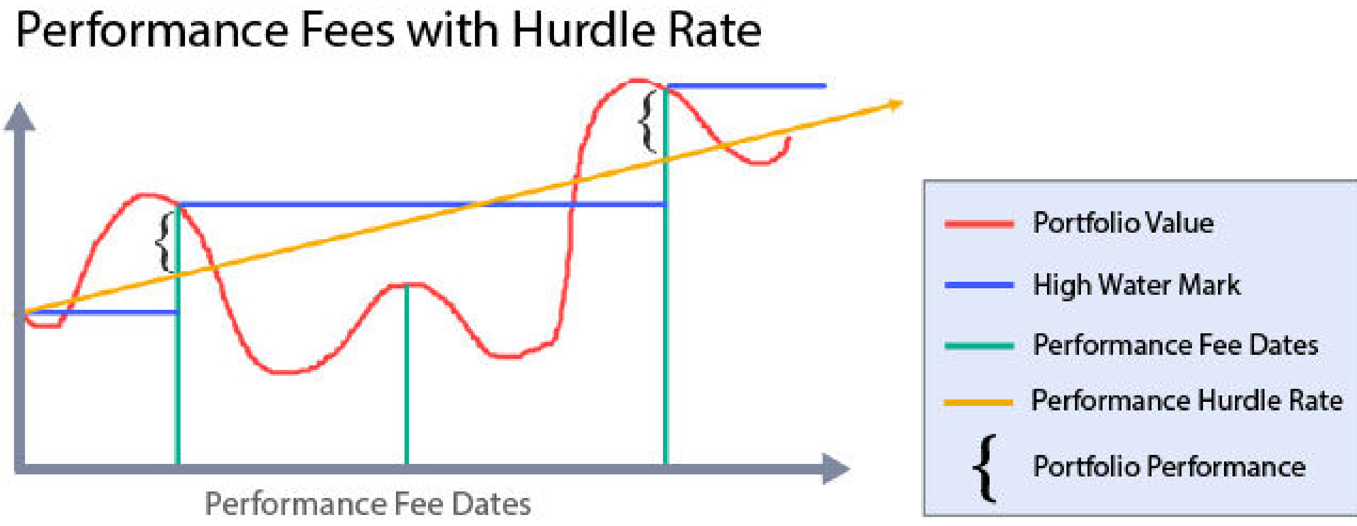
For more information on where the resulting performance fees are reported, see the `backtestEngine` object read-only property “Fees” on page 15-0 .

Performance Hurdle

A hurdle is an optional feature of a performance fee.

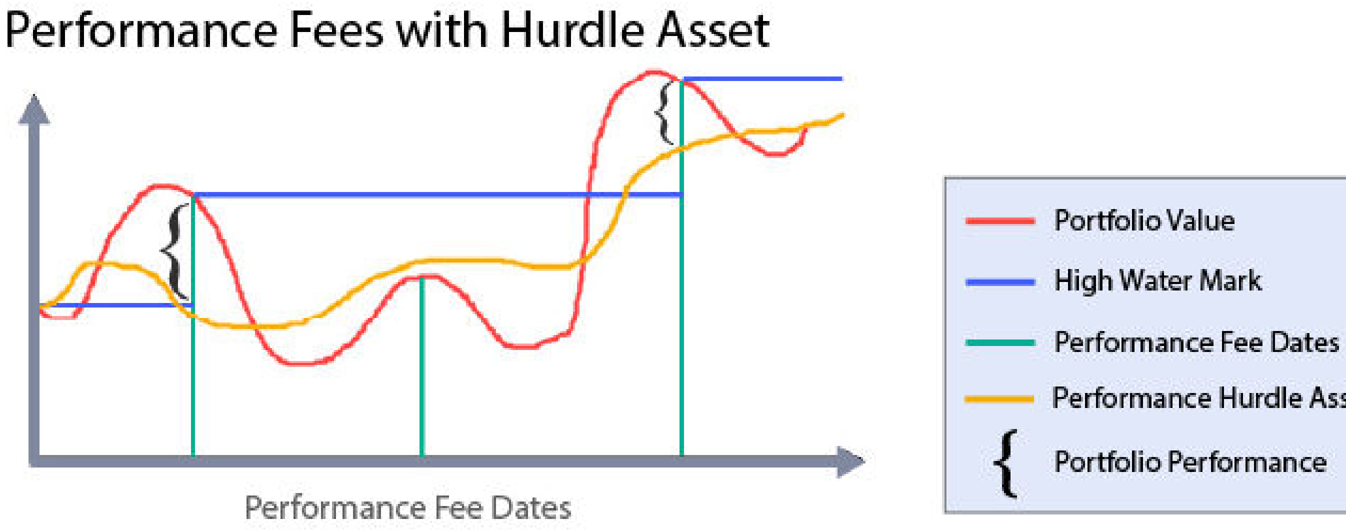
A hurdle sets a minimum performance threshold that a fund must beat before the performance fee is charged. Hurdles can be fixed rates of return, a *hurdle rate*, such as 5%. For example, if the fund NAV goes from $1M to $1.2M, the performance fee is charged only on the performance beyond 5%. A 5% hurdle rate on $1M sets the target hurdle value at $1.05M. The $1.2M portfolio is $150k over the hurdle value. The performance fee is charged only on that $150k, so 20% of $150k is a $30k performance fee.

The following figure illustrates a 5% hurdle rate.



You can also specify a performance hurdle as a benchmark asset or index. In this case, the performance fee is paid only on the fund performance in excess of the hurdle instrument. For example, assume that the fund NAV goes from $1M to $1.2M and you have specified the S&P500 as your hurdle. If the S&P500 index returns 25% over the same period, then no performance fee is paid because the fund did not produce returns in excess of the hurdle instrument. If the fund value is greater than the hurdle, but still less than the previous high-water mark, again, no performance fee is paid.

At each performance fee date, the fund charges the performance fee on the difference between the current fund value and the maximum of the high-water mark and the hurdle value. The high-water mark is updated only if a performance fee is paid.



For more information on where the resulting performance fees are reported, see the `backtestEngine` object read-only property “Fees” on page 15-0 .

Version History

Introduced in R2020b

R2023a: Support for data sharing in user-defined function handles

The `backtestStrategy` name-value argument for `UserData` supports strategy-specific user data for use in the user-defined function handles for the rebalance function. Also the `backtestStrategy` name-value argument for `EngineDataList` enables you to specify the set of optional backtest state data that a strategy needs in the user-defined function handles.

R2022b: Management and performance fees

The `backtestStrategy` object supports name-value arguments for `ManagementFee`, `ManagementFeeSchedule`, `PerformanceFee`, `PerformanceHurdle`, and `PerformanceFeeSchedule`.

R2022a: Include NaN values in asset price data

Behavior changed in R2022a

The `backtestStrategy` object supports `NaN`s in the `assetPrices` timetable and `NaN`s and `<missing>` in the `signalData` timetable.

Backtesting Strategy Framework in Financial Toolbox (2 min 17 sec)

backtestEngine

Create backtestEngine object to backtest strategies and analyze results

Description

Create a backtestEngine to run a backtest of portfolio investment strategies on historical data.

Use this workflow to develop and run a backtest:

1. Define the strategy logic using a backtestStrategy object to specify how a strategy rebalances a portfolio of assets.
2. Use backtestEngine to create a backtestEngine object that specifies parameters of the backtest.
3. Use runBacktest to run the backtest against historical asset price data and, optionally, trading signal data.
4. Use equityCurve to plot the equity curves of each strategy.
5. Use summary to summarize the backtest results in a table format.

For more detailed information on this workflow, see “Backtest Investment Strategies Using Financial Toolbox™” on page 4-231.

Creation

Syntax

```
backtester = backtestEngine(strategies)
backtester = backtestEngine( ___ ,Name,Value)
```

Description

backtester = backtestEngine(strategies) creates a backtestEngine object. Use the backtestEngine object to backtest the portfolio trading strategies defined in the backtestStrategy objects.

backtester = backtestEngine(___ ,Name,Value) sets properties on page 15-236 using name-value pair arguments and any of the arguments in the previous syntax. You can specify multiple name-value pair arguments. For example, backtester = backtestEngine(strategies,'RiskFreeRate',0.02,'InitialPortfolioValue',1000,'RatesConvention',"Annualized",'Basis',2).

Input Arguments

strategies — Backtest strategies
vector of backtestStrategy objects

Backtest strategies, specified as a vector of backtestStrategy objects. Each backtestStrategy object defines a portfolio trading strategy.

Data Types: `object`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `backtester = backtestEngine(strategies,'RiskFreeRate',0.02,'InitialPortfolioValue',1000,'RatesConvention',"Annualized",'Basis',2)`

`RiskFreeRate` — Risk free rate

`0` (default) | numeric | timetable

Risk free rate, specified as the comma-separated pair consisting of `'RiskFreeRate'` and a scalar numeric or a one-column timetable.

Note If you specify a timetable:

- The dates in the specified `timetable` must include the start and end dates of the backtest.
- The series of dates in the specified timetable between the start and end dates (inclusive) must correspond exactly to the corresponding series of dates in the `assetPrices` timetable.

If `RatesConvention` is `"Annualized"`, then `RiskFreeRate` specifies an annualized rate.

If `RatesConvention` is `"PerStep"`, then the `RiskFreeRate` is a decimal percentage and represents the risk free rate for one time step in the backtest. For example, if the backtest uses daily asset price data, then the `RiskFreeRate` value must be the daily rate of return for cash.

Data Types: `double` | `timetable`

`CashBorrowRate` — Cash borrowing rate

`0` (default) | numeric | timetable

Cash borrowing rate, specified as the comma-separated pair consisting of `'CashBorrowRate'` and a scalar numeric or a one-column timetable.

Note If you specify a timetable:

- The dates in the specified `timetable` must include the start and end dates of the backtest.
- The series of dates in the specified timetable between the start and end dates (inclusive) must correspond exactly to the corresponding series of dates in the `assetPrices` timetable.

The `CashBorrowRate` specifies the rate of interest accrual on negative cash balances (margin) during the backtest.

If `RatesConvention` is `"Annualized"`, then `CashBorrowRate` specifies an annualized rate.

If RatesConvention is "PerStep", then the CashBorrowRate value is a decimal percentage and represents the interest accrual rate for one time step in the backtest. For example, if the backtest is using daily asset price data, then the CashBorrowRate value must be the daily interest rate for negative cash balances.

Data Types: double | timetable

InitialPortfolioValue — Initial portfolio value

10000 (default) | numeric

Initial portfolio value, specified as the comma-separated pair consisting of 'InitialPortfolioValue' and a scalar numeric.

Data Types: double

RatesConvention — Defines how backtest engine uses RiskFreeRate and CashBorrowRate to compute interest

"Annualized" (default) | character vector with value 'Annualized' or 'PerStep' | string with value "Annualized" or "PerStep"

Defines how backtest engine uses RiskFreeRate and CashBorrowRate to compute interest, specified as the comma-separated pair consisting of 'RatesConvention' and a character vector or string.

- 'Annualized' — The rates are treated as annualized rates and the backtest engine computes incremental interest based on the day count convention specified in the Basis property. This is the default.
- 'PerStep' — The rates are treated as per-step rates and the backtest engine computes interest at the provided rates at each step of the backtest.

Data Types: char | string

DateAdjustment — Date handling behavior for rebalance dates that are missing from asset prices timetable

"Previous" (default) | character vector with value 'Previous', 'Next', or 'None' | string with value "Previous", "Next", or "None"

Date handling behavior for rebalance dates that are missing from asset prices timetable, specified as the comma-separated pair consisting of 'DateAdjustment' and a character vector or string.

- 'Previous' — For each rebalance date in the rebalance schedule, the rebalance occurs on the nearest date in the asset timetable that occurs on or before the requested rebalance date. This is the default.
- 'Next' — Move to the next date.
- 'None' — Dates are not adjusted and the backtest engine errors when encountering a rebalance date that does not appear in the asset prices timetable.

Data Types: char | string

Basis — Defines day-count convention when computing interest at RiskFreeRate or CashBorrowRate

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Defines the day-count convention when computing interest at the `RiskFreeRate` or `CashBorrowRate`, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-16.

Note `Basis` is only used when the `RatesConvention` property is set to `"Annualized"`. If the `RatesConvention` is `"PerStep"`, and `Basis` is set, `backtestEngine` ignores the `Basis` value.

Data Types: `double`

Properties

`Strategies` — Backtest strategies
vector of `backtestStrategy` objects

Backtest strategies, specified as a vector of `backtestStrategy` objects.

Data Types: `object`

`RiskFreeRate` — Risk free rate
`0` (default) | numeric | timetable

Risk free rate, specified as a scalar numeric or timetable.

Data Types: `double`

`CashBorrowRate` — Cash borrowing rate
`0` (default) | numeric | timetable

Cash borrowing rate, specified as a scalar numeric or timetable.

Data Types: `double`

InitialPortfolioValue — Initial portfolio value

10000 (default) | numeric

Initial portfolio value, specified as a scalar numeric.

Data Types: double

AnnualizedRates — Use annualized rates for RiskFreeRate and CashBorrowRate

true (default) | logical with value true or false

Use annualized rates for RiskFreeRate and CashBorrowRate, specified as a scalar logical.

Data Types: logical

DateAdjustment — Date handling behavior for rebalance dates that are missing from asset prices timetable

"Previous" (default) | string with value "Previous", "Next", or "None"

Date handling behavior for rebalance dates that are missing from asset prices timetable, specified as a string.

Data Types: char | string

Basis — Day-count basis of annualized rates for RiskFreeRate and CashBorrowRate

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of annualized rates for RiskFreeRate and CashBorrowRate, specified a scalar integer.

Data Types: double

NumAssets — Number of assets in portfolio universe

[] (default) | numeric

This property is read-only.

Number of assets in the portfolio universe, a numeric. NumAssets is derived from the timetable of adjusted prices passed to runBacktest. NumAssets is empty until you run the backtest using the runBacktest function.

Data Types: double

Returns — Strategy returns

[] (default) | timetable

This property is read-only.

Strategy returns, a NumTimeSteps-by-NumStrategies timetable of strategy returns. Returns are per time step. For example, if you use daily prices with runBacktest, then Returns is the daily strategy returns. Returns is empty until you run the backtest using the runBacktest function.

Data Types: timetable

Positions — Asset positions for each strategy

[] (default) | structure

This property is read-only.

Asset positions for each strategy, a structure containing a NumTimeSteps-by-NumAssets timetable of asset positions for each strategy. For example, if you use daily prices in the runBacktest, then the

`Positions` structure holds timetables containing the daily asset positions. `Positions` is empty until you run the backtest using the `runBacktest` function.

Data Types: `struct`

`Turnover` — Strategy turnover
`[]` (default) | timetable

This property is read-only.

Strategy turnover, a `NumTimeSteps`-by-`NumStrategies` timetable. `Turnover` is empty until you run the backtest using the `runBacktest` function.

Data Types: `timetable`

`BuyCost` — Transaction costs for asset purchases of each strategy
`[]` (default) | timetable

This property is read-only.

Transaction costs for the asset purchases of each strategy, a `NumTimeSteps`-by-`NumStrategies` timetable. `BuyCost` is empty until you run the backtest using the `runBacktest` function.

Data Types: `timetable`

`SellCost` — Transaction costs for asset sales of each strategy
`[]` (default) | timetable

This property is read-only.

Transaction costs for the asset sales of each strategy, a `NumTimeSteps`-by-`NumStrategies` timetable. `SellCost` is empty until you run the backtest using the `runBacktest` function.

Data Types: `timetable`

`Fees` — Paid fees for management and performance fees
`[]` (default) | struct

This property is read-only.

Paid fees for management and performance fees, a struct containing a timetable for each strategy which holds all the fees paid by the strategy. The `Fees` timetable contains an entry for each date where at least one fee was paid. Each column holds the amount paid for a particular type of fee. If no fees are paid, then the `Fees` timetable is empty.

For more information on management and performance fees defined using a `backtestStrategy` object, see "Management Fees" on page 15-227, "Performance Fees" on page 15-229, and "Performance Hurdle" on page 15-230.

Data Types: `timetable`

Object Functions

runBacktest	Run backtest on one or more strategies
summary	Generate summary table of backtest results
equityCurve	Plot equity curves of strategies

Examples

Backtest Strategy Using backtestEngine

Use a backtesting engine in MATLAB® to run a backtest on an investment strategy over a time series of market data. You can define a backtesting engine by using `backtestEngine` object. A `backtestEngine` object sets properties of the backtesting environment, such as the risk-free rate, and holds the results of the backtest. In this example, you can create a backtesting engine to run a simple backtest and examine the results.

Create Strategy

Define an investment strategy by using the `backtestStrategy` function. This example builds a simple equal-weighted investment strategy that invests equally across all assets. For more information on creating backtest strategies, see `backtestStrategy`.

```
% The rebalance function is simple enough that you can use an anonymous function
equalWeightRebalanceFcn = @(current_weights,~) ones(size(current_weights)) / numel(current_weigh

% Create the strategy
strategy = backtestStrategy("EqualWeighted",equalWeightRebalanceFcn,...
    'RebalanceFrequency',20,...
    'TransactionCosts',[0.0025 0.005],...
    'LookbackWindow',0)
```

```
strategy = 
  backtestStrategy with properties:

                    Name: "EqualWeighted"
            RebalanceFcn: @(current_weights,~)ones(size(current_weights))/numel(current_weights
      RebalanceFrequency: 20
        TransactionCosts: [0.0025 0.0050]
          LookbackWindow: 0
          InitialWeights: [1x0 double]
           ManagementFee: 0
   ManagementFeeSchedule: 1y
          PerformanceFee: 0
  PerformanceFeeSchedule: 1y
       PerformanceHurdle: 0
                UserData: [0x0 struct]
          EngineDataList: [0x0 string]
```

Set Backtesting Engine Properties

The backtesting engine has several properties that you set by using parameters to the `backtestEngine` function.

Risk-Free Rate

The `RiskFreeRate` property holds the interest rate earned for uninvested capital (that is, cash). When the sum of portfolio weights is below 1, the remaining capital is invested in cash and earns the risk-free rate. The risk-free rate and the cash-borrow rate can be defined in annualized terms or as explicit "per-time-step" interest rates. The `RatesConvention` property is used to specify how the `backtestEngine` interprets the two rates (the default interpretation is "Annualized"). For this example, set the risk-free rate to 2% annualized.

```
% 2% annualized risk-free rate
riskFreeRate = 0.02;
```

Cash Borrow Rate

The CashBorrowRate property sets the interest accrual rate applied to negative cash balances. If at any time the portfolio weights sum to a value greater than 1, then the cash position is negative by the amount in excess of 1. This behavior of portfolio weights is analogous to borrowing capital on margin to invest with leverage. Like the RiskFreeRate property, the CashBorrowRate property can either be annualized or per-time-step depending on the value of the RatesConvention property.

```
% 6% annualized margin interest rate
cashBorrowRate = 0.06;
```

Initial Portfolio Value

The InitialPortfolioValue property sets the value of the portfolio at the start of the backtest for all strategies. The default is $10,000.

```
% Start backtest with $1M
initPortfolioValue = 1000000;
```

Create Backtest Engine

Using the prepared properties, create the backtesting engine using the backtestEngine function.

```
% The backtesting engine takes an array of backtestStrategy objects as the first argument
backtester = backtestEngine(strategy,...
    'RiskFreeRate',riskFreeRate,...
    'CashBorrowRate',cashBorrowRate,...
    'InitialPortfolioValue',initPortfolioValue)
```

```
backtester = 
  backtestEngine with properties:

               Strategies: [1x1 backtestStrategy]
             RiskFreeRate: 0.0200
           CashBorrowRate: 0.0600
          RatesConvention: "Annualized"
                    Basis: 0
    InitialPortfolioValue: 1000000
           DateAdjustment: "Previous"
                NumAssets: []
                  Returns: []
                Positions: []
                 Turnover: []
                  BuyCost: []
                 SellCost: []
                     Fees: []
```

Several additional properties of the backtesting engine are initialized to empty. The backtesting engine populates these properties, which contain the results of the backtest, upon completion of the backtest.

Load Data and Run Backtest

Run the backtest over daily price data from the 30 component stocks of the DJIA.

```
% Read table of daily adjusted close prices for 2006 DJIA stocks
T = readtable('dowPortfolio.xlsx');

% Remove the DJI index column and convert to timetable
pricesTT = table2timetable(T(:,[1 3:end]),'RowTimes','Dates');
```

Run the backtest using the `runBacktest` function.

```
backtester = runBacktest(backtester,pricesTT)
```

```
backtester = 
  backtestEngine with properties:

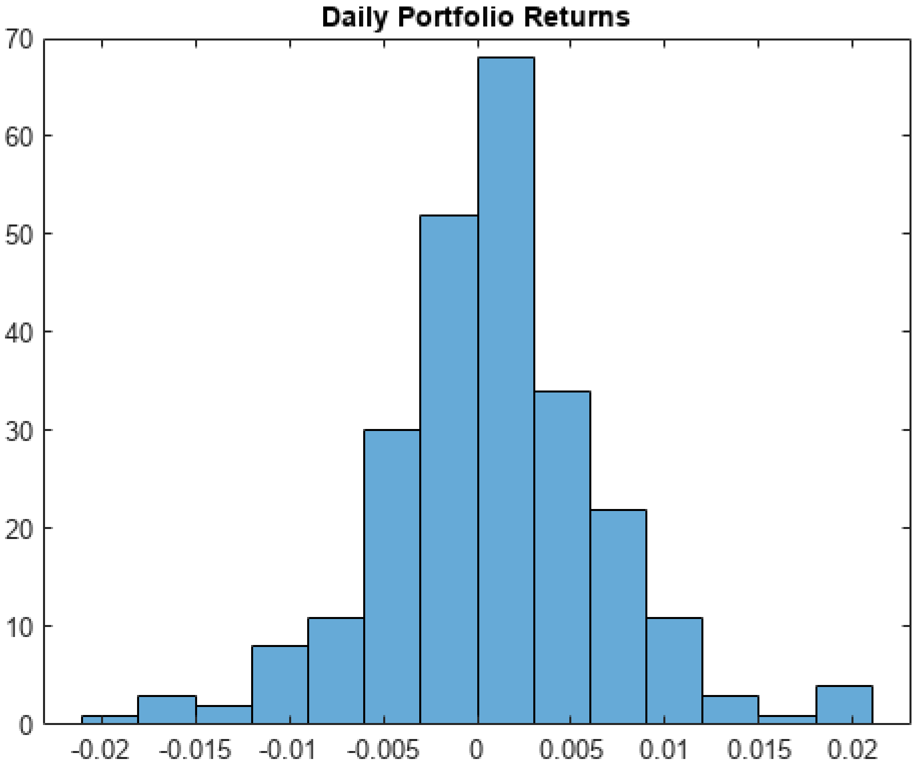
               Strategies: [1x1 backtestStrategy]
             RiskFreeRate: 0.0200
           CashBorrowRate: 0.0600
          RatesConvention: "Annualized"
                    Basis: 0
    InitialPortfolioValue: 1000000
           DateAdjustment: "Previous"
                NumAssets: 30
                  Returns: [250x1 timetable]
                Positions: [1x1 struct]
                 Turnover: [250x1 timetable]
                  BuyCost: [250x1 timetable]
                 SellCost: [250x1 timetable]
                     Fees: [1x1 struct]
```

Examine Results

The backtesting engine populates the read-only properties of the `backtestEngine` object with the backtest results. Daily values for portfolio returns, asset positions, turnover, transaction costs, and fees are available to examine.

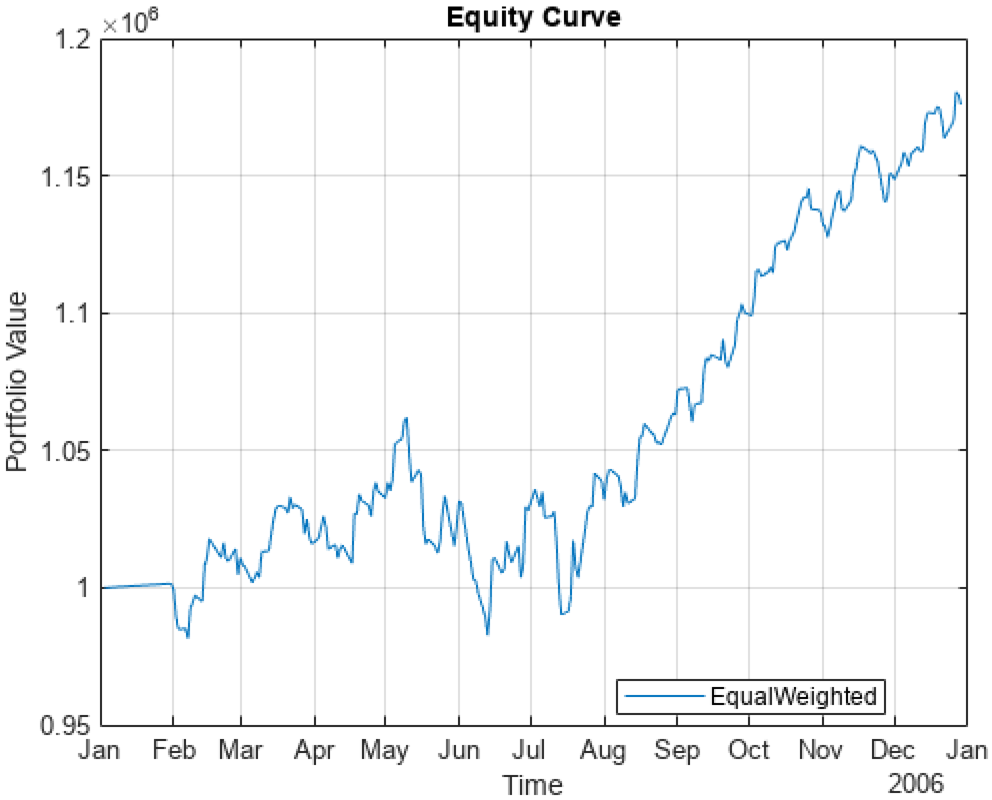
Examine the daily returns.

```
% Generate a histogram of daily portfolio returns
histogram(backtester.Returns{:,1})
title('Daily Portfolio Returns')
```



Use `equityCurve` to plot the equity curve for the simple equal-weighted investment strategy.

```
equityCurve(backtester)
```



Version History

Introduced in R2020b

R2022b: Management and performance fees

Behavior changed in R2022b

The `backtestEngine` object supports a read-only property for `Fees`that reports the management and performance fees paid during a backtest. The `Fees` property is a struct containing a timetable for each strategy and the timetable holds all the fees paid by the strategy.

R2022a: Specify time varying cash rates of return

The `backtestEngine` name-value arguments for `RiskFreeRate` and `CashBorrowRate` support a `timetable` data type.

R2022a: Control how the backtesting framework handles missing rebalance dates

Behavior changed in R2022a

The name-value argument for `DateAdjustment` enables you to control the date handling behavior for rebalance dates that are missing from the `assetPrices` timetable. If a rebalance date falls on a holiday, you can specify the `"Next"` or `"None"` option for `DateAdjustment`.

Backtesting Strategy Framework in Financial Toolbox (2 min 17 sec)

runBacktest

Run backtest on one or more strategies

Syntax

```
backtester = runBacktest(backtester,pricesTT)
backtester = runBacktest(backtester,pricesTT,signalTT)
backtester = runBacktest( ___ ,Name,Value)
```

Description

`backtester = runBacktest(backtester,pricesTT)` runs the backtest over the timetable of adjusted asset price data.

`runBacktest` initializes each strategy previously defined using `backtestStrategy` to the `InitialPortfolioValue` and then begins processing the timetable of price data (`pricesTT`) as follows:

1. At each time step, the `runBacktest` function applies the asset returns to the strategy portfolio positions.
2. The `runBacktest` function determines which strategies to rebalance based on the `RebalanceFrequency` property of the `backtestStrategy` objects.
3. For strategies that need rebalancing, the `runBacktest` function calls their rebalance functions with a rolling window of asset price data based on the `LookbackWindow` property of each `backtestStrategy`.
4. Transaction costs are calculated and charged based on the changes in asset positions and the `TransactionCosts` property of each `backtestStrategy` object.
5. After the backtest is complete, the results are stored in several properties of the `backtestEngine` object.

`backtester = runBacktest(backtester,pricesTT,signalTT)` run the backtest using the adjusted asset price data and signal data. When you specify the signal data timetable (`signalTT`), then the `runBacktest` function runs the backtest and additionally passes a rolling window of signal data to the rebalance function of each strategy during the rebalance step.

`backtester = runBacktest( ___ ,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax. For example, `backtester = runBacktest(backtester,assetPrices,'Start',50,'End',100)`.

Examples

Run Backtests

The MATLAB® backtesting engine runs backtests of portfolio investment strategies over timeseries of asset price data. After creating a set of backtest strategies using `backtestStrategy` and the backtest engine using `backtestEngine`, the `runBacktest` function executes the backtest. This example illustrates how to use the `runBacktest` function to test investment strategies.

Load Data

Load one year of stock price data. For readability, this example only uses a subset of the DJIA stocks.

```
% Read table of daily adjusted close prices for 2006 DJIA stocks
T = readtable('dowPortfolio.xlsx');

% Prune the table on only hold the dates and selected stocks
timeColumn = "Dates";
assetSymbols = ["BA", "CAT", "DIS", "GE", "IBM", "MCD", "MSFT"];
T = T(:,[timeColumn assetSymbols]);

% Convert to timetable
pricesTT = table2timetable(T,'RowTimes','Dates');

% View the final asset price timetable
head(pricesTT)
```

```
       Dates         BA       CAT      DIS      GE       IBM      MCD      MSFT 
    ___________    _____    _____    _____    _____    _____    _____    _____

    03-Jan-2006    68.63    55.86    24.18     33.6    80.13    32.72    26.19
    04-Jan-2006    69.34    57.29    23.77    33.56    80.03    33.01    26.32
    05-Jan-2006    68.53    57.29    24.19    33.47    80.56    33.05    26.34
    06-Jan-2006    67.57    58.43    24.52     33.7    82.96    33.25    26.26
    09-Jan-2006    67.01    59.49    24.78    33.61    81.76    33.88    26.21
    10-Jan-2006    67.33    59.25    25.09    33.43     82.1    33.91    26.35
    11-Jan-2006     68.3    59.28    25.33    33.66    82.19     34.5    26.63
    12-Jan-2006     67.9    60.13    25.41    33.25    81.61    33.96    26.48
```

Create Strategy

In this introductory example, test an equal weighted investment strategy. This strategy invests an equal portion of the available capital into each asset. This example does describe the details about how create backtest strategies. For more information on creating backtest strategies, see `backtestStrategy`.

Set the `RebalanceFrequency` to rebalance the portfolio every 60 days. This example does not use a lookback window to rebalance.

```
% Create the strategy
numAssets = size(pricesTT,2);
equalWeightsVector = ones(1,numAssets) / numAssets;
equalWeightsRebalanceFcn = @(~,~) equalWeightsVector;

ewStrategy = backtestStrategy("EqualWeighted",equalWeightsRebalanceFcn, ...
    'RebalanceFrequency',60, ...
    'LookbackWindow',0, ...
    'TransactionCosts',0.005, ...
    'InitialWeights',equalWeightsVector)
```

```
ewStrategy = 
  backtestStrategy with properties:

                      Name: "EqualWeighted"
              RebalanceFcn: @(~,~)equalWeightsVector
        RebalanceFrequency: 60
          TransactionCosts: 0.0050
```

```
            LookbackWindow: 0
            InitialWeights: [0.1429 0.1429 0.1429 0.1429 0.1429 0.1429 0.1429]
             ManagementFee: 0
     ManagementFeeSchedule: 1y
            PerformanceFee: 0
    PerformanceFeeSchedule: 1y
         PerformanceHurdle: 0
                  UserData: [0x0 struct]
            EngineDataList: [0x0 string]
```

Run Backtest

Create a backtesting engine and run a backtest over a year of stock data. For more information on creating backtest engines, see `backtestEngine`.

```
% Create the backtest engine. The backtest engine properties that hold the
% results are initialized to empty.
backtester = backtestEngine(ewStrategy)
```

```
backtester = 
  backtestEngine with properties:

               Strategies: [1x1 backtestStrategy]
             RiskFreeRate: 0
           CashBorrowRate: 0
          RatesConvention: "Annualized"
                    Basis: 0
    InitialPortfolioValue: 10000
           DateAdjustment: "Previous"
                NumAssets: []
                  Returns: []
                Positions: []
                 Turnover: []
                  BuyCost: []
                 SellCost: []
                     Fees: []
```

```
% Run the backtest. The empty properties are now populated with
% timetables of detailed backtest results.
backtester = runBacktest(backtester,pricesTT)
```

```
backtester = 
  backtestEngine with properties:

               Strategies: [1x1 backtestStrategy]
             RiskFreeRate: 0
           CashBorrowRate: 0
          RatesConvention: "Annualized"
                    Basis: 0
    InitialPortfolioValue: 10000
           DateAdjustment: "Previous"
                NumAssets: 7
                  Returns: [250x1 timetable]
                Positions: [1x1 struct]
                 Turnover: [250x1 timetable]
                  BuyCost: [250x1 timetable]
                 SellCost: [250x1 timetable]
```

```
                        Fees: [1x1 struct]
```

Backtest Summary

Use the `summary` function to generate a summary table of backtest results.

```
% Examing results. The summary table shows several performance metrics.
summary(backtester)
```

```
ans=9×1 table
                       EqualWeighted
                       _____________

    TotalReturn            0.22943  
    SharpeRatio            0.11415  
    Volatility           0.0075013  
    AverageTurnover     0.00054232  
    MaxTurnover           0.038694  
    AverageReturn       0.00085456  
    MaxDrawdown           0.098905  
    AverageBuyCost        0.030193  
    AverageSellCost       0.030193  
```

Warm Starting Backtests

When running a backtest in MATLAB®, you need to understand what the initial conditions are when the backtest begins. The initial weights for each strategy, the size of the strategy lookback window, and any potential split of the dataset into training and testing partitions affects the results of the backtest. This example shows how to use the `runBacktest` function with the `'Start'` and `'End'` name-value pair arguments that interact with the `'LookbackWindow'` and `'RebalanceFrequency'` properties of the `backtestStrategy` object to "warm start" a backtest.

Load Data

Load one year of stock price data. For readability, this example uses only a subset of the DJIA stocks.

```
% Read table of daily adjusted close prices for 2006 DJIA stocks.
T = readtable('dowPortfolio.xlsx');

% Prune the table to include only the dates and selected stocks.
timeColumn = "Dates";
assetSymbols = ["BA", "CAT", "DIS", "GE", "IBM", "MCD", "MSFT"];
T = T(:,[timeColumn assetSymbols]);

% Convert to timetable.
pricesTT = table2timetable(T,'RowTimes','Dates');

% View the final asset price timetable.
head(pricesTT)
```

```
       Dates        BA       CAT      DIS      GE      IBM      MCD     MSFT 
    ___________    _____    _____    _____    ____    _____    _____    _____

    03-Jan-2006    68.63    55.86    24.18    33.6    80.13    32.72    26.19
    04-Jan-2006    69.34    57.29    23.77    33.56    80.03    33.01    26.32
    05-Jan-2006    68.53    57.29    24.19    33.47    80.56    33.05    26.34
    06-Jan-2006    67.57    58.43    24.52     33.7    82.96    33.25    26.26
    09-Jan-2006    67.01    59.49    24.78    33.61    81.76    33.88    26.21

```

Create Strategy

This example backtests an "inverse variance" strategy. The inverse variance rebalance function is implemeted in the Local Functions on page 15-255 section. For more information on creating backtest strategies, see `backtestStrategy`. The inverse variance strategy uses the covariance of asset returns to make decisions about asset allocation. The `LookbackWindow` for this strategy must contain at least 30 days of trailing data (about 6 weeks), and at most, 60 days (about 12 weeks).

Set `RebalanceFrequency` for `backtestStrategy` to rebalance the portfolio every 25 days.

```
% Create the strategy
minLookback = 30;
maxLookback = 60;
ivStrategy = backtestStrategy("InverseVariance",@inverseVarianceFcn, ...
    'RebalanceFrequency',25, ...
    'LookbackWindow',[minLookback maxLookback], ...
    'TransactionCosts',[0.0025 0.005])
```

```
ivStrategy = 
  backtestStrategy with properties:

                      Name: "InverseVariance"
              RebalanceFcn: @inverseVarianceFcn
        RebalanceFrequency: 25
          TransactionCosts: [0.0025 0.0050]
            LookbackWindow: [30 60]
            InitialWeights: [1x0 double]
             ManagementFee: 0
     ManagementFeeSchedule: 1y
            PerformanceFee: 0
    PerformanceFeeSchedule: 1y
         PerformanceHurdle: 0
                  UserData: [0x0 struct]
            EngineDataList: [0x0 string]
```

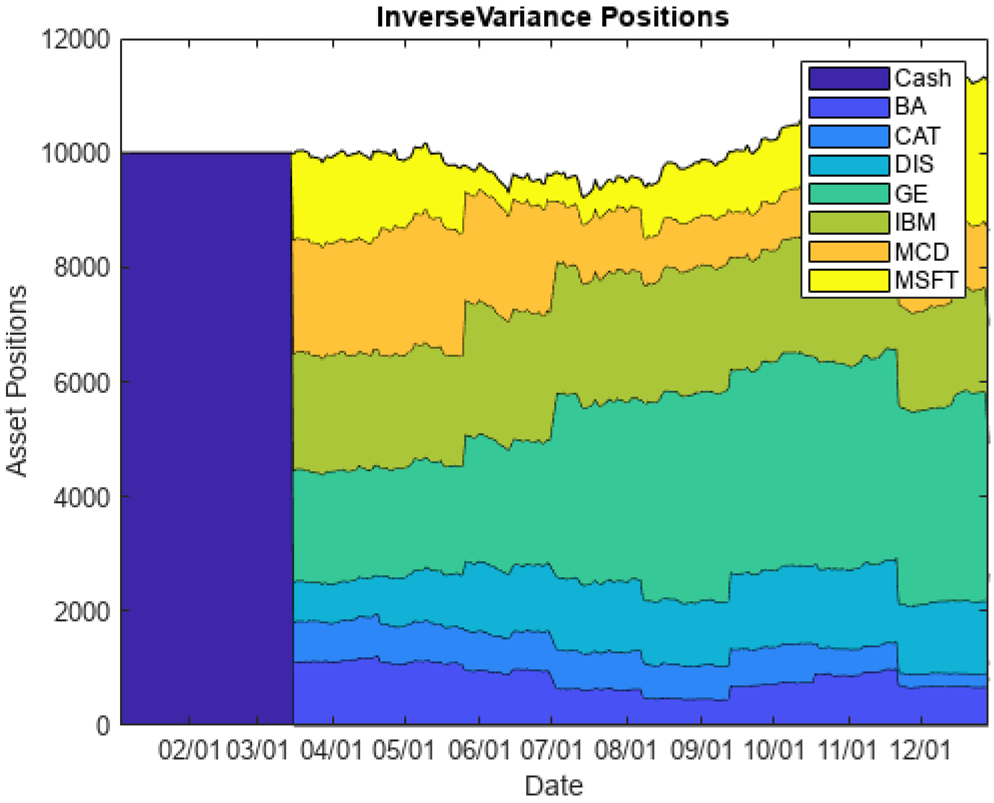
Run Backtest and Examine Results

Create a backtesting engine and run a backtest over a year of stock data. For more information on creating backtest engines, see `backtestEngine`.

```
% Create the backtest engine.
backtester = backtestEngine(ivStrategy);
% Run the backtest.
backtester = runBacktest(backtester,pricesTT);
```

Use the `assetAreaPlot` helper function, defined in the Local Functions on page 15-255 section of this example, to display the change in the asset allocation over the course of the backtest.

```
assetAreaPlot(backtester,"InverseVariance")
```



Notice that the inverse variance strategy begins all in cash and remains in that state for about 2.5 months. This is because the `backtestStrategy` object does not have a specified set of initial weights, which you specify using the `InitialPortfolioValue` name-value pair argument. The inverse variance strategy requires 30 days of trailing asset price history before rebalancing. You can use the `printRebalanceTable` helper function, defined in the Local Functions on page 15-255 section, to display the rebalance schedule.

```
printRebalanceTable(ivStrategy,pricesTT,minLookback);
```

```

      16-Mar-2006                     51                            "Yes"         
      21-Apr-2006                     76                            "Yes"         
      26-May-2006                    101                            "Yes"         
      03-Jul-2006                    126                            "Yes"         
      08-Aug-2006                    151                            "Yes"         
      13-Sep-2006                    176                            "Yes"         
      18-Oct-2006                    201                            "Yes"         
      22-Nov-2006                      226                             "Yes"  
      29-Dec-2006                      251                             "Yes"  
```

The first rebalance date comes on February 8 but the strategy does not have enough price history to fill out a valid lookback window (minimum is 30 days), so no rebalance occurs. The next rebalance date is on March 16, a full 50 days into the backtest.

This situation is not ideal as these 50 days sitting in an all-cash position represent approximately 20% of the total backtest. Consequently, when the backtesting engine reports on the performance of the strategy (that is, the total return, Sharpe ratio, volatility, and so on), the results do not reflect the "true" strategy performance because the strategy only began to make asset allocation decisions only about 20% into the backtest.

Warm Start Backtest

It is possible to "warm start" the backtest. A warm start means that the backtest results reflect the strategy performance in the market conditions reflected in the price timetable. To start, set the initial weights of the strategy to avoid starting all in cash.

The inverse variance strategy requires 30 days of price history to fill out a valid lookback window, so you can partition the price data set into two sections, a "warm-up" set and a "test" set.

```
warmupRange = 1:30;
% The 30th row is included in both ranges since the day 30 price is used
% to compute the day 31 returns.
testRange = 30:height(pricesTT);
```

Use the warm-up partition to set the initial weights of the inverse variance strategy. By doing so, you can begin the backtest with the strategy already "running" and avoid the initial weeks spent in the cash position.

```
% Use the rebalance function to set the initial weights. This might
% or might not be possible for other strategies depending on the details of
% the strategy logic.
initWeights = inverseVarianceFcn([],pricesTT(warmupRange,:));
```

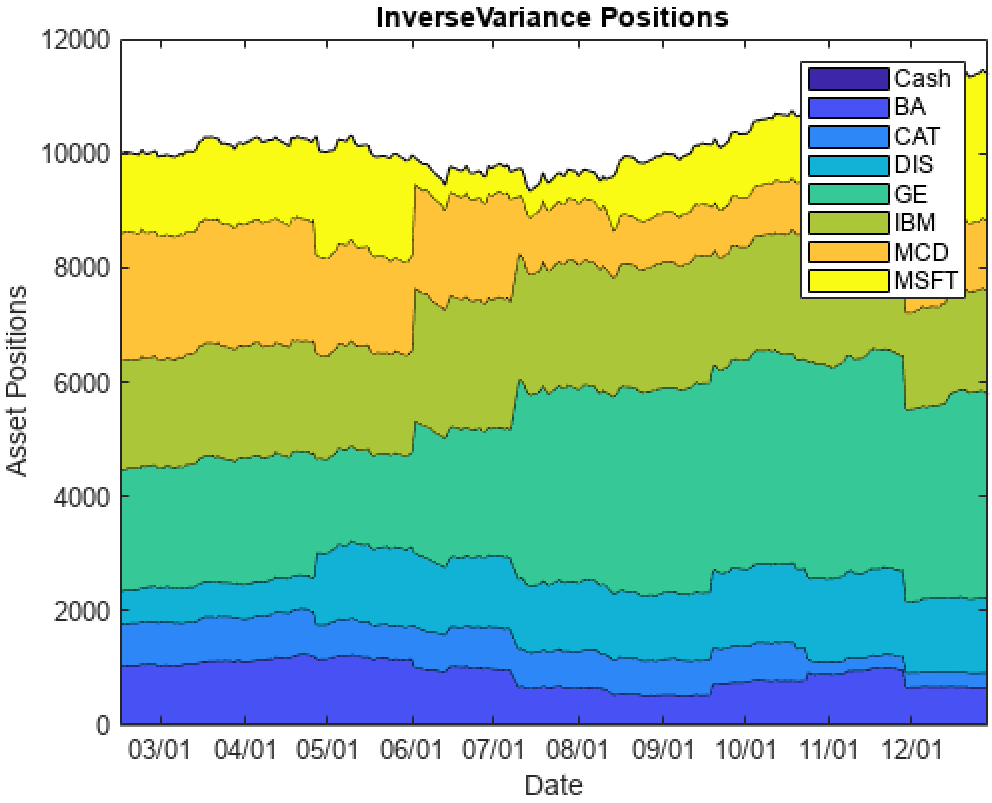
Update the strategy and rerun the backtest. Since the warm-up range is used to initialize the inverse variance strategy, you must omit this data from the backtest to avoid a look-ahead bias, or "seeing the future," and to backtest only over the "test range."

```
% Set the initial weights on the strategy in the backtester. You can do this when you
% create the strategy as well, using the 'InitialWeights' parameter.
backtester.Strategies(1).InitialWeights = initWeights;

% Rerun the backtest over the "test" range.
backtester = runBacktest(backtester,pricesTT(testRange,:));
```

When you generate the area plot, you can see that the issue where the strategy is in cash for the first portion of the backtest is avoided.

```
assetAreaPlot(backtester,"InverseVariance")
```



However, if you look at the rebalance table, you can see that the strategy still "missed" the first rebalance date. When you run the backtest over the test range of the data set, the first rebalance date is on March 22. This is because the warm-up range is omitted from the price history and the strategy had only 26 days of history available on that date (less than the minimum 30 days required for the lookback window). Therefore, the March 22 rebalance is skipped.

To avoid backtesting over the warm-up range, the range was removed it from the data set. This means the new backtest start date and all subsequent rebalance dates are 30 days later. The price history data contained in the warm-up range was completely removed, so when the backtest engine hit the first rebalance date the price history was insufficient to rebalance.

```
printRebalanceTable(ivStrategy,pricesTT(testRange,:),minLookback);
```

```
    First Day of Data    Backtest Start Date    Minimum Days to Rebalance
    _________________    ___________________    _________________________

       14-Feb-2006           14-Feb-2006                   30            

    Rebalance Dates    Days of Available Price History    Enough Data to Rebalance
    _______________    _______________________________    ________________________

      22-Mar-2006                     26                            "No"          
      27-Apr-2006                     51                            "Yes"         
      02-Jun-2006                     76                            "Yes"         
      10-Jul-2006                    101                            "Yes"         
      14-Aug-2006                     126                             "Yes"
      19-Sep-2006                     151                             "Yes"
      24-Oct-2006                     176                             "Yes"
      29-Nov-2006                     201                             "Yes"
```

This scenario is also not correct since the original price timetable (warm-up and test partitions together) does have enough price history by March 22 to fill out a valid lookback window. However, the earlier data is not available to the backtest engine because the backtest was run using only the test partition.

Use `Start` and End Parameters for `runBacktest`

The ideal workflow in this situation is to both *omit* the warm-up data range from the backtest to avoid the look-ahead bias but *include* the warm-up data in the price history to be able to fill out the lookback window of the strategy with all available price history data. You can do so by using the `'Start'` parameter for the `runBacktest` function.

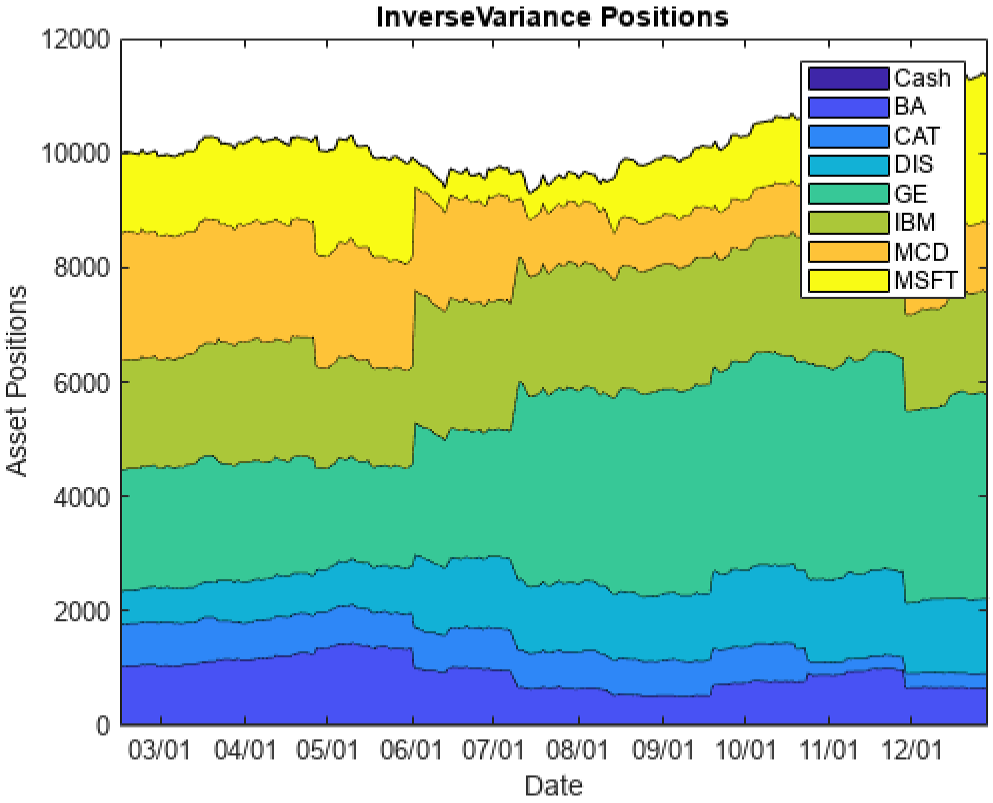
The `'Start'` and `'End'` name-value pair arguments for `runBacktest` enable you to start and end the backtest on specific dates. You can specify `'Start'` and `'End'` as rows of the prices timetable or as datetime values (see the documentation for the `runBacktest` function for details). The `'Start'` argument lets the backtest begin on a particular date while giving the backtest engine access to the full data set.

Rerun the backtest using the `'Start'` name-value pair argument rather than only running on a partition of the original data set.

```
% Rerun the backtest starting on the last day of the warmup range.
startRow = warmupRange(end);
backtester = runBacktest(backtester,pricesTT,'Start',startRow);
```

Plot the new asset area plot.

```
assetAreaPlot(backtester,"InverseVariance")
```



View the new rebalance table with the new `'Start'` parameter.

```
printRebalanceTable(ivStrategy,pricesTT,minLookback,startRow);
```

```
    First Day of Data    Backtest Start Date    Minimum Days to Rebalance
    _________________    ___________________    _________________________

       03-Jan-2006           14-Feb-2006                   30            

    Rebalance Dates    Days of Available Price History    Enough Data to Rebalance
    _______________    _______________________________    ________________________

      22-Mar-2006                     55                            "Yes"         
      27-Apr-2006                     80                            "Yes"         
      02-Jun-2006                    105                            "Yes"         
      10-Jul-2006                    130                            "Yes"         
      14-Aug-2006                    155                            "Yes"         
      19-Sep-2006                    180                            "Yes"         
      24-Oct-2006                    205                            "Yes"         
      29-Nov-2006                    230                            "Yes"         
```

The inverse variance strategy now has enough data to rebalance on the first rebalance date (March 22) and the backtest is "warm started." By using the original data set, the first day of data remains January 3, and the `'Start'` parameter allows you to move the backtest start date forward to avoid the warm-up range.

Even though the results are not dramatically different, this example illustrates the interaction between the LookbackWindow and RebalanceFrequency name-value pair arguments for a backtestStrategy object and the range of data used in the runBacktest when you evaluate the performance of a strategy in a backtest.

Local Functions

The strategy rebalance function is implemented as follows. For more information on creating strategies and writing rebalance functions, see backtestStrategy.

```
function new_weights = inverseVarianceFcn(current_weights, pricesTT)
% Inverse-variance portfolio allocation.

assetReturns = tick2ret(pricesTT);
assetCov = cov(assetReturns{:,:});
new_weights = 1 ./ diag(assetCov);
new_weights = new_weights / sum(new_weights);

end
```

This helper function plots the asset allocation as an area plot.

```
function assetAreaPlot(backtester,strategyName)

t = backtester.Positions.(strategyName).Time;
positions = backtester.Positions.(strategyName).Variables;
h = area(t,positions);
title(sprintf('%s Positions',strategyName));
xlabel('Date');
ylabel('Asset Positions');
datetick('x','mm/dd','keepticks');
xlim([t(1) t(end)])
oldylim = ylim;
ylim([0 oldylim(2)]);
cm = parula(numel(h));
for i = 1:numel(h)
    set(h(i),'FaceColor',cm(i,:));
end
legend(backtester.Positions.(strategyName).Properties.VariableNames)

end
```

This helper function generates a table of rebalance dates along with the available price history at each date.

```
function printRebalanceTable(strategy,pricesTT,minLookback,startRow)

if nargin < 4
    startRow = 1;
end

allDates = pricesTT.(pricesTT.Properties.DimensionNames{1});
rebalanceDates = allDates(startRow:strategy.RebalanceFrequency:end);
[~,rebalanceIndices] = ismember(rebalanceDates,pricesTT.Dates);

disp(table(allDates(1),rebalanceDates(1),minLookback,'VariableNames',{'First Day of Data','Backte
fprintf('\n\n');
numHistory = rebalanceIndices(2:end);
```

```
sufficient = repmat("No",size(numHistory));
sufficient(numHistory > minLookback) = "Yes";
disp(table(rebalanceDates(2:end),rebalanceIndices(2:end),sufficient,'VariableNames',{'Rebalance

end
```

Input Arguments

backtester — Backtesting engine

backtestEngine object

Backtesting engine, specified as a backtestEngine object. Use backtestEngine to create the backtester object.

Data Types: object

pricesTT — Asset prices

timetable

Asset prices, specified as a timetable of asset prices that the backtestEngine uses to backtest the strategies. Each column of the prices timetable must contain a timeseries of prices for an asset. Historical asset prices must be adjusted for splits and dividends.

Data Types: timetable

signalTT — Signal data

timetable

(Optional) Signal data, specified as a timetable of trading signals that the strategies use to make trading decisions. signalTT is optional. If provided, the backtestEngine calls the strategy rebalance functions with both asset price data and signal data. The signalTT timetable must have the same time dimension as the pricesTT timetable.

Data Types: timetable

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: backtester = runBacktest(backtester,assetPrices,'Start',50,'End',100)

Start — Time step to start backtest

1 (default) | integer | datetime

Time step to start the backtest, specified as the comma-separated pair consisting of 'Start' and a scalar integer or datetime.

If an integer, the Start time refers to the row in the pricesTT timetable where the backtest begins.

If a datetime object, the backtest will begin at the first time in the prices timetable that occurs on or after the 'Start' parameter. The backtest will end on the last time in the pricesTT timetable that occurs on or before the 'End' parameter. The 'Start' and 'End' parameters set the boundary of the data that is included in the backtest.

Data Types: double | datetime

End — Time step to end backtest
Last row in pricesTT timetable (default) | integer | datetime

Time step to end the backtest, specified as the comma-separated pair consisting of 'End' and a scalar integer or datetime.

If an integer, the End time refers to the row in the pricesTT timetable where the backtest ends.

If a datetime object, the backtest will end on the last time in the pricesTT timetable that occurs on or before the 'End' parameter.

Data Types: double | datetime

Output Arguments

backtester — Backtesting engine
backtestEngine object

Backtesting engine, returned as an updated backtestEngine object. After backtesting is complete, runBacktest populates several properties in the backtestEngine object with the results of the backtest. You can summarize the results by using the summary function.

Version History

Introduced in R2020b

summary

Generate summary table of backtest results

Syntax

```
summaryTable = summary(backtester)
```

Description

`summaryTable = summary(backtester)` generates a table of metrics to summarize the backtest. Each row of the table is a calculated metric and each column represents a strategy. You must run the summary function only after running the `runBacktest` function.

Examples

Examining Backtest Results

The MATLAB® backtesting engine runs backtests of portfolio investment strategies over time series of asset price data. You can use `summary` to compare multiple strategies over the same market scenario. This example shows how to examine the results of a backtest with two strategies.

Load Data

Load one year of stock price data. For readability, this example uses a subset of the DJIA stocks.

```
% Read table of daily adjusted close prices for 2006 DJIA stocks
T = readtable('dowPortfolio.xlsx');

% Prune the table to include only the dates and selected stocks
timeColumn = "Dates";
assetSymbols = ["BA", "CAT", "DIS", "GE", "IBM", "MCD", "MSFT"];
T = T(:,[timeColumn assetSymbols]);

% Convert to timetable
pricesTT = table2timetable(T,'RowTimes','Dates');

% View the final asset price timetable
head(pricesTT)
```

```
       Dates         BA       CAT      DIS       GE       IBM      MCD      MSFT 
    ___________    _____    _____    _____    _____    _____    _____    _____

    03-Jan-2006    68.63    55.86    24.18     33.6    80.13    32.72    26.19
    04-Jan-2006    69.34    57.29    23.77    33.56    80.03    33.01    26.32
    05-Jan-2006    68.53    57.29    24.19    33.47    80.56    33.05    26.34
    06-Jan-2006    67.57    58.43    24.52     33.7    82.96    33.25    26.26
    09-Jan-2006    67.01    59.49    24.78    33.61    81.76    33.88    26.21
    10-Jan-2006    67.33    59.25    25.09    33.43     82.1    33.91    26.35
    11-Jan-2006     68.3    59.28    25.33    33.66    82.19     34.5    26.63
    12-Jan-2006     67.9    60.13    25.41    33.25    81.61    33.96    26.48
```

The inverse variance strategy requires some price history to initialize, so you can allocate a portion of the data to use for setting initial weights. By doing this, you can "warm start" the backtest.

```
warmupRange = 1:20;
testRange = 21:height(pricesTT);
```

Create Strategies

Define an investment strategy by using the `backtestStrategy` function. This example builds two strategies:

- Equal weighted
- Inverse variance

This example does not provide details on how to build the strategies. For more information on creating strategies, see `backtestStrategy`. The strategy rebalance functions are implemented in the Rebalance Functions on page 15-268 section.

```
% Create the strategies
ewInitialWeights = equalWeightFcn([],pricesTT(warmupRange,:));
ewStrategy = backtestStrategy("EqualWeighted",@equalWeightFcn, ...
    'RebalanceFrequency',20, ...
    'TransactionCosts',[0.0025 0.005], ...
    'LookbackWindow',0, ...
    'InitialWeights',ewInitialWeights)
```

```
ewStrategy = 
  backtestStrategy with properties:

                      Name: "EqualWeighted"
              RebalanceFcn: @equalWeightFcn
        RebalanceFrequency: 20
          TransactionCosts: [0.0025 0.0050]
            LookbackWindow: 0
            InitialWeights: [0.1429 0.1429 0.1429 0.1429 0.1429 0.1429 0.1429]
             ManagementFee: 0
     ManagementFeeSchedule: 1y
            PerformanceFee: 0
    PerformanceFeeSchedule: 1y
         PerformanceHurdle: 0
                  UserData: [0x0 struct]
            EngineDataList: [0x0 string]
```

```
ivInitialWeights = inverseVarianceFcn([],pricesTT(warmupRange,:));
ivStrategy = backtestStrategy("InverseVariance",@inverseVarianceFcn, ...
    'RebalanceFrequency',20, ...
    'TransactionCosts',[0.0025 0.005], ...
    'InitialWeights',ivInitialWeights)
```

```
ivStrategy = 
  backtestStrategy with properties:

                      Name: "InverseVariance"
              RebalanceFcn: @inverseVarianceFcn
        RebalanceFrequency: 20
          TransactionCosts: [0.0025 0.0050]
```

```
            LookbackWindow: [0 Inf]
            InitialWeights: [0.1401 0.0682 0.0795 0.2187 0.1900 0.1875 0.1160]
             ManagementFee: 0
     ManagementFeeSchedule: 1y
            PerformanceFee: 0
    PerformanceFeeSchedule: 1y
         PerformanceHurdle: 0
                  UserData: [0x0 struct]
            EngineDataList: [0x0 string]
```

```
% Aggregate the strategies into an array
strategies = [ewStrategy ivStrategy];
```

Run Backtest

Create a backtesting engine and run a backtest over a year of stock data. For more information on creating backtesting engines, see `backtestEngine`. The software initializes several properties of the `backtestEngine` object to empty. These read-only properties are populated by the engine after you run the backtest.

```
% Create the backtesting engine using the default settings
backtester = backtestEngine(strategies)
```

```
backtester = 
  backtestEngine with properties:

               Strategies: [1x2 backtestStrategy]
             RiskFreeRate: 0
           CashBorrowRate: 0
          RatesConvention: "Annualized"
                    Basis: 0
    InitialPortfolioValue: 10000
           DateAdjustment: "Previous"
                NumAssets: []
                  Returns: []
                Positions: []
                 Turnover: []
                  BuyCost: []
                 SellCost: []
                     Fees: []
```

Run the backtest using `runBacktest`.

```
% Run the backtest
backtester = runBacktest(backtester,pricesTT(testRange,:));
```

Examine Summary Results

The `summary` function uses the results of the backtest and returns a table of high-level results from the backtest.

```
s1 = summary(backtester)
```

```
s1=9×2 table
                       EqualWeighted    InverseVariance
                       _____________    _______________
```

```
    TotalReturn            0.17567            0.17155
    SharpeRatio           0.097946            0.10213
    Volatility           0.0074876          0.0069961
    AverageTurnover      0.0007014          0.0024246
    MaxTurnover           0.021107           0.097472
    AverageReturn       0.00073178         0.00071296
    MaxDrawdown           0.097647           0.096299
    AverageBuyCost        0.018532           0.061913
    AverageSellCost       0.037064            0.12383
```

Each row of the table output is a measurement of the performance of a strategy. Each strategy occupies a column. The `summary` function reports on the following metrics:

- `TotalReturn` — The nonannulaized total return of the strategy, inclusive of fees, over the full backtest period.
- `SharpeRatio` — The nonannualized Sharpe ratio of each strategy over the backtest. For more information, see `sharpe`.
- `Volatility` — The nonannualized standard deviation of per-time-step strategy returns.
- `AverageTurnover` — The average per-time-step portfolio turnover, expressed as a decimal percentage.
- `MaxTurnover` — The maximum portfolio turnover in a single rebalance, expressed as a decimal percentage.
- `AverageReturn` —The arithmetic mean of the per-time step portfolio returns.
- `MaxDrawdown` — The maximum drawdown of the portfolio, expressed as a decimal percentage. For more information, see `maxdrawdown`.
- `AverageBuyCost` — The average per-time-step transaction costs the portfolio incurred for asset purchases.
- `AverageSellCost` — The average per-time-step transaction costs the portfolio incurred for asset sales.

Sometimes it is useful to transpose the `summary` table when plotting the metrics of different strategies.

```
s2 = rows2vars(s1);
s2.Properties.VariableNames{1} = 'StrategyName'
```

```
s2=2×10 table
       StrategyName        TotalReturn    SharpeRatio    Volatility    AverageTurnover    MaxTurn

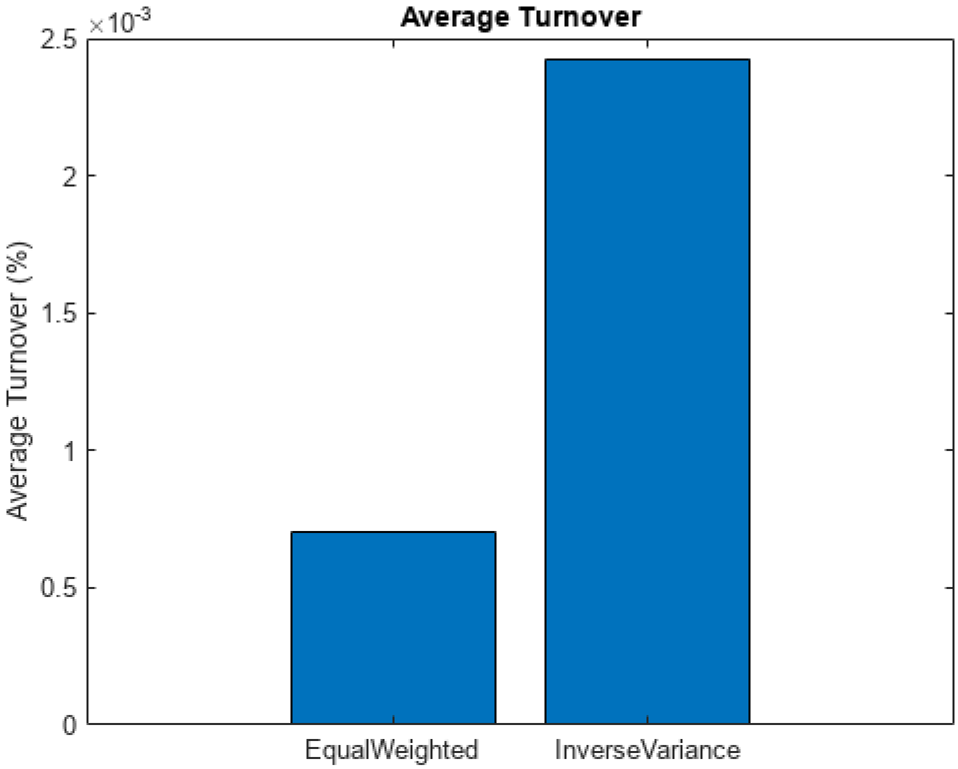
    {'EqualWeighted'  }      0.17567       0.097946      0.0074876        0.0007014        0.0211
    {'InverseVariance'}      0.17155        0.10213      0.0069961        0.0024246        0.0974
```

```
bar(s2.AverageTurnover)
title('Average Turnover')
ylabel('Average Turnover (%)')
set(gca,'xticklabel',s2.StrategyName)
```



Examine Detailed Results

After you run the backtest, the `backtestEngine` object updates the read-only fields with the detailed results of the backtest. The `Returns`, `Positions`, `Turnover`, `BuyCost`, `SellCost`, and `Fees` properties each contain a timetable of results. Since this example uses daily price data in the backtest, these timetables hold daily results.

```
backtester
```

```
backtester = 
  backtestEngine with properties:

               Strategies: [1x2 backtestStrategy]
             RiskFreeRate: 0
           CashBorrowRate: 0
          RatesConvention: "Annualized"
                    Basis: 0
    InitialPortfolioValue: 10000
           DateAdjustment: "Previous"
                NumAssets: 7
                  Returns: [230x2 timetable]
                Positions: [1x1 struct]
                 Turnover: [230x2 timetable]
                  BuyCost: [230x2 timetable]
                 SellCost: [230x2 timetable]
                     Fees: [1x1 struct]
```

Returns

The `Returns` property holds a timetable of strategy (simple) returns for each time step. These returns are inclusive of all transaction fees.

```
head(backtester.Returns)
```

```
       Time         EqualWeighted    InverseVariance
    ___________    _____________    _______________

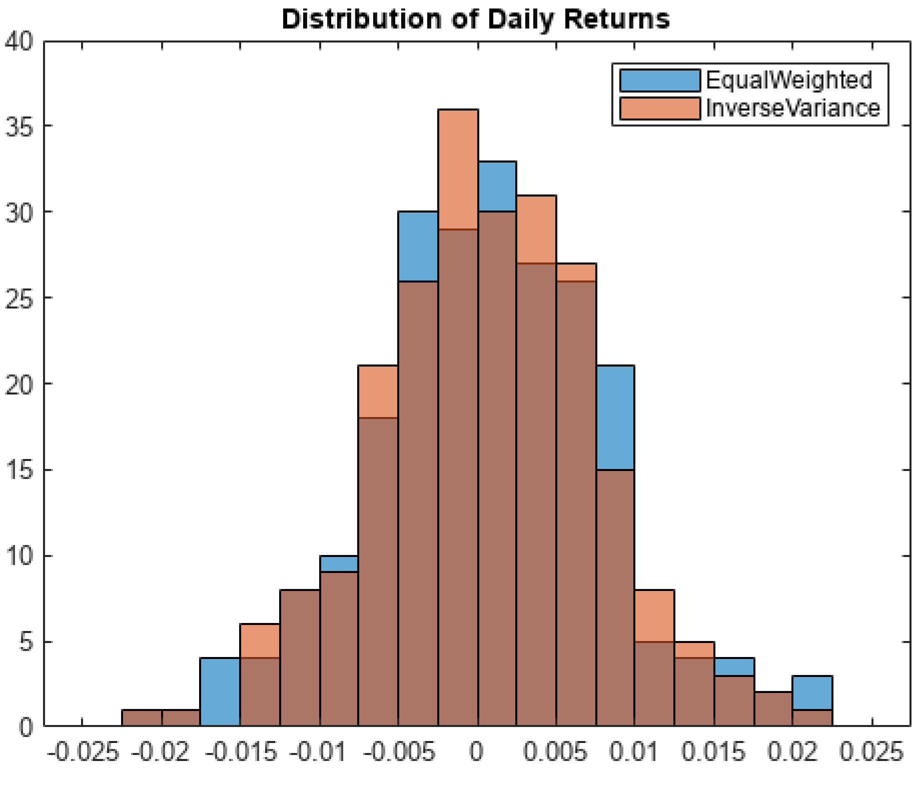
h1 = histogram(backtester.Returns.EqualWeighted,'BinEdges',binedges);
hold on
histogram(backtester.Returns.InverseVariance,'BinEdges',binedges);
hold off
title('Distribution of Daily Returns')
legend([strategies.Name]);
```



Positions

The `Positions` property holds a structure of timetables, one per strategy.

```
backtester.Positions
```

```
ans = struct with fields:
      EqualWeighted: [231x8 timetable]
    InverseVariance: [231x8 timetable]
```

The `Positions` timetable of each strategy holds the per-time-step positions for each asset as well as the `Cash` asset (which earns the risk-free rate). The `Positions` timetables contain one more row than the other results timetables because the `Positions` timetables include initial positions of the strategy as their first row. You can consider the initial positions as the `Time = 0` portfolio positions. In this example, the `Positions` timetables start with February 1, while the others start on February 2.

```
head(backtester.Positions.InverseVariance)
```

```

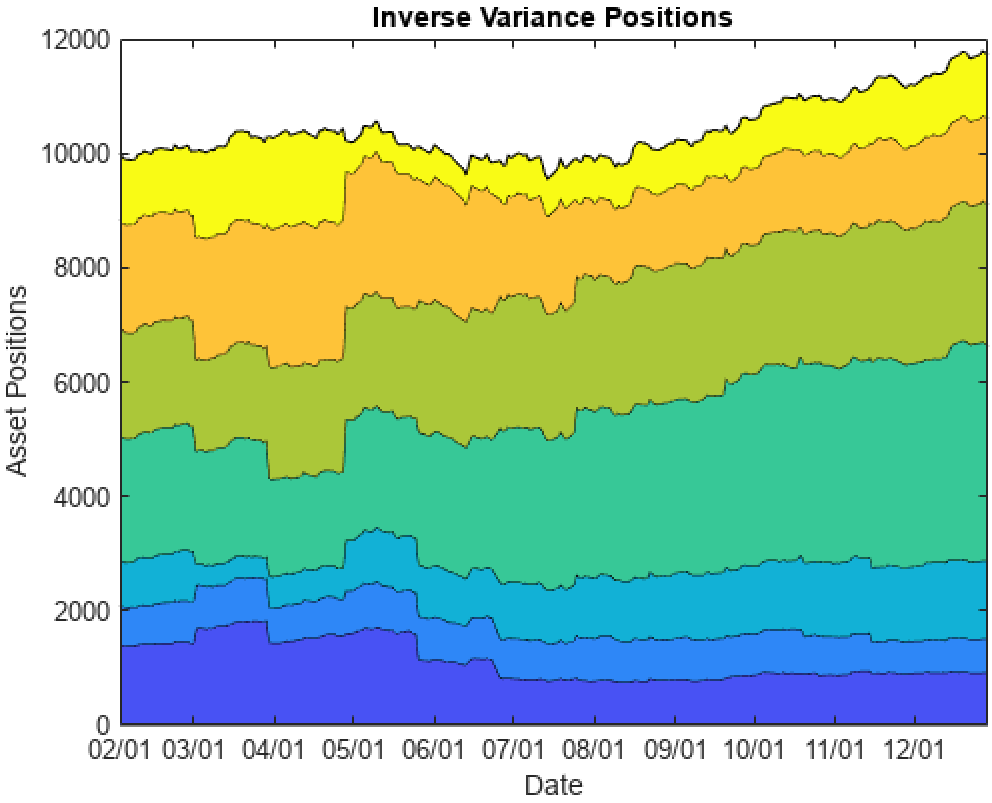
cm = parula(numel(h));
for i = 1:numel(h)
    set(h(i),'FaceColor',cm(i,:));
end
```



Turnover

The `Turnover` timetable holds the per-time-step portfolio turnover.

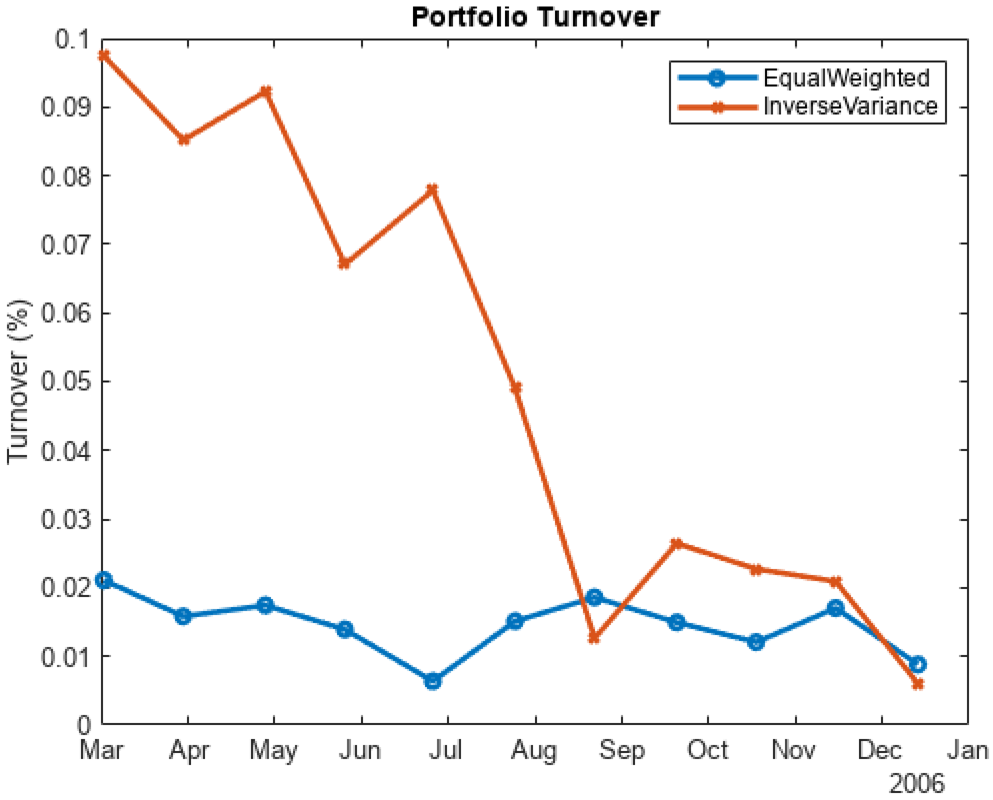
```
head(backtester.Turnover)
```

```
       Time        EqualWeighted    InverseVariance
    ___________    _____________    _______________

    02-Feb-2006          0                 0       
    03-Feb-2006          0                 0       
    06-Feb-2006          0                 0       
    07-Feb-2006          0                 0       
    08-Feb-2006          0                 0       
    09-Feb-2006          0                 0       
    10-Feb-2006          0                 0       
    13-Feb-2006          0                 0       
```

Depending on your rebalance frequency, the `Turnover` table can contain mostly zeros. Removing these zeros when you visualize the portfolio turnover is useful.

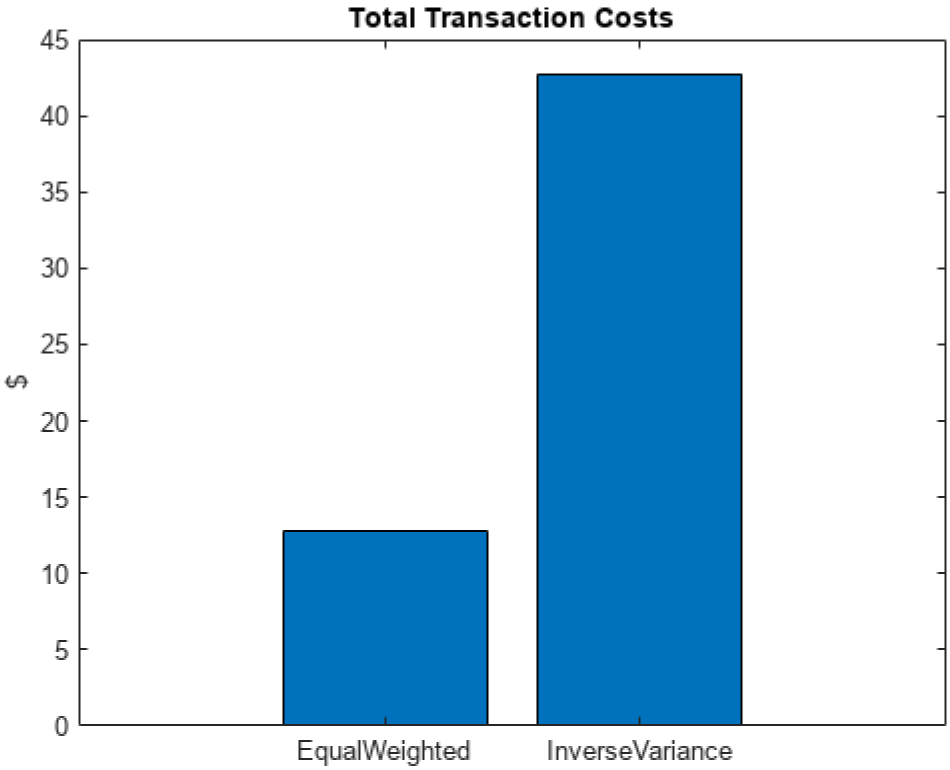
```
nonZeroIdx = sum(backtester.Turnover.Variables,2) > 0;
to = backtester.Turnover(nonZeroIdx,:);
plot(to.Time,to.EqualWeighted,'-o',to.Time,to.InverseVariance,'-x',...
    'LineWidth',2,'MarkerSize',5);
legend([strategies.Name]);
title('Portfolio Turnover');
ylabel('Turnover (%)');
```



BuyCost and SellCost

The BuyCost and SellCost timetables hold the per-time-step transaction fees for each type of transaction, purchases, and sales.

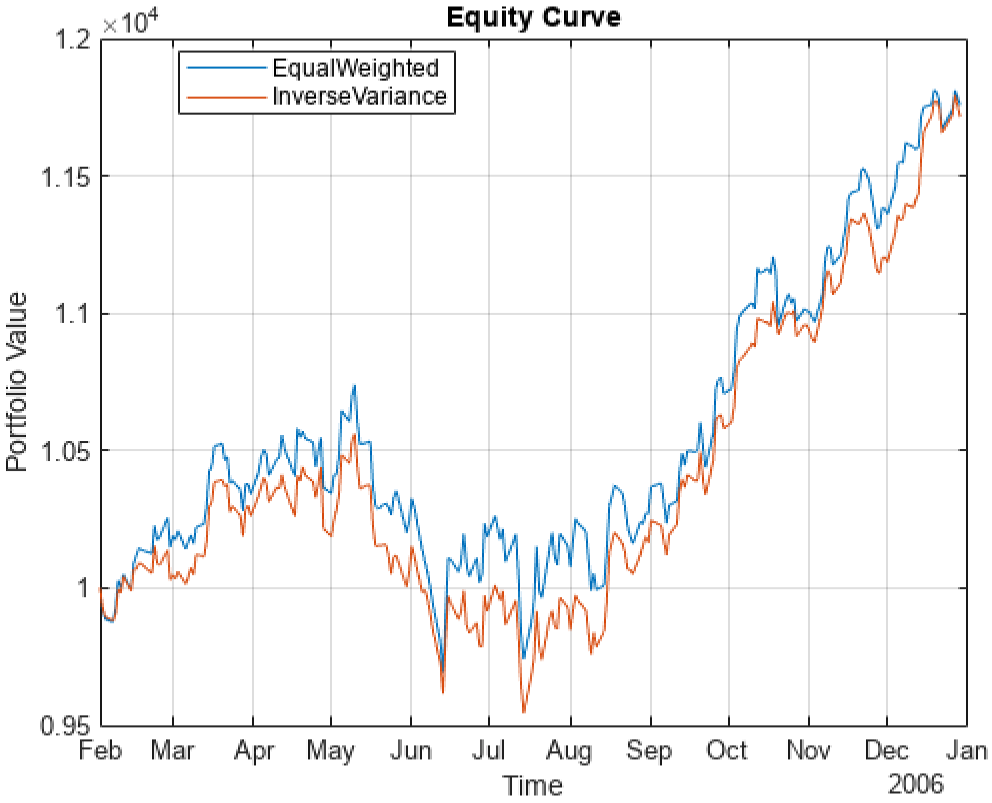
```
totalCost = sum(backtester.BuyCost{:,:}) + sum(backtester.SellCost{:,:});
bar(totalCost);
title('Total Transaction Costs');
ylabel('$')
set(gca,'xticklabel',[strategies.Name])
```



Generate Equity Curve

Use `equityCurve` to plot the equity curve for the equal weighted and inverse variance strategies.

```
equityCurve(backtester)
```



Rebalance Functions

This section contains the implementation of the strategy rebalance functions. For more information on creating strategies and writing rebalance functions, see `backtestStrategy`.

```
function new_weights = equalWeightFcn(current_weights, pricesTT) %#ok<INUSL>
% Equal weighted portfolio allocation

nAssets = size(pricesTT, 2);
new_weights = ones(1,nAssets);
new_weights = new_weights / sum(new_weights);

end

function new_weights = inverseVarianceFcn(current_weights, pricesTT) %#ok<INUSL>
% Inverse-variance portfolio allocation

assetReturns = tick2ret(pricesTT);
assetCov = cov(assetReturns{:,:});
new_weights = 1 ./ diag(assetCov);
new_weights = new_weights / sum(new_weights);
```

```
end
```

Input Arguments

backtester — Backtesting engine
backtestEngine object

Backtesting engine, specified as a backtestEngine object. Use backtestEngine to create the backtesting engine and then use runBacktest to run a backtest.

Data Types: object

Output Arguments

summaryTable — Metrics summarizing backtest
table

Metrics summarizing the backtest, returned as a table where each row of the table is a calculated metric and each column represents a strategy. The reported metrics are as follows:

- TotalReturn — The total return of the strategy over the entire backtest
- SharpeRatio — The Sharpe ratio for each strategy
- Volatility — The volatility of each strategy over the backtest
- AverageTurnover — Average turnover per-time-step as a decimal percent
- MaxTurnover — Maximum turnover in a single time step
- AverageReturn — Average return per-time-step
- MaxDrawdown — Maximum portfolio drawdown as a decimal percent
- AverageBuyCost — Average per-time-step transaction costs for asset purchases
- AverageSellCost — Average per-time-step transaction costs for asset sales

equityCurve

Plot equity curves of strategies

Syntax

```
equityCurve(backtester)
h = equityCurve(ax,backtester)
```

Description

`equityCurve(backtester)` plots the equity curves of each strategy that you create using `backtestStrategy`. After creating the backtesting engine using `backtestEngine` and running the backtest with `runBacktest`, use `equityCurve` to plot the strategies and compare their performance.

`h = equityCurve(ax,backtester)` additionally returns the figure handle `h`.

Examples

Generate Equity Curve for Backtest

The MATLAB® backtesting engine runs backtests of portfolio investment strategies over time series of asset price data. After creating a set of backtest strategies using `backtestStrategy` and the backtesting engine using `backtestEngine`, the `runBacktest` function executes the backtest. After using the `runBacktest` function to test investment strategies, you can run the `equityCurve` function to plot the equity curves of strategies.

Load Data

Load one year of stock price data. For readability, this example uses only a subset of the DJIA stocks.

```
% Read a table of daily adjusted close prices for 2006 DJIA stocks
T = readtable('dowPortfolio.xlsx');

% Prune the table to hold only the dates and selected stocks
timeColumn = "Dates";
assetSymbols = ["BA", "CAT", "DIS", "GE", "IBM", "MCD", "MSFT"];
T = T(:,[timeColumn assetSymbols]);

% Convert to timetable
pricesTT = table2timetable(T,'RowTimes','Dates');

% View the final asset price timetable
head(pricesTT)
```

```
       Dates        BA       CAT      DIS       GE       IBM      MCD      MSFT 
    ___________    _____    _____    _____    _____    _____    _____    _____

    03-Jan-2006    68.63    55.86    24.18     33.6    80.13    32.72    26.19

```

Create Strategy

Test an equal-weighted investment strategy. This strategy invests an equal portion of the available capital into each asset. This example does not describe how to create backtesting strategies. For more information on creating backtesting strategies, see `backtestStrategy`.

Set `'RebalanceFrequency'` to rebalance the portfolio every 60 days. This example does not use a lookback window to rebalance.

```
% Create the strategy
numAssets = size(pricesTT,2);
equalWeightsVector = ones(1,numAssets) / numAssets;
equalWeightsRebalanceFcn = @(~,~) equalWeightsVector;

ewStrategy = backtestStrategy("EqualWeighted",equalWeightsRebalanceFcn, ...
    'RebalanceFrequency',60, ...
    'LookbackWindow',0, ...
    'TransactionCosts',0.005, ...
    'InitialWeights',equalWeightsVector)
```

```
ewStrategy = 
  backtestStrategy with properties:

                      Name: "EqualWeighted"
              RebalanceFcn: @(~,~)equalWeightsVector
        RebalanceFrequency: 60
          TransactionCosts: 0.0050
            LookbackWindow: 0
            InitialWeights: [0.1429 0.1429 0.1429 0.1429 0.1429 0.1429 0.1429]
             ManagementFee: 0
     ManagementFeeSchedule: 1y
            PerformanceFee: 0
    PerformanceFeeSchedule: 1y
         PerformanceHurdle: 0
                  UserData: [0x0 struct]
            EngineDataList: [0x0 string]
```

Run Backtest

Create a backtesting engine and run a backtest over a year of stock data. For more information on creating backtest engines, see `backtestEngine`.

```
% Create the backtesting engine. The backtesting engine properties that hold the
% results are initialized to empty.
backtester = backtestEngine(ewStrategy)
```

```
backtester = 
  backtestEngine with properties:

               Strategies: [1x1 backtestStrategy]
```

```
             RiskFreeRate: 0
            CashBorrowRate: 0
           RatesConvention: "Annualized"
                     Basis: 0
     InitialPortfolioValue: 10000
            DateAdjustment: "Previous"
                 NumAssets: []
                   Returns: []
                 Positions: []
                  Turnover: []
                   BuyCost: []
                  SellCost: []
                      Fees: []
```

```
% Run the backtest. The empty properties are now populated with
% timetables of detailed backtest results.
backtester = runBacktest(backtester,pricesTT)
```

```
backtester = 
  backtestEngine with properties:

               Strategies: [1x1 backtestStrategy]
             RiskFreeRate: 0
            CashBorrowRate: 0
           RatesConvention: "Annualized"

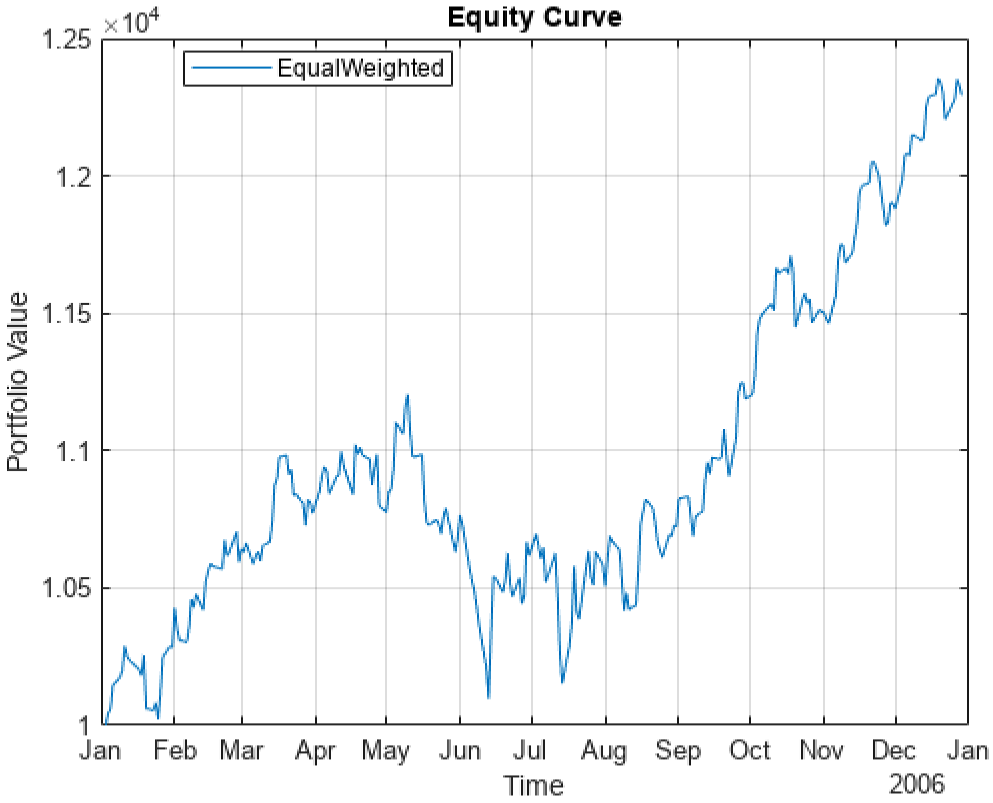
                  Turnover: [250x1 timetable]
                   BuyCost: [250x1 timetable]
                  SellCost: [250x1 timetable]
                      Fees: [1x1 struct]
```

Generate Equity Curve

Use the `equityCurve` to plot the equity curve for the equal-weight strategy.

```
equityCurve(backtester)
```



Input Arguments

backtester — Backtesting engine

backtestEngine object

Backtesting engine, specified as a backtestEngine object. Use backtestEngine to create the backtester object.

Note The backtester argument must use a backtestEngine object that has been run using runBacktest.

Data Types: object

ax — Valid axis object

ax object

(Optional) Valid axis object, specified as an ax object that you create using axes. The plot is created on the axes specified by the optional ax argument instead of on the current axes (gca). The optional argument ax can precede any of the input argument combinations.

Data Types: object

Output Arguments

h — Figure handle
handle object

Figure handle for the equity curve plot, returned as handle object.

Version History

Introduced in R2021a

simByEuler

Simulate `Bates` sample paths by Euler approximation

Syntax

```
[Paths,Times,Z,N] = simByEuler(MDL,NPeriods)
[Paths,Times,Z,N] = simByEuler(___,Name,Value)
```

Description

`[Paths,Times,Z,N] = simByEuler(MDL,NPeriods)` simulates `NTrials` sample paths of Bates bivariate models driven by `NBrowns` Brownian motion sources of risk and `NJumps` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods. The simulation approximates continuous-time stochastic processes by the Euler approach.

`[Paths,Times,Z,N] = simByEuler(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`. For more information, see "Quasi-Monte Carlo Simulation" on page 14-62.

Examples

Simulate Bates Sample Paths by Euler Approximation

Create a `bates` object.

```
AssetPrice = 80;
            Return = 0.03;
            JumpMean = 0.02;
            JumpVol = 0.08;
            JumpFreq = 0.1;

            V0 = 0.04;
            Level = 0.05;
            Speed = 1.0;
            Volatility = 0.2;
            Rho = -0.7;
            StartState = [AssetPrice;V0];
            Correlation = [1 Rho;Rho 1];

batesObj = bates(Return, Speed, Level, Volatility,...
                JumpFreq, JumpMean, JumpVol,'startstate',StartState,...
                'correlation',Correlation)
```

```
batesObj = 
   Class BATES: Bates Bivariate Stochastic Volatility
   --------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   --------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
    Correlation: 2x2 double array
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.03
          Speed: 1
          Level: 0.05
     Volatility: 0.2
       JumpFreq: 0.1
       JumpMean: 0.02
        JumpVol: 0.08
```

Use `simByEuler` to simulate `NTrials` sample paths of this Bates bivariate model driven by `NBrowns` Brownian motion sources of risk and `NJumps` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods. This function approximates continuous-time stochastic processes by the Euler approach.

```
NPeriods = 2;
[Paths,Times,Z,N] = simByEuler(batesObj,NPeriods)
```

```
Paths = 3×2

   80.0000    0.0400
   90.8427    0.0873
   32.7458    0.1798

Times = 3×1

     0
     1
     2

Z = 2×2

    0.5377    0.9333
   -2.2588    2.1969

N = 2×1

     0
     0
```

The output `Paths` is `3 x 2` dimension. Row number `3` is from `NPeriods + 1`. The first row is defined by the `bates` name-value pair argument `StartState`. The remaining rows are simulated data. `Paths` always has two columns because the Bates model is a bivariate model. In this case, the first column is the simulated asset price and the second column is the simulated volatilities.

Quasi-Monte Carlo Simulation with `simByEuler` Using a Bates Model

Create a `bates` object.

```
AssetPrice = 80;
            Return = 0.03;
            JumpMean = 0.02;
            JumpVol = 0.08;
            JumpFreq = 0.1;

            V0 = 0.04;
            Level = 0.05;
            Speed = 1.0;
            Volatility = 0.2;
            Rho = -0.7;
            StartState = [AssetPrice;V0];
            Correlation = [1 Rho;Rho 1];

batesObj = bates(Return, Speed, Level, Volatility,...
                JumpFreq, JumpMean, JumpVol,'startstate',StartState,...
                'correlation',Correlation)
```

```
batesObj = 
   Class BATES: Bates Bivariate Stochastic Volatility
   --------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   --------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
    Correlation: 2x2 double array
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.03
          Speed: 1
          Level: 0.05
     Volatility: 0.2
       JumpFreq: 0.1
       JumpMean: 0.02
        JumpVol: 0.08
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for `'MonteCarloMethod'`,`'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time,z] = simByEuler(batesObj,10,'ntrials',4096,'montecarlomethod','quasi','quasisequence
```

Input Arguments

`MDL` — Stochastic differential equation model

object

Stochastic differential equation model, specified as a `bates` object. You can create a `bates` object using `bates`.

Data Types: `object`

NPeriods — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of NPeriods determines the number of rows of the simulated output series.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Paths,Times,Z,N] = simByEuler(bates,NPeriods,'DeltaTimes',dt)

NTrials — Simulated trials (sample paths)

1 (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of NPeriods observations each, specified as the comma-separated pair consisting of 'NTrials' and a positive scalar integer.

Data Types: double

DeltaTimes — Positive time increments between observations

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTimes' and a scalar or an NPeriods-by-1 column vector.

DeltaTimes represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

NSteps — Number of intermediate time steps within each time increment *dt*

1 (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as DeltaTimes), specified as the comma-separated pair consisting of 'NSteps' and a positive scalar integer.

The simByEuler function partitions each time increment *dt* into NSteps subintervals of length *dt*/NSteps, and refines the simulation by evaluating the simulated state vector at NSteps - 1 intermediate points. Although simByEuler does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

Antithetic — Flag to use antithetic sampling to generate the Gaussian random variates

false (no antithetic sampling) (default) | logical with values true or false

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of 'Antithetic' and a scalar numeric or logical 1 (true) or 0 (false).

When you specify `true`, `simByEuler` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials `(1,3,5,...)` correspond to the primary Gaussian paths.
- Even trials `(2,4,6,...)` are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see `Z`), `simByEuler` ignores the value of `Antithetic`.

Data Types: `logical`

`Z` — Direct specification of the dependent random noise process for generating Brownian motion vector

generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of `'Z'` and a function or as an `(NPeriods  NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify `Z` as a function, it must return an `NBrowns`-by-`1` column vector, and you must call it with two inputs:

- A real-valued scalar observation time t
- An `NVars`-by-`1` state vector X_t

Data Types: `double` | `function`

`N` — Dependent random counting process for generating number of jumps

random numbers from Poisson distribution with parameter `JumpFreq` from a `bates` object (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as the comma-separated pair consisting of `'N'` and a function or an (`NPeriods` `NSteps`) -by-`NJumps`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify a function, `N` must return an `NJumps`-by-`1` column vector, and you must call it with two inputs: a real-valued scalar observation time t followed by an `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function`

`StorePaths` — Flag that indicates how `Paths` is stored and returned

`true` (default) | logical with values `true` or `false`

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of `'StorePaths'` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

If `StorePaths` is `true` (the default value) or is unspecified, `simByEuler` returns `Paths` as a three-dimensional time-series array.

If `StorePaths` is `false` (logical `0`), `simByEuler` returns `Paths` as an empty matrix.

Data Types: `logical`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes
`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of `'MonteCarloMethod'` and a string or character vector with one of the following values:

- `"standard"` — Monte Carlo using pseudo random numbers.
- `"quasi"` — Quasi-Monte Carlo using low-discrepancy sequences.
- `"randomized-quasi"` — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see `Z` and `N`), `simByEuler` ignores the value of `MonteCarloMethod`.

Data Types: `string` | `char`

`QuasiSequence` — Low discrepancy sequence to drive the stochastic processes
`"sobol"` (default) | string with value `"sobol"` | character vector with value `'sobol'`

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of `'QuasiSequence'` and a string or character vector with one of the following values:

- `"sobol"` — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If `MonteCarloMethod` option is not specified or specified as`"standard"`, `QuasiSequence` is ignored.

Data Types: `string` | `char`

`BrownianMotionMethod` — Brownian motion construction method
`"standard"` (default) | string with value `"brownian-bridge"` or `"principal-components"` | character vector with value `'brownian-bridge'` or `'principal-components'`

Brownian motion construction method, specified as the comma-separated pair consisting of `'BrownianMotionMethod'` and a string or character vector with one of the following values:

- `"standard"` — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- `"brownian-bridge"` — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- `"principal-components"` — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the Z input argument, BrownianMotionMethod is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the MonteCarloMethod using pseudo random numbers. However, the performance differs between the two when the MonteCarloMethod option "quasi" is introduced, with faster convergence seen for "brownian-bridge" construction option and the fastest convergence when using the "principal-components" construction option.

Data Types: string | char

Processes — Sequence of end-of-period processes or state vector adjustments

simByEuler makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The simByEuler function runs processing functions at each interpolation time. The functions must accept the current interpolation time t, and the current state vector X_t and return a state vector that can be an adjustment to the input state.

If you specify more than one processing function, simByEuler invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

The end-of-period Processes argument allows you to terminate a given trial early. At the end of each time step, simByEuler tests the state vector X_t for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be NaN. This test enables you to define a Processes function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Data Types: cell | function

Output Arguments

Paths — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as a (NPeriods + 1)-by-NVars-by-NTrials three-dimensional time series array.

For a given trial, each row of Paths is the transpose of the state vector X_t at time t. When StorePaths is set to false, simByEuler returns Paths as an empty matrix.

Times — Observation times associated with simulated paths

column vector

Observation times associated with the simulated paths, returned as an `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates for generating Brownian motion vector
array

Dependent random variates for generating the Brownian motion vector (Wiener processes) that drive the simulation, returned as an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional time-series array.

`N` — Dependent random variates for generating jump counting process vector
array

Dependent random variates used to generate the jump counting process vector, returned as an `(NPeriods ⨉ NSteps)`-by-`NJumps`-by-`NTrials` three-dimensional time series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another that has the same expected value but a smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent other pairs, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

Bates models are bivariate composite models. Each Bates model consists of two coupled univariate models.

- One model is a geometric Brownian motion (`gbm`) model with a stochastic volatility function and jumps.

  $$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t} + Y(t)X_{1t}dN_t$$

  This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.
- The other model is a Cox-Ingersoll-Ross (`cir`) square root diffusion model.

  $$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

  This model describes the evolution of the variance rate of the coupled Bates price process.

This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as `DeltaTimes` approaches zero.

Version History

Introduced in R2020a

R2022a: Perform Quasi-Monte Carlo simulation

Behavior changed in R2022a

Perform Quasi-Monte Carlo simulation using the name-value arguments `MonteCarloMethod` and `QuasiSequence`.

R2022b: Perform Brownian bridge and principal components construction

Behavior changed in R2022b

Perform Brownian bridge and principal components construction using the name-value argument `BrownianMotionMethod`.

simByEuler

Simulate `Merton` jump diffusion sample paths by Euler approximation

Syntax

```
[Paths,Times,Z,N] = simByEuler(MDL,NPeriods)
[Paths,Times,Z,N] = simByEuler( ___ ,Name,Value)
```

Description

`[Paths,Times,Z,N] = simByEuler(MDL,NPeriods)` simulates `NTrials` sample paths of `NVars` correlated state variables driven by `NBrowns` Brownian motion sources of risk and `NJumps` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods. The simulation approximates the continuous-time Merton jump diffusion process by the Euler approach.

`[Paths,Times,Z,N] = simByEuler( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Simulate Merton Jump Diffusion Sample Paths by Euler Approximation

Create a `merton` object.

```
AssetPrice = 80;
            Return = 0.03;
            Sigma = 0.16;
            JumpMean = 0.02;
            JumpVol = 0.08;
            JumpFreq = 2;

            mertonObj = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol,...
                'startstat',AssetPrice)
```

```
mertonObj = 
   Class MERTON: Merton Jump Diffusion
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 80
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
```

```
            Sigma: 0.16
           Return: 0.03
         JumpFreq: 2
         JumpMean: 0.02
          JumpVol: 0.08
```

Use simByEuler to simulate NTrials sample paths of NVars correlated state variables driven by NBrowns Brownian motion sources of risk and NJumps compound Poisson processes representing the arrivals of important events over NPeriods consecutive observation periods. The function simByEuler approximates a continuous-time Merton jump diffusion process by the Euler approach.

```
NPeriods = 2;
[Paths,Times,Z,N] = simByEuler(mertonObj,NPeriods)
```

```
Paths = 3×1

   80.0000
  266.5590
  306.2600

Times = 3×1

     0
     1
     2

Z = 2×1

    1.8339
   -2.2588

N = 2×1

     1
     2
```

Paths is a 3-by-1 matrix. The only column is the path of the simulated AssetPrice. The output Z is a series of matrices used to generate the Brownian motion vector. The output N is a series of matrices used to generate jump vectors.

Quasi-Monte Carlo Simulation with simByEuler Using a Merton Model

Create a merton object.

```
AssetPrice = 80;
            Return = 0.03;
            Sigma = 0.16;
            JumpMean = 0.02;
            JumpVol = 0.08;
            JumpFreq = 2;
            mertonObj = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol,...
                'startstat',AssetPrice)
```

```
mertonObj = 
   Class MERTON: Merton Jump Diffusion
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 80
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.16
         Return: 0.03
       JumpFreq: 2
       JumpMean: 0.02
        JumpVol: 0.08
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for `'MonteCarloMethod'`,`'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time,z] = simByEuler(mertonObj,10,'ntrials',4096,'montecarlomethod','quasi','quasisequence
```

Input Arguments

`MDL` — Stochastic differential equation model

object

Stochastic differential equation model, specified as a `merton` object. You can create a `merton` object using `merton`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Paths,Times,Z,N] = simByEuler(merton,NPeriods,'DeltaTimes',dt)`

`NTrials` — Simulated trials (sample paths)

`1` (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of NPeriods observations each, specified as the comma-separated pair consisting of 'NTrials' and a positive scalar integer.

Data Types: double

DeltaTimes — Positive time increments between observations

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTimes' and a scalar or a NPeriods-by-1 column vector.

DeltaTimes represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

NSteps — Number of intermediate time steps within each time increment

1 (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as DeltaTimes), specified as the comma-separated pair consisting of 'NSteps' and a positive scalar integer.

The simByEuler function partitions each time increment *dt* into NSteps subintervals of length *dt*/NSteps, and refines the simulation by evaluating the simulated state vector at NSteps - 1 intermediate points. Although simByEuler does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

Antithetic — Flag to use antithetic sampling to generate the Gaussian random variates

false (no antithetic sampling) (default) | logical with values true or false

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of 'Antithetic' and a scalar numeric or logical 1 (true) or 0 (false).

When you specify true, simByEuler performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials (1,3,5,...) correspond to the primary Gaussian paths.
- Even trials (2,4,6,...) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see Z), simByEuler ignores the value of Antithetic.

Data Types: logical

Z — Direct specification of the dependent random noise process for generating Brownian motion vector

generates correlated Gaussian variates based on the Correlation member of the SDE object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of `'Z'` and a function or as an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify `Z` as a function, it must return an `NBrowns`-by-`1` column vector, and you must call it with two inputs:

- A real-valued scalar observation time *t*
- An `NVars`-by-`1` state vector X_t

Data Types: `double` | `function`

`N` — Dependent random counting process for generating number of jumps
random numbers from Poisson distribution with parameter `JumpFreq` from `merton` object (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as the comma-separated pair consisting of `'N'` and a function or an (`NPeriods` ⨉ `NSteps`) -by-`NJumps`-by-`NTrials` three-dimensional array of dependent random variates.

If you specify a function, `N` must return an `NJumps`-by-`1` column vector, and you must call it with two inputs: a real-valued scalar observation time *t* followed by an `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function`

`StorePaths` — Flag that indicates how `Paths` is stored and returned
`true` (default) | logical with values `true` or `false`

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of `'StorePaths'` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

If `StorePaths` is `true` (the default value) or is unspecified, `simByEuler` returns `Paths` as a three-dimensional time series array.

If `StorePaths` is `false` (logical `0`), `simByEuler` returns `Paths` as an empty matrix.

Data Types: `logical`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes
`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of `'MonteCarloMethod'` and a string or character vector with one of the following values:

- `"standard"` — Monte Carlo using pseudo random numbers.
- `"quasi"` — Quasi-Monte Carlo using low-discrepancy sequences.
- `"randomized-quasi"` — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see `Z` and `N`), `simByEuler` ignores the value of `MonteCarloMethod`.

Data Types: string | char

QuasiSequence — Low discrepancy sequence to drive the stochastic processes

"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If MonteCarloMethod option is not specified or specified as"standard", QuasiSequence is ignored.

Data Types: string | char

BrownianMotionMethod — Brownian motion construction method

"standard" (default) | string with value "brownian-bridge" or "principal-components" | character vector with value 'brownian-bridge' or 'principal-components'

Brownian motion construction method, specified as the comma-separated pair consisting of 'BrownianMotionMethod' and a string or character vector with one of the following values:

- "standard" — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- "brownian-bridge" — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- "principal-components" — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the Z input argument, BrownianMotionMethod is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the MonteCarloMethod using pseudo random numbers. However, the performance differs between the two when the MonteCarloMethod option "quasi" is introduced, with faster convergence seen for "brownian-bridge" construction option and the fastest convergence when using the "principal-components" construction option.

Data Types: string | char

Processes — Sequence of end-of-period processes or state vector adjustments

simByEuler makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simByEuler` function runs processing functions at each interpolation time. The functions must accept the current interpolation time t, and the current state vector X_t and return a state vector that can be an adjustment to the input state.

If you specify more than one processing function, `simByEuler` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simByEuler` tests the state vector X_t for an all-`NaN` condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be `NaN`. This test enables you to define a `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables
array

Simulated paths of correlated state variables, returned as an `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When `StorePaths` is set to `false`, `simByEuler` returns `Paths` as an empty matrix.

`Times` — Observation times associated with simulated paths
column vector

Observation times associated with the simulated paths, returned as an `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates for generating Brownian motion vector
array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional time-series array.

`N` — Dependent random variates used for generating jump counting process vector
array

Dependent random variates for generating the jump counting process vector, returned as an `(NPeriods ⨉ NSteps)`-by-`NJumps`-by-`NTrials` three-dimensional time-series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another that has the same expected value but a smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent other pairs, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

This function simulates any vector-valued SDE of the following form:

$$dX_t = B(t, X_t)X_t dt + D(t, X_t)V(t, x_t)dW_t + Y(t, X_t, N_t)X_t dN_t$$

Here:

- X_t is an `NVars`-by-`1` state vector of process variables.
- $B(t,X_t)$ is an `NVars`-by-`NVars` matrix of generalized expected instantaneous rates of return.
- $D(t,X_t)$ is an `NVars`-by-`NVars` diagonal matrix in which each element along the main diagonal is the corresponding element of the state vector.
- $V(t,X_t)$ is an `NVars`-by-`NVars` matrix of instantaneous volatility rates.
- dW_t is an `NBrowns`-by-`1` Brownian motion vector.
- $Y(t,X_t,N_t)$ is an `NVars`-by-`NJumps` matrix-valued jump size function.
- dN_t is an `NJumps`-by-`1` counting process vector.

`simByEuler` simulates `NTrials` sample paths of `NVars` correlated state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, using the Euler approach to approximate continuous-time stochastic processes.

This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as `DeltaTimes` approaches zero.

Version History

Introduced in R2020a

R2022a: Perform Quasi-Monte Carlo simulation

Behavior changed in R2022a

Perform Quasi-Monte Carlo simulation using the name-value arguments `MonteCarloMethod` and `QuasiSequence`.

R2022b: Perform Brownian bridge and principal components construction

Behavior changed in R2022b

Perform Brownian bridge and principal components construction using the name-value argument `BrownianMotionMethod`.

simBySolution

Simulate approximate solution of diagonal-drift Merton jump diffusion process

Syntax

```
[Paths,Times,Z,N] = simBySolution(MDL,NPeriods)
[Paths,Times,Z,N] = simBySolution( ___ ,Name,Value)
```

Description

[Paths,Times,Z,N] = simBySolution(MDL,NPeriods) simulates NNTrials sample paths of NVars correlated state variables driven by NBrowns Brownian motion sources of risk and NJumps compound Poisson processes representing the arrivals of important events over NPeriods consecutive observation periods. The simulation approximates continuous-time Merton jump diffusion process by an approximation of the closed-form solution.

[Paths,Times,Z,N] = simBySolution(___ ,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for MonteCarloMethod, QuasiSequence, and BrownianMotionMethod. For more information, see "Quasi-Monte Carlo Simulation" on page 14-62.

Examples

Use simBySolution with merton Object

Simulate the approximate solution of diagonal-drift Merton process.

Create a merton object.

```
AssetPrice = 80;
            Return = 0.03;
            Sigma = 0.16;
            JumpMean = 0.02;
            JumpVol = 0.08;
            JumpFreq = 2;

            mertonObj = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol,...
                'startstat',AssetPrice)
```

```
mertonObj = 
   Class MERTON: Merton Jump Diffusion
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 80
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.16
         Return: 0.03
       JumpFreq: 2
       JumpMean: 0.02
        JumpVol: 0.08
```

Use simBySolution to simulate NTrials sample paths of NVARS correlated state variables driven by NBrowns Brownian motion sources of risk and NJumps compound Poisson processes representing the arrivals of important events over NPeriods consecutive observation periods. The function approximates continuous-time Merton jump diffusion process by an approximation of the closed-form solution.

```
nPeriods = 100;
[Paths,Times,Z,N] = simBySolution(mertonObj, nPeriods,'nTrials', 3)
```

```

Quasi-Monte Carlo Simulation Using Merton Model

This example shows how to use `simBySolution` with a Merton model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Create a `merton` object.

```
AssetPrice = 80;
Return = 0.03;
Sigma = 0.16;
JumpMean = 0.02;
JumpVol = 0.08;
JumpFreq = 2;

Merton = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol,'startstat',AssetPrice)
```

```
Merton = 
   Class MERTON: Merton Jump Diffusion
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 80
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.16
         Return: 0.03
       JumpFreq: 2
       JumpMean: 0.02
        JumpVol: 0.08
```

Perform a quasi-Monte Carlo simulation by using `simBySolution` with the optional name-value arguments for `'MonteCarloMethod'`,`'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time,z,n] = simBySolution(Merton, 10,'ntrials',4096,'montecarlomethod','quasi','QuasiSeque
```

Input Arguments

`MDL` — Merton model

`merton` object

Merton model, specified as a `merton` object. You can create a `merton` object using `merton`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Paths,Times,Z,N] = simBySolution(merton,NPeriods,'DeltaTimes',dt,'NNTrials',10)`

`NNTrials` — Simulated NTrials (sample paths)

`1` (single path of correlated state variables) (default) | positive integer

Simulated NTrials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of `'NNTrials'` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations

`1` (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of `'DeltaTimes'` and a scalar or an `NPeriods`-by-`1` column vector.

`DeltaTimes` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps within each time increment

`1` (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment *dt* (specified as `DeltaTimes`), specified as the comma-separated pair consisting of `'NSteps'` and a positive scalar integer.

The `simBySolution` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps − 1` intermediate points. Although `simBySolution` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`Antithetic` — Flag to use antithetic sampling to generate the Gaussian random variates

`false` (no antithetic sampling) (default) | logical with values `true` or `false`

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of `'Antithetic'` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

When you specify `true`, `simBySolution` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd NTrials `(1,3,5,...)` correspond to the primary Gaussian paths.
- Even NTrials `(2,4,6,...)` are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see `Z`), `simBySolution` ignores the value of `Antithetic`.

Data Types: `logical`

MonteCarloMethod — Monte Carlo method to simulate stochastic processes
"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see Z and N), simBySolution ignores the value of MonteCarloMethod.

Data Types: string | char

QuasiSequence — Low discrepancy sequence to drive the stochastic processes
"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note

- If MonteCarloMethod option is not specified or specified as"standard", QuasiSequence is ignored.
- If you specify an input noise process (see Z), simBySolution ignores the value of QuasiSequence.

Data Types: string | char

BrownianMotionMethod — Brownian motion construction method
"standard" (default) | string with value "brownian-bridge" or "principal-components" | character vector with value 'brownian-bridge' or 'principal-components'

Brownian motion construction method, specified as the comma-separated pair consisting of 'BrownianMotionMethod' and a string or character vector with one of the following values:

- "standard" — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- "brownian-bridge" — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- "principal-components" — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the `Z` input argument, `BrownianMotionMethod` is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the `MonteCarloMethod` using pseudo random numbers. However, the performance differs between the two when the `MonteCarloMethod` option `"quasi"` is introduced, with faster convergence seen for `"brownian-bridge"` construction option and the fastest convergence when using the `"principal-components"` construction option.

Data Types: `string` | `char`

Z — Direct specification of the dependent random noise process for generating Brownian motion vector

generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of `'Z'` and a function or an `(NPeriods * NSteps)`-by-`NBrowns`-by-`NNTrials` three-dimensional array of dependent random variates.

The input argument `Z` allows you to directly specify the noise generation process. This process takes precedence over the `Correlation` parameter of the input `merton` object and the value of the `Antithetic` input flag.

Specifically, when `Z` is specified, `Correlation` is not explicitly used to generate the Gaussian variates that drive the Brownian motion. However, `Correlation` is still used in the expression that appears in the exponential term of the log[X_t] Euler scheme. Thus, you must specify `Z` as a correlated Gaussian noise process whose correlation structure is consistently captured by `Correlation`.

Note If you specify `Z` as a function, it must return an `NBrowns`-by-`1` column vector, and you must call it with two inputs:

- A real-valued scalar observation time t
- An `NVars`-by-`1` state vector X_t

Data Types: `double` | `function`

N — Dependent random counting process for generating number of jumps

random numbers from Poisson distribution with `merton` object parameter `JumpFreq` (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as the comma-separated pair consisting of `'N'` and a function or an (`NPeriods` □ `NSteps`) -by-`NJumps`-by-`NNTrials` three-dimensional array of dependent random variates. If you specify a function, `N` must return an `NJumps`-by-`1` column vector, and you must call it with two inputs: a real-valued scalar observation time t followed by an `NVars`-by-`1` state vector X_t.

Data Types: double | function

StorePaths — Flag that indicates how Paths is stored and returned
true (default) | logical with values true or false

Flag that indicates how the output array Paths is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar numeric or logical 1 (true) or 0 (false).

If StorePaths is true (the default value) or is unspecified, simBySolution returns Paths as a three-dimensional time series array.

If StorePaths is false (logical 0), simBySolution returns Paths as an empty matrix.

Data Types: logical

Processes — Sequence of end-of-period processes or state vector adjustments of the form
simBySolution makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

simBySolution applies processing functions at the end of each observation period. These functions must accept the current observation time t and the current state vector X_t, and return a state vector that can be an adjustment to the input state.

The end-of-period Processes argument allows you to terminate a given trial early. At the end of each time step, simBySolution tests the state vector X_t for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be NaN. This test enables a user-defined Processes function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

If you specify more than one processing function, simBySolution invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: cell | function

Output Arguments

Paths — Simulated paths of correlated state variables
array

Simulated paths of correlated state variables, returned as an (NPeriods + 1)-by-NVars-by-NNTrials three-dimensional time-series array.

For a given trial, each row of Paths is the transpose of the state vector X_t at time t. When StorePaths is set to false, simBySolution returns Paths as an empty matrix.

Times — Observation times associated with simulated paths
column vector

Observation times associated with the simulated paths, returned as an (NPeriods + 1)-by-1 column vector. Each element of Times is associated with the corresponding row of Paths.

Z — Dependent random variates for generating the Brownian motion vector

array

Dependent random variates for generating the Brownian motion vector (Wiener processes) that drive the simulation, returned as a `(NPeriods * NSteps)`-by-`NBrowns`-by-`NNTrials` three-dimensional time-series array.

N — Dependent random variates for generating the jump counting process vector

array

Dependent random variates for generating the jump counting process vector, returned as an `(NPeriods □ NSteps)`-by-`NJumps`-by-`NNTrials` three-dimensional time-series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another that has the same expected value but a smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent other pairs, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo NTrials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

The `simBySolution` function simulates the state vector X_t by an approximation of the closed-form solution of diagonal drift Merton jump diffusion models. Specifically, it applies a Euler approach to the transformed `log`[X_t] process (using Ito's formula). In general, this is not the exact solution to the Merton jump diffusion model because the probability distributions of the simulated and true state vectors are identical only for piecewise constant parameters.

This function simulates any vector-valued `merton` process of the form

$$dX_t = B(t, X_t)X_tdt + D(t, X_t)V(t, x_t)dW_t + Y(t, X_t, N_t)X_tdN_t$$

Here:

- X_t is an `NVars`-by-`1` state vector of process variables.
- $B(t,X_t)$ is an `NVars`-by-`NVars` matrix of generalized expected instantaneous rates of return.
- $D(t,X_t)$ is an `NVars`-by-`NVars` diagonal matrix in which each element along the main diagonal is the corresponding element of the state vector.
- $V(t,X_t)$ is an `NVars`-by-`NVars` matrix of instantaneous volatility rates.

- dW_t is an `NBrowns`-by-`1` Brownian motion vector.
- $Y(t,X_t,N_t)$ is an `NVars`-by-`NJumps` matrix-valued jump size function.
- dN_t is an `NJumps`-by-`1` counting process vector.

Version History

Introduced in R2020a

R2022a: Perform Quasi-Monte Carlo simulation

Behavior changed in R2022a

simByQuadExp

Simulate Bates, Heston, and CIR sample paths by quadratic-exponential discretization scheme

Syntax

```
[Paths,Times,Z] = simByQuadExp(MDL,NPeriods)
[Paths,Times,Z] = simByQuadExp( ___ ,Name,Value)

[Paths,Times,Z,N] = simByQuadExp(MDL,NPeriods)
[Paths,Times,Z,N] = simByQuadExp( ___ ,Name,Value)
```

Description

[Paths,Times,Z] = simByQuadExp(MDL,NPeriods) simulates NTrials sample paths of a Heston model driven by two Brownian motion sources of risk, or a CIR model driven by one Brownian motion source of risk. Both Heston and Bates models approximate continuous-time stochastic processes by a quadratic-exponential discretization scheme. The simByQuadExp simulation derives directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as DeltaTimes approaches zero.

[Paths,Times,Z] = simByQuadExp(___ ,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

[Paths,Times,Z,N] = simByQuadExp(MDL,NPeriods) simulates NTrials sample paths of a Bates model driven by two Brownian motion sources of risk, approximating continuous-time stochastic processes by a quadratic-exponential discretization scheme. The simByQuadExp simulation derives directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as DeltaTimes approaches zero.

[Paths,Times,Z,N] = simByQuadExp(___ ,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for MonteCarloMethod, QuasiSequence, and BrownianMotionMethod. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Simulate Bates Sample Paths by Quadratic-Exponential Discretization Scheme

Create a bates object.

```
AssetPrice = 80;
            Return = 0.03;
            JumpMean = 0.02;
            JumpVol = 0.08;
            JumpFreq = 0.1;
            V0 = 0.04;
            Level = 0.05;
            Speed = 1.0;
            Volatility = 0.2;
            Rho = -0.7;
            StartState = [AssetPrice;V0];
            Correlation = [1 Rho;Rho 1];

batesObj = bates(Return, Speed, Level, Volatility,...
                JumpFreq, JumpMean, JumpVol,'startstate',StartState,...
                'correlation',Correlation)
```

```
batesObj = 
   Class BATES: Bates Bivariate Stochastic Volatility
   --------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   --------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
    Correlation: 2x2 double array
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.03
          Speed: 1
          Level: 0.05
     Volatility: 0.2
       JumpFreq: 0.1
       JumpMean: 0.02
        JumpVol: 0.08
```

Use simByQuadExp to simulate NTrials sample paths directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as DeltaTimes approaches zero.

```
NPeriods = 2;
[Paths,Times,Z,N] = simByQuadExp(batesObj,NPeriods)
```

```
Paths = 3×2

   80.0000    0.0400
   64.3377    0.1063
   31.5703    0.1009

Times = 3×1

     0
     1
     2

Z = 2×2

    0.5377    1.8339
   -2.2588    0.8622
```

```
N = 2×1

     0
     0
```

The output Paths is returned as a (NPeriods + 1)-by-NVars-by-NTrials three-dimensional time-series array.

Quasi-Monte Carlo Simulation Using Bates Model

This example shows how to use simByQuadExp with a Bates model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Define the parameters for the bates object.

```
AssetPrice = 80;
Return = 0.03;
JumpMean = 0.02;
JumpVol = 0.08;
JumpFreq = 0.1;

V0 = 0.04;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;
Rho = -0.7;
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];
```

Create a bates object.

```
Bates = bates(Return, Speed, Level, Volatility, ...
                JumpFreq, JumpMean, JumpVol,'startstate',StartState, ...
                'correlation',Correlation)
```

```
Bates = 
   Class BATES: Bates Bivariate Stochastic Volatility
   --------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   --------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
    Correlation: 2x2 double array
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.03
          Speed: 1
          Level: 0.05
     Volatility: 0.2
       JumpFreq: 0.1
       JumpMean: 0.02
        JumpVol: 0.08
```

Perform a quasi-Monte Carlo simulation by using `simByQuadExp` with the optional name-value arguments for `'MonteCarloMethod'`,`'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time,z] = simByQuadExp(Bates,10,'ntrials',4096,'montecarlomethod','quasi','quasisequence'
```

Input Arguments

`MDL` — Stochastic differential equation model

bates object | heston object | cir object

Stochastic differential equation model, specified as a `bates`, `heston`, or `cir` object. You can create these objects using `bates`, `heston`, or `cir`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Paths,Times,Z,N] = simByQuadExp(bates_obj,NPeriods,'DeltaTime',dt)`

`NTrials` — Simulated trials (sample paths) of `NPeriods` observations each

`1` (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of `'NTrials'` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations

`1` (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of `'DeltaTimes'` and a scalar or a `NPeriods`-by-`1` column vector.

`DeltaTimes` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps within each time increment *dt* (specified as `DeltaTimes`)

`1` (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as `DeltaTimes`), specified as the comma-separated pair consisting of `'NSteps'` and a positive scalar integer.

The `simByQuadExp` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps - 1` intermediate points. Although `simByQuadExp` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes
`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of `'MonteCarloMethod'` and a string or character vector with one of the following values:

- `"standard"` — Monte Carlo using pseudo random numbers.
- `"quasi"` — Quasi-Monte Carlo using low-discrepancy sequences.
- `"randomized-quasi"` — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see `Z` and `N`), `simByQuadExp` ignores the value of `MonteCarloMethod`.

Data Types: `string` | `char`

`QuasiSequence` — Low discrepancy sequence to drive the stochastic processes
`"sobol"` (default) | string with value `"sobol"` | character vector with value `'sobol'`

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of `'QuasiSequence'` and a string or character vector with one of the following values:

- `"sobol"` — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If `MonteCarloMethod` option is not specified or specified as`"standard"`, `QuasiSequence` is ignored.

Data Types: `string` | `char`

`BrownianMotionMethod` — Brownian motion construction method
`"standard"` (default) | string with value `"brownian-bridge"` or `"principal-components"` | character vector with value `'brownian-bridge'` or `'principal-components'`

Brownian motion construction method, specified as the comma-separated pair consisting of `'BrownianMotionMethod'` and a string or character vector with one of the following values:

- `"standard"` — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.

- `"brownian-bridge"` — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- `"principal-components"` — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the `Z` input argument, `BrownianMotionMethod` is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the `MonteCarloMethod` using pseudo random numbers. However, the performance differs between the two when the `MonteCarloMethod` option `"quasi"` is introduced, with faster convergence seen for `"brownian-bridge"` construction option and the fastest convergence when using the `"principal-components"` construction option.

Data Types: `string` | `char`

`Antithetic` — Flag to use antithetic sampling to generate the Gaussian random variates

`false` (no antithetic sampling) (default) | logical with values `true` or `false`

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of `'Antithetic'` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

When you specify `true`, `simByQuadExp` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials `(1,3,5,...)` correspond to the primary Gaussian paths.
- Even trials `(2,4,6,...)` are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see `Z`), `simByEuler` ignores the value of `Antithetic`.

Data Types: `logical`

`Z` — Direct specification of dependent random noise process for generating Brownian motion vector

generates correlated Gaussian variates based on the `Correlation` member of the `heston`, `bates`, or `cir` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of `'Z'` and a function or an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

If you specify `Z` as a function, it must return an `NBrowns`-by-`1` column vector, and you must call it with two inputs:

- A real-valued scalar observation time t
- An `NVars`-by-`1` state vector X_t

Data Types: `double` | `function`

`N` — Dependent random counting process for generating number of jumps
random numbers from Poisson distribution with parameter `JumpFreq` from a `bates` object (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as the comma-separated pair consisting of `'N'` and a function or an (`NPeriods` □ `NSteps`) -by-`NJumps`-by-`NTrials` three-dimensional array of dependent random variates. If you specify a function, `N` must return an `NJumps`-by-`1` column vector, and you must call it with two inputs: a real-valued scalar observation time t followed by an `NVars`-by-`1` state vector X_t.

Note The `N` name-value pair argument is supported only when you use a `bates` object for the `MDL` input argument.

Data Types: `double` | `function`

`StorePaths` — Flag that indicates how `Paths` is stored and returned
`true` (default) | logical with values `true` or `false`

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of `'StorePaths'` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

If `StorePaths` is `true` (the default value) or is unspecified, `simByQuadExp` returns `Paths` as a three-dimensional time-series array.

If `StorePaths` is `false` (logical `0`), `simByQuadExp` returns `Paths` as an empty matrix.

Data Types: `logical`

`Processes` — Sequence of end-of-period processes or state vector adjustments
`simByQuadExp` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of `'Processes'` and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simByQuadExp` function runs processing functions at each interpolation time. The functions must accept the current interpolation time t, and the current state vector X_t and return a state vector that can be an adjustment to the input state.

If you specify more than one processing function, `simByQuadExp` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simByQuadExp` tests the state vector X_t for an all-`NaN` condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be `NaN`. This test enables you to define a `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables for a heston, bates, or cir model, returned as a `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When `StorePaths` is set to `false`, `simByQuadExp` returns `Paths` as an empty matrix.

`Times` — Observation times associated with simulated paths

column vector

Observation times for a heston, bates, or cir model associated with the simulated paths, returned as a `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates for generating Brownian motion vector

array

Dependent random variates for a heston, bates, or cir model for generating the Brownian motion vector (Wiener processes) that drive the simulation, returned as an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional time-series array.

`N` — Dependent random variates for generating jump counting process vector

array

Dependent random variates for a bates model for generating the jump counting process vector, returned as a `(NPeriods ⨉ NSteps)`-by-`NJumps`-by-`NTrials` three-dimensional time-series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

Heston

In the Heston stochastic volatility model, the asset value process and volatility process are defined as

$$dS(t) = \gamma(t)S(t)dt + \sqrt{V(t)}S(t)dW_S(t)$$
$$dV(t) = \kappa(\theta - V(t))dt + \sigma\sqrt{V(t)}dW_V(t)$$

Here:

- γ is the continuous risk-free rate.
- θ is a long-term variance level.
- κ is the mean reversion speed for the variance.
- σ is the volatility of volatility.

CIR

You can simulate any vector-valued CIR process of the form

$$dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW_t$$

Here:

- X_t is an `NVars`-by-`1` state vector of process variables.
- S is an `NVars`-by-`NVars` matrix of mean reversion speeds (the rate of mean reversion).
- L is an `NVars`-by-`1` vector of mean reversion levels (long-run mean or level).
- D is an `NVars`-by-`NVars` diagonal matrix, where each element along the main diagonal is the square root of the corresponding element of the state vector.
- V is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- dW_t is an `NBrowns`-by-`1` Brownian motion vector.

Bates

Bates models are bivariate composite models. Each Bates model consists of two coupled univariate models.

- A geometric Brownian motion (`gbm`) model with a stochastic volatility function and jumps that is expressed as follows.

  $$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t} + Y(t)X_{1t}dN_t$$

  This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.
- A Cox-Ingersoll-Ross (`cir`) square root diffusion model that is expressed as follows.

  $$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

  This model describes the evolution of the variance rate of the coupled Bates price process.

Version History

Introduced in R2020a

R2022a: Perform Quasi-Monte Carlo simulation

Behavior changed in R2022a

Perform Quasi-Monte Carlo simulation using the name-value arguments `MonteCarloMethod` and `QuasiSequence`.

simByEuler

Euler simulation of stochastic differential equations (SDEs) for SDE, BM, GBM, CEV, CIR, HWV, Heston, SDEDDO, SDELD, or SDEMRD models

Syntax

```
[Paths,Times,Z] = simByEuler(MDL,NPeriods)
[Paths,Times,Z] = simByEuler( ___ ,Name,Value)
```

Description

[Paths,Times,Z] = simByEuler(MDL,NPeriods) simulates NTrials sample paths of NVars correlated state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods. simByEuler uses the Euler approach to approximate continuous-time stochastic processes.

[Paths,Times,Z] = simByEuler(___ ,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for MonteCarloMethod, QuasiSequence, and BrownianMotionMethod. For more information, see "Quasi-Monte Carlo Simulation" on page 14-62.

Examples

Simulate Equity Markets Using simByEuler

Load the Data and Specify the SDE Model

```
load Data_GlobalIdx2
prices  = [Dataset.TSX Dataset.CAC Dataset.DAX ...
    Dataset.NIK Dataset.FTSE Dataset.SP];

returns =  tick2ret(prices);

nVariables  = size(returns,2);
expReturn   = mean(returns);
sigma       = std(returns);
correlation = corrcoef(returns);
t           = 0;
X           = 100;
X           = X(ones(nVariables,1));

F = @(t,X) diag(expReturn)* X;
G = @(t,X) diag(X) * diag(sigma);

SDE = sde(F, G, 'Correlation', ...
    correlation, 'StartState', X);
```

Simulate a Single Path Over a Year

```
nPeriods = 249;      % # of simulated observations
dt       =   1;      % time increment = 1 day
rng(142857,'twister')
[S,T] = simByEuler(SDE, nPeriods, 'DeltaTime', dt);
```

Simulate 10 trials and examine the SDE model

```
rng(142857,'twister')
[S,T] = simulate(SDE, nPeriods, 'DeltaTime', dt, 'nTrials', 10);

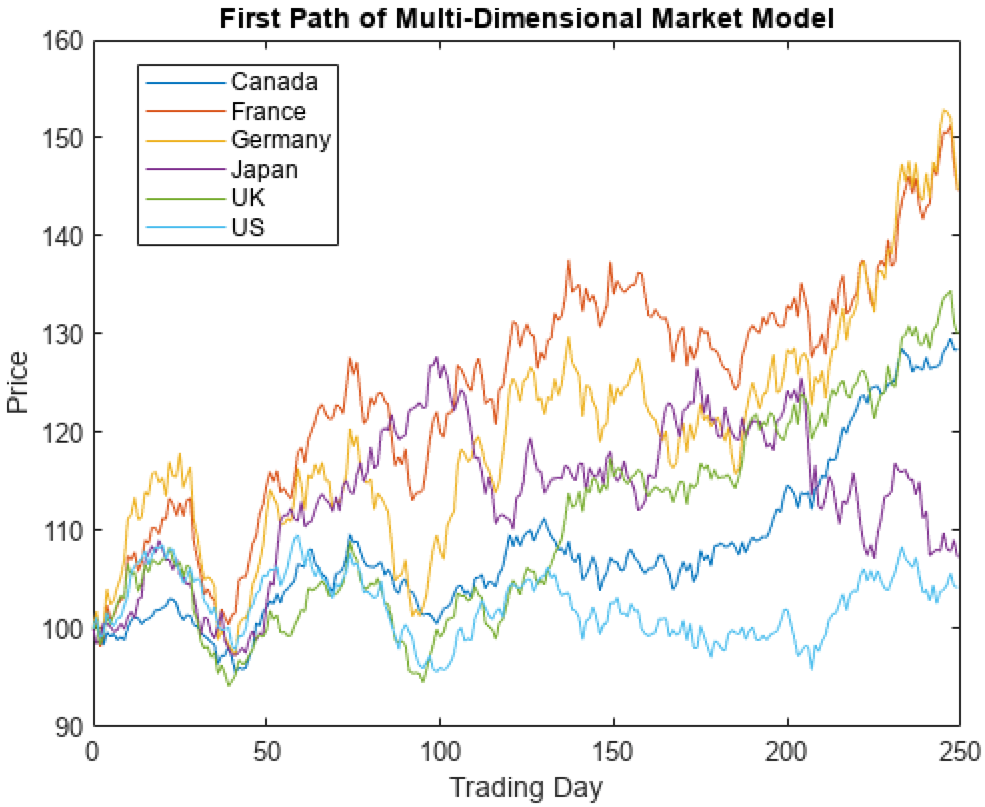
whos S
```

```
  Name          Size                 Bytes  Class     Attributes

  S           250x6x10              120000  double
```

Plot the paths

```
plot(T, S(:,:,1)), xlabel('Trading Day'), ylabel('Price')
title('First Path of Multi-Dimensional Market Model')
legend({'Canada' 'France' 'Germany' 'Japan' 'UK' 'US'},...
    'Location', 'Best')
```



Euler Simulation for a CIR Object

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift (`SDEMRD`): $dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$

where D is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model: $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$.

```
CIR = cir(0.2, 0.1, 0.05)  % (Speed, Level, Sigma)
```

```
CIR = 
   Class CIR: Cox-Ingersoll-Ross
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.1
          Speed: 0.2
```

Simulate a single path over a year using `simByEuler`.

```
nPeriods = 249;      % # of simulated observations
dt       =   1;      % time increment = 1 day
rng(142857,'twister')
[Paths,Times] = simByEuler(CIR,nPeriods,'Method','higham-mao','DeltaTime', dt)
```

```
Paths = 250×1

Quasi-Monte Carlo Simulation with `simByEuler` Using a CIR Model

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift (`SDEMRD`): $dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$

where D is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model: $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$.

```
cir_obj = cir(0.2, 0.1, 0.05)  % (Speed, Level, Sigma)
```

```
cir_obj = 
   Class CIR: Cox-Ingersoll-Ross
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.1
          Speed: 0.2
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for `'MonteCarloMethod'`,`'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time,z] = simByEuler(cir_obj,10,'ntrials',4096,'method','basic','montecarlomethod','quasi
```

Quasi-Monte Carlo Simulation with `simByEuler` Using a Heston Model

The Heston (`heston`) class derives directly from SDE from Drift and Diffusion (`sdeddo`). Each Heston model is a bivariate composite model, consisting of two coupled univariate models:

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

Create a heston object.

```
heston_obj = heston (0.1, 0.2, 0.1, 0.05)  % (Return, Speed, Level, Volatility)
```

```
heston_obj = 
   Class HESTON: Heston Bivariate Stochastic Volatility
   ----------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   ----------------------------------------------------
      StartTime: 0
     StartState: 1 (2x1 double array) 
    Correlation: 2x2 diagonal double array 
          Drift: drift rate function F(t,X(t)) 
      Diffusion: diffusion rate function G(t,X(t)) 
     Simulation: simulation method/function simByEuler
         Return: 0.1
          Speed: 0.2
          Level: 0.1
     Volatility: 0.05
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for 'MonteCarloMethod','QuasiSequence', and 'BrownianMotionMethod'.

```
[paths,time,z] = simByEuler(heston_obj,10,'ntrials',4096,'montecarlomethod','quasi','quasisequen
```

Quasi-Monte Carlo Simulation with simByEuler Using GBM Model

Create a univariate gbm object to represent the model: $dX_t = 0.25X_tdt + 0.3X_tdW_t$.

```
gbm_obj = gbm(0.25, 0.3)  % (B = Return, Sigma)
```

```
gbm_obj = 
   Class GBM: Generalized Geometric Brownian Motion
   ------------------------------------------------
     Dimensions: State = 1, Brownian = 1
   ------------------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t)) 
      Diffusion: diffusion rate function G(t,X(t)) 
     Simulation: simulation method/function simByEuler
         Return: 0.25
          Sigma: 0.3
```

gbm objects display the parameter B as the more familiar Return.

Define the quasi-Monte Carlo simulation using the optional name-value arguments for 'MonteCarloMethod','QuasiSequence', and 'BrownianMotionMethod'.

```
[paths,time,z] = simByEuler(gbm_obj,10,'ntrials',4096,'montecarlomethod','quasi','quasisequence',
```

Input Arguments

`MDL` — Stochastic differential equation model

object

Stochastic differential equation model, specified as an `sde`, `bm`, `gbm`, `cev`, `cir`, `hwv`, `heston`, `sdeddo`, `sdeld`, or `sdemrd` object.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Paths,Times,Z] = simByEuler(SDE,NPeriods,'DeltaTime',dt)`

`Method` — Method to handle negative values

`'basic'` (default) | character vector with values`'basic'`, `'absorption'`, `'reflection'`, `'partial-truncation'`, `'full-truncation'`, or `'higham-mao'` | string with values `"basic"`, `"absorption"`, `"reflection"`, `"partial-truncation"`, `"full-truncation"`, or `"higham-mao"`

Method to handle negative values, specified as the comma-separated pair consisting of `'Method'` and a character vector or string with a supported value.

Note The `Method` argument is only supported when using a `CIR` object. For more information on creating a `CIR` object, see `cir`.

Data Types: `char` | `string`

`NTrials` — Simulated trials (sample paths) of `NPeriods` observations each

`1` (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of `'NTrials'` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations

`1` (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of `'DeltaTimes'` and a scalar or a `NPeriods`-by-`1` column vector.

`DeltaTime` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps within each time increment *dt* (specified as `DeltaTime`)

`1` (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as `DeltaTime`), specified as the comma-separated pair consisting of `'NSteps'` and a positive scalar integer.

The `simByEuler` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps - 1` intermediate points. Although `simByEuler` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`Antithetic` — Flag to indicate whether `simByEuler` uses antithetic sampling to generate the Gaussian random variates

`False` (no antithetic sampling) (default) | logical with values `True` or `False`

Flag indicates whether `simByEuler` uses antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes). This argument is specified as the comma-separated pair consisting of `'Antithetic'` and a scalar logical flag with a value of `True` or `False`.

When you specify `True`, `simByEuler` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials `(1,3,5,...)` correspond to the primary Gaussian paths.
- Even trials `(2,4,6,...)` are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see `Z`), `simByEuler` ignores the value of `Antithetic`.

Data Types: `logical`

`Z` — Direct specification of the dependent random noise process used to generate the Brownian motion vector

generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process used to generate the Brownian motion vector (Wiener process) that drives the simulation. This argument is specified as the comma-separated pair consisting of `'Z'` and a function or as an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify `Z` as a function, it must return an `NBrowns`-by-`1` column vector, and you must call it with two inputs:

- A real-valued scalar observation time *t*.
- An NVars-by-1 state vector X_t.

Data Types: double | function

StorePaths — Flag that indicates how the output array Paths is stored and returned
True (default) | logical with values True or False

Flag that indicates how the output array Paths is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar logical flag with a value of True or False.

If StorePaths is True (the default value) or is unspecified, simByEuler returns Paths as a three-dimensional time series array.

If StorePaths is False (logical 0), simByEuler returns the Paths output array as an empty matrix.

Data Types: logical

MonteCarloMethod — Monte Carlo method to simulate stochastic processes
"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see Z), simByEuler ignores the value of MonteCarloMethod.

Data Types: string | char

QuasiSequence — Low discrepancy sequence to drive the stochastic processes
"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If MonteCarloMethod option is not specified or specified as"standard", QuasiSequence is ignored.

Data Types: string | char

BrownianMotionMethod — Brownian motion construction method

"standard" (default) | string with value "brownian-bridge" or "principal-components" | character vector with value 'brownian-bridge' or 'principal-components'

Brownian motion construction method, specified as the comma-separated pair consisting of 'BrownianMotionMethod' and a string or character vector with one of the following values:

- "standard" — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- "brownian-bridge" — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- "principal-components" — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the Z input argument, BrownianMotionMethod is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the MonteCarloMethod using pseudo random numbers. However, the performance differs between the two when the MonteCarloMethod option "quasi" is introduced, with faster convergence seen for "brownian-bridge" construction option and the fastest convergence when using the "principal-components" construction option.

Data Types: string | char

Processes — Sequence of end-of-period processes or state vector adjustments

simByEuler makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments of the form, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The simByEuler function runs processing functions at each interpolation time. They must accept the current interpolation time t, and the current state vector X_t, and return a state vector that may be an adjustment to the input state.

If you specify more than one processing function, simByEuler invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: cell | function

Output Arguments

Paths — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as a `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When the input flag `StorePaths` = `False`, `simByEuler` returns `Paths` as an empty matrix.

`Times` — Observation times associated with the simulated paths
column vector

Observation times associated with the simulated paths, returned as a `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates used to generate the Brownian motion vector
array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as a `(NPeriods □ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional time series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

This function simulates any vector-valued SDE of the form

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- X is an *NVars*-by-`1` state vector of process variables (for example, short rates or equity prices) to simulate.
- W is an *NBrowns*-by-`1` Brownian motion vector.
- F is an *NVars*-by-`1` vector-valued drift-rate function.
- G is an *NVars*-by-*NBrowns* matrix-valued diffusion-rate function.

simByEuler simulates NTrials sample paths of NVars correlated state variables driven by NBrowns Brownian motion sources of risk over NPeriods consecutive observation periods, using the Euler approach to approximate continuous-time stochastic processes.

- This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as DeltaTime approaches zero.
- The input argument Z allows you to directly specify the noise-generation process. This process takes precedence over the Correlation parameter of the sde object and the value of the Antithetic input flag. If you do not specify a value for Z, simByEuler generates correlated Gaussian variates, with or without antithetic sampling as requested.
- The end-of-period Processes argument allows you to terminate a given trial early. At the end of each time step, simByEuler tests the state vector X_t for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be NaN. This test enables a user-defined Processes function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Version History

Introduced in R2008a

R2022a: Perform Quasi-Monte Carlo simulation

Behavior changed in R2022a

Perform Quasi-Monte Carlo simulation using the name-value arguments MonteCarloMethod and QuasiSequence.

R2022b: Perform Brownian bridge and principal components construction

Behavior changed in R2022b

Perform Brownian bridge and principal components construction using the name-value argument BrownianMotionMethod.

simByTransition

Simulate `CIR` sample paths with transition density

Syntax

```
[Paths,Times] = simByTransition(MDL,NPeriods)
[Paths,Times] = simByTransition(___,Name,Value)
```

Description

`[Paths,Times] = simByTransition(MDL,NPeriods)` simulates `NTrials` sample paths of `NVars` independent state variables driven by the Cox-Ingersoll-Ross (CIR) process sources of risk over `NPeriods` consecutive observation periods. `simByTransition` approximates a continuous-time CIR model using an approximation of the transition density function.

`[Paths,Times] = simByTransition(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`. For more information, see "Quasi-Monte Carlo Simulation" on page 14-62.

Examples

Simulate Future Term Structures Using a CIR Model

Using the short rate, simulate the rate dynamics and term structures in the future using a CIR model. The CIR model is expressed as

$$dr(t) = \alpha(b - r(t))dt + \sigma\sqrt{r(t)}dW(t)$$

The exponential affine form of the bond price is

$$B(t,T) = e^{-A(t,T)r(t) + C(t,T)}$$

where

$$A(t,T) = \frac{2(e^{\gamma(T-t)} - 1)}{(\gamma + \alpha)(e^{\gamma(T-t)} - 1) + 2\gamma}$$

$$B(t,T) = \frac{2\alpha b}{\sigma^2}\log\left(\frac{2\gamma e^{(\alpha+\gamma)(T-t)/2}}{(\gamma + \alpha)(e^{\gamma(T-t)} - 1) + 2\gamma}\right)$$

and

$$\gamma = \sqrt{\alpha^2 + 2\sigma^2}$$

Define the parameters for the `cir` object.

```
alpha = .1;
b = .05;
sigma = .05;
r0 = .04;
```

Define the function for bond prices.

```
gamma = sqrt(alpha^2 + 2*sigma^2);
A_func = @(t, T) ...
    2*(exp(gamma*(T-t))-1)/((alpha+gamma)*(exp(gamma*(T-t))-1)+2*gamma);
C_func = @(t, T) ...
    (2*alpha*b/sigma^2)*log(2*gamma*exp((alpha+gamma)*(T-t)/2)/((alpha+gamma)*(exp(gamma*(T-t))-1
P_func = @(t,T,r_t) exp(-A_func(t,T)*r_t+C_func(t,T));
```

Create a `cir` object.

```
obj = cir(alpha,b,sigma,'StartState',r0)
```

```
obj = 
   Class CIR: Cox-Ingersoll-Ross
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 0.04
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.05
          Speed: 0.1
```

Define the simulation parameters.

```
nTrials = 100;
nPeriods = 5;   % Simulate future short over the next five years
nSteps = 12;    % Set intermediate steps to improve the accuracy
```

Simulate the short rates. The returning path is a (NPeriods + 1)-by-`NVars`-by-`NTrials` three-dimensional time-series array. For this example, the size of the output is `6`-by-`1`-by-`100`.

```
rng('default');    % Reproduce the same result
rPaths = simByTransition(obj,nPeriods,'nTrials',nTrials,'nSteps',nSteps);
size(rPaths)
```

```
ans = 1×3

     6     1   100

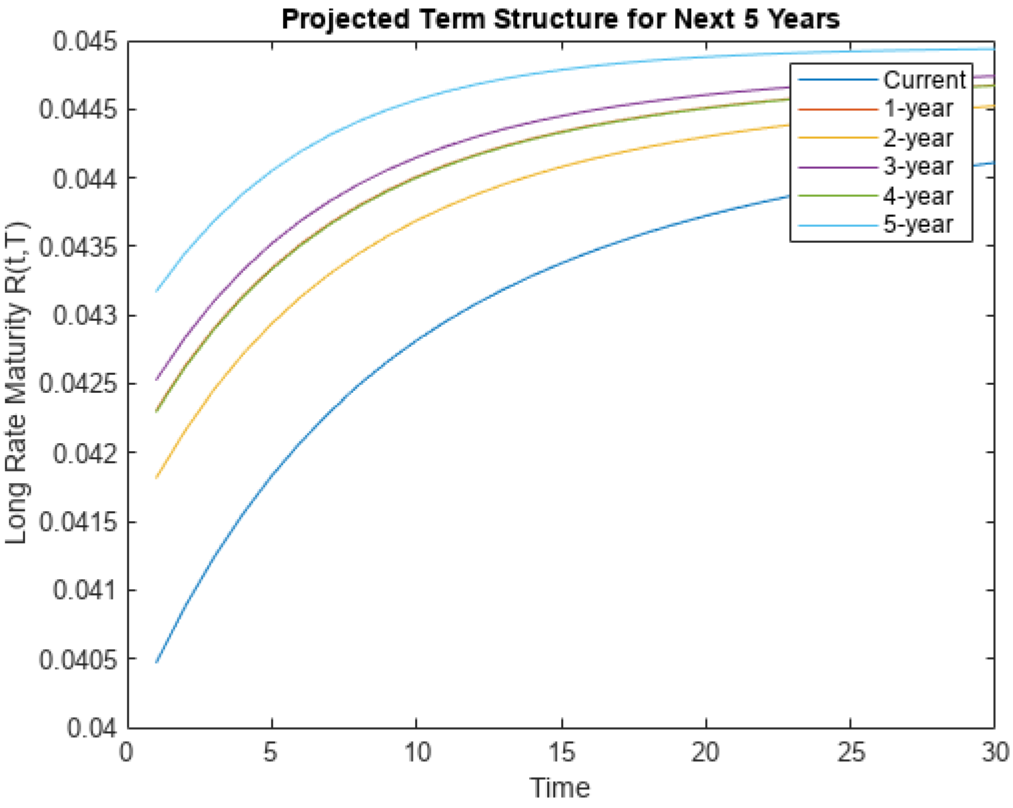
```

```
rPathsExp = mean(rPaths,3);
```

Determine the term structure over the next 30 years.

```
maturity = 30;
T = 1:maturity;
futuresTimes = 1:nPeriods+1;
```

```
% Preallocate simTermStruc
simTermStructure = zeros(nPeriods+1,30);
for i = futuresTimes
    for t = T
        bondPrice = P_func(i,i+t,rPathsExp(i));
        simTermStructure(i,t) = -log(bondPrice)/t;
    end
end
plot(simTermStructure')
legend('Current','1-year','2-year','3-year','4-year','5-year')
title('Projected Term Structure for Next 5 Years')
ylabel('Long Rate Maturity R(t,T)')
xlabel('Time')
```



Quasi-Monte Carlo Simulation Using a CIR Model

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift (SDEMRD): $dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$

where D is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model: $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$.

```
cir_obj = cir(0.2, 0.1, 0.05)  % (Speed, Level, Sigma)
```

```
cir_obj = 
   Class CIR: Cox-Ingersoll-Ross
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.1
          Speed: 0.2
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for `'MonteCarloMethod'`,`'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time] = simByTransition(cir_obj,10,'ntrials',4096,'montecarlomethod','quasi','quasisequen
```

Input Arguments

`MDL` — Stochastic differential equation model

object

Stochastic differential equation model, specified as a `cir` object. For more information on creating a `CIR` object, see `cir`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Paths,Times] = simByTransition(CIR,NPeriods,'DeltaTimes',dt)`

`NTrials` — Simulated trials (sample paths)

`1` (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of NPeriods observations each, specified as the comma-separated pair consisting of 'NTrials' and a positive scalar integer.

Data Types: double

DeltaTimes — Positive time increments between observations
1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTimes' and a scalar or a NPeriods-by-1 column vector.

DeltaTime represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

NSteps — Number of intermediate time steps
1 (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment *dt* (defined as DeltaTimes), specified as the comma-separated pair consisting of 'NSteps' and a positive scalar integer.

The simByTransition function partitions each time increment *dt* into NSteps subintervals of length *dt*/NSteps, and refines the simulation by evaluating the simulated state vector at NSteps − 1 intermediate points. Although simByTransition does not report the output state vector at these intermediate points, the refinement improves accuracy by enabling the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

StorePaths — Flag for storage and return method
True (default) | logical with values True or False

Flag for storage and return method that indicates how the output array Paths is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar logical flag with a value of True or False.

- If StorePaths is True (the default value) or is unspecified, then simByTransition returns Paths as a three-dimensional time series array.
- If StorePaths is False (logical 0), then simByTransition returns the Paths output array as an empty matrix.

Data Types: logical

MonteCarloMethod — Monte Carlo method to simulate stochastic processes
"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of 'MonteCarloMethod' and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers that has a convergence rate of $O(N^{-½})$.
- "quasi" — Quasi-Monte Carlo rate of convergence is faster than standard Monte Carlo with errors approaching size of $O(N^{-1})$.

- "randomized-quasi" — Quasi-random sequences, also called low-discrepancy sequences, are deterministic uniformly distributed sequences which are specifically designed to place sample points as uniformly as possible.

Data Types: string | char

QuasiSequence — Low discrepancy sequence to drive the stochastic processes
"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of 'QuasiSequence' and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If MonteCarloMethod option is not specified or specified as"standard", QuasiSequence is ignored.

Data Types: string | char

BrownianMotionMethod — Brownian motion construction method
"standard" (default) | string with value "brownian-bridge" or "principal-components" | character vector with value 'brownian-bridge' or 'principal-components'

Brownian motion construction method, specified as the comma-separated pair consisting of 'BrownianMotionMethod' and a string or character vector with one of the following values:

- "standard" — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- "brownian-bridge" — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- "principal-components" — The Brownian motion path is calculated by minimizing the approximation error.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the MonteCarloMethod using pseudo random numbers. However, the performance differs between the two when the MonteCarloMethod option "quasi" is introduced, with faster convergence seen for "brownian-bridge" construction option and the fastest convergence when using the "principal-components" construction option.

Data Types: string | char

Processes — Sequence of end-of-period processes or state vector adjustments
simByEuler makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

.

`simByTransition` applies processing functions at the end of each observation period. The processing functions accept the current observation time t and the current state vector X_t, and return a state vector that may adjust the input state.

If you specify more than one processing function, `simByTransition` invokes the functions in the order in which they appear in the cell array.

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as an `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When the input flag `StorePaths` = `False`, `simByTransition` returns `Paths` as an empty matrix.

`Times` — Observation times associated with the simulated paths

column vector

Observation times associated with the simulated paths, returned as an `(NPeriods + 1)`-by-1 column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

More About

Transition Density Simulation

The SDE has no solution such that $r(t) = f(r(0),\cdots)$.

In other words, the equation is not explicitly solvable. However, the transition density for the process is known.

The exact simulation for the distribution of $r(t\_1\ ),\cdots,r(t\_n)$ is that of the process at times $t\_1,\cdots,t\_n$ for the same value of $r(0)$. The transition density for this process is known and is expressed as

$$r(t) = \frac{\sigma^2(1 - e^{-\alpha(t-u)}}{4\alpha} x_d^2 \left(\frac{4\alpha e^{-\alpha(t-u)}}{\sigma^2(1 - e^{-\alpha(t-u)})} r(u) \right), t > u$$

where

$$d \equiv \frac{4b\alpha}{\sigma^2}$$

Algorithms

Use the `simByTransition` function to simulate any vector-valued CIR process of the form

$$dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW_t$$

where

- X_t is an `NVars`-by-`1` state vector of process variables.
- S is an `NVars`-by-`NVars` matrix of mean reversion speeds (the rate of mean reversion).
- L is an `NVars`-by-`1` vector of mean reversion levels (long-run mean or level).
- D is an `NVars`-by-`NVars` diagonal matrix, where each element along the main diagonal is the square root of the corresponding element of the state vector.
- V is an `NVars`-by-`NBrowns` instantaneous volatility rate matrix.
- dW_t is an `NBrowns`-by-`1` Brownian motion vector.

Version History

Introduced in R2018b

R2022a: Perform Quasi-Monte Carlo simulation

Behavior changed in R2022a

Perform Quasi-Monte Carlo simulation using the name-value arguments `MonteCarloMethod` and `QuasiSequence`.

R2022b: Perform Brownian bridge and principal components construction

Behavior changed in R2022b

Perform Brownian bridge and principal components construction using the name-value argument `BrownianMotionMethod`.

“SDEs” on page 14-2
“SDE Models” on page 14-7
“SDE Class Hierarchy” on page 14-5
“Quasi-Monte Carlo Simulation” on page 14-62

simulate

Simulate multivariate stochastic differential equations (SDEs) for `SDE`, `BM`, `GBM`, `CEV`, `CIR`, `HWV`, `Heston`, `SDEDDO`, `SDELD`, `SDEMRD`, `Merton`, or `Bates` models

Syntax

```
[Paths,Times,Z] = simulate(MDL)
[Paths,Times,Z] = simulate( ___ ,Optional,Scheme)
```

Description

`[Paths,Times,Z] = simulate(MDL)` simulates `NTrials` sample paths of `NVars` correlated state variables, driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes.

`[Paths,Times,Z] = simulate( ___ ,Optional,Scheme)` adds optional inputs for `Optional` and `Scheme`.

The `Optional` input argument for `simulate` accepts any variable-length list of input arguments that the simulation method or function referenced by the `SDE.Simulation` parameter requires or accepts. It passes this input list directly to the appropriate SDE simulation method or user-defined simulation function.

The optional input `Scheme` lets you specify an approximation scheme used to simulate the sample paths and you can use this optional input with or without an `Optional` input argument.

Examples

Antithetic Sampling to a Path-Dependent Barrier Option

Consider a European up-and-in call option on a single underlying stock. The evolution of this stock's price is governed by a Geometric Brownian Motion (GBM) model with constant parameters:

$$dX_t = 0.05X_t dt + 0.3X_t dW_t$$

Assume the following characteristics:

- The stock currently trades at 105.
- The stock pays no dividends.
- The stock volatility is 30% per annum.
- The option strike price is 100.
- The option expires in three months.
- The option barrier is 120.
- The risk-free rate is constant at 5% per annum.

The goal is to simulate various paths of daily stock prices, and calculate the price of the barrier option as the risk-neutral sample average of the discounted terminal option payoff. Since this is a barrier option, you must also determine if and when the barrier is crossed.

This example performs antithetic sampling by explicitly setting the `Antithetic` flag to `true`, and then specifies an end-of-period processing function to record the maximum and terminal stock prices on a path-by-path basis.

Create a GBM model using `gbm`.

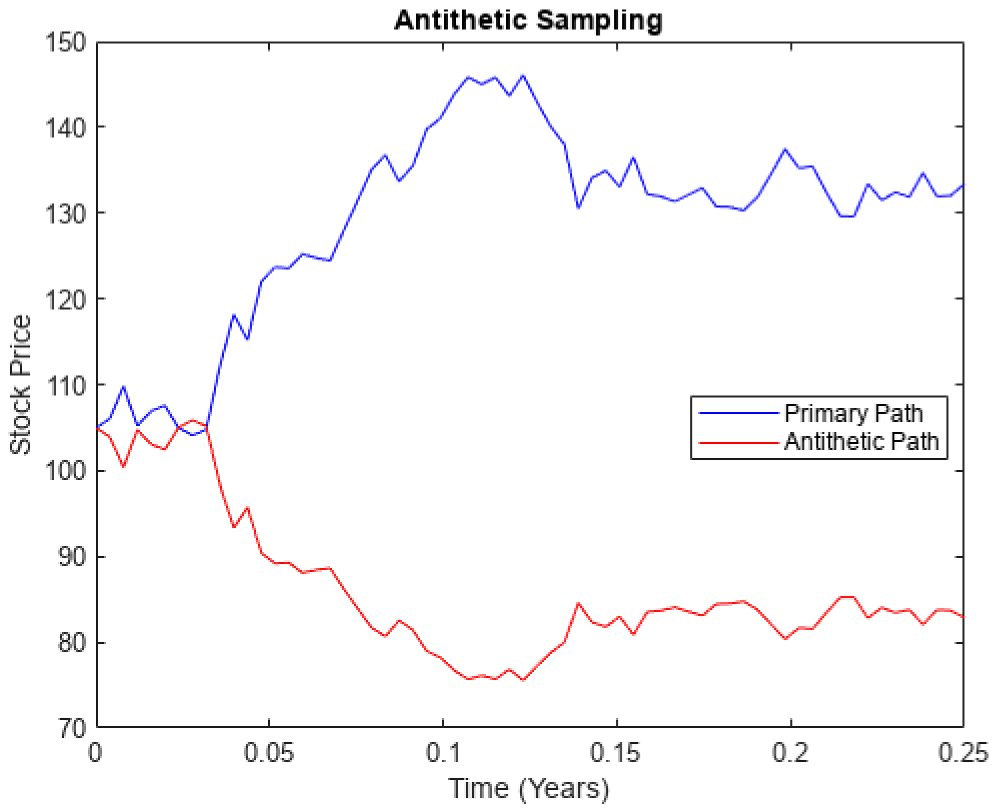
```
barrier      = 120;          % barrier
strike       = 100;          % exercise price
rate         = 0.05;         % annualized risk-free rate
sigma        = 0.3;          % annualized volatility
nPeriods     = 63;           % 63 trading days
dt           = 1 / 252;      % time increment = 252 days
Time        = nPeriods * dt; % expiration time = 0.25 years
obj        = gbm(rate, sigma, 'StartState', 105);
```

Perform a small-scale simulation that explicitly returns two simulated paths.

```
rng('default')               % make output reproducible
[X, T] = obj.simBySolution(nPeriods, 'DeltaTime', dt, ...
                'nTrials', 2, 'Antithetic', true);
```

Perform antithetic sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs. Odd paths (1,3,5,...) correspond to the primary Gaussian paths. Even paths (2,4,6,...) are the matching antithetic paths of each pair, derived by negating the Gaussian draws of the corresponding primary (odd) path. Verify this by examining the matching paths of the primary/antithetic pair.

```
plot(T, X(:,:,1), 'blue', T, X(:,:,2), 'red')
xlabel('Time (Years)'), ylabel('Stock Price'), ...
            title('Antithetic Sampling')
legend({'Primary Path' 'Antithetic Path'}, ...
            'Location', 'Best')
```



To price the European barrier option, specify an end-of-period processing function to record the maximum and terminal stock prices. This processing function is accessible by time and state, and is implemented as a nested function with access to shared information that allows the option price and corresponding standard error to be calculated. For more information on using an end-of-period processing function, see “Pricing Equity Options” on page 14-45.

Simulate 200 paths using the processing function method.

```
rng('default')              % make output reproducible
barrier  = 120;             % barrier
strike   = 100;             % exercise price
rate     = 0.05;            % annualized risk-free rate
sigma    = 0.3;             % annualized volatility
nPeriods = 63;              % 63 trading days
dt       = 1 / 252;         % time increment = 252 days
Time     = nPeriods * dt;   % expiration time = 0.25 years
obj    = gbm(rate, sigma, 'StartState', 105);
nPaths = 200;          % # of paths = 100 sets of pairs
f      = Example_BarrierOption(nPeriods, nPaths);
simulate(obj, nPeriods, 'DeltaTime' , dt, ...
            'nTrials', nPaths, 'Antithetic', true, ...
            'Processes', f.SaveMaxLast);
```

Approximate the option price with a 95% confidence interval.

```
optionPrice   = f.OptionPrice(strike, rate, barrier);
standardError = f.StandardError(strike, rate, barrier,...
                          true);
lowerBound    = optionPrice - 1.96 * standardError;
upperBound    = optionPrice + 1.96 * standardError;

displaySummary(optionPrice, standardError, lowerBound, upperBound);
```

```
  Up-and-In Barrier Option Price:   6.6572
         Standard Error of Price:   0.7292
 Confidence Interval Lower Bound:   5.2280
 Confidence Interval Upper Bound:   8.0864
```

Utility Function

```
function displaySummary(optionPrice, standardError, lowerBound, upperBound)
fprintf('  Up-and-In Barrier Option Price: %8.4f\n', ...
            optionPrice);
fprintf('         Standard Error of Price: %8.4f\n', ...
            standardError);
fprintf(' Confidence Interval Lower Bound: %8.4f\n', ...
            lowerBound);
fprintf(' Confidence Interval Upper Bound: %8.4f\n', ...
            upperBound);
end
```

Specify Approximation Scheme with `simulate` Using a CIR Model

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift (`SDEMRD`): $dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$

where D is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model: $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$.

```
cir_obj = cir(0.2, 0.1, 0.05)  % (Speed, Level, Sigma)
```

```
cir_obj = 
   Class CIR: Cox-Ingersoll-Ross
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t)) 
      Diffusion: diffusion rate function G(t,X(t)) 
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.1
          Speed: 0.2
```

Use the optional name-value argument for `'Scheme'` to specify a scheme to simulate the sample paths.

```
[paths,times] = simulate(cir_obj,10,'ntrials',4096,'scheme','quadratic-exponential');
```

Use simulate with Quasi-Monte Carlo Simulation with simByEuler Using a CIR Model

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift (SDEMRD): $dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$

where D is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a `cir` object to represent the model: $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$.

```
cir_obj = cir(0.2, 0.1, 0.05)  % (Speed, Level, Sigma)
```

```
cir_obj = 
   Class CIR: Cox-Ingersoll-Ross
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.1
          Speed: 0.2
```

Use optional name-value inputs for the `simByEuler` method that you can call through `simulate` interface using the `simulate` `'Scheme'` for `'quadratic-exponential'`. The optional inputs for `simByEuler` define a quasi-Monte Carlo simulation using the name-value arguments for `'MonteCarloMethod'`,`'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time] = simulate(cir_obj,10,'ntrials',4096,'montecarlomethod','quasi','quasisequence','sol
```

Input Arguments

MDL — Stochastic differential equation model
object

Stochastic differential equation model, specified as an `sde`, `bates`, `bm`, `gbm`, `cev`, `cir`, `hwv`, `heston`,`merton` `sdeddo`, `sdeld`, or `sdemrd` object.

Data Types: `object`

Optional — Any variable-length list of input arguments that the simulation method or function referenced by the SDE.Simulation parameter requires or accepts
input arguments

(Optional) Any variable-length list of input arguments that the simulation method or function referenced by the `SDE.Simulation` parameter requires or accepts, specified as a variable-length list of input arguments. This input list is passed directly to the appropriate SDE simulation method or user-defined simulation function.

Data Types: `double`

`Scheme` — Approximation scheme used to simulate the sample paths
character vector with values `'euler'`, `'solution'`,`'quadratic-exponential'`, `'transition'`, or `'milstein'` | string with values `"euler"`, `"solution"`,`"quadratic-exponential"`, `"transition"`, or `"milstein"`

(Optional) Approximation scheme used to simulate the sample paths, specified as a character vector or string. When you specify `Scheme`, the MDL simulation method using the corresponding scheme is used instead of the one defined in the `MDL.Simulation` property which is the `simByEuler` method by default.

Note The supported `Scheme` depends on which SDE object you use with the `simulate` method as follows:

`simulate` Scheme Value	Supported Objects
`"euler"`	`sde`, `sdeddo`, `sdeld`, `sdemrd`, `bm`, `cev`, `gbm`, `merton`, `hwv`, `cir`, `heston`, or `bates`
`"solution"`	`gbm`, `merton`, or `hwv`
`"transition"`	`cir`, `heston`, or `bates`
`"quadratic-exponential"`	`cir`, `heston`, or `bates`
`"milstein"`	`sdeddo`, `sdeld`, `sdemrd`, `bm`, `cev`, `gbm`, `merton`, `hwv`, `cir`, `heston`, or `bates`

Data Types: `char` | `string`

Output Arguments

`Paths` — Three-dimensional time series array, consisting of simulated paths of correlated state variables
array

Three-dimensional time series array, consisting of simulated paths of correlated state variables, returned as an `(NPeriods + 1)`-by-`NVars`-by-`NTrials` array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t.

`Times` — Observation times associated with the simulated paths
column vector

Observation times associated with the simulated paths, returned as a `(NPeriods + 1)`-by-`1` column vector.

Z — Three-dimensional time series array of dependent random variates used to generate the Brownian motion vector (Wiener processes)
array | matrix | table | timetable

Three-dimensional time series array of dependent random variates used to generate the Brownian motion vector (Wiener processes) that drove the simulated results found in `Paths`, returned as a `NTimes`-by-`NBrowns`-by-`NTrials` array.

`NTimes` is the number of time steps at which the `simulate` function samples the state vector. `NTimes` includes intermediate times designed to improve accuracy, which `simulate` does not necessarily report in the `Paths` output time series.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

This function simulates any vector-valued SDE of the form:

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t \qquad (15\text{-}4)$$

where:

- X is an *NVars*-by-1 state vector of process variables (for example, short rates or equity prices) to simulate.
- W is an *NBrowns*-by-1 Brownian motion vector.
- F is an *NVars*-by-1 vector-valued drift-rate function.
- G is an *NVars*-by-*NBrowns* matrix-valued diffusion-rate function.

Version History

Introduced in R2008a

R2023a: Added "milstein" value to Scheme name-value argument
Behavior changed in R2023a

When the MDL input argument is a cir, heston, bates, or merton object, you can use a Scheme value of "milstein".

Use the simByMilstein method to approximate a numerical solution of a stochastic differential equation.

R2022b: Approximation scheme to simulate the sample paths
Behavior changed in R2022b

When you specify Scheme, the MDL simulation method using the corresponding scheme is used instead of the one defined in the MDL.Simulation property.

Convert time series arrays to functions of time and state

Syntax

```
F = ts2func(Array)
F = ts2func(___,Name,Value)
```

Description

`F = ts2func(Array)` encapsulates a time series array associated with a vector of real-valued observation times within a MATLAB function suitable for Monte Carlo simulation of an `NVars`-by-`1` state vector X_t.

n periods.

`F = ts2func(___,Name,Value)` adds optional name-value pair arguments.

Examples

Illustrate the Dynamic Behavior of Market Parameters

Load the data.

```
load Data_GlobalIdx2
```

Simulate risk-neutral sample paths.

```
dt      = 1/250;
returns = tick2ret(Dataset.CAC);
sigma   = std(returns)*sqrt(250);
yields  = Dataset.EB3M;
yields  = 360*log(1 + yields);
```

Simulate paths using a constant, risk-free return

```
nPeriods = length(yields);  % Simulated observations
rng(5713,'twister')
obj    = gbm(mean(yields),diag(sigma),'StartState',100)
```

```
obj = 
   Class GBM: Generalized Geometric Brownian Motion
   ------------------------------------------------
     Dimensions: State = 1, Brownian = 1
   ------------------------------------------------
      StartTime: 0
     StartState: 100
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
```

```
          Return: 0.0278117
           Sigma: 0.231906
```

```
[X1,T] = simulate(obj,nPeriods,'DeltaTime',dt);
```

Simulate paths using a dynamic, deterministic rate of return (get r)

```
r = ts2func(yields,'Times',(0:nPeriods - 1)');
```

Simulate paths using a dynamic, deterministic rate of return (r output 1)

```
r(0,100)
```

```
ans = 0.0470
```

Simulate paths using a dynamic, deterministic rate of return (r output 2)

```
r(7.5,200)
```

```
ans = 0.0472
```

Simulate paths using a dynamic, deterministic rate of return (r output 3)

```
r(7.5)
```

```
ans = 0.0472
```

Simulate paths using a dynamic, deterministic rate of return

```
rng(5713,'twister')
obj = gbm(r, diag(sigma),'StartState',100)
```

```

Input Arguments

`Array` — Time series array to encapsulate within a callable function of time and state

vector | 2-dimensional matrix | three-dimensional array

Time series array to encapsulate within a callable function of time and state, specified as a vector, two-dimensional matrix, or three-dimensional array

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `F = ts2func(yields,'Times',(0:nPeriods - 1)')`

Times — Monotonically increasing observation times associated with the time series input array Array

zero-based, unit-increment vector of the same length as that of the dimension of Array (default) | vector

Monotonically increasing observation times associated with the time series input array (Array), specified as the comma-separated pair consisting of 'Times' and a vector.

Data Types: double

TimeDimension — Specifies which dimension of the input time series array Array is associated with time

1 (indicates that time is associated with the rows of Array) (default) | scalar integer

Specifies which dimension of the input time series array (Array) is associated with time, specified as the comma-separated pair consisting of 'TimeDimension' and a scalar integer.

Data Types: double

StateDimension — Specifies which dimension of the input time series array Array is associated with the NVars state variables

first dimension of Array not already associated with time is associated with first available dimension of Array not already assigned to TimeDimension (default) | positive scalar integer

Specifies which dimension of the input time series array (Array) is associated with the NVars state variables, specified as the comma-separated pair consisting of 'StateDimension' and a positive scalar integer.

Data Types: double

Deterministic — Flag to indicate whether the output function is a deterministic function of time alone

false (meaning F is a callable function of time and state, *F(t,X)*) (default) | scalar logical

Flag to indicate whether the output function is a deterministic function of time alone, specified as the comma-separated pair consisting of 'Determininistic' and a scalar integer flag.

If Deterministic is true, the output function F is a deterministic function of time, *F(t)*, and the only input it accepts is a scalar, real-valued time *t*. If Deterministic is false, the output function F accepts two inputs, a scalar, real-valued time *t* followed by an NVars-by-1 state vector*X(t)*.

Data Types: logical

Output Arguments

F — Callable function *F(t)* of a real-valued scalar observation time *t*

vector | matrix | table | timetable

Callable function *F(t)* of a real-valued scalar observation time *t*, returned as a function.

If the optional input argument Deterministic is true, F is a deterministic function of time, *F(t)*, and the only input it accepts is a scalar, real-valued time *t*. Otherwise, if Deterministic is false (the default), F accepts a scalar, real-valued time *t* followed by an NVars-by-1 state vector *X(t)*.

Note You can invoke `F` with a second input (such as an `NVars`-by-`1` state vector *X*), which is a placeholder that `ts2func` ignores. For example, while *F(t)* and *F(t,X)* produce identical results, the latter directly supports SDE simulation methods.

Algorithms

- When you specify `Array` as a scalar or a vector (row or column), `ts2func` assumes that it represents a univariate time series.
- `F` returns an array with one less dimension than the input time series array `Array` with which `F` is associated. Thus, when `Array` is a vector, a 2-dimensional matrix, or a three-dimensional array, `F` returns a scalar, vector, or 2-dimensional matrix, respectively.
- When the scalar time *t* at which `ts2func` evaluates the function `F` does not coincide with an observation time in `Times`, `F` performs a zero-order-hold interpolation. The only exception is if *t* precedes the first element of `Times`, in which case *F(t) = F(Times(1))*.
- To support Monte Carlo simulation methods, the output function `F` returns an `NVars`-by-`1` column vector or a two-dimensional matrix with `NVars` rows.
- The output function `F` is always a deterministic function of time, *F(t)*, and may always be called with a single input regardless of the `Deterministic` flag. The distinction is that when `Deterministic` is false, the function `F` may also be called with a second input, an `NVars`-by-`1` state vector *X(t)*, which is a placeholder and ignored. While *F(t)* and *F(t,X)* produce identical results, the former specifically indicates that the function is a deterministic function of time, and may offer significant performance benefits in some situations.

Version History

Introduced in R2008a

abs2active

Convert constraints from absolute to active format

Syntax

```
ActiveConSet = abs2active(AbsConSet,Index)
```

Description

`ActiveConSet = abs2active(AbsConSet,Index)` transforms a constraint matrix to an equivalent matrix expressed in active weight format (relative to the index).

Examples

Convert Constraints in Terms of Absolute Weights Into Constraints in Terms of Active Portfolio Weights

Set up constraints for a portfolio optimization for portfolio w0 with constraints in the form `A*w <= b`, where `w` is absolute portfolio weights. (Absolute weights do not depend on the tracking portfolio.) Use `abs2active` to convert constraints in terms of absolute weights into constraints in terms of active portfolio weights, defined relative to the tracking portfolio `w0`. Assume three assets with the following mean and covariance of asset returns:

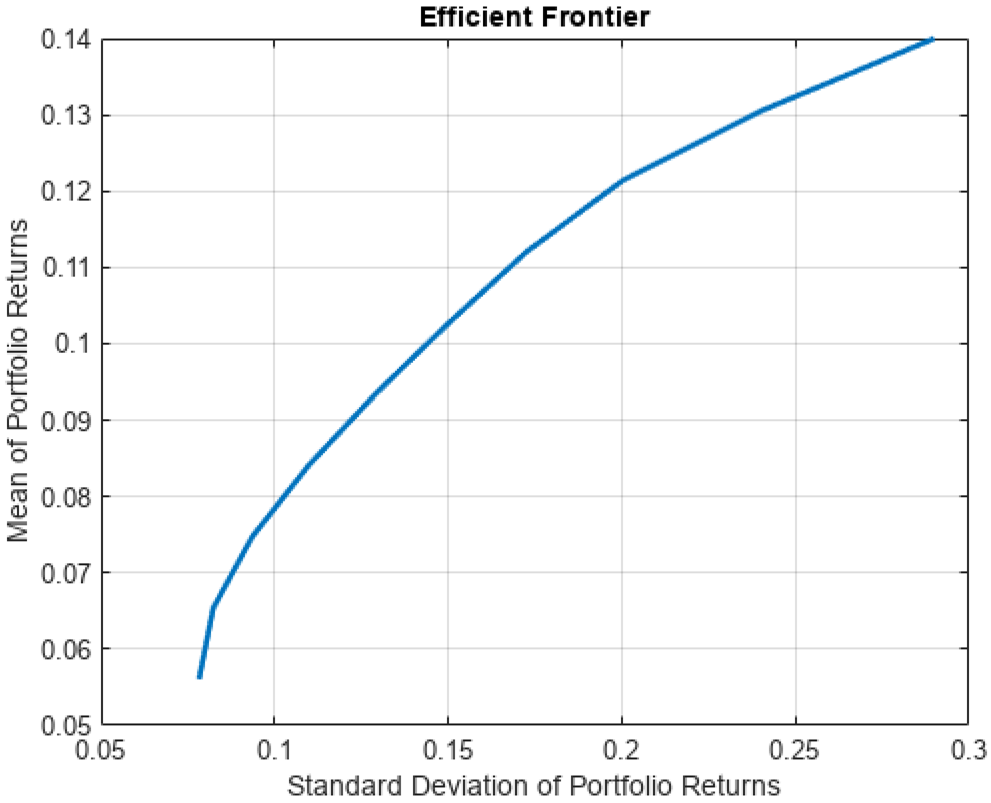
```
m = [ 0.14; 0.10; 0.05 ];
C = [ 0.29^2 0.4*0.29*0.17 0.1*0.29*0.08; 0.4*0.29*0.17 0.17^2 0.3*0.17*0.08;...
0.1*0.29*0.08 0.3*0.17*0.08 0.08^2 ];
```

Absolute portfolio constraints are the typical ones (weights sum to `1` and fall from `0` through `1`), create the `A` and `b` matrices using `portcons`.

```
AbsCons = portcons('PortValue',1,3,'AssetLims', [0; 0; 0], [1; 1; 1;]);
```

Use the `Portfolio` object to determine the efficient frontier.

```
p = Portfolio('AssetMean', m, 'AssetCovar', C);
p = p.setInequality(AbsCons(:,1:end-1), AbsCons(:,end));
p.plotFrontier;
```



The tracking portfolio `w0` is:

```
w0 = [ 0.1; 0.55; 0.35 ];
```

Use `abs2active` to compute the constraints for active portfolio weights.

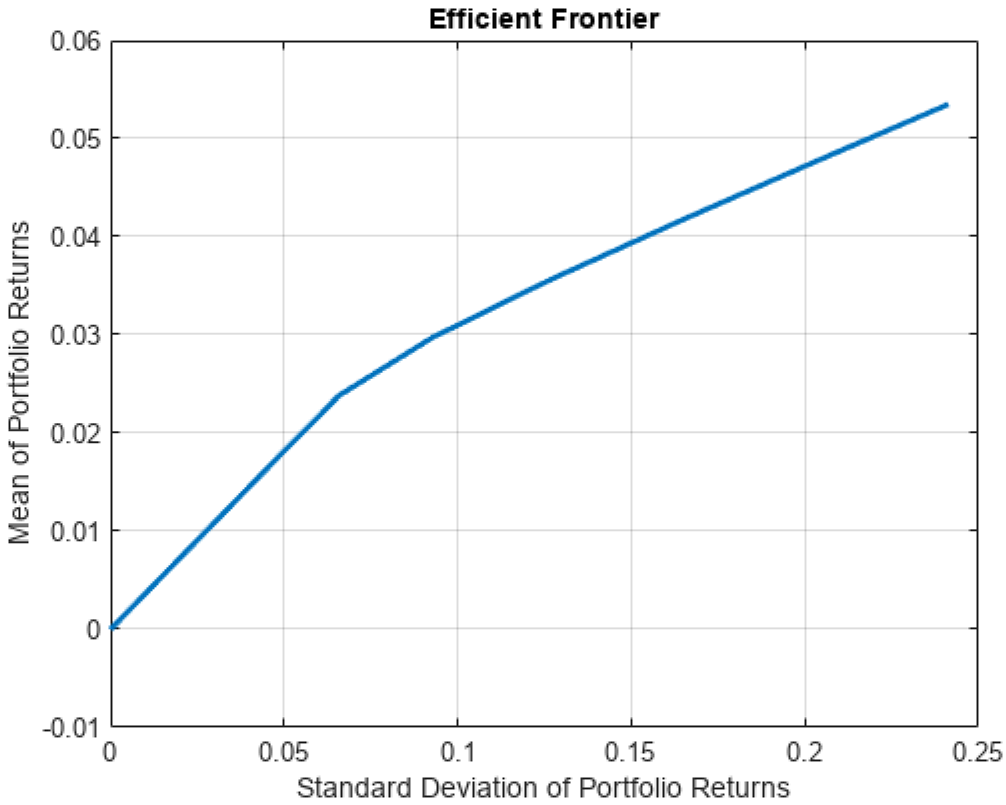
```
ActCons = abs2active(AbsCons, w0)
```

```
ActCons = 8×4

    1.0000    1.0000    1.0000         0
   -1.0000   -1.0000   -1.0000         0
    1.0000         0         0    0.9000
         0    1.0000         0    0.4500
         0         0    1.0000    0.6500
   -1.0000         0         0    0.1000
         0   -1.0000         0    0.5500
         0         0   -1.0000    0.3500
```

Use the `Portfolio` object `p` and its efficient frontier to demonstrate expected returns and risk relative to the tracking portfolio `w0`.

```
p = p.setInequality(ActCons(:,1:end-1), ActCons(:,end));
p.plotFrontier;
```



Note, when using `abs2active` to compute “active constraints” for use with a `Portfolio` object, don't use the Portfolio object’s default constraints because the relative weights can be positive or negative (the `setDefaultConstraints` function for a `Portfolio` object specifies weights to be nonnegative).

Input Arguments

`AbsConSet` — Portfolio linear inequality constraint matrix expressed in absolute weight format

matrix

Portfolio linear inequality constraint matrix expressed in absolute weight format, specified as `[A b]` such that `A*w <= b`, where `A` is a number of constraints (`NCONSTRAINTS`) by number of assets (`NASSETS`) weight coefficient matrix, and `b` and `w` are column vectors of length `NASSETS`. The value `w` represents a vector of absolute asset weights whose elements sum to the total portfolio value. See the output `ConSet` from `portcons` for additional details about constraint matrices.

Data Types: `double`

`Index` — Index portfolio weights

vector

Index portfolio weights, specified as a `NASSETS`-by-`1` vector. The sum of the index weights must equal the total portfolio value (for example, a standard portfolio optimization imposes a sum-to-1 budget constraint).

Data Types: `double`

Output Arguments

`ActiveConSet` — Transformed portfolio linear inequality constraint matrix expressed in active weight format

matrix

Transformed portfolio linear inequality constraint matrix expressed in active weight format, returned in the form `[A b]` such that `A*w <= b`. The value `w` represents a vector of active asset weights (relative to the index portfolio) whose elements sum to zero.

Algorithms

`abs2active` transforms a constraint matrix to an equivalent matrix expressed in active weight format (relative to the index). The transformation equation is

$$Aw_{absolute} = A(w_{active} + w_{index}) \leq b_{absolute}.$$

Therefore

$$Aw_{active} \leq b_{absolute} - Aw_{index} = b_{active}.$$

The initial constraint matrix consists of `NCONSTRAINTS` portfolio linear inequality constraints expressed in absolute weight format. The index portfolio vector contains `NASSETS` assets.

accrfrac

Fraction of coupon period before settlement

Syntax

```
Fraction = accrfrac(Settle,Maturity)
Fraction = accrfrac( ___ ,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,
LastCouponDate)
```

Description

`Fraction = accrfrac(Settle,Maturity)` returns the fraction of the coupon period before settlement.

Use `accrfrac` for computing accrued interest. `accrfrac` calculates accrued interest for bonds with regular or odd first or last coupon periods.

Required input arguments must be number of bonds, `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS`, conforming vectors or scalars.

`Fraction = accrfrac( ___ ,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate, LastCouponDate)` returns the fraction of the coupon period before settlement with optional inputs.

Optional input arguments must be either `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

Examples

Find Accrued Interest for a Bond

This example shows how to find the accrued interest for given bond data.

```
Settle = datetime(1997,3,14);
Maturity = [datetime(2000,11,30) datetime(2000,12,31) datetime(2001,1,31)];
Period = 2;
Basis = 0;
EndMonthRule = 1;

Fraction = accrfrac(Settle, Maturity, Period, Basis,...
EndMonthRule)
```

```
Fraction = 3×1

    0.5714
    0.4033
    0.2320
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a scalar, or an `NUMBONDS`-by-`1` vector using a datetime array, or string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `accrfrac` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a scalar, or an `NUMBONDS`-by-`1` vector using a datetime array, or string array, or date character vectors.

To support existing code, `accrfrac` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Period` — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

Coupons per year of the bond, specified as a scalar or an `NUMBONDS`-by-`1` vector of positive integers from the set `[1,2,3,4,6,12]`.

Data Types: `single` | `double`

`Basis` — Day-count basis of the instrument

`0` (actual/actual) (default) | numeric with value `0` through `13` | vector of numerics with values `0` through `13`

Day-count basis of the instrument, specified as a scalar integer with a value of `0` through `13` or a `NUMBONDS`-by-`1` vector of integers with values of `0` through `13`.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: single | double

EndMonthRule — End-of-month rule flag for month having 30 or fewer days

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag for month having 30 or fewer days, specified as a scalar nonnegative integer or an NUMBONDS-by-1 vector of values. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond issue date, specified as a scalar, or an NUMBONDS-by-1 vector using a datetime array, or string array, or date character vectors.

To support existing code, accrfrac also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Date when bond makes first coupon payment

datetime array | string array | date character vector

Date when a bond makes its first coupon payment, specified as a scalar, or an NUMBONDS-by-1 vector using a datetime array, or string array, or date character vectors.

FirstCouponDate is used when a bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, accrfrac also accepts serial date numbers as inputs, but they are not recommended.

Data Types: double | char | string | datetime

LastCouponDate — Last coupon date of bond before maturity date

datetime array | string array | date character vector

Last coupon date of a bond before maturity date, specified as a scalar, or an NUMBONDS-by-1 vector using a datetime array, or string array, or date character vectors.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, accrfrac also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

Fraction — Fraction of coupon period before settlement

vector

Fraction of the coupon period before settlement, returned as an NUMBONDS-by-1 vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although accrfrac supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

acrubond

Accrued interest of security with periodic interest payments

Syntax

```
AccruInterest = acrubond(IssueDate,Settle,FirstCouponDate,Face,CouponRate)
AccruInterest = acrubond( ___ ,Period,Basis)
```

Description

`AccruInterest = acrubond(IssueDate,Settle,FirstCouponDate,Face,CouponRate)` returns the accrued interest for a security with periodic interest payments. `acrubond` computes the accrued interest for securities with standard, short, and long first coupon periods.

Note `cfamounts` or `accrfrac` is recommended when calculating accrued interest beyond the first period.

`AccruInterest = acrubond( ___ ,Period,Basis)` adds optional arguments for `Period` and `Basis`.

Examples

Find Accrued Interest of a Bond with Periodic Interest Payments

This example shows how to find the accrued interest for a bond with semiannual interest payments.

```
AccruInterest = acrubond(datetime(1983,1,31), datetime(1993,3,1),datetime(1983,7,31),  100,  0.1
```

```
AccruInterest = 0.8011
```

Input Arguments

`IssueDate` — Issue date of security
datetime array | string array | date character vector

Issue date of the security, specified as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `acrubond` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Settle` — Settlement date of security
datetime array | string array | date character vector

Settlement date of the security, specified as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `acrubond` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — First coupon date of security
datetime array | string array | date character vector

First coupon date of the security, specified as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `acrubond` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Redemption value of security
numeric

Redemption value (par value) of the security, specified as a scalar or a `NINST`-by-`1` vector.

Data Types: `double`

`CouponRate` — Coupon rate of security
decimal fraction

Coupon rate of the security, specified as a scalar or a `NINST`-by-`1` vector of decimal fraction values.

Data Types: `double`

`Period` — Number of coupon payments per year
`2` (default) | numeric with values `0`, `1`, `2`, `3`, `4`, `6` or `12`

(Optional) Number of coupon payments per year for the security, specified as scalar or a `NINST`-by-`1` vector using the values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

(Optional) Day-count basis for the security, specified as a scalar or a `NINST`-by-`1` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

Output Arguments

AccruInterest — Accrued interest

numeric

Accrued interest for the security, returned as a scalar or a NINST-by-1 vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although acrubond supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```

acrudisc

Accrued interest of discount security paying at maturity

Syntax

```
AccruInterest = acrudisc(Settle,Maturity,Face,Discount)
AccruInterest = acrudisc( ___ ,Period,Basis)
```

Description

`AccruInterest = acrudisc(Settle,Maturity,Face,Discount)` returns the accrued interest of a discount security paid at maturity.

`AccruInterest = acrudisc( ___ ,Period,Basis)` adds optional arguments for `Period` and `Basis`.

Examples

Find Accrued Interest of a Discount Security Paid at Maturity

This example shows how to find the accrued interest of a discount security paid at maturity.

```
AccruInterest = acrudisc(datetime(1992,5,1), datetime(1992,7,15), 100,  0.1,  2,  0)
```

```
AccruInterest = 2.0604
```

Input Arguments

`Settle` — Settlement date of security
datetime array | string array | date character vector

Settlement date of the security, specified as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `acrudisc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of security
datetime array | string array | date character vector

Maturity date of the security, specified as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `acrudisc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Redemption value of security

numeric

Redemption value (par value) of the security, specified as a scalar or a `NINST`-by-`1` vector.

Data Types: `double`

`Discount` — Discount rate of security

decimal fraction

Discount rate of the security, specified as a scalar or a `NINST`-by-`1` vector of decimal fraction values.

Data Types: `double`

`Period` — Number of coupon payments per year

`2` (default) | numeric with values `0`, `1`, `2`, `3`, `4`, `6` or `12`

(Optional) Number of coupon payments per year for security, specified as scalar or a `NINST`-by-`1` vector using the values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

(Optional) Day-count basis for security, specified as a scalar or a `NINST`-by-`1` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`AccruInterest` — Accrued interest

numeric

Accrued interest, returned as a scalar or a `NINST`-by-`1` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `acrudisc` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

active2abs

Convert constraints from active to absolute format

Syntax

```
AbsConSet = active2abs(ActiveConSet,Index)
```

Description

`AbsConSet = active2abs(ActiveConSet,Index)` transforms a constraint matrix to an equivalent matrix expressed in absolute weight format. The transformation equation is

$$Aw_{active} = A(w_{absolute} - w_{index}) \leq b_{active} .$$

Therefore

$$Aw_{absolute} \leq b_{active} + Aw_{index} = b_{absolute} .$$

The initial constraint matrix consists of `NCONSTRAINTS` portfolio linear inequality constraints expressed in active weight format (relative to the index portfolio). The index portfolio vector contains `NASSETS` assets.

`AbsConSet` is the transformed portfolio linear inequality constraint matrix expressed in absolute weight format, also of the form `[A b]` such that `A*w <= b`. The value `w` represents a vector of active asset weights (relative to the index portfolio) whose elements sum to the total portfolio value.

Input Arguments

`ActiveConSet` — Portfolio linear inequality constraint matrix expressed in active weight format

matrix

Portfolio linear inequality constraint matrix expressed in active weight format, formatted as `[A b]` such that `A*w <= b`, where `A` is a number of constraints (`NCONSTRAINTS`) by number of assets (`NASSETS`) weight coefficient matrix, and `b` and `w` are column vectors of length `NASSETS`. The value `w` represents a vector of active asset weights (relative to the index portfolio) whose elements sum to `0`.

See the output `ConSet` from `portcons` for additional details about constraint matrices.

Data Types: `double`

`Index` — Index of portfolio weights

vector

Index of portfolio weights, specified as an `ASSETS`-by-`1` vector. The sum of the index weights must equal the total portfolio value. For example, a standard portfolio optimization imposes a sum to `1` budget constraint.

Data Types: `double`

Output Arguments

`AbsConSet` — Transformed portfolio linear inequality constraint

matrix

Transformed portfolio linear inequality constraint, returned as a matrix and expressed in absolute weight format, also of the form `[A b]` such that `A*w <= b`. The value `w` represents a vector of active asset weights (relative to the index portfolio) whose elements sum to the total portfolio value.

addEquality

Add linear equality constraints for portfolio weights to existing constraints

Syntax

```
obj = addEquality(obj,AEquality,bEquality)
```

Description

`obj = addEquality(obj,AEquality,bEquality)` adds linear equality constraints for portfolio weights to existing constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Given a linear equality constraint matrix `AEquality` and vector `bEquality`, every weight in a portfolio `Port` must satisfy the following:

```
AEquality * Port = bEquality
```

This function "stacks" additional linear equality constraints onto any existing linear equality constraints that exist in the input portfolio object. If no constraints exist, this method is the same as `setEquality`.

Examples

Add a Linear Equality Constraint for a Portfolio Object

Use the `addEquality` method to create linear equality constraints. Add another linear equality constraint to ensure that the last three assets constitute 50% of a portfolio.

```
p = Portfolio;
A = [ 1 1 1 0 0 ];    % First equality constraint
b = 0.5;
p = setEquality(p, A, b);

A = [ 0 0 1 1 1 ];    % Second equality constraint
b = 0.5;
p = addEquality(p, A, b);

disp(p.NumAssets);

     5

disp(p.AEquality);

     1     1     1     0     0
     0     0     1     1     1

disp(p.bEquality);
```

```
    0.5000
    0.5000
```

Add a Linear Equality Constraint for a PortfolioCVaR Object

Use the `addEquality` method to create linear equality constraints. Add another linear equality constraint to ensure that the last three assets constitute 50% of a portfolio.

```
p = PortfolioCVaR;
A = [ 1 1 1 0 0 ];    % First equality constraint
b = 0.5;
p = setEquality(p, A, b);

A = [ 0 0 1 1 1 ];    % Second equality constraint
b = 0.5;
p = addEquality(p, A, b);

disp(p.NumAssets);

     5

disp(p.AEquality);

     1     1     1     0     0
     0     0     1     1     1

disp(p.bEquality);

    0.5000
    0.5000
```

Add a Linear Equality Constraint for a PortfolioMAD Object

Use the `addEquality` method to create linear equality constraints. Add another linear equality constraint to ensure that the last three assets constitute 50% of a portfolio.

```
p = PortfolioMAD;
A = [ 1 1 1 0 0 ];    % First equality constraint
b = 0.5;
p = setEquality(p, A, b);

A = [ 0 0 1 1 1 ];    % Second equality constraint
b = 0.5;
p = addEquality(p, A, b);

disp(p.NumAssets);

     5

disp(p.AEquality);

     1     1     1     0     0
     0     0     1     1     1
```

```
disp(p.bEquality);

    0.5000
    0.5000
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`AEquality` — Linear equality constraints formed from matrix

matrix

Linear equality constraints, specified as a matrix.

Note An error results if `AEquality` is empty and `bEquality` is nonempty.

Data Types: `double`

`bEquality` — Linear equality constraints formed from vector

vector

Linear equality constraints, specified as a vector.

Note An error results if `bEquality` is empty and `AEquality` is nonempty.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Tips

- You can also use dot notation to add the linear equality constraints for portfolio weights.

  ```
  obj = obj.addEquality(AEquality, bEquality)
  ```
- You can also remove linear equality constraints from a portfolio object using dot notation.

  ```
  obj = obj.setEquality([ ], [ ])
  ```

Version History

Introduced in R2011a

addGroupRatio

Add group ratio constraints for portfolio weights to existing group ratio constraints

Syntax

```
obj = addGroupRatio(obj,GroupA,GroupB,LowerRatio)
obj = addGroupRatio(obj,GroupA,GroupB,LowerRatio,UpperRatio)
```

Description

`obj = addGroupRatio(obj,GroupA,GroupB,LowerRatio)` adds group ratio constraints for portfolio weights to existing group ratio constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-15.

Given base and comparison group matrices `GroupA` and `GroupB` and, either `LowerRatio`, or `UpperRatio` bounds, group ratio constraints require any portfolio in `Port` to satisfy the following:

```
(GroupB * Port) .* LowerRatio <= GroupA * Port <= (GroupB * Port) .* UpperRatio
```

Note This collection of constraints usually requires that portfolio weights be nonnegative and that the products `GroupA * Port` and `GroupB * Port` are always nonnegative. Although negative portfolio weights and non-Boolean group ratio matrices are supported, use with caution.

`obj = addGroupRatio(obj,GroupA,GroupB,LowerRatio,UpperRatio)` adds group ratio constraints for portfolio weights to existing group ratio constraints with an additional option for `UpperRatio`.

Given base and comparison group matrices `GroupA` and `GroupB` and, either `LowerRatio`, or `UpperRatio` bounds, group ratio constraints require any portfolio in `Port` to satisfy the following:

```
(GroupB * Port) .* LowerRatio <= GroupA * Port <= (GroupB * Port) .* UpperRatio
```

Note This collection of constraints usually requires that portfolio weights be nonnegative and that the products `GroupA * Port` and `GroupB * Port` are always nonnegative. Although negative portfolio weights and non-Boolean group ratio matrices are supported, use with caution.

Examples

Add Group Ratio Constraints to a Portfolio Object

Set a group ratio constraint to ensure that the weight in financial assets does not exceed 50% of the weight in nonfinancial assets. Then add another group ratio constraint to ensure that the weight in financial assets constitute at least 20% of the weight in nonfinancial assets of the portfolio.

```
p = Portfolio;
GA = [ true true true false false false ];    % financial companies
```

```
GB = [ false false false true true true ];    % nonfinancial companies
p = setGroupRatio(p, GA, GB, [], 0.5);

GA = [ true false true false true false ];    % odd-numbered companies
GB = [ false false false true true true ];    % nonfinancial companies
p = addGroupRatio(p, GA, GB, 0.2);

disp(p.NumAssets);

     6

disp(p.GroupA);

     1     1     1     0     0     0
     1     0     1     0     1     0

disp(p.GroupB);

     0     0     0     1     1     1
     0     0     0     1     1     1

disp(p.LowerRatio);

      -Inf
    0.2000

disp(p.UpperRatio);

    0.5000
       Inf
```

Add Group Ratio Constraints to a PortfolioCVaR Object

Set a group ratio constraint to ensure that the weight in financial assets does not exceed 50% of the weight in nonfinancial assets. Then add another group ratio constraint to ensure that the weight in financial assets constitute at least 20% of the weight in nonfinancial assets of the portfolio.

```
p = PortfolioCVaR;
GA = [ true true true false false false ];    % financial companies
GB = [ false false false true true true ];    % nonfinancial companies
p = setGroupRatio(p, GA, GB, [], 0.5);

GA = [ true false true false true false ];    % odd-numbered companies
GB = [ false false false true true true ];    % nonfinancial companies
p = addGroupRatio(p, GA, GB, 0.2);

disp(p.NumAssets);

     6

disp(p.GroupA);

     1     1     1     0     0     0
     1     0     1     0     1     0

disp(p.GroupB);
```

```
     0     0     0     1     1     1
     0     0     0     1     1     1
```

```
disp(p.LowerRatio);
```

```
      -Inf
    0.2000
```

```
disp(p.UpperRatio);
```

```
    0.5000
       Inf
```

Add Group Ratio Constraints to a PortfolioMAD Object

Set a group ratio constraint to ensure that the weight in financial assets does not exceed 50% of the weight in nonfinancial assets. Then add another group ratio constraint to ensure that the weight in financial assets constitute at least 20% of the weight in nonfinancial assets of the portfolio.

```
p = PortfolioMAD;
GA = [ true true true false false false ];    % financial companies
GB = [ false false false true true true ];    % nonfinancial companies
p = setGroupRatio(p, GA, GB, [], 0.5);

GA = [ true false true false true false ];    % odd-numbered companies
GB = [ false false false true true true ];    % nonfinancial companies
p = addGroupRatio(p, GA, GB, 0.2);

disp(p.NumAssets);
```

```
     6
```

```
disp(p.GroupA);
```

```
     1     1     1     0     0     0
     1     0     1     0     1     0
```

```
disp(p.GroupB);
```

```
     0     0     0     1     1     1
     0     0     0     1     1     1
```

```
disp(p.LowerRatio);
```

```
      -Inf
    0.2000
```

```
disp(p.UpperRatio);
```

```
    0.5000
       Inf
```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`GroupA` — Base groups for comparison
matrix of logical or numerical arrays

Base groups for comparison, specified as a matrix of logical or numerical arrays.

Note The group matrices `GroupA` and `GroupB` are usually indicators of membership in groups, which means that their elements are usually either `0` or `1`. Because of this interpretation, the `GroupA` and `GroupB` matrices can be logical or numerical arrays.

Data Types: `double`

`GroupB` — Comparison group
matrix of logical or numerical arrays

Comparison group, specified as a matrix of logical or numerical arrays.

Note The group matrices `GroupA` and `GroupB` are usually indicators of membership in groups, which means that their elements are usually either `0` or `1`. Because of this interpretation, the `GroupA` and `GroupB` matrices can be logical or numerical arrays.

Data Types: `double`

`LowerRatio` — Lower-bound for ratio of `GroupB` groups to `GroupA` groups
vector

Lower-bound for ratio of `GroupB` groups to `GroupA` groups, specified as a vector.

Note If input is scalar, `LowerRatio` undergoes scalar expansion to be conformable with the group matrices.

Data Types: `double`

`UpperRatio` — Upper-bound for ratio of `GroupB` groups to `GroupA` groups
vector

Upper-bound for ratio of `GroupB` groups to `GroupA` groups, specified as a vector.

Note If input is scalar, `UpperRatio` undergoes scalar expansion to be conformable with the group matrices.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Tips

- You can also use dot notation to add group ratio constraints for the portfolio weights to existing group ratio constraints.

  ```
  obj = obj.addGroupRatio(GroupA, GroupB, LowerRatio, UpperRatio)
  ```
- To remove group ratio constraints from any of the portfolio objects using dot notation, enter empty arrays for the corresponding arrays.

Version History

Introduced in R2011a

addGroups

Add group constraints for portfolio weights to existing group constraints

Syntax

```
obj = addGroups(obj,GroupMatrix,LowerGroup)
obj = addGroups(obj,GroupMatrix,LowerGroup,UpperGroup)
```

Description

`obj = addGroups(obj,GroupMatrix,LowerGroup)` adds group constraints for portfolio weights to existing group constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Given `GroupMatrix` and either `LowerGroup` or `UpperGroup`, a portfolio `Port` must satisfy the following:

```
LowerGroup <= GroupMatrix * Port <= UpperGroup
```

`obj = addGroups(obj,GroupMatrix,LowerGroup,UpperGroup)` adds group constraints for portfolio weights to existing group constraints with an additional option for `UpperGroup`.

Given `GroupMatrix` and either `LowerGroup` or `UpperGroup`, a portfolio `Port` must satisfy the following:

```
LowerGroup <= GroupMatrix * Port <= UpperGroup
```

Examples

Add Group Constraints to a Portfolio Object

Set a group constraint to ensure that the first three assets constitute at most 30% of a portfolio. Then add another group constraint to ensure that the odd-numbered assets constitute at least 20% of a portfolio.

```
p = Portfolio;
G = [ true true true false false ];    % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ];    % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);
```

```
     5
```

```
disp(p.GroupMatrix);
```

```
     1     1     1     0     0
     1     0     1     0     1
```

```
disp(p.LowerGroup);

      -Inf
    0.2000

disp(p.UpperGroup);

    0.3000
       Inf
```

Add Group Constraints to a PortfolioCVaR Object

Set a group constraint to ensure that the first three assets constitute at most 30% of a portfolio. Then add another group constraint to ensure that the odd-numbered assets constitute at least 20% of a portfolio.

```
p = PortfolioCVaR;
G = [ true true true false false ];    % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ];    % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);

     5

disp(p.GroupMatrix);

     1     1     1     0     0
     1     0     1     0     1

disp(p.LowerGroup);

      -Inf
    0.2000

disp(p.UpperGroup);

    0.3000
       Inf
```

Add Group Constraints to a PortfolioMAD Object

Set a group constraint to ensure that the first three assets constitute at most 30% of a portfolio. Then add another group constraint to ensure that the odd-numbered assets constitute at least 20% of a portfolio.

```
p = PortfolioMAD;
G = [ true true true false false ];    % group matrix for first group constraint
p = setGroups(p, G, [], 0.3);
G = [ true false true false true ];    % group matrix for second group constraint
p = addGroups(p, G, 0.2);
disp(p.NumAssets);

     5
```

```
disp(p.GroupMatrix);

     1     1     1     0     0
     1     0     1     0     1

disp(p.LowerGroup);

      -Inf
    0.2000

disp(p.UpperGroup);

    0.3000
       Inf
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

GroupMatrix — Group constraint matrix

matrix

Group constraint matrix, specified as a matrix.

Note The group matrix `GroupMatrix` often indicates membership in groups, which means that its elements are usually either `0` or `1`. Because of this interpretation,`GroupMatrix` can be a logical or numerical matrix.

Data Types: `double`

LowerGroup — Lower bound for group constraints

vector

Lower bound for group constraints, specified as a vector.

Note If input is scalar, `LowerGroup` undergoes scalar expansion to be conformable with `GroupMatrix`.

Data Types: `double`

UpperGroup — Upper bound for group constraints

vector

Upper bound for group constraints, specified as a vector.

Note If input is scalar, `UpperGroup` undergoes scalar expansion to be conformable with `GroupMatrix`.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Tips

- You can also use dot notation to add group constraints for portfolio weights.

  ```
  obj = obj.addGroups(GroupMatrix, LowerGroup, UpperGroup)
  ```
- To remove group constraints from any of the portfolio objects using dot notation, enter empty arrays for the corresponding arrays.

addInequality

Add linear inequality constraints for portfolio weights to existing constraints

Syntax

```
obj = addInequality(obj,AInequality,bInequality)
```

Description

`obj = addInequality(obj,AInequality,bInequality)` adds linear inequality constraints for portfolio weights to existing constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Given a linear inequality constraint matrix `AInequality` and vector `bInequality`, every weight in a portfolio `Port` must satisfy the following:

```
AInequality * Port <= bInequality
```

This function "stacks" additional linear inequality constraints onto any existing linear inequality constraints that exist in the input portfolio object. If no constraints exist, this function is the same as `setInequality`.

Examples

Add Linear Inequality Constraint to a Portfolio Object

Set a linear inequality constraint to ensure that the first three assets constitute at most 50% of a portfolio. Then add another linear inequality constraint to ensure that the last three assets constitute at least 50% of a portfolio.

```
p = Portfolio;
A = [ 1 1 1 0 0 ];    % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);

A = [ 0 0 -1 -1 -1 ];    % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);

disp(p.NumAssets);
```

```
     5
```

```

Add Linear Inequality Constraint to a PortfolioCVaR Object

Set a linear inequality constraint to ensure that the first three assets constitute at most 50% of a portfolio. Then add another linear inequality constraint to ensure that the last three assets constitute at least 50% of a portfolio.

```
p = PortfolioCVaR;
A = [ 1 1 1 0 0 ];    % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);

A = [ 0 0 -1 -1 -1 ];    % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);

disp(p.NumAssets);

     5

disp(p.AInequality);

     1     1     1     0     0
     0     0    -1    -1    -1

disp(p.bInequality);

    0.5000
   -0.5000
```

Add Linear Inequality Constraint to a PortfolioMAD Object

Set a linear inequality constraint to ensure that the first three assets constitute at most 50% of a portfolio. Then add another linear inequality constraint to ensure that the last three assets constitute at least 50% of a portfolio.

```
p = PortfolioMAD;
A = [ 1 1 1 0 0 ];    % first inequality constraint
b = 0.5;
p = setInequality(p, A, b);

A = [ 0 0 -1 -1 -1 ];    % second inequality constraint
b = -0.5;
p = addInequality(p, A, b);

disp(p.NumAssets);

     5

disp(p.AInequality);
```

```
     1     1     1     0     0
     0     0    -1    -1    -1
```

```
disp(p.bInequality);
```

```
    0.5000
   -0.5000
```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

AInequality — Linear inequality constraints formed from matrix
matrix

Linear inequality constraints, specified as a matrix.

Note An error results if `AInequality` is empty and `bInequality` is nonempty.

Data Types: `double`

bInequality — Linear inequality constraints formed from vector
vector

Linear inequality constraints, specified as a vector.

Note An error results if `bInequality` is empty and `AInequality` is nonempty.

Data Types: `double`

Output Arguments

obj — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`

- `PortfolioCVaR`
- `PortfolioMAD`

Tips

- You can also use dot notation to add the linear inequality constraints for portfolio weights.

  ```
  obj = obj.addInequality(AInequality, bInequality)
  ```
- You can also remove linear inequality constraints from any of the portfolio objects using dot notation.

  ```
  obj = obj.setInequality([ ], [ ])
  ```

Version History

Introduced in R2011a

adline

Accumulation/Distribution line

Syntax

```
ADline = adline(Data)
```

Description

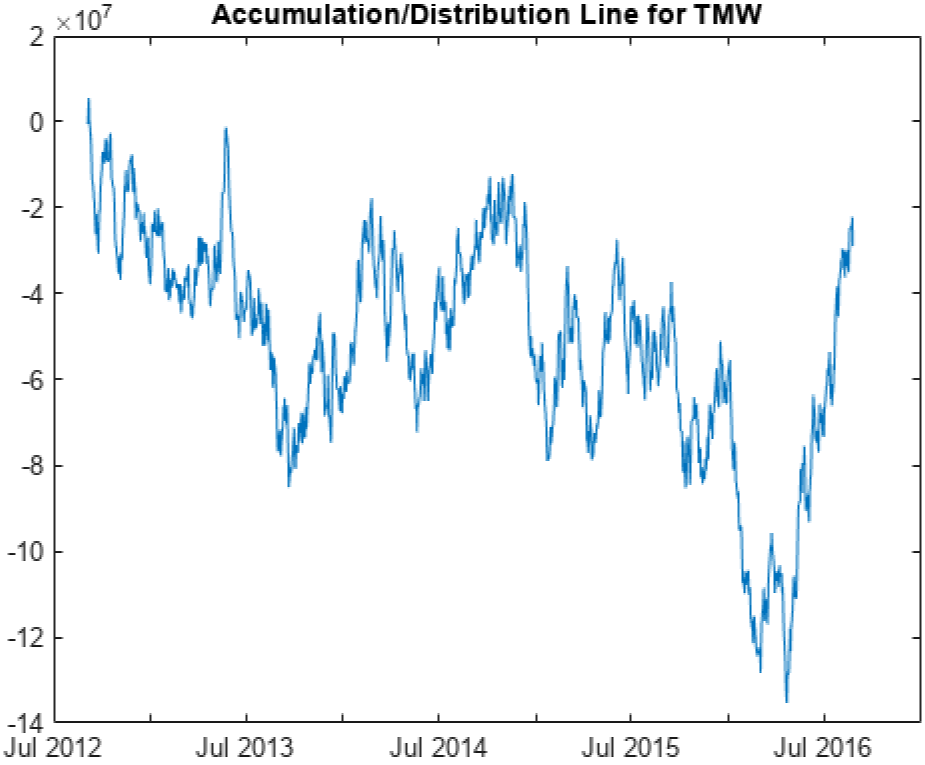
`ADline = adline(Data)` calculates the Accumulation/Distribution Line from a set of high, low, closing prices, and volume traded of a security.

Examples

Calculate the Accumulation/Distribution Line for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
line = adline(TMW);
plot(line.Time,line.ADLine)
title('Accumulation/Distribution Line for TMW')
```



Input Arguments

`Data` — Data with high, low, closing prices, and volume traded

matrix | table | timetable

Data with high, low, closing prices and volume traded, specified as a matrix, table, or timetable. For matrix input, `Data` is `M`-by-4 with high, low, closing prices, and volume traded. Timetables and tables with `M` rows must contain a variable named `'High'`, `'Low'`, `'Close'`, and `'Volume'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

`ADline` — Accumulation/Distribution line

matrix | table | timetable

Accumulation/Distribution line, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

adosc

Accumulation/Distribution oscillator

Syntax

```
ado = adosc(Data)
```

Description

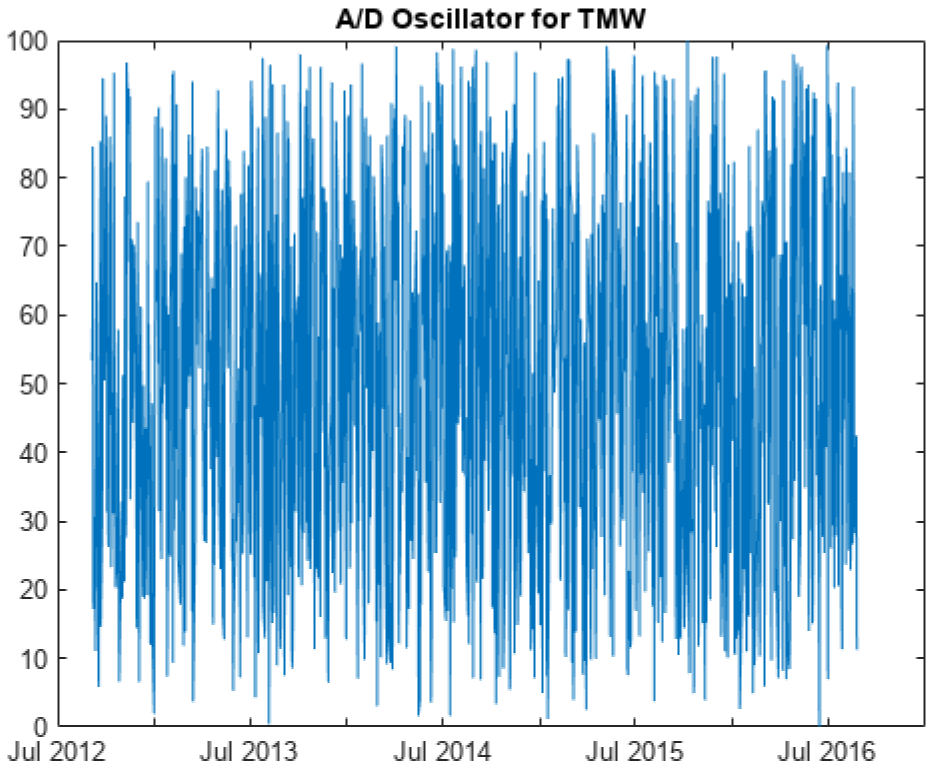
`ado = adosc(Data)` calculates the Accumulation/Distribution (A/D) oscillator.

Examples

Calculate the Accumulation/Distribution Oscillator for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
ADOsc = adosc(TMW);
plot(ADOsc.dates, ADOsc.ADOscillator)
title('A/D Oscillator for TMW')
```



Input Arguments

Data — Data with open, high, low, close information
matrix | table | timetable

Data with open, high, low, close information, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-4 matrix of open, high, low, and closing prices. Timetables and tables with `M` rows must contain variables named `'Open'`, `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

ado — Accumulation/Distribution oscillator
matrix | table | timetable

Accumulation/Distribution oscillator, returned with the same number of rows (`M`) and type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument
Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

amortize

Amortization schedule

Syntax

```
[Principal,Interest,Balance,Payment] = amortize(Rate,NumPeriods,PresentValue)
[Principal,Interest,Balance,Payment] = amortize( ___ ,FutureValue,Due)
```

Description

`[Principal,Interest,Balance,Payment] = amortize(Rate,NumPeriods,PresentValue)` returns the principal and interest payments of a loan, the remaining balance of the original loan amount, and the periodic payment.

`[Principal,Interest,Balance,Payment] = amortize( ___ ,FutureValue,Due)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute an Amortization Schedule for a Conventional 30-Year, Fixed-Rate Mortgage With Fixed Monthly Payments

Compute an amortization schedule for a conventional 30-year, fixed-rate mortgage with fixed monthly payments and assume a fixed rate of 12% APR and an initial loan amount of $100,000.

```
Rate         = 0.12/12;   % 12 percent APR = 1 percent per month
NumPeriods   = 30*12;     % 30 years = 360 months
PresentValue = 100000;

[Principal, Interest, Balance, Payment] = amortize(Rate, ...
NumPeriods, PresentValue);
```

The output argument `Payment` contains the fixed monthly payment.

```
format bank

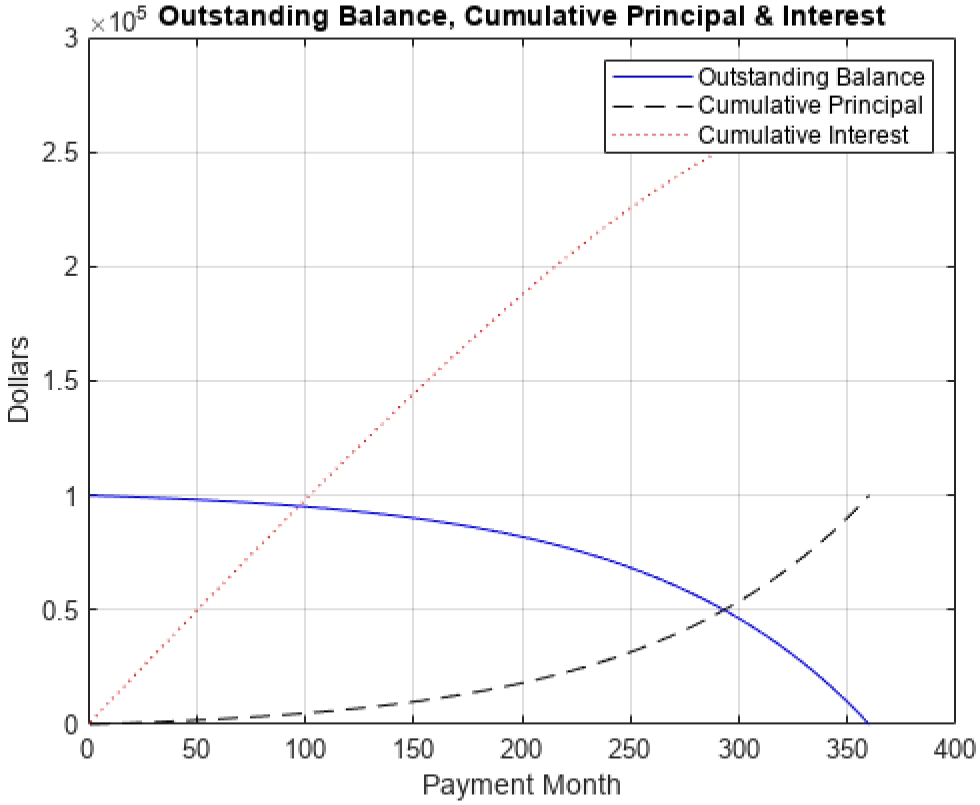
Payment
```

```
Payment =
       1028.61
```

Summarize the amortization schedule graphically by plotting the current outstanding loan balance, the cumulative principal, and the interest payments over the life of the mortgage. In particular, note that total interest paid over the life of the mortgage exceeds $270,000, far in excess of the original loan amount.

```
plot(Balance,'b'), hold('on')
plot(cumsum(Principal),'--k')
plot(cumsum(Interest),':r')

xlabel('Payment Month')
ylabel('Dollars')
grid('on')
title('Outstanding Balance, Cumulative Principal & Interest')
legend('Outstanding Balance', 'Cumulative Principal', ...
'Cumulative Interest')
```



The solid blue line represents the declining principal over the 30-year period. The dotted red line indicates the increasing cumulative interest payments. Finally, the dashed black line represents the cumulative principal payments, reaching $100,000 after 30 years.

Input Arguments

Rate — Interest-rate per period

scalar numeric decimal

Interest-rate per period, specified as a scalar numeric decimal.

Data Types: `double`

`NumPeriods` — Number of payment periods

scalar numeric

Number of payment periods, specified as a scalar numeric.

Data Types: `double`

`PresentValue` — Present value of the loan

scalar numeric

Present value of the loan, specified as a scalar numeric.

Data Types: `double`

`FutureValue` — Future value of the loan

`0` (default) | scalar numeric

(Optional) Future value of the loan, specified as a scalar numeric.

Data Types: `double`

`Due` — When payments are due

`0` (end of period) (default) | scalar integer with value of `0` or `1`

(Optional) When payments are due, specified as a scalar integer with value of `0` (end of period) or `1` (beginning of period).

Data Types: `double`

Output Arguments

`Principal` — Principal paid in each period

vector

Principal paid in each period, returned as a `1`-by-`NumPeriods` vector.

`Interest` — Interest paid in each period

vector

Interest paid in each period, returned as a `1`-by-`NumPeriods` vector.

`Balance` — Remaining balance of the loan in each payment period

vector

Remaining balance of the loan in each payment period, returned as a `1`-by-`NumPeriods` vector.

`Payment` — Payment per period

scalar numeric

Payment per period, returned as a scalar numeric.

Version History

Introduced before R2006a

annurate

Periodic interest rate of annuity

Syntax

```
Rate = annurate(NumPeriods,Payment,PresentValue)
Rate = annurate( ___ ,FutureValue,Due)
```

Description

`Rate = annurate(NumPeriods,Payment,PresentValue)` returns the periodic interest rate paid on a loan or annuity.

`Rate = annurate( ___ ,FutureValue,Due)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Calculate the Periodic Interest Rate Paid on a Loan or Annuity

This example shows how to find the periodic interest rate of a four-year, $5000 loan with a $130 monthly payment made at the end of each month.

```
Rate = annurate(4*12, 130, 5000, 0, 0)
```

```
Rate = 0.0094
```

Rate multiplied by 12 gives an annual interest rate of 11.32% on the loan.

Input Arguments

`NumPeriods` — Number of payment periods
scalar numeric

Number of payment periods, specified as a scalar numeric.

Data Types: `double`

`Payment` — Payment per period
scalar numeric

Payment per period, specified as a scalar numeric.

Data Types: `double`

`PresentValue` — Present value of the loan
scalar numeric

Present value of the loan, specified as a scalar numeric.

Data Types: `double`

`FutureValue` — Future value of the loan

`0` (default) | scalar numeric

(Optional) Future value of the loan, specified as a scalar numeric.

Data Types: `double`

`Due` — When payments are due

`0` (end of period) (default) | scalar integer with value of `0` or `1`

(Optional) When payments are due, specified as a scalar integer with value of `0` (end of period) or `1` (beginning of period).

Data Types: `double`

Output Arguments

`Rate` — Periodic interest-rate paid of a loan or annuity

scalar numeric decimal

Periodic interest-rate paid of a loan or annuity, returned as a scalar numeric decimal.

annuterm

Number of periods to obtain value

Syntax

```
NumPeriods = annuterm(Rate,Payment,PresentValue)
NumPeriods = annuterm( ___ ,FutureValue,Due)
```

Description

`NumPeriods = annuterm(Rate,Payment,PresentValue)` calculates the number of periods needed to obtain a future value. To calculate the number of periods needed to pay off a loan, enter the payment or the present value as a negative value.

`NumPeriods = annuterm( ___ ,FutureValue,Due)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Calculate the Number of Periods Needed to Obtain a Future Value

This example shows a savings account with a starting balance of $1500. $200 is added at the end of each month and the account pays 9% interest, compounded monthly. How many months will it take to save $5,000?

```
NumPeriods = annuterm(0.09/12, 200, 1500, 5000, 0)
```

```
NumPeriods = 15.6752
```

Input Arguments

`Rate` — Interest-rate per period
scalar numeric decimal

Interest-rate per period, specified as a scalar numeric decimal.

Data Types: `double`

`Payment` — Payment per period
scalar numeric

Payment per period, specified as a scalar numeric.

Data Types: `double`

`PresentValue` — Present value of the loan
scalar numeric

Present value of the loan, specified as a scalar numeric.

Data Types: `double`

`FutureValue` — Future value of the loan
`0` (default) | scalar numeric

(Optional) Future value of the loan, specified as a scalar numeric.

Data Types: `double`

`Due` — When payments are due
`0` (end of period) (default) | scalar integer with value of `0` or `1`

(Optional) When payments are due, specified as a scalar integer with value of `0` (end of period) or `1` (beginning of period).

Data Types: `double`

Output Arguments

`NumPeriods` — Number of payment periods
scalar numeric

Number of payment periods, returned as a scalar numeric.

Version History

Introduced before R2006a

arith2geom

Arithmetic to geometric moments of asset returns

Syntax

```
[mg,Cg = arith2geom(ma,Ca)
[mg,Cg = arith2geom( ___ ,t)
```

Description

`[mg,Cg = arith2geom(ma,Ca)` transforms moments associated with a simple Brownian motion into equivalent continuously compounded moments associated with a geometric Brownian motion with a possible change in periodicity.

`[mg,Cg = arith2geom( ___ ,t)` adds an optional argument `t`.

Examples

Obtain Arithmetic to Geometric Moments of Asset Returns

This example shows several variations of using `arith2geom`.

Given arithmetic mean `m` and covariance `C` of monthly total returns, obtain annual geometric mean `mg` and covariance `Cg`. In this case, the output period (1 year) is 12 times the input period (1 month) so that the optional input `t = 12`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
[mg, Cg] = arith2geom(m, C, 12)
```

```
mg = 4×1

    0.8934
    2.9488
    4.9632
   17.0835

Cg = 4×4
10^3 ×

    0.0003    0.0004    0.0003         0
    0.0004    0.0065    0.0065    0.0110
    0.0003    0.0065    0.0354    0.0536
         0    0.0110    0.0536    1.0952
```

Given annual arithmetic mean `m` and covariance `C` of asset returns, obtain monthly geometric mean `mg` and covariance `Cg`. In this case, the output period (1 month) is 1/12 times the input period (1 year) so that the optional input `t = 1/12`.

```
[mg, Cg] = arith2geom(m, C, 1/12)
```

```
mg = 4×1

    0.0044
    0.0096
    0.0125
    0.0203

Cg = 4×4

    0.0005    0.0003    0.0002         0
    0.0003    0.0025    0.0017    0.0010
    0.0002    0.0017    0.0049    0.0029
         0    0.0010    0.0029    0.0107
```

Given arithmetic mean `m` and covariance `C` of monthly total returns, obtain quarterly continuously compounded return moments. In this case, the output is `3` of the input periods so that the optional input `t = 3`.

```
[mg, Cg] = arith2geom(m, C, 3)
```

```
mg = 4×1

    0.1730
    0.4097
    0.5627
    1.0622

Cg = 4×4

    0.0267    0.0204    0.0106         0
    0.0204    0.1800    0.1390    0.1057
    0.0106    0.1390    0.4606    0.3418
         0    0.1057    0.3418    1.8886
```

Input Arguments

`ma` — Arithmetic mean of asset-return data

vector

Arithmetic mean of asset-return data, specified as an *n*-vector.

Data Types: `double`

`Ca` — Arithmetic covariance of asset-return data

matrix

Arithmetic covariance of asset-return data, specified as an n-by-n symmetric, positive semidefinite matrix. If Ca is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

Data Types: double

t — Target period of geometric moments in terms of periodicity of arithmetic moments
1 (default) | scalar positive numeric

(Optional) Target period of geometric moments in terms of periodicity of arithmetic moments, specified as a scalar positive numeric.

Data Types: double

Output Arguments

mg — Continuously compounded or "geometric" mean of asset returns over the target period
vector

Continuously compounded or "geometric" mean of asset returns over the target period (t), returned as an *n*-vector.

Cg — Continuously compounded or "geometric" covariance of asset returns over the target period
matrix

Continuously compounded or "geometric" covariance of asset returns over the target period (t), returned as an n-by-n matrix.

Algorithms

Arithmetic returns over period t_A are modeled as multivariate normal random variables with moments

$$E[\mathrm{X}] = \mathrm{m}_A$$

and

$$\mathrm{cov}(\mathrm{X}) = \mathrm{C}_A$$

Geometric returns over period t_G are modeled as multivariate lognormal random variables with moments

$$E[\mathrm{Y}] = 1 + \mathrm{m}_G$$

$$\mathrm{cov}(\mathrm{Y}) = \mathrm{C}_G$$

Given $t = t_G / t_A$, the transformation from geometric to arithmetic moments is

$$1 + \mathrm{m}_{G_i} = \exp(t\mathrm{m}_{A_i} + \frac{1}{2}t\mathrm{C}_{A_{ii}})$$

$$\mathrm{C}_{G_{ij}} = (1 + \mathrm{m}_{G_i})(1 + \mathrm{m}_{G_\mathrm{j}})(\exp(t\mathrm{C}_{Aij}) - 1)$$

For $i,j = 1,\ldots, n$.

Note If $t = 1$, then $\mathbf{Y} = \exp(\mathbf{X})$.

The `arith2geom` function has no restriction on the input mean `ma` but requires the input covariance `Ca` to be a symmetric positive-semidefinite matrix.

The functions `arith2geom` and `geom2arith` are complementary so that, given `m`, `C`, and `t`, the sequence

```
[mg,Cg] = arith2geom(m,C,t);
[ma,Ca] = geom2arith(mg,Cg,1/t);
```

yields `ma` = `m` and `Ca` = `C`.

Version History

Introduced before R2006a

See Also

`geom2arith` | `nearcorr`

beytbill

Bond equivalent yield for Treasury bill

Syntax

```
Yield = beytbill(Settle,Maturity,Discount)
```

Description

`Yield = beytbill(Settle,Maturity,Discount)` returns the bond equivalent yield for a Treasury bill.

Examples

Find the Bond Equivalent Yield for a Treasury Bill

This example shows how to find the bond equivalent yield for a Treasury bill that has a settlement date of February 11, 2000, a maturity date of August 7, 2000, and a discount rate is 5.77.

```
Yield = beytbill(datetime(2000,2,11),datetime(2000,8,7), 0.0577)
```

```
Yield = 0.0602
```

Input Arguments

`Settle` — Settlement date of Treasury bill
datetime array | string array | date character vector

Settlement date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `beytbill` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of Treasury bill
datetime array | string array | date character vector

Maturity date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `beytbill` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Discount` — Discount rate of Treasury bill
decimal

Discount rate of the Treasury bill, specified as a scalar of a `NTBILLS`-by-`1` vector of decimal fraction values.

Data Types: `double`

Output Arguments

`Yield` — Treasury bill yield

decimal

Treasury bill yield, returned as a scalar or `NTBILLS`-by-`1` vector.

Note The number of days to maturity is typically quoted as: md - sd - 1. A `NaN` is returned for all cases in which negative prices are implied by the discount rate, `Discount`, and the number of days between `Settle` and `Maturity`.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `beytbill` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

See Also

binprice

Binomial put and call American option pricing using Cox-Ross-Rubinstein model

Syntax

```
[AssetPrice,OptionValue] = binprice(Price,Strike,Rate,Time,Increment,
Volatility,Flag)
[AssetPrice,OptionValue] = binprice( ___ ,DividendRate,Dividend,ExDiv)
```

Description

`[AssetPrice,OptionValue] = binprice(Price,Strike,Rate,Time,Increment, Volatility,Flag)` prices an American option using the Cox-Ross-Rubinstein binomial pricing model. An American option can be exercised any time until its expiration date.

`[AssetPrice,OptionValue] = binprice( ___ ,DividendRate,Dividend,ExDiv)` adds optional arguments for `DividendRate`,`Dividend`, and `ExDiv`.

Examples

Price an American Option Using the Cox-Ross-Rubinstein Binomial Pricing Model

This example shows how to price an American put option with an exercise price of $50 that matures in 5 months. The current asset price is $52, the risk-free interest rate is 10%, and the volatility is 40%. There is one dividend payment of $2.06 in 3-1/2 months. When specifying the input argument `ExDiv` in terms of number of periods, divide the ex-dividend date, specified in years, by the time `Increment`.

ExDiv = (3.5/12) / (1/12) = 3.5

```
[Price, Option] = binprice(52, 50, 0.1, 5/12, 1/12, 0.4, 0, 0, 2.06, 3.5)
```

```
Price = 6×6

   52.0000   58.1367   65.0226   72.7494   79.3515   89.0642
         0   46.5642   52.0336   58.1706   62.9882   70.6980
         0         0   41.7231   46.5981   49.9992   56.1192
         0         0         0   37.4120   39.6887   44.5467

```

The output returned is the asset price and American option value at each node of the binary tree.

Input Arguments

`Price` — Current price of underlying asset
numeric

Current price of underlying asset, specified as a scalar numeric value.

Data Types: `double`

`Strike` — Exercise price of the option
numeric

Exercise price of the option, specified as a scalar numeric value.

Data Types: `double`

`Rate` — Risk-free interest rate
decimal

Risk-free interest rate, specified as scalar decimal fraction.

Data Types: `double`

`Time` — Option time until maturity
numeric

Option time until maturity, specified as a scalar for the number of years.

Data Types: `double`

`Increment` — Time increment
numeric

Time increment, specified as a scalar numeric. `Increment` is adjusted so that the length of each interval is consistent with the maturity time of the option. (`Increment` is adjusted so that `Time` divided by `Increment` equals an integer number of increments.)

Data Types: `double`

`Volatility` — Asset volatility
numeric

Asset volatility, specified as a scalar numeric.

Data Types: `double`

`Flag` — Flag indicating whether option is a call or put
integer with values `0` or `1`

Flag indicating whether option is a call or put, specified as a scalar `Flag = 1` for a call option, or `Flag = 0` for a put option.

Data Types: `logical`

DividendRate — Dividend rate

0 (default) | decimal

(Optional) Dividend rate, specified as a scalar decimal. If you enter a value for DividendRate, set Dividend and ExDiv = 0 or do not enter them. If you enter values for Dividend and ExDiv, set DividendRate = 0

Data Types: double

Dividend — Dividend payment

0 (default) | numeric

(Optional) Dividend payment at an ex-dividend date (ExDiv), specified as a 1-by-N row vector. For each dividend payment, there must be a corresponding ex-dividend date. If you enter values for Dividend and ExDiv, set DividendRate = 0.

Data Types: double

ExDiv — Ex-dividend date

0 (default) | numeric

(Optional) Ex-dividend date, specified as a 1-by-N vector row vector for the number of periods.

Data Types: double

Output Arguments

AssetPrice — Asset price

vector

Asset price, returned as a vector that represents each node of the Cox-Ross-Rubinstein (CRR) binary tree.

OptionValue — Option value

vector

Option value, returned as a vector that represents each node of the Cox-Ross-Rubinstein (CRR) binary tree.

Version History

Introduced before R2006a

blkimpv

Implied volatility for futures options from Black model

Syntax

```
Volatility = blkimpv(Price,Strike,Rate,Time,Value)
Volatility = blkimpv( ___ ,Name,Value)
```

Description

`Volatility = blkimpv(Price,Strike,Rate,Time,Value)` computes the implied volatility of a futures price from the market value of European futures options using Black's model. If the `Class` name-value argument is empty or unspecified, the default is a call option

Note Any input argument can be a scalar, vector, or matrix. When a value is a scalar, that value is used to compute the implied volatility of all the options. If more than one input is a vector or matrix, the dimensions of all nonscalar inputs must be identical.

Ensure that `Rate` and `Time` are expressed in consistent units of time.

`Volatility = blkimpv( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Find Implied Volatility for Futures Options from Black's Model

This example shows how to find the implied volatility for a European call futures option that expires in four months, trades at $1.1166, and has an exercise price of $20. Assume that the current underlying futures price is also $20 and that the risk-free rate is 9% per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 (50% per annum). Under these conditions, the following commands all return an implied volatility of 0.25, or 25% per annum.

```
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5);
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5,'Class',{'Call'});
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5,'Class',true);
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 'Limit',0.5,'Class',true,'Method','jackel2016')
```

```
Volatility = 0.2500
```

Input Arguments

`Price` — Current price of underlying asset

scalar numeric

Current price of the underlying asset (that is, a futures contract), specified as a scalar numeric.

Data Types: `double`

`Strike` — Exercise price of the futures option

scalar numeric

Exercise price of the futures option, specified as a scalar numeric.

Data Types: `double`

`Rate` — Annualized continuously compounded risk-free rate of return over life of the option

scalar positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a scalar positive decimal.

Data Types: `double`

`Time` — Time to expiration of the futures option

scalar numeric

Time to expiration of the futures option, specified as the number of years using a scalar numeric.

Data Types: `double`

`Value` — Price of a European option from which implied volatility of underlying asset is derived

scalar numeric

Price of a European futures option from which the implied volatility of the underlying asset is derived, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Volatility = blkimpv(Yield,CouponRate,Settle,Maturity,'Method','jackel2016')`

`Limit` — Upper bound of implied volatility search interval

`10` (1000% per annum) (default) | positive scalar numeric

Upper bound of the implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar numeric. If `Limit` is empty or unspecified, the default is `10`, or 1000% per annum.

Note If you are using `Method` with a value of `'jackel2016'`, the `Limit` argument is ignored.

Data Types: `double`

`Tolerance` — Implied volatility termination tolerance

`1e6` (default) | positive scalar numeric

Implied volatility termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar numeric. If empty or missing, the default is `1e6`.

Note If you are using `Method` with a value of `'jackel2016'`, the `Tolerance` argument is ignored.

Data Types: `double`

`Class` — Option class from which implied volatility is derived

`true` (call option) (default) | logical | cell array of character vectors | string array

Option class indicating option type (call or put) from which implied volatility is derived, specified as the comma-separated pair consisting of `'Class'` and a logical indicator, cell array of character vectors, or string array.

To specify call options, set `Class = true` or `Class = {'call'}`. To specify put options, set `Class = false` or `Class = {'put'}` or `Class = ["put"]`. If `Class` is empty or unspecified, the default is a call option.

Data Types: `logical` | `cell` | `string`

`Method` — Method for computing implied volatility

`'jackel2016'` (default) | character vector with values `'search'` or `'jackel2016'` | string with values `"search"` or `"jackel2016"`

Method for computing implied volatility, specified as the comma-separated pair consisting of `'Method'` and a character vector with a value of `'search'` or `'jackel2016'` or a string with a value of `"search"` or `"jackel2016"`.

Data Types: `char` | `string`

Output Arguments

`Volatility` — Implied volatility of underlying asset derived from European futures option prices

decimal

Implied volatility of the underlying asset derived from European futures option prices, returned as a decimal. If no solution is found, `blkimpv` returns `NaN`.

blkprice

Black model for pricing futures options

Syntax

```
[Call,Put] = blkprice(Price,Strike,Rate,Time,Volatility)
```

Description

`[Call,Put] = blkprice(Price,Strike,Rate,Time,Volatility)` computes European put and call futures option prices using Black's model.

Note Any input argument can be a scalar, vector, or matrix. If a scalar, then that value is used to price all options. If more than one input is a vector or matrix, then the dimensions of those non-scalar inputs must be the same.

Ensure that `Rate`, `Time`, and `Volatility` are expressed in consistent units of time.

Examples

Compute European Put and Call Futures Option Prices Using Black's Model

This example shows how to price European futures options with exercise prices of $20 that expire in four months. Assume that the current underlying futures price is also $20 with a volatility of 25% per annum. The risk-free rate is 9% per annum.

```
 [Call, Put] = blkprice(20, 20, 0.09, 4/12, 0.25)
```

```
Call = 1.1166

Put = 1.1166
```

Input Arguments

`Price` — Current price of underlying asset
numeric

Current price of the underlying asset (that is, a futures contract), specified as a numeric value.

Data Types: `double`

`Strike` — Exercise price of the futures option
numeric

Exercise price of the futures option, specified as a numeric value.

Data Types: `double`

`Rate` — Annualized continuously compounded risk-free rate of return over life of the option

positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal number.

Data Types: `double`

`Time` — Time to expiration of option

numeric

Time to expiration of the option, specified as the number of years. `Time` must be greater than `0`.

Data Types: `double`

`Volatility` — Annualized asset price volatility

positive decimal

Annualized futures price volatility, specified as a positive decimal number.

Data Types: `double`

Output Arguments

`Call` — Price of a European call futures option

matrix

Price of a European call futures option, returned as a matrix.

`Put` — Price of a European put futures option

matrix

Price of a European put futures option, returned as a matrix.

blsdelta

Black-Scholes sensitivity to underlying price change

Syntax

```
[CallDelta,PutDelta] = blsdelta(Price,Strike,Rate,Time,Volatility)
[CallDelta,PutDelta] = blsdelta( ___ ,Yield)
```

Description

`[CallDelta,PutDelta] = blsdelta(Price,Strike,Rate,Time,Volatility)` returns delta, the sensitivity in option value to change in the underlying asset price. Delta is also known as the hedge ratio. `blsdelta` uses `normcdf`, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

In addition, you can use the Financial Instruments Toolbox object framework with the `BlackScholes` pricer object to obtain price and `delta` values for a `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument using a `BlackScholes` model.

Note `blsdelta` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

`[CallDelta,PutDelta] = blsdelta( ___ ,Yield)` adds an optional argument for `Yield`.

Examples

Find the Sensitivity in Option Value to Change in the Underlying Asset Price

This example shows how to find the Black-Scholes delta sensitivity for an underlying asset price change.

```
[CallDelta, PutDelta] = blsdelta(50, 50, 0.1, 0.25, 0.3, 0)
```

```
CallDelta = 0.5955
```

```
PutDelta = -0.4045
```

Input Arguments

`Price` — Current price of underlying asset
numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: `double`

`Strike` — Exercise price of option
numeric

Exercise price of the option, specified as a numeric value.

Data Types: `double`

`Rate` — Annualized, continuously compounded risk-free rate of return over life of option
positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: `double`

`Time` — Time (in years) to expiration of the option
numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: `double`

`Volatility` — Annualized asset price volatility
positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: `double`

`Yield` — Annualized, continuously compounded yield of the underlying asset over life of option
`0` (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, `Yield` could represent the dividend yield. For currency options, `Yield` could be the foreign risk-free interest rate.

Data Types: `double`

Output Arguments

`CallDelta` — Delta of call option
numeric

Delta of the call option, returned as a numeric value.

`PutDelta` — Delta of put option
numeric

Delta of the put option, returned as a numeric.

blsgamma

Black-Scholes sensitivity to underlying delta change

Syntax

```
Gamma = blsgamma(Price,Strike,Rate,Time,Volatility)
Gamma = blsgamma( ___ ,Yield)
```

Description

`Gamma = blsgamma(Price,Strike,Rate,Time,Volatility)` returns gamma, the sensitivity of delta to change in the underlying asset price. `blsgamma` uses `normpdf`, the probability density function in the Statistics and Machine Learning Toolbox.

In addition, you can use the Financial Instruments Toolbox object framework with the `BlackScholes` pricer object to obtain price and `gamma` values for a `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument using a `BlackScholes` model.

Note `blsgamma` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

`Gamma = blsgamma( ___ ,Yield)` adds an optional argument for `Yield`.

Examples

Find Gamma for a Change in the Underlying Asset Price

This example shows how to find the gamma, the sensitivity of delta to a change in the underlying asset price.

```
Gamma = blsgamma(50, 50, 0.12, 0.25, 0.3, 0)
```

```
Gamma = 0.0512
```

Input Arguments

`Price` — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: `double`

`Strike` — Exercise price of option
numeric

Exercise price of the option, specified as a numeric value.

Data Types: `double`

`Rate` — Annualized, continuously compounded risk-free rate of return over life of option
positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: `double`

`Time` — Time (in years) to expiration of the option
numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: `double`

`Volatility` — Annualized asset price volatility
positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: `double`

`Yield` — Annualized, continuously compounded yield of the underlying asset over life of option
`0` (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, `Yield` could represent the dividend yield. For currency options, `Yield` could be the foreign risk-free interest rate.

Data Types: `double`

Output Arguments

`Gamma` — Delta to change in underlying security price
numeric

Delta to change in underlying security price, returned as a numeric value.

Version History
Introduced in R2006a

blsimpv

Black-Scholes implied volatility

Syntax

```
Volatility = blsimpv(Price,Strike,Rate,Time,Value)
Volatility = blsimpv( ___ ,Name,Value)
```

Description

`Volatility = blsimpv(Price,Strike,Rate,Time,Value)` using a Black-Scholes model computes the implied volatility of an underlying asset from the market value of European options. If the `Class` name-value argument is empty or unspecified, the default is a call option

Note The input arguments `Price`, `Strike`, `Rate`, `Time`, `Value`, `Yield`, and `Class` can be scalars, vectors, or matrices. If scalars, then that value is used to compute the implied volatility from all options. If more than one of these inputs is a vector or matrix, then the dimensions of all non-scalar inputs must be the same.

Also, ensure that `Rate`, `Time`, and `Yield` are expressed in consistent units of time.

`Volatility = blsimpv( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Implied Volatility of an Underlying Asset Using a Black-Scholes Model

This example shows how to compute the implied volatility for a European call option trading at $10 with an exercise price of $95 and three months until expiration. Assume that the underlying stock pays no dividend and trades at $100. The risk-free rate is 7.5% per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 (50% per annum). Under these conditions, the following statements all compute an implied volatility of 0.3130, or 31.30% per annum.

```
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit', 0.5);
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit',0.5,'Yield',0,'Class', {'Call'});
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit',0.5,'Yield',0, 'Class', true);
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 'Limit',0.5,'Yield',0, 'Class', true,'Method','ja
```

```
Volatility = 0.3130
```

Input Arguments

`Price` — Current price of underlying asset

scalar numeric

Current price of the underlying asset, specified as a scalar numeric.

Data Types: `double`

`Strike` — Exercise price of the option
scalar numeric

Exercise price of the option, specified as a scalar numeric.

Data Types: `double`

`Rate` — Annualized continuously compounded risk-free rate of return over life of the option
scalar positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a scalar positive decimal.

Data Types: `double`

`Time` — Time to expiration of option
scalar numeric

Time to expiration of the option, specified as the number of years using a scalar numeric.

Data Types: `double`

`Value` — Price of a European option from which implied volatility of underlying asset is derived
scalar numeric

Price of a European option from which the implied volatility of the underlying asset is derived, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Volatility = blsimpv(Yield,CouponRate,Settle,Maturity,'Method','jackel2016')`

`Limit` — Upper bound of implied volatility search interval
`10` (1000% per annum) (default) | positive scalar numeric

Upper bound of the implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar numeric. If `Limit` is empty or unspecified, the default is `10`, or 1000% per annum.

Note If you are using `Method` with a value of `'jackel2016'`, the `Limit` argument is ignored.

Data Types: `double`

`Yield` — Annualized continuously compounded yield of underlying asset over life of the option

`0` (default) | decimal

Annualized continuously compounded yield of the underlying asset over the life of the option,specified as the comma-separated pair consisting of `'Yield'` and a decimal number. If `Yield` is empty or missing, the default value is `0`.

For example, for options written on stock indices, `Yield` could represent the dividend yield. For currency options, `Yield` could be the foreign risk-free interest rate.

Note `blsimpv` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

Data Types: `double`

`Tolerance` — Implied volatility termination tolerance

`1e6` (default) | positive scalar numeric

Implied volatility termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar numeric. If empty or missing, the default is `1e6`.

Note If you are using `Method` with a value of `'jackel2016'`, the `Tolerance` argument is ignored.

Data Types: `double`

`Class` — Option class from which implied volatility is derived

`true` (call option) (default) | logical | cell array of character vectors | string array

Option class indicating option type (call or put) from which implied volatility is derived, specified as the comma-separated pair consisting of `'Class'` and a logical indicator, cell array of character vectors, or string array.

To specify call options, set `Class = true` or `Class = {'call'}`. To specify put options, set `Class = false` or `Class = {'put'}` or `Class = ["put"]`. If `Class` is empty or unspecified, the default is a call option.

Data Types: `logical` | `cell` | `string`

`Method` — Method for computing implied volatility

`'jackel2016'` (default) | character vector with values `'search'` or `'jackel2016'` | string with values `"search"` or `"jackel2016"`

Method for computing implied volatility, specified as the comma-separated pair consisting of `'Method'` and a character vector with a value of `'search'` or `'jackel2016'` or a string with a value of `"search"` or `"jackel2016"`.

Data Types: `char` | `string`

Output Arguments

`Volatility` — Implied volatility of underlying asset derived from European option prices
decimal

Implied volatility of the underlying asset derived from European option prices, returned as a decimal. If no solution is found, `blsimpv` returns `NaN`.

blslambda

Black-Scholes elasticity

Syntax

```
[CallEl,PutEl] = blslambda(Price,Strike,Rate,Time,Volatility)
[CallEl,PutEl] = blslambda( ___ ,Yield)
```

Description

`[CallEl,PutEl] = blslambda(Price,Strike,Rate,Time,Volatility)` returns the elasticity of an option. `CallEl` is the call option elasticity or leverage factor, and `PutEl` is the put option elasticity or leverage factor. Elasticity (the leverage of an option position) measures the percent change in an option price per 1 percent change in the underlying asset price. `blslambda` uses `normcdf`, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

In addition, you can use the Financial Instruments Toolbox object framework with the `BlackScholes` pricer object to obtain price and `lambda` values for a `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument using a `BlackScholes` model.

Note `blslambda` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

`[CallEl,PutEl] = blslambda( ___ ,Yield)` adds an optional argument for `Yield`.

Examples

Find the Black-Scholes Elasticity (Lambda) for an Option

This example shows how to find the Black-Scholes elasticity, or leverage, of an option position.

```
[CallEl, PutEl] = blslambda(50, 50, 0.12, 0.25, 0.3)
```

```
CallEl = 8.1274
```

```
PutEl = -8.6466
```

Input Arguments

`Price` — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: `double`

`Strike` — Exercise price of option

numeric

Exercise price of the option, specified as a numeric value.

Data Types: `double`

`Rate` — Annualized, continuously compounded risk-free rate of return over life of option

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: `double`

`Time` — Time (in years) to expiration of the option

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: `double`

`Volatility` — Annualized asset price volatility

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: `double`

`Yield` — Annualized, continuously compounded yield of the underlying asset over life of option

`0` (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, `Yield` could represent the dividend yield. For currency options, `Yield` could be the foreign risk-free interest rate.

Data Types: `double`

Output Arguments

`CallEl` — Call option elasticity

numeric

Call option elasticity or leverage factor, returned as a numeric value.

`PutEl` — Put option elasticity
numeric

Put option elasticity or leverage factor, returned as a numeric value.

blsprice

Black-Scholes put and call option pricing

Syntax

```
[Call,Put] = blsprice(Price,Strike,Rate,Time,Volatility)
[Call,Put] = blsprice( ___ ,Yield)
```

Description

`[Call,Put] = blsprice(Price,Strike,Rate,Time,Volatility)` computes European put and call option prices using a Black-Scholes model.

Note Any input argument can be a scalar, vector, or matrix. If a scalar, then that value is used to price all options. If more than one input is a vector or matrix, then the dimensions of those non-scalar inputs must be the same.

Ensure that `Rate`, `Time`, `Volatility`, and `Yield` are expressed in consistent units of time.

In addition, you can use the Financial Instruments Toolbox object framework with the `BlackScholes` pricer object to obtain price values for a `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument using a `BlackScholes` model.

`[Call,Put] = blsprice( ___ ,Yield)` adds an optional an argument for `Yield`.

Examples

Compute European Put and Call Option Prices Using a Black-Scholes Model

This example shows how to price European stock options that expire in three months with an exercise price of $95. Assume that the underlying stock pays no dividend, trades at $100, and has a volatility of 50% per annum. The risk-free rate is 10% per annum.

```
[Call, Put] = blsprice(100, 95, 0.1, 0.25, 0.5)
```

```
Call = 13.6953
```

```
Put = 6.3497
```

Compute European Put and Call Option Prices on a Stock Index Using a Black-Scholes Model

The S&P 100 index is at 910 and has a volatility of 25% per annum. The risk-free rate of interest is 2% per annum and the index provides a dividend yield of 2.5% per annum. Calculate the value of a three-month European call and put with a strike price of 980.

```
 [Call,Put] = blsprice(910,980,.02,.25,.25,.025)
```

```
Call = 19.6863
```

```
Put = 90.4683
```

Price a European Call Option with the Garman-Kohlhagen Model

Price an FX option on buying GBP with USD.

```
S = 1.6;  % spot exchange rate
X = 1.6;  % strike
T = .3333;
r_d = .08;  % USD interest rate
r_f = .11;  % GBP interest rate
sigma = .2;

Price = blsprice(S,X,r_d,T,sigma,r_f)
```

```
Price = 0.0639
```

Input Arguments

`Price` — Current price of underlying asset
numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: `double`

`Strike` — Exercise price of the option
numeric

Exercise price of the option, specified as a numeric value.

Data Types: `double`

`Rate` — Annualized continuously compounded risk-free rate of return over life of the option
positive decimal

Annualized continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal number.

Data Types: `double`

`Time` — Time to expiration of option
numeric

Time to expiration of the option, specified as the number of years.

Data Types: `double`

`Volatility` — Annualized asset price volatility
positive decimal

Annualized asset price volatility (that is, annualized standard deviation of the continuously compounded asset return), specified as a positive decimal number.

Data Types: `double`

`Yield` — Annualized continuously compounded yield of underlying asset over life of the option

`0` (default) | decimal

(Optional) Annualized continuously compounded yield of the underlying asset over the life of the option, specified as a decimal number. If `Yield` is empty or missing, the default value is `0`.

For example, `Yield` could represent the dividend yield (annual dividend rate expressed as a percentage of the price of the security) or foreign risk-free interest rate for options written on stock indices and currencies.

Note `blsprice` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

Data Types: `double`

Output Arguments

`Call` — Price of a European call option

matrix

Price of a European call option, returned as a matrix.

`Put` — Price of a European put option

matrix

Price of a European put option, returned as a matrix.

blsrho

Black-Scholes sensitivity to interest-rate change

Syntax

```
[CallRho,PutRho] = blsrho(Price,Strike,Rate,Time,Volatility)
[CallRho,PutRho] = blsrho( ___ ,Yield)
```

Description

`[CallRho,PutRho] = blsrho(Price,Strike,Rate,Time,Volatility)` returns the call option rho `CallRho`, and the put option rho `PutRho`. Rho is the rate of change in value of derivative securities with respect to interest rates. `blsrho` uses `normcdf`, the normal cumulative distribution function in the Statistics and Machine Learning Toolbox.

In addition, you can use the Financial Instruments Toolbox object framework with the `BlackScholes` pricer object to obtain price and `rho` values for a `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument using a `BlackScholes` model.

Note `blsrho` can also handle an underlying asset such as currencies. When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

`[CallRho,PutRho] = blsrho( ___ ,Yield)` adds an optional argument for `Yield`.

Examples

Find the Black-Scholes Sensitivity (Rho) to Interest-Rate Change

This example shows how to find the Black-Scholes sensitivity, rho, to interest-rate change.

```
[CallRho, PutRho] = blsrho(50, 50, 0.12, 0.25, 0.3, 0)
```

```
CallRho = 6.6686
```

```
PutRho = -5.4619
```

Input Arguments

`Price` — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: `double`

`Strike` — Exercise price of option
numeric

Exercise price of the option, specified as a numeric value.

Data Types: `double`

`Rate` — Annualized, continuously compounded risk-free rate of return over life of option
positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: `double`

`Time` — Time (in years) to expiration of the option
numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: `double`

`Volatility` — Annualized asset price volatility
positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: `double`

`Yield` — Annualized, continuously compounded yield of the underlying asset over life of option
`0` (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, `Yield` could represent the dividend yield. For currency options, `Yield` could be the foreign risk-free interest rate.

Data Types: `double`

Output Arguments

`CallRho` — Call option rho
numeric

Call option rho, returned as a numeric value.

`PutRho` — Put option rho
numeric

Put option rho, returned as a numeric value.

blstheta

Black-Scholes sensitivity to time-until-maturity change

Syntax

```
[CallTheta,PutTheta] = blstheta(Price,Strike,Rate,Time,Volatility)
[CallTheta,PutTheta] = blstheta( ___ ,Yield)
```

Description

`[CallTheta,PutTheta] = blstheta(Price,Strike,Rate,Time,Volatility)` returns the call option theta `CallTheta`, and the put option theta `PutTheta`.

Theta is the sensitivity in option value with respect to time and is measured in years. `CallTheta` or `PutTheta` can be divided by 365 to get Theta per calendar day or by 252 to get Theta by trading day.

`blstheta` uses `normcdf`, the normal cumulative distribution function, and `normpdf`, the normal probability density function, in the Statistics and Machine Learning Toolbox.

In addition, you can use the Financial Instruments Toolbox object framework with the `BlackScholes` pricer object to obtain price and `theta` values for a `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument using a `BlackScholes` model.

Note `blstheta` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

`[CallTheta,PutTheta] = blstheta( ___ ,Yield)` adds an optional argument for `Yield`.

Examples

Compute the Black-Scholes Sensitivity to Time-Until-Maturity Change (Theta)

This example shows how to compute theta, the sensitivity in option value with respect to time.

```
[CallTheta, PutTheta] = blstheta(50, 50, 0.12, 0.25, 0.3, 0)
```

```
CallTheta = -8.9630
```

```
PutTheta = -3.1404
```

Input Arguments

`Price` — Current price of underlying asset

numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: `double`

`Strike` — Exercise price of option

numeric

Exercise price of the option, specified as a numeric value.

Data Types: `double`

`Rate` — Annualized, continuously compounded risk-free rate of return over life of option

positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: `double`

`Time` — Time (in years) to expiration of the option

numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: `double`

`Volatility` — Annualized asset price volatility

positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: `double`

`Yield` — Annualized, continuously compounded yield of the underlying asset over life of option

`0` (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, `Yield` could represent the dividend yield. For currency options, `Yield` could be the foreign risk-free interest rate.

Data Types: `double`

Output Arguments

`CallTheta` — Call option theta

numeric

Call option theta, returned as a numeric value.

`PutTheta` — Put option theta
numeric

Put option theta, returned as a numeric value.

blsvega

Black-Scholes sensitivity to underlying price volatility

Syntax

```
Vega = blsvega(Price,Strike,Rate,Time,Volatility)
Vega = blsvega( ___ ,Yield)
```

Description

`Vega = blsvega(Price,Strike,Rate,Time,Volatility)` returns the rate of change of the option value with respect to the volatility of the underlying asset. `blsvega` uses `normpdf`, the normal probability density function in the Statistics and Machine Learning Toolbox.

In addition, you can use the Financial Instruments Toolbox object framework with the `BlackScholes` pricer object to obtain price and `vega` values for a `Vanilla`, `Barrier`, `Touch`, `DoubleTouch`, or `Binary` instrument using a `BlackScholes` model.

Note `blsvega` can handle other types of underlies like Futures and Currencies. When pricing Futures (Black model), enter the input argument `Yield` as:

```
Yield = Rate
```

When pricing currencies (Garman-Kohlhagen model), enter the input argument `Yield` as:

```
Yield = ForeignRate
```

where `ForeignRate` is the continuously compounded, annualized risk-free interest rate in the foreign country.

`Vega = blsvega( ___ ,Yield)` adds an optional argument for `Yield`.

Examples

Compute Black-Scholes Sensitivity to Underlying Price Volatility (Vega)

This example shows how to compute vega, the rate of change of the option value with respect to the volatility of the underlying asset.

```
Vega = blsvega(50, 50, 0.12, 0.25, 0.3, 0)
```

```
Vega = 9.6035
```

Input Arguments

`Price` — Current price of underlying asset
numeric

Current price of the underlying asset, specified as a numeric value.

Data Types: `double`

`Strike` — Exercise price of option
numeric

Exercise price of the option, specified as a numeric value.

Data Types: `double`

`Rate` — Annualized, continuously compounded risk-free rate of return over life of option
positive decimal

Annualized, continuously compounded risk-free rate of return over the life of the option, specified as a positive decimal value.

Data Types: `double`

`Time` — Time (in years) to expiration of the option
numeric

Time (in years) to expiration of the option, specified as a numeric value.

Data Types: `double`

`Volatility` — Annualized asset price volatility
positive decimal

Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), specified as a positive decimal value.

Data Types: `double`

`Yield` — Annualized, continuously compounded yield of the underlying asset over life of option
`0` (default) | decimal

(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, specified as a decimal value. For example, for options written on stock indices, `Yield` could represent the dividend yield. For currency options, `Yield` could be the foreign risk-free interest rate.

Data Types: `double`

Output Arguments

`Vega` — Rate of change of option value with respect to volatility of underlying asset
numeric

Rate of change of the option value with respect to the volatility of the underlying asset, returned as a numeric value.

bondDefaultBootstrap

Bootstrap default probability curve from bond prices

Syntax

```
[ProbabilityData,HazardData] = bondDefaultBootstrap(ZeroData,MarketData,
Settle)
[ProbabilityData,HazardData] = bondDefaultBootstrap( ___ ,Name,Value)
```

Description

`[ProbabilityData,HazardData] = bondDefaultBootstrap(ZeroData,MarketData,Settle)` bootstraps the default probability curve from bond prices.

Using `bondDefaultBootstrap`, you can:

- Extract discrete default probabilities for a certain period from market bond data.
- Interpolate these default probabilities to get the default probability curve for pricing and risk management purposes.

`[ProbabilityData,HazardData] = bondDefaultBootstrap( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Determine the Default Probability and Hazard Rate Values for Treasury Bonds

Use the following bond data.

```
Settle = datenum('08-Jul-2016');
MarketDate = datenum({'06/15/2018', '01/08/2019', '02/01/2021', '03/18/2021', '08/04/2025'}','mm
CouponRate = [2.240 2.943 5.750 3.336 4.134]'/100;
MarketPrice = [101.300 103.020 115.423 104.683 108.642]';
MarketData = [MarketDate,MarketPrice,CouponRate];
```

Calculate the `ProbabilityData` and `HazardData`.

```
TreasuryParYield = [0.26 0.28 0.36 0.48 0.61 0.71 0.95 1.19 1.37 1.69 2.11]'/100;
TreasuryDates = datemnth(Settle, [[1 3 6], 12 * [1 2 3 5 7 10 20 30]]');
[ZeroRates, CurveDates] = pyld2zero(TreasuryParYield, TreasuryDates, Settle);
ZeroData = [CurveDates, ZeroRates];
format longg
[ProbabilityData,HazardData]=bondDefaultBootstrap(ZeroData,MarketData,Settle)
```

```
ProbabilityData = 5×2

                    737226        0.0299675399937611
                    737433        0.0418832295824674
                    738188         0.090518332884262
                    738233         0.101248065083713
                    739833         0.233002708031915

HazardData = 5×2

                    737226        0.0157077745460244
                    737433        0.0217939816590403
                    738188         0.025184912824721
                    738233        0.0962608718640789
                    739833        0.0361632398787917
```

In bondDefaultBootstrap, the first column of the ProbabilityData output and the first column of the HazardData output contain the respective ending dates for the corresponding default probabilities and hazard rates. However, the starting dates used for the computation of the time ranges for default probabilities can be different from those of hazard rates. For default probabilities, the time ranges are all computed from the Settle date to the respective end dates shown in the first column of ProbabilityData. In contrast, the time ranges for the hazard rates are computed using the Settle date and the first column of HazardData, so that the first hazard rate applies from the Settle date to the first market date, the second hazard rate from the first to the second market date, and so on, and the last hazard rate applies from the second-to-last market date onwards.

```
datestr(Settle)

ans = 
'08-Jul-2016'

datestr(ProbabilityData(:,1))

ans = 5x11 char array
    '15-Jun-2018'
    '08-Jan-2019'
    '01-Feb-2021'
    '18-Mar-2021'
    '04-Aug-2025'

datestr(HazardData(:,1))

ans = 5x11 char array
    '15-Jun-2018'
    '08-Jan-2019'
    '01-Feb-2021'
    '18-Mar-2021'
    '04-Aug-2025'
```

The time ranges for the default probabilities all start on '08-Jul-2016' and they end on '15-Jun-2018', '08-Jan-2019', '01-Feb-2021', '18-Mar-2021', and '04-Aug-2025', respectively. As for the hazard rates, the first hazard rate starts on '08-Jul-2016' and ends on '15-Jun-2018', the second hazard rate starts on '15-Jun-2018' and ends on '08-Jan-2019', the third hazard rate starts on '08-Jan-2019' and ends on '01-Feb-2021', and so forth.

Reprice a Bond Listed on the Default Probability Curve

Reprice one of the bonds from bonds list based on the default probability curve. The expected result of this repricing is a perfect match with the market quote.

Use the following Treasury data from US Department of the Treasury.

```
Settle = datetime('08-Jul-2016','Locale','en_US');
TreasuryParYield = [0.26 0.28 0.36 0.48 0.61 0.71 0.95 1.19 1.37 1.69 2.11]'/100;
TreasuryDates = datemnth(Settle, [[1 3 6], 12 * [1 2 3 5 7 10 20 30]]');
```

Preview the bond date using semiannual coupon bonds with market quotes, coupon rates, and a settle date of July-08-2016.

```
MarketDate = datenum({'06/01/2017','06/01/2019','06/01/2020','06/01/2022'}','mm/dd/yyyy');
CouponRate = [7 8 9 10]'/100;
MarketPrice = [101.300 109.020 114.42 118.62]';
MarketData = [MarketDate, MarketPrice, CouponRate];

BondList = array2table(MarketData, 'VariableNames', {'Maturity', 'Price','Coupon'});
BondList.Maturity = datetime(BondList.Maturity,'Locale','en_US','ConvertFrom','datenum');
BondList.Maturity.Format = 'MMM-dd-yyyy'
```

```
BondList=4×3 table
     Maturity      Price     Coupon
    ___________    ______    ______

    Jun-01-2017     101.3     0.07 
    Jun-01-2019    109.02     0.08 
    Jun-01-2020    114.42     0.09 
    Jun-01-2022    118.62      0.1 
```

Choose the second coupon bond as the one to be priced.

```
number = 2;
TestCase = BondList(number, :);
```

Preview the risk-free rate data provided here that is based on a continuous compound rate.

```
[ZeroRates, CurveDates] = pyld2zero(TreasuryParYield, TreasuryDates, Settle);
ZeroData = [datenum(CurveDates), ZeroRates];
RiskFreeRate = array2table(ZeroData, 'VariableNames', {'Date', 'Rate'});
RiskFreeRate.Date = datetime(RiskFreeRate.Date,'Locale','en_US','ConvertFrom','datenum');
RiskFreeRate.Date.Format = 'MMM-dd-yyyy'
```

Input Arguments

ZeroData — Zero rate data

matrix | IRDataCurve object

Zero rate data, specified as an M-by-2 matrix of dates and zero rates or an IRDataCurve object of zero rates. For array input, the dates must be entered as serial date numbers, and discount rate must be in decimal form.

When ZeroData is an IRDataCurve object, ZeroCompounding and ZeroBasis are implicit in ZeroData and are redundant inside this function. In this case, specify these optional parameters when constructing the IRDataCurve object before using this bondDefaultBootstrap function.

For more information on an IRDataCurve object, see “Creating an IRDataCurve Object” (Financial Instruments Toolbox).

Data Types: double

MarketData — Bond market data

matrix

Bond market data, specified as an N-by-3 matrix of maturity dates, market prices, and coupon rates for bonds. The dates must be entered as serial date numbers, market prices must be numeric values, and coupon rate must be in decimal form.

Note A warning is displayed when MarketData is not sorted in ascending order by time.

Data Types: double

Settle — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector. Settle must be earlier than or equal to the maturity dates in MarketData.

To support existing code, bondDefaultBootstrap also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | datetime | string

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Note Any optional input of size `N`-by-`1` is also acceptable as an array of size `1`-by-`N`, or as a single value applicable to all contracts.

Example: `[ProbabilityData,HazardData] = bondDefaultBootstrap(ZeroData,MarketData,Settle,'RecoveryRate',Recovery,'ZeroCompounding',-1)`

`RecoveryRate` — Recovery rate

`0.4` (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a `N`-by-`1` vector of recovery rates, expressed as a decimal from `0` through `1`.

Data Types: `double`

`ProbabilityDates` — Dates for output of default probability data

column of dates in `MarketData` (default) | datetime array | string array | date character vector

Dates for the output of default probability data, specified as the comma-separated pair consisting of `'ProbabilityDates'` and a `P`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondDefaultBootstrap` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `datetime` | `string`

`ZeroCompounding` — Compounding frequency of the zero curve

2 (semiannual) (default) | integer with value of 1,2,3,4,6,12, or –1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of `'ZeroCompounding'` and a `N`-by-`1` vector. Values are:

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding
- `−1` — Continuous compounding

Data Types: `double`

ZeroBasis — Basis of the zero curve

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and the same values listed for Basis.

Data Types: double

RecoveryMethod — Recovery method

'facevalue' (default) | character vector with value of 'presentvalue' or 'facevalue' | string object with value of 'presentvalue' or 'facevalue'

Recovery method, specified as the comma-separated pair consisting of 'RecoveryMethod' and a character vector or a string with a value of 'presentvalue' or 'facevalue'.

- 'presentvalue' assumes that upon default, a bond is valued at a given fraction to the hypothetical present value of its remaining cash flows, discounted at risk-free rate.
- 'facevalue' assumes that a bond recovers a given fraction of its face value upon recovery.

Data Types: char | string

Face — Face or par value

100 (default) | numeric

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector of bonds.

Data Types: double

Period — Payment frequency

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Payment frequency, specified as the comma-separated pair consisting of 'Period' and a N-by-1 vector with values of 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

Basis — Day-count basis of the instrument

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-16.

Data Types: double

EndMonthRule — End-of-month rule flag

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer, 0 or 1, using a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

IssueDate — Bond issue date

if IssueDate not specified, cash flow payment dates determined from other inputs (default) | datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a N-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, bondDefaultBootstrap also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | datetime | string

FirstCouponDate — First actual coupon date

if you do not specify a FirstCouponDate, cash flow payment dates are determined from other inputs (default) | datetime scalar | string scalar | date character vector

First actual coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar datetime, string, or date character vector. FirstCouponDate is used when a bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

To support existing code, bondDefaultBootstrap also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | datetime | string

LastCouponDate — Last actual coupon date

if you do not specify a LastCouponDate, cash flow payment dates are determined from other inputs (default) | datetime scalar | string scalar | date character vector

Last actual coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar datetime, string, or date character vector. `LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

To support existing code, `bondDefaultBootstrap` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `datetime` | `string`

`StartDate` — Forward starting date of payments
if you do not specify `StartDate`, effective start date is `Settle` date (default) | datetime scalar | string scalar | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar datetime, string, or date character vector. `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

To support existing code, `bondDefaultBootstrap` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `datetime` | `string`

`BusinessDayConvention` — Business day conventions
`'actual'` (default) | character vector or string object with values`'actual'`, `'follow'`, `'modifiedfollow'`, `'previous'`or `'modifiedprevious'`

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a string object. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `'actual'` — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `'follow'` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `'modifiedfollow'` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `'previous'` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `'modifiedprevious'` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

Output Arguments

`ProbabilityData` — Default probability values

matrix

Default probability values, returned as a `P`-by-2 matrix with dates and corresponding cumulative default probability values. The dates match those in `MarketData`, unless the optional input parameter `ProbabilityDates` is provided.

`HazardData` — Hazard rate values

matrix

Hazard rate values, returned as an `N`-by-2 matrix with dates and corresponding hazard rate values for the survival probability model. The dates match those in `MarketData`.

Note A warning is displayed when nonmonotone default probabilities (that is, negative hazard rates) are found.

More About

Bootstrap Default Probability

A default probability curve can be bootstrapped from a collection of bond market quotes.

Extracting discrete default probabilities for a certain period from market bond data is represented by the formula

$$Price = Disc(t_N) \times FV \times Q(t_N) + \frac{C}{f} \times \sum_{i=1}^{N} Disc(t_i) \times Q(t_i) + \sum_{(i=1)}^{N} Disc(t_i) \times R(t_i) \times (Q(t_i - 1) - Q(t_i))$$

where:

FV — Face value

Q — Survival probability

C — Coupon

R — Recovery amount

f — Payment frequency (for example, 2 for semiannual coupon bonds)

The default probability is:

`DefaultProbability` = 1 – `SurvivalProbability`

Version History

Introduced in R2017a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although bondDefaultBootstrap supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Creating an IRDataCurve Object” (Financial Instruments Toolbox)

bndconvp

Bond convexity given price

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`,`FirstCouponDate`, `LastCouponDate`, `StartDate`,`Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

Syntax

```
[YearConvexity,PerConvexity] = bndconvp(Price,CouponRate,Settle,Maturity)
[YearConvexity,PerConvexity] = bndconvp( ___ ,Name,Value)
```

Description

`[YearConvexity,PerConvexity] = bndconvp(Price,CouponRate,Settle,Maturity)` computes the convexity of `NUMBONDS` fixed income securities given a clean price for each bond. The clean price of a bond excludes any interest that has accrued since issue or the most recent coupon payment.

`bndconvp` determines the convexity for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bndconvp` also determines the convexity of a zero coupon bond. Convexity is a measure of the rate of change in duration; measured in time. The greater the rate of change, the more the duration changes as yield changes.

`[YearConvexity,PerConvexity] = bndconvp( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Find Bond Convexity Given Price

This example shows how to compute the convexity of three bonds given their prices.

```
Price = [106; 100; 98];
CouponRate = 0.055;
Settle = datetime(1999,8,2);
Maturity = datetime(2004,6,15);
Period = 2;
Basis = 0;

[YearConvexity, PerConvexity] = bndconvp(Price,...
CouponRate,Settle, Maturity, Period, Basis)
```

```
YearConvexity = 3×1
```

```
   21.4447
   21.0363
   20.8951

PerConvexity = 3×1

   85.7788
   84.1454
   83.5803
```

Input Arguments

`Price` — Clean price (excludes accrued interest)
numeric

Clean price (excludes accrued interest), specified as numeric value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`CouponRate` — Annual percentage rate used to determine coupons payable on a bond
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`Settle` — Settlement date for certificate of deposit
datetime array | string array | date character vector

Settlement date for the certificate of deposit, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `bndconvp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date for certificate of deposit
datetime array | string array | date character vector

Maturity date for the certificate of deposit, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndconvp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[YearConvexity,PerConvexity] = bndconvp(Price,CouponRate,Settle, Maturity,'Period',4,'Basis',7)`

`Period` — Number of coupon payments per year

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using the values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis of instrument

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

To support existing code, bndconvp also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Irregular or normal first coupon date

datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bndconvp also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Irregular or normal last coupon date

datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bndconvp also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

StartDate — Forward starting date of payments

datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array,

string array, or date character vectors. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

To support existing code, `bndconvp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Face — Face value of bond
`100` (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`CompoundingFrequency` — Compounding frequency for yield calculation
SIA bases uses`2`, ICMA bases uses `1` (default) | integer with value of `1`, `2`, `3`, `4`, `6`, or `12`

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompundingFrequency'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

Note By default, SIA bases (`0`-`7`) and `BUS/252` use a semiannual compounding convention and ICMA bases (`8`-`12`) use an annual compounding convention.

Data Types: `double`

`DiscountBasis` — Basis used to compute the discount factors for computing the yield
SIA uses `0` (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of `'DiscountBasis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

Data Types: `double`

`LastCouponInterest` — Compounding convention for computing yield of a bond in last coupon period
`compound` (default) | values are `simple` or `compound`

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of `'LastCouponInterest'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. `LastCouponInterest` is based on only the last coupon and the face value to be repaid. Acceptable values are:

- `simple`
- `compound`

Data Types: `char` | `cell`

Output Arguments

`YearConvexity` — Yearly (annualized) convexity
numeric

Yearly (annualized) convexity, returned as a `NUMBONDS`-by-`1` vector.

`PerConvexity` — Periodic convexity reported on semiannual bond basis
numeric

Periodic convexity reported on a semiannual bond basis (in accordance with SIA convention), returned as a `NUMBONDS`-by-`1` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `bndconvp` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bndconvy

Bond convexity given yield

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`,`FirstCouponDate`, `LastCouponDate`, `StartDate`,`Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

Syntax

```
[YearConvexity,PerConvexity] = bndconvy(Yield,CouponRate,Settle,Maturity)
[YearConvexity,PerConvexity] = bndconvy( ___ ,Name,Value)
```

Description

`[YearConvexity,PerConvexity] = bndconvy(Yield,CouponRate,Settle,Maturity)` computes the convexity of `NUMBONDS` fixed income securities given a clean price for each bond.

`bndconvy` determines the convexity for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bndconvy` also determines the convexity of a zero coupon bond.

`[YearConvexity,PerConvexity] = bndconvy( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Find Bond Convexity Given Yield

This example shows how to compute the convexity of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = datetime(1999,8,2);
Maturity = datetime(2004,6,15);
Period = 2;
Basis = 0;

[YearConvexity, PerConvexity]=bndconvy(Yield, CouponRate,...
Settle, Maturity, Period, Basis)
```

```
YearConvexity = 3×1

   21.4825
   21.0358
   20.8885
```

```
PerConvexity = 3×1

   85.9298
   84.1434
   83.5541
```

Input Arguments

`Yield` — Yield to maturity on semiannual basis
numeric

Yield to maturity on a semiannual basis, specified as numeric value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`CouponRate` — Annual percentage rate used to determine coupons payable on a bond
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`Settle` — Settlement date for certificate of deposit
datetime array | string array | date character vector

Settlement date for the certificate of deposit, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `bndconvy` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date for certificate of deposit
datetime array | string array | date character vector

Maturity date for the certificate of deposit, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndconvy` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[YearConvexity,PerConvexity] = bndconvy(Yield,CouponRate,Settle, Maturity,'Period',4,'Basis',7)`

`Period` — Number of coupon payments per year
2 (default) | numeric with values `0`, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using the values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndconvy` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

FirstCouponDate — Irregular or normal first coupon date

datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndconvy` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

LastCouponDate — Irregular or normal last coupon date

datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndconvy` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

StartDate — Forward starting date of payments

datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

To support existing code, `bndconvy` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Face — Face value of bond
100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

CompoundingFrequency — Compounding frequency for yield calculation
SIA bases uses2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

Note By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Data Types: double

DiscountBasis — Basis used to compute the discount factors for computing the yield
SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

Data Types: `double`

`LastCouponInterest` — Compounding convention for computing yield of a bond in last coupon period
`compound` (default) | values are `simple` or `compound`

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of `'LastCouponInterest'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. `LastCouponInterest` is based on only the last coupon and the face value to be repaid. Acceptable values are:

- `simple`
- `compound`

Data Types: `char` | `cell`

Output Arguments

`YearConvexity` — Yearly (annualized) convexity
numeric

Yearly (annualized) convexity, returned as a `NUMBONDS`-by-`1` vector.

`PerConvexity` — Periodic convexity reported on semiannual bond basis
numeric

Periodic convexity reported on a semiannual bond basis (in accordance with SIA convention), returned as a `NUMBONDS`-by-`1` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although `bndconvy` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```

bnddurp

Bond duration given price

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`,`FirstCouponDate`, `LastCouponDate`, `StartDate`,`Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

Syntax

```
[ModDuration,YearDuration,PerDuration] = bnddurp(Price,CouponRate,Settle,
Maturity)
[ModDuration,YearDuration,PerDuration] = bnddurp( ___ ,Name,Value)
```

Description

`[ModDuration,YearDuration,PerDuration] = bnddurp(Price,CouponRate,Settle, Maturity)` computes the Macaulay and modified duration of `NUMBONDS` fixed-income securities given a clean price for each bond.

`bnddurp` determines the Macaulay and modified duration for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bnddurp` also determines the Macaulay and modified duration for a zero coupon bond.

`[ModDuration,YearDuration,PerDuration] = bnddurp( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Find Bond Duration Given Price

This example shows how to compute the duration of three bonds given their prices.

```
Price = [106; 100; 98];
CouponRate = 0.055;
Settle = datetime(1999,8,2);
Maturity = datetime(2004,6,15);
Period = 2;
Basis = 0;

[ModDuration, YearDuration, PerDuration] = bnddurp(Price,...
CouponRate, Settle, Maturity, Period, Basis)
```

```
ModDuration = 3×1

    4.2400
    4.1925
    4.1759

YearDuration = 3×1

    4.3275
    4.3077
    4.3007

PerDuration = 3×1

    8.6549
    8.6154
    8.6014
```

Input Arguments

`Price` — Clean price (excludes accrued interest)
numeric

Clean price (excludes accrued interest), specified as numeric value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`CouponRate` — Annual percentage rate used to determine coupons payable on a bond
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`Settle` — Settlement date for certificate of deposit
datetime array | string array | date character vector

Settlement date for the certificate of deposit, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `bnddurp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date for certificate of deposit
datetime array | string array | date character vector

Maturity date for the certificate of deposit, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `bnddurp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [ModDuration,YearDuration,PerDuration] = bnddurp(Price,CouponRate,Settle,Maturity,'Period',4,'Basis',7)

Period — Number of coupon payments per year

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

Basis — Day-count basis of instrument

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

EndMonthRule — End-of-month rule flag

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date
datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

To support existing code, bnddurp also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Irregular or normal first coupon date
datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bnddurp also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Irregular or normal last coupon date
datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bnddurp also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

StartDate — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array,

string array, or date character vectors. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

To support existing code, `bnddurp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Face — Face value of bond
`100` (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`CompoundingFrequency` — Compounding frequency for yield calculation
SIA bases uses`2`, ICMA bases uses `1` (default) | integer with value of `1`, `2`, `3`, `4`, `6`, or `12`

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompoundingFrequency'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

Note By default, SIA bases (`0`-`7`) and `BUS/252` use a semiannual compounding convention and ICMA bases (`8`-`12`) use an annual compounding convention.

Data Types: `double`

`DiscountBasis` — Basis used to compute the discount factors for computing the yield
SIA uses `0` (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of `'DiscountBasis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-16.

Note If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

Data Types: `double`

`LastCouponInterest` — Compounding convention for computing yield of a bond in last coupon period
`compound` (default) | values are `simple` or `compound`

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of `'LastCouponInterest'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. `LastCouponInterest` is based on only the last coupon and the face value to be repaid. Acceptable values are:

- `simple`
- `compound`

Data Types: `char` | `cell`

Output Arguments

`ModDuration` — Modified duration in years
numeric

Modified duration in years reported on a semiannual bond basis (in accordance with SIA convention), returned as a `NUMBONDS`-by-`1` vector.

`YearDuration` — Macaulay duration in years
numeric

Macaulay duration in years, returned as a `NUMBONDS`-by-`1` vector.

`PerDuration` — Periodic Macaulay duration
numeric

Periodic Macaulay duration reported on a semiannual bond basis (in accordance with SIA convention), returned as a NUMBONDS-by-1 vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although bnddurp supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bnddury

Bond duration given yield

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`,`FirstCouponDate`, `LastCouponDate`, `StartDate`,`Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

Syntax

```
[ModDuration,YearDuration,PerDuration] = bnddury(Yield,CouponRate,Settle,
Maturity)
[ModDuration,YearDuration,PerDuration] = bnddury( ___ ,Name,Value)
```

Description

`[ModDuration,YearDuration,PerDuration] = bnddury(Yield,CouponRate,Settle, Maturity)` computes the Macaulay and modified duration of `NUMBONDS` fixed income securities given yield to maturity for each bond.

`bnddury` determines the Macaulay and modified duration for a bond whether the first or last coupon periods in the coupon structure are short or long (that is, whether the coupon structure is synchronized to maturity). `bnddury` also determines the Macaulay and modified duration for a zero coupon bond.

`[ModDuration,YearDuration,PerDuration] = bnddury( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Find Bond Duration Given Yield

This example shows how to compute the duration of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];
CouponRate = 0.055;
Settle = datetime(1999,8,2);
Maturity = datetime(2004,6,15);
Period = 2;
Basis = 0;

[ModDuration,YearDuration,PerDuration]=bnddury(Yield,...
CouponRate, Settle, Maturity, Period, Basis)
```

```
ModDuration = 3×1

    4.2444
    4.1924
    4.1751

YearDuration = 3×1

    4.3292
    4.3077
    4.3004

PerDuration = 3×1

    8.6585
    8.6154
    8.6007
```

Input Arguments

`Yield` — Yield to maturity on a semiannual basis
decimal

Yield to maturity on a semiannual basis, specified as a decimal value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`CouponRate` — Annual percentage rate used to determine coupons payable on a bond
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`Settle` — Settlement date for certificate of deposit
datetime array | string array | date character vector

Settlement date for the certificate of deposit, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `bnddury` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date for certificate of deposit
datetime array | string array | date character vector

Maturity date for the certificate of deposit, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `bnddury` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[ModDuration,YearDuration,PerDuration] = bnddury(Yield,CouponRate,Settle,Maturity,'Period',4,'Basis',7)`

`Period` — Number of coupon payments per year

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using the values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis of instrument

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date
datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

To support existing code, bnddury also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Irregular or normal first coupon date
datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bnddury also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Irregular or normal last coupon date
datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bnddury also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

StartDate — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array,

string array, or date character vectors. The StartDate is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a StartDate, the effective start date is the Settle date.

To support existing code, bnddury also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Face — Face value of bond
100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

CompoundingFrequency — Compounding frequency for yield calculation
SIA bases uses2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

Note By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Data Types: double

DiscountBasis — Basis used to compute the discount factors for computing the yield
SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-16.

Note If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

Data Types: `double`

`LastCouponInterest` — Compounding convention for computing yield of a bond in last coupon period
`compound` (default) | values are `simple` or `compound`

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of `'LastCouponInterest'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. `LastCouponInterest` is based on only the last coupon and the face value to be repaid. Acceptable values are:

- `simple`
- `compound`

Data Types: `char` | `cell`

Output Arguments

`ModDuration` — Modified duration in years
numeric

Modified duration in years reported on a semiannual bond basis (in accordance with SIA convention), returned as a `NUMBONDS`-by-`1` vector.

`YearDuration` — Macaulay duration in years
numeric

Macaulay duration in years, returned as a `NUMBONDS`-by-`1` vector.

`PerDuration` — Periodic Macaulay duration
numeric

Periodic Macaulay duration reported on a semiannual bond basis (in accordance with SIA convention), returned as a `NUMBONDS`-by-`1` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `bnddury` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bndkrdur

Bond key rate duration given zero curve

Syntax

```
KeyRateDuration = bndkrdur(ZeroData,CouponRate,Settle,Maturity)
KeyRateDuration = bndkrdur( ___ ,Name,Value)
```

Description

`KeyRateDuration = bndkrdur(ZeroData,CouponRate,Settle,Maturity)` computes the key rate durations for one or more bonds given a zero curve and a set of key rates.

`KeyRateDuration = bndkrdur( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Find the Bond Key Rate Duration Given the Zero Curve

This example shows how to compute the key rate duration of a bond for key rate times of 2, 5, 10, and 30 years.

```
ZeroRates = [0.0476 .0466 .0465 .0468 .0473 .0478 ...
.0493 .0539 .0572 .0553 .0530]';

ZeroDates = daysadd('31-Dec-1998',[30 360 360*2 360*3 360*5 ...
360*7 360*10 360*15 360*20 360*25 360*30],1);

ZeroData = [ZeroDates ZeroRates];

krdur = bndkrdur(ZeroData,.0525,'12/31/1998',...
'11/15/2028','KeyRates',[2 5 10 30])
```

```
krdur = 1×4

    0.2986    0.8791    4.1353    9.5814
```

Find the Bond Key Rate Duration Given the Zero Curve Using datetime Inputs

This example shows how to use `datetime` inputs for `Settle` and `Maturity` and also use a table for `ZeroData` to compute the key rate duration of a bond for key rate times of 2, 5, 10, and 30 years.

```
ZeroRates = [0.0476 .0466 .0465 .0468 .0473 .0478 ...
.0493 .0539 .0572 .0553 .0530]';

ZeroDates = daysadd('31-Dec-1998',[30 360 360*2 360*3 360*5 ...
360*7 360*10 360*15 360*20 360*25 360*30],1);
```

```
ZeroData = table(datetime(ZeroDates,'ConvertFrom','datenum','Locale','en_US'), ZeroRates);

krdur = bndkrdur(ZeroData,.0525,datetime('12/31/1998','Locale','en_US'),...
datetime('11/15/2028','Locale','en_US'),'KeyRates',[2 5 10 30])
```

```
krdur = 1×4

    0.2986    0.8791    4.1353    9.5814
```

Input Arguments

ZeroData — Zero curve

matrix | table

Zero Curve, specified as a numRates-by-2 matrix or a numRates-by-2 table.

If ZeroData is represented as a numRates-by-2 matrix, the first column is a MATLAB serial date number and the second column is the accompanying zero rates.

If ZeroData is a table, the first column can be a datetime array, string array, or date character vectors. The second column must be numeric data corresponding to the zero rates.

Data Types: double | datetime | char | string | table

CouponRate — Annual percentage rate used to determine coupons payable on a bond

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal value using a scalar or a NUMBONDS-by-1 vector.

Data Types: double

Settle — Settlement date for all bonds and zero curve

datetime scalar | string scalar | date character vector

Settlement date for all bonds and zero curve, specified as a scalar datetime, string, or date character vector. Settle must be the same settlement date for all the bonds and the zero curve.

To support existing code, bndkrdur also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Maturity — Maturity date for bonds

datetime array | string array | date character vector

Maturity date for bonds, specified as a scalar or a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, bndkrdur also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `KeyRateDuration = bndkrdur(ZeroData,.0525,'12/31/1998','11/15/2028','KeyRates',[2 5 10 30])`

`InterpMethod` — Interpolation method used to obtain points from zero curve

`'linear'` (default) | `'cubic'`, `'pchip'`

Interpolation method used to obtain points from the zero curve, specified as the comma-separated pair consisting of `'InterpMethod'` and a character vector using one of the following values:

- `'linear'` (default)
- `'cubic'`
- `'pchip'`

Data Types: `char`

`ShiftValue` — Value that zero curve is shifted up and down to compute duration

`.01` (100 basis points) (default) | numeric

Value that zero curve is shifted up and down to compute duration, specified as the comma-separated pair consisting of `'ShiftValue'` and a scalar numeric value.

Data Types: `double`

`KeyRates` — Rates to perform the duration calculation

set to each of the zero dates (default) | numeric

Rates to perform the duration calculation, specified as the comma-separated pair consisting of `'KeyRates'` and a time to maturity using a scalar or a `NUMBONDS`-by-`1` vector.

Data Types: `double`

`CurveCompounding` — Compounding frequency of curve

2 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency of the curve, specified as the comma-separated pair consisting of `'CurveCompounding'` and a scalar using one of the following values:

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

.

Data Types: `double`

`CurveBasis` — Basis of the curve
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Basis of the curve, specified as the comma-separated pair consisting of `'CurveBasis'` and a scalar using one of the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`Period` — Number of coupon payments per year
`2` (default) | numeric with values `0`, `1`, `2`, `3`, `4`, `6` or `12`

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a `NUMBONDS`-by-`1` vector using the values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a `NUMBONDS`-by-`1` vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar or a `NUMBONDS`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

If you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndkrdur` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — Irregular or normal first coupon date
datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndkrdur` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Irregular or normal last coupon date
datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndkrdur` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`StartDate` — Forward starting date of payments

datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

To support existing code, `bndkrdur` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Face value of bond

`100` (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a `NUMBONDS`-by-`1` vector.

Data Types: `double`

Output Arguments

`KeyRateDuration` — Key rate durations

matrix

Key rate durations, returned as a `numBonds`-by-`numRates` matrix.

Algorithms

`bndkrdur` computes the key rate durations for one or more bonds given a zero curve and a set of key rates. By default, the key rates are each of the zero curve rates. For each key rate, the duration is computed by shifting the zero curve up and down by a specified amount (`ShiftValue`) at that particular key rate, computing the present value of the bond in each case with the new zero curves, and then evaluating the following:

$$krdur_i = \frac{(PV_{down} - PV_{up})}{(PV \times ShiftValue \times 2)}$$

Note The shift to the curve is computed by shifting the particular key rate by the `ShiftValue` and then interpolating the values of the curve in the interval between the previous and next key rates. For the first key rate, any curve values before the date are equal to the ShiftValue; likewise, for the last key rate, any curve values after the date are equal to the ShiftValue.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although bndkrdur supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bndprice

Price fixed-income security from yield to maturity

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`,`FirstCouponDate`, `LastCouponDate`, `StartDate`,`Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

Syntax

```
[Price,AccruedInt] = bndprice(Yield,CouponRate,Settle,Maturity)
[Price,AccruedInt] = bndprice( ___ ,Name,Value)
```

Description

`[Price,AccruedInt] = bndprice(Yield,CouponRate,Settle,Maturity)` given bonds with SIA date parameters and yields to maturity, returns the clean prices and accrued interest due.

In addition, you can use the Financial Instruments Toolbox object framework with a `FixedBond` instrument to price a fixed bond.

`[Price,AccruedInt] = bndprice( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Treasury Bond from Yield to Maturity

This example shows how to price a treasury bond at three different yield values.

```
Yield = [0.04; 0.05; 0.06];
CouponRate = 0.05;
Settle = '20-Jan-1997';
Maturity = '15-Jun-2002';
Period = 2;
Basis = 0;

[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle,...
Maturity, Period, Basis)
```

```
Price = 3×1

  104.8106
   99.9951
   95.4384

AccruedInt = 3×1
```

```
    0.4945
    0.4945
    0.4945
```

Price a Treasury Bond from Yield to Maturity Using datetime Inputs

This example shows how to use `datetime` inputs to price a treasury bond at three different yield values.

```
Yield = [0.04; 0.05; 0.06];
CouponRate = 0.05;
Settle = datetime('20-Jan-1997','Locale','en_US');
Maturity = datetime('15-Jun-2002','Locale','en_US');
Period = 2;
Basis = 0;
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle,...
Maturity, Period, Basis)
```

```
Price = 3×1

  104.8106
   99.9951
   95.4384

AccruedInt = 3×1

    0.4945
    0.4945
    0.4945
```

Price a Treasury Bond with Different Yield Values

This example shows how to price a Treasury bond at two different yield values that include parameter/value pairs for `CompoundingFrequency`, `DiscountBasis`, and `LastCouponPeriodInterest`.

```
bndprice(.04,0.08,datetime(2004,5,25),datetime(2005,4,21),'Period',1,'Basis',8, ...
'LastCouponInterest','simple')
```

```
ans = 103.4743
```

Input Arguments

`Yield` — Bond yield to maturity
numeric

Bond yield to maturity is specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Yield is on a semiannual basis for Basis values 0 through 7 and 13 and an annual basis for Basis values 8 through 12.

Data Types: double

CouponRate — Annual percentage rate used to determine coupons payable on a bond
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal using a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

Settle — Settlement date of bond
datetime array | string array | date character vector

Settlement date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors. The Settle date must be before the Maturity date.

To support existing code, bndprice also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Maturity — Maturity date of bond
datetime array | string array | date character vector

Maturity date of the bond, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

To support existing code, bndprice also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: `[Price,AccruedInt] = bndprice(Yield,CouponRate,Settle,Maturity,'Period',4,'Basis',9)`

Period — Number of coupon payments per year
2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

Basis — Day-count basis of instrument
0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndprice` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

FirstCouponDate — Irregular or normal first coupon date

datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bndprice also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Irregular or normal last coupon date

datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bndprice also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

StartDate — Forward starting date of payments

datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a StartDate, the effective start date is the Settle date.

To support existing code, bndprice also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Face — Face value of bond

100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

Data Types: double

CompoundingFrequency — Compounding frequency for yield calculation

SIA bases uses2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

Note By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Data Types: double

DiscountBasis — Basis used to compute the discount factors for computing the yield
SIA bases uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If a SIA day-count basis is defined in the Basis input argument and there is no value assigned for DiscountBasis, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the Basis input argument and there is no value assigned for DiscountBasis, the specified bases from the Basis input argument are used.

Data Types: double

`LastCouponInterest` — Compounding convention for computing yield of a bond in last coupon period

`compound` (default) | values are `simple` or `compound`

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of `'LastCouponInterest'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. `LastCouponInterest` is based on only the last coupon and the face value to be repaid. Acceptable values are:

- `simple`
- `compound`

Data Types: `char` | `cell`

Output Arguments

`Price` — Clean price of bond

numeric

Clean price of bond, returned as a `NUMBONDS`-by-`1` vector. The dirty price of the bond is the clean price plus the accrued interest. It equals the present value of the bond cash flows of the yield to maturity with semiannual compounding.

`AccruedInt` — Accrued interest payable at settlement

numeric

accrued interest payable at settlement, returned as a `NUMBONDS`-by-`1` vector.

More About

Price and Yield Conventions

The `Price` and `Yield` are related to different formulae for SIA and ICMA conventions.

For SIA conventions, `Price` and `Yield` are related by the formula:

```
Price + Accrued Interest = sum(Cash_Flow*(1+Yield/2)^(-Time))
```

where the sum is over the bond's cash flows and corresponding times in units of semiannual coupon periods.

For ICMA conventions, the `Price` and `Yield` are related by the formula:

```
Price + Accrued Interest = sum(Cash_Flow*(1+Yield)^(-Time))
```

Algorithms

For SIA conventions, the following formula defines bond price and yield:

$$PV = \sum_{i=1}^{n} \left(\frac{CF}{(1+\frac{z}{f})^{TF}} \right),$$

where:

PV =	Present value of a cash flow.
CF =	Cash flow amount.
z =	Risk-adjusted annualized rate or yield corresponding to a given cash flow. The yield is quoted on a semiannual basis.
f =	Frequency of quotes for the yield. Default is 2 for Basis values 0 to 7 and 13 and 1 for Basis values 8 to 12. The default can be overridden by specifying the CompoundingFrequency name-value pair.
TF =	Time factor for a given cash flow. The time factor is computed using the compounding frequency and the discount basis. If these values are not specified, then the defaults are as follows: CompoundingFrequency default is 2 for Basis values 0 to 7 and 13 and 1 for Basis values 8 to 12. DiscountBasis is 0 for Basis values 0 to 7 and 13 and the input Basis for Basis values 8 to 12.

Note The Basis is always used to compute accrued interest.

For ICMA conventions, the frequency of annual coupon payments determines bond price and yield.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although bndprice supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

bndspread

Static spread over spot curve

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`,`FirstCouponDate`, `LastCouponDate`, `StartDate`,`Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

Syntax

```
Spread = bndspread(SpotInfo,Price,Coupon,Settle,Maturity)
Spread = bndspread( ___ ,Name,Value)
```

Description

`Spread = bndspread(SpotInfo,Price,Coupon,Settle,Maturity)` computes the static spread (Z-spread) to benchmark in basis points.

`Spread = bndspread( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Static Spread Over a Spot Curve Using datetime Inputs

This example shows how to compute a Federal National Mortgage Association (FNMA) 4 3/8 spread over a Treasury spot curve using `datetime` inputs for `Settle` and `Maturity` and a table for `SpotInfo` and plot the results.

```
RefMaturity = [datenum('02/27/2003');
               datenum('05/29/2003');
               datenum('10/31/2004');
               datenum('11/15/2007');
               datenum('11/15/2012');
               datenum('02/15/2031')];

RefCpn = [0;
          0;
          2.125;
          3;
          4;
          5.375] / 100;

RefPrices =  [99.6964;
              99.3572;
             100.3662;

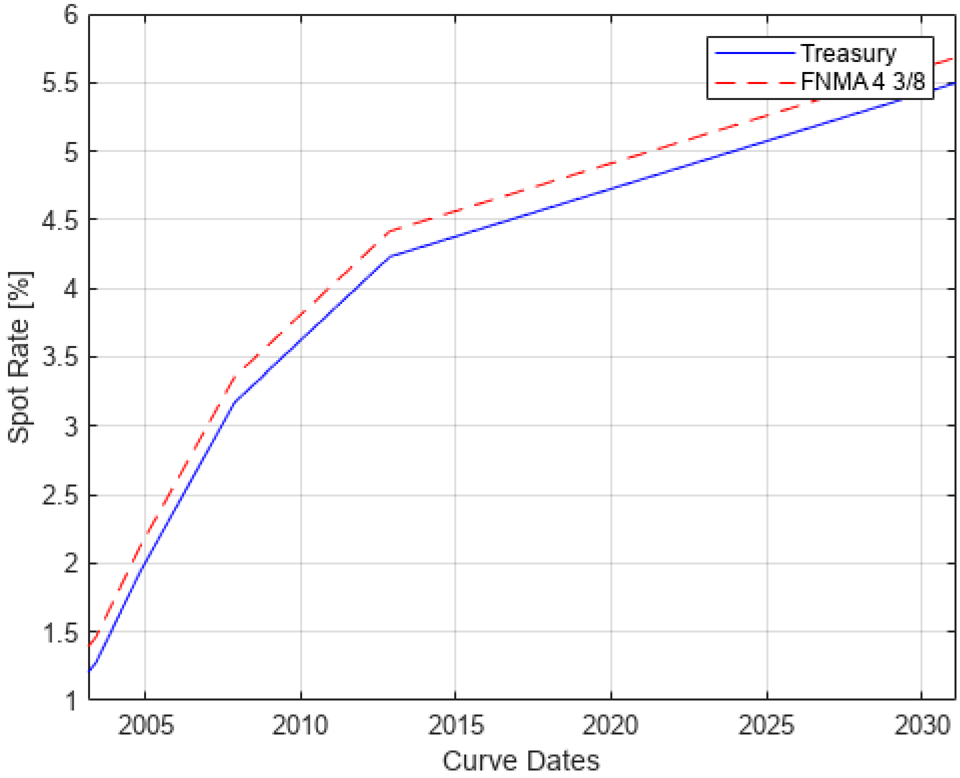
ylabel('Spot Rate [%]')
grid;
```



Input Arguments

`SpotInfo` — Spot-rates information

matrix | table | term structure

Spot-rates information, specified as matrix of two columns, an annualized term structure created by `intenvset`, or a table.

- Matrix of two columns— The first column is the `SpotDate`, and the second column, `ZeroRates`, is the zero-rate corresponding to maturities on the `SpotDate`. It is recommended that the spot-rates are spaced as evenly apart as possible, perhaps one that is built from 3-months deposit rates. For example, using the 3-month deposit rates:

  ```
  SpotInfo = ...
  [datenum('2-Jan-2004') ,  0.03840;
  datenum('2-Jan-2005') ,  0.04512;
  datenum('2-Jan-2006') ,  0.05086];
  ```
- Annualized term structure — Refer to `intenvset` to create an annualized term structure. For example:

  ```
  Settle = datetime(2004,1,1);
  Rates = [0.03840; 0.04512; 0.05086];
  EndDates = [datetime(2004,1,2) datenum('2-Jan-2004'); datetime(2005,1,2);...
               datetime(2006,1,2)];
  SpotInfo = intenvset('StartDates' , Settle  ,...
  ```

```
                           'Rates'      , Rates   ,...
                           'EndDates'   , EndDates,...
                           'Compounding', 2       ,...
                           'Basis'      , 0);
```

- Table — If `SpotInfo` is a table, the first column can be either a datetime array, string array, or date character vector. The second column is numerical data representing zero rates. For example:

  ```
  ZeroRates = [0.012067955808764;0.012730933424479;0.019360902068703;0.031704525214251;0.042306085224510;0.054987415342936];
  CurveDates = [731639;731730;732251;733361;735188;741854];
  Settle   = datetime(2002,11,26);
  Price    = 105.484;
  Coupon   = 0.04375;
  Maturity = datetime(2006,10,15);
  Period = 2;
  Basis  = 1;
  SpotInfo = table(datestr(CurveDates), ZeroRates);
  ```

Data Types: `double` | `string` | `char` | `datetime` | `table` | `struct`

`Price` — Price for every $100 notional amount of bonds whose spreads are computed

numeric

Price for every $100 notional amount of bonds whose spreads are computed, specified as numeric value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`Coupon` — Annual coupon rate of bonds whose spreads are computed

decimal

Annual coupon rate of bonds whose spreads are computed, specified as decimal value using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`Settle` — Settlement date of bond

datetime array | string array | date character vector

Settlement date of the bond, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `bndspread` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of bond

datetime array | string array | date character vector

Maturity date of the bond, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndspread` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Spread = bndspread(SpotInfo,Price,Coupon,Settle,Maturity,'Period',4,'Basis',7)`

`Period` — Number of coupon payments per year

`2` (default) | numeric with values `0`, `1`, `2`, `3`, `4`, `6` or `12`

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using the values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag

`1` (in effect) (default) | nonnegative integer `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

To support existing code, bndspread also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Irregular or normal first coupon date

datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bndspread also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Irregular or normal last coupon date

datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, bndspread also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

StartDate — Forward starting date of payments

datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array,

string array, or date character vectors. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

To support existing code, `bndspread` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Face — Face value of bond
`100` (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`CompoundingFrequency` — Compounding frequency for yield calculation
SIA bases uses`2`, ICMA bases uses `1` (default) | integer with value of `1`, `2`, `3`, `4`, `6`, or `12`

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompoundingFrequency'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

Note By default, SIA bases (`0-7`) and `BUS/252` use a semiannual compounding convention and ICMA bases (`8-12`) use an annual compounding convention.

Data Types: `double`

`DiscountBasis` — Basis used to compute the discount factors for computing the yield
SIA uses `0` (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of `'DiscountBasis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

Data Types: `double`

`LastCouponInterest` — Compounding convention for computing yield of a bond in last coupon period
`compound` (default) | values are `simple` or `compound`

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of `'LastCouponInterest'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. `LastCouponInterest` is based on only the last coupon and the face value to be repaid. Acceptable values are:

- `simple`
- `compound`

Data Types: `char` | `cell`

Output Arguments

Spread — Static spread to benchmark in basis points
numeric

Static spread to benchmark, returned in basis points as a scalar or a `NUMBONDS`-by-`1` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although bndspread supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bndtotalreturn

Total return of fixed-coupon bond

Syntax

```
[BondEquiv,EffectiveRate] = bndtotalreturn(Price,CouponRate,Settle,Maturity,
ReinvestRate)
[BondEquiv,EffectiveRate] = bndtotalreturn( ___ ,Name,Value)
```

Description

`[BondEquiv,EffectiveRate] = bndtotalreturn(Price,CouponRate,Settle,Maturity, ReinvestRate)` calculates the total return for fixed-coupon bonds to maturity or to a specific investment horizon.

`[BondEquiv,EffectiveRate] = bndtotalreturn( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Total Return of a Fixed-Coupon Bond

Use `bndtotalreturn` to compute the total return for a fixed-coupon bond, given an investment horizon date.

Define fixed-coupon bond.

```
Price = 101;
CouponRate = 0.05;
Settle = '15-Nov-2011';
Maturity = '15-Nov-2031';
ReinvestRate = 0.04;
```

Calculate the total return to maturity.

```
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate)
```

```
BondEquiv = 0.0460

EffectiveRate = 0.0466
```

Specify an investment horizon.

```
HorizonDate = '15-Nov-2021';
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)
```

```
BondEquiv = 0.0521

EffectiveRate = 0.0528
```

Perform scenario analysis on the reinvestment rate.

```
ReinvestRate = [0.03; 0.035; 0.04; 0.045; 0.05];
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)
```

```
BondEquiv = 5×1

    0.0557
    0.0538
    0.0521
    0.0505
    0.0490

EffectiveRate = 5×1

    0.0565
    0.0546
    0.0528
    0.0511
    0.0496
```

Compute the Total Return of a Fixed-Coupon Bond Using datetime Inputs

Use `bndtotalreturn` with `datetime` inputs to compute the total return for a fixed-coupon bond, given an investment horizon date.

```
Price = 101;
CouponRate = 0.05;
Settle = datetime('15-Nov-2011','Locale','en_US');
Maturity = datetime('15-Nov-2031','Locale','en_US');
HorizonDate = datetime('15-Nov-2021','Locale','en_US');
ReinvestRate = 0.04;
[BondEquiv, EffectiveRate] = bndtotalreturn(Price, CouponRate, ...
Settle, Maturity, ReinvestRate, 'HorizonDate', HorizonDate)
```

```
BondEquiv = 0.0521

EffectiveRate = 0.0528
```

Input Arguments

`Price` — Clean price at settlement date

matrix

Clean price at the settlement date, specified as a scalar or a `NINST`-by-`1` vector.

Data Types: `double`

`CouponRate` — Coupon rate

decimal

Coupon rate, specified as a scalar or a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date of fixed-coupon bond

datetime array | string array | date character vector

Settlement date of the fixed-coupon bond, specified as scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. If supplied as a `NINST`-by-`1` vector of dates, settlement dates can be different, as long as they are before the `Maturity` date and `HorizonDate`.

To support existing code, `bndtotalreturn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of fixed-coupon bond

datetime array | string array | date character vector

Maturity date of the fixed-coupon bond, specified as scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndtotalreturn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`ReinvestRate` — Reinvestment rate

decimal

Reinvestment rate (the rate earned by reinvesting the coupons), specified as scalar or a `NINST`-by-`2` vector of decimal values.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[BondEquiv,EffectiveRate] = bndtotalreturn(Price,CouponRate,Settle,Maturity,ReinvestRate,'HorizonDate','15-Nov-2021')`

`HorizonDate` — Investment horizon date

`Maturity` date (default) | datetime array | string array | date character vector

Investment horizon date, specified as the comma-separated pair consisting of `'HorizonDate'` and a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

If `HorizonDate` is unspecified, the total return is calculated to `Maturity`.

To support existing code, `bndtotalreturn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`HorizonPrice` — Price at investment horizon date

calculated based on `ReinvestRate` (default) | numeric

Price at investment horizon date, specified as the comma-separated pair consisting of `'HorizonPrice'` and a scalar or a `NINST`-by-`1` vector.

If `HorizonPrice` is unspecified, the price at the `HorizonDate` is calculated based on the `ReinvestRate`. If the `HorizonDate` equals the `Maturity` date, the `HorizonPrice` is ignored and the total return to maturity is calculated based on the `Face` value.

Data Types: `double`

`Period` — Number of coupon payments per year

`2` (default) | numeric with values `0`, `1`, `2`, `3`, `4`, `6` or `12`

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a `NINST`-by-`1` vector using the values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar or a `NINST`-by-`1` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag

`1` (in effect) (default) | nonnegative integer `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar or a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

If you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndtotalreturn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — Irregular or normal first coupon date
datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndtotalreturn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Irregular or normal last coupon date
datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndtotalreturn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

If you do not specify a StartDate, the effective start date is the Settle date.

To support existing code, bndtotalreturn also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Face — Face value of bond
100 (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar or a NINST-by-1 vector.

Data Types: double

CompoundingFrequency — Compounding frequency for yield calculation
integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NINST-by-1 vector.

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

Note By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Data Types: double

DiscountBasis — Basis used to compute the discount factors for computing the yield
integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note The default behavior is for SIA bases (0-7) to use the actual/actual day count to compute discount factors, and for ICMA day counts (8 – 12) and BUS/252 to use the specified DiscountBasis.

Data Types: double

Output Arguments

BondEquiv — Total return in bond equivalent basis
numeric

Total return in bond equivalent basis, returned as a NUMBONDS-by-1 vector.

EffectiveRate — Total return in effective rate basis
numeric

Total return in effective rate basis, returned as a NUMBONDS-by-1 vector.

Version History

Introduced in R2012b

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although bndtotalreturn supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

bndyield

Yield to maturity for fixed-income security

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Period`, `Basis`, `EndMonthRule`, `IssueDate`,`FirstCouponDate`, `LastCouponDate`, `StartDate`,`Face`, `CompoundingFrequency`, `DiscountBasis`, and `LastCouponInterest`.

Syntax

```
Yield = bndyield(Price,CouponRate,Settle,Maturity)
Yield = bndyield(___,Name,Value)
```

Description

`Yield = bndyield(Price,CouponRate,Settle,Maturity)` given `NUMBONDS` bonds with SIA date parameters and clean prices (excludes accrued interest), returns the bond equivalent yields to maturity.

`Yield = bndyield(___,Name,Value)` adds optional name-value arguments.

Examples

Compute Yield to Maturity for a Treasury Bond

This example shows how to compute the yield of a Treasury bond at three different price values.

```
Price = [95; 100; 105];
CouponRate = 0.05;
Settle = '20-Jan-1997';
Maturity = '15-Jun-2002';
Period = 2;
Basis = 0;

Yield = bndyield(Price, CouponRate, Settle,...
Maturity, Period, Basis)
```

```
Yield = 3×1

    0.0610
    0.0500
    0.0396
```

Compute Yield to Maturity for a Treasury Bond Using datetime Inputs

This example shows how to use `datetime` inputs to compute the yield of a Treasury bond at three different price values.

```
Price = [95; 100; 105];
CouponRate = 0.05;
Settle = datetime('20-Jan-1997','Locale','en_US');
Maturity = datetime('15-Jun-2002','Locale','en_US');
Period = 2;
Basis = 0;
Yield = bndyield(Price, CouponRate, Settle,...
Maturity, Period, Basis)
```

```
Yield = 3×1

    0.0610
    0.0500
    0.0396
```

Compute the Yield of a Treasury Bond Using the Same Basis for Discounting and Generating the Cash Flows

Compute the yield of a Treasury bond.

```
Price = [95; 100; 105];
CouponRate = 0.0345;
Settle = datetime(2016,5,15);
Maturity = datetime(2026,2,2);
Period = 2;
Basis = 1;
format long

Yield = bndyield(Price,CouponRate,Settle,Maturity,Period,Basis)
```

```
Yield = 3×1

   0.040764403932618
   0.034482347625316
   0.028554719853118
```

Using the same data, compute the yield of a Treasury bond using the same basis for discounting and generating the cash flows.

```
DiscountBasis = 1;

Yield = bndyield(Price,CouponRate,Settle,Maturity,'Period',Period,'Basis',Basis, ...
'DiscountBasis',DiscountBasis)
```

```
Yield = 3×1

   0.040780176658036
   0.034495592361619
```

```
    0.028565614029497
```

Input Arguments

`Price` — Clean price of the bond

numeric

Clean price of the bond (current price without accrued interest), specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`CouponRate` — Annual percentage rate used to determine coupons payable on a bond

decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal using a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`Settle` — Settlement date of bond

datetime array | string array | date character vector

Settlement date of the bond, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `bndyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of bond

datetime array | string array | date character vector

Maturity date of the bond, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `bndyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Yield = bndyield(Price,CouponRate,Settle,Maturity,'Period',4,'Basis',9)`

Period — Number of coupon payments per year

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

Basis — Day-count basis of instrument

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

EndMonthRule — End-of-month rule flag

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — Irregular or normal first coupon date

datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Irregular or normal last coupon date

datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `bndyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`StartDate` — Forward starting date of payments

datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

To support existing code, `bndyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Face value of bond

`100` (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

Data Types: `double`

`CompoundingFrequency` — Compounding frequency for yield calculation
SIA uses `2`, ICMA uses `1` (default) | integer with value of `1`, `2`, `3`, `4`, `6`, or `12`

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompoundingFrequency'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. Values are:

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

Note By default, SIA bases (`0`-`7`) and `BUS/252` use a semiannual compounding convention and ICMA bases (`8`-`12`) use an annual compounding convention.

Data Types: `double`

`DiscountBasis` — Basis used to compute the discount factors for computing the yield
SIA uses `0` (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of `'DiscountBasis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If a SIA day-count basis is defined in the Basis input argument and there is no value assigned for DiscountBasis, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the Basis input argument and there is no value assigned for DiscountBasis, the specified bases from the Basis input argument are used.

Data Types: double

LastCouponInterest — Compounding convention for computing yield of a bond in last coupon period

compound (default) | values are simple or compound

Compounding convention for computing the yield of a bond in the last coupon period, specified as the comma-separated pair consisting of 'LastCouponInterest' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This is based on only the last coupon and the face value to be repaid. Acceptable values are:

- simple
- compound

Data Types: char | cell

Output Arguments

Yield — Yield to maturity with semiannual compounding

numeric

Yield to maturity with semiannual compounding, returned as a NUMBONDS-by-1 vector.

More About

Price and Yield Conventions

The Price and Yield are related to different formulae for SIA and ICMA conventions.

For SIA conventions, Price and Yield are related by the formula:

```
Price + Accrued Interest = sum(Cash_Flow*(1+Yield/2)^(-Time))
```

where the sum is over the bond's cash flows and corresponding times in units of semiannual coupon periods.

For ICMA conventions, the Price and Yield are related by the formula:

```
Price + Accrued Interest = sum(Cash_Flow*(1+Yield)^(-Time))
```

Algorithms

For SIA conventions, the following formula defines bond price and yield:

$$PV = \frac{CF}{(1 + \frac{z}{f})^{TF}},$$

where:

PV =	Present value of a cash flow.
CF =	The cash flow amount.
z =	The risk-adjusted annualized rate or yield corresponding to a given cash flow. The yield is quoted on a semiannual basis.
f =	The frequency of quotes for the yield.
TF =	Time factor for a given cash flow. Time is measured in semiannual periods from the settlement date to the cash flow date. In computing time factors, use SIA `actual/actual` day count conventions for all time factor calculations.

For ICMA conventions, the frequency of annual coupon payments determines bond price and yield.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `bndyield` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bollinger

Time series Bollinger band

Syntax

```
[middle,upper,lower] = bollinger(Data)
[middle,upper,lower] = bollinger( ___ ,Name,Value)
```

Description

`[middle,upper,lower] = bollinger(Data)` calculates the middle, upper, and lower bands that make up the Bollinger bands from a series of data. A Bollinger band chart plots actual asset data along with three other bands of data: the upper band that is two standard deviations above a user-specified moving average; the lower band that is two standard deviations below that moving average; and the middle band that is the moving average itself.

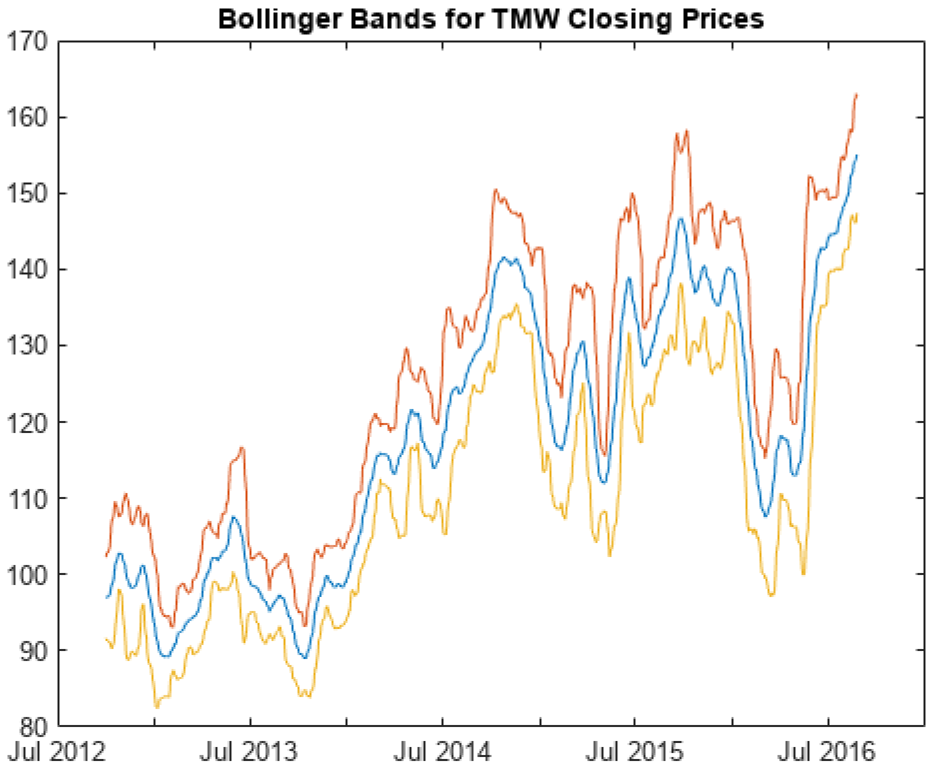
`[middle,upper,lower] = bollinger( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Bollinger Bands for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
[middle,upper,lower]= bollinger(TMW);
CloseBolling = [middle.Close, upper.Close,...
lower.Close];
plot(middle.Time,CloseBolling)
title('Bollinger Bands for TMW Closing Prices')
```



Input Arguments

`Data` — Data for market prices

matrix | table | timetable

Data for market prices, specified as a matrix, table, or timetable. For matrix input, `Data` must be column-oriented.

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[middle,upper,lower] = bollinger(TMW_CLOSE,'WindowSize',10,'Type',1)`

`WindowSize` — Number of observations of input series to include in moving average in periods

`10` (default) | positive integer

Number of observations of the input series to include in the moving average in periods, specified as the comma-separated pair consisting of `'WindowSize'` and a scalar positive integer.

Data Types: `double`

Type — Type of moving average to compute

`0` (simple) (default) | integer with value `0` or `1`

Type of moving average to compute, specified as the comma-separated pair consisting of `'Type'` and a scalar integer with a value of `0` (simple) or `1` (linear).

Data Types: `double`

`NumStd` — Number of standard deviations for the upper and lower bounds

2 (default) | positive integer

Number of standard deviations for the upper and lower bounds, specified as the comma-separated pair consisting of `'NumStd'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`middle` — Moving average series representing the middle band

matrix | table | timetable

Moving average series representing the middle band, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

`upper` — Moving average series representing the upper band

matrix | table | timetable

Moving average series representing the upper band, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

`lower` — Moving average series representing the lower band

matrix | table | timetable

Moving average series representing the lower band, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

boxcox

Box-Cox transformation

Syntax

```
[transdat,lambda] = boxcox(data)
transdat = boxcox(lambda,data)
```

Description

`[transdat,lambda] = boxcox(data)` transforms the data vector `data` using the Box-Cox transformation method into `transdat`. It also estimates the transformation parameter λ.

`transdat = boxcox(lambda,data)` transform the `data` using a certain specified λ for the Box-Cox transformation. This syntax does not find the optimum λ that maximizes the LLF.

Examples

Transform a Data Series Contained in Vector of Data

Use `boxcox` to transform the data series contained in a vector of data into another set of data series with relatively normal distributions.

Load the `SimulatedStock.mat` data file.

```
load SimulatedStock.mat
```

Transform the nonnormally distributed filled data series `TMW_CLOSE` into a normally distributed one using Box-Cox transformation.

```
 [Xbc, lambdabc] = boxcox(TMW_CLOSE)
```

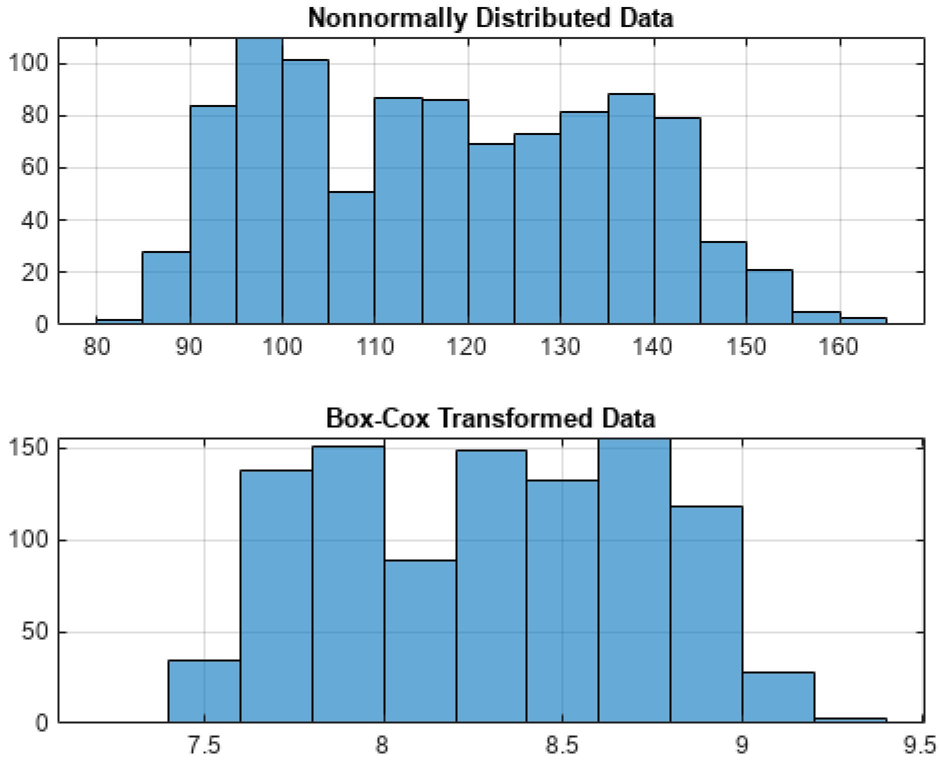
```
Xbc = 1000×1

    7.8756
    7.8805
    7.9173
    7.8557
    7.8245
    7.7844
    7.7811
    7.8029
    7.8015
    7.7229
      ⋮

lambdabc = 0.2151
```

Compare the result of the `TMW_CLOSE` data series with a normal (Gaussian) probability distribution function and the nonnormally distributed `TMW_CLOSE`.

```
subplot(2, 1, 1);
histogram(TMW_CLOSE);
grid; title('Nonnormally Distributed Data');
subplot(2, 1, 2);
histogram(Xbc);
grid; title('Box-Cox Transformed Data');
```



The bar chart on the top represents the probability distribution function of the data series, TMW_CLOSE, which is the original data series. The distribution is skewed toward the left (not normally distributed). The bar chart on the bottom is less skewed to the left. If you plot a Gaussian probability distribution function (PDF) with similar mean and standard deviation, the distribution of the transformed data is close to normal (Gaussian). When you examine the contents of the resulting object Xbc, you find an identical object to the original object TMW_CLOSE but the contents are the transformed data series.

Input Arguments

data — Data
positive column vector

Data, specified as a positive column vector.

Data Types: double

lambda — Lambda
numeric | structure

Lambda, specified as a scalar numeric or structure.

If the input `data` is a vector, `lambda` is a scalar. If the input is a financial time series object (`tsobj`), `lambda` is a structure with fields similar to the components of the object. For example, if `tsobj` contains series names `Open` and `Close`, `lambda` has fields `lambda.Open` and `lambda.Close`.

Data Types: `double` | `struct`

Output Arguments

`transdat` — Data Box-Cox transformation
vector

Data Box-Cox transformation, returned as a vector.

`lambda` — Lambda transformation parameter
numeric

Lambda transformation parameter, returned as a numeric.

More About

Box Cox Transformation

`boxcox` transforms nonnormally distributed data to a set of data that has approximately normal distribution. The Box-Cox transformation is a family of power transformations.

If λ is not = `0`, then

$$data(\lambda) = \frac{data^{\lambda} - 1}{\lambda}$$

If λ is = `0`, then

$$data(\lambda) = \log(data)$$

The logarithm is the natural logarithm (log base e). The algorithm calls for finding the λ value that maximizes the Log-Likelihood Function (LLF). The search is conducted using `fminsearch`.

Version History

Introduced before R2006a

R2023a: `fints` support for `tsobj` input argument and `transfts` output argument are removed
Behavior changed in R2023a

The `tsobj` input argument that supports a `fints` object is and the `transfts` output argument are removed from `boxcox`.

See Also

`fminsearch`

busdate

Next or previous business day

Syntax

```
Busday = busdate(Date)
Busday = busdate(___,DirFlag,Holiday,Weekend)
```

Description

`Busday = busdate(Date)` returns the scalar, vector, or matrix of the next or previous business days, depending on the definition for `Holiday`.

`Busday = busdate(___,DirFlag,Holiday,Weekend)` returns the scalar, vector, or matrix of the next or previous business days, depending on the optional input arguments, including `Holiday`.

If both `Date` and `Holiday` are either strings or date character vectors, `Busday` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

However, if either `Date` or `Holiday` are datetime arrays, `Busday` is returned as a datetime array.

Examples

Determine Business Days

Determine the next business day when `Date` is a character vector.

```
 Busday = busdate('3-Jul-2001', 1)
```

```
Busday = 731037
```

```
datestr(Busday)
```

```
ans = 
'05-Jul-2001'
```

Indicate that Saturday is a business day by appropriately setting the `Weekend` argument. July 4, 2003 falls on a Friday. Use `busdate` to verify that Saturday, July 5, is actually a business day.

```
Weekend = [1 0 0 0 0 0 0];
Date = datestr(busdate('3-Jul-2003', 1, [], Weekend))
```

```
Date = 
'05-Jul-2003'
```

If either `Date` or `Holiday` are datetime arrays, `Busday` is returned as a datetime array.

```
Busday = busdate(datetime('3-Jul-2001','Locale','en_US'), 1)
Busday = datetime
   05-Jul-2001
```

Also, you can bypass a holiday.

```
busdate(datetime(2022,11,23),1,NaT)
```

```
ans = datetime
   24-Nov-2022
```

Input Arguments

Date — Reference business date

datetime array | string array | date character vector

Reference business date, specified as a scalar, vector, or matrix using a datetime array, string array, or date character vectors.

To support existing code, `busdate` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

DirFlag — Business day convention

`follow` (default) | date character vector with values of `follow`, `modifiedfollow`, `previous`, or `modifiedprevious` | cell array of date character vectors with values of `follow`, `modifiedfollow`, `previous`, or `modifiedprevious`

Business day convention, specified date character vector or cell array of date character vectors with values of `follow`, `modifiedfollow`, `previous`, or `modifiedprevious`.

Also, `DirFlag` can be a scalar, vector, or matrix of search directions, where Next is `DIREC = 1` (default) or Previous is `DIREC = -1`.

Data Types: `double` | `char` | `datetime`

Holiday — Holidays and nontrading-day dates

non-trading day vector is determined by the routine `holidays` (default) | datetime array | string array | date character vector

Holidays and nontrading-day dates, specified as vector using a datetime array, string array, or date character vectors.

All dates in `Holiday` must be the same format: either datetimes, strings, or date character vectors.

To support existing code, `busdate` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Weekend — Weekend days

`[1 0 0 0 0 0 1]` (Saturday and Sunday form the weekend) (default) | vector of length 7, containing `0` and `1`, where `1` indicates weekend days

Weekend days, specified as a vector of length 7, containing `0` and `1`, where `1` indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: `double`

Output Arguments

Busday — Next or previous business day

scalar | vector | matrix

Next or previous business day, returned as a scalar, vector, or matrix depending on the definition for `Holiday`. `Busday`.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `busdate` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

busdays

Business days for given period

Syntax

```
bdates = busdays(sdate,edate)
bdates = busdays( ___ ,bdmode,Holiday)
```

Description

`bdates = busdays(sdate,edate)` generates a vector of business days between the last business date of the period that contains the start date (`sdate`), and the last business date of period that contains the end date (`edate`).

`bdates = busdays( ___ ,bdmode,Holiday)` generates a vector of business days between the last business date of the period that contains the start date (`sdate`), and the last business date of period that contains the end date (`edate`) using optional input arguments. If `Holiday` is not supplied, the dates are generated based on United States holidays. If you do not supply `bdmode`, `bdates` generates a daily vector.

Examples

Determine Business Days for a Given Period

Determine the business days for a weekly period.

```
 bdates = datestr(busdays('1/2/01','1/9/01','weekly'))
```

```
bdates = 2x11 char array
    '05-Jan-2001'
    '12-Jan-2001'
```

The end of the week is considered to be a Friday. Between 1/2/01 (Monday) and 1/9/01 (Tuesday), there is only one end-of-week day, 1/5/01 (Friday). Because 1/9/01 is part of the following week, the following Friday (1/12/01) is also reported.

Determine the business days for a weekly period using a datetime input for `sdate`.

```
bdates = busdays(datetime('2-Jan-2001','Locale','en_US'),'9-Jan-2001','weekly')
```

```
bdates = 2x1 datetime
   05-Jan-2001
   12-Jan-2001
```

Determine the business days for a monthly period.

```
vec = datestr(busdays('1/8/16','3/1/16','monthly'))
```

```
vec = 3x11 char array
    '29-Jan-2016'
    '29-Feb-2016'
    '31-Mar-2016'
```

The start date (1/8/16) is in the month of January, 2016. The last business day for the month of January is 1/29/16 (Friday). The end date (3/1/16) is in the month of March, 2016. The last business day for the month of March is 3/31/16 (Thursday). The month of February, 2016 lies between the start date and the end date. The last business day for the month of February is 2/29/16 (Monday).

Input Arguments

sdate — Start date

datetime scalar | string scalar | date character vector

Start date, specified as a scalar datetime, string, or date character vector.

To support existing code, busdays also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

edate — End date

datetime scalar | string scalar | date character vector

End date, specified as a scalar datetime, string, or date character vector.

To support existing code, busdays also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

bdmode — Frequency of business days

DAILY (1) (default) | nonnegative numeric with values 1 through 5 | date character vector with values DAILY, WEEKLY, MONTHLY, QUARTERLY, SEMIANNUAL or ANNUAL

Frequency of business days, specified as a nonnegative numeric with values 1 through 5 or date character vector with values of DAILY, WEEKLY, MONTHLY, QUARTERLY, SEMIANNUAL, or ANNUAL

Valid periodicities include:

- DAILY, Daily, daily, D, d, 1 (default)
- WEEKLY, Weekly, weekly, W, w, 2
- MONTHLY, Monthly, monthly, M, m, 3
- QUARTERLY, Quarterly, quarterly, Q, q, 4
- SEMIANNUAL, Semiannual, semiannual, S, s, 5
- ANNUAL, Annual, annual, A, a, 6

  Character vectors must be enclosed in single quotation marks.

For example, if bdmode is set to monthly, busdays returns end-of-month business dates for all full or partial months between the start date and end date inclusive.

Data Types: double | char

Holiday — Holiday and nontrading-day dates

if Holiday is [ ] holiday dates are based on United States holidays specified by holidays (default) | datetime array | string array | date character vector

Holiday and nontrading-day dates, specified as a vector using a datetime array, string array, or date character vectors. If you specify Holiday, you must also supply the frequency bdmode. Using a Holiday value of NaN uses a holiday list that has no dates.

To support existing code, busdays also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

bdates — Business days

column vector

Business days, returned as a column vector of business dates, in datetime format (if sdate, edate, or Holiday are in datetime format). Business dates can exist before and/or after the specified sdate and edate.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although busdays supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

candle

Candlestick chart

Note `candle` is updated to accept data input as a matrix, `timetable`, or `table`.

Syntax

```
candle(Data)
candle(Data,Color)
h = candle(ax___)
```

Description

`candle(Data)` plots a candlestick chart from a series of opening, high, low, and closing prices of a security. If the closing price is greater than the opening price, the body (the region between the open and close price) is unfilled; otherwise the body is filled.

`candle(Data,Color)` adds an optional argument for `Color`.

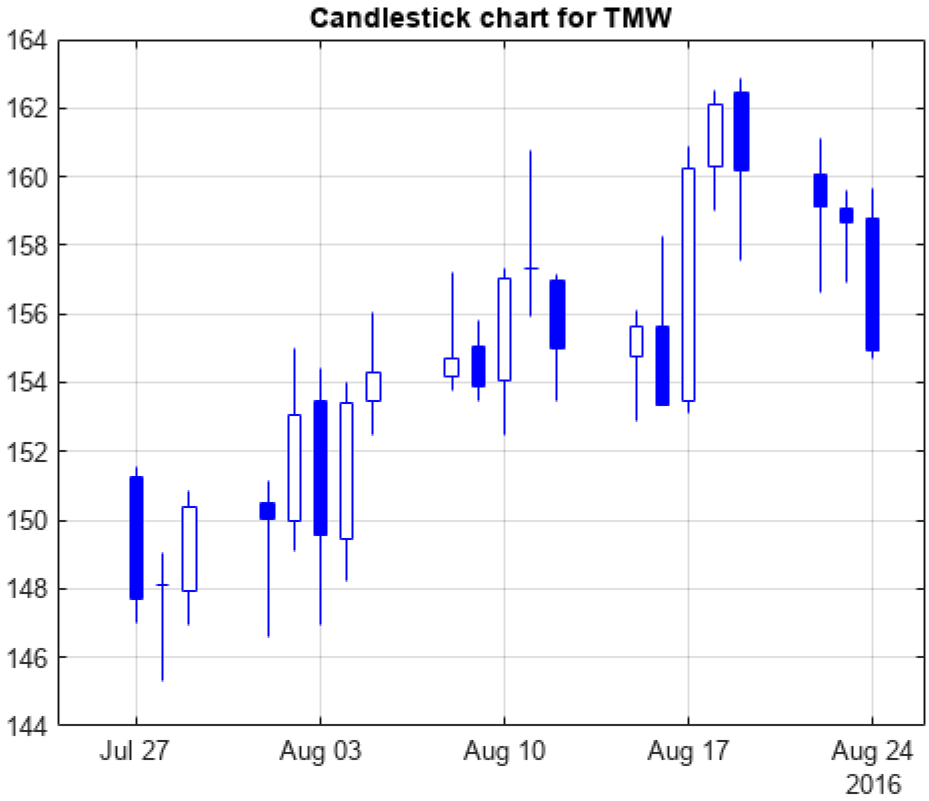
`h = candle(ax___)` adds an optional argument for `ax`.

Examples

Generate a Candlestick Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock. This is a candlestick chart with blue candles, for the most recent 21 days in SimulatedStock`.mat`.

```
load SimulatedStock.mat;
candle(TMW(end-20:end,:),'b');
title('Candlestick chart for TMW')
```



Input Arguments

`Data` — Data for opening, high, low, and closing prices

matrix | table | timetable

Data for opening, high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-4 matrix of opening, high, low, and closing prices stored in the corresponding columns. Timetables and tables with `M` rows must contain variables named `'Open'`, `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

`Color` — (Optional) Three element color vector

background color of figure window (default) | color vector `[R G B]` | string

Three element color vector, specified as a `[R G B]` color vector or a string specifying the color name. The default color differs depending on the background color of the figure window.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`.

- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
`"red"`	`"r"`	`[1 0 0]`	`"#FF0000"`	🟥
`"green"`	`"g"`	`[0 1 0]`	`"#00FF00"`	🟩
`"blue"`	`"b"`	`[0 0 1]`	`"#0000FF"`	🟦
`"cyan"`	`"c"`	`[0 1 1]`	`"#00FFFF"`	🟦
`"magenta"`	`"m"`	`[1 0 1]`	`"#FF00FF"`	🟪
`"yellow"`	`"y"`	`[1 1 0]`	`"#FFFF00"`	🟨
`"black"`	`"k"`	`[0 0 0]`	`"#000000"`	⬛
`"white"`	`"w"`	`[1 1 1]`	`"#FFFFFF"`	⬜

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
`[0 0.4470 0.7410]`	`"#0072BD"`	🟦
`[0.8500 0.3250 0.0980]`	`"#D95319"`	🟧
`[0.9290 0.6940 0.1250]`	`"#EDB120"`	🟨
`[0.4940 0.1840 0.5560]`	`"#7E2F8E"`	🟪

Data Types: `double` | `string`

ax — Valid axis object

current axes (`ax = gca`) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The candle plot is created in the axes specified by `ax` instead of in the current axes (`ax = gca`). The option `ax` can precede any of the input argument combinations.

Data Types: `object`

Output Arguments

h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

Version History

Introduced before R2006a

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

cdai

Accrued interest on certificate of deposit

Syntax

```
AccrInt = cdai(CouponRate,Settle,Maturity,IssueDate)
AccrInt = cdai( ___ ,Basis)
```

Description

`AccrInt = cdai(CouponRate,Settle,Maturity,IssueDate)` computes the accrued interest on a certificate of deposit.

`cdai` assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, this function is best used for short-term maturities (less than 1 year). The default simple interest calculation uses the `Basis` for the actual/360 convention (2).

`AccrInt = cdai( ___ ,Basis)` adds an optional argument for `Basis`.

Examples

Find the Accrued Interest on a Certificate of Deposit

This example shows how to compute the accrued interest due, given a certificate of deposit with the following characteristics.

```
CouponRate      =  0.05;
Settle          =  '02-Jan-02';
Maturity        =  '31-Mar-02';
IssueDate       =  '1-Oct-01';

AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)
```

```
AccrInt = 1.2917
```

Find the Accrued Interest on a Certificate of Deposit Using datetime Inputs

This example shows how to use `datetime` inputs to compute the accrued interest due, given a certificate of deposit with the following characteristics.

```
CouponRate =  0.05;
Settle =  datetime('02-Jan-02','Locale','en_US');
Maturity =  datetime('31-Mar-02','Locale','en_US');
IssueDate =  datetime('1-Oct-01','Locale','en_US');
AccrInt = cdai(CouponRate, Settle, Maturity, IssueDate)
```

```
AccrInt = 1.2917
```

Input Arguments

CouponRate — Annual interest rate
decimal

Annual interest rate, specified as decimal using a scalar or a NCDS-by-1 or 1-by-NCDS vector.

Data Types: double

Settle — Settlement date for certificate of deposit
datetime array | string array | date character vector

Settlement date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using a datetime array, string array, or date character vectors. The Settle date must be before the Maturity date.

To support existing code, cdai also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Maturity — Maturity date for certificate of deposit
datetime array | string array | date character vector

Maturity date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using a datetime array, string array, or date character vectors.

To support existing code, cdai also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

IssueDate — Issue date for certificate of deposit
datetime array | string array | date character vector

Issue date for the certificate of deposit, specified as a scalar or a NCDS-by-1 or 1-by-NCDS vector using a datetime array, string array, or date character vectors.

To support existing code, cdai also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Basis — Day-count basis for certificate of deposit
2 (actual/360) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for the certificate of deposit, specified as a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`AccrInt` — Accrued interest per $100 of face value

numeric

Accrued interest per $100 of face value, returned as a `NCDS`-by-`1` or `1`-by-`NCDS` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `cdai` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cdprice

Price of certificate of deposit

Syntax

```
[Price,AccrInt] = cdprice(Yield,CouponRate,Settle,Maturity,IssueDate)
[PriceAccrInt] = cdprice( ___ ,Basis)
```

Description

`[Price,AccrInt] = cdprice(Yield,CouponRate,Settle,Maturity,IssueDate)` computes the price of a certificate of deposit given its yield.

`cdprice` assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, this function is best used for short-term maturities (less than 1 year). The default simple interest calculation uses the `Basis` for the actual/360 convention (2).

`[PriceAccrInt] = cdprice( ___ ,Basis)` adds an optional argument for `Basis`.

Examples

Compute the Price and Accrued Interest for a Certificate of Deposit

This example shows how to compute the price and the accrued interest due on the settlement date, given a certificate of deposit with the following characteristics.

```
Yield          =  0.0525;
CouponRate     =  0.05;
Settle         =  '02-Jan-02';
Maturity       =  '31-Mar-02';
IssueDate      =  '1-Oct-01';

[Price, AccruedInt] = cdprice(Yield, CouponRate, Settle, ...
Maturity, IssueDate)
```

```
Price = 99.9233

AccruedInt = 1.2917
```

Compute the Price and Accrued Interest for a Certificate of Deposit Using datetime Inputs

This example shows how to use `datetime` inputs to compute the price and the accrued interest due on the settlement date, given a certificate of deposit with the following characteristics.

```
Yield =  0.0525;
CouponRate =  0.05;
Settle =  datetime('02-Jan-02','Locale','en_US');
Maturity =  datetime('31-Mar-02','Locale','en_US');
```

```
IssueDate =  datetime('1-Oct-01','Locale','en_US');

[Price, AccruedInt] = cdprice(Yield, CouponRate, Settle, ...
Maturity, IssueDate)

Price = 99.9233

AccruedInt = 1.2917
```

Input Arguments

`Yield` — Simple yield to maturity over basis denominator

numeric

Simple yield to maturity over the basis denominator, specified as a numeric value using a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector.

Data Types: `double`

`CouponRate` — Coupon annual interest rate

decimal

Coupon annual interest rate, specified as decimal using a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector.

Data Types: `double`

`Settle` — Settlement date for certificate of deposit

datetime array | string array | date character vector

Settlement date for the certificate of deposit, specified as a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `cdprice` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date for certificate of deposit

datetime array | string array | date character vector

Maturity date for the certificate of deposit, specified as a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `cdprice` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`IssueDate` — Issue date for certificate of deposit

datetime array | string array | date character vector

Issue date for the certificate of deposit, specified as a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `cdprice` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Basis` — Day-count basis for certificate of deposit
2 (actual/360) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

(Optional) Day-count basis for the certificate of deposit, specified as a scalar or a `NINST`-by-`1` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`Price` — Clean price of certificate of deposit per $100
numeric

Clean price of the certificate of deposit per $100, returned as a `NCDS`-by-`1` or `1`-by-`NCDS` vector.

`AccrInt` — Accrued interest payable at settlement per unit of face value
numeric

Accrued interest payable at settlement per unit of face value, returned as a `NCDS`-by-`1` or `1`-by-`NCDS` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although `cdprice` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cdsbootstrap

Bootstrap default probability curve from credit default swap market quotes

Syntax

```
[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle)
[ProbData,HazData] = cdsbootstrap( ___ ,Name,Value)
```

Description

`[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle)` bootstraps the default probability curve using credit default swap (CDS) market quotes. The market quotes can be expressed as a list of maturity dates and corresponding CDS market spreads, or as a list of maturities and corresponding upfronts and standard spreads for standard CDS contracts. The estimation uses the standard model of the survival probability.

Note Alternatively, you can use the Financial Instruments Toolbox `defprobstrip` function to bootstrap a `defprobcurve` object from market CDS instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” (Financial Instruments Toolbox).

`[ProbData,HazData] = cdsbootstrap( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Bootstrap Default Probability Curve from Credit Default Swap Market Quotes

This example shows how to use `cdsbootstrap` with market quotes for CDS contracts to generate `ProbData` and `HazData` values.

```
Settle = datetime(2009,7,17); % valuation date for the CDS
Spread_Time = [1 2 3 5 7]';
Spread = [140 175 210 265 310]';
Market_Dates = daysadd(datenum(Settle),360*Spread_Time,1);
MarketData = [Market_Dates Spread];
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(datenum(Settle),360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];

format long
[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle)
```

```
ProbData = 5×2
10^5 ×

   7.343360000000000   0.000000233427859
   7.347010000000000   0.000000575839968

   7.357970000000000   0.000002064539982
   7.365280000000000   0.000003234110940

HazData = 5×2
10^5 ×

   7.343360000000000   0.000000232959886
   7.347010000000000   0.000000352000512
   7.350670000000000   0.000000476383354
   7.357970000000000   0.000000609055766
   7.365280000000000   0.000000785241515
```

Input Arguments

ZeroData — Zero rate data

vector | IRDataCurve object

Zero rate data, specified as a M-by-2 vector of dates, using a serial date number format, and zero rates or an IRDataCurve object of zero rates.

When ZeroData is an IRDataCurve object, ZeroCompounding and ZeroBasis are implicit in ZeroData and are redundant inside this function. In this case, specify these optional parameters when constructing the IRDataCurve object before using the cdsbootstrap function.

For more information on an IRDataCurve object, see “Creating an IRDataCurve Object” (Financial Instruments Toolbox).

Data Types: double | object

MarketData — Bond market data

matrix

Bond market data, specified as a N-by-2 matrix of dates and corresponding market spreads or N-by-3 matrix of dates, upfronts, and standard spreads of CDS contracts. The dates must be entered as serial date numbers, upfronts must be numeric values between 0 and 1, and spreads must be in basis points.

Data Types: double

Settle — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector. The Settle date must be earlier than or equal to the dates in MarketData

To support existing code, cdsbootstrap also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Note Any optional input of size `N`-by-`1` is also acceptable as an array of size `1`-by-`N`, or as a single value applicable to all contracts. Single values are internally expanded to an array of size `N`-by-`1`.

Example: `[ProbData,HazData] = cdsbootstrap(ZeroData,MarketData,Settle,'RecoveryRate',Recovery,'ZeroCompounding',-1)`

`RecoveryRate` — Recovery rate

`0.4` (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryDate'` and a `N`-by-`1` vector of recovery rates, specified as a decimal from `0` to `1`.

Data Types: `double`

`Period` — Premium payment frequency

`4` (default) | numeric with values `1`, `2`, `3`, `4`, `6` or `12`

Premium payment frequency, specified as the comma-separated pair consisting of `'Period'` and a `N`-by-`1` vector with values of `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis of contract

`2` (actual/360) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

Day-count basis of the contract, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`BusinessDayConvention` — Business day conventions

`'actual'` (default) | character vector

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `'actual'` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `'follow'` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `'modifiedfollow'` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `'previous'` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `'modifiedprevious'` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char`

`PayAccruedPremium` — Flag for accrued premiums paid upon default

`true` (default) | integer with value `1` or `0`

Flag for accrued premiums paid upon default, specified as the comma-separated pair consisting of `'PayAccruedPremium'` and a `N`-by-`1` vector of Boolean flags that is `true` (default) if accrued premiums are paid upon default, `false` otherwise.

Data Types: `logical`

`TimeStep` — Number of days as time step for numerical integration

`10` (days) (default) | nonnegative integer

Number of days to take as time step for the numerical integration, specified as the comma-separated pair consisting of `'TimeStep'` and a nonnegative integer.

Data Types: `double`

`ZeroCompounding` — Compounding frequency of the zero curve

2 (semiannual) (default) | integer with value of `1`,`2`,`3`,`4`,`6`,`12`, or `–1`

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of `'ZeroCompounding'` and an integer with values:

- `1` — Annual compounding

- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- −1 — Continuous compounding

Data Types: double

ZeroBasis — Basis of the zero curve

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and an integer with values that are identical to Basis.

Data Types: double

ProbDates — Dates for probability data

column of dates in MarketData (default) | datetime array | string array | date character vector

Dates for probability data, specified as the comma-separated pair consisting of 'ProbDates' and a P-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cdsbootstrap also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

ProbData — Default probability values

matrix

Default probability values, returned as a P-by-2 matrix with dates and corresponding cumulative default probability values. The dates match those in MarketData, unless the optional input parameter ProbDates is provided.

HazData — Hazard rate values

matrix

Hazard rate values, returned as a N-by-2 matrix with dates and corresponding hazard rate values for the survival probability model. The dates match those in MarketData.

Note A warning is displayed when non-monotone default probabilities (that is, negative hazard rates) are found.

Algorithms

If the time to default is denoted by *τ*, the default probability curve, or function, *PD(t)*, and its complement, the survival function *Q(t)*, are given by:

$$PD(t) = P[\tau \le t] = 1 - P[\tau > t] = 1 - Q(t)$$

In the standard model, the survival probability is defined in terms of a piecewise constant hazard rate *h(t)*. For example, if *h(t)* =

λ_1, for $0 \leq t \leq t_1$

λ_2, for $t_1 < t \leq t_2$

λ_3, for $t_2 < t$

then the survival function is given by *Q(t)* =

$e^{-\lambda 1t}$, for $0 \leq t \leq t_1$

$e^{-\lambda 1t - \lambda 2(t - t1)}$, for $t_1 < t \leq t_2$

$e^{-\lambda 1t1 - \lambda 2(t2 - t1) - \lambda 3(t - t2)}$, for $t_2 < t$

Given *n* market dates $t_1,\ldots,t_n$ and corresponding market CDS spreads $S_1,\ldots,S_n$, `cdsbootstrap` calibrates the parameters $\lambda_1,\ldots,\lambda_n$ and evaluates *PD(t)* on the market dates, or an optional user-defined set of dates.

Version History

Introduced in R2010b

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `cdsbootstrap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cdsprice

Determine price for credit default swap

Syntax

```
[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice(ZeroData,
ProbData,Settle,Maturity,ContractSpread)
[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice( ___ ,
Name,Value)
```

Description

`[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice(ZeroData, ProbData,Settle,Maturity,ContractSpread)` computes the price, or the mark-to-market value for CDS instruments.

Note Alternatively, you can use the Financial Instruments Toolbox CDS object to price credit default swaps. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" (Financial Instruments Toolbox).

`[Price,AccPrem,PaymentDates,PaymentTimes,PaymentCF] = cdsprice( ___ , Name,Value)` adds optional name-value pair arguments.

Examples

Determine the Price for a Credit Default Swap

This example shows how to use `cdsprice` to compute the clean price for a CDS contract using the following data.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];

ProbData = [daysadd(datenum(Settle),360,1), 0.0247];
Maturity = datetime(2010,9,20);
ContractSpread = 135;

[Price,AccPrem] = cdsprice(ZeroData,ProbData,Settle,Maturity,ContractSpread)
```

```
Price = 1.5461e+04

AccPrem = 10500
```

Input Arguments

ZeroData — Zero rate data

vector | IRDataCurve object

Zero rate data, specified as a M-by-2 vector of dates, using a serial date number format, and zero rates or an IRDataCurve object of zero rates.

When ZeroData is an IRDataCurve object, ZeroCompounding and ZeroBasis are implicit in ZeroData and are redundant inside this function. In this case, specify these optional parameters when constructing the IRDataCurve object before using the cdsprice function.

For more information on an IRDataCurve object, see “Creating an IRDataCurve Object” (Financial Instruments Toolbox).

Data Types: double | object

ProbData — Default probability values

matrix

Default probability values, specified as a P-by-2 matrix with dates, using a serial date number format, and the corresponding cumulative default probability values.

Data Types: double

Settle — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector. The Settle date must be earlier than or equal to the dates in Maturity.

To support existing code, cdsprice also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Maturity — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a N-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cdsprice also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

ContractSpread — Contract spreads

numeric

Contract spreads, specified as a N-by-1 vector of spreads, expressed in basis points.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Note Any optional input of size `N`-by-`1` is also acceptable as an array of size `1`-by-`N`, or as a single value applicable to all contracts. Single values are internally expanded to an array of size `N`-by-`1`.

Example: `[Price,AccPrem] = cdsprice(ZeroData,ProbData,Settle,Maturity,ContractSpread,'Basis',7,'BusinessDayConvention','previous')`

`RecoveryRate` — Recovery rate

`0.4` (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a `N`-by-`1` vector of recovery rates, specified as a decimal from `0` to `1`.

Data Types: `double`

`Period` — Premium payment frequency

4 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payment frequency, specified as the comma-separated pair consisting of `'Period'` and a `N`-by-`1` vector with values of `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis of contract

2 (actual/360) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the contract, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`BusinessDayConvention` — Business day conventions

`actual` (default) | character vector

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char`

`PayAccruedPremium` — Flag for accrued premiums paid upon default

`true` (default) | integer with value `1` or `0`

Flag for accrued premiums paid upon default, specified as the comma-separated pair consisting of `'PayAccruedPremium'` and a `N`-by-`1` vector of Boolean flags that is `true` (default) if accrued premiums are paid upon default, `false` otherwise.

Data Types: `logical`

`Notional` — Contract notional values

`10MM` (default) | positive or negative integer

Contract notional values, specified as the comma-separated pair consisting of `'Notional'` and a `N`-by-`1`vector of integers. Use positive integer values for long positions and negative integer values for short positions.

Data Types: `double`

`TimeStep` — Number of days as time step for numerical integration

`10` (days) (default) | nonnegative integer

Number of days to take as time step for the numerical integration, specified as the comma-separated pair consisting of `'TimeStep'` and a nonnegative integer.

Data Types: double

ZeroCompounding — Compounding frequency of the zero curve

2 (semiannual) (default) | integer with value of 1,2,3,4,6,12, or –1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCmpounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- −1 — Continuous compounding

Data Types: double

ZeroBasis — Basis of the zero curve

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and an integer with values that are identical to Basis.

Data Types: double

Output Arguments

Price — CDS clean prices

vector

CDS clean prices, returned as a N-by-1 vector.

AccPrem — Accrued premiums

vector

Accrued premiums, returned as a N-by-1 vector.

PaymentDates — Payment dates

matrix

Payment dates, returned as a N-by-numCF matrix.

PaymentTimes — Payment times

matrix

Payment times, returned as a N-by-numCF matrix of accrual fractions.

PaymentCF — Payments

matrix

Payments, returned as a N-by-numCF matrix.

More About

CDS Price

The price or mark-to-market (MtM) value of an existing CDS contract.

The CDS price is computed using the following formula:

```
CDS price = Notional * (Current Spread - Contract Spread) * RPV01
```

`Current Spread` is the current breakeven spread for a similar contract, according to current market conditions. `RPV01` is the 'risky present value of a basis point,' the present value of the premium payments, considering the default probability. This formula assumes a long position, and the right side is multiplied by -1 for short positions.

Algorithms

The premium leg is computed as the product of a spread S and the risky present value of a basis point (`RPV01`). The `RPV01` is given by:

$$RPV01 = \sum_{j=1}^{N} Z(tj)\Delta(tj-1, tj, B)Q(tj)$$

when no accrued premiums are paid upon default, and it can be approximated by

$$RPV01 \approx \frac{1}{2}\sum_{j=1}^{N} Z(tj)\Delta(tj-1, tj, B)(Q(tj-1)+Q(tj))$$

when accrued premiums are paid upon default. Here, $t_0 = 0$ is the valuation date, and $t_1,...,t_n = T$ are the premium payment dates over the life of the contract,T is the maturity of the contract, $Z(t)$ is the discount factor for a payment received at time t, and $\Delta(t_{j-1}, t_j, B)$ is a day count between dates t_{j-1} and t_j corresponding to a basis B.

The protection leg of a CDS contract is given by the following formula:

$$ProtectionLeg = \int_0^T Z(\tau)(1-R)dPD(\tau)$$

$$\approx (1-R)\sum_{i=1}^{M} Z(\tau i)(PD(\tau i) - PD(\tau i-1))$$

$$= (1-R)\sum_{i=1}^{M} Z(\tau i)(Q(\tau i-1) - Q(\tau i))$$

where the integral is approximated with a finite sum over the discretization $\tau_0 = 0,\tau_1,...,\tau_M = T$.

If the spread of an existing CDS contract is S_C, and the current breakeven spread for a comparable contract is S_0, the current price, or mark-to-market value of the contract is given by:

`MtM` = `Notional` $(S_0 - S_C)$`RPV01`

This assumes a long position from the protection standpoint (protection was bought). For short positions, the sign is reversed.

Version History

Introduced in R2010b

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although cdsprice supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cdsspread

Determine spread of credit default swap

Syntax

`[Spread,PaymentDates,PaymentTimes,] = cdsspread(ZeroData,ProbData,Settle, Maturity,)`
`[Spread,PaymentDates,PaymentTimes,] = cdsspread(___,Name,Value)`

Description

`[Spread,PaymentDates,PaymentTimes,] = cdsspread(ZeroData,ProbData,Settle, Maturity,)` computes the spread of the CDS.

`[Spread,PaymentDates,PaymentTimes,] = cdsspread(___,Name,Value)` adds optional name-value pair arguments.

Examples

Determine the Spread of a Credit Default Swap

This example shows how to use `cdsspread` to compute the spread (in basis points) for a CDS contract with the following data.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];
ProbData = [daysadd(datenum(Settle),360,1), 0.0247];
Maturity = datetime(2010,9,20);

Spread = cdsspread(ZeroData,ProbData,Settle,Maturity)
```

```
Spread = 148.2705
```

Input Arguments

ZeroData — Zero rate data

vector | `IRDataCurve` object

Zero rate data, specified as a `M`-by-`2` vector of dates, using a serial date number format, and zero rates or an `IRDataCurve` object of zero rates.

When `ZeroData` is an `IRDataCurve` object, `ZeroCompounding` and `ZeroBasis` are implicit in `ZeroData` and are redundant inside this function. In this case, specify these optional parameters when constructing the `IRDataCurve` object before using the `cdsspread` function.

For more information on an `IRDataCurve` object, see “Creating an IRDataCurve Object” (Financial Instruments Toolbox).

Data Types: `double` | `object`

`ProbData` — Default probability values
matrix

Default probability values, specified as a `P`-by-2 matrix with dates, using a serial date number format, and corresponding cumulative default probability values.

Data Types: `double`

`Settle` — Settlement date
datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector. The `Settle` date must be earlier than or equal to the dates in `Maturity`.

To support existing code, `cdsspread` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `N`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cdsspread` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Note Any optional input of size `N`-by-`1` is also acceptable as an array of size `1`-by-`N`, or as a single value applicable to all contracts. Single values are internally expanded to an array of size `N`-by-`1`.

Example: `Spread = cdsspread(ZeroData,ProbData,Settle,Maturity,'Basis',7,'BusinessDayConvention','previous')`

`RecoveryRate` — Recovery rate
`0.4` (default) | decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a `N`-by-`1` vector of recovery rates, specified as a decimal from `0` to `1`.

Data Types: `double`

`Period` — Premium payment frequency

4 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payment frequency, specified as the comma-separated pair consisting of `'Period'` and a `N`-by-`1` vector with values of `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis of contract

2 (actual/360) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the contract, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`BusinessDayConvention` — Business day conventions

`actual` (default) | character vector

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.

- modifiedfollow — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- previous — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- modifiedprevious — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char

PayAccruedPremium — Flag for accrued premiums paid upon default

true (default) | integer with value 1 or 0

Flag for accrued premiums paid upon default, specified as the comma-separated pair consisting of 'PayAccruedPremium' and a N-by-1 vector of Boolean flags that is true (default) if accrued premiums are paid upon default, false otherwise.

Data Types: logical

TimeStep — Number of days as time step for numerical integration

10 (days) (default) | nonnegative integer

Number of days to take as time step for the numerical integration, specified as the comma-separated pair consisting of 'TimeStep' and a nonnegative integer.

Data Types: double

ZeroCompounding — Compounding frequency of the zero curve

2 (semiannual) (default) | integer with value of 1,2,3,4,6,12, or –1

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of 'ZeroCompounding' and an integer with values:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- −1 — Continuous compounding

Data Types: double

ZeroBasis — Basis of the zero curve

0 (actual/actual) (default) | integer with value of 0 to 13

Basis of the zero curve, specified as the comma-separated pair consisting of 'ZeroBasis' and a positive integer with values that are identical to Basis.

Data Types: double

Output Arguments

Spread — Spreads (in basis points)
vector

Spreads (in basis points), returned as a N-by-1 vector.

PaymentDates — Payment dates
matrix

Payment dates, returned as a N-by-numCF matrix.

PaymentTimes — Payment times
matrix

Payment times, returned as a N-by-numCF matrix of accrual fractions.

More About

CDS Spread

The market, or breakeven, spread value of a CDS.

The CDS spread can be computed by equating the value of the protection leg with the value of the premium leg:

```
Market Spread * RPV01 = Value of Protection Leg
```

The left side corresponds to the value of the premium leg, and this has been decomposed as the product of the market or breakeven spread times the RPV01 or 'risky present value of a basis point' of the contract. The latter is the present value of the premium payments, considering the default probability. The Market Spread can be computed as the ratio of the value of the protection leg, to the RPV01 of the contract. cdsspread returns the resulting spread in basis points.

Algorithms

The premium leg is computed as the product of a spread S and the risky present value of a basis point (RPV01). The RPV01 is given by:

$$RPV01 = \sum_{j=1}^{N} Z(tj)\Delta(tj-1, tj, B)Q(tj)$$

when no accrued premiums are paid upon default, and it can be approximated by

$$RPV01 \approx \frac{1}{2}\sum_{j=1}^{N} Z(tj)\Delta(tj-1, tj, B)(Q(tj-1) + Q(tj))$$

when accrued premiums are paid upon default. Here, t_0 = 0 is the valuation date, and $t_1,...,t_n = T$ are the premium payment dates over the life of the contract,T is the maturity of the contract, $Z(t)$ is the discount factor for a payment received at time t, and $\Delta(t_{j-1}, t_j, B)$ is a day count between dates t_{j-1} and t_j corresponding to a basis B.

The protection leg of a CDS contract is given by the following formula:

$$ProtectionLeg = \int_0^T Z(\tau)(1 - R)dPD(\tau)$$

$$\approx (1 - R)\sum_{i = 1}^{M} Z(\tau i)(PD(\tau i) - PD(\tau i - 1))$$

$$= (1 - R)\sum_{i = 1}^{M} Z(\tau i)(Q(\tau i - 1) - Q(\tau i))$$

where the integral is approximated with a finite sum over the discretization $\tau_0 = 0, \tau_1, \ldots, \tau_M = T$.

A breakeven spread S_0 makes the value of the premium and protection legs equal. It follows that:

$$S0 = \frac{ProtectionLeg}{RPV01}$$

Version History

Introduced in R2010b

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `cdsspread` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cdsrpv01

Compute risky present value of a basis point for credit default swap

Syntax

```
RPV01 = cdsrpv01(ZeroData,ProbData,Settle,Maturity)
RPV01 = cdsrpv01(___,Name,Value)
```

```
[RPV01,PaymentDates,PaymentTimes] = cdsrpv01(ZeroData,ProbData,Settle,
Maturity)
[RPV01,PaymentDates,PaymentTimes] = cdsrpv01(___,Name,Value)
```

Description

`RPV01 = cdsrpv01(ZeroData,ProbData,Settle,Maturity)` computes the risky present value of a basis point (RPV01) for a credit default swap (CDS).

`RPV01 = cdsrpv01(___,Name,Value)` adds optional name-value arguments.

`[RPV01,PaymentDates,PaymentTimes] = cdsrpv01(ZeroData,ProbData,Settle, Maturity)` computes the risky present value of a basis point (RPV01), `PaymentDates`, and `PaymentTimes` for a credit default swap (CDS).

`[RPV01,PaymentDates,PaymentTimes] = cdsrpv01(___,Name,Value)` computes the risky present value of a basis point (RPV01), `PaymentDates`, and `PaymentTimes` for a credit default swap (CDS) using optional name-value pair arguments.

Examples

Calculate the RPV01 Value for a CDS

Calculate the `RPV01` value, given the following specification for a CDS.

```
Settle = '17-Jul-2009'; % valuation date for the CDS
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];
ProbData = [daysadd(datenum(Settle),360,1), 0.0247];
Maturity = datetime(2010,9,20);

RPV01 = cdsrpv01(ZeroData,ProbData,Settle,Maturity)
```

```
RPV01 = 1.1651
```

Input Arguments

ZeroData — Dates and zero rates

object from `IRDataCurve` or vector of dates and zero rates

Dates and zero rates, specified by an `M`-by-`2` vector of dates, using a serial date number format, and zero rates or the `IRDataCurve` object for zero rates. For more information on an `IRDataCurve` object, see “Creating an IRDataCurve Object” (Financial Instruments Toolbox).

Data Types: `object` | `double`

`ProbData` — Dates and default probabilities

vector of dates and default probabilities

Dates and default probabilities, specified by a `P`-by-`2` array, where dates use a serial date number format.

Data Types: `double`

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified by a scalar datetime, string, or date character vector. This must be earlier than or equal to the dates in `Maturity`.

To support existing code, `cdsrpv01` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — CDS maturity date

datetime array | string array | date character vector | serial date number

CDS maturity date, specified by an `N`-by-`1` vector using a datetime array, string array, or date character vectors. The CDS premium payment dates occur at regular intervals, and the last payment occurs on these maturity dates.

To support existing code, `cdsrpv01` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `RPV01 = cdsrpv01(ZeroData,ProbData,Settle,Maturity,'Period',1,'StartDate','20-Sep-2010','Basis',1, 'BusinessDayConvention',actual,'CleanRPV01',true,'PayAccruedPremium',true,'ZeroCompounding',1,'ZeroBasis',1)`

`Period` — Number of premium payments per year

4 (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Number of premium payments per year, specified as the comma-separated pair consisting of `'Period'` and an `N`-by-`1` vector. Values are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: double

StartDate — Dates the CDS premium leg starts

Settle date (default) | datetime array | string array | date character vector

Dates when the CDS premium leg actually starts, specified as the comma-separated pair consisting of 'StartDate' and an N-by-1 vector using a datetime array, string array, or date character vectors. Must be on or between the Settle and Maturity dates. For a forward-starting CDS, specify this date as a future date after Settle.

To support existing code, cdsrpv01 also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Basis — Day-count basis of contract

2 (actual/360) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the contract, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

BusinessDayConvention — Business day conventions

actual (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or N-by-1 cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`CleanRPV01` — Flag for premium accrual

`true` (default) | boolean flag with value `true` or `false`

Flag for premium accrual, specified as the comma-separated pair consisting of `'CleanRPV01'` and a `N`-by-`1` vector of Boolean flags, which is `true` if the premium accrued at `StartDate` is excluded in the RPV01, and `false` otherwise.

Data Types: `logical`

`PayAccruedPremium` — Flag for accrued premium payment

`true` (default) | boolean flag with value `true` or `false`

Flag for accrued premium payment, specified as the comma-separated pair consisting of `'PayAccruedPremium'` and a `N`-by-`1` vector of Boolean flags, `true` if accrued premiums are paid upon default, `false` otherwise.

Data Types: `logical`

`ZeroCompounding` — Compounding frequency of zero curve

2 semiannual compounding (default) | integer with acceptable value [`1,2,3,4,6,12, −1`]

Compounding frequency of the zero curve, specified as the comma-separated pair consisting of `'ZeroCompounding'` and an integer with values:

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding
- `−1` — Continuous compounding

Note When `ZeroData` is an `IRDataCurve` object, the arguments `ZeroCompounding` and `ZeroBasis` are implicit in `ZeroData` and are redundant inside this function. In that case, specify these optional arguments when constructing the `IRDataCurve` object before calling this function.

Data Types: `double`

`ZeroBasis` — Basis of zero curve
`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Basis of the zero curve, specified as the comma-separated pair consisting of `'ZeroBasis'` and a positive integer using a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`RPV01` — RPV01 value
scalar | vector

RPV01 value, returned as an `N`-by-`1` vector.

`PaymentDates` — Payment dates
scalar | vector

Payment dates, returned as an `N`-by-`numCF` matrix of dates.

`PaymentTimes` — Payment times
scalar | vector

Payment times, returned as an `N`-by-`numCF` matrix of accrual fractions.

More About

RPV01

RPV01, associated with a CDS, is the value of a stream of 1-basis-point premiums according to the payment structure of the CDS contract, and considering the default probability over time.

For more information, see [3] and [4] for details.

Version History

Introduced in R2013b

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `cdsrpv01` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

creditexposures

Compute credit exposures from contract values

Syntax

```
[exposures,exposurecpty] = creditexposures(values,counterparties)
[exposures,exposurecpty] = creditexposures( ___ ,Name,Value)
```

```
[exposures,exposurecpty,collateral] = creditexposures( ___ ,Name,Value)
```

Description

`[exposures,exposurecpty] = creditexposures(values,counterparties)` computes the counterparty credit exposures from an array of mark-to-market OTC contract values. These exposures are used when calculating the CVA (credit value adjustment) for a portfolio.

`[exposures,exposurecpty] = creditexposures( ___ ,Name,Value)` adds optional name-value arguments.

`[exposures,exposurecpty,collateral] = creditexposures( ___ ,Name,Value)` computes the counterparty credit exposures from an array of mark-to-market OTC contract values using optional name-value pair arguments for `CollateralTable` and `Dates`, the `collateral` output is returned for the simulated collateral amounts available to counterparties at each simulation date and over each scenario.

Examples

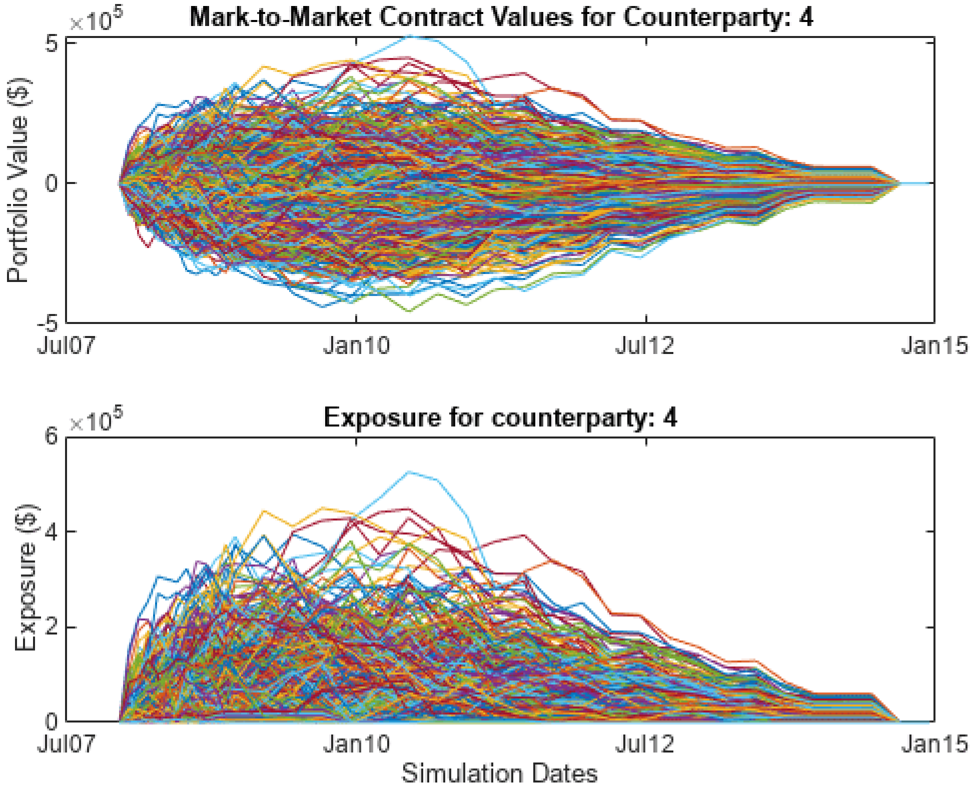
View Contract Values and Exposures Over Time for a Particular Counterparty

After computing the mark-to-market contract values for a portfolio of swaps over many scenarios, compute the credit exposure for a particular counterparty. View the contract values and credit exposure over time.

First, load data (`ccr.mat`) containing the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
% Look at one counterparty.
cpID = 4;
cpValues = squeeze(sum(values(:,swaps.Counterparty == cpID,:),2));
subplot(2,1,1)
plot(simulationDates,cpValues);
title(sprintf('Mark-to-Market Contract Values for Counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Portfolio Value ($)')
% Compute the exposure by counterparty.
[exposures, expcpty] = creditexposures(values,swaps.Counterparty,...
'NettingID',swaps.NettingID);
% View the credit exposure over time for the counterparty.
subplot(2,1,2)
```

```
cpIdx = find(expcpty == cpID);
plot(simulationDates,squeeze(exposures(:,cpIdx,:)));
title(sprintf('Exposure for counterparty: %d',cpIdx));
datetick('x','mmmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```



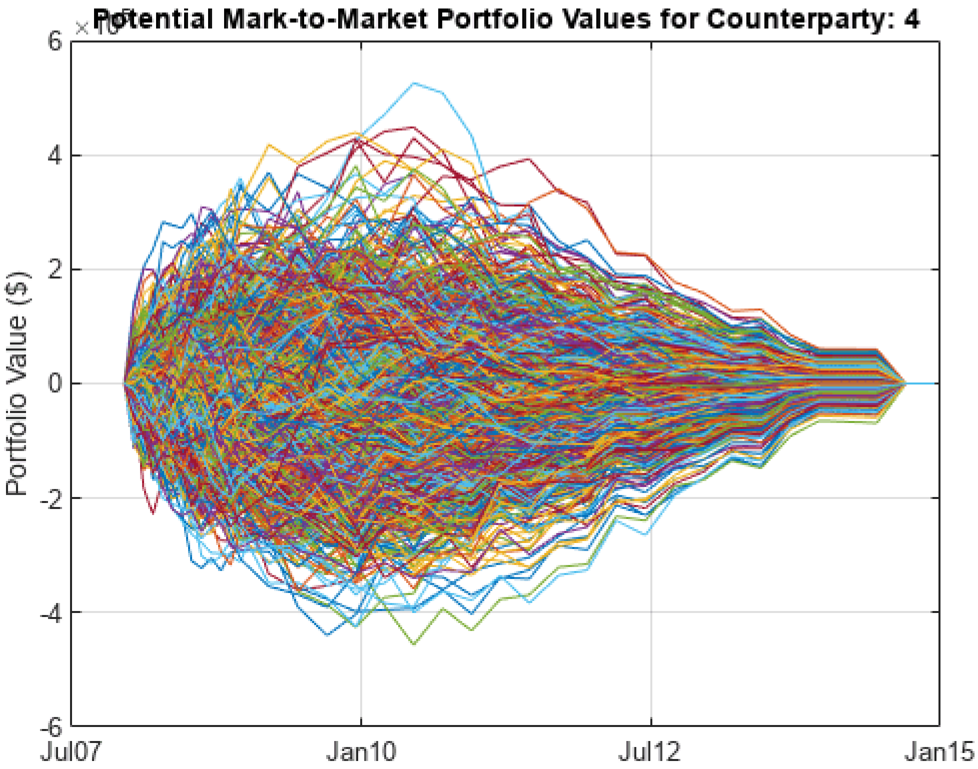
Compute the Credit Exposure and Determine the Incremental Exposure for a New Trade

Load the data (`ccr.mat`) containing the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
```

Look at one counterparty.

```
cpID = 4;
cpIdx = swaps.Counterparty == cpID;
cpValues = values(:,cpIdx,:);
plot(simulationDates,squeeze(sum(cpValues,2)));
grid on;
title(sprintf('Potential Mark-to-Market Portfolio Values for Counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Portfolio Value ($)')
```

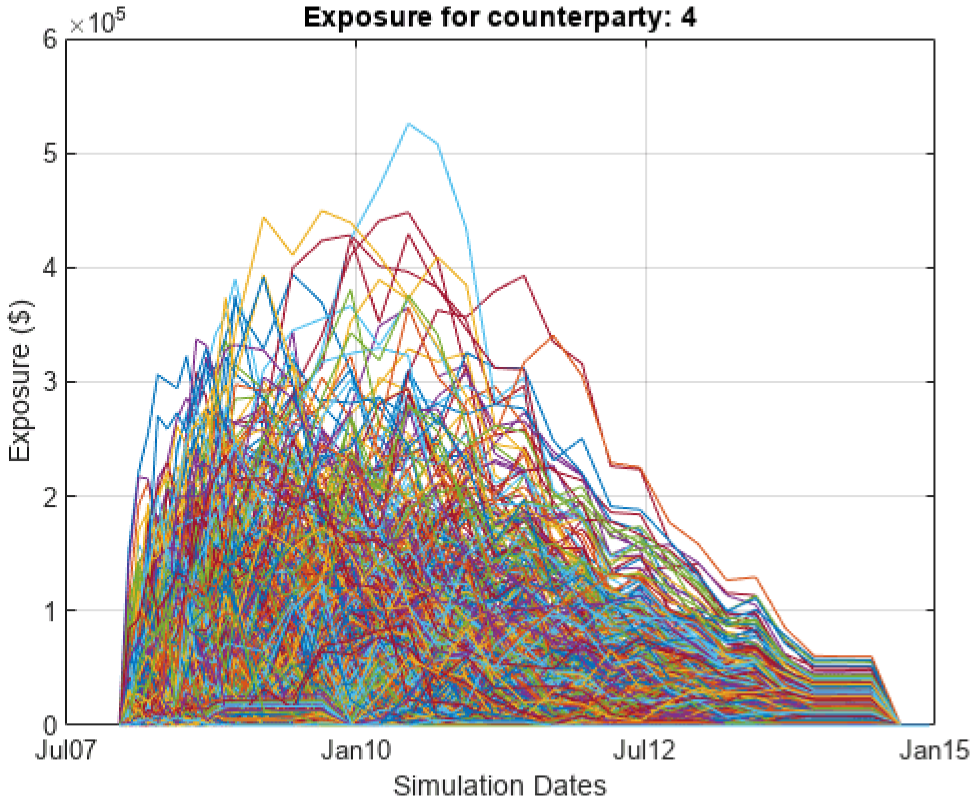


Compute the exposures.

```
netting = swaps.NettingID(cpIdx);
exposures = creditexposures(cpValues,cpID,'NettingID',netting);
```

View the credit exposure over time for the counterparty.

```
figure;
plot(simulationDates,squeeze(exposures));
grid on
title(sprintf('Exposure for counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```



Compute the credit exposure profiles.

```
profilesBefore = exposureprofiles(simulationDates,exposures)
```

```
profilesBefore = struct with fields:
     Dates: [37x1 double]
        EE: [37x1 double]
       PFE: [37x1 double]
      MPFE: 2.1580e+05
     EffEE: [37x1 double]
       EPE: 2.8602e+04
    EffEPE: 4.9579e+04
```

Consider a new trade with a counterparty. For this example, take another trade from the original swap portfolio and "copy" it for a new counterparty. This example is only for illustrative purposes.

```
newTradeIdx = 3;
newTradeValues = values(:,newTradeIdx,:);

% Append a new trade to your existing portfolio.
cpValues = [cpValues newTradeValues];
netting = [netting; cpID];
exposures = creditexposures(cpValues,cpID,'NettingID',netting);
```

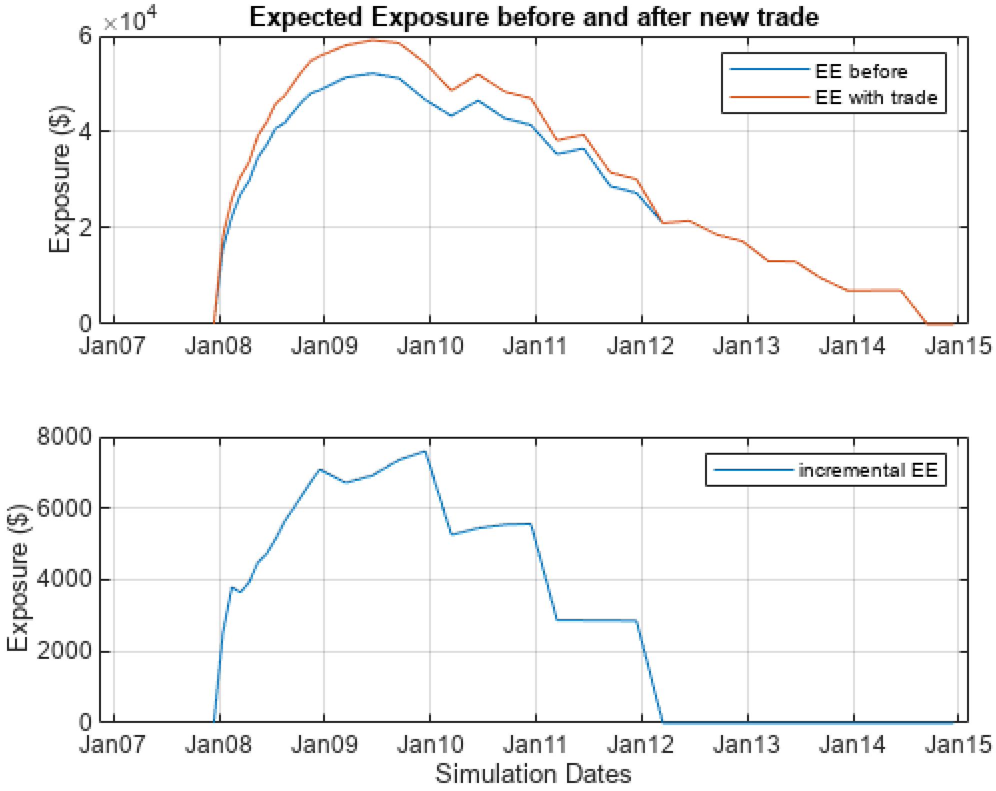
Compute the new credit exposure profiles.

```
profilesAfter = exposureprofiles(simulationDates,exposures)
profilesAfter = struct with fields:
     Dates: [37x1 double]
        EE: [37x1 double]
       PFE: [37x1 double]
      MPFE: 2.4689e+05
     EffEE: [37x1 double]
       EPE: 3.1609e+04
    EffEPE: 5.6178e+04
```

Visualize the expected exposures and the new trade's incremental exposure. Use the incremental exposure to compute the incremental credit value adjustment (CVA) charge.

```
figure;
subplot(2,1,1)
plot(simulationDates,profilesBefore.EE,...
    simulationDates,profilesAfter.EE);
grid on;
legend({'EE before','EE with trade'})
datetick('x','mmmyy','keeplimits')
title('Expected Exposure before and after new trade');
ylabel('Exposure ($)')

subplot(2,1,2)
incrementalEE = profilesAfter.EE - profilesBefore.EE;
plot(simulationDates,incrementalEE);
grid on;
legend('incremental EE')
datetick('x','mmmyy','keeplimits')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```



Compute Exposures for Counterparties Under Collateral Agreement

Load the data (`ccr.mat`) containing the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
```

Only look at a single counterparty for this example.

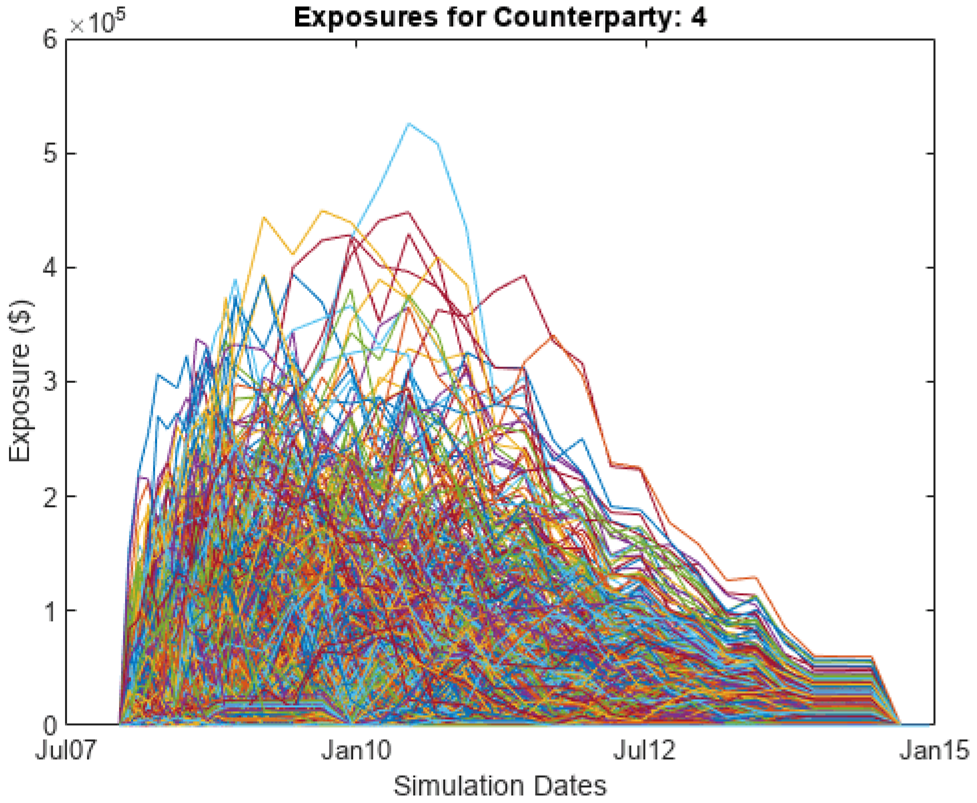
```
cpID = 4;
cpIdx = swaps.Counterparty == cpID;
cpValues = values(:,cpIdx,:);
```

Compute the uncollateralized exposures.

```
exposures = creditexposures(cpValues,swaps.Counterparty(cpIdx),...
'NettingID',swaps.NettingID(cpIdx));
```

View the credit exposure over time for the counterparty.

```
plot(simulationDates,squeeze(exposures));
expYLim = get(gca,'YLim');
title(sprintf('Exposures for Counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```



Add a collateral agreement for the counterparty. The `'CollateralTable'` parameter is a MATLAB® table. You can create tables from spreadsheets or other data sources, in addition to building them inline as seen here. For more information, see `table`.

```
collateralVariables = {'Counterparty';'PeriodOfRisk';'Threshold';'MinimumTransfer'};
periodOfRisk = 14;
threshold = 100000;
minTransfer = 10000;
collateralTable = table(cpID,periodOfRisk,threshold,minTransfer,...
'VariableNames',collateralVariables)
```

```
collateralTable=1×4 table
    Counterparty    PeriodOfRisk    Threshold    MinimumTransfer
    ____________    ____________    _________    _______________

         4               14           1e+05           10000
```

Compute the collateralized exposures.

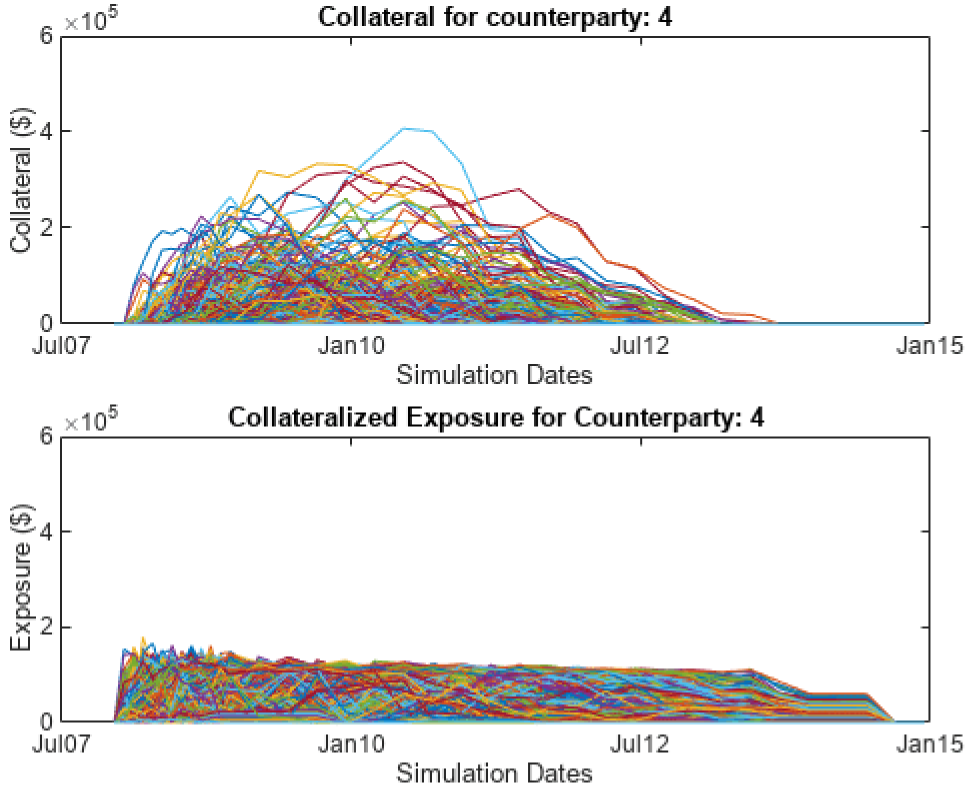
```
[collatExp, collatcpty, collateral] = creditexposures(cpValues,...
    swaps.Counterparty(cpIdx),'NettingID',swaps.NettingID(cpIdx),...
    'CollateralTable',collateralTable,'Dates',simulationDates);
```

Plot the collateral levels and collateralized exposures.

```
figure;
subplot(2,1,1)
```

```
plot(simulationDates,squeeze(collateral));
set(gca,'YLim',expYLim);
title(sprintf('Collateral for counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Collateral ($)')
xlabel('Simulation Dates')

subplot(2,1,2)
plot(simulationDates,squeeze(collatExp));
set(gca,'YLim',expYLim);
title(sprintf('Collateralized Exposure for Counterparty: %d',cpID));
datetick('x','mmmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates');
```



Collateral for counterparty: 4

Collateralized Exposure for Counterparty: 4

Input Arguments

values — 3-D array of simulated mark-to-market values of portfolio of contracts

array

3-D array of simulated mark-to-market values of a portfolio of contracts simulated over a series of simulation dates and across many scenarios, specified as a `NumDates`-by-`NumContracts`-by-`NumScenarios` “cube” of contract values. Each row represents a different simulation date, each column a different contract, and each “page” is a different scenario from a Monte-Carlo simulation.

Data Types: `double`

counterparties — Counterparties corresponding to each contract
vector | cell array

Counterparties corresponding to each contract in `values`, specified as a `NumContracts`-element vector of counterparties. Counterparties can be a vector of numeric IDs or a cell array of counterparty names. By default, each counterparty is assumed to have one netting set that covers all of its contracts. If counterparties are covered by multiple netting sets, then use the `NettingID` parameter. A value of `NaN` (or `''` in a cell array) indicates that a contract is not included in any netting set unless otherwise specified by `NettingID`. `counterparties` is case insensitive and leading or trailing white spaces are removed.

Data Types: `double` | `cell`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[exposures,exposurecpty] = creditexposures(values,counterparties,'NettingID','10','ExposureType','Additive')`

NettingID — Netting set IDs indicate which netting set each contract belongs
vector | cell array

Netting set IDs to indicate to which netting set each contract in `values` belongs, specified by a `NumContracts`-element vector of netting set IDs. `NettingID` can be a vector of numeric IDs or else a cell array of character vector identifiers. The `creditexposures` function uses `counterparties` and `NettingID` to define each unique netting set (all contracts in a netting set must be with the same counterparty). By default, each counterparty has a single netting set which covers all of their contracts. A value of `NaN` (or `''` in a cell array) indicates that a contract is not included in any netting set. `NettingID` is case insensitive and leading or trailing white spaces are removed.

Data Types: `double` | `cell`

ExposureType — Calculation method for exposures
`'Counterparty'` (default) | character vector with value of `'Counterparty'` or `'Additive'`

Calculation method for exposures, specified with values:

- `'Counterparty'` — Compute exposures per counterparty.
- `'Additive'` — Compute additive exposures at the contract level. Exposures are computed per contract and sum to the total counterparty exposure.

Data Types: `char`

CollateralTable — Table containing information on collateral agreements of counterparties
MATLAB table

Table containing information on collateral agreements of counterparties, specified as a MATLAB table. The table consists of one entry (row) per collateralized counterparty and must have the following variables (columns):

- 'Counterparty' — Counterparty name or ID. The Counterparty name or ID should match the parameter 'Counterparty' for the ExposureType argument.
- 'PeriodOfRisk' — Margin period of risk in days. The number of days from a margin call until the posted collateral is available from the counterparty.
- 'Threshold' — Collateral threshold. When counterparty exposures exceed this amount, the counterparty must post collateral.
- 'MinimumTransfer' — Minimum transfer amount. The minimum amount over/under the threshold required to trigger transfer of collateral.

Note When computing collateralized exposures, both the CollateralTable parameter and the Dates parameter must be specified.

Data Types: table

Dates — Simulation dates corresponding to each row of the values array
vector of date numbers | cell array of character vectors

Simulation dates corresponding to each row of the values array, specified as a NUMDATES-by-1 vector of simulation dates. Dates is either a vector of MATLAB date numbers or else a cell array of character vectors in a known date format. See datenum for known date formats.

Note When computing collateralized exposures, both the CollateralTable parameter and the Dates parameter must be specified.

Data Types: double | cell

Output Arguments

exposures — 3-D array of credit exposures
array

3-D array of credit exposures representing the potential losses from each counterparty or contract at each date and over all scenarios. The size of exposures depends on the ExposureType input argument:

- When ExposureType is 'Counterparty', exposures returns a NumDates-by-NumCounterparties-by-NumScenarios "cube" of credit exposures representing potential losses that could be incurred over all dates, counterparties, and scenarios, if a counterparty defaulted (ignoring any post-default recovery).
- When ExposureType is 'Additive', exposures returns a NumDates-by-NumContracts-by-NumScenarios "cube," where each element is the additive exposure of each contract (over all dates and scenarios). Additive exposures sum to the counterparty-level exposure.

exposurecpty — Counterparties that correspond to columns of exposures array
vector

Counterparties that correspond to columns of the exposures array, returned as NumCounterparties or NumContracts elements depending on the ExposureType.

`collateral` — Simulated collateral amounts available to counterparties at each simulation date and over each scenario
3D array

Simulated collateral amounts available to counterparties at each simulation date and over each scenario, returned as a `NumDates`-by-`NumCounterparties`-by-`NumScenarios` 3D array. Collateral amounts are calculated using a Brownian bridge to estimate contract values between simulation dates. For more information, see “Brownian Bridge” on page 15-596. If the `CollateralTable` was not specified, this output is empty.

More About

Brownian Bridge

A Brownian bridge is used to simulate portfolio values at intermediate dates to compute collateral available at the subsequent simulation dates.

For example, to estimate collateral available at a particular simulation date, t_i, you need to know the state of the portfolio at time t_i – *dt*, where *dt* is the margin period of risk. Portfolio values are simulated at these intermediate dates by drawing from a distribution defined by the Brownian bridge between t_i and the previous simulation date, t_{i-1}.

If the contract values at time $t_{i\ -1}$ and t_i are known and you want to estimate the contract value at time t_c (where t_c is t_i – *dt*), then a sample from a normal distribution is used with variance:

$$\frac{(t_i - t_c)(t_c - t_{i-1})}{(t_i - t_{i-1})}$$

and with mean that is simply the linear interpolation of the contract values between the two simulation dates at time t_c. For more details, see References.

exposureprofiles

Compute exposure profiles from credit exposures

Syntax

```
profilestructs = exposureprofiles(dates,exposures)
profilestructs = exposureprofiles( ___ ,Name,Value)
```

Description

`profilestructs = exposureprofiles(dates,exposures)` computes common counterparty credit exposures profiles from an array of exposures.

`profilestructs = exposureprofiles( ___ ,Name,Value)` adds optional name-value arguments.

Examples

View Exposure Profiles of a Particular Counterparty

After computing the mark-to-market contract values for a portfolio of swaps over many scenarios, view the exposure profiles of a particular counterparty.

Load the data (`ccr.mat`) that contains the mark-to-market contract values for a portfolio of swaps over many scenarios.

```
load ccr.mat
```

Compute the exposure by counterparty.

```
[exposures, expcpty] = creditexposures(values,swaps.Counterparty,...
'NettingID',swaps.NettingID);
```

Compute the credit exposure profiles for all counterparties.

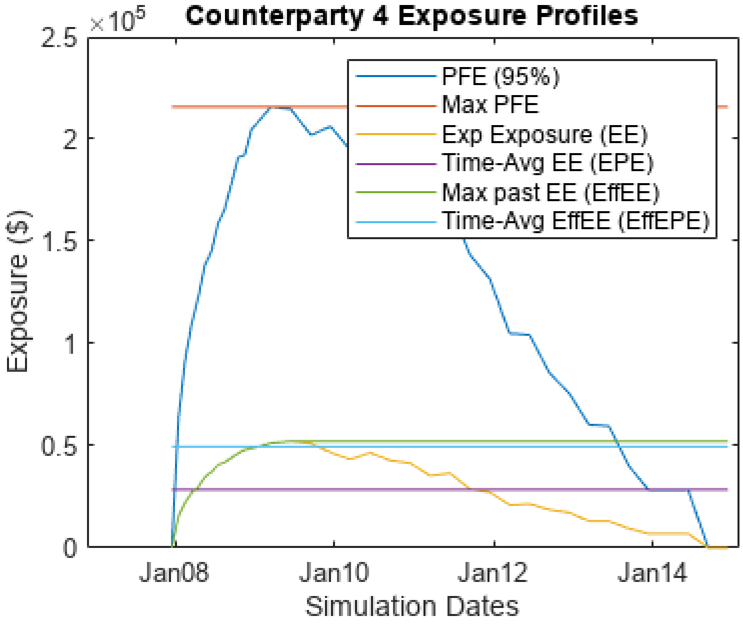
```
 cpProfiles = exposureprofiles(simulationDates,exposures)
```

```
cpProfiles=5×1 struct array with fields:
    Dates
    EE
    PFE
    MPFE
    EffEE
    EPE
    EffEPE
```

Visualize the exposure profiles for a particular counterparty.

```
cpIdx = find(expcpty == 4);
numDates = numel(simulationDates);
```

```
plot(simulationDates,cpProfiles(cpIdx).PFE,...
        simulationDates,cpProfiles(cpIdx).MPFE * ones(numDates,1),...
        simulationDates,cpProfiles(cpIdx).EE,...
        simulationDates,cpProfiles(cpIdx).EPE * ones(numDates,1),...
        simulationDates,cpProfiles(cpIdx).EffEE,...
        simulationDates,cpProfiles(cpIdx).EffEPE * ones(numDates,1));
legend({'PFE (95%)','Max PFE','Exp Exposure (EE)',...
        'Time-Avg EE (EPE)','Max past EE (EffEE)',...
        'Time-Avg EffEE (EffEPE)'})
datetick('x','mmmyy','keeplimits')
title(sprintf('Counterparty %d Exposure Profiles',cpIdx));
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```



Input Arguments

dates — Simulation dates

vector of date numbers | cell array of character vectors

Simulation dates, specified as vector of date numbers or a cell array of character vectors in a known date format. For more information for known date formats, see the function `datenum`.

Data Types: `double` | `char` | `cell`

exposures — 3-D array of potential losses due to counterparty default

array

3-D array of potential losses due to counterparty default on a set of instruments simulated over a series of simulation dates and across many scenarios, specified as a `NumDates`-by-`NumCounterParties`-by-`NumScenarios` “cube” of credit exposures. Each row represents a different simulation date, each column a different counterparty, and each “page” is a different scenario from a Monte-Carlo simulation.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `profilestructs = exposureprofiles(dates,exposures,'ProfileSpec','PFE','PFEProbabilityLevel',.9)`

`ProfileSpec` — Exposure profiles

`All` (generate all profiles) (default) | character vector with possible values `EE`, `PFE`, `MPE`, `EffEE`, `EPE`, `EffEPE`, `All` | cell array of character vectors with possible values `EE`, `PFE`, `MPE`, `EffEE`, `EPE`, `EffEPE`

Exposure profiles, specified as a character vector or cell array of character vectors with the following possible values:

- `EE` — Expected Exposure. The mean of the distribution of exposures at each date. A `[NumDates-by-1]` vector.
- `PFE` — Potential Future Exposure. A high percentile (default 95%) of the distribution of possible exposures at each date. This is sometimes referred to as “Peak Exposure.” A `[NumDates-by-1]` vector.
- `MPFE` — Maximum Potential Future Exposure. The maximum potential future exposure (PFE) over all dates
- `EffEE` — Effective Expected Exposure. The maximum expected exposure (at a specific date) that occurs at that date or any prior date. This is the expected exposure, but constrained to be nondecreasing over time. A `[NumDates-by-1]` vector.
- `EPE` — Expected Positive Exposure. The weighted average over time of expected exposures. A scalar.
- `EffEPE` — Effective Expected Positive Exposure. The weighted average over time of the effective expected exposure (EffEE). A scalar.
- `All` — Generate all the previous profiles.

Note Exposure profiles are computed on a per-counterparty basis.

Data Types: `char` | `cell`

`PFEProbabilityLevel` — Level for potential future exposure (PFE) and maximum potential future exposure (MPFE)

`.95` (the 95th percentile) (default) | scalar with value `[0..1]`

Level for potential future exposure (PFE) and maximum potential future exposure (MPFE), specified as a scalar with value `[0..1]`.

Data Types: `double`

Output Arguments

`profilestructs` — Structure of credit exposure profiles
array of structs holding credit exposure profiles for each counterparty

Structure of credit exposure profiles, returned as an array of structs holding credit exposure profiles for each counterparty, returned as a struct, with the fields of the struct as the (abbreviated) names of every exposure profile. Profiles listed in the `ProfileSpec` (and their related profiles) are populated, while those not requested contain empty (`[]`). `profilestructs` contains the `dates` information as a vector of MATLAB date numbers requested in the `ProfileSpec` argument.

cdyield

Yield on certificate of deposit (CD)

Syntax

```
Yield = cdyield(Price,CouponRate,Settle,Maturity,IssueDate)
Yield = cdyield( ___ ,Basis)
```

Description

`Yield = cdyield(Price,CouponRate,Settle,Maturity,IssueDate)` computes the yield to maturity of a certificate of deposit given its clean price.

`cdyield` assumes that the certificates of deposit pay interest at maturity. Because of the simple interest treatment of these securities, this function is best used for short-term maturities (less than 1 year). The default simple interest calculation uses the `Basis` for the actual/360 convention (2).

`Yield = cdyield( ___ ,Basis)` adds an optional argument for `Basis`.

Examples

Compute the Yield to Maturity of a Certificate of Deposit

This example shows how to compute the yield on the certificate of deposit (CD), given a CD with the following characteristics.

```
Price      = 101.125;
CouponRate = 0.05;
Settle     = '02-Jan-02';
Maturity   = '31-Mar-02';
IssueDate = '1-Oct-01';

Yield = cdyield(Price, CouponRate, Settle, Maturity, IssueDate)
```

```
Yield = 0.0039
```

Compute the Yield to Maturity of a Certificate of Deposit Using datetime Inputs

This example shows how to use `datetime` inputs to compute the yield on the certificate of deposit (CD), given a CD with the following characteristics.

```
Price      = 101.125;
CouponRate = 0.05;
Settle     = datetime('02-Jan-02','Locale','en_US');
Maturity   = datetime('31-Mar-02','Locale','en_US');
IssueDate = datetime('1-Oct-01','Locale','en_US');

Yield = cdyield(Price, CouponRate, Settle, Maturity, IssueDate)
Yield = 0.0039
```

Input Arguments

`Price` — Clean price of certificate of deposit per $100 face

numeric

Clean price of the certificate of deposit per $100 face, specified as a numeric value using a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector.

Data Types: `double`

`CouponRate` — Coupon annual interest rate

decimal

Coupon annual interest rate, specified as decimal using a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector.

Data Types: `double`

`Settle` — Settlement date of certificate of deposit

datetime array | string array | date character vector

Settlement date of the certificate of deposit, specified as a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `cdyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of certificate of deposit

datetime array | string array | date character vector

Maturity date of the certificate of deposit, specified as a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `cdyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`IssueDate` — Issue date for certificate of deposit

datetime array | string array | date character vector

Issue date for the certificate of deposit, specified as a scalar or a `NCDS`-by-`1` or `1`-by-`NCDS` vector using a datetime array, string array, or date character vectors.

To support existing code, `cdyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `string` | `char` | `datetime`

`Basis` — Day-count basis for certificate of deposit

`2` (actual/360) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

(Optional) Day-count basis for the certificate of deposit, specified as a scalar or a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

Output Arguments

Yield — Simple yield to maturity of certificate of deposit
numeric

Simple yield to maturity of the certificate of deposit, returned as a NCDS-by-1 or 1-by-NCDS vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although cdyield supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cfamounts

Cash flow and time mapping for bond portfolio

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: Period, Basis, EndMonthRule, IssueDate,FirstCouponDate, LastCouponDate, StartDate,Face, AdjustCashFlowsBasis, BusinessDayConvention, CompoundingFrequency, DiscountBasis, Holidays, and PrincipalType.

Syntax

```
[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts(
CouponRate,Settle,Maturity)
[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts(___,
Name,Value)
```

Description

[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts(CouponRate,Settle,Maturity) returns matrices of cash flow amounts, cash flow dates, time factors, and cash flow flags for a portfolio of NUMBONDS fixed-income securities.

The elements contained in the cfamounts outputs for the cash flow matrix, time factor matrix, and cash flow flag matrix correspond to the cash flow dates for each security. The first element of each row in the cash flow matrix is the accrued interest payable on each bond. This accrued interest is zero in the case of all zero coupon bonds. cfamounts determines all cash flows and time mappings for a bond whether or not the coupon structure contains odd first or last periods. All output matrices are padded with NaNs as necessary to ensure that all rows have the same number of elements.

[CFlowAmounts,CFlowDates,TFactors,CFlowFlags,CFPrincipal] = cfamounts(___, Name,Value) adds optional name-value arguments.

Examples

Compute the Cash Flow Structure and Time Factors for a Bond Portfolio

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually.

```
Settle = '01-Nov-1993';
Maturity = ['15-Dec-1994';'15-Jun-1995'];
CouponRate= [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate,Settle, Maturity, Period, Basis)
```

```
CFlowAmounts = 2×6

   -0.7667    1.5000    1.5000    1.5000    1.5000  101.5000
   -1.8989    2.5000    2.5000    2.5000  102.5000       NaN

CFlowDates = 2×6

      728234      728278      728368      728460      728552      728643
      728234      728278      728460      728643      728825         NaN

TFactors = 2×6

         0    0.2404    0.7403    1.2404    1.7403    2.2404
         0    0.2404    1.2404    2.2404    3.2404       NaN

CFlowFlags = 2×6

     0     3     3     3     3     4
     0     3     3     3     4   NaN
```

Compute the Cash Flow Structure and Time Factors for a Bond Portfolio and Return a datetime array for `CFlowDates`

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually and `CFlowDates` is returned as a datetime array.

```
Settle = datetime(1993,11,1);
Maturity = [datetime(1994,12,15) ; datetime(1995,6,15)];
CouponRate= [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = cfamounts(CouponRate,...
Settle, Maturity, Period, Basis)
```

```
CFlowAmounts = 2×6

   -0.7667    1.5000    1.5000    1.5000    1.5000  101.5000
   -1.8989    2.5000    2.5000    2.5000  102.5000       NaN

CFlowDates = 2x6 datetime
   01-Nov-1993   15-Dec-1993   15-Mar-1994   15-Jun-1994   15-Sep-1994   15-Dec-1994
   01-Nov-1993   15-Dec-1993   15-Jun-1994   15-Dec-1994   15-Jun-1995   NaT

TFactors = 2×6

         0    0.2404    0.7403    1.2404    1.7403    2.2404
         0    0.2404    1.2404    2.2404    3.2404       NaN
```

```
CFlowFlags = 2×6

     0     3     3     3     3     4
     0     3     3     3     4   NaN
```

Compute the Cash Flow Structure and Time Factors for a Bond Portfolio Using Optional Name-Value Pairs

This example shows how to compute the cash flow structure and time factors for a bond portfolio that contains a corporate bond paying interest quarterly and a Treasury bond paying interest semiannually. This example uses the following Name-Value pairs for `Period`, `Basis`, `BusinessDayConvention`, and `AdjustCashFlowsBasis`.

```
Settle = '01-Jun-2010';
Maturity = ['15-Dec-2011';'15-Jun-2012'];
CouponRate= [0.06; 0.05];
Period = [4; 2];
Basis = [1; 0];

[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate,Settle, Maturity, 'Period',Period, ...
'Basis', Basis, 'AdjustCashFlowsBasis', true,...
'BusinessDayConvention','modifiedfollow')
```

```
CFlowAmounts = 2×8

   -1.2667    1.5000    1.5000    1.5000    1.5000    1.5000    1.5000  101.5000
   -2.3077    2.4932    2.5068    2.4932    2.5000  102.5000       NaN       NaN

CFlowDates = 2×8

      734290      734304      734396      734487      734577      734669      734761      734852
      734290      734304      734487      734669      734852      735035         NaN         NaN

TFactors = 2×8

         0    0.0778    0.5778    1.0778    1.5778    2.0778    2.5778    3.0778
         0    0.0769    1.0769    2.0769    3.0769    4.0769       NaN       NaN

CFlowFlags = 2×8

     0     3     3     3     3     3     3     4
     0     3     3     3     3     4   NaN   NaN
```

Use `cfamounts` With a CouponRate Schedule

This example shows how to use `cfamounts` with a `CouponRate` schedule. For `CouponRate` and `Face` that change over the life of the bond, schedules for `CouponRate` and `Face` can be specified with an NINST-by-1 cell array, where each element is a NumDates-by-2 matrix where the first column is dates and the second column is associated rates.

```
CouponSchedule = {[datenum('15-Mar-2012') .04;datenum('15- Mar -2013') .05;...
datenum('15- Mar -2015') .06]}
```

```
CouponSchedule = 1x1 cell array
    {3x2 double}
```

```
cfamounts(CouponSchedule,'01-Mar-2011','15-Mar-2015' )
```

```
ans = 1×10

   -1.8453    2.0000    2.0000    2.0000    2.5000    2.5000    3.0000    3.0000    3.0000  103.0
```

Use cfamounts With a Face Schedule

This example shows how to use cfamounts with a Face schedule. For CouponRate and Face that change over the life of the bond, schedules for CouponRate and Face can be specified with an NINST-by-1 cell array, where each element is a NumDates-by-2 matrix where the first column is dates and the second column is associated rates.

```
FaceSchedule = {[datenum('15-Mar-2012') 100;datenum('15- Mar -2013') 90;...
datenum('15- Mar -2015') 80]}
```

```
FaceSchedule = 1x1 cell array
    {3x2 double}
```

```
cfamounts(.05,'01-Mar-2011','15-Mar-2015', 'Face', FaceSchedule)
```

```
ans = 1×10

   -2.3066    2.5000    2.5000   12.5000    2.2500   12.2500    2.0000    2.0000    2.0000   82.0
```

Use cfamounts to Generate the Cash Flows for a Sinking Bond

This example shows how to use cfamounts to generate the cash flows for a sinking bond.

```
[CFlowAmounts,CFDates,TFactors,CFFlags,CFPrincipal] = cfamounts(.05,'04-Nov-2010',...
{'15-Jul-2014';'15-Jul-2015'},'Face',{[datenum('15-Jul-2013') 100;datenum('15-Jul-2014')...
90;datenum('15-Jul-2015') 80]})
```

```
CFlowAmounts = 2×11

   -1.5217    2.5000    2.5000    2.5000    2.5000    2.5000   12.5000    2.2500   92.2500
   -1.5217    2.5000    2.5000    2.5000    2.5000    2.5000   12.5000    2.2500   12.2500    2.0
```

```
CFDates = 2×11
```

```
      734446      734518      734699      734883      735065      735249      735430      735614
      734446      734518      734699      734883      735065      735249      735430      735614

TFactors = 2×11

         0    0.3913    1.3913    2.3913    3.3913    4.3913    5.3913    6.3913    7.3913
         0    0.3913    1.3913    2.3913    3.3913    4.3913    5.3913    6.3913    7.3913    8.

CFFlags = 2×11

     0     3     3     3     3     3    13     3     4   NaN   NaN
     0     3     3     3     3     3    13     3    13     3     4

CFPrincipal = 2×11

     0     0     0     0     0     0    10     0    90   NaN   NaN
     0     0     0     0     0     0    10     0    10     0    80
```

Input Arguments

`CouponRate` — Annual percentage rate used to determine coupons payable on a bond
decimal

Annual percentage rate used to determine the coupons payable on a bond, specified as decimal using a scalar or a `NBONDS`-by-`1` vector.

`CouponRate` is `0` for zero coupon bonds.

Note `CouponRate` and `Face` can change over the life of the bond. Schedules for `CouponRate` and `Face` can be specified with an `NBONDS`-by-`1` cell array, where each element is a `NumDates`-by-2 matrix or cell array, where the first column is dates (serial date numbers or character vectors) and the second column is associated rates. The date indicates the last day that the coupon rate or face value is valid. This means that the corresponding `CouponRate` and `Face` value applies "on or before" the specified ending date.

Data Types: `double` | `cell` | `char`

`Settle` — Settlement date of bond
datetime array | string array | date character vector

Settlement date of the bond, specified as a scalar or a `NBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `cfamounts` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of bond
datetime array | string array | date character vector

Maturity date of the bond, specified as a scalar or a NBONDS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cfamounts also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ... cfamounts(CouponRate,Settle, Maturity,'Period',4,'Basis',3,'AdjustCashFlowsBasis',true,'BusinessDayConvention','modifiedfollow')

Period — Number of coupon payments per year for bond

2 (default) | numeric with values 0, 1, 2, 3, 4, 6 or 12

Number of coupon payments per year for the bond, specified as the comma-separated pair consisting of 'Period' and a scalar or a NBONDS-by-1 vector using the values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

Basis — Day-count basis of bond

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the bond, specified as the comma-separated pair consisting of 'Basis' and a scalar or a NBONDS-by-1 vector using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar or a `NBONDS`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date (the date the bond begins to accrue interest), specified as the comma-separated pair consisting of `'IssueDate'` and a scalar or a `NBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. The `IssueDate` cannot be after the `Settle` date.

If you do not specify an `IssueDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `cfamounts` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — Irregular or normal first coupon date
datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or a `NBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

Note When `FirstCouponDate` and `LastCouponDate`

are both specified, the `FirstCouponDate` takes precedence in determining the coupon payment structure. If `FirstCouponDate` is not specified, then `LastCouponDate` determines the coupon structure of the bond.

To support existing code, `cfamounts` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Irregular or normal last coupon date
datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or a `NBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

Note When `FirstCouponDate` and `LastCouponDate` are both specified, the `FirstCouponDate` takes precedence in determining the coupon payment structure. If `FirstCouponDate` is not specified, then `LastCouponDate` determines the coupon structure of the bond.

To support existing code, `cfamounts` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`StartDate` — Forward starting date of coupon payments

datetime array | string array | date character vector

Forward starting date of coupon payments after the `Settle` date, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a `NBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

Note To make an instrument forward starting, specify `StartDate` as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

To support existing code, `cfamounts` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Face value of bond

`100` (default) | numeric

Face value of the bond, specified as the comma-separated pair consisting of `'Face'` and a scalar or a `NBONDS`-by-`1` vector.

Note `CouponRate` and `Face` can change over the life of the bond. Schedules for `CouponRate` and `Face` can be specified with an `NBONDS`-by-`1` cell array where each element is a `NumDates`-by-`2` matrix or cell array, where the first column is dates (serial date numbers or character vectors) and the second column is associated rates. The date indicates the last day that the coupon rate or face value is valid. This means that the corresponding `CouponRate` and `Face` value applies "on or before" the specified ending date.

When the corresponding `Face` value is used to compute the coupon cashflow on the specified ending date. Three things happen on the specified ending date:

1. The last coupon corresponding to the current `Face` value is paid.
2. The principal differential (between the current and the next `Face` value) is paid.
3. The date marks the beginning of the period with the next `Face` value, for which the cashflow does not occur until later.

Data Types: double | cell | char

AdjustCashFlowsBasis — Adjusts cash flows according to accrual amount based on actual period day count
false (default) | logical with a value of true or false

Adjusts cash flows according to the accrual amount based on the actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a scalar or a NBONDS-by-1 vector.

Data Types: logical

BusinessDayConvention — Business day conventions
'actual' (default) | character vector with values'actual', 'follow', 'modifiedfollow', 'previous'or 'modifiedprevious'

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar or NBONDS-by-1 cell array of character vectors of business day conventions to be used in computing payment dates. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

CompoundingFrequency — Compounding frequency for yield calculation
SIA uses2, ICMA uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of 'CompoundingFrequency' and a scalar or a NBONDS-by-1 vector. Values are:

- 1 — Annual compounding
- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

Note By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Data Types: double

DiscountBasis — Basis used to compute the discount factors for computing the yield

SIA uses 0 (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of 'DiscountBasis' and a scalar or a NBONDS-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If a SIA day-count basis is defined in the Basis input argument and there is no value assigned for DiscountBasis, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the Basis input argument and there is no value assigned for DiscountBasis, the specified bases from the Basis input argument are used.

Data Types: double

Holidays — Dates for holidays

holidays.m used (default) | datetime array | string array | date character vector

Dates for holidays, specified as the comma-separated pair consisting of 'Holidays' and a NHOLIDAYS-by-1 vector using a datetime array, string array, or date character vectors. Holidays are used in computing business days.

To support existing code, cfamounts also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

PrincipalType — Type of principal when a Face schedule is specified

sinking (default) | character vector with values 'sinking' or 'bullet'

Type of principal when a Face schedule, specified as the comma-separated pair consisting of 'PrincipalType' and a value of 'sinking' or 'bullet' using a scalar or a NBONDS-by-1 vector.

If 'sinking', principal cash flows are returned throughout the life of the bond.

If 'bullet', principal cash flow is only returned at maturity.

Data Types: char | cell

Output Arguments

CFlowAmounts — Cash flow amounts

matrix

Cash flow amounts, returned as a NBONDS-by-NCFS (number of cash flows) matrix. The first entry in each row vector is the accrued interest due at settlement. This amount could be zero, positive or negative. If no accrued interest is due, the first column is zero. If the bond is trading ex-coupon then the accrued interest is negative.

CFlowDates — Cash flow dates for a portfolio of bonds

matrix

Cash flow dates for a portfolio of bonds, returned as a NBONDS-by-NCFS matrix. Each row represents a single bond in the portfolio. Each element in a column represents a cash flow date of that bond.

If all the above inputs (Settle, Maturity, IssueDate, FirstCouponDate, LastCouponDate, and StartDate) are either strings s or date character vectors, then CFlowDates is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors. If any of these inputs are datetime arrays, then CFlowDates is returned as a datetime array.

TFactors — Matrix of time factors for a portfolio of bonds

matrix

Matrix of time factors for a portfolio of bonds, returned as a NBONDS-by-NCFS matrix. Each row corresponds to the vector of time factors for each bond. Each element in a column corresponds to the specific time factor associated with each cash flow of a bond.

Time factors are for price/yield conversion and time factors are in units of whole semiannual coupon periods plus any fractional period using an actual day count. For more information on time factors, see “Time Factors” on page 15-617.

CFlowFlags — Cash flow flags for a portfolio of bonds

matrix

Cash flow flags for a portfolio of bonds, returned as a NBONDS-by-NCFS matrix. Each row corresponds to the vector of cash flow flags for each bond. Each element in a column corresponds to the specific flag associated with each cash flow of a bond. Flags identify the type of each cash flow (for example, nominal coupon cash flow, front, or end partial, or "stub" coupon, maturity cash flow).

Flag	Cash Flow Type
`0`	Accrued interest due on a bond at settlement.
`1`	Initial cash flow amount smaller than normal due to a “stub” coupon period. A stub period is created when the time from issue date to first coupon date is shorter than normal.
`2`	Larger than normal initial cash flow amount because the first coupon period is longer than normal.
`3`	Nominal coupon cash flow amount.
`4`	Normal maturity cash flow amount (face value plus the nominal coupon amount).
`5`	End “stub” coupon amount (last coupon period is abnormally short and actual maturity cash flow is smaller than normal).
`6`	Larger than normal maturity cash flow because the last coupon period longer than normal.
`7`	Maturity cash flow on a coupon bond when the bond has less than one coupon period to maturity.
`8`	Smaller than normal maturity cash flow when the bond has less than one coupon period to maturity.
`9`	Larger than normal maturity cash flow when the bond has less than one coupon period to maturity.
`10`	Maturity cash flow on a zero coupon bond.
`11`	Sinking principal and initial cash flow amount smaller than normal due to a "stub" coupon period. A stub period is created when the time from issue date to first coupon date is shorter than normal.
`12`	Sinking principal and larger than normal initial cash flow amount because the first coupon period is longer than normal.
`13`	Sinking principal and nominal coupon cash flow amount.

`CFPrincipal` — Principal cash flows
matrix

Principal cash flows, returned as a `NBONDS`-by-`NCFS` matrix.

If `PrincipalType` is `'sinking'`, `CFPrincipal` output indicates when the principal is returned.

If `PrincipalType` is `'bullet'`, `CFPrincipal` is all zeros and, at `Maturity`, the appropriate `Face` value.

More About

Time Factors

Time factors help determine the present value of a stream of cash flows.

The term time factors refer to the exponent *TF* in the discounting equation

$$PV = \sum_{i=1}^{n}\left(\frac{CF}{(1+\frac{z}{f})^{TF}}\right),$$

where:

PV =	Present value of a cash flow.
CF =	Cash flow amount.
z =	Risk-adjusted annualized rate or yield corresponding to a given cash flow. The yield is quoted on a semiannual basis.
f =	Frequency of quotes for the yield. Default is `2` for `Basis` values `0` to `7` and `13` and `1` for `Basis` values `8` to `12`. The default can be overridden by specifying the `CompoundingFrequency` name-value pair.
TF =	Time factor for a given cash flow. The time factor is computed using the compounding frequency and the discount basis. If these values are not specified, then the defaults are as follows: `CompoundingFrequency` default is `2` for `Basis` values `0` to `7` and `13` and `1` for `Basis` values `8` to `12`. `DiscountBasis` is `0` for `Basis` values `0` to `7` and `13` and the value of the input `Basis` for `Basis` values `8` to `12`.

Note The `Basis` is always used to compute accrued interest.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `cfamounts` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

cfconv

Cash flow convexity

Syntax

```
CFlowConvexity = cfconv(CashFlow,Yield)
```

Description

`CFlowConvexity = cfconv(CashFlow,Yield)` returns the convexity of a cash flow in periods.

Examples

Compute the Convexity of a Cash Flow

This example shows how to return the convexity of a cash flow, given a cash flow of nine payments of $2.50 and a final payment $102.50, with a periodic yield of 2.5%.

```
CashFlow = [2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];
```

```
Convex = cfconv(CashFlow, 0.025)
```

```
Convex = 90.4493
```

Input Arguments

`CashFlow` — Cash flow
vector of real numbers

Cash flow, specified as a vector of real numbers.

Data Types: `double`

`Yield` — Periodic yield
scalar decimal

Periodic yield, specified as a scalar decimal.

Data Types: `double`

Output Arguments

`CFlowConvexity` — Convexity
scalar

Convexity returned as a scalar.

cfdates

Cash flow dates for fixed-income security

Syntax

```
CFlowDates = cfdates(Settle,Maturity)
CFlowDates = cfdates( ___ ,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,
LastCouponDate)
```

Description

CFlowDates = cfdates(Settle,Maturity) generates a matrix of actual cash flow payment dates for NUMBONDS fixed income securities. All cash flow dates are determined regardless of whether the first and last coupon periods are normal, long or short.

CFlowDates = cfdates(___ ,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate, LastCouponDate) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Obtain Cash Flow Dates for Fixed-Income Security

Compute the cash flow dates given the Settle and Maturity dates.

```
CFlowDates = cfdates('14 Mar 1997', '30 Nov 1998', 2, 0, 1)
```

```
CFlowDates = 1×4

      729541      729724      729906      730089
```

```
datestr(CFlowDates)
```

```
ans = 4x11 char array
    '31-May-1997'
    '30-Nov-1997'
    '31-May-1998'
    '30-Nov-1998'
```

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, or LastCouponDate are datetime arrays, then CFlowDates is returned as a datetime array. For example:

```
CFlowDates = cfdates('14-Mar-1997', datetime('30-Nov-1998','Locale','en_US'), 2, 0, 1)
```

```
CFlowDates = 1x4 datetime
   31-May-1997   30-Nov-1997   31-May-1998   30-Nov-1998
```

Given three securities with different maturity dates and the same default arguments:

```
Maturity = ['30-Sep-1997'; '31-Oct-1998'; '30-Nov-1998'];
CFlowDates = cfdates('14-Mar-1997', Maturity)
```

```
CFlowDates = 3×4

      729480      729663         NaN         NaN
      729510      729694      729875      730059
      729541      729724      729906      730089
```

To look at the cash-flow dates for the last security:

```
datestr(CFlowDates(3,:))
```

```
ans = 4x11 char array
    '31-May-1997'
    '30-Nov-1997'
    '31-May-1998'
    '30-Nov-1998'
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `cfdates` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cfdates` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Period` — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

(Optional) Coupons per year of the bond, specified as a vector of positive integers from the set `[1,2,3,4,6,12]`.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

(Optional) Day-count basis, specified as positive integers using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

EndMonthRule — End-of-month rule flag
1 (in effect) (default) | nonnegative integer 0 or 1

(Optional) End-of-month rule flag, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date
cash flow payment dates are determined from other inputs (default) | datetime array | string array | date character vector

(Optional) Bond Issue date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

To support existing code, cfdates also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Irregular or normal first coupon date
cash flow payment dates are determined from other inputs (default) | datetime array | string array | date character vector

Irregular or normal first coupon date, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `cfdates` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Irregular or normal last coupon date
cash flow payment dates are determined from other inputs (default) | datetime array | string array | date character vector

Irregular or normal last coupon date, specified as a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors.

If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `cfdates` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Output Arguments

`CFlowDates` — Actual cash flow payment dates
matrix

Actual cash flow payment dates, returned as a `N`-row matrix of dates in datetime format (if inputs are in datetime format). `CFlowDates` has `NUMBONDS` rows and the number of columns is determined by the maximum number of cash flow payment dates required to hold the bond portfolio. `NaN`s are padded for bonds which have less than the maximum number of cash flow payment dates.

If all of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, or `LastCouponDate` are either strings or date character vectors, then `CFlowDates` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, or `LastCouponDate` are datetime arrays, then `CFlowDates` is returned as a datetime array.

Note The cash flow flags for a portfolio of bonds were formerly available as the `cfdates` second output argument, `CFlowFlags`. You can now use `cfamounts` to get these flags. If you specify a `CFlowFlags` argument, `cfdates` displays a message directing you to use `cfamounts`.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although cfdates supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cfdatesq

Quasi-coupon dates for fixed-income security

Syntax

```
QuasiCouponDates = cfdatesq(Settle,Maturity)
QuasiCouponDates = cfdatesq(___,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,PeriodsBeforeSettle,PeriodsAfterMaturity)
```

Description

`QuasiCouponDates = cfdatesq(Settle,Maturity)` returns a matrix of quasi-coupon dates expressed in datetime format (if any inputs are in datetime format).

Successive quasi-coupon dates determine the length of the standard coupon period for the fixed-income security of interest, and do not necessarily coincide with actual coupon payment dates. Quasi-coupon dates are determined regardless of whether the first or last coupon periods are normal, long, or short.

`QuasiCouponDates` has `NUMBONDS` rows and the number of columns is determined by the maximum number of quasi-coupon dates required to hold the bond portfolio. `NaN`s are padded for bonds which have less than the maximum number quasi-coupon dates. By default, quasi-coupon dates after settlement and on or preceding maturity are returned. If settlement occurs on maturity, and maturity is a quasi-coupon date, then the maturity date is returned.

`QuasiCouponDates = cfdatesq(___,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate,PeriodsBeforeSettle,PeriodsAfterMaturity)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Obtain Quasi-Coupon Dates for Fixed-Income Security

Compute the quasi-coupon dates given the `Settle` and `Maturity` dates.

```
QuasiCouponDates = cfdatesq('14-Mar-1997', '30-Nov-1998', 2, 0, 1)
```

```
QuasiCouponDates = 1×4

      729541      729724      729906      730089
```

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, or `LastCouponDate` are datetime arrays, then `QuasiCouponDates` is returned as a datetime array. For example:

```
QuasiCouponDates = cfdatesq('14-Mar-1997', datetime('30-Nov-1998','Locale','en_US'), 2, 0, 1)
QuasiCouponDates = 1x4 datetime
   31-May-1997   30-Nov-1997   31-May-1998   30-Nov-1998
```

Input Arguments

Settle — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors. Settle must be earlier than Maturity.

To support existing code, cfdatesq also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Maturity — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cfdatesq also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1,2,3,4,6,12]

(Optional) Coupons per year of the bond, specified as a vector of positive integers from the set [1,2,3,4,6,12].

Data Types: double

Basis — Day-count basis

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

(Optional) Day-count basis, specified as positive integers using a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

EndMonthRule — End-of-month rule flag
1 (in effect) (default) | nonnegative integer 0 or 1

(Optional) End-of-month rule flag, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date
cash flow payment dates are determined from other inputs (default) | datetime array | string array | date character vector

(Optional) Bond Issue date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

To support existing code, cfdatesq also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Irregular or normal first coupon date
cash flow payment dates are determined from other inputs (default) | datetime array | string array | date character vector

Irregular or normal first coupon date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cfdatesq also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Irregular or normal last coupon date
cash flow payment dates are determined from other inputs (default) | datetime array | string array | date character vector

Irregular or normal last coupon date, specified as a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cfdatesq also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

PeriodsBeforeSettle — Number of quasi-coupon dates on or before settlement to include
0 (default) | nonnegative integer

(Optional) Number of quasi-coupon dates on or before settlement to include, specified as a nonnegative integer.

Data Types: double

PeriodsAfterMaturity — Number of quasi-coupon dates after maturity to include
0 (default) | nonnegative integer

(Optional) Number of quasi-coupon dates after maturity to include, specified as a nonnegative integer.

Data Types: double

Output Arguments

QuasiCouponDates — Quasi-coupon dates
matrix

Quasi-coupon dates, returned as a N-row matrix of dates in datetime format (if any inputs are in datetime format). QuasiCouponDates has NUMBONDS rows and the number of columns is determined by the maximum number of quasi-coupon dates required to hold the bond portfolio. NaNs are padded for bonds which have less than the maximum number quasi-coupon dates. By default, quasi-coupon dates after settlement and on or preceding maturity are returned. If settlement occurs on maturity, and maturity is a quasi-coupon date, then the maturity date is returned.

If all of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, or LastCouponDate are either strings or date character vectors, then QuasiCouponDates is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, or LastCouponDate are datetime arrays, then QuasiCouponDates is returned as a datetime array.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although cfdatesq supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Analyzing and Computing Cash Flows” on page 2-11

cfdur

Cash-flow duration and modified duration

Syntax

```
[Duration,ModDuration] = cfdur(CashFlow,Yield)
```

Description

`[Duration,ModDuration] = cfdur(CashFlow,Yield)` calculates the duration and modified duration of a cash flow in periods.

Examples

Compute the Duration and Modified Duration of a Cash Flow

This example shows how to calculate the duration and modified duration of a cash flow, given a cash flow of nine payments of $2.50 and a final payment $102.50, with a periodic yield of 2.5%.

```
CashFlow=[2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];
```

```
[Duration, ModDuration] = cfdur(CashFlow, 0.025)
```

```
Duration = 8.9709
```

```
ModDuration = 8.7521
```

Input Arguments

`CashFlow` — Cash flow
vector of real numbers | matrix of real numbers

Cash flow, specified as a vector or matrix of real numbers. When using a matrix, each column of the matrix is a separate `CashFlow`.

Data Types: `double`

`Yield` — Periodic yield
scalar decimal | vector of decimals

Periodic yield, specified as a scalar decimal or a vector of decimals.

Data Types: `double`

Output Arguments

`Duration` — Duration
vector

Duration returned as a scalar or vector.

`ModDuration` — Modified duration
vector

Modified duration, returned as a scalar or vector.

Version History

Introduced before R2006a

Topics

“Analyzing and Computing Cash Flows” on page 2-11

cfplot

Visualize cash flows of financial instruments

Syntax

```
cfplot(CFlowDates,CFlowAmounts)
cfplot(___,Name,Value)

h = cfplot(___,Name,Value)
[h,axes_handle] = cfplot(___,Name,Value)
```

Description

`cfplot(CFlowDates,CFlowAmounts)` plots a cash flow diagram for the specified cash flow amounts (`CFlowAmounts`) and dates (`CFlowDates`). The length and orientation of each arrow correspond to the cash flow amount.

`cfplot(___,Name,Value)` plots a cash flow diagram for the specified cash flow amounts (`CFlowAmounts`), dates (`CFlowDates`), and optional name-value pair arguments.

`h = cfplot(___,Name,Value)` returns the handle to the line objects used in the cash flow diagram.

`[h,axes_handle] = cfplot(___,Name,Value)` returns the handles to the line objects and the axes using optional name-value pair arguments.

Examples

Plot Cash Flows

Define `CFlowAmounts` and `CFlowDates` using the `cfamounts` function.

```
CouponRate = [0.06; 0.05; 0.03];
Settle = '03-Jun-1999';
Maturity = ['15-Aug-2000';'15-Dec-2000';'15-Jun-2000'];
Period = [1; 2; 2];  Basis = [1; 0; 0];
[CFlowAmounts, CFlowDates] = cfamounts(...
CouponRate, Settle, Maturity, Period, Basis)
```

```
CFlowAmounts = 3×5

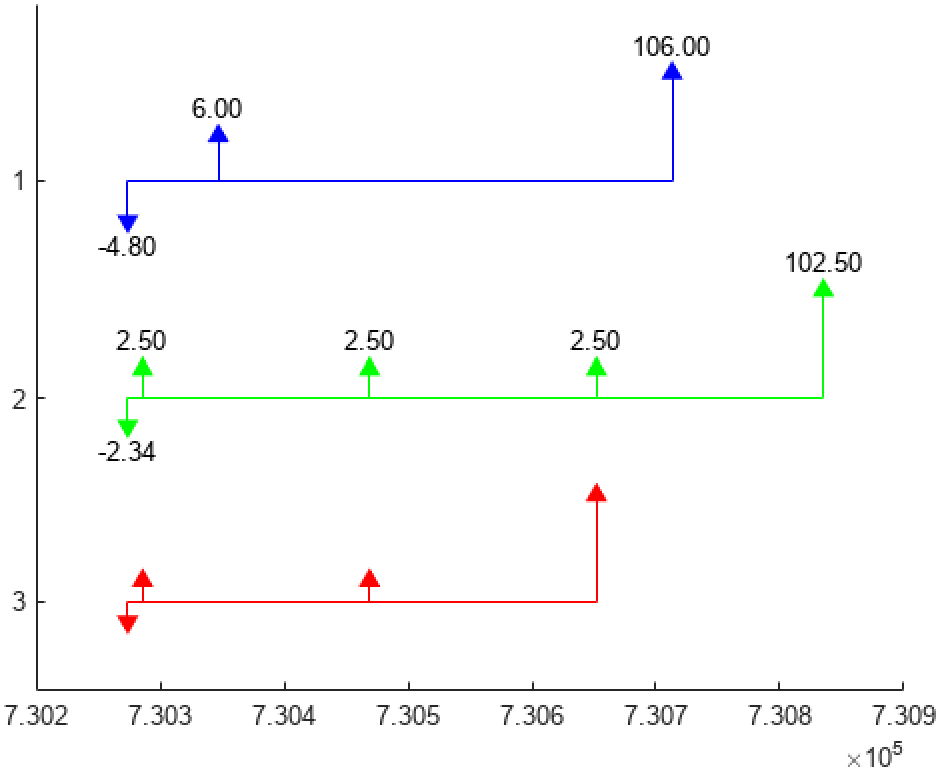
   -4.8000    6.0000  106.0000       NaN       NaN
   -2.3352    2.5000    2.5000    2.5000  102.5000
   -1.4011    1.5000    1.5000  101.5000       NaN

CFlowDates = 3×5

      730274      730347      730713         NaN         NaN
      730274      730286      730469      730652      730835
      730274        730286        730469        730652           NaN
```

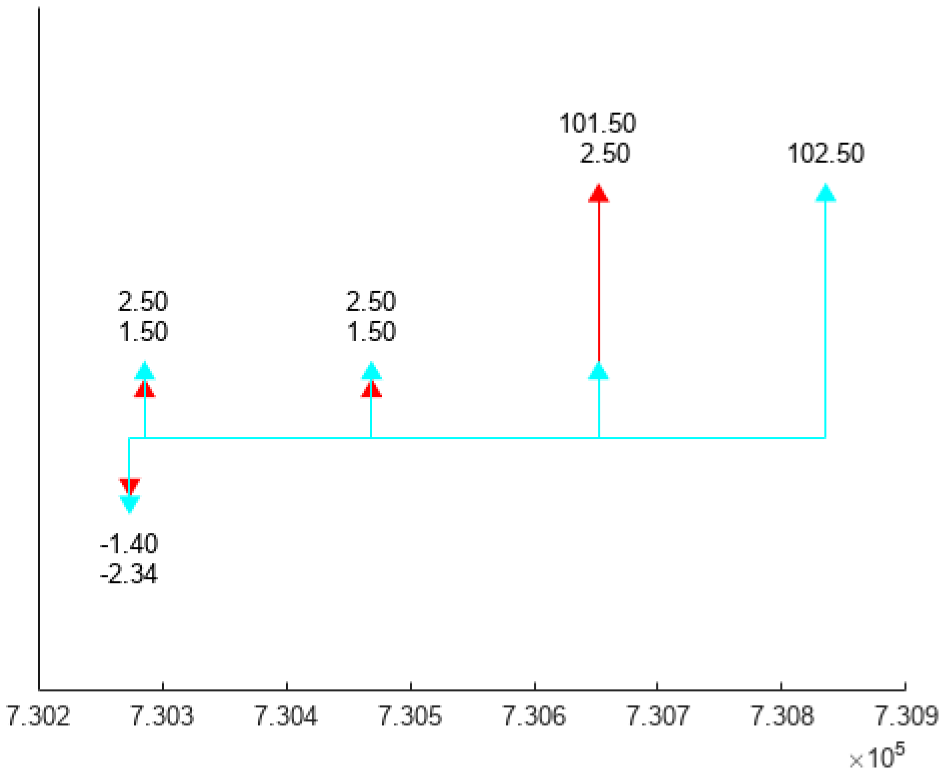
Plot all cash flows on the same axes, and label the first two.

```
cfplot(CFlowDates, CFlowAmounts, 'ShowAmnt', [1 2])
```



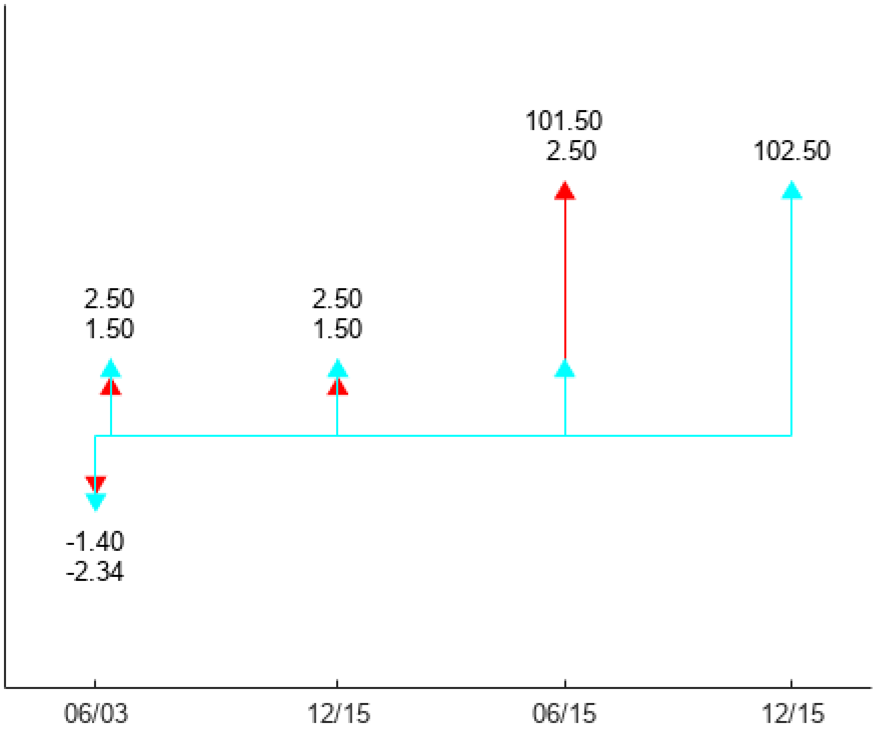
Group the second and third cash flows.

```
figure;
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmnt', 1);
```



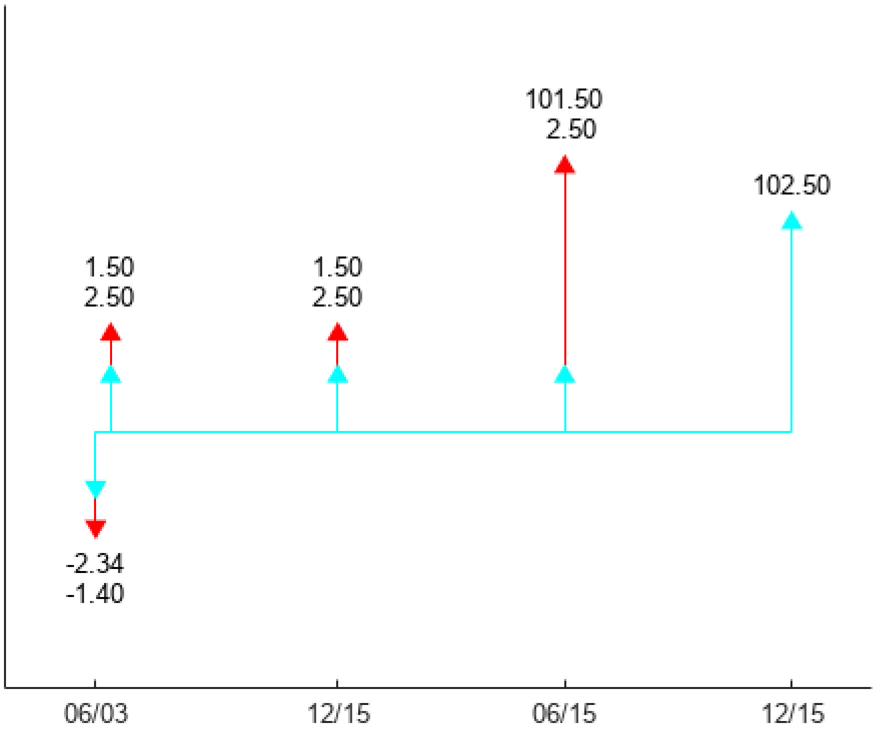
Format the date axis and place ticks on actual cash flow dates.

```
figure;
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmnt', 1, ...
'DateFormat', 6, 'DateSpacing', 100);
```



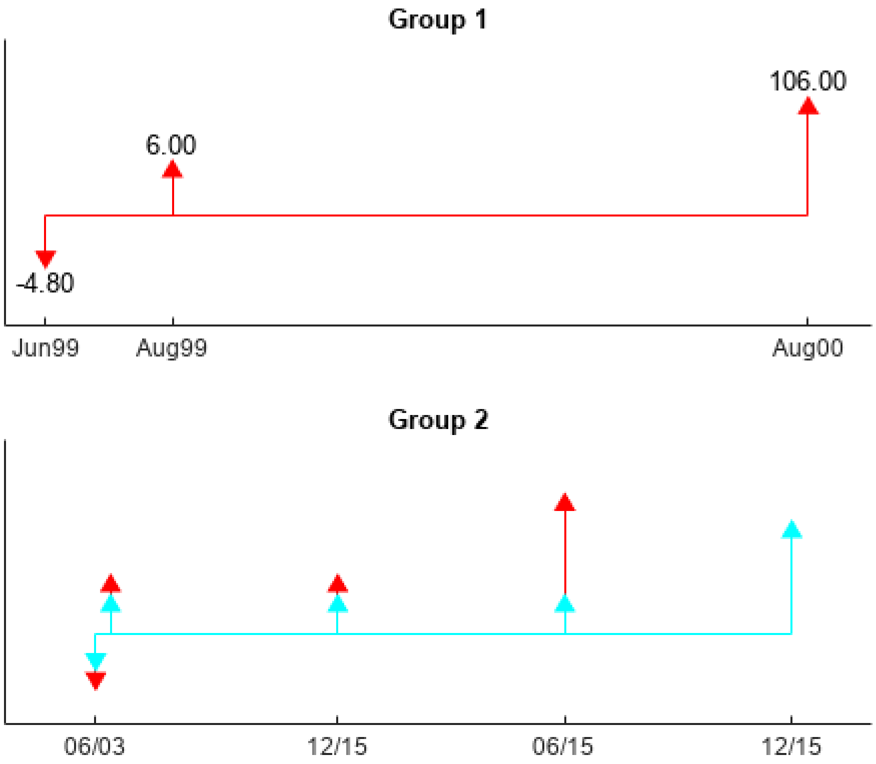
Stack the cash flow arrows occurring on the same dates.

```
figure;
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[2 3]}, 'ShowAmnt', 1, ...
'DateFormat', 6, 'DateSpacing', 100, 'Stacked', 1);
```



Form subplots of multiple groups and add titles using axes handles.

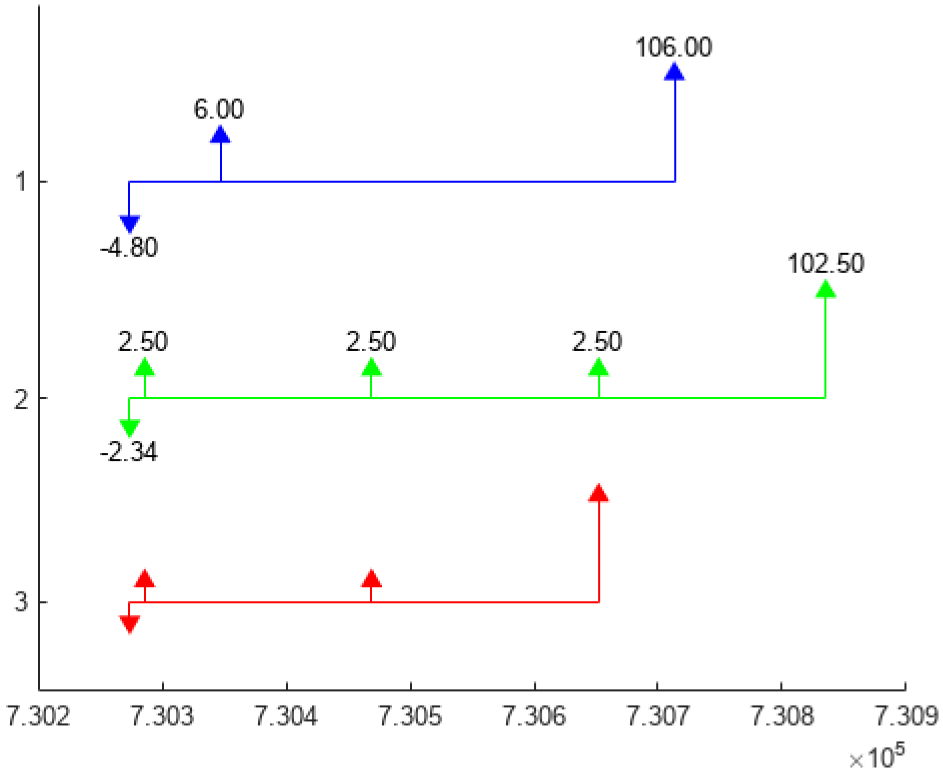
```
figure;
[h, axes_handle] = cfplot(CFlowDates, CFlowAmounts, ...
'Groups', {[1] [2 3]}, 'ShowAmnt', 1, 'Stacked', 2, ...
'DateSpacing', [1 60 2 100], 'DateFormat', [1 12 2 6]);
title(axes_handle(1), 'Group 1', 'FontWeight', 'bold');
title(axes_handle(2), 'Group 2', 'FontWeight', 'bold');
```



Plot Cash Flows Using datetime Input for CFlowDates

Define `CFlowDates` using `datetime` input and plot the cash flow.

```
CouponRate = [0.06; 0.05; 0.03];
Settle = '03-Jun-1999';
Maturity = ['15-Aug-2000';'15-Dec-2000';'15-Jun-2000'];
Period = [1; 2; 2];  Basis = [1; 0; 0];
[CFlowAmounts, CFlowDates] = cfamounts(...
CouponRate, Settle, Maturity, Period, Basis);
cfplot(datetime(CFlowDates,'ConvertFrom','datenum','Locale','en_US'), CFlowAmounts, 'ShowAmnt',
```



Plot Cash Flows for Swap

Define the swap using the swapbyzero function.

```
Settle = datetime(2010,6,8);
RateSpec = intenvset('Rates', [.005 .0075 .01 .014 .02 .025 .03]',...
'StartDates',Settle, 'EndDates',[datetime(2010,12,8),datetime(2011,6,8),datetime(2012,6,8),datet
Maturity = datenum('15-Sep-2020');
LegRate = [.025 50];
LegType = [1 0]; % fixed/floating
LatestFloatingRate = .005;
[Price, SwapRate, AI, RecCF, RecCFDates, PayCF,PayCFDates] = ...
swapbyzero(RateSpec, LegRate, Settle, Maturity,'LegType',LegType,...
'LatestFloatingRate',LatestFloatingRate)
```

```
Price = -6.7258

SwapRate = NaN

AI = 1.4575

RecCF = 1×12

   -1.8219    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5000    2.5
```

```
RecCFDates = 1×12

      734297       734396       734761       735127       735492       735857       736222       736588

PayCF = 1×12

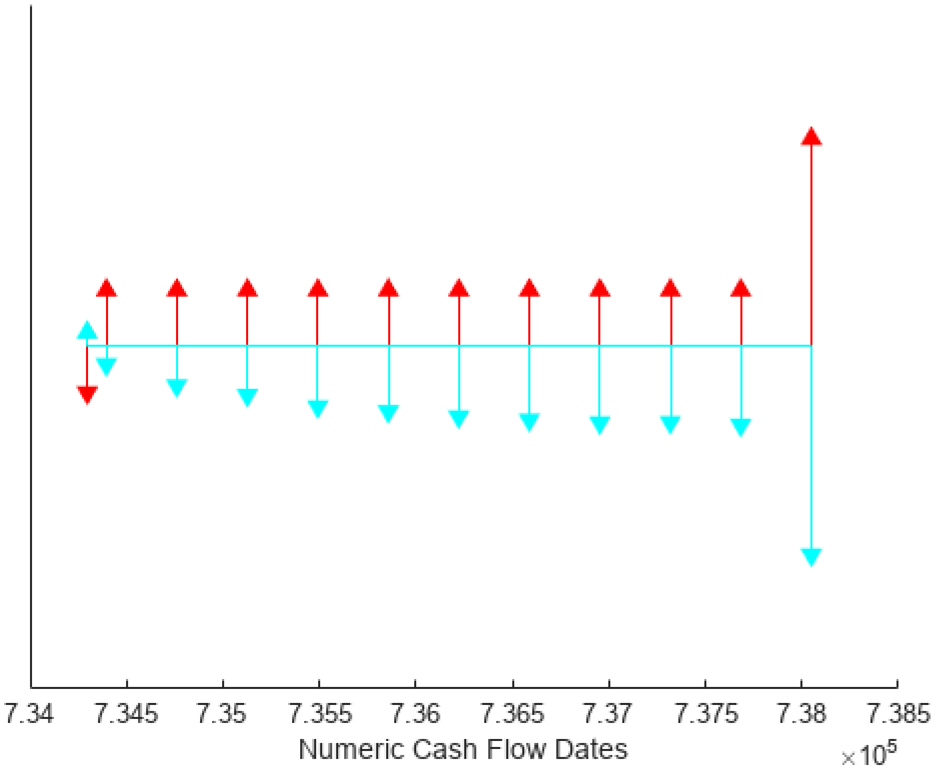
   -0.3644     0.5000     1.4048     1.9823     2.8436     3.2842     3.8218     4.1733     4.5164     4.4

PayCFDates = 1×12

      734297       734396       734761       735127       735492       735857       736222       736588
```

Define `CFlowDates` and `CFlowAmounts` for the swap and generate a cash flow plot using `cfplot`.

```
CFlowDates = [PayCFDates;RecCFDates];
CFlowAmounts = [-PayCF;RecCF];
cfplot(CFlowDates, CFlowAmounts, 'Groups', {[1 2]});
xlabel('Numeric Cash Flow Dates');
```



Input Arguments

`CFlowDates` — Matrix of dates for cash flows

vector

Matrix of datetime arrays for cash flows, specified as a NINST-by-(Number of cash flows) matrix of cash flow dates using datetime format, with empty entries padded with NaNs.

Each row of the CFlowDates matrix represents an instrument so that CFlowDates(k,:) is the vector of cash flow dates for the kth instrument. Rows are padded with trailing NaNs if the number of cash flows is not the same for all instruments.

cfamounts can be used to generate CFlowDates.

Data Types: datetime

CFlowAmounts — Matrix of cash flow amounts
vector

Matrix of cash flow amounts, specified as a NINST-by-(Number of cash flows) matrix of cash flow amounts, with empty entries padded with NaNs. The CFlowAmounts matrix must be the same size as CFlowDates.

cfamounts can be used to generate CFlowAmounts.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: cfplot(CFlowDates,CFlowAmounts,'Groups',{[2 3]},'ShowAmnt',1,'DateFormat',6,'DateSpacing',100)

Groups — Group cash flows
'off' (default) | character vector with value 'off' or 'individual' | cell array of character vectors

Group cash flows, specified as the comma-separated pair consisting of 'Groups' and the following values:

- 'off' — Show all instruments in one set of axes, arranged from top to bottom.
- 'individual' — Generate subplots and plot each instrument in its own axis.
- GRP — Cell array of instrument groups, {Group1, Group2,... }. This generates subplots and plots each group in each axis. When specifying {Group1, Group2,... }, each Group must be mutually exclusive vectors of INSTIndex. Unspecified instruments are not shown in the grouped plot.

Data Types: char | cell

Stacked — Stack arrows if cash flows are in same direction on same day
ignored when 'Groups' is 'off', otherwise 'off' (default) | character vector with values 'off', 'all', or 'GRPIndex'

Stack arrows if the cash flows are in the same direction on the same day, specified as the comma-separated pair consisting of 'Stacked' and the following values:

- 'off' — For all groups, all arrows originate from the horizontal line.
- 'all' — For all groups, arrows are stacked if the cash flows are in the same direction on the same day.
- 'GRPIndex' — For specified groups, arrows are stacked if the cash flows are in the same direction on the same day.

Data Types: char

ShowAmnt — Show amount on arrows

'off' (default) | character vector with values 'off' or 'individual' | cell array of character vectors

Show amount on the arrows, specified as the comma-separated pair consisting of 'ShowAmnt' and the following values:

- 'off' — Hide cash flow amounts on arrows.
- 'all' — Show cash flow amounts on arrows.
- [INSTIndex or GRPIndex] — Show cash flow amounts for the specified vector of instruments (when 'Groups' is 'off') or groups.

Data Types: char | cell

DateSpacing — Control for date axis tick spacing

'off' (default) | character vector with values 'off' or TickDateSpace | numeric value for TickDateSpace

Control for data spacing, specified as the comma-separated pair consisting of 'DateSpacing' and the following values:

- 'off' — The date axis ticks are spaced regularly.
- TickDateSpace — The date axis ticks are placed on actual cash flow dates. The ticks skip some cash flows if they are less than TickDateSpace apart.

Data Types: char | double

DateFormat — Date format

'off' (default) | character vector with values 'off' or DateFormNum | numeric value for DateFormNum

Date format, specified as the comma-separated pair consisting of 'DateFormat' and the following values:

- 'off' — The date axis tick labels are in date numbers.
- DateFormNum — The date format number (2 = 'mm/dd/yy', 6 = 'mm/dd', and 10 = 'yyyy'). Additional values for DateFormNum are as follows:

DateFormNum	Example
2	03/01/00
3	Mar
5	03
6	03/01

DateFormNum	Example
7	01
8	Wed
9	W
10	2000
11	00
12	Mar00
17	Q1–00
18	Q1
19	01/03
20	01/03/00
27	Q1–2000
28	Mar2000
29	2000–03–01

Data Types: char | double

Output Arguments

h — Handles to line objects

vector

Handles to line objects, returned as a NINST-by-3 matrix of handles to line objects, containing [hLines, hUArrowHead, hDArrowHead] where:

- hLines — Horizontal and vertical lines used in the cash flow diagram
- hUArrowHead — "Up" arrowheads
- hDArrowHead — "Down" arrowheads

axes_handle — Handles to axes for plot or subplots

vector

Handles to axes for the plot or subplots, returned as a (Number of axes)-by-1 vector of handles to axes.

Version History

Introduced in R2013a

cfport

Portfolio form of cash flow amounts

Syntax

```
[CFBondDate,AllDates,AllTF,IndByBond] = cfport(CFlowAmounts,CFlowDates)
[CFBondDate,AllDates,AllTF,IndByBond] = cfport( ___ ,TFactors)
```

Description

`[CFBondDate,AllDates,AllTF,IndByBond] = cfport(CFlowAmounts,CFlowDates)` computes a vector of all cash flow dates of a bond portfolio, and a matrix mapping the cash flows of each bond to those dates. Use the matrix for pricing the bonds against a curve of discount factors.

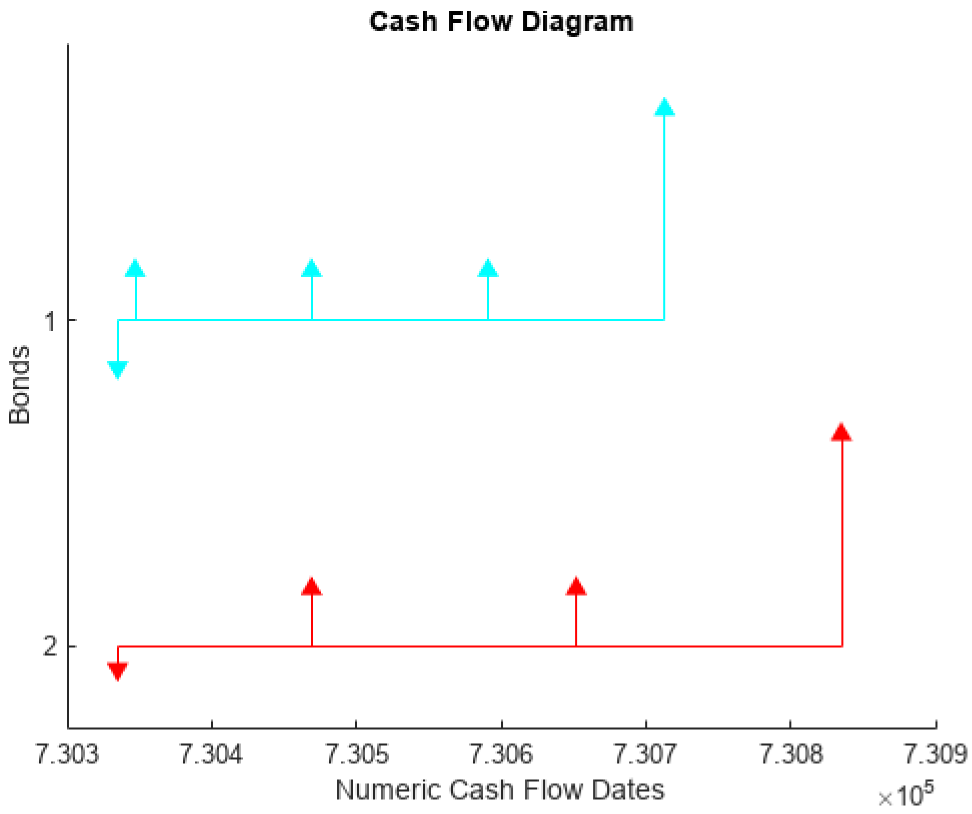
`[CFBondDate,AllDates,AllTF,IndByBond] = cfport( ___ ,TFactors)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Calculate the Cash Flow Amounts, Cash Flow Dates, and Time Factors for Each of Two Bonds

Use the function `cfamounts` to calculate the cash flow amounts, cash flow dates, and time factors for each of two bonds. Then use the function `cfplot` to plot the cash flow diagram.

```
Settle = '03-Aug-1999';
Maturity = ['15-Aug-2000';'15-Dec-2000'];
CouponRate= [0.06; 0.05];
Period = [3;2];
Basis = [1;0];
[CFlowAmounts, CFlowDates, TFactors] = cfamounts(CouponRate,...
Settle, Maturity, Period, Basis);
cfplot(CFlowDates,CFlowAmounts)
xlabel('Numeric Cash Flow Dates')
ylabel('Bonds')
title('Cash Flow Diagram')
```



Call the function `cfport` to map the cash flow amounts to the cash flow dates. Each row in the resultant `CFBondDate` matrix represents a bond. Each column represents a date on which one or more of the bonds has a cash flow. A 0 means the bond did not have a cash flow on that date. The dates associated with the columns are listed in `AllDates`. For example, the first bond had a cash flow of `2.000` on `730347`. The second bond had no cash flow on this date For each bond, `IndByBond` indicates the columns of `CFBondDate`, or dates in `AllDates`, for which a bond has a cash flow.

```
[CFBondDate, AllDates, AllTF, IndByBond] = ...
cfport(CFlowAmounts, CFlowDates, TFactors)
```

```
CFBondDate = 2×7

   -1.8000    2.0000    2.0000    2.0000         0  102.0000         0
   -0.6694         0    2.5000         0    2.5000         0  102.5000

AllDates = 7×1

      730335
      730347
      730469
      730591
      730652
      730713
      730835
```

```
AllTF = 7×1

         0
    0.0663
    0.7322
    1.3989
    1.7322
    2.0663
    2.7322

IndByBond = 2×5

     1     2     3     4     6
     1     3     5     7   NaN
```

Calculate the Cash Flow Amounts, Cash Flow Dates Using a datetime Array, and Time Factors for Each of Two Bonds

Use the function `cfamounts` to calculate the cash flow amounts, cash flow dates, and time factors for each of two bonds.

```
Settle = datetime(1999,8,3);
Maturity = [datetime(2000,8,15) ; datetime(2000,12,15)];
CouponRate= [0.06; 0.05];
Period = [3;2];
Basis = [1;0];
[CFlowAmounts, CFlowDates, TFactors] = cfamounts(CouponRate,...
Settle, Maturity, Period, Basis);
```

Call the function `cfport` to map the cash flow amounts to the cash flow dates. Each row in the resultant `CFBondDate` matrix represents a bond. Each column represents a date on which one or more of the bonds has a cash flow. A `0` means the bond did not have a cash flow on that date. The dates associated with the columns are listed in `AllDates` returned as a datetime array.

```
[CFBondDate, AllDates, AllTF, IndByBond] = ...
cfport(CFlowAmounts, CFlowDates, TFactors)
```

```
CFBondDate = 2×7

   -1.8000    2.0000    2.0000    2.0000         0  102.0000         0
   -0.6694         0    2.5000         0    2.5000         0  102.5000

AllDates = 7x1 datetime
   03-Aug-1999
   15-Aug-1999
   15-Dec-1999
   15-Apr-2000
   15-Jun-2000
   15-Aug-2000
   15-Dec-2000

AllTF = 7×1
```

```
         0
    0.0663
    0.7322
    1.3989
    1.7322
    2.0663
    2.7322

IndByBond = 2×5

     1     2     3     4     6
     1     3     5     7   NaN
```

Input Arguments

CFlowAmounts — Cash flow amounts
matrix

Cash flow amounts, specified as number of bonds (NUMBONDS) by number of cash flows (NUMCFS) matrix with entries listing cash flow amounts corresponding to each date in CFlowDates.

Data Types: double

CFlowDates — Cash flow dates
datetime array | string array | date character vector

Cash flow dates, specified as an NUMBONDS-by-NUMCFS matrix with rows listing cash flow dates using a datetime array, string array, or date character vectors for each bond and padded with NaNs. If CFlowDates is a serial date number or a date character vector, AllDates is returned as an array of serial date numbers. If CFlowDates is a datetime array, then AllDates is returned as a datetime array.

To support existing code, cfport also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

TFactors — Time between settlement and the cash flow date
matrix

(Optional) Time between settlement and the cash flow date, specified as an NUMBONDS-by-NUMCFS matrix with entries listing the time between settlement and the cash flow date measured in semiannual coupon periods.

Data Types: double

Output Arguments

CFBondDate — Cash flows indexed by bond and by date
matrix

Cash flows indexed by bond and by date, returned as an NUMBONDS by number of dates (NUMDATES) matrix. Each row contains a bond's cash flow values at the indices corresponding to entries in AllDates. Other indices in the row contain zeros.

AllDates — List of all dates that have any cash flow from the bond portfolio
matrix

List of all dates that have any cash flow from the bond portfolio, returned as an NUMDATES-by-1 matrix. The AllDates matrix is expressed in datetime format (if CFlowDates is in datetime format).

AllTF — Time factors corresponding to the dates in AllDates
matrix

Time factors corresponding to the dates in AllDates, returned as an NUMDATES-by-1 matrix. If TFactors is not entered, AllTF contains the number of days from the first date in AllDates.

IndByBond — Indices by bond
matrix

Indices by bond, returned as an NUMBONDS-by-NUMCFS matrix. The *i*th row contains a list of indices into AllDates where the *i*th bond has cash flows. Since some bonds have more cash flows than others, the matrix is padded with NaNs.

Version History
Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although cfport supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

cfprice

Compute price for cash flow given yield to maturity

Syntax

```
Price = cfprice(CFlowAmounts,CFlowDates,Yield,Settle)
Price = cfprice( ___ ,Name,Value)
```

Description

`Price = cfprice(CFlowAmounts,CFlowDates,Yield,Settle)` computes a price given yield for a cash flow.

`Price = cfprice( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Price for a Cash Flow Given Yield to Maturity

Use `cfprice` to compute the price for a cash flow given yield to maturity.

Define data for the yield curve.

```
Settle = datetime(2003,7,1);
Yield = .05;
CFAmounts = [30;40;30];
CFDates = [datetime(2004,7,15) ; datetime(2005,7,15) ; datetime(2006,7,15)];
```

Compute the `Price`.

```
Price = cfprice(CFAmounts, CFDates, Yield, Settle)
```

```
Price = 3×1

   28.4999
   36.1689
   25.8195
```

Input Arguments

`CFlowAmounts` — Cash flow amounts

vector

Cash flow amounts, specified as an `NINST`-by-`MOSTCFS` matrix. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with `NaN`s.

Data Types: `double`

`CFlowDates` — Cash flow dates

datetime array | string array | date character vector

Cash flow dates, specified as an `NINST`-by-`MOSTCFS` matrix using a datetime array, string array, or date character vectors. Each entry contains the date of the corresponding cash flow in `CFlowAmounts`.

To support existing code, `cfprice` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Yield` — Yields

vector

Yields specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NMBS`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date is the date on which the cash flows are priced.

To support existing code, `cfprice` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Note An optional input of size `NINST`-by-`1` is also acceptable as a single value applicable to all contracts. Single values are internally expanded to an array of size `NINST`-by-`1`.

Example: `Price = cfprice(CFlowAmounts,CFlowDates,Yield,Settle,'Basis',4,'CompoundingFrequency',4)`

`Basis` — Day-count basis

`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `N`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`CompoundingFrequency` — Compounding frequency
SIA bases uses2, ICMA bases uses 1 (default) | integer with value of 1, 2, 3, 4, 6, or 12

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompoundingFrequency'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

Note By default, SIA bases (`0`-`7`) and `BUS/252` use a semiannual compounding convention and ICMA bases (`8`-`12`) use an annual compounding convention.

Data Types: `double`

Output Arguments

`Price` — Price of cash flows
vector

Price of cash flows, returned as an `NINST`-by-`1` vector.

Version History

Introduced in R2012a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `cfprice` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cfspread

Compute spread over yield curve for cash flow

Syntax

```
Spread = cfspread(RateSpec,Price,CFlowAmounts,CFlowDates,Settle)
Spread = cfspread( ___ ,Name,Value)
```

Description

`Spread = cfspread(RateSpec,Price,CFlowAmounts,CFlowDates,Settle)` computes spread over a yield curve for a cash flow.

`Spread = cfspread( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Spread Over a Yield Curve for a Cash Flow

Use `cfspread` to compute the spread over a yield curve for a cash flow.

Define data for the yield curve.

```
Settle = datetime(2003,7,1) %datenum('01-Jul-2003');
```

```
Settle = datetime
   01-Jul-2003
```

```
CurveDates = daysadd(Settle,360*[.25 .5 1 2 3 5 7 10 20],1);
ZeroRates = [.0089 .0096 .0107 .0130 .0166 .0248 .0306 .0356 .0454]';
```

Compute the `RateSpec`.

```
RateSpec = intenvset('StartDates', Settle, 'EndDates', CurveDates,...
'Rates', ZeroRates)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [9x1 double]
            Rates: [9x1 double]
         EndTimes: [9x1 double]
       StartTimes: [9x1 double]
         EndDates: [9x1 double]
       StartDates: 731763
    ValuationDate: 731763
            Basis: 0
     EndMonthRule: 1
```

Compute the spread.

```
Price = 98;
CFAmounts = [30;40;30];
CFDates = [datetime(2004,7,15); datetime(2005,7,15) ; datetime(2006,7,15)];

Spread = cfspread(RateSpec, Price, CFAmounts, CFDates, Settle)
```

```
Spread = 3×1
10^3 ×

   -8.7956
   -4.0774
   -3.7073
```

Input Arguments

RateSpec — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial risk-free rate curve, specified by the RateSpec obtained from intenvset. For information on the interest-rate specification, see intenvset.

Data Types: struct

Price — Price of cash flows

vector

Price of cash flows, specified as an NINST-by-1 vector.

Data Types: double

CFlowAmounts — Cash flow amounts

vector

Cash flow amounts, specified as an NINST-by-MOSTCFS matrix . Each row is a list of cash flow values for one instrument. If an instrument has fewer than MOSTCFS cash flows, the end of the row is padded with NaNs.

Data Types: double

CFlowDates — Cash flow dates

datetime array | string array | date character vector

Cash flow dates, specified as an NINST-by-MOSTCFS matrix using a datetime array, string array, or date character vectors. Each entry contains the date of the corresponding cash flow in CFlowAmounts.

To support existing code, cfspread also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Settle — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date is the date on which the cash flows are priced.

To support existing code, `cfspread` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Note An optional input of size `NINST`-by-`1` is also acceptable as a single value applicable to all contracts. Single values are internally expanded to an array of size `NINST`-by-`1`.

Example: `Spread = cfspread(RateSpec,Price,CFlowAmounts,CFlowDates,Settle,'Basis',4)`

`Basis` — Day-count basis

`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

Spread — Spread of cash flows over a zero curve

vector

Spread of cash flows over a zero curve, returned as an `NINST`-by-`1` vector. The `Spread` is expressed in basis points.

Version History

Introduced in R2012a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `cfspread` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cfyield

Compute yield to maturity for cash flow given price

Syntax

```
Yield = cfyield(CFlowAmounts,CFlowDates,Price,Settle)
Yield = cfyield( ___ ,Name,Value)
```

Description

`Yield = cfyield(CFlowAmounts,CFlowDates,Price,Settle)` computes yield to maturity for a cash flow given price.

`Yield = cfyield( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Yield to Maturity for a Cash Flow When Given a Price

Use `cfyield` to compute yield to maturity for a cash flow when given a price.

Define data for the yield curve and price.

```
Settle = datetime(2003,7,1);
Price = 98;
CFlowAmounts = [30 40 30];
CFlowDates = [datetime(2004,7,15) ; datetime(2005,7,15) ; datetime(2006,7,15)]';
```

Compute the `Yield`.

```
 Yield = cfyield(CFlowAmounts, CFlowDates, Price, Settle)
```

```
Yield = 0.0099
```

Input Arguments

`CFlowAmounts` — Cash flow amounts
vector

Cash flow amounts, specified as an `NINST`-by-`MOSTCFS` matrix. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with `NaN`s.

Data Types: `double`

`CFlowDates` — Cash flow dates
datetime array | string array | date character vector

Cash flow dates, specified as an NINST-by-MOSTCFS matrix using a datetime array, string array, or date character vectors. Each entry contains the date of the corresponding cash flow in CFlowAmounts.

To support existing code, cfyield also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Price — Prices
vector

Prices specified as an NINST-by-1 vector.

Data Types: double

Settle — Settlement date
datetime array | string array | date character vector

Settlement date, specified as an NMBS-by-1 vector using a datetime array, string array, or date character vectors. The Settle date is the date on which the cash flows are priced.

To support existing code, cfyield also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Note An optional input of size NINST-by-1 is also acceptable as a single value applicable to all contracts. Single values are internally expanded to an array of size NINST-by-1.

Example: Yield = cfyield(CFAmounts,CFDates,Yield,Settle,'Basis',4,'CompoundingFrequency',4)

Basis — Day-count basis
0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a N-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`CompoundingFrequency` — Compounding frequency
2 (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Compounding frequency, specified as the comma-separated pair consisting of `'CompoundingFrequency'` and a positive integer using a `N`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`CompoundingFrequency` — Compounding frequency
SIA bases uses`2`, ICMA bases uses `1` (default) | integer with value of `1`, `2`, `3`, `4`, `6`, or `12`

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompundingFrequency'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

- `1` — Annual compounding

- 2 — Semiannual compounding
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

Note By default, SIA bases (0-7) and BUS/252 use a semiannual compounding convention and ICMA bases (8-12) use an annual compounding convention.

Data Types: double

Output Arguments

Yield — Yield for cash flows
vector

Yield for cash flows, returned as an NINST-by-1 vector.

Version History
Introduced in R2012a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although cfyield supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

cftimes

Time factors corresponding to bond cash flow dates

Syntax

```
TFactors = cftimes(Settle,Maturity)
TFactors = cftimes( ___ ,Name,Value)
```

Description

`TFactors = cftimes(Settle,Maturity)` determines the time factors corresponding to the cash flows of a bond or set of bonds.

`cftimes` computes the time factor of a cash flow, which is the difference between the settlement date and the cash flow date, in units of semiannual coupon periods. In computing time factors, use SIA actual/actual day count conventions for all time factor calculations.

`TFactors = cftimes( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Time Factor of a Cash Flow

This example shows how to calculate a cash flow time factor.

```
Settle = datetime(1997,3,15);
Maturity = datetime(1999,9,1);
Period = 2;
TFactors = cftimes(Settle, Maturity, Period)
```

```
TFactors = 1×5

    0.9239    1.9239    2.9239    3.9239    4.9239
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `cftimes` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NINST-by-1` vector using a datetime array, string array, or date character vectors. The `Settle` date is the date on which the cash flows are priced.

To support existing code, `cftimes` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `TFactors = cftimes(Settle,Maturity,'Period',4)`

`Period` — Number of coupon payments per year

2 (default) | numeric with values `0`, `1`, `2`, `3`, `4`, `6` or `12`

Number of coupon payments per year, specified as the comma-separated pair consisting of `'Period'` and a scalar or a `NUMBONDS-by-1` or `1-by-NUMBONDS` vector using the values: `0`, `1`, `2`, `3`, `4`, `6`, or `12`.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST-by-1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

EndMonthRule — End-of-month rule flag
1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date
datetime array | string array | date character vector

Bond Issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify an IssueDate, the cash flow payment dates are determined from other inputs.

To support existing code, cftimes also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Irregular or normal first coupon date
datetime array | string array | date character vector

Irregular or normal first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cftimes also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Irregular or normal last coupon date
datetime array | string array | date character vector

Irregular or normal last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar or a NUMBONDS-by-1 or 1-by-NUMBONDS vector using a datetime array, string array, or date character vectors.

If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, `cftimes` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector using a datetime array, string array, or date character vectors. The `StartDate` is when a bond actually starts (the date from which a bond cash flow is considered). To make an instrument forward-starting, specify this date as a future date.

If you do not specify a `StartDate`, the effective start date is the `Settle` date.

To support existing code, `cftimes` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`CompoundingFrequency` — Compounding frequency for yield calculation
SIA bases uses2, ICMA bases uses `1` (default) | integer with value of `1`, `2`, `3`, `4`, `6`, or `12`

Compounding frequency for yield calculation, specified as the comma-separated pair consisting of `'CompundingFrequency'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector.

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

Note By default, SIA bases (`0-7`) and `BUS/252` use a semiannual compounding convention and ICMA bases (`8-12`) use an annual compounding convention.

Data Types: `double`

`DiscountBasis` — Basis used to compute the discount factors for computing the yield
SIA uses `0` (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

Basis used to compute the discount factors for computing the yield, specified as the comma-separated pair consisting of `'DiscountBasis'` and a scalar or a `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If a SIA day-count basis is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the default behavior is for SIA bases to use the actual/actual day count to compute discount factors.

If an ICMA day-count basis or BUS/252 is defined in the `Basis` input argument and there is no value assigned for `DiscountBasis`, the specified bases from the `Basis` input argument are used.

Data Types: `double`

Output Arguments

`TFactors` — Time to cash flow

matrix

Time to cash flow, returned as an `NUMBONDS` rows. The number of columns is determined by the maximum number of cash flow payment dates required to hold the bond portfolio. `NaN`s are padded for bonds which have less than the maximum number of cash flow payment dates.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `cftimes` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

chaikosc

Chaikin oscillator

Syntax

```
chosc = chaikocs(Data)
```

Description

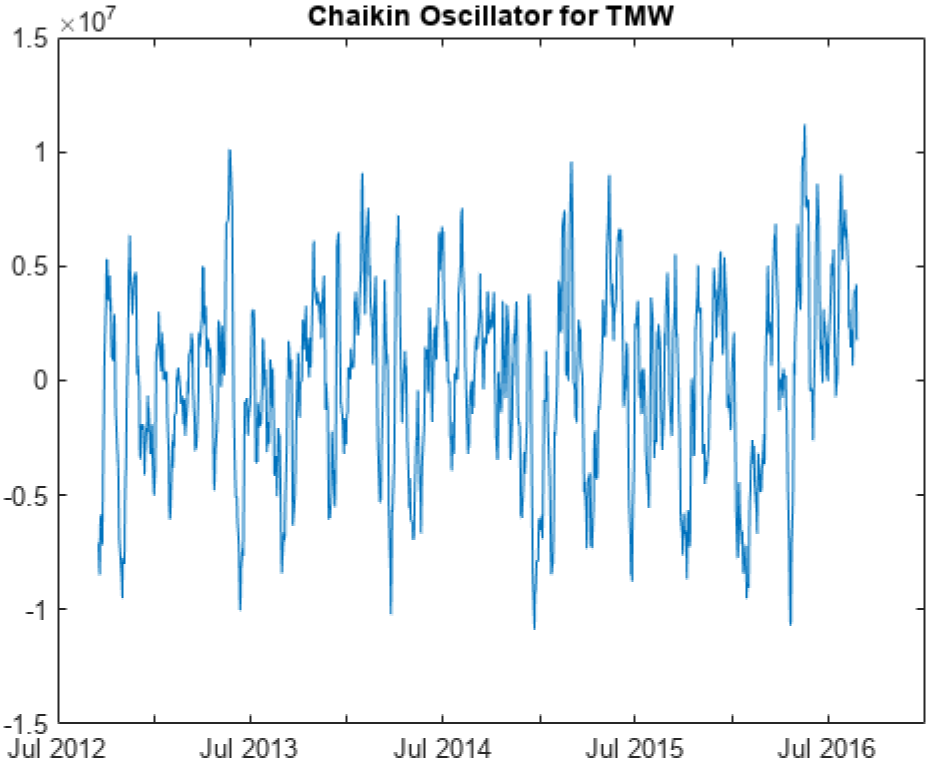
`chosc = chaikocs(Data)` calculates the Chaikin oscillator.

Examples

Calculate the Chaikin Oscillator for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
oscillator = chaikosc(TMW);
plot(oscillator.Time, oscillator.ChaikinOscillator)
title('Chaikin Oscillator for TMW')
```



Input Arguments

Data — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-4 matrix of high, low, opening, and closing prices. Timetables and tables with M rows must contain variables named 'High', 'Low', 'Open', and 'Close' (case insensitive).

Data Types: double | table | timetable

Output Arguments

chosc — Chaikin oscillator

matrix | table | timetable

Chaikin oscillator, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input Data.

Version History

Introduced before R2006a

R2023a: fints support removed for Data input argument

Behavior changed in R2023a

fints object support for the Data input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The Data input accepts negative prices.

chaikvolat

Chaikin volatility

Syntax

```
volatility = chaikvolat(Data)
volatility = chaikvolat(___,Name,Value)
```

Description

`volatility = chaikvolat(Data)` calculates the Chaikin volatility from a data series of high and low stock prices.

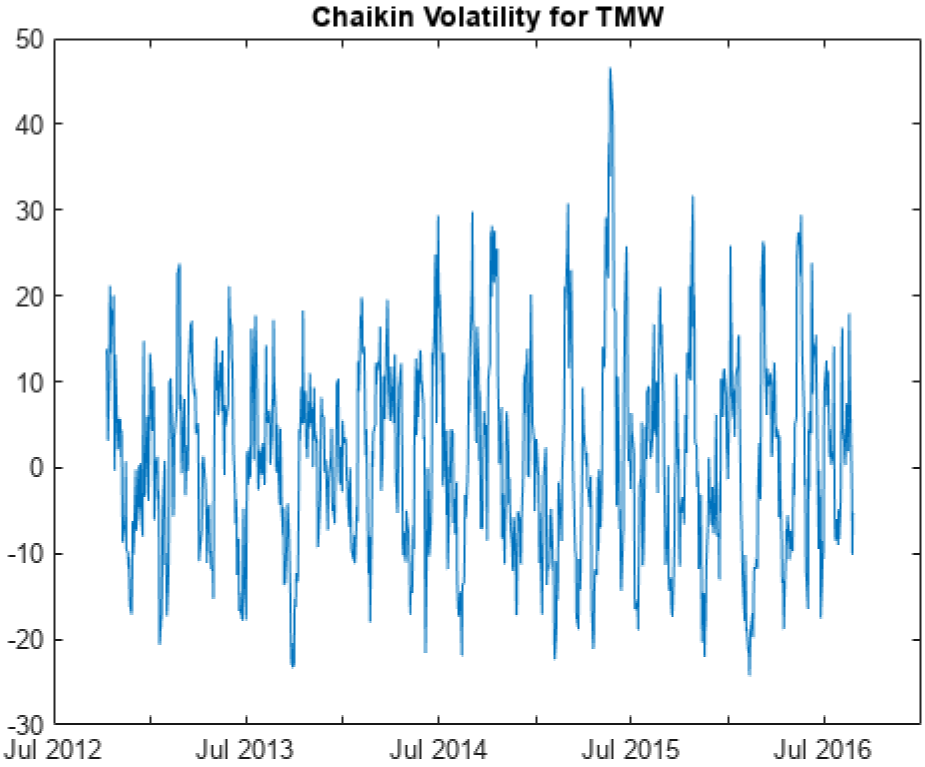
`volatility = chaikvolat(___,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Chaikin Volatility for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
volatility = chaikvolat(TMW,'NumPeriods',14,'WindowSize',14);
plot(volatility.Time,volatility.ChaikinVolatility)
title('Chaikin Volatility for TMW')
```



Input Arguments

`Data` — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a vector, matrix, table, or timetable. For matrix input, `Data` is an `M`-by-2 matrix of high and low prices stored in the first and second columns. Timetables and tables with `M` rows must contain variables named `'High'` and `'Low'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `volatility = chaikvolat(TMW,'NumPeriods',10,'WindowSize',10)`

`NumPeriods` — Period difference

`10` (default) | positive integer

Period difference, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: `double`

`WindowSize` — Length of the exponential moving average in periods
`10` (default) | positive integer

Length of the exponential moving average in periods, specified as the comma-separated pair consisting of `'WindowSize'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`volatility` — Chaikin volatility
matrix | table | timetable

Chaikin volatility, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

More About

Chaikin volatility

Chaikin volatility calculates the Chaikin's volatility from the series of high and low stock prices.

By default, Chaikin's volatility values are based on a 10-period exponential moving average and 10-period difference.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument
Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

checkFeasibility

Check feasibility of input portfolios against portfolio object

Syntax

```
status = checkFeasibility(obj,pwgt)
```

Description

`status = checkFeasibility(obj,pwgt)` checks the feasibility of input portfolios against a portfolio object.

Use the `checkFeasibility` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to check the feasibility of input portfolios against a portfolio object. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Examples

Determine if the Portfolio Is Feasible for a Portfolio Object

Given portfolio `p`, determine if `p` is feasible.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p);

checkFeasibility(p, pwgt)
```

```
ans = 1x10 logical array

   1   1   1   1   1   1   1   1   1   1
```

Determine if the Portfolio Is Feasible for a PortfolioCVaR Object

Given portfolio `p`, determine if `p` is feasible.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
```

```
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontier(p);

checkFeasibility(p, pwgt)
```

```
ans = 1x10 logical array

   1   1   1   1   1   1   1   1   1   1
```

Determine if the Portfolio Is Feasible for a PortfolioMAD Object

Given portfolio p, determine if p is feasible.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontier(p);

checkFeasibility(p, pwgt)
```

```
ans = 1x10 logical array

   1   1   1   1   1   1   1   1   1   1
```

Input Arguments

`obj` — Object for portfolio
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`pwgt` — Portfolios to check
matrix

Portfolios to check, specified as a `NumAssets`-by-`NumPorts` matrix.

Data Types: `double`

Output Arguments

`status` — Indicator if portfolio is feasible
row vector

Indicator if portfolio is feasible, returned as a row vector of `NumPorts` indicators that are `true` if portfolio is feasible and `false` otherwise.

Note By definition, any portfolio set must be nonempty and bounded. If the set is empty, no portfolios can be feasible. Use `estimateBounds` to test for nonempty and bounded sets.

Feasibility `status` is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Tips

- You can also use dot notation to check the feasibility of input portfolios against a portfolio object.

  ```
  status = obj.checkFeasibility(pwgt);
  ```
- The constraint tolerance to assess whether a constraint is satisfied is obtained from the hidden property `obj.defaultTolCon`.

Version History

Introduced in R2011a

convert2sur

Convert multivariate normal regression model to seemingly unrelated regression (SUR) model

Syntax

```
DesignSUR = convert2sur(Design,Group)
```

Description

`DesignSUR = convert2sur(Design,Group)` converts a multivariate normal regression model into a seemingly unrelated regression model with a specified grouping of the data series.

Examples

Use convert2sur to Estimate Stock Alpha and Beta Values

This example shows a CAPM demonstration using 6 stocks and 60 months of simulated asset returns, where the model for each stock is `AssetReturn = Alpha * 1 + CashReturn + Beta * (MarketReturn - CashReturn) + Noise` and the parameters to estimate are `Alpha` and `Beta`.

Using simulated data, where the `Alpha` estimate(s) are displayed in the first row(s) and the `Beta` estimate(s) are display in the second row(s).

```
Market = (0.1 - 0.04) + 0.17*randn(60, 1);
Asset = (0.1 - 0.04) + 0.35*randn(60, 6);

Design = cell(60, 1);
for i = 1:60
            Design{i} = repmat([ 1, Market(i) ], 6, 1);
end
```

Obtain the aggregate estimates for all stocks.

```
[Param, Covar] = mvnrmle(Asset, Design);

disp({'All 6 Assets Combined'});
```

```
    {'All 6 Assets Combined'}
```

```
disp(Param);
```

```
    0.0233
    0.1050
```

Estimate parameters for individual stocks using `convert2sur`

```
Group = 1:6;
DesignSUR = convert2sur(Design, Group);
[Param, Covar] = mvnrmle(Asset, DesignSUR);
Param = reshape(Param, 2, 6);

disp({ 'A', 'B', 'C', 'D', 'E', 'F' });
```

```
    {'A'}    {'B'}    {'C'}    {'D'}    {'E'}    {'F'}
```

```
disp(Param);
```

```
    0.0144    0.0270    0.0046    0.0419    0.0376    0.0291
    0.3264   -0.1716    0.3248   -0.0630   -0.0001    0.0637
```

Estimate parameters for pairs of stocks by forming groups.

```
disp({'A & B', 'C & D','E & F'});
```

```
    {'A & B'}    {'C & D'}    {'E & F'}
```

```
Group = { [1,2 ],[3,4],[5,6]};
DesignSUR = convert2sur(Design, Group);
[Param, Covar] = mvnrmle(Asset, DesignSUR);

Param = reshape(Param, 2, 3);

disp(Param);
```

```
    0.0186    0.0190    0.0334
    0.0988    0.1757    0.0293
```

Input Arguments

Design — Data series

matrix | cell array

Data series, specified as a matrix or a cell array that depends on the number of data series NUMSERIES.

- If NUMSERIES = 1, convert2sur returns the Design matrix.
- If NUMSERIES > 1, Design is a cell array with NUMSAMPLES cells, where each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.

Data Types: double | cell

Group — Grouping for data series

vector | cell array

Grouping for data series, specified using separate parameters for each group. Specify groups either by series or by groups:

- To identify groups by series, construct an index vector that has NUMSERIES elements. Element i = 1, ..., NUMSERIES in the vector, and has the index j = 1, ..., NUMGROUPS of the group in which series *i* is a member.
- To identify groups by groups, construct a cell array with NUMGROUPS elements. Each cell contains a vector with the indexes of the series that populate a given group.

  In either case, the number of series is NUMSERIES and the number of groups is NUMGROUPS, with 1 ≤ NUMGROUPS ≤ NUMSERIES.

Data Types: double | cell

Output Arguments

`DesignSUR` — Seemingly unrelated regression model with a specified grouping of the data series
matrix | cell array

Seemingly unrelated regression model with a specified grouping of the data series, returned as either a matrix or a cell array that depends on the value of `NUMSERIES`.

- If `NUMSERIES = 1`, `DesignSUR = Design`, which is a `NUMSAMPLES`-by-`NUMPARAMS` matrix.
- If `NUMSERIES > 1` and `NUMGROUPS` groups are to be formed, `Design` is a cell array with `NUMSAMPLES` cells, where each cell contains a `NUMSERIES`-by-`(NUMGROUPS * NUMPARAMS)` matrix of known values.

The original collection of parameters that are common to all series are replicated to form collections of parameters for each group.

Version History

Introduced in R2006a

corr2cov

Convert standard deviation and correlation to covariance

Syntax

```
ExpCovariance = corr2cov(ExpSigma)
ExpCovariance = corr2cov( ___ ,ExpCorrC)
```

Description

`ExpCovariance = corr2cov(ExpSigma)` converts standard deviation and correlation to covariance.

`ExpCovariance = corr2cov( ___ ,ExpCorrC)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Convert Standard Deviation and Correlation to Covariance

This example shows how to convert standard deviation and correlation to covariance.

```
ExpSigma = [0.5  2.0];

ExpCorrC = [1.0 -0.5
           -0.5  1.0];

ExpCovariance = corr2cov(ExpSigma, ExpCorrC)
```

```
ExpCovariance = 2×2

    0.2500   -0.5000
   -0.5000    4.0000
```

Input Arguments

`ExpSigma` — Standard deviations of each process
vector

Standard deviations of each process, specified as a vector of length `n` with the standard deviations of each process. `n` is the number of random processes.

Data Types: `double`

`ExpCorrC` — Correlation matrix
matrix

(Optional) Correlation matrix, specified as an n-by-n correlation coefficient matrix. A correlation coefficient is a statistic in which the covariance is scaled to a value between minus one (perfect negative correlation) and plus one (perfect positive correlation).

If ExpCorrC is not specified, the processes are assumed to be uncorrelated, and the identity matrix is used.

Data Types: double

Output Arguments

ExpCovariance — Covariance matrix
matrix

Covariance matrix, returned as an n-by-n covariance matrix, where n is the number of processes.

The (*i*,*j*) entry is the expectation of the *i*'th fluctuation from the mean times the *j*'th fluctuation from the mean.

```
ExpCov(i,j) = ExpCorrC(i,j)*ExpSigma(i)*ExpSigma(j)
```

Version History
Introduced before R2006a

See Also
cov2corr | ewstats | nearcorr

cov2corr

Convert covariance to standard deviation and correlation coefficient

Syntax

```
[ExpSigma,ExpCorrC] = cov2corr(ExpCovariance)
```

Description

`[ExpSigma,ExpCorrC] = cov2corr(ExpCovariance)` converts covariance to standard deviations and correlation coefficients.

Examples

Convert Covariance to Standard Deviations and Correlation Coefficients

This example shows how to convert a covariance matrix to standard deviations and correlation coefficients.

```
ExpCovariance = [0.25 -0.5
                -0.5   4.0];
```

```
[ExpSigma, ExpCorrC] = cov2corr(ExpCovariance)
```

```
ExpSigma = 1×2

    0.5000    2.0000

ExpCorrC = 2×2

    1.0000   -0.5000
   -0.5000    1.0000
```

Input Arguments

ExpCovariance — Covariance matrix
matrix

Covariance matrix, specified as an `n`-by-`n` covariance matrix, where `n` is the number of random processes. For an example, see `cov` or `ewstats`.

Data Types: `double`

Output Arguments

ExpSigma — Standard deviation of each process
vector

Standard deviation of each process, returned as an 1-by-n vector.

The entries of ExpCorrC range from 1 (completely correlated) to -1 (completely anti-correlated). A value of 0 in the (*i*,*j*) entry indicates that the *i*'th and *j*'th processes are uncorrelated.

```
ExpSigma(i) = sqrt( ExpCovariance(i,i) );
ExpCorrC(i,j) = ExpCovariance(i,j)/( ExpSigma(i)*ExpSigma(j) );
```

Data Types: double

ExpCorrC — Correlation coefficients
matrix

Correlation coefficients, returned as an n-by-n matrix.

Version History

Introduced before R2006a

cpncount

Coupon payments remaining until maturity

Syntax

```
NumCouponsRemaining = cpncount(Settle,Maturity)
NumCouponsRemaining = cpncount( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

Description

`NumCouponsRemaining = cpncount(Settle,Maturity)` returns the whole number of coupon payments between the `Settle` and `Maturity` dates for a coupon bond or set of bonds. Coupons falling on or before `Settle` are not counted, except for the `Maturity` payment which is always counted.

Required input arguments must be number of bonds, `NUMBONDS`-by-1 or 1-by-`NUMBONDS`, conforming vectors or scalars.

`NumCouponsRemaining = cpncount( ___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate)` returns the whole number of coupon payments between the `Settle` and `Maturity` dates for a coupon bond or set of bonds using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-1 or 1-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

Examples

Find Coupon Payments Remaining Until Maturity

This example shows how to find the coupon payments remaining until maturity.

```
NumCouponsRemaining = cpncount(datetime(1997,3,14), datetime(2000,11,30), 2, 0, 0)
```

```
NumCouponsRemaining = 8
```

Find Coupon Payments Remaining Until Maturity for Different Maturity Dates

This example shows how to find the coupon payments remaining until maturity, given three coupon bonds with different maturity dates and the same default arguments.

```
Maturity = [datetime(2000,9,30) ; datetime(2001,10,31) ; datetime(2002,11,30)];
NumCouponsRemaining = cpncount(datetime(1997,9,14), Maturity)
```

```
NumCouponsRemaining = 3×1

     7
     9
```

```
    11
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `cpncount` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpncount` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Period` — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

Coupons per year of the bond, specified as a vector of positive integers from the set `[1,2,3,4,6,12]`.

Data Types: `double`

`Basis` — Day-count basis of the bond

`0` (actual/actual) (default) | numeric with value `0` through `13` | vector of numerics with values `0` through `13`

Day-count basis of the bond, specified as an integer with a value of `0` through `13` or an `N`-by-`1` vector of integers with values of `0` through `13`.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-16.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [`0`, `1`] or a using an `N`-by-`1` vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as a `NBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpncount` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — Date when bond makes first coupon payment
datetime array | string array | date character vector

Date when a bond makes its first coupon payment, specified as a `NBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `cpncount` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Last coupon date of bond before maturity date
datetime array | string array | date character vector

Last coupon date of a bond before maturity date, specified as a NBONDS-by-1 vector using a datetime array, string array, or date character vectors.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpncount also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NumCouponsRemaining — Whole number of coupon payments between the settlement and maturity dates for a coupon bond or set of bonds
vector

Whole number of coupon payments between the settlement and maturity dates for a coupon bond or set of bonds, returned as an NBONDS-by-1 vector.

Coupons falling on or before settlement are not counted, except for the maturity payment which is always counted.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although cpncount supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Pricing and Computing Yields for Fixed-Income Securities” on page 2-15

cpndaten

Next coupon date for fixed-income security

Syntax

```
NextCouponDate = cpndaten(Settle,Maturity)
NextCouponDate = cpndaten( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

Description

`NextCouponDate = cpndaten(Settle,Maturity)` returns the next coupon date after the `Settle` date. This function finds the next coupon date whether or not the coupon structure is synchronized with the `Maturity` date.

Required input arguments must be number of bonds, `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS`, conforming vectors or scalars.

`NextCouponDate = cpndaten( ___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate)` returns the next coupon date after the `Settle` date using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either strings or date character vectors, then `NextCouponDate` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `NextCouponDate` is returned as a datetime array.

Examples

Calculate the Next Coupon Date After the Settlement Date

Determine the `NextCouponDate` when using character vectors for input arguments.

```
NextCouponDate = cpndaten('14-Mar-1997', '30-Nov-2000', 2, 0, 0);
datestr(NextCouponDate)
```

```
ans =
'30-May-1997'
```

Determine the `NextCouponDate` when using a datetime array for input arguments.

```
NextCouponDate = cpndaten(datetime(1997,3,14),datetime(2000,11,30), 2, 0, 0)
```

```
NextCouponDate = datetime
   30-May-1997
```

Determine the NextCouponDate when using character vectors for input arguments and the optional argument for EndMonthRule.

```
NextCouponDate = cpndaten('14-Mar-1997', '30-Nov-2000', 2, 0, 1);
datestr(NextCouponDate)
```

```
ans = 
'31-May-1997'
```

Determine the NextCouponDate when using an input vector for Maturity.

```
Maturity = ['30-Sep-2000'; '31-Oct-2000'; '30-Nov-2000'];
NextCouponDate = cpndaten('14-Mar-1997', Maturity);
datestr(NextCouponDate)
```

```
ans = 3x11 char array
    '31-Mar-1997'
    '30-Apr-1997'
    '31-May-1997'
```

Input Arguments

Settle — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors. Settle must be earlier than Maturity.

To support existing code, cpndaten also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Maturity — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cpndaten also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Period — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set [1,2,3,4,6,12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1,2,3,4,6,12].

Data Types: single | double

Basis — Day-count basis of the bond

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the bond, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-16.

Data Types: single | double

EndMonthRule — End-of-month rule flag for month having 30 or fewer days

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using an N-by-1 vector of values. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond issue date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cpndaten also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Date when bond makes first coupon payment

datetime array | string array | date character vector

Date when a bond makes its first coupon payment, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

FirstCouponDate is used when a bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpndaten also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Last coupon date of bond before maturity date
datetime array | string array | date character vector

Last coupon date of a bond before maturity date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpndaten also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NextCouponDate — Next coupon date after the settlement date
vector

Next coupon date after the settlement date, returned as an NUMBONDS-by-1 vector of next actual coupon dates after settlement. If settlement is a coupon date, this function never returns the settlement date. Instead, the actual coupon date strictly after settlement is returned, but not exceeding the maturity date. Thus, this function will always return the lesser of the actual maturity date and the next coupon payment date.

If all the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are either strings or date character vectors, then NextCouponDate is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are datetime arrays, then NextCouponDate is returned as a datetime array.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although cpndaten supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

"Pricing and Computing Yields for Fixed-Income Securities" on page 2-15

cpndatenq

Next quasi-coupon date for fixed-income security

Syntax

```
NextQuasiCouponDate = cpndatenq(Settle,Maturity)
NextQuasiCouponDate = cpndatenq( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

Description

NextQuasiCouponDate = cpndatenq(Settle,Maturity) determines the next quasi coupon date for a portfolio of NUMBONDS fixed income securities whether or not the first or last coupon is normal, short, or long. For zero coupon bonds, cpndatenq returns quasi coupon dates as if the bond had a semiannual coupon structure. Successive quasi coupon dates determine the length of the standard coupon period for the fixed income security of interest and do not necessarily coincide with actual coupon payment dates.

Required input arguments must be number of bonds, NUMBONDS-by-1 or 1-by-NUMBONDS, conforming vectors or scalars.

NextQuasiCouponDate = cpndatenq(___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate) determines the next quasi coupon date for a portfolio of NUMBONDS fixed income securities whether or not the first or last coupon is normal, short, or long using optional input arguments.

Optional input arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

If all the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are either strings or date character vectors, then NextQuasiCouponDate is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are datetime arrays, then NextQuasiCouponDate is returned as a datetime array.

Examples

Determine the Next Quasi Coupon Date for a Portfolio of Fixed-Income Securities

Given a pair of bonds with the following characteristics:

```
Settle = [datetime(1997,5,30), datetime(1997,12,10)];
Maturity = [datetime(2002,11,30), datetime(2004,6,10)];
```

Compute NextCouponDate for this pair of bonds.

```
NextCouponDate = cpndaten(Settle, Maturity)
NextCouponDate = 2x1 datetime
   31-May-1997
   10-Jun-1998
```

Compute the next quasi coupon dates for these two bonds.

```
NextQuasiCouponDate = cpndatenq(Settle, Maturity)
```

```
NextQuasiCouponDate = 2x1 datetime
   31-May-1997
   10-Jun-1998
```

Because no `FirstCouponDate` has been specified, the results are identical.

Now supply an explicit `FirstCouponDate` for each bond.

```
FirstCouponDate = [datetime(1997,11,30), datetime(1998,12,10)];
```

Compute the next coupon dates.

```
NextCouponDate = cpndaten(Settle, Maturity, 2, 0, 1, [],FirstCouponDate)
```

```
NextCouponDate = 2x1 datetime
   30-Nov-1997
   10-Dec-1998
```

The next coupon dates are identical to the specified first coupon dates.

Now recompute the next quasi coupon dates.

```
NextQuasiCouponDate = cpndatenq(Settle, Maturity, 2, 0, 1, [],FirstCouponDate)
```

```
NextQuasiCouponDate = 2x1 datetime
   31-May-1997
   10-Jun-1998
```

These results illustrate the distinction between actual coupon payment dates and quasi coupon dates. `FirstCouponDate` (and `LastCouponDate`, as well), when specified, is associated with an actual coupon payment and also serves as the synchronization date for determining all quasi coupon dates. Since each bond in this example pays semiannual coupons, and the first coupon date occurs more than six months after settlement, each will have an intermediate quasi coupon date before the actual first coupon payment occurs.

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `cpndatenq` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpndatenq` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Period` — Coupons per year of the bond

`2` (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

Coupons per year of the bond, specified as a vector of positive integers from the set `[1,2,3,4,6,12]`.

Data Types: `single` | `double`

`Basis` — Day-count basis of the instrument

`0` (actual/actual) (default) | numeric with value `0` through `13` | vector of numerics with values `0` through `13`

Day-count basis of the instrument, specified as an integer with a value of `0` through `13` or an `N`-by-`1` vector of integers with values of `0` through `13`.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `single` | `double`

`EndMonthRule` — End-of-month rule flag for month having 30 or fewer days

`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond issue date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cpndatenq also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Date when bond makes first coupon payment

datetime array | string array | date character vector

Date when a bond makes its first coupon payment, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

FirstCouponDate is used when a bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpndatenq also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Last coupon date of bond before maturity date

datetime array | string array | date character vector

Last coupon date of a bond before maturity date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpndatenq also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NextQuasiCouponDate — Next quasi coupon date for portfolio of NUMBONDS fixed income securities

vector

Next quasi coupon date for a portfolio of NUMBONDS fixed income securities, whether or not the first or last coupon is normal, short, or long, returned as a NUMBONDS-by-1 vector.

For zero coupon bonds, cpndatenq returns quasi coupon dates as if the bond had a semiannual coupon structure. Successive quasi coupon dates determine the length of the standard coupon period for the fixed income security of interest and do not necessarily coincide with actual coupon payment dates.

If all of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are either strings or date character vectors, then NextQuasiCouponDate is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are datetime arrays, then NextQuasiCouponDate is returned as a datetime array.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although cpndatenq supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Pricing and Computing Yields for Fixed-Income Securities” on page 2-15

cpndatepq

Previous quasi-coupon date for fixed-income security

Syntax

```
PreviousQuasiCouponDate = cpndatepq(Settle,Maturity)
PreviousQuasiCouponDate = cpndatepq( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

Description

PreviousQuasiCouponDate = cpndatepq(Settle,Maturity) determines the previous quasi-coupon date for a set of NUMBONDS fixed income securities. Prior quasi-coupon dates determine the length of the standard coupon period for the fixed income security of interest, and do not necessarily coincide with actual coupon payment dates. This function finds the previous quasi-coupon date for bonds with a coupon structure whose first or last period is either normal, short, or long.

Required input arguments must be number of bonds, NUMBONDS-by-1 or 1-by-NUMBONDS, conforming vectors or scalars.

PreviousQuasiCouponDate = cpndatepq(___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate), using optional input arguments, determines the previous quasi-coupon date for a set of NUMBONDS fixed income securities.

Optional input arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

If all the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are either strings or date character vectors, then PreviousQuasiCouponDate is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are datetime arrays, then PreviousQuasiCouponDate is returned as a datetime array.

Examples

Determine the Previous Quasi Coupon Date for a Portfolio of Fixed-Income Securities

Given a pair of bonds with the following characteristics:

```
Settle = [datetime(1997,5,30) ; datetime(1997,12,10)];
Maturity = [datetime(2002,11,30) ; datetime(2004,6,10)];
```

With no FirstCouponDate explicitly supplied, compute the PreviousCouponDate for this pair of bonds.

```
PreviousCouponDate = cpndatep(Settle, Maturity)
PreviousCouponDate = 2x1 datetime
   30-Nov-1996
   10-Dec-1997
```

Note that since the settlement date for the second bond is also a coupon date, `cpndatep` returns this date as the previous coupon date.

Now establish a `FirstCouponDate` and `IssueDate` for this pair of bonds.

```
FirstCouponDate = [datetime(1997,11,30) ; datetime(1998,12,10)];
IssueDate = [datetime(1996,5,30) ; datetime(1996,12,10)];
```

Recompute the `PreviousCouponDate` for this pair of bonds.

```
PreviousCouponDate = cpndatep(Settle, Maturity, 2, 0, 1, IssueDate, FirstCouponDate)
```

```
PreviousCouponDate = 2x1 datetime
   30-May-1996
   10-Dec-1996
```

Since both of these bonds settled before the first coupon had been paid, `cpndatep` returns the `IssueDate` as the `PreviousCouponDate`.

Using the same data, compute `PreviousQuasiCouponDate`.

```
PreviousQuasiCouponDate = cpndatepq(Settle, Maturity, 2, 0, 1,IssueDate, FirstCouponDate)
```

```
PreviousQuasiCouponDate = 2x1 datetime
   30-Nov-1996
   10-Dec-1997
```

For the first bond the settlement date is not a normal coupon date. The `PreviousQuasiCouponDate` is the coupon date before or on the settlement date. Since the coupon structure is synchronized to `FirstCouponDate`, the previous quasi coupon date is `30-Nov-1996`. `PreviousQuasiCouponDate` disregards `IssueDate` and `FirstCouponDate` in this case. For the second bond the settlement date (10-Dec-1997) occurs on a date when a coupon would normally be paid in the absence of an explicit `FirstCouponDate`. `cpndatepq` returns this date as `PreviousQuasiCouponDate`.

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `cpndatepq` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cpndatepq also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Period — Coupons per year of the bond
2 (semiannual) (default) | vector of positive integers from the set [1,2,3,4,6,12]

Coupons per year of the bond, specified as a vector of positive integers from the set [1,2,3,4,6,12].

Data Types: single | double

Basis — Day-count basis of the instrument
0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: single | double

EndMonthRule — End-of-month rule flag for month having 30 or fewer days
1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.

- `1` = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpndatepq` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — Date when bond makes first coupon payment
datetime array | string array | date character vector

Date when a bond makes its first coupon payment, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `cpndatepq` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Last coupon date of bond before maturity date
datetime array | string array | date character vector

Last coupon date of a bond before maturity date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

`LastCouponDate` is used when a bond has an irregular last coupon period. In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `cpndatepq` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Output Arguments

`PreviousQuasiCouponDate` — Previous quasi coupon date for portfolio of `NUMBONDS` fixed income securities
vector

Previous quasi coupon date for a portfolio of NUMBONDS fixed income securities, whether or not the first or last coupon is normal, short, or long, returned as a NUMBONDS-by-1 vector of previous quasi-coupon dates before settlement. If settlement is a coupon date, this function returns the settlement date.

If all the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are either strings or date character vectors, then PreviousQuasiCouponDate is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are datetime arrays, then PreviousQuasiCouponDate is returned as a datetime array.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although cpndatepq supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

"Pricing and Computing Yields for Fixed-Income Securities" on page 2-15

cpndatep

Previous coupon date for fixed-income security

Syntax

```
PreviousCouponDate = cpndatep(Settle,Maturity)
PreviousCouponDate = cpndatep( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

Description

`PreviousCouponDate = cpndatep(Settle,Maturity)` returns the previous coupon date on or before settlement for a portfolio of bonds. This function finds the previous coupon date whether or not the coupon structure is synchronized with the maturity date. For zero coupon bonds the previous coupon date is the issue date, if available. However, if the issue date is not supplied, the previous coupon date for zero coupon bonds is the previous quasi coupon date calculated as if the frequency is semiannual.

Required input arguments must be number of bonds, `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS`, conforming vectors or scalars.

`PreviousCouponDate = cpndatep( ___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate)` returns the previous coupon date on or before settlement for a portfolio of bonds.

Optional input arguments must be either `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

If all the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are either strings or date character vectors, then `PreviousCouponDate` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

If any of the inputs for `Settle`, `Maturity`, `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are datetime arrays, then `PreviousCouponDate` is returned as a datetime array.

Examples

Calculate the Previous Coupon Date on or Before Settlement

Determine the `PreviousCouponDate` when using character vectors for input arguments.

```
PreviousCouponDate = cpndatep(datetime(1997,3,14),datetime(2000,6,30),2, 0, 0)
```

```
PreviousCouponDate = datetime
   30-Dec-1996
```

Determine the `PreviousCouponDate` when using datetime arrays for input arguments.

```
PreviousCouponDate = cpndatep(datetime(1997,3,14),datetime(2000,6,30),2, 0, 0)
```

```
PreviousCouponDate = datetime
   30-Dec-1996
```

Determine the `PreviousCouponDate` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
PreviousCouponDate = cpndatep(datetime(1997,3,14),datetime(2000,6,30),2, 0, 1)
```

```
PreviousCouponDate = datetime
   31-Dec-1996
```

Determine the `PreviousCouponDate` when using an input vector for `Maturity`.

```
Maturity = [datetime(2000,4,30) ; datetime(2000,5,31) ; datetime(2000,6,30)];
PreviousCouponDate = cpndatep(datetime(1997,3,14), Maturity)
```

```
PreviousCouponDate = 3x1 datetime
   31-Oct-1996
   30-Nov-1996
   31-Dec-1996
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `cpndatep` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpndatep` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Period` — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

Coupons per year of the bond, specified as a vector of positive integers from the set `[1,2,3,4,6,12]`.

Data Types: `single` | `double`

Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or an N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-16.

Data Types: single | double

EndMonthRule — End-of-month rule flag for month having 30 or fewer days

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [0, 1] using an N-by-1 vector of values. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond issue date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cpndatep also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

FirstCouponDate — Date when bond makes first coupon payment

datetime array | string array | date character vector

Date when a bond makes its first coupon payment, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

FirstCouponDate is used when a bond has an irregular first coupon period. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpndatep also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

LastCouponDate — Last coupon date of bond before maturity date

datetime array | string array | date character vector

Last coupon date of a bond before maturity date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpndatep also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

PreviousCouponDate — Previous coupon date on or before settlement for portfolio of bonds

vector

Previous coupon date on or before settlement for portfolio of bonds, returned as an NUMBONDS-by-1 vector. If settlement is a coupon date, this function returns the settlement date. The actual coupon date strictly on or before settlement is returned, but not exceeding the issue date, if available. Thus, this function always returns the lesser of the actual issue date and the previous coupon payment date with respect to the settlement date.

If all the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are either strings or date character vectors, then PreviousCouponDate is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.

If any of the inputs for Settle, Maturity, IssueDate, FirstCouponDate, and LastCouponDate are datetime arrays, then PreviousCouponDate is returned as a datetime array.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `cpndatep` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cpndaysn

Number of days to next coupon date

Syntax

```
NumDaysNext = cpndaysn(Settle,Maturity)
NumDaysNext = cpndaysn( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

Description

`NumDaysNext = cpndaysn(Settle,Maturity)` returns the number of days from the settlement date to the next coupon date for a bond or set of bonds. For zero coupon bonds coupon dates are computed as if the bonds have a semiannual coupon structure. `NumDaysNext` returns a `NUMBONDS`-by-`1` vector containing the number of days to the next coupon date.

Required input arguments must be number of bonds, `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS`, conforming vectors or scalars.

`NumDaysNext = cpndaysn( ___ ,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,LastCouponDate)` returns the number of days from the settlement date to the next coupon date for a bond or set of bonds using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

Examples

Calculate the Number of Days From Settlement Date to Next Coupon Date

Determine the `NumDaysNext` when using datetimes for input arguments.

```
NumDaysNext = cpndaysn(datetime(2000,9,14) , datetime(2001,6,30), 2, 0, 0)
```

```
NumDaysNext = 107
```

Determine the `NumDaysNext` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
NumDaysNext = cpndaysn('14-Sep-2000', '30-Jun-2001', 2, 0, 1)
```

```
NumDaysNext = 108
```

Determine the `NumDaysNext` when using a datetime array for `Maturity`.

```
Maturity = [datetime(2001,4,30) ; datetime(2001,5,31) ; datetime(2001,6,30)];
NumDaysNext = cpndaysn(datetime(2000,9,14), Maturity)
```

```
NumDaysNext = 3×1

    47
    77
   108
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `cpndaysn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpndaysn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Period` — Coupons per year of the bond

`2` (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

Coupons per year of the bond, specified as a vector of positive integers from the set `[1,2,3,4,6,12]`.

Data Types: `single` | `double`

`Basis` — Day-count basis of the instrument

`0` (actual/actual) (default) | numeric with value `0` through `13` | vector of numerics with values `0` through `13`

Day-count basis of the instrument, specified as an integer with a value of `0` through `13` or an `N`-by-`1` vector of integers with values of `0` through `13`.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `single` | `double`

`EndMonthRule` — End-of-month rule flag for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [`0`, `1`] using an `N`-by-`1` vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpndaysn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — Date when bond makes first coupon payment
datetime array | string array | date character vector

Date when a bond makes its first coupon payment, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `cpndaysn` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Last coupon date of bond before maturity date
datetime array | string array | date character vector

Last coupon date of a bond before maturity date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpndaysn also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NumDaysNext — Number of days from settlement date to next coupon date
vector

Number of days from settlement date to next coupon date, returned as an NUMBONDS-by-1 vector. For zero coupon bonds coupon dates are computed as if the bonds have a semiannual coupon structure.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although cpndaysn supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Pricing and Computing Yields for Fixed-Income Securities” on page 2-15

cpndaysp

Number of days since previous coupon date

Syntax

```
NumDaysPrevious = cpndaysp(Settle,Maturity)
NumDaysPrevious = cpndaysp( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

Description

`NumDaysPrevious = cpndaysp(Settle,Maturity)` returns the number of days between the previous coupon date and the settlement date for a bond or set of bonds. When the coupon frequency is 0 (a zero coupon bond), the previous coupon date is calculated as if the frequency were semiannual. `NumDaysPrevious` returns a `NUMBONDS`-by-`1` vector containing the number of days from the previous coupon date to settlement.

Required input arguments must be number of bonds, `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS`, conforming vectors or scalars.

`NumDaysPrevious = cpndaysp( ___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate)` returns the number of days between the previous coupon date and the settlement date for a bond or set of bonds using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

Examples

Calculate the Number of Days Between Previous Coupon Date and Settlement Date

Determine the `NumDaysPrevious` when using datetimes for input arguments.

```
NumDaysPrevious = cpndaysp(datetime(2000,3,14),datetime(2001,6,30), 2, 0, 0)
```

```
NumDaysPrevious = 75
```

Determine the `NumDaysPrevious` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
NumDaysPrevious = cpndaysp('14-Mar-2000','30-Jun-2001', 2, 0, 1)
```

```
NumDaysPrevious = 74
```

Determine the `NumDaysPrevious` when using a datetime array for `Maturity`.

```
Maturity = [datetime(2001,4,30) ; datetime(2001,5,31) ; datetime(2001,6,30)];
NumDaysPrevious = cpndaysp(datetime(2000,3,14), Maturity)
```

```
NumDaysPrevious = 3×1
```

```
   135
   105
    74
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `cpndaysp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpndaysp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Period` — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

Coupons per year of the bond, specified as a vector of positive integers from the set `[1,2,3,4,6,12]`.

Data Types: `single` | `double`

`Basis` — Day-count basis of the instrument

`0` (actual/actual) (default) | numeric with value `0` through `13` | vector of numerics with values `0` through `13`

Day-count basis of the instrument, specified as an integer with a with value `0` through `13` or an `N`-by-`1` vector of integers with values `0` through `13`.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `single` | `double`

`EndMonthRule` — End-of-month rule flag for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [`0`, `1`] using an `N`-by-`1` vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpndaysp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — Date when bond makes first coupon payment
datetime array | string array | date character vector

Date when a bond makes its first coupon payment, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `cpndaysp` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Last coupon date of bond before maturity date
datetime array | string array | date character vector

Last coupon date of a bond before maturity date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpndaysp also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NumDaysPrevious — Number of days between previous coupon date and settlement date
vector

Number of days between the previous coupon date and the settlement date, returned as an NUMBONDS-by-1 vector. If the settlement date is a coupon date, this function always returns the settlement date.

When the coupon frequency is 0 (a zero coupon bond), the previous coupon date is calculated as if the frequency were semiannual.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although cpndaysp supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Pricing and Computing Yields for Fixed-Income Securities” on page 2-15

cpnpersz

Number of days in coupon period

Syntax

```
NumDaysPeriod = cpnpersz(Settle,Maturity)
NumDaysPeriod = cpnpersz( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate)
```

Description

`NumDaysPeriod = cpnpersz(Settle,Maturity)` returns the number of days in the coupon period containing the settlement date. For zero coupon bonds, coupon dates are computed as if the bonds have a semiannual coupon structure. `NumDaysPeriod` returns a `NUMBONDS`-by-`1` vector containing the number of days in the coupon period containing the settlement date.

.

Required input arguments must be number of bonds, `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS`, conforming vectors or scalars.

`NumDaysPeriod = cpnpersz( ___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate)` returns the number of days in the coupon period containing the settlement date using optional input arguments.

Optional input arguments must be either `NUMBONDS`-by-`1` or `1`-by-`NUMBONDS` conforming vectors, scalars, or empty matrices.

Examples

Calculate the Number of Days in the Coupon Period Containing Settlement Date

Determine the `NumDaysPeriod` when using datetimes for input arguments.

```
NumDaysPeriod = cpnpersz(datetime(2000,9,14),datetime(2001,6,30), 2, 0, 0)
```

```
NumDaysPeriod = 183
```

Determine the `NumDaysPeriod` when using character vectors for input arguments and the optional argument for `EndMonthRule`.

```
NumDaysPeriod = cpnpersz('14-Sep-2000', '30-Jun-2001', 2, 0, 1)
```

```
NumDaysPeriod = 184
```

Determine the `NumDaysPeriod` when using an input vector for `Maturity`.

```
Maturity = [datetime(2001,6,30) ; datetime(2001,5,31) ; datetime(2001,6,30)];
NumDaysPeriod = cpnpersz('14-Sep-2000', Maturity)
```

```
NumDaysPeriod = 3×1
```

```
   184
   183
   184
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `cpnpersz` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpnpersz` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Period` — Coupons per year of the bond

2 (semiannual) (default) | vector of positive integers from the set `[1,2,3,4,6,12]`

Coupons per year of the bond, specified as a vector of positive integers from the set `[1,2,3,4,6,12]`.

Data Types: `single` | `double`

`Basis` — Day-count basis of the instrument

`0` (actual/actual) (default) | numeric with value `0` through `13` | vector of numerics with values `0` through `13`

Day-count basis of the instrument, specified as an integer with a value of `0` through `13` or an `N`-by-`1` vector of integers with values of `0` through `13`.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)

- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `single` | `double`

`EndMonthRule` — End-of-month rule flag for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for month having 30 or fewer days, specified as a nonnegative integer [`0`, `1`] using an `N`-by-`1` vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond’s coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond’s coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cpnpersz` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`FirstCouponDate` — Date when bond makes first coupon payment
datetime array | string array | date character vector

Date when a bond makes its first coupon payment, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

`FirstCouponDate` is used when a bond has an irregular first coupon period. When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

To support existing code, `cpnpersz` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`LastCouponDate` — Last coupon date of bond before maturity date
datetime array | string array | date character vector

Last coupon date of a bond before maturity date, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

LastCouponDate is used when a bond has an irregular last coupon period. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

To support existing code, cpnpersz also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NumDaysPeriod — Number of days in coupon period containing settlement date
vector

Number of days in the coupon period containing the settlement date, returned as an NUMBONDS-by-1 vector. For zero coupon bonds, coupon dates are computed as if the bonds have a semiannual coupon structure.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although cpnpersz supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics
“Pricing and Computing Yields for Fixed-Income Securities” on page 2-15

createholidays

Create trading calendars

Syntax

createholidays(Filename,Codefile,InfoFile,TargetDir,IncludeWkds,Wprompt,NoGUI)

Description

createholidays(Filename,Codefile,InfoFile,TargetDir,IncludeWkds,Wprompt,NoGUI) programmatically generates the market-specific holidays.m files (from FinancialCalendar.com financial center holiday data) without displaying the interface.

Note To use createholidays, you must obtain data, codes, and info files from https://www.FinancialCalendar.com trading calendars. The data files must be in the required MATLAB format.

Examples

Create holidays.m Files Using createholidays

Use createholidays to create holidays*.m files from My_datafile.csv in the folder c:\work. Weekends are included in the holidays list based on the input flag INCLUDEWDKS = 1

```
createholidays('FinancialCalendar\My_datafile.csv',...
'FinancialCalendar\My_codesfile.csv',...
'FinancialCalendar\My_infofile.csv','c:\work',1,1,1)
```

Input Arguments

Filename — Data file name

character vector

Data file name, specified using a character vector.

Data Types: char

Codefile — Code file name

character vector

Code file name, specified using a character vector.

Data Types: char

InfoFile — Info file name

character vector

Info file name, specified using a character vector.

Data Types: `char`

`TargetDir` — Target folder where to write new `holidays.m` files

character vector

Target folder where to write the new `holidays.m` files, specified using a character vector.

Data Types: `char`

`IncludeWkds` — Option to include weekends in holiday list

numeric with value `0` or `1`

Option to include weekends in the holiday list, specified using a numeric with value `0` or `1`. Values are:

- `0` – Do not include weekends in the holiday list.
- `1` – Include weekends in the holiday list.

Data Types: `logical`

`Wprompt` — Option to prompt for file location for each `holiday.m` file that is created

numeric with value `0` or `1`

Option to prompt for the file location for each `holiday.m` file that is created, specified using a numeric with value `0` or `1`. Values are:

- `0` – Do not prompt for the file location.
- `1` – Prompt for the file location.

Data Types: `logical`

`NoGUI` — Run `createholidays` without displaying Trading Calendars user interface

numeric with value `0` or `1`

Run `createholidays` without displaying the Trading Calendars user interface, specified using a numeric with value `0` or `1`. Values are:

- `0` – Display the GUI.
- `1` – Do not display the GUI.

Data Types: `logical`

Version History

Introduced in R2007b

cur2frac

Decimal currency values to fractional values

Syntax

```
Fraction = cur2frac(Decimal,Denominator)
```

Description

`Fraction = cur2frac(Decimal,Denominator)` converts decimal currency values to fractional values. `Fraction` is returned as a character vector.

Examples

Convert Decimal Currency Values to Fractional Values

This example shows how to convert decimal currency values to fractional values.

```
Fraction = cur2frac(12.125, 8)
```

```
Fraction =
'12.1'
```

Input Arguments

`Decimal` — Decimal currency value
numeric decimal

Decimal currency value, specified as a scalar or vector using numeric decimal values.

Data Types: `double`

`Denominator` — Denominator of the fractions
numeric

Denominator of the fractions, specified as a scalar or vector using numeric values for the denominator.

Data Types: `double`

Output Arguments

`Fraction` — Fractional values
character vector | cell array of character vectors

Fractional values, returned as a character vector or cell array of character vectors.

Version History

Introduced before R2006a

See Also

`cur2str` | `frac2cur`

cur2str

Bank-formatted text

Syntax

```
BankText = cur2str(Value,Digits)
```

Description

`BankText = cur2str(Value,Digits)` returns the given value in bank format.

The output format for `BankText` is a numerical format with dollar sign prefix, two decimal places, and negative numbers in parentheses; for example, ($123.45) and $6789.01. The standard MATLAB bank format uses two decimal places, no dollar sign, and a minus sign for negative numbers; for example, −123.45 and 6789.01.

Examples

Return Bank Formatted Text

Return bank formatted text for a negative numeric value.

```
BankText = cur2str(-826444.4456,3)
```

```
BankText = 
'($826444.446)'
```

```
% Negative numbers are displayed in parentheses.
```

Input Arguments

`Value` — Value to be formatted
numeric value

Value to be formatted, specified as a numeric value.

Data Types: `double`

`Digits` — Number of significant digits
2 (default) | integer

Number of significant digits, specified as an integer. A negative `Digits` rounds the value to the left of the decimal point.

Data Types: `double`

Output Arguments

BankText — Bank-formatted text

character vector

Bank-formatted text (BankText) is returned as a character vector with a leading dollar sign ($). Negative numbers are displayed in parentheses.

Version History

Introduced before R2006a

frac2cur | cur2frac

date2time

Time and frequency from dates

Syntax

```
[TFactors,F] = date2time(Settle,Maturity)
[TFactors,F] = date2time( ___ ,Compounding,Basis,EndMonthRule)
```

Description

`[TFactors,F] = date2time(Settle,Maturity)` computes time factors appropriate to compounded rate quotes between the `Settle` and `Maturity` dates. `date2time` is the inverse of `time2date`.

`[TFactors,F] = date2time( ___ ,Compounding,Basis,EndMonthRule)` computes time factors appropriate to compounded rate quotes between the `Settle` and `Maturity` dates using optional input arguments for `Compounding`, `Basis`, and `EndMonthRule`. `date2time` is the inverse of `time2date`.

Examples

Compute `date2time` Using an actual/actual Basis

To get the `date2time` period between '31-Jul-2015' and '30-Sep-2015' using an actual/actual basis:

```
date2time(datetime(2015,7,31),datetime(2015,9,30), 2, 0, 1)
```

```
ans = 0.3333
```

When using `date2time` quasi coupon, two quasi coupon dates are computed for a bond with a maturity corresponding to the `Dates` input. In this case, that would be "30-Sep-2015". Assuming that the compounding frequency is `2`, the other quasi coupon date is six months prior to this date. Assuming the end of month rule is in place, then the other quasi coupon date is "31-Mar-2015". You can use these two dates to compute the total number of actual days in a period (which is 183). Given this, the fraction of time between the start and end date for the actual/actual basis is computed as follows.

```
(Actual Days between Start Date and End Date)/(Actual Number of Days between
Quasi Coupon Dates)
```

There are 61 days between 31-Jul-2015 and 30-Sep-2015 and 183 days between the quasi coupon dates ("31-Mar-2015" and "30-Sep-2015") which leads to a final result of 61/183 or exactly 1/3.

Input Arguments

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `date2time` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a scalar or `N`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `date2time` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Compounding` — Rate at which input zero rates are compounded when annualized

2 (Semiannual compounding) (default) | scalar with numeric values of `0`, `1`, `2`, `3`, `4`, `5`, `6`, `12`, `365`, `−1`

Rate at which input zero rates are compounded when annualized, specified as a scalar with numeric values of: `0`, `1`, `2`, `3`, `4`, `5`, `6`, `12`, `365`, or `−1`. Allowed values are defined as:

- `0` — Simple interest (no compounding)
- `1` — Annual compounding
- `2` — Semiannual compounding (default)
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding
- `365` — Daily compounding
- `-1` — Continuous compounding

The optional `Compounding` argument determines the formula for the discount factors (`Disc`):

- `Compounding` = `0` for simple interest
  - `Disc = 1/(1 + Z * T)`, where `T` is time in years and simple interest assumes annual times `F = 1`.
- `Compounding` = `1`, `2`, `3`, `4`, `6`, `12`
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units, for example, `T = F` is one year.
- `Compounding` = `365`
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- `Compounding` = `-1`
  - `Disc = exp(-T*Z)`, where `T` is time in years.

Basis — Day-count basis

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis, specified as an integer with a value 0 through 13 or a N-by-1 vector of integers with values 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: single | double

EndMonthRule — End-of-month rule flag for month having 30 or fewer days

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using a N-by-1 vector of values. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

Output Arguments

TFactors — Time factors

vector

Time factors, appropriate to compounded rate quotes between Settle and Maturity dates, returned as a vector.

F — Compounding frequencies

scalar

Compounding frequencies, returned as a scalar.

More About

Difference Between yearfrac and date2time

The difference between `yearfrac` and `date2time` is that `date2time` counts full periods as a whole integer, even if the number of actual days in the periods are different. `yearfrac` does not count full periods.

For example,

```
yearfrac('1/1/2000', '1/1/2001', 9)
```

```
ans =

    1.0167
```

`yearfrac` for `Basis 9` (ACT/360 ICMA) calculates 366/360 = 1.0167. So, even if the dates have the same month and date, with a difference of 1 in the year, the returned value may not be exactly 1. On the other hand, `date2time` calculates one full year period:

```
date2time('1/1/2000', '1/1/2001', 1, 9)
```

```
ans =

     1
```

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `date2time` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

dateaxis

Convert serial-date axis labels to calendar-date axis labels

Syntax

```
dateaxis(Tickaxis,DateForm,StartDate)
```

Description

`dateaxis(Tickaxis,DateForm,StartDate)` replaces axis tick labels with date labels.

Examples

Replace Axis Tick Labels with Date Labels

This example shows how to use dateaxis to replaces axis tick labels with date labels on a graphic figure.

Convert the *x*-axis labels to an automatically determined date format.

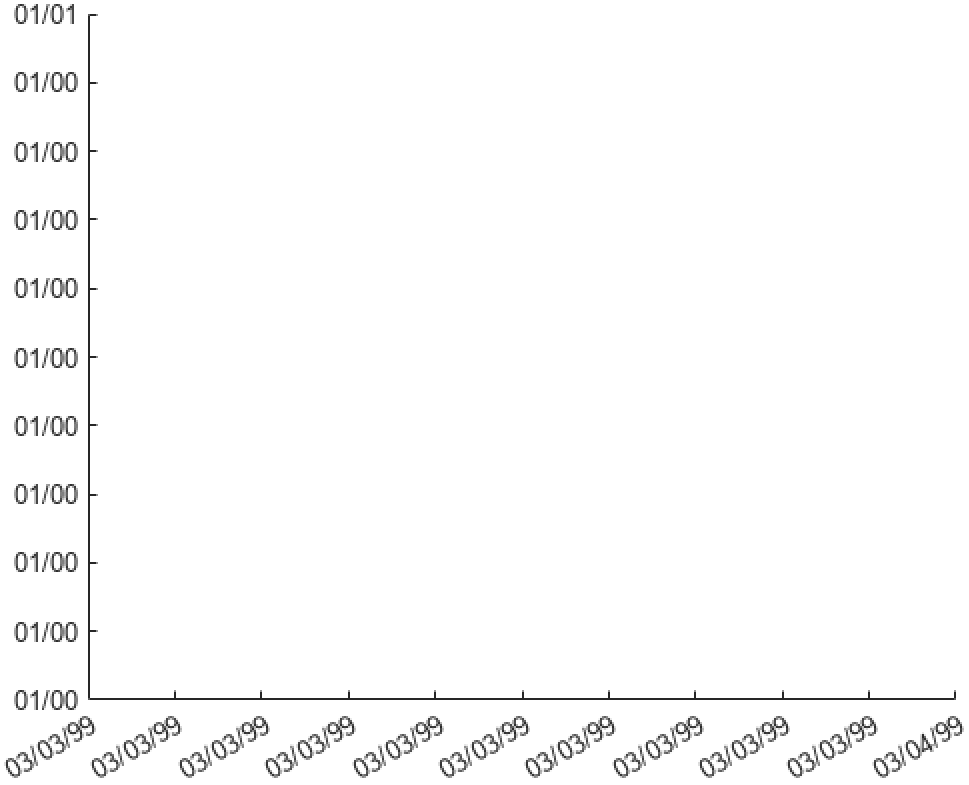
```
dateaxis('y', 6)
```

Convert the *y*-axis labels to the month/day format.

```
dateaxis('x', 2, datetime(1999,3,3))
```

Convert the *x*-axis labels to the month/day/year format. The minimum *x*-tick value is treated as March 3, 1999.

```
dateaxis('x', 2, datetime(1999,3,3))
```



Input Arguments

`Tickaxis` — Determines which axis tick labels, x, y, z to replace

`'x'` (default) | character vector with value `'x'`, `'y'`, or `'z'`

(Optional) Determines which axis tick labels —*x*, *y*, or *z*— to replace, specified as a character vector.

Data Types: `char`

`DateForm` — Defines which date format to use

date format based on the span of the axis limits (default) | integer from `0` to `17`

(Optional) Defines which date format to use, specified as an integer from `0` to `17`.

If no `DateForm` argument is entered, this function determines the date format based on the span of the axis limits. For example, if the difference between the axis minimum and maximum is less than 15, the tick labels are converted to three-letter day-of-the-week abbreviations (`DateForm = 8`).

DateForm	Format	Description
0	`01-Mar-1999 15:45:17`	day-month-year hour:minute:second
1	`01-mar-1999`	day-month-year
2	`03/01/99`	month/day/year
3	`Mar`	month, three letters

DateForm	Format	Description
4	M	month, single letter
5	3	month
6	03/01	month/day
7	1	day of month
8	Wed	day of week, three letters
9	W	day of week, single letter
10	1999	year, four digits
11	99	year, two digits
12	Mar99	month year
13	15:45:17	hour:minute:second
14	03:45:17 PM	hour:minute:second AM or PM
15	15:45	hour:minute
16	03:45 PM	hour:minute AM or PM
17	95/03/01	year month day

Refer to the MATLAB `set` command for information on modifying the axis tick values and other axis parameters.

Data Types: `double`

`StartDate` — Assigns the date to the first axis tick value
lower axis limit converted to the appropriate date number (default) | datetime scalar | string scalar | date character vector

(Optional) Assigns the date to the first axis tick value, specified as a scalar datetime, string, or date character vector.

The default `StartDate` is the lower axis limit converted to the appropriate date number. For example, a tick value of `1` is converted to the date 01-Jan-0000. Entering `StartDate` as `'06-apr-1999'` assigns the date April 6, 1999 to the first tick value and the axis tick labels are set accordingly.

To support existing code, `dateaxis` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `dateaxis` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

datedisp

Display date entries

Syntax

```
datedisp(NumMat)
datedisp( ___ ,DateForm)
CharMat = datedisp(NumMat,DateForm)
```

Description

datedisp(NumMat) displays a matrix with the serial dates formatted as date character vectors, using a matrix with mixed numeric entries and serial date number entries. Integers between datenum('01-Jan-1900') and datenum('01-Jan-2200') are assumed to be serial date numbers, while all other values are treated as numeric entries.

datedisp(___ ,DateForm), using the optional argument DateForm, displays a matrix with the serial dates formatted as date character vectors, using a matrix with mixed numeric entries and serial date number entries. Integers between datenum('01-Jan-1900') and datenum('01-Jan-2200') are assumed to be serial date numbers, while all other values are treated as numeric entries.

CharMat = datedisp(NumMat,DateForm) returns CharMat, character array representing NumMat. If no output variable is assigned, the function prints the array to the display.

Examples

Display a Matrix with the Serial Dates Formatted as Date Character Vectors

This example shows how to display a matrix with the serial dates formatted as date character vectors.

```
NumMat = [730730, 0.03, 1200 730100;
          730731, 0.05, 1000 NaN];

datedisp(NumMat)
```

```
01-Sep-2000   0.03   1200   11-Dec-1998
02-Sep-2000   0.05   1000      NaN
```

Input Arguments

NumMat — Numeric matrix to display
serial date numbers

Numeric matrix to display, specified as serial date numbers.

Data Types: double

`DateForm` — Date format

scalar character vector to indicate format of text representing dates

Date format, specified as a scalar character vector to indicate the format of text representing dates. See `datestr` for available and default format flags.

Data Types: `char`

Output Arguments

`CharMat` — Character array representing `NumMat`

array of date character vectors

Character array representing `NumMat`, returned as an array of date character vectors. If no output variable is assigned, the function prints the array to the display.

Version History

Introduced before R2006a

Topics

"Handle and Convert Dates" on page 2-2

datefind

Indices of dates in matrix

Syntax

```
Indices = datefind(Subset,Superset)
Indices = datefind( ___ ,Tolerance)
```

Description

`Indices = datefind(Subset,Superset)` returns a vector of indices to the date numbers in `Superset` that are present in `Subset`. If no date numbers match, `Indices = []`.

`Indices = datefind( ___ ,Tolerance)` returns a vector of indices to the date numbers in `Superset` that are present in `Subset`, plus the optional argument for `Tolerance`. If no date numbers match, `Indices = []`.

Examples

Return a Vector of Indices to Date Numbers

This example shows how to return a vector of indices to date numbers.

```
Superset = datetime(1999,7,1:31);
Subset = [datetime(1999,7,10) ; datetime(1999,7,20)];
Indices = datefind(Subset, Superset, 1)
```

```
Indices = 6×1

     9
    10
    11
    19
    20
    21
```

Input Arguments

`Subset` — Subset of dates to find matching dates
datetime array | string array | date character vector

Subset of dates to find matching dates in `Superset`, specified as a matrix using a datetime array, string array, or date character vectors.

`Subset` and `Superset` can be either be a datetime array, string array, or date character vectors. These types do not have to match. `datefind` determines the underlying date to match dates of different data types.

Note The elements of `Subset` must be contained in `Superset`, without repetition. `datefind` works with non-repeating sequences of dates.

Example: `Subset = [datetime(1997,7,10); datetime(1997,7,20)];`

To support existing code, `datefind` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Superset` — Superset of dates

datetime array | string array | date character vector

Superset of dates, specified as a matrix of using a datetime array, string array, or date character vectors, whose elements are sought.

`Subset` and `Superset` can be either a datetime array, string array, or date character vectors. These types do not have to match. `datefind` determines the underlying date to match dates of different data types.

Note The elements of `Subset` must be contained in `Superset`, without repetition. `datefind` works with non-repeating sequences of dates.

Example: `Superset = datetime(1997,7,1:31);`

To support existing code, `datefind` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Tolerance` — Tolerance for matching dates in `Superset`

`0` (default) | positive integer or duration object

Tolerance for matching dates (`+/-`) in `Superset`, specified as a positive integer or duration object.

Data Types: `single` | `double`

Output Arguments

`Indices` — Indices of dates in `Superset` that are present in `Subset`

vector

Indices of dates in `Superset` that are present in `Subset` (plus or minus the tolerance if defined using the optional argument `Tolerance`), returned as a vector of indices.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although datefind supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

datenum | datetime

Topics

“Handle and Convert Dates” on page 2-2

datemnth

Date of day in future or past month

Syntax

```
TargetDate = datemnth(StartDate,NumberMonths)
TargetDate = datemnth( ___ ,DayFlag,Basis,EndMonthRule)
```

Description

`TargetDate = datemnth(StartDate,NumberMonths)` determines a date in a future or past month based on movement either forward or backward in time by a given number of months.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row datetime, then `NumberMonths` must be an `N`-by-`1` vector of integers or a single integer. `TargetDate` is then an `N`-by-`1` vector of datetimes.

If `StartDate` is a string or date character vector, `TargetDate` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

If `StartDate` is a datetime array, then `TargetDate` is returned as a datetime array.

`TargetDate = datemnth( ___ ,DayFlag,Basis,EndMonthRule)` determines a date in a future or past month based on movement either forward or backward in time by a given number of months, using optional input arguments for `DayFlag`,`Basis`, and `EndMonthRule`.

Examples

Determine the Dates of Days in a Future Month

Determine the `TargetDate` in a future month using a datetime for `StartDate`.

```
StartDate = datetime(1997,6,3);
NumberMonths = 6;
DayFlag = 0;
Basis = 0;
EndMonthRule = 1;

TargetDate = datemnth(StartDate, NumberMonths, DayFlag,Basis, EndMonthRule)
```

```
TargetDate = datetime
   03-Dec-1997
```

Determine the `TargetDate` in a future month using a vector for `NumberMonths`.

```
NumberMonths = [1; 3; 5; 7; 9];
TargetDate = datemnth(datetime(2001,1,31), NumberMonths)
TargetDate = 5x1 datetime
   28-Feb-2001
   30-Apr-2001
   30-Jun-2001
   31-Aug-2001
   31-Oct-2001
```

Input Arguments

StartDate — Start date

datetime array | string array | date character vector

Start date, specified as an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, datemnth also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

NumberMonths — Number of months in future (positive) or past (negative)

positive or negative integers

Number of months in future (positive) or past (negative), specified as an N-by-1 or 1-by-N vector containing positive or negative integers.

Data Types: double

DayFlag — Flag for how actual day number for target date in future or past month is determined

0 (day number should be the day in the future or past month corresponding to the actual day number of the start date) (default) | numeric with values 0, 1, or 2

Flag for how the actual day number for the target date in future or past month is determined, specified as an N-by-1 or 1-by-N vector using a numeric with values0, 1, or 2.

Possible values are:

- 0 (default) = day number should be the day in the future or past month corresponding to the actual day number of the start date.
- 1 = day number should be the first day of the future or past month.
- 2 = day number should be the last day of the future or past month.

This flag has no effect if EndMonthRule is set to 1.

Data Types: double

Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis to be used when determining the past or future date, specified as a scalar value with an integer with value of 0 through 13, or an N-by-1 or 1-by-N vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `single` | `double`

`EndMonthRule` — End-of-month rule flag for month having 30 or fewer days
`0` (not in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for month having 30 or fewer days, specified as a scalar with a nonnegative integer `0` or `1`, or as an `N`-by-`1` or `1`-by-`N` vector of values `0` or `1`.

- `0` = Ignore rule, meaning that rule is not in effect.
- `1` = Set rule on, meaning that if you are beginning on the last day of a month, and the month has 30 or fewer days, you will end on the last actual day of the future or past month regardless of whether that month has 28, 29, 30 or 31 days.

Data Types: `logical`

Output Arguments

`TargetDate` — Target date in the future or past month
vector

Target date in the future or past month, returned as an `N`-by-`1` or `1`-by-`N` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although `datemnth` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

datewrkdy

Date of future or past workday

Syntax

```
EndDate = datewrkdy(StartDate,NumberWorkDays,NumberHolidays)
```

Description

`EndDate = datewrkdy(StartDate,NumberWorkDays,NumberHolidays)` returns the datetime of the date a given number of workdays before or after the start date.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all.

For example, if `StartDate` is an *n*-row datetime, then `NumberWorkDays` must be an `N`-by-`1` vector of integers or a single integer. `EndDate` is then an `N`-by-`1` vector of datetimes.

If `StartDate` is a string or date character vector, `EndDate` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

If `StartDate` is a datetime array, then `EndDate` is returned as a datetime array.

Examples

Determine the Date for a Future Workday

Determine the `EndDate` for a future workday using a date character vector for `StartDate`.

```
StartDate = '20-Dec-1994';
NumberWorkDays = 16;
NumberHolidays = 2;

EndDate = datewrkdy(StartDate, NumberWorkDays, NumberHolidays)
```

```
EndDate = 728671
```

```
datestr(EndDate)
```

```
ans =
'12-Jan-1995'
```

Determine the `EndDate` for a future workday using a datetime for `StartDate`.

```
EndDate = datewrkdy(datetime(2000,12,12), 16, 2)
```

```
EndDate = datetime
   04-Jan-2001
```

Determine the `EndDate` for future workdays using a vector for `NumberWorkDays`.

```
NumberWorkDays = [16; 20; 44];
EndDate = datewrkdy(datetime(2000,12,12), NumberWorkDays, 2)
```

```
EndDate = 3x1 datetime
   04-Jan-2001
   10-Jan-2001
   13-Feb-2001
```

Input Arguments

StartDate — Start date

datetime array | string array | date character vector

Start date, specified as an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, datewrkdy also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

NumberWorkDays — Number of work or business days in future (positive) or past (negative)

positive or negative integers

Number of work or business days in future (positive) or past (negative) that includes the starting date, specified as an N-by-1 or 1-by-N vector containing positive or negative integers.

NumberHolidays and NumberWorkDays must have the same sign.

Data Types: double

NumberHolidays — Number of holidays within NumberWorkDays

positive or negative integers

Number of holidays within NumberWorkDays, specified as positive or negative integers using an N-by-1 or 1-by-N containing values for the number of days movement in terms of holidays into the future (if positive) or past (if negative).

NumberHolidays and NumberWorkDays must have the same sign.

Data Types: double

Output Arguments

EndDate — Date of future or past workday

vector

Date of future or past workday, returned as an N-by-1 or 1-by-N vector for the future or past date.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although `datewrkdy` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

days252bus

Number of business days between dates

Syntax

```
NumberDays = days252bus(StartDate,EndDate)
NumberDays = days252bus( ___ HolidayVector)
```

Description

`NumberDays = days252bus(StartDate,EndDate)` computes the number of business days (that is, non-holiday or non-weekend) between the two input dates.

`NumberDays = days252bus( ___ HolidayVector)` adds an optional argument for `HolidayVector`. If a holiday vector is not optionally specified, then the `holidays.m` file is used to determine the holidays.

Examples

Computes the Number of Business Days Between Two Input Dates

This example shows how to compute the number of business days (i.e. non-holiday or non-weekend) between two dates using the days252bus convention.

```
NumberDays = days252bus(datetime(2009,1,1), datetime(2009,8,1))
```

```
NumberDays = 146
```

Input Arguments

`StartDate` — Start date
datetime array | string array | date character vector

Start date, specified as a scalar or an `N`-by-`1` or `1`-by-`N` vector using a datetime array, string array, or date character vectors.

To support existing code, `days252bus` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `double` | `char` | `string` | `datetime`

`EndDate` — End date
datetime array | string array | date character vector

End date, specified as a scalar or an `N`-by-`1` or `1`-by-`N` vector using a datetime array, string array, or date character vectors.

To support existing code, `days252bus` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

HolidayVector — Holidays
holidays.m (default) | datetime array | string array | date character vector | serial date number

Holidays, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, days252bus also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NumberDays — Number of days between two dates
vector

Number of days between two dates, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although days252bus supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

days360

Days between dates based on 360-day year

Syntax

```
NumDays = days360(StartDate,EndDate)
```

Description

`NumDays = days360(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 360-day year (that is, all months contain 30 days). If `EndDate` is earlier than `StartDate`, `NumDays` is negative.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row datetime, then `EndDate` must be an `N`-by-`1` vector of integers or a single integer. `NumDays` is then an `N`-by-`1` vector of date numbers.

Examples

Determine the Number of Days Between Two Dates Based on a 360-Day Year

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = days360('15-jan-2000', '15-mar-2000')
```

```
NumDays = 60
```

Determine the `NumDays` using a datetime for `StartDate` and `EndDate`.

```
NumDays = days360(datetime(2000,1,15) , datetime(2000,3,15))
```

```
NumDays = 60
```

Determine the `NumDays` using a datetime array for `EndDate`.

```
MoreDays = [datetime(2000,3,15) ; datetime(2000,4,15) ; datetime(2000,6,15)];
NumDays = days360(datetime(2000,1,15), MoreDays)
```

```
NumDays = 3×1

    60
    90
   150
```

Input Arguments

`StartDate` — Start date
datetime array | string array | date character vector

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, `days360` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`EndDate` — End date
datetime array | string array | date character vector

End date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, `days360` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Output Arguments

`NumDays` — Number of days between two dates
vector

Number of days between two dates, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

Version History
Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although `days360` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

days360e

Days between dates based on 360-day year (European)

Syntax

```
NumDays = days360e(StartDate,EndDate)
```

Description

`NumDays = days360e(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 360-day year (that is, all months contain 30 days). If `EndDate` is earlier than `StartDate`, `NumDays` is negative. This day count convention is used primarily in Europe. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row datetime, then `EndDate` must be an `N`-by-`1` vector of integers or a single integer. `NumDays` is then an `N`-by-`1` vector of date numbers.

Examples

Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on European Convention

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate` for the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
NumDays = days360e(StartDate, EndDate)
```

```
NumDays = 30
```

Determine the `NumDays` in the month of January using datetimes for `StartDate` and `EndDate`.

```
NumDays = days360e(datetime(2002,1,1), datetime(2002,2,1))
```

```
NumDays = 30
```

Determine the `NumDays` using a datatime arrayr for `EndDate`.

```
MoreDays = [datetime(2000,3,15) ; datetime(2000,4,15) ; datetime(2000,6,15)];
NumDays = days360e(datetime(2000,1,15), MoreDays)
```

```
NumDays = 3×1

    60
    90
   150
```

Input Arguments

StartDate — Start date

datetime array | string array | date character vector

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, days360e also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

EndDate — End date

datetime array | string array | date character vector

End date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, days360e also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NumDays — Number of days between two dates given a basis of 30/360 based on European convention

vector

Number of days between two dates given a basis of 30/360 based on European convention, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although days360e supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021

days360isda

Days between dates based on 360-day year (International Swap Dealer Association (ISDA) compliant)

Syntax

```
NumDays = days360isda(StartDate,EndDate)
```

Description

`NumDays = days360isda(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 360-day year (that is, all months contain 30 days) and is International Swap Dealer Association (ISDA) compliant. If `EndDate` is earlier than `StartDate`, `NumDays` is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row datetime, then `EndDate` must be an `N`-by-`1` vector of integers or a single integer. `NumDays` is then an `N`-by-`1` vector of date numbers.

Examples

Determine the Number of Days Between Two Dates Given a Basis of 30/360 Based on ISDA Compliance

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate` for the month of January.

```
StartDate = '1-Jan-2002';
EndDate = '1-Feb-2002';
NumDays = days360isda(StartDate, EndDate)
```

```
NumDays = 30
```

Determine the `NumDays` in the month of January using datetimes for `StartDate` and `EndDate`.

```
NumDays = days360isda(datetime(2002,1,1), datetime(2002,2,1))
```

```
NumDays = 30
```

Determine the `NumDays` using a datatime array for `EndDate`.

```
MoreDays = [datetime(2000,3,15) ; datetime(2000,4,15) ; datetime(2000,6,15)];

Topics

"Handle and Convert Dates" on page 2-2

days365

Days between dates based on 365-day year

Syntax

```
NumDays = days365(StartDate,EndDate)
```

Description

`NumDays = days365(StartDate,EndDate)` returns the number of days between `StartDate` and `EndDate` based on a 365-day year. All months contain their actual number of days. February always contains 28 days.

If `EndDate` is earlier than `StartDate`, `NumDays` is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row datetime, then `EndDate` must be an `N`-by-`1` vector of integers or a single integer. `NumDays` is then an `N`-by-`1` vector of date numbers.

Examples

Determine the Number of Days Between Two Dates Based on a 365-Day Year

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = days365('15-jan-2000', '15-mar-2000')
```

```
NumDays = 59
```

Determine the `NumDays` using datetimes for `StartDate` and `EndDate`.

```
NumDays = days365(datetime(2000,1,15) , datetime(2000,3,15))
```

```
NumDays = 59
```

Determine the `NumDays` using a datetime array for `EndDate`.

```
MoreDays = [datetime(2000,3,15) ; datetime(2000,4,15) ; datetime(2000,6,15)];
NumDays = days365('15-jan-2000', MoreDays)
```

```
NumDays = 3×1

    59
    90
   151
```

Input Arguments

StartDate — Start date

datetime array | string array | date character vector

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, days365 also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

EndDate — End date

datetime array | string array | date character vector

End date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, days365 also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NumDays — Number of days between two dates based on 365-day year

vector

Number of days between two dates based on a 365-day year, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although days365 supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

"Handle and Convert Dates" on page 2-2

daysact

Actual number of days between dates

Syntax

```
NumDays = daysact(StartDate)
NumDays = daysact( ___ ,EndDate)
```

Description

`NumDays = daysact(StartDate)` returns the actual number of days between the MATLAB base date and `StartDate`. In MATLAB, the base date `1` is 1-Jan-0000 A.D. See `datenum` for a similar function.

`NumDays = daysact( ___ ,EndDate)` returns the actual number of days between `StartDate` and the optional argument `EndDate`.

If `EndDate` is earlier than `StartDate`, `NumDays` is negative. Under this convention, all months contain 30 days.

Either input argument can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row datetime, then `EndDate` must be an `N`-by-`1` vector of integers or a single integer. `NumDays` is then an `N`-by-`1` vector of date numbers.

Examples

Determine the Number of Days Between Two Dates Based the Actual Number of Days

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = daysact('7-sep-2002',  '25-dec-2002')
```

```
NumDays = 109
```

Determine the `NumDays` using datetimes for `StartDate` and `EndDate`.

```
NumDays = daysact(datetime(2002,9,7) , datetime(2002,12,25))
```

```
NumDays = 109
```

Determine the `NumDays` using a datetime array for `EndDate`.

```
MoreDays = [datetime(2002,9,7) ; datetime(2002,10,22) ; datetime(2002,11,5)];
NumDays = daysact(MoreDays, '12/25/2002')
```

```
NumDays = 3×1

   109
    64
    50
```

Input Arguments

StartDate — Start date

datetime array | string array | date character vector

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, daysact also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

EndDate — End date

datetime array | string array | date character vector

End date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, daysact also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

NumDays — Number of days between two dates based actual number of days

vector

Number of days between two dates based on the actual number of days, returned as a scalar or an N-by-1 or 1-by-N vector containing the number of days.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although daysact supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

daysadd

Date away from starting date for any day-count basis

Syntax

```
NewDate = daysadd(StartDate,NumDays)
NewDate = daysadd( ___ ,Basis)
```

Description

`NewDate = daysadd(StartDate,NumDays)` returns a date `NewDate` number of days away from `StartDate`.

If `StartDate` is a string or date character vector, `NewDate` is returned as a serial date number.

If `StartDate` is a datetime array, then `NewDate` is returned as a datetime array.

`NewDate = daysadd( ___ ,Basis)` returns a date `NewDate` number of days away from `StartDate`, using the optional argument `Basis` for day-count.

If `StartDate` is a string or date character vector, `NewDate` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

If `StartDate` is a datetime array, then `NewDate` is returned as a datetime array.

Examples

Determine the Date for Given Number of Days Away From `StartDate`

Determine the `NewDate` using a date character vector for `StartDate`.

```
NewDate = daysadd('01-Feb-2004', 31)
```

```
NewDate = 732009
```

```
datestr(NewDate)
```

```
ans = 
'03-Mar-2004'
```

Determine the `NewDate` using a datetime for `StartDate`.

```
NewDate = daysadd(datetime(2004,2,1), 31)
```

```
NewDate = datetime
   03-Mar-2004
```

Determine the `NewDate` using a datetime arraay for `StartDate`.

```
MoreDays = [datetime(2002,9,7) ; datetime(2002,10,22) ; datetime(2002,11,5)];
NewDate = daysadd(MoreDays, 31 ,2)
NewDate = 3x1 datetime
   08-Oct-2002
   22-Nov-2002
   06-Dec-2002
```

Input Arguments

StartDate — Start date

datetime array | string array | date character vector

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, daysadd also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

NumDays — Number of days from StartDate

positive or negative integer

Number of days from StartDate, specified an N-by-1 or 1-by-N vector using positive or negative integers. Enter a negative integer for dates before start date.

Data Types: double

Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or a N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note When using the 30/360 day-count basis, it is not always possible to find the exact date NewDate number of days away because of a known discontinuity in the method of counting days. A warning is displayed if this occurs.

Data Types: double

Output Arguments

NewDate — Date for given number of days away from StartDate
vector

Date for given number of days away from StartDate, returned as a scalar or an N-by-1 vector containing dates.

If StartDate is a string or date character vector, NewDate is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.

If StartDate is a datetime array, then NewDate is returned as a datetime array.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although daysadd supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

daysdif | datetime

Topics

"Handle and Convert Dates" on page 2-2
"Trading Calendars User Interface" on page 12-2

“UICalendar User Interface” on page 12-4

daysdif

Days between dates for any for any day-count basis

Syntax

```
NumDays = daysdif(StartDate,EndDate)
NumDays = daysdif( ___ ,Basis)
```

Description

`NumDays = daysdif(StartDate,EndDate)` returns the number of days between dates `StartDate` and `EndDate`. The first date for `StartDate` is not included when determining the number of days between first and last date.

Any input argument can contain multiple values, but if so, the other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row cell array of character vectors , then `EndDate` must be an *n*-row cell array of character vectors or a single date character vector. `NumDays` is then an `N`-by-`1` vector of numbers.

`NumDays = daysdif( ___ ,Basis)` returns the number of days between dates `StartDate` and `EndDate` using the optional argument `Basis` for day-count. The first date for `StartDate` is not included when determining the number of days between first and last date.

Any input argument can contain multiple values, but if so, the other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an *n*-row datetime array, then `EndDate` must be an *n*-row datetime array or a single datetime. `NumDays` is then an `N`-by-`1` vector of numbers.

Examples

Determine the Number of Days Between StartDate and EndDate

Determine the `NumDays` using date character vectors for `StartDate` and `EndDate`.

```
NumDays = daysdif('3/1/99', '3/1/00', 1)
```

```
NumDays = 360
```

Determine the `NumDays` using datetimes for `StartDate` and `EndDate`.

```
NumDays = daysdif(datetime(1999,3,1) ,datetime(2000,3,1), 1)
```

```
NumDays = 360
```

Determine the `NumDays` using a datetime array for `EndDate`.

```
MoreDays = [datetime(2001,3,1) ; datetime(2002,3,1) ; datetime(2003,3,1)];
NumDays = daysdif(datetime(1998,3,1), MoreDays)
```

```
NumDays = 3×1
```

```
    1096
    1461
    1826
```

Input Arguments

StartDate — Start date

datetime array | string array | date character vector

Start date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, daysdif also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

EndDate — End date

datetime array | string array | date character vector

End date, specified as a scalar or an N-by-1 or 1-by-N vector using a datetime array, string array, or date character vectors.

To support existing code, daysdif also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Basis — Day-count basis of the instrument

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis of the instrument, specified as an integer with a value of 0 through 13 or a N-by-1 vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`NumDays` — Number of days between dates `StartDate` and `EndDate`
integer

Number of days between the `StartDate` and `EndDate`. `NumDays` is returned as an integer.

Note The first date for `StartDate` is not included when determining the number of days between first and last date.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `daysdif` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Handle and Convert Dates” on page 2-2

dec2thirtytwo

Decimal to thirty-second quotation

Syntax

```
[OutNumber,Fractions] = dec2thirtytwo(InNumber,Accuracy)
```

Description

`[OutNumber,Fractions] = dec2thirtytwo(InNumber,Accuracy)` changes a decimal price quotation for a bond or bond future to a fraction with a denominator of 32.

Examples

Convert Decimal to Thirty-Second Quotation

This example shows two bonds that are quoted with decimal prices of 101.78 and 102.96. These prices are converted to fractions with a denominator of 32.

```
InNumber  = [101.78; 102.96];
[OutNumber, Fractions] = dec2thirtytwo(InNumber)
```

```
OutNumber = 2×1

   101
   102

Fractions = 2×1

    25
    31
```

Input Arguments

`InNumber` — Input number
numeric decimal fraction

Input number, specified as an `N`-by-`1` vector of numeric decimal fractions.

Data Types: `double`

`Accuracy` — Rounding
`1` (round down to nearest thirty second) (default) | numeric with values `1`, `2`, `4` or `10`

Rounding, specified as an `N`-by-`1` vector of accuracy desired with numeric values of `1`, `2`, `4` or `10`. The values are: `1`, round down to nearest thirty second, `2` (nearest half), `4` (nearest quarter), or `10` (nearest decile).

Data Types: `double`

Output Arguments

`OutNumber` — Output number which is `InNumber` rounded downward to closest integer

numeric

Output number which is `InNumber` rounded downward to closest integer, returned as a numeric value.

`Fractions` — Fractional part in units of thirty-second

numeric

Fractional part in units of thirty-second, returned as a numeric value. The `Fractions` output conforms to accuracy as prescribed by the input `Accuracy`.

`thirtytwo2dec`

depfixdb

Fixed declining-balance depreciation schedule

Syntax

```
Depreciation = depfixdb(Cost,Salvage,Life,Period)
Depreciation = depfixdb( ___ ,Month)
```

Description

`Depreciation = depfixdb(Cost,Salvage,Life,Period)` computes the fixed declining-balance depreciation for each `Period`.

`Depreciation = depfixdb( ___ ,Month)` adds an optional argument.

Examples

Compute the Fixed Declining-Balance Depreciation

This example shows how to calculate the depreciation for the first five years for a car is purchased for $11,000, with a salvage value of $1500, and a lifetime of eight years.

```
Depreciation = depfixdb(11000, 1500, 8, 5)
```

```
Depreciation = 1×5
10³ ×

    2.4251    1.8904    1.4737    1.1488    0.8955
```

Input Arguments

`Cost` — Initial value of the asset
numeric

initial value of the asset, specified as a scalar numeric.

Data Types: `double`

`Salvage` — Salvage value of the asset
numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: `double`

`Life` — Life of the asset in years
numeric

life of the asset in years, specified as scalar numeric.

Data Types: `double`

`Period` — Number of years to calculate

integer

Number of years to calculate, specified as scalar integer.

Data Types: `double`

`Month` — Number of months in the first year of asset life

`12` (default) | numeric

(Optional) Number of months in the first year of asset life, specified as a scalar numeric.

Data Types: `double`

Output Arguments

`Depreciation` — Depreciation

vector

Depreciation, returned as the fixed declining-balance depreciation for each `Period`.

Version History

Introduced before R2006a

See Also

`depgendb` | `deprdv` | `depsoyd` | `depstln`

Topics

"Analyzing and Computing Cash Flows" on page 2-11

depgendb

General declining-balance depreciation schedule

Syntax

```
Depreciation = depgendb(Cost,Salvage,Life,Factor)
```

Description

`Depreciation = depgendb(Cost,Salvage,Life,Factor)` computes the declining-balance depreciation for each period.

Examples

Calculate the Declining-Balance Depreciation

A car is purchased for $10,000 and is to be depreciated over five years. The estimated salvage value is $1000. Using the double-declining-balance method, the function calculates the depreciation for each year and returns the remaining depreciable value at the end of the life of the car.

Define the depreciation.

```
Life = 5;
Salvage = 0;
Cost = 10000;
Factor=2;
```

Use `depgendb` to calculate the depreciation.

```
Depreciation = depgendb(10000, 1000, 5, 2)
```

```
Depreciation = 1×5
10^3 ×

    4.0000    2.4000    1.4400    0.8640    0.2960
```

The large value returned at the final year is the sum of the depreciation over the life time and is equal to the difference between the `Cost` and `Salvage`. The value of the asset in the final year is computed as (`Cost` - `Salvage`) = `Sum_Depreciation_Upto_Final_Year`.

Input Arguments

`Cost` — Initial value of the asset
numeric

initial value of the asset, specified as a scalar numeric.

Data Types: `double`

`Salvage` — Salvage value of the asset

numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: `double`

`Life` — Number of periods over which the asset is depreciated

numeric

Number of periods over which the asset is depreciated, specified as a scalar numeric.

Data Types: `double`

`Factor` — Depreciation factor

numeric

Depreciation factor, specified as a scalar numeric. When `Factor` = `2`, then the double-declining-balance method is used.

Data Types: `double`

Output Arguments

`Depreciation` — Depreciation

vector

Depreciation, returned as the declining-balance depreciation for each period.

Version History

Introduced before R2006a

deprdv

Remaining depreciable value

Syntax

```
Depreciation = deprdv(Cost,Salvage,Accum)
```

Description

`Depreciation = deprdv(Cost,Salvage,Accum)` computes the remaining depreciable value for an asset.

Examples

Compute the Remaining Depreciable Value for an Asset

This example shows how to find the remaining depreciable value after six years for the cost of an asset for $13,000 with a life of 10 years. The salvage value is $1000.

```
Accum = depstln(13000, 1000, 10) * 6
```

```
Accum = 7200
```

```
Value = deprdv(13000, 1000, 7200)
```

```
Value = 4800
```

Input Arguments

`Cost` — Initial value of the asset
numeric

Initial value of the asset, specified as a scalar numeric.

Data Types: `double`

`Salvage` — Salvage value of the asset
numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: `double`

`Accum` — Accumulated depreciation of the asset for prior periods
numeric

Accumulated depreciation of the asset for prior periods, specified as a scalar numeric.

Data Types: `double`

Output Arguments

`Depreciation` — Depreciation

numeric

Depreciation, returned as the remaining depreciable value for an asset.

Version History

Introduced before R2006a

depsoyd

Sum of years' digits depreciation

Syntax

```
Sum = depsoyd(Cost,Salvage,Life)
```

Description

`Sum = depsoyd(Cost,Salvage,Life)` computes the depreciation for an asset using the sum of years' digits method.

Examples

Compute the Depreciation for an Asset Using the Sum of Years' Digits Method

This example shows how to calculate the depreciation for an asset using the sum of years' digits method where the asset is $13,000 with a life of 10 years. The salvage value of the asset is $1000.

```
Sum = depsoyd(13000, 1000, 10)'
```

```
Sum = 10×1
10^3 ×

    2.1818
    1.9636

    1.5273
    1.3091
    1.0909
    0.8727
    0.6545
    0.4364
    0.2182
```

Input Arguments

`Cost` — Initial value of the asset

numeric

initial value of the asset, specified as a scalar numeric.

Data Types: `double`

`Salvage` — Salvage value of the asset

numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: `double`

`Life` — Depreciable life of the asset in years

numeric

Depreciable life of the asset in years, specified as a scalar numeric.

Data Types: `double`

Output Arguments

`Sum` — Depreciation values

vector

Depreciation values, returned as a `1`-by-`Life` vector of depreciation values with each element corresponding to a year of the asset's life.

Version History

Introduced before R2006a

depstln

Straight-line depreciation schedule

Syntax

```
Depreciation = depstln(Cost,Salvage,Life)
```

Description

`Depreciation = depstln(Cost,Salvage,Life)` computes the straight-line depreciation for an asset.

Examples

Compute the Straight-Line Depreciation for an Asset

This example shows how to calculate the straight-line depreciation for an asset that costs $13,000 with a life of 10 years. The salvage value of the asset is $1000.

```
Depreciation = depstln(13000, 1000, 10)
```

```
Depreciation = 1200
```

Input Arguments

`Cost` — Initial value of the asset
numeric

Initial value of the asset, specified as a scalar numeric.

Data Types: `double`

`Salvage` — Salvage value of the asset
numeric

Salvage value of the asset, specified as a scalar numeric.

Data Types: `double`

`Life` — Depreciable life of the asset in years
numeric

Depreciable life of the asset in years, specified as a scalar numeric.

Data Types: `double`

Output Arguments

`Depreciation` — Depreciation

numeric

Depreciation, returned as a straight-line depreciation for an asset.

disc2zero

Zero curve given discount curve

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Compounding` and `Basis`.

Syntax

```
[ZeroRates,CurveDates] = disc2zero(DiscRates,CurveDates,Settle)
[ZeroRates,CurveDates] = disc2zero( ___ ,Name,Value)
```

Description

`[ZeroRates,CurveDates] = disc2zero(DiscRates,CurveDates,Settle)` returns a zero curve given a discount curve and its maturity dates. If either inputs for `CurveDates` or `Settle` are datetime arrays, the output `CurveDates` is returned as datetime arrays.

`[ZeroRates,CurveDates] = disc2zero( ___ ,Name,Value)` adds optional name-value pair arguments

Examples

Determine the Zero Curve Given a Discount Curve and Maturity Dates

Given the following discount factors `DiscRates` over a set of maturity dates `CurveDates`, and a settlement date `Settle`:

```
DiscRates = [0.9996
             0.9947
             0.9896
             0.9866
             0.9826
             0.9786
             0.9745
             0.9665
             0.9552
             0.9466];

CurveDates = [datetime(2000,11,6)
              datetime(2000,12,11)
              datetime(2001,1,15)
              datetime(2001,2,5)
              datetime(2001,3,4)
              datetime(2001,4,2)
              datetime(2001,4,30)
              datetime(2001,6,25)
              datetime(2001,9,4)
              datetime(2001,11,12)];
```

```
Settle = datetime(2000,11,3);
```

Set daily compounding for the output zero curve, on an actual/365 basis.

```
Compounding = 365;
Basis = 3;
```

Execute the function `disc2zero` which returns the zero curve `ZeroRates` at the maturity dates `CurveDates`.

```
[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle, Compounding, Basis)
```

```
ZeroRates = 10×1

    0.0487

```

For readability, `DiscRates` and `ZeroRates` are shown here only to the basis point. However, MATLAB® software computed them at full precision. If you enter `DiscRates` as shown, `ZeroRates` may differ due to rounding.

Input Arguments

`DiscRates` — Discount factors

decimal fraction

Discount factors, specified as a `NDATES`-by-`1` column vector of decimal fractions. In aggregate, the factors in `DiscRates` constitute a discount curve for the investment horizon represented by `CurveDates`.

Data Types: `double`

`CurveDates` — Maturity dates

datetime array | string array | date character vector

Maturity dates that correspond to the discount factors in `DiscRates`, specified as a `NDATES`-by-`1` column vector using a datetime array, string array, or date character vectors.

To support existing code, `disc2zero` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `datetime` | `string` | `char`

`Settle` — Common settlement date for discount rates in `DiscRates`

datetime scalar | string scalar | date character vector | serial date number

Common settlement date for the discount rates in `DiscRates`, specified as scalar datetime, string, or date character vector.

To support existing code, `disc2zero` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `datetime` | `string` | `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[ZeroRates,CurveDates] = disc2zero(DiscRates,CurveDates,Settle,'Compounding',6,'Basis',9)`

`Compounding` — Rate at which output zero rates are compounded when annualized

`2` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `12`, `365`, `-1`

Rate at which the output zero rates are compounded when annualized, specified as a numeric value. Allowed values are:

- `0` — Simple interest (no compounding)
- `1` — Annual compounding
- `2` — Semiannual compounding (default)
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding
- `365` — Daily compounding
- `-1` — Continuous compounding

Data Types: `double`

`Basis` — Day-count basis used for annualizing output zero rates

`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count basis used for annualizing the output zero rates, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-16.

Data Types: double

Output Arguments

ZeroRates — Zero curve for investment horizon represented by CurveDates

vector

Zero curve for the investment horizon represented by CurveDates, returned as a NDATES-by-1 column vector of decimal fractions. The zero rates are the yields to maturity on theoretical zero-coupon bonds.

CurveDates — Maturity dates that correspond to ZeroRates

vector

Maturity dates that correspond to the ZeroRates, returned as a NDATES-by-1 column vector. This vector is the same as the input vector CurveDates, but the output is sorted by ascending maturity. If either inputs for CurveDates or Settle are datetime arrays, the output CurveDates is returned as datetime arrays.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although disc2zero supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

discrate

Bank discount rate of security

Syntax

```
DiscRate = discrate(Settle,Maturity,Face,Price)
DiscRate = discrate(___,Basis)
```

Description

`DiscRate = discrate(Settle,Maturity,Face,Price)`computes the bank discount rate of a security. The bank discount rate normalizes by the face value of the security (for example, U. S. Treasury Bills) and understates the true yield earned by investors.

`DiscRate = discrate(___,Basis)` adds an optional argument for `Basis`.

Examples

Compute the Bank Discount Rate of a Security

This example shows how to find the bank discount rate of a security.

```
DiscRate = discrate(datetime(2000,1,12),datetime(2000,6,25), 100, 97.74, 0)
```

```
DiscRate = 0.0501
```

Input Arguments

`Settle` — Settlement date
datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `discrate` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `datetime` | `string` | `char`

`Maturity` — Maturity date
datetime scalar | string scalar | date character vector

Maturity date, specified as scalar datetime, string, or date character vector.

To support existing code, `discrate` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Face — Redemption (par, face) value
numeric

Redemption (par, face) value, specified as a scalar numeric value.

Data Types: `double`

`Price` — Security price

numeric

Security price, specified as a scalar numeric value.

Data Types: `double`

`Basis` — Day-count basis of the instrument

`0` (actual/actual) (default) | integer with value of `0` to `13`

(Optional) Day-count basis of the instrument, specified as a scalar integer.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`DiscRate` — Discount rate of security

decimal

Discount rate of security, returned as a decimal.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `discrate` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

ecmlsrmle

Least-squares regression with missing data

Syntax

```
[Parameters,Covariance,Resid,Info] = ecmlsrmle(Data,Design)
[Parameters,Covariance,Resid,Info] = ecmlsrmle( ___ ,MaxIterations,TolParam,
TolObj,Param0,Covar0,CovarFormat)
```

Description

`[Parameters,Covariance,Resid,Info] = ecmlsrmle(Data,Design)` estimates a least-squares regression model with missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters,\ Covariance)$$

for samples k = 1, ... , `NUMSAMPLES`.

`ecmlsrmle` estimates a `NUMPARAMS`-by-`1` column vector of model parameters called `Parameters`, and a `NUMSERIES`-by-`NUMSERIES` matrix of covariance parameters called `Covariance`.

`ecmlsrmle(Data,Design)` with no output arguments plots the log-likelihood function for each iteration of the algorithm.

`[Parameters,Covariance,Resid,Info] = ecmlsrmle( ___ ,MaxIterations,TolParam, TolObj,Param0,Covar0,CovarFormat)` estimates a least-squares regression model with missing data using optional arguments.

Input Arguments

`Data` — Data sample

matrix

Data sample, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. If a data sample has missing values, represented as `NaN`s, the sample is ignored. (Use `mvnrmle` to handle missing data.)

Data Types: `double`

`Design` — Model design

matrix | cell array of character vectors

Model design, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES` ≥ `1`, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix of known values.

  If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

These points concern how Design handles missing data:

- Although Design should not have NaN values, ignored samples due to NaN values in Data are also ignored in the corresponding Design array.
- If Design is a 1-by-1 cell array, which has a single Design matrix for each sample, no NaN values are permitted in the array. A model with this structure must have NUMSERIES ≥ NUMPARAMS with rank(Design{1}) = NUMPARAMS.
- ecmlsrmle is more strict than mvnrmle about the presence of NaN values in the Design array.

Data Types: double | cell

MaxIterations — Maximum number of iterations for the estimation algorithm

100 (default) | numeric

(Optional) Maximum number of iterations for the estimation algorithm, specified as a numeric. The default value is 100.

Data Types: double

TolParam — Convergence tolerance for estimation algorithm

sqrt(eps) (default) | numeric

(Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates, specified as a numeric. The Default value is sqrt(eps) which is about 1.0e-8 for double precision. The convergence test for changes in model parameters is

$$\|Param_k - Param_{k-1}\| < TolParam \times (1 + \|Param_k\|)$$

where Param represents the output Parameters, and iteration $k = 2, 3, \ldots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.

Data Types: double | table | timetable

TolObj — Convergence tolerance for estimation algorithm based on changes in objective function

eps ∧ 3/4 (default) | numeric

(Optional) Convergence tolerance for estimation algorithm based on changes in the objective function, specified as a numeric. The default value is eps ∧ 3/4 which is about 1.0e-12 for double precision. The convergence test for changes in the objective function is

$$|Obj_k - Obj_{k-1}| < \ TolObj \times (1 + |Obj_k|)$$

for iteration $k = 2, 3, \ldots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.

Data Types: double

Param0 — User-supplied initial estimate for the parameters of regression model

zero vector (default) | vector

(Optional) User-supplied initial estimate for the parameters of the regression model, specified as an NUMPARAMS-by-1 column vector.

Data Types: double

Covar0 — User-supplied initial or known estimate for the covariance matrix of the regression residuals

identity matrix (default) | matrix

(Optional) User-supplied initial or known estimate for the covariance matrix of the regression residuals, specified as an NUMSERIES-by-NUMSERIES matrix.

For covariance-weighted least-squares calculations, this matrix corresponds with weights for each series in the regression. The matrix also serves as an initial guess for the residual covariance in the expectation conditional maximization (ECM) algorithm.

Data Types: double

CovarFormat — Format for covariance matrix

'full' (default) | character vector with value 'full' or 'diagonal'

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- 'full' — This is the default method that computes the full covariance matrix.
- 'diagonal' — This forces the covariance matrix to be a diagonal matrix.

Data Types: char

Output Arguments

Parameters — Parameters of the regression model

vector

Parameters of the regression model, returned as an NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.

Covariance — Covariance of the regression model's residuals

matrix

Covariance of the regression model's residuals, returned as an NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals.

Resid — Residuals from the regression

matrix

Residuals from the regression, returned as an NUMSAMPLES-by-NUMSERIES matrix of residuals from the regression.

Info — Structure containing additional information from the regression

structure

Structure containing additional information from the regression, returned as a structure. The structure has these fields:

- Info.Obj – A variable-extent column vector, with no more than MaxIterations elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, Obj(end), is the terminal estimate of the objective function. If you do least squares, the objective function is the least squares objective function.

- `Info.PrevParameters` – `NUMPARAMS`-by-`1` column vector of estimates for the model parameters from the iteration just before the terminal iteration.
- `Info.PrevCovariance` – `NUMSERIES`-by-`NUMSERIES` matrix of estimates for the covariance parameters from the iteration just before the terminal iteration.

Use the estimates in the output structure `Info` for diagnostic purposes.

Version History

Introduced in R2006a

ecmlsrobj

Log-likelihood function for least-squares regression with missing data

Syntax

```
Objective = ecmlsrobj(Data,Design,Parameters)
Objective = ecmlsrobj( ___ ,Covariance)
```

Description

`Objective = ecmlsrobj(Data,Design,Parameters)` computes a least-squares objective function based on current parameter estimates with missing data. `Objective` is a scalar that contains the least-squares objective function.

`Objective = ecmlsrobj( ___ ,Covariance)` computes a least-squares objective function based on current parameter estimates with missing data using an optional argument.

Input Arguments

`Data` — Data sample

matrix

Data sample, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. If a data sample has missing values, represented as `NaN`s. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one `NaN`, use `mvnrmle`.)

Data Types: `double`

`Design` — Model design

matrix | cell array of character vectors

Model design, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES` ≥ `1`, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix of known values.

  If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

Data Types: `double` | `cell`

`Parameters` — Estimates for the parameters of regression model

vector

Estimates for the parameters of regression model, specified as an `NUMPARAMS`-by-`1` column vector.

Data Types: `double`

`Covariance` — User-supplied estimate for covariance matrix of residuals of the regression
vector

(Optional) User-supplied estimate for the covariance matrix of the residuals of the regression, specified as an `NUMPARAMS`-by-`1` column vector.

`ecmlsrobj` requires that `Covariance` be positive-definite.

Note that

```
ecmlsrobj(Data, Design, Parameters) = ecmmvnrobj(Data, Design, Parameters, IdentityMatrix)
```

where `IdentityMatrix` is a `NUMSERIES`-by-`NUMSERIES` identity matrix.

Data Types: `double`

Output Arguments

`Objective` — Least-squares objective function
scalar

Least-squares objective function, returned as scalar.

ecmmvnrfish

Fisher information matrix for multivariate normal regression model

Syntax

```
Fisher] = ecmmvnrfish(Data,Design,Covariance)
Fisher = ecmmvnrfish( ___ ,Method,MatrixFormat,CovarFormat)
```

Description

`Fisher] = ecmmvnrfish(Data,Design,Covariance)` computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates that account for missing data.

`Fisher` is a `NUMPARAMS`-by-`NUMPARAMS` Fisher information matrix or Hessian matrix. The size of `NUMPARAMS` depends on `MatrixFormat` and on current parameter estimates. If `MatrixFormat = 'full'`,

```
NUMPARAMS = NUMSERIES * (NUMSERIES + 3)/2
```

If `MatrixFormat = 'paramonly'`,

```
NUMPARAMS = NUMSERIES
```

Note `ecmmvnrfish` operates slowly if you calculate the full Fisher information matrix.

`Fisher = ecmmvnrfish( ___ ,Method,MatrixFormat,CovarFormat)` computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates that account for missing data using optional arguments.

Input Arguments

Data — Data sample

matrix

Data sample, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. If a data sample has missing values, represented as `NaN`s, the sample is ignored. (Use `mvnrmle` to handle missing data.)

Data Types: `double`

Design — Model design

matrix | cell array of character vectors

Model design, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.

- If `NUMSERIES` ≥ 1, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix of known values.

  If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

Data Types: `double` | `cell`

`Covariance` — Estimates for the covariance of the residuals of the regression
matrix

Estimates for the covariance of the residuals of the regression, specified as an `NUMSERIES`-by-`NUMSERIES` matrix.

Data Types: `double`

`Method` — Method of calculation for information matrix
`'hessian'` (default) | character vector with value `'hessian'` or `'fisher'`

(Optional) Method of calculation for the information matrix, specified as a character vector. The choices are:

- `'hessian'` — This is the default method using the expected Hessian matrix of the observed log-likelihood function. This method is recommended since the resultant standard errors incorporate the increased uncertainties due to missing data.
- `'fisher'` — This computes using the Fisher information matrix.

Data Types: `char`

`MatrixFormat` — Parameters to be included in Fisher information matrix
`'full'` (default) | character vector with value `'full'` or `'paramonly'`

(Optional) Parameters to be included in the Fisher information matrix, specified as a character vector. The choices are:

- `'full'` — This is the default method that computes the full Fisher information matrix for both model and covariance parameter estimates.
- `'paramonly'` — This computes only components of the Fisher information matrix associated with the model parameter estimates.

Data Types: `char`

`CovarFormat` — Format for covariance matrix
`'full'` (default) | character vector with value `'full'` or `'diagonal'`

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- `'full'` — This is the default method that computes the full covariance matrix.
- `'diagonal'` — This forces the covariance matrix to be a diagonal matrix.

Data Types: `char`

Output Arguments

`Fisher` — Fisher information matrix

matrix

Fisher information matrix, returned as an `NUMPARAMS`-by-`NUMPARAMS` Fisher information matrix or Hessian matrix, depending on the optional input argument `Method`.

ecmmvnrmle

Multivariate normal regression with missing data

Syntax

```
[Param,Covar] = ecmmvnrmle(Data,Design)
[Param,Covar,Resid,Info] = ecmmvnrmle( ___ ,MaxIterations,TolParam,TolObj,
Param0,Covar0,CovarFormat)
```

Description

`[Param,Covar] = ecmmvnrmle(Data,Design)` estimates a multivariate normal regression model with missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters, Covariance)$$

for samples $k = 1, \ldots ,$ `NUMSAMPLES`.

`[Param,Covar,Resid,Info] = ecmmvnrmle( ___ ,MaxIterations,TolParam,TolObj, Param0,Covar0,CovarFormat)` adds an optional arguments for `MaxIterations`, `TolParam`, `TolObj`, `Param0`, `Covar0`, and `CovarFormat`.

Examples

Compute Multivariate Normal Regression With Missing Data

This example shows how to estimate a multivariate normal regression model with missing data.

First, load dates, total returns, and ticker symbols for the twelve stocks from the MAT-file.

```
load CAPMuniverse
whos Assets Data Dates
```

```
  Name           Size                Bytes  Class     Attributes

  Assets         1x14                 1568  cell                
  Data        1471x14               164752  double              
  Dates       1471x1                 11768  double              
```

```
Dates = datetime(Dates,'ConvertFrom','datenum');
```

The assets in the model have the following symbols, where the last two series are proxies for the market and the riskless asset.

```
Assets(1:14)
```

```
ans = 1x14 cell
    {'AAPL'}    {'AMZN'}    {'CSCO'}    {'DELL'}    {'EBAY'}    {'GOOG'}    {'HPQ'}    {'IBM'}
```

The data covers the period from January 1, 2000 to November 7, 2005 with daily total returns. Two stocks in this universe have missing values that are represented by NaNs. One of the two stocks had an IPO during this period and, consequently, has significantly less data than the other stocks.

Compute separate regressions for each stock, where the stocks with missing data have estimates that reflect their reduced observability.

```
[NumSamples, NumSeries] = size(Data);
NumAssets = NumSeries - 2;

StartDate = Dates(1);
EndDate = Dates(end);

Alpha = NaN(1, length(NumAssets));
Beta = NaN(1, length(NumAssets));
Sigma = NaN(1, length(NumAssets));
StdAlpha = NaN(1, length(NumAssets));
StdBeta = NaN(1, length(NumAssets));
StdSigma = NaN(1, length(NumAssets));
for i = 1:NumAssets
    % Set up separate asset data and design matrices
    TestData = zeros(NumSamples,1);
    TestDesign = zeros(NumSamples,2);

    TestData(:) = Data(:,i) - Data(:,14);
    TestDesign(:,1) = 1.0;
    TestDesign(:,2) = Data(:,13) - Data(:,14);

    % Estimate the multivariate normal regression for each asset separately.
    [Param, Covar] = ecmmvnrmle(TestData, TestDesign)

end
```

Input Arguments

Data — Data

matrix

Data, specified as an NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use mvnrmle.)

Data Types: double

Design — Design model

matrix | cell array

Design model, specified as a matrix or a cell array that handles two model structures:

- If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.
- If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.

  If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.

Data Types: double | cell

MaxIterations — Maximum number of iterations for the estimation algorithm

100 (default) | numeric

(Optional) Maximum number of iterations for the estimation algorithm, specified as a numeric.

Data Types: double

TolParam — Convergence tolerance for estimation algorithm based on changes in model parameter estimates

1.0e-8 (default) | numeric

(Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates, specified as a numeric. The convergence test for changes in model parameters is

$$\|Param_k - Param_{k-1}\| < TolParam \times (1 + \|Param_k\|)$$

where Param represents the output Parameters, and iteration k = 2, 3, ... Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.

Data Types: `double`

`TolObj` — Convergence tolerance for estimation algorithm based on changes in objective function

`1.0e-12` (default) | numeric

(Optional) Convergence tolerance for estimation algorithm based on changes in the objective function, specified as a numeric. The convergence test for changes in the objective function is

$$|Obj_k - Obj_{k-1}| < TolObj \times (1 + |Obj_k|)$$

for iteration k = 2, 3, ... Convergence is assumed when both the `TolParam` and `TolObj` conditions are satisfied. If both `TolParam ≤ 0` and `TolObj ≤ 0`, do the maximum number of iterations (`MaxIterations`), whatever the results of the convergence tests.

Data Types: `double`

`Param0` — Estimate for the parameters of regression model

`[]` (default) | vector

(Optional) Estimate for the parameters of the regression model, specified as an `NUMPARAMS`-by-`1` column vector.

Data Types: `double`

`Covar0` — Estimate for the covariance matrix of regression residuals

`[]` (default) | matrix

(Optional) Estimate for the covariance matrix of the regression residuals, specified as `NUMSERIES`-by-`NUMSERIES` matrix.

Data Types: `double`

`CovarFormat` — Format for the covariance matrix

`'full'` (default) | character vector

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- `'full'` — Compute the full covariance matrix.
- `'diagonal'` — Force the covariance matrix to be a diagonal matrix.

Data Types: `char`

Output Arguments

`Param` — Estimates for parameters of the regression model

vector

Estimates for the parameters of the regression model, returned as a `NUMPARAMS`-by-`1` column vector.

`Covar` — Estimates for the covariance of regression model's residuals

matrix

Estimates for the covariance of the regression model's residuals, returned as a `NUMSERIES`-by-`NUMSERIES` matrix.

Resid — Residuals from regression

matrix

Residuals from the regression, returned as a NUMSAMPLES-by-NUMSERIES matrix. For any missing values in Data, the corresponding residual is the difference between the conditionally imputed value for Data and the model, that is, the imputed residual.

Note The covariance estimate Covariance cannot be derived from the residuals.

Info — Additional information from regression

structure

Additional information from the regression, returned as a structure. The structure has these fields:

- Info.Obj — A variable-extent column vector, with no more than MaxIterations elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, Obj(end), is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.
- Info.PrevParameters — NUMPARAMS-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal iteration.Info.PrevCovariance – NUMSERIES-by-NUMSERIES matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

ecmmvnrobj

Log-likelihood function for multivariate normal regression with missing data

Syntax

```
Objective = ecmmvnrobj(Data,Design,Parameters,Covariance)
Objective = ecmmvnrobj( ___ ,CovarFormat)
```

Description

`Objective = ecmmvnrobj(Data,Design,Parameters,Covariance)` computes a log-likelihood function based on current maximum likelihood parameter estimates with missing data. `Objective` is a scalar that contains the least-squares objective function.

`Objective = ecmmvnrobj( ___ ,CovarFormat)` computes a log-likelihood function based on current maximum likelihood parameter estimates with missing data using an optional argument.

Input Arguments

`Data` — Data sample

matrix

Data sample, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. If a data sample has missing values, represented as `NaN`s. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one `NaN`, use `mvnrmle`.)

Data Types: `double`

`Design` — Model design

matrix | cell array of character vectors

Model design, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES` ≥ `1`, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix of known values.

  If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

Data Types: `double` | `cell`

`Parameters` — Estimates for the parameters of regression model

vector

Estimates for the parameters of regression model, specified as an `NUMPARAMS`-by-`1` column vector.

Data Types: `double`

`Covariance` — Estimates for covariance matrix of residuals of the regression
matrix

Estimates for the covariance matrix of the residuals of the regression, specified as an `NUMSERIES`-by-`NUMSERIES` matrix.

Data Types: `double`

`CovarFormat` — Format for covariance matrix
`'full'` (default) | character vector with value `'full'` or `'diagonal'`

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- `'full'` — This is the default method that computes the full covariance matrix.
- `'diagonal'` — This forces the covariance matrix to be a diagonal matrix.

Data Types: `char`

Output Arguments

`Objective` — Least-squares objective function
scalar

Least-squares objective function, returned as scalar.

ecmmvnrstd

Evaluate standard errors for multivariate normal regression model

Syntax

```
[StdParameters,StdCovariance] = ecmmvnrstd(Data,Design,Covariance)
[StdParameters,StdCovariance] = ecmmvnrstd( ___ ,Method,CovarFormat)
```

Description

`[StdParameters,StdCovariance] = ecmmvnrstd(Data,Design,Covariance)` evaluates standard errors for a multivariate normal regression model with missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters, Covariance)$$

for samples $k = 1, \ldots,$ `NUMSAMPLES`.

`[StdParameters,StdCovariance] = ecmmvnrstd( ___ ,Method,CovarFormat)` adds an optional arguments for `Method` and `CovarFormat`.

Examples

Compute Standard Errors for Multivariate Normal Regression

This example shows how to compute standard errors for a multivariate normal regression model.

First, load dates, total returns, and ticker symbols for the twelve stocks from the MAT-file.

```
load CAPMuniverse
whos Assets Data Dates
```

```
  Name            Size              Bytes  Class     Attributes

  Assets          1x14               1568  cell
  Data         1471x14             164752  double
  Dates        1471x1               11768  double
```

```
Dates = datetime(Dates,'ConvertFrom','datenum');
```

The assets in the model have the following symbols, where the last two series are proxies for the market and the riskless asset.

```
Assets(1:14)
```

```
ans = 1x14 cell
    {'AAPL'}    {'AMZN'}    {'CSCO'}    {'DELL'}    {'EBAY'}    {'GOOG'}    {'HPQ'}    {'IBM'}
```

The data covers the period from January 1, 2000 to November 7, 2005 with daily total returns. Two stocks in this universe have missing values that are represented by NaNs. One of the two stocks had an IPO during this period and, consequently, has significantly less data than the other stocks.

```
[Mean,Covariance] = ecmnmle(Data);
```

Compute separate regressions for each stock, where the stocks with missing data have estimates that reflect their reduced observability.

```
[NumSamples, NumSeries] = size(Data);
NumAssets = NumSeries - 2;

StartDate = Dates(1);
EndDate = Dates(end);

Alpha = NaN(1, length(NumAssets));
Beta = NaN(1, length(NumAssets));
Sigma = NaN(1, length(NumAssets));
StdAlpha = NaN(1, length(NumAssets));
StdBeta = NaN(1, length(NumAssets));
StdSigma = NaN(1, length(NumAssets));
for i = 1:NumAssets
    % Set up separate asset data and design matrices
    TestData = zeros(NumSamples,1);
    TestDesign = zeros(NumSamples,2);

    TestData(:) = Data(:,i) - Data(:,14);
    TestDesign(:,1) = 1.0;
    TestDesign(:,2) = Data(:,13) - Data(:,14);

    [Param, Covar] = ecmmvnrmle(TestData, TestDesign);

    % Estimate the sample standard errors for model parameters for each asset.
    StdParam = ecmmvnrstd(TestData, TestDesign, Covar,'hessian')

end
```

```
StdParam = 2×1

    0.0008
    0.0715

StdParam = 2×1

    0.0012
    0.1000

    0.0008
    0.0709

StdParam = 2×1

    0.0010
    0.0853
```

Input Arguments

Data — Data
matrix

Data, specified as an NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use mvnrmle.)

Data Types: double

Design — Design model

matrix | cell array

Design model, specified as a matrix or a cell array that handles two model structures:

- If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.
- If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.

  If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.

Data Types: double | cell

Covariance — Estimates for covariance of regression residuals

matrix

Estimates for the covariance of the regression residuals, specified as an NUMSERIES-by-NUMSERIES matrix.

Data Types: double

Method — Method of calculation for the information matrix

'hessian' (default) | character vector

(Optional) Method of calculation for the information matrix, specified as a character vector defined as:

- 'hessian' — The expected Hessian matrix of the observed log-likelihood function. This method is recommended since the resultant standard errors incorporate the increased uncertainties due to missing data.
- 'fisher' — The Fisher information matrix.

Note If Method = 'fisher', to obtain more quickly just the standard errors of variance estimates without the standard errors of the covariance estimates, set CovarFormat = 'diagonal' regardless of the form of the covariance matrix.

Data Types: char

CovarFormat — Format for the covariance matrix

'full' (default) | character vector

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- 'full' — Compute the full covariance matrix.
- 'diagonal' — Force the covariance matrix to be a diagonal matrix.

Data Types: char

Output Arguments

StdParameters — Standard errors for each element of Parameters

vector

Standard errors for each element of Parameters, returned as an NUMPARAMS-by-1 column vector.

StdCovariance — Standard errors for each element of Covariance

matrix

Standard errors for each element of Covariance, returned as an NUMSERIES-by-NUMSERIES matrix.

ecmnfish

Fisher information matrix

Syntax

```
Fisher = ecmnfish(Data,Covariance)
Fisher = ecmnfish( ___ ,InvCovar,MatrixType)
```

Description

`Fisher = ecmnfish(Data,Covariance)` computes an NUMPARAMS-by-NUMPARAMS Fisher information matrix based on the current maximum likelihood parameter estimates.

Use `ecmnfish` after estimating the mean and covariance of `Data` with `ecmnmle`.

`Fisher = ecmnfish( ___ ,InvCovar,MatrixType)` adds optional arguments for `InvCovar` and `MatrixType`.

Examples

Compute Fisher Information Matrix Based on Parameter Estimates for Data

This example shows how to compute the Fisher information matrix based on paraemter estimates for `Data` for five years of daily total returns for 12 computer technology stocks, with six hardware and six software companies

```
load ecmtechdemo.mat
```

The time period for this data extends from April 19, 2000 to April 18, 2005. The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as NaNs. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

```
[ECMMean, ECMCovar] = ecmnmle(Data)
```

```
ECMMean = 12×1

      ⋮
```

Input Arguments

`Data` — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by `NaN`s.

Data Types: `double`

`Covariance` — Maximum likelihood parameter estimates for covariance of `Data`

matrix

Maximum likelihood parameter estimates for the covariance of the `Data` using the ECM algorithm, specified as a `NUMSERIES`-by-`NUMSERIES` matrix.

`InvCovar` — Cholesky decomposition of covariance matrix

`[ ]` (default) | matrix

(Optional) Inverse of covariance matrix, specified as a matrix using `inv` as:

```
inv(Covariance)
```

Data Types: `double`

`MatrixType` — Matrix format

`'full'` (default) | character vector

(Optional) Matrix format, specified as a character vector with a value of:

- `'full'` — Computes the full Fisher information matrix.
- `'meanonly'` — Computes only the components of the Fisher information matrix associated with the mean.

Data Types: `char`

Output Arguments

`Fisher` — Fisher information matrix

matrix

Fisher information matrix, returned as an `NUMPARAMSNUMPARAMS` matrix based on current parameter estimates, where `NUMPARAMS = NUMSERIES * (NUMSERIES + 3)/2` if the `MatrixFormat` = `'full'`. If the `MatrixFormat` = `'meanonly'`, then the `NUMPARAMS = NUMSERIES`.

ecmnhess

Hessian of negative log-likelihood function

Syntax

```
Hessian = ecmnhess(Data,Covariance)
Hessian = ecmnhess( ___ ,InvCovar,MatrixType)
```

Description

`Hessian = ecmnhess(Data,Covariance)` computes an `NUMPARAMS`-by-`NUMPARAMS` Hessian matrix of the observed negative log-likelihood function based on current parameter estimates.

Use `ecmnhess` after estimating the mean and covariance of `Data` with `ecmnmle`.

`Hessian = ecmnhess( ___ ,InvCovar,MatrixType)` adds optional arguments for `InvCovar` and `MatrixType`.

Examples

Input Arguments

`Data` — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by `NaN`s.

Data Types: `double`

`Covariance` — Maximum likelihood parameter estimates for covariance of `Data`

matrix

Maximum likelihood parameter estimates for the covariance of the `Data` using the ECM algorithm, specified as a `NUMSERIES`-by-`NUMSERIES` matrix.

`InvCovar` — Cholesky decomposition of covariance matrix

[ ] (default) | matrix

(Optional) Inverse of covariance matrix, specified as a matrix using `inv` as:

```
inv(Covariance)
```

Data Types: `double`

`MatrixType` — Matrix format

`'full'` (default) | character vector

(Optional) Matrix format, specified as a character vector with a value of:

- `'full'` — Computes the full Hessian matrix.
- `'meanonly'` — Computes only the components of the Hessian matrix associated with the mean.

Data Types: `char`

Output Arguments

`Hessian` — Hessian matrix

matrix

Hessian matrix, returned as an `NUMPARAMSNUMPARAMS` matrix of the observed log-likelihood function based on current parameter estimates, where `NUMPARAMS = NUMSERIES * (NUMSERIES + 3)/2` if the `MatrixFormat = 'full'`. If the `MatrixFormat = 'meanonly'`, then the `NUMPARAMS = NUMSERIES`.

ecmninit

Initial mean and covariance

Syntax

```
[Mean,Covariance] = ecmninit(Data,InitMethod)
[Mean,Covariance] = ecmninit(___,InitMethod)
```

Description

`[Mean,Covariance] = ecmninit(Data,InitMethod)` creates initial mean and covariance estimates for the function `ecmnmle`.

`[Mean,Covariance] = ecmninit(___,InitMethod)` adds an optional argument for `InitMethod`.

Examples

Compute Initial Mean and Covariance

This example shows how to compute the initial mean and covariance for five years of daily total return data for 12 computer technology stocks, with six hardware and six software companies

```
load ecmtechdemo.mat
```

The time period for this data extends from April 19, 2000 to April 18, 2005. The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as `NaN`s. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

A naïve approach to the estimation of the mean and covariance for these 12 assets is to eliminate all days that have missing values for any of the 12 assets. Use the `ecminit` function with the `'nanskip'` option to do this.

```
[NaNMean, NaNCovar] = ecmninit(Data,'nanskip')
```

```
NaNMean = 12×1

Input Arguments

Data — Data

matrix

Data, specified as an NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs.

Data Types: double

InitMethod — Initialization methods to compute initial estimates for mean and covariance of data

'nanskip' (default) | character vector

(Optional) Initialization methods to compute the initial estimates for the mean and covariance of data, specified as a character vector. The initialization methods are:

- 'nanskip' — Skip all records with NaNs.
- 'twostage' — Estimate mean. Fill NaNs with the mean. Then estimate the covariance.
- 'diagonal' — Form a diagonal covariance.

Data Types: char

Output Arguments

Mean — Initial estimate of mean of Data

vector

Initial estimate of the mean of the Data, returned as a NUMSERIES-by-1 column vector.

Covariance — Initial estimate of covariance of Data

matrix

Initial estimate of covariance of the Data, returned as a NUMSERIES-by-NUMSERIES matrix.

Algorithms

Model

The general model is

Z ~ *N*(*Mean*, *Covariance*),

where each row of `Data` is an observation of *Z*.

Each observation of *Z* is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR).

Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages.

nanskip

The `nanskip` method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with `NaN`s and estimates initial values from complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the `twostage` method if it determines that significant numbers of records contain `NaN`.

twostage

The `twostage` method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as `NaN`s. This initialization method is robust but tends to result in slower convergence of the ECM algorithm.

diagonal

The `diagonal` method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than 33% missing data). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm.

ecmnmle

Mean and covariance of incomplete multivariate normal data

Syntax

```
ecmnmle(Data)
[Mean,Covariance] = ecmnmle(Data)
[Mean,Covariance] = ecmnmle(___,InitMethod,MaxIterations,Tolerance,Mean0,
Covar0)
```

Description

`ecmnmle(Data)` with no output arguments, this mode displays the convergence of the ECM algorithm in a plot by estimating objective function values for each iteration of the ECM algorithm until termination.

`[Mean,Covariance] = ecmnmle(Data)` estimates the mean and covariance of a data set (`Data`). If the data set has missing values, this routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3]. ECM stands for a conditional maximization form of the EM algorithm of Dempster, Laird, and Rubin [4].

`[Mean,Covariance] = ecmnmle(___,InitMethod,MaxIterations,Tolerance,Mean0, Covar0)` adds an optional arguments for `InitMethod`, `MaxIterations`, `Tolerance`,`Mean0`, and `Covar0`.

Examples

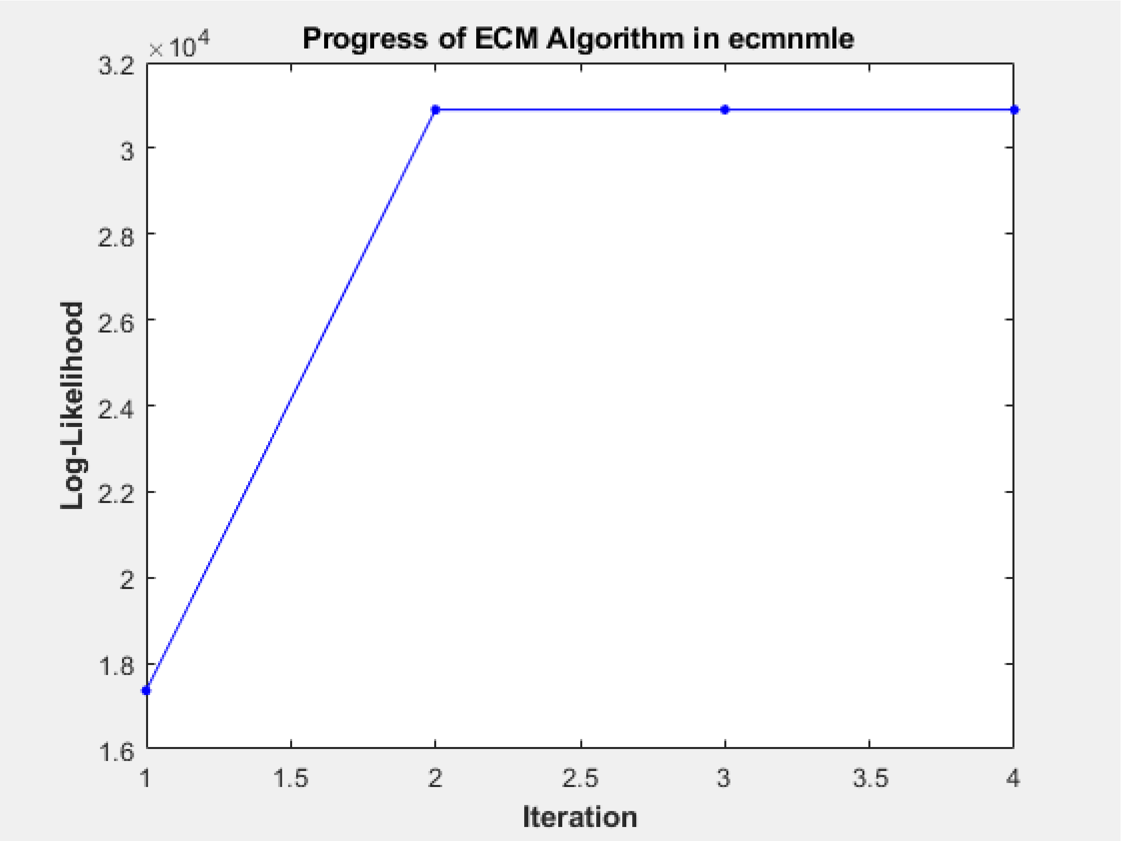
Compute Mean and Covariance of Incomplete Multivariate Normal Data

This example shows how to compute the mean and covariance of incomplete multivariate normal data for five years of daily total return data for 12 computer technology stocks, with six hardware and six software companies

```
load ecmtechdemo.mat
```

The time period for this data extends from April 19, 2000 to April 18, 2005. The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as `NaN`s. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

```
ecmnmle(Data)
```



```
ans = 12×1

    0.0008
    0.0008
   -0.0005
    0.0002
    0.0011
    0.0038
   -0.0003
   -0.0000
   -0.0003
   -0.0000
      ⋮
```

This plot shows that, even with almost 87% of the Google data being `NaN` values, the algorithm converges after only four iterations.

```
[Mean,Covariance] = ecmnmle(Data)
```

```

Input Arguments

`Data` — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by `NaN`s.

Data Types: `double`

`InitMethod` — Initialization methods to compute initial estimates for mean and covariance of data

`'nanskip'` (default) | character vector

(Optional) Initialization methods to compute the initial estimates for the mean and covariance of data, specified as a character vector. The initialization methods are:

- `'nanskip'` — Skip all records with `NaN`s.
- `'twostage'` — Estimate mean. Fill `NaN`s with the mean. Then estimate the covariance.
- `'diagonal'` — Form a diagonal covariance.

Note If you supply `Mean0` and `Covar0`, `InitMethod` is not executed.

Data Types: `char`

`MaxIterations` — Maximum number of iterations

`50` (default) | numeric

(Optional) Maximum number of iterations for the expectation conditional maximization (ECM) algorithm, specified as a numeric.

Data Types: `double`

Tolerance — Convergence tolerance

1.0e-8 (default) | numeric

(Optional) Convergence tolerance for the ECM algorithm, specified as a numeric. If Tolerance ≤ 0, perform maximum iterations specified by MaxIterations and do not evaluate the objective function at each step unless in display mode.

Data Types: double

Mean0 — Estimate for the mean

[ ] (default) | matrix

(Optional) Estimate for the mean, specified as an NUMSERIES-by-1 column vector. If you leave Mean0 unspecified ([ ]), the method specified by InitMethod is used. If you specify Mean0, you must also specify Covar0.

Data Types: double

Covar0 — Estimate for the covariance

[ ] (default) | matrix

(Optional) Estimate for the covariance, specified as an NUMSERIES-by-NUMSERIES matrix, where the input matrix must be positive-definite. If you leave Covar0 unspecified ([ ]), the method specified by InitMethod is used. If you specify Covar0, you must also specify Mean0.

Data Types: double

Output Arguments

Mean — Maximum likelihood parameter estimates for mean of Data

vector

Maximum likelihood parameter estimates for the mean of the Data using ECM algorithm, returned as a NUMSERIES-by-1 column vector.

Covariance — Maximum likelihood parameter estimates for covariance of Data

matrix

Maximum likelihood parameter estimates for the covariance of the Data using ECM algorithm, returned as a NUMSERIES-by-NUMSERIES matrix.

Algorithms

Model

The general model is

$$Z \sim N(Mean, Covariance),$$

where each row of Data is an observation of Z.

Each observation of Z is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR). See Little and Rubin [1] for a precise definition of MAR.

This routine estimates the mean and covariance from given data. If data values are missing, the routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3].

If a record is empty (every value in a sample is NaN), this routine ignores the record because it contributes no information. If such records exist in the data, the number of nonempty samples used in the estimation is ≤ NumSamples.

The estimate for the covariance is a biased maximum likelihood estimate (MLE). To convert to an unbiased estimate, multiply the covariance by Count/(Count – 1), where Count is the number of nonempty samples used in the estimation.

Requirements

This routine requires consistent values for NUMSAMPLES and NUMSERIES with NUMSAMPLES > NUMSERIES. It must have enough nonmissing values to converge. Finally, it must have a positive-definite covariance matrix. Although the references provide some necessary and sufficient conditions, general conditions for existence and uniqueness of solutions in the missing-data case, do not exist. The main failure mode is an ill-conditioned covariance matrix estimate. Nonetheless, this routine works for most cases that have less than 15% missing data (a typical upper bound for financial data).

Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages. The ECM algorithm always converges to a minimum of the observed negative log-likelihood function. If you override the initialization methods, you must ensure that the initial estimate for the covariance matrix is positive-definite.

The following is a guide to the supported initialization methods.

- nanskip — The nanskip method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with NaNs and estimates initial values from complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the twostage method if it determines that significant numbers of records contain NaN.
- twostage — The twostage method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as NaNs. This initialization method is robust but tends to result in slower convergence of the ECM algorithm.
- diagonal —

  The diagonal method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than 33% of data missing). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm. If problems occur with this method, use display mode to examine convergence and modify either MaxIterations or Tolerance, or try alternative initial estimates with Mean0 and Covar0. If all else fails, try

  ```
  Mean0 = zeros(NumSeries);
  Covar0 = eye(NumSeries,NumSeries);
  ```

  Given estimates for mean and covariance from this routine, you can estimate standard errors with the companion routine ecmnstd.

Convergence

The ECM algorithm does not work for all patterns of missing values. Although it works in most cases, it can fail to converge if the covariance becomes singular. If this occurs, plots of the log-likelihood function tend to have a constant upward slope over many iterations as the log of the negative determinant of the covariance goes to zero. In some cases, the objective fails to converge due to machine precision errors. No general theory of missing data patterns exists to determine these cases. An example of a known failure occurs when two time series are proportional wherever both series contain nonmissing values.

ecmnobj

Multivariate normal negative log-likelihood function

Syntax

```
Objective = ecmnobj(Data,Mean,Covariance)
Objective = ecmnobj(___,CholCovariance)
```

Description

`Objective = ecmnobj(Data,Mean,Covariance)` evaluates the negative log-likelihood function for `ecmnmle`.

Use `ecmnobj` after estimating the mean and covariance of `Data` with `ecmnmle`.

`Objective = ecmnobj(___,CholCovariance)` adds an optional argument for `CholCovariance`.

Examples

Compute Value of the Observed Negative Log-Likelihood Function for Data

This example shows how to compute the value of the observed negative log-likelihood function for five years of daily total return data for 12 computer technology stocks, with six hardware and six software companies

```
load ecmtechdemo.mat
```

The time period for this data extends from April 19, 2000 to April 18, 2005. The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as `NaN`s. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

```
[ECMMean, ECMCovar] = ecmnmle(Data)
```

```
ECMMean = 12×1

    0.0008
    0.0008

    0.0005    0.0024    0.0007    0.0006    0.0010    0.0004    0.0005    0.0003    0.0006    0.0
    0.0006    0.0007    0.0013    0.0007    0.0007    0.0003    0.0006    0.0004    0.0008    0.0
    0.0005    0.0006    0.0007    0.0009    0.0006    0.0002    0.0005    0.0003    0.0007    0.0
    0.0005    0.0010    0.0007    0.0006    0.0016    0.0006    0.0005    0.0003    0.0006    0.0
    0.0003    0.0004    0.0003    0.0002    0.0006    0.0022    0.0001    0.0002    0.0002    0.0
    0.0005    0.0005    0.0006    0.0005    0.0005    0.0001    0.0009    0.0003    0.0005    0.0
    0.0003    0.0003    0.0004    0.0003    0.0003    0.0002    0.0003    0.0005    0.0004    0.0
    0.0006    0.0006    0.0008    0.0007    0.0006    0.0002    0.0005    0.0004    0.0011    0.0
    0.0003    0.0004    0.0005    0.0004    0.0004    0.0001    0.0004    0.0003    0.0005    0.0
      ⋮
```

To evaluate the negative log-likelihood function for `ecmnmle`, use `ecmnobj` based on the current maximum likelihood parameter estimates.

```
Objective = ecmnobj(Data,ECMMean,ECMCovar)
```

```
Objective = -3.0898e+04
```

Input Arguments

`Data` — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by `NaN`s.

Data Types: `double`

`Mean` — Maximum likelihood parameter estimates for mean of `Data`

vector

Maximum likelihood parameter estimates for the mean of the `Data` using the ECM algorithm, specified as a `NUMSERIES`-by-`1` column vector.

`Covariance` — Maximum likelihood parameter estimates for covariance of `Data`

matrix

Maximum likelihood parameter estimates for the covariance of the `Data` using the ECM algorithm, specified as a `NUMSERIES`-by-`NUMSERIES` matrix.

`CholCovariance` — Cholesky decomposition of covariance matrix

`[ ]` (default) | matrix

(Optional) Cholesky decomposition of covariance matrix, specified as a matrix using `chol` as:

```
chol(Covariance)
```

Data Types: `double`

Output Arguments

`Objective` — Value of the observed negative log-likelihood function over `Data`

numeric

Value of the observed negative log-likelihood function over the `Data`, returned as a numeric value.

Version History

Introduced before R2006a

ecmnstd

Standard errors for mean and covariance of incomplete data

Syntax

```
[StdMean,StdCovar] = ecmnstd(Data,Mean,Covariance)
[StdMean,StdCovar] = ecmnstd( ___ ,Method)
```

Description

`[StdMean,StdCovar] = ecmnstd(Data,Mean,Covariance)` computes standard errors for mean and covariance of incomplete data.

Use `ecmnstd` after estimating the mean and covariance of `Data` with `ecmnmle`. If the mean and distinct covariance elements are treated as the parameter θ in a complete-data maximum-likelihood estimation, then as the number of samples increases, θ attains asymptotic normality such that

$$\theta - E[\theta] \sim N\left(0, I^{-1}(\theta)\right),$$

where $E[\theta]$ is the mean and $I(\theta)$ is the Fisher information matrix.

With missing data, the Hessian $H(\theta)$ is a good approximation for the Fisher information (which can only be approximated when data is missing).

`[StdMean,StdCovar] = ecmnstd( ___ ,Method)` adds an optional argument for `Method`.

Examples

Compute Standard Errors for Mean and Covariance of Incomplete Data

This example shows how to compute the standard errors for mean and covariance of incomplete data for five years of daily total return data for 12 computer technology stocks, with six hardware and six software companies

```
load ecmtechdemo.mat
```

The time period for this data extends from April 19, 2000 to April 18, 2005. The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. So, all returns before August 20, 2004 are missing and represented as `NaN`s. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past five years.

```

    0.0005    0.0010    0.0007    0.0006    0.0016    0.0006    0.0005    0.0003    0.0006    0.0
    0.0003    0.0004    0.0003    0.0002    0.0006    0.0022    0.0001    0.0002    0.0002    0.0
    0.0005    0.0005    0.0006    0.0005    0.0005    0.0001    0.0009    0.0003    0.0005    0.0
    0.0003    0.0003    0.0004    0.0003    0.0003    0.0002    0.0003    0.0005    0.0004    0.0
    0.0006    0.0006    0.0008    0.0007    0.0006    0.0002    0.0005    0.0004    0.0011    0.0
    0.0003    0.0004    0.0005    0.0004    0.0004    0.0001    0.0004    0.0003    0.0005    0.0
      ⋮
```

To evaluate the impact of the estimation error and, in particular, the effect of missing data, use `ecmnstd` to calculate standard errors. Although it is possible to estimate the standard errors for both the mean and covariance, the standard errors for the mean estimates alone are usually the main quantities of interest.

```
StdMeanF = ecmnstd(Data,ECMMean,ECMCovar,'fisher')
```

```
StdMeanF = 12×1

    0.0010
    0.0014
    0.0010
    0.0009
    0.0011
    0.0013
    0.0009
    0.0006
    0.0009
    0.0007
      ⋮
```

Calculate standard errors that use the data-generated Hessian matrix (which accounts for the possible loss of information due to missing data) with the option `'hessian'`.

```
StdMeanH = ecmnstd(Data,ECMMean,ECMCovar,'hessian')
```

```
StdMeanH = 12×1

    0.0010
    0.0014
    0.0010
    0.0009
    0.0011
    0.0021
    0.0009
    0.0006
    0.0009
    0.0007
      ⋮
```

The difference in the standard errors shows the increase in uncertainty of estimation of asset expected returns due to missing data. To view the differences:

```
Assets
```

```
Assets = 1x12 cell
    {'AAPL'}    {'AMZN'}    {'CSCO'}    {'DELL'}    {'EBAY'}    {'GOOG'}    {'HPQ'}    {'IBM'}
```

```
StdMeanH'
```

```
ans = 1×12

    0.0010    0.0014    0.0010    0.0009    0.0011    0.0021    0.0009    0.0006    0.0009    0.0
```

```
StdMeanF'
```

```
ans = 1×12

    0.0010    0.0014    0.0010    0.0009    0.0011    0.0013    0.0009    0.0006    0.0009    0.0
```

```
StdMeanH' - StdMeanF'
```

```
ans = 1×12
10^-3 ×

   -0.0000    0.0021   -0.0000   -0.0000   -0.0000    0.7742   -0.0000   -0.0000   -0.0000   -0.0
```

The two assets with missing data, AMZN and GOOG, are the only assets to have differences due to missing information.

Input Arguments

`Data` — Data

matrix

Data, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. Missing values are indicated by `NaN`s.

Data Types: `double`

`Mean` — Maximum likelihood parameter estimates for mean of `Data`

vector

Maximum likelihood parameter estimates for the mean of the `Data` using the ECM algorithm, specified as a `NUMSERIES`-by-`1` column vector.

Covariance — Maximum likelihood parameter estimates for covariance of Data
matrix

Maximum likelihood parameter estimates for the covariance of the Data using the ECM algorithm, specified as a NUMSERIES-by-NUMSERIES matrix.

Method — Method of estimation for standard error calculations
'hessian' (default) | character vector

(Optional) Method of estimation for standard error calculations, specified as a character vector. The estimation methods are:

- 'hessian' — The Hessian of the observed negative log-likelihood function. This method is recommended since the resultant standard errors incorporate the increase uncertainties due to missing data. In particular, standard errors calculated with the Hessian are generally larger than standard errors calculated with the Fisher information matrix.
- 'fisher' — The Fisher information matrix.

Data Types: char

Output Arguments

StdMean — Standard errors of estimates for each element of Mean vector
vector

Standard errors of estimates for each element of Mean vector, returned as a NUMSERIES-by-1 column vector.

StdCovar — Standard errors of estimates for each element of Covariance matrix
matrix

Standard errors of estimates for each element of Covariance matrix, returned as a NUMSERIES-by-NUMSERIES matrix.

Version History

Introduced before R2006a

effrr

Effective rate of return

Syntax

```
Return = effrr(Rate,NumPeriods)
```

Description

`Return = effrr(Rate,NumPeriods)` calculates the annual effective rate of return. Compounding continuously returns `Return` equivalent to `(e^Rate-1)`.

Examples

Compute the Annual Effective Rate of Return

This example shows how to find the effective annual rate of return based on an annual percentage rate of 9% compounded monthly.

```
Return = effrr(0.09, 12)
```

```
Return = 0.0938
```

Input Arguments

`Rate` — Annual percentage rate
scalar numeric decimal

Annual percentage rate, specified as a scalar numeric decimal.

Data Types: `double`

`NumPeriods` — Number of compounding periods per year
scalar integer

Number of compounding periods per year, specified as a scalar integer.

Data Types: `double`

Output Arguments

`Return` — Annual effective rate of return
scalar numeric decimal

Annual effective rate of return, returned as a scalar numeric decimal.

Version History

Introduced before R2006a

"Analyzing and Computing Cash Flows" on page 2-11

elpm

Compute expected lower partial moments for normal asset returns

Syntax

```
elpm(Mean,Sigma)
elpm(Mean,Sigma,MAR)
elpm(Mean,Sigma,MAR,Order)
Moment = elpm(MeanSigmaMAROrder)
```

Description

elpm(Mean,Sigma) compute expected lower partial moments (elpm) relative to a default value of MAR for each asset in a NUMORDERS-by-NUMSERIES matrix.

elpm(Mean,Sigma,MAR) computes expected lower partial moments (elpm) relative to a MAR for each asset in a NUMORDERS-by-NUMSERIES matrix.

elpm(Mean,Sigma,MAR,Order) computes expected lower partial moments (elpm) relative to a MAR and Order for each asset in a NUMORDERS-by-NUMSERIES matrix.

Moment = elpm(MeanSigmaMAROrder) computes expected lower partial moments (elpm) relative to a default value of MAR for each asset in a NUMORDERS-by-NUMSERIES matrix Moment.

Examples

Compute Expected Lower Partial Moments

This example shows how to compute expected lower partial moments based on the mean and standard deviations of normally distributed asset returns. The elpm function works with the mean and standard deviations for multiple assets and multiple orders.

```
load FundMarketCash
Returns = tick2ret(TestData);
MAR = mean(Returns(:,3))
```

```
MAR = 0.0017
```

```
Mean = mean(Returns)
```

```
Mean = 1×3

    0.0038    0.0030    0.0017
```

```
Sigma = std(Returns, 1)
```

```
Sigma = 1×3

    0.0229    0.0389    0.0009
```

```
Assets
```

```
Assets = 1x3 cell
    {'Fund'}    {'Market'}    {'Cash'}
```

```
ELPM = elpm(Mean, Sigma, MAR, [0 1 2])
```

```
ELPM = 3×3

    0.4647    0.4874    0.5000
    0.0082    0.0149    0.0004
    0.0002    0.0007    0.0000
```

Based on the moments of each asset, the expected values for lower partial moments imply better than expected performance for the fund and market and worse than expected performance for cash. The `elpm` function works with either degenerate or nondegenerate normal random variables. For example, if cash were truly riskless, its standard deviation would be 0. You can examine the difference in average shortfall.

```
RisklessCash = elpm(Mean(3), 0, MAR, 1)
```

```
RisklessCash = 0
```

Input Arguments

`Mean` — Mean returns

vector

Mean returns, specified as a `NUMSERIES` vector with mean returns for a collection of `NUMSERIES` assets.

Data Types: `double`

`Sigma` — Standard deviation of returns

vector

Standard deviation of returns, specified as a `NUMSERIES` vector with standard deviation of returns for a collection of `NUMSERIES` assets.

Data Types: `double`

`MAR` — Minimum acceptable return

`0` (default) | numeric

(Optional) Minimum acceptable return, specified as a scalar numeric. `MAR` is a cutoff level of return such that all returns above `MAR` contribute nothing to the lower partial moment.

Data Types: `double`

`Order` — Moment orders

`0` (default) | scalar numeric | vector

(Optional) Moment orders, specified as a either a scalar or a `NUMORDERS` vector of nonnegative integer moment orders. If no order specified, the default `Order = 0`, which is the shortfall probability. The `elpm` function does not work for negative or a noninteger `Order`.

Data Types: double

Output Arguments

Moment — Expected lower partial moments
matrix

Expected Lower partial moments, returned as a NUMORDERS-by-NUMSERIES matrix of expected lower partial moments with NUMORDERS Orders and NUMSERIES series, that is, each row contains expected lower partial moments for a given Order. The output Moment for the lower partial moment represents the moments of asset returns that fall below a minimum acceptable level of return.

Note To compute upper partial moments, reverse the signs of both the input Mean and MAR (do not reverse the signs of either Sigma or the output). This function computes expected lower partial moments with the mean and standard deviation of normally distributed asset returns. To compute sample lower partial moments from asset returns which have no distributional assumptions, use lpm.

More About

Lower Partial Moments

Use *lower partial moments* to examine what is colloquially known as “downside risk.”

The main idea of the lower partial moment framework is to model moments of asset returns that fall below a minimum acceptable level of return. To compute lower partial moments from data, use lpm to calculate lower partial moments for multiple asset return series and for multiple moment orders. To compute expected values for lower partial moments under several assumptions about the distribution of asset returns, use elpm to calculate lower partial moments for multiple assets and for multiple orders.

"Performance Metrics Overview" on page 7-2

emaxdrawdown

Compute expected maximum drawdown for Brownian motion

Syntax

```
ExpDrawdown = emaxdrawdown(Mu,Sigma,T)
```

Description

`ExpDrawdown = emaxdrawdown(Mu,Sigma,T)` computes the expected maximum drawdown for a Brownian motion for each time period in `T` using the following equation:

$$dX(t) = \mu dt + \sigma dW(t) .$$

If the Brownian motion is geometric with the stochastic differential equation

$$dS(t) = \mu_0 S(t)dt + \sigma_0 S(t)dW(t)$$

then use Ito's lemma with $X(t) = \log(S(t))$ such that

$$\mu = \mu_0 - 0.5\sigma_0 2,$$
$$\sigma = \sigma_0$$

converts it to the form used here.

Examples

Compute Expected Maximum Drawdown

This example shows how to use log-return moments of a fund to compute the expected maximum drawdown (`EMaxDD`) and then compare it with the realized maximum drawdown (`MaxDD`).

```
load FundMarketCash
logReturns = log(TestData(2:end,:) ./ TestData(1:end - 1,:));
Mu = mean(logReturns(:,1));
Sigma = std(logReturns(:,1),1);
T = size(logReturns,1);

MaxDD = maxdrawdown(TestData(:,1),'geometric')
```

```
MaxDD = 0.1813
```

```
EMaxDD = emaxdrawdown(Mu, Sigma, T)
```

```
EMaxDD = 0.1545
```

The drawdown observed in this time period is above the expected maximum drawdown. There is no contradiction here. The expected maximum drawdown is not an upper bound on the maximum losses from a peak, but an estimate of their average, based on a geometric Brownian motion assumption.

Input Arguments

Mu — Drift term of a Brownian motion with drift
numeric

Drift term of a Brownian motion with drift., specified as a scalar numeric.

Data Types: double

Sigma — Diffusion term of a Brownian motion with drift
numeric

Diffusion term of a Brownian motion with drift, specified as a scalar numeric.

Data Types: double

T — A time period of interest
numeric | vector

A time period of interest, specified as a scalar numeric or vector.

Data Types: double

Output Arguments

ExpDrawdown — Expected maximum drawdown
numeric

Expected maximum drawdown, returned as a numeric. ExpDrawdown is computed using an interpolation method. Values are accurate to a fraction of a basis point. Maximum drawdown is nonnegative since it is the change from a peak to a trough.

Note To compare the actual results from maxdrawdown with the expected results of emaxdrawdown, set the Format input argument of maxdrawdown to either of the nondefault values ('arithmetic' or 'geometric'). These are the only two formats that emaxdrawdown supports.

“Performance Metrics Overview” on page 7-2

estimateCustomObjectivePortfolio

Estimate optimal portfolio for user-defined objective function for `Portfolio` object

Syntax

```
[pwgt,pbuy,psell,exitflag] = estimateCustomObjectivePortfolio(obj,fun)
[pwgt,pbuy,psell,exitflag] = estimateCustomObjectivePortfolio( ___ ,Name=Value)
```

Description

`[pwgt,pbuy,psell,exitflag] = estimateCustomObjectivePortfolio(obj,fun)` estimates optimal portfolio with a user-defined objective function for a `Portfolio` object. For details on using `estimateCustomObjectivePortfolio`, see “Solver Guidelines for Custom Objective Problems Using Portfolio Objects” on page 4-115.

`[pwgt,pbuy,psell,exitflag] = estimateCustomObjectivePortfolio( ___ ,Name=Value)` adds optional name-value arguments.

Examples

Solve Continuous Problems Using Custom Objectives

This example shows how to use `estimateCustomObjectivePortfolio` to solve a portfolio problem with a custom objective. You define the constraints for portfolio problems using functions for the `Portfolio` object and then you specify the objective function as an input to `estimateCustomObjectivePortfolio`. The objective function must be continuous (and preferably smooth).

Create `Portfolio` Object

Find the portfolio that solves the problem:

$$
\begin{aligned}
&\min_{x}\; x^T x \\
&s.t.\; \sum_{i} x_i = 1 \\
&\qquad x \geq 0
\end{aligned}
$$

Create a `Portfolio` object and set the default constraints using `setDefaultConstraints`. In this case, the portfolio problem does not involve the mean or covariance of the assets returns. Therefore, you do not need to define the assets moments to create the `Portfolio` object. You need only to define the number of assets in the problem.

```
% Create a Portfolio object
p = Portfolio(NumAssets=6);
% Define the constraints of the portfolio methods
p = setDefaultConstraints(p); % Long-only, fully invested weights
```

Define Objective Function

Define a function handle for the objective function $x^T x$.

```
% Define the objective function
objFun = @(x) x'*x;
```

Solve Portfolio Problem

Use `estimateCustomObjectivePortfolio` to compute the solution to the problem.

```
% Solve portfolio problem
wMin = estimateCustomObjectivePortfolio(p,objFun)
```

```
wMin = 6×1

    0.1667
    0.1667
    0.1667
    0.1667
    0.1667
    0.1667
```

The `estimateCustomObjectivePortfolio` function automatically assumes that the objective sense is to minimize. You can change that default behavior by using the `estimateCustomObjectivePortfolio` name-value argument `ObjectiveSense='maximize'`.

Add Gross or Net Return Constraints for Problems with Custom Objectives

This example shows how to use `estimateCustomObjectivePortfolio` to solve a portfolio problem with a custom objective and a return constraint. You define the constraints for portfolio problems, other than the return constraint, using functions for the `Portfolio` object and then you specify the objective function as an input to `estimateCustomObjectivePortfolio`. The objective function must be continuous (and preferably smooth). To specify a return constraint, you use the `TargetReturn` name-value argument.

Create `Portfolio` Object

Find the portfolio that solves the problem:

$$\begin{aligned} &\min_{x} \; x^T x \\ &s.t. \; \sum_i x_i = 1 \\ &\qquad x \geq 0 \end{aligned}$$

Create a `Portfolio` object and set the default constraints using `setDefaultConstraints`.

```
% Create a Portfolio object
load('SixStocks.mat')
p = Portfolio(AssetMean=AssetMean,AssetCovar=AssetCovar);
% Define the constraints of the portfolio methods
p = setDefaultConstraints(p); % Long-only, fully invested weights
```

Define Objective Function

Define a function handle for the objective function $x^T x$.

```
% Define the objective function
objFun = @(x) x'*x;
```

Add Return Constraints

When using the Portfolio object, you can use estimateFrontierByReturn to add a return constraint to the portfolio. However, when using the estimateCustomObjectivePortfolio function with a Portfolio object, you must add return constraints by using the TargetReturn name-value argument with a return target value.

The Portfolio object supports two types of return constraints: gross return and net return. The type of return constraint that is added to the portfolio problem is implicitly defined by whether you provide buy or sell costs to the Portfolio object using setCosts. If no buy or sell costs are present, the added return constraint is a gross return constraint. Otherwise, a net return constraint is added.

Gross Return Constraint

The gross portfolio return constraint for a portfolio is

$$r_0 + (\mu - r_0)^T x \geq \mu_0,$$

where r_0 is the risk-free rate (with 0 as default), μ is the mean of assets returns, and μ_0 is the target return.

Since buy or sell costs are not needed to add a gross return constraint, the Portfolio object does not need to be modified before using estimateCustomObjectivePortfolio.

```
% Set a return target
ret0 = 0.03;
% Solve portfolio problem with a gross return constraint
wGross = estimateCustomObjectivePortfolio(p,objFun, ...
    TargetReturn=ret0)
```

```
wGross = 6×1

    0.1377
    0.1106
    0.1691
    0.1829
    0.1179
    0.2818
```

The return constraint is not added to the Portfolio object. In other words, the Portfolio properties are not modified by adding a gross return constraint in estimateCustomObjectivePortfolio.

Net Return Constraint

The net portfolio return constraint for a portfolio is

$$r_0 + (\mu - r_0)^T x - c_B^T \max\{0, x - x_0\} - c_S^T \max\{0, x_0 - x\} \geq \mu_0,$$

where r_0 is the risk-free rate (with 0 as default), μ is the mean of assets returns, c_B is the proportional buy cost, c_S is the proportional sell cost, x_0 is the initial portfolio, and μ_0 is the target return.

To add net return constraints to the portfolio problem, you must use `setCosts` with the `Portfolio` object. If the `Portfolio` object has either of these costs, `estimateCustomObjectivePortfolio` automatically assumes that any added return constraint is a net return constraint.

```
% Add buy and sell costs to the Portfolio object
buyCost = 0.002;
sellCost = 0.001;
initPort = zeros(p.NumAssets,1);
p = setCosts(p,buyCost,sellCost,initPort);
% Solve portfolio problem with a net return constraint
% wNet = estimateCustomObjectivePortfolio(p,objFun, ...
%    TargetReturn=ret0)
```

As with the gross return constraint, the net return constraint is not added to the `Portfolio` object properties, however the `Portfolio` object is modified by the addition of buy or sell costs. Adding buy or sell costs to the `Portfolio` object does not affect any constraints besides the return constraint, but these costs do affect the solution of maximum return problems because the solution is the maximum *net* return instead of the maximum *gross* return.

Solve Portfolio Problems with Custom Objectives and Cardinality Constraints

This example shows how to use `estimateCustomObjectivePortfolio` to solve a portfolio problem with a custom objective and cardinality constraints. You define the constraints for portfolio problems using functions for the `Portfolio` object and then you specify the objective function as an input to `estimateCustomObjectivePortfolio`. For problems with cardinality constraints or continuous bounds, the objective function must be continuous and convex.

Create `Portfolio` Object

Find a long-only, fully weighted portfolio with half the assets that minimizes the tracking error to the equally weighted portfolio. Furthermore, if an asset is present in the portfolio, at least 10% should be invested in that asset. The porfolio problem is as follows:

$$\begin{aligned} &\min_x \ (x - x_0)^T \Sigma (x - x_0) \\ &s.t. \ \sum_i x_i = 1, \\ &\qquad \sum_i \#(x_i \neq 0) = 3, \\ &\qquad x_i \geq 0.1 \text{ or } x_i = 0 \end{aligned}$$

Create a `Portfolio` object and set the assets moments.

```
load('SixStocks.mat')
p = Portfolio(AssetMean=AssetMean,AssetCovar=AssetCovar);
nAssets = size(AssetMean,1);
```

Define the `Portfolio` constraints.

```
% Fully invested portfolio
p = setBudget(p,1,1);
% Cardinality constraint
p = setMinMaxNumAssets(p,3,3);
% Conditional bounds
p = setBounds(p,0.1,[],BoundType="conditional");
```

Define Objective Function

Define a function handle for the objective function.

```
% Define the objective function
EWP = 1/nAssets*ones(nAssets,1);
trackingError = @(x) (x-EWP)'*p.AssetCovar*(x-EWP);
```

Solve Portfolio Problem

Use `estimateCustomObjectivePortfolio` to compute the solution to the problem.

```
% Solve portfolio problem
wMinTE = estimateCustomObjectivePortfolio(p,trackingError)
```

```
wMinTE = 6×1

    0.1795
    0.3507
         0
    0.4698
         0
         0
```

Input Arguments

obj — Object for portfolio
`Portfolio` object

Object for portfolio, specified using a `Portfolio` object. When using a `Portfolio` object in the custom objective workflow, you do not need to use the mean-variance framework to estimate the mean and covariance. However, the custom objective workflow does require that you specify portfolio constraints. The `Portfolio` object that you use with the `estimateCustomObjectivePortfolio` function supports only the following constraints:

- Simple bounds — For more information, see “Working with 'Simple' Bound Constraints Using Portfolio Object” on page 4-61 and `setBounds`.
- Conditional bounds and cardinality constraints — For more information, see “Working with 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints Using Portfolio Objects” on page 4-78 and `setBounds` and `setMinMaxNumAssets`.

Note When using `estimateCustomObjectivePortfolio`, you cannot use tracking error constraints with conditional bounds and cardinality constraints. For more information, see “Solve Portfolio Problems with Custom Objectives and Cardinality Constraints” on page 15-852.

- Linear equalities — For more information, see “Working with Linear Equality Constraints Using Portfolio Object” on page 4-72 and `setEquality`.

- Linear inequalities — For more information, see “Working with Linear Inequality Constraints Using Portfolio Object” on page 4-75 and `setInequality`.
- Budget — For more information, see “Working with Budget Constraints Using Portfolio Object” on page 4-64 and `setBudget`.
- Group — For more information, see “Working with Group Constraints Using Portfolio Object” on page 4-66 and `setGroups`.
- Group ratio — For more information, see “Working with Group Ratio Constraints Using Portfolio Object” on page 4-69 and `setGroupRatio`.
- Turnover — For more information, see “Working with Average Turnover Constraints Using Portfolio Object” on page 4-81 and `setTurnover`.
- One-way turnover — For more information, see “Working with One-Way Turnover Constraints Using Portfolio Object” on page 4-84 and `setOneWayTurnover`.
- Tracking error — For more information, see “Working with Tracking Error Constraints Using Portfolio Object” on page 4-87 and `setTrackingError`.

Note If no initial portfolio is specified in `obj.InitPort`, the initial portfolio is assumed to be `0` so that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`. If no tracking portfolio is specified in `obj.TrackingPort`, the tracking portfolio is assumed to be `0`.

Data Types: `object`

`fun` — Function handle that defines objective function
function handle

Function handle that defines the objective function, specified using a function handle in terms of the portfolio weights.

Note The objective function must be continuous and defined using only the portfolio weights as variables. If the portfolio problem has cardinality constraints and/or conditional bounds using `setMinMaxNumAssets` or `setBounds`, the objective function must also be convex. For more information, see “Role of Convexity in Portfolio Problems” on page 4-148.

Data Types: `function_handle`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `pwgt = estimateCustomObjectivePortfolio(p,fun,ObjectiveSense="maximize",TargetReturn=0.05)`

`ObjectiveSense` — Sense of optimization
`"minimize"` (default) | string with value `"mimimize"` or `"maximize"` | character vector with value `'mimimize'` or `'maximize'`

Sense of the optimization, specified as `ObjectiveSense` and a string or character vector with one of the following values:

- `"minimize"` — The solution minimizes the objective function.
- `"maximize"` — The solution maximizes the objective function.

Data Types: `string` | `char`

`TargetReturn` — Target value for portfolio return
`[]` (default) | positive or negative scalar

Target value for the portfolio return, specified as `TargetReturn` and a positive or negative scalar.

Note In the `Portfolio` object, use `estimateFrontierByReturn` to add a return constraint to the portfolio. When you use `estimateCustomObjectivePortfolio`, return constraints are added by passing the name-value argument `TargetReturn` with the return target.

Data Types: `double`

Output Arguments

`pwgt` — Optimal weight allocation of portfolio problem
vector

Optimal weight allocation of the portfolio problem, returned as a `NumAssets`-by-`1` vector.

`pbuy` — Purchases relative to initial portfolio to achieve optimal weight allocation of portfolio problem
vector

Purchases relative to initial portfolio to achieve the optimal weight allocation of the portfolio problem, returned as a `NumAssets`-by-`1` vector.

`psell` — Sales relative to initial portfolio to achieve optimal weight allocation of the portfolio problem
vector

Sales relative to initial portfolio to achieve the optimal weight allocation of the portfolio problem, returned as a `NumAssets` vector.

`exitflag` — Reason solver stopped
enumeration variable | integer

Reason the solver stopped, returned as an enumeration variable or integer. There are two types of `exitflag` output. If the problem is continuous, the `exitflag` output is an enumeration variable. If the problem is mixed-integer, then the `exitflag` output is an integer.

Version History

Introduced in R2022b

estimateAssetMoments

Estimate mean and covariance of asset returns from data

Note Using a `fints` object for the `AssetReturns` argument of `estimateAssetMoments` is not recommended. Use `timetable` instead for financial time series. For more information, see “Convert Financial Time Series Objects (fints) to Timetables”.

Syntax

```
obj = estimateAssetMoments(obj,AssetReturns)
obj = estimateAssetMoments( ___ ,Name,Value)
```

Description

`obj = estimateAssetMoments(obj,AssetReturns)` estimates mean and covariance of asset returns from data for a `Portfolio` object. For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

`obj = estimateAssetMoments( ___ ,Name,Value)` estimates mean and covariance of asset returns from data for a Portfolio object with additional options for one or more `Name,Value` pair arguments.

Examples

Estimate Mean and Covariance of Asset Returns from Data for a Portfolio Object

To illustrate using the `estimateAssetMoments` function, generate random samples of 120 observations of asset returns for four assets from the mean and covariance of asset returns in the variables `m` and `C` with the `portsim` function. The default behavior `portsim` creates simulated data with estimated mean and covariance identical to the input moments `m` and `C`. In addition to a return series created by the `portsim` function in the variable `X`, a price series is created in the variable `Y`:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
X = portsim(m', C, 120);
Y = ret2tick(X);
```

Given asset returns and prices in the variables `X` and `Y` from above, the following examples demonstrate equivalent ways to estimate asset moments for the Portfolio object. A Portfolio object is created in `p` with the moments of asset returns set directly in the `Portfolio` object and a second Portfolio object is created in `q` to obtain the mean and covariance of asset returns from asset return data in `X` using the `estimateAssetMoments` function.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

X = portsim(m', C, 120);
p = Portfolio('mean',m,'covar',C);
q = Portfolio;
q = estimateAssetMoments(q, X);

[passetmean, passetcovar] = getAssetMoments(p)
```

```
passetmean = 4×1

    0.0042
    0.0083
    0.0100
    0.0150

passetcovar = 4×4

    0.0005    0.0003    0.0002         0
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
         0    0.0010    0.0028    0.0102
```

```
[qassetmean, qassetcovar] = getAssetMoments(q)
```

```
qassetmean = 4×1

    0.0042
    0.0083
    0.0100
    0.0150

qassetcovar = 4×4

    0.0005    0.0003    0.0002   -0.0000
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
   -0.0000    0.0010    0.0028    0.0102
```

Notice how either approach yields the same moments. The default behavior of the `estimateAssetMoments` function is to work with asset returns. If, instead, you have asset prices, such as in the variable `Y`, the `estimateAssetMoments` function accepts a parameter name `'DataFormat'` with a corresponding value set to `'prices'` to indicate that the input to the method is in the form of asset prices and not returns (the default parameter value for `'DataFormat'` is `'returns'`). The following example compares direct assignment of moments in the Portfolio object `p` with estimated moments from asset price data in `Y` in the Portfolio object `q`:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
```

```
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

X = portsim(m', C, 120);
Y = ret2tick(X);

p = Portfolio('mean',m,'covar',C);

q = Portfolio;
q = estimateAssetMoments(q, Y, 'dataformat', 'prices');

[passetmean, passetcovar] = getAssetMoments(p)

passetmean = 4×1

    0.0042
    0.0083
    0.0100
    0.0150

passetcovar = 4×4

    0.0005    0.0003    0.0002         0
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
         0    0.0010    0.0028    0.0102

[qassetmean, qassetcovar] = getAssetMoments(q)

qassetmean = 4×1

    0.0042
    0.0083
    0.0100
    0.0150

qassetcovar = 4×4

    0.0005    0.0003    0.0002   -0.0000
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
   -0.0000    0.0010    0.0028    0.0102
```

Estimate Mean and Covariance of Asset Returns from Timetable Data for a Portfolio Object

To illustrate using the `estimateAssetMoments` function with `AssetReturns` data continued in a `timetable` object, use the `CAPMuniverse.mat` which contains a `timetable` object (`AssetTimeTable`) for returns data.

```
load CAPMuniverse
AssetsTimeTable.Properties;
head(AssetsTimeTable,5)
```

```
        Time          AAPL        AMZN        CSCO        DELL        EBAY       GOOG      H
    ___________    _________    _________    _________    _________    _________    ____    ____

    03-Jan-2000     0.088805      0.1742     0.008775    -0.002353     0.12829     NaN       0.0
    04-Jan-2000    -0.084331    -0.08324     -0.05608     -0.08353   -0.093805     NaN     -0.07
    05-Jan-2000     0.014634    -0.14877    -0.003039     0.070984    0.066875     NaN     -0.00
    06-Jan-2000    -0.086538   -0.060072    -0.016619    -0.038847   -0.012302     NaN     -0.06
    07-Jan-2000     0.047368    0.061013       0.0587    -0.037708   -0.000964     NaN      0.02
```

Notice that GOOG has missing data (NaN), because it was not listed before Aug 2004. The estimateAssetMoments function has a name-value pair argument 'MissingData' that indicates with a Boolean value whether to use the missing data capabilities of Financial Toolbox™ software. The default value for 'MissingData' is false which removes all samples with NaN values. If, however, 'MissingData' is set to true, estimateAssetMoments uses the ECM algorithm to estimate asset moments.

```
r = Portfolio;
r = estimateAssetMoments(r,AssetsTimeTable,'dataformat','returns','missingdata',true);
```

In addition, the estimateAssetMoments function also extracts asset names or identifiers from a timetable object when the name-value argument 'GetAssetList' set to true (its default value is false). If the 'GetAssetList' value is true, the timetable column identifiers are used to set the AssetList property of the Portfolio object. To show this, the formation of the Portfolio object r is repeated with the 'GetAssetList' flag set to true.

```
r = estimateAssetMoments(r,AssetsTimeTable,'GetAssetList',true);
disp(r.AssetList')
```

```
    {'AAPL'  }
    {'AMZN'  }
    {'CSCO'  }
    {'DELL'  }
    {'EBAY'  }
    {'GOOG'  }
    {'HPQ'   }
    {'IBM'   }
    {'INTC'  }
    {'MSFT'  }
    {'ORCL'  }
    {'YHOO'  }
    {'MARKET'}
    {'CASH'  }
```

Estimate Mean and Covariance of Asset Returns from Data for a Portfolio Object with Integrality Constraints

Create a Portfolio object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
AssetMean = AssetMean/12
```

```
AssetMean = 3×1

    0.0008
    0.0004
    0.0011
```

```
AssetCovar = AssetCovar/12
```

```
AssetCovar = 3×3
10^-3 ×

    0.2705    0.0192    0.3503
    0.0192    0.0416    0.0160
    0.3503    0.0160    0.6367
```

```
X = portsim(AssetMean', AssetCovar, 120);

p = Portfolio('AssetMean',AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semi-continuous constraints to set *xi*=0 or 0.02<=*xi*<=0.5 for all *i*=1,...NumAssets.

```
p = setBounds(p, 0.02, 0.5,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the `Portfolio` object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets=MaxNumAssets=2`, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimateAssetMoments` to estimate mean and covariance of asset returns from data for a `Portfolio` object.

```
p = estimateAssetMoments(p, X);
[passetmean, passetcovar] = getAssetMoments(p)
```

```
passetmean = 3×1

    0.0008
    0.0004
    0.0011
```

```
passetcovar = 3×3
10^-3 ×

    0.2705    0.0192    0.3503
    0.0192    0.0416    0.0160
    0.3503    0.0160    0.6367
```

The estimateAssetMoments function uses the MINLP solver to solve this problem. Use the setSolverMINLP function to configure the SolverType and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
                    RelativeGapTolerance: 1.0000e-05

    NumIterationsEarlyIntegerConvergence: 30
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using a Portfolio object. For more information on creating a portfolio object, see

- Portfolio

Data Types: object

AssetReturns — Matrix, table, or timetable that contains asset price data that can be converted to asset returns

matrix | table | table

Matrix, table, or timetable that contains asset price data that can be converted to asset returns, specified by a NumSamples-by-NumAssets matrix.

AssetReturns data can be:

- NumSamples-by-NumAssets matrix.
- Table of NumSamples prices or returns at a given periodicity for a collection of NumAssets assets
- Timetable object with NumSamples observations and NumAssets time series

Use the optional DataFormat argument to convert AssetReturns input data that is asset prices into asset returns. Be careful when using asset price data because portfolio optimization usually requires total returns and not simply price returns.

Data Types: double | table | timetable

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `p = estimateAssetMoments(p,Y,'dataformat','prices')`

`DataFormat` — Flag to convert input data as prices into returns

`'Returns'` (default) | character vector with values `'Returns'` or `'Prices'`

Flag to convert input data as prices into returns, specified as the comma-separated pair consisting of `'DataFormat'` and a character vector with the values:

- `'Returns'` — Data in `AssetReturns` contains asset total returns.
- `'Prices'` — Data in `AssetReturns` contains asset total return prices.

Data Types: `char`

`MissingData` — Flag indicating whether to use ECM algorithm or exclude samples with `NaN` values

`false` (default) | logical with value `true` or `false`

Flag indicating whether to use ECM algorithm or excludes samples with `NaN` values, specified as the comma-separated pair consisting of `'MissingData'` and a logical with a value of `true` or `false`.

To handle time series with missing data (indicated with `NaN` values), the `MissingData` flag either uses the ECM algorithm to obtain maximum likelihood estimates in the presences of `NaN` values or excludes samples with `NaN` values. Since the default is `false`, it is necessary to specify `MissingData` as `true` to use the ECM algorithm.

Acceptable values for `MissingData` are:

- `false` — Do not use ECM algorithm to handle `NaN` values (exclude `NaN` values).
- `true` — Use ECM algorithm to handle `NaN` values.

For more information on the ECM algorithm, see `ecmnmle` and “Multivariate Normal Regression” on page 9-2.

Data Types: `logical`

`GetAssetList` — Flag indicating which asset names to use for asset list

`false` (default) | logical with value `true` or `false`

Flag indicating which asset names to use for the asset list, specified as the comma-separated pair consisting of `'GetAssetList'` and a logical with a value of `true` or `false`. Acceptable values for `GetAssetList` are:

- `false` — Do not extract or create asset names.
- `true` — Extract or create asset names from a table or timetable object.

If a `table` or `timetable` is passed into this function using the `AssetReturns` argument and the `GetAssetList` flag is `true`, the column names from the table or timetable object are used as asset names in `obj.AssetList`.

If a matrix is passed and the `GetAssetList` flag is `true`, default asset names are created based on the `AbstractPortfolio` property `defaultforAssetList`, which is `'Asset'`.

If the `GetAssetList` flag is `false`, no action occurs, which is the default behavior.

Data Types: `logical`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

Tips

You can also use dot notation to estimate the mean and covariance of asset returns from data.

```
obj = obj.estimateAssetMoments(AssetReturns);
```

Version History

Introduced in R2011a

estimateBounds

Estimate global lower and upper bounds for set of portfolios

Syntax

```
[glb,gub,isbounded] = estimateBounds(obj)
[glb,gub,isbounded] = estimateBounds(obj,obtainExactBounds)
```

Description

`[glb,gub,isbounded] = estimateBounds(obj)` estimates global lower and upper bounds for set of portfolios for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Note The `estimateBounds` function does not consider cardinality or semicontinuous constraints. For more information, see “Working with 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints Using Portfolio Objects” on page 4-78.

`[glb,gub,isbounded] = estimateBounds(obj,obtainExactBounds)` estimates global lower and upper bounds for set of portfolios with an additional option specified for `obtainExactBounds`.

Examples

Create an Unbounded Portfolio for a Portfolio Object

Create an unbounded portfolio set.

```
p = Portfolio('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
```

```
lb = 2×1

  -Inf
  -Inf

ub = 2×1

     0
   Inf

isbounded = logical
   0
```

The estimateBounds function returns (possibly infinite) bounds and sets the isbounded flag to false. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

Create an Unbounded Portfolio for a PortfolioCVaR Object

Create an unbounded portfolio set.

```
p = PortfolioCVaR('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
```

```
lb = 2×1

  -Inf
  -Inf

ub = 2×1

     0
   Inf

isbounded = logical
   0
```

The estimateBounds function returns (possibly infinite) bounds and sets the isbounded flag to false. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

Create an Unbounded Portfolio for a PortfolioMAD Object

Create an unbounded portfolio set.

```
p = PortfolioMAD('AInequality', [1 -1; 1 1 ], 'bInequality', 0);
[lb, ub, isbounded] = estimateBounds(p)
```

```
lb = 2×1

  -Inf
  -Inf

ub = 2×1

     0
   Inf

isbounded = logical
   0
```

The `estimateBounds` function returns (possibly infinite) bounds and sets the `isbounded` flag to `false`. The result shows which assets are unbounded so that you can apply bound constraints as necessary.

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`obtainExactBounds` — Flag to specify whether to solve for all bounds or to accept specified bounds whenever available

`true` (default) | logical

Flag to specify whether to solve for all bounds or to accept specified bounds whenever available, specified as a logical with values of `true` or `false`. If bounds are known, set `obtainExactBounds` to `false` to accept known bounds. The default for `obtainExactBounds` is `true`.

Data Types: `logical`

Output Arguments

`glb` — Global lower bounds for portfolio set

vector

Global lower bounds for portfolio set, returned as vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`gub` — Global upper bounds for portfolio set

vector

Global upper bounds for portfolio set, returned as vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`isbounded` — Indicator for whether portfolio set is empty, bounded, or unbounded

logical

Indicator for whether portfolio set is empty (`[]`), bounded (`true`), or unbounded (`false`), returned as a logical.

Note By definition, any portfolio set must be nonempty and bounded:

- If the set is empty, `isbounded = [ ]`.

- If the set is nonempty and unbounded, `isbounded` = `false`.
- If the set is nonempty and bounded, `isbounded = true`.
- If the set is empty, `glb` and `gub` are set to `NaN` vectors.

An `isbounded` value is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Tips

- You can also use dot notation to estimate the global lower and upper bounds for a given set of portfolios.

  ```
  [glb, gub, isbounded] = obj.estimateBounds;
  ```
- Estimated bounds are accurate in most cases to within `1.0e-8`. If you intend to use these bounds directly in a portfolio object, ensure that if you impose such bound constraints, a lower bound of `0` is probably preferable to a lower bound of, for example, `1.0e-10` for portfolio weights.

estimateFrontier

Estimate specified number of optimal portfolios on the efficient frontier

Syntax

```
[pwgt,pbuy,psell] = estimateFrontier(obj)
[pwgt,pbuy,psell] = estimateFrontier(obj,NumPorts)
```

Description

`[pwgt,pbuy,psell] = estimateFrontier(obj)` estimates the specified number of optimal portfolios on the efficient frontier for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[pwgt,pbuy,psell] = estimateFrontier(obj,NumPorts)` estimates the specified number of optimal portfolios on the efficient frontier with an additional option specified for `NumPorts`.

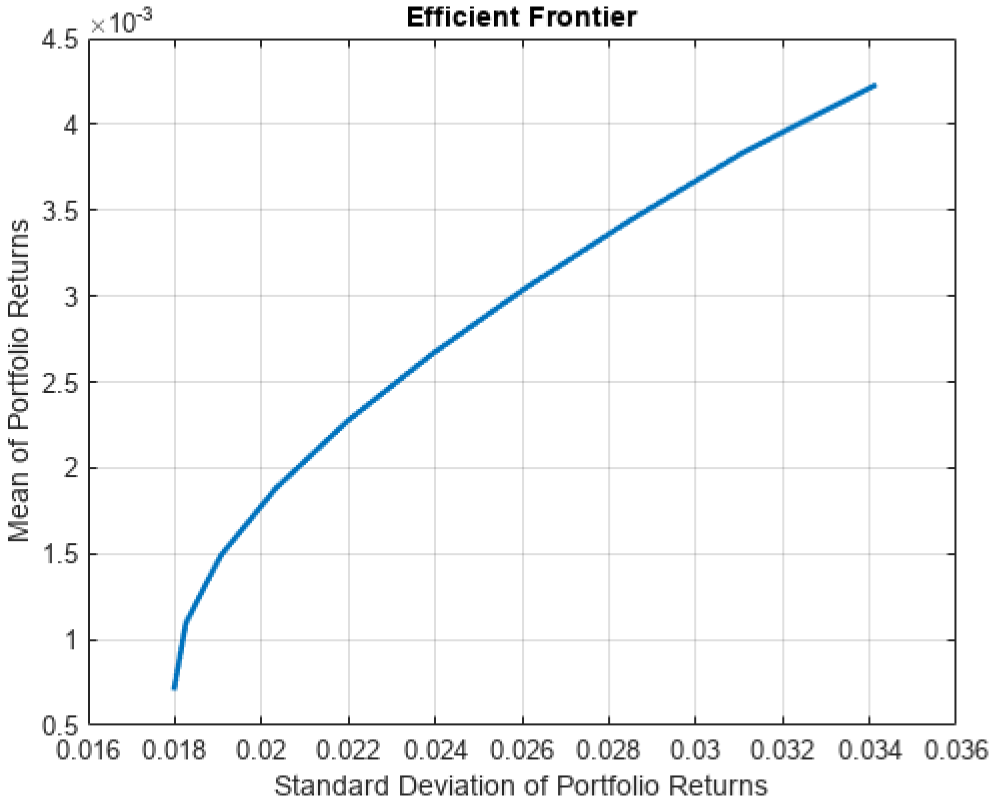
Examples

Create a `Portfolio` Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = Portfolio('AssetList',Assets(1:12));
p = estimateAssetMoments(p, Data(:,1:12),'missingdata',true);
p = setDefaultConstraints(p);
plotFrontier(p);
```



```
pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames],'obsnames',p.AssetList);

disp(Blotter);
```

```

```

Create a Portfolio Object with BoundType and MaxNumAssets Constraints and Determine Efficient Portfolios

Create a Portfolio object for 12 stocks based on CAPMuniverse.mat.

```
load CAPMuniverse
p0 = Portfolio('AssetList',Assets(1:12));
p0 = estimateAssetMoments(p0, Data(:,1:12),'missingdata',true);
p0 = setDefaultConstraints(p0);
```

Use setMinMaxNumAssets to define a maximum number of 3 assets.

```
p1 = setMinMaxNumAssets(p0, [], 3);
```

Use setBounds to define a lower and upper bound and a BoundType of 'Conditional'.

```
p1 = setBounds(p1, 0.1, 0.5,'BoundType', 'Conditional');
pwgt = estimateFrontier(p1, 5);
```

The following table shows that the optimized allocations only have maximum 3 assets invested, and small positions less than 0.1 are avoided.

```
result = table(p0.AssetList', pwgt)
```

```
result=12×2 table
      Var1                                 pwgt                  
    ________    ___________________________________________________

Obtain Purchases and Sales for Portfolios on the Efficient Frontier for a Portfolio Object

Starting from the initial portfolio, the `estimateFrontier` function returns purchases and sales to get from your initial portfolio to each efficient portfolio on the efficient frontier. Given an initial portfolio in `pwgt0`, you can obtain purchases and sales.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt0 = [ 0.3; 0.3; 0.2; 0.1 ];
p = setInitPort(p, pwgt0);
[pwgt, pbuy, psell] = estimateFrontier(p);

display(pwgt);
```

```
pwgt = 4×10

    0.0637    0.0041         0         0         0         0         0         0         0
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`NumPorts` — Number of points to obtain on efficient frontier

value from hidden property `defaultNumPorts` (default value is `10`) (default) | scalar integer

Number of points to obtain on the efficient frontier, specified as a scalar integer.

Note If no value is specified for `NumPorts`, the default value is obtained from the hidden property `defaultNumPorts` (default value is `10`). If `NumPorts = 1`, this function returns the portfolio specified by the hidden property `defaultFrontierLimit` (current default value is `'min'`).

Data Types: `double`

Output Arguments

`pwgt` — Optimal portfolios on efficient frontier with specified number of portfolios spaced equally from minimum to maximum portfolio return
matrix

Optimal portfolios on the efficient frontier with specified number of portfolios spaced equally from minimum to maximum portfolio return, returned as a `NumAssets`-by-`NumPorts` matrix. `pwgt` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`pbuy` — Purchases relative to initial portfolio for optimal portfolios on efficient frontier
matrix

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as `NumAssets`-by-`NumPorts` matrix.

Note If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be `0` such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

`pbuy` is returned for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`psell` — Sales relative to initial portfolio for optimal portfolios on efficient frontier
matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a `NumAssets`-by-`NumPorts` matrix.

Note If no initial portfolio is specified in `obj.InitPort`, that value is assumed to be `0` such that `pbuy = max(0, pwgt)` and `psell = max(0, -pwgt)`.

`psell` is returned for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Tips

- You can also use dot notation to estimate the specified number of optimal portfolios over the entire efficient frontier.

  ```
  [pwgt, pbuy, psell] = obj.estimateFrontier(NumPorts);
  ```
- When introducing transaction costs and turnover constraints to the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object, the portfolio optimization objective contains a term with an absolute value. For more information on how Financial Toolbox handles such cases algorithmically, see “References” on page 15-881.

estimateFrontierByReturn

Estimate optimal portfolios with targeted portfolio returns

Syntax

```
[pwgt,pbuy,psell] = estimateFrontierByReturn(obj,TargetReturn)
```

Description

`[pwgt,pbuy,psell] = estimateFrontierByReturn(obj,TargetReturn)` estimates optimal portfolios with targeted portfolio returns for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Examples

Obtain the Portfolio for Targeted Portfolio Returns for a Portfolio Object

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 6%, 9%, and 12%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.06, 0.09, 0.12]);

display(pwgt);
```

```
pwgt = 4×3

    0.8772    0.5032    0.1293
    0.0434    0.2488    0.4541
    0.0416    0.0780    0.1143
    0.0378    0.1700    0.3022
```

Obtain Portfolios with Targeted Portfolio Returns for a Portfolio Object with BoundType, MinNumAsset, and MaxNumAsset Constraints

When any one, or any combination of the constraints from 'Conditional' BoundType, MinNumAssets, and MaxNumAssets are active, the portfolio problem is formulated as mixed integer programming problem and the MINLP solver is used.

Create a Portfolio object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use setBounds with semicontinuous constraints to set *xi* = 0 or 0.02 <= *xi* <= 0.5 for all *i* = 1,...NumAssets.

```
p = setBounds(p, 0.02, 0.7,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up the limits on the number of assets invested (as known as cardinality) constraints. This sets the total number of allocated assets satisfying the Bound constraints that are between MinNumAssets and MaxNumAssets. By setting MinNumAssets = MaxNumAssets = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use estimateFrontierByReturn to estimate optimal portfolios with targeted portfolio returns.

```
[pwgt, pbuy, psell] = estimateFrontierByReturn(p,[ 0.0072321, 0.0119084 ])
```

```
pwgt = 3×2

         0    0.5000
    0.6922         0
    0.3078    0.5000

pbuy = 3×2

         0    0.5000
    0.6922         0
    0.3078    0.5000

psell = 3×2

     0     0
     0     0
     0     0
```

The estimateFrontierByReturn function uses the MINLP solver to solve this problem. Use the setSolverMINLP function to configure the SolverType and options.

```
p.solverTypeMINLP
```

```
ans =
'OuterApproximation'
```

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
                         MaxIterations: 1000
                  AbsoluteGapTolerance: 1.0000e-07
                  RelativeGapTolerance: 1.0000e-05
                NonlinearScalingFactor: 1000
                ObjectiveScalingFactor: 1000
                               Display: 'off'
                         CutGeneration: 'basic'
              MaxIterationsInactiveCut: 30
                    ActiveCutTolerance: 1.0000e-07
                  IntMainSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

Obtain the Portfolio for Targeted Portfolio Returns for a PortfolioCVaR Object

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 7%, 10%, and 13%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioCVaR;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierByReturn(p, [0.07 0.10, 0.13]);

display(pwgt);
```

```
pwgt = 4×3

    0.7371    0.3072         0
    0.1504    0.3919    0.4396
    0.0286    0.1011    0.1360
    0.0839    0.1999    0.4244
```

The function `rng(`*seed*`)` is used to reset the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Obtain the Portfolio for Targeted Portfolio Returns for a PortfolioMAD Object

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 7%, 10%, and 13%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);

pwgt = estimateFrontierByReturn(p, [0.07 0.10, 0.13]);

display(pwgt);
```

```
pwgt = 4×3

    0.7437    0.3146         0
    0.1356    0.3837    0.4423
    0.0326    0.0939    0.1323
    0.0881    0.2079    0.4254
```

The function `rng`(*seed*) is used to reset the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`TargetReturn` — Target values for portfolio return

vector

Target values for portfolio return, specified as a `NumPorts` vector.

Note `TargetReturn` specifies target returns for portfolios on the efficient frontier. If any `TargetReturn` values are outside the range of returns for efficient portfolios, the `TargetReturn` is replaced with the minimum or maximum efficient portfolio return, depending upon whether the target return is below or above the range of efficient portfolio returns.

Data Types: double

Output Arguments

pwgt — Optimal portfolios on efficient frontier with specified target returns

matrix

Optimal portfolios on the efficient frontier with specified target returns from TargetReturn, returned as a NumAssets-by-NumPorts matrix. pwgt is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

pbuy — Purchases relative to initial portfolio for optimal portfolios on efficient frontier

matrix

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as NumAssets-by-NumPorts matrix.

Note If no initial portfolio is specified in obj.InitPort, that value is assumed to be 0 such that pbuy = max(0, pwgt) and psell = max(0, -pwgt).

pbuy is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

psell — Sales relative to initial portfolio for optimal portfolios on efficient frontier

matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

Note If no initial portfolio is specified in obj.InitPort, that value is assumed to be 0 such that pbuy = max(0, pwgt) and psell = max(0, -pwgt).

psell is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Tips

You can also use dot notation to estimate optimal portfolios with targeted portfolio returns.

```
[pwgt, pbuy, psell] = obj.estimateFrontierByReturn(TargetReturn);
```

Version History

Introduced in R2011a

estimateFrontierByRisk

Estimate optimal portfolios with targeted portfolio risks

Syntax

`[pwgt,pbuy,psell] = estimateFrontierByRisk(obj,TargetRisk)`

`[pwgt,pbuy,psell] = estimateFrontierByRisk( ___ ,Name,Value)`

Description

`[pwgt,pbuy,psell] = estimateFrontierByRisk(obj,TargetRisk)` estimates optimal portfolios with targeted portfolio risks for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[pwgt,pbuy,psell] = estimateFrontierByRisk( ___ ,Name,Value)` adds name-optional name-value pair arguments for `Portfolio` or `PortfolioMAD` objects.

Examples

Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 14%, and 16%. This example uses the default `'direct'` method to estimate the optimal portfolios with targeted portfolio risks.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

 p = Portfolio;
 p = setAssetMoments(p, m, C);
 p = setDefaultConstraints(p);
 pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);

 display(pwgt);
```

```
pwgt = 4×3

    0.3984    0.2659    0.1416
    0.3064    0.3791    0.4474
    0.0882    0.1010    0.1131
    0.2071    0.2540    0.2979
```

Obtain Portfolios with Targeted Portfolio Risks for a `Portfolio` Object with `BoundType`, `MinNumAsset`, and `MaxNumAsset` Constraints

When any one, or any combination of the constraints from `'Conditional'` `BoundType`, `MinNumAssets`, and `MaxNumAssets` are active, the portfolio problem is formulated as mixed integer programming problem and the MINLP solver is used.

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semicontinuous constraints to set *xi* = `0` or `0.02` <= *`xi`* <= `0.5` for all *i* = `1`,...`NumAssets`.

```
p = setBounds(p, 0.02, 0.7,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested (as known as cardinality) constraints. This sets the total number of allocated assets satisfying the Bound constraints that are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets` = `MaxNumAssets` = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimateFrontierByRisk` to estimate optimal portfolios with targeted portfolio risks.

```
[pwgt, pbuy, psell] = estimateFrontierByRisk(p,[0.0324241, 0.0694534 ])
```

```
pwgt = 3×2

    0.0000    0.5000
    0.6907    0.0000
    0.3093    0.5000

pbuy = 3×2

    0.0000    0.5000
    0.6907    0.0000
    0.3093    0.5000

psell = 3×2

     0     0
     0     0
     0     0
```

The `estimateFrontierByRisk` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverTypeMINLP

ans = 
'OuterApproximation'

p.solverOptionsMINLP

ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
                    RelativeGapTolerance: 1.0000e-05
                  NonlinearScalingFactor: 1000
                  ObjectiveScalingFactor: 1000
                                 Display: 'off'
                           CutGeneration: 'basic'
                MaxIterationsInactiveCut: 30
                      ActiveCutTolerance: 1.0000e-07
                    IntMainSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object Using the Direct Method and Solver Options

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 14%, and 16%. This example uses the default`'direct'` method to estimate the optimal portfolios with targeted portfolio risks. The `'direct'` method uses `fmincon` to solve the optimization problem that maximizes portfolio return, subject to the target risk as the quadratic nonlinear constraint. `setSolver` specifies the `solverType` and `SolverOptions` for `fmincon`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

 p = Portfolio;
 p = setAssetMoments(p, m, C);
 p = setDefaultConstraints(p);

 p = setSolver(p, 'fmincon', 'Display', 'off', 'Algorithm', 'sqp', ...
        'SpecifyObjectiveGradient', true, 'SpecifyConstraintGradient', true, ...
        'ConstraintTolerance', 1.0e-8, 'OptimalityTolerance', 1.0e-8, 'StepTolerance', 1.0e-8);

 pwgt = estimateFrontierByRisk(p, [0.12, 0.14, 0.16]);

 display(pwgt);

pwgt = 4×3

    0.3984    0.2659    0.1416
    0.3064    0.3791    0.4474
    0.0882    0.1010    0.1131
    0.2071    0.2540    0.2979
```

Obtain Portfolios with Targeted Portfolio Risks for a PortfolioCVaR Object

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 20%, and 30%.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioCVaR;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierByRisk(p, [0.12, 0.20, 0.30]);

display(pwgt);
```

```
pwgt = 4×3

    0.5363    0.1387         0
    0.2655    0.4991    0.3830
    0.0570    0.1239    0.1461
    0.1412    0.2382    0.4709
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Obtain Portfolios with Targeted Portfolio Risks for a PortfolioMAD Object

To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 20%, and 25%. This example uses the default `'direct'` method to estimate the optimal portfolios with targeted portfolio risks.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
```

```
rng(11);

p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);

pwgt = estimateFrontierByRisk(p, [0.12, 0.20, 0.25]);

display(pwgt);
```

```
pwgt = 4×3

    0.1611         0         0
    0.4774    0.2137    0.0047
    0.1126    0.1384    0.1200
    0.2488    0.6480    0.8753
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Obtain Portfolios with Targeted Portfolio Risks for a PortfolioMAD Object Using the Direct Method and Solver Options

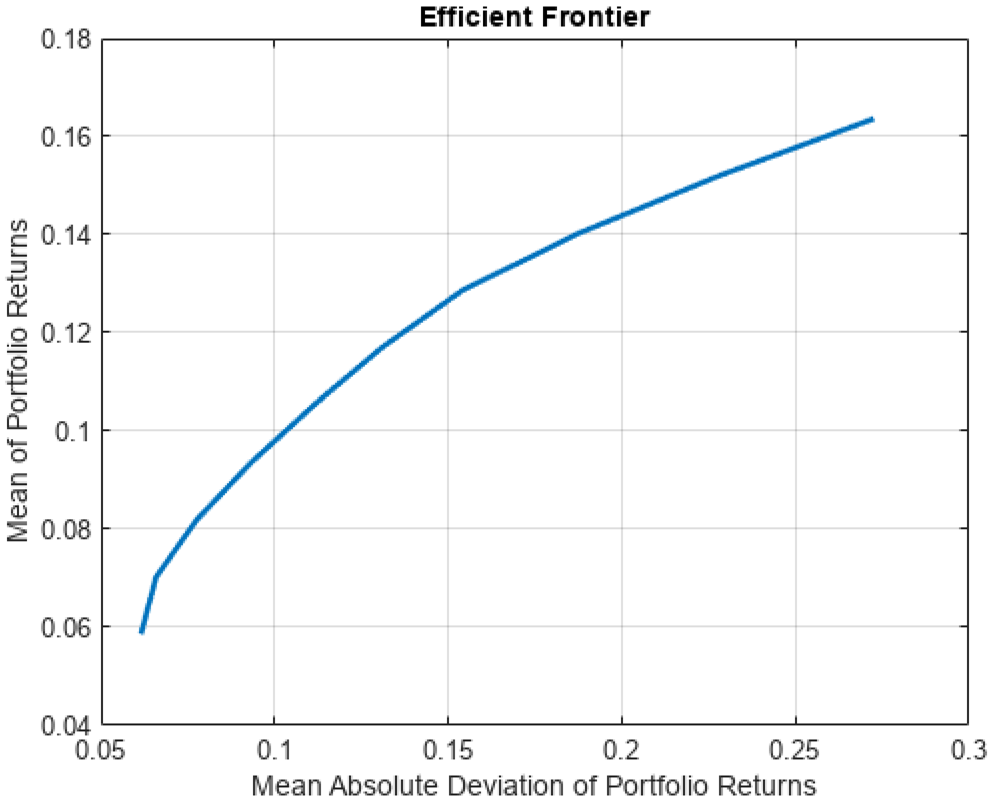
To obtain efficient portfolios that have targeted portfolio risks, the `estimateFrontierByRisk` function accepts one or more target portfolio risks and obtains efficient portfolios with the specified risks. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio risks of 12%, 20%, and 25%. This example uses the default `'direct'` method to estimate the optimal portfolios with targeted portfolio risks. The `'direct'` method uses `fmincon` to solve the optimization problem that maximizes portfolio return, subject to the target risk as the quadratic nonlinear constraint. `setSolver` specifies the `solverType` and `SolverOptions` for `fmincon.`

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

rng(11);

p = PortfolioMAD;
p = simulateNormalScenariosByMoments(p, m, C, 2000);
p = setDefaultConstraints(p);

p = setSolver(p, 'fmincon', 'Display', 'off', 'Algorithm', 'sqp', ...
        'SpecifyObjectiveGradient', true, 'SpecifyConstraintGradient', true, ...
        'ConstraintTolerance', 1.0e-8, 'OptimalityTolerance', 1.0e-8, 'StepTolerance', 1.0e-8);
    plotFrontier(p);
```



```
pwgt = estimateFrontierByRisk(p, [0.12 0.20, 0.25]);

display(pwgt);

pwgt = 4×3

    0.1613    0.0000    0.0000
    0.4777    0.2139    0.0037
    0.1118    0.1381    0.1214
    0.2492    0.6480    0.8749
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Note If no initial portfolio is specified in `obj.InitPort`, it is assumed to be `0` so that `pbuy = max(0,pwgt)` and `psell = max(0,-pwgt)`. For more information on setting an initial portfolio, see `setInitPort`.

Data Types: `object`

`TargetRisk` — Target values for portfolio risk
vector

Target values for portfolio risk, specified as a `NumPorts` vector.

Note If any `TargetRisk` values are outside the range of risks for efficient portfolios, the target risk is replaced with the minimum or maximum efficient portfolio risk, depending on whether the target risk is below or above the range of efficient portfolio risks.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[pwgt,pbuy,psell] = estimateFrontierByRisk(p,‘method’,‘direct’)`

`Method` — Method to estimate frontier by risk for `Portfolio` or `PortfolioMAD` objects
`'direct'` (default) | character vector with value `'direct'` or `'iterative'`

Method to estimate frontier by risk for `Portfolio` or `PortfolioMAD` objects, specified as the comma-separated pair consisting of `'Method'` and a character vector with one of the following values:

- `'direct'` — Construct one optimization problem to maximize the portfolio return with target risk as the nonlinear constraint, and solve it directly using `fmincon`, instead of iteratively exploring the efficient frontier. For an example of using the `'direct'` option, see “Obtain Portfolios with Targeted Portfolio Risks for a Portfolio Object Using the Direct Method and Solver Options” on page 15-890 and “Obtain Portfolios with Targeted Portfolio Risks for a PortfolioMAD Object Using the Direct Method and Solver Options” on page 15-892.
- `'iterative'` — One-dimensional optimization using `fminbnd` to find the portfolio return between min and max return on the frontier that minimizes the difference between the actual risk and target risk. Then the portfolio weights are obtained by solving a frontier by return problem. Consequently, the `'iterative'` method is slower than the `'direct'`.

Data Types: `char`

Output Arguments

`pwgt` — Optimal portfolios on efficient frontier with specified target risks
matrix

Optimal portfolios on the efficient frontier with specified target returns from TargetRisk, returned as a NumAssets-by-NumPorts matrix. pwgt is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

pbuy — Purchases relative to initial portfolio for optimal portfolios on efficient frontier
matrix

Purchases relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as NumAssets-by-NumPorts matrix.

Note If no initial portfolio is specified in obj.InitPort, that value is assumed to be 0 such that pbuy = max(0,pwgt) and psell = max(0,-pwgt).

pbuy is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

psell — Sales relative to initial portfolio for optimal portfolios on efficient frontier
matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

Note If no initial portfolio is specified in obj.InitPort, that value is assumed to be 0 such that pbuy = max(0,pwgt) and psell = max(0,-pwgt).

psell is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Tips

You can also use dot notation to estimate optimal portfolios with targeted portfolio risks.

```
[pwgt,pbuy,psell] = obj.estimateFrontierByRisk(TargetRisk);
```

or

```
[pwgt,pbuy,psell] = obj.estimateFrontierByRisk(TargetRisk,Name,Value);
```

estimateFrontierLimits

Estimate optimal portfolios at endpoints of efficient frontier

Syntax

```
[pwgt,pbuy,psell] = estimateFrontierLimits(obj)
[pwgt,pbuy,psell] = estimateFrontierLimits(obj,Choice)
```

Description

`[pwgt,pbuy,psell] = estimateFrontierLimits(obj)` estimates optimal portfolios at endpoints of efficient frontier for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[pwgt,pbuy,psell] = estimateFrontierLimits(obj,Choice)` estimates optimal portfolios at endpoints of efficient frontier with an additional option specified for the `Choice` argument.

Examples

Obtain Endpoint Portfolios for a Portfolio Object

Given portfolio `p`, the `estimateFrontierLimits` function obtains the endpoint portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);

disp(pwgt);
```

```
    0.8891         0
    0.0369         0
    0.0404         0
    0.0336    1.0000
```

Obtain Endpoint Portfolios for a Portfolio Object with BoundType, MinNumAsset, and MaxNumAsset Constraints

When any one, or any combination of the constraints from 'Conditional' BoundType, MinNumAssets, and MaxNumAssets are active, the portfolio problem is formulated as mixed integer programming problem and the MINLP solver is used.

Create a Portfolio object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use setBounds with semicontinuous constraints to set *xi* = 0 or 0.02 <= *xi* <= 0.5 for all *i* = 1,...NumAssets.

```
p = setBounds(p, 0.02, 0.7,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up the limits on the number of assets invested (as known as cardinality) constraints. This sets the total number of allocated assets satisfying the Bound constraints that are between MinNumAssets and MaxNumAssets. By setting MinNumAssets = MaxNumAssets = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use estimateFrontierLimits to estimate the optimal portfolios at endpoints of the efficient frontier.

```
[pwgt, pbuy, psell] = estimateFrontierLimits(p,'Both')
```

```
pwgt = 3×2

    0.3000    0.3000
    0.7000         0
         0    0.7000

pbuy = 3×2

    0.3000    0.3000
    0.7000         0
         0    0.7000

psell = 3×2

     0     0
     0     0
     0     0
```

The estimateFrontierLimits function uses the MINLP solver to solve this problem. Use the setSolverMINLP function to configure the SolverType and options.

```
p.solverTypeMINLP

ans =
'OuterApproximation'

p.solverOptionsMINLP

ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
                    RelativeGapTolerance: 1.0000e-05
                  NonlinearScalingFactor: 1000
                  ObjectiveScalingFactor: 1000
                                 Display: 'off'
                           CutGeneration: 'basic'
                MaxIterationsInactiveCut: 30
                      ActiveCutTolerance: 1.0000e-07
                    IntMainSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

Obtain Endpoint Portfolios for a PortfolioCVaR Object

Given portfolio p, the estimateFrontierLimits function obtains the endpoint portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);

disp(pwgt);

    0.8454         0
    0.0606         0
    0.0456         0
    0.0484    1.0000
```

The function rng(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Obtain Endpoint Portfolios for a PortfolioMAD Object

Given portfolio p, the estimateFrontierLimits function obtains the endpoint portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);

disp(pwgt);
```

```
    0.8823         0
    0.0420         0
    0.0394         0
    0.0363    1.0000
```

The function rng(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Data Types: object

Choice — Indicator for which portfolios to obtain at extreme ends of efficient frontier

[] (default) | character vector with values 'Both', 'Min', 'Max' | string with values "Both", "Min", "Max"

(Optional) Indicator which portfolios to obtain at the extreme ends of the efficient frontier, specified as a character vector with values 'Both' or "Both", 'Min' or "Min", or 'Max' or "Max". The options for a Choice action are:

- [] — Compute both minimum-risk and maximum-return portfolios.
- 'Both' or "Both" — Compute both minimum-risk and maximum-return portfolios.
- 'Min' or "Min" — Compute minimum-risk portfolio only.
- 'Max' or "Max" — Compute maximum-return portfolio only.

Data Types: char | string

Output Arguments

pwgt — Optimal portfolios at endpoints of efficient frontier

matrix

Optimal portfolios at the endpoints of the efficient frontier TargetReturn, returned as a NumAssets-by-NumPorts matrix. pwgt is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

pbuy — Purchases relative to an initial portfolio for optimal portfolios at endpoints of efficient frontier

matrix

Purchases relative to an initial portfolio for optimal portfolios at the endpoints of the efficient frontier, returned as NumAssets-by-NumPorts matrix.

Note If no initial portfolio is specified in obj.InitPort, that value is assumed to be 0 such that pbuy = max(0, pwgt) and psell = max(0, -pwgt).

pbuy is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

psell — Sales relative to an initial portfolio for optimal portfolios at endpoints of efficient frontier

matrix

Sales relative to an initial portfolio for optimal portfolios on the efficient frontier, returned as a NumAssets-by-NumPorts matrix.

Note If no initial portfolio is specified in obj.InitPort, that value is assumed to be 0 such that pbuy = max(0, pwgt) and psell = max(0, -pwgt).

psell is returned for Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Tips

You can also use dot notation to estimate the optimal portfolios at the endpoints of the efficient frontier.

```
[pwgt, pbuy, psell] = obj.estimateFrontierLimits(Choice);
```

estimateMaxSharpeRatio

Estimate efficient portfolio to maximize Sharpe ratio for Portfolio object

Syntax

```
[pwgt,pbuy,psell] = estimateMaxSharpeRatio(obj)
[pwgt,pbuy,psell] = estimateMaxSharpeRatio( ___ ,Name,Value)
```

Description

`[pwgt,pbuy,psell] = estimateMaxSharpeRatio(obj)` estimates efficient portfolio to maximize Sharpe ratio for `Portfolio` object. For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

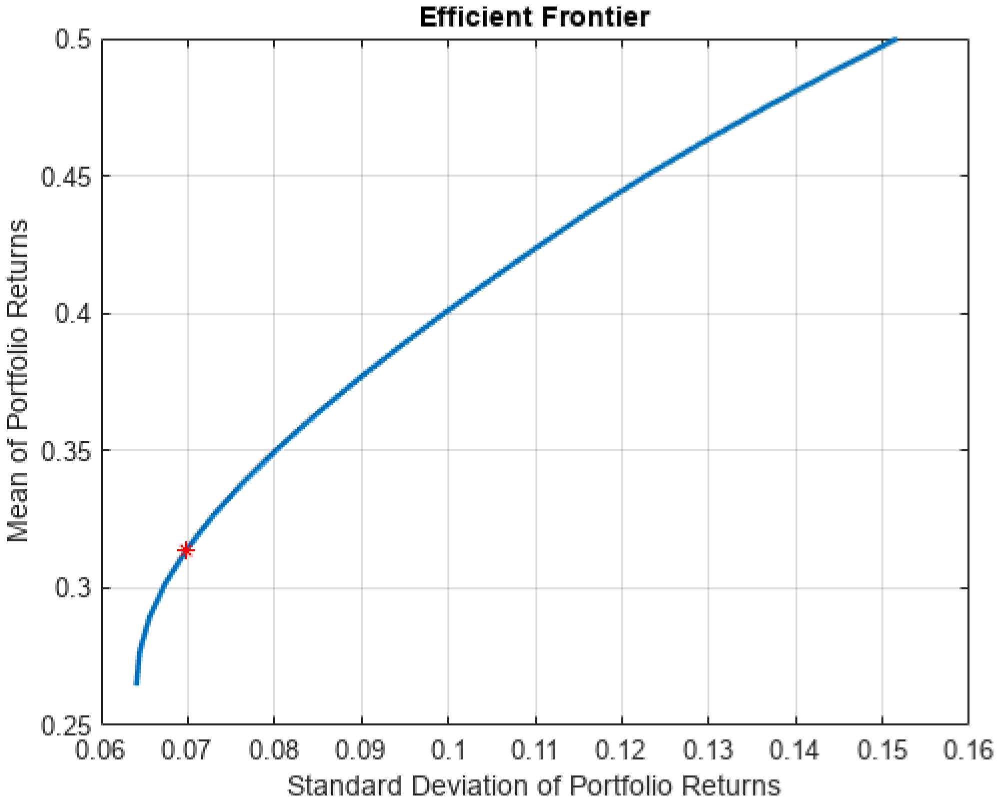
`[pwgt,pbuy,psell] = estimateMaxSharpeRatio( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object

Estimate the efficient portfolio that maximizes the Sharpe ratio. The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. This example uses the default `'direct'` method to estimate the maximum Sharpe ratio. For more information on the `'direct'` method, see “Algorithms” on page 15-912.

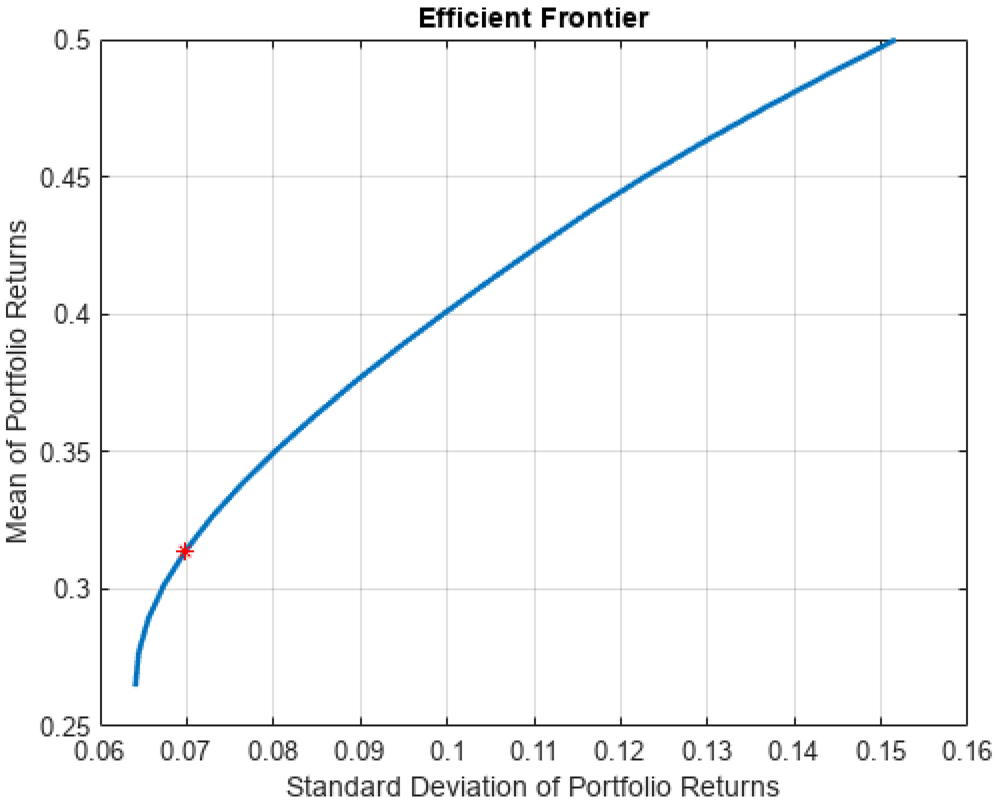
```
p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010,  0.004; -0.010,  0.040, -0.002;  0.004, -0.002,  0.023]);
p = setDefaultConstraints(p);
plotFrontier(p, 20);
weights = estimateMaxSharpeRatio(p);
[risk, ret] = estimatePortMoments(p, weights);
hold on
plot(risk,ret,'*r');
```



Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object Using Solver Options with the Direct Method

Estimate the efficient portfolio that maximizes the Sharpe ratio. The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. This example uses the `'direct'` method for a `Portfolio` object (`p`) that does not specify a tracking error and only uses linear constraints. The `setSolver` function is used to control the `SolverType` and `SolverOptions`. In this case, the `SolverType` is `quadprog`. For more information on the `'direct'` method, see “Algorithms” on page 15-912.

```
p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010,  0.004; -0.010,  0.040, -0.002;  0.004, -0.002,  0.023]);
p = setDefaultConstraints(p);
plotFrontier(p, 20);
p = setSolver(p,'quadprog','Display','off','ConstraintTolerance',1.0e-8,'OptimalityTolerance',1.0
weights = estimateMaxSharpeRatio(p);
[risk, ret] = estimatePortMoments(p, weights);
hold on
plot(risk,ret,'*r');
```



Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object With Tracking Error Using the Direct Method and Solver Options

Estimate the efficient portfolio that maximizes the Sharpe ratio. The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. This example uses the `'direct'` method for a `Portfolio` object (`p`) that specifies a tracking error uses nonlinear constraints. The `setSolver` function is used to control the `SolverType` and `SolverOptions`. In this case `fmincon` is the `SolverType`.

```
p = Portfolio('AssetMean',[0.3, 0.1, 0.5], 'AssetCovar',...
[0.01, -0.010,  0.004; -0.010,  0.040, -0.002;  0.004, -0.002,  0.023],'lb', 0,'budget', 1);
plotFrontier(p, 20);

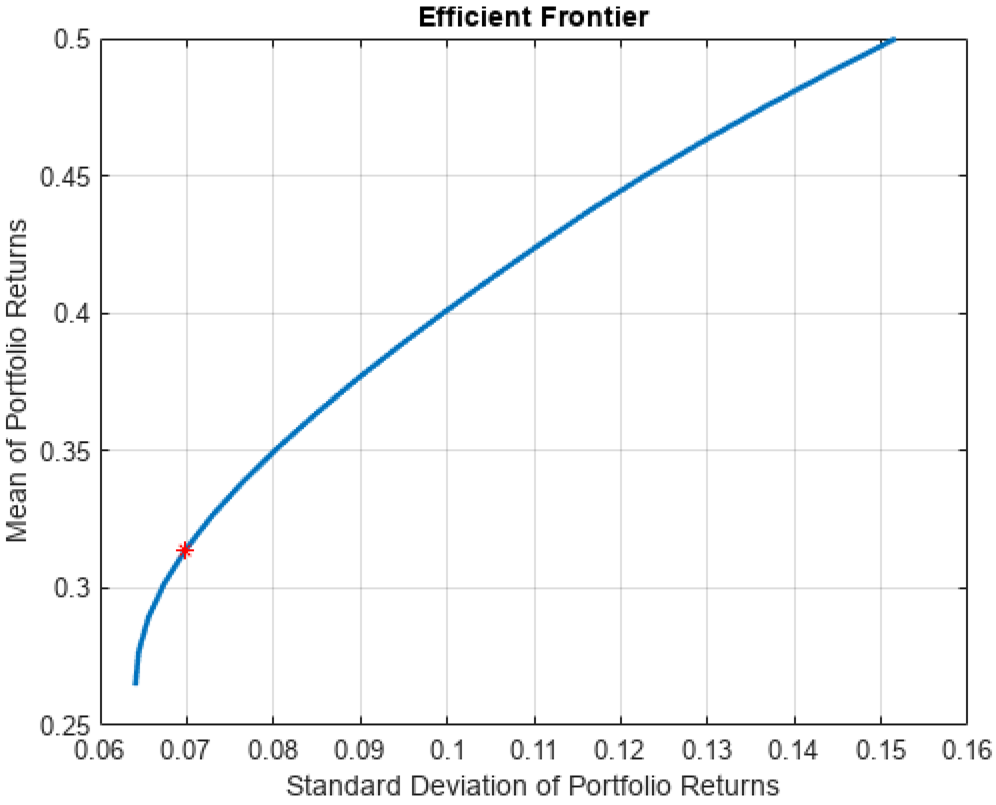
p = setSolver(p, 'fmincon', 'Display', 'off', 'Algorithm', 'sqp', ...
        'SpecifyObjectiveGradient', true, 'SpecifyConstraintGradient', true, ...
        'ConstraintTolerance', 1.0e-8, 'OptimalityTolerance', 1.0e-8, 'StepTolerance', 1.0e-8);

weights = estimateMaxSharpeRatio(p);

te = 0.08;
p = setTrackingError(p,te,weights);

[risk, ret] = estimatePortMoments(p,weights);
```

```
hold on
plot(risk,ret,'*r');
```



Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object With a Risk-Free Asset Using the Direct and Iterative Method

The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier. In the case of Portfolio with a risk-free asset, there are multiple efficient portfolios that maximize the Sharpe ratio on the capital asset line. Because of the nature of `'direct'` and `'iterative'` methods, the portfolio weights (`pwgts`) output from each of these methods might be different, but the Sharpe ratio is the same. This example demonstrates the scenario where the `pwgts` are different and the Sharpe ratio is the same.

```
load BlueChipStockMoments

mret = MarketMean;
mrsk = sqrt(MarketVar);
cret = CashMean;
crsk = sqrt(CashVar);

p = Portfolio('AssetList', AssetList, 'RiskFreeRate', CashMean);
p = setAssetMoments(p, AssetMean, AssetCovar);

p = setInitPort(p, 1/p.NumAssets);
```

```
[ersk, eret] = estimatePortMoments(p, p.InitPort);

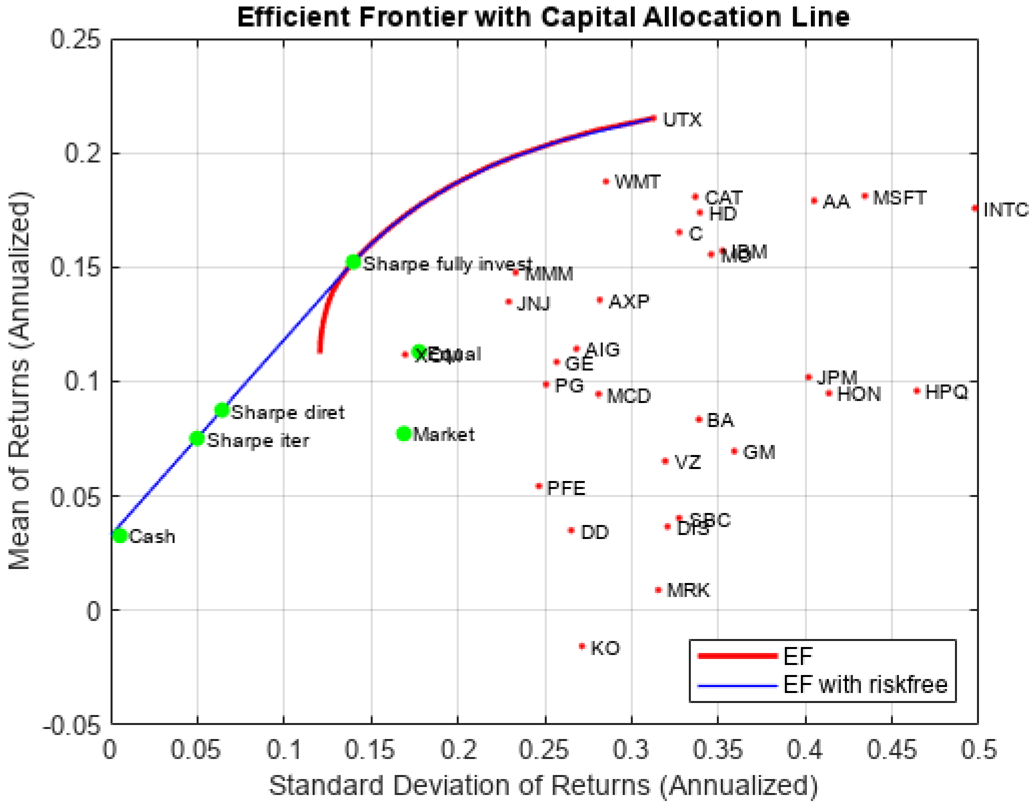
p = setDefaultConstraints(p);
pwgt = estimateFrontier(p, 20);
[prsk, pret] = estimatePortMoments(p, pwgt);
pwgtshpr_fully = estimateMaxSharpeRatio(p,'Method','direct');
[riskshpr_fully, retshpr_fully] = estimatePortMoments(p,pwgtshpr_fully);

q = setBudget(p, 0, 1);
qwgt = estimateFrontier(q, 20);
[qrsk, qret] = estimatePortMoments(q, qwgt);
```

Plot the efficient frontier with a tangent line (0 to 1 cash).

```
pwgtshpr_direct = estimateMaxSharpeRatio(q,'Method','direct');
pwgtshpr_iter = estimateMaxSharpeRatio(q,'Method','iterative'); % Default for 'TolX' is 1e-8
[riskshpr_diret, retshpr_diret] = estimatePortMoments(q,pwgtshpr_direct);
[riskshpr_iter, retshpr_iter] = estimatePortMoments(q,pwgtshpr_iter);

clf;
portfolioexamples_plot('Efficient Frontier with Capital Allocation Line', ...
                {'line', prsk, pret, {'EF'}, '-r', 2}, ...
                {'line', qrsk, qret, {'EF with riskfree'}, '-b', 1}, ...
                {'scatter', [mrsk, crsk, ersk, riskshpr_fully, riskshpr_diret, riskshpr_iter], .
    [mret, cret, eret, retshpr_fully , retshpr_diret, retshpr_iter], {'Market', 'Cash', 'Equal',
                {'scatter', sqrt(diag(p.AssetCovar)), p.AssetMean, p.AssetList, '.r'});
```



When a risk-free asset is not available to the portfolio, or in other words, the portfolio is fully invested, the efficient frontier is curved, corresponding to the red line in the above figure. Therefore, there is a unique (risk, return) point that maximizes the Sharpe ratio, which the `'iterative'` and `'direct'` methods will both find. If the portfolio is allowed to invest in a risk-free asset, part of the red efficient frontier line is replaced by the capital allocation line, resulting in the efficient frontier of a portfolio with a risk-free investment (blue line). All the (risk, return) points on the straight blue line share the same Sharpe ratio. Also, it is likely that the `'iterative'` and `'direct'` methods end up with different points, therefore there are different portfolio allocations.

When using the `'iterative'` method, you can use an optional `'TolX'` name-value argument. `TolX` is a termination tolerance that is related to the possible return levels of the efficient frontier. If the selected `TolX` value is large compared to the range of returns, then the accuracy of the solution is poor. `TolX` should be a number smaller than 0.01*(`maxReturn` - `minReturn`).

```
maxReturn = max(qret); % Max return portfolio
minReturn = min(qret); % Min return portfolio
display(0.01*(maxReturn-minReturn))
```

```
   1.5193e-04
```

The purpose of increasing the termination tolerance is to speed up the convergence of the `'iterative'` algorithm. However, as previously mentioned, the accuracy of the solution will decrease. You can see this in the table that follows.

```
pwgtshpr_iter_largerTol = estimateMaxSharpeRatio(q, 'Method', 'iterative',...
    'TolX', 1e-4);
display(table(pwgtshpr_iter, pwgtshpr_iter_largerTol,...
    'VariableNames', {'Default TolX = 1e-8','TolX = 1e-4'}))
```

```
  30x2 table

    Default TolX = 1e-8    TolX = 1e-4
    ___________________    ___________

                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
                  0                0
          0.0094789        0.0093895
           0.032042         0.031739
                  0                0
                  0                0
                  0                0
           0.055162         0.054642
           0.049805         0.049335
                  0                0
           0.015934         0.015784
           0                  0
    0.026542           0.026292
           0                  0
    0.021371           0.021169
           0                  0
    0.078468           0.077728
    0.067045           0.066412
```

In the table, the value of the weights varies slightly with respect to the weights obtained with the default tolerance, as expected.

Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a `Portfolio` Object with Semicontinuous and Cardinality Constraints

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semicontinuous constraints to set *xi* = `0` or `0.02 <= xi <= 0.5` for all *i* = `1`,...`NumAssets`.

```
p = setBounds(p, 0.02, 0.5,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the `Portfolio` object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets` = `MaxNumAssets` = 2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimateMaxSharpeRatio` to estimate efficient portfolio to maximize Sharpe ratio.

```
weights = estimateMaxSharpeRatio(p,'Method','iterative')
```

```
weights = 3×1

         0
    0.5000
    0.5000
```

The `estimateMaxSharpeRatio` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
```

```

             MaxIterationsInactiveCut: 30
                 ActiveCutTolerance: 1.0000e-07
               IntMainSolverOptions: [1x1 optim.options.Intlinprog]
   NumIterationsEarlyIntegerConvergence: 30
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using a `Portfolio` object.

Note The risk-free rate is obtained from the property `RiskFreeRate` in the Portfolio object. If you leave the `RiskFreeRate` unset, it is assumed to be `0`. If the max return of portfolio is less than the `RiskFreeRate`, the solution is set as `pwgt` at max return and the resulting Sharpe ratio will be negative.

For more information on creating a portfolio object, see

- `Portfolio`

Data Types: `object`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[pwgt,pbuy,psell] = estimateMaxSharpeRatio(p,'Method’,'iterative')`

Method — Method to estimate Sharpe ratio

`'direct'` (default) | character vector with value `'direct'` or `'iterative'`

Method to estimate Sharpe ratio, specified as the comma-separated pair consisting of `'Method'` and a character vector with one of the following values:

- `'direct'` — Transform the Sharpe ratio function into a quadratic one and solve one optimization problem directly, instead of iteratively exploring the efficient frontier. The `'direct'` option either uses the solver `quadprog` (for a problem with linear constraints) or `fmincon` (for a problem with nonlinear constraints). For an example of using the `'direct'` option, see “Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object Using Solver Options with the Direct Method” on page 15-904 and “Estimate Efficient Portfolio that Maximizes the Sharpe Ratio for a Portfolio Object With Tracking Error Using the Direct Method and Solver Options” on page 15-905.

- 'iterative' — One-dimensional optimization using fminbnd to find the portfolio that maximizes the Sharpe ratio by iteratively exploring the efficient frontier.

Note If you are using estimateMaxSharpeRatio with a Portfolio object with semicontinuous and cardinality constraints specified by setBounds and setMinMaxNumAssets, you can only use the 'iterative' method.

Data Types: char

TolX — Tolerance on the step size for fminbnd convergence when using 'iterative' method
1e-8 (default) | positive scalar

Tolerance on the step size for fminbnd convergence when using 'iterative' method, specified as the comma-separated pair consisting of 'TolX' and a positive scalar. The step size is related to the return levels achieved on the efficient frontier and tried by fminbnd. If the specified TolX is large compared to the range of returns, the accuracy of the solution is poor. TolX should be a number smaller than 0.01*(maxReturn - minReturn).

Note If the 'direct' method is selected, TolX is ignored.

Data Types: double

Output Arguments

pwgt — Portfolio on efficient frontier with maximum Sharpe ratio
vector

Portfolio on the efficient frontier with a maximum Sharpe ratio, returned as a NumAssets vector.

pbuy — Purchases relative to initial portfolio for portfolio on efficient frontier with maximum Sharpe ratio
vector

Purchases relative to an initial portfolio for a portfolio on the efficient frontier with a maximum Sharpe ratio, returned as a NumAssets vector.

pbuy is returned for a Portfolio input object (obj).

psell — Sales relative to initial portfolio for portfolio on efficient frontier with maximum Sharpe ratio
vector

Sales relative to an initial portfolio for a portfolio on the efficient frontier with maximum Sharpe ratio, returned as a NumAssets vector.

psell is returned for a Portfolio input object (obj).

More About

Sharpe Ratio

The Sharpe ratio is the ratio of the difference between the mean of portfolio returns and the risk-free rate divided by the standard deviation of portfolio returns.

The `estimateMaxSharpeRatio` function maximizes the Sharpe ratio among portfolios on the efficient frontier.

Tips

You can also use dot notation to estimate an efficient portfolio that maximizes the Sharpe ratio.

```
[pwgt,pbuy,psell] = obj.estimateMaxSharpeRatio;
```

Algorithms

The maximization of the Sharpe ratio is accomplished by either using the `'direct'` or `'iterative'` method. For the `'direct'` method, consider the following scenario. To maximize the Sharpe ratio is to:

$$Maximize\frac{\mu^T x - r_f}{\sqrt{x^T C x}}, s.t. \sum x_i = 1, \;\; 0 \le x_i \le 1,$$

where μ and C are the mean and covariance matrix, and r_f is the risk-free rate.

If μ^T x - $r_f \le 0$ for all x the portfolio that maximizes the Sharpe ratio is the one with maximum return.

If μ^T x - $r_f > 0$, let $t = \dfrac{1}{\mu^T x - r_f}$

and $y = tx$ (Cornuejols [1] section 8.2). Then after some substitutions, you can transform the original problem into the following form,

$$Minimize\ y^T C y,\ s.t.\ \sum y_i = t,\ t > 0,\ 0 \le y_i \le \mathrm{t}\ ,\ \mu^T y - r_f \mathrm{t} = 1.$$

Only one optimization needs to be solved, hence the name “direct”. The portfolio weights can be recovered by $x^* = y^* / t^*$.

For the `'iterative'` method, the idea is to iteratively explore the portfolios at different return levels on the efficient frontier and locate the one with maximum Sharpe ratio. Therefore, multiple optimization problems are solved during the process, instead of only one in the `'direct'` method. Consequently, the `'iterative'` method is slow compared to `'direct'` method.

Version History

Introduced in R2011b

estimatePortSharpeRatio

Estimate Sharpe ratio of given portfolio weights for Portfolio object

Syntax

```
psharpe = estimatePortSharpeRatio(obj,pwgt)
```

Description

`psharpe = estimatePortSharpeRatio(obj,pwgt)` estimates the Sharpe ratio of given portfolio weights for a `Portfolio` object. For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

Examples

Estimate Sharpe Ratios of the Given Portfolio Weights

This example shows how to find efficient portfolios that satisfy the target returns and then find the Sharpe ratios corresponding to each of the portfolios.

To obtain efficient portfolios that have targeted portfolio returns, the `estimateFrontierByReturn` function accepts one or more target portfolio returns and obtains efficient portfolios with the specified returns. Assume you have a universe of four assets where you want to obtain efficient portfolios with target portfolio returns of 6%, 9%, and 12%. Use `estimatePortSharpeRatio` to obtain the Sharpe ratio for the collection of portfolios (`pwgt`).

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierByReturn(p, [0.06, 0.09, 0.12]);

display(pwgt);
```

```
pwgt = 4×3

    0.8772    0.5032    0.1293
    0.0434    0.2488    0.4541
    0.0416    0.0780    0.1143
    0.0378    0.1700    0.3022
```

`pwgt` is a `NumAssets`-by-`NumPorts` matrix where `NumAssets` is the number of asset in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

```
psharpe = estimatePortSharpeRatio(p,pwgt)
psharpe = 3×1

    0.7796
    0.8519
    0.7406
```

psharpe is a NumPorts-by-1 vector, where NumPorts is the number of portfolios in the collection of portfolios.

Estimate Sharpe Ratios of the Given Portfolio Weights Portfolio Object with Integrality Constraints

Create a Portfolio object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use setBounds with semi-continuous constraints to set *xi*=0 or 0.02<=*xi*<=0.5 for all *i*=1,...NumAssets.

```
p = setBounds(p, 0.02, 0.5,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the Portfolio object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between MinNumAssets and MaxNumAssets. By setting MinNumAssets=MaxNumAssets=2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use estimatePortSharpeRatio to estimate Sharpe ratio of given portfolio weights for a Portfolio object.

```
pwgt = estimateFrontierByReturn(p, [ 0.0072321, 0.0119084 ]);
psharpe = estimatePortSharpeRatio(p,pwgt)
```

```
psharpe = 2×1

    0.2230
    0.1715
```

The estimatePortSharpeRatio function uses the MINLP solver to solve this problem. Use the setSolverMINLP function to configure the SolverType and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
```

```
                     RelativeGapTolerance: 1.0000e-05
                   NonlinearScalingFactor: 1000
                   ObjectiveScalingFactor: 1000
                                  Display: 'off'
                            CutGeneration: 'basic'
                 MaxIterationsInactiveCut: 30
                       ActiveCutTolerance: 1.0000e-07
                     IntMainSolverOptions: [1x1 optim.options.Intlinprog]
     NumIterationsEarlyIntegerConvergence: 30
```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using a Portfolio object.

Note The risk-free rate is obtained from the property RiskFreeRate in the Portfolio object. If you leave the RiskFreeRate unset, it is assumed to be 0. For more information on creating a portfolio object, see Portfolio.

Data Types: object

pwgt — Collection of portfolios
matrix

Collection of portfolios, specified as a NumAssets-by- NumPorts matrix where NumAssets is the number of assets in the universe and NumPorts is the number of portfolios in the collection of portfolios.

Data Types: double

Output Arguments

psharpe — Sharpe ratios of the given portfolios
vector

Sharpe ratios of the given portfolios, returned as a NumPorts-by-1 vector.

More About

Sharpe Ratio

The Sharpe ratio is the ratio of the difference between the mean of portfolio returns and the risk-free rate divided by the standard deviation of portfolio returns for each portfolio in pwgt.

estimatePortSharpeRatio computes the Sharpe ratio with mean and standard deviation (which is the square-root of variance) of portfolio returns.

Tips

You can also use dot notation to estimate the Sharpe ratio of given portfolio weights.

```
psharpe = obj.estimatePortSharpeRatio(pwgt);
```

Version History

Introduced in R2018a

estimatePortMoments

Estimate moments of portfolio returns for Portfolio object

Syntax

```
[prsk,pret] = estimatePortMoments(obj,pwgt)
```

Description

`[prsk,pret] = estimatePortMoments(obj,pwgt)` estimate moments of portfolio returns for a `Portfolio` object. For details on the workflow, see "Portfolio Object Workflow" on page 4-17.

The estimate of port moments is specific to mean-variance portfolio optimization and computes the mean and standard deviation (which is the square-root of variance) of portfolio returns.

Examples

Identify the Range of Risks and Returns for Efficient Portfolios for a Portfolio Object

Given portfolio `p`, use the `estimatePortMoments` function to show the range of risks and returns for efficient portfolios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);

[prsk, pret] = estimatePortMoments(p, pwgt);
disp([prsk, pret]);
```

```
    0.0769    0.0590
    0.3500    0.1800
```

Identify the Range of Risks and Returns for Efficient Portfolios `Portfolio` Object with Integrality Constraints

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
```

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semi-continuous constraints to set *xi*=`0` or `0.02<=`*xi*`<=0.5` for all *i*=1,...`NumAssets`.

```
p = setBounds(p, 0.02, 0.5,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the `Portfolio` object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets=MaxNumAssets=`2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimatePortMoments` to estimate moments of portfolio returns for a `Portfolio` object.

```
pwgt = estimateFrontierLimits(p);
[prsk, pret] = estimatePortMoments(p, pwgt)
```

```
prsk = 2×1

    0.0324
    0.0695

pret = 2×1

    0.0072
    0.0119
```

The `estimatePortMoments` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
                    RelativeGapTolerance: 1.0000e-05
                  NonlinearScalingFactor: 1000
                  ObjectiveScalingFactor: 1000
                                 Display: 'off'
                           CutGeneration: 'basic'
                MaxIterationsInactiveCut: 30
                      ActiveCutTolerance: 1.0000e-07
                    IntMainSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

Calculate Portfolio Weights For a Target Risk Level

The `Portfolio` object is able to find an efficient portfolio with respect to a specified target risk.

Load Portfolio

Load a vector of expected returns and a covariance matrix for 30 stocks.

```
load StockStats
```

Create `Portfolio` Object with Default Constraints

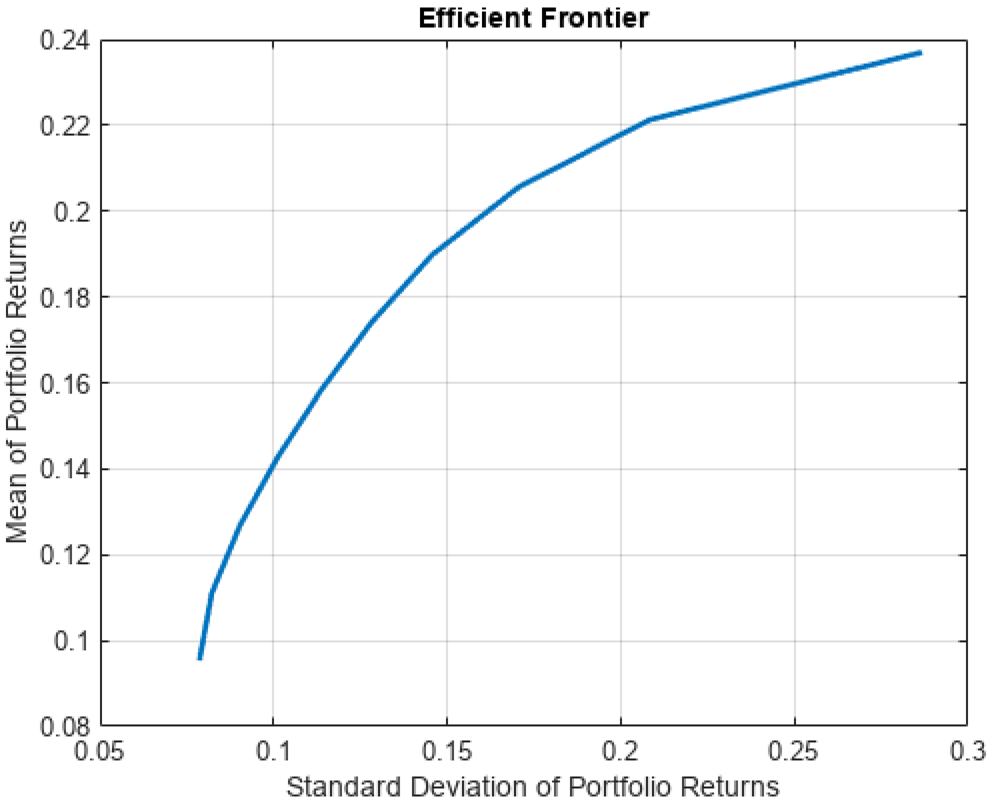
The default constraints for a `Portfolio` object are that it is a long-only portfolio and that it is 100% invested. Many other constraint types are possible.

```
P = Portfolio('mean',expRet,'covar',expCov);
P = setDefaultConstraints(P);
```

Plot Full Efficient Frontier

Use the `plotFrontier` function with the `Portfolio` object to visualize the full frontier. Other functions exist that allow you to probe into particular portfolios along the frontier.

```
P.plotFrontier
```



Capture Upper and Lower Bounds of Portfolio Risks and Returns

It is useful to know what are the upper and lower limits of the portfolio moments along the efficient frontier. This information allows you to determine what are feasible targets. Use the `estimateFrontierLimits` function with the `Portfolio` object to identify the weights at these extremes. Then you can use the `estimatePortMoments` function `Portfolio` object to find the limiting moments.

```
P_Weights1 = P.estimateFrontierLimits;
[P_risklimits, P_returnlimits] = P.estimatePortMoments(P_Weights1)
```

```
P_risklimits = 2×1

    0.0786
    0.2868

P_returnlimits = 2×1

    0.0954
    0.2370
```

Estimate Efficient Portfolio with Target Return

Select a target return for the portfolio somewhere in the feasible region. You can estimate its makeup with `estimateFrontierByRisk` and then confirm its moments using `estimatePortMoments`.

```
targetReturn = 0.15;

P_Weights2 = P.estimateFrontierByReturn(targetReturn);
[P_risk2, P_return2] = P.estimatePortMoments(P_Weights2)
```

```
P_risk2 = 0.1068

P_return2 = 0.1500
```

The return matches the `targetReturn` value and the risk is in agreement with the efficient frontier plot.

Estimate Efficient Portfolio with Target Risk

The `Portfolio` object is able to find an efficient portfolio with a specified target risk.

```
targetRisk = 0.2;

P_Weights3 = P.estimateFrontierByRisk(targetRisk);
[P_risk3, P_return3] = P.estimatePortMoments(P_Weights3)
```

```
P_risk3 = 0.2000

P_return3 = 0.2182
```

Another useful feature of the `estimateFrontierByReturn` and `estimateFrontierByRisk` functions is what happens if you specify an infeasible (too high or too low) target. In this case, these functions provide a warning message to suggest the best solution.

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see `Portfolio`.

Data Types: `object`

pwgt — Collection of portfolios
matrix

Collection of portfolios, specified as a NumAssets-by-NumPorts matrix where NumAssets is the number of assets in the universe and NumPorts is the number of portfolios in the collection of portfolios.

Data Types: double

Output Arguments

prsk — Estimates for standard deviations of portfolio returns for each portfolio in pwgt
vector

Estimates for standard deviations of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.

prsk is returned for a Portfolio input object (obj).

pret — Estimates for means of portfolio returns for each portfolio in pwgt
vector

Estimates for means of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.

pret is returned for a Portfolio input object (obj).

Tips

You can also use dot notation to estimate the moments of portfolio returns.

```
[prsk, pret] = obj.estimatePortMoments(pwgt);
```

Version History

estimatePortReturn

Estimate mean of portfolio returns

Syntax

```
pret = estimatePortReturn(obj,pwgt)
```

Description

`pret = estimatePortReturn(obj,pwgt)` estimates the mean of portfolio returns (as the proxy for portfolio return) for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Examples

Estimate the Mean of Portfolio Returns for a Portfolio Object

Given portfolio `p`, use the `estimatePortReturn` function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)
```

```
    0.0590
    0.1800
```

Estimate the Mean of Portfolio Returns for a `Portfolio` Object with Integrality Constraints

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use setBounds with semi-continuous constraints to set *xi*=0 or 0.02<=*xi*<=0.5 for all *i*=1,...NumAssets.

```
p = setBounds(p, 0.02, 0.5,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the Portfolio object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between MinNumAssets and MaxNumAssets. By setting MinNumAssets=MaxNumAssets=2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use estimatePortReturn to estimate the mean of portfolio returns for a Portfolio object.

```
pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt)
```

```
pret = 2×1

    0.0072
    0.0119
```

The estimatePortReturn function uses the MINLP solver to solve this problem. Use the setSolverMINLP function to configure the SolverType and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
                    RelativeGapTolerance: 1.0000e-05
                  NonlinearScalingFactor: 1000
                  ObjectiveScalingFactor: 1000
                                 Display: 'off'
                           CutGeneration: 'basic'
                MaxIterationsInactiveCut: 30
                      ActiveCutTolerance: 1.0000e-07
                    IntMainSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

Estimate the Mean of Portfolio Returns for a PortfolioCVaR Object

Given portfolio p, use the estimatePortReturn function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;
```

```
rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)

    0.0050
    0.0154
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Estimate the Mean of Portfolio Returns for a PortfolioMAD Object

Given portfolio `p`, use the `estimatePortReturn` function to estimate the mean of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);
pret = estimatePortReturn(p, pwgt);
disp(pret)

    0.0048
    0.0154
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Input Arguments

`obj` — Object for portfolio
object

Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Data Types: object

pwgt — Collection of portfolios
matrix

Collection of portfolios, specified as a NumAssets-by-NumPorts matrix, where NumAssets is the number of assets in the universe and NumPorts is the number of portfolios in the collection of portfolios.

Data Types: double

Output Arguments

pret — Estimates for means of portfolio returns for each portfolio in pwgt
vector

Estimates for means of portfolio returns for each portfolio in pwgt, returned as a NumPorts vector.

pret is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note Depending on whether costs have been set, the portfolio return is either gross or net portfolio returns. For information on setting costs, see setCosts.

Tips

You can also use dot notation to estimate the mean of portfolio returns (as the proxy for portfolio return).

```
pret = obj.estimatePortReturn(pwgt);
```

estimatePortRisk

Estimate portfolio risk according to risk proxy associated with corresponding object

Syntax

```
prsk = estimatePortRisk(obj,pwgt)
```

Description

`prsk = estimatePortRisk(obj,pwgt)` estimates portfolio risk according to the risk proxy associated with the corresponding object (`obj`) for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-15.

Examples

Standard Deviation of Portfolio Returns as the Proxy for Portfolio Risk for a Portfolio Object

Given portfolio `p`, use the `estimatePortRisk` function to show the standard deviation of portfolio returns for each portfolio in `pwgt`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = setAssetMoments(p, m, C);
p = setDefaultConstraints(p);
pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)

    0.0769
    0.3500
```

Standard Deviation of Portfolio Returns as the Proxy for Portfolio Risk for a `Portfolio` Object with Integrality Constraints

Create a `Portfolio` object for three assets.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
```

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

Use `setBounds` with semi-continuous constraints to set *xi*=0 or 0.02<=*xi*<=0.5 for all *i*=1,...NumAssets.

```
p = setBounds(p, 0.02, 0.5,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up cardinality constraints for a long-only portfolio. This sets the cardinality constraints for the `Portfolio` object, where the total number of allocated assets satisfying the nonzero semi-continuous constraints are between `MinNumAssets` and `MaxNumAssets`. By setting `MinNumAssets`=`MaxNumAssets`=2, only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Use `estimatePortRisk` to estimate the portfolio risk according to a risk proxy associated with a `Portfolio` object.

```
pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt)
```

```
prsk = 2×1

    0.0324
    0.0695
```

The `estimatePortRisk` function uses the MINLP solver to solve this problem. Use the `setSolverMINLP` function to configure the `SolverType` and options.

```
p.solverOptionsMINLP
```

```
ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
                    RelativeGapTolerance: 1.0000e-05
                  NonlinearScalingFactor: 1000
                  ObjectiveScalingFactor: 1000
                                 Display: 'off'
                           CutGeneration: 'basic'
                MaxIterationsInactiveCut: 30
                      ActiveCutTolerance: 1.0000e-07
                    IntMainSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

Conditional Value-at-Risk of Portfolio Returns as the Proxy for Portfolio Risk for a PortfolioCVaR Object

Given a portfolio `pwgt`, use the `estimatePortRisk` function to show the conditional value-at-risk (CVaR) of portfolio returns for each portfolio.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
```

```
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)
```

```
    0.0407
    0.1911
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Mean-Absolute Deviation Returns as the Proxy for Portfolio Risk for a PortfolioMAD Object

Given a portfolio `pwgt`, use the `estimatePortRisk` function to show the mean-absolute deviation of portfolio returns for each portfolio.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

pwgt = estimateFrontierLimits(p);
prsk = estimatePortRisk(p, pwgt);
disp(prsk)
```

```
    0.0177
    0.0809
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Data Types: object

pwgt — Collection of portfolios
matrix

Collection of portfolios, specified as a NumAssets-by-NumPorts matrix, where NumAssets is the number of assets in the universe and NumPorts is the number of portfolios in the collection of portfolios.

Data Types: double

Output Arguments

prsk — Estimates for portfolio risk according to the risk proxy associated with the corresponding object (obj) for each portfolio in pwgt
vector

Estimates for portfolio risk according to the risk proxy associated with the corresponding object (obj) for each portfolio in pwgt, returned as a NumPorts vector.

prsk is returned for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Tips

You can also use dot notation to estimate portfolio risk according to the risk proxy associated with the corresponding object (obj).

```
prsk = obj.estimatePortRisk(pwgt);
```

estimatePortStd

Estimate standard deviation of portfolio returns

Syntax

```
pstd = estimatePortStd(obj,pwgt)
```

Description

`pstd = estimatePortStd(obj,pwgt)` estimate standard deviation of portfolio returns for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-16 and “PortfolioMAD Object Workflow” on page 6-15.

Examples

Estimate Standard Deviations for Portfolio Returns for a PortfolioCVaR Object

Given a portfolio `pwgt`, use the `estimatePortStd` function to show the standard deviation of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);

pstd = estimatePortStd(p, pwgt);
disp(pstd)
```

```
    0.0223
    0.1010
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Estimate Standard Deviations for Portfolio Returns for a PortfolioMAD Object

Given a portfolio pwgt, use the estimatePortStd function to show the standard deviation of portfolio returns.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;

estimatePortVaR

Estimate value-at-risk for PortfolioCVaR object

Syntax

```
pvar = estimatePortVaR(obj,pwgt)
```

Description

`pvar = estimatePortVaR(obj,pwgt)` estimates value-at-risk for a `PortfolioCVaR` object where the probability level used is from the `PortfolioCVaR` property `ProbabilityLevel`. For details on the workflow, see “PortfolioCVaR Object Workflow” on page 5-16.

Examples

Estimate Value-at-Risk for a PortfolioCVaR Object

Given a portfolio `pwgt`, use the `estimatePortVaR` function to estimate the value-at-risk of portfolio.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

pwgt = estimateFrontierLimits(p);

pvar = estimatePortVaR(p, pwgt);
disp(pvar)

    0.0314
    0.1483
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using a `PortfolioCVaR` object.

For more information on creating a `PortfolioCVaR` object, see

- `PortfolioCVaR`

Data Types: `object`

pwgt — Collection of portfolios
matrix

Collection of portfolios, specified as a `NumAssets`-by-`NumPorts` matrix, where `NumAssets` is the number of assets in the universe and `NumPorts` is the number of portfolios in the collection of portfolios.

Data Types: `double`

Output Arguments

pvar — Estimates for value-at-risk of portfolio returns for each portfolio in pwgt
vector

Estimates for value-at-risk of portfolio returns for each portfolio in `pwgt`, returned as a `NumPorts` vector.

Tips

You can also use dot notation to estimate the value-at-risk of PortfolioCVaR object.

```
pvar = obj.estimatePortVaR(pwgt);
```

estimateScenarioMoments

Estimate mean and covariance of asset return scenarios

Syntax

```
[ScenarioMean,ScenarioCovar] = estimateScenarioMoments(obj)
```

Description

`[ScenarioMean,ScenarioCovar] = estimateScenarioMoments(obj)` estimates mean and covariance of asset return scenarios for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Examples

Estimate Mean and Covariance of Asset Return Scenarios for a PortfolioCVaR Object

Given PortfolioCVaR object `p`, use the `estimatePortRisk` function to estimate mean and covariance of asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(p)
```

```
ScenarioMean = 4×1

    0.0039
    0.0082
    0.0102
    0.0154

ScenarioCovar = 4×4

    0.0005    0.0003    0.0001   -0.0001
    0.0003    0.0024    0.0017    0.0010
    0.0001    0.0017    0.0048    0.0028
   -0.0001    0.0010    0.0028    0.0102
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Estimate Mean and Covariance of Asset Return Scenarios for a PortfolioMAD Object

Given PortfolioMAD object `p`, use the `estimatePortRisk` function to estimate mean and covariance of asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

[ScenarioMean, ScenarioCovar] = estimateScenarioMoments(p)
```

```
ScenarioMean = 4×1

    0.0039
    0.0082
    0.0102
    0.0154

ScenarioCovar = 4×4

    0.0005    0.0003    0.0001   -0.0001
    0.0003    0.0024    0.0017    0.0010
    0.0001    0.0017    0.0048    0.0028
   -0.0001    0.0010    0.0028    0.0102
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Input Arguments

`obj` — Object for portfolio
object

Object for portfolio, specified using a PortfolioCVaR or PortfolioMAD object.

For more information on creating a PortfolioCVaR or PortfolioMAD object, see

- PortfolioCVaR
- PortfolioMAD

Data Types: object

Output Arguments

ScenarioMean — Estimate for mean of scenarios

[ ] (default) | vector

Estimate for mean of scenarios, returned as a NumPorts vector or [].

Note If no scenarios are associated with the specified object, both ScenarioMean and ScenarioCovar are set to empty [].

ScenarioCovar — Estimate for covariance of scenarios

[ ] (default) | matrix

Estimate for covariance of scenarios, returned as a NumAssets-by-NumAssets matrix or [].

Note If no scenarios are associated with the specified object, both ScenarioMean and ScenarioCovar are set to empty [].

Tips

You can also use dot notation to estimate the mean and covariance of asset return scenarios for a portfolio.

```
[ScenarioMean, ScenarioCovar] = obj.estimateScenarioMoments
```

Version History

Introduced in R2012b

ewstats

Expected return and covariance from return time series

Syntax

```
[ExpReturn,ExpCovariance,NumEffObs] = ewstats(RetSeries)
[ExpReturn,ExpCovariance,NumEffObs] = ewstats(___,DecayFactor,WindowLength)
```

Description

`[ExpReturn,ExpCovariance,NumEffObs] = ewstats(RetSeries)` computes estimated expected returns (`ExpReturn`), estimated covariance matrix (`ExpCovariance`), and the number of effective observations (`NumEffObs`). These outputs are maximum likelihood estimates which are biased.

`[ExpReturn,ExpCovariance,NumEffObs] = ewstats(___,DecayFactor,WindowLength)` adds optional input arguments for `DecayFactor` and `WindowLength`.

Examples

Compute Estimated Expected Returns and Estimated Covariance Matrix

This example shows how to compute the estimated expected returns and the estimated covariance matrix.

```
RetSeries = [ 0.24 0.08
              0.15 0.13
              0.27 0.06
              0.14 0.13 ];

DecayFactor = 0.98;

[ExpReturn, ExpCovariance] = ewstats(RetSeries, DecayFactor)
```

```
ExpReturn = 1×2

    0.1995    0.1002

ExpCovariance = 2×2

    0.0032   -0.0017
   -0.0017    0.0010
```

Input Arguments

`RetSeries` — Return series
matrix

Return series, specified the number of observations (NUMOBS) by number of assets (NASSETS) matrix of equally spaced incremental return observations. The first row is the oldest observation, and the last row is the most recent.

Data Types: double

DecayFactor — Controls how much less each observation is weighted than its successor

1 (default) | numeric

(Optional) Controls how much less each observation is weighted than its successor, specified as a numeric value. The kth observation back in time has weight $\mathtt{DecayFactor}^k$. DecayFactor must lie in the range: 0 < DecayFactor <= 1.

The default value of 1 is the equally weighted linear moving average model (BIS).

Data Types: double

WindowLength — Number of recent observations in computation

NUMOBS (default) | numeric

(Optional) Number of recent observations in the computation, specified as a numeric value.

Data Types: double

Output Arguments

ExpReturn — Estimated expected returns

vector

Estimated expected returns, returned as a 1-by-NASSETS vector.

ExpCovariance — Estimated covariance matrix

matrix

Estimated covariance matrix, returned as a NASSETS-by-NASSETS matrix.

The standard deviations of the asset return processes are defined as

```
STDVec = sqrt(diag(ExpCovariance))
```

The correlation matrix is

```
CorrMat = ExpCovariance./( STDVec*STDVec' )
```

NumEffObs — Number of effective observations

numeric

NumEffObs is the number of effective observations where

$$NumEffObs = \frac{1 - DecayFactor^{WindowLength}}{1 - DecayFactor}$$

A smaller DecayFactor or WindowLength emphasizes recent data more strongly but uses less of the available data set.

Algorithms

For a return series $r(1),\ldots,r(n)$, where (n) is the most recent observation, and w is the decay factor, the expected returns (`ExpReturn`) are calculated by

$$E(r) = \frac{(r(n) + wr(n-1) + w^2 r(n-2) + \ldots + w^{n-1} r(1))}{NumEffObs}$$

where the number of effective observations `NumEffObs` is defined as

$$NumEffObs = 1 + w + w^2 + \ldots + w^{n-1} = \frac{1 - w^n}{1 - w}$$

$E(r)$ is the weighed average of $r(n),\ldots,r(1)$. The unnormalized weights are w, w^2, …, $w^{(n-1)}$. The unnormalized weights do not sum up to `1`, so `NumEffObs` rescales the unnormalized weights. After rescaling, the normalized weights (which sum up to `1`) are used for averaging. When w `= 1`, then `NumEffObs =` n, which is the number of observations. When w `< 1`, `NumEffObs` is still interpreted as the sample size, but it is less than n due to the down-weight on the observations of the remote past.

Note There is no relationship between `ewstats` function and the RiskMetrics® approach for determining the expected return and covariance from a return time series.

fanplot

Plot combined historical and forecast data to visualize possible outcomes

Syntax

```
fanplot(historical,forecast)
fanplot( ___ ,Name,Value)
```

```
fanplot(ax,historical,forecast)
fanplot( ___ ,Name,Value)
```

```
h = fanplot(ax,historical,forecast)
h = fanplot( ___ ,Name,Value)
```

Description

`fanplot(historical,forecast)` generates a fan chart. In time series analysis, a fan chart is a chart that joins a simple line chart for observed past data with ranges for possible values of future data. The historical data and possible future data are joined with a line showing a central estimate or most likely value for the future outcomes.

`fanplot` supports three plotting scenarios:

- Matching — This scenario occurs when the time period perfectly matches for `historical` and `forecast` data.
- Backtest — This scenario occurs when there are overlaps between `historical` and `forecast` data.
- Gap — This scenario occurs when there are `NaN` values in the `historical` or `forecast` data.

`fanplot( ___ ,Name,Value)` generates a fan chart using optional name-value pair arguments.

`fanplot(ax,historical,forecast)` generates a fan chart using an optional `ax` argument.

`fanplot( ___ ,Name,Value)` generates a fan chart using optional name-value pair arguments.

`h = fanplot(ax,historical,forecast)` generates a fan chart and returns the figure handle `h`. In time series analysis, a fan chart is a chart that joins a simple line chart for observed past data with ranges for possible values of future data. The historical data and possible future data are joined with a line showing a central estimate or most likely value for the future outcomes.

`fanplot` supports three plotting scenarios:

- Matching — This scenario occurs when the time period perfectly matches for `historical` and `forecast` data.
- Backtest — This scenario occurs when there are overlaps between `historical` and `forecast` data.
- Gap — This scenario occurs when there are `NaN` values in the `historical` or `forecast` data.

`h = fanplot( ___ ,Name,Value)` generates a fan chart and returns the figure handle `h` using optional name-value pair arguments.

Examples

Create a Fan Plot Using Cell Array Data

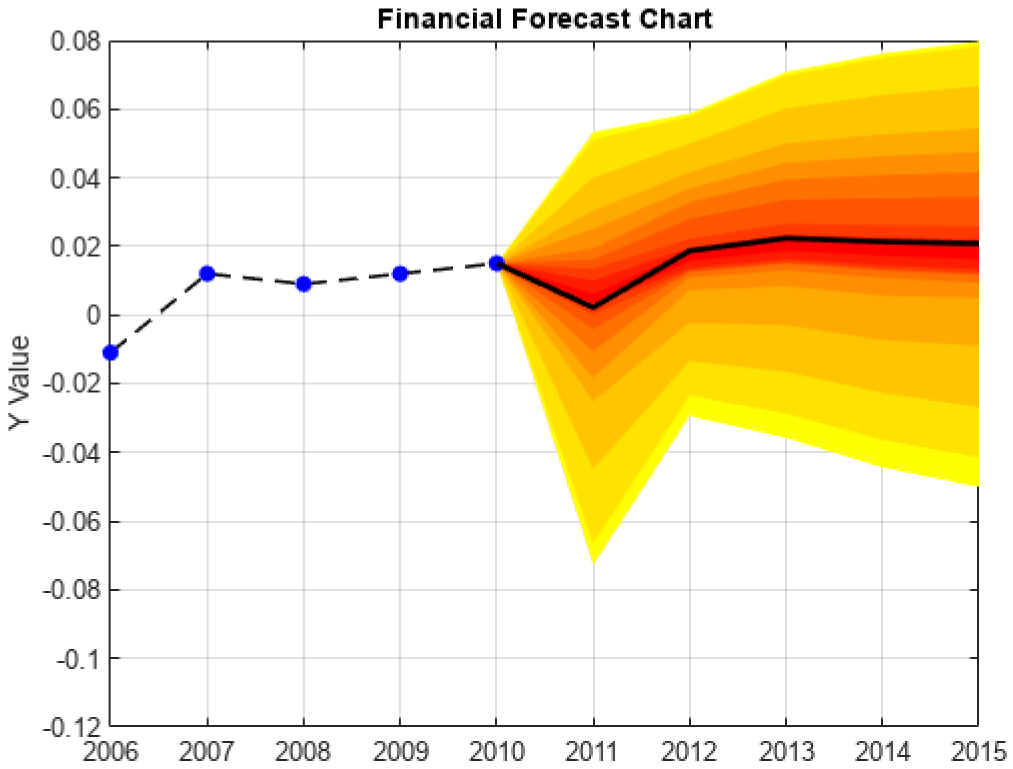
Define the data inputs for `historical` as a 5-by-2 cell array and `forecast` as a 5-by-21 cell array with 20 observations.

```
historical =  {[2006]    [-0.0110]
               [2007]    [ 0.0120]
               [2008]    [ 0.0090]
               [2009]    [ 0.0120]
               [2010]    [ 0.0150]};

forecast =    {[2011]  [0.0203]      [-0.0155]    [0.0311]     [-0.0026]     [0.0035]    [0.0049]
                       [0.0533]      [0.0139]     [0.0037]     [-0.0727]     [-0.0291]   [-0.0058
               [2012]  [0.0430]      [-0.0094]    [0.0587]     [ 0.0095]     [0.0185]    [0.0205]
                       [0.0141]      [0.0337]     [0.0187]     [0.0132]      [-0.0292]   [0.0048]
               [2013]  [0.0518]      [-0.0116]    [0.0708]     [0.0112]      [0.0221]    [0.0246]
                       [0.0168]      [0.0405]     [0.0224]     [0.0157]      [-0.0356]   [0.0056]
               [2014]  [0.0546]      [-0.0171]    [0.0762]     [0.0088]      [0.0210]    [0.0239]
                       [0.0151]      [0.0419]     [0.0214]     [0.0139]      [-0.0442]   [0.0024]
               [2015]  [0.0565]      [-0.0207]    [0.0797]     [0.0072]      [0.0203]    [0.0234]
                       [0.0139]      [0.0428]     [0.0207]     [0.0126]      [-0.0499]   [0.0026]
```

Generate the fan plot.

```
fanplot (historical, forecast);
```



The dotted points are the historical lines and the filled lines indicate the mean for the forecasts. This fanplot represents a matching scenario where the time period perfectly matches for the historical and forecast data.

Create a Fan Plot Using Matrix Data

Define the data inputs for `historical` as a 5-by-2 matrix and `forecast` as a 5-by-21 matrix with 20 observations.

```
historical =  [ 1.0000    2.8046 ;
                2.0000    4.1040 ;
                3.0000    6.7292 ;
                4.0000    8.6486 ;
                5.0000   10.4747 ];

forecast  =   [ 3.0000   28.9874   18.3958   19.6376   29.5627    8.3462    7.1502   25.3845    2
                         20.8557   27.0691   23.0803   20.7885   18.0205   17.2294   10.0197   29

                4.0000    4.8933   27.2659    7.2206   24.4703   10.5895   15.0212   29.1137    6
                          8.0007   18.7114   19.1691   24.5963    4.2835    4.0676    3.2612   29

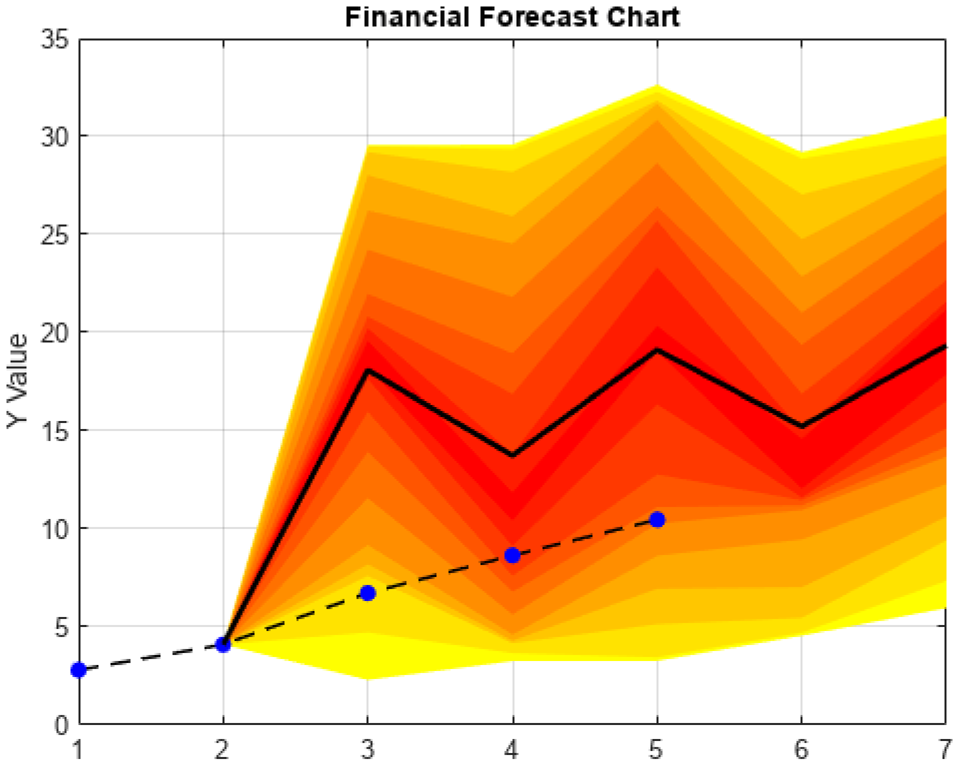
                5.0000   20.9732   19.7069   11.6862   25.7018   31.8940    7.2664   19.2113   10
                         31.7996    3.6419    3.2695   27.1422   10.5487   32.6529   18.8370    6

                6.0000   11.0069   29.1965    4.5551   20.2627   10.9209   15.2675   28.5359   11
                         23.9532   18.4804   25.5484    4.8747    8.0036   11.5329   11.6807   21

                7.0000    5.9699   11.1486   26.0449   13.4619   21.1196   28.8068   26.2525   10
                         21.2390   29.2396   18.4828   28.3945   21.9342   14.4642   17.2613   15
```

Generate the fan plot and return the figure handle.

```
h = fanplot(historical, forecast)
```



```
h = 
  Figure (1) with properties:

      Number: 1
        Name: ''
       Color: [1 1 1]
    Position: [360 402 560 420]
       Units: 'pixels'

  Show all properties
```

The dotted points are the historical lines and the filled lines indicate the mean for the forecasts. This fanplot represents a backtest scenario where there is an overlap between the historical and forecast data.

Create a Fan Plot Using Cell Array Data and Customize the Plot With Name-Value Pair Arguments

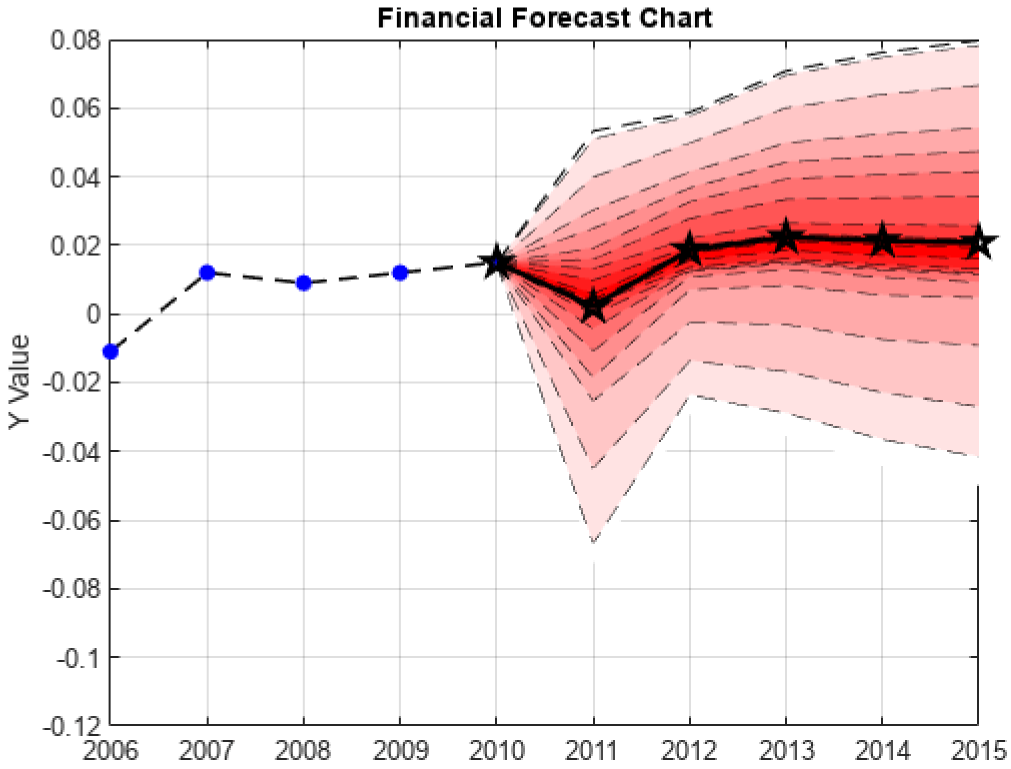
Define the data inputs for `historical` as a 5-by-2 cell array and `forecast` as a 5-by-21 cell array with 20 observations.

```
historical =  {[2006]    [-0.0110]
               [2007]    [ 0.0120]
               [2008]    [ 0.0090]
               [2009]    [ 0.0120]
               [2010]    [ 0.0150]};

forecast =    {[2011]  [0.0203]      [-0.0155]    [0.0311]     [-0.0026]     [0.0035]    [0.0049
                       [0.0533]      [0.0139]     [0.0037]     [-0.0727]     [-0.0291]   [-0.0058
               [2012]  [0.0430]      [-0.0094]    [0.0587]     [ 0.0095]     [0.0185]    [0.0205
                       [0.0141]      [0.0337]     [0.0187]     [0.0132]      [-0.0292]   [0.0048
               [2013]  [0.0518]      [-0.0116]    [0.0708]     [0.0112]      [0.0221]    [0.0246
                       [0.0168]      [0.0405]     [0.0224]     [0.0157]      [-0.0356]   [0.0056
               [2014]  [0.0546]      [-0.0171]    [0.0762]     [0.0088]      [0.0210]    [0.0239
                       [0.0151]      [0.0419]     [0.0214]     [0.0139]      [-0.0442]   [0.0024
               [2015]  [0.0565]      [-0.0207]    [0.0797]     [0.0072]      [0.0203]    [0.0234
                       [0.0139]      [0.0428]     [0.0207]     [0.0126]      [-0.0499]   [0.0026
```

Generate the fan plot using name-value pair arguments to customize the presentation.

```
fanplot(historical,forecast,'FanFaceColor',[1 1 1;1 0 0],'FanLineStyle','--','ForecastMarker','p
```



Create a Fan Plot Using Table Data

Create table of historical dates and data.

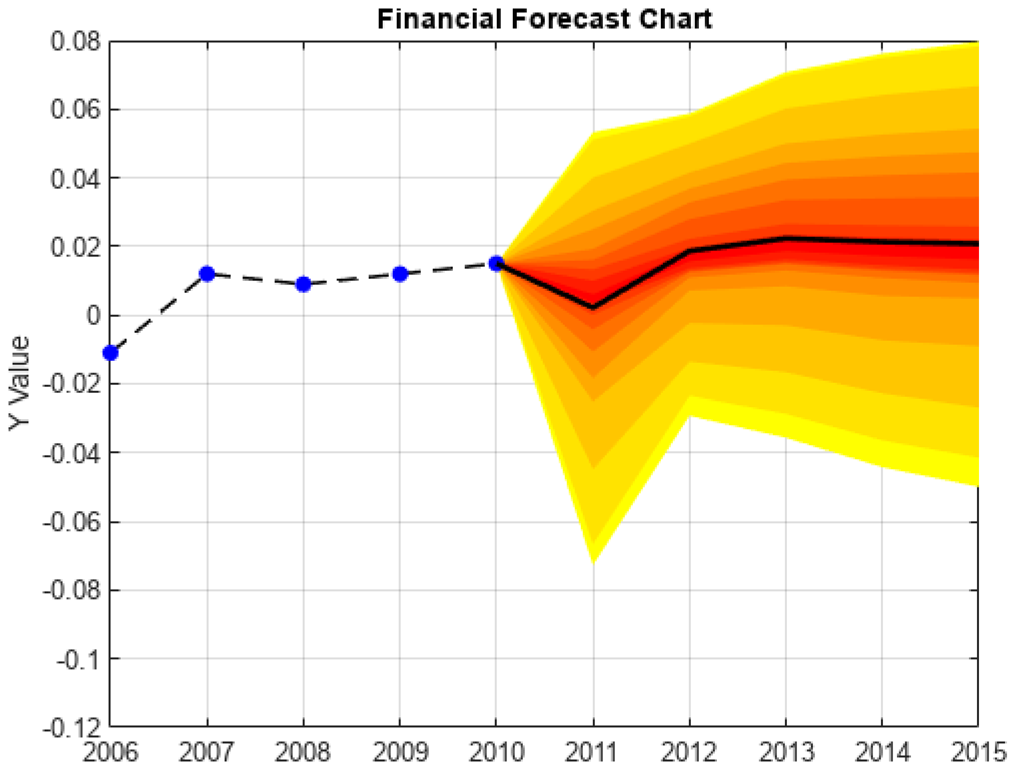
```
historicalDates = datetime(2006:2010,1,1)';
historicalData = [-0.0110;0.0120;0.0090;0.0120;0.0150];
historical = table(historicalDates,historicalData,'VariableNames',{'Dates','Data'});
```

Create table of forecast dates and data.

```
forecastDates = datetime(2011:2015,1,1)';
forecastData =      [0.0203      -0.0155    0.0311     -0.0026     0.0035    0.0049      0.0026
                     0.0533      0.0139     0.0037     -0.0727     -0.0291   -0.0058     0.0183
                     0.0430      -0.0094    0.0587     0.0095      0.0185    0.0205      0.0172
                     0.0141      0.0337     0.0187     0.0132      -0.0292   0.0048      0.0400
                     0.0518      -0.0116    0.0708     0.0112      0.0221    0.0246      0.0205
                     0.0168      0.0405     0.0224     0.0157      -0.0356   0.0056      0.0482
                     0.0546      -0.0171    0.0762     0.0088      0.0210    0.0239      0.0193
                     0.0151      0.0419     0.0214     0.0139      -0.0442   0.0024      0.0506
                     0.0565      -0.0207    0.0797     0.0072      0.0203    0.0234      0.0185
                     0.0139      0.0428     0.0207     0.0126      -0.0499   0.0026      0.0522
forecast = [table(forecastDates,'VariableName',{'Dates'}),array2table(forecastData)];
```

Plot the data using `fanplot`.

```
fanplot(historical,forecast);
```



Input Arguments

`historical` — Historical dates and data

matrix | cell array | table | timetable

Historical dates and data, specified as an `N`-by-2 matrix, cell array, table, or timetable where the first column is the date, and the second column is the data associated for that date. `N` indicates the number of dates. By using the cell array format for the input, you can make the first column datetime and produce the same plot as would serial date numbers or date character vectors. For example:

```
historical(:,1) = num2cell(datetime(2006:2010,1,1));
forecast(:,1) = num2cell(datetime(2011:2015,1,1));
fanplot (historical, forecast);
```

Data Types: `cell` | `double` | `table` | `timetable`

`forecast` — Forecast dates and data

matrix | cell array of character vectors | table | timetable

Forecast dates and data, specified as an `N`-by-`M` matrix, cell array, table, or timetable where the first column is the date, and the second to the last columns are the data observations. `N` indicates the number of the dates and (`M` – `1`) is the number for data observations. By using the cell array format for the input, you can make the first column datetime and produce the same plot as would serial date numbers or date character vectors. For example:

```
historical(:,1) = num2cell(datetime(2006:2010,1,1));
forecast(:,1) = num2cell(datetime(2011:2015,1,1));
fanplot (historical, forecast);
```

Data Types: `cell` | `double` | `table` | `timetable`

ax — Valid axis object

object

(Optional) Valid axis object, specified as an `ax` object that is created using `axes`. The plot will be created in the axes specified by the optional `ax` argument instead of in the current axes (gca). The optional argument `ax` can precede any of the input argument combinations.

Data Types: `object`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example:
`fanplot(historical,forecast,'NumQuantiles',14,'FanLineColor','blue','HistoricalLineWidth', 1.8,'ForecastLineColor','red')`

`NumQuantiles` — Number of quantiles to display

20 (default) | positive integer

Number of quantiles to display in fan chart, specified as a positive integer.

Data Types: `double`

`FanLineStyle` — Style of the lines separating fans

`'none'` (default) | character vector

Style of the lines separating fans, specified as a character vector. For more information on supported character vectors for line styles, see Primitive Line.

Data Types: `char`

`FanLineColor` — Color of lines separating fans

`'black'` (default) | character vector for color or RGB triplet

Color of lines separating fans, specified as a character vector for color or an RGB triplet. For more information on supported color character vectors, see Primitive Line.

Data Types: `double` | `char`

`FanFaceColor` — Color of each fan

`[1 1 0;1 0 0]` (yellow to red) (default) | matrix

Color of each fan, specified as an `N`-by-`3` matrix controlling the color of each fan, where each row is an RGB triplet. There are three possible values of `N`:

- When `N` = `NumQuantiles`, the color of each fan is specified by the corresponding row in the matrix.
- When `N` = `ceil`(`NumQuantiles`/`2`), the specified colors represent the bottom half of the fans. The colors of the top half are determined by reversing the order of these colors. For more information, see `ceil`.
- When `N` = `2`, the colors in the bottom half of the fan are a linear interpolation between the two specified colors. The pattern is reversed for the top half.

Data Types: `double`

`HistoricalMarker` — Marker symbol of historical line

`'o'` (default) | character vector

Marker symbol of historical line, specified as a character vector. For more information on supported character vectors for markers, see Primitive Line.

Data Types: `char`

`HistoricalMarkerSize` — Marker size of historical line

`5` (default) | positive value in point units

Marker size of historical line, specified as a positive value in point units.

Data Types: `double` | `char`

`HistoricalMarkerFaceColor` — Marker fill color of historical line

`'blue'` (default) | character vector with a value of `'none'`, `'auto'`, color identifier, or RGB triplet

Marker fill color of historical line, specified as a character vector with a value of `'none'`, `'auto'`, a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: `double` | `char`

`HistoricalMarkerEdgeColor` — Marker outline color of historical line

`'blue'` (default) | character vector with a value of `'none'`, `'auto'`, color identifier, or RGB triplet

Marker outline color of historical line, specified as a character vector with a value of `'none'`, `'auto'`, a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: `double` | `char`

`HistoricalLineColor` — Color of historical line

`'black'` (default) | character vector with a value of `'none'`, color identifier, or RGB triplet

Color of historical line, specified as a character vector with a value of `'none'`, a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: `double` | `char`

`HistoricalLineStyle` — Style of historical line

`'--'` (default) | character vector

Style of historical line, specified as a character vector. For more information on supported character vectors for line styles, see Primitive Line.

Data Types: `char`

`HistoricalLineWidth` — Width of historical line

`1.5` (default) | positive value in point units

Width of historical line, specified as a positive value in point units.

Data Types: `double`

`ForcecastMarker` — Marker symbol of forecast line

`'none'` (default) | character vector

Marker symbol of forecast line, specified as a character vector. For more information on supported character vectors for marker symbols, see Primitive Line.

Data Types: `char`

`ForecastMarkerSize` — Marker size of forecast line

`5` (default) | positive value in point units

Marker size of forecast line, specified as a positive value in point units.

Data Types: `double`

`ForecastMarkerFaceColor` — Marker fill color of forecast line

`'none'` (default) | character vector with a value of `'none'`, `'auto'`, color identifier, or RGB triplet

Marker fill color of forecast line, specified as a character vector with a value of `'none'`, `'auto'`, a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: `double` | `char`

`ForecastMarkerEdgeColor` — Marker outline color of forecast line

`'auto'` (default) | character vector with a value of `'none'`, `'auto'`, color identifier, or RGB triplet

Marker outline color of forecast line, specified as a character vector with a value of `'none'`, `'auto'`, character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: `double` | `char`

`ForecastLineColor` — Color of forecast line
`'black'` (default) | character vector with a value of `'none'`, color identifier, or RGB triplet

Color of forecast line, specified as a character vector with a value of `'none'`, a character vector for color, or an RGB triplet. For more information on supported character vectors for color, see Primitive Line.

Data Types: `double` | `char`

`ForecastLineStyle` — Style of forecast line
`'-'` (default) | character vector

Style of forecast line, specified as a character vector. For more information on supported character vectors for line styles, see Primitive Line.

Data Types: `char`

`ForecastLineWidth` — Width of forecast line
`2` (default) | positive value in point units

Width of forecast line, specified as a positive value in point units.

Data Types: `double`

Output Arguments

`h` — Figure handle for fanplot
handle object

Figure handle for the fanplot, returned as handle object.

Version History

Introduced in R2014b

fbusdate

First business date of month

Syntax

```
Date = fbusdate(Year,Month)
Date = fbusdate( ___ ,Holiday,Weekend,outputType)
```

Description

`Date = fbusdate(Year,Month)` returns the serial date number for the first business date of the given year and month.

`Year` and `Month` can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if`Year` is a `1`-by-`N` vector of integers, then `Month` must be a `1`-by-`N` vector of integers or a single integer. `Date` is then a `1`-by-`N` vector of datetimes or serial date numbers.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

`Date = fbusdate( ___ ,Holiday,Weekend,outputType)` returns the serial date number for the first business date of the given year and month using optional input arguments. The optional argument `Holiday` specifies nontrading days.

If neither `Holiday` nor `outputType` are specified, `Date` is returned as a serial date number. If `Holiday` is specified, but not `outputType`, then the type of the holiday variable controls the type of date. If `Holiday` is a string or date character vector, then `Date` is returned as a serial date number.

Examples

Return a Serial Date Number for the First Business Date

This example shows how to return serial date numbers for the first business date, given year and month.

```
Date = fbusdate(2001, 11)
```

```
Date = 731156
```

```
datestr(Date)
```

```
ans = 
'01-Nov-2001'
```

```
Year = [2002 2003 2004];
Date = fbusdate(Year, 11)
```

```
Date = 1×3
```

```
      731521      731888      732252
```

```
datestr(Date)
```

```
ans = 3x11 char array
    '01-Nov-2002'
    '03-Nov-2003'
    '01-Nov-2004'
```

Return a Serial Date Number for the First Business Date Using the Weekend Argument

This example shows how to return serial date numbers for the first business date, given year and month, and also indicate that Saturday is a business day by setting the `Weekend` argument. March 1, 2003, is a Saturday. Use `fbusdate` to check that this Saturday is actually the first business day of the month.

```
Weekend = [1 0 0 0 0 0 0];
Date = datestr(fbusdate(2003, 3, [], Weekend))
```

```
Date = 
'01-Mar-2003'
```

Return a datetime array for `Date` for the First Business Date Using the `outputType` Argument

This example shows how to return a datetime array for `Date` using an `outputType` of `'datetime'`.

```
Date = fbusdate(2001, 11,[],[],'datetime')
```

```
Date = datetime
   01-Nov-2001
```

Input Arguments

Year — Year to determine occurrence of weekday
4-digit integer | vector of 4-digit integers

Year to determine occurrence of weekday, specified as a 4-digit integer or vector of 4-digit integers.

Data Types: `double`

`Month` — Month to determine occurrence of weekday
integer with value `1` through `12` | vector of integers with values `1` through `12`

Month to determine occurrence of weekday, specified as an integer or vector of integers with values `1` through `12`.

Data Types: `double`

Holiday — Holidays and nontrading-day dates
non-trading day vector is determined by the routine holidays (default) | datetime array | string array | date character vector

Holidays and nontrading-day dates, specified as vector using a datetime array, string array, date character vectors, or serial date numbers.

All dates in Holiday must be the same format: either datetimes, strings, or date character vectors. The holidays function supplies the default vector.

If Holiday is a datetime array, then Date is returned as a datetime array. If outputType is specified, then its value determines the output type of Date. This overrides any influence of Holiday.

To support existing code, fbusdate also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Weekend — Weekend days
[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: double

outputType — Year to determine days
'datenum' (default) | character vector with values 'datenum' or 'datetime'

A character vector specified as either 'datenum' or 'datetime'. The output Date is in serial date format if 'datenum' is specified, or datetime format if 'datetime' is specified. By default the output Date is in serial date format, or match the format of Holiday, if specified.

Data Types: char

Output Arguments

Date — Date for the first business date of given year and month
serial date number | datetime array

Date for the first business date of a given year and month, returned as a datetime or serial date number.

If neither Holiday nor outputType are specified, Date is returned as a serial date number. If Holiday is specified, but not outputType, then the type of the holiday variable controls the type of date:

- If Holiday is a string or date character vector, then Date is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.
- If Holiday is a datetime array, then Date is returned as a datetime array.

.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `fbusdate` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floatdiscmargin

Discount margin for floating-rate bond

Syntax

```
Margin = floatdiscmargin(Price,SpreadSettle,Maturity,RateInfo,
LatestFloatingRate)
Margin = floatdiscmargin( ___ ,Name,Value)
```

Description

`Margin = floatdiscmargin(Price,SpreadSettle,Maturity,RateInfo, LatestFloatingRate)` calculates the discount margin or zero discount margin for a floating-rate bond.

The input `RateInfo` determines whether the discount margin or the zero discount margin is calculated. Principal schedules are supported using `Principal`.

`Margin = floatdiscmargin( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Zero Discount Margin Using a Yield Curve

Use `floatdiscmargin` to compute the discount margin and zero discount margin for a floating-rate note.

Define data for the floating-rate note.

```
Price = 99.99;
Spread = 50;
Settle = datetime(2011,1,20);
Maturity = datetime(2012,1,15);
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;
```

Compute the discount margin.

```
dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...
[StubRate, SpotRate], LatestFloatingRate,'Reset', Reset, 'Basis', Basis, ...
'AdjustCashFlowsBasis', true)
```

```
dMargin = 48.4810
```

Usually you want to set `AdjustCashFlowsBasis` to `true`, so cash flows are calculated with adjustments on accrual amounts.

Create an annualized zero-rate term structure to calculate the zero discount margin.

```
Rates = [0.0500;
         0.0505;
         0.0510;
         0.0520];
StartDates = [datetime(2011,1,20);
              datetime(2011,4,15);
              datetime(2011,7,15);
              datetime(2011,11,15)];
EndDates =   [datetime(2011,4,15);
              datetime(2011,7,15);
              datetime(2011,11,15);
              datetime(2012,1,15)];
ValuationDate = datetime(2011,1,20);
RateSpec = intenvset('Compounding', Reset, 'Rates', Rates,...
'StartDates', StartDates, 'EndDates', EndDates,...
'ValuationDate', ValuationDate, 'Basis', Basis);
```

Calculate the zero discount margin using the previous yield curve.

```
dMargin = floatdiscmargin(Price, Spread, Settle, Maturity, ...
RateSpec, LatestFloatingRate,'Reset', Reset, 'Basis', Basis, ...
'AdjustCashFlowsBasis', true)
```

```
dMargin = 46.0689
```

Input Arguments

Price — Bond prices where discount margin is to be computed

matrix

Bond prices where discount margin is to be computed, specified as a NINST-by-1 matrix.

Note The spread is calculated against the clean price (the function internally does not add the accrued interest to the price specified by the Price input). If the spread is required against the dirty price, the price of a bond that includes the accrued interest, you must supply the dirty price for the Price input.

Data Types: double

Spread — Number of basis points over the reference rate

numeric

Number of basis points over the reference rate, specified as a NINST-by-1 matrix.

Data Types: double

Settle — Settlement date of the floating-rate bonds

datetime array | string array | date character vector

Settlement date of the floating-rate bonds, specified as a scalar or a NINST-by-1 vector using a datetime array, string array, or date character vectors. If supplied as a NINST-by-1 vector of dates, all settlement dates must be the same (only a single settlement date is supported)

To support existing code, `floatdiscmargin` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of the floating-rate bond
datetime array | string array | date character vector

Maturity date of the floating-rate bond, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floatdiscmargin` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`RateInfo` — Interest-rate information
numeric

interest-rate information, specified as `NINST`-by-`2` vector where the:

- First column is the stub rate between the settlement date and the first coupon rate.
- Second column is the reference rate for the term of the floating coupons (for example, the 3-month LIBOR from settlement date for a bond with a `Reset` of `4`).

Note If the `RateInfo` argument is an annualized zero-rate term structure created by `intenvset`, the zero discount margin is calculated.

Data Types: `double`

`LatestFloatingRate` — Rate for next floating payment set at last reset date
numeric

Rate for the next floating payment set at the last reset date, specified as `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Margin = floatdiscmargin(Price,Spread,Settle,Maturity,RateInfo,LatestFloatingRate,'Reset',2,'Basis',5)`

`Reset` — Frequency of payments per year
`1` (default) | numeric

Frequency of payments per year, specified as `NINST`-by-`1` vector.

Data Types: `double`

Basis — Day-count basis used for time factor calculations

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

Day-count basis used for time factor calculations, specified as a NINST-by-1 vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

Principal — Notional principal amounts

100 (default) | numeric

Notional principal amounts, specified as a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NUMDATES-by-2 cell array where the first column is dates and the second column is the associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: double | cell

EndMonthRule — End-of-month rule flag

1 (in effect) (default) | nonnegative integer 0 or 1

End-of-month rule flag, specified as a NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

AdjustCashFlowsBasis — Adjust cash flows according to accrual amount

0 (not in effect) (default) | nonnegative integer 0 or 1

Adjusts cash flows according to the accrual amount, specified as a NINST-by-1 vector of logicals.

Note Usually you want to set AdjustCashFlowsBasis to 1, so cash flows are calculated with adjustments on accrual amounts. The default is set to 0 to be consistent with floatbyzero.

Data Types: logical

Holidays — Dates for holidays

holidays.m used (default) | datetime array | string array | date character vector | serial date number

Dates for holidays, specified as NHOLIDAYS-by-1 vector using a datetime array, string array, or date character vectors. Holidays are used in computing business days.

To support existing code, floatdiscmargin also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

BusinessDayConvention — Business day conventions

'actual' (default) | character vector with values'actual', 'follow', 'modifiedfollow', 'previous'or 'modifiedprevious'

Business day conventions, specified as a NINST-by-1 cell array of character vectors of business day conventions to be used in computing payment dates. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

Output Arguments

Margin — Discount margin

numeric

Discount margin, returned as a NINST-by-1 vector of the discount margin if RateInfo is specified as a NINST-by-2 vector of stub and spot rates.

If RateInfo is specified as an annualized zero rate term structure created by intenvset, Margin is returned as a NINST-by-NCURVES matrix of the zero discount margin.

Version History

Introduced in R2012b

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `floatdiscmargin` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floatmargin

Margin measures for floating-rate bond

Syntax

```
[Margin,AdjPrice] = floatmargin(Price,SpreadSettle,Maturity)
[Margin,AdjPrice] = floatmargin( ___ ,Name,Value)
```

Description

`[Margin,AdjPrice] = floatmargin(Price,SpreadSettle,Maturity)` calculates margin measures for a floating-rate bond.

Use `floatmargin` to calculate the following types of margin measures for a floating-rate bond:

- Spread for life
- Adjusted simple margin
- Adjusted total margin

To calculate the discount margin or zero discount margin, see `floatdiscmargin`.

`[Margin,AdjPrice] = floatmargin( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute Margin Measures for a Floating-Rate Bond

Use `floatmargin` to compute margin measures for `spreadforlife`, `adjustedsimple`, and `adjustedtotal` for a floating-rate note.

Define data for the floating-rate note.

```
Price = 99.99;
Spread = 50;
Settle = datetime(2011,1,20);
Maturity = datetime(2012,1,15);
LatestFloatingRate = 0.05;
StubRate = 0.049;
SpotRate = 0.05;
Reset = 4;
Basis = 2;
```

Calculate `spreadforlife`.

```
Margin = floatmargin(Price, Spread, Settle, Maturity, 'Reset', Reset, 'Basis', Basis)
```

```
Margin = 51.0051
```

Calculate `adjustedsimple` margin.

```
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ...
'SpreadType', 'adjustedsimple', 'RateInfo', [StubRate, SpotRate], ...
'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)
```

```
Margin = 53.2830

AdjPrice = 99.9673
```

Calculate `adjustedtotal` margin.

```
[Margin, AdjPrice] = floatmargin(Price, Spread, Settle, Maturity, ...
'SpreadType', 'adjustedtotal', 'RateInfo', [StubRate, SpotRate], ...
'LatestFloatingRate', LatestFloatingRate, 'Reset', Reset, 'Basis', Basis)
```

```
Margin = 53.4463

AdjPrice = 99.9673
```

Input Arguments

`Price` — Bond prices where spreads are to be computed

matrix

Bond prices where spreads are to be computed, specified as a `NINST`-by-`1` matrix.

Data Types: `double`

`Spread` — Number of basis points over the reference rate

numeric

Number of basis points over the reference rate, specified as a `NINST`-by-`1` matrix.

Data Types: `double`

`Settle` — Settlement date of the floating-rate bonds

datetime array | string array | date character vector

Settlement date of the floating-rate bonds, specified as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. If supplied as a `NINST`-by-`1` vector of dates, all settlement dates must be the same (only a single settlement date is supported)

To support existing code, `floatmargin` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of the floating-rate bond

datetime array | string array | date character vector

Maturity date of the floating-rate bond, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floatmargin` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Margin,AdjPrice] = floatmargin(Price,Spread,Settle,Maturity, 'SpreadType','adjustedtotal','RateInfo', [StubRate,SpotRate],'LatestFloatingRate',.0445,'Reset',2,'Basis',5)`

`SpreadType` — Type of spread to calculate

`spreadforlife` (default) | `adjustedsimpleadjustedtotal`

Type of spread to calculates, specified by type, specified as `spreadforlife`,`adjustedsimple`, or `adjustedtotal`.

Note If the `SpreadType` is `spreadforlife` (default), then the name-value arguments `LatestFloatingRate` and `RateInfo` are not used. If the `SpreadType` is `adjustedsimple` or `adjustedtotal`, then the name-value arguments `LatestFloatingRate` and `RateInfo` must be specified.

Data Types: `double`

`LatestFloatingRate` — Rate for next floating payment set at last reset date

numeric

Rate for the next floating payment set at the last reset date, specified as `NINST`-by-`1` vector.

Note This rate must be specified for a `SpreadType` of `adjustedsimple` and `adjustedtotal`.

Data Types: `double`

`RateInfo` — Interest-rate information

numeric

interest-rate information, specified as `NINST`-by-`2` vector where the:

- First column is the stub rate between the settlement date and the first coupon rate.
- Second column is the reference rate for the term of the floating coupons (for example, the 3-month LIBOR from settlement date for a bond with a `Reset` of `4`).

Note The `RateInfo` must be specified for `SpreadType` of `adjustedsimple` and `adjustedtotal`.

Data Types: `double`

`Reset` — Frequency of payments per year

`1` (default) | numeric

Frequency of payments per year, specified as `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis used for time factor calculations

`0` (actual/actual) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

Day-count basis used for time factor calculations, specified as a `NINST`-by-`1` vector. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

`Principal` — Notional principal amounts

`100` (default) | numeric

Notional principal amounts, specified as `NINST`-by-`1` vector.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag

`1` (in effect) (default) | nonnegative integer `0` or `1`

End-of-month rule flag, specified as a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `logical`

`Holidays` — Dates for holidays

`holidays.m` used (default) | datetime array | string array | date character vector

Dates for holidays, specified as NHOLIDAYS-by-1 vector using a datetime array, string array, or date character vectors. Holidays are used in computing business days.

To support existing code, floatmargin also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

BusinessDayConvention — Business day conventions
'actual' (default) | character vector with values'actual', 'follow', 'modifiedfollow', 'previous'or 'modifiedprevious'

Business day conventions, specified as a NINST-by-1 cell array of character vectors of business day conventions to be used in computing payment dates. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- 'actual' — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- 'follow' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- 'modifiedfollow' — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- 'previous' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- 'modifiedprevious' — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

Output Arguments

Margin — Spreads for floating-rate bond
numeric

Spreads for the floating-rate bond, returned as a NINST-by-1 vector.

AdjPrice — Adjusted price used to calculate spreads for SpreadType of adjustedsimple and adjustedtotal
numeric

Adjusted price used to calculate spreads for SpreadType of adjustedsimple and adjustedtotal, returned as a NINST-by-1 vector.

Version History

Introduced in R2012b

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although floatmargin supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");

frac2cur

Fractional currency value to decimal value

Syntax

```
Decimal = frac2cur(Fraction,Denominator)
```

Description

`Decimal = frac2cur(Fraction,Denominator)` converts a fractional currency value to a decimal value. `Fraction` is the fractional currency value input as a character vector, and `Denominator` is the denominator of the fraction.

Examples

Convert a Fractional Currency Value to a Decimal Value

This example shows how to convert a fractional currency value to a decimal value.

```
Decimal = frac2cur('12.1', 8)
```

```
Decimal = 12.1250
```

Input Arguments

`Fraction` — Fractional currency values

character vector | cell array of character vectors

Fractional currency values, specified as a character vector or cell array of character vectors.

Data Types: `char` | `cell`

`Denominator` — Denominator of the fractions

numeric

Denominator of the fractions, specified as a scalar or vector using numeric values for the denominator.

Data Types: `double`

Output Arguments

`Decimal` — Decimal currency value

numeric decimal

Decimal currency value, returned as a scalar or vector with numeric decimal values.

Data Types: `double`

Version History

Introduced before R2006a

`cur2frac` | `cur2str`

frontier

Rolling efficient frontier

Syntax

```
[PortWts,AllMean,AllCovariance] = frontier(Universe,Window,Offset,NumPorts)
[PortWts,AllMean,AllCovariance] = frontier( ___ ,ActiveMap,Conset,NumNonNan)
```

Description

`[PortWts,AllMean,AllCovariance] = frontier(Universe,Window,Offset,NumPorts)` generates a surface of efficient frontiers showing how asset allocation influences risk and return over time.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

`[PortWts,AllMean,AllCovariance] = frontier( ___ ,ActiveMap,Conset,NumNonNan)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Input Arguments

`Universe` — Total return data for a group of securities

array

Total return data for a group of securities, specified as a number of observations (`NUMOBS`) by number of assets plus one (`NASSETS + 1`) time series array. Each row represents an observation. Column 1 contains MATLAB serial date numbers. The remaining columns contain the total return data for each security.

Data Types: `double`

`Window` — Number of data periods used to calculate each frontier

positive integer

Number of data periods used to calculate each frontier, specified as a positive integer value.

Data Types: `double`

`Offset` — Increment in number of periods between each frontier

numeric

Increment in number of periods between each frontier, specified as a numeric value.

Data Types: `double`

`NumPorts` — Number of portfolios to calculate on each frontier

positive integer

Number of portfolios to calculate on each frontier, specified as a positive integer.

Data Types: `double`

`ActiveMap` — Indicates if an asset is part of the `Universe` on the corresponding date

`NUMOBS`-by-`NASSETS` matrix of `1`'s (all assets active on all dates) (default) | matrix

(Optional) Indicates if an asset is part of the `Universe` on the corresponding date, specified as a number of observations (`NUMOBS`) by number of assets (`NASSETS`) matrix with Boolean elements corresponding to the `Universe`.

Data Types: `double`

`Conset` — Constraint matrix for a portfolio of asset investments

matrix

Constraint matrix for a portfolio of asset investments, specified using `portcons` with the `'Default'` constraint type. This single constraint matrix is applied to each frontier..

Data Types: `double`

`NumNonNan` — Minimum number of non-`NaN` points for each active asset in each window of data

`Window` - `NASSETS` (default) | numeric value

Minimum number of non-`NaN` points for each active asset in each window of data needed to perform the optimization, specified as a numeric value.

Data Types: `double`

Output Arguments

`PortWts` — Weights allocated to each asset

matrix

Weights allocated to each asset., returned as a number of curves (`NCURVES`)-by-`1` cell array, where each element is a `NPORTS`-by-`NASSETS` matrix of weights.

`AllMean` — Expected asset returns used to generate each curve on the surface

vector

Expected asset returns used to generate each curve on the surface, returned as an `NCURVES`-by-`1` cell array, where each element is a `1`-by-`NASSETS` vector of the expected asset returns.

`AllCovariance` — Covariance matrix used to generate each curve on the surface

vector

Covariance matrix used to generate each curve on the surface, returned as an `NCURVES`-by-`1` cell array, where each element is a `NASSETS`-by-`NASSETS` vector.

Version History

Introduced before R2006a

fvdisc

Future value of discounted security

Syntax

```
FutureVal = fvdisc(Settle,Maturity,Price,Discount)
FutureVal = fvdisc( ___ ,Basis)
```

Description

`FutureVal = fvdisc(Settle,Maturity,Price,Discount)` finds the amount received at maturity for a fully vested security.

`FutureVal = fvdisc( ___ ,Basis)` specifies options using an optional argument in addition to the input arguments in the previous syntax.

Examples

Find the Amount Received at Maturity for a Fully-Vested Security Using datetime Inputs

This example shows how to use `datetime` inputs to find the amount received at maturity for a fully-vested security, using the following data.

```
Settle = datetime(2001,2,15);
Maturity = datetime(2001,5,15);
Price = 100;
Discount = 0.0575;
Basis = 2;

FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis)
```

```
FutureVal = 101.4420
```

Input Arguments

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `fvdisc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime scalar | string scalar | date character vector

Maturity date, specified as a scalar datetime, string, or date character vector.

To support existing code, `fvdisc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Price` — Price (present value) of security

scalar numeric

Price (present value) of the security, specified as a scalar numeric.

Data Types: `double`

`Discount` — Bank discount rate of security

scalar decimal

Bank discount rate of security, specified as a scalar decimal.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count basis of the instrument, specified as a scalar integer using one of the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`FutureVal` — Amount received at maturity for fully vested security

scalar numeric

Amount received at maturity for a fully vested security, returned as a scalar numeric.

Data Types: `double`

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `fvdisc` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

fvfix

Future value with fixed periodic payments

Syntax

```
FutureVal = fvfix(Rate,NumPeriods,Payment)
FutureVal = fvfix( ___ ,PresentVal,Due)
```

Description

`FutureVal = fvfix(Rate,NumPeriods,Payment)` returns the future value of a series of equal payments.

`FutureVal = fvfix( ___ ,PresentVal,Due)` specifies options using one or more optional argument in addition to the input arguments in the previous syntax.

Examples

Return the Future Value of a Series of Equal Payments

This example shows how to compute the future value of a series of equal payments using a savings account that has a starting balance of $1500. $200 is added at the end of each month for 10 years and the account pays 9% interest compounded monthly.

```
FutureVal = fvfix(0.09/12, 12*10, 200, 1500, 0)
```

```
FutureVal = 4.2380e+04
```

Input Arguments

`Rate` — Interest-rate per period

scalar numeric decimal

Interest-rate per period, specified as a scalar numeric decimal.

Data Types: `double`

`NumPeriods` — Number of payment periods

scalar numeric

Number of payment periods, specified as a scalar numeric.

Data Types: `double`

`Payment` — Payment per period

scalar numeric

Payment per period, specified as a scalar numeric.

Data Types: `double`

`PresentVal` — Present value

`0` (default) | scalar numeric

(Optional) Present value, specified as a scalar numeric.

Data Types: `double`

`Due` — When payments are due

`0` (end of period) (default) | scalar integer with value of `0` or `1`

(Optional) When payments are due, specified as a scalar integer with value of `0` (end of period) or `1` (beginning of period).

Data Types: `double`

Output Arguments

`FutureVal` — Future value of series of equal payments

scalar numeric

Future value of a series of equal payments, returned as a scalar numeric.

Version History

Introduced before R2006a

“Analyzing and Computing Cash Flows” on page 2-11

fvvar

Future value of varying cash flow

Syntax

```
FutureVal = fvvar(CashFlow,Rate)
FutureVal = fvvar( ___ ,CFDates)
```

Description

`FutureVal = fvvar(CashFlow,Rate)` returns the future value of a varying cash flow.

`FutureVal = fvvar( ___ ,CFDates)` specifies options using an optional argument in addition to the input arguments in the previous syntax.

Examples

Calculate Future Value of Varying Cash Flows

This cash flow represents the yearly income from an initial investment of $10,000. The annual interest rate is 2%.

- Year 1 — $2000
- Year 2 — $1500
- Year 3 — $3000
- Year 4 — $3800
- Year 5 — $5000

For the future value of this regular (periodic) cash flow:

```
FutureVal = fvvar([-10000 2000 1500 3000 3800 5000], 0.02)
```

```
FutureVal = 4.7131e+03
```

An investment of $10,000 returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is 3%.

- -$1000 — January 12, 2000
- $2500 — February 14, 2001
- $2000 — March 3, 2001
- $3000 — June 14, 2001
- $4000 — December 1, 2001

To calculate the future value of this irregular (nonperiodic) cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
```

```
CFDates = [datetime(2000,1,12)
           datetime(2001,2,14)
           datetime(2001,3,3)
           datetime(2001,6,14)
           datetime(2001,12,1)];

FutureVal = fvvar(CashFlow, 0.03, CFDates)
```

```
FutureVal = 1.0731e+03
```

Input Arguments

`CashFlow` — Varying cash flows

vector

Varying cash flows, specified as a vector.

Note You must include the initial investment as the initial cash flow value (a negative number).

.

Data Types: `double`

`Rate` — Periodic Interest rate

scalar numeric decimal

Periodic interest rate, specified as a scalar numeric decimal.

Data Types: `double`

`CFDates` — Dates on which the cash flows occur

assumes `CashFlow` contains regular (periodic) cash flows (default) | datetime array | string array | date character vector | serial date number

(Optional) Dates on which the cash flows occur, specified as a vector using a datetime array, string array, or date character vectors.

Note Use `CFDates` for irregular (nonperiodic) cash flows.

To support existing code, `fvvar` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Output Arguments

`FutureVal` — Future value of a varying cash flow

scalar numeric

Future value of a varying cash flow, returned as a scalar numeric.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although fvvar supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

fwd2zero

Zero curve given forward curve

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

Syntax

```
[ZeroRates,CurveDates] = fwd2zero(ForwardRates,CurveDates,Settle)
[ZeroRates,CurveDates] = fwd2zero( ___ ,Name,Value)
```

Description

`[ZeroRates,CurveDates] = fwd2zero(ForwardRates,CurveDates,Settle)` returns a zero curve given an implied forward rate curve and its maturity dates. If both inputs for `CurveDates` and `Settle` are strings or date character vectors, `CurveDates` is returned as serial date numbers. However, if either of the inputs for `CurveDates` and `Settle` are a datetime array, `CurveDates` is returned as a datetime array.

`[ZeroRates,CurveDates] = fwd2zero( ___ ,Name,Value)` adds optional name-value pair arguments

Examples

Compute the Zero Curve Given the Forward Curve Using datetime Inputs

This example shows how to use `datetime` inputs compute the zero curve, given an implied forward rate curve over a set of maturity dates, a settlement date, and a compounding rate.

```
ForwardRates = [0.0469
                0.0519
                0.0549
                0.0535
                0.0558
                0.0508
                0.0560
                0.0545
                0.0615
                0.0486];

CurveDates = [datetime(2000,11,6)
              datetime(2000,12,11)
              datetime(2001,1,15)
              datetime(2001,2,5)
              datetime(2001,3,4)
              datetime(2001,4,2)
              datetime(2001,4,30)
              datetime(2001,6,25)
              datetime(2001,9,4)
              datetime(2001,11,12)];

Settle = datetime(2000,11,3);

InputCompounding = 1;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;
[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates,...
Settle,'InputCompounding',1,'InputBasis',2,'OutputCompounding',1,'OutputBasis',2)

ZeroRates = 10×1

    0.0469
    0.0515
    0.0531
    0.0532

    0.0532
    0.0536
    0.0539
    0.0556
    0.0543

CurveDates = 10x1 datetime
   06-Nov-2000
   11-Dec-2000
   15-Jan-2001
   05-Feb-2001
   04-Mar-2001
   02-Apr-2001
   30-Apr-2001
   25-Jun-2001
   04-Sep-2001
   12-Nov-2001
```

Input Arguments

ForwardRates — Annualized implied forward rates

decimal fraction

Annualized implied forward rates, specified as a (NUMBONDS)-by-1 vector using decimal fractions. In aggregate, the rates in ForwardRates constitute an implied forward curve for the investment horizon represented by CurveDates. The first element pertains to forward rates from the settlement date to the first curve date.

Data Types: double

CurveDates — Maturity dates

datetime array | string array | date character vector

Maturity dates, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors, that correspond to the ForwardRates.

To support existing code, fwd2zero also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

Settle — Common settlement date for ForwardRates

datetime scalar | string scalar | date character vector

Common settlement date for ForwardRates, specified as scalar datetime, string, or date character vector.

To support existing code, fwd2zero also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [ZeroRates,CurveDates] = fwd2zero(ForwardRates,CurveDates,Settle,'InputCompounding',3,'InputBasis',5,'OutputCompounding',4,'OutputBasis',5)

InputCompounding — Compounding frequency of input forward rates

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input forward rates, specified with allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

Note If InputCompounding is not specified, then InputCompounding is assigned the value specified for OutputCompounding. If either InputCompounding or OutputCompounding are not specified, the default is 2

Data Types: double

`InputBasis` — Day-count basis of input forward rates

`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day count basis of input forward rates, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-16.

Note If `InputBasis` is not specified, then `InputBasis` is assigned the value specified for `OutputBasis`. If either `InputBasis` or `Outputbasis` are not specified, the default is `0` (actual/actual) for both.

Data Types: `double`

`OutputCompounding` — Compounding frequency of output zero rates

2 (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `12`, `365`, `-1`

Compounding frequency of output zero rates, specified with the allowed values:

- `0` — Simple interest (no compounding)
- `1` — Annual compounding
- `2` — Semiannual compounding (default)
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding
- `365` — Daily compounding
- `-1` — Continuous compounding

Note If `OutputCompounding` is not specified, then `OutputCompounding` is assigned the value specified for `InputCompounding`. If either `InputCompounding` or `OutputCompounding` are not specified, the default is `2` (semiannual) for both.

Data Types: `double`

`OutputBasis` — Day-count basis of output zero rates

`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day count basis of output zero rates, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If `OutputBasis` is not specified, then `OutputBasis` is assigned the value specified for `InputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is `0` (actual/actual) for both.

Data Types: `double`

Output Arguments

`ZeroRates` — Zero curve for investment horizon represented by `CurveDates`

numeric

Zero curve for the investment horizon represented by `CurveDates`, returned as a `NUMBONDS`-by-`1` vector of decimal fractions. In aggregate, the rates in `ZeroRates` constitute a zero curve for the investment horizon represented by `CurveDates`.

`CurveDates` — Maturity dates that correspond to `ZeroRates`

datetime | serial date number

Maturity dates that correspond to the ZeroRates, returned as a NUMBONDS-by-1 vector of maturity dates that correspond to the zero rates in ZeroRates. This vector is the same as the input vector CurveDates, but is sorted by ascending maturity.

If both inputs for CurveDates and Settle are strings or date character vectors, CurveDates is returned as serial date numbers. Use the function datestr to convert serial date numbers to formatted date character vectors. However, if either of the inputs for CurveDates and Settle are a datetime array, CurveDates is returned as a datetime array.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although fwd2zero supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

geom2arith

Geometric to arithmetic moments of asset returns

Syntax

```
[ma,Ca = geom2arith(mg,Cg)
[ma,Ca = geom2arith( ___ ,t)
```

Description

`[ma,Ca = geom2arith(mg,Cg)` transforms moments associated with a continuously compounded geometric Brownian motion into equivalent moments associated with a simple Brownian motion with a possible change in periodicity.

`[ma,Ca = geom2arith( ___ ,t)` adds an optional argument `t`.

Examples

Obtain Geometric to Arithmetic Moments of Asset Returns

This example shows several variations of using `geom2arith`.

Given geometric mean `m` and covariance `C` of monthly total returns, obtain annual arithmetic mean `ma` and covariance `Ca`. In this case, the output period (1 year) is 12 times the input period (1 month) so that the optional input `t = 12`.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
[ma, Ca] = geom2arith(m, C, 12)
```

```
ma = 4×1

    0.5508
    1.0021
    1.0906
    1.4802

Ca = 4×4

    0.0695    0.0423    0.0196         0
    0.0423    0.2832    0.1971    0.1095
    0.0196    0.1971    0.5387    0.3013
         0    0.1095    0.3013    1.0118
```

Given annual geometric mean `m` and covariance `C` of asset returns, obtain monthly arithmetic mean `ma` and covariance `Ca`. In this case, the output period (1 month) is 1/12 times the input period (1 year) so that the optional input `t = 1/12`.

```
[ma, Ca] = geom2arith(m, C, 1/12)
```

```
ma = 4×1

    0.0038
    0.0070
    0.0076
    0.0103

Ca = 4×4

    0.0005    0.0003    0.0001         0
    0.0003    0.0020    0.0014    0.0008
    0.0001    0.0014    0.0037    0.0021
         0    0.0008    0.0021    0.0070
```

Given geometric mean `m` and covariance `C` of monthly total returns, obtain quarterly arithmetic return moments. In this case, the output is `3` of the input periods so that the optional input `t = 3`.

```
[ma, Ca] = geom2arith(m, C, 3)
```

```
ma = 4×1

    0.1377
    0.2505
    0.2726
    0.3701

Ca = 4×4

         0    0.0274    0.0753    0.2530
```

Input Arguments

`mg` — Continuously compounded or geometric mean of asset returns

vector

Continuously compounded or geometric mean of asset returns, specified as an *n*-vector.

Data Types: `double`

`Cg` — Continuously compounded or geometric covariance of asset returns

matrix

Continuously compounded or geometric covariance of asset returns, specified as an `n`-by-`n` symmetric, positive semidefinite matrix. If `Cg` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.

Data Types: `double`

`t` — Target period of arithmetic moments in terms of periodicity of geometric moments
`1` (default) | scalar positive numeric

(Optional) Target period of geometric moments in terms of periodicity of arithmetic moments, specified as a scalar positive numeric.

Data Types: `double`

Output Arguments

`ma` — Arithmetic mean of asset returns over the target period
vector

Arithmetic mean of asset returns over the target period (`t`), returned as an *n*-vector.

`Ca` — Arithmetic covariance of asset returns over the target period
matrix

Arithmetic covariance of asset returns over the target period (`t`), returned as an `n`-by-`n` matrix.

Algorithms

Geometric returns over period t_G are modeled as multivariate lognormal random variables with moments

$$E[\mathrm{Y}] = 1 + \mathrm{m}_G$$

and

$$\mathrm{cov}(\mathrm{Y}) = \mathrm{C}_G$$

Arithmetic returns over period t_A are modeled as multivariate normal random variables with moments

$$E[\mathrm{X}] = \mathrm{m}_A$$

$$\mathrm{cov}(\mathrm{X}) = \mathrm{C}_A$$

Given $t = t_A / t_G$, the transformation from geometric to arithmetic moments is

$$\mathrm{C}_{A_{ij}} = t\log\left(1 + \frac{\mathrm{C}_{G_{ij}}}{(1 + \mathrm{m}_{G_i})(1 + \mathrm{m}_{G_j})}\right)$$

$$\mathrm{m}_{A_i} = t\log(1 + \mathrm{m}_{G_i}) - \frac{1}{2}\mathrm{C}_{A_{ii}}$$

For $i,j = 1,\ldots, n$.

Note If $t = 1$, then $\mathbf{X} = \log(\mathbf{Y})$.

This function requires that the input mean must satisfy `1 + mg > 0` and that the input covariance `Cg` must be a symmetric, positive, semidefinite matrix.

The functions `geom2arith` and `arith2geom` are complementary so that, given `m`, `C`, and `t`, the sequence

```
[ma,Ca] = geom2arith(m,C,t);
[mg,Cg] = arith2geom(ma,Ca,1/t);
```

yields `mg` = `m` and `Cg` = `C`.

Version History

Introduced before R2006a

`arith2geom` | `nearcorr`

getAssetMoments

Obtain mean and covariance of asset returns from Portfolio object

Syntax

```
[AssetMean,AssetCovar] = getAssetMoments(obj)
```

Description

Use the `getAssetMoments` function with a `Portfolio` object to obtain mean and covariance of asset returns.

For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

`[AssetMean,AssetCovar] = getAssetMoments(obj)` obtains mean and covariance of asset returns for a `Portfolio` object.

Examples

Obtain Asset Moment Properties for a Portfolio Object

Given the mean and covariance of asset returns in the variables `m` and `C`, the asset moment properties can be set and then obtained using the `getAssetMoments` function:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

p = Portfolio;
p = setAssetMoments(p, m, C);
[assetmean, assetcovar] = getAssetMoments(p)
```

```
assetmean = 4×1

    0.0042
    0.0083
    0.0100
    0.0150

assetcovar = 4×4

    0.0005    0.0003    0.0002         0
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
         0    0.0010    0.0028    0.0102
```

Input Arguments

`obj` — Object for portfolio
object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

Data Types: `object`

Output Arguments

`AssetMean` — Mean of asset returns
vector

Mean of asset returns, returned as a vector.

`AssetCovar` — Covariance of asset returns
matrix

Covariance of asset returns, returned as a matrix.

Tips

You can also use dot notation to obtain the mean and covariance of asset returns from a Portfolio object:

```
[AssetMean, AssetCovar] = obj.getAssetMoments;
```

Version History

Introduced in R2011a

getBounds

Obtain bounds for portfolio weights from portfolio object

Syntax

```
[LowerBound,UpperBound] = getBounds(obj)
```

Description

Use the `getBounds` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain bounds for portfolio weights from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[LowerBound,UpperBound] = getBounds(obj)` obtains bounds for portfolio weights from portfolio objects.

Examples

Obtain Values for Lower and Upper Bounds for a Portfolio Object

Given portfolio `p` with the default constraints set, obtain the values for `LowerBound` and `UpperBound`.

```
p = Portfolio;
p = setDefaultConstraints(p, 5);
[LowerBound, UpperBound] = getBounds(p)
```

```
LowerBound = 5×1

     0
     0

     0
     0

UpperBound =

     []
```

Obtain Values for Lower and Upper Bounds for a PortfolioCVaR Object

Given a PortfolioCVaR object `p` with the default constraints set, obtain the values for `LowerBound` and `UpperBound`.

```
p = PortfolioCVaR;
p = setDefaultConstraints(p, 5);
[LowerBound, UpperBound] = getBounds(p)
```

```
LowerBound = 5×1

     0
     0
     0
     0
     0

UpperBound =

     []
```

Obtain Values for Lower and Upper Bounds for a PortfolioMAD Object

Given a PortfolioMAD object `p` with the default constraints set, obtain the values for `LowerBound` and `UpperBound`.

```
p = PortfolioMAD;
p = setDefaultConstraints(p, 5);
[LowerBound, UpperBound] = getBounds(p)
```

```
LowerBound = 5×1

     0
     0
     0
     0
     0

UpperBound =

     []
```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

Output Arguments

LowerBound — Lower-bound weight for each asset

vector

Lower-bound weight for each asset, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`). For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

UpperBound — Upper-bound weight for each asset

vector

Upper-bound weight for each asset, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`). For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Tips

You can also use dot notation to obtain bounds for portfolio weights from portfolio objects.

```
[LowerBound, UpperBound] = obj.getBounds;
```

getBudget

Obtain budget constraint bounds from portfolio object

Syntax

```
[LowerBudget,UpperBudget] = getBudget(obj)
```

Description

Use the `getBudget` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain budget constraint bounds from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[LowerBudget,UpperBudget] = getBudget(obj)` obtains budget constraint bounds from portfolio objects.

Examples

Obtain Values for Lower and Upper Budgets for a Portfolio Object

Given portfolio `p` with the default constraints set, obtain the values for `LowerBudget` and `UpperBudget`.

```
p = Portfolio;
p = setDefaultConstraints(p, 5);
[LowerBudget, UpperBudget] = getBudget(p)
```

```
LowerBudget = 1

UpperBudget = 1
```

Obtain Values for Lower and Upper Budgets for a PortfolioCVaR Object

Given a PortfolioCVaR object `p` with the default constraints set, obtain the values for `LowerBudget` and `UpperBudget`.

```
p = PortfolioCVaR;
p = setDefaultConstraints(p, 5);
[LowerBudget, UpperBudget] = getBudget(p)
```

```
LowerBudget = 1

UpperBudget = 1
```

Obtain Values for Lower and Upper Budgets for a PortfolioMAD Object

Given a PortfolioMAD object `p` with the default constraints set, obtain the values for `LowerBudget` and `UpperBudget`.

```
p = PortfolioMAD;
p = setDefaultConstraints(p, 5);
[LowerBudget, UpperBudget] = getBudget(p)
```

```
LowerBudget = 1

UpperBudget = 1
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

Output Arguments

`LowerBudget` — Lower-bound weight for each asset

scalar

Lower bound for budget constraint, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`UpperBudget` — Upper bound for budget constraint

scalar

Upper bound for budget constraint, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Tips

You can also use dot notation to obtain the budget constraint bounds from portfolio objects.

```
[LowerBudget, UpperBudget] = obj.getBudget;
```

Version History

Introduced in R2011a

getCosts

Obtain buy and sell transaction costs from portfolio object

Syntax

```
[BuyCost,SellCost] = getCosts(obj)
```

Description

Use the `getCosts` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain buy and sell transaction costs from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[BuyCost,SellCost] = getCosts(obj)` obtains buy and sell transaction costs from portfolio objects.

Examples

Obtain Buy and Sell Costs for a Portfolio Object

Given portfolio `p` with the costs set, obtain the values for `BuyCost` and `SellCost`.

```
p = Portfolio;
p = setCosts(p, 0.001, 0.001, 5);
[BuyCost, SellCost] = getCosts(p)
```

```
BuyCost = 1.0000e-03

SellCost = 1.0000e-03
```

Obtain Buy and Sell Costs for a PortfolioCVaR Object

Given a PortfolioCVaR object `p` with the costs set, obtain the values for `BuyCost` and `SellCost`.

```
p = PortfolioCVaR;
p = setCosts(p, 0.001, 0.001, 5);
[BuyCost, SellCost] = getCosts(p)
```

```
BuyCost = 1.0000e-03

SellCost = 1.0000e-03
```

Obtain Buy and Sell Costs for a PortfolioMAD Object

Given a PortfolioMAD object `p` with the costs set, obtain the values for `BuyCost` and `SellCost`.

```
p = PortfolioMAD;
p = setCosts(p, 0.001, 0.001, 5);
[BuyCost, SellCost] = getCosts(p)
```

```
BuyCost = 1.0000e-03

SellCost = 1.0000e-03
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

Output Arguments

`BuyCost` — Proportional transaction cost to purchase each asset

vector

Proportional transaction cost to purchase each asset, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`SellCost` — Proportional transaction cost to sell each asset

vector

Proportional transaction cost to sell each asset, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Tips

You can also use dot notation to obtain the buy and sell transaction costs from portfolio objects.

```
[BuyCost, SellCost] = obj.getCosts;
```

Version History

Introduced in R2011a

getEquality

Obtain equality constraint arrays from portfolio object

Syntax

```
[AEquality,bEquality] = getEquality(obj)
```

Description

Use the `getEquality` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain equality constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[AEquality,bEquality] = getEquality(obj)` obtains equality constraint arrays from portfolio objects.

Examples

Obtain Equality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are exactly 50% of your portfolio. Given a Portfolio object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)
```

```
AEquality = 1×5

     1     1     1     0     0

bEquality = 0.5000
```

Obtain Equality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a PortfolioCVaR object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
```

```
p = PortfolioCVaR;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)
```

```
AEquality = 1×5

     1     1     1     0     0

bEquality = 0.5000
```

Obtain Equality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a PortfolioMAD object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)
```

```
AEquality = 1×5

     1     1     1     0     0

bEquality = 0.5000
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

Output Arguments

`AEquality` — Matrix to form linear equality constraints

matrix

Matrix to form linear equality constraints, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

bEquality — Vector to form linear equality constraints

vector

Vector to form linear equality constraints, returned as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Tips

You can also use dot notation to obtain the equality constraint arrays from portfolio objects.

```
[AEquality, bEquality] = obj.getEquality;
```

Version History

Introduced in R2011a

getGroupRatio

Obtain group ratio constraint arrays from portfolio object

Syntax

```
[GroupA,GroupB,LowerRatio,UpperRatio] = getGroupRatio(obj)
```

Description

Use the getGroupRatio function with a Portfolio, PortfolioCVaR, or PortfolioMAD object to obtain group ratio constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

[GroupA,GroupB,LowerRatio,UpperRatio] = getGroupRatio(obj) obtains equality constraint arrays from portfolio objects.

Examples

Obtain Group Ratio Constraints for a Portfolio Object

Suppose you want to make sure that the ratio of financial to nonfinancial companies in your portfolios never goes above 50%. Assume you have 6 assets with 3 financial companies (assets 1-3) and 3 nonfinancial companies (assets 4-6). After setting group ratio constraints, obtain the values for GroupA, GroupB, LowerRatio, and UpperRatio.

```
GA = [ true true true false false false ];    % financial companies
GB = [ false false false true true true ];    % nonfinancial companies
p = Portfolio;
p = setGroupRatio(p, GA, GB, [], 0.5);
[GroupA, GroupB, LowerRatio, UpperRatio] = getGroupRatio(p)
```

```
GroupA = 1×6

     1     1     1     0     0     0

GroupB = 1×6

     0     0     0     1     1     1

LowerRatio =

     []

UpperRatio = 0.5000
```

Obtain Group Ratio Constraints for a PortfolioCVaR Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolios never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). After setting group ratio constraints, obtain the values for `GroupA`, `GroupB`, `LowerRatio`, and `UpperRatio`.

```
GA = [ true true true false false false ];   % financial companies
GB = [ false false false true true true ];   % nonfinancial companies
p = PortfolioCVaR;
p = setGroupRatio(p, GA, GB, [], 0.5);
[GroupA, GroupB, LowerRatio, UpperRatio] = getGroupRatio(p)
```

```
GroupA = 1×6

     1     1     1     0     0     0

GroupB = 1×6

     0     0     0     1     1     1

LowerRatio =

     []

UpperRatio = 0.5000
```

Obtain Group Ratio Constraints for a PortfolioMAD Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolios never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). After setting group ratio constraints, obtain the values for `GroupA`, `GroupB`, `LowerRatio`, and `UpperRatio`.

```
GA = [ true true true false false false ];   % financial companies
GB = [ false false false true true true ];   % nonfinancial companies
p = PortfolioMAD;
p = setGroupRatio(p, GA, GB, [], 0.5);
[GroupA, GroupB, LowerRatio, UpperRatio] = getGroupRatio(p)
```

```
GroupA = 1×6

     1     1     1     0     0     0

GroupB = 1×6

     0     0     0     1     1     1

LowerRatio =

     []
```

```
UpperRatio = 0.5000
```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

Output Arguments

GroupA — Matrix that forms base groups for comparison
matrix

Matrix that forms base groups for comparison, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

GroupB — Matrix that forms comparison groups
matrix

Matrix that forms comparison groups, returned as a matrix `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

LowerRatio — Lower bound for ratio of GroupB groups to GroupA groups
vector

Lower bound for ratio of `GroupB` groups to `GroupA` groups, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

UpperRatio — Upper bound for ratio of GroupB groups to GroupA groups
vector

Upper bound for ratio of `GroupB` groups to `GroupA` groups, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Tips

You can also use dot notation to obtain group ratio constraint arrays from portfolio objects.

```
[GroupA, GroupB, LowerRatio, UpperRatio] = obj.getGroupRatio;
```

Version History

Introduced in R2011a

getGroups

Obtain group constraint arrays from portfolio object

Syntax

```
[GroupMatrix,LowerGroup,UpperGroup] = getGroups(obj)
```

Description

Use the `getGroups` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain group constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[GroupMatrix,LowerGroup,UpperGroup] = getGroups(obj)` obtains group constraint arrays from portfolio objects.

Examples

Obtain Group Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute no more than 30% of your portfolio. Given a Portfolio object `p` with the group constraints set, obtain the values for `GroupMatrix`, `LowerGroup`, and `UpperGroup`.

```
G = [ true true true false false ];
p = Portfolio;
p = setGroups(p, G, [], 0.3);
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(p)
```

```
GroupMatrix = 1×5

     1     1     1     0     0

LowerGroup =

     []

UpperGroup = 0.3000
```

Obtain Group Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a PortfolioCVaR object `p` with the group constraints set, obtain the values for `GroupMatrix`, `LowerGroup`, and `UpperGroup`.

```
G = [ true true true false false ];
p = PortfolioCVaR;
p = setGroups(p, G, [], 0.3);
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(p)

GroupMatrix = 1×5

     1     1     1     0     0

LowerGroup =

     []

UpperGroup = 0.3000
```

Obtain Group Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a PortfolioMAD object `p` with the group constraints set, obtain the values for `GroupMatrix`, `LowerGroup`, and `UpperGroup`.

```
G = [ true true true false false ];
p = PortfolioMAD;
p = setGroups(p, G, [], 0.3);
[GroupMatrix, LowerGroup, UpperGroup] = getGroups(p)

GroupMatrix = 1×5

     1     1     1     0     0

LowerGroup =

     []

UpperGroup = 0.3000
```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

Output Arguments

`GroupMatrix` — Group constraint matrix

matrix

Group constraint matrix, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`LowerGroup` — Lower bound for group constraints

vector

Lower bound for group constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`UpperGroup` — Upper bound for group constraints

vector

Upper bound for group constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Tips

You can also use dot notation to obtain the group constraint arrays from portfolio objects.

```
[GroupMatrix, LowerGroup, UpperGroup] = obj.getGroups;
```

Version History

Introduced in R2011a

getScenarios

Obtain scenarios from portfolio object

Syntax

```
Y = getScenarios(obj)
```

Description

Use the `getScenarios` function with a `PortfolioCVaR` or `PortfolioMAD` objects to obtain scenarios.

For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`Y = getScenarios(obj)` obtains scenarios for `PortfolioCVaR` or `PortfolioMAD` objects.

Examples

Obtain Scenarios for a CVaR Portfolio Object

For a given PortfolioCVaR object `p`, display the defined scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 10);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

Y = getScenarios(p)
```

```
Y = 10×4

   -0.0056    0.0440    0.1186    0.0488
   -0.0368   -0.0753    0.0087    0.1124
    0.0025    0.0856    0.0484    0.1404
    0.0318    0.0826    0.0377    0.0404
    0.0013   -0.0561   -0.1466   -0.0621
    0.0035    0.0310   -0.0183    0.1225
   -0.0519   -0.1634   -0.0526    0.1528
    0.0029   -0.1163   -0.0627   -0.0760
    0.0192   -0.0182   -0.1243   -0.1346
    0.0440    0.0189    0.0098    0.0821
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Obtain Scenarios for a MAD Portfolio Object

For a given PortfolioMAD object `p`, display the defined scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

rng(11);

AssetScenarios = mvnrnd(m, C, 10);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

Y = getScenarios(p)
```

```
Y = 10×4

   -0.0056    0.0440    0.1186    0.0488
   -0.0368   -0.0753    0.0087    0.1124
    0.0025    0.0856    0.0484    0.1404
    0.0318    0.0826    0.0377    0.0404
    0.0013   -0.0561   -0.1466   -0.0621
    0.0035    0.0310   -0.0183    0.1225
   -0.0519   -0.1634   -0.0526    0.1528
    0.0029   -0.1163   -0.0627   -0.0760
    0.0192   -0.0182   -0.1243   -0.1346
    0.0440    0.0189    0.0098    0.0821
```

The function `rng`(*seed*) resets the random number generator to produce the documented results. It is not necessary to reset the random number generator to simulate scenarios.

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

Output Arguments

Y — Scenarios matrix

matrix

Scenarios matrix, returned as a `NumScenarios`-by-`NumAssets` matrix for a `PortfolioCVaR` or `PortfolioMAD` object.

Tips

You can also use dot notation to obtain scenarios from a `PortfolioCVaR` or `PortfolioMAD` object.

```
Y = obj.getScenarios;
```

Version History

Introduced in R2012b

getInequality

Obtain inequality constraint arrays from portfolio object

Syntax

```
[AInequality,bInequality] = getInequality(obj)
```

Description

Use the `getInequality` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain inequality constraint arrays from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[AInequality,bInequality] = getInequality(obj)` obtains equality constraint arrays from portfolio objects.

Examples

Obtain Inequality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than 50% of your portfolio. Given a Portfolio object `p`, set the linear inequality constraints and then obtain values for `AInequality` and `bInequality`.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setInequality(p, A, b);
[AInequality, bInequality] = getInequality(p)
```

```
AInequality = 1×5

     1     1     1     0     0

bInequality = 0.5000
```

Obtain Inequality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 50% of your portfolio. Given a PortfolioCVaR object `p`, set the linear inequality constraints and then obtain values for `AInequality` and `bInequality`.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
```

```
p = PortfolioCVaR;
p = setInequality(p, A, b);
[AInequality, bInequality] = getInequality(p)
```

```
AInequality = 1×5

     1     1     1     0     0

bInequality = 0.5000
```

Obtain Inequality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 50% of your portfolio. Given a PortfolioMAD object `p`, set the linear inequality constraints and then obtain values for `AInequality` and `bInequality`.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setInequality(p, A, b);
[AInequality, bInequality] = getInequality(p)
```

```
AInequality = 1×5

     1     1     1     0     0

bInequality = 0.5000
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

Output Arguments

`AInequality` — Matrix to form linear inequality constraints

matrix

Matrix to form linear inequality constraints, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`bInequality` — Vector to form linear inequality constraints
vector

Vector to form linear inequality constraints, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Tips

You can also use dot notation to obtain the inequality constraint arrays from portfolio objects.

```
[AInequality, bInequality] = obj.getInequality;
```

Version History

Introduced in R2011a

getOneWayTurnover

Obtain one-way turnover constraints from portfolio object

Syntax

```
[BuyTurnover,SellTurnover] = getOneWayTurnover(obj)
```

Description

Use the `getOneWayTirnover` function with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object to obtain one-way turnover constraints from portfolio objects.

For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

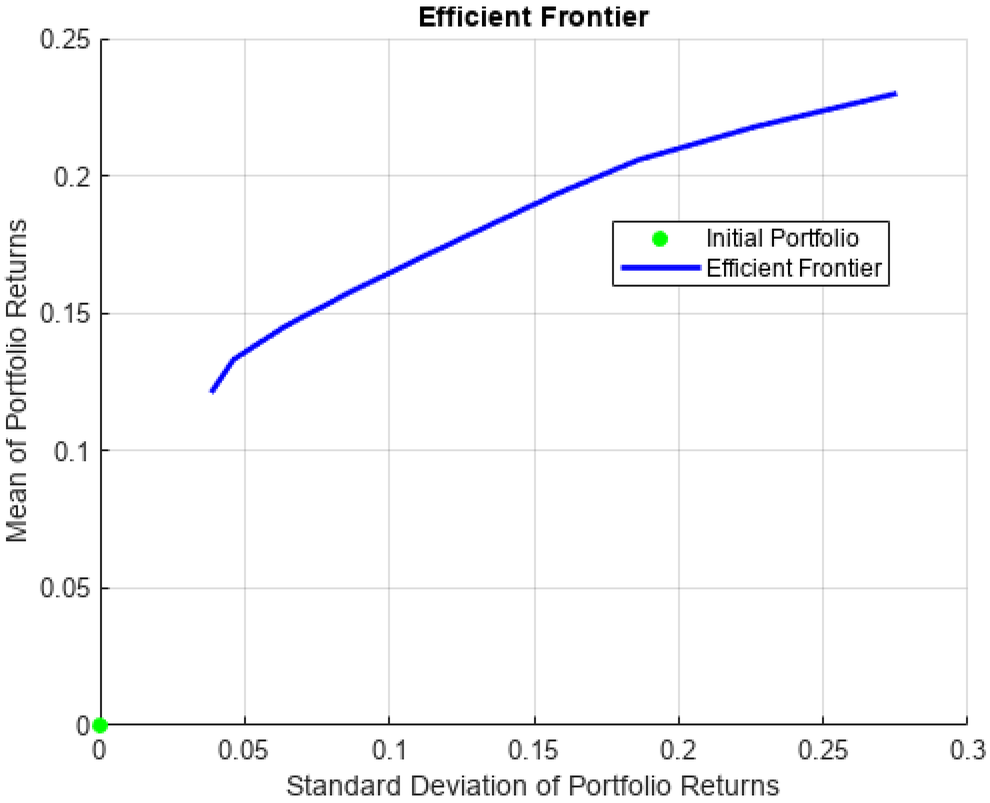
`[BuyTurnover,SellTurnover] = getOneWayTurnover(obj)` obtain one-way turnover constraints from portfolio objects.

Examples

Obtain One-Way Turnover Costs for a Portfolio Object

Set one-way turnover costs.

```
p = Portfolio('AssetMean',[0.1, 0.2, 0.15], 'AssetCovar',...
[ 0.005, -0.010,  0.004; -0.010,  0.040, -0.002;  0.004, -0.002,  0.023]);
p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0);    %130-30 portfolio
plotFrontier(p);
```



Obtain one-way turnover costs.

```
[BuyTurnover,SellTurnover] = getOneWayTurnover(p)
```

```
BuyTurnover = 1.3000
```

```
SellTurnover = 0.3000
```

Obtain One-Way Turnover Costs for a PortfolioCVaR Object

Set one-way turnover costs and obtain the buy and sell turnover values.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
```

```
p = setProbabilityLevel(p, 0.95);

p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0); %130-30 portfolio

[BuyTurnover,SellTurnover] = getOneWayTurnover(p)
```

```
BuyTurnover = 1.3000

SellTurnover = 0.3000
```

Obtain One-Way Turnover Costs for a PortfolioMAD Object

Set one-way turnover costs and obtain the buy and sell turnover values.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0); %130-30 portfolio

[BuyTurnover,SellTurnover] = getOneWayTurnover(p)
```

```
BuyTurnover = 1.3000

SellTurnover = 0.3000
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

Output Arguments

`BuyTurnover` — Turnover constraint on purchases
scalar

Turnover constraint on purchases, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`SellTurnover` — Turnover constraint on sales
scalar

Turnover constraint on sales, returned as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

More About

One-way Turnover Constraint

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales.

The constraints take the form

$$1^T \max\{0, x - x_0\} \leq \tau_B$$

$$1^T \max\{0, x_0 - x\} \leq \tau_S$$

with

- `x` — The portfolio (*NumAssets* vector)
- x_0 — Initial portfolio (*NumAssets* vector)
- τ_B — Upper-bound for turnover constraint on purchases (scalar)
- τ_S — Upper-bound for turnover constraint on sales (scalar)

Specify one-way turnover constraints using the following properties in a supported portfolio object: `BuyTurnover` for τ_B, `SellTurnover` for τ_S, and `InitPort` for x_0.

Note The average turnover constraint (which is set using `setTurnover`) is not just the combination of the one-way turnover constraints with the same value for the constraint.

Tips

You can also use dot notation to get the one-way turnover constraint for portfolio objects.

```
[BuyTurnover,SellTurnover] = obj.getOneWayTurnover
```

Version History

Introduced in R2011a

hhigh

Highest high

Syntax

```
values = hhigh(Data)
values = hhigh( ___ ,Name,Value)
```

Description

`values = hhigh(Data)` generates a vector of highest high values from the series of high prices for the past *n* periods.

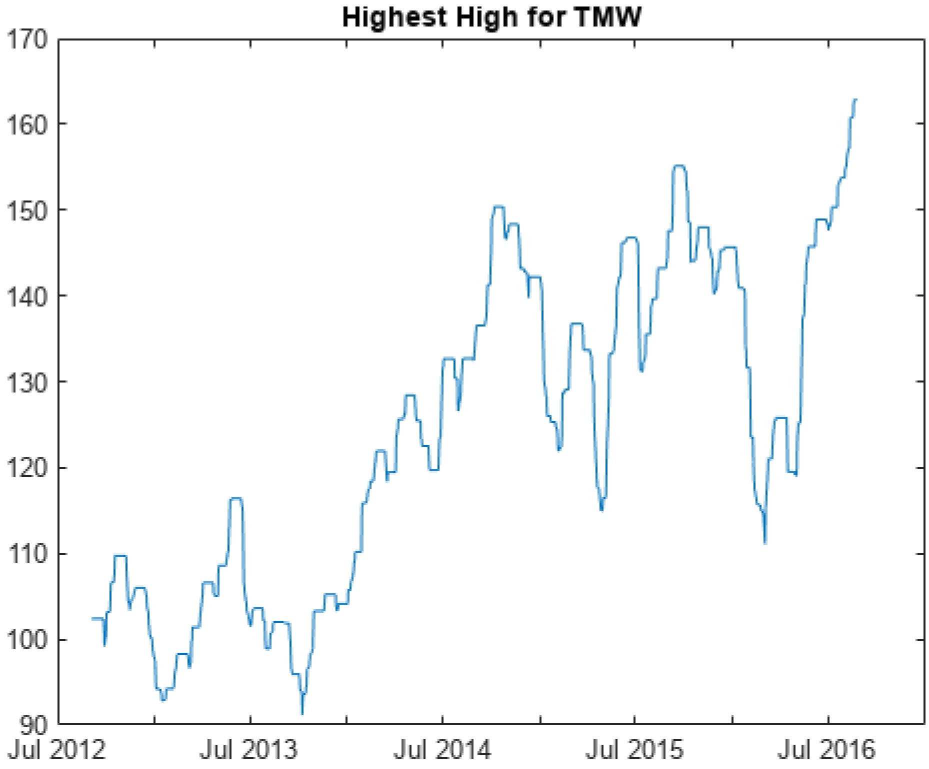
`values = hhigh( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Highest High for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
values = hhigh(TMW);
plot(values.Time,values.HighestHigh)
title('Highest High for TMW')
```



Input Arguments

`Data` — Data for high prices

matrix | table | timetable

Data for high prices, specified as a matrix, table, or timetable. Timetables and tables with `M` rows must contain a variable named `'High'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `values = hhigh(TMW_HIGH,'NumPeriods',10)`

`NumPeriods` — Moving window for the highest high calculation

`14` (default) | positive integer

Moving window for the highest high calculation, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`values` — Highest high series
matrix | table | timetable

Highest high series, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

highlow

High, low, open, close chart

Note highlow is updated to accept data input as a matrix, timetable, or table.

Syntax

```
highlow(Data)
highlow(Data,Color)
h = highlow(ax, ___ )
```

Description

highlow(Data) displays a highlow chart from a series of opening, high, low, and closing prices of a security. The plots are vertical lines whose top is the high, bottom is the low, open is a left tick, and close is a right tick.

highlow(Data,Color) adds an optional argument for Color.

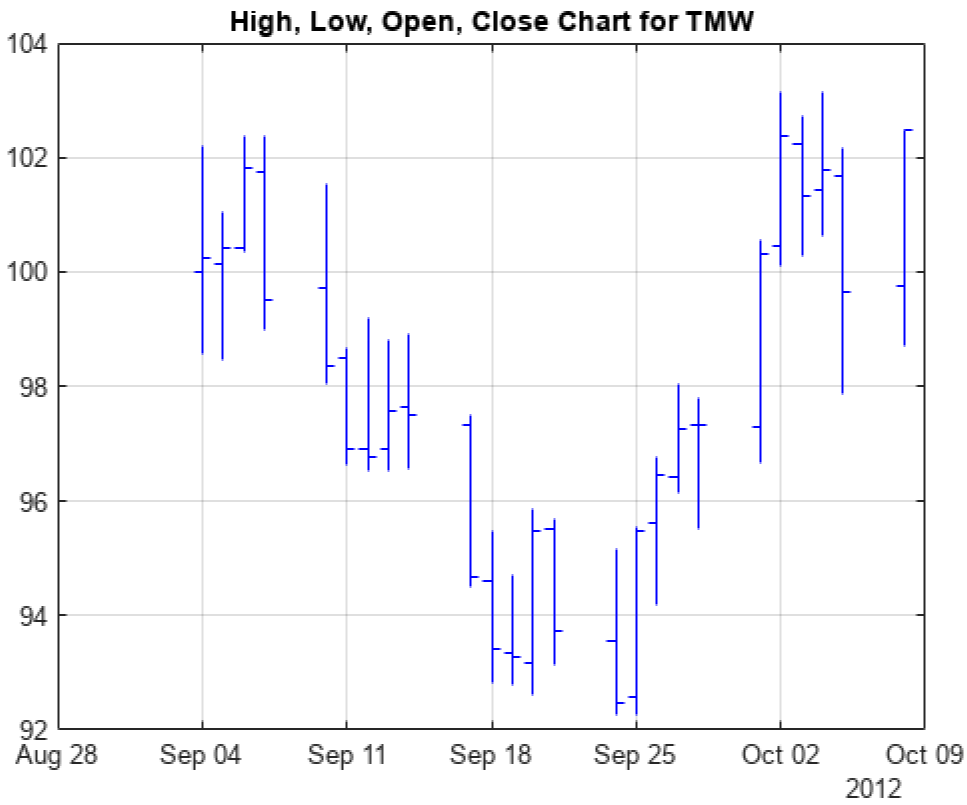
h = highlow(ax, ___) adds an optional argument for ax.

Examples

Generate a Highlow Chart for a Data Series for a Stock

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data for TMW stock. The highlow chart plots the price data using blue lines.

```
load SimulatedStock.mat
range = 1:25;
highlow(TMW(range,:),'b');
title('High, Low, Open, Close Chart for TMW')
```



Input Arguments

`Data` — Data for opening, high, low, and closing prices

matrix | table | timetable

Data for opening, high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-4 matrix of opening, high, low, and closing prices stored in the corresponding columns. Timetables and tables with `M` rows must contain variables named `'Open'`, `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

`Color` — Three element color vector

background color of figure window (default) | color vector `[R G B]` | string

(Optional) Three element color vector, specified as a `[R G B]` color vector or a string specifying the color name. The default color differs depending on the background color of the figure window.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`.

- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
`"red"`	`"r"`	`[1 0 0]`	`"#FF0000"`	🟥
`"green"`	`"g"`	`[0 1 0]`	`"#00FF00"`	🟩
`"blue"`	`"b"`	`[0 0 1]`	`"#0000FF"`	🟦
`"cyan"`	`"c"`	`[0 1 1]`	`"#00FFFF"`	🟦
`"magenta"`	`"m"`	`[1 0 1]`	`"#FF00FF"`	🟪
`"yellow"`	`"y"`	`[1 1 0]`	`"#FFFF00"`	🟨
`"black"`	`"k"`	`[0 0 0]`	`"#000000"`	⬛
`"white"`	`"w"`	`[1 1 1]`	`"#FFFFFF"`	⬜

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
`[0 0.4470 0.7410]`	`"#0072BD"`	🟦
`[0.8500 0.3250 0.0980]`	`"#D95319"`	🟧
`[0.9290 0.6940 0.1250]`	`"#EDB120"`	🟨
`[0.4940 0.1840 0.5560]`	`"#7E2F8E"`	🟪
`[0.4660 0.6740 0.1880]`	`"#77AC30"`	🟩
`[0.3010 0.7450 0.9330]`	`"#4DBEEE"`	🟦
`[0.6350 0.0780 0.1840]`	`"#A2142F"`	🟥

Data Types: `double` | `string`

ax — Valid axis object

current axes (`ax = gca`) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The highlow plot is created in the axes specified by `ax` instead of in the current axes (`ax = gca`). The option `ax` can precede any of the input argument combinations.

Data Types: `object`

Output Arguments

h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

Version History

Introduced before R2006a

R2022b: Support for negative price data

The Data input accepts negative prices.

holdings2weights

Portfolio holdings into weights

Syntax

```
Weights = holdings2weights(Holdings,Prices)
Weights = holdings2weights( ___ ,Budget)
```

Description

`Weights = holdings2weights(Holdings,Prices)` converts portfolio holdings into portfolio weights. The weights must satisfy a budget constraint such that the weights sum to `Budget` for each portfolio.

`Weights = holdings2weights( ___ ,Budget)` converts portfolio holdings into portfolio weights using an optional argument for `Budget`.

Input Arguments

`Holdings` — Holdings value

matrix

Holdings value, returned as an `NPORTS`-by-`NASSETS` matrix that contains the holdings of `NPORTS` portfolios that contain `NASSETS` assets.

Note

- `Holdings` may be negative to indicate a short position, but the overall portfolio weights must satisfy a nonzero budget constraint.
- The weights in each portfolio sum to the `Budget` value (which is `1` if `Budget` is unspecified.)

Data Types: `double`

`Prices` — Asset prices

vector

Asset prices, specified as an `NASSETS` vector.

Data Types: `double`

`Budget` — Budget constraints

`1` (default) | scalar numeric | vector

(Optional) Budget constraints, specified as a scalar or an `NPORTS` vector of nonzero budget constraints.

Data Types: `double`

Output Arguments

`Weights` — Portfolio weights

matrix

Portfolio weights, returned as an `NPORTS`-by-`NASSETS` matrix containing the normalized weights of `NPORTS` portfolios containing `NASSETS` assets.

Data Types: `double`

Version History

Introduced before R2006a

`weights2holdings`

holidays

Holidays and nontrading days

Syntax

```
H = holidays
H = holidays(StartDate,EndDate)
H = holidays( ___ ,AltHolidays)
```

Description

`H = holidays` returns a vector or datetime array corresponding to all holidays and nontrading days.

`H = holidays(StartDate,EndDate)` returns a vector or datetime array corresponding to the holidays and nontrading days between `StartDate` and `EndDate`, inclusive.

`H = holidays( ___ ,AltHolidays)` returns a vector or datetime array corresponding to the alternate list of holidays and nontrading days.

Examples

Determine Holidays for a Given StartDate and EndDate

Create a vector of serial date numbers corresponding to all holidays and nontrading dates between a specified `StartDate` and `EndDate`:

```
H = holidays('jan 1 2001', 'jun 23 2001')
```

```
H = 5×1

      730852
      730866
      730901
      730954
      730999
```

```
datestr(H)
```

```
ans = 5x11 char array
    '01-Jan-2001'
    '15-Jan-2001'
    '19-Feb-2001'
    '13-Apr-2001'
    '28-May-2001'
```

Alternatively, using a datetime array for `StartDate` and `EndDate` returns a datetime array for `H`.

```
H = holidays(datetime(2001,1,1),datetime(2001,6,23))
```

```
H = 5x1 datetime
   01-Jan-2001
   15-Jan-2001
   19-Feb-2001
   13-Apr-2001
   28-May-2001
```

Input Arguments

`StartDate` — Start date

datetime array | string array | date character vector

Start date, specified using a scalar or vector using a datetime array, string array, or date character vectors.

To support existing code, `holidays` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`EndDate` — End date

datetime array | string array | date character vector

End date, specified scalar or vector using a datetime array, string array, or date character vectors.

To support existing code, `holidays` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`AltHolidays` — Alternate list of holidays and nontrading days

datetime array | string array | date character vector

Alternate list of holidays and nontrading days, specified scalar or vector using a datetime array, string array, or date character vectors.

To support existing code, `holidays` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Output Arguments

`H` — Dates corresponding to all holidays and nontrading days

vector | datetime

Dates corresponding to all holidays and nontrading days, returned as a vector or a datetime array of dates.

Note If `StartDate`, `EndDate`, and `AltHolidays` are all either strings or date character vectors, `H` is returned as serial date numbers. Use the function `datestr` to convert serial date numbers to formatted date character vectors. If either `StartDate`, `EndDate`, or `AltHolidays` are datetime arrays, `H` is returned as a datetime array.

More About

holidays

The holidays function is based on a modern five-day workweek.

This function contains all holidays and special nontrading days for the New York Stock Exchange from January 1, 1885 to December 31, 2070.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 2070 include Saturday trading days. To capture these dates, use the function nyseclosures. The results from holidays and nyseclosures are identical if the WorkWeekFormat in nyseclosures is 'Modern'.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although holidays supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

inforatio

Calculate information ratio for one or more assets

Syntax

```
inforatio(Asset,Benchmark)
[Ratio,TE] = inforatio(Asset,Benchmark)
```

Description

`inforatio(Asset,Benchmark)` computes the information ratio for each asset relative to the `Benchmark`.

`[Ratio,TE] = inforatio(Asset,Benchmark)` computes the information ratio and tracking error for each asset relative to the `Benchmark`.

Examples

Compute Information Ratio

This example show how to calculate the information ratio using `inforatio` with example data, where the mean return of the market series is used as the return of the benchmark.

You can use inforatio to compute the information ratio for the given asset return data and the riskless asset return.

```
load FundMarketCash
Returns = tick2ret(TestData);
Benchmark = Returns(:,2);
InfoRatio = inforatio(Returns, Benchmark)
```

```
InfoRatio = 1×3

    0.0432       NaN   -0.0315
```

Since the market series has no risk relative to itself, the information ratio for the second series is undefined (which is represented as `NaN` in MATLAB®.

Use Information Ratio to Compute Tracking Error

This example show how to calculate the tracking error using `inforatio` with example data, where the mean return of the market series is used as the return of the benchmark.

Given an asset or portfolio of assets and a benchmark, the relative standard deviation of returns between the asset or portfolio of assets and the benchmark is called tracking error.

```
load FundMarketCash
Returns = tick2ret(TestData);
Benchmark = Returns(:,2);
[InfoRatio, TrackingError] = inforatio(Returns, Benchmark)
```

```
InfoRatio = 1×3

    0.0432       NaN   -0.0315

TrackingError = 1×3

    0.0187         0    0.0390
```

Tracking error, also know as active risk, measures the volatility of active returns. Tracking error is a useful measure of performance relative to a benchmark since it is in units of asset returns. For example, the tracking error of 1.87% for the fund relative to the market in this example is reasonable for an actively managed, large-cap value fund.

Input Arguments

Asset — Asset returns

matrix

Asset returns, specified as a `NUMSAMPLES x NUMSERIES` matrix with `NUMSAMPLES` observations of asset returns for `NUMSERIES` asset return series.

Data Types: `double`

Benchmark — Returns for a benchmark asset

vector

Returns for a benchmark asset, specified as a `NUMSAMPLES` vector of returns for a benchmark asset. The periodicity must be the same as the periodicity of `Asset`. For example, if `Asset` is monthly data, then `Benchmark` should be monthly returns.

Data Types: `double`

Output Arguments

Ratio — Information ratios

vector

Information ratios, returned as a `1 x NUMSERIES` row vector of information ratios for each series in `Asset`. Any series in `Asset` with a tracking error of `0` has a `NaN` value for its information ratio.

TE — Tracking errors

vector

Tracking errors, returned as a `1 x NUMSERIES` row vector of tracking errors, that is, the standard deviation of `Asset` relative to `Benchmark` returns, for each series.

Note `NaN` values in the data are ignored. If the `Asset` and `Benchmark` series are identical, the information ratio is `NaN` since the tracking error is `0`. The information ratio and the Sharpe ratio of an

Asset versus a riskless Benchmark (a Benchmark with standard deviation of returns equal to 0) are equivalent. This equivalence is not necessarily true if the Benchmark is risky.

Version History

Introduced in R2006b

“Performance Metrics Overview” on page 7-2

irr

Internal rate of return

Syntax

```
Return = irr(CashFlow)
[Return,AllRates] = irr( ___ )
```

Description

`Return = irr(CashFlow)` calculates the internal rate of return for a series of periodic cash flows.

`irr` uses the following conventions:

- If one or more internal rates of returns (warning if multiple) are strictly positive rates, `Return` sets to the minimum.
- If there is no strictly positive rate of returns, but one or multiple (warning if multiple) returns are nonpositive rates, `Return` sets to the maximum.
- If no real-valued rates exist, `Return` sets to `NaN` (no warnings).

`[Return,AllRates] = irr( ___ )` calculates the internal rate of return and a vector of all internal rates for a series of periodic cash flows.

Examples

Find a Single and Multiple Internal Rates of Return

Find the internal rate of return for a simple investment with a unique positive rate of return. The initial investment is $100,000 and the following cash flows represent the yearly income from the investment

Year 1 $10,000

Year 2 $20,000

Year 3 $30,000

Year 4 $40,000

Year 5 $50,000

Calculate the internal rate of return on the investment:

```
Return = irr([-100000 10000 20000 30000 40000 50000])
```

```
Return = 0.1201
```

If the cash flow payments were monthly, then the resulting rate of return is multiplied by 12 for the annual rate of return.

Find Multiple Internal Rates of Return

Find the internal rate of return for multiple rates of return. The project has the following cash flows and a market rate of 10%.

```
CashFlow = [-1000 6000 -10900 5800]
```

```
CashFlow = 1×4

       -1000        6000      -10900        5800
```

```
[Return, AllRates] = irr(CashFlow)
```

```
Return = 1.0000
```

```
AllRates = 3×1

   -0.0488
    1.0000
    2.0488
```

The rates of return in `AllRates` are -4.88%, 100%, and 204.88%. Though some rates are lower and some higher than the market rate, based on the work of Hazen, any rate gives a consistent recommendation on the project. However, you can use a present value analysis in these kinds of situations. To check the present value of the project, use `pvvar`:

```
PV = pvvar(CashFlow,0.10)
```

```
PV = -196.0932
```

The second argument is the 10% market rate. The present value is -196.0932, negative, so the project is undesirable.

Input Arguments

`CashFlow` — Stream of periodic cash flows
vector | matrix

Stream of periodic cash flows, specified as a vector or matrix. The first entry in `CashFlow` is the initial investment. If `CashFlow` is a matrix, `irr` handles each column of `CashFlow` as a separate cash-flow stream.

Data Types: `double`

Output Arguments

`Return` — Internal rate of return
vector

Internal rate of return associated to `CashFlow`, returned as a vector whose entry `j` is an internal rate of return for column `j` in `CashFlow`

`AllRates` — All the internal rates of return
serial date number | matrix

All the internal rates of return associated with CashFlow, returned as a matrix with the same number of columns as CashFlow and one less row. Also, column j in AllRates contains all the rates of return associated to column j in CashFlow (including complex-valued rates).

Version History

Introduced before R2006a

isbusday

True for dates that are business days

Syntax

```
Busday = isbusday(Date)
Busday = isbusday( ___ ,Holiday,Weekend)
```

Description

`Busday = isbusday(Date)` returns logical true (`1`) if `Date` is a business day and logical false (`0`) otherwise.

`Busday = isbusday( ___ ,Holiday,Weekend)`, using optional input arguments, returns logical true (`1`) if `Date` is a business day, and logical false (`0`) otherwise.

Examples

Determine If a Given Date Is a Business Day

Determine if `Date` is a business day.

```
Busday = isbusday('16 jun 2001')
```

```
Busday = logical
   0
```

Determine if a `Date` vector are business days.

```
Date = ['15 feb 2001'; '16 feb 2001'; '17 feb 2001'];
Busday = isbusday(Date)
```

```
Busday = 3x1 logical array

   1
   1
   0
```

Determine if a `Date` vector are business days using a datetime array.

```
Date = [datetime(2001,2,15); datetime(2001,2,16) ; datetime(2001,2,17)];
Busday = isbusday(Date)
```

```
Busday = 3x1 logical array

   1
   1
   0
```

Set June 21, 2003 (a Saturday) as a business day.

```
Weekend = [1 0 0 0 0 0 0];
isbusday(datetime(2003,6,21), [], Weekend)
```

```
ans = logical
   1
```

If the second argument, `Holiday`, is empty (`[ ]`), the default `Holidays` vector (generated with `holidays` and then associated to the NYSE calendar) is used.

Input Arguments

`Date` — Date being checked

datetime array | string array | date character vector

Date being checked, specified as a scalar or a vector using a datetime array, string array, or date character vectors. `Date` can contain multiple dates, but they must all be in the same format. Dates are assumed to be whole date numbers or date stamps with no fractional or time values.

To support existing code, `isbusday` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Holiday` — Holidays and nontrading-day dates

non-trading day vector is determined by the routine `holidays` (default) | datetime array | string array | date character vector

Holidays and nontrading-day dates, specified as a vector using a datetime array, string array, or date character vectors.

All dates in `Holiday` must be the same format: either datetimes, strings, date character vectors, or serial date numbers. The `holidays` function supplies the default vector.

To support existing code, `isbusday` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Weekend` — Weekend days

`[1 0 0 0 0 0 1]` (Saturday and Sunday form the weekend) (default) | vector of length 7, containing `0` and `1`, where `1` indicates weekend days

Weekend days, specified as a vector of length 7, containing `0` and `1`, where `1` indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: `double`

Output Arguments

`Busday` — Logical true if a business day

logical `0` or `1`

Logical true if a business day, returned as a logical true (`1`) if `Date` is a business day and logical false (`0`) otherwise.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `isbusday` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

kagi

Kagi chart

Note kagi is updated to accept data input as a matrix, timetable, or table.

The syntax for kagi has changed. Previously, when using table input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using table input, the new syntax for kagi supports:

- No need for time information. If you want to pass in date information, use timetable input.
- No requirement of specific number of columns. However, you must provide valid column names. kagi must contain a column named ‘price’ (case insensitive).

Syntax

```
kagi(Data)
h = kagi(ax,Data)
```

Description

kagi(Data) plots a Kagi chart from a series of prices.

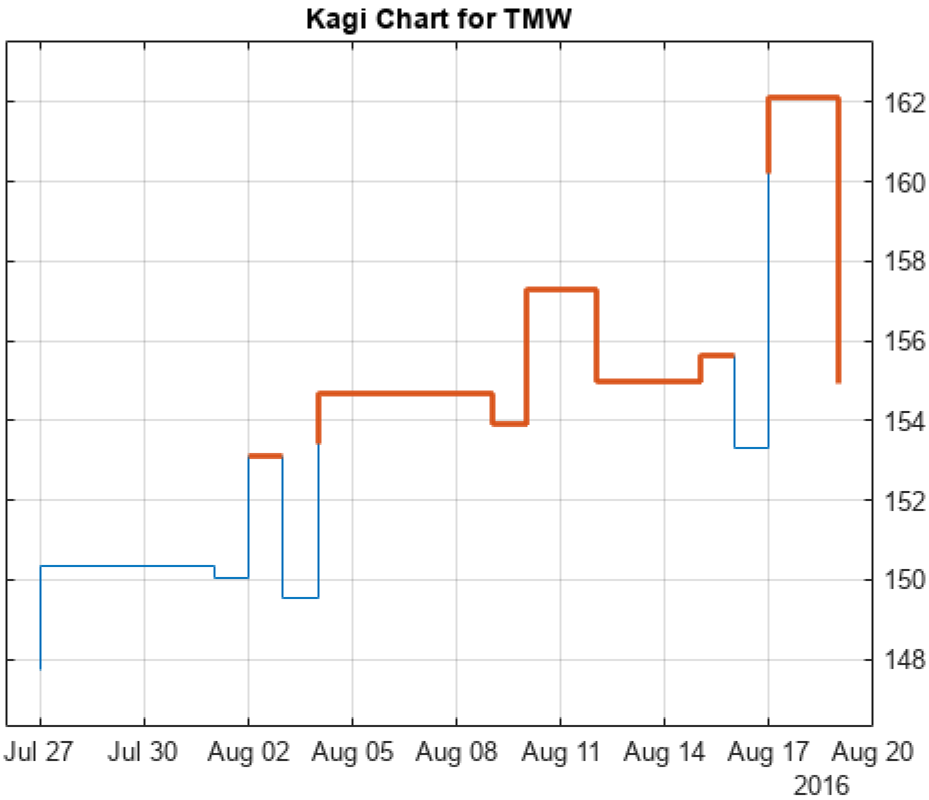
h = kagi(ax,Data) adds an optional argument for ax.

Examples

Generate a Kagi Chart for a Data Series for a Stock

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data for TMW stock. This Kagi chart is for closing prices of the stock TMW for the most recent 21 days. Note that the variable name of asset price is be renamed to 'Price' (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
kagi(TMW(end-20:end,:))
title('Kagi Chart for TMW')
```



Input Arguments

`Data` — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with `M` rows must contain a variable named `'Price'` (case insensitive).

Data Types: `double` | `table` | `timetable`

ax — Valid axis object

current axes (`ax = gca`) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The kagi plot is created in the axes specified by `ax` instead of in the current axes (`ax = gca`). The option `ax` can precede any of the input argument combinations.

Data Types: `object`

Output Arguments

h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

Version History

Introduced in R2008a

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

"Use Timetables in Finance" on page 11-7
"Convert Financial Time Series Objects (fints) to Timetables" on page 11-2

lbusdate

Last business date of month

Syntax

```
Date = lbusdate(Year,Month)
Date = lbusdate( ___ ,Holiday,Weekend,outputType)
```

Description

`Date = lbusdate(Year,Month)` returns the serial date number for the last business date of the given year and month.

`Year` and `Month` can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if `Year` is a `1`-by-`N` vector of integers, then `Month` must be a `1`-by-`N` vector of integers or a single integer. `Date` is then a `1`-by-`N` vector of serial date numbers.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

`Date = lbusdate( ___ ,Holiday,Weekend,outputType)` returns the serial date number for the last business date of the given year and month using optional input arguments. The optional argument `Holiday` specifies nontrading days.

If neither `Holiday` nor `outputType` are specified, `Date` is returned as a serial date number. If `Holiday` is specified, but not `outputType`, then the type of the holiday variable controls the type of date. If `Holiday` is a string or date character vector, then `Date` is returned as a serial date number.

Examples

Determine the Last Business Date of a Given Year and Month

Determine the `Date` using an input argument for `Year` and `Month`.

```
Date = lbusdate(2001, 5)
```

```
Date = 731002
```

```
datestr(Date)
```

```
ans = 
'31-May-2001'
```

Determine the `Date` using the optional input argument for `outputType`.

```
Date = lbusdate(2001, 11,[],[],'datetime')
```

```
Date = datetime
   30-Nov-2001
```

Indicate that Saturday is a business day by appropriately setting the Weekend argument. May 31, 2003, is a Saturday. Use lbusdate to check that this Saturday is actually the last business day of the month.

```
Weekend = [1 0 0 0 0 0 0];
Date = lbusdate(2003, 5, [], Weekend,'datetime')
```

```
Date = datetime
   31-May-2003
```

Input Arguments

Year — Year to determine occurrence of weekday

4-digit integer | vector of 4-digit integers

Year to determine occurrence of weekday, specified as a 4-digit integer or vector of 4-digit integers.

Data Types: double

Month — Month to determine occurrence of weekday

integer with value 1 through 12 | vector of integers with values 1 through 12

Month to determine occurrence of weekday, specified as an integer or vector of integers with values 1 through 12.

Data Types: double

Holiday — Holidays and nontrading-day dates

non-trading day vector is determined by the routine holidays (default) | datetime array | string array | date character vector

Holidays and nontrading-day dates, specified as a vector using a datetime array, string array, or date character vectors.

All dates in Holiday must be the same format: either datetimes, strings, or date character vectors. The holidays function supplies the default vector.

If Holiday is a datetime array, then Date is returned as a datetime array. If outputType is specified, then its value determines the output type of Date. This overrides any influence of Holiday.

To support existing code, lbusdate also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Weekend — Weekend days

[1 0 0 0 0 0 1] (Saturday and Sunday form the weekend) (default) | vector of length 7, containing 0 and 1, where 1 indicates weekend days

Weekend days, specified as a vector of length 7, containing 0 and 1, where 1 indicates weekend days and the first element of this vector corresponds to Sunday.

Data Types: double

outputType — Year to determine days

'datenum' (default) | character vector with values 'datenum' or 'datetime'

A character vector specified as either 'datenum' or 'datetime'. The output Date is in serial date format if 'datenum' is specified, or datetime format if 'datetime' is specified. By default the output Date is in serial date format, or match the format of Holiday, if specified.

Data Types: char

Output Arguments

Date — Date for the last business date of given year and month

datetime | serial date number

Date for the last business date of a given year and month, returned as a datetime or serial date number.

If neither Holiday nor outputType are specified, Date is returned as a serial date number. If Holiday is specified, but not outputType, then the type of the holiday variable controls the type of date:

- If Holiday is a string or date character vector, then Date is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors.
- If Holiday is a datetime array, then Date is returned as a datetime array.

.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although lbusdate supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

lifetableconv

Convert life table series into life tables with forced termination

Syntax

```
[qx,lx,dx] = lifetableconv(x0,lx0)
```

```
[qx,lx,dx] = lifetableconv(x0,y0,y0type)
```

Description

`[qx,lx,dx] = lifetableconv(x0,lx0)` converts life table with ages `x0` and survival counts `lx0` into life tables with termination.

`[qx,lx,dx] = lifetableconv(x0,y0,y0type)` converts life table with ages `x0` and series `y0`, specified by the optional argument `y0type`, into life tables with termination.

Examples

Convert Life Table Series into Life Tables with Forced Termination

Load the life table data file.

```
load us_lifetable_2009
```

Convert life table series into life tables with forced termination.

```
[qx,lx,dx] = lifetableconv(x,lx);
display(qx(1:20,:))
```

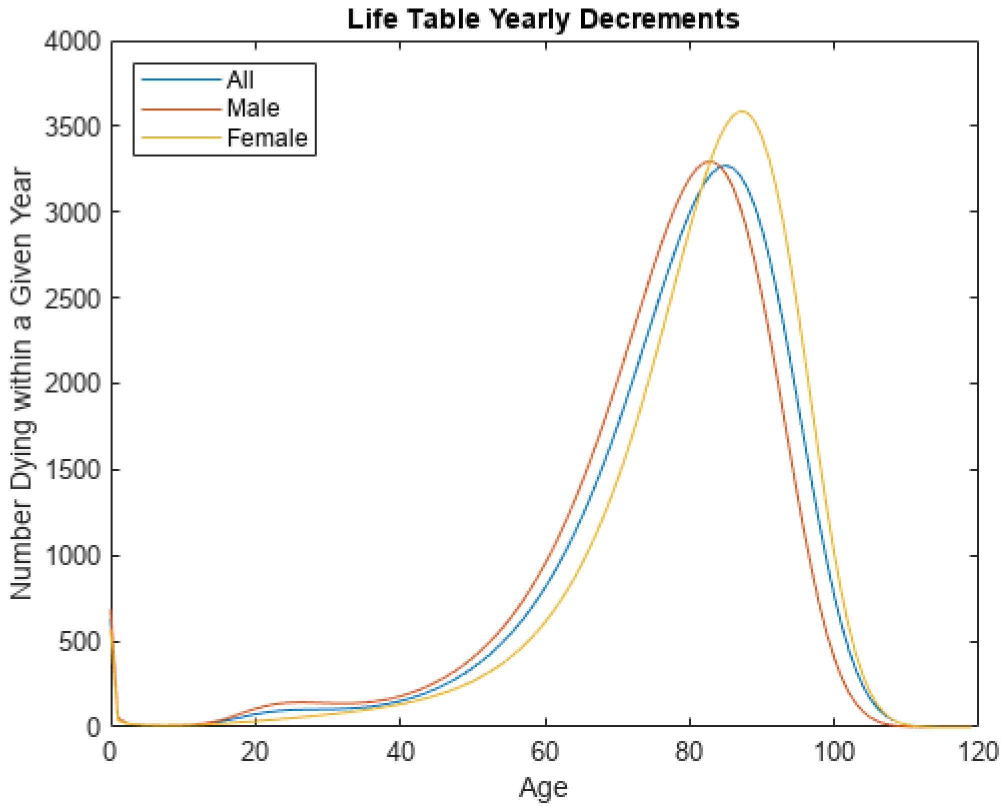
Plot the `dx` series and display the legend. The series `dx` is the number of people who die out of 100,000 alive at birth between age *x* and the next age in the series.

```
plot((0:119),dx(1:end-1,:));
legend(series, 'location', 'northwest');
title('\bfLife Table Yearly Decrements');
xlabel('Age');
ylabel('Number Dying within a Given Year');
```



Input Arguments

`x0` — Increasing ages for raw data

vector of nonnegative integer values

Increasing ages for raw data, specified as nonnegative integer values in an `N0` vector.

The vector of ages *x* must contain nonnegative integer values. If the input series is the discrete survival function `lx`, then the starting age need only be nonnegative. Otherwise, the starting age must be `0`.

Data Types: `double`

`lx0` — Collection of `num` standardized survivor series

matrix

Collection of `num` standardized survivor series, specified as an `N0`-by-`num` matrix. The input `lx0` series is the number of people alive at age *x*, given 100,000 alive at birth. Values of `0` or `NaN` in the input table `lx0` are ignored.

Data Types: `double`

`y0` — Collection of `num` life table series to be converted

matrix

Collection of num life table series to be converted, specified as an N0-by-num matrix. The default y0 series is lx0.

Data Types: double

y0type — Type of mortality series for input y0 with default 'lx'
'lx' (default) | character vector with values 'qx', 'lx', 'dx'

(Optional) Type of mortality series for input y0, specified as a character vector with one of the following values:

- 'qx' — Input is a table of discrete hazards (qx).
- 'lx' — Input is a table of discrete survival counts (lx).
- 'dx' — Input is a table of discrete decrements (dx).

Whereas the output series have forced termination, the input series (y0) can have one of several types of termination:

- Natural termination runs out to the last person so that lx goes to 0, qx goes to 1, and dx goes to 0. For more information, see "Natural Termination" on page 15-1059.
- Truncated termination stops at a terminal age so that lx is positive, qx is less than 1, and dx is positive. Any ages after the terminal age are NaN values. For more information, see "Truncated Termination" on page 15-1060.

Data Types: char

Output Arguments

qx — Discrete hazard function
matrix

Discrete hazard function, returned as an N0-by-num matrix with forced termination. For more information, see "Forced Termination" on page 15-1059.

The series qx is the conditional probability that a person at age x will die between age *x* and the next age in the series.

lx — Discrete survival function
matrix

Discrete survival function, returned as an N0-by-num matrix with forced termination. For more information, see "Forced Termination" on page 15-1059.

The series lx is the number of people alive at age *x*, given 100,000 alive at birth.

dx — Discrete decrements function
matrix

Discrete decrements function, returned as an N0-by-num matrix with forced termination. For more information, see "Forced Termination" on page 15-1059.

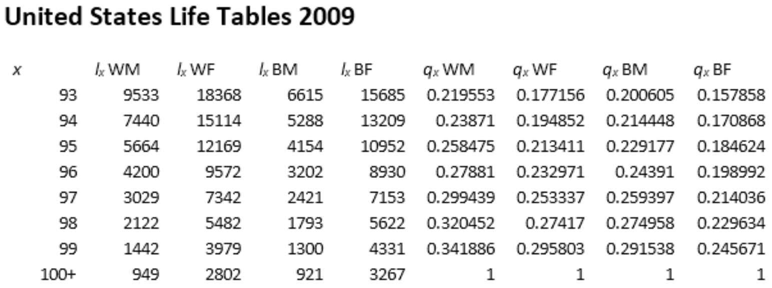
The series dx is the number of people who die out of 100,000 alive at birth, between age *x* and the next age in the series.

More About

Forced Termination

Most modern life tables have “forced” termination. Forced termination means that the last row of the life table applies for all persons with ages on or after the last age in the life table.

This sample illustrates forced termination.



United States Life Tables 2009

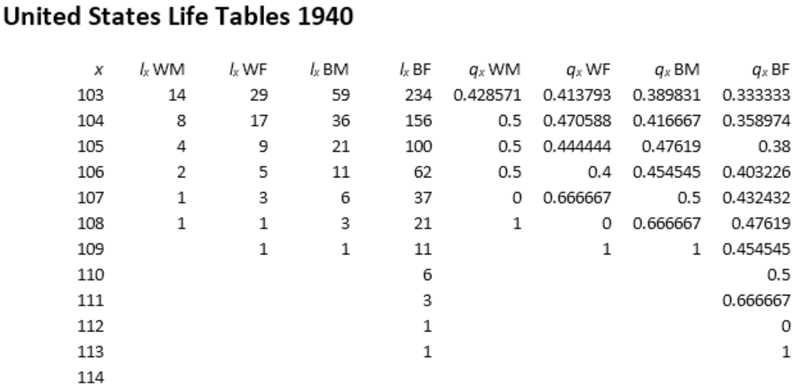
x	l_x WM	l_x WF	l_x BM	l_x BF	q_x WM	q_x WF	q_x BM	q_x BF
93	9533	18368	6615	15685	0.219553	0.177156	0.200605	0.157858
94	7440	15114	5288	13209	0.23871	0.194852	0.214448	0.170868
95	5664	12169	4154	10952	0.258475	0.213411	0.229177	0.184624
96	4200	9572	3202	8930	0.27881	0.232971	0.24391	0.198992
97	3029	7342	2421	7153	0.299439	0.253337	0.259397	0.214036
98	2122	5482	1793	5622	0.320452	0.27417	0.274958	0.229634
99	1442	3979	1300	4331	0.341886	0.295803	0.291538	0.245671
100+	949	2802	921	3267	1	1	1	1

In this case, the last row of the life table applies for all persons aged 100 or older. Specifically, q_x probabilities are ${}_1q_x$ for ages less than 100 and, technically, ${}_\infty q_x$ for age 100.

Forced termination has terminal age values that apply to all ages after the terminal age so that `lx` is positive, `qx` is `1`, and `dx` is positive. Ages after the terminal age are `NaN` values, although `lx` and `dx` can be `0` and `qx` can be `1` for input series. Forced termination is triggered by a naturally terminating series, the last age in a truncated series, or the first `NaN` value in a series.

Natural Termination

Before 1970, life tables were often published with data that included all ages for which persons associated with a given series were still alive. Tables in this form have "natural" termination. In natural termination, the last row of the life table for each series counts the deaths or probabilities of deaths of the last remaining person at the corresponding age. Tables in this form can be problematic due to the granularity of the data and the fact that groups of series can terminate at distinct ages. Natural termination is illustrated in the following sample of the last few years of a life table.



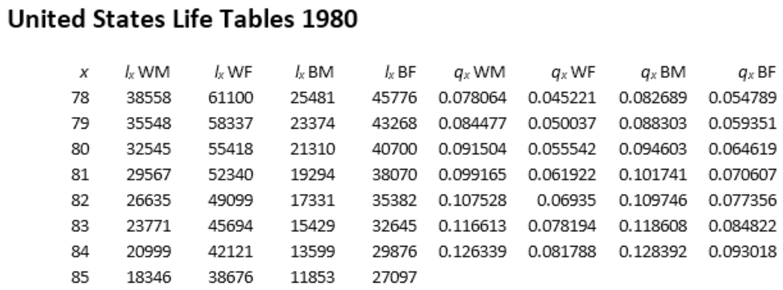
United States Life Tables 1940

x	l_x WM	l_x WF	l_x BM	l_x BF	q_x WM	q_x WF	q_x BM	q_x BF
103	14	29	59	234	0.428571	0.413793	0.389831	0.333333
104	8	17	36	156	0.5	0.470588	0.416667	0.358974
105	4	9	21	100	0.5	0.444444	0.47619	0.38
106	2	5	11	62	0.5	0.4	0.454545	0.403226
107	1	3	6	37	0	0.666667	0.5	0.432432
108	1	1	3	21	1	0	0.666667	0.47619
109		1	1	11		1	1	0.454545
110				6				0.5
111				3				0.666667
112				1				0
113				1				1
114								

This form for life tables poses a number of issues that go beyond the obvious statistical issues. First, the l_x table on the left terminates at ages 108, 109, 109, and 113 for the four series in the table. Technically, the numbers after these ages are `0`, but can also be `NaN` values because no person is alive after these terminating ages. Second, the probabilities q_x on the right terminate with fluctuating probabilities that go from `0` to `1` in some cases. In this case, however, all probabilities are ${}_1q_x$ probabilities (unlike the forced termination probabilities). You can argue that the probabilities after the ages of termination can be `1` (anyone alive at this age is expected to die in the next year), `0` (the age lies outside the support of the probability distribution), or `NaN` values.

Truncated Termination

Truncated termination occurs with truncation of life tables at an arbitrary age. For example, from 1970–1990, United States life tables truncated at age 85. This format is problematic because life table probabilities must either terminate with probability `1` (forced termination) or discard data that exceeds the terminating age. This sample of the last few years of a life table illustrates truncated termination. The raw data for this table is the l_x series. The q_x series is derived from this series.



United States Life Tables 1980

x	l_x WM	l_x WF	l_x BM	l_x BF	q_x WM	q_x WF	q_x BM	q_x BF
78	38558	61100	25481	45776	0.078064	0.045221	0.082689	0.054789
79	35548	58337	23374	43268	0.084477	0.050037	0.088303	0.059351
80	32545	55418	21310	40700	0.091504	0.055542	0.094603	0.064619
81	29567	52340	19294	38070	0.099165	0.061922	0.101741	0.070607
82	26635	49099	17331	35382	0.107528	0.06935	0.109746	0.077356
83	23771	45694	15429	32645	0.116613	0.078194	0.118608	0.084822
84	20999	42121	13599	29876	0.126339	0.081788	0.128392	0.093018
85	18346	38676	11853	27097				

This life table format poses problems for termination because, for example, over 27% of the population for the fourth l_x series is still alive at age 85. To claim that the probability of dying for all ages after age 85 is 100% might be true but is uninformative. Notwithstanding the statistical issues, however, tables in this form are completed by forced termination.

Version History

Introduced in R2015a

lifetablefit

Calibrate life table from survival data with parametric models

Syntax

```
[a,elx] = lifetablefit(x,lx)
[a,elx] = lifetablefit(___,lifemodel,objtype,interpmethod,a0)
```

Description

`[a,elx] = lifetablefit(x,lx)` calibrates a life table, `x`, from survival data, `lx`, using parametric models.

`[a,elx] = lifetablefit(___,lifemodel,objtype,interpmethod,a0)` calibrates a life table, `x`, from survival data, `lx`, using parametric models using optional arguments for `lifemodel`, `objtype`, `interpmethod`, and `a0`.

Examples

Calibrate Life Table from Survival Data Using a Heligman-Pollard Parametric Model

Load the life table data file.

```
load us_lifetable_2009
```

Calibrate the life table from survival data using the default `heligman-pollard` parametric model.

```
[a,elx] = lifetablefit(x,lx);
display(a)
```

```

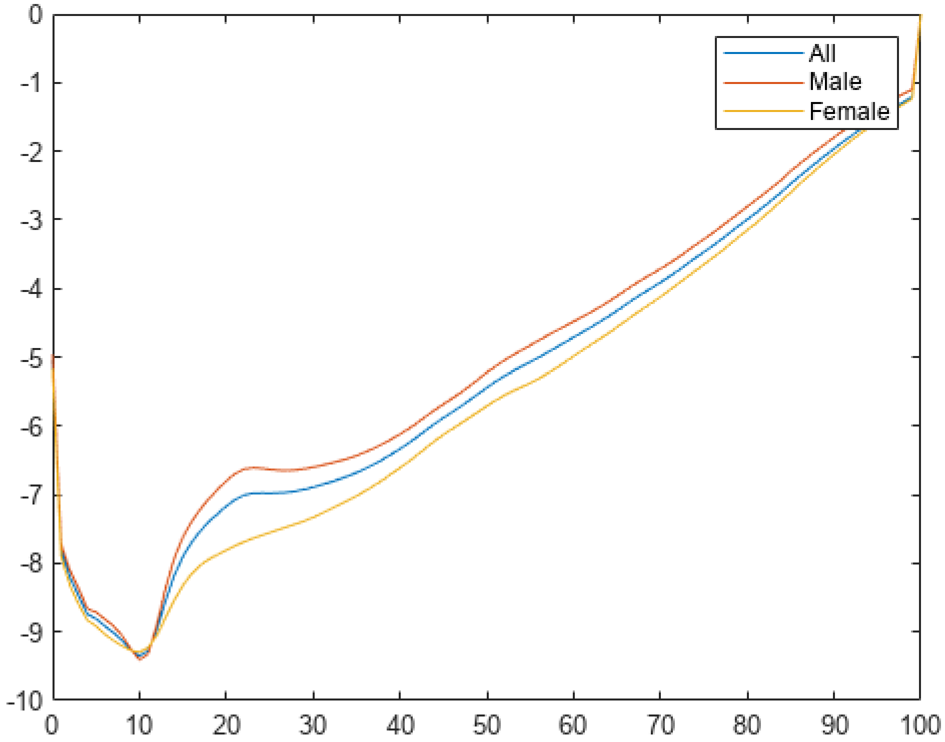
Plot the qx series and display the legend. The series qx is the conditional probability that a person at age *x* will die between age *x* and the next age in the series

```
plot(x,log(qx))
legend(series)
```



Input Arguments

x — Increasing ages for raw data
vector of nonnegative integers

Increasing ages for raw data, specified as a `N` vector for nonnegative integers.

Data Types: `double`

`lx` — Collection of `num` discrete survival counts

matrix

Collection of `num` discrete survival counts, specified as an `N`-by-`num` matrix. The input `lx` series is the number of people alive at age *x*, given 100,000 alive at birth. Values of `0` or `NaN` in the input table `lx` are ignored.

Data Types: `double`

`lifemodel` — Parametric mortality model type

`'heligman-pollard'` (default) | character vector with values `'heligman-pollard'`, `'heligman-pollard-2''heligman-pollard-3'`, `'gompertz'`, `'makeham'`, `'siler'`

(Optional) Parametric mortality model type, specified as a character vector with one of the following values:

- `'heligman-pollard'` — Eight-parameter Heligman-Pollard model (version 1), specified in terms of the discrete hazard function:

  $$\frac{q(x)}{1-q(x)} = A^{(x+B)^C} + D\exp(-E(\log\frac{x}{F})^2) + GH^X$$

  for ages $x \geq 0$, with parameters $A, B, C, D, E, F, G, H \geq 0$.
- `'heligman-pollard-2'` — Eight-parameter Heligman-Pollard model (version 2), specified in terms of the discrete hazard function:

  $$\frac{q(x)}{1-q(x)} = A^{(x+B)^C} + D\exp(-E(\log\frac{x}{F})^2) + \frac{GH^X}{1+GH^X}$$

  for ages $x \geq 0$, with parameters $A, B, C, D, E, F, G, H \geq 0$.
- `'heligman-pollard-3'` — Eight-parameter Heligman-Pollard model (version 3), specified in terms of the discrete hazard function:

  $$q(x) = A^{(x+B)^C} + D\exp(-E(\log\frac{x}{F})^2) + GH^X$$

  for ages $x \geq 0$, with parameters $A, B, C, D, E, F, G, H \geq 0$.
- `'gompertz'` — Two-parameter Gompertz model, specified in terms of the continuous hazard function:

  ```
  h(x) = A exp(Bx)
  ```

  for ages $x \geq 0$, with parameters $A, B \geq 0$.
- `'makeham'` — Three-parameter Gompertz-Makeham model, specified in terms of the continuous hazard function:

  ```
  h(x) = A exp(Bx) + C
  ```

  for ages $x \geq 0$, with parameters$A, B, C \geq 0$.
- `'siler'` — Five-parameter Siler model, specified in terms of the continuous hazard function:

```
h(x) = A exp(Bx) + C + D exp(-Ex)
```

for ages $x \geq 0$, with parameters $A, B, C, D, E \geq 0$.

Data Types: `char`

`objtype` — Objective for nonlinear least-squares estimation
`'ratio'` (default) | character vector with values `'ratio'` `'logratio'`

(Optional) Objective for nonlinear least-squares estimation, specified as a character vector with the following values:

- `'ratio'` — Given raw data q_x and model estimates $\widehat{q}_x$ for $x = 1, \ldots, N$, the first objective (which is the preferred objective) has the form

  $$\Phi = \sum_{x=1}^{N} \left(1 - \frac{\widehat{q}_x}{q_x}\right)^2$$
- `'logratio'` — Given raw data q_x and model estimates $\widehat{q}_x$ for $x = 1, \ldots, N$, the second objective has the form

  $$\Phi = \sum_{x=1}^{N} \left(\log(\widehat{q}_x) - \log(q_x)\right)^2$$

Data Types: `char`

`interpmethod` — Interpolation method to use for abridged life table inputs
`'cubic'` (default) | character vector with values `'cubic'`, `'linear'`, `'none'`

(Optional) Interpolation method to use for abridged life table inputs, specified as a character vector with the following values:

- `'cubic'` — Cubic interpolation that uses `'pchip'` method in `interp1`.
- `'linear'` — Linear interpolation.
- `'none'` — No interpolation.

Note If the ages in `x` are not consecutive years and interpolation is set to `'none'`, then the estimates for the parameters are suitable only for the age vector `x`.

If you use the parameter estimates to compute life table values for arbitrary years, interpolate using the default `'cubic'` method.

Interpolation with abridged life tables forms internal interpolated full life tables, which usually improves model fits.

Data Types: `char`

`a0` — Initial parameter estimate to be applied to all series
vector

(Optional) Initial parameter estimate to be applied to all series, specified as a `numparam` vector. This vector must conform to the number of parameters in the model specified using the `lifemodel` argument.

Data Types: `double`

Output Arguments

`a` — Parameter estimates for each `num` series

matrix

Parameter estimates for each `num` series, returned as a `numparam`-by-`num` matrix.

`elx` — Estimated collection of `num` standardized survivor series

matrix

Estimated collection of `num` standardized survivor series, returned as an `N`-by-`num` matrix. The `elx` output series is the number of people alive at age *x*, given 100,000 alive at birth. Values of `0` or `NaN` in the input table `lx` are ignored.

Version History

Introduced in R2015a

lifetablegen

Generate life table series from calibrated mortality model

Syntax

```
[qx,lx,dx] = lifetablegen(x,a)
[qx,lx,dx] = lifetablegen(x,a,lifemodel)
```

Description

`[qx,lx,dx] = lifetablegen(x,a)` generates a life table series from a calibrated mortality model.

`[qx,lx,dx] = lifetablegen(x,a,lifemodel)` generates a life table series from a calibrated mortality model using the optional argument for `lifemodel`.

Examples

Generate Life Table Series from a Calibrated Mortality Model for Heligman-Pollard

Load the life table data file.

```
load us_lifetable_2009
```

Calibrate the life table from survival data using the default `heligman-pollard` parametric model.

```
a = lifetablefit(x, lx)
```

```
a = 8×3

    0.0005    0.0006    0.0004
    0.0592    0.0819    0.0192
    0.1452    0.1626    0.1048

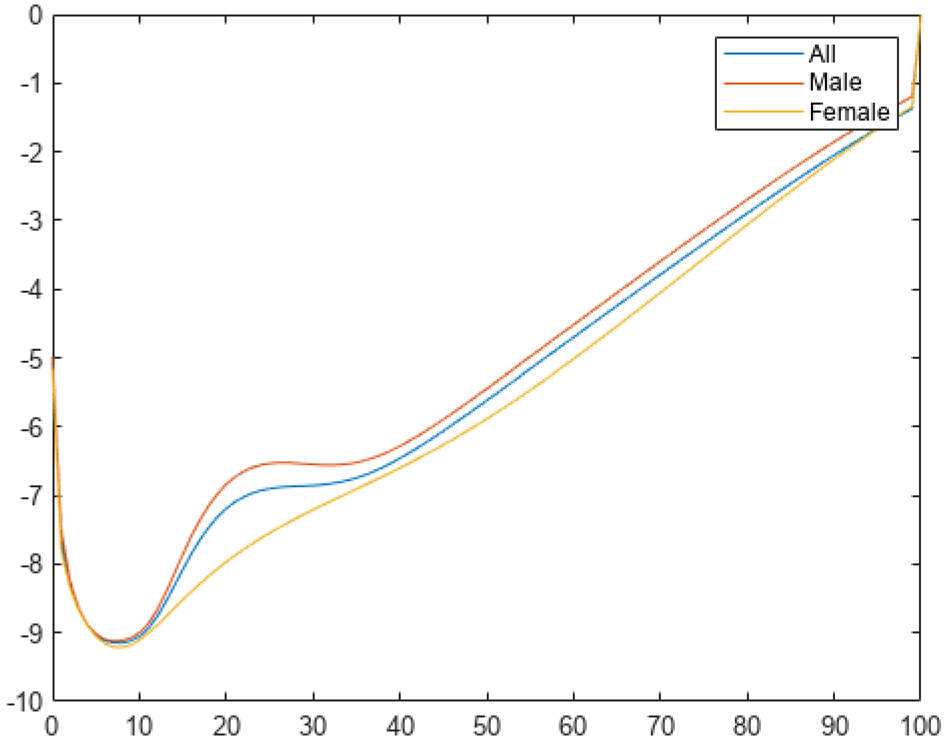
    0.0007    0.0009    0.0003
```

Plot the qx series and display the legend. The series qx is the conditional probability that a person at age *x* will die between age *x* and the next age in the series.

```
plot(x,log(qx))
legend(series)
```



Prepare Life Table Data Using the qx Series and Generate the qx Life Table

Load the life table data file.

```
load us_lifetable_2009
```

Convert the life table series into life tables with forced termination.

```
[~, lx] = lifetableconv(x, qx, 'qx');
```

Calibrate the life table from survival data using the default `heligman-pollard` parametric model.

```
a = lifetablefit(x, lx)
```

```
a = 8×3

    0.0005    0.0006    0.0004
    0.0592    0.0819    0.0192

    0.0001    0.0001    0.0001
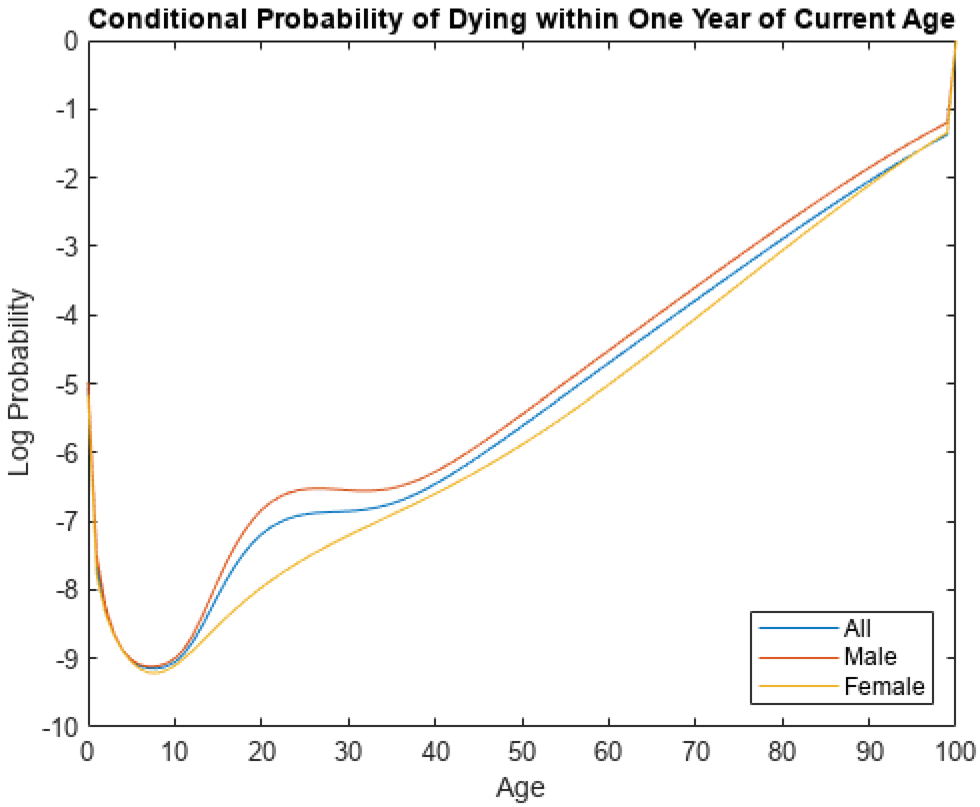
      ⋮
```

Plot the `qx` series and display the legend. The series `qx` is the conditional probability that a person at age *x* will die between age *x* and the next age in the series.

```
plot((0:100), log(qx));
legend(series, 'location', 'southeast');
title('Conditional Probability of Dying within One Year of Current Age');
xlabel('Age');
ylabel('Log Probability');
```



Input Arguments

x — Increasing ages for raw data

vector of nonnegative integers

Increasing ages for raw data, specified as a `N` vector of nonnegative integer values. The ages must start at `0` (birth).

Data Types: `double`

a — Model parameters for `num` models

matrix

Model parameters for `num` models, specified as a `numparam`-by-`num` matrix, where the number of parameters (`numparam`) depends on the model specified using the `lifemodel` argument.

Data Types: `double`

`lifemodel` — Parametric mortality model type

`'heligman-pollard'` (default) | character vector with values `'heligman-pollard'`, `'heligman-pollard-2'``'heligman-pollard-3'`, `'gompertz'`, `'makeham'`, `'siler'`

(Optional) Parametric mortality model type, specified as a character vector with one of the following values:

- `'heligman-pollard'` — Eight-parameter Heligman-Pollard model (version 1), specified in terms of the discrete hazard function:

  $$\frac{q(x)}{1 - q(x)} = A^{(x + B)^C} + D\exp(- E(\log\frac{x}{F})^2) + GH^X$$

  for ages $x \geq$ `0`, with parameters $A, B, C, D, E, F, G, H \geq$ `0`.
- `'heligman-pollard-2'` — Eight-parameter Heligman-Pollard model (version 2), specified in terms of the discrete hazard function:

  $$\frac{q(x)}{1 - q(x)} = A^{(x + B)^C} + D\exp(- E(\log\frac{x}{F})^2) + \frac{GH^X}{1 + GH^X}$$

  for ages $x \geq$ `0`, with parameters $A, B, C, D, E, F, G, H \geq$ `0`.
- `'heligman-pollard-3'` — Eight-parameter Heligman-Pollard model (version 3), specified in terms of the discrete hazard function:

  $$q(x) = A^{(x + B)^C} + D\exp(- E(\log\frac{x}{F})^2) + GH^X$$

  for ages $x \geq$ `0`, with parameters $A, B, C, D, E, F, G, H \geq$ `0`.
- `'gompertz'` — Two-parameter Gompertz model, specified in terms of the continuous hazard function:

  ```
  h(x) = A exp(Bx)
  ```

  for ages $x \geq$ `0`, with parameters $A, B \geq$ `0`.
- `'makeham'` — Three-parameter Gompertz-Makeham model, specified in terms of the continuous hazard function:

  ```
  h(x) = A exp(Bx) + C
  ```

  for ages $x \geq$ `0`, with parameters$A, B, C \geq$ `0`.
- `'siler'` — Five-parameter Siler model, specified in terms of the continuous hazard function:

  ```
  h(x) = A exp(Bx) + C + D exp(-Ex)
  ```

  for ages $x \geq$ `0`, with parameters $A, B, C, D, E \geq$ `0`.

Data Types: `char`

Output Arguments

qx — Conditional probabilities of dying for N ages and num series

matrix

Conditional probabilities of dying for `N` ages and `num` series, returned as an `N`-by-`num` matrix. The series `qx` is the conditional probability that a person at age *x* will die between age *x* and the next age in the series. For the last age, `qx` represents probabilities or counts for all ages after the last age.

The last row of the `N`-by-`num` output for `qx` is the values for all ages on or after the last age in *x* (due to “Forced Termination” on page 15-1071). Therefore, the last row of `qx` contains `1` (100% probability of dying on or after the last age).

`lx` — Survival counts for `N` ages and `num` series

matrix

Survival counts for `N` ages and `num` series, returned as an `N`-by-`num` matrix. The series `lx` is the number of people alive at age *x*, given 100,000 alive at birth.

`dx` — Decrement counts for `N` ages and `num` series

matrix

Decrement counts for `N` ages and `num` series, returned as an `N`-by-`num` matrix. The series `dx` is the number of people out of 100,000 alive at birth who die between age *x* and the next age in the series. For the last age, `dx` represent probabilities or counts for all ages after the last age.

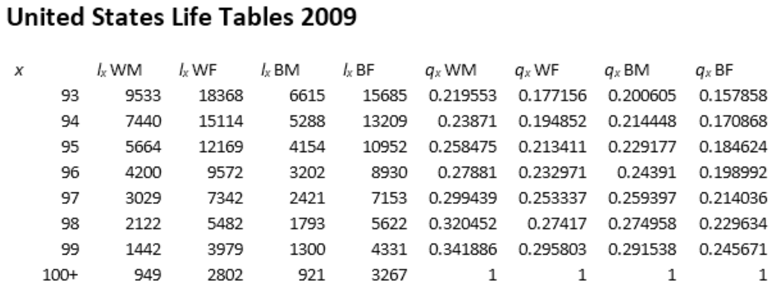
The last row of the `N`-by-`num` output for `dx` are values for all ages on or after the last age in *x* (due to "Forced Termination" on page 15-1071). Therefore, the last row of `dx` contains the remaining count of 100,000 people alive at birth who have not died by the last age.

More About

Forced Termination

Most modern life tables have "forced" termination. Forced termination means that the last row of the life table applies for all persons with ages on or after the last age in the life table.

This sample illustrates forced termination.



United States Life Tables 2009

x	l_x WM	l_x WF	l_x BM	l_x BF	q_x WM	q_x WF	q_x BM	q_x BF
93	9533	18368	6615	15685	0.219553	0.177156	0.200605	0.157858
94	7440	15114	5288	13209	0.23871	0.194852	0.214448	0.170868
95	5664	12169	4154	10952	0.258475	0.213411	0.229177	0.184624
96	4200	9572	3202	8930	0.27881	0.232971	0.24391	0.198992
97	3029	7342	2421	7153	0.299439	0.253337	0.259397	0.214036
98	2122	5482	1793	5622	0.320452	0.27417	0.274958	0.229634
99	1442	3979	1300	4331	0.341886	0.295803	0.291538	0.245671
100+	949	2802	921	3267	1	1	1	1

In this case, the last row of the life table applies for all persons aged 100 or older. Specifically, q_x probabilities are ${}_1q_x$ for ages less than 100 and, technically, ${}_\infty q_x$ for age 100.

Forced termination has terminal age values that apply to all ages after the terminal age so that `lx` is positive, `qx` is `1`, and `dx` is positive. Ages after the terminal age are `NaN` values, although `lx` and `dx` can be `0` and `qx` can be `1` for input series. Forced termination is triggered by a naturally terminating series, the last age in a truncated series, or the first `NaN` value in a series.

Version History

Introduced in R2015a

linebreak

Line break chart

Note `linebreak` is updated to accept data input as a matrix, `timetable`, or `table`.

The syntax for `linebreak` has changed. Previously, when using table input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using table input, the new syntax for `linebreak` supports:

- No need for time information. If you want to pass in date information, use timetable input.
- No requirement of specific number of columns. However, you must provide valid column names. `linebreak` must contain a column named `‘price’` (case insensitive).

Syntax

```
linebreak(Data)
h = linebreak(ax,Data)
```

Description

`linebreak(Data)` plots the asset data, in a line break chart.

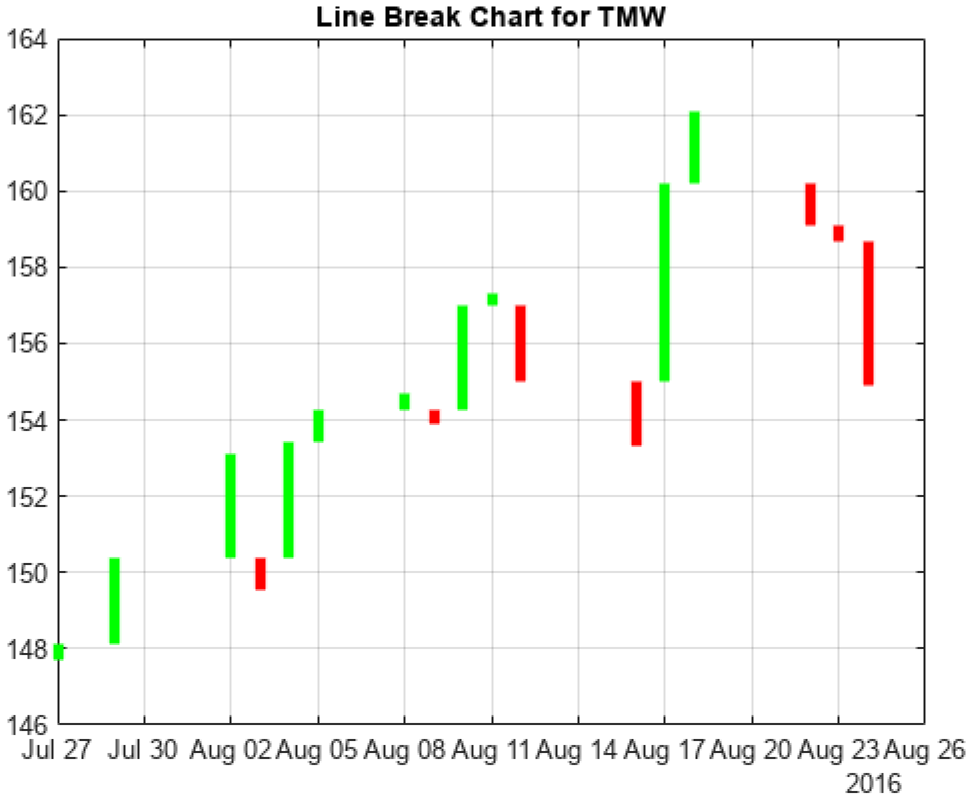
`h = linebreak(ax,Data)` adds an optional argument for `ax`.

Examples

Generate a Line Break Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock. This Linebreak chart is for closing prices of the stock TMW for the most recent 21 days. Note that the variable name of asset price is be renamed to `'Price'` (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
linebreak(TMW(end-20:end,:))
title('Line Break Chart for TMW')
```



Input Arguments

`Data` — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with `M` rows must contain a variable named `'Price'` (case insensitive).

Data Types: `double` | `table` | `timetable`

ax — Valid axis object

current axes (`ax = gca`) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The linebreak plot is created in the axes specified by `ax` instead of in the current axes (`ax = gca`). The option `ax` can precede any of the input argument combinations.

Data Types: `object`

Output Arguments

h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

Version History

Introduced in R2008a

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

`timetable` | `table` | `movavg` | `pointfig` | `highlow` | `kagi` | `priceandvol` | `renko` | `volarea` | `candle`

Topics

"Use Timetables in Finance" on page 11-7
"Convert Financial Time Series Objects (fints) to Timetables" on page 11-2

llow

Lowest low

Syntax

```
values = llow(Data)
values = llow( ___ ,Name,Value)
```

Description

`values = llow(Data)` generates a vector of lowest low values from the series of low prices for the past *n* periods.

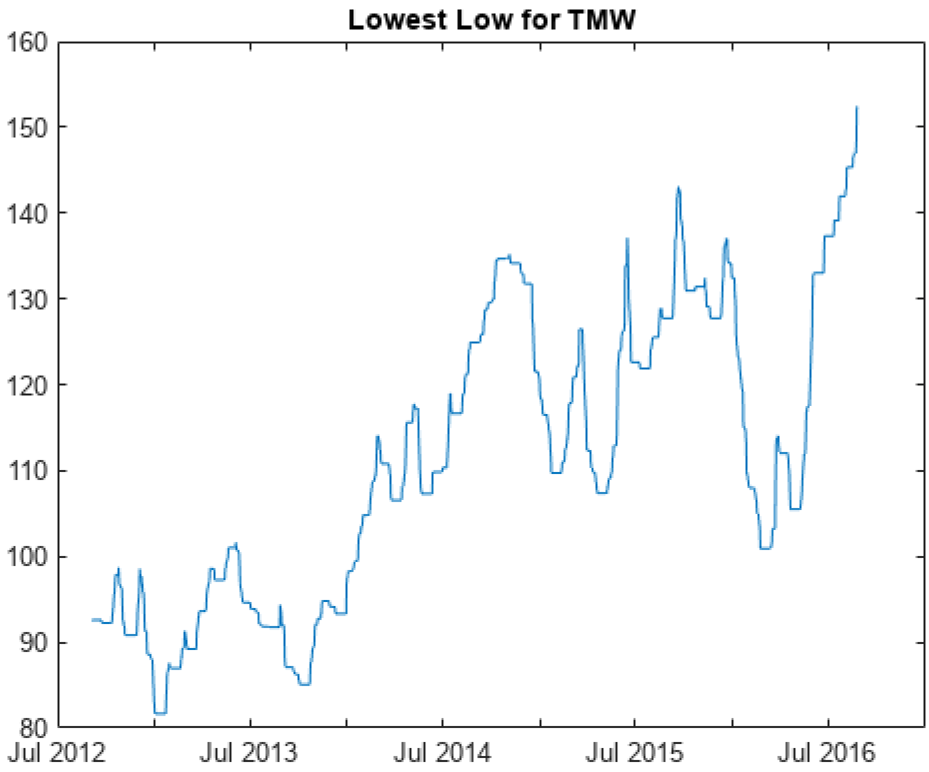
`values = llow( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Lowest Low for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
values = llow(TMW);
plot(values.Time,values.LowestLow)
title('Lowest Low for TMW')
```



Input Arguments

`Data` — Data for low prices

matrix | table | timetable

Data for low prices, specified as a matrix, table, or timetable. Timetables and tables with `M` rows must contain a variable named `'Low'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `values = llow(TMW_LOW,'NumPeriods',10)`

`NumPeriods` — Moving window for the lowest low calculation

`14` (default) | positive integer

Moving window for the lowest low calculation, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`values` — Lowest low series
matrix | table | timetable

Lowest low series, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument
Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

lpm

Compute sample lower partial moments of data

Syntax

```
lpm(Data)
lpm(Data,MAR,Order)
Moment = lpm(Data,MAR,Order)
```

Description

`lpm(Data)` computes lower partial moments for asset returns `Data` relative to a default value for `MAR` for each asset in a `NUMORDERS x NUMSERIES` matrix and a default value for `Order`.

`lpm(Data,MAR,Order)` computes lower partial moments for asset returns `Data` relative to `MAR` for each asset in a `NUMORDERS x NUMSERIES` matrix.

`Moment = lpm(Data,MAR,Order)` computes lower partial moments for asset returns `Data` relative to `MAR` for each asset in a `NUMORDERS x NUMSERIES` matrix `Moment`.

Examples

Compute Lower Partial Moments

This example shows how to compute the zero-order, first-order, and second-order lower partial moments for the three time series, where the mean of the third time series is used to compute `MAR` (minimum acceptable return) with the so-called risk-free rate.

```
load FundMarketCash
Returns = tick2ret(TestData);
Assets
```

```
Assets = 1x3 cell
    {'Fund'}    {'Market'}    {'Cash'}
```

```
MAR = mean(Returns(:,3))
```

```
MAR = 0.0017
```

```
LPM = lpm(Returns, MAR, [0 1 2])
```

```
LPM = 3×3

    0.4333    0.4167    0.6167
    0.0075    0.0140    0.0004
    0.0003    0.0008    0.0000
```

The first row of LPM contains zero-order lower partial moments of the three series. The fund and market index fall below MAR about 40% of the time and cash returns fall below its own mean about 60% of the time.

The second row contains first-order lower partial moments of the three series. The fund and market have large average shortfall returns relative to MAR by 75 and 140 basis points per month. On the other hand, cash underperforms MAR by about only four basis points per month on the downside.

The third row contains second-order lower partial moments of the three series. The square root of these quantities provides an idea of the dispersion of returns that fall below the MAR. The market index has a much larger variation on the downside when compared to the fund.

Input Arguments

Data — Asset returns

matrix

Asset returns, specified as a NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations of NUMSERIES asset returns.

Data Types: double

MAR — Minimum acceptable return

0 (default) | numeric

(Optional) Minimum acceptable return, specified as a scalar numeric. MAR is a cutoff level of return such that all returns above MAR contribute nothing to the lower partial moment.

Data Types: double

Order — Moment orders

0 (default) | scalar numeric | vector

(Optional) Moment orders, specified as a either a scalar or a NUMORDERS vector of nonnegative integer moment orders. If no order specified, the default Order = 0, which is the shortfall probability. Although the lpm function works for noninteger orders and, in some cases, for negative orders, this falls outside customary usage.

Data Types: double

Output Arguments

Moment — Lower partial moments

matrix

Lower partial moments, returned as a NUMORDERS x NUMSERIES matrix of lower partial moments with NUMORDERS Orders and NUMSERIES series, that is, each row contains lower partial moments for a given order.

Note To compute upper partial moments, reverse the signs of both Data and MAR (do not reverse the sign of the output). The lpm function computes sample lower partial moments from data. To compute expected lower partial moments for multivariate normal asset returns with a specified mean and covariance, use `elpm`. With `lpm`, you can compute various investment ratios such as `Omega` ratio, `Sortino` ratio, and `Upside Potential` ratio, where:

- `Omega = lpm(-Data, -MAR, 1) / lpm(Data, MAR, 1)`
- `Sortino = (mean(Data) - MAR) / sqrt(lpm(Data, MAR, 2))`
- `Upside = lpm(-Data, -MAR, 1) / sqrt(lpm(Data, MAR, 2))`

More About

Lower Partial Moments

Use *lower partial moments* to examine what is colloquially known as “downside risk.”

The main idea of the lower partial moment framework is to model moments of asset returns that fall below a minimum acceptable level of return. To compute lower partial moments from data, use `lpm` to calculate lower partial moments for multiple asset return series and for multiple moment orders. To compute expected values for lower partial moments under several assumptions about the distribution of asset returns, use `elpm` to calculate lower partial moments for multiple assets and for multiple orders.

Version History

Introduced in R2006b

Topics

“Performance Metrics Overview” on page 7-2

macd

Moving Average Convergence/Divergence (MACD)

Syntax

`[MACDLine,SignalLine] = macd(Data)`

Description

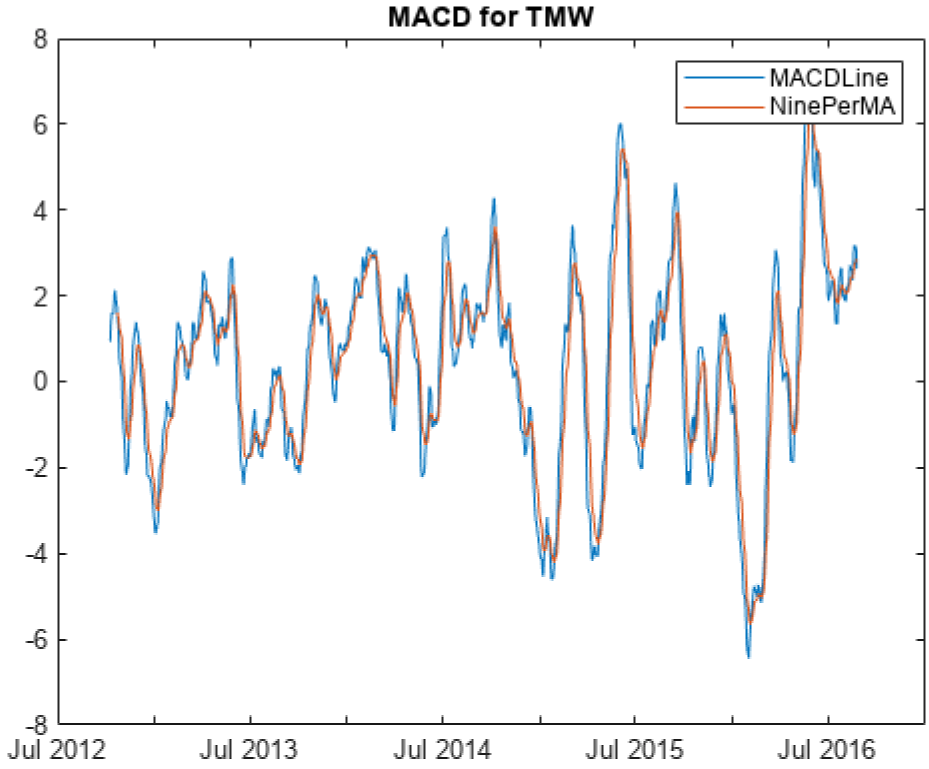
`[MACDLine,SignalLine] = macd(Data)` calculates the Moving Average Convergence/Divergence (MACD) line from the series of data and the nine-period exponential moving average from the `MACDLine`.

Examples

Calculate the Moving Average Convergence/Divergence for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
[MACDLine, signalLine]= macd(TMW);
plot(MACDLine.Time,MACDLine.Close,signalLine.Time,signalLine.Close);
legend('MACDLine','NinePerMA')
title('MACD for TMW')
```



Input Arguments

`Data` — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-4 matrix of high, low, opening, and closing prices. Timetables and tables with `M` rows must contain variables named `'High'`, `'Low'`, `'Open'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

`MACDLine` — MACD series

matrix | table | timetable

MACD series, returned with the same number of rows (`M`) and type (matrix, table, or timetable) as the input `Data`. The `MACDLine` is calculated by subtracting the 26-period (7.5%) exponential.

`SignalLine` — Nine-period exponential series

matrix | table | timetable

Nine-period exponential series, returned with the same number of rows (`M`) and type (matrix, table, or timetable) as the input `Data`. The nine-period (20%) exponential moving average of the `MACDLine` is used as the `SignalLine`.

More About

MACD

The MACD is calculated by subtracting the 26-period (7.5%) exponential moving average from the 12-period (15%) moving average.

The nine-period (20%) exponential moving average of the MACD line is used as the "signal" line. When the two lines are plotted, they can give you indications on when to buy or sell a stock, when overbought or oversold is occurring, and when the end of trend may occur. For example, when the MACD and the 20-day moving average line have crossed and the MACD line becomes below the other line, it is time to sell.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

maxdrawdown

Compute maximum drawdown for one or more price series

Syntax

```
MaxDD = maxdrawdown(Data)
MaxDD = maxdrawdown( ___ ,Format)
[MaxDD,MaxDDIndex] = maxdrawdown( ___ )
```

Description

`MaxDD = maxdrawdown(Data)` computes maximum drawdown for each series in an N-vector MaxDD and identifies start and end indexes of maximum drawdown periods for each series in a 2-by-N matrix MaxDDIndex.

`MaxDD = maxdrawdown( ___ ,Format)` adds an optional argument for `Format`.

`[MaxDD,MaxDDIndex] = maxdrawdown( ___ )` adds an optional output for `MaxDDIndex`.

Examples

Calculate Maximum Drawdown

Calculate the maximum drawdown (MaxDD) using example data with a fund, market, and cash series:

```
load FundMarketCash
MaxDD = maxdrawdown(TestData)
```

```
MaxDD = 1×3

    0.1658    0.3381         0
```

The maximum drop in the given time period was 16.58% for the fund series, and 33.81% for the market series. There was no decline in the cash series, as expected, because the cash account never loses value.

`maxdrawdown` also returns the indices (MaxDDIndex) of the maximum drawdown intervals for each series in an optional output argument.

```
[MaxDD, MaxDDIndex] = maxdrawdown(TestData)
```

```
MaxDD = 1×3

    0.1658    0.3381         0

MaxDDIndex = 2×3

     2     2   NaN
    18    18   NaN
```

The first two series experience their maximum drawdowns from the second to the 18th month in the data. The indices for the third series are NaNs because it never has a drawdown.

The 16.58% value loss from month 2 to month 18 for the fund series is verified using the reported indices.

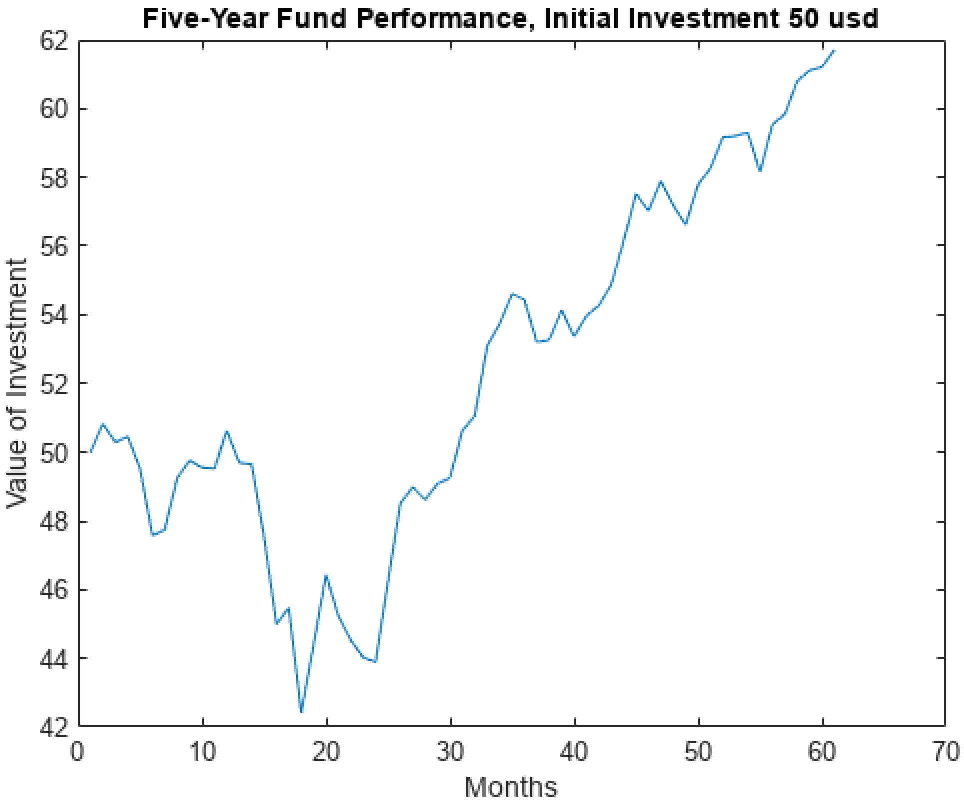
```
Start = MaxDDIndex(1,:);
End = MaxDDIndex(2,:);
(TestData(Start(1),1) - TestData(End(1),1))/TestData(Start(1),1)
```

```
ans = 0.1658
```

```
ans = 0.1658
```

Although the maximum drawdown is measured in terms of returns, maxdrawdown can measure the drawdown in terms of absolute drop in value, or in terms of log-returns. To contrast these alternatives more clearly, you can work with the fund series, assuming an initial investment of 50 dollars:

```
Fund50 = 50*TestData(:,1);
plot(Fund50);
title('\bfFive-Year Fund Performance, Initial Investment 50 usd');
xlabel('Months');
ylabel('Value of Investment');
```



First, compute the standard maximum drawdown, which coincides with the results above because returns are independent of the initial amounts invested.

```
MaxDD50Ret = maxdrawdown(Fund50)
```

```
MaxDD50Ret = 0.1658
```

Next, compute the maximum drop in value, using the `'arithmetic'` argument.

```
[MaxDD50Arith, Ind50Arith] = maxdrawdown(Fund50,'arithmetic')
```

```
MaxDD50Arith = 8.4285

Ind50Arith = 2×1

     2
    18
```

The value of this investment was $50.84 in month 2, but by month 18 the value was down to $42.41, a drop of $8.43. This is the largest loss in dollar value from a previous high in the given time period. In this case, the maximum drawdown period, from the 2nd to 18th month, is the same independently of whether drawdown is measured as return or as dollar value loss.

```
[MaxDD50LogRet, Ind50LogRet] = maxdrawdown(Fund50,'geometric')
```

```
MaxDD50LogRet = 0.1813

Ind50LogRet = 2×1

     2
    18
```

Note, the last measure is equivalent to finding the arithmetic maximum drawdown for the log of the series.

```
MaxDD50LogRet2 = maxdrawdown(log(Fund50),'arithmetic')
```

```
MaxDD50LogRet2 = 0.1813
```

Input Arguments

Data — Total return price series
matrix

Total return price series, specified as a `T`-by-`N` matrix with `T` samples of `N` total return price series.

Data Types: `double`

Format — (Optional) Format of Data
character vector with value of `'return'`, `'arithmetic'`, or `'geometric'`

Format of `Data`, specified as character vector with the following possible values:

- `'return'` (default) — Maximum drawdown in terms of maximum percentage drop from a peak.

- `'arithmetic'`

  — Maximum drawdown of an arithmetic Brownian motion with drift (differences of data from peak to trough) using the equation

  $$dX(t) = \mu dt + \sigma dW(t) .$$
- `'geometric'`

  — Maximum drawdown of a geometric Brownian motion with drift (differences of log of data from peak to trough) using the equation

  $$dS(t) = \mu_0 S(t)dt + \sigma_0 S(t)dW(t)$$

Data Types: `char`

Output Arguments

`MaxDD` — Maximum drawdown

vector

Maximum drawdown, returned as a `1`-by-`N` vector with maximum drawdown for each of `N` time series.

Note

- Drawdown is the percentage drop in total returns from the start to the end of a period. If the total equity time series is increasing over an entire period, drawdown is 0. Otherwise, it is a positive number. Maximum drawdown is an ex-ante proxy for downside risk that computes the largest drawdown over all intervals of time that can be formed within a specified interval of time.
- Maximum drawdown is sensitive to quantization error.

`MaxDDIndex` — Start and end indexes for each maximum drawdown period for each total equity time series

vector

Start and end indexes for each maximum drawdown period for each total equity time series, returned as a `2`-by-`N` vector of start and end indexes. The first row of the vector contains the start indexes and the second row contains the end indexes of each maximum drawdown period.

Version History

medprice

Median price from the series of high and low prices

Syntax

```
MedianPrice = medprice(Data)
```

Description

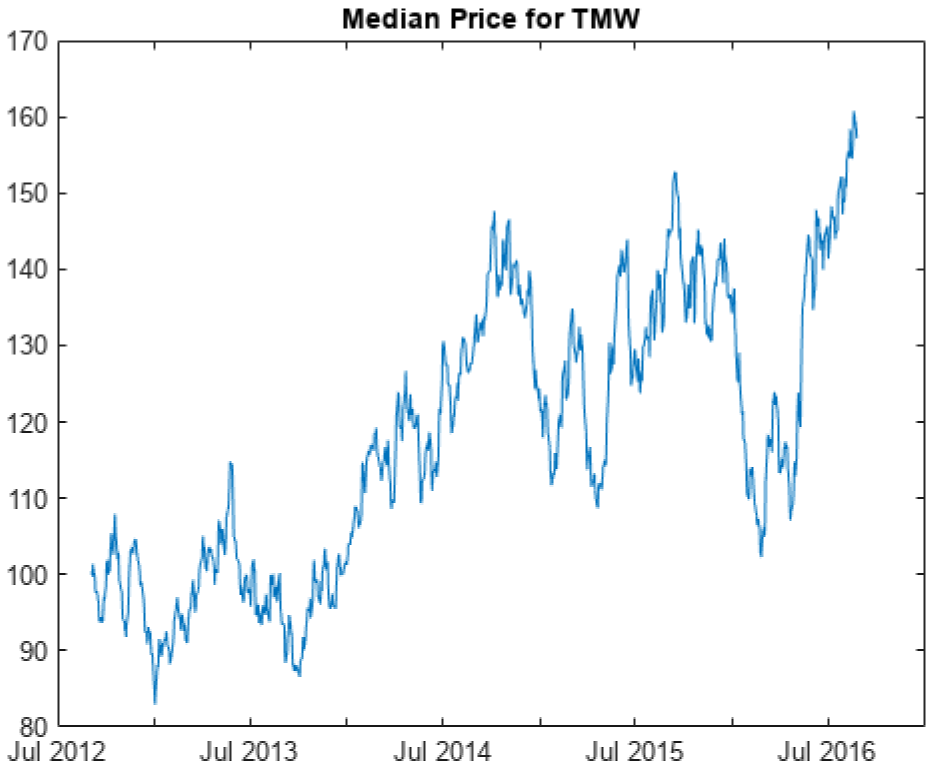
`MedianPrice = medprice(Data)` calculates the median prices from the series of high and low prices. The median price is the average of the high and low prices for each period.

Examples

Calculate the Median Prices for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
MedianPrice = medprice(TMW);
plot(MedianPrice.Time,MedianPrice.MedianPrice)
title('Median Price for TMW')
```



Input Arguments

`Data` — Data for high and low prices

matrix | table | timetable

Data for high and low prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-2 matrix of high and low prices stored in the corresponding columns. The columns can be in either order because the median price is the average of the high and low prices for each period. Timetables and tables with `M` rows must contain a variable named `'High'` and `'Low'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

`MedianPrice` — Median price series

matrix | table | timetable

Median price series, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

mirr

Modified internal rate of return

Syntax

```
Return = mirr(CashFlow,FinRate,Reinvest)
```

Description

`Return = mirr(CashFlow,FinRate,Reinvest)` calculates the modified internal rate of return for a series of periodic cash flows. This function calculates only positive rates of return; for nonpositive rates of return, `Return = 0`.

Examples

Compute Modified Internal Rate of Return

This cash flow represents the yearly income from an initial investment of $100,000. The finance rate is 9% and the reinvestment rate is 12%.

Year 1 $20,000

Year 2 ($10,000)

Year 3 $30,000

Year 4 $38,000

Year 5 $50,000

To calculate the modified internal rate of return on the investment:

```
Return = mirr([-100000 20000 -10000 30000 38000 50000], 0.09,0.12)
```

```
Return = 0.0832
```

Input Arguments

`CashFlow` — Cash flow
vector | matrix

Cash flow, specified as a vector or matrix. The first entry is the initial investment. If `CashFlow` is entered as a matrix, each column is treated as a separate cash flow.

Data Types: `double`

`FinRate` — Finance rate for negative cash flow values
decimal

Finance rate for negative cash flow values, specified as a decimal.

Data Types: `double`

`Reinvest` — Reinvestment rate for positive cash flow values
decimal

Reinvestment rate for positive cash flow values, specified as a decimal.

Data Types: `double`

Output Arguments

`Return` — Modified internal rate of return
numeric

Modified internal rate of return, returned as a scalar or vector.

Version History

Introduced before R2006a

movavg

Moving average of a financial time series

Note The syntax for `movavg` has changed. There is no longer support for the input arguments `Lead` and `Lag`, only a single `windowSize` is supported, and there is only one output argument (`ma`). If you want to compute the leading and lagging moving averages, you need to run `movavg` twice and adjust the `windowSize`.

Syntax

```
ma = movavg(Data,type,windowSize)
ma = movavg(___,Initialpoints)

ma = movavg(Data,type,weights)
ma = movavg(___,Initialpoints)
```

Description

`ma = movavg(Data,type,windowSize)` computes the moving average (MA) of a financial time series.

`ma = movavg(___,Initialpoints)` adds an optional argument for `Initialpoints`.

`ma = movavg(Data,type,weights)` computes the moving average (MA) of a financial time series using a `'custom'` `type` and `weights`.

`ma = movavg(___,Initialpoints)` adds an optional argument for `Initialpoints`.

Examples

Calculate the Moving Average for a Data Series

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data.

```
load SimulatedStock.mat
type = 'linear';
windowSize = 14;
ma = movavg(TMW_CLOSE,type,windowSize)
```

```
ma = 1000×1

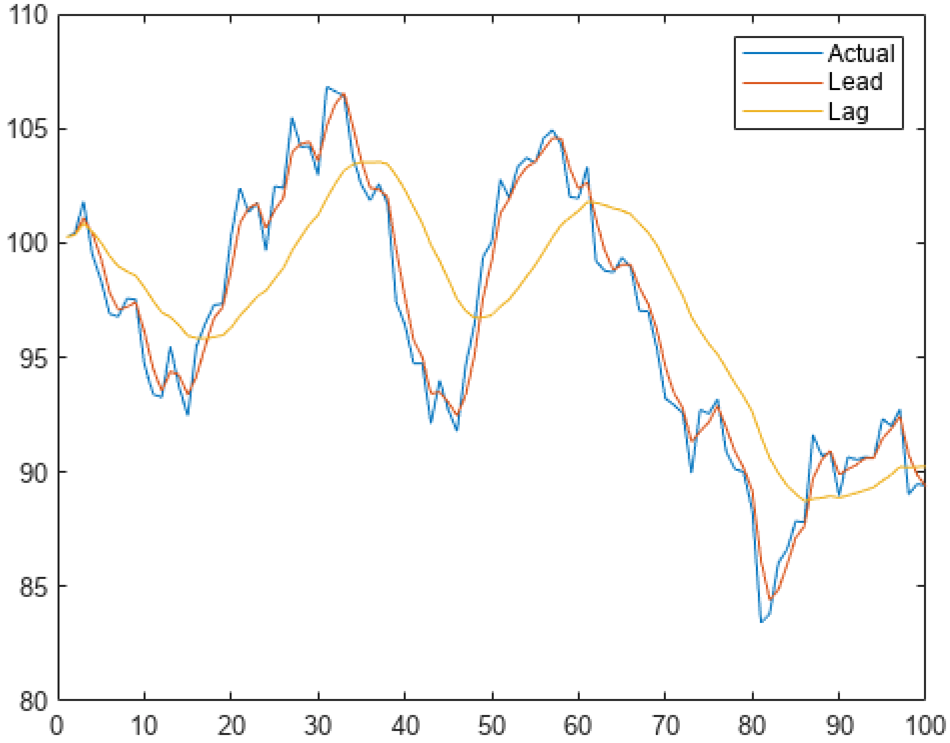
   96.1133
      ⋮
```

Plot the leading and lagging moving averages.

```
plot(TMW_CLOSE(1:100))
hold on
plot(malead(1:100))
plot(malag(1:100))
hold off
legend('Actual','Lead','Lag')
```



Input Arguments

`Data` — Data for a financial series

matrix | table | timetable

Data for a financial series, specified as a column-oriented matrix, table, or timetable. Timetables and tables must contain variables with only a numeric type.

Data Types: `double` | `table` | `timetable`

`type` — Type of moving average to compute

character vector with value of `'simple'`, `'square-root'`, `'linear'`, `'square'`, `'exponential'`, `'triangular'`, `'modified'`, or `'custom'` | string with value of `"simple"`, `"square-root"`, `"linear"`, `"square"`, `"exponential"`, `"triangular"`, `"modified"`, or `"custom"`

Type of moving average to compute, specified as a character vector or string with an associated value.

Data Types: `char` | `string`

`windowSize` — Number of observations of the input series to include in moving average

positive integer

Number of observations of the input series to include in moving average, specified as a scalar positive integer. The observations include (`windowSize` - 1) previous data points and the current data point.

Note The windowSize argument applies only to moving averages whose type is 'simple', 'square-root', 'linear', 'square', 'exponential', 'triangular', or 'modified'.

Data Types: double

weights — Custom weights used to compute moving average
vector

Custom weights used to compute the moving average, specified as a vector.

Note The length of weights (*N*) determines the size of the moving average window (windowSize). The weights argument applies only to a 'custom' type of moving average.

To compute moving average with custom weights, the weights (w) are first normalized such that they sum to one:

```
W(i) = w(i)/sum(w), for i = 1,2,...,N
```

The normalized weights (W) are then used to form the *N*-point weighted moving average (*y*) of the input Data (*x*):

```
y(t) = W(1)*x(t) + W(2)*x(t-1) + ... + W(N)*x(t-N)
```

The initial moving average values within the window size are then adjusted according to the method specified in the name-value pair argument Initialpoints.

Data Types: double

Initialpoints — Indicates how moving average is calculated at initial points
'shrink' (default) | character vector with values of 'shrink', 'fill', or 'zero' | string with values of "shrink", "fill", or "zero"

(Optional) Indicates how the moving average is calculated at initial points (before there is enough data to fill the window), specified as a character vector or string using one of the following values:

- 'shrink' - Initializes the moving average such that the initial points include only observed data
- 'zero' - Initializes the initial points with 0
- 'fill' - Fills initial points with NaNs

Note The Initialpoints argument applies to all type specifications except for the 'exponential' and 'modified' options.

Data Types: char | string

Output Arguments

ma — Moving average series
matrix | table | timetable

Moving average series, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

mvnrfish

Fisher information matrix for multivariate normal or least-squares regression

Syntax

```
Fisher = mvnrfish(Data,Design,Covariance)
Fisher = mvnrfish( ___ ,MatrixFormat,CovarFormat)
```

Description

`Fisher = mvnrfish(Data,Design,Covariance)` computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates.

`Fisher` is a `TOTALPARAMS`-by-`TOTALPARAMS` Fisher information matrix. The size of `TOTALPARAMS` depends on `MatrixFormat` and on current parameter estimates. If `MatrixFormat = 'full'`,

```
TOTALPARAMS = NUMPARAMS + NUMSERIES * (NUMSERIES + 1)/2
```

If `MatrixFormat = 'paramonly'`,

```
TOTALPARAMS = NUMPARAMS
```

Note `mvnrfish` operates slowly if you calculate the full Fisher information matrix.

`Fisher = mvnrfish( ___ ,MatrixFormat,CovarFormat)` computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates using optional arguments.

Input Arguments

`Data` — Data sample

matrix

Data sample, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. If a data sample has missing values, represented as `NaN`s, the sample is ignored. (Use `mvnrmle` to handle missing data.)

Data Types: `double`

`Design` — Model design

matrix | cell array of character vectors

Model design, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES` ≥ `1`, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix of known values.

If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.

Data Types: double | cell

Covariance — Estimates for the covariance of the residuals of the regression

matrix

Estimates for the covariance of the residuals of the regression, specified as an NUMSERIES-by-NUMSERIES matrix.

Data Types: double

MatrixFormat — Parameters to be included in Fisher information matrix

'full' (default) | character vector with value 'full' or 'paramonly'

(Optional) Parameters to be included in the Fisher information matrix, specified as a character vector. The choices are:

- 'full' — This is the default method that computes the full Fisher information matrix for both model and covariance parameter estimates.
- 'paramonly' — This computes only components of the Fisher information matrix associated with the model parameter estimates.

Data Types: char

CovarFormat — Format for covariance matrix

'full' (default) | character vector with value 'full' or 'diagonal'

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- 'full' — This is the default method that computes the full covariance matrix.
- 'diagonal' — This forces the covariance matrix to be a diagonal matrix.

Data Types: char

Output Arguments

Fisher — Fisher information matrix

matrix

Fisher information matrix, returned as an TOTALPARAMS-by-TOTALPARAMS matrix.

mvnrmle

Multivariate normal regression (ignore missing data)

Syntax

```
[Parameters,Covariance,Resid,Info] = mvnrmle(Data,Design)
[Parameters,Covariance,Resid,Info] = mvnrmle( ___ ,MaxIterations,TolParam,
TolObj,Covar0,CovarFormat)
```

Description

`[Parameters,Covariance,Resid,Info] = mvnrmle(Data,Design)` estimates a multivariate normal regression model without missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters,\ Covariance)$$

for samples k = 1, ... , `NUMSAMPLES`.

`mvnrmle` estimates a `NUMPARAMS`-by-`1` column vector of model parameters called `Parameters`, and a `NUMSERIES`-by-`NUMSERIES` matrix of covariance parameters called `Covariance`.

`mvnrmle(Data, Design)` with no output arguments plots the log-likelihood function for each iteration of the algorithm.

`[Parameters,Covariance,Resid,Info] = mvnrmle( ___ ,MaxIterations,TolParam, TolObj,Covar0,CovarFormat)` estimates a multivariate normal regression model without missing data using optional arguments.

Input Arguments

`Data` — Data sample

matrix

Data sample, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. If a data sample has missing values, represented as `NaN`s, the sample is ignored. (Use `mvnrmle` to handle missing data.)

Data Types: `double`

`Design` — Model design

matrix | cell array of character vectors

Model design, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES` ≥ `1`, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix of known values.

  If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

These points concern how Design handles missing data:

- Although Design should not have NaN values, ignored samples due to NaN values in Data are also ignored in the corresponding Design array.
- If Design is a 1-by-1 cell array, which has a single Design matrix for each sample, no NaN values are permitted in the array. A model with this structure must have NUMSERIES ≥ NUMPARAMS with rank(Design{1}) = NUMPARAMS.
- Two functions for handling missing data, ecmmvnrmle and ecmlsrmle, are stricter about the presence of NaN values in Design.

Data Types: double | cell

MaxIterations — Maximum number of iterations for the estimation algorithm
100 (default) | numeric

(Optional) Maximum number of iterations for the estimation algorithm, specified as a numeric. The default value is 100.

Data Types: double

TolParam — Convergence tolerance for estimation algorithm
sqrt(eps) (default) | numeric

(Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates, specified as a numeric. The Default value is sqrt(eps) which is about 1.0e-8 for double precision. The convergence test for changes in model parameters is

$$\|Param_k - Param_{k-1}\| < TolParam \times (1 + \|Param_k\|)$$

where Param represents the output Parameters, and iteration $k = 2, 3, \ldots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.

Data Types: double | table | timetable

TolObj — Convergence tolerance for estimation algorithm based on changes in objective function
eps ∧ 3/4 (default) | numeric

(Optional) Convergence tolerance for estimation algorithm based on changes in the objective function, specified as a numeric. The default value is eps ∧ 3/4 which is about 1.0e-12 for double precision. The convergence test for changes in the objective function is

$$|Obj_k - Obj_{k-1}| < TolObj \times (1 + |Obj_k|)$$

for iteration $k = 2, 3, \ldots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.

Data Types: double

Covar0 — User-supplied initial or known estimate for the covariance matrix of the regression residuals
identity matrix (default) | matrix

(Optional) user-supplied initial or known estimate for the covariance matrix of the regression residuals, specified as an `NUMSERIES`-by-`NUMSERIES` matrix.

Data Types: `double`

`CovarFormat` — Format for covariance matrix
`'full'` (default) | character vector with value `'full'` or `'diagonal'`

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- `'full'` — This is the default method that computes the full covariance matrix.
- `'diagonal'` — This forces the covariance matrix to be a diagonal matrix.

Data Types: `char`

Output Arguments

`Parameters` — Parameters of the regression model
vector

Parameters of the regression model, returned as an `NUMPARAMS`-by-`1` column vector of estimates for the parameters of the regression model.

`Covariance` — Covariance of the regression model's residuals
matrix

Covariance of the regression model's residuals, returned as an `NUMSERIES`-by-`NUMSERIES` matrix of estimates for the covariance of the regression model's residuals.

`Resid` — Residuals from the regression
matrix

Residuals from the regression, returned as an `NUMSAMPLES`-by-`NUMSERIES` matrix of residuals from the regression. For any row with missing values in `Data`, the corresponding row of residuals is represented as all `NaN` missing values, since this routine ignores rows with `NaN` values.

`Info` — Structure containing additional information from the regression
structure

Structure containing additional information from the regression, returned as a structure. The structure has these fields:

- `Info.Obj` – A variable-extent column vector, with no more than `MaxIterations` elements, that contain each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, `Obj(end)`, is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.
- `Info.PrevParameters` – `NUMPARAMS`-by-`1` column vector of estimates for the model parameters from the iteration just before the terminal iteration.
- `Info.PrevCovariance` – `NUMSERIES`-by-`NUMSERIES` matrix of estimates for the covariance parameters from the iteration just before the terminal iteration.

Use the estimates in the output structure `Info` for diagnostic purposes.

Version History

Introduced in R2006a

mvnrobj

Log-likelihood function for multivariate normal regression without missing data

Syntax

```
Objective = mvnrobj(Data,Design,Parameters,Covariance)
Objective = mvnrobj( ___ ,CovarFormat)
```

Description

`Objective = mvnrobj(Data,Design,Parameters,Covariance)` computes the log-likelihood function based on current maximum likelihood parameter estimates without missing data. `Objective` is a scalar that contains the log-likelihood function.

`Objective = mvnrobj( ___ ,CovarFormat)` computes the log-likelihood function based on current maximum likelihood parameter estimates without missing data using an optional argument.

Input Arguments

`Data` — Data sample

matrix

Data sample, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. If a data sample has missing values, represented as `NaN`s, the sample is ignored. (Use `ecmmvnrmle` to handle missing data.)

Data Types: `double`

`Design` — Model design

matrix | cell array of character vectors

Model design, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES ≥ 1`, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix of known values.

  If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

Data Types: `double` | `cell`

`Parameters` — Estimates for the parameters of regression model

vector

Estimates for the parameters of regression model, specified as an `NUMPARAMS`-by-`1` column vector.

Data Types: `double`

`Covariance` — Estimates for the covariance of the residuals of the regression
matrix

Estimates for the covariance of the residuals of the regression, specified as an `NUMSERIES`-by-`NUMSERIES` matrix.

Data Types: `double`

`CovarFormat` — Format for covariance matrix
`'full'` (default) | character vector with value `'full'` or `'diagonal'`

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- `'full'` — This is the default method that computes the full covariance matrix.
- `'diagonal'` — This forces the covariance matrix to be a diagonal matrix.

Data Types: `char`

Output Arguments

`Objective` — Log-likelihood function
scalar

Log-likelihood function, returned as scalar.

Version History

Introduced in R2006a

mvnrstd

Evaluate standard errors for multivariate normal regression model

Syntax

```
[StdParameters,StdCovariance] = mvnrstd(Data,Design,Covariance)
[StdParameters,StdCovariance] = mvnrstd( ___ ,CovarFormat)
```

Description

`[StdParameters,StdCovariance] = mvnrstd(Data,Design,Covariance)` evaluates standard errors for a multivariate normal regression model without missing data. The model has the form

$$Data_k \sim N(Design_k \times Parameters,\ Covariance)$$

for samples $k = 1, \ldots,$ `NUMSAMPLES`.

`mvnrstd` computes two outputs:

- `StdParameters` is a `NUMPARAMS`-by-`1` column vector of standard errors for each element of `Parameters`, the vector of estimated model parameters.
- `StdCovariance` is a `NUMSERIES`-by-`NUMSERIES` matrix of standard errors for each element of `Covariance`, the matrix of estimated covariance parameters.

Note `mvnrstd` operates slowly when you calculate the standard errors associated with the covariance matrix `Covariance`.

`[StdParameters,StdCovariance] = mvnrstd( ___ ,CovarFormat)` computes the log-likelihood function based on current maximum likelihood parameter estimates without missing data using an optional argument.

Input Arguments

`Data` — Data sample

matrix

Data sample, specified as an `NUMSAMPLES`-by-`NUMSERIES` matrix with `NUMSAMPLES` samples of a `NUMSERIES`-dimensional random vector. If a data sample has missing values, represented as `NaN`s, the sample is ignored. (Use `ecmmvnrmle` to handle missing data.)

Data Types: `double`

`Design` — Model design

matrix | cell array of character vectors

Model design, specified as a matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a `NUMSAMPLES`-by-`NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.

- If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.

  If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.

Data Types: double | cell

Covariance — Estimates for the covariance of the residuals of the regression
matrix

Estimates for the covariance of the residuals of the regression, specified as an NUMSERIES-by-NUMSERIES matrix.

Data Types: double

CovarFormat — Format for covariance matrix
'full' (default) | character vector with value 'full' or 'diagonal'

(Optional) Format for the covariance matrix, specified as a character vector. The choices are:

- 'full' — This is the default method that computes the full covariance matrix.
- 'diagonal' — This forces the covariance matrix to be a diagonal matrix.

Data Types: char

Output Arguments

StdParameters — standard errors for each element of Parameters, the vector of estimated model parameters
vector

Standard errors for each element of Parameters, the vector of estimated model parameters, returned as an NUMPARAMS-by-1 column vector.

StdCovariance — standard errors for each element of Covariance, the matrix of estimated covariance parameters
matrix

Standard errors for each element of Covariance, the matrix of estimated covariance parameters, returned as an NUMSERIES-by-NUMSERIES matrix.

negvolidx

Negative volume index

Syntax

```
volume = negvolidx(Data)
volume = negvolidx(___,Name,Value)
```

Description

`volume = negvolidx(Data)` calculates the negative volume index from the series of closing stock prices and trade volume.

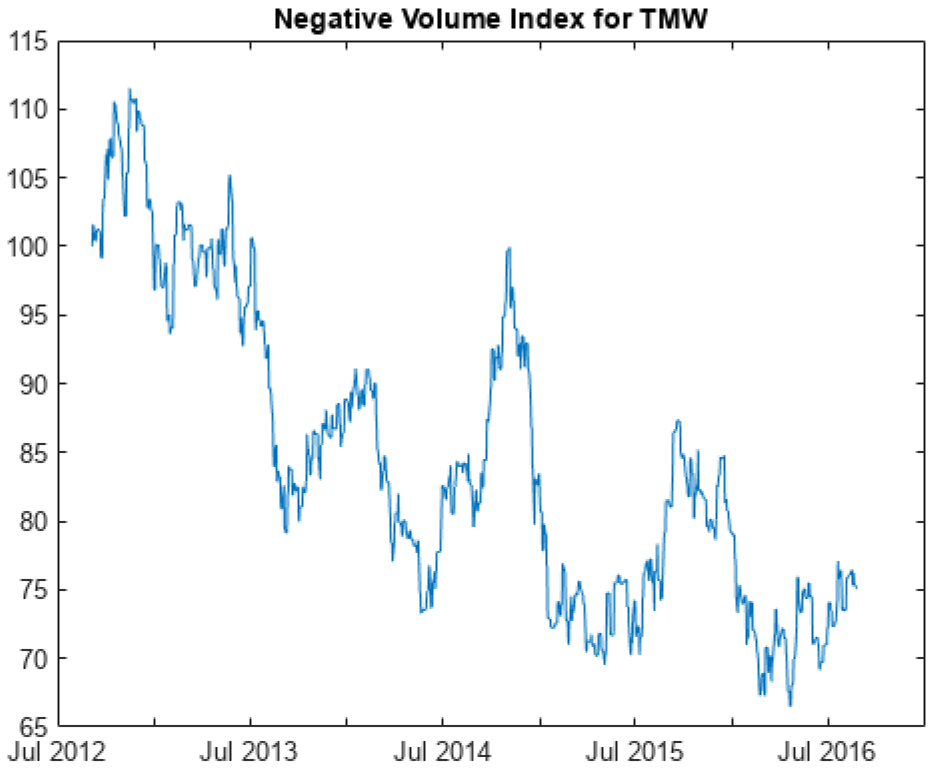
`volume = negvolidx(___,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Negative Volume Index for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
volume = negvolidx(TMW);
plot(volume.Time,volume.NegativeVolume)
title('Negative Volume Index for TMW')
```



Input Arguments

`Data` — Data with closing prices and trade volume

matrix | table | timetable

Data with closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-2 with closing prices and trade volume stored in the first and second columns. Timetables and tables with `M` rows must contain variables named `'Close'` and `'Volume'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `volume = negvolidx(TMW,'InitialValue',500)`

`InitialValue` — Initial value for negative volume index

`100` (default) | positive integer

Initial value for negative volume index, specified as the comma-separated pair consisting of `'InitialValue'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`volume` — Negative volume index
matrix | table | timetable

Negative volume index, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

More About

Negative Volume Index

Negative volume index shows the days when the trading volume of a particular security is substantially lower than other days.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument
Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

nomrr

Nominal rate of return

Syntax

`Return = nomrr(Rate,NumPeriods)`

Description

`Return = nomrr(Rate,NumPeriods)` calculates the nominal rate of return.

Examples

Calculate the Nominal Rate of Return

This example shows how to calculate the nominal rate of return based on an effective annual percentage rate of 9.38% compounded monthly.

```
Return = nomrr(0.0938, 12)
```

```
Return = 0.0900
```

Input Arguments

`Rate` — Effective annual percentage rate
decimal

Effective annual percentage rate, specified as a decimal.

Data Types: `double`

`NumPeriods` — Number of compounding periods per year
scalar numeric

Number of compounding periods per year, specified as a scalar numeric.

Data Types: `double`

Output Arguments

`Return` — Nominal rate of return
numeric

Nominal rate of return, returned as a numeric.

nyseclosures

New York Stock Exchange closures from 1885 to 2070

Syntax

```
Closures = nyseclosures
[Closures,SatTransition] = nyseclosures(StartDate,EndDate,WorkWeekFormat)
```

Description

`Closures = nyseclosures` returns a vector of dates for all known or anticipated closures from January 1, 1885 to December 31, 2070.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 1952 are based on a 6-day workweek. `nyseclosures` contains all holiday and special non-trading days for the New York Stock Exchange from 1885 through 2070 based on a six-day work week (always closed on Sundays).

`[Closures,SatTransition] = nyseclosures(StartDate,EndDate,WorkWeekFormat)`, using optional input arguments, returns a vector of dates corresponding to market closures between `StartDate` and `EndDate`, inclusive.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 1952 are based on a 6-day workweek. `nyseclosures` contains all holiday and special non-trading days for the New York Stock Exchange from 1885 through 2070 based on a six-day work week (always closed on Sundays). Use `WorkWeekFormat` to modify the list of dates.

Examples

Find NYSE Closures

Find the NYSE closures for 1899:

```
datestr(nyseclosures('1-jan-1899','31-dec-1899'),'dd-mmm-yyyy ddd')
```

```
ans = 16x15 char array
    '02-Jan-1899 Mon'
    '11-Feb-1899 Sat'
    '13-Feb-1899 Mon'
    '22-Feb-1899 Wed'
    '31-Mar-1899 Fri'
    '29-May-1899 Mon'
    '30-May-1899 Tue'
    '03-Jul-1899 Mon'
    '04-Jul-1899 Tue'
    '04-Sep-1899 Mon'
    '29-Sep-1899 Fri'
    '30-Sep-1899 Sat'
    '07-Nov-1899 Tue'
    '25-Nov-1899 Sat'
    '30-Nov-1899 Thu'
    '25-Dec-1899 Mon'
```

Find the NYSE closures for 1899 using a datetime array:

```
[Closures,SatTransition] = nyseclosures(datetime(1899,1,1),datetime(1899,6,30))
```

```
Closures = 7x1 datetime
   02-Jan-1899
   11-Feb-1899
   13-Feb-1899
   22-Feb-1899
   31-Mar-1899
   29-May-1899
   30-May-1899

SatTransition = datetime
   29-Sep-1952
```

Find the NYSE closure dates using the `'Archaic'` value for `WorkWeekFormat`:

```
nyseclosures(datetime(1952,9,1),datetime(1952,10,31),'a')
```

```
ans = 10x1 datetime
   01-Sep-1952
   06-Sep-1952
   13-Sep-1952
   20-Sep-1952
   27-Sep-1952
   04-Oct-1952
   11-Oct-1952
   13-Oct-1952
   18-Oct-1952
   25-Oct-1952
```

The exchange was closed on Saturdays for much of 1952 before the official transition to a 5-day workweek.

Input Arguments

`StartDate` — Start date

start of default date range, January 1, 1885 (default) | datetime array | string array | date character vector

Start date, specified as a scalar or a vector using a datetime array, string array, or date character vectors.

To support existing code, `nyseclosures` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

EndDate — End date

end of default date range, December 31, 2070 (default) | datetime array | string array | date character vector

End date, specified as a scalar or a vector using a datetime array, string array, or date character vectors.

To support existing code, `nyseclosures` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

WorkWeekFormat — Method to handle the workweek

`'Implicit'` (default) | date character vector with values `'Modern'`, `'Implicit'`, or `'Archaic'`

Method to handle the workweek, specified using a date character vector with values `'Modern'`, `'Implicit'`, or `'Archaic'`. This function accepts the first letter for each method as input and is not case-sensitive. Acceptable values are:

- `'Modern'` — 5-day workweek with all Saturday trading days removed.
- `'Implicit'` — 6-day workweek until 1952 and 5-day week afterward (no need to exclude Saturdays).
- `'Archaic'` — 6-day workweek throughout and Saturdays treated as closures after 1952.

Data Types: `char`

Output Arguments

Closures — Market closures between StartDate and EndDate, inclusive

vector

Market closures between the `StartDate` and `EndDate`, inclusive, returned as a vector of dates.

If `StartDate` or `EndDate` are all either strings or date character vectors, both `Closures` and `SatTransition` are returned as serial date numbers. Use the function `datestr` to convert serial date numbers to formatted date character vectors. If either `StartDate` or `EndDate` are datetime arrays, both `Closures` and `SatTransition` are returned as datetime arrays.

If both `StartDate` and `EndDate` are not specified or are empty, `Closures` contains all known or anticipated closures from January 1, 1885 to December 31, 2070 based on a `WorkWeekFormat` of `'implicit'`.

SatTransition — Date of transition for New York Stock Exchange from 6-day workweek to 5-day workweek

serial date number | datetime array

Date of transition for the New York Stock Exchange from a 6-day workweek to a 5-day workweek, returned as the date September 29, 1952 (serial date number `713226`).

If `StartDate` or `EndDate` are all either strings or date character vectors, both `Closures` and `SatTransition` are returned as serial date numbers. Use the function `datestr` to convert serial date numbers to formatted date character vectors. If either `StartDate` or `EndDate` are datetime arrays, both `Closures` and `SatTransition` are returned as datetime arrays.

More About

holidays

The holidays function is based on a modern 5-day workweek.

This function contains all holidays and special nontrading days for the New York Stock Exchange from January 1, 1885 to December 31, 2070.

Since the New York Stock Exchange was open on Saturdays before September 29, 1952, exact closures from 1885 to 2070 should include Saturday trading days. To capture these dates, use nyseclosures. The results from holidays and nyseclosures are identical if the WorkWeekFormat in nyseclosures is 'Modern'.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although nyseclosures supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

onbalvol

On-Balance Volume (OBV)

Syntax

```
volume = onbalvol(Data)
```

Description

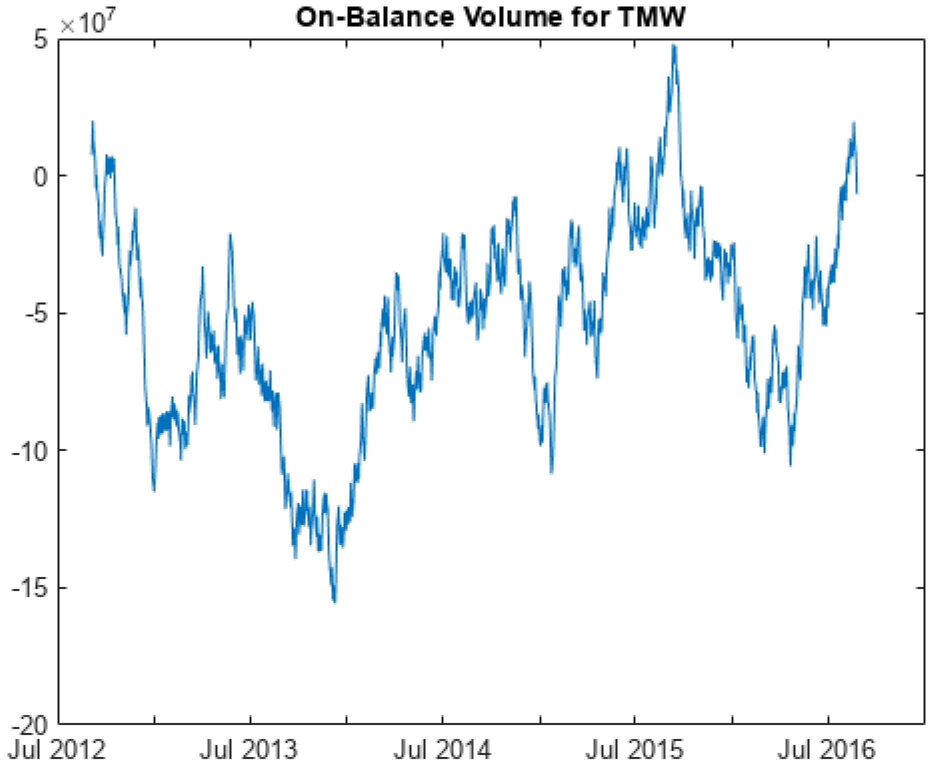
`volume = onbalvol(Data)` calculates the On-Balance Volume from the series of closing stock prices and trade volume.

Examples

Calculate the On-Balance Volume for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
volume = onbalvol(TMW);
plot(volume.Time,volume.OnBalanceVolume)
title('On-Balance Volume for TMW')
```



Input Arguments

`Data` — Data for closing prices and trade volume

matrix | table | timetable

Data for closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-2 matrix of closing prices and trade volume stored in the first and second columns. Timetables and tables with `M` rows must contain variables named `'Close'` and `'Volume'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

`volume` — On-Balance Volume

matrix | table | timetable

On-Balance Volume, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

opprofit

Option profit

Syntax

```
Profit = opprofit(AssetPrice,Strike,Cost,PosFlag,OptType)
```

Description

`Profit = opprofit(AssetPrice,Strike,Cost,PosFlag,OptType)` returns the profit of an option.

Examples

Calculate the Profit of an Option

This example shows how to return the profit of an option. For example, consider buying (going long on) a call option with a strike price of $90 on an underlying asset with a current price of $100 for a cost of $4.

```
Profit = opprofit(100, 90, 4, 0, 0)
```

```
Profit = 6
```

Input Arguments

`AssetPrice` — Asset price
numeric

Asset price, specified as a scalar or a `NINST`-by-`1` vector.

Data Types: `double`

`Strike` — Strike or exercise price
numeric

Strike or exercise price, specified as a scalar or a `NINST`-by-`1` vector.

Data Types: `double`

`Cost` — Cost of option
numeric

Cost of the option, specified as a scalar or a `NINST`-by-`1` vector.

Data Types: `double`

`PosFlag` — Option position
`0` = long | `1` = short

Option position, specified as a scalar or a NINST-by-1 vector using the values 0 (long) or 1 (short).

Data Types: logical

OptType — Option type
0 = call option | 1 = put option

Option type, specified as a scalar or a NINST-by-1 vector using the values 0 (call option) or 1 (put option).

Data Types: logical

Output Arguments

Profit — Option profit
vector

Option profit, returned as a scalar or a NINST-by-1 vector.

payadv

Periodic payment given number of advance payments

Syntax

```
Payment = payadv(Rate,NumPeriods,PresentValue,FutureValue,Advance)
```

Description

`Payment = payadv(Rate,NumPeriods,PresentValue,FutureValue,Advance)` computes the periodic payment given a number of advance payments.

Examples

Compute the Periodic Payment

This example shows how to compute the periodic payment, given a number of advance payments. For example, the present value of a loan is $1000.00 and it will be paid in full in 12 months. The annual interest rate is 10% and three payments are made at closing time.

```
Payment = payadv(0.1/12, 12, 1000, 0, 3)
```

```
Payment = 85.9389
```

Input Arguments

`Rate` — Lending or borrowing rate per period
decimal

Lending or borrowing rate per period, specified as a decimal. The `Rate` must be greater than or equal to `0`.

Data Types: `double`

`NumPeriods` — Number of periods in the life of the instrument
integer

Number of periods in the life of the instrument, specified as an integer.

Data Types: `double`

`PresentValue` — Present value of instrument
numeric

Present value of the instrument, specified as a numeric.

Data Types: `double`

`FutureValue` — Future value or target value attained after `NumPeriods` periods
numeric

Future value or target value to be attained after `NumPeriods` periods, specified as a numeric.

Data Types: `double`

`Advance` — Number of advance payments

integer

Number of advance payments, specified as an integer. If the payments are made at the beginning of the period, add `1` to `Advance`.

Data Types: `double`

Output Arguments

`Payment` — Periodic payment

numeric

Periodic payment, returned as the periodic payment given a number of advance payments.

Version History

Introduced before R2006a

payodd

Payment of loan or annuity with odd first period

Syntax

```
Payment = payodd(Rate,NumPeriods,PresentValue,FutureValue,Days)
```

Description

`Payment = payodd(Rate,NumPeriods,PresentValue,FutureValue,Days)` computes the payment for a loan or annuity with an odd first period.

Examples

Compute the Payment for a Loan or Annuity With an Odd First Period

This example shows how to return the payment for a loan or annuity with an odd first period. For example, consider a two-year loan for $4000 that has an annual interest rate of 11% and the first payment will be made in 36 days.

```
Payment = payodd(0.11/12, 24, 4000, 0, 36)
```

```
Payment = 186.7731
```

Input Arguments

`Rate` — Interest rate per period
decimal

Interest rate per period, specified as a decimal.

Data Types: `double`

`NumPeriods` — Number of periods in the life of the instrument
integer

Number of periods in the life of the instrument, specified as an integer.

Data Types: `double`

`PresentValue` — Present value of instrument
numeric

Present value of the instrument, specified as a numeric.

Data Types: `double`

`FutureValue` — Future value or target value attained after `NumPeriods` periods
numeric

Future value or target value to be attained after `NumPeriods` periods, specified as a numeric.

Data Types: `double`

`Days` — Actual number of days until first payment is made
integer

Actual number of days until the first payment is made, specified as an integer.

Data Types: `double`

Output Arguments

`Payment` — Payment
numeric

Payment, returns the payment for a loan or annuity with an odd first period.

Version History

Introduced before R2006a

Topics

"Analyzing and Computing Cash Flows" on page 2-11

payper

Periodic payment of loan or annuity

Syntax

```
Payment = payper(Rate,NumPeriods,PresentValue)
Payment = payper( ___ ,FutureValue,Due)
```

Description

`Payment = payper(Rate,NumPeriods,PresentValue)` returns the periodic payment of a loan or annuity.

`Payment = payper( ___ ,FutureValue,Due)` adds optional arguments.

Examples

Compute the Periodic Payment of a Loan or Annuity

This example shows how to find the monthly payment for a three-year loan of $9000 with an annual interest rate of 11.75%.

```
Payment = payper(0.1175/12, 36, 9000, 0, 0)
```

```
Payment = 297.8553
```

Input Arguments

`Rate` — Interest rate per period

decimal

Interest rate per period, specified as a decimal.

Data Types: `double`

`NumPeriods` — Number of payment periods in life of instrument

integer

Number of payment periods in the life of instrument, specified as an integer.

Data Types: `double`

`PresentValue` — Present value of the instrument

numeric

Present value of the instrument, specified as a numeric.

Data Types: `double`

`FutureValue` — Future value or target value attained after `NumPeriods` periods

`0` (default) | numeric

(Optional) Future value or target value to be attained after `NumPeriods` periods, specified as a numeric.

Data Types: `double`

`Due` — Indicator for when payments are due

`0` (default) | logical with value of `1` or `0`

(Optional) Indicator for when payments are due, specified as a logical with a value of `0` = end of period (default), or `1` = beginning of period.

Data Types: `logical`

Output Arguments

`Payment` — Periodic payment

numeric

Periodic payment, returns the periodic payment of a loan or annuity.

More About

Annuity

An annuity is a series of payments over a period of time.

The payments are usually in equal amounts and usually at regular intervals such as quarterly, semiannually, or annually.

Topics

"Analyzing and Computing Cash Flows" on page 2-11

payuni

Uniform payment equal to varying cash flow

Syntax

```
Series = payuni(CashFlow,Rate)
```

Description

`Series = payuni(CashFlow,Rate)` computes the uniform series value of a varying cash flow.

Examples

Calculate the Uniform Series Value

This example shows how to calculate the uniform series value using `payuni`.

The following cash flow represents the yearly income from an initial investment of $10,000. The annual interest rate is 8%.

Year 1 - $2000

Year 2 - $1500

Year 3 - $3000

Year 4 - $3800

Year 5 - $5000

To calculate the uniform series value:

```
Series = payuni([-10000 2000 1500 3000 3800 5000], 0.08)
```

```
Series = 429.6296
```

Input Arguments

`CashFlow` — Cash flows
vector

Cash flows, specified as a vector of varying cash flows. Include the initial investment as the initial cash flow value (a negative number).

Data Types: `double`

`Rate` — Periodic interest rate
decimal

Periodic interest rate, specified as a decimal.

Data Types: `double`

Output Arguments

`Series` — Uniform series

numeric

Uniform series, returned as the value of a varying cash flow.

pcalims

Linear inequalities for individual asset allocation

Syntax

```
[A,b] = pcalims(AssetMin,AssetMax)
[A,b] = pcalims( ___ ,NumAssets)
```

Description

As an alternative to `pcalims`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “Portfolio Object Workflow” on page 4-17.

`[A,b] = pcalims(AssetMin,AssetMax)` specifies the lower and upper bounds of portfolio allocations in each of `NumAssets` available asset investments. `pcalims` specifies the lower and upper bounds of portfolio allocations in each of `NASSETS` available asset investments.

Note If `pcalims` is called with fewer than two output arguments, the function returns `A` concatenated with `b` `[A,b]`.

`[A,b] = pcalims( ___ ,NumAssets)` specifies options using an optional argument in addition to the input arguments in the previous syntax.

Examples

Compute Linear Inequalities for Individual Asset Allocation

Set the minimum weight in every asset to `0` (no short-selling), and set the maximum weight of IBM stock to `0.5` and CSCO to `0.8`, while letting the maximum weight in INTC float.

Minimum weight:

- IBM — 0
- INTC — 0
- CSCO — 0

Maximum weight:

- IBM — 0.5
- INTC —
- CSCO — 0.8

```
AssetMin = 0
AssetMin = 0
```

```
AssetMax = [0.5 NaN 0.8]
```

```
AssetMax = 1×3

    0.5000       NaN    0.8000
```

```
[A,b] = pcalims(AssetMin, AssetMax)
```

```
A = 5×3

     1     0     0
     0     0     1
    -1     0     0
     0    -1     0
     0     0    -1

b = 5×1

    0.5000
    0.8000
         0
         0
         0
```

Portfolio weights of 50% in IBM and 50% in INTC satisfy the constraints

Set the minimum weight in every asset to `0` and the maximum weight to `1`.

Minimum weight:

- IBM — 0
- INTC — 0
- CSCO — 0

Maximum weight:

- IBM — 1
- INTC — 1
- CSCO — 1

```
AssetMin = 0
```

```
AssetMin = 0
```

```
AssetMax = 1
```

```
AssetMax = 1
```

```
NumAssets = 3
```

```
NumAssets = 3
```

```
[A,b] = pcalims(AssetMin, AssetMax, NumAssets)
```

```
A = 6×3

     1     0     0
     0     1     0
     0     0     1
    -1     0     0
     0    -1     0
     0     0    -1

b = 6×1

     1
     1
     1
     0
     0
     0
```

Portfolio weights of 50% in IBM and 50% in INTC satisfy the constraints.

Input Arguments

`AssetMin` — Minimum allocations in each asset

scalar numeric | vector

Minimum allocations in each asset, specified as a scalar numeric or `NASSETS` vector. `NaN` indicates no constraint.

Data Types: `double`

`AssetMax` — Maximum allocations in each asset

scalar numeric | vector

Maximum allocations in each asset, specified as a scalar numeric or `NASSETS` vector. `NaN` indicates no constraint.

Data Types: `double`

`NumAssets` — Number of assets

length of `AssetMin` or `AssetMax` (default) | scalar numeric

(Optional) Number of assets, specified as a scalar numeric.

Data Types: `double`

Output Arguments

A — Lower bound

matrix

Lower bound, returned as a matrix such that `A*PortWts' <= b`, where `PortWts` is a 1-by-`NASSETS` vector of asset allocations.

b — Upper bound
vector

Upper bound, returned as a vector such that `A*PortWts' <= b`, where `PortWts` is a 1-by-`NASSETS` vector of asset allocations.

Version History

Introduced before R2006a

pcgcomp

Linear inequalities for asset group comparison constraints

Syntax

```
[A,b] = pcgcomp(GroupA,AtoBmin,AtoBmax,GroupB)
```

Description

As an alternative to `pcgcomp`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “Portfolio Object Workflow” on page 4-17.

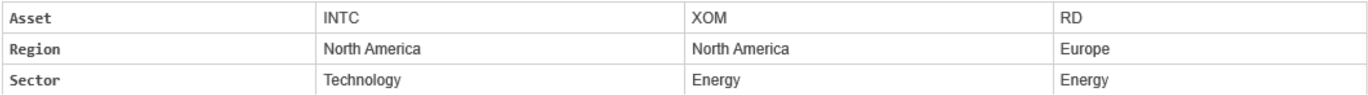
`[A,b] = pcgcomp(GroupA,AtoBmin,AtoBmax,GroupB)` specifies that the ratio of allocations in one group to allocations in another group is at least `AtoBmin` to `1` and at most `AtoBmax` to `1`. Comparisons can be made between an arbitrary number of group pairs `NGROUPS` comprising subsets of `NASSETS` available investments.

If `pcgcomp` is called with fewer than two output arguments, the function returns `A` concatenated with `b` `[A,b]`.

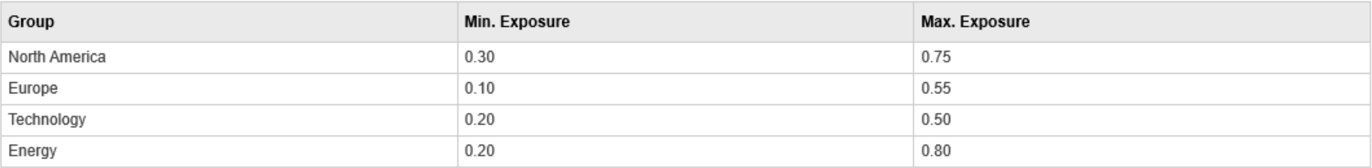
Examples

Linear Inequalities for Asset Group-to-Group Comparison Constraints

Use the following assets and groupings.



Asset	INTC	XOM	RD
Region	North America	North America	Europe
Sector	Technology	Energy	Energy



Group	Min. Exposure	Max. Exposure
North America	0.30	0.75
Europe	0.10	0.55
Technology	0.20	0.50
Energy	0.20	0.80

Make the North American energy sector compose exactly 20% of the North American investment.

```
%           INTC  XOM  RD
GroupA = [   0    1   0  ];  % North American Energy
GroupB = [   1    1   0  ];  % North America

AtoBmin = 0.20;
AtoBmax = 0.20;

[A,b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)
```

```
A = 2×3

    0.2000   -0.8000         0
   -0.2000    0.8000         0

b = 2×1

     0
     0
```

Portfolio weights of 40% for INTC, 10% for XOM, and 50% for RD satisfy the constraints.

Input Arguments

`GroupA` — Grouping A

vector

Grouping A, specified as a number of groups (`NGROUPS`) by number of assets (`NASSETS`) vector of groups to compare. Each row specifies a group. For a specific group, `Group(i,j) = 1` if the group contains asset `j`; otherwise, `Group(i,j) = 0`.

Data Types: `double`

`AtoBmin` — Minimum ratios

scalar | vector

Minimum ratios, specified as a scalar or `NGROUPS`-long vectors of minimum ratios of allocations in `GroupA` to allocations in `GroupB`. `NaN` indicates no constraint between the two groups. Scalar bounds are applied to all group pairs. The total number of assets allocated to `GroupA` divided by the total number of assets allocated to `GroupB` is >= `AtoBmin` and <= `AtoBmax`.

Data Types: `double`

`AtoBmax` — Maximum ratios

scalar | vector

Maximum ratios, specified as a scalar or `NGROUPS`-long vectors of maximum ratios of allocations in `GroupA` to allocations in `GroupB`. `NaN` indicates no constraint between the two groups. Scalar bounds are applied to all group pairs. The total number of assets allocated to `GroupA` divided by the total number of assets allocated to `GroupB` is >= `AtoBmin` and <= `AtoBmax`.

Data Types: `double`

`GroupB` — Grouping A

vector

Grouping B, specified as a number of groups (`NGROUPS`) by number of assets (`NASSETS`) vector of groups to compare. Each row specifies a group. For a specific group, `Group(i,j) = 1` if the group contains asset `j`; otherwise, `Group(i,j) = 0`.

Data Types: `double`

Output Arguments

A — Lower bound

matrix

Lower bound, returned as a matrix such that `A*PortWts' <= b`, where `PortWts` is a 1-by-`NASSETS` vector of asset allocations.

b — Upper bound

vector

Upper bound, returned as a vector such that `A*PortWts' <= b`, where `PortWts` is a 1-by-`NASSETS` vector of asset allocations.

Version History

Introduced before R2006a

pcglims

Linear inequalities for asset group minimum and maximum allocation

Syntax

```
[A,b] = pcglims(Groups,GroupMin,GroupMax)
```

Description

As an alternative to `pcglims`, use the Portfolio object (`Portfolio`) for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “Portfolio Object Workflow” on page 4-17.

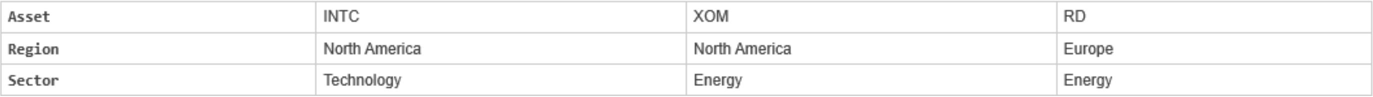
`[A,b] = pcglims(Groups,GroupMin,GroupMax)` specifies minimum and maximum allocations to groups of assets. Bounds can be specified for an arbitrary number of groups `NGROUPS`,made up as subsets of the `NASSETS` investments.

If `pcglims` is called with fewer than two output arguments, the function returns `A` concatenated with `b [A,b]`.

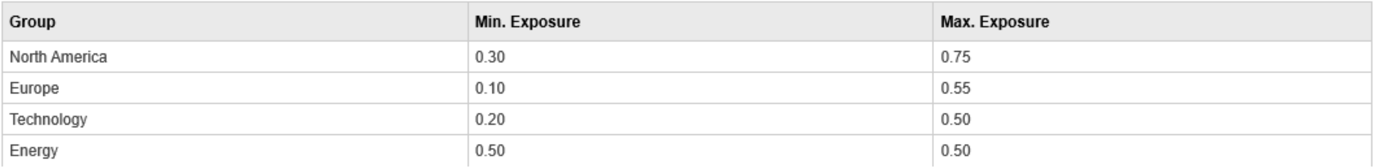
Examples

Linear Inequalities for Asset Group Minimum and Maximum Allocation

Use the following assets and groupings.



Asset	INTC	XOM	RD
Region	North America	North America	Europe
Sector	Technology	Energy	Energy



Group	Min. Exposure	Max. Exposure
North America	0.30	0.75
Europe	0.10	0.55
Technology	0.20	0.50
Energy	0.50	0.50

Set the minimum and maximum investment in various groups.

```
%           INTC  XOM  RD
Groups = [   1    1   0  ;  % North America
             0    0   1  ;  % Europe
             1    0   0  ;  % Technology
             0    1   1  ]; % Energy

GroupMin = [0.30
            0.10
            0.20
            0.50];

GroupMax = [0.75
            0.55
            0.50
            0.50];

[A,b] = pcglims(Groups, GroupMin, GroupMax)
```

```
A = 8×3

    -1    -1     0
     0     0    -1
    -1     0     0
     0    -1    -1
     1     1     0
     0     0     1
     1     0     0
     0     1     1

b = 8×1

   -0.3000
   -0.1000
   -0.2000
   -0.5000
    0.7500
    0.5500
    0.5000
    0.5000
```

Portfolio weights of 50% in INTC, 25% in XOM, and 25% in RD satisfy the constraints.

Input Arguments

Groups — Grouping

vector

Grouping, specified as a number of groups (NGROUPS) by number of assets (NASSETS) vector of which assets belong to which group. Each row specifies a group. For a specific group, Group(i,j) = 1 if the group contains asset j; otherwise, Group(i,j) = 0.

Data Types: double

GroupMin — Minimum allocations

scalar | vector

Minimum allocations, specified as a scalar or NGROUPS-long vectors of minimum combined allocations in each group. NaN indicates no constraint. Scalar bounds are applied to all groups.

Data Types: double

GroupMax — Maximum allocations

scalar | vector

Maximum allocations, specified as a scalar or NGROUPS-long vectors maximum combined allocations in each group. NaN indicates no constraint. Scalar bounds are applied to all groups.

Data Types: double

Output Arguments

A — Lower bound

matrix

Lower bound, returned as a matrix such that A*PortWts' <= b, where PortWts is a 1-by-NASSETS vector of asset allocations.

b — Upper bound

vector

Upper bound, returned as a vector such that A*PortWts' <= b, where PortWts is a 1-by-NASSETS vector of asset allocations.

Version History

Introduced before R2006a

pcpval

Linear inequalities for fixing total portfolio value

Syntax

```
[A,b] = pcpval(PortValue,NumAssets)
```

Description

`[A,b] = pcpval(PortValue,NumAssets)` scales the total value of a portfolio of `NumAssets` assets to `PortValue`. All portfolio weights, bounds, return, and risk values except `ExpReturn` and `ExpCovariance` (see `portopt`) are in terms of `PortValue`.

Note As an alternative to `pcpval`, use the `Portfolio` object (`Portfolio`) for mean-variance portfolio optimization. The `Portfolio` object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using Portfolio objects, see “Portfolio Object Workflow” on page 4-17.

Examples

Scale the Value of a Portfolio

Scale the value of a portfolio of three assets that are equal to 1, so all return values are rates and all weight values are in fractions of the portfolio.

```
PortValue = 1;
NumAssets = 3;

[A,b] = pcpval(PortValue, NumAssets)
```

```
A = 2×3

     1     1     1
    -1    -1    -1

b = 2×1

     1
    -1
```

Portfolio weights of 40%, 10%, and 50% in the three assets satisfy the constraints.

Input Arguments

PortValue — Total value of asset portfolio

numeric

Total value of asset portfolio, specified as a scalar numeric representing the sum of the allocations in all assets. `PortValue = 1` specifies weights as fractions of the portfolio and return and risk numbers as rates instead of value.

Data Types: `double`

NumAssets — Number of available asset investments

numeric

Number of available asset investments, specified as a scalar numeric.

Data Types: `double`

Output Arguments

A — Asset allocations

matrix

Asset allocations, returned as a matrix such that `A*PortWts' <= b`, where `PortWts` is a `1`-by-`NASSETS` vector of asset allocations.

b — Asset allocations

vector

Asset allocations, returned as a vector such that `A*PortWts' <= b`, where `PortWts` is a `1`-by-`NASSETS` vector of asset allocations.

Note If `pcpcval` is called with fewer than two output arguments, returns `A` and `b` are concatenated together:

```
Cons = [A, b];
Cons = pcpval(PortValue, NumAssets)
```

Version History

Introduced before R2006a

periodicreturns

Periodic total returns from total return prices

Syntax

```
TotalReturn = periodicreturns(TotalReturnPrices)
TotalReturn = periodicreturns(___,Period)
```

Description

`TotalReturn = periodicreturns(TotalReturnPrices)` calculates the daily total returns from a daily total return price series.

`TotalReturn = periodicreturns(___,Period)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Compute TotalReturn Using datetime Input for TotalReturnPrices

Compute `TotalReturn` returned as a table using `datetime` input in a table for `TotalReturnPrices`.

```
Dates = datetime(2015,1,1:10,'Locale','en_US')';
Prices = [0.01 0.03 0.1  -0.05  0.02 0.07 0.03 -0.01 -0.02 0.01]';
TotalReturnPrices = table(Dates,Prices);
TotalReturn = periodicreturns(TotalReturnPrices)
```

```
TotalReturn=9×2 table
       Dates         Prices 
    ___________    ________

    02-Jan-2015           2
    03-Jan-2015      2.3333
    04-Jan-2015        -1.5
    05-Jan-2015        -1.4
    06-Jan-2015         2.5
    07-Jan-2015    -0.57143
    08-Jan-2015     -1.3333
    09-Jan-2015           1
    10-Jan-2015        -1.5
```

Input Arguments

`TotalReturnPrices` — Total return prices for a given security
matrix | table

Total return prices for a given security, specified as an `NUMOBS`-by-`NASSETS + 1` matrix where Column 1 contains MATLAB serial date numbers. The remaining columns contain total return price data.

If you specify `TotalReturnPrices` as a table, the first column of the table represents the dates (as either a datetime array, string array, date character vectors, or serial date numbers) while the other columns represent the returns data. If a table is used, `TotalReturn` is returned as a table.

Note Although input returns can have dates in either ascending or descending order, output total returns in `TotalReturn` have dates in ascending order, with the earliest date in the first row of `TotalReturn`, and the most recent date in the last row of `TotalReturn`.

Data Types: `double` | `datetime` | `string` | `char` | `table`

`Period` — Periodicity flag used to compute total returns
`'d'` (default) | character vector | numeric

(Optional) Periodicity flag used to compute total returns, specified as one of the following values:

- `'d'` = daily values (default)
- `'w'` = weekly values
- `'m'` = monthly values
- *n* = rolling return periodic values, where *n* is an integer

Data Types: `char` | `double`

Output Arguments

`TotalReturn` — Total return values
matrix | table

Total return values, returned as a `P`-by-`N` matrix or table consisting of either Dates in column 1 and daily return values in the remaining columns or period-end dates in column 1 and monthly return values in the remaining columns. The format of `TotalReturn` matches the format of the input `TotalReturnPrices`.

Version History

Introduced before R2006a

plotFrontier

Plot efficient frontier

Syntax

```
[prsk,pret] = plotFrontier(obj)

[prsk,pret] = plotFrontier(obj,NumPorts)
[prsk,pret] = plotFrontier(obj,PortWeights)
[prsk,pret] = plotFrontier(obj,PortRisk,PortReturn)
```

Description

`[prsk,pret] = plotFrontier(obj)` estimates the efficient frontier with default number of 10 portfolios on the frontier, and plots the corresponding efficient frontier for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`[prsk,pret] = plotFrontier(obj,NumPorts)` estimates the efficient frontier with a specified number portfolios on the frontier, and plots the corresponding efficient frontier. The number of portfolios is defined by `NumPorts`.

`[prsk,pret] = plotFrontier(obj,PortWeights)` estimates efficient portfolio risks and returns with `PortWeights`, and plots the efficient frontier with those portfolios. This syntax assumes that you provide valid efficient portfolio weights as input. `PortWeights` is a `NumAsset`-by-`NumPorts` matrix.

`[prsk,pret] = plotFrontier(obj,PortRisk,PortReturn)` plots the efficient frontier with the given risks and returns. This syntax assumes that you provide valid inputs for efficient portfolio risks and returns. `PortRisk` and `PortReturn` are vectors with the same size.

Note `plotFrontier` handles multiple input formats as described above. Given an asset universe with `NumAssets` assets and an efficient frontier with `NumPorts` portfolios, remember that portfolio weights are `NumAsset`-by-`NumPorts` matrices and that portfolio risks and returns are `NumPorts` column vectors.

Examples

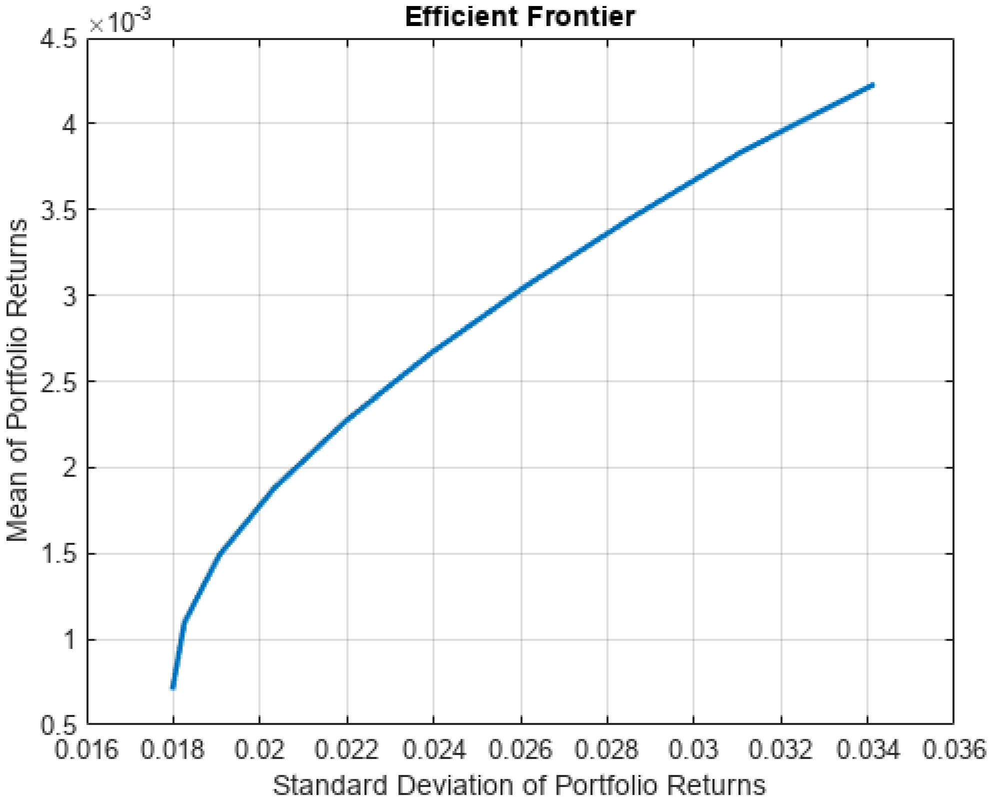
Plot the Efficient Frontier for the Portfolio Object

Given a portfolio `p`, plot the efficient frontier.

```
load CAPMuniverse

p = Portfolio('AssetList',Assets(1:12));
p = estimateAssetMoments(p, Data(:,1:12),'missingdata',true);
```

```
p = setDefaultConstraints(p);
plotFrontier(p);
```



Plot the Efficient Frontier for the Portfolio Object with BoundType and MaxNumAssets Constraints

Create a `Portfolio` object for 12 stocks based on `CAPMuniverse.mat`.

```
load CAPMuniverse
p0 = Portfolio('AssetList',Assets(1:12));
p0 = estimateAssetMoments(p0, Data(:,1:12),'missingdata',true);
p0 = setDefaultConstraints(p0);
```

Use `setMinMaxNumAssets` to define a maximum number of 3 assets.

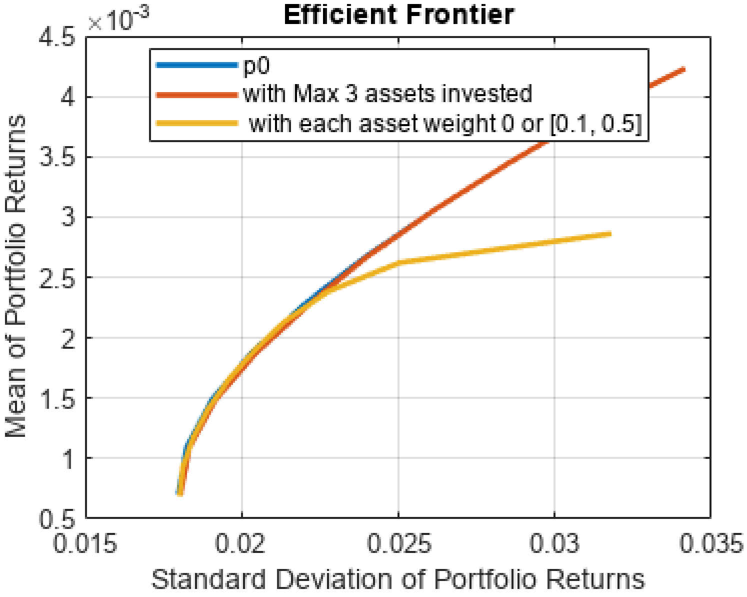
```
pWithMaxNumAssets = setMinMaxNumAssets(p0, [], 3);
```

Use `setBounds` to define a lower and upper bound and a `BoundType` of `'Conditional'`.

```
pWithConditionalBound = setBounds(p0, 0.1, 0.5,'BoundType', 'Conditional');
```

Use `plotFrontier` to compare the different portfolio objects.

```
figure;
plotFrontier(p0); hold on;
plotFrontier(pWithMaxNumAssets); hold on;
plotFrontier(pWithConditionalBound); hold off;
legend('p0', 'with Max 3 assets invested', ' with each asset weight 0 or [0.1, 0.5]', 'location'
```



Define a target return and use `estimateFrontierByReturn` to compare the three portfolio objects.

```
targetRetn = 2.0e-3;
pwgt0 = estimateFrontierByReturn(p0, targetRetn);
pwgtWithMaxNumAssets = estimateFrontierByReturn(pWithMaxNumAssets, targetRetn);
pwgtConditionalBound = estimateFrontierByReturn(pWithConditionalBound, targetRetn);
```

The following table shows the final allocation for specified target return among the three portfolio objects. You can see that the small positions in `'AAPL'`and `'HPQ'` are avoided in `pwgtConditionalBound`, and only three assets are invested in `pwgtWithMaxNumAssets`.

```
result = table(p0.AssetList',pwgt0,pwgtWithMaxNumAssets,pwgtConditionalBound)
```

```
result=12×4 table
      Var1         pwgt0       pwgtWithMaxNumAssets     pwgtConditionalBound
    ________    ________    ____________________    ____________________

    {'YHOO'}           0                  0                     0
```

Plot the Efficient Frontier for the PortfolioCVaR Object

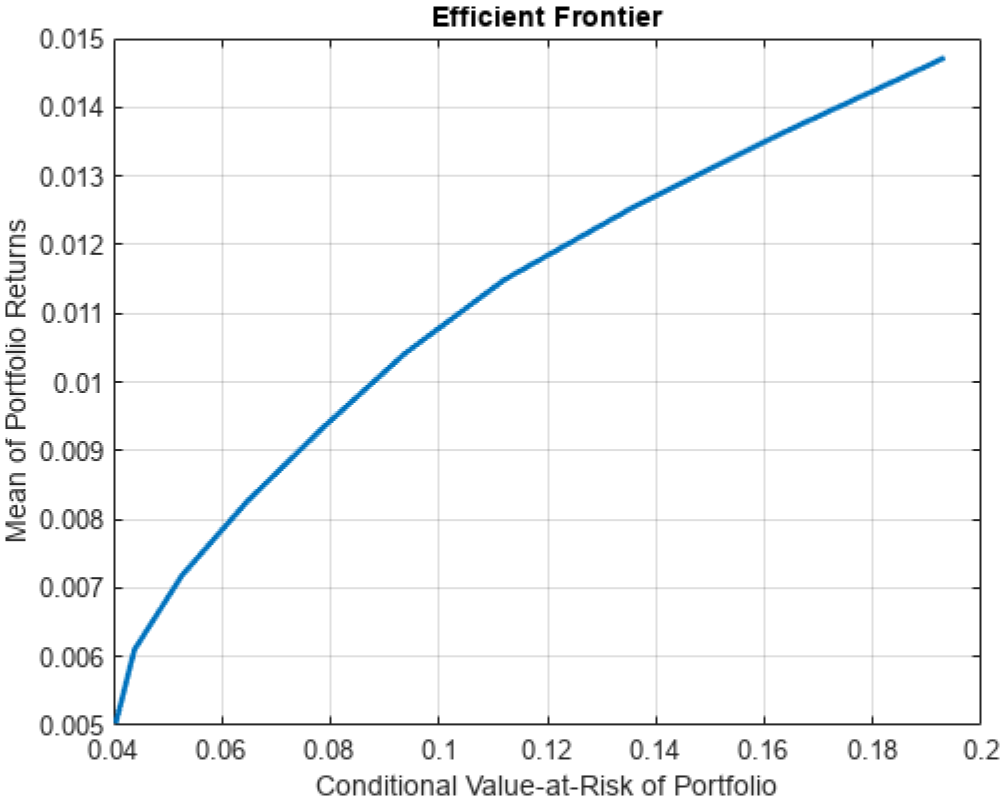
Given a PortfolioCVaR p, plot the efficient frontier.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);
```



Plot Efficient Frontier for PortfolioMAD Object

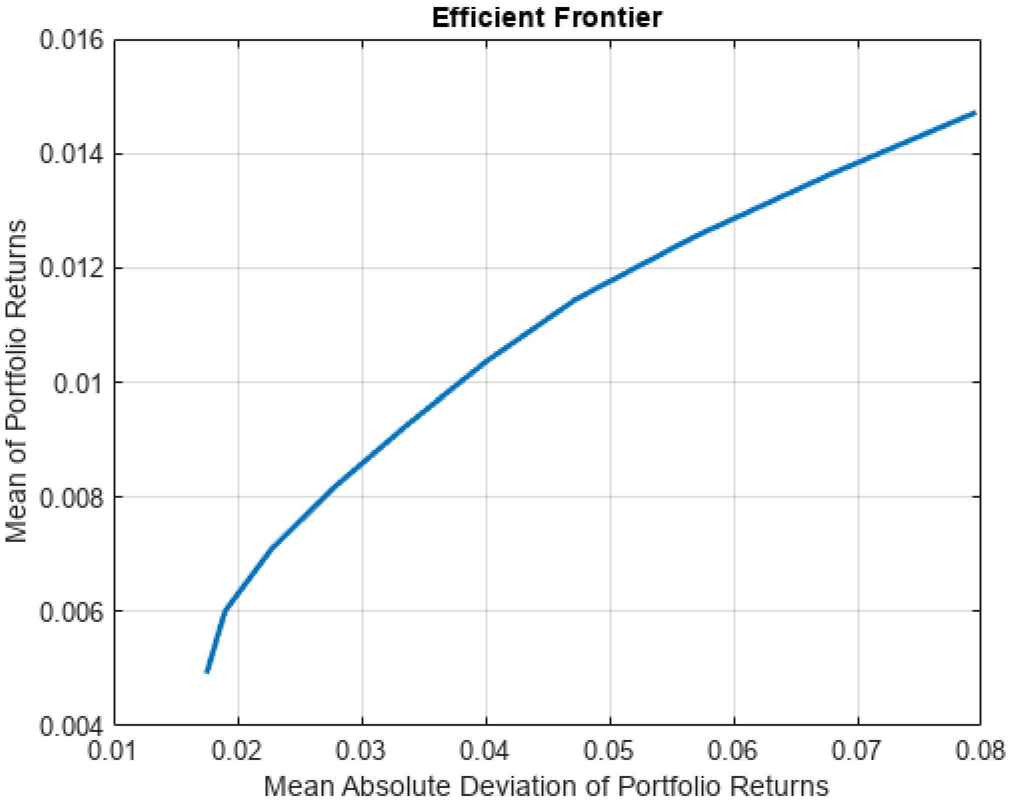
Given a PortfolioMAD p, plot the efficient frontier.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

plotFrontier(p);
```



Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`NumPorts` — Number of points to obtain on efficient frontier
value from hidden property `defaultNumPorts` (default value is `10`) (default) | scalar integer

Number of points to obtain on the efficient frontier, specified as a scalar integer.

Note If no value is specified for `NumPorts`, the default value is obtained from the hidden property `defaultNumPorts` (default value is `10`). If `NumPorts = 1`, this function returns the portfolio specified by the hidden property `defaultFrontierLimit` (current default value is `'min'`).

Data Types: `double`

`PortRisk` — Standard deviations of portfolio returns for each portfolio
`[]` (default) | vector

Standard deviations of portfolio returns for each portfolio, specified as a vector.

Note `PortRisk` and `PortReturn` must be vectors with the same size.

Data Types: `double`

`PortReturn` — Means of portfolio returns for each portfolio
`[]` (default) | vector

Means of portfolio returns for each portfolio, specified as a vector.

Note `PortRisk` and `PortReturn` must be vectors with the same size.

Data Types: `double`

`PortWeights` — Optimal portfolios on the efficient frontier
`[]` (default) | matrix

Optimal portfolios on the efficient frontier, specified as a `NumAsset`-by-`NumPorts` matrix.

Data Types: `double`

Output Arguments

`prsk` — Estimated efficient portfolio risks (standard deviation of returns
vector

Estimated efficient portfolio risks (standard deviation of returns, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note

- If the portfolio object has a name in the `Name` property, the name is displayed as the title of the plot. Otherwise, the plot is labeled “Efficient Frontier.”
- If the portfolio object has an initial portfolio in the `InitPort` property, the initial portfolio is plotted and labeled.
- If portfolio risks and returns are inputs, make sure that risks come first in the calling sequence. In addition, if portfolio risks and returns are not sorted in ascending order, this method performs the sort. On output, the sorted moments are returned.

`pret` — Estimated efficient portfolio returns
vector

Estimated efficient portfolio returns, returned as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note

- If the portfolio object has a name in the `Name` property, the name is displayed as the title of the plot. Otherwise, the plot is labeled “Efficient Frontier.”
- If the portfolio object has an initial portfolio in the `InitPort` property, the initial portfolio is plotted and labeled.
- If portfolio risks and returns are inputs, make sure that risks come first in the calling sequence. In addition, if portfolio risks and returns are not sorted in ascending order, this method performs the sort. On output, the sorted moments are returned.

Tips

You can also use dot notation to plot the efficient frontier.

```
[prsk, pret] = obj.plotFrontier;
```

Version History

Introduced in R2011a

pointfig

Point and figure chart

Note `pointfig` is updated to accept data input as a matrix, `timetable`, or `table`.

Syntax

```
pointfig(Data)
h = pointfig(ax,Data)
```

Description

`pointfig(Data)` plots a point and figure chart from a series of prices of a security. Upward price movements are plotted as `X`'s and downward price movements are plotted as `O`'s.

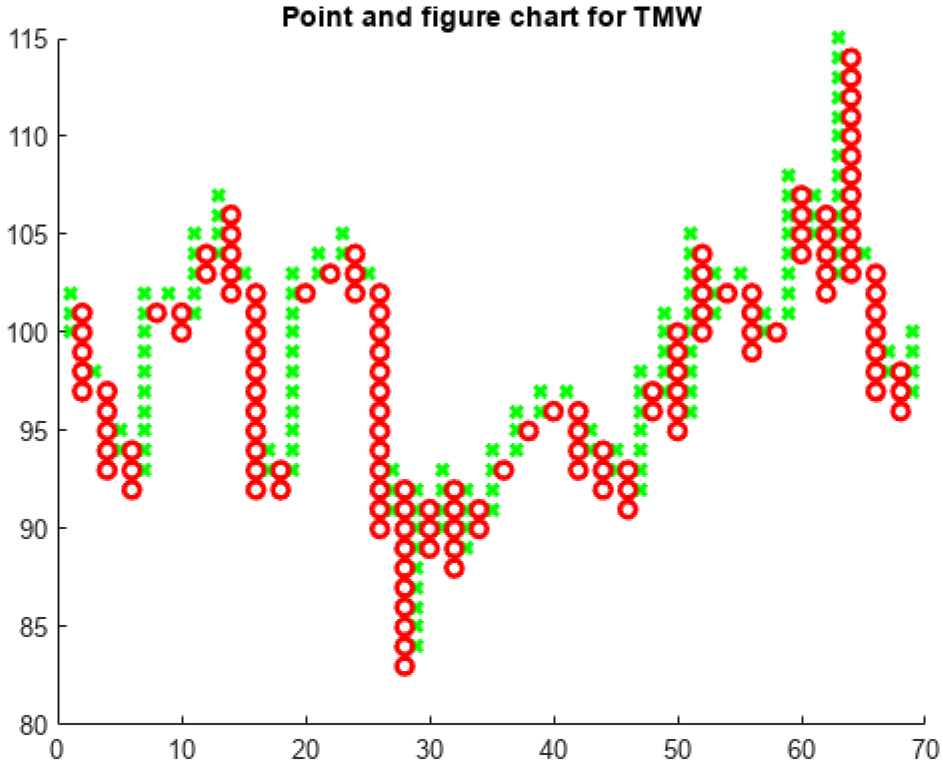
`h = pointfig(ax,Data)` adds an optional argument for `ax`.

Examples

Generate a Point and Figure Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock. This Point and Figure chart is for closing prices of the stock TMW for the most recent 21 days. Note that the variable name of asset price is be renamed to `'Price'` (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
pointfig(TMW(1:200,:))
title('Point and figure chart for TMW')
```



Input Arguments

Data — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with M rows must contain a variable named `'Price'` (case insensitive).

Data Types: `double` | `table` | `timetable`

ax — Valid axis object

current axes (`ax = gca`) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The point and figure plot is created in the axes specified by `ax` instead of in the current axes (`ax = gca`). The option `ax` can precede any of the input argument combinations.

Data Types: `object`

Output Arguments

h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

Version History

Introduced in R2006a

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

portalloc

Optimal capital allocation to efficient frontier portfolios

Syntax

```
[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] =
portalloc(PortRisk,PortReturn,PortWts,RisklessRate)
[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] =
portalloc( ___ ,BorrowRate,RiskAversion)
```

```
portalloc(PortRisk,PortReturn,PortWts,RisklessRate,BorrowRate,RiskAversion)
```

Description

`[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] = portalloc(PortRisk,PortReturn,PortWts,RisklessRate)` calculates the optimal risky portfolio and the optimal allocation of funds between that risky portfolio of `NASSETS` and the risk-free asset.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

`[RiskyRisk,RiskyReturn,RiskyWts,RiskyFraction,OverallRisk,OverallReturn] = portalloc( ___ ,BorrowRate,RiskAversion)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

`portalloc(PortRisk,PortReturn,PortWts,RisklessRate,BorrowRate,RiskAversion)` when invoked without any output arguments, a graph of the optimal capital allocation decision is displayed.

Examples

Compute the Optimal Risky Portfolio

This example shows how to compute the optimal risky portfolio by generating the efficient frontier from the asset data and then finding the optimal risky portfolio and allocate capital. The risk-free investment return is 8%, and the borrowing rate is 12%.

```
ExpReturn = [0.1 0.2 0.15];

ExpCovariance = [0.005   -0.010    0.004
                -0.010    0.040   -0.002
                 0.004   -0.002    0.023];
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn,...
ExpCovariance);

RisklessRate  = 0.08;
BorrowRate    = 0.12;
RiskAversion  = 3;

[RiskyRisk, RiskyReturn, RiskyWts, RiskyFraction, ...
OverallRisk, OverallReturn] = portalloc(PortRisk, PortReturn,...
PortWts, RisklessRate, BorrowRate, RiskAversion)
```

```
RiskyRisk = 0.1283

RiskyReturn = 0.1788

RiskyWts = 1×3

    0.0265    0.6023    0.3712

RiskyFraction = 1.1898

OverallRisk = 0.1527

OverallReturn = 0.1899
```

Input Arguments

PortRisk — Standard deviation of each risky asset efficient frontier portfolio
vector

Standard deviation of each risky asset efficient frontier portfolio, specified as an NPORTS-by-1 vector.

Data Types: double

PortReturn — Expected return of each risky asset efficient frontier portfolio
vector

Expected return of each risky asset efficient frontier portfolio, specified an NPORTS-by-1 vector.

Data Types: double

PortWts — Weights allocated to each asset
numeric

Weights allocated to each asset, specified as an NPORTS by number of assets (NASSETS) matrix of weights allocated to each asset. Each row represents an efficient frontier portfolio of risky assets. Total of all weights in a portfolio is 1.

Data Types: double

RisklessRate — Risk-free lending rate
scalar decimal

Risk-free lending rate, specified as a scalar decimal.

Data Types: double

BorrowRate — Borrowing rate
NaN (default) | scalar decimal

(Optional) Borrowing rate, specified as a scalar decimal. If borrowing is not desired, or not an option, set the BorrowRate to NaN (which is the default value).

Data Types: double

RiskAversion — Coefficient of investor's degree of risk aversion
3 (default) | scalar numeric

(Optional) Coefficient of investor's degree of risk aversion, specified as a scalar numeric. Higher numbers indicate greater risk aversion. Typical coefficients range from 2.0 through 4.0. The default value of RiskAversion is 3.

Note Consider that a less risk-averse investor would be expected to accept much greater risk and, consequently, a more risk-averse investor would accept less risk for a given level of return. Therefore, making the RiskAversion argument higher reflects the risk-return tradeoff in the data.

Data Types: double

Output Arguments

RiskyRisk — Standard deviation of the optimal risky portfolio
numeric

Standard deviation of the optimal risky portfolio, returned as a scalar.

RiskyReturn — Expected return of the optimal risky portfolio
numeric

Expected return of the optimal risky portfolio, returned as a scalar.

RiskyWts — Weights allocated to the optimal risky portfolio
vector

Weights allocated to the optimal risky portfolio, returned a 1-by-NASSETS vector. The total of all weights in the portfolio is 1.

RiskyFraction — Fraction of the complete portfolio allocated to the risky portfolio
numeric

Fraction of the complete portfolio (that is, the overall portfolio including risky and risk-free assets) allocated to the risky portfolio, returned as a scalar.

OverallRisk — Standard deviation of the optimal overall portfolio
numeric

Standard deviation of the optimal overall portfolio, returned as a scalar.

OverallReturn — Expected rate of return of the optimal overall portfolio
numeric

Expected rate of return of the optimal overall portfolio, returned as a scalar.

Version History

Introduced before R2006a

portfolioRiskContribution

Compute individual asset risk contribution to overall portfolio volatility

Syntax

```
riskCont = portfolioRiskContribution(portWeights,Sigma)
riskCont = portfolioRiskContribution( ___ ,Name=Value)
```

Description

`riskCont = portfolioRiskContribution(portWeights,Sigma)` computes individual asset risk contribution to overall portfolio volatility and returns `riskCont` as a matrix of risk contributions.

`riskCont = portfolioRiskContribution( ___ ,Name=Value)` specifies an option using a name-value argument in addition to the input arguments in the previous syntax.

Examples

Compute Individual Asset Risk Contribution

Use `portfolioRiskContribution` to compute the risk contribution per asset with respect to the portfolio total risk.

Assume the returns covariance matrix is given by the following values.

```
Sigma = [0.0100    0.0075    0.0100    0.0150
         0.0075    0.0225    0.0150    0.0225
         0.0100    0.0150    0.0400    0.0450
         0.0150    0.0225    0.0450    0.0900];
```

The `portWeights` are the following values:

```
portWeights = [0.4101; 0.2734; 0.1899; 0.1266];
```

Use `portfolioRiskContribution` to compute the percent of risk contribution per asset.

```
riskCont = portfolioRiskContribution(portWeights,Sigma)
```

```
riskCont = 4×1

    0.2500
    0.2500
    0.2500
    0.2500
```

The default is to compute the relative risk contribution. However, you can compute the absolute risk contribution by using the name-value argument `RiskContributionType="absolute"`. Use `portfolioRiskContribution` to compute each asset's relative risk contribution.

```
riskCont = portfolioRiskContribution(portWeights,Sigma,RiskContributionType="relative")
riskCont = 4×1

    0.2500
    0.2500
    0.2500
    0.2500
```

Compute Individual Asset Risk Contribution When Returns Contain NaN Values

Use `portfolioRiskContribution` to compute the risk contribution of each asset with respect to the portfolio total risk when the assets returns used to compute the variance have `NaN` values.

Assume the returns covariance matrix is given by the following values.

```
load('CAPMuniverse.mat','AssetsTimeTable')
Sigma = cov(AssetsTimeTable{:,1:12},'partialrows')
```

```
Sigma = 12×12

    0.0012    0.0005    0.0005    0.0005    0.0005    0.0001    0.0004    0.0003    0.0006    0.0
    0.0005    0.0023    0.0007    0.0005    0.0009    0.0001    0.0005    0.0003    0.0006    0.0
    0.0005    0.0007    0.0012    0.0006    0.0007    0.0000    0.0006    0.0004    0.0007    0.0
    0.0005    0.0005    0.0006    0.0009    0.0006    0.0000    0.0005    0.0003    0.0006    0.0
    0.0005    0.0009    0.0007    0.0006    0.0017    0.0002    0.0005    0.0003    0.0005    0.0
    0.0001    0.0001    0.0000    0.0000    0.0002    0.0006   -0.0000    0.0000    0.0000    0.0
    0.0004    0.0005    0.0006    0.0005    0.0005   -0.0000    0.0009    0.0003    0.0005    0.0
    0.0003    0.0003    0.0004    0.0003    0.0003    0.0000    0.0003    0.0004    0.0003    0.0
    0.0006    0.0006    0.0007    0.0006    0.0005    0.0000    0.0005    0.0003    0.0010    0.0
    0.0003    0.0004    0.0005    0.0004    0.0004    0.0000    0.0003    0.0002    0.0005    0.0
      ⋮
```

The risk parity portfolio is subject to the following weights for all the assets.

```
portWeights = [0.1; 0.1; 0.1; 0.03; 0.1; 0.1; 0.1; 0.05; 0.1; 0.1; 0.1; 0.1];
```

Use `portfolioRiskContribution` to compute the percentage risk contribution per asset.

```
riskCont = portfolioRiskContribution(portWeights,Sigma)
```

```
riskCont = 12×1

    0.0911
    0.1261
    0.1103
    0.0251
    0.1197
    0.0203
    0.0805
    0.0258
    0.0978
    0.0660
      ⋮
```

The default values returned by portfolioRiskContribution are the relative risk contribution of the individual assets to the overall portfolio risk. Also, you can compute the absolute risk contribution by using the name-value argument RiskContributionType="absolute". Use portfolioRiskContribution to compute each asset's absolute risk contribution.

```
riskCont = portfolioRiskContribution(portWeights,Sigma,RiskContributionType="absolute")
```

```
riskCont = 12×1

    0.0023
    0.0031
    0.0027
    0.0006
    0.0030
    0.0005
    0.0020
    0.0006
    0.0024
    0.0016
      ⋮
```

Compute Individual Asset Risk Contribution When portWeights Is Matrix

Use portfolioRiskContribution to compute the risk contribution per asset with respect to the portfolio total risk when portWeights is a matrix.

Assume the returns covariance matrix is given by the following values.

```
Sigma = [0.0100    0.0075    0.0100    0.0150
         0.0075    0.0225    0.0150    0.0225
         0.0100    0.0150    0.0400    0.0450
         0.0150    0.0225    0.0450    0.0900];
```

The matrix of portWeights is the values:

```
portWeights = [0.25    0.10    0.10828;
               0.25    0.20    0.17197;
               0.25    0.30    0.28026;
               0.25    0.40    0.43949];
```

Use portfolioRiskContribution to compute the percent of risk contribution per asset.

```
riskCont = portfolioRiskContribution(portWeights,Sigma)
```

```
riskCont = 4×3

    0.1083    0.0308    0.0322
    0.1720    0.1005    0.0816
    0.2803    0.2735    0.2455
    0.4395    0.5952    0.6407
```

The default is to compute the relative risk contribution. However, you can compute the absolute risk contribution by using the name-value argument RiskContributionType="absolute". Use portfolioRiskContribution to compute each asset's absolute risk contribution.

```
riskCont = portfolioRiskContribution(portWeights,Sigma,RiskContributionType="absolute")
```

```
riskCont = 4×3

    0.0170    0.0060    0.0064
    0.0269    0.0194    0.0162
    0.0439    0.0528    0.0488
    0.0688    0.1149    0.1274
```

Input Arguments

portWeights — Portfolio weights
matrix

Portfolio weights, specified using an NumAssets-by-NumPortfolios matrix. portWeights must be nonempty, numeric, finite, and real. portWeights can be negative and does not need to sum to 1. portWeights and Sigma must have the same number of NumAssets.

Data Types: double

Sigma — Covariance matrix of returns
positive semidefinite covariance matrix

Covariance matrix of returns, specified using an NumAssets-by-NumAssets positive semidefinite covariance matrix. Sigma and portWeights must have the same number of NumAssets.

Note If Sigma is not a positive symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: riskCont = portfolioRiskContribution(portWeights,Sigma,RiskContributionType="relative")

RiskContributionType — Type of risk contribution to compute
"relative" (relative risk contribution) (default) | character vector with value of 'relative' or 'absolute' | string with value of "relative" or "absolute"

Type of risk contribution to compute, specified as RiskContributionType and a scalar character vector or string:

- "relative" — Computes the relative contribution.
- "absolute" — Computes the absolute risk contribution.

Data Types: char | string

Output Arguments

`riskCont` — Risk contributions
matrix

Risk contributions, returned as a matrix. The default values returned by `portfolioRiskContribution` are the relative contribution of the assets to the portfolio. However, `portfolioRiskContribution` can also return the absolute risk contribution by passing the name-value argument `RiskContributionType` with a value of `"absolute"`.

riskBudgetingPortfolio

Compute risk budgeting portfolios

Syntax

```
pwgt = riskBudgetingPortfolio(Sigma)
pwgt = riskBudgetingPortfolio(Sigma,budget)
pwgt = riskBudgetingPortfolio( ___ ,Name=Value)
[pwgt,exitflag] = riskBudgetingPortfolio( ___ ,Name=Value)
```

Description

`pwgt = riskBudgetingPortfolio(Sigma)` computes risk budgeting portfolios for long-only, fully invested, risk budgeting portfolios. When a `budget` input argument is not provided, the budget is set the same for all assets.

A risk budgeting portfolio is an allocation strategy that focuses on the allocation of risk without considering the returns. The goal of this strategy is to ensure that each asset in a portfolio contributes a given target risk level to the overall portfolio volatility.

`pwgt = riskBudgetingPortfolio(Sigma,budget)` computes risk budgeting portfolios for the long-only, fully invested, risk budgeting portfolios associated with the target risk budgets (`Budget`).

`pwgt = riskBudgetingPortfolio( ___ ,Name=Value)` specifies options using name-value arguments in addition to the input arguments in the previous syntaxes.

`[pwgt,exitflag] = riskBudgetingPortfolio( ___ ,Name=Value)` add an output argument for `exitflag` and specifies options using name-value arguments in addition to the input arguments in the previous syntax.

Examples

Compute Risk Budgeting Portfolio

Use `riskBudgetingPortfolio` to compute long-only, fully invested, risk budgeting portfolios.

Assume the returns covariance matrix is given by the following values.

```
Sigma = [0.0100    0.0075    0.0100    0.0150
         0.0075    0.0225    0.0150    0.0225
         0.0100    0.0150    0.0400    0.0450
         0.0150    0.0225    0.0450    0.0900];
```

When a `budget` input argument is not provided, by default, the `riskBudgetingPortfolio` function computes a risk parity portfolio. The `riskBudgetingPortfolio` default is to consider that the risk contribution is the same for all assets and the weights are long-only and fully invested.

```
pwgt = riskBudgetingPortfolio(Sigma)
```

```
pwgt = 4×1
```

```
    0.4101
    0.2734
    0.1899
    0.1266
```

However, if a vector is passed for the optional input `budget`, the `riskBudgetingPortfolio` function computes the long-only, fully invested, risk budgeting portfolios that achieve the target risk contributions specified in `budget`.

```
pwgt = riskBudgetingPortfolio(Sigma, [0.1;0.2;0.3;0.4])
```

```
pwgt = 4×1

    0.2292
    0.2800
    0.2633
    0.2275
```

Compute Risk Budgeting Portfolio When Returns Contain NaN Values

Use `riskBudgetingPortfolio` to compute the risk budgeting portfolio when the asset returns contain `NaN` values.

Assume the returns covariance matrix is given by the following values.

```
load('CAPMuniverse.mat','AssetsTimeTable')
Sigma = cov(AssetsTimeTable{:,1:12},'partialrows')
```

```
Sigma = 12×12

    0.0012    0.0005    0.0005    0.0005    0.0005    0.0001    0.0004    0.0003    0.0006    0.0
    0.0005    0.0023    0.0007    0.0005    0.0009    0.0001    0.0005    0.0003    0.0006    0.0
    0.0005    0.0007    0.0012    0.0006    0.0007    0.0000    0.0006    0.0004    0.0007    0.0
    0.0005    0.0005    0.0006    0.0009    0.0006    0.0000    0.0005    0.0003    0.0006    0.0
    0.0005    0.0009    0.0007    0.0006    0.0017    0.0002    0.0005    0.0003    0.0005    0.0
    0.0001    0.0001    0.0000    0.0000    0.0002    0.0006   -0.0000    0.0000    0.0000    0.0
    0.0004    0.0005    0.0006    0.0005    0.0005   -0.0000    0.0009    0.0003    0.0005    0.0
    0.0003    0.0003    0.0004    0.0003    0.0003    0.0000    0.0003    0.0004    0.0003    0.0
    0.0006    0.0006    0.0007    0.0006    0.0005    0.0000    0.0005    0.0003    0.0010    0.0
    0.0003    0.0004    0.0005    0.0004    0.0004    0.0000    0.0003    0.0002    0.0005    0.0
      ⋮
```

If only the covariance matrix is provided, the `riskBudgetingPortfolio` default is to consider that the risk contribution is the same for all assets and the weights are long-only and fully invested. Basically, the default is to obtain the risk parity portfolio.

```
pwgt = riskBudgetingPortfolio(Sigma)
```

```
pwgt = 12×1

    0.0718
    0.0576
    0.0610
    0.0757
    0.0574
    0.1940
    0.0817
    0.1178
    0.0676
    0.0981
       ⋮
```

However, if a vector is passed for the optional input `budget`, then the risk budgeting portfolio is computed using the default `ccd` algorithm.

```
pwgt = riskBudgetingPortfolio(Sigma,[0.1; 0.04; 0.2; 0.05; 0.1; 0.1; 0.1; 0.05; 0.1; 0.03; 0.1;
```

```
pwgt = 12×1

    0.0871
    0.0315
    0.1415
    0.0482
    0.0717
    0.2235
    0.0995
    0.0757
    0.0829
    0.0386
       ⋮
```

Compute Risk Budgeting Portfolio When `budget` Is Matrix

This example shows how to use `riskBudgetingPortfolio` to compute the risk budgeting portfolio when the `budget` values are a matrix.

Assume the returns covariance matrix is given by the following values.

```
Sigma = [0.0100    0.0075    0.0100    0.0150;
         0.0075    0.0225    0.0150    0.0225;
         0.0100    0.0150    0.0400    0.0450;
         0.0150    0.0225    0.0450    0.0900];
```

If only the covariance matrix is provided, the `riskBudgetingPortfolio` default is to consider that the risk contribution is the same for all assets and the weights are long-only and fully invested. Basically, the default is to obtain the risk parity portfolio.

```
pwgt = riskBudgetingPortfolio(Sigma)
```

```
pwgt = 4×1

    0.4101
    0.2734
    0.1899
    0.1266
```

If a matrix is passed for the optional input `budget`, then the risk budgeting portfolio is computed.

```
B = [0.25    0.10    0.10828;
     0.25    0.20    0.17197;
     0.25    0.30    0.28026;
     0.25    0.40    0.43949];
pwgt = riskBudgetingPortfolio(Sigma,B)
```

```
pwgt = 4×3

    0.4101    0.2292    0.2500
    0.2734    0.2800    0.2500
    0.1899    0.2633    0.2500
    0.1266    0.2275    0.2500
```

Input Arguments

`Sigma` — Covariance matrix of returns

positive semidefinite covariance matrix

Covariance matrix of returns, specified using an `NumAssets`-by-`NumAssets` positive semidefinite covariance matrix.

`Sigma` and `budget` must have the same number of `NumAssets`.

Note If `Sigma` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix.

Data Types: `double`

`budget` — Target risk budget for each asset

matrix

Target risk budget for each asset, specified using an `NumAssets`-by-`NumPortfolios` matrix. `budget` must be nonnegative and all columns must sum to `1` because the values for `budget` represent the percentage of risk that each asset contributes of the total portfolio risk.

`budget` and `Sigma` must have the same number of `NumAssets`.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `pwgt = riskBudgetingPortfolio(Sigma, [0.1;0.2;0.3;0.4],Algorithm="newton",BudgetTolerance=1e6)`

`Algorithm` — Optimization algorithm

`"ccd"` (default) | character vector with value `'ccd'` or `'newton'` | string with value `"ccd"` or `"newton"`

Optimization algorithm, specified as Algorithm and a character vector or string:

- "ccd" — Cyclical coordinate descent algorithm
- "newton" — Newton algorithm with backtracking line-search

Data Types: char | string

BudgetTolerance — Deviation tolerance from target budget
1e-8 (default) | positive numeric

Deviation tolerance from target budget, specified as BudgetTolerance and a scalar positive numeric.

Data Types: double

MaxIterations — Maximum number of iterations allowed for the Algorithm
1e6 for "ccd" or 1e3 for "newton" (default) | positive integer

Maximum number of iterations allowed for the Algorithm, specified as MaxIterations and a scalar positive integer.

Data Types: double

Output Arguments

pwgt — Portfolio weights
matrix

Portfolio weights, returned as a matrix in which each column represents a portfolio.

exitflag — Indication of why the algorithm stopped
vector

Indication of why the algorithm stopped, returned as a 1-by-NumPortfolios vector with one of the following values:

- 1 — The weights of the portfolio achieve the target risk budget up to BudgetTolerance accuracy.
- 0 — The number of iterations exceeded MaxIterations.
- -1 — The solver cannot find a descent direction. This value applies only to the "newton" option for the Algorithm.

.

portalpha

Compute risk-adjusted alphas and returns for one or more assets

Syntax

```
portalpha(Asset,Benchmark)
portalpha(Asset,Benchmark,Cash)
[Alpha,RAReturn] = portalpha(Asset,Benchmark,Cash,Choice)
```

Description

`portalpha(Asset,Benchmark)` computes risk-adjusted alphas.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

`portalpha(Asset,Benchmark,Cash)` computes risk-adjusted alphas using the optional argument `Cash`.

`[Alpha,RAReturn] = portalpha(Asset,Benchmark,Cash,Choice)` computes risk-adjusted alphas and returns for one or more methods specified by `Choice`.

Examples

Calculate the Risk-Adjusted Return

This example shows how to calculate the risk-adjusted return using `portalpha` and compare it with the fund and market's mean returns.

Use the example data with a fund, a market, and a cash series.

```
load FundMarketCash
Returns = tick2ret(TestData);
Fund = Returns(:,1);
Market = Returns(:,2);
Cash = Returns(:,3);
MeanFund = mean(Fund)
```

```
MeanFund = 0.0038
```

```
MeanMarket = mean(Market)
```

```
MeanMarket = 0.0030
```

```
[MM, aMM] = portalpha(Fund, Market, Cash, 'MM')
```

```
MM = 0.0022

aMM = 0.0052

[GH1, aGH1] = portalpha(Fund, Market, Cash, 'gh1')

GH1 = 0.0013

aGH1 = 0.0025

[GH2, aGH2] = portalpha(Fund, Market, Cash, 'gh2')

GH2 = 0.0022

aGH2 = 0.0052

[SML, aSML] = portalpha(Fund, Market, Cash, 'sml')

SML = 0.0013

aSML = 0.0025
```

Since the fund's risk is much less than the market's risk, the risk-adjusted return of the fund is much higher than both the nominal fund and market returns.

Input Arguments

Asset — Asset returns

matrix

Asset returns, specified as a NUMSAMPLES x NUMSERIES matrix with NUMSAMPLES observations of asset returns for NUMSERIES asset return series.

Data Types: double

Benchmark — Returns for a benchmark asset

vector

Returns for a benchmark asset, specified as a NUMSAMPLES vector of returns for a benchmark asset. The periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Benchmark should be monthly returns.

Data Types: double

Cash — Riskless asset

0 (default) | numeric | vector

(Optional) Riskless asset, specified as a either a scalar return for a riskless asset or a vector of asset returns to be a proxy for a “riskless” asset. In either case, the periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Cash must be monthly returns. If no value is supplied, the default value for Cash returns is 0.

Data Types: double

Choice — Computed measures

'xs' (default) | character vector | cell array of character vectors

(Optional) Computed measures, specified as a character vector or cell array of character vectors to indicate one or more measures to be computed from among various risk-adjusted alphas and return measures. The number of choices selected in `Choice` is `NUMCHOICES`. The list of choices is given in the following table:

Code	Description
`'xs'`	Excess Return (no risk adjustment)
`'sml'`	Security Market Line — The security market line shows that the relationship between risk and return is linear for individual securities (that is, increased risk = increased return).
`'capm'`	Jensen's Alpha — Risk-adjusted performance measure that represents the average return on a portfolio or investment, above or below that predicted by the capital asset pricing model (CAPM), given the portfolio's or investment's beta and the average market return.
`'mm'`	Modigliani & Modigliani — Measures the returns of an investment portfolio for the amount of risk taken relative to some benchmark portfolio.
`'gh1'`	Graham-Harvey 1 — Performance measure developed by John Graham and Campbell Harvey. The idea is to lever a fund's portfolio to exactly match the volatility of the S&P 500. The difference between the fund's levered return and the S&P 500 return is the performance measure.
`'gh2'`	Graham-Harvey 2 — In this measure, the idea is to lever up or down the fund's recommended investment strategy (using a Treasury bill), so that the strategy has the same volatility as the S&P 500.
`'all'`	Compute all measures.

`Choice` is specified by using the code from the table (for example, to select the Modigliani & Modigliani measure, `Choice` = `'mm'`). A single choice is either a character vector or a scalar cell array with a single code from the table.

Multiple choices can be selected with a cell array of character vectors for choice codes (for example, to select both Graham-Harvey measures, `Choice = {'gh1','gh2'}`). To select all choices, specify `Choice` = `'all'`. If no value is supplied, the default choice is to compute the excess return with `Choice` = `'xs'`. `Choice` is not case-sensitive.

Data Types: `char` | `cell`

Output Arguments

`Alpha` — Risk-adjusted alphas

matrix

Risk-adjusted alphas, returned as an `NUMCHOICES`-by-`NUMSERIES` matrix of risk-adjusted alphas for each series in `Asset` with each row corresponding to a specified measure in `Choice`.

`RAReturn` — Risk-adjusted returns

matrix

Risk-adjusted returns, returned as an `NUMCHOICES`-by-`NUMSERIES` matrix of risk-adjusted returns for each series in `Asset` with each row corresponding to a specified measure in `Choice`.

Note NaN values in the data are ignored and, if NaNs are present, some results could be unpredictable. Although the alphas are comparable across measures, risk-adjusted returns depend on whether the Asset or Benchmark is levered or unlevered to match its risk with the alternative. If Choice = 'all', the order of rows in Alpha and RAReturn follows the order in the table. In addition, Choice = 'all' overrides all other choices.

portcons

Portfolio constraints

Syntax

```
ConSet = portcons(ConstType,consttype_values)
```

Description

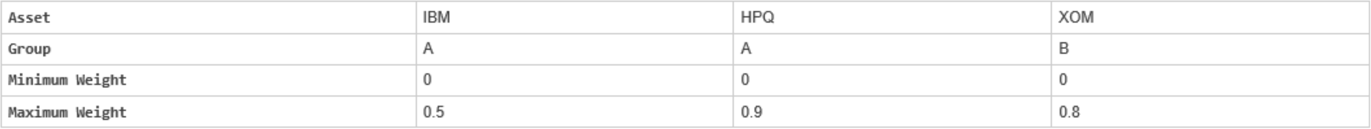
`ConSet = portcons(ConstType,consttype_values)` generates a matrix of constraints, using linear inequalities, for a portfolio of asset investments. The inequalities are of the type `A*Wts' <= b`, where `Wts` is the matrix of weights. The matrix `ConSet` is defined as `ConSet = [A b]`.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

Examples

Generate Matrix of Constraints for Portfolio of Asset Investments

Constrain a portfolio of three assets:



Asset	IBM	HPQ	XOM
Group	A	A	B
Minimum Weight	0	0	0
Maximum Weight	0.5	0.9	0.8

```
NumAssets = 3;
PVal = 1; % Scale portfolio value to 1.
AssetMin = 0;
AssetMax = [0.5 0.9 0.8];
GroupA = [1 1 0];
GroupB = [0 0 1];
AtoBmax = 1.5 % Value of assets in Group A at most 1.5 times value
```

```
AtoBmax = 1.5000
```

```
              % in group B.
```

```
ConSet = portcons('PortValue', PVal, NumAssets,'AssetLims',...
AssetMin, AssetMax, NumAssets, 'GroupComparison',GroupA, NaN,...
AtoBmax, GroupB)
```

```
ConSet = 9×4

    1.0000    1.0000    1.0000    1.0000
```

```
   -1.0000   -1.0000   -1.0000   -1.0000
    1.0000         0         0    0.5000
         0    1.0000         0    0.9000
         0         0    1.0000    0.8000
   -1.0000         0         0         0
         0   -1.0000         0         0
         0         0   -1.0000         0
    1.0000    1.0000   -1.5000         0
```

For instance, one possible solution for portfolio weights that satisfy the constraints is 30% in IBM, 30% in HPQ, and 40% in XOM.

Input Arguments

ConstType — Constraint type

character vector with value 'Default', 'PortValue', 'AssetLims', 'GroupLims' ,'GroupComparison' , or 'Custom'

Constraint type, specified as a character vector defined as follows:

Constraint Type	Description	Values
'Default'	All allocations are >= 0; no short selling allowed. Combined value of portfolio allocations normalized to 1.	NumAssets (required). Scalar representing number of assets in portfolio.
'PortValue'	Fix total value of portfolio to PVal.	PVal (required). Scalar representing total value of portfolio. NumAssets (required). Scalar representing number of assets in portfolio. See pcpval.
'AssetLims'	Minimum and maximum allocation per asset.	AssetMin (required). Scalar or vector of length NASSETS, specifying minimum allocation per asset. AssetMax (required). Scalar or vector of length NASSETS, specifying maximum allocation per asset. NumAssets (optional). See pcalims.
'GroupLims'	Minimum and maximum allocations to asset group.	Groups (required). NGROUPS-by-NASSETS matrix specifying which assets belong to each group. GroupMin (required). Scalar or a vector of length NGROUPS, specifying minimum combined allocations in each group. GroupMax (required). Scalar or a vector of length NGROUPS, specifying maximum combined allocations in each group. See pcglims.

Constraint Type	Description	Values
'GroupComparison'	Group-to-group comparison constraints.	GroupA (required). NGROUPS-by-NASSETS matrix specifying first group in the comparison. AtoBmin (required). Scalar or vector of length NGROUPS specifying minimum ratios of allocations in GroupA to allocations in GroupB. AtoBmax (required). Scalar or vector of length NGROUPS specifying maximum ratios of allocations in GroupA to allocations in GroupB. GroupB (required). NGROUPS-by-NASSETS matrix specifying second group in the comparison. See pcgcomp.
'Custom'	Custom linear inequality constraints A*PortWts' <= b.	A (required). NCONSTRAINTS-by-NASSETS matrix, specifying weights for each asset in each inequality equation. b (required). Vector of length NCONSTRAINTS specifying the right-hand sides of the inequalities. **Note** For more information using Custom, see “Specifying Group Constraints” on page 3-23.

Note You can specify multiple 'ConstType' arguments as ConSet = portcons('ConstType1',consttype_value1,'ConstType2',consttype_value2,'ConstTypeN',consttype_valueN).

Data Types: char

Output Arguments

ConSet — Constraints
matrix

Constraints, returned as a matrix. ConSet is defined as ConSet = [A b]. A is a matrix and b a vector such that A*Wts' <= b sets the value, where Wts is the matrix of weights.

Version History

Portfolio

Create Portfolio object for mean-variance portfolio optimization and analysis

Description

Use the `Portfolio` function to create a `Portfolio` object for mean-variance portfolio optimization.

The main workflow for portfolio optimization is to create an instance of a `Portfolio` object that completely specifies a portfolio optimization problem and to operate on the `Portfolio` object using supported functions to obtain and analyze efficient portfolios. For details on this workflow, see “Portfolio Object Workflow” on page 4-17.

You can use the `Portfolio` object in several ways. To set up a portfolio optimization problem in a `Portfolio` object, the simplest syntax is:

```
p = Portfolio;
```

This syntax creates a `Portfolio` object, `p`, such that all object properties are empty.

The `Portfolio` object also accepts collections of name-value pair arguments for properties and their values. The `Portfolio` object accepts inputs for properties with the general syntax:

```
    p = Portfolio('property1',value1,'property2',value2, ... );
```

If a `Portfolio` object exists, the syntax permits the first (and only the first argument) of the `Portfolio` object to be an existing object with subsequent name-value pair arguments for properties to be added or modified. For example, given an existing `Portfolio` object in `p`, the general syntax is:

```
p = Portfolio(p,'property1',value1,'property2',value2, ... );
```

Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see “Shortcuts for Property Names” on page 15-1196). The `Portfolio` object tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a `Portfolio` object is a value object so that, given portfolio `p`, the following code creates two objects, `p` and `q`, that are distinct:

```
q = Portfolio(p, ...)
```

After creating a `Portfolio` object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For more detailed information on the theoretical basis for mean-variance optimization, see “Portfolio Optimization Theory” on page 4-3.

Creation

Syntax

```
p = Portfolio
```

```
p = Portfolio(Name,Value)
```

```
p = Portfolio(p,Name,Value)
```

Description

`p = Portfolio` creates an empty `Portfolio` object for mean-variance portfolio optimization and analysis. You can then add elements to the `Portfolio` object using the supported "add" and "set" functions. For more information, see “Creating the Portfolio Object” on page 4-24.

`p = Portfolio(Name,Value)` creates a `Portfolio` object (`p`) and sets Properties on page 15-1182 using name-value pairs. For example, `p = Portfolio('AssetList',Assets(1:12))`. You can specify multiple name-value pairs.

`p = Portfolio(p,Name,Value)` creates a `Portfolio` object (`p`) using a previously created `Portfolio` object `p` and sets Properties on page 15-1182 using name-value pairs. You can specify multiple name-value pairs.

Input Arguments

p — Previously constructed Portfolio object
object

Previously constructed `Portfolio` object, specified using `Portfolio`.

Properties

Setting Up the Portfolio Object

`AssetList` — Names or symbols of assets in universe
`[]` (default) | cell array of character vectors | string array

Names or symbols of assets in the universe, specified as a cell array of character vectors or a string array.

Data Types: `cell` | `string`

`InitPort` — Initial portfolio
`[]` (default) | vector

Initial portfolio, specified as a vector.

Data Types: `double`

`Name` — Name for instance of Portfolio object
`[]` (default) | character vector | string

Name for instance of the `Portfolio` object, specified as a character vector or a string.

Data Types: `char` | `string`

`NumAssets` — Number of assets in the universe
`[]` (default) | integer scalar

Number of assets in the universe, specified as an integer scalar.

Data Types: `double`

Portfolio Object Constraints

`AEquality` — Linear equality constraint matrix

[ ] (default) | matrix

Linear equality constraint matrix, specified as a matrix. For more information, see “Linear Equality Constraints” on page 4-9.

Data Types: `double`

`AInequality` — Linear inequality constraint matrix

[ ] (default) | matrix

Linear inequality constraint matrix, specified as a matrix. For more information, see “Linear Inequality Constraints” on page 4-8.

Data Types: `double`

`bEquality` — Linear equality constraint vector

[ ] (default) | vector

Linear equality constraint vector, specified as a vector. For more information, see “Linear Equality Constraints” on page 4-9.

Data Types: `double`

`bInequality` — Linear inequality constraint vector

[ ] (default) | vector

Linear inequality constraint vector, specified as a vector. For more information, see “Linear Inequality Constraints” on page 4-8.

Data Types: `double`

`GroupA` — Group A weights to be bounded by weights in group B

[ ] (default) | matrix

Group A weights to be bounded by weights in group B, specified as a matrix. For more information, see “Group Constraints” on page 4-11.

Data Types: `double`

`GroupB` — Group B weights

[ ] (default) | matrix

Group B weights, specified as a matrix. For more information, see “Group Constraints” on page 4-11.

Data Types: `double`

`GroupMatrix` — Group membership matrix

[ ] (default) | matrix

Group membership matrix, specified as a matrix. For more information, see “Group Ratio Constraints” on page 4-12.

Data Types: `double`

`LowerBound` — Lower-bound constraint

[ ] (default) | vector

Lower-bound constraint, specified as a vector. For more information, see “'Simple' Bound Constraints” on page 4-9 and “'Conditional' Bound Constraints” on page 4-10.

Data Types: `double`

`LowerBudget` — Lower-bound budget constraint

`[ ]` (default) | scalar

Lower-bound budget constraint, specified as a scalar. For more information, see “Budget Constraints” on page 4-10.

Data Types: `double`

`LowerGroup` — Lower-bound group constraint

`[ ]` (default) | vector

Lower-bound group constraint, specified as a vector. For more information, see “Group Constraints” on page 4-11.

Data Types: `double`

`LowerRatio` — Minimum ratio of allocations between Groups A and B

`[ ]` (default) | vector

Minimum ratio of allocations between `GroupA` and `GroupB`, specified as a vector. For more information, see “Group Ratio Constraints” on page 4-12.

Data Types: `double`

`TrackingError` — Upper bound for tracking error constraint

`[ ]` (default) | scalar

Upper bound for tracking error constraint, specified as a scalar. For more information, see “Tracking Error Constraints” on page 4-14.

Data Types: `double`

`TrackingPort` — Tracking portfolio for tracking error constraint

`[ ]` (default) | vector

Tracking portfolio for tracking error constraint, specified as a vector.

Data Types: `double`

`UpperBound` — Upper-bound constraint

`[ ]` (default) | vector

Upper-bound constraint, specified as a vector. For more information, see “'Simple' Bound Constraints” on page 4-9 and “'Conditional' Bound Constraints” on page 4-10.

Data Types: `double`

`UpperBudget` — Upper-bound budget constraint

`[ ]` (default) | scalar

Upper-bound budget constraint, specified as a scalar. For more information, see “Budget Constraints” on page 4-10.

Data Types: `double`

`UpperGroup` — Upper-bound group constraint

`[]` (default) | vector

Upper-bound group constraint, specified as a vector. For more information, see “Group Constraints” on page 4-11.

Data Types: `double`

`UpperRatio` — Maximum ratio of allocations between Groups A and B

`[]` (default) | vector

Maximum ratio of allocations between `GroupA` and `GroupB`, specified as a vector. For more information, see “Group Ratio Constraints” on page 4-12.

Data Types: `double`

`BoundType` — Type of bounds for each asset weight

`'Simple'` (default) | character vector with value `'Simple'` or `'Conditional'` | string with value `"Simple"` or `"Conditional"` | cell array of character vectors with values `'Simple'` or `'Conditional'` | string array with values `"Simple"` or `"Conditional"`

Type of bounds for each asset weight, specified as a scalar character vector or string, or a cell array of character vectors or a string array. For more information, see `setBounds`.

Data Types: `char` | `cell` | `string`

`MinNumAssets` — Minimum number of assets allocated in portfolio

`[]` (default) | numeric

Minimum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets` and “Cardinality Constraints” on page 4-14.

Data Types: `double`

`MaxNumAssets` — Maximum number of assets allocated in portfolio

`[]` (default) | numeric

Maximum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets` and “Cardinality Constraints” on page 4-14.

Data Types: `double`

`SellTurnover` — Turnover constraint on sales

`[]` (default) | scalar

Turnover constraint on sales, specified as a scalar. For more information, see “Average Turnover Constraints” on page 4-12 and “One-Way Turnover Constraints” on page 4-13.

Data Types: `double`

`BuyTurnover` — Turnover constraint on purchases

`[]` (default) | scalar

Turnover constraint on purchases, specified as a scalar. For more information, see “Average Turnover Constraints” on page 4-12 and “One-Way Turnover Constraints” on page 4-13.

Data Types: `double`

`Turnover` — Turnover constraint

[ ] (default) | scalar

Turnover constraint, specified as a scalar. For more information, see “Average Turnover Constraints” on page 4-12 and “One-Way Turnover Constraints” on page 4-13.

Data Types: `double`

Portfolio Object Modeling

`AssetCovar` — Covariance of asset returns

[ ] (default) | square matrix

Covariance of asset returns, specified as a square matrix.

- If `AssetCovar` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.
- In some situations, the traditional sample approximation of the covariance matrix performs poorly. An intuitive example is when the number of variables is larger than the number of observations; this results in a noninvertible covariance matrix. Furthermore, because covariance estimation is performed using observations from random data, the estimator contains a certain amount of noise. This noise usually results in ill-conditioned covariance estimates. Working with an ill-conditioned matrix magnifies the impact of estimation errors. You can use `covarianceShrinkage` and `covarianceDenoising` for covariance estimation and noise reduction.

Data Types: `double`

`AssetMean` — Mean of asset returns

[ ] (default) | vector

Mean of asset returns, specified as a vector.

Data Types: `double`

`BuyCost` — Proportional purchase costs

[ ] (default) | vector

Proportional purchase costs, specified as a vector. For more information, see “Net Portfolio Returns” on page 4-4.

Data Types: `double`

`RiskFreeRate` — Risk-free rate

[ ] (default) | scalar

Risk-free rate, specified as a scalar.

Data Types: `double`

`SellCost` — Proportional sales costs

[ ] (default) | vector

Proportional sales costs, specified as a vector. For more information, see “Net Portfolio Returns” on page 4-4.

Data Types: `double`

Object Functions

setAssetList	Set up list of identifiers for assets
setInitPort	Set up initial or current portfolio
setDefaultConstraints	Set up portfolio constraints with nonnegative weights that sum to 1
getAssetMoments	Obtain mean and covariance of asset returns from Portfolio object
setAssetMoments	Set moments (mean and covariance) of asset returns for Portfolio object
estimateAssetMoments	Estimate mean and covariance of asset returns from data
setCosts	Set up proportional transaction costs for portfolio
addEquality	Add linear equality constraints for portfolio weights to existing constraints
addGroupRatio	Add group ratio constraints for portfolio weights to existing group ratio constraints
addGroups	Add group constraints for portfolio weights to existing group constraints
addInequality	Add linear inequality constraints for portfolio weights to existing constraints
getBounds	Obtain bounds for portfolio weights from portfolio object
getBudget	Obtain budget constraint bounds from portfolio object
getCosts	Obtain buy and sell transaction costs from portfolio object
getEquality	Obtain equality constraint arrays from portfolio object
getGroupRatio	Obtain group ratio constraint arrays from portfolio object
getGroups	Obtain group constraint arrays from portfolio object
getInequality	Obtain inequality constraint arrays from portfolio object
getOneWayTurnover	Obtain one-way turnover constraints from portfolio object
setGroups	Set up group constraints for portfolio weights
setInequality	Set up linear inequality constraints for portfolio weights
setBounds	Set up bounds for portfolio weights for portfolio
setBudget	Set up budget constraints for portfolio
setCosts	Set up proportional transaction costs for portfolio
setEquality	Set up linear equality constraints for portfolio weights
setGroupRatio	Set up group ratio constraints for portfolio weights
setInitPort	Set up initial or current portfolio
setOneWayTurnover	Set up one-way portfolio turnover constraints
setTurnover	Set up maximum portfolio turnover constraint
setTrackingPort	Set up benchmark portfolio for tracking error constraint
setTrackingError	Set up maximum portfolio tracking error constraint
setMinMaxNumAssets	Set cardinality constraints on the number of assets invested in a portfolio
checkFeasibility	Check feasibility of input portfolios against portfolio object
estimateBounds	Estimate global lower and upper bounds for set of portfolios
estimateFrontier	Estimate specified number of optimal portfolios on the efficient frontier
estimateFrontierByReturn	Estimate optimal portfolios with targeted portfolio returns
estimateFrontierByRisk	Estimate optimal portfolios with targeted portfolio risks
estimateFrontierLimits	Estimate optimal portfolios at endpoints of efficient frontier
plotFrontier	Plot efficient frontier
estimateMaxSharpeRatio	Estimate efficient portfolio to maximize Sharpe ratio for Portfolio object

estimatePortMoments	Estimate moments of portfolio returns for Portfolio object
estimatePortReturn	Estimate mean of portfolio returns
estimatePortRisk	Estimate portfolio risk according to risk proxy associated with corresponding object
estimateCustomObjectivePortfolio	Estimate optimal portfolio for user-defined objective function for Portfolio object
setSolver	Choose main solver and specify associated solver options for portfolio optimization
setSolverMINLP	Choose mixed integer nonlinear programming (MINLP) solver for portfolio optimization

Examples

Create an Empty Portfolio Object

You can create a Portfolio object, `p`, with no input arguments and display it using `disp`.

```
p = Portfolio;
disp(p);
```

```
  Portfolio with properties:

          BuyCost: []
         SellCost: []
     RiskFreeRate: []
        AssetMean: []
       AssetCovar: []
    TrackingError: []
     TrackingPort: []
         Turnover: []
      BuyTurnover: []
     SellTurnover: []
             Name: []
        NumAssets: []
        AssetList: []
         InitPort: []
      AInequality: []
      bInequality: []
        AEquality: []
        bEquality: []
       LowerBound: []
       UpperBound: []
      LowerBudget: []
      UpperBudget: []
      GroupMatrix: []
       LowerGroup: []
       UpperGroup: []
           GroupA: []
           GroupB: []
       LowerRatio: []
       UpperRatio: []
     MinNumAssets: []
     MaxNumAssets: []
        BoundType: []
```

This approach provides a way to set up a portfolio optimization problem with the Portfolio function. You can then use the associated set functions to set and modify collections of properties in the Portfolio object.

Create a Portfolio Object Using a Single-Step Setup

You can use the Portfolio object directly to set up a “standard” portfolio optimization problem, given a mean and covariance of asset returns in the variables m and C.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

p = Portfolio('assetmean', m, 'assetcovar', C, ...
'lowerbudget', 1, 'upperbudget', 1, 'lowerbound', 0)
```

```
p = 
  Portfolio with properties:

          BuyCost: []
         SellCost: []
     RiskFreeRate: []
        AssetMean: [4x1 double]
       AssetCovar: [4x4 double]
    TrackingError: []
     TrackingPort: []
         Turnover: []
      BuyTurnover: []
     SellTurnover: []
             Name: []
        NumAssets: 4
        AssetList: []
         InitPort: []
      AInequality: []
      bInequality: []
        AEquality: []
        bEquality: []
       LowerBound: [4x1 double]
       UpperBound: []
      LowerBudget: 1
      UpperBudget: 1
      GroupMatrix: []
       LowerGroup: []
       UpperGroup: []
           GroupA: []
           GroupB: []
       LowerRatio: []
       UpperRatio: []
     MinNumAssets: []
     MaxNumAssets: []
        BoundType: []
```

Note that the LowerBound property value undergoes scalar expansion since AssetMean and AssetCovar provide the dimensions of the problem.

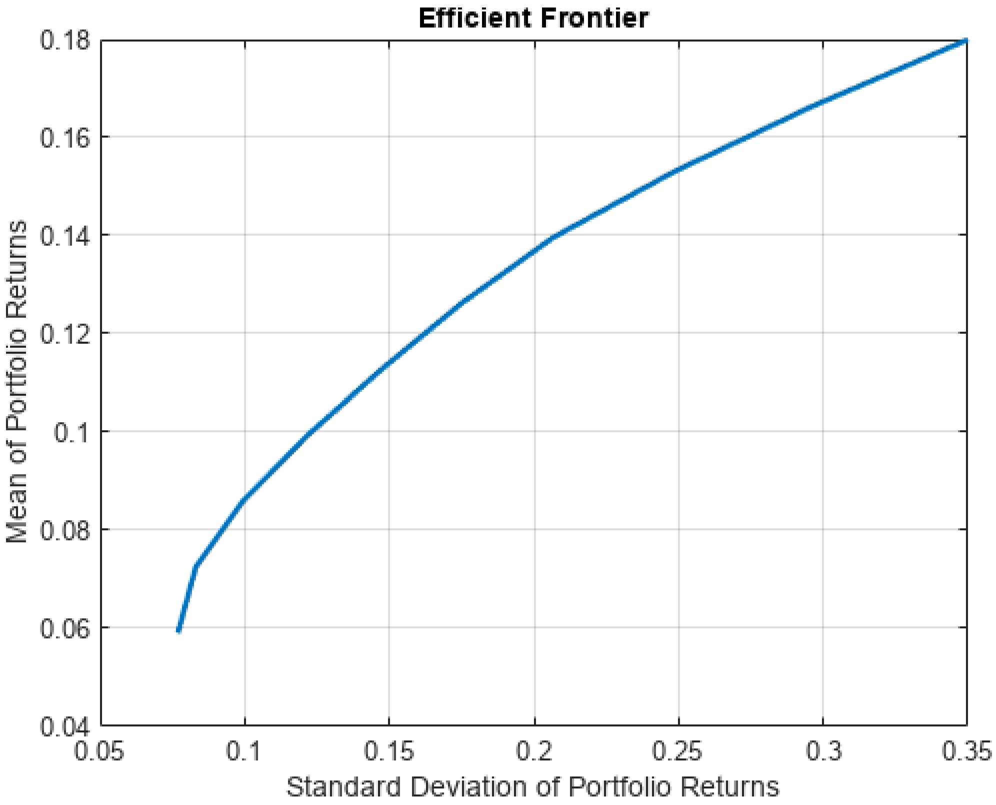
Create a Portfolio Object Using a Sequence of Steps

Using a sequence of steps is an alternative way to accomplish the same task of setting up a “standard” portfolio optimization problem, given a mean and covariance of asset returns in the variables m and C (which also illustrates that argument names are not case sensitive).

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = Portfolio(p, 'assetmean', m, 'assetcovar', C);
p = Portfolio(p, 'lowerbudget', 1, 'upperbudget', 1);
p = Portfolio(p, 'lowerbound', 0);

plotFrontier(p);
```

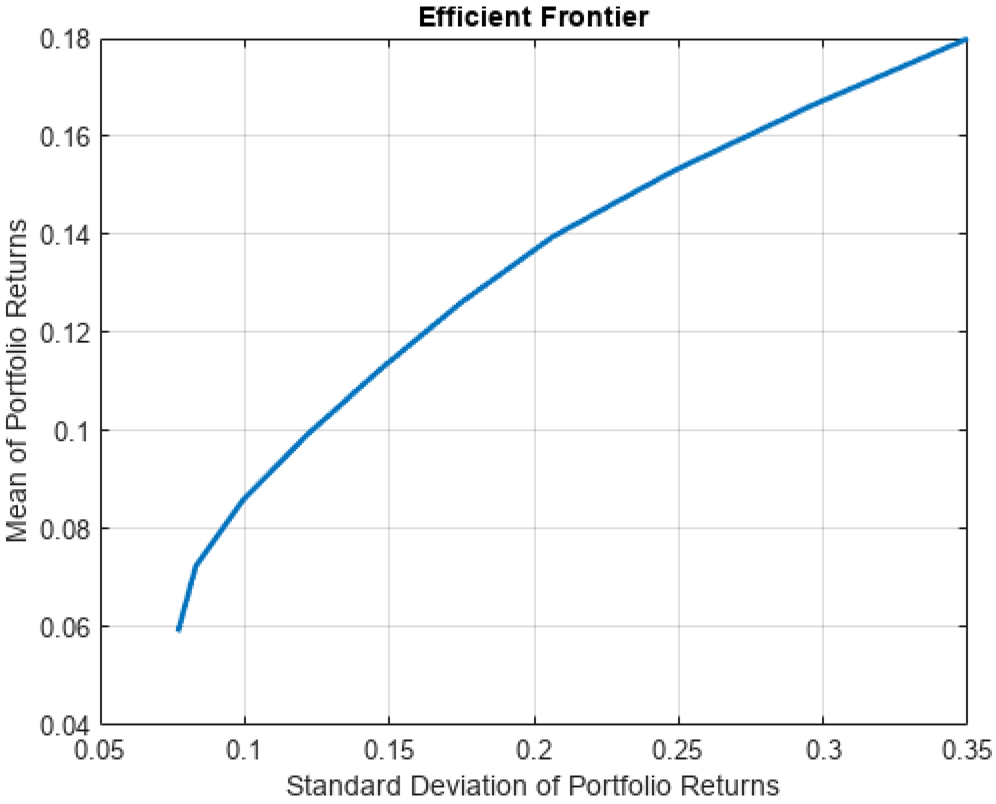


This way works because the calls to Portfolio are in this particular order. In this case, the call to initialize AssetMean and AssetCovar provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the LowerBound property as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p = Portfolio(p, 'LowerBound', zeros(size(m)));
p = Portfolio(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = Portfolio(p, 'AssetMean', m, 'AssetCovar', C);

plotFrontier(p);
```



If you did not specify the size of `LowerBound` but, instead, input a scalar argument, the `Portfolio` object assumes that you are defining a single-asset problem and produces an error at the call to set asset moments with four assets.

Create a Portfolio Object Using Shortcuts for Property Names

You can create a Portfolio object, `p` with `Portfolio` using shortcuts for property names.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

p = Portfolio('mean', m, 'covar', C, 'budget', 1, 'lb', 0)

p = 
  Portfolio with properties:

          BuyCost: []
         SellCost: []
     RiskFreeRate: []
        AssetMean: [4x1 double]
       AssetCovar: [4x4 double]
    TrackingError: []
     TrackingPort: []
         Turnover: []
      BuyTurnover: []
     SellTurnover: []
             Name: []
        NumAssets: 4
        AssetList: []
         InitPort: []
      AInequality: []
      bInequality: []
        AEquality: []
        bEquality: []
       LowerBound: [4x1 double]
       UpperBound: []
      LowerBudget: 1
      UpperBudget: 1
      GroupMatrix: []
       LowerGroup: []
       UpperGroup: []
           GroupA: []
           GroupB: []
       LowerRatio: []
       UpperRatio: []
     MinNumAssets: []
     MaxNumAssets: []
        BoundType: []
```

Direct Setting of Portfolio Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

p = Portfolio;
p.NumAssets = numel(m);
p.AssetMean = m;
```

```
p.AssetCovar = C;
p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
disp(p)
```

```
  Portfolio with properties:

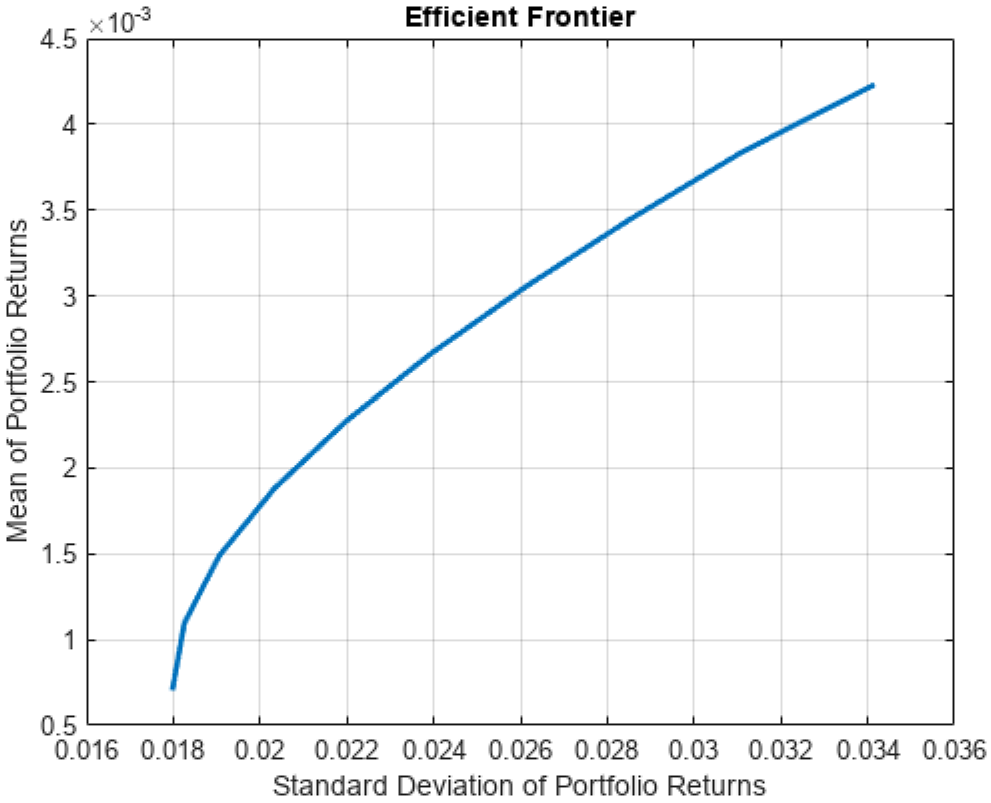
          BuyCost: []
         SellCost: []
     RiskFreeRate: []
        AssetMean: [4x1 double]
       AssetCovar: [4x4 double]
    TrackingError: []
     TrackingPort: []
         Turnover: []
      BuyTurnover: []
     SellTurnover: []
             Name: []
        NumAssets: 4
        AssetList: []
         InitPort: []
      AInequality: []
      bInequality: []
        AEquality: []
        bEquality: []
       LowerBound: [4x1 double]
       UpperBound: []
      LowerBudget: 1
      UpperBudget: 1
      GroupMatrix: []
       LowerGroup: []
       UpperGroup: []
           GroupA: []
           GroupB: []
       LowerRatio: []
       UpperRatio: []
     MinNumAssets: []
     MaxNumAssets: []
        BoundType: []
```

Create a `Portfolio` Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = Portfolio('AssetList',Assets(1:12));
p = estimateAssetMoments(p, Data(:,1:12),'missingdata',true);
p = setDefaultConstraints(p);
plotFrontier(p);
```



```
pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames],'obsnames',p.AssetList);

disp(Blotter);
```

```
            Port1        Port2       Port3       Port4      Port5
    AAPL     0.017926    0.058247    0.097816    0.12955    0
    AMZN            0           0           0          0    0
    CSCO            0           0           0          0    0
    DELL    0.0041906           0           0          0    0
    EBAY            0           0           0          0    0
    GOOG      0.16144     0.35678     0.55228    0.75116    1
    HPQ      0.052566    0.032302    0.011186          0    0
    IBM       0.46422     0.36045     0.25577    0.11928    0
    INTC            0           0           0          0    0
    MSFT      0.29966     0.19222    0.082949          0    0
    ORCL            0           0           0          0    0

```

More About

Mean-Variance Portfolio Optimization

A mean-variance optimization problem is completely specified with three elements.

The three elements for a mean-variance optimization problem are:

- A universe of assets with estimates for the prospective mean and covariance of asset total returns for a period of interest.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk, which, for mean-variance optimization, is either the gross or net mean of portfolio returns and the standard deviation of portfolio returns.

After you specify these three elements in an unambiguous way, you can solve and analyze portfolio optimization problems. The simplest mean-variance portfolio optimization problem has:

- A mean and covariance of asset total returns
- Nonnegative weights for all portfolios that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk that use the mean and covariance of asset total returns

For more information on the theory and definition of mean-variance optimization supported by portfolio optimization tools in Financial Toolbox, see “Portfolio Optimization Theory” on page 4-3.

Portfolio Problem Sufficiency

A mean-variance portfolio optimization is completely specified with the Portfolio object if two condition are met.

The following are the two conditions that must be met:

- The moments of asset returns must be specified such that the property `AssetMean` contains a valid finite mean vector of asset returns and the property `AssetCovar` contains a valid symmetric positive-semidefinite matrix for the covariance of asset returns.

  The first condition is satisfied by setting the properties associated with the moments of asset returns.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded.

  The second condition is satisfied by an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed, and several functions, such as `estimateBounds`, provide ways to ensure that your problem is properly formulated.

Given mean and covariance of asset returns in the variables `AssetMean` and `AssetCovar`, this problem is completely specified by:

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar,...
'LowerBound', 0, 'UpperBudget',1, 'LowerBudget',1)
```

or equivalently by:

```
p = Portfolio;
p = setAssetMoments(p, AssetMean, AssetCovar);
p = setDefaultConstraints(p);
```

Although the general sufficiency conditions for mean-variance portfolio optimization go beyond these two conditions, the `Portfolio` object implemented in Financial Toolbox implicitly handles all these additional conditions. For more information on the Markowitz model for mean-variance portfolio optimization, see “Portfolio Optimization” on page A-5.

Shortcuts for Property Names

The `Portfolio` object has shorter argument names that replace longer argument names associated with specific properties of the `Portfolio` object.

For example, rather than enter `'assetcovar'`, the `Portfolio` object accepts the case-insensitive name `'covar'` to set the `AssetCovar` property in a `Portfolio` object. Every shorter argument name corresponds with a single property in the `Portfolio` object. The one exception is the alternative argument name `'budget'`, which signifies both the `LowerBudget` and `UpperBudget` properties. When `'budget'` is used, then the `LowerBudget` and `UpperBudget` properties are set to the same value to form an equality budget constraint.

Shortcuts for Property Names

Shortcut Argument Name	Equivalent Argument / Property Name
`ae`	`AEquality`
`ai`	`AInequality`
`covar`	`AssetCovar`
`assetnames` or `assets`	`AssetList`
`mean`	`AssetMean`
`be`	`bEquality`
`bi`	`bInequality`
`group`	`GroupMatrix`
`lb`	`LowerBound`
`n` or `num`	`NumAssets`
`rfr`	`RiskFreeRate`
`ub`	`UpperBound`
`budget`	`UpperBudget` and `LowerBudget`

Version History

Introduced in R2011a

PortfolioCVaR

Creates PortfolioCVaR object for conditional value-at-risk portfolio optimization and analysis

Description

Use `PortfolioCVaR` to create a `PortfolioCVaR` object for conditional value-at-risk portfolio optimization.

The main workflow for CVaR portfolio optimization is to create an instance of a `PortfolioCVaR` object that completely specifies a portfolio optimization problem and to operate on the `PortfolioCVaR` object using supported functions to obtain and analyze efficient portfolios. For details on this workflow, see “PortfolioCVaR Object Workflow” on page 5-16.

You can use the `PortfolioCVaR` object in several ways. To set up a portfolio optimization problem in a `PortfolioCVaR` object, the simplest syntax is:

```
p = PortfolioCVaR;
```

This syntax creates a `PortfolioCVaR` object, `p`, such that all object properties are empty.

The `PortfolioCVaR` object also accepts collections of name-value pair arguments for properties and their values. The `PortfolioCVaR` function accepts inputs for properties with the general syntax:

```
    p = PortfolioCVaR('property1',value1,'property2',value2, ... );
```

If a `PortfolioCVaR` object already exists, the syntax permits the first (and only the first argument) of the `PortfolioCVaR` object to be an existing object with subsequent name-value pair arguments for properties to be added or modified. For example, given an existing `PortfolioCVaR` object in `p`, the general syntax is:

```
p = PortfolioCVaR(p,'property1',value1,'property2',value2, ... );
```

Input argument names are not case sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see “Shortcuts for Property Names” on page 15-1213). The `PortfolioCVaR` object tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a `PortfolioCVaR` object is a value object so that, given portfolio `p`, the following code creates two objects, `p` and `q`, that are distinct:

```
q = PortfolioCVaR(p, ...)
```

After creating a `PortfolioCVaR` object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For more detailed information on the theoretical basis for conditional value-at-risk portfolio optimization, see “Portfolio Optimization Theory” on page 5-3.

Creation

Syntax

```
p = PortfolioCVaR
p = PortfolioCVaR(Name,Value)

p = PortfolioCVaR(p,Name,Value)
```

Description

`p = PortfolioCVaR` creates an empty `PortfolioCVaR` object for conditional value-at-risk portfolio optimization and analysis. You can then add elements to the `PortfolioCVaR` object using the supported "add" and "set" functions. For more information, see “Creating the PortfolioCVaR Object” on page 5-22.

`p = PortfolioCVaR(Name,Value)` creates a `PortfolioCVaR` object (`p`) and sets Properties on page 15-1199 using name-value pairs. For example, `p = PortfolioCVaR('AssetList',Assets(1:12))`. You can specify multiple name-value pairs.

`p = PortfolioCVaR(p,Name,Value)` creates a `PortfolioCVaR` object (`p`) using a previously created `PortfolioCVaR` object `p` and sets Properties on page 15-1199 using name-value pairs. You can specify multiple name-value pairs.

Input Arguments

p — Previously constructed PortfolioCVaR object
object

Previously constructed `PortfolioCVaR` object, specified using `PortfolioCVaR`.

Properties

Setting Up the PortflioCVaR Object

`AssetList` — Names or symbols of assets in universe
`[ ]` (default) | cell array of character vectors | string array

Names or symbols of assets in the universe, specified as a cell array of character vectors or a string array.

Data Types: `cell` | `string`

`InitPort` — Initial portfolio
`[ ]` (default) | vector

Initial portfolio, specified as a vector.

Data Types: `double`

`Name` — Name for instance of PortfolioCVaR object
`[ ]` (default) | character vector | string

Name for instance of the `PortfolioCVaR` object, specified as a character vector or string.

Data Types: `char` | `string`

`NumAssets` — Number of assets in the universe

`[ ]` (default) | integer scalar

Number of assets in the universe, specified as an integer scalar.

Data Types: `double`

PortfolioCVaR Object Constraints

`AEquality` — Linear equality constraint matrix

`[ ]` (default) | matrix

Linear equality constraint matrix, specified as a matrix. For more information, see “Linear Equality Constraints” on page 5-9.

Data Types: `double`

`AInequality` — Linear inequality constraint matrix

`[ ]` (default) | matrix

Linear inequality constraint matrix, specified as a matrix. For more information, see “Linear Inequality Constraints” on page 5-8.

Data Types: `double`

`bEquality` — Linear equality constraint vector

`[ ]` (default) | vector

Linear equality constraint vector, specified as a vector. For more information, see “Linear Equality Constraints” on page 5-9.

Data Types: `double`

`bInequality` — Linear inequality constraint

`[ ]` (default) | vector

Linear inequality constraint vector, specified as a vector. For more information, see “Linear Inequality Constraints” on page 5-8.

Data Types: `double`

`GroupA` — Group A weights to be bounded by weights in group B

`[ ]` (default) | matrix

Group A weights to be bounded by weights in group B, specified as a matrix. For more information, see “Group Constraints” on page 5-11.

Data Types: `double`

`GroupB` — Group B weights

`[ ]` (default) | matrix

Group B weights, specified as a matrix. For more information, see “Group Constraints” on page 5-11.

Data Types: `double`

GroupMatrix — Group membership matrix

[ ] (default) | matrix

Group membership matrix, specified as a matrix. For more information, see "Group Ratio Constraints" on page 5-11.

Data Types: double

LowerBound — Lower-bound constraint

[ ] (default) | vector

Lower-bound constraint, specified as a vector. For more information, see "'Simple' Bound Constraints" on page 5-9 and "'Conditional' Bound Constraints" on page 5-10.

Data Types: double

LowerBudget — Lower-bound budget constraint

[ ] (default) | scalar

Lower-bound budget constraint, specified as a scalar. For more information, see "Budget Constraints" on page 5-10.

Data Types: double

LowerGroup — Lower-bound group constraint

[ ] (default) | vector

Lower-bound group constraint, specified as a vector. For more information, see "Group Constraints" on page 5-11.

Data Types: double

LowerRatio — Minimum ratio of allocations between Groups A and B

[ ] (default) | vector

Minimum ratio of allocations between GroupA and GroupB, specified as a vector. For more information, see "Group Ratio Constraints" on page 5-11.

Data Types: double

UpperBound — Upper-bound constraint

[ ] (default) | vector

Upper-bound constraint, specified as a vector. For more information, see "'Simple' Bound Constraints" on page 5-9 and "'Conditional' Bound Constraints" on page 5-10.

Data Types: double

UpperBudget — Upper-bound budget constraint

[ ] (default) | scalar

Upper-bound budget constraint, specified as a scalar. For more information, see "Budget Constraints" on page 5-10.

Data Types: double

UpperGroup — Upper-bound group constraint

[ ] (default) | vector

Upper-bound group constraint, specified as a vector. For more information, see “Group Constraints” on page 5-11.

Data Types: double

UpperRatio — Maximum ratio of allocations between Groups A and B

[ ] (default) | vector

Maximum ratio of allocations between GroupA and GroupB, specified as a vector. For more information, see “Group Ratio Constraints” on page 5-11.

Data Types: double

BoundType — Type of bounds for each asset weight

'Simple' (default) | character vector with value 'Simple' or 'Conditional' | string with value "Simple" or "Conditional" | cell array of character vectors with values 'Simple' or 'Conditional' | string array with values "Simple" or "Conditional"

Type of bounds for each asset weight, specified as a scalar character vector or string, or a cell array of character vectors or a string array. For more information, see setBounds.

Data Types: char | cell | string

MinNumAssets — Minimum number of assets allocated in portfolio

[ ] (default) | numeric

Minimum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see setMinMaxNumAssets and “Cardinality Constraints” on page 5-13.

Data Types: double

MaxNumAssets — Maximum number of assets allocated in portfolio

[ ] (default) | numeric

Maximum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see setMinMaxNumAssets and “Cardinality Constraints” on page 5-13.

Data Types: double

Turnover — Turnover constraint

[ ] (default) | scalar

Turnover constraint, specified as a scalar. For more information, see “Average Turnover Constraints” on page 5-12 and “One-way Turnover Constraints” on page 5-13.

Data Types: double

SellTurnover — Turnover constraint on sales

[ ] (default) | scalar

Turnover constraint on sales, specified as a scalar. For more information, see “Average Turnover Constraints” on page 5-12 and “One-way Turnover Constraints” on page 5-13.

Data Types: double

BuyTurnover — Turnover constraint on purchases

[ ] (default) | scalar

Turnover constraint on purchases, specified as a scalar. For more information, see “Average Turnover Constraints” on page 5-12 and “One-way Turnover Constraints” on page 5-13.

Data Types: `double`

PortfolioCVaR Object Modeling

`BuyCost` — Proportional purchase costs

`[]` (default) | vector

Proportional purchase costs, specified as a vector. For more information, see “Net Portfolio Returns” on page 5-4.

Data Types: `double`

`RiskFreeRate` — Risk-free rate

`[]` (default) | scalar

Risk-free rate, specified as a scalar.

Data Types: `double`

`ProbabilityLevel` — Value-at-risk probability level which is 1 − (loss probability)

`[]` (default) | scalar

Value-at-risk probability level which is 1 − (loss probability), specified as a scalar.

Data Types: `double`

`NumScenarios` — Number of scenarios

`[]` (default) | integer scalar

Number of scenarios, specified as an integer scalar.

Data Types: `double`

`SellCost` — Proportional sales costs

`[]` (default) | vector

Proportional sales costs, specified as a vector. For more information, see “Net Portfolio Returns” on page 5-4.

Data Types: `double`

Object Functions

setAssetList	Set up list of identifiers for assets
setInitPort	Set up initial or current portfolio
setDefaultConstraints	Set up portfolio constraints with nonnegative weights that sum to 1
estimateAssetMoments	Estimate mean and covariance of asset returns from data
setCosts	Set up proportional transaction costs for portfolio
addEquality	Add linear equality constraints for portfolio weights to existing constraints
addGroupRatio	Add group ratio constraints for portfolio weights to existing group ratio constraints

addGroups	Add group constraints for portfolio weights to existing group constraints
addInequality	Add linear inequality constraints for portfolio weights to existing constraints
getBounds	Obtain bounds for portfolio weights from portfolio object
getBudget	Obtain budget constraint bounds from portfolio object
getCosts	Obtain buy and sell transaction costs from portfolio object
getEquality	Obtain equality constraint arrays from portfolio object
getGroupRatio	Obtain group ratio constraint arrays from portfolio object
getGroups	Obtain group constraint arrays from portfolio object
getInequality	Obtain inequality constraint arrays from portfolio object
getOneWayTurnover	Obtain one-way turnover constraints from portfolio object
setGroups	Set up group constraints for portfolio weights
setInequality	Set up linear inequality constraints for portfolio weights
setBounds	Set up bounds for portfolio weights for portfolio
setMinMaxNumAssets	Set cardinality constraints on the number of assets invested in a portfolio
setBudget	Set up budget constraints for portfolio
setCosts	Set up proportional transaction costs for portfolio
setDefaultConstraints	Set up portfolio constraints with nonnegative weights that sum to 1
setEquality	Set up linear equality constraints for portfolio weights
setGroupRatio	Set up group ratio constraints for portfolio weights
setInitPort	Set up initial or current portfolio
setOneWayTurnover	Set up one-way portfolio turnover constraints
setTurnover	Set up maximum portfolio turnover constraint
checkFeasibility	Check feasibility of input portfolios against portfolio object
estimateBounds	Estimate global lower and upper bounds for set of portfolios
estimateFrontier	Estimate specified number of optimal portfolios on the efficient frontier
estimateFrontierByReturn	Estimate optimal portfolios with targeted portfolio returns
estimateFrontierByRisk	Estimate optimal portfolios with targeted portfolio risks
estimateFrontierLimits	Estimate optimal portfolios at endpoints of efficient frontier
plotFrontier	Plot efficient frontier
estimatePortReturn	Estimate mean of portfolio returns
estimatePortRisk	Estimate portfolio risk according to risk proxy associated with corresponding object
setSolver	Choose main solver and specify associated solver options for portfolio optimization
setProbabilityLevel	Set probability level for VaR and CVaR calculations
setScenarios	Set asset returns scenarios by direct matrix
getScenarios	Obtain scenarios from portfolio object
simulateNormalScenariosByData	Simulate multivariate normal asset return scenarios from data
simulateNormalScenariosByMoments	Simulate multivariate normal asset return scenarios from mean and covariance of asset returns
estimateScenarioMoments	Estimate mean and covariance of asset return scenarios
estimatePortVaR	Estimate value-at-risk for PortfolioCVaR object
estimatePortStd	Estimate standard deviation of portfolio returns

Examples

Create an Empty PortfolioCVaR Object

You can create a PortfolioCVaR object, `p`, with no input arguments and display it using `disp`.

```
p = PortfolioCVaR;
disp(p);
```

```
  PortfolioCVaR with properties:

             BuyCost: []
            SellCost: []
        RiskFreeRate: []
    ProbabilityLevel: []
            Turnover: []
         BuyTurnover: []
        SellTurnover: []
        NumScenarios: []
                Name: []
           NumAssets: []
           AssetList: []
            InitPort: []
         AInequality: []
         bInequality: []
           AEquality: []
           bEquality: []
          LowerBound: []
          UpperBound: []
         LowerBudget: []
         UpperBudget: []
         GroupMatrix: []
          LowerGroup: []
          UpperGroup: []
              GroupA: []
              GroupB: []
          LowerRatio: []
          UpperRatio: []
        MinNumAssets: []
        MaxNumAssets: []
           BoundType: []
```

This approach provides a way to set up a portfolio optimization problem with the `PortfolioCVaR` function. You can then use the associated set functions to set and modify collections of properties in the `PortfolioCVaR` object.

Create a PortfolioCVaR Object Using a Single-Step Setup

You can use the `PortfolioCVaR` object directly to set up a “standard” portfolio optimization problem. Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
```

```
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR('Scenarios', AssetScenarios, ...
'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1, ...
'ProbabilityLevel', 0.95)
```

```
p = 
  PortfolioCVaR with properties:

             BuyCost: []
            SellCost: []
        RiskFreeRate: []
    ProbabilityLevel: 0.9500
            Turnover: []
         BuyTurnover: []
        SellTurnover: []
        NumScenarios: 20000
                Name: []
           NumAssets: 4
           AssetList: []
            InitPort: []
         AInequality: []
         bInequality: []
           AEquality: []
           bEquality: []
          LowerBound: [4x1 double]
          UpperBound: []
         LowerBudget: 1
         UpperBudget: 1
         GroupMatrix: []
          LowerGroup: []
          UpperGroup: []
              GroupA: []
              GroupB: []
          LowerRatio: []
          UpperRatio: []
        MinNumAssets: []
        MaxNumAssets: []
           BoundType: []
```

Note that the `LowerBound` property value undergoes scalar expansion since `AssetScenarios` provides the dimensions of the problem.

Create a PortfolioCVaR Object Using a Sequence of Steps

Using a sequence of steps is an alternative way to accomplish the same task of setting up a “standard” CVaR portfolio optimization problem, given `AssetScenarios` variable is:

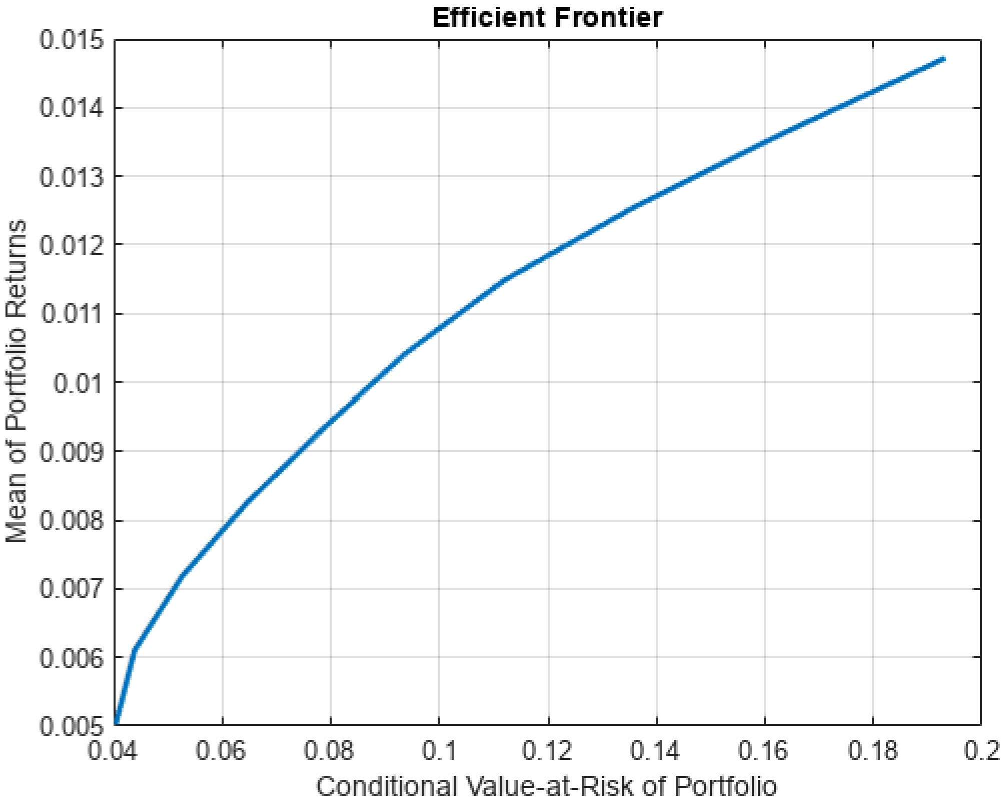
```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = PortfolioCVaR(p, 'LowerBound', 0);
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);
```



This way works because the calls to `PortfolioCVaR` are in this particular order. In this case, the call to initialize `AssetScenarios` provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the `LowerBound` property as follows:

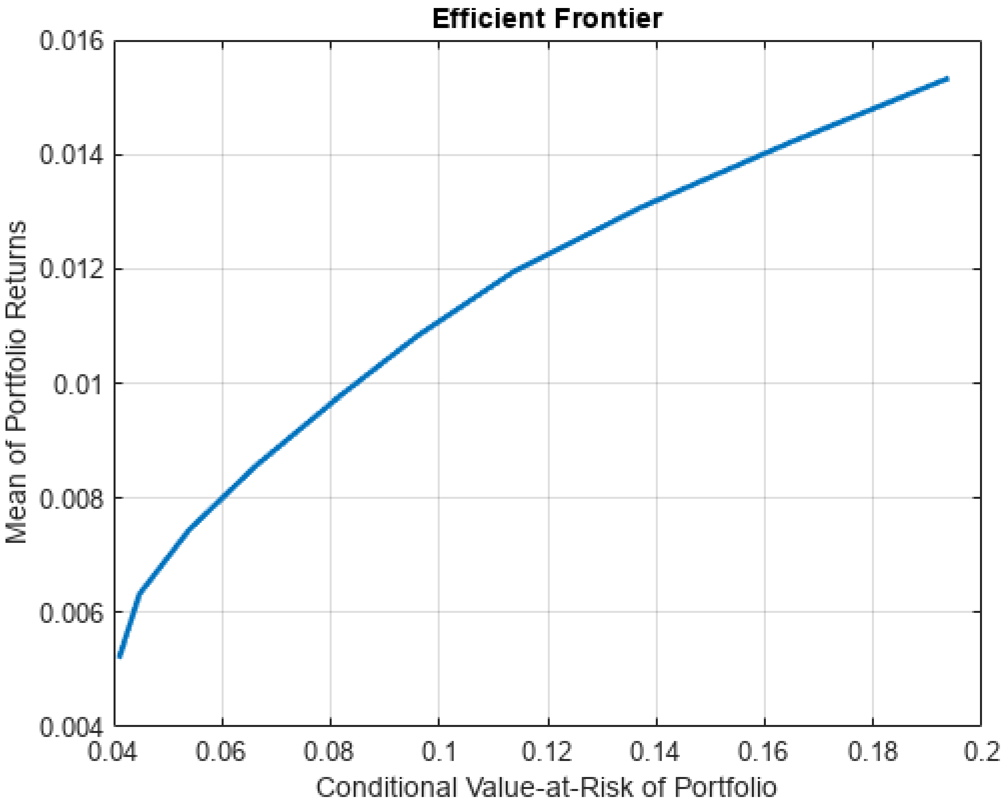
```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = PortfolioCVaR(p, 'LowerBound', zeros(size(m)));
p = PortfolioCVaR(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setProbabilityLevel(p, 0.95);
p = setScenarios(p, AssetScenarios);

plotFrontier(p);
```



If you did not specify the size of `LowerBound` but, instead, input a scalar argument, the `PortfolioCVaR` object assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

Create a PortfolioCVaR Object Using Shortcuts for Property Names

You can create a PortfolioCVaR object, `p` with the `PortfolioCVaR` object using shortcuts for property names.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR('scenario', AssetScenarios, 'lb', 0, 'budget', 1, 'plevel', 0.95)
```

```
p = 
  PortfolioCVaR with properties:

             BuyCost: []
            SellCost: []
        RiskFreeRate: []
    ProbabilityLevel: 0.9500
            Turnover: []
         BuyTurnover: []
        SellTurnover: []
        NumScenarios: 20000
                Name: []
           NumAssets: 4
           AssetList: []
            InitPort: []
         AInequality: []
         bInequality: []
           AEquality: []
           bEquality: []
          LowerBound: [4x1 double]
          UpperBound: []
         LowerBudget: 1
         UpperBudget: 1
         GroupMatrix: []
          LowerGroup: []
          UpperGroup: []
              GroupA: []
              GroupB: []
          LowerRatio: []
          UpperRatio: []
        MinNumAssets: []
        MaxNumAssets: []
           BoundType: []
```

Direct Setting of PortfolioCVaR Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
```

```
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;

p = setScenarios(p, AssetScenarios);
p.ProbabilityLevel = 0.95;

p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
disp(p)
```

Scenarios cannot be assigned directly to a PortfolioCVaR object. Scenarios must always be set through either the `PortfolioCVaR` function, the `setScenarios` function, or any of the scenario simulation functions.

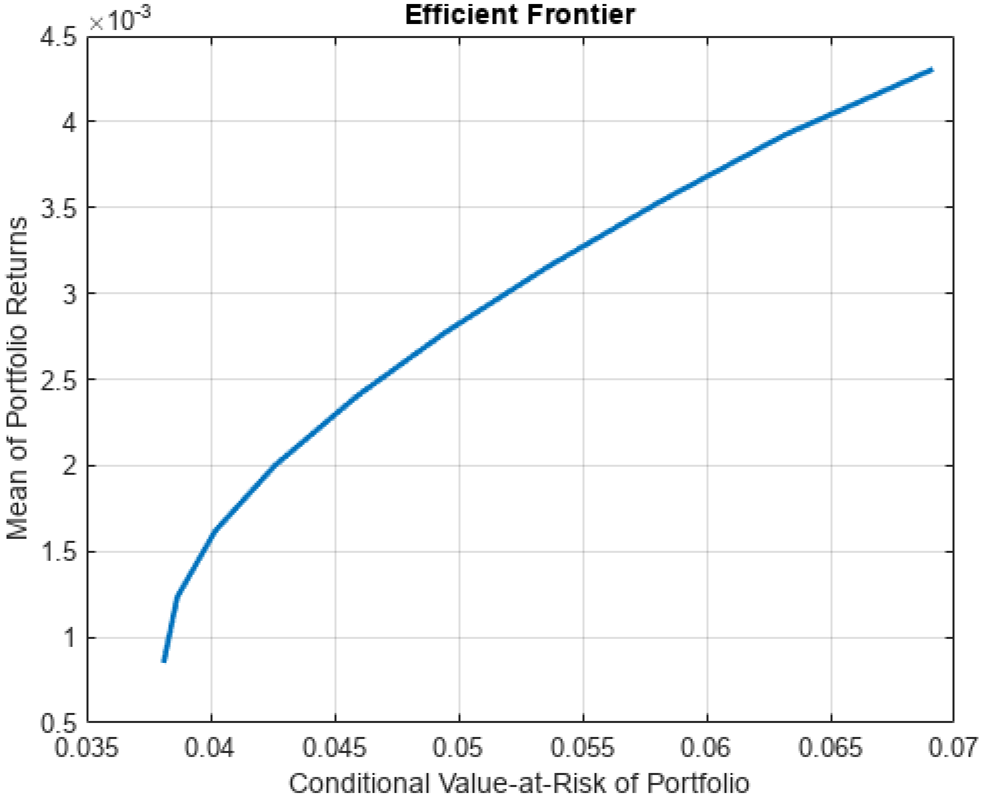
Construct a PortfolioCVaR Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = PortfolioCVaR('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 ,'missingdata',true);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

plotFrontier(p);
```



```
pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames],'obsnames',p.AssetList);

disp(Blotter);
```

```
            Port1        Port2         Port3        Port4       Port5
    AAPL    0.011002       0.07341       0.11855    0.12957     0
    AMZN           0             0             0          0     0
    CSCO           0            0            0           0    0
    DELL    0.023234            0            0           0    0
    EBAY           0            0            0           0    0
    GOOG     0.20304       0.3804      0.56259     0.75956    1
    HPQ     0.041781    0.0094108            0           0    0
    IBM       0.4452      0.36408       0.2625     0.11086    0
    INTC           0            0            0           0    0
    MSFT     0.27575       0.1727     0.056365           0    0
    ORCL           0            0            0           0    0
    YHOO           0            0            0           0    0
```

More About

Conditional Value-at-Risk Portfolio Optimization

A CVaR optimization problem is completely specified with four elements.

The four elements for a CVaR optimization problem are:

- A universe of assets with scenarios of asset total returns for a period of interest, where scenarios comprise a collection of samples from the underlying probability distribution for asset total returns. This collection must be sufficiently large for asymptotic convergence of sample statistics. Asset return moments and related statistics are derived exclusively from the scenarios.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk proxies, which, for CVaR optimization, is either the gross or net mean of portfolio returns and the conditional value-at-risk of portfolio returns.
- A probability level that specifies the probability that a loss is less than or equal to the value-at-risk. Typical values are 0.9 and 0.95, which indicate 10% and 5% loss probabilities.

After these four elements have been specified in an unambiguous way, it is possible to solve and analyze CVaR portfolio optimization problems.

The simplest CVaR portfolio optimization problem has:

- Scenarios of asset total returns
- A requirement that all portfolios have nonnegative weights that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk proxies that use scenarios of asset total returns
- A probability level of 0.95

Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified by:

```
p = PortfolioCVaR('Scenarios', AssetScenarios, 'LowerBound', 0, 'Budget', 1, ...
'ProbabilityLevel', 0.95);
```

or equivalently by:

```
p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
```

To confirm that this is a valid portfolio optimization problem, the following function determines whether the set of PortfolioCVaR choices is bounded (a necessary condition for portfolio optimization).

```
[lb, ub, isbounded] = estimateBounds(p);
```

Given the problem specified in the `PortfolioCVaR` object `p`, the efficient frontier for this problem can be displayed with:

```
plotFrontier(p);
```

and efficient portfolios can be obtained with:

```
pwgt = estimateFrontier(p);
```

For more information on the theory and definition of conditional value-at-risk optimization supported by portfolio optimization tools in Financial Toolbox, see “Portfolio Optimization Theory” on page 5-3.

PortfolioCVaR Problem Sufficiency

A CVaR portfolio optimization problem is completely specified with the `PortfolioCVaR` object if three conditions are met.

The following are the three conditions that must be met:

- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition can be satisfied by the `setScenarios` function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the `estimateBounds` function, provide ways to ensure that your problem is properly formulated.
- You must specify a probability level to locate the level of tail loss above which the conditional value-at-risk is to be minimized. This condition can be satisfied by the `setProbabilityLevel` function.

  Although the general sufficient conditions for CVaR portfolio optimization go beyond the first three conditions, the `PortfolioCVaR` object handles all these additional conditions.

Shortcuts for Property Names

The `PortfolioCVaR` object has shorter argument names that replace longer argument names associated with specific properties of the `PortfolioCVaR` object.

For example, rather than enter `'ProbabilityLevel'`, the `PortfolioCVaR` object accepts the case-insensitive name `'plevel'` to set the `ProbabilityLevel` property in a `PortfolioCVaR` object. Every shorter argument name corresponds with a single property in the `PortfolioCVaR` object. The one exception is the alternative argument name `'budget'`, which signifies both the `LowerBudget` and `UpperBudget` properties. When `'budget'` is used, then the `LowerBudget` and `UpperBudget` properties are set to the same value to form an equality budget constraint.

Shortcuts for Property Names

Shortcut Argument Name	Equivalent Argument / Property Name
ae	AEquality
ai	AInequality
assetnames or assets	AssetList
be	bEquality
bi	bInequality
budget	UpperBudget and LowerBudget
group	GroupMatrix
lb	LowerBound
n or num	NumAssets
level, problevel, or plevel	ProbabilityLevel
rfr	RiskFreeRate
scenario or assetscenarios	Scenarios
ub	UpperBound

Version History

Introduced in R2012b

PortfolioMAD

Create PortfolioMAD object for mean-absolute deviation portfolio optimization and analysis

Description

The PortfolioMAD object implements mean-absolute deviation portfolio optimization, where MAD stands for “mean-absolute deviation.” PortfolioMAD objects support functions that are specific to MAD portfolio optimization.

The main workflow for MAD portfolio optimization is to create an instance of a PortfolioMAD object that completely specifies a portfolio optimization problem and to operate on the PortfolioMAD object to obtain and analyze efficient portfolios. For more information on the workflow when using PortfolioMAD objects, see “PortfolioMAD Object Workflow” on page 6-15.

You can use the PortfolioMAD object in several ways. To set up a portfolio optimization problem in a PortfolioMAD object, the simplest syntax is:

```
p = PortfolioMAD;
```

This syntax creates a PortfolioMAD object, p, such that all object properties are empty.

The PortfolioMAD object also accepts collections of name-value pair arguments for properties and their values. The PortfolioMAD object accepts inputs for properties with the general syntax:

```
    p = PortfolioMAD('property1',value1,'property2',value2, ... );
```

If a PortfolioMAD object exists, the syntax permits the first (and only the first argument) of the PortfolioMAD object to be an existing object with subsequent name-value pair arguments for properties to be added or modified. For example, given an existing PortfolioMAD object in p, the general syntax is:

```
p = PortfolioMAD(p,'property1',value1,'property2',value2, ... );
```

Input argument names are not case-sensitive, but must be completely specified. In addition, several properties can be specified with alternative argument names (see “Shortcuts for Property Names” on page 15-1231). The PortfolioMAD object tries to detect problem dimensions from the inputs and, once set, subsequent inputs can undergo various scalar or matrix expansion operations that simplify the overall process to formulate a problem. In addition, a PortfolioMAD object is a value object so that, given portfolio p, the following code creates two objects, p and q, that are distinct:

```
q = PortfolioMAD(p, ...)
```

After creating a PortfolioMAD object, you can use the associated object functions to set portfolio constraints, analyze the efficient frontier, and validate the portfolio model.

For more detailed information on the theoretical basis for conditional value-at-risk portfolio optimization, see “Portfolio Optimization Theory” on page 6-2.

Creation

Syntax

```
p = PortfolioMAD
p = PortfolioMAD(Name,Value)

p = PortfolioMAD(p,Name,Value)
```

Description

`p = PortfolioMAD` creates an empty `PortfolioMAD` object for mean-absolute deviation portfolio optimization and analysis. You can then add elements to the `PortfolioMAD` object using the supported "add" and "set" functions. For more information, see “Creating the PortfolioMAD Object” on page 6-21.

`p = PortfolioMAD(Name,Value)` creates a `PortfolioMAD` object (`p`) and sets Properties on page 15-1217 using name-value pairs. For example, `p = PortfolioMAD('AssetList',Assets(1:12))`. You can specify multiple name-value pairs.

`p = PortfolioMAD(p,Name,Value)` creates a `PortfolioMAD` object (`p`) using a previously created `PortfolioMAD` object `p` and sets Properties on page 15-1217 using name-value pairs. You can specify multiple name-value pairs.

Input Arguments

p — Previously constructed PortfolioMAD object
object

Previously constructed `PortfolioMAD` object, specified using `PortfolioMAD`.

Properties

Setting Up the PortfolioMAD Object

`AssetList` — Names or symbols of assets in universe
`[]` (default) | cell array of character vectors | string array

Names or symbols of assets in the universe, specified as a cell array of character vectors or a string array.

Data Types: `cell` | `string`

`InitPort` — Initial portfolio
`[]` (default) | vector

Initial portfolio, specified as a vector.

Data Types: `double`

`Name` — Name for instance of PortfolioMAD object
`[]` (default) | character vector | string

Name for instance of the `PortfolioMAD` object, specified as a character vector.

Data Types: `char` | `string`

`NumAssets` — Number of assets in the universe

`[ ]` (default) | integer scalar

Number of assets in the universe, specified as an integer scalar.

Data Types: `double`

PortfolioMAD Object Constraints

`AEquality` — Linear equality constraint matrix

`[ ]` (default) | matrix

Linear equality constraint matrix, specified as a matrix. For more information, see “Linear Equality Constraints” on page 6-8.

Data Types: `double`

`AInequality` — Linear inequality constraint matrix

`[ ]` (default) | matrix

Linear inequality constraint matrix, specified as a matrix. For more information, see “Linear Inequality Constraints” on page 6-7.

Data Types: `double`

`bEquality` — Linear equality constraint vector

`[ ]` (default) | vector

Linear equality constraint vector, specified as a vector. For more information, see “Linear Equality Constraints” on page 6-8.

Data Types: `double`

`bInequality` — Linear inequality constraint

`[ ]` (default) | vector

Linear inequality constraint vector, specified as a vector. For more information, see “Linear Inequality Constraints” on page 6-7.

Data Types: `double`

`GroupA` — Group A weights to be bounded by weights in group B

`[ ]` (default) | matrix

Group A weights to be bounded by weights in group B, specified as a matrix. For more information, see “Group Constraints” on page 6-10.

Data Types: `double`

`GroupB` — Group B weights

`[ ]` (default) | matrix

Group B weights, specified as a matrix. For more information, see “Group Constraints” on page 6-10.

Data Types: `double`

`GroupMatrix` — Group membership matrix

[ ] (default) | matrix

Group membership matrix, specified as a matrix. For more information, see “Group Ratio Constraints” on page 6-10.

Data Types: `double`

`LowerBound` — Lower-bound constraint

[ ] (default) | vector

Lower-bound constraint, specified as a vector. For more information, see “'Simple' Bound Constraints” on page 6-8 and “'Conditional' Bound Constraints” on page 6-9.

Data Types: `double`

`LowerBudget` — Lower-bound budget constraint

[ ] (default) | scalar

Lower-bound budget constraint, specified as a scalar. For more information, see “Budget Constraints” on page 6-9.

Data Types: `double`

`LowerGroup` — Lower-bound group constraint

[ ] (default) | vector

Lower-bound group constraint, specified as a vector. For more information, see “Group Constraints” on page 6-10.

Data Types: `double`

`LowerRatio` — Minimum ratio of allocations between Groups A and B

[ ] (default) | vector

Minimum ratio of allocations between `GroupA` and `GroupB`, specified as a vector. For more information, see “Group Ratio Constraints” on page 6-10.

Data Types: `double`

`UpperBound` — Upper-bound constraint

[ ] (default) | vector

Upper-bound constraint, specified as a vector. For more information, see “'Simple' Bound Constraints” on page 6-8 and “'Conditional' Bound Constraints” on page 6-9.

Data Types: `double`

`UpperBudget` — Upper-bound budget constraint

[ ] (default) | scalar

Upper-bound budget constraint, specified as a scalar. For more information, see “Budget Constraints” on page 6-9.

Data Types: `double`

`UpperGroup` — Upper-bound group constraint

[ ] (default) | vector

Upper-bound group constraint, specified as a vector. For more information, see “Group Constraints” on page 6-10.

Data Types: `double`

`UpperRatio` — Maximum ratio of allocations between Groups A and B

`[]` (default) | vector

Maximum ratio of allocations between `GroupA` and `GroupB`, specified as a vector. For more information, see “Group Ratio Constraints” on page 6-10.

Data Types: `double`

`BoundType` — Type of bounds for each asset weight

`'Simple'` (default) | character vector with value `'Simple'` or `'Conditional'` | string with value `"Simple"` or `"Conditional"` | cell array of character vectors with values `'Simple'` or `'Conditional'` | string array with values `"Simple"` or `"Conditional"`

Type of bounds for each asset weight, specified as a scalar character vector or string, or a cell array of character vectors or a string array. For more information, see `setBounds`.

Data Types: `char` | `cell` | `string`

`MinNumAssets` — Minimum number of assets allocated in portfolio

`[]` (default) | numeric

Minimum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets` and “Cardinality Constraints” on page 6-12.

Data Types: `double`

`MaxNumAssets` — Maximum number of assets allocated in portfolio

`[]` (default) | numeric

Maximum number of assets allocated in portfolio, specified as a scalar numeric value. For more information, see `setMinMaxNumAssets` and “Cardinality Constraints” on page 6-12.

Data Types: `double`

`BuyTurnover` — Turnover constraint on purchases

`[]` (default) | scalar

Turnover constraint on purchases, specified as a scalar. For more information, see “Average Turnover Constraints” on page 6-11 and “One-way Turnover Constraints” on page 6-12.

Data Types: `double`

`SellTurnover` — Turnover constraint on sales

`[]` (default) | scalar

Turnover constraint on sales, specified as a scalar. For more information, see “Average Turnover Constraints” on page 6-11 and “One-way Turnover Constraints” on page 6-12.

Data Types: `double`

`Turnover` — Turnover constraint

`[]` (default) | scalar

Turnover constraint, specified as a scalar. For more information, see “Average Turnover Constraints” on page 6-11 and “One-way Turnover Constraints” on page 6-12.

Data Types: `double`

PortfolioMAD Object Modeling

`BuyCost` — Proportional purchase costs

`[]` (default) | vector

Proportional purchase costs, specified as a vector. For more information, see “Net Portfolio Returns” on page 6-3.

Data Types: `double`

`RiskFreeRate` — Risk-free rate

`[]` (default) | scalar

Risk-free rate, specified as a scalar.

Data Types: `double`

`ProbabilityLevel` — Value-at-risk probability level which is 1 − (loss probability)

`[]` (default) | scalar

Value-at-risk probability level which is 1 − (loss probability), specified as a scalar.

Data Types: `double`

`NumScenarios` — Number of scenarios

`[]` (default) | integer scalar

Number of scenarios, specified as an integer scalar.

Data Types: `double`

`SellCost` — Proportional sales costs

`[]` (default) | vector

Proportional sales costs, specified as a vector. For more information, see “Net Portfolio Returns” on page 6-3.

Data Types: `double`

Object Functions

setAssetList	Set up list of identifiers for assets
setInitPort	Set up initial or current portfolio
setDefaultConstraints	Set up portfolio constraints with nonnegative weights that sum to 1
estimateAssetMoments	Estimate mean and covariance of asset returns from data
setCosts	Set up proportional transaction costs for portfolio
addEquality	Add linear equality constraints for portfolio weights to existing constraints
addGroupRatio	Add group ratio constraints for portfolio weights to existing group ratio constraints

addGroups	Add group constraints for portfolio weights to existing group constraints
addInequality	Add linear inequality constraints for portfolio weights to existing constraints
getBounds	Obtain bounds for portfolio weights from portfolio object
getBudget	Obtain budget constraint bounds from portfolio object
getCosts	Obtain buy and sell transaction costs from portfolio object
getEquality	Obtain equality constraint arrays from portfolio object
getGroupRatio	Obtain group ratio constraint arrays from portfolio object
getGroups	Obtain group constraint arrays from portfolio object
getInequality	Obtain inequality constraint arrays from portfolio object
getOneWayTurnover	Obtain one-way turnover constraints from portfolio object
setGroups	Set up group constraints for portfolio weights
setInequality	Set up linear inequality constraints for portfolio weights
setBounds	Set up bounds for portfolio weights for portfolio
setMinMaxNumAssets	Set cardinality constraints on the number of assets invested in a portfolio
setBudget	Set up budget constraints for portfolio
setCosts	Set up proportional transaction costs for portfolio
setDefaultConstraints	Set up portfolio constraints with nonnegative weights that sum to 1
setEquality	Set up linear equality constraints for portfolio weights
setGroupRatio	Set up group ratio constraints for portfolio weights
setInitPort	Set up initial or current portfolio
setOneWayTurnover	Set up one-way portfolio turnover constraints
setTurnover	Set up maximum portfolio turnover constraint
checkFeasibility	Check feasibility of input portfolios against portfolio object
estimateBounds	Estimate global lower and upper bounds for set of portfolios
estimateFrontier	Estimate specified number of optimal portfolios on the efficient frontier
estimateFrontierByReturn	Estimate optimal portfolios with targeted portfolio returns
estimateFrontierByRisk	Estimate optimal portfolios with targeted portfolio risks
estimateFrontierLimits	Estimate optimal portfolios at endpoints of efficient frontier
plotFrontier	Plot efficient frontier
estimatePortReturn	Estimate mean of portfolio returns
estimatePortRisk	Estimate portfolio risk according to risk proxy associated with corresponding object
setSolver	Choose main solver and specify associated solver options for portfolio optimization
setProbabilityLevel	Set probability level for VaR and CVaR calculations
setScenarios	Set asset returns scenarios by direct matrix
getScenarios	Obtain scenarios from portfolio object
simulateNormalScenariosByData	Simulate multivariate normal asset return scenarios from data
simulateNormalScenariosByMoments	Simulate multivariate normal asset return scenarios from mean and covariance of asset returns
estimateScenarioMoments	Estimate mean and covariance of asset return scenarios
estimatePortStd	Estimate standard deviation of portfolio returns

Examples

Create an Empty PortfolioMAD Object

You can create a PortfolioMAD object, `p`, with no input arguments and display it using `disp`.

```
p = PortfolioMAD;
disp(p);
```

```
  PortfolioMAD with properties:

         BuyCost: []
        SellCost: []
    RiskFreeRate: []
        Turnover: []
     BuyTurnover: []
    SellTurnover: []
    NumScenarios: []
            Name: []
       NumAssets: []
       AssetList: []
        InitPort: []
     AInequality: []
     bInequality: []
       AEquality: []
       bEquality: []
      LowerBound: []
      UpperBound: []
     LowerBudget: []
     UpperBudget: []
     GroupMatrix: []
      LowerGroup: []
      UpperGroup: []
          GroupA: []
          GroupB: []
      LowerRatio: []
      UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
       BoundType: []
```

This approach provides a way to set up a portfolio optimization problem with the `PortfolioMAD` function. You can then use the associated set functions to set and modify collections of properties in the `PortfolioMAD` object.

Create a PortfolioMAD Object Using a Single-Step Setup

You can use the `PortfolioMAD` object directly to set up a “standard” portfolio optimization problem. Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified as follows:

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
```

```
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD('Scenarios', AssetScenarios, ...
'LowerBound', 0, 'LowerBudget', 1, 'UpperBudget', 1)

p = 
  PortfolioMAD with properties:

          BuyCost: []
         SellCost: []
     RiskFreeRate: []
         Turnover: []
      BuyTurnover: []
     SellTurnover: []
     NumScenarios: 20000
             Name: []
        NumAssets: 4
        AssetList: []
         InitPort: []
      AInequality: []
      bInequality: []
        AEquality: []
        bEquality: []
       LowerBound: [4x1 double]
       UpperBound: []
      LowerBudget: 1
      UpperBudget: 1
      GroupMatrix: []
       LowerGroup: []
       UpperGroup: []
           GroupA: []
           GroupB: []
       LowerRatio: []
       UpperRatio: []
     MinNumAssets: []
     MaxNumAssets: []
        BoundType: []
```

Note that the `LowerBound` property value undergoes scalar expansion since `AssetScenarios` provides the dimensions of the problem.

Create a PortfolioMAD Object Using a Sequence of Steps

Using a sequence of steps is an alternative way to accomplish the same task of setting up a “standard” MAD portfolio optimization problem, given `AssetScenarios` variable is:

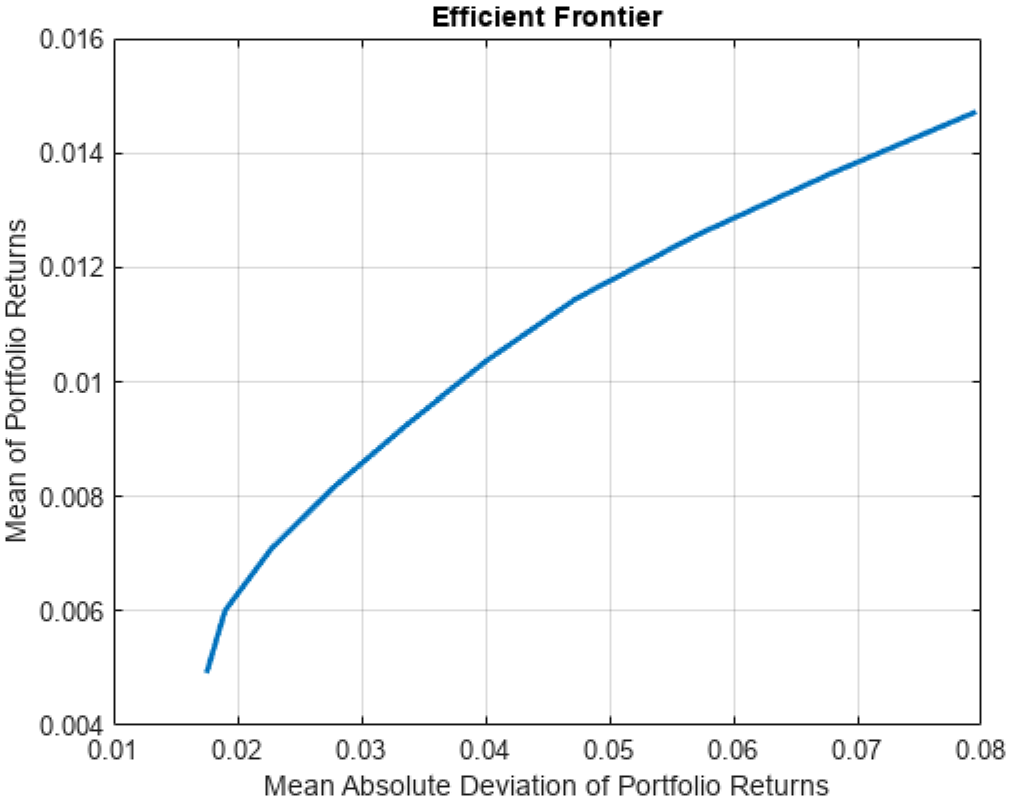
```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];
```

```
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = PortfolioMAD(p, 'LowerBound', 0);
p = PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);

plotFrontier(p);
```



This way works because the calls to `PortfolioMAD` are in this particular order. In this case, the call to initialize `AssetScenarios` provides the dimensions for the problem. If you were to do this step last, you would have to explicitly dimension the `LowerBound` property as follows:

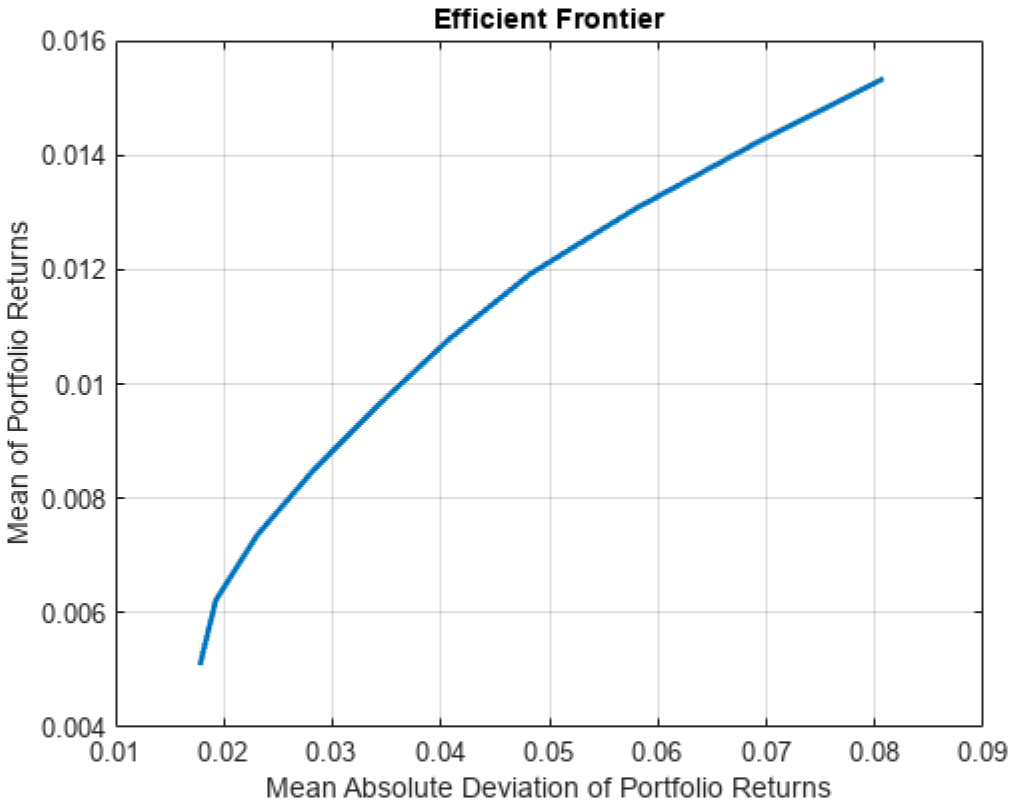
```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);
```

```
p = PortfolioMAD;
p = PortfolioMAD(p, 'LowerBound', zeros(size(m)));
p = PortfolioMAD(p, 'LowerBudget', 1, 'UpperBudget', 1);
p = setScenarios(p, AssetScenarios);

plotFrontier(p);
```



If you did not specify the size of `LowerBound` but, instead, input a scalar argument, the `PortfolioMAD` object assumes that you are defining a single-asset problem and produces an error at the call to set asset scenarios with four assets.

Create a PortfolioMAD Object Using Shortcuts for Property Names

You can create a PortfolioMAD object, `p` with the `PortfolioMAD` object using shortcuts for property names.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
0.00408 0.0289 0.0204 0.0119;
0.00192 0.0204 0.0576 0.0336;
0 0.0119 0.0336 0.1225 ];

m = m/12;
C = C/12;
```

```
AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD('scenario', AssetScenarios, 'lb', 0, 'budget', 1)

p = 
  PortfolioMAD with properties:

          BuyCost: []
         SellCost: []
     RiskFreeRate: []
         Turnover: []
      BuyTurnover: []
     SellTurnover: []
     NumScenarios: 20000
             Name: []

```

Direct Setting of PortfolioMAD Object Properties

Although not recommended, you can set properties directly, however no error-checking is done on your inputs.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
```

```
p = setScenarios(p, AssetScenarios);

p.LowerBudget = 1;
p.UpperBudget = 1;
p.LowerBound = zeros(size(m));
disp(p);
```

```
  PortfolioMAD with properties:

          BuyCost: []
         SellCost: []
     RiskFreeRate: []
         Turnover: []
      BuyTurnover: []
     SellTurnover: []
     NumScenarios: 20000
             Name: []
        NumAssets: 4
        AssetList: []
         InitPort: []
      AInequality: []
      bInequality: []
        AEquality: []
        bEquality: []
       LowerBound: [4x1 double]
       UpperBound: []
      LowerBudget: 1
      UpperBudget: 1
      GroupMatrix: []
       LowerGroup: []
       UpperGroup: []
           GroupA: []
           GroupB: []
       LowerRatio: []
       UpperRatio: []
     MinNumAssets: []
     MaxNumAssets: []
        BoundType: []
```

Scenarios cannot be assigned directly to a PortfolioMAD object. Scenarios must always be set through either the `PortfolioMAD` function, the `setScenarios` function, or any of the scenario simulation functions.

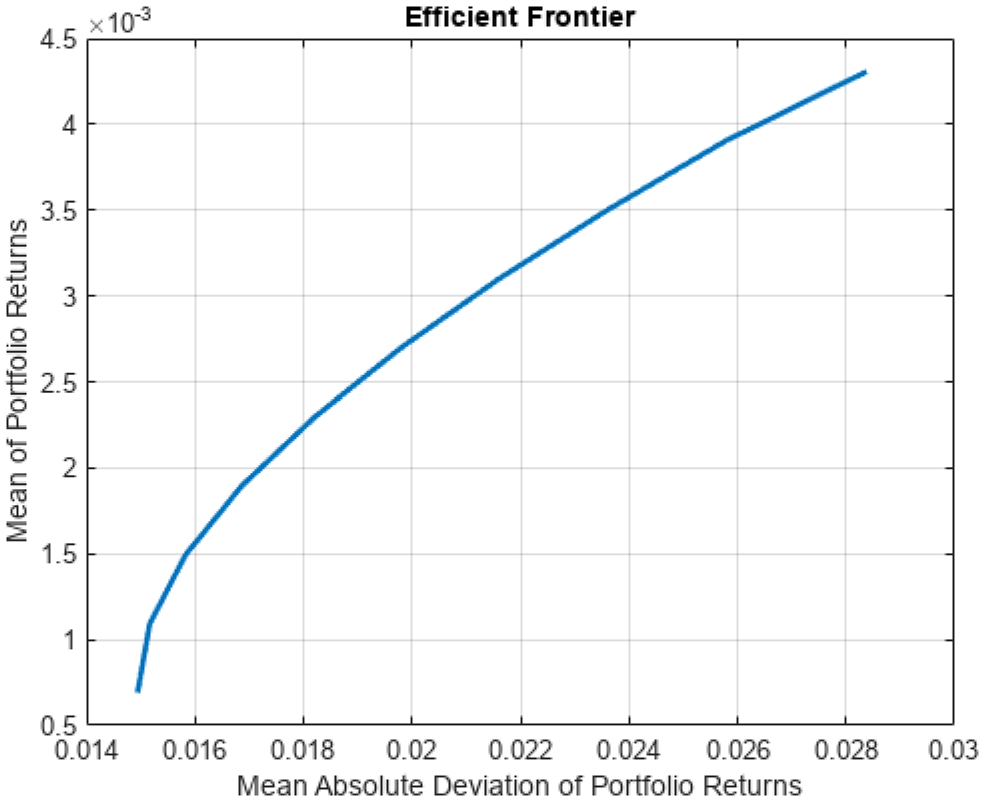
Create a `PortfolioMAD` Object and Determine Efficient Portfolios

Create efficient portfolios:

```
load CAPMuniverse

p = PortfolioMAD('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 ,'missingdata',true);
p = setDefaultConstraints(p);

plotFrontier(p);
```



```
pwgt = estimateFrontier(p, 5);

pnames = cell(1,5);
for i = 1:5
    pnames{i} = sprintf('Port%d',i);
end

Blotter = dataset([{pwgt},pnames],'obsnames',p.AssetList);

disp(Blotter);
```

```
            Port1       Port2       Port3       Port4      Port5
    AAPL    0.030785    0.074603     0.11383    0.13349    0
    AMZN           0           0           0          0    0
    CSCO           0           0           0          0    0
    DELL    0.010139           0           0          0    0
    EBAY           0           0           0          0    0
    GOOG      0.1607     0.35186     0.54435    0.74908    1
    HPQ     0.056834    0.024903           0          0    0
    IBM      0.45716     0.38008     0.29373    0.11743    0
    INTC           0           0           0          0    0
    MSFT     0.28438     0.16855    0.048097          0    0
    ORCL           0           0           0          0    0
    YHOO           0           0           0          0    0
```

More About

Mean-Absolute Deviation Portfolio Optimization

A MAD optimization problem is completely specified with three elements.

The three elements for a A MAD optimization problem are:

- A universe of assets with scenarios of asset total returns for a period of interest, where scenarios comprise a collection of samples from the underlying probability distribution for asset total returns. This collection must be sufficiently large for asymptotic convergence of sample statistics. Asset return moments and related statistics are derived exclusively from the scenarios.
- A portfolio set that specifies the set of portfolio choices in terms of a collection of constraints.
- A model for portfolio return and risk proxies, which, for MAD optimization, is either the gross or net mean of portfolio returns and the mean-absolute deviation of portfolio returns.

After these three elements have been specified unambiguously, it is possible to solve and analyze MAD portfolio optimization problems.

The simplest MAD portfolio optimization problem has:

- Scenarios of asset total returns
- A requirement that all portfolios have nonnegative weights that sum to 1 (the summation constraint is known as a budget constraint)
- Built-in models for portfolio return and risk proxies that use scenarios of asset total returns

Given scenarios of asset returns in the variable `AssetScenarios`, this problem is completely specified by:

```
p = PortfolioMAD('Scenarios', AssetScenarios, 'LowerBound', 0, 'Budget', 1);
```

or equivalently by:

```
p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
```

To confirm that this is a valid portfolio optimization problem, the following function determines whether the set of PortfolioMAD choices is bounded (a necessary condition for portfolio optimization).

```
[lb, ub, isbounded] = estimateBounds(p);
```

Given the problem specified in the `PortfolioMAD` object `p`, the efficient frontier for this problem can be displayed with:

```
plotFrontier(p);
```

and efficient portfolios can be obtained with:

```
pwgt = estimateFrontier(p);
```

For more detailed information on the theoretical basis for mean-absolute deviation optimization, see “Portfolio Optimization Theory” on page 6-2.

PortfolioMAD Problem Sufficiency

A MAD portfolio optimization problem is completely specified with the `PortfolioMAD` object if three conditions are met.

The following are the three conditions that must be met:

- You must specify a collection of asset returns or prices known as scenarios such that all scenarios are finite asset returns or prices. These scenarios are meant to be samples from the underlying probability distribution of asset returns. This condition can be satisfied by the `setScenarios` function or with several canned scenario simulation functions.
- The set of feasible portfolios must be a nonempty compact set, where a compact set is closed and bounded. You can satisfy this condition using an extensive collection of properties that define different types of constraints to form a set of feasible portfolios. Since such sets must be bounded, either explicit or implicit constraints can be imposed and several tools, such as the `estimateBounds` function, provide ways to ensure that your problem is properly formulated.

  Although the general sufficient conditions for MAD portfolio optimization go beyond these conditions, the `PortfolioMAD` object handles all these additional conditions.

Shortcuts for Property Names

The `PortfolioMAD` object has shorter argument names that replace longer argument names associated with specific properties of the `PortfolioMAD` object.

For example, rather than enter `'AInequality'`, `PortfolioMAD` accepts the case-insensitive name `'ai'` to set the `AInequality` property in a `PortfolioMAD` object. Every shorter argument name corresponds with a single property in the `PortfolioMAD` function. The one exception is the alternative argument name `'budget'`, which signifies both the `LowerBudget` and `UpperBudget` properties. When `'budget'` is used, then the `LowerBudget` and `UpperBudget` properties are set to the same value to form an equality budget constraint.

Shortcuts for Property Names

Shortcut Argument Name	Equivalent Argument / Property Name
`ae`	`AEquality`
`ai`	`AInequality`
`assetnames` or `assets`	`AssetList`
`be`	`bEquality`
`bi`	`bInequality`
`budget`	`UpperBudget` and `LowerBudget`
`group`	`GroupMatrix`
`lb`	`LowerBound`
`n` or `num`	`NumAssets`
`rfr`	`RiskFreeRate`
`scenario` or `assetscenarios`	`Scenarios`
`ub`	`UpperBound`

Version History

Introduced in R2013b

portopt

Portfolios on constrained efficient frontier

Note `portopt` has been partially removed and will no longer accept `ConSet` or `varargin` arguments. Use `Portfolio` instead to solve portfolio problems that are more than a long-only fully-invested portfolio. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow”. For more information on migrating `portopt` code to `Portfolio`, see “portopt Migration to Portfolio Object”.

Syntax

```
[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance)
[PortRisk,PortReturn,PortWts] = portopt( ___ ,NumPorts,PortReturn)
portopt( ___ ,NumPorts,PortReturn)
```

Description

`[PortRisk,PortReturn,PortWts] = portopt(ExpReturn,ExpCovariance)` sets up the most basic portfolio problem with weights greater than or equal to `0` that must sum to `1`. All that is necessary to solve this problem is the mean and covariance of asset returns. By default, `portopt` returns 10 equally-spaced points on the efficient frontier.

`portopt` solves the "standard" mean-variance portfolio optimization problem for a long-only fully-invested investor with no additional constraints. Specifically, every portfolios on the efficient frontier has non-negative weights that sum to 1.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

`[PortRisk,PortReturn,PortWts] = portopt( ___ ,NumPorts,PortReturn)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

`portopt( ___ ,NumPorts,PortReturn)` returns a plot of the efficient frontier if `portopt` is invoked with no output arguments.

Examples

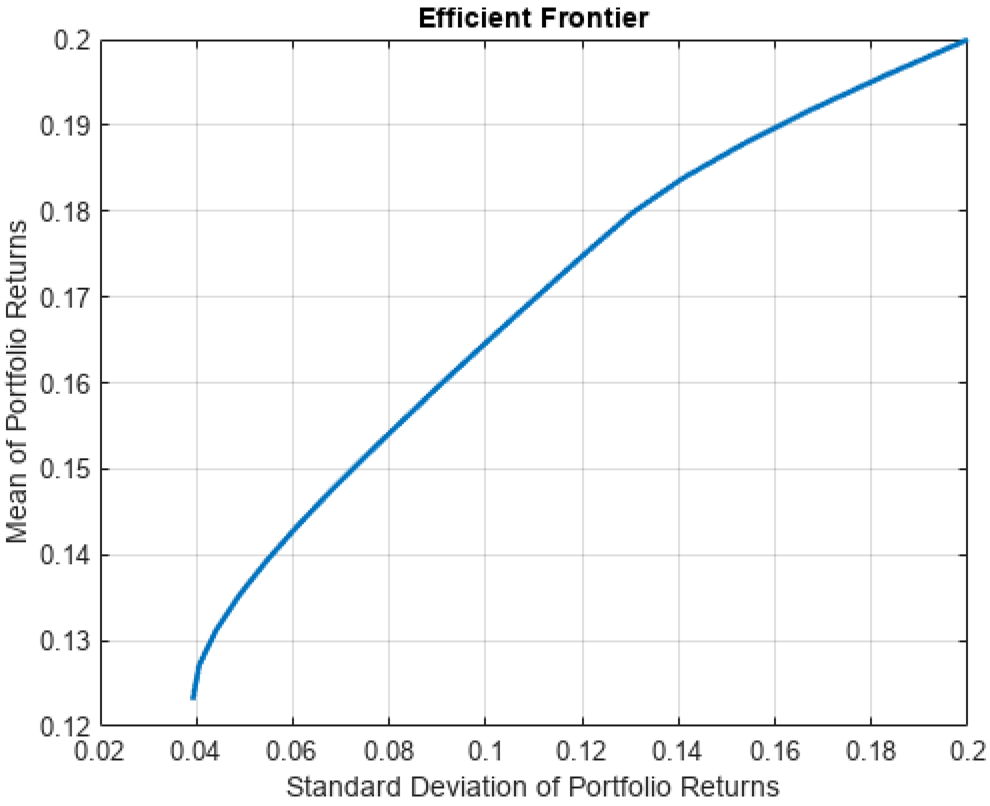
Plot the Risk-Return Efficient Frontier

Use `portopt` to connect 20 portfolios along the efficient frontier having evenly spaced returns. By default, choose among portfolios without short-selling and scale the value of the portfolio to 1.

```
ExpReturn = [0.1 0.2 0.15];

ExpCovariance = [0.005   -0.010    0.004
                -0.010    0.040   -0.002
                 0.004   -0.002    0.023];

NumPorts = 20;
portopt(ExpReturn, ExpCovariance, NumPorts)
```



Input Arguments

`ExpReturn` — Expected (mean) return of each asset

vector

Expected (mean) return of each asset, specified as a `1`-by-number of assets (`NASSETS`) vector.

Data Types: `double`

`ExpCovariance` — Covariance of the asset returns

matrix

Covariance of the asset returns, specified as a `NASSETS`-by-`NASSETS` matrix.

Data Types: `double`

`NumPorts` — Number of portfolios generated along the efficient frontier

`10` (default) | scalar numeric

(Optional) Number of portfolios generated along the efficient frontier, specified as a scalar numeric. Returns are equally spaced between the maximum possible return and the minimum risk point. If `NumPorts` is empty (entered as `[]`), `portopt` computes 10 equally spaced points. If you specify `1`, `portopt` returns the minimum-risk portfolio.

Note If not over-ridden by `PortReturn`, these portfolios are spaced evenly from the minimum to the maximum return on the efficient frontier. If `NumPorts = 1`, then the minimum-risk portfolio is computed (positive integer).

Data Types: `double`

`PortReturn` — Target portfolio returns to be computed on the efficient frontier
[ ] (default) | vector

(Optional) Target portfolio returns to be computed on the efficient frontier, specified as a number of portfolios (`NPORTS`-by-`1` vector). If not entered or empty, `NumPorts` equally spaced returns between the minimum and maximum possible values are used.

Note `portopt` requires that if you set `PortReturn`, `NumPorts` should be empty. If you specify `PortReturn` with a nonempty vector, `PortReturn` overrides `NumPorts`. If any returns in `PortReturn` fall outside the range of returns on the efficient frontier, `portopt` generates a warning and the efficient portfolios closest to the endpoints of the efficient frontier are computed.

Data Types: `double`

Output Arguments

`PortRisk` — Standard deviation of each portfolio
vector

Standard deviation of each portfolio, returned as a `NPORTS`-by-`1` vector.

`PortWts` is an `NPORTS`-by-`NASSETS` matrix of weights allocated to each asset. Each row represents a portfolio. The total of all weights in a portfolio is 1.

`PortReturn` — expected return of each portfolio
vector

Expected return of each portfolio, returned as a `NPORTS`-by-`1` vector.

`PortWts` — Weights allocated to each asset
matrix

Weights allocated to each asset, returned as a `NPORTS`-by-`NASSETS` matrix. Each row represents a portfolio. The total of all weights in a portfolio is 1.

portrand

Randomized portfolio risks, returns, and weights

Syntax

```
[PortRisk,PortReturn,PortWts] = portrand(Asset)
[PortRisk,PortReturn,PortWts] = portrand( ___ ,Return,Points,Method)
portrand(Asset,Return,Points,Method)
```

Description

`[PortRisk,PortReturn,PortWts] = portrand(Asset)` returns the risks, rates of return, and weights of random portfolio configurations. Portfolios are selected at random from a set of portfolios such that portfolio weights are nonnegative and sum to 1. The sample mean and covariance of asset returns are used to compute portfolio returns for each random portfolio.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

`[PortRisk,PortReturn,PortWts] = portrand( ___ ,Return,Points,Method)` returns the risks, rates of return, and weights of random portfolio configurations using optional arguments.

`portrand(Asset,Return,Points,Method)` plots the points representing each portfolio configuration. It does not return any data to the MATLAB workspace.

Input Arguments

`Asset` — Financial time series data

matrix

Financial time series data, specified as a matrix where each row is an observation and each column represents a single security.

Data Types: `double`

`Return` — Rate of return for corresponding security in `Asset`

`Return` computed by taking average value of each column of `Asset` (default) | row vector

(Optional) Rate of return for corresponding security in `Asset`, specified as a row vector,where each column represents the rate of return for the corresponding security.

Data Types: `double`

`Points` — Defines number of random points generated

`1000` (default) | numeric

(Optional) Defines number of random points generated, specified as a numeric.

Data Types: `double`

`Method` — Method to generate random portfolios from set of portfolios
`'uniform'` (default) | character vector with value `'uniform'` or `'geometric'`

(Optional) Method to generate random portfolios from set of portfolios, specified as a character vector for one of the following:

- `'uniform'` — Portfolio weights are generated that are uniformly distributed on the set of portfolio weights.
- `'geometric'` — Portfolio weights are generated that are concentrated around the geometric center of the set of portfolio weights.

Note The `'uniform'` and `'geometric'` methods generate weights that are distributed symmetrically around the geometric center of the set of weights.

Data Types: `double`

Output Arguments

`PortRisk` — Portfolio risk
vector

Portfolio risk, returned as a `POINTS`-by-`1` vector of standard deviations.

`PortReturn` — Portfolio return
vector

Portfolio return, returned as a `POINTS`-by-`1` vector of expected rates of return.

`PortWts` — Portfolio asset weights
matrix

Portfolio asset weights, returned as a `POINTS`-by-(number of securities) matrix of asset weights. Each row of `PortWts` is a different portfolio configuration.

Topics
“Portfolio Construction Examples” on page 3-5

"Portfolio Optimization Functions" on page 3-3

portror

Portfolio expected rate of return

Syntax

```
R = portror(Return,Weight)
```

Description

`R = portror(Return,Weight)` returns a `1`-by-`M` vector for the expected rate of return.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

Examples

Portfolio Expected Rate of Return

This example shows a portfolio that is made up of two assets ABC and XYZ having expected rates of return of 10% and 14%, respectively. If 40% percent of the portfolio's funds are allocated to asset ABC and the remaining funds are allocated to asset XYZ, the portfolio's expected rate of return is:

```
r = portror([.1 .14],[.4 .6])
```

```
r = 0.1240
```

Input Arguments

`Return` — Rates of return
matrix

Rates of return, specified as a `1`-by-`N` matrix. Each column of `Return` represents the rate of return for a single security.

Data Types: `double`

`Weight` — Weights
matrix

Weights, specified as a `M`-by-`N` matrix. Each row of `Weight` represents a different weighting combination of the assets in the portfolio.

Data Types: `double`

Output Arguments

R — Expected rate of return

vector

Expected rate of return, returned as a 1-by-M vector.

portsim

Monte Carlo simulation of correlated asset returns

Syntax

```
RetSeries = portsim(ExpReturn,ExpCovariance,NumObs)
RetSeries = portsim( ___ ,RetIntervals,NumSim,Method)
```

Description

`RetSeries = portsim(ExpReturn,ExpCovariance,NumObs)` simulates correlated returns of `NASSETS` assets over `NUMOBS` consecutive observation intervals. Asset returns are simulated as the proportional increments of constant drift, constant volatility stochastic processes, thereby approximating continuous-time geometric Brownian motion.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

`RetSeries = portsim( ___ ,RetIntervals,NumSim,Method)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Distinction Between Simulation Methods

This example shows the distinction between the `Exact` and `Expected` methods of simulation.

Consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns (where `ExpReturn` and `Sigmas` are divided by 100 to convert percentages to returns).

```
ExpReturn     = [0.0246  0.0189  0.0273  0.0141  0.0311]/100;
Sigmas        = [0.9509  1.4259  1.5227  1.1062  1.0877]/100;
Correlations  = [1.0000  0.4403  0.4735  0.4334  0.6855
                 0.4403  1.0000  0.7597  0.7809  0.4343
                 0.4735  0.7597  1.0000  0.6978  0.4926
                 0.4334  0.7809  0.6978  1.0000  0.4289
                 0.6855  0.4343  0.4926  0.4289  1.0000];
```

Convert the correlations and standard deviations to a covariance matrix.

```
ExpCovariance = corr2cov(Sigmas, Correlations)
```

```
ExpCovariance = 5×5
10^-3 ×
```

```
    0.0904    0.0597    0.0686    0.0456    0.0709
    0.0597    0.2033    0.1649    0.1232    0.0674
    0.0686    0.1649    0.2319    0.1175    0.0816
    0.0456    0.1232    0.1175    0.1224    0.0516
    0.0709    0.0674    0.0816    0.0516    0.1183
```

Assume that there are 252 trading days in a calendar year, and simulate two sample paths (realizations) of daily returns over a two-year period. Since ExpReturn and ExpCovariance are expressed daily, set RetIntervals = 1.

```
StartPrice    = 100;
NumObs        = 504;  % two calendar years of daily returns
NumSim        = 2;
RetIntervals  = 1;    % one trading day
NumAssets     = 5;
```

To illustrate the distinction between methods, simulate two paths by each method, starting with the same random number state.

```
rng('default');
RetExact = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Exact');
rng(0);
RetExpected = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Expected');
```

Compare the mean and covariance of RetExact with the inputs (ExpReturn and ExpCovariance), you will observe that they are almost identical.

At this point, RetExact and RetExpected are both 504-by-5-by-2 arrays. Now assume an equally weighted portfolio formed from the five assets and create arrays of portfolio returns in which each column represents the portfolio return of the corresponding sample path of the simulated returns of the five assets. The portfolio arrays PortRetExact and PortRetExpected are 504-by-2 matrices.

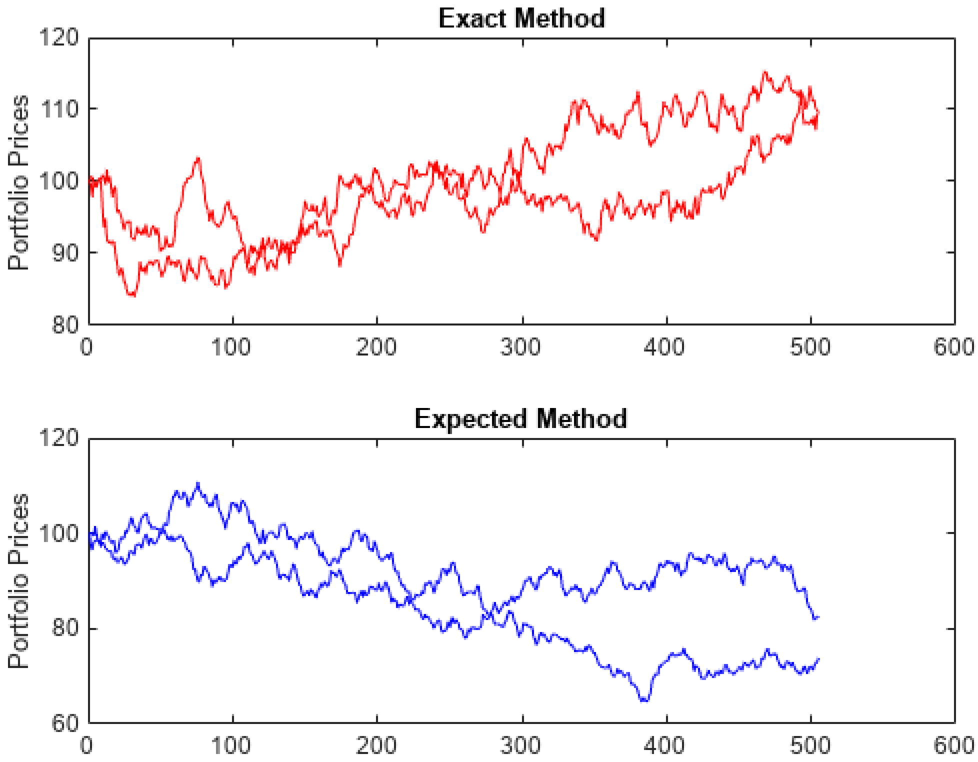
```
Weights         = ones(NumAssets, 1)/NumAssets;
PortRetExact    = zeros(NumObs, NumSim);
PortRetExpected = zeros(NumObs, NumSim);

for i = 1:NumSim
    PortRetExact(:,i)    = RetExact(:,:,i) * Weights;
    PortRetExpected(:,i) = RetExpected(:,:,i) * Weights;
end
```

Finally, convert the simulated portfolio returns to prices and plot the data. In particular, note that since the Exact method matches expected return and covariance, the terminal portfolio prices are virtually identical for each sample path. This is not true for the Expected simulation method. Although this example examines portfolios, the same methods apply to individual assets as well. Thus, Exact simulation is most appropriate when unique paths are required to reach the same terminal prices.

```
PortExact   = ret2tick(PortRetExact, ...
repmat(StartPrice,1,NumSim));
PortExpected = ret2tick(PortRetExpected, ...
repmat(StartPrice,1,NumSim));
subplot(2,1,1), plot(PortExact, '-r')
```

```
ylabel('Portfolio Prices')
title('Exact Method')
subplot(2,1,2), plot(PortExpected, '-b')
ylabel('Portfolio Prices')
title('Expected Method')
```



Interaction Between ExpReturn, ExpCovariance, and RetIntervals

This example shows the interplay among `ExpReturn`, `ExpCovariance`, and `RetIntervals`. Recall that `portsim` simulates correlated asset returns over an interval of length *dt*, given by the equation

$$\frac{dS}{S} = \mu dt + \sigma dz = \mu dt + \sigma\varepsilon\sqrt{dt},$$

where S is the asset price, μ is the expected rate of return, σ is the volatility of the asset price, and ε represents a random drawing from a standardized normal distribution.

The time increment *dt* is determined by the optional input `RetIntervals`, either as an explicit input argument or as a unit time increment by default. Regardless, the periodicity of `ExpReturn`, `ExpCovariance`, and `RetIntervals` must be consistent. For example, if `ExpReturn` and `ExpCovariance` are annualized, then `RetIntervals` must be in years. This point is often misunderstood.

To illustrate the interplay among `ExpReturn`, `ExpCovariance`, and `RetIntervals`, consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns.

```
ExpReturn     = [0.0246  0.0189  0.0273  0.0141  0.0311]/100;

Sigmas        = [0.9509  1.4259  1.5227  1.1062  1.0877]/100;

Correlations  = [1.0000  0.4403  0.4735  0.4334  0.6855
                 0.4403  1.0000  0.7597  0.7809  0.4343
                 0.4735  0.7597  1.0000  0.6978  0.4926
                 0.4334  0.7809  0.6978  1.0000  0.4289
                 0.6855  0.4343  0.4926  0.4289  1.0000];
```

Convert the correlations and standard deviations to a covariance matrix of daily returns.

```
 ExpCovariance = corr2cov(Sigmas, Correlations);
```

Assume 252 trading days per calendar year, and simulate a single sample path of daily returns over a four-year period. Since the `ExpReturn` and `ExpCovariance` inputs are expressed daily, set `RetIntervals = 1`.

```
StartPrice    = 100;
NumObs        = 1008;   % four calendar years of daily returns
RetIntervals  = 1;      % one trading day
NumAssets     = length(ExpReturn);
randn('state',0);
RetSeries1 = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, 1, 'Expected');
```

Now annualize the daily data, thereby changing the periodicity of the data, by multiplying `ExpReturn` and `ExpCovariance` by 252 and dividing `RetIntervals` by 252 (`RetIntervals =` 1/252 of a year). Resetting the random number generator to its initial state, you can reproduce the results.

```
rng('default');
RetSeries2 = portsim(ExpReturn*252, ExpCovariance*252, ...
NumObs, RetIntervals/252, 1, 'Expected');
```

Assume an equally weighted portfolio and compute portfolio returns associated with each simulated return series.

```
Weights  = ones(NumAssets, 1)/NumAssets;

PortRet1 = RetSeries2 * Weights;
PortRet2 = RetSeries2 * Weights;
```

Comparison of the data reveals that `PortRet1` and `PortRet2` are identical.

Univariate Geometric Brownian Motion

This example shows how to simulate a univariate geometric Brownian motion process. It is based on an example found in Hull, *Options, Futures, and Other Derivatives*, 5th Edition (see example 12.2 on page 236). In addition to verifying Hull's example, it also graphically illustrates the lognormal property of terminal stock prices by a rather large Monte Carlo simulation.

Assume that you own a stock with an initial price of $20, an annualized expected return of 20% and volatility of 40%. Simulate the daily price process for this stock over the course of one full calendar year (252 trading days).

```
StartPrice    = 20;
ExpReturn     = 0.2;
ExpCovariance = 0.4^2;
NumObs        = 252;
NumSim        = 10000;
RetIntervals  = 1/252;
```

`RetIntervals` is expressed in years, consistent with the fact that `ExpReturn` and `ExpCovariance` are annualized. Also, `ExpCovariance` is entered as a variance rather than the more familiar standard deviation (volatility).

Set the random number generator state, and simulate 10,000 trials (realizations) of stock returns over a full calendar year of 252 trading days.

```
rng('default');
RetSeries = squeeze(portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Expected'));
```

The `squeeze` function reformats the output array of simulated returns from a `252`-by-`1`-by-`10000` array to more convenient `252`-by-`10000` array. (Recall that `portsim` is fundamentally a multivariate simulation engine).

In accordance with Hull's equations 12.4 and 12.5 on page 236

$$E(S_T) = S_0 e^{\mu T}$$

$$var(S_T) = S_0{}^2 e^{2\mu T}\left(e^{\sigma^2 T} - 1\right)$$

convert the simulated return series to a price series and compute the sample mean and the variance of the terminal stock prices.

```
StockPrices = ret2tick(RetSeries, repmat(StartPrice, 1, NumSim));

SampMean = mean(StockPrices(end,:))
SampVar = var(StockPrices(end,:))
```

```
SampMean =

   24.4489

SampVar =

  101.4243
```

Compare these values with the values you obtain by using Hull's equations.

```
ExpValue = StartPrice*exp(ExpReturn)
ExpVar = ...
StartPrice*StartPrice*exp(2*ExpReturn)*(exp((ExpCovariance)) - 1)
```

```
ExpValue =

   24.4281

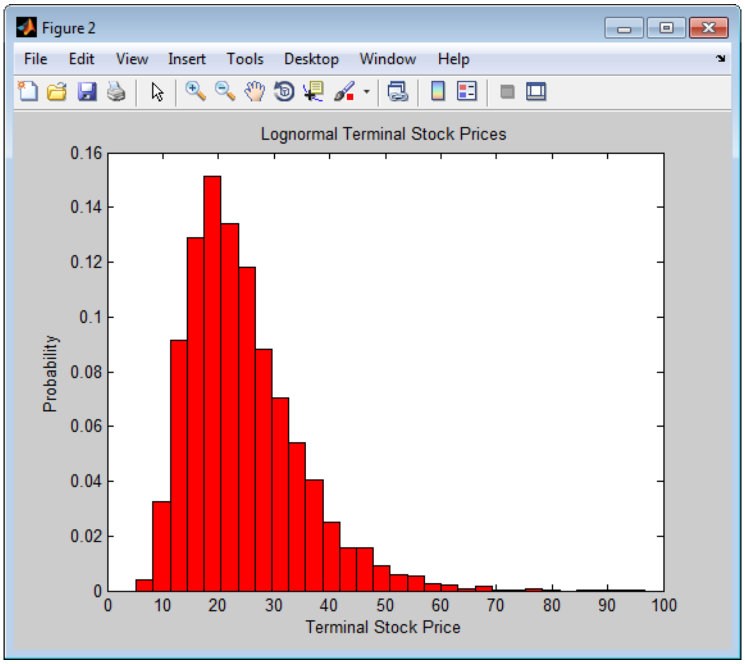
ExpVar =

  103.5391
```

These results are very close to the results shown in Hull's example 12.2.

Display the sample density function of the terminal stock price after one calendar year. From the sample density function, the lognormal distribution of terminal stock prices is apparent.

```
[count, BinCenter] = hist(StockPrices(end,:), 30);
figure
bar(BinCenter, count/sum(count), 1, 'r')
xlabel('Terminal Stock Price')
ylabel('Probability')
title('Lognormal Terminal Stock Prices')
```



Input Arguments

ExpReturn — Expected (mean) return of each asset

vector

Expected (mean) return of each asset, specified as a 1-by-NASSETS vector.

Data Types: double

ExpCovariance — Asset return covariances

matrix

Asset return covariances, specified as an NASSETS-by-NASSETS matrix. ExpCovariance must be symmetric and positive semidefinite (no negative eigenvalues). The standard deviations of the returns are ExpSigma = sqrt(diag(ExpCovariance)). If ExpCovariance is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

Data Types: double

NumObs — Number of consecutive observations in the return time series

positive scalar integer

number of consecutive observations in the return time series, specified as a positive scalar integer. If NumObs is entered as the empty matrix [], the length of RetIntervals is used.

Data Types: double

RetIntervals — Interval times between observations

1 (default) | positive scalar | vector

(Optional) Interval times between observations, specified as a positive scalar or a number of observations NUMOBS-by-1 vector. If RetIntervals is not specified, all intervals are assumed to have length 1.

Data Types: double

NumSim — Number of simulated sample paths (realizations) of NUMOBS observations

1 (default) | positive scalar integer

(Optional) Number of simulated sample paths (realizations) of NUMOBS observations, specified as a positive scalar integer. The default value for NumSim is 1 (single realization of NUMOBS correlated asset returns).

Data Types: double

Method — Type of Monte Carlo simulation

'Exact' (default) | character vector

(Optional) Type of Monte Carlo simulation, specified as a character vector with one of the following values:

- 'Exact' (default) generates correlated asset returns in which the sample mean and covariance match the input mean (ExpReturn) and covariance (ExpCovariance) specifications.
- 'Expected' generates correlated asset returns in which the sample mean and covariance are statistically equal to the input mean and covariance specifications. (The expected values of the sample mean and covariance are equal to the input mean (ExpReturn) and covariance (ExpCovariance) specifications.)

For either Method, the sample mean and covariance returned are appropriately scaled by RetIntervals.

Data Types: char

Output Arguments

RetSeries — Three-dimensional array of correlated, normally distributed, proportional asset returns

array

Three-dimensional array of correlated, normally distributed, proportional asset returns, returned as a NUMOBS-by-NASSETS-by-NUMSIM three-dimensional array.

Asset returns over an interval of length *dt* are given by

$$\frac{dS}{S} = \mu dt + \sigma dz = \mu dt + \sigma\varepsilon\sqrt{dt},$$

where S is the asset price, μ is the expected rate of return, σ is the volatility of the asset price, and ε represents a random drawing from a standardized normal distribution.

Notes

- When Method is 'Exact', the sample mean and covariance of all realizations (scaled by RetIntervals) match the input mean and covariance. When the returns are then converted to asset prices, all terminal prices for a given asset are in close agreement. Although all realizations are drawn independently, they produce similar terminal asset prices. Set Method to 'Expected' to avoid this behavior.
- The returns from the portfolios in PortWts are given by PortReturn = PortWts * RetSeries(:,:,1)', where PortWts is a matrix in which each row contains the asset allocations of a portfolio. Each row of PortReturn corresponds to one of the portfolios identified in PortWts, and each column corresponds to one of the observations taken from the first realization (the first plane) in RetSeries. See portopt and portstats for portfolio specification and optimization.

portstats

Portfolio expected return and risk

Syntax

```
[PortRisk,PortReturn] = portstats(ExpReturn,ExpCovariance)
[PortRisk,PortReturn] = portstats( ___ ,Wts)
```

Description

`[PortRisk,PortReturn] = portstats(ExpReturn,ExpCovariance)` computes the expected rate of return and risk for a portfolio of assets.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

`[PortRisk,PortReturn] = portstats( ___ ,Wts)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

Examples

Computes the Expected Rate of Return and Risk for a Portfolio of Assets

This example shows how to calculate the expected rate of return and risk for a portfolio of assets.

```
ExpReturn = [0.1 0.2 0.15];

ExpCovariance = [0.0100   -0.0061    0.0042
                -0.0061    0.0400   -0.0252
                 0.0042   -0.0252    0.0225 ];

PortWts=[0.4 0.2 0.4; 0.2 0.4 0.2];

[PortRisk, PortReturn] = portstats(ExpReturn, ExpCovariance,...
PortWts)
```

```
PortRisk = 2×1

    0.0560
    0.0550

PortReturn = 2×1

    0.1400
    0.1300
```

Input Arguments

ExpReturn — Expected (mean) return of each asset
vector

Expected (mean) return of each asset, specified as a 1-by-NASSETS vector.

Data Types: double

ExpCovariance — Asset return covariances
matrix

Asset return covariances, specified as an NASSETS-by-NASSETS matrix.

Data Types: double

Wts — Weights allocated to each asset
1/NASSETS (equally weighted) (default) | matrix

(Optional) Weights allocated to each asset, specified as an NPORTS-by-NASSETS matrix. Each row represents a different weighting combination of the assets in the portfolio. If Wts is not entered, weights of 1/NASSETS are assigned to each security.

Data Types: double

Output Arguments

PortRisk — Standard deviation of each portfolio
vector

Standard deviation of each portfolio, returned as an NPORTS-by-1 vector.

PortReturn — Expected return of each portfolio
vector

Expected return of each portfolio, returned an NPORTS-by-1 vector.

portvar

Variance for portfolio of assets

Syntax

```
V = portvar(Asset)
V = portvar(Asset,Weight)
```

Description

`V = portvar(Asset)` assigns each security an equal weight when calculating the portfolio variance.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see "Portfolio Object Workflow" on page 4-17.

`V = portvar(Asset,Weight)` returns the portfolio variance as an R-by-1 vector (assuming `Weight` is a matrix of size R-by-N) with each row representing a variance calculation for each row of `Weight`.

Examples

Compute Variance of Portfolio Assets

This example shows how to use `portvar` to compute the variance of portfolio assets. When you don't specify weights, `portvar` assigns each security an equal weight when calculating the portfolio variance.

```
load FundMarketCash
Returns = tick2ret(TestData);
Fund = Returns(:,1);
portvar(Fund)
```

```
ans = 5.3465e-04
```

Input Arguments

`Asset` — Asset returns

matrix

Asset Returns, specified as a `M`-by-`N` matrix of `M` asset returns for `N` securities.

Data Types: `double`

`Weight` — Portfolio weights

matrix

Portfolio weights, specified as a `R`-by-`N` matrix of `R` portfolio weights for `N` securities. Each row of `Weight` constitutes a portfolio of securities in `Asset`.

, specified as a scalar numeric value.

Data Types: `double`

Output Arguments

`V` — Variance of portfolio assets

numeric

Variance of portfolio assets, returned as a numeric value.

Version History

Introduced before R2006a

portvrisk

Portfolio value at risk (VaR)

Syntax

```
ValueAtRisk = portvrisk(PortReturn,PortRisk)
ValueAtRisk = portvrisk( ___ ,RiskThreshold,PortValue)
```

Description

`ValueAtRisk = portvrisk(PortReturn,PortRisk)` returns the maximum potential loss in the value of a portfolio over one period of time (that is, monthly, quarterly, yearly, and so on) given the loss probability level. `portvrisk` calculates `ValueAtRisk` using a normal distribution.

Note An alternative for portfolio optimization is to use the `Portfolio` object for mean-variance portfolio optimization. This object supports gross or net portfolio returns as the return proxy, the variance of portfolio returns as the risk proxy, and a portfolio set that is any combination of the specified constraints to form a portfolio set. For information on the workflow when using `Portfolio` objects, see “Portfolio Object Workflow” on page 4-17.

`ValueAtRisk = portvrisk( ___ ,RiskThreshold,PortValue)` adds optional arguments for `RiskThreshold` and `PortValue`.

Examples

Compute the Maximum Potential Loss in the Value of a Portfolio Over One Period of Time

This example shows how to return the maximum potential loss in the value of a portfolio over one period of time, where `ValueAtRisk` is computed on a per-unit basis.

```
PortReturn = 0.29/100;
PortRisk = 3.08/100;
RiskThreshold = [0.01;0.05;0.10];
PortValue = 1;
ValueAtRisk = portvrisk(PortReturn,PortRisk,...
RiskThreshold,PortValue)
```

```
ValueAtRisk = 3×1

    0.0688
    0.0478
    0.0366
```

Compute the Maximum Potential Loss in the Value of a Portfolio Over One Period of Time Using Actual Values

This example shows how to return the maximum potential loss in the value of a portfolio over one period of time, where `ValueAtRisk` is computed with actual values.

```
PortReturn = [0.29/100;0.30/100];
PortRisk = [3.08/100;3.15/100];
RiskThreshold = 0.10;
PortValue = [1000000000;500000000];
ValueAtRisk = portvrisk(PortReturn,PortRisk,...
RiskThreshold,PortValue)
```

```
ValueAtRisk = 2×1
10^7 ×

    3.6572
    1.8684
```

Compute the Maximum Potential Loss in the Value of a Portfolio Over One Period of Time Using Dollar Units for `PortReturn` and `PortRisk`

This example shows how to return the maximum potential loss in the value of a portfolio over one period of time, where the portfolio return (`PortReturn`) and risk (`PortRisk`) are specified in dollar units. The returned `ValueAtRisk` is also in dollar units. Note that the `PortValue` input for `portvrisk` is not used in this example. `PortValue` is only used as a scaling factor to convert from percent to dollars when `PortReturn` and `PortRisk` are specified on a percentage basis.

```
PortReturn = [2900000;1500000];
PortRisk = [30800000;15750000];
RiskThreshold = 0.10;
ValueAtRisk = portvrisk(PortReturn,PortRisk,RiskThreshold)
```

```
ValueAtRisk = 2×1
10^7 ×

    3.6572
    1.8684
```

Input Arguments

`PortReturn` — Expected return of each portfolio over period

scalar numeric | vector

Expected return of each portfolio over the period, specified as a scalar numeric or an `NPORTS`-by-`1` vector.

Data Types: `double`

`PortRisk` — Standard deviation of each portfolio over period

scalar numeric | vector

Standard deviation of each portfolio over period, specified as a scalar numeric or NPORTS-by-1 vector.

Data Types: double

RiskThreshold — Loss probability

0.05 (5%) (default) | scalar decimal | vector

(Optional) Loss probability, specified as a scalar decimal or an NPORTS-by-1 vector.

Data Types: double

PortValue — Total value of asset portfolio

1 (default) | scalar numeric | vector

(Optional) Total value of asset portfolio, specified as a scalar numeric or an NPORTS-by-1 vector.

Note The PortValue input is used as a scaling factor for ValueAtRisk. The ValueAtRisk output is computed using the PortReturn and PortRisk inputs first, and then scaled by PortValue. Therefore, if you specify PortValue in dollar units, then PortReturn and PortRisk must be given on a percentage basis. Conversely, when PortReturn and PortRisk are specified in dollar units, PortValue must be 1 (default value).

Data Types: double

Output Arguments

ValueAtRisk — Estimated maximum loss in portfolio

vector

Estimated maximum loss in the portfolio, returned as an NPORTS-by-1 vector. ValueAtRisk is predicted with a confidence probability of 1 − RiskThreshold.

Note When PortValue is the default value of 1, ValueAtRisk is presented as a percent. A value of 0 for ValueAtRisk indicates no losses.

"Portfolio Optimization Functions" on page 3-3

posvolidx

Positive volume index

Syntax

```
volume = posvolidx(Data)
volume = posvolidx( ___ ,Name,Value)
```

Description

`volume = posvolidx(Data)` calculates the positive volume index from the series of closing stock prices and trade volume.

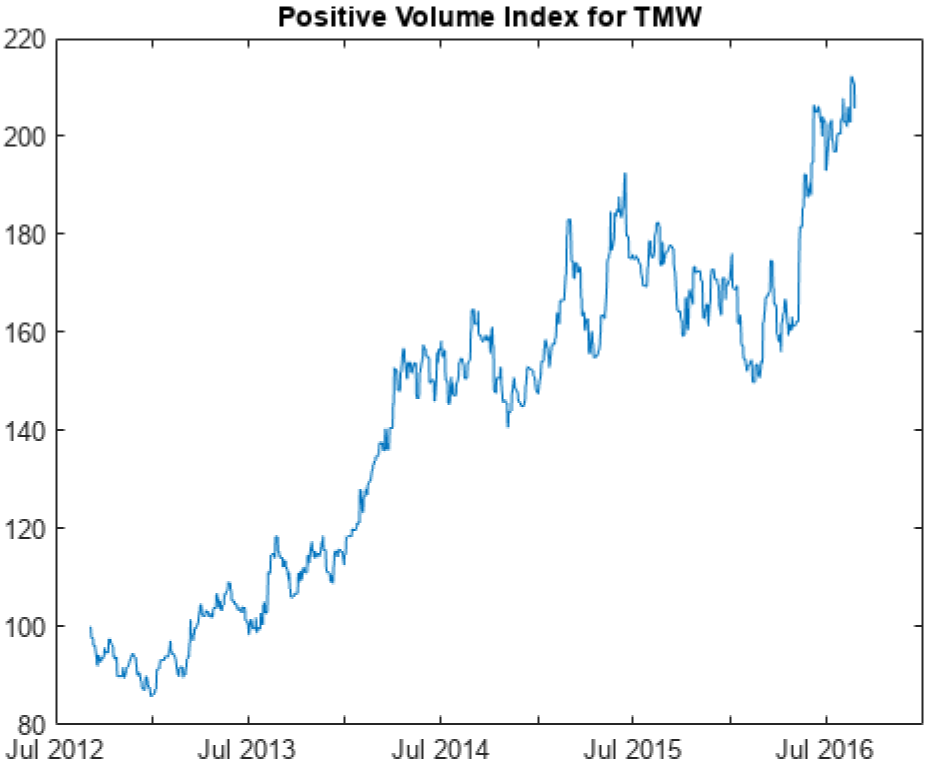
`volume = posvolidx( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Positive Volume Index for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
volume = posvolidx(TMW);
plot(volume.Time,volume.PositiveVolume)
title('Positive Volume Index for TMW')
```



Input Arguments

`Data` — Data with closing prices and trade volume

matrix | table | timetable

Data with closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-2 with closing prices and trade volume stored in the first and second columns. Timetables and tables with `M` rows must contain variables named `'Close'` and `'Volume'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `volume = posvolidx(TMW,'InitialValue',500)`

`InitialValue` — Initial value for positive volume index

`100` (default) | positive integer

Initial value for positive volume index, specified as the comma-separated pair consisting of `'InitialValue'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`volume` — Positive volume index

matrix | table | timetable

Positive volume index, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

More About

Positive Volume Index

Positive volume index shows the days when the trading volume of a particular security is substantially higher than other days.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

prbyzero

Price bonds in portfolio by set of zero curves

Syntax

```
BondPrices = prbyzero(Bonds,Settle,ZeroRates,ZeroDates)
BondPrices = prbyzero( ___ ,Compounding)
```

Description

`BondPrices = prbyzero(Bonds,Settle,ZeroRates,ZeroDates)` computes the bond prices in a portfolio using a set of zero curves.

`BondPrices = prbyzero( ___ ,Compounding)` adds an optional argument for `Compounding`.

Examples

Compute the Bond Prices in a Portfolio Using a Set of Zero Curves

This example uses the function `zbtprice` to compute a zero curve given a portfolio of coupon bonds and their prices. It then reverses the process, using the zero curve as input to the function `prbyzero` to compute the prices.

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
         datenum('7/1/2000') 0.06 100 2 0 0;
         datenum('7/1/2000') 0.09375 100 6 1 0;
         datenum('6/30/2001') 0.05125 100 1 3 1;
         datenum('4/15/2002') 0.07125 100 4 1 0;
         datenum('1/15/2000') 0.065 100 2 0 0;
         datenum('9/1/1999') 0.08 100 3 3 0;
         datenum('4/30/2001') 0.05875 100 2 0 0;
         datenum('11/15/1999') 0.07125 100 2 0 0;
         datenum('6/30/2000') 0.07 100 2 3 1;
         datenum('7/1/2001') 0.0525 100 2 3 0;
         datenum('4/30/2002') 0.07 100 2 0 0];

Prices = [ 99.375;
           99.875;
          105.75 ;
           96.875;
          103.625;
          101.125;
          103.125;
           99.375;
          101.0  ;
          101.25 ;
           96.375;
          102.75 ];

Settle = datenum('12/18/1997');
```

Set semiannual compounding for the zero curve, on an actual/365 basis.

```
OutputCompounding = 2;
```

Execute the function `zbtprice` which returns the zero curve at the maturity dates.

```
[ZeroRates, ZeroDates] = zbtprice(Bonds, Prices, Settle,...
OutputCompounding)
```

```
ZeroRates = 11×1

    0.0616
    0.0609
    0.0658
    0.0590
    0.0647
    0.0655
    0.0606
    0.0601
    0.0642
    0.0621
      ⋮

ZeroDates = 11×1

      729907
      730364
      730439
      730500
      730667
      730668
      730971
      731032
      731033
      731321
      ⋮
```

Execute the function `prbyzero`.

```
BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates)
```

```
BondPrices = 12×1

   99.3750
   98.7980
  106.8270
   96.8750
  103.6249
  101.1250
  103.1250
   99.3637
  101.0000
  101.2500
      ⋮
```

In this example `zbtprice` and `prbyzero` do not exactly reverse each other. Many of the bonds have the end-of-month rule off (`EndMonthRule = 0`). The rule subtly affects the time factor computation.

If you set the rule on (`EndMonthRule = 1`) everywhere in the `Bonds` matrix, then `prbyzero` returns the original prices, except when the two incompatible prices fall on the same maturity date.

Compute the Bond Prices in a Portfolio Using a Set of Zero Curves and datetime Inputs

This example uses the function `zbtprice` to compute a zero curve given a portfolio of coupon bonds and their prices. It then reverses the process, using the zero curve as input to the function `prbyzero` with `datetime` inputs to compute the prices.

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
         datenum('7/1/2000') 0.06 100 2 0 0;
         datenum('7/1/2000') 0.09375 100 6 1 0;
         datenum('6/30/2001') 0.05125 100 1 3 1;

      ⋮
```

Input Arguments

Bonds — Coupon bond information to compute prices
table | matrix

Coupon bond information to compute prices, specified as a 6-column table or a `NumBonds`-by-`6` matrix of bond information where the table columns or matrix columns contains:

- `Maturity` (Required) Maturity date of the bond as a serial date number. Use `datenum` to convert date character vectors to serial date numbers. If the input `Bonds` is a table, the `Maturity` dates can be a datetime array, string array, or date character vectors.
- `CouponRate` (Required) Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
- `Face` (Optional) Face or par value of the bond. Default = `100`.
- `Period` (Optional) Coupons per year of the bond. Allowed values are `0`, `1`, `2` (default), `3`, `4`, `6`, and `12`.
- `Basis` (Optional) Day-count basis of the bond. A vector of integers.

  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see “Basis” on page 2-16.
- `EndMonthRule` (Optional) End-of-month rule. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. `0` = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. `1` = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month

:

Note

- If Bonds is a table, the table columns have the same meaning as when a matrix is used, but the Maturity dates can be a datetime array, string array, or date character vectors.
- If Bonds is a matrix, it is a NUMBONDS-by-6 matrix of bonds where each row describes one bond. The first two columns are required; the remaining columns are optional but must be added in order. All rows in Bonds must have the same number of columns. The columns are Maturity, CouponRate, Face, Period, Basis, and EndMonthRule.

.

Data Types: double | char | string | datetime | table

Settle — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, prbyzero also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

ZeroRates — Observed zero rates

decimal fractions

Observed zero rates, specified as NUMDATES-by-NUMCURVES matrix of decimal fractions. Each column represents a rate curve. Each row represents an observation date.

Data Types: double

ZeroDates — Observed dates for ZeroRates

datetime array | string array | date character vector

Observed dates for ZeroRates, specified as a NUMDATES-by-1 column vector using a datetime array, string array, or date character vectors.

To support existing code, prbyzero also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

Compounding — Compounding frequency of input ZeroRates when annualized

2 (default) | numeric values: 1, 2, 3, 4, 6, 12,

(Optional) Compounding frequency of input ZeroRates when annualized, specified using the allowed values:

- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding

- 12 — Monthly compounding

Data Types: double

Output Arguments

BondPrices — Clean bond prices

numeric

Clean bond prices, returned as a NUMBONDS-by-NUMCURVES matrix. Each column is derived from the corresponding zero curve in ZeroRates.

In addition, you can use the Financial Instruments Toolbox method getZeroRates for an IRDataCurve object with a Dates property to create a vector of dates and data acceptable for prbyzero. For more information, see “Converting an IRDataCurve or IRFunctionCurve Object” (Financial Instruments Toolbox).

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although prbyzero supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

prcroc

Price rate of change

Syntax

```
PriceChangeRate = prcroc(Data)
PriceChangeRate = prcroc( ___ ,Name,Value)
```

Description

`PriceChangeRate = prcroc(Data)` calculates the price rate-of-change, `PriceChangeRate`, from the series of closing stock prices. By default, the price rate-of-change is calculated between the current closing price and the closing price 12 periods ago.

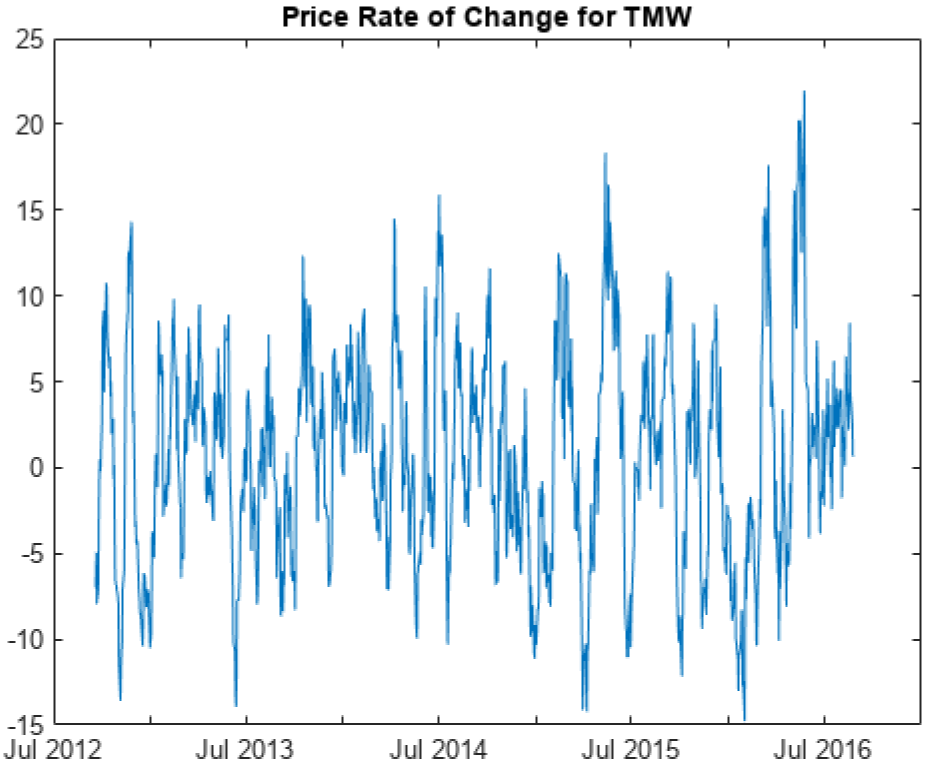
`PriceChangeRate = prcroc( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Price Rate-of-Change for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
PriceChangeRate = prcroc(TMW);
plot(PriceChangeRate.Time,PriceChangeRate.PriceRoc)
title('Price Rate of Change for TMW')
```



Input Arguments

`Data` — Data for closing prices

matrix | table | timetable

Data for closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-`1` matrix of closing prices. Timetables and tables with `M` rows must contain a variable named `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceChangeRate = prcroc(TMW,'NumPeriods',18)`

`NumPeriods` — Period difference

`12` (default) | positive integer

Period difference, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`PriceChangeRate` — Closing price rate-of-change

matrix | table | timetable

Closing price rate-of-change, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

prdisc

Price of discounted security

Syntax

```
Price = prdisc(Settle,Maturity,FaceDiscount)
Price = prdisc( ___ ,Basis)
```

Description

`Price = prdisc(Settle,Maturity,FaceDiscount)` returns the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

`Price = prdisc( ___ ,Basis)` adds an optional argument for `Basis`.

Examples

Calculate the Price of a Security Whose Yield is Quoted as a Bank Discount Rate

This example shows how to return the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Discount = 0.087;
Basis = 2;

Price = prdisc(Settle, Maturity, Face, Discount, Basis)
```

```
Price = 96.2783
```

Calculate the Price of a Security Whose Yield is Quoted as a Bank Discount Rate Using datetime Inputs

This example shows how to use `datetime` inputs to return the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

```
Settle = datetime(2000,10,14);
Maturity = datetime(2001,3,17);
Face = 100;
Discount = 0.087;
Basis = 2;

Price = prdisc(Settle,Maturity,Face, Discount, Basis)
```

```
Price = 96.2783
```

Input Arguments

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

Settle must be earlier than `Maturity`.

To support existing code, `prdisc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `datetime` | `string` | `char`

`Maturity` — Maturity date

datetime scalar | string scalar | date character vector

Maturity date, specified as a scalar datetime, string, or date character vector.

To support existing code, `prdisc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `datetime` | `string` | `char`

`Face` — Redemption (par, face) value

numeric

Redemption (par, face) value, specified as a numeric value.

Data Types: `double`

`Discount` — Bank discount rate of the security

decimal fraction

Bank discount rate of the security, specified as a decimal fraction value.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

(Optional) Day-count basis of the instrument, specified as a numeric value. Allowed values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`Price` — Price of discounted security

numeric

Price of discounted security, returned as a numeric value.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `prdisc` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

“Pricing Functions” on page 2-21
“Fixed-Income Terminology” on page 2-15

priceandvol

Price and Volume chart

Note `priceandvol` is updated to accept data input as a matrix, `timetable`, or `table`.

The syntax for `priceandvol` has changed. Previously, when using table input, the first column of dates could be a datetime array, date character vectors, or serial date numbers, and you were required to have specific number of columns.

When using table input, the new syntax for `priceandvol` supports:

- No need for time information. If you want to pass in date information, use timetable input.
- No requirement of specific number of columns. However, you must provide valid column names. `linebreak` must contain columns named `'open'`, `'high'`, `'low'`, `'close'`, and `'volume'` (case insensitive).

Syntax

```
priceandvol(Data)
h = priceandvol(Data)
```

Description

`priceandvol(Data)` plots two charts from a series of opening, high, low, closing prices, and traded volume. Opening, high, low, and closing prices are on one axis and the volume series are on a second axis.

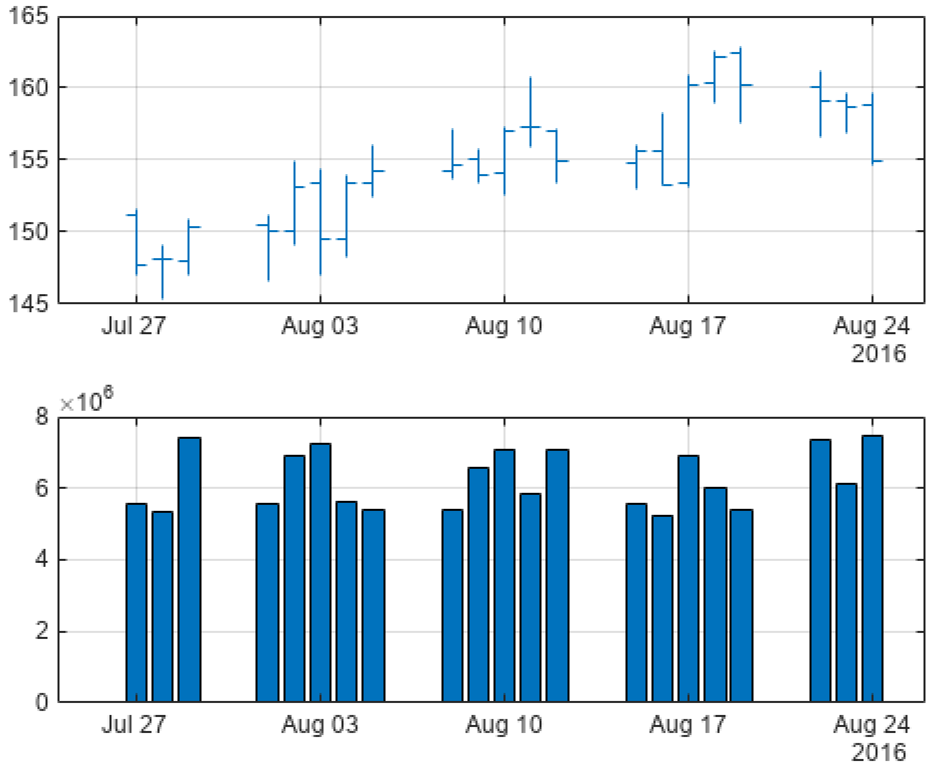
`h = priceandvol(Data)` adds a Graphic handle for the figure.

Examples

Generate a Price and Volume Chart for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock. This price and volume chart for the TMW stock contains the open, high, low, close, and volume for the most recent 21 days.

```
load SimulatedStock.mat
priceandvol(TMW(end-20:end,:));
```



Input Arguments

`Data` — Data for opening, high, low, closing prices, and volume traded

matrix | table | timetable

Data for opening, high, low, closing prices, and volume traded, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-`5` matrix of opening, high, low, closing prices and traded volume. Timetables and tables with `M` rows must contain variables named `'Open'`, `'High'`, `'Low'`, `'Close'`, and `'Volume'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

`h` — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

Version History

Introduced in R2008a

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

prmat

Price with interest at maturity

Syntax

```
[Price,AccruInterest] = prmat(Settle,Maturity,Issue,Face,CouponRateYield)
[Price,AccruInterest] = prmat( ___ ,Basis)
```

Description

`[Price,AccruInterest] = prmat(Settle,Maturity,Issue,Face,CouponRateYield)` returns the price and accrued interest of a security that pays interest at maturity. This function also applies to zero coupon bonds or pure discount securities by setting `CouponRate` = `0`.

`[Price,AccruInterest] = prmat( ___ ,Basis)` adds an optional argument for `Basis`.

Examples

Compute Price and Accrued Interest of a Security That Pays Interest at Maturity

This example shows how to compute the price and accrued interest of a security that pays interest at maturity.

```
Settle = '02/07/2002';
Maturity = '04/13/2002';
Issue = '10/11/2001';
Face = 100;
CouponRate = 0.0608;
Yield = 0.0608;
Basis = 1;

[Price, AccruInterest] = prmat(Settle, Maturity, Issue, Face,...
CouponRate, Yield, Basis)
```

```
Price = 99.9784

AccruInterest = 1.9591
```

Compute Price and Accrued Interest of a Security That Pays Interest at Maturity Using datetime Inputs

This example shows how to use `datetime` inputs compute the price and accrued interest of a security that pays interest at maturity.

```
Settle = datetime(2002,2,7);
Maturity = datetime(2002,4,13);
Issue = datetime(2001,10,11);
Face = 100;
```

```
CouponRate = 0.0608;
Yield = 0.0608;
Basis = 1;

[Price, AccruInterest] = prmat(Settle, Maturity, Issue, Face, CouponRate, Yield, Basis)
```

```
Price = 99.9784

AccruInterest = 1.9591
```

Input Arguments

`Settle` — Settlement date of security

datetime scalar | string scalar | date character vector

Settlement date of the security, specified as a scalar datetime, string, or date character vector. The `Settle` date must be before the `Maturity` date.

To support existing code, `prmat` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of security

datetime scalar | string scalar | date character vector

Maturity date of the security, specified as a scalar datetime, string, or date character vector.

To support existing code, `prmat` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `datetime` | `string`

`Issue` — Issue date

datetime scalar | string scalar | date character vector

Issue date of the security, specified as a scalar datetime, string, or date character vector.

To support existing code, `prmat` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Redemption value

numeric

Redemption value (par value), specified as a numeric value.

Data Types: `double`

`CouponRate` — Coupon rate

decimal fraction

Coupon rate, specified as a decimal fraction value.

Data Types: `double`

`Yield` — Annual yield

decimal fraction

Annual yield, specified as a decimal fraction value.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

(Optional) Day-count basis of the security, specified using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`Price` — Security price

numeric

Security price, returned as a numeric value.

`AccruInterest` — Accrued interest

numeric

Accrued interest for security, returned as a numeric value.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although prmat supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

prtbill

Price of Treasury bill

Syntax

```
Price = prtbill(Settle,Maturity,Face,Discount)
```

Description

`Price = prtbill(Settle,Maturity,Face,Discount)` returns the price for a Treasury bill.

Examples

Calculate the Price for a Treasury Bill

This example shows how to return the price for a Treasury bill, where the settlement date of a Treasury bill is February 10, 2002, the maturity date is August 6, 2002, the discount rate is 3.77%, and the par value is $1000.

```
Price = prtbill('2/10/2002', '8/6/2002', 1000, 0.0377)
```

```
Price = 981.4642
```

Calculate the Price for a Treasury Bill Using datetime Inputs

This example shows how to use `datetime` inputs to return the price for a Treasury bill, where the settlement date of a Treasury bill is February 10, 2002, the maturity date is August 6, 2002, the discount rate is 3.77%, and the par value is $1000.

```
Price = prtbill(datetime(2002,2,10), datetime(2002,8,6), 1000, 0.0377)
```

```
Price = 981.4642
```

Input Arguments

`Settle` — Settlement date for Treasury bill

datetime scalar | string scalar | date character vector

Settlement date for the Treasury bill, specified as a scalar datetime, string, or date character vector. The `Settle` date must be before the `Maturity` date.

To support existing code, `prtbill` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date for Treasury bill

datetime scalar | string scalar | date character vector

Maturity date for the Treasury bill, specified as a scalar datetime, string, or date character vector.

To support existing code, `prtbill` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Redemption value of Treasury bill

numeric

Redemption value (par value) of the Treasury bill, specified as a numeric value.

Data Types: `double`

`Discount` — Discount rate of Treasury bill

decimal fraction

Discount rate of the Treasury bill, specified as a decimal fraction value.

Data Types: `double`

Output Arguments

`Price` — Treasury bill price

numeric

Treasury bill price, returned as a numeric value.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `prtbill` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

pvfix

Present value with fixed periodic payments

Syntax

```
PresentVal = pvfix(Rate,NumPeriods,Payment)
PresentVal = pvfix( ___ ,ExtraPayment,Due)
```

Description

`PresentVal = pvfix(Rate,NumPeriods,Payment)` computes the present value of a series of equal payments.

`PresentVal = pvfix( ___ ,ExtraPayment,Due)` adds optional arguments.

Examples

Calculate the Present Value of a Series of Equal Payments

This example shows how to return the present value of a series of equal payments, where $200 is paid monthly into a savings account earning 6%. The payments are made at the end of the month for five years.

```
PresentVal = pvfix(0.06/12, 5*12, 200, 0, 0)
```

```
PresentVal = 1.0345e+04
```

Input Arguments

`Rate` — Periodic interest rate
decimal

Periodic interest rate, specified as a decimal.

Data Types: `double`

`NumPeriods` — Number of periods
integer

Number of periods, specified as an integer.

Data Types: `double`

`Payment` — Periodic payment
numeric

Periodic payment., specified as a numeric.

Data Types: `double`

`ExtraPayment` — Payment received other than `Payment` in the last period

`0` (default) | numeric

(Optional) Payment received other than `Payment` in the last period, specified as a numeric.

Data Types: `double`

`Due` — Indicator for when payments are due

`0` (default) | logical with value of `1` or `0`

(Optional) Indicator for when payments are due, specified as a logical with a value of `0` = end of period (default), or `1` = beginning of period.

Data Types: `logical`

Output Arguments

`PresentVal` — Present value

numeric

Present value, returned as a series of equal payments.

Version History

Introduced before R2006a

pvtrend

Price and Volume Trend (PVT)

Syntax

```
trend = pvtrend(Data)
```

Description

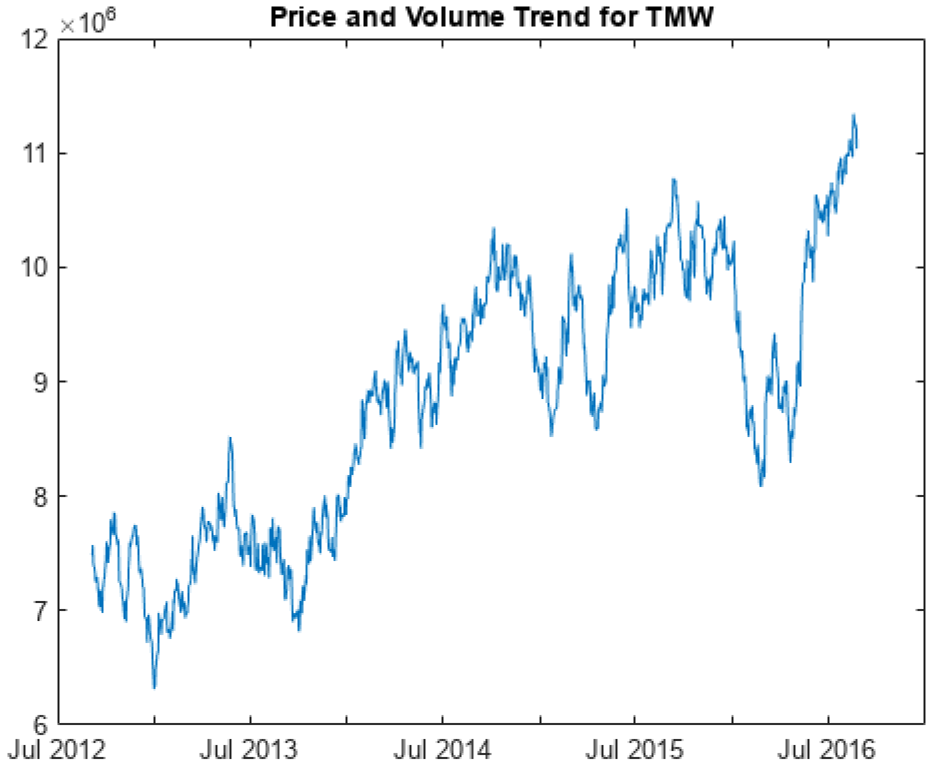
`trend = pvtrend(Data)` calculates the Price and Volume Trend (PVT) from the series of closing stock prices and trade volume.

Examples

Calculate the Price and Volume Trend for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
trend = pvtrend(TMW);
plot(trend.Time,trend.PriceVolumeTrend)
title('Price and Volume Trend for TMW')
```



Input Arguments

`Data` — Data for closing prices and trade volume

matrix | table | timetable

Data for closing prices and trade volume, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-2 matrix of closing prices and trade volume. Timetables and tables with `M` rows must contain variables named `'Close'` and `'Volume'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

`trend` — Price and volume trend

matrix | table | timetable

Price and volume trend (PVT), returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

pvvar

Present value of varying cash flow

Syntax

```
PresentVal = pvvar(CashFlow,Rate)
PresentVal = pvvar( ___ ,CFDates)
```

Description

`PresentVal = pvvar(CashFlow,Rate)` calculates present value of a varying cash flow.

`PresentVal = pvvar( ___ ,CFDates)` adds an optional argument for `CFDates`.

Examples

Calculate Present Value for Regular and Irregular Cash Flow

Calculate the net present value for a regular and irregular cash flow.

Regular Cash Flow

This cash flow represents the yearly income from an initial investment of $10,000. The annual interest rate is 8%.

Year 1 - $2000

Year 2 - $1500

Year 3 - $3000

Year 4 - $3800

Year 5 - $5000

To calculate the net present value of this regular cash flow:

```
PresentVal = pvvar([-10000 2000 1500 3000 3800 5000], 0.08)
```

```
PresentVal = 1.7154e+03
```

Irregular Cash Flow

An investment of $10,000 returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is 9%.

January 12, 1987 - ($10000)

February 14, 1988 - $1500

March 3, 1988 - $2000

June 14, 1988 - $3000

December 1, 1988 - $4000

To calculate the net present value of this irregular cash flow:

```
CashFlow = [-10000, 1500, 2000, 3000, 4000];

CFDates = ['01/12/1987'
            '02/14/1988'
            '03/03/1988'
            '06/14/1988'
            '12/01/1988'];

PresentVal = pvvar(CashFlow, 0.09, CFDates)
```

```
PresentVal = -768.1461
```

The net present value of the same investment under different discount rates of 7%, 9%, and 11% is obtained by:

```
PresentVal = pvvar(repmat(CashFlow,3,1)', [.07 .09 .11], CFDates)
```

```
PresentVal = 1×3
10^3 ×

   -0.5099   -0.7681   -1.0146
```

Input Arguments

CashFlow — Cash flow amounts

vector

Cash flow amounts, specified as a vector of varying cash flows. Include the initial investment as the initial cash flow value (a negative number). If CashFlow is a matrix, each column is treated as a separate cash-flow stream.

Data Types: double

Rate — Periodic interest rate

decimal

Periodic interest rate, specified as a decimal. If CashFlow is a matrix, a scalar Rate is allowed when the same rate applies to all cash-flow streams in CashFlow. When multiple cash-flow streams require different discount rates, Rate must be a vector whose length equals the number of columns in CashFlow.

Data Types: double

CFDates — Indicates irregular cash flow

datetime array | string array | cell array of date character vectors

(Optional) Indicates irregular cash flow, specified as a datetime array, string array, or cell array of date character vectors on which the cash flows occur.

Specify CFDates when there are irregular (nonperiodic) cash flows. The default assumes that CashFlow contains regular (periodic) cash flows. If CashFlow is a matrix, and all cash-flow streams share the same dates, CFDates can be a vector whose length matches the number of rows in CashFlow. When different cash-flow streams have different payment dates, specify CFDates as a matrix the same size as CashFlow.

To support existing code, pvvar also accepts serial date numbers as inputs, but they are not recommended.

Data Types: cell | string | char | datetime

Output Arguments

PresentVal — Present value
numeric

Present value, returns the net present value of a varying cash flow. Present value is calculated at the time the first cash flow occurs.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although pvvar supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

pyld2zero

Zero curve given par yield curve

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

Syntax

```
[ZeroRates,CurveDates] = pyld2zero(ParRates,CurveDates,Settle)
[ZeroRates,CurveDates] = pyld2zero( ___ ,Name,Value)
```

Description

`[ZeroRates,CurveDates] = pyld2zero(ParRates,CurveDates,Settle)` returns a zero curve given a par yield curve and its maturity dates. If either input for `CurveDates` or `Settle` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number.

`[ZeroRates,CurveDates] = pyld2zero( ___ ,Name,Value)` adds optional name-value pair arguments

Examples

Compute Zero Curve Given Par Yield Curve

Define the settlement date, maturity, and zero rates.

```
Settle = datenum('01-Feb-2013');
CurveDates = datemnth(Settle,12*[1 2 3 5 7 10 20 30]');
ZeroRates = [.11 0.30 0.64 1.44 2.07 2.61 3.29 3.55]'/100;
InputCompounding = 2;
InputBasis = 1;
OutputCompounding = 2;
OutputBasis = 1;
```

Compute par yield curve from zero rates.

```
ParRates = zero2pyld(ZeroRates, CurveDates, Settle,'InputCompounding',2,...
'InputBasis',1,'OutputCompounding',2,'OutputBasis',1)
```

```
ParRates = 8×1

    0.0011
    0.0030
    0.0064
    0.0142
    0.0201
    0.0251
    0.0309
    0.0330
```

Compute zero curve from the par yield curve.

```
ZeroRates = pyld2zero(ParRates, CurveDates, Settle,'InputCompounding',2,...
'InputBasis',1,'OutputCompounding',2,'OutputBasis',1)
```

```
ZeroRates = 8×1

    0.0011
    0.0030
    0.0064
    0.0144
    0.0207
    0.0261
    0.0329
    0.0355
```

Compute Zero Curve Given Par Yield Curve Using datetime Inputs

Use `datetime` inputs to compute the zero curve given the par yield curve.

```
Settle = datetime(2013,2,1);

CurveDates = [datetime(2014,2,1)
    datetime(2015,2,1)
    datetime(2016,2,1)
    datetime(2018,2,1)
    datetime(2020,2,1)
    datetime(2023,2,1)
    datetime(2033,2,1)
    datetime(2043,2,1)];

OriginalParRates = [0.11 0.30 0.64 1.42 2.02 2.51 3.10 3.31]'/100;

InputCompounding = 1;
InputBasis = 0;
OutputCompounding = 1;
OutputBasis = 0;

[ZeroRates Dates] = pyld2zero(OriginalParRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
```

```
ZeroRates = 8×1

    0.0011
    0.0030
    0.0064
    0.0144
    0.0207
    0.0261
    0.0329
    0.0356

Dates = 8x1 datetime
   01-Feb-2014
   01-Feb-2015
   01-Feb-2016
   01-Feb-2018
   01-Feb-2020
   01-Feb-2023
   01-Feb-2033
   01-Feb-2043
```

Demonstrate a Roundtrip From pyld2zero to zero2pyld

Given the following a par yield curve and its maturity dates, return the `ZeroRates`.

```
Settle = datetime(2013,2,1);

CurveDates = [datetime(2014,2,1)
    datetime(2015,2,1)
    datetime(2016,2,1)
    datetime(2018,2,1)
    datetime(2020,2,1)
    datetime(2023,2,1)
    datetime(2033,2,1)
    datetime(2043,2,1)];

OriginalParRates = [0.11 0.30 0.64 1.42 2.02 2.51 3.10 3.31]'/100;

InputCompounding = 1;
InputBasis = 0;
OutputCompounding = 1;
OutputBasis = 0;

ZeroRates = pyld2zero(OriginalParRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
```

```
ZeroRates = 8×1

    0.0011
    0.0030
    0.0064
    0.0144
    0.0207
    0.0261
    0.0329
    0.0356
```

With the `ZeroRates`, use the `zero2pyld` function to return the `ParRatesOut` and determine the roundtrip error.

```
ParRatesOut = zero2pyld(ZeroRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
```

```
ParRatesOut = 8×1

    0.0011
    0.0030
    0.0064
    0.0142
    0.0202
    0.0251
    0.0310
    0.0331
```

```
max(abs(OriginalParRates - ParRatesOut)) % Roundtrip error
```

```
ans = 1.2750e-16
```

Input Arguments

ParRates — Annualized par yields

decimal fraction

Annualized par yields (coupon rates), specified as a NUMBONDS-by-1 vector using decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by CurveDates.

Data Types: double

CurveDates — Maturity dates

datetime array | string array | date character vector

Maturity dates which correspond to the input ParRates, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, pyld2zero also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

Settle — Common settlement date for ZeroRates

datetime scalar | string scalar | date character vector

Common settlement date for input ParRates, specified as a scalar datetime, string, or data character vector.

To support existing code, pyld2zero also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[ZeroRates,CurveDates] = pyld2zero(ParRates,CurveDates,Settle,'OutputCompounding',3,'OutputBasis',5,'InputCompounding',4,'InputBasis',5)`

`OutputCompounding` — Compounding frequency of output `ZeroRates`

2 (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `12`, `365`, `-1`

Compounding frequency of output `ZeroRates`, specified using the allowed values:

- `0` — Simple interest (no compounding)
- `1` — Annual compounding
- `2` — Semiannual compounding (default)
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding
- `365` — Daily compounding
- `-1` — Continuous compounding

Note

- If `OutputCompounding` is set to `0` (simple), `-1` (continuous), or `365` (daily), the `InputCompounding` must also be specified using a valid value.
- If `OutputCompounding` is not specified, then `OutputCompounding` is assigned the value specified for `InputCompounding`.
- If either `OutputCompounding` or `InputCompounding` are not specified, the default is `2` (semiannual) for both.

Data Types: `double`

`OutputBasis` — Day-count basis of output `ZeroRates`

`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day count basis of output `ZeroRates`, specified using allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If `OutputBasis` is not specified, then `OutputBasis` is assigned the value specified for `InputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is `0` (actual/actual) for both.

Data Types: `double`

`InputCompounding` — Compounding frequency of input `ParRates`
2 (default) | numeric values: `0`,1, 2, 3, 4, 6, 12, 365, `-1`

Compounding frequency of input `ParRates`, specified using allowed values:

- `1` — Annual compounding
- `2` — Semiannual compounding (default)
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

Note

- If `OutputCompounding` is `1`, `2`, `3`, `4`, `6`, or `12` and `InputCompounding` is not specified, the value of `OutputCompounding` is used.
- If `OutputCompounding` is `0` (simple), `-1` (continuous), or `365` (daily), a valid `InputCompounding` value must also be specified.
- If either `InputCompounding` or `OutputCompounding` are not specified, the default is `2` (semiannual) for both.

Data Types: `double`

`InputBasis` — Day-count basis of input `ParRates`
`0` (default) | numeric values: `0`,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of the input `ParRates`, specified using allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If `InputBasis` is not specified, then `InputBasis` is assigned the value specified for `OutputBasis`. If either `InputBasis` or `Outputbasis` are not specified, the default is `0` (actual/actual) for both.

Data Types: `double`

Output Arguments

`ZeroRates` — Zero rates

numeric

Zero rates, returned as a `NUMBONDS`-by-`1` numeric vector. In aggregate, the rates in `ZeroRates` constitute a zero curve for the investment horizon represented by `CurveDates`. `ZeroRates` are ordered by ascending maturity.

`CurveDates` — Maturity dates that correspond to `ZeroRates`

datetime | serial date number

Maturity dates that correspond to the `ZeroRates`, returned as a `NUMBONDS`-by-`1` vector of maturity dates that correspond to each par rate contained in `ZeroRates`. `CurveDates` are ordered by ascending maturity.

If either input for `CurveDates` or `Settle` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` are returned as a serial date numbers. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although `pyld2zero` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

renko

Renko

Note renko is updated to accept data input as a matrix, timetable, or table.

The syntax for renko has changed. Previously, when using table input, the first column of dates could be a datetime array, date character vectors, or serial date numbers, and you were required to have specific number of columns.

When using table input, the new syntax for renko supports:

- No need for time information. If you want to pass in date information, use timetable input.
- No requirement of specific number of columns. However, you must provide valid column names. renko must contain a column named ‘price’ (case insensitive).

Syntax

```
renko(Data)
renko(Data,Threshold,)
h = renko(ax,___)
```

Description

renko(Data) plots a Renko chart from a series of prices of a security.

renko(Data,Threshold,) adds an optional argument for Threshold.

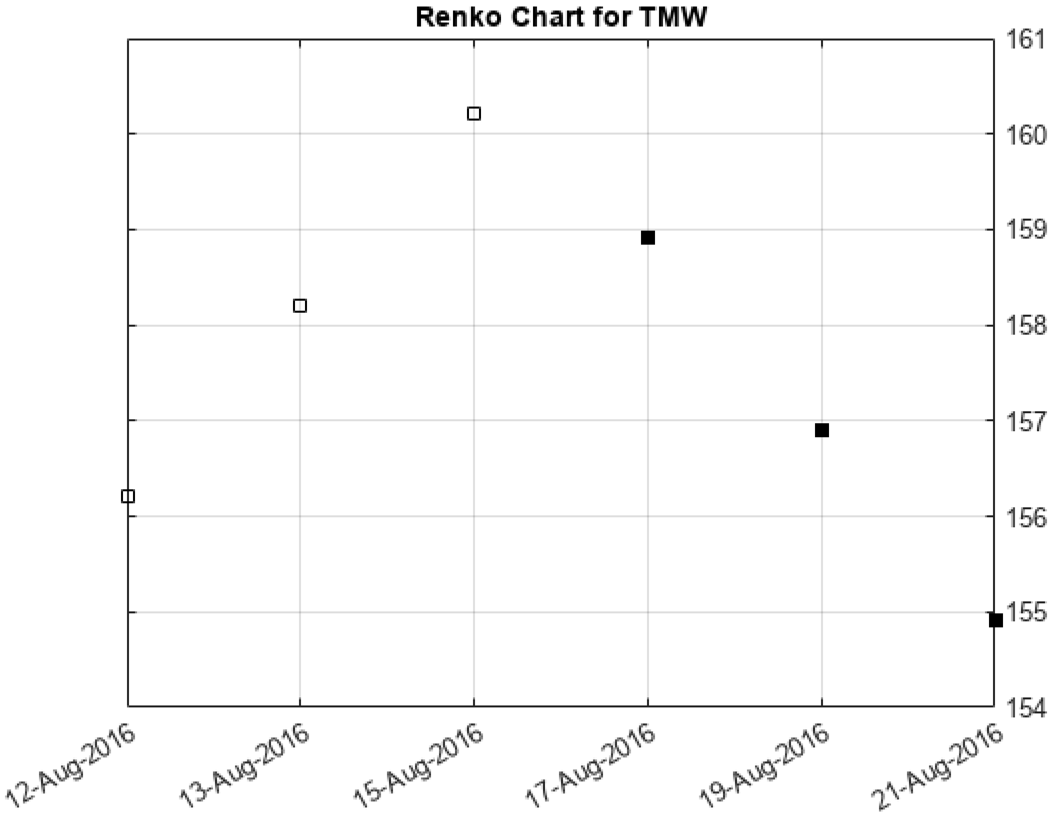
h = renko(ax,___) adds an optional argument for ax.

Examples

Generate a Renko Chart for a Data Series for a Stock

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data for TMW stock. This example shows how to plot a Renko chart for the most recent 21 days. Note that the variable name of asset price is be renamed to 'Price' (case insensitive).

```
load SimulatedStock.mat
TMW.Properties.VariableNames{'Close'} = 'Price';
renko(TMW(end-8:end,:),2)
title('Renko Chart for TMW')
```



Input Arguments

`Data` — Data for a series of prices

matrix | table | timetable

Data for a series of prices, specified as a matrix, table, or timetable. Timetables and tables with `M` rows must contain a variable named `'Price'` (case insensitive).

Data Types: `double` | `table` | `timetable`

`Threshold` — (Optional) Least price change value when adding a new box

`1` (default) | positive numeric

Least price change value when adding a new box, specified as a scalar positive numeric value.

Data Types: `double`

`ax` — Valid axis object

current axes (`ax = gca`) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The renko plot is created in the axes specified by `ax` instead of in the current axes (`ax = gca`). The option `ax` can precede any of the input argument combinations.

Data Types: `object`

Output Arguments

h — Graphic handle of the figure
handle object

Graphic handle of the figure, returned as a handle object.

Version History

Introduced in R2008a

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

ret2tick

Convert return series to price series

Syntax

```
[TickSeries,TickTimes] = ret2tick(Data)
[TickSeries,TickTimes] = ret2tick( ___ ,Name,Value)
```

Description

`[TickSeries,TickTimes] = ret2tick(Data)` computes prices from the start prices of `NASSET` assets and `NUMOBS` return observations.

`[TickSeries,TickTimes] = ret2tick( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Convert a Return Series to a Price Series

Compute the price increase of two stocks over a year's time based on three incremental return observations.

```
RetSeries = [0.10 0.12
             0.05 0.04
            -0.05 0.05];

RetIntervals = [182
                 91
                 92];

StartTime = datetime('18-Dec-2000','Locale','en_US');

[TickSeries,TickTimes] = ret2tick(RetSeries,'ReturnIntervals',RetIntervals,...
    'StartTime',StartTime)
```

```
TickSeries = 4×2

    1.0000    1.0000
    1.1000    1.1200
    1.1550    1.1648
    1.0973    1.2230

TickTimes = 4x1 datetime
   18-Dec-2000
   18-Jun-2001
   17-Sep-2001
   18-Dec-2001
```

Convert a Price Series to a Return Series Using `timetable` Input

Use `timetable` input to convert a price series to a return series, given periodic returns of two stocks observed in the first, second, third, and fourth quarters.

```
RetSeries = [0.10 0.12
             0.05 0.04
            -0.05 0.05];

RetTimes = datetime({'6/18/2001','9/17/2001','12/18/2001'},'InputFormat','MM/dd/uuuu','Locale','e
RetSeries = array2timetable(RetSeries,'RowTimes',RetTimes);
StartTime = datetime('12/18/2000','InputFormat','MM/dd/uuuu','Locale','en_US');

[TickSeries,TickTimes] = ret2tick(RetSeries,'StartTime',StartTime)
```

```
TickSeries=4×2 timetable
       Time        RetSeries1    RetSeries2
    ___________    __________    __________

    18-Dec-2000          1             1   
    18-Jun-2001        1.1          1.12   
    17-Sep-2001      1.155        1.1648   
    18-Dec-2001     1.0973         1.223   

TickTimes = 4x1 datetime
   18-Dec-2000
   18-Jun-2001
   17-Sep-2001
   18-Dec-2001
```

Input Arguments

`Data` — Data for asset returns

matrix | table | timetable

Data for asset returns, specified as a `NUMOBSNASSETS` matrix, `table`, or `timetable`. The returns are not normalized by the time increments between successive price observations.

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[TickSeries,TickTimes] = ret2tick(RetSeries,'StartTime',StartTime)`

`StartPrice` — Initial prices for each asset

`1` for all assets (default) | numeric

Initial prices for each asset, specified as the comma-separated pair consisting of `'StartPrice'` and a `NASSETS`-by-`1` vector indicating initial prices for each asset, or a single scalar initial price applied to all assets.

Data Types: `double`

`ReturnIntervals` — Return interval between prices
`1` for all assets (default) | numeric | duration | calendar duration

Return interval between prices, specified as the comma-separated pair consisting of `'ReturnIntervals'` and a scalar return interval applied to all returns, or a vector of length `NUMOBS` return intervals between successive returns. `ReturnIntervals` is defined as:

```
ReturnIntervals(t) = TickTimes(t) - TickTimes(t-1).
```

Note If the type of `Data` is a timetable, `ReturnIntervals` is ignored.

Data Types: `double`

`StartTime` — Starting time for first observation applied to the prices of all assets
`0` if `ReturnIntervals` is numeric (default) | numeric | duration | calendar duration

Starting time for first observation applied to the price series of all assets, specified as the comma-separated pair consisting of `'StartTime'` and a scalar string, character vector, double, or datetime.

Note If `ReturnIntervals` is a duration or calendar duration value, the default for `StartTime` is `datetime('today')`.

If `Data` is a timetable and `StartTime` is not specified, the resulting asset prices in the first period are not reported.

Data Types: `double` | `string` | `char` | `datetime`

`Method` — Method to convert asset returns to prices
`'Simple'` (default) | character vector with value of `'Simple'` or `'Continuous'` | string with value of `"Simple"` or `"Continuous"`

Method to convert asset returns to prices, specified as the comma-separated pair consisting of `'Method'` and a string or character vector indicating the method to convert asset prices to returns.

If the method is `'Simple'`, then simple periodic returns are used:

```
TTickSeries(t) = TickSeries(t-1)*(1 + ReturnSeries(t)).
```

If the method is `'Continuous'`, then continuous returns are used:

```
TickSeries(t) = TickSeries(t-1)*exp(ReturnSeries(t)).
```

Data Types: `char` | `string`

Output Arguments

`TickSeries` — Time series array of asset prices

matrix | table | timetable

Time series array of asset prices, returned as `NUMBOBS+1`-by-`NASSETS` time series of asset prices of the same type (matrix, table, or timetable) as the input `Data`. The first row contains the oldest prices and the last row contains the most recent. Prices across a given row are assumed to occur at the same time for all columns, and each column is a price series of an individual asset.

`TickTimes` — Observation times associated with prices in `TickSeries`

vector

Observation times associated with the prices in `TickSeries`, returned as a `NUMBOBS+1` length column vector of monotonically increasing observation times associated with the prices in `TickSeries`. The initial time is `StartTime`. For matrix and table `Data`, sequential observations occur at increments specified in `ReturnIntervals` and for `Data` timetables, sequential observations are derived from times and dates in `Data`.

Version History

Introduced before R2006a

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports input `Data` that is specified as a tall column vector, a tall table, or a tall timetable. For more information, see `tall` and “Tall Arrays”.

rsindex

Relative Strength Index (RSI)

Syntax

```
index = rsindex(Data)
index = rsindex( ___ ,Name,Value)
```

Description

`index = rsindex(Data)` calculates the Relative Strength Index (RSI) from the series of closing stock prices.

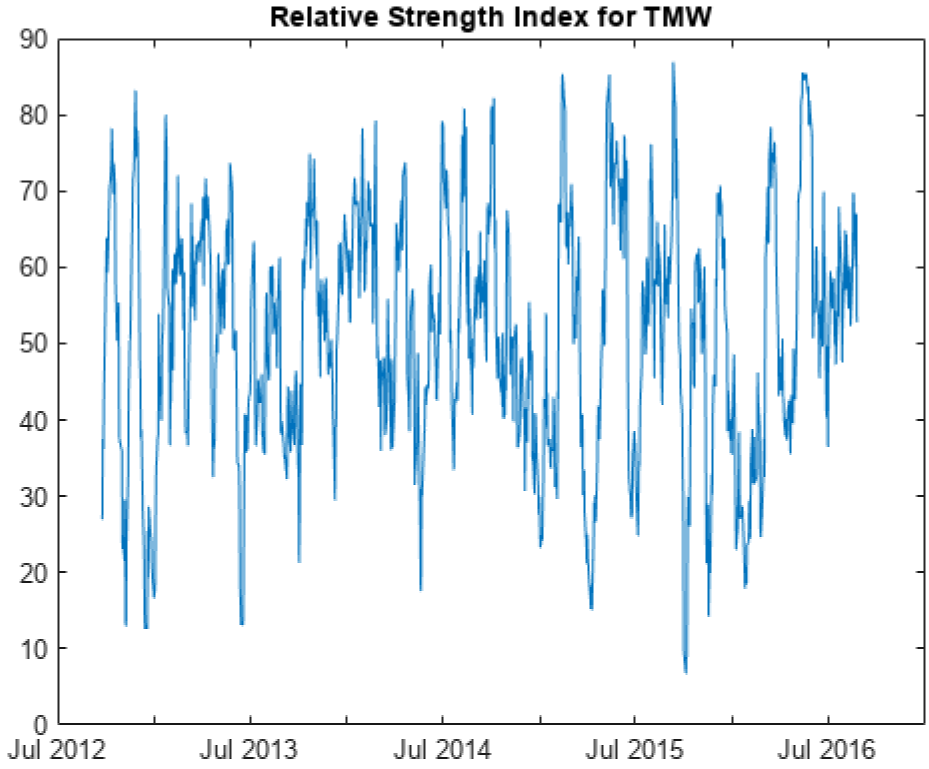
`index = rsindex( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Relative Strength Index for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
index = rsindex(TMW);
plot(index.Time,index.RelativeStrengthIndex)
title('Relative Strength Index for TMW')
```



Input Arguments

`Data` — Data with closing prices

matrix | table | timetable

Data with closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is `M`-by-`1` with closing prices. Timetables and tables with `M` rows must contain a variable named `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `index = rsindex(TMW,'WindowSize',10)`

`WindowSize` — Moving window size for relative strength index

`14` (default) | positive integer

Moving window size for relative strength index, specified as the comma-separated pair consisting of `'WindowSize'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`index` — Relative strength index
matrix | table | timetable

Relative strength index, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

More About

Relative Strength Index

Relative strength index is calculated by dividing the average of the gains by the average of the losses within a specified period.

```
RS = (average gains) / (average losses)
```

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument
Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

selectreturn

Portfolio configurations from 3-D efficient frontier

Syntax

```
PortConfigs = selectreturn(AllMean,AllCovariance,Target)
```

Description

`PortConfigs = selectreturn(AllMean,AllCovariance,Target)` returns the portfolio configurations (`PortConfigs`) for a target return given the average return and covariance for a rolling efficient frontier.

Input Arguments

`AllMean` — Expected asset returns used to generate each curve on surface

vector

Expected asset returns used to generate each curve on the surface, specified as a number of curves (`NCURVES`-by-`1` cell array), where each element is a `1`-by-`NASSETS` (number of assets) vector

Data Types: `double`

`AllCovariance` — Covariance matrix used to generate each curve on surface

cell array

Covariance matrix used to generate each curve on the surface, specified as an `NCURVES`-by-`1` cell array where each element is an `NASSETS`-by-`NASSETS` vector.

Data Types: `cell`

`Target` — Target return value for each curve in the frontier

numeric

Target return value for each curve in the frontier, specified as a numeric.

Data Types: `double`

Output Arguments

`PortConfigs` — Asset allocation weights needed to obtain target rate of return

matrix

Asset allocation weights needed to obtain the target rate of return, returned as an `NASSETS`-by-`NCURVES` matrix.

Version History

Introduced before R2006a

setAssetList

Set up list of identifiers for assets

Syntax

```
obj = setAssetList(obj,AssetList)
obj = setAssetList(obj,'asset1','asset2',asset3',...)
```

Description

`obj = setAssetList(obj,AssetList)` sets up the list of identifiers for assets for `Portfolio`, `PortfolioCVaR`, or `PorfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`obj = setAssetList(obj,'asset1','asset2',asset3',...)` sets up a list of asset identifiers, specified as a comma-separated list of character vectors, a cell array of character vectors, or string array where each character vector or string is an asset identifier.

Note

- If an asset list is entered as an input, this function overwrites an existing asset list in the object if one exists.
- If no asset list is entered as an input, three actions can occur:
  - If `NumAssets` is nonempty and `AssetList` is empty, `AssetList` becomes a numbered list of assets with default names according to the hidden property in `defaultforAssetList` (`'Asset'`).
  - If `NumAssets` is nonempty and `AssetList` is nonempty, nothing happens.
  - If `NumAssets` is empty and `AssetList` is empty, the default `NumAssets =1` is set and a default asset list is created (`'Asset1'`).

Examples

Create a Default List of Asset Names with Three Assets for a Portfolio Object

Create a default list of asset names with three assets.

```
p = Portfolio('NumAssets',3);
p = setAssetList(p);
disp(p.AssetList);
```

```
    {'Asset1'}    {'Asset2'}    {'Asset3'}
```

Create an Explicitly Named List of Asset Names with Three Assets for a Portfolio Object

Create a list of asset names for three equities AGG, EEM, and VEU.

```
p = Portfolio;
p = setAssetList(p, 'AGG', 'EEM', 'VEU');
disp(p.AssetList);
```

```
    {'AGG'}    {'EEM'}    {'VEU'}
```

Create a Default List of Asset Names with Three Assets for a PortfolioCVaR Object

Create a default list of asset names with three assets.

```
p = PortfolioCVaR('NumAssets',3);
p = setAssetList(p);
disp(p.AssetList);
```

```
    {'Asset1'}    {'Asset2'}    {'Asset3'}
```

Create an Explicitly Named List of Asset Names with Three Assets for a PortfolioCVaR Object

Create a list of asset names for three equities AGG, EEM, and VEU.

```
p = PortfolioCVaR;
p = setAssetList(p, 'AGG', 'EEM', 'VEU');
disp(p.AssetList);
```

```
    {'AGG'}    {'EEM'}    {'VEU'}
```

Create a Default List of Asset Names with Three Assets for a PortfolioMAD Object

Create a default list of asset names with three assets.

```
p = PortfolioMAD('NumAssets',3);
p = setAssetList(p);
disp(p.AssetList);
```

```
    {'Asset1'}    {'Asset2'}    {'Asset3'}
```

Create an Explicitly Named List of Asset Names with Three Assets for a PortfolioMAD Object

Create a list of asset names for three equities AGG, EEM, and VEU.

```
p = PortfolioMAD;
p = setAssetList(p, 'AGG', 'EEM', 'VEU');
disp(p.AssetList);
```

```
    {'AGG'}    {'EEM'}    {'VEU'}
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

AssetList — List of assets

character vector | cell array of character vectors | string array

List of assets, specified using a character vector, cell array of character vectors, or string array where each character vector or string is an asset identifier.

Data Types: `char` | `cell` | `string`

Output Arguments

obj — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

The underlying object (`obj`) has a number of public hidden properties to format the asset list:

- `defaultforAssetList` — Default name for assets (`'Asset'`). Change this name to create default asset names such as `'ETF'`, `'Bond'`.
- `sortAssetList` — Reserved for future implementation.
- `uppercaseAssetList` — If `true`, make all asset identifiers uppercase character vectors. Otherwise do nothing. Default is `false`.

Tips

- You can also use dot notation to set up list of identifiers for assets.

```
obj = obj.setAssetList(AssetList);
```

- To clear an `AssetList`, call this function with `[]` or `{[]}`.

Version History

Introduced in R2011a

setAssetMoments

Set moments (mean and covariance) of asset returns for Portfolio object

Syntax

```
obj = setAssetMoments(obj,AssetMean)
obj = setAssetMoments(obj,AssetMean,AssetCovar,NumAssets)
```

Description

obj = setAssetMoments(obj,AssetMean) obtains mean and covariance of asset returns for a Portfolio object. For details on the workflow, see “Portfolio Object Workflow” on page 4-17.

obj = setAssetMoments(obj,AssetMean,AssetCovar,NumAssets) obtains mean and covariance of asset returns for a Portfolio object with additional options for AssetCovar and NumAssets.

Examples

Set Asset Moments for a Portfolio Object

Set the asset moment properties, given the mean and covariance of asset returns in the variables m and C.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

p = Portfolio;
p = setAssetMoments(p, m, C);
[assetmean, assetcovar] = getAssetMoments(p)
```

```
assetmean = 4×1

    0.0042
    0.0083
    0.0100
    0.0150

assetcovar = 4×4

    0.0005    0.0003    0.0002         0
    0.0003    0.0024    0.0017    0.0010
    0.0002    0.0017    0.0048    0.0028
         0    0.0010    0.0028    0.0102
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using a Portfolio object. For more information on creating a portfolio object, see

- Portfolio

Data Types: object

AssetMean — Mean of asset returns

vector

Mean of asset returns, specified as a vector.

Note If AssetMean is a scalar and the number of assets is known, scalar expansion occurs. If the number of assets cannot be determined, this method assumes that NumAssets = 1.

Data Types: double

AssetCovar — Covariance of asset returns

symmetric positive semidefinite matrix

Covariance of asset returns, specified as a symmetric positive semidefinite matrix.

Note

- If AssetCovar is a scalar and the number of assets is known, a diagonal matrix is formed with the scalar value along the diagonals. If it is not possible to determine the number of assets, this method assumes that NumAssets = 1.
- If AssetCovar is a vector, a diagonal matrix is formed with the vector along the diagonal.
- If AssetCovar is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

Data Types: double

NumAssets — Number of assets

integer

Number of assets, specified as an integer.

Note If NumAssets is not already set in the object, NumAssets can be entered to resolve array expansions with AssetMean or AssetCovar.

Data Types: double

Output Arguments

obj — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio` object. For more information on creating a portfolio object, see

- `Portfolio`

Tips

- You can also use dot notation to set moments (mean and covariance) of the asset returns.

  ```
  obj = obj.setAssetMoments(obj, AssetMean, AssetCovar, NumAssets);
  ```
- To clear `NumAssets` and `AssetCovar`, use this function to set these respective inputs to `[]`.

Version History

Introduced in R2011a

"Portfolio Optimization Theory" on page 4-3

setBounds

Set up bounds for portfolio weights for portfolio

Syntax

```
obj = setBounds(obj,LowerBound)
obj = setBounds( ___ ,Name,Value)
```

```
obj = setBounds(obj,LowerBound,UpperBound)
obj = setBounds( ___ ,Name,Value)
```

Description

`obj = setBounds(obj,LowerBound)` sets up bounds for portfolio weights for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`obj = setBounds( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax, including `BoundType` as `'Simple'` or `'Conditional'`.

`obj = setBounds(obj,LowerBound,UpperBound)` sets up bounds for portfolio weights for portfolio objects with an additional option for `UpperBound`.

Given bound constraints `LowerBound` and `UpperBound` and `'Simple'` `BoundType`, every weight in a portfolio `Port` must satisfy the following:

```
LowerBound <= Port <= UpperBound
```

Given bound constraints `LowerBound` and `UpperBound`, and `'Conditional'` `BoundType`, every weight in a portfolio `Port` must satisfy the following:

```
Port = 0 or LowerBound <= Port <= UpperBound
```

`obj = setBounds( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax, including `BoundType` as `'Simple'` or `'Conditional'`.

Examples

Set Bound Constraints for a Portfolio Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. Use `setBounds` to set the bound constraints for a balanced fund. Note that this sets default `'Simple'` `BoundType`, which enforces 0.5<=x1<=0.75, 0.25<=x2<=0.5.

```
lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
```

```
p = Portfolio;
p = setBounds(p, lb, ub);
disp(p.NumAssets);
```

```
     2
```

```
disp(p.LowerBound);
```

```
    0.5000
    0.2500
```

```
disp(p.UpperBound);
```

```
    0.7500
    0.5000
```

Set Bound Constraints to Define 'Conditional' BoundType Constraints for a Portfolio Object

Suppose you have the mean and covariance of the asset returns for a three asset portfolio:

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
```

The following uses `setBounds` with `'Conditional'` `BoundType` (semicontinuous) constraints to set *xi* = `0` or `0.02 <= `*`xi`*` <= 0.5` for all *i* = 1,...`NumAssets`.

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setBounds(p, 0.02, 0.5,'BoundType', 'Conditional', 'NumAssets', 3)
```

```
p =

Set Bound Constraints to Define Mixed BoundTypes for a Portfolio Object

Suppose you have the mean and covariance of the asset returns for a three asset portfolio:

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
```

The following uses `setBounds` with both `'Simple'` and `'Conditional'` `BoundType` constraints for all *i* = 1,...`NumAssets`.

```
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setBounds(p, 0.1, 0.5, 'BoundType',["simple"; "conditional"; "conditional"])
```

```
p = 
  Portfolio with properties:

          BuyCost: []
         SellCost: []
     RiskFreeRate: []
        AssetMean: [3x1 double]
       AssetCovar: [3x3 double]
    TrackingError: []
     TrackingPort: []
```

```
          Turnover: []
       BuyTurnover: []
      SellTurnover: []
              Name: []
         NumAssets: 3
         AssetList: []
          InitPort: []

         BoundType: [3x1 categorical]
```

```
disp(p.LowerBound);

    0.1000
    0.1000
    0.1000

disp(p.UpperBound);

    0.5000
    0.5000
    0.5000

disp(p.BoundType);

     simple
     conditional
     conditional
```

You can use supply lower and upper bounds as vectors, which defines different values for each asset. The following have -0.8 <= $x1$ <= 0.2; $x2$ = 0 or 0.1 <= $x2$ <= 0.5; $x3$ = 0 or 0.1 <= $x3$ <=0.5. Note that as `'Simple'` `BoundType`, the assets can be held as short or long positions. However, when using `'Conditional'` `BoundType`, the assets can only be long positions.

```
p = setBounds(p, [-0.8, 0.1, 0.1], [-0.2,0.5,0.5], 'BoundType',["simple"; "conditional"; "condit
disp(p.LowerBound);

   -0.8000
    0.1000
    0.1000

disp(p.UpperBound);
```

```
   -0.2000
    0.5000
    0.5000
```

```
disp(p.BoundType);
```

```
     simple
     conditional
     conditional
```

Set MinNumAssets Constraint for a Portfolio Object

Set the minimum cardinality constraint for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up limits on the number of assets invested. These limits are also known as cardinality constraints. When managing a portfolio, it is common that you want to invest in at least a certain number of assets. In addition, you should also clearly define the weight requirement for each invested asset. You can do this using `setBounds` with a `'Conditional'` `BoundType`. If you do not specify a `'Conditional'` `BoundType`, the optimizer cannot understand which assets are invested assets and cannot formulate the `MinNumAssets` constraint.

The following example specifies that at least two assets should be invested and the investments should be greater than 16%.

```
p = setMinMaxNumAssets(p, 2, []);
p = setBounds(p, 0.16, 'BoundType', 'conditional');
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.008, 0.01 ])
```

```
pwgt = 3×2

    0.2861    0.3967
    0.5001    0.2437
    0.2138    0.3595
```

Set Bound Constraints for a PortfolioCVaR Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. To set the bound constraints for a balanced fund.

```
lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];

p = PortfolioCVaR;
p = setBounds(p, lb, ub);
disp(p.NumAssets);
```

```
     2
```

```
disp(p.LowerBound);
```

```
    0.5000
    0.2500
```

```
disp(p.UpperBound);
```

```
    0.7500
    0.5000
```

Set Bound Constraints to Define 'Conditional' BoundType Constraints for a PortfolioCVaR Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. To set the bound constraints for a balanced fund with semicontinuous constraints, use `setBounds` with `'Conditional'` `BoundType` constraints to set *xi* = `0.25` or `0.5` <= *`xi`* <= `0.5 or 0.75` for all *i* = 1,...`NumAssets`.

```
lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];

p = PortfolioCVaR;
p = setBounds(p,lb,ub,'BoundType',["conditional"; "conditional"]);
disp(p.NumAssets);
```

```
     2
```

```
disp(p.LowerBound);
```

```
    0.5000
    0.2500
```

```
disp(p.UpperBound);
```

```
    0.7500
    0.5000
```

Set Bound Constraints for a PortfolioMAD Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. To set the bound constraints for a balanced fund.

```
lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];
```

```
p = PortfolioMAD;
p = setBounds(p, lb, ub);
disp(p.NumAssets);

     2

disp(p.LowerBound);

    0.5000
    0.2500

disp(p.UpperBound);

    0.7500
    0.5000
```

Set Bound Constraints to Define 'Conditional' BoundType Constraints for a PortfolioMAD Object

Suppose you have a balanced fund with stocks that can range from 50% to 75% of your portfolio and bonds that can range from 25% to 50% of your portfolio. To set the bound constraints for a balanced fund with semicontinuous constraints, use `setBounds` with `'Conditional'` `BoundType` constraints to set *xi* = `0.25` or `0.5 <= xi <= 0.5 or 0.75` for all *i* = 1,...`NumAssets`.

```
lb = [ 0.5; 0.25 ];
ub = [ 0.75; 0.5 ];

p = PortfolioMAD;
p = setBounds(p,lb,ub,'BoundType',["conditional"; "conditional"]);
disp(p.NumAssets);

     2

disp(p.LowerBound);

    0.5000
    0.2500

disp(p.UpperBound);

    0.7500
    0.5000
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`

- `PortfolioMAD`

Data Types: `object`

`LowerBound` — Lower-bound weight for each asset
scalar | vector

Lower-bound weight for each asset, specified as a scalar or vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note

- If either `LowerBound` or `UpperBound` are input as empties with `[]`, the corresponding attributes in the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object are cleared and set to `[]`.
- If `LowerBound` or `UpperBound` are specified as scalars and `NumAssets` exists or can be computed, then they undergo scalar expansion. The default value for `NumAssets` is `1`.
- If both `LowerBound` and `UpperBound` exist and they are not ordered correctly, the `setBounds` function switches bounds if necessary.
- If `'Conditional'``BoundType` is specified, the `LowerBound` cannot be a negative value.

Data Types: `double`

`UpperBound` — Upper-bound weight for each asset
scalar | vector

(Optional) Upper-bound weight for each asset, specified as a scalar or vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note

- If either `LowerBound` or `UpperBound` are input as empties with `[]`, the corresponding attributes in the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object are cleared and set to `[]`.
- If `LowerBound` or `UpperBound` are specified as scalars and `NumAssets` exists or can be computed, then they undergo scalar expansion. The default value for `NumAssets` is `1`.
- If both `LowerBound` and `UpperBound` exist and they are not ordered correctly, the `setBounds` function switches bounds if necessary.
- If `'Conditional'``BoundType` is specified, the `UpperBound` cannot be a negative value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `obj = setBounds(p,0.02,'BoundType','Conditional');`

BoundType — Type of bounds for each asset weight
'Simple' (default) | character vector with value 'Simple' or 'Conditional' | string with value "Simple" or "Conditional" | cell array of character vectors with values 'Simple' or 'Conditional' | string array with values "Simple" or "Conditional"

Type of bounds for each asset weight, specified as the comma-separated pair consisting of 'BoundType' and a scalar character vector or string with a value of 'Simple' or 'Conditional' or a cell array of character vectors with values of 'Simple' or 'Conditional'.

- 'Simple' is LowerBound <= AssetWeight <= UpperBound.
- 'Conditional' is LowerBound <= AssetWeight <= UpperBound or AssetWeight = 0.

Warning If you specify the Bound range to be inclusive of zero (using either a ‘Simple’ or ‘Conditional’ BoundType), when you use setMinMaxNumAssets to specify the MinNumAssets constraint, and then use one of the estimate functions, it is ambiguous for the optimizer to define the minimum requirement for an allocated asset. In this case, the optimizer considers that an asset with zero weight is a valid allocated asset and the optimization proceeds, but with the warning that the allocation has less than the MinNumAssets required. For more information, see “Troubleshooting for Setting 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints” on page 4-139.

Data Types: char | cell | string

NumAssets — Number of assets in portfolio
1 (default) | scalar numeric

Number of assets in portfolio, specified as the comma-separated pair consisting of 'NumAssets' and a scalar numeric value.

Note NumAssets cannot be used to change the dimension of a Portfolio, PortfolioCVaR, or PortfolioMAD object.

- If either LowerBound or UpperBound are input as empties with [], the corresponding attributes in the Portfolio, PortfolioCVaR, or PortfolioMAD object are cleared and set to [].
- If LowerBound or UpperBound are specified as scalars and NumAssets exists or can be imputed, then they undergo scalar expansion. The default value for NumAssets is 1.
- If both LowerBound and UpperBound exist and they are not ordered correctly, the setBounds function switches bounds if necessary.

Data Types: double

Output Arguments

obj — Updated portfolio object
object

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object.

Tips

You can also use dot notation to set up the bounds for portfolio weights.

```
 obj = obj.setBounds(LowerBound, UpperBound, Name,Value);
```

If any of `LowerBound`, `UpperBound`, or `BoundType`are input as empties with `[ ]`, the corresponding attributes in the portfolio object are cleared and set to `[ ]`. If `BoundType` is cleared as `[ ]`, the bound type defaults to `'Simple'`.

```
 p = setBounds(p, LowerBound, [ ], 'BoundType',[ ]);
```

To reset a portfolio object to be a continuous problem, run the following:

```
p = setMinMaxNumAssets(p, [],[]);
p = setBounds(p, p.LowerBound, p.UpperBound, 'BoundType', 'Simple');
```

setBudget

Set up budget constraints for portfolio

Syntax

```
obj = setBudget(obj,LowerBudget)
obj = setBudget(obj,LowerBudget,UpperBudget)
```

Description

`obj = setBudget(obj,LowerBudget)` sets up budget constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`obj = setBudget(obj,LowerBudget,UpperBudget)` sets up budget constraints for portfolio objects with an additional option for `UpperBudget`.

Examples

Set Budget Constraint for a Portfolio Object

Assume you have a fund that permits up to 10% leverage, which means that your portfolio can be from 100% to 110% invested in risky assets. Given a Portfolio object `p`, set the budget constraint.

```
p = Portfolio;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
```

```
     1
```

```
disp(p.UpperBudget);
```

```
    1.1000
```

Set Budget Constraint for a PortfolioCVaR Object

Assume you have a fund that permits up to 10% leverage, which means that your portfolio can be from 100% to 110% invested in risky assets. Given a CVaR portfolio object `p`, set the budget constraint.

```
p = PortfolioCVaR;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
```

```
     1
```

```
disp(p.UpperBudget);
```

```
    1.1000
```

Set Budget Constraint for a PortfolioMAD Object

Assume you have a fund that permits up to 10% leverage, which means that your portfolio can be from 100% to 110% invested in risky assets. Given PortfolioMAD object `p`, set the budget constraint.

```
p = PortfolioMAD;
p = setBudget(p, 1, 1.1);
disp(p.LowerBudget);
```

```
     1
```

```
disp(p.UpperBudget);
```

```
    1.1000
```

Control the Allocation of a Risk-Free Asset Using setBudget

Define mean and covariance of risk asset returns.

```
m = [ 0.05; 0.1; 0.12; 0.18; ];
C = [ 0.0064 0.00408 0.00192 0,;
    0.00408 0.0289 0.0204 0.0119,;
    0.00192 0.0204 0.0576 0.0336,;
   0 0.0119 0.0336 0.1225];
```

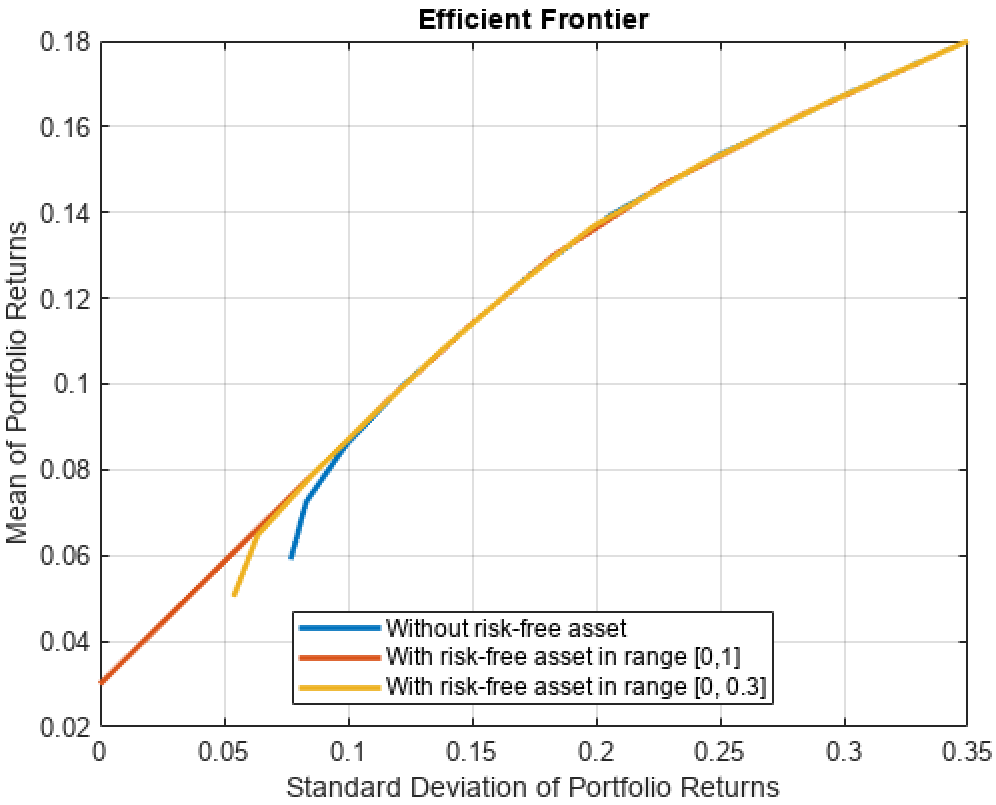
Create a `Portfolio` object defining the risk-free rate.

```
p = Portfolio('RiskFreeRate',0.03, 'assetmean', m, 'assetcovar', C, ...
'lowerbudget', 1, 'upperbudget', 1, 'lowerbound', 0);
```

Create multiple `Portfolio` objects with different budgets on risky assets. By defining the risky assets, you can control how much is invested in a risk-free asset.

```
p = setBudget(p, 1, 1);    % allow 0% risk-free asset allocation, meaning fully invested in risky
p1 = setBudget(p, 0, 1);   % allow 0 to 100% risk-free asset allocation
p2 = setBudget(p, 0.7, 1);  % allow 0 to 30% risk-free asset allocation

plotFrontier(p); hold on;
plotFrontier(p1);hold on;
plotFrontier(p2);
legend('Without risk-free asset', 'With risk-free asset in range [0,1]', 'With risk-free asset in
```



`setBudget` defines the bound for total weights for the allocated risky assets, and the remaining is automatically the bound for a risk-free asset. Use `setBudget` to control the level of allowed allocation to a risk-free asset. For additional information on using `setBudget` with a risk-free asset, see "Leverage in Portfolio Optimization with a Risk-Free Asset" on page 4-210.

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`LowerBudget` — Lower-bound for budget constraint

scalar

Lower-bound for budget constraint, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note Given bounds for a budget constraint in either `LowerBudget` or `UpperBudget`, budget constraints require any portfolio in `Port` to satisfy:

```
LowerBudget <= sum(Port) <= UpperBudget
```

One or both constraints may be specified. The usual budget constraint for a fully invested portfolio is to have `LowerBudget = UpperBudget = 1`. However, if the portfolio has allocations in cash, the budget constraints can be used to specify the cash constraints. For example, if the portfolio can hold between 0% and 10% in cash, the budget constraint would be set up with

```
obj = setBudget(obj, 0.9, 1)
```

Data Types: `double`

`UpperBudget` — Upper-bound for budget constraint

scalar

Upper-bound for budget constraint, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note Given bounds for a budget constraint in either `LowerBudget` or `UpperBudget`, budget constraints require any portfolio in `Port` to satisfy:

```
LowerBudget <= sum(Port) <= UpperBudget
```

One or both constraints may be specified. The usual budget constraint for a fully invested portfolio is to have `LowerBudget = UpperBudget = 1`. However, if the portfolio has allocations in cash, the budget constraints can be used to specify the cash constraints. For example, if the portfolio can hold between 0% and 10% in cash, the budget constraint would be set up with

```
obj = setBudget(obj, 0.9, 1)
```

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Tips

You can also use dot notation to set up the budget constraints.

```
obj = obj.setBudget(LowerBudget, UpperBudget);
```

setCosts

Set up proportional transaction costs for portfolio

Syntax

```
obj = setCosts(obj,BuyCost)
```

```
obj = setCosts(obj,BuyCost,SellCost,InitPort,NumAssets)
```

Description

`obj = setCosts(obj,BuyCost)` sets up proportional transaction costs for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-15.

`obj = setCosts(obj,BuyCost,SellCost,InitPort,NumAssets)` sets up proportional transaction costs for portfolio objects with additional options specified for `SellCost`, `InitPort`, and `NumAssets`.

Given proportional transaction costs and an initial portfolio in the variables `BuyCost`, `SellCost`, and `InitPort`, the transaction costs for any portfolio `Port` reduce expected portfolio return by:

```
BuyCost' * max{0, Port - InitPort} + SellCost' * max{0, InitPort - Port}
```

Examples

Set Up Transaction Costs for a Portfolio Object

Given a Portfolio object `p` with an initial portfolio already set, use the `setCosts` function to set up transaction costs.

```
bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];

p = Portfolio('InitPort', x0);
p = setCosts(p, bc, sc);

disp(p.NumAssets);
```

```
     5
```

```
disp(p.BuyCost);
```

```
    0.0013
    0.0013
    0.0013
    0.0013
    0.0013
```

```
disp(p.SellCost);
```

```
    0.0013
    0.0070
    0.0013
    0.0013
    0.0024
```

```
disp(p.InitPort);
```

```
    0.4000
    0.2000
    0.2000
    0.1000
    0.1000
```

Set Up Transaction Costs for a PortfolioCVaR Object

Given a CVaR portfolio object `p` with an initial portfolio already set, use the `setCosts` function to set up transaction costs.

```
bc = [ 0.00125; 0.00125; 0.00125; 0.00125; 0.00125 ];
sc = [ 0.00125; 0.007; 0.00125; 0.00125; 0.0024 ];
x0 = [ 0.4; 0.2; 0.2; 0.1; 0.1 ];

p = PortfolioCVaR('InitPort', x0);
p = setCosts(p, bc, sc);

disp(p.NumAssets);
```

```
     5
```

```
disp(p.BuyCost);
```

```
    0.0013
    0.0013

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`BuyCost` — Proportional transaction cost to purchase each asset

vector

Proportional transaction cost to purchase each asset, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note

- If `BuyCost`, `SellCost`, or `InitPort` are specified as scalars and `NumAssets` exists or can be imputed, then these values undergo scalar expansion. The default value for `NumAssets` is `1`.
- Transaction costs in `BuyCost` and `SellCost` are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.

Data Types: `double`

`SellCost` — Proportional transaction cost to sell each asset

vector

Proportional transaction cost to sell each asset, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note

- If `BuyCost`, `SellCost`, or `InitPort` are specified as scalars and `NumAssets` exists or can be imputed, then these values undergo scalar expansion. The default value for `NumAssets` is `1`.
- Transaction costs in `BuyCost` and `SellCost` are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.

Data Types: `double`

`InitPort` — Initial or current portfolio weights

vector

Initial or current portfolio weights, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note If no `InitPort` is specified, that value is assumed to be `0`.

- If `BuyCost`, `SellCost`, or `InitPort` are specified as scalars and `NumAssets` exists or can be imputed, then these values undergo scalar expansion. The default value for `NumAssets` is `1`.
- Transaction costs in `BuyCost` and `SellCost` are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.

Data Types: `double`

`NumAssets` — Number of assets in portfolio

scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).
