Note NumAssets cannot be used to change the dimension of a portfolio object.

- If BuyCost, SellCost, or InitPort are specified as scalars and NumAssets exists or can be imputed, then these values undergo scalar expansion. The default value for NumAssets is 1.
- Transaction costs in BuyCost and SellCost are positive valued if they introduce a cost to trade. In some cases, they can be negative valued, which implies trade credits.

Data Types: double

Output Arguments

obj — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Tips

- You can also use dot notation to set up proportional transaction costs.

  ```
  obj = obj.setCosts(BuyCost, SellCost, InitPort, NumAssets);
  ```
- If BuyCost or SellCost are input as empties with [], the corresponding attributes in the portfolio object are cleared and set to []. If InitPort is set to empty with [], it will only be cleared and set to [] if BuyCost, SellCost, and Turnover are also empty. Otherwise, it is an error.

Version History

Introduced in R2011a

setDefaultConstraints

Set up portfolio constraints with nonnegative weights that sum to 1

Syntax

```
obj = setDefaultConstraints(obj)
obj = setDefaultConstraints(obj,NumAssets)
```

Description

`obj = setDefaultConstraints(obj)` sets up portfolio constraints with nonnegative weights that sum to 1 for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`obj = setDefaultConstraints(obj,NumAssets)` sets up portfolio constraints with nonnegative weights that sum to 1 with an additional option for `NumAssets`.

A "default" portfolio set has `LowerBound = 0` and `LowerBudget = UpperBudget = 1` such that a portfolio `Port` must satisfy `sum(Port) = 1` with `Port >= 0`.

Examples

Define Default Constraints for the Portfolio Object

Assuming you have 20 assets, you can define the "default" portfolio set.

```
p = Portfolio('NumAssets', 20);
p = setDefaultConstraints(p);
disp(p);
```

```
  Portfolio with properties:

          BuyCost: []
         SellCost: []

      UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
       BoundType: [20x1 categorical]
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`NumAssets` — Number of assets in portfolio
scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note `NumAssets` cannot be used to change the dimension of a portfolio object. The default for `NumAssets` is `1`.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Tips

- You can also use dot notation to set up the default portfolio set.

  ```
  obj = obj.setDefaultConstraints(NumAssets);
  ```
- This function does not modify any existing constraints in a portfolio object other than the bound and budget constraints. If an `UpperBound` constraint exists, it is cleared and set to `[]`.

setEquality

Set up linear equality constraints for portfolio weights

Syntax

```
obj= setEquality(obj,AEquality,bEquality)
```

Description

`obj= setEquality(obj,AEquality,bEquality)` sets up linear equality constraints for portfolio weights for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Given linear equality constraint matrix `AEquality` and vector `bEquality`, every weight in a portfolio `Port` must satisfy the following:

```
 AEquality * Port = bEquality
```

Examples

Set Linear Equality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets, and you want to ensure that the first three assets are 50% of your portfolio. Given a Portfolio object `p`, set the linear equality constraints with the following.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setEquality(p, A, b);

disp(p.NumAssets);

     5

disp(p.AEquality);

     1     1     1     0     0

disp(p.bEquality);

    0.5000
```

Set Linear Equality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a PortfolioCVaR object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioCVaR;
p = setEquality(p, A, b);
disp(p.NumAssets);
```

```
     5
```

```
disp(p.AEquality);
```

```
     1     1     1     0     0
```

```
disp(p.bEquality);
```

```
    0.5000
```

Set Linear Equality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are 50% of your portfolio. Given a PortfolioMAD object `p`, set the linear equality constraints and obtain the values for `AEquality` and `bEquality`:

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setEquality(p, A, b);
[AEquality, bEquality] = getEquality(p)
```

```
AEquality = 1×5

     1     1     1     0     0

bEquality = 0.5000
```

Input Arguments

`obj` — Object for portfolio
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`AEquality` — Matrix to form linear equality constraints
matrix

Matrix to form linear equality constraints, returned as a matrix for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note An error results if AEquality is empty and bEquality is nonempty.

Data Types: double

bEquality — Vector to form linear equality constraints
vector

Vector to form linear equality constraints, returned as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note An error results if AEquality is nonempty and bEquality is empty.

Data Types: double

Output Arguments

obj — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Tips

- You can also use dot notation to set up linear equality constraints for portfolio weights.

  ```
  obj = obj.setEquality(AEquality, bEquality);
  ```
- Linear equality constraints can be removed from a portfolio object by entering [] for each property you want to remove.

setGroupRatio

Set up group ratio constraints for portfolio weights

Syntax

```
obj = setGroupRatio(obj,GroupA,GroupB,LowerRatio)
obj = setGroupRatio(___,UpperRatio)
```

Description

`obj = setGroupRatio(obj,GroupA,GroupB,LowerRatio)` sets up group ratio constraints for portfolio weights for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`obj = setGroupRatio(___,UpperRatio)` sets up group ratio constraints for portfolio weights for portfolio objects with an additional optional argument for `UpperRatio`.

Given base and comparison group matrices `GroupA` and `GroupB` and `LowerRatio` or `UpperRatio` bounds, group ratio constraints require any portfolio in `Port` to satisfy the following:

```
(GroupB * Port) .* LowerRatio <= GroupA * Port <= (GroupB * Port) .* UpperRatio
```

Caution This collection of constraints usually requires that portfolio weights be nonnegative and that the products `GroupA * Port` and `GroupB * Port` are always nonnegative. Although negative portfolio weights and non-Boolean group ratio matrices are supported, use with caution.

Examples

Set Group Ratio Constraints for a Portfolio Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolio never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). Group ratio constraints can be set with:

```
GA = [ true true true false false false ];    % financial companies
GB = [ false false false true true true ];    % nonfinancial companies
p = Portfolio;
p = setGroupRatio(p, GA, GB, [], 0.5);

disp(p.NumAssets);

     6

disp(p.GroupA);

     1     1     1     0     0     0

disp(p.GroupB);
```

```
     0     0     0     1     1     1
```

```
disp(p.UpperRatio);
```

```
    0.5000
```

Set Group Ratio Constraints for a PortfolioCVaR Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolio never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). Group ratio constraints can be set with:

```
GA = [ true true true false false false ];    % financial companies
GB = [ false false false true true true ];    % nonfinancial companies
p = PortfolioCVaR;
p = setGroupRatio(p, GA, GB, [], 0.5);

disp(p.NumAssets);
```

```
     6
```

```
disp(p.GroupA);
```

```
     1     1     1     0     0     0
```

```
disp(p.GroupB);
```

```
     0     0     0     1     1     1
```

```
disp(p.UpperRatio);
```

```
    0.5000
```

Set Group Ratio Constraints for a PortfolioMAD Object

Suppose you want to ensure that the ratio of financial to nonfinancial companies in your portfolio never exceeds 50%. Assume you have six assets with three financial companies (assets 1-3) and three nonfinancial companies (assets 4-6). Group ratio constraints can be set with:

```
GA = [ true true true false false false ];    % financial companies
GB = [ false false false true true true ];    % nonfinancial companies
p = PortfolioMAD;
p = setGroupRatio(p, GA, GB, [], 0.5);

disp(p.NumAssets);
```

```
     6
```

```
disp(p.GroupA);
```

```
     1     1     1     0     0     0
```

```
disp(p.GroupB);
```

```
     0     0     0     1     1     1
```

```
disp(p.UpperRatio);

    0.5000
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Data Types: object

GroupA — Matrix that forms base groups for comparison

matrix

Matrix that forms base groups for comparison, specified as a matrix for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note The group matrices GroupA and GroupB are usually indicators of membership in groups, which means that their elements are usually either 0 or 1. Because of this interpretation, GroupA and GroupB matrices can be either logical or numerical arrays.

Data Types: double | logical

GroupB — Matrix that forms comparison groups

matrix

Matrix that forms comparison groups, specified as a matrix Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note The group matrices GroupA and GroupB are usually indicators of membership in groups, which means that their elements are usually either 0 or 1. Because of this interpretation, GroupA and GroupB matrices can be either logical or numerical arrays.

Data Types: double | logical

LowerRatio — Lower bound for ratio of GroupB groups to GroupA groups

vector

Lower bound for ratio of GroupB groups to GroupA groups, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note If input is scalar, LowerRatio undergoes scalar expansion to be conformable with the group matrices.

Data Types: double

UpperRatio — Upper bound for ratio of GroupB groups to GroupA groups

vector

Upper bound for ratio of GroupB groups to GroupA groups, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note If input is scalar, UpperRatio undergoes scalar expansion to be conformable with the group matrices.

Data Types: double

Output Arguments

obj — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Tips

- You can also use dot notation to set up group ratio constraints for portfolio weight.

  ```
  obj = obj.setGroupRatio(GroupA, GroupB, LowerRatio, UpperRatio);
  ```
- To remove group ratio constraints, enter empty arrays for the corresponding arrays. To add to existing group ratio constraints, use addGroupRatio.

Version History

Introduced in R2011a

setGroups

Set up group constraints for portfolio weights

Syntax

```
obj = setGroups(obj,GroupMatrix,LowerGroup)
obj = setGroups(obj,GroupMatrix,LowerGroup,UpperGroup)
```

Description

`obj = setGroups(obj,GroupMatrix,LowerGroup)` sets up group constraints for portfolio weights for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-15.

`obj = setGroups(obj,GroupMatrix,LowerGroup,UpperGroup)` sets up group constraints for portfolio weights for portfolio objects with an additional option specified for `UpperGroup`.

Given `GroupMatrix` and either `LowerGroup` or `UpperGroup`, a portfolio `Port` must satisfy the following:

```
LowerGroup <= GroupMatrix * Port <= UpperGroup
```

Examples

Set Group Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a Portfolio object `p`, set the group constraints with the following.

```
G = [ true true true false false ];
p = Portfolio;
p = setGroups(p, G, [], 0.3);

disp(p.NumAssets);

     5

disp(p.GroupMatrix);

     1     1     1     0     0

disp(p.UpperGroup);

    0.3000
```

Set Group Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given a CVaR portfolio object p, set the group constraints with the following.

```
G = [ true true true false false ];
p = PortfolioCVaR;
p = setGroups(p, G, [], 0.3);

disp(p.NumAssets);

     5

disp(p.GroupMatrix);

     1     1     1     0     0

disp(p.UpperGroup);

    0.3000
```

Set Group Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets constitute at most 30% of your portfolio. Given PortfolioMAD object p, set the group constraints with the following.

```
G = [ true true true false false ];
p = PortfolioMAD;
p = setGroups(p, G, [], 0.3);

disp(p.NumAssets);

     5

disp(p.GroupMatrix);

     1     1     1     0     0

disp(p.UpperGroup);

    0.3000
```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`

- PortfolioMAD

Data Types: object

GroupMatrix — Group constraint matrix

logical or numeric matrix

Group constraint matrix, specified as a matrix for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note The group matrix GroupMatrix is usually an indicator of membership in groups, which means that its elements are usually either 0 or 1. Because of this interpretation, GroupMatrix can be either a logical or numerical matrix.

Data Types: double

LowerGroup — Lower bound for group constraints

vector

Lower bound for group constraints, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note If input is scalar, LowerGroup undergoes scalar expansion to be conformable with GroupMatrix.

Data Types: double

UpperGroup — Upper bound for group constraints

vector

Upper bound for group constraints, returned as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note If input is scalar, UpperGroup undergoes scalar expansion to be conformable with GroupMatrix.

Data Types: double

Output Arguments

obj — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR

- `PortfolioMAD`

Tips

- You can also use dot notation to set up group constraints for portfolio weights.

  ```
  obj = obj.setGroups(GroupMatrix, LowerGroup, UpperGroup);
  ```
- To remove group constraints, enter empty arrays for the corresponding arrays. To add to existing group constraints, use `addGroups`.

setInequality

Set up linear inequality constraints for portfolio weights

Syntax

```
obj = setInequality(obj,AInequality,bInequality)
```

Description

`obj = setInequality(obj,AInequality,bInequality)` sets up linear inequality constraints for portfolio weights for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Given a linear inequality constraint matrix `AInequality` and vector `bInequality`, every weight in a portfolio `Port` must satisfy the following:

```
AInequality * Port <= bInequality
```

Examples

Set Linear Inequality Constraints for a Portfolio Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than 50% of your portfolio. Given a Portfolio object `p`, set the linear inequality constraints with the following.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = Portfolio;
p = setInequality(p, A, b);

disp(p.NumAssets);

     5

disp(p.AInequality);

     1     1     1     0     0

disp(p.bInequality);

    0.5000
```

Set Linear Inequality Constraints for a PortfolioCVaR Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than 50% of your portfolio. Given a CVaR portfolio object p, set the linear inequality constraints with the following.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioCVaR;
p = setInequality(p, A, b);

disp(p.NumAssets);

     5

disp(p.AInequality);

     1     1     1     0     0

disp(p.bInequality);

    0.5000
```

Set Linear Inequality Constraints for a PortfolioMAD Object

Suppose you have a portfolio of five assets and you want to ensure that the first three assets are no more than 50% of your portfolio. Given PortfolioMAD object p, set the linear inequality constraints with the following.

```
A = [ 1 1 1 0 0 ];
b = 0.5;
p = PortfolioMAD;
p = setInequality(p, A, b);

disp(p.NumAssets);

     5

disp(p.AInequality);

     1     1     1     0     0

disp(p.bInequality);

    0.5000
```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Data Types: object

AInequality — Matrix to form linear inequality constraints
matrix

Matrix to form linear inequality constraints, specified as a matrix for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note An error results if AInequality is empty and bInequality is nonempty.

Data Types: double

bInequality — Vector to form linear inequality constraints
vector

Vector to form linear inequality constraints, specified as a vector for a Portfolio, PortfolioCVaR, or PortfolioMAD input object (obj).

Note An error results if AInequality is nonempty and bInequality is empty.

Data Types: double

Output Arguments

obj — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Tips

- You can also use dot notation to set up linear inequality constraints for portfolio weights.

  ```
  obj = obj.setInequality(AInequality, bInequality);
  ```
- To remove inequality constraints, enter empty arguments. To add to existing inequality constraints, use addInequality.

Version History

setInitPort

Set up initial or current portfolio

Syntax

```
obj = setInitPort(obj,InitPort)
obj = setInitPort(obj,InitPort,NumAssets)
```

Description

`obj = setInitPort(obj,InitPort)` sets up initial or current portfolio for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`obj = setInitPort(obj,InitPort,NumAssets)` sets up initial or current portfolio for portfolio objects with an additional options specified for `NumAssets`.

Examples

Set the InitPort Property for a Portfolio Object

Given an initial portfolio in `x0`, use the `setInitPort` function to set the `InitPort` property.

```
p = Portfolio('NumAssets', 4);
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setInitPort(p, x0);
disp(p.InitPort);
```

```
    0.3000
    0.2000
    0.2000
         0
```

Set InitPort to Create an Equally-Weighted Portfolio of Four Assets for a Portfolio Object

Create an equally weighted portfolio of four assets using the `setInitPort` function.

```
p = Portfolio('NumAssets', 4);
p = setInitPort(p, 1/4, 4);
disp(p.InitPort);
```

```
    0.2500
    0.2500
    0.2500
    0.2500
```

Set the InitPort Property for a PortfolioCVaR Object

Given an initial portfolio in `x0`, use the `setInitPort` function to set the `InitPort` property.

```
p = PortfolioCVaR('NumAssets', 4);
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setInitPort(p, x0);
disp(p.InitPort);
```

```
    0.3000
    0.2000
    0.2000
         0
```

Set InitPort to Create an Equally-Weighted Portfolio of Four Assets for a PortfolioCVaR Object

Create an equally weighted portfolio of four assets using the `setInitPort` function.

```
p = PortfolioCVaR('NumAssets', 4);
p = setInitPort(p, 1/4, 4);
disp(p.InitPort);
```

```
    0.2500
    0.2500
    0.2500
    0.2500
```

Set the InitPort Property for a PortfolioMAD Object

Given an initial portfolio in `x0`, use the `setInitPort` function to set the `InitPort` property.

```
p = PortfolioMAD('NumAssets', 4);
x0 = [ 0.3; 0.2; 0.2; 0.0 ];
p = setInitPort(p, x0);
disp(p.InitPort);
```

```
    0.3000
    0.2000
    0.2000
         0
```

Set InitPort to Create an Equally-Weighted Portfolio of Four Assets for a PortfolioMAD Object

Create an equally weighted portfolio of four assets using the `setInitPort` function.

```
p = PortfolioMAD('NumAssets', 4);
p = setInitPort(p, 1/4, 4);
disp(p.InitPort);
```

```
    0.2500
    0.2500
    0.2500
    0.2500
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`InitPort` — Initial or current portfolio weights

vector

Initial or current portfolio weights, specified as a vector for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note If `InitPort` is specified as a scalar and `NumAssets` exists, then `InitPort` undergoes scalar expansion.

Data Types: `double`

`NumAssets` — Number of assets in portfolio

`1` (default) | scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note If it is not possible to obtain a value for `NumAssets`, it is assumed that `NumAssets` is `1`.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`

- `PortfolioCVaR`
- `PortfolioMAD`

Tips

- You can also use dot notation to set up an initial or current portfolio.

  ```
  obj = obj.setInitPort(InitPort, NumAssets);
  ```
- To remove an initial portfolio, call this function with an empty argument `[]` for `InitPort`.

setMinMaxNumAssets

Set cardinality constraints on the number of assets invested in a portfolio

Syntax

```
obj = setMinMaxNumAssets(obj,MinNumAssets,MaxNumAssets)
```

Description

`obj = setMinMaxNumAssets(obj,MinNumAssets,MaxNumAssets)` sets cardinality constraints for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

`MinNumAssets` and `MaxNumAssets` are the minimum and maximum number of assets invested in the portfolio, respectively. The total number of allocated assets satisfying the Bound constraints is between [`MinNumAssets`, `MaxNumAssets`]. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

Examples

Set `MaxNumAssets` Constraint for a `Portfolio` Object

Set the maximum cardinality constraint for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

When working with a `Portfolio` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested. Use `setMinMaxNumAssets` to limit the total number of allocated assets to no more than two.

```
 p = setMinMaxNumAssets(p, [], 2);
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.008, 0.01 ])
```

```
pwgt = 3×2

         0         0
    0.6101    0.3962
    0.3899    0.6038
```

Set MinNumAssets Constraint for a Portfolio Object

Set the minimum cardinality constraint for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up limits on the number of assets invested. These limits are also known as cardinality constraints. When managing a portfolio, it is common that you want to invest in at least a certain number of assets. In addition, you should also clearly define the weight requirement for each invested asset. You can do this using setBounds with a 'Conditional' BoundType. If you do not specify a 'Conditional' BoundType, the optimizer cannot understand which assets are invested assets and cannot formulate the MinNumAssets constraint.

The following example specifies that at least two assets should be invested and the investments should be greater than 16%.

```
p = setMinMaxNumAssets(p, 2, []);
p = setBounds(p, 0.16, 'BoundType', 'conditional');
```

Use estimateFrontierByReturn to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.008, 0.01 ])
```

```
pwgt = 3×2

    0.2861    0.3967
    0.5001    0.2437
    0.2138    0.3595
```

Set 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints for a Portfolio Object

Set the minimum and maximum cardinality constraints and a 'Conditional' BoundType for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];

p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
p = setDefaultConstraints(p);
```

When working with a Portfolio object, the setMinMaxNumAssets function enables you to set up the limits on the number of assets invested. The following example specifies that exactly two assets should be invested using `setMinMaxNumAssets` and the investment should be equally allocated among the two assets using `setBounds`.

```
p = setMinMaxNumAssets(p, 2, 2);
p = setBounds(p, 0.5, 0.5, 'BoundType', 'conditional');
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.008, 0.01 ])
```

```
pwgt = 3×2

         0    0.5000
    0.5000         0
    0.5000    0.5000
```

Set 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints for a PortfolioCVaR Object

Suppose you have a universe of 12 stocks where you want to find the optimal portfolios with targeted returns and you want to set semicontinuous and cardinality constraints for the portfolio.

```
load CAPMuniverse
p = PortfolioCVaR('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 ,'missingdata',true);
p = setProbabilityLevel(p, 0.80);
```

When working with a `PortfolioCVaR` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested. The following example specifies that a minimum of five assets and a maximum of 10 assets should be invested using `setMinMaxNumAssets` and the investments should be greater than 4% and less than 45% using `setBounds`.

```
p = setMinMaxNumAssets(p, 5, 10);
p = setBounds(p, 0.04, 0.45, 'BoundType', 'conditional');
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.00026, 0.00038 ])
```

```
pwgt = 12×2

    0.0400    0.0400
    0.0000         0
         0         0
         0         0
         0         0
    0.0496    0.0786
         0    0.0400
    0.0400    0.0400
         0         0
    0.0400    0.0400
      ⋮
```

Set 'Conditional' BoundType, MinNumAssets, and MaxNumAssets Constraints for a PortfolioMAD Object

Suppose you have a universe of 12 stocks where you want to find the optimal portfolios with targeted returns and you want to set semicontinuous and cardinality constraints for the portfolio.

```
load CAPMuniverse
p = PortfolioMAD('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 ,'missingdata',true);
```

When working with a `PortfolioMAD` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested. The following example specifies that a minimum of five assets and a maximum of 10 assets should be invested using `setMinMaxNumAssets` and the investments should be greater than 4% and less than 45% using `setBounds`.

```
p = setMinMaxNumAssets(p, 5, 10);
p = setBounds(p, 0.04, 0.45, 'BoundType', 'conditional');
```

Use `estimateFrontierByReturn` to estimate optimal portfolios with targeted portfolio returns.

```
pwgt = estimateFrontierByReturn(p,[ 0.00026, 0.00038 ])
```

```
pwgt = 12×2

    0.0400    0.0400
         0         0
         0         0
         0         0
         0         0
    0.0507    0.0786
    0.0400    0.0400
    0.0400    0.0400
         0         0
    0.0400    0.0400
      ⋮
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

MinNumAssets — Minimum number of assets allocated in portfolio

scalar numeric

Minimum number of assets allocated in the portfolio, specified using a scalar numeric.

Data Types: `double`

`MaxNumAssets` — Maximum number of assets allocated in portfolio
scalar numeric

Maximum number of assets allocated in the portfolio, specified using a scalar numeric.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

Tips

- You can also use dot notation to set up a list of identifiers for assets.

  ```
  obj = obj.setMinMaxNumAssets(MinNumAssets,MaxNumAssets);
  ```
- Specifying empty values (`[[]`) for `MinNumAssets` and `MaxNumAsssets` removes limit constraints from the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

setOneWayTurnover

Set up one-way portfolio turnover constraints

Syntax

```
obj = setOneWayTurnover(obj,BuyTurnover)
obj = setOneWayTurnover(obj,BuyTurnover,SellTurnover,InitPort,NumAssets)
```

Description

`obj = setOneWayTurnover(obj,BuyTurnover)` sets up one-way portfolio turnover constraints for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see “Portfolio Object Workflow” on page 4-17, “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`obj = setOneWayTurnover(obj,BuyTurnover,SellTurnover,InitPort,NumAssets)` sets up one-way portfolio turnover constraints for portfolio objects with additional options specified for `SellTurnover`, `InitPort`, and `NumAssets`.

Given an initial portfolio in `InitPort` and an upper bound for portfolio turnover on purchases in `BuyTurnover` or sales in `SellTurnover`, the one-way turnover constraints require any portfolio `Port` to satisfy the following:

```
1' * max{0, Port - InitPort} <= BuyTurnover
1' * max{0, InitPort - Port} <= SellTurnover
```

Note If `Turnover =BuyTurnover = SellTurnover`, the constraint is not equivalent to:

```
1' * | Port - InitPort | <= Turnover
```

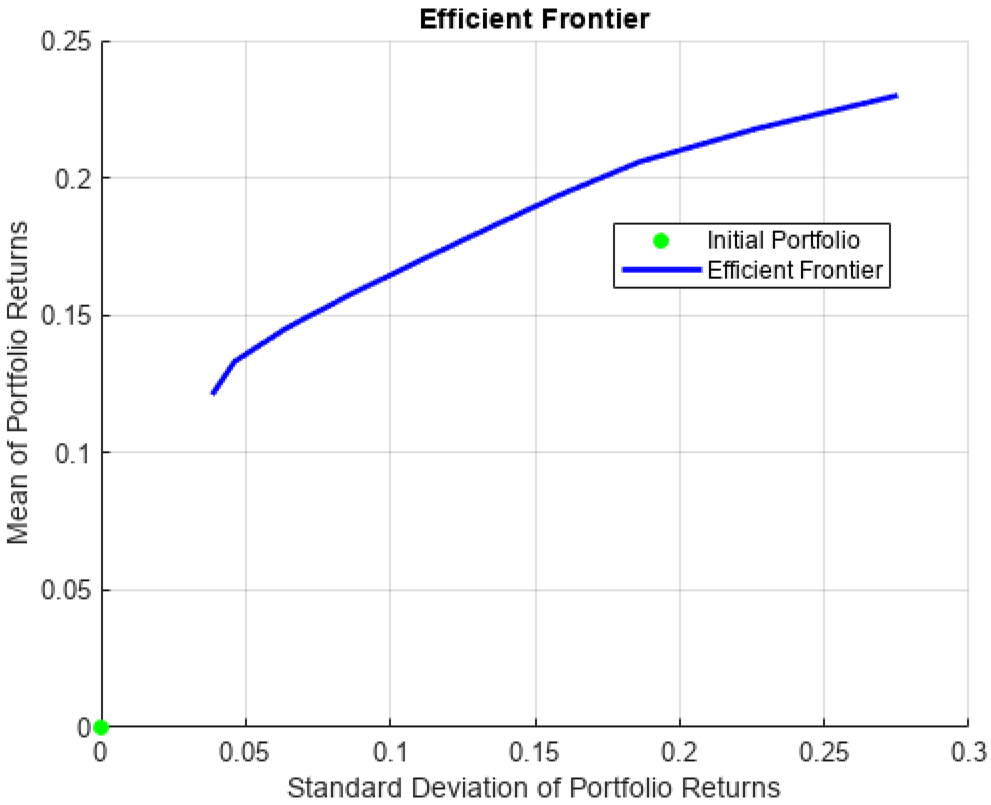
To set this constraint, use `setTurnover`.

Examples

Set One-Way Turnover Constraints for a Portfolio Object

Set one-way turnover constraints.

```
p = Portfolio('AssetMean',[0.1, 0.2, 0.15], 'AssetCovar',...
[ 0.005, -0.010,  0.004; -0.010,  0.040, -0.002;  0.004, -0.002,  0.023]);
p = setBudget(p, 1, 1);
p = setOneWayTurnover(p, 1.3, 0.3, 0); %130-30 portfolio
plotFrontier(p);
```



Set One-Way Turnover Constraints for a PortfolioCVaR Object

Set one-way turnover constraints.

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioCVaR('InitPort', x0);
p = setOneWayTurnover(p, 0.3, 0.2);
disp(p.NumAssets);
```

```
    10
```

```
disp(p.BuyTurnover)
```

```
    0.3000
```

```

    0.1500
    0.1100
    0.0800
    0.1000
```

Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

BuyTurnover — Turnover constraint on purchases

nonnegative and finite scalar

Turnover constraint on purchases, specified as a nonnegative and finite scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`SellTurnover` — Turnover constraint on sales
nonnegative and finite scalar

Turnover constraint on sales, specified as a nonnegative and finite scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`InitPort` — Initial or current portfolio weights
`0` (default) | finite vector with `NumAssets` > `0` elements

Initial or current portfolio weights, specified as a finite vector with `NumAssets` > `0` elements for a `Portfolio`, `PortfolioCVaR`, `PortfolioMAD` input object (`obj`).

Note If no `InitPort` is specified, that value is assumed to be `0`.

If `InitPort` is specified as a scalar and `NumAssets` exists, then `InitPort` undergoes scalar expansion.

Data Types: `double`

`NumAssets` — Number of assets in portfolio
`1` (default) | scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note If it is not possible to obtain a value for `NumAssets`, it is assumed that `NumAssets` is `1`.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

More About

One-way Turnover Constraint

One-way turnover constraints ensure that estimated optimal portfolios differ from an initial portfolio by no more than specified amounts according to whether the differences are purchases or sales.

The constraints take the form

$$1^T \max\{0, x - x_0\} \le \tau_B$$

$$1^T \max\{0, x_0 - x\} \le \tau_S$$

with

- x — The portfolio (*NumAssets* vector)
- x_0 — Initial portfolio (*NumAssets* vector)
- τ_B — Upper-bound for turnover constraint on purchases (scalar)
- τ_S — Upper-bound for turnover constraint on sales (scalar)

Specify one-way turnover constraints using the following properties in a supported portfolio object: `BuyTurnover` for τ_B, `SellTurnover` for τ_S, and `InitPort` for x_0.

Note The average turnover constraint (which is set using `setTurnover`) is not just the combination of the one-way turnover constraints with the same value for the constraint.

Tips

You can also use dot notation to set up one-way portfolio turnover constraints.

```
obj = obj.setOneWayTurnover(BuyTurnover,SellTurnover,InitPort,NumAssets)
```

setProbabilityLevel

Set probability level for VaR and CVaR calculations

Syntax

```
obj = setProbabilityLevel(obj,ProbabilityLevel)
```

Description

`obj = setProbabilityLevel(obj,ProbabilityLevel)` sets probability level for VaR and CVaR calculations for a `PortfolioCVaR` object. For details on the workflow, see “PortfolioCVaR Object Workflow” on page 5-16.

Examples

Set Probability Level for a PortfolioCVaR Object

Set the `ProbabilityLevel` for a CVaR portfolio object.

```
p = PortfolioCVaR;
p = setProbabilityLevel(p, 0.95);
disp(p.ProbabilityLevel)
```

```
    0.9500
```

Input Arguments

`obj` — Object for portfolio
object

Object for portfolio, specified using a `PortfolioCVaR` object.

For more information on creating a `PortfolioCVaR` object, see

- `PortfolioCVaR`

Data Types: `object`

`ProbabilityLevel` — Probability level which is 1 minus the probability of losses greater than the value-at-risk
scalar with value from `0` to `1`

Probability level which is 1 minus the probability of losses greater than the value-at-risk, specified as a scalar with value from `0` to `1`.

Note `ProbabilityLevel` must be a value from `0` to `1` and, in most cases, should be a value from `0.9` to `0.99`.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `PortfolioCVaR` object. For more information on creating a portfolio object, see

- `PortfolioCVaR`

Tips

You can also use dot notation to set the probability level for VaR and CVaR calculations:

```
obj = obj.setProbabilityLevel(ProbabilityLevel)
```

Version History

Introduced in R2012b

CVaR Portfolio Optimization (4 min 56 sec)

setSolver

Choose main solver and specify associated solver options for portfolio optimization

Syntax

```
obj = setSolver(obj,solverType)
```

```
obj = setSolver(obj,solverType,Name,Value)
```

```
obj = setSolver(obj,solverType,optimoptions)
```

Description

`obj = setSolver(obj,solverType)` selects the main solver and enables you to specify associated solver options for portfolio optimization for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-15.

`obj = setSolver(obj,solverType,Name,Value)` selects the main solver and enables you to specify associated solver options for portfolio optimization for portfolio objects with additional options specified by using one or more `Name,Value` pair arguments.

`obj = setSolver(obj,solverType,optimoptions)` selects the main solver and enables you to specify associated solver options for portfolio optimization for portfolio objects with an `optimoptions` object.

Examples

Set Solver Type for a Portfolio Object

If you use the `quadprog` function as the `solverType`, the default is the `interior-point-convex` version of `quadprog`.

```
load CAPMuniverse
p = Portfolio('AssetList',Assets(1:12));
p = setDefaultConstraints(p);
p = setSolver(p, 'quadprog');
display(p.solverType);
```

```
quadprog
```

You can switch back to `lcprog` with:

```
p = setSolver(p, 'lcprog');
display(p.solverType);
```

```
lcprog
```

Set the Solver Type as 'fmincon' for a PortfolioCVaR Object

Use `'fmincon'` as the `solverType`.

```
p = PortfolioCVaR;
p = setSolver(p, 'fmincon');
display(p.solverType);
```

```
fmincon
```

Set the Solver Type as 'fmincon' and Use Name-Value Pair Arguments to Set the Algorithm for a PortfolioCVaR Object

Use `'fmincon'` as the `solverType` and use name-value pair arguments to set the algorithm to `'interior-point'` and to turn off the display.

```
p = PortfolioCVaR;
p = setSolver(p, 'fmincon', 'Algorithm', 'interior-point', 'Display', 'off');
display(p.solverOptions.Algorithm);
```

```
interior-point
```

```
display(p.solverOptions.Display);
```

```
off
```

Set the Solver Type as 'fmincon' and Use an optimoptions Object to Set the Algorithm for a PortfolioCVaR Object

Use `'fmincon'` as the `solverType` and use an `optimoptions` object to set the algorithm to `'interior-point'` and to turn off the display.

```
p = PortfolioCVaR;
options = optimoptions('fmincon', 'Algorithm', 'interior-point', 'Display', 'off');
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
```

```
interior-point
```

```
display(p.solverOptions.Display);
```

```
off
```

Set `'TrustRegionCP'` as the Solver Type with Default Options for a PortfolioCVaR Object

Use `'TrustRegionCP'` as the `solverType` with default options.

```
p = PortfolioCVaR;
p = setSolver(p,'TrustRegionCP');
display(p.solverType);
```

```
trustregioncp
```

```
display(p.solverOptions);
```

```
  struct with fields:

                MaxIterations: 1000
         AbsoluteGapTolerance: 1.0000e-07
         RelativeGapTolerance: 1.0000e-05
       NonlinearScalingFactor: 1000
       ObjectiveScalingFactor: 1000
            MainSolverOptions: [1x1 optim.options.Linprog]
                      Display: 'off'
                CutGeneration: 'basic'
     MaxIterationsInactiveCut: 30
           ActiveCutTolerance: 1.0000e-07
                  ShrinkRatio: 0.7500

                 InitialDelta: 0.5000
                   DeltaLimit: 1000000
```

Set 'TrustRegionCP' as the Solver Type with 'ShrinkRatio' for a PortfolioCVaR Object

Use the name-value pair `'ShrinkRatio'` to shrink the size of the trust region by `0.75`.

```
p = PortfolioCVaR;
p = setSolver(p,'TrustRegionCP','ShrinkRatio',0.75);
display(p.solverType);
```

```
trustregioncp
```

```
display(p.solverOptions);
```

```
  struct with fields:

                MaxIterations: 1000
         AbsoluteGapTolerance: 1.0000e-07
         RelativeGapTolerance: 1.0000e-05
       NonlinearScalingFactor: 1000
       ObjectiveScalingFactor: 1000
            MainSolverOptions: [1x1 optim.options.Linprog]
                      Display: 'off'
                CutGeneration: 'basic'
     MaxIterationsInactiveCut: 30
           ActiveCutTolerance: 1.0000e-07
                  ShrinkRatio: 0.7500
    TrustRegionStartIteration: 2
                 InitialDelta: 0.5000
                   DeltaLimit: 1000000
```

Set 'TrustRegionCP' as the Solver Type and Change the Main Solver Option for a PortfolioCVaR Object

For the main solver, continue using the `dual-simplex` algorithm with no display, but tighten its termination tolerance to `1e8`.

```
p = PortfolioCVaR;
options = optimoptions('linprog','Algorithm','Dual-Simplex','Display','off','OptimalityTolerance
p = setSolver(p,'TrustRegionCP','MainSolverOptions',options);
display(p.solverType)
```

```
trustregioncp
```

```
display(p.solverOptions)
```

```
  struct with fields:

                MaxIterations: 1000
         AbsoluteGapTolerance: 1.0000e-07
         RelativeGapTolerance: 1.0000e-05
       NonlinearScalingFactor: 1000
       ObjectiveScalingFactor: 1000
            MainSolverOptions: [1x1 optim.options.Linprog]
                      Display: 'off'
                CutGeneration: 'basic'
     MaxIterationsInactiveCut: 30
           ActiveCutTolerance: 1.0000e-07
                  ShrinkRatio: 0.7500
    TrustRegionStartIteration: 2
                 InitialDelta: 0.5000
                   DeltaLimit: 1000000
```

```
display(p.solverOptions.MainSolverOptions.Algorithm)
```

```
dual-simplex
```

```
display(p.solverOptions.MainSolverOptions.Display)
```

```
off
```

```
display(p.solverOptions.MainSolverOptions.TolFun)
```

```
   100000000
```

For the main solver, use the `interior-point` algorithm with no display and with a termination tolerance of `1e7`.

```
p = PortfolioCVaR;
options = optimoptions('linprog','Algorithm','interior-point','Display','off','OptimalityToleran
p = setSolver(p,'TrustRegionCP','MainSolverOptions',options);
display(p.solverType)
```

```
trustregioncp
```

```
display(p.solverOptions)
```

```
  struct with fields:

                MaxIterations: 1000
         AbsoluteGapTolerance: 1.0000e-07
         RelativeGapTolerance: 1.0000e-05
       NonlinearScalingFactor: 1000
       ObjectiveScalingFactor: 1000
            MainSolverOptions: [1x1 optim.options.Linprog]
                      Display: 'off'
                CutGeneration: 'basic'
     MaxIterationsInactiveCut: 30
           ActiveCutTolerance: 1.0000e-07
                  ShrinkRatio: 0.7500
    TrustRegionStartIteration: 2
                 InitialDelta: 0.5000
                   DeltaLimit: 1000000
```

```
display(p.solverOptions.MainSolverOptions.Algorithm)
```

```
interior-point
```

```
display(p.solverOptions.MainSolverOptions.Display)
```

```
off
```

```
display(p.solverOptions.MainSolverOptions.TolFun)
```

```
    10000000
```

Set Solver Type as 'fmincon' for a PortfolioMAD Object

Use 'fmincon' as the solverType.

```
p = PortfolioMAD;
p = setSolver(p, 'fmincon');
display(p.solverType);
```

```
fmincon
```

Set the Solver Type as 'fmincon' and Use Name-Value Pair Arguments to Set the Algorithm for a PortfolioMAD Object

Use 'fmincon' as the solverType and use name-value pair arguments to set the algorithm to 'sqp' and to turn on the display.

```
p = PortfolioMAD;
p = setSolver(p, 'fmincon', 'Algorithm', 'sqp', 'Display', 'final');
display(p.solverOptions.Algorithm);
```

```
sqp
```

```
display(p.solverOptions.Display);
```

```
final
```

Set Solver Type as 'fmincon' and Use an optimoptions Structure to Set the Algorithm for a PortfolioMAD Object

Use `'fmincon'` as the `solverType` and use an `optimoptions` object to set the algorithm to `'trust-region-reflective'` and to turn off the display.

```
p = PortfolioMAD;
options = optimoptions('fmincon', 'Algorithm', 'trust-region-reflective', 'Display', 'off');
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
```

```
trust-region-reflective
```

```
display(p.solverOptions.Display);
```

```
off
```

Set the Solver Type as 'fmincon' and Use an optimoptions Structure to Set the Algorithm and Use of Gradients for a PortfolioMAD Object

Use `'fmincon'` as the `solverType` and use an `optimoptions` object to set the algorithm to `'active-set'` and to set the gradients flag `'on'` for `'GradObj'` and turn off the display.

```
p = PortfolioMAD;
options = optimoptions('fmincon','algorithm','active-set','display','off','gradobj','on');
p = setSolver(p, 'fmincon', options);
display(p.solverOptions.Algorithm);
```

```
active-set
```

```
display(p.solverOptions.Display);
```

```
off
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`solverType` — Solver to use for portfolio optimization

character vector | string

Solver to use for portfolio optimization, specified using a character vector or string for the supported `solverType`.

The solverType input argument depends on which type of object (obj) is being used for a portfolio optimization.

For a Portfolio object, the supported solverType are:

- 'lcprog' (Default).
  - The 'lcprog' solver uses linear complementary programming with Lemke's algorithm with control variables name-value pair arguments for 'maxiter', 'tiebreak', 'tolpiv'. For more information about 'lcprog' name-value pair options, see “Portfolio Object Name-Value Pair Arguments” on page 15-1383.
- 'fmincon'
  - The default algorithm for 'fmincon' is 'sqp'. For more information about 'fmincon' name-value pair options, see “Portfolio Object Name-Value Pair Arguments” on page 15-1383.
- 'quadprog'
  - The default algorithm for 'quadprog' is interior-point-convex. For more information about 'quadprog' name-value pair options, see “Portfolio Object Name-Value Pair Arguments” on page 15-1383.

For a PortfolioCVaR object, the supported solverType are:

- 'TrustRegionCP' (Default)
  - 'TrustRegionCP' is an implementation of Kelley's [1] cutting-plane method for convex optimization. For more information about 'TrustRegionCP' name-value pair options, see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 15-1385.
- 'ExtendedCP'
  - 'ExtendedCP' is an implementation of Kelley's [1] cutting-plane method for convex optimization. For more information about 'ExtendedCP' name-value pair options, see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 15-1385.
- 'fmincon'
  - The default algorithm for 'fmincon' is 'sqp'. For more information about 'fmincon' name-value pair options, see “PortfolioCVaR Object Name-Value Pair Arguments” on page 15-1384.
- 'cuttingplane'
  - The 'cuttingplane' solver is an implementation of Kelley's [1] cutting-plane method for convex optimization with name-value pair arguments for 'MaxIter', 'Abstol', 'Reltol' and 'MainSolverOptions'. For more information about 'cuttingplane' name-value pair options, see “PortfolioCVaR Object Name-Value Pair Arguments” on page 15-1384.

For a PortfolioMAD object, the supported solverType are:

- 'TrustRegionCP' (Default)
  - 'TrustRegionCP' is an implementation of Kelley's [1] cutting-plane method for convex optimization. For more information about 'TrustRegionCP' name-value pair options, see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 15-1385.
- 'ExtendedCP'

  - 'ExtendedCP' is an implementation of Kelley's [1] cutting-plane method for convex optimization. For more information about 'ExtendedCP' name-value pair options, see "Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'" on page 15-1385.
- 'fmincon'
  - The default algorithm for 'fmincon' is the 'sqp' algorithm and 'GradObj' set to 'on'. For more information about 'fmincon' name-value pair options, see "PortfolioMAD Object Name-Value Pair Arguments" on page 15-1385.

Note setSolver can also configure solver options for 'linprog'. linprog is a helper solver used in estimating efficient frontier problems for a Portfolio, PorfolioCVaR, or PortfolioMAD object. The default algorithm for 'linprog' is 'dual-simplex'. For more information about 'linprog' name-value pair options, see "Name-Value Pair Arguments" on page 15-1383. For more details on using a helper solver, see "Solver Guidelines for Portfolio Objects" on page 4-111, "Solver Guidelines for PortfolioCVaR Objects" on page 5-97, or "Solver Guidelines for PortfolioMAD Objects" on page 6-93.

Data Types: char | string

optimoptions — optimoptions object
object

(Optional) optimoptions object, specified as an optimoptions object that is created using optimoptions from Optimization Toolbox. For example:

```
p = setSolver(p,'fmincon',optimoptions('fmincon','Display','iter'));
```

Note optimoptions is the default and recommended method to set solver options, however optimset is also supported.

Data Types: object

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: p = setSolver(p,'cuttingplane','MainSolverOptions',options) sets cuttingplane options for a PortfolioCVaR object.

Depending on the obj type (Portfolio, PortfolioCVaR, or PortfolioMAD) and the specified solverType, the options for the associated name-value pair arguments are different.

Portfolio Object Name-Value Pair Arguments

- For a Portfolio object using a solverType of lcprog, choose a name-value value in this table.

Value	Description
'maxiter'	Maximum number of iterations,specified as the comma-separated pair consisting of 'MaxIter' and a positive integer. The default value is 1 + n^3, where n is the dimension of the input.
'tiebreak'	Method to break ties for pivot selection, specified as the comma-separated pair consisting of 'tiebreak' and one of the following options: • first - Select pivot with lowest index. • last - Select pivot with highest index. • random - Select a pivot at random. The default value is first.
'tolpiv'	Pivot tolerance below which a number is considered to be zero, specified as the comma-separated pair consisting of 'tolpiv' and a numeric value. The default value is 1.0e-9.

- For a Portfolio object using a solverType of fmincon, see “options” to choose name-value pair arguments.
- For a Portfolio object using a solverType of linprog, see “options” to choose name-value pair arguments.
- For a Portfolio object using a solverType of quadprog, see “options” to choose name-value pair arguments.

PortfolioCVaR Object Name-Value Pair Arguments

- For a PortfolioCVaR object using a solverType of fmincon, see “options” to choose name-value pair arguments.
- For a PorfolioCVaR object using a solverType of 'TrustRegionCP' or 'ExtendedCP', see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 15-1385 to choose name-value pair arguments.
- For a PorfolioCVaR object using a solverType of 'cuttingplane', choose a name-value pair value in this table.

Value	Description
'MaxIter'	Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer. The default value is 1000.
'AbsTol'	Absolute stopping tolerance, specified as the comma-separated pair consisting of 'AbsTol' and a positive scalar. The default value is 1e6.
'RelTol'	Relative stopping tolerance, specified as the comma-separated pair consisting of 'RelTol' and a positive scalar. The default value is 1e5.
'MainSolverOptions'	Options for the main solver linprog, specified as the comma-separated pair consisting of 'MainSolverOptions' and an optimoptions object. The default is optimoptions('linprog','Algorithm','Dual-Simplex','Display','off').

- For a `PortfolioCVaR` object using a `solverType` of `linprog`, see “options” to choose name-value pair arguments.

`PortfolioMAD` Object Name-Value Pair Arguments

- For a `PortfolioMAD` object using a `solverType` of `fmincon`, see “options” to choose name-value pair arguments.
- For a `PorfolioMAD` object using a `solverType` of `'TrustRegionCP'` or `'ExtendedCP'`, see “Name-Value Pair Arguments for 'TrustRegionCP' and 'ExtendedCP'” on page 15-1385 to choose name-value pair arguments.
- For a `PortfolioMAD` object using a `solverType` of `linprog`, see “options” to choose name-value pair arguments.

Name-Value Pair Arguments for `'TrustRegionCP'` and `'ExtendedCP'`

For a `PortfolioCVaR` or `PortfolioMAD` object using a `solverType` of `'TrustRegionCP'` or `'ExtendedCP'`, choose a name-value pair value in this table.

Value	Description
`'MaxIterations'`	Maximum number of iterations, specified as the comma-separated pair consisting of `'MaxIterations'` and a positive real number. The default value is `1e3`.
`'NonlinearScalingFactor'`	Scales the nonlinear function and its gradient by a factor, specified as the comma-separated pair consisting of `'NonlinearScalingFactor'` and a positive real number. The default value is `1e3`.
`'ObjectiveScalingFactor'`	Scales the objective function by a factor, specified as the comma-separated pair consisting of `'ObjectiveScalingFactor'` and a positive real number. The default value is `1e3`.
`'AbsoluteGapTolerance'`	Solver stops if the absolute difference between the approximated nonlinear function value and its true value is less than or equal to `AbsoluteGapTolerance`, specified as the comma-separated pair consisting of `'AbsoluteGapTolerance'` and a positive real number. The default value is `1e7`.
`'RelativeGapTolerance'`	Solver stops if the relative difference between the approximated nonlinear function value and its true value is less than or equal to `RelativeGapTolerance`, specified as the comma-separated pair consisting of `'RelativeGapTolerance'` and a positive real number. The default value is `1e5`.
`'Display'`	Level of display, specified as the comma-separated pair consisting of `'Display'` and a supported value of: • `'iter'` displays output at each iteration and gives the technical exit message. • `'final'` displays just the final output and gives the final technical exit message. • `'off'` is the default and displays no output.

Value	Description
'CutGeneration'	Method to add the cut, specified as the comma-separated pair consisting of 'CutGeneration' and a supported value of: • 'basic' is the default and the new cut is added at the latest solution found. • 'midway' is where the new cut is added at the mid point between the latest and previous solution found.
'MaxIterationsInactiveCut'	Removes constraints that are not active for the last MaxIterationsInactiveCut iterations, specified as the comma-separated pair consisting of 'MaxIterationsInactiveCut' and a positive integer. The default value is 30.
'ActiveCutTolerance'	Determines if the cuts are active and is used together with MaxIterationsInactiveCut to decide which cuts to remove from the LP subproblem, specified as the comma-separated pair consisting of 'ActiveCutTolerance' and a real number. The default value is 1e7.
'MainSolverOptions'	Options for the main solver linprog, specified as the comma-separated pair consisting of 'MainSolverOptions' and an optimoptions object. The default is optimoptions('linprog','Algorithm','Dual-Simplex','Display','off').
'TrustRegionStartIteration'	Use this parameter only for a solverType of 'TrustRegionCP'. Solver starts to apply the trust region heuristic at TrustRegionStartIteration. Nonnegative integer. Default is 2.
'ShrinkRatio'	Use this parameter only for a solverType of 'TrustRegionCP'. If the approximated functions are not agreeing well in the previous iterations, the algorithm will shrink the size of trust region by the ShrinkRatio. Nonnegative real between 0 and 1. Default is 0.75.
'InitialDelta'	Use this parameter only for a solverType of 'TrustRegionCP'. Value to initialize trust region. Nonnegative real. Default is 0.5.
'DeltaLimit'	Use this parameter only for a solverType of 'TrustRegionCP'. The trust region of the approximated functions is bounded by DeltaLimit during the iterations. The DeltaLimit value is a nonnegative real and the default value is 1e6. **Note** Modifying 'DeltaLimit' might result in the solver not being able to find a solution. If you modify 'DeltaLimit' without specifying a value for 'InitialDelta', the 'InitialDelta' is automatically set to InitialDelta' = 'DeltaLimit'/2.
'DeltaLowerBound'	Use this parameter only for a solverType of 'TrustRegionCP'. Use 'DeltaLowerBound' to set the lower bound for the trust-region radius. The 'DeltaLowerBound' numeric value must be in [0,1] and you can include 0 and 1. The default value is 0.01.

Output Arguments

obj — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Tips

You can also use dot notation to choose the solver and specify associated solver options.

```
obj = obj.setSolver(solverType,Name,Value);
```

Algorithms

To solve the efficient frontier of a portfolio, one version of the portfolio optimization problem minimizes the portfolio risk `Risk`(x), subject to a target return, and other linear constraints specified for the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For the definition of portfolio risk and return, see “Risk Proxy” on page 4-5 and “Return Proxy” on page 4-4.

$$Minimize_x Risk(x)$$

$$\text{subject to } \; Return(x) \geq TargetReturn$$

$$Ax \leq b$$

$$A_{eq}x = b_{eq}$$

$$lb \leq x \leq ub$$

An alternative version of the portfolio optimization problem maximizes the expected return of the portfolio, subject to a target risk and other linear constraints specified for the `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

$$Maximize_x Return(x)$$

$$\text{subject to } \; Risk(x) \leq \text{Targ}etRisk$$

$$Ax \leq b$$

$$A_{eq}x = b_{eq}$$

$$lb \leq x \leq ub$$

The return proxy is always a linear function. Therefore, depending on the risk proxy and whether it is used as the objective or constraints, the problem needs to be solved by different solvers. For example, `quadprog` is appropriate for problems with a quadratic function as the objective and only linear constraints, and `fmincon` is appropriate for problems with nonlinear objective or constraints. In addition, there are solvers in Financial Toolbox suitable for certain special types of problems, such as the `solverType` `lcprog`, `'TrustRegionCP'`, or `'ExtendedCP'`.

Version History

Introduced in R2011a

R2023a: Added name-value argument `'DeltaLowerBound'` for `solverType` of `'TrustRegionCP'`

When using a `solverType` of `'TrustRegionCP'`, you can use the name-value argument `'DeltaLowerBound'` to set the lower bound for the trust-region radius.

R2023a: Renamed `'MasterSolverOptions'` name-value argument to `'MainSolverOptions'`

The `'MasterSolverOptions'` name-value argument is renamed to `'MainSolverOptions'`. The use of `'MasterSolverOptions'` name-value argument is discouraged.

setSolverMINLP

Choose mixed integer nonlinear programming (MINLP) solver for portfolio optimization

Syntax

```
obj = setSolverMINLP(obj,solverTypeMINLP)
```

```
obj = setSolverMINLP(___,Name,Value)
```

Description

`obj = setSolverMINLP(obj,solverTypeMINLP)` selects the mixed integer nonlinear programming (MINLP) solver and enables you to specify associated solver options for portfolio optimization for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object.

When any one or any combination of `'Conditional'` `BoundType`, `MinNumAssets`, or `MaxNumAssets` constraints are active, the portfolio problem is formulated by adding `NumAssets` binary variables. The binary variable `0` indicates that an asset is not invested and the binary variable `1` indicates that an asset is invested. For more information on using `'Conditional'` `BoundType`, see `setBounds`. For more information on specifying `MinNumAssets` and `MaxNumAssets`, see `setMinMaxNumAssets`.

If you use the `estimate` functions with a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object for which any of the `'Conditional'` `BoundType`, `MinNumAssets`, or `MaxNumAssets` constraints are active, MINLP solver is automatically used. For details on MINLP, see “Algorithms” on page 15-1399.

`obj = setSolverMINLP(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Configure MINLP Solver and Options When Using a Portfolio Object

Configure the MINLP solver for a three-asset portfolio for which you have the mean and covariance values of the asset returns.

```
AssetMean = [ 0.0101110; 0.0043532; 0.0137058 ];
AssetCovar = [ 0.00324625 0.00022983 0.00420395;
               0.00022983 0.00049937 0.00019247;
               0.00420395 0.00019247 0.00764097 ];
p = Portfolio('AssetMean', AssetMean, 'AssetCovar', AssetCovar);
```

When working with a `Portfolio` object, use `setBounds` with a `'Conditional'BoundType` constraint to set xi = `0` or `0.02` <= xi <= `0.5` for all i = 1,...`NumAssets`.

```
p = setBounds(p, 0.02, 0.5,'BoundType', 'Conditional', 'NumAssets', 3);
```

When working with a `Portfolio` object, use `setMinMaxNumAssets` function to set up `MinNumAssets` and `MaxNumAssets` constraints for a portfolio. This sets limit constraints for the `Portfolio` object, where the total number of allocated assets satisfying the constraints is between

`MinNumAssets` and `MaxNumAssets`. Setting `MinNumAssets` = `MaxNumAssets` = 2, specifies that only two of the three assets are invested in the portfolio.

```
p = setMinMaxNumAssets(p, 2, 2);
```

Three different MINLP solvers (`OuterApproximation`, `ExtendedCP`, `TrustRegionCP`) use the cutting plane method. Use the `setSolverMINLP` function to configure the `OuterApproximation` solver and options.

```
pint = setSolverMINLP(p,'OuterApproximation', 'NonlinearScalingFactor', 1e4, 'Display', 'iter',
pint.solverTypeMINLP
```

```
ans = 
'OuterApproximation'
```

```
pint.solverOptionsMINLP
```

```
ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
                    RelativeGapTolerance: 1.0000e-05
                  NonlinearScalingFactor: 10000
                  ObjectiveScalingFactor: 1000
                                 Display: 'iter'
                           CutGeneration: 'basic'
                MaxIterationsInactiveCut: 30
                      ActiveCutTolerance: 1.0000e-07
                    IntMainSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

You can also configure the options for `intlinprog`,which is the Main solver for mixed integer linear programming problems in the MINLP solver.

```
pint = setSolverMINLP(p,'OuterApproximation', 'IntMainSolverOptions', optimoptions('intlinprog',
pint.solverOptionsMINLP.IntMainSolverOptions
```

```
ans = 
  intlinprog options:

   Set properties:
                          Display: 'off'

   Default properties:
             AbsoluteGapTolerance: 0
                       BranchRule: 'reliability'
              ConstraintTolerance: 1.0000e-04
                    CutGeneration: 'basic'
                 CutMaxIterations: 10
                       Heuristics: 'basic'
               HeuristicsMaxNodes: 50
                IntegerPreprocess: 'basic'
                 IntegerTolerance: 1.0000e-05
                  LPMaxIterations: 'max(30000,10*(numberOfEqualities+numberOfInequalities+number
            LPOptimalityTolerance: 1.0000e-07
                MaxFeasiblePoints: Inf
                         MaxNodes: 10000000
                          MaxTime: 7200
                    NodeSelection: 'simplebestproj'
                 ObjectiveCutOff: Inf
    ObjectiveImprovementThreshold: 0
                       OutputFcn: []
                         PlotFcn: []
             RelativeGapTolerance: 1.0000e-04
                  RootLPAlgorithm: 'dual-simplex'
              RootLPMaxIterations: 'max(30000,10*(numberOfEqualities+numberOfInequalities+number(
```

Configure MINLP Solver and Options When Using a PortfolioCVaR Object

Configure the MINLP solver for a 12 asset portfolio that is using semicontinuous and cardinality constraints.

```
load CAPMuniverse
p = PortfolioCVaR('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12),20000,'missingdata',true);
p = setProbabilityLevel(p, 0.95);
```

When working with a `PortfolioCVaR` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested. The following example specifies that a minimum of five assets and a maximum of 10 assets should be invested using `setMinMaxNumAssets` and the investments should be greater than 4% and less than 45% using `setBounds`.

```
p = setMinMaxNumAssets(p, 5, 10);
p = setBounds(p, 0.04, 0.45, 'BoundType','conditional');
```

Three different MINLP solvers (`OuterApproximation`, `ExtendedCP`, `TrustRegionCP`) use the cutting plane method. Use the `setSolverMINLP` function to configure the `OuterApproximation` solver and options.

```
pint = setSolverMINLP(p,'OuterApproximation','NonlinearScalingFactor', 1e4, 'Display', 'iter', '(
pint.solverTypeMINLP
```

```
ans = 
'OuterApproximation'
```

```
pint.solverOptionsMINLP
```

```
ans = struct with fields:
                       MaxIterations: 1000
                si AbsoluteGapTolerance: 1.0000e-07
```

```
pint = setSolverMINLP(p,'OuterApproximation','IntMainSolverOptions', optimoptions('intlinprog','D
pint.solverOptionsMINLP.IntMainSolverOptions

ans = 
  intlinprog options:

   Set properties:
                           Display: 'off'

   Default properties:
             AbsoluteGapTolerance: 0
                       BranchRule: 'reliability'
              ConstraintTolerance: 1.0000e-04
                    CutGeneration: 'basic'
                 CutMaxIterations: 10
                       Heuristics: 'basic'
               HeuristicsMaxNodes: 50
                IntegerPreprocess: 'basic'
                 IntegerTolerance: 1.0000e-05
                  LPMaxIterations: 'max(30000,10*(numberOfEqualities+numberOfInequalities+number
            LPOptimalityTolerance: 1.0000e-07
                MaxFeasiblePoints: Inf
                         MaxNodes: 10000000
                          MaxTime: 7200
                    NodeSelection: 'simplebestproj'
                  ObjectiveCutOff: Inf
    ObjectiveImprovementThreshold: 0
                        OutputFcn: []
                          PlotFcn: []
             RelativeGapTolerance: 1.0000e-04
                  RootLPAlgorithm: 'dual-simplex'
              RootLPMaxIterations: 'max(30000,10*(numberOfEqualities+numberOfInequalities+number
```

Configure MINLP Solver and Options When Using a PortfolioMAD Object

Configure the MINLP solver for a 12 asset portfolio that is using semicontinuous and cardinality constraints.

```
load CAPMuniverse
p = PortfolioMAD('AssetList',Assets(1:12));
p = simulateNormalScenariosByData(p, Data(:,1:12), 20000 ,'missingdata',true);
```

When working with a `PortfolioMAD` object, the `setMinMaxNumAssets` function enables you to set up the limits on the number of assets invested. The following example specifies that a minimum of five assets and a maximum of 10 assets should be invested using `setMinMaxNumAssets` and the investments should be greater than 4% and less than 45% using `setBounds`.

```
p = setMinMaxNumAssets(p, 5, 10);
p = setBounds(p, 0.04, 0.45, 'BoundType', 'conditional');
```

Three different MINLP solvers (`OuterApproximation`, `ExtendedCP`, `TrustRegionCP`) use the cutting plane method. Use the `setSolverMINLP` function to configure the `OuterApproximation` solver and options.

```
pint = setSolverMINLP(p,'OuterApproximation', 'NonlinearScalingFactor', 1e4, 'Display', 'iter',
pint.solverTypeMINLP
```

```
ans = 
'OuterApproximation'
```

```
pint.solverOptionsMINLP
```

```
ans = struct with fields:
                           MaxIterations: 1000
                    AbsoluteGapTolerance: 1.0000e-07
                    RelativeGapTolerance: 1.0000e-05
                  NonlinearScalingFactor: 10000
                  ObjectiveScalingFactor: 1000
                                 Display: 'iter'
                           CutGeneration: 'basic'
                MaxIterationsInactiveCut: 30
                      ActiveCutTolerance: 1.0000e-07
                    IntMainSolverOptions: [1x1 optim.options.Intlinprog]
    NumIterationsEarlyIntegerConvergence: 30
```

You can also configure the options for `intlinprog`,which is the Main solver for mixed integer linear programming problems in the MINLP solver.

```
pint = setSolverMINLP(p,'OuterApproximation', 'IntMainSolverOptions', optimoptions('intlinprog',
pint.solverOptionsMINLP.IntMainSolverOptions
```

```
ans = 
  intlinprog options:

   Set properties:
                          Display: 'off'

   Default properties:

                       BranchRule: 'reliability'
              ConstraintTolerance: 1.0000e-04
                    CutGeneration: 'basic'
                 CutMaxIterations: 10
                       Heuristics: 'basic'
               HeuristicsMaxNodes: 50
                IntegerPreprocess: 'basic'
                 IntegerTolerance: 1.0000e-05
                  LPMaxIterations: 'max(30000,10*(numberOfEqualities+numberOfInequalities+number
             LPOptimalityTolerance: 1.0000e-07
                MaxFeasiblePoints: Inf
                         MaxNodes: 10000000
                          MaxTime: 7200
                    NodeSelection: 'simplebestproj'
                  ObjectiveCutOff: Inf
    ObjectiveImprovementThreshold: 0
                        OutputFcn: []
                          PlotFcn: []
             RelativeGapTolerance: 1.0000e-04
                  RootLPAlgorithm: 'dual-simplex'
              RootLPMaxIterations: 'max(30000,10*(numberOfEqualities+numberOfInequalities+number
```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using Portfolio, PortfolioCVaR, or PortfolioMAD object. For more information on creating a portfolio object, see

- Portfolio
- PortfolioCVaR
- PortfolioMAD

Data Types: object

solverTypeMINLP — MINLP solver for portfolio optimization
character vector with a value of 'OuterApproximation', 'ExtendedCP', or 'TrustRegionCP' | string with a value of "OuterApproximation", "ExtendedCP", or "TrustRegionCP"

MINLP solver for portfolio optimization when any one or any combination of 'Conditional' BoundType, MinNumAssets, or MaxNumAssets constraints are active. Specify solverTypeMINLP using a character vector or string with a value of 'OuterApproximation', 'ExtendedCP', or 'TrustRegionCP'.

For a Portfolio object, the default value of the solverTypeMINLP is 'OuterApproximation' with the following default settings for name-value pairs for setSolverMINLP:

- MaxIterations — 1000
- AbsoluteGapTolerance — 1.0000e-07
- RelativeGapTolerance — 1.0000e-05
- Display — 'off'
- NonlinearScalingFactor — 1000
- ObjectiveScalingFactor — 1000
- CutGeneration — 'basic'
- MaxIterationsInactiveCut — 30
- NumIterationsEarlyIntegerConvergence — 30
- ActiveCutTolerance — 1.0000e-07
- IntMainSolverOptions — optimoptions('intlinprog','Algorithm','Dual-Simplex','Display','off')

For a PortfolioCVaR and PortfolioMAD object, the default value of the solverTypeMINLP is 'TrustRegionCP' with the following default settings for name-value pairs for setSolverMINLP:

- MaxIterations — 1000
- AbsoluteGapTolerance — 1.0000e-07
- RelativeGapTolerance — 1.0000e-05
- Display — 'off'
- NonlinearScalingFactor — 1000
- ObjectiveScalingFactor — 1000

- CutGeneration — 'basic'
- MaxIterationsInactiveCut — 30
- NumIterationsEarlyIntegerConvergence — 30
- ActiveCutTolerance — 1.0000e-07
- TrustRegionStartIteration - 2
- ShrinkRatio — 0.75
- InitialDelta — 0.5
- DeltaLimit — 1e6
- DeltaLowerBound — 0.01
- IntMainSolverOptions — optimoptions('intlinprog','Algorithm','Dual-Simplex','Display','off')

Data Types: char | string

Name-Value Pair Arguments or optimoptions Object

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: p = setSolverMINLP(p,'ExtendedCP','MaxIterations',10000,'NonlinearScalingFactor',1000)

MaxIterations — Maximum number of iterations
1000 (default) | nonnegative integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIterations' and a nonnegative integer value.

Data Types: double

NonlinearScalingFactor — Scaling factor for nonlinear function and gradient
1000 (default) | nonnegative real

Scaling factor for nonlinear function and gradient, specified as the comma-separated pair consisting of 'NonlinearScalingFactor' and a nonnegative real value.

Data Types: double

ObjectiveScalingFactor — Scales the objective function used by MainSolver by a factor
1000 (default) | nonnegative real

Scales the objective function used by MainSolver by a factor, specified as the comma-separated pair consisting of 'ObjectiveScalingFactor' and a nonnegative real value.

Data Types: double

AbsoluteGapTolerance — Solver stops if absolute difference between approximated nonlinear function value and its true value is less than or equal to AbsoluteGapTolerance
0.0000001 (default) | nonnegative real

The solver stops if the absolute difference between the approximated nonlinear function value and its true value is less than or equal to AbsoluteGapTolerance. AbsoluteGapTolerance is specified as the comma-separated pair consisting of 'AbsoluteGapTolerance' and a nonnegative real value.

Data Types: double

RelativeGapTolerance — Solver stops if the relative difference between approximated nonlinear function value and its true value is less than or equal to RelativeGapTolerance
0.00001 (default) | nonnegative real

The solver stops if the relative difference between the approximated nonlinear function value and its true value is less than or equal to RelativeGapTolerance. RelativeGapTolerance is specified as the comma-separated pair consisting of 'AbsoluteGapTolerance' and a nonnegative real value.

Data Types: double

Display — Display output format
'off' (default) | character vector with value of 'iter', 'final', or 'off'

Display output format, specified as the comma-separated pair consisting of 'Display' and a character vector with a value of:

- 'off' - Display no output
- 'iter' - Display output at each iteration and the technical exit message
- 'final' - Display only the final output and the final technical exit message

Data Types: char

CutGeneration — Cut specification
'basic' (default) | character vector with value of 'midway' or 'basic'

Cut specification, specified as the comma-separated pair consisting of 'CutGeneration' and a character vector with one of these values:

- 'midway' - Add the new cut at the midpoint between the latest and previous solutions found.
- 'basic' - Add the new cut at the latest solution found.

Data Types: char

MaxIterationsInactiveCut — Removes constraints that are not active for last MaxIterationsInactiveCut iterations
30 (default) | nonnegative integer

Removes constraints that are not active for the last MaxIterationsInactiveCut iterations, specified as the comma-separated pair consisting of 'MaxIterationsInactiveCut' and a nonnegative integer value. Generally, the MaxIterationsInactiveCut value is larger than 10.

Data Types: double

NumIterationsEarlyIntegerConvergence — When integer variable solution is stable for the last NumIterationsEarlyIntegerConvergence iterations, the solver computes a final NLP by using latest integer variable solution in the MILP
30 (default) | nonnegative integer

When the integer variable solution is stable for the last NumIterationsEarlyIntegerConvergence iterations, the solver computes a final NLP by using the latest integer variable solution in the MILP. NumIterationsEarlyIntegerConvergence is specified as the comma-separated pair consisting of 'NumIterationsEarlyIntegerConvergence' and a nonnegative integer value.

Data Types: double

ActiveCutTolerance — Determines if the cuts are active
0.0000001 (default) | nonnegative real

Determines if the cuts are active, specified as the comma-separated pair consisting of 'ActiveCutTolerance' and a nonnegative real value. ActiveCutTolerance is used together with MaxIterationsInactiveCut to decide which cuts to remove from the MILP subproblem.

Data Types: double

TrustRegionStartIteration — Solver starts to apply trust region heuristic at TrustRegionStartIteration
2 (default) | nonnegative integer

Solver starts to apply the trust region heuristic at TrustRegionStartIteration, specified as the comma-separated pair consisting of 'TrustRegionStartIteration' and a nonnegative integer.

Note The TrustRegionStartIteration name-value pair argument can only be used with a solverTypeMINLP of 'TrustRegionCP'.

Data Types: double

ShrinkRatio — Ratio to shrink size of trust region
0.75 (default) | nonnegative real between 0 and 1

Ratio to shrink size of trust region, specified as the comma-separated pair consisting of 'ShrinkRatio' and a nonnegative real value between 0 and 1. If the approximated functions do not have good agreement in the previous iterations, the algorithm uses this ratio to shrink the trust-region size.

Note The ShrinkRatio name-value pair argument can only be used with a solverTypeMINLP of 'TrustRegionCP'.

Data Types: double

InitialDelta — Value to initialize trust region
0.5 (default) | nonnegative real

Value to initialize trust region, specified as the comma-separated pair consisting of 'InitialDelta' and a nonnegative real value.

Note The InitialDelta name-value pair argument can only be used with a solverTypeMINLP of 'TrustRegionCP'.

Data Types: double

DeltaLimit — Trust region of the approximated functions is bounded by DeltaLimit during iterations

1e6 (default) | nonnegative real

Trust region of the approximated functions is bounded by DeltaLimit during the iterations, specified as the comma-separated pair consisting of 'DeltaLimit' and a nonnegative real value.

Note The DeltaLimit name-value pair argument can only be used with a solverTypeMINLP of 'TrustRegionCP'.

Modifying 'DeltaLimit' might result in the solver not being able to find a solution.

If you modify 'DeltaLimit' without specifying a value for 'InitialDelta', the 'InitialDelta' is automatically set to InitialDelta' = 'DeltaLimit'/2.

Data Types: double

DeltaLowerBound — Set lower bound for trust-region radius

0.01 (default) | numeric value in [0,1]

Set lower bound for the trust-region radius, specified as the comma-separated pair consisting of 'DeltaLowerBound' and a numeric value in [0,1] that can include 0 and 1.

Note The DeltaLowerBound name-value pair argument can only be used with a solverTypeMINLP of 'TrustRegionCP'.

Data Types: double

IntMainSolverOptions — Options for main solver

optimoptions('intlinprog','Display','off', 'ConstraintTolerance',1e5,'MaxTime',1000,'IPPreprocess','none','CutGeneration','advanced','Heuristics','rins','IntegerTolerance',1e5, 'NodeSelection','mininfeas','LPPreprocess','none') (default) | optimoptions object

Options for the main solverintlinprog, specified as the comma-separated pair consisting of 'IntMainSolverOptions' and an optimoptions object.

Example: 'IntMainSolverOptions', optimoptions('intlinprog','Display','off')

Output Arguments

obj — Updated portfolio object

object

Updated portfolio object, returned as a Portfolio, PortfolioCVaR, or PortfolioMAD object.

More About

MINLP Solvers

All three MINLP solvers (`'OuterApproximation'`, `'ExtendedCP'`, and `'TrustRegionCP'`) defined by `solverTypeMINLP` rely on the cutting plane concept.

These MINLP solvers approximate the nonlinear convex function $f(x)$ by a piecewise linear approximation, which is a sequence of linear cuts around the original function. In this way, the original MINLP is reduced to a sequence of MILP subproblems, each one with a more refined approximation to $f(x)$ than previous MILPs, and yields a more optimal solution. The process continues until the solution found from MILP converges to the true function value within a certain tolerance.

- The `'ExtendedCP'` solver iteratively adds a linear cut at the latest solution found to approximate $f(x)$.
- The `'OuterApproximation'` solver is similar to `'ExtendedCP'`, but they differ in where to add the cut. Instead of using the solution from the latest MILP, `OuterApproximation` uses the values of integer variables from the latest MILP solution and fixes them to reduce the MINLP to a nonlinear programming (NLP) problem. The cut is added at the solution from this NLP problem.
- The `'TrustRegionCP'` solver is a version of `'ExtendedCP'` that is modified to speed up the optimization process. In general, the trust region method uses a model to approximate the true function within a region at each iteration. In the context of the MINLP solver, the model is the maximum of all the added cuts. The true function is the nonlinear function $f(x)$ in the optimization problem. The region of the model is updated based on how well the model approximates the true function for the iteration. This approximation is the comparison of the predicted reduction of the objective function using the model vs. the true reduction.

Tips

You can also use dot notation to specify associated name-value pair options.

```
obj = obj.setSolverMINLP(Name,Value);
```

Note The `solverTypeMINLP` and `solverOptionsMINLP` properties cannot be set using dot notation because they are hidden properties. To set the `solverTypeMINLP` and `solverOptionsMINLP` properties, use the `setSolverMINLP` function directly.

Algorithms

When any one, or any combination of `'Conditional'` `BoundType`, `MinNumAssets`, or `MaxNumAssets` constraints is active, the portfolio problem is formulated by adding `NumAssets` binary variables. The binary variable `0` indicates that an asset is not invested and the binary variable `1` indicates that an asset is invested.

The `MinNumAssets` and `MaxNumAssets` constraints narrow down the number of active positions in a portfolio to the range of [*minN*, *maxN*]. In addition, the `'Conditional'` `BoundType` constraint is to set a lower and upper bound so that the position is either `0` or lies in the range [*minWgt*, *maxWgt*]. These two types of constraints are incorporated into the portfolio optimization model by introducing n variables, ν_i, which only take binary values `0` and `1` to indicate whether the corresponding asset is invested (`1`) or not invested (`0`). Here n is the total number of assets and the constraints can be formulated as the following linear inequality constraints:

$$minN \leq \sum_{i=1}^{n} \upsilon_i \leq \ maxN$$

$$minWgt * \upsilon_i \leq x_i \leq maxWgt * \upsilon_i$$

$$0 \leq \upsilon \leq 1$$

υ_i are integers

In this equation, *minN* and *maxN* are representations for `MinNumAsset` and `MaxNumAsset` that are set using `setMinMaxNumAssets`. Also, *minWgt* and *maxWgt* are representations for `LowerBound` and `UpperBound` that are set using `setBounds`.

The portfolio optimization problem to minimize the variance of the portfolio, subject to achieving a target expected return and some additional linear constraints on the portfolio weights, is formulated as

$$minimize_x \ \ x^T Hx$$

$$s.t. \ \ m^T x \geq TargetReturn$$

$$Ax \leq b$$

$$A_{eq}x = b_{eq}$$

$$lb \leq x \leq ub$$

In this equation, *H* represents the covariance and *m* represents the asset returns.

The portfolio optimization problem to maximize the return, subject to an upper limit on the variance of the portfolio return and some additional linear constraints on the portfolio weights, is formulated as

$$maximize_x \ \ m^T x$$

$$s.t. \ \ x^T Hx \leq TargetRisk$$

$$Ax \leq b$$

$$A_{eq}x = b_{eq}$$

$$lb \leq x \leq ub$$

When the `'Conditional'` `BoundType`, `MinNumAssets`, and `MaxNumAssets` constraints are added to the two optimization problems, the problems become:

$$minimize_{x\upsilon} \ \ x^T Hx$$

$$s.t. \ \ m^T x \geq TargetReturn$$

$$A'[x;\upsilon] \leq b'$$

$$A_{eq}x = b_{eq}$$

$$minN \leq \sum_{i=1}^{n} \upsilon_i \leq maxN$$

$$minWgt(\upsilon_i) \leq x_i \leq maxWgt(\upsilon_i)$$

$$lb \leq x \leq ub$$

$$0 \leq \upsilon \leq 1$$

υ_i are integers

$$
\begin{aligned}
&maximize_{x\upsilon} \;\; m^T x \\
&s.t. \;\; x^T H x \geq TargetRisk \\
&A'[x; \upsilon] \leq b' \\
&A_{eq} x = b_{eq} \\
&minN \leq \sum_{i=1}^{n} \upsilon_i \leq maxN \\
&minWgt * \upsilon_i \leq x_i \leq maxWgt(\upsilon_i) \\
&0 \leq \upsilon \leq 1 \\
&\upsilon_i \text{ are integers}
\end{aligned}
$$

Version History

Introduced in R2018b

R2023a: Added name-value argument `'DeltaLowerBound'` for `solverTypeMINLP` of `'TrustRegionCP'`

When using a `solverTypeMINLP` of `'TrustRegionCP'`, you can use the `'DeltaLowerBound'` name-value argument to set the lower bound for the trust-region radius.

R2023a: Renamed `'IntMasterSolverOptions'` name-value argument to `'IntMainSolverOptions'`

The `'IntMasterSolverOptions'` name-value argument is renamed to `'IntMainSolverOptions'`. The use of `'IntMasterSolverOptions'` name-value argument is discouraged.

setScenarios

Set asset returns scenarios by direct matrix

Note Using a `fints` object for the `AssetScenarios` argument of `setScenarios` is not recommended. Use `timetable` instead for financial time series. For more information, see “Convert Financial Time Series Objects (fints) to Timetables”.

Syntax

```
obj = setScenarios(obj,AssetScenarios)
obj = setScenarios(obj,AssetScenarios,Name,Value)
```

Description

`obj = setScenarios(obj,AssetScenarios)` sets asset returns scenarios by direct matrix for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-16, and “PortfolioMAD Object Workflow” on page 6-15.

`obj = setScenarios(obj,AssetScenarios,Name,Value)` set asset returns scenarios by direct matrix for `PortfolioCVaR` or `PortfolioMAD` objects using additional options specified by one or more `Name,Value` pair arguments.

Examples

Set Asset Returns Scenarios for a PortfolioCVaR Object

Given a PortfolioCVaR object `p`, use the `setScenarios` function to set asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
disp(p)
```

```

Set Asset Returns Scenarios for a PortfolioMAD Object

Given PortfolioMAD object `p`, use the `setScenarios` function to set asset return scenarios.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
disp(p)
```

```

Set Asset Returns Scenarios for a PortfolioCVaR Object Using Timetable Data

To illustrate using the `setScenarios` function with `AssetScenarios` data continued in a `timetable` object, use the `CAPMuniverse.mat` which contains a `timetable` object (`AssetTimeTable`) for returns data.

```
load CAPMuniverse;
AssetsTimeTable.Properties;
head(AssetsTimeTable,5)
```

```
       Time          AAPL         AMZN         CSCO         DELL         EBAY       GOOG       HP
    ___________    _________    _________    _________    _________    _________    ____    _____

    03-Jan-2000     0.088805       0.1742     0.008775    -0.002353      0.12829    NaN       0.0
    04-Jan-2000    -0.084331     -0.08324     -0.05608     -0.08353    -0.093805    NaN     -0.07
    05-Jan-2000     0.014634     -0.14877    -0.003039     0.070984     0.066875    NaN     -0.00
    06-Jan-2000    -0.086538    -0.060072    -0.016619    -0.038847    -0.012302    NaN     -0.06
    07-Jan-2000     0.047368     0.061013       0.0587    -0.037708    -0.000964    NaN      0.02
```

`setScenarios` accepts a name-value pair argument name `'DataFormat'` with a corresponding value set to `'prices'` to indicate that the input to the function is in the form of asset prices and not returns (the default value for the `'DataFormat'` argument is `'returns'`).

```
r = PortfolioCVaR;
r = setScenarios(r,AssetsTimeTable,'dataformat','returns');
```

In addition, the `setScenarios` function also extracts asset names or identifiers from a timetable object when the name-value argument `'GetAssetList'` set to `true` (its default value is `false`). If the `'GetAssetList'` value is `true`, the timetable column identifiers are used to set the `AssetList` property of the PortfolioCVaR object. To show this, the formation of the PortfolioCVaR object `r` is repeated with the `'GetAssetList'` flag set to `true`.

```
r = setScenarios(r,AssetsTimeTable,'GetAssetList',true);
disp(r.AssetList')
```

```
    {'AAPL'  }
    {'AMZN'  }
    {'CSCO'  }
    {'DELL'  }
    {'EBAY'  }
    {'GOOG'  }
    {'HPQ'   }
    {'IBM'   }
    {'INTC'  }
    {'MSFT'  }
    {'ORCL'  }
    {'YHOO'  }
    {'MARKET'}
    {'CASH'  }
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`AssetScenarios` — Scenarios for asset returns or prices

matrix | table | timetable

Scenarios for asset returns or prices, specified as a matrix, `table`, or `timetable` that contains asset data that can be converted into asset returns ([`NumSamples`-by-`NumAssets`] matrix).

`AssetReturns` data can be:

- `NumSamples`-by-`NumAssets` matrix.
- Table of `NumSamples` prices or returns at a given periodicity for an underlying single-period investment horizon for a collection of `NumAssets` assets
- Timetable object with `NumSamples` observations and `NumAssets` time series

If the input data are prices, they can be converted into returns with the `DataFormat` name-value pair argument, where the default format is assumed to be `'Returns'`. Be careful using price data because portfolio optimization usually requires total returns and not simply price returns.

This function sets up a function handle to indirectly access input `AssetScenarios` without needing to make a copy of the data.

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `p = setScenarios(p, AssetScenarios,'DataFormat','Returns','GetAssetList',false);`

`DataFormat` — Flag to convert input data as prices into returns
`'Returns'` (default) | character vector with values `'Returns'` or `'Prices'`

Flag to convert input data as prices into returns, specified as the comma-separated pair consisting of `'DataFormat'` and a character vector with the values:

- `'Returns'` — Data in `AssetReturns` contains asset total returns.
- `'Prices'` — Data in `AssetReturns` contains asset total return prices.

Data Types: `char`

`GetAssetList` — Flag indicating which asset names to use for the asset list
`false` (default) | logical with value `true` or `false`

Flag indicating which asset names to use for the asset list, specified as the comma-separated pair consisting of `'GetAssetList'` and a logical with a value of `true` or `false`. Acceptable values for `GetAssetList` are:

- `false` — Do not extract or create asset names.
- `true` — Extract or create asset names from table or timetable.

If a `table` or `timetable` is passed into this function as `AssetScenarios` and the `GetAssetList` flag is `true`, the column names from the `table` or `timetable` are used as asset names in `obj.AssetList`.

If a matrix is passed and the `GetAssetList` flag is `true`, default asset names are created based on the `AbstractPortfolio` property `defaultforAssetList`, which is currently `'Asset'`.

If the `GetAssetList` flag is `false`, no action occurs, which is the default behavior.

Data Types: `logical`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `PortfolioCVaR` or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Tips

You can also use dot notation to set asset return scenarios.

```
obj = obj.setScenarios(AssetScenarios);
```

setTrackingError

Set up maximum portfolio tracking error constraint

Syntax

```
obj = setTrackingError(obj,TrackingError)
obj = setTrackingError( ___ ,TrackingPort,NumAssets)
```

Description

`obj = setTrackingError(obj,TrackingError)` sets up a maximum portfolio tracking error constraint for a `Portfolio` object. For details on the workflow when using a Portfolio object, see "Portfolio Object Workflow" on page 4-17.

`obj = setTrackingError( ___ ,TrackingPort,NumAssets)` sets up a maximum portfolio tracking error constraint using optional arguments for `TrackingPort` and `NumAssets`.

Examples

Set up a Tracking Error Constraint

Create a `Portfolio` object.

```
AssetMean = [ 0.05; 0.1; 0.12; 0.18 ];
AssetCovar = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

p = Portfolio('mean', AssetMean, 'covar', AssetCovar, 'lb', 0, 'budget', 1)
```

```
p = 
  Portfolio with properties:

          BuyCost: []
         SellCost: []

    0.0800
```

```
display(p.TrackingPort);
```

```
    0.6608
    0.1622
    0.0626
    0.1143
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see `Portfolio`.

Data Types: `object`

`TrackingError` — Upper bound for portfolio tracking error

nonnegative and finite scalar

Upper bound for portfolio tracking error, specified using a nonnegative and finite scalar.

Given an upper bound for portfolio tracking error in `TrackingError` and a tracking portfolio in `TrackingPort`, the tracking error constraint requires any portfolio in Port to satisfy

```
(Port - TrackingPort)'*AssetCovar*(Port - TrackingPort) <= TrackingError^2 .
```

For more information, see “Tracking Error Constraints” on page 4-14.

Data Types: double

TrackingPort — Tracking portfolio weights
finite vector

Tracking portfolio weights, specified using a vector. TrackingPort must be a finite vector with NumAssets > 0 elements.

If no TrackingPort is specified, it is assumed to be 0. If TrackingPort is specified as a scalar and NumAssets exists, then TrackingPort undergoes scalar expansion.

Data Types: double

NumAssets — Number of assets in portfolio
scalar

Number of assets in portfolio, specified using a scalar. If it is not possible to obtain a value for NumAssets, it is assumed that NumAssets is 1.

Data Types: double

Output Arguments

obj — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a Portfolio object. For more information on creating a portfolio object, see Portfolio.

Note The tracking error constraints can be used with any of the other supported constraints in the Portfolio object without restrictions. However, since the portfolio set necessarily and sufficiently must be a non-empty compact set, the application of a tracking error constraint can result in an empty portfolio set. Use estimateBounds to confirm that the portfolio set is non-empty and compact.

Tips

You can also use dot notation to set up a maximum portfolio tracking error constraint.

```
obj = obj.setTrackingError(TrackingError, NumAssets);
```

To remove a tracking portfolio, call this function with an empty argument ([]) for TrackingError.

```
obj = setTrackingError(obj, [ ]);
```

setTrackingPort

Set up benchmark portfolio for tracking error constraint

Syntax

```
obj = setTrackingPort(obj,TrackingPort)
obj = setTrackingPort(___,NumAssets)
```

Description

`obj = setTrackingPort(obj,TrackingPort)` sets up a benchmark portfolio for a tracking error constraint for a `Portfolio` object. For details on the workflow when using a Portfolio object, see “Portfolio Object Workflow” on page 4-17.

`obj = setTrackingPort(___,NumAssets)` sets up a benchmark portfolio for a tracking error constraint using an optional input argument for `NumAssets`.

Examples

Set up a Tracking Port

Create a `Portfolio` object.

```
AssetMean = [ 0.05; 0.1; 0.12; 0.18 ];
AssetCovar = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];

p = Portfolio('mean', AssetMean, 'covar', AssetCovar, 'lb', 0, 'budget', 1)
```

```
p = 
  Portfolio with properties:

          BuyCost: []

```

Estimate the Sharpe ratio for the Portfolio object `p` and define the tracking port.

```
x0 = estimateMaxSharpeRatio(p);
p = setTrackingPort(p, x0);

display(p.NumAssets);
```

```
     4
```

```
display(p.TrackingPort);
```

```
    0.6608
    0.1622
    0.0626
    0.1143
```

Input Arguments

`obj` — Object for portfolio
object

Object for portfolio, specified using a `Portfolio` object. For more information on creating a portfolio object, see `Portfolio`.

Data Types: `object`

`TrackingPort` — Tracking portfolio weights
vector

Tracking portfolio weights, specified using a vector. If `TrackingPort` is specified as a scalar and `NumAssets` exists, then `TrackingPort` undergoes scalar expansion.

Data Types: `double`

`NumAssets` — Number of assets in portfolio
scalar

Number of assets in portfolio, specified using a scalar. If it is not possible to obtain a value for `NumAssets`, it is assumed that `NumAssets` is `1`.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio` object. For more information on creating a portfolio object, see `Portfolio`.

Note The tracking error constraints can be used with any of the other supported constraints in the Portfolio object without restrictions. However, since the portfolio set necessarily and sufficiently must be a non-empty compact set, the application of a tracking error constraint can result in an empty portfolio set. Use `estimateBounds` to confirm that the portfolio set is non-empty and compact.

Tips

You can also use dot notation to set up a benchmark portfolio for tracking error constraint.

```
obj = obj.setTrackingPort(TrackingPort, NumAssets);
```

To remove a tracking portfolio, call this function with an empty argument (`[]`) for `TrackingPort`.

```
obj = setTrackingPort(obj, [ ]);
```

setTurnover

Set up maximum portfolio turnover constraint

Syntax

```
obj = setTurnover(obj,Turnover)
obj = setTurnover(obj,Turnover,InitPort,NumAssets)
```

Description

`obj = setTurnover(obj,Turnover)` sets up maximum portfolio turnover constraint for `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` objects. For details on the respective workflows when using these different objects, see "Portfolio Object Workflow" on page 4-17, "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-15.

`obj = setTurnover(obj,Turnover,InitPort,NumAssets)` sets up maximum portfolio turnover constraint for portfolio objects with additional options specified for `Turnover`, `InitPort`, and `NumAssets`.

Given an upper bound for portfolio turnover in `Turnover` and an initial portfolio in `InitPort`, the turnover constraint requires any portfolio in `Port` to satisfy the following:

```
1' *1/2* | Port - InitPort | <= Turnover
```

Examples

Set Turnover Constraint for a Portfolio Object

Given a Portfolio object `p`, to ensure that average turnover is no more than 30% with an initial portfolio of 10 assets in a variable `x0`, use the `setTurnover` method to set the turnover constraint.

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = Portfolio('InitPort', x0);
p = setTurnover(p, 0.3);

disp(p.NumAssets);

    10

disp(p.Turnover);

    0.3000

disp(p.InitPort);

    0.1200
    0.0900
    0.0800
    0.0700
    0.1000
    0.1000
    0.1500
    0.1100
    0.0800
    0.1000
```

Set Turnover Constraint for a CVaR Portfolio Object

Given a CVaR portfolio object `p`, to ensure that average turnover is no more than 30% with an initial portfolio of 10 assets in a variable `x0`, use the `setTurnover` method to set the turnover constraint.

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioCVaR('InitPort', x0);
p = setTurnover(p, 0.3);

disp(p.NumAssets);

    10

disp(p.Turnover);

    0.3000

disp(p.InitPort);

    0.1200
    0.0900
    0.0800
    0.0700
    0.1000
    0.1000
    0.1500
    0.1100
    0.0800
    0.1000
```

Set Turnover Constraint for a MAD Portfolio Object

Given PortfolioMAD object `p`, to ensure that average turnover is no more than 30% with an initial portfolio of 10 assets in a variable `x0`, use the `setTurnover` method to set the turnover constraint.

```
x0 = [ 0.12; 0.09; 0.08; 0.07; 0.1; 0.1; 0.15; 0.11; 0.08; 0.1 ];
p = PortfolioMAD('InitPort', x0);
p = setTurnover(p, 0.3);

disp(p.NumAssets);

    10

disp(p.Turnover);

    0.3000

disp(p.InitPort);
```

    0.1500
    0.1100
    0.0800
    0.1000
```

Input Arguments

`obj` — Object for portfolio

object

Object for portfolio, specified using `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: `object`

`Turnover` — Portfolio turnover constraint

nonnegative and finite scalar

Portfolio turnover constraint, specified as a nonnegative and finite scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

`InitPort` — Initial or current portfolio weights

`0` (default) | finite vector with `NumAssets` > `0` elements.

Initial or current portfolio weights, specified as a finite vector with `NumAssets` > `0` elements for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note If no `InitPort` is specified, that value is assumed to be `0`.

If `InitPort` is specified as a scalar and `NumAssets` exists, then `InitPort` undergoes scalar expansion.

Data Types: `double`

`NumAssets` — Number of assets in portfolio

`1` (default) | scalar

Number of assets in portfolio, specified as a scalar for a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` input object (`obj`).

Note If it is not possible to obtain a value for `NumAssets`, it is assumed that `NumAssets` is `1`.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `Portfolio`, `PortfolioCVaR`, or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `Portfolio`
- `PortfolioCVaR`
- `PortfolioMAD`

Tips

You can also use dot notation to set up the maximum portfolio turnover constraint.

```
obj = obj.setTurnover(Turnover, InitPort, NumAssets);
```

Version History

Introduced in R2011a

simulateNormalScenariosByData

Simulate multivariate normal asset return scenarios from data

Syntax

```
obj = simulateNormalScenariosByData(obj,AssetReturns)
```

```
obj = simulateNormalScenariosByData(obj,AssetReturns,NumScenarios,Name,Value)
```

Description

`obj = simulateNormalScenariosByData(obj,AssetReturns)` simulates multivariate normal asset return scenarios from data for portfolio object for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-15.

`obj = simulateNormalScenariosByData(obj,AssetReturns,NumScenarios,Name,Value)` simulates multivariate normal asset return scenarios from data for portfolio object for `PortfolioCVaR` or `PortfolioMAD` objects using additional options specified by one or more `Name,Value` pair arguments.

This function estimates the mean and covariance of asset returns from either price or return data and then uses these estimates to generate the specified number of scenarios with the function `mvnrnd`.

Data can be in a `NumSamples`-by-`NumAssets` matrix of `NumSamples` prices or returns at a given periodicity for a collection of `NumAssets` assets, a `table` or a `timetable`.

Note If you want to use the method multiple times and you want to simulate identical scenarios each time the function is called, precede each function call with `rng`(*seed*) using a specified integer seed.

Examples

Simulate Multivariate Normal Asset Return Scenarios from Data for a PortfolioCVaR Object

Given a PortfolioCVaR object `p`, use the `simulateNormalScenariosByData` function to simulate multivariate normal asset return scenarios from data.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

RawData = mvnrnd(m, C, 240);
NumScenarios = 2000;
```

```
p = PortfolioCVaR;
p = simulateNormalScenariosByData(p, RawData, NumScenarios)
```

```
p =

Simulate Multivariate Normal Asset Return Scenarios from Data for `PortfolioCVaR` Object Using Financial Timetable Data

To illustrate using the `simulateNormalScenariosByData` function with `AssetReturns` data continued in a `timetable` object, use the `CAPMuniverse.mat` which contains a `timetable` object (`AssetTimeTable`) for returns data.

```
load CAPMuniverse;
AssetsTimeTable.Properties
```

```
ans = 
  TimetableProperties with properties:

             Description: ''
                UserData: []
          DimensionNames: {'Time'  'Variables'}
           VariableNames: {'AAPL'  'AMZN'  'CSCO'  'DELL'  'EBAY'  'GOOG'  'HPQ'  'IBM'  'INTC'
    VariableDescriptions: {}
           VariableUnits: {}
      VariableContinuity: []
                RowTimes: [1471x1 datetime]
               StartTime: 03-Jan-2000
              SampleRate: NaN
                TimeStep: NaN
                  Events: []
        CustomProperties: No custom properties are set.
      Use addprop and rmprop to modify CustomProperties.
```

```
head(AssetsTimeTable,5)
```

```
       Time          AAPL        AMZN        CSCO        DELL        EBAY       GOOG      H
    ___________    _________   _________   _________   _________   _________    ____    _____

    03-Jan-2000     0.088805      0.1742    0.008775   -0.002353     0.12829    NaN       0.0
    04-Jan-2000    -0.084331    -0.08324    -0.05608    -0.08353   -0.093805    NaN     -0.07
    05-Jan-2000     0.014634    -0.14877   -0.003039    0.070984    0.066875    NaN     -0.00
    06-Jan-2000    -0.086538   -0.060072   -0.016619   -0.038847   -0.012302    NaN     -0.06
    07-Jan-2000     0.047368    0.061013      0.0587   -0.037708   -0.000964    NaN      0.02
```

Notice that GOOG has missing data (NaN) because it was not listed before Aug 2004. The simulateNormalScenariosByData function has a name-value pair argument 'MissingData' that indicates with a Boolean value whether to use the missing data capabilities of Financial Toolbox™ software. The default value for 'MissingData' is false which removes all samples with NaN values. If, however, 'MissingData' is set to true, the estimateAssetMoments function uses the ECM algorithm to estimate asset moments. The simulateNormalScenariosByData function also accepts a name-value pair argument 'DataFormat' with a corresponding value set to 'prices' to indicate that the input to the function is in the form of asset prices and not returns (the default value for the 'DataFormat' argument is 'returns').

```
NumScenarios = 100;
r = PortfolioCVaR;
r = simulateNormalScenariosByData(r,AssetsTimeTable,NumScenarios,'DataFormat','Returns','MissingD
```

In addition, simulateNormalScenariosByData extracts asset names or identifiers from a timetable object when the name-value argument 'GetAssetList' is set to true (its default value is false). If the 'GetAssetList' value is true, the timetable column identifiers are used to set the AssetList property of the PortfolioCVaR object. To show this, the formation of the PortfolioCVaR object r is repeated with the 'GetAssetList' flag set to true.

```
r = simulateNormalScenariosByData(r,AssetsTimeTable,NumScenarios,'GetAssetList',true);
disp(r.AssetList)
```

```
    {'AAPL'}    {'AMZN'}    {'CSCO'}    {'DELL'}    {'EBAY'}    {'GOOG'}    {'HPQ'}    {'IBM'}
```

Estimate Mean and Covariance of Asset Returns from Market Data for a PortfolioCVaR Object

Create a PortfolioCVaR object p and use the simulateNormalScenariosByData function with market data loaded from CAPMuniverse.mat to simulate multivariate normal asset return scenarios. The market data, AssetsTimeTable, is a timetable of asset returns.

```
load CAPMuniverse

p = PortfolioCVaR('AssetList',Assets);
disp(p);
```

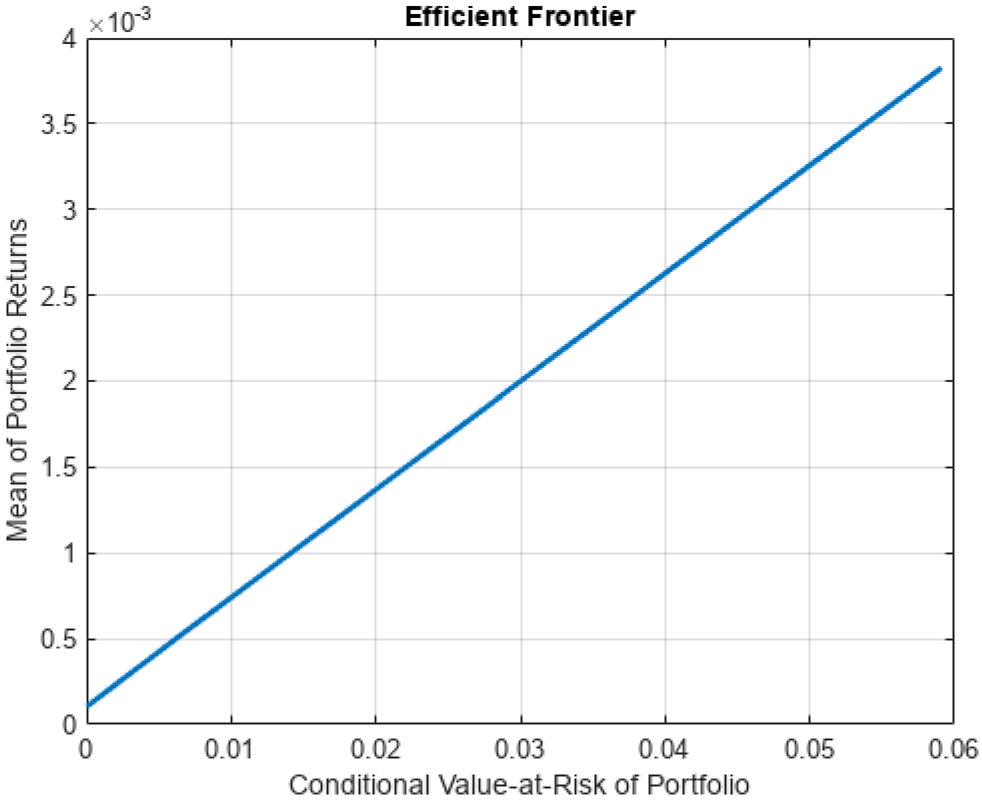
```
  PortfolioCVaR with properties:

             BuyCost: []
            SellCost: []
        RiskFreeRate: []
    ProbabilityLevel: []
            Turnover: []
         BuyTurnover: []
        SellTurnover: []
        NumScenarios: []
                Name: []
           NumAssets: 14
           AssetList: {'AAPL'  'AMZN'  'CSCO'  'DELL'  'EBAY'  'GOOG'  'HPQ'  'IBM'  'INTC'  'MSI
            InitPort: []
         AInequality: []
         bInequality: []
           AEquality: []
```

```
          bEquality: []
         LowerBound: []
         UpperBound: []
        LowerBudget: []
        UpperBudget: []
        GroupMatrix: []
         LowerGroup: []
         UpperGroup: []
             GroupA: []
             GroupB: []
         LowerRatio: []
         UpperRatio: []
       MinNumAssets: []
       MaxNumAssets: []
          BoundType: []
```

Simulate the scenarios from the timetable data for each of the assets from `CAPMuniverse.mat` and plot the efficient frontier.

```
p = simulateNormalScenariosByData(p,AssetsTimeTable,10000,'missingdata',true);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.9);
plotFrontier(p);
```



Estimate Mean and Covariance of Asset Returns from Data for a PortfolioMAD Object

Given a PortfolioMAD object `p`, use the `simulateNormalScenariosByData` function to simulate multivariate normal asset return scenarios from data.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

RawData = mvnrnd(m, C, 240);
NumScenarios = 2000;

p = PortfolioMAD;
p = simulateNormalScenariosByData(p, RawData, NumScenarios);
p = setDefaultConstraints(p);

disp(p);
```

```
  PortfolioMAD with properties:

         BuyCost: []
        SellCost: []
    RiskFreeRate: []
        Turnover: []
     BuyTurnover: []
    SellTurnover: []
    NumScenarios: 2000
            Name: []
       NumAssets: 4
       AssetList: []
        InitPort: []
     AInequality: []
     bInequality: []
       AEquality: []
       bEquality: []
      LowerBound: [4x1 double]
      UpperBound: []
     LowerBudget: 1
     UpperBudget: 1
     GroupMatrix: []
      LowerGroup: []
      UpperGroup: []
          GroupA: []
          GroupB: []
      LowerRatio: []
      UpperRatio: []
    MinNumAssets: []
    MaxNumAssets: []
       BoundType: [4x1 categorical]
```

Estimate Mean and Covariance of Asset Returns from Market Data for a PortfolioMAD Object

Create a PortfolioMAD object p and use the simulateNormalScenariosByData function with market data loaded from CAPMuniverse.mat to simulate multivariate normal asset return scenarios. The market data, AssetsTimeTable, is a timetable of asset returns.

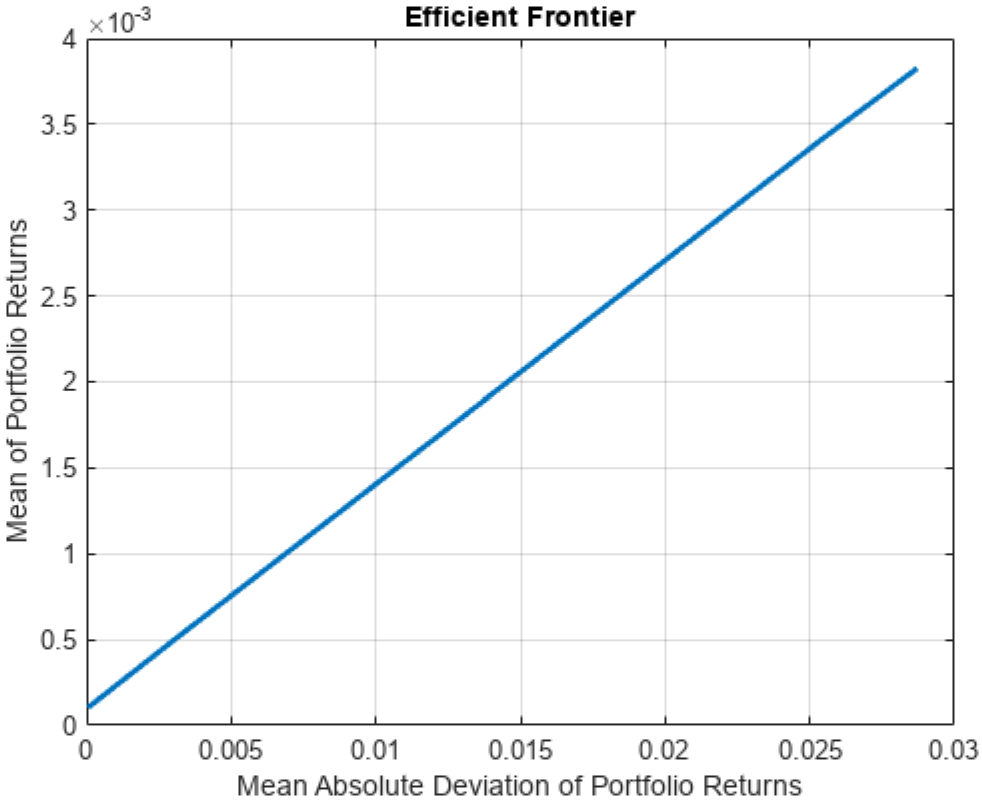
```
load CAPMuniverse

p = PortfolioMAD('AssetList',Assets);
disp(p.AssetList');
```

```
    {'AAPL'  }
    {'AMZN'  }
    {'CSCO'  }
    {'DELL'  }
    {'EBAY'  }
    {'GOOG'  }
    {'HPQ'   }
    {'IBM'   }
    {'INTC'  }
    {'MSFT'  }
    {'ORCL'  }
    {'YHOO'  }
    {'MARKET'}
    {'CASH'  }
```

Simulate the scenarios from the timetable data for each of the assets from CAPMuniverse.mat and plot the efficient frontier.

```
p = simulateNormalScenariosByData(p,AssetsTimeTable,10000,'missingdata',true);
p = setDefaultConstraints(p);
plotFrontier(p);
```



Input Arguments

obj — Object for portfolio

object

Object for portfolio, specified using a PortfolioCVaR or PortfolioMAD object.

For more information on creating a PortfolioCVaR or PortfolioMAD object, see

- PortfolioCVaR
- PortfolioMAD

Data Types: object

AssetReturns — Asset data that can be converted into asset returns

matrix | table | timetable

Asset data that can be converted into asset returns ([NumSamples-by-NumAssets] matrix), specified as a matrix, table, or timetable.

AssetReturns data can be:

- NumSamples-by-NumAssets matrix.
- Table of NumSamples prices or returns at a given periodicity for a collection of NumAssets assets

- Timetable object with `NumSamples` observations and `NumAssets` time series

Data Types: `double` | `table` | `timetable`

`NumScenarios` — Number of scenarios to simulate
positive integer

Number of scenarios to simulate, specified as a positive integer.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `p = simulateNormalScenariosByData(p,RawData,NumScenarios,'DataFormat','Returns','MissingData',true,'GetAssetList',true)`

`DataFormat` — Flag to convert input data as prices into returns
`'Returns'` (default) | character vector with values `'Returns'` or `'Prices'`

Flag to convert input data as prices into returns, specified as the comma-separated pair consisting of `'DataFormat'` and a character vector with the values:

- `'Returns'` — Data in `AssetReturns` contains asset total returns.
- `'Prices'` — Data in `AssetReturns` contains asset total return prices.

Data Types: `char`

`MissingData` — Flag to use ECM algorithm to handle `NaN` values
`false` (default) | logical with values `true` or `false`

Flag to use ECM algorithm to handle `NaN` values, specified as the comma-separated pair consisting of `'MissingData'` and a logical with a value of `true` or `false`.

- `false` — Do not use ECM algorithm to handle `NaN` values (exclude `NaN` values).
- `true` — Use ECM algorithm to handle `NaN` values.

Data Types: `logical`

`GetAssetList` — Flag indicating which asset names to use for the asset list
`false` (default) | logical with values `true` or `false`

Flag indicating which asset names to use for the asset list, specified as the comma-separated pair consisting of `'GetAssetList'` and a logical with a value of `true` or `false`.

- `false` — Do not extract or create asset names.
- `true` — Extract or create asset names from the table or timetable.

If a `table` or `timetable` is passed into this function using the `AssetReturns` argument and the `GetAssetList` flag is `true`, the column names from the `table` or `timetable` are used as asset names in `obj.AssetList`.

If a matrix is passed and the `GetAssetList` flag is `true`, default asset names are created based on the `AbstractPortfolio` property `defaultforAssetList`, which is `'Asset'`.

If the `GetAssetList` flag is `false`, no action occurs, which is the default behavior.

Data Types: `logical`

Output Arguments

`obj` — Updated portfolio object
object for portfolio

Updated portfolio object, returned as a `PortfolioCVaR` or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Tips

You can also use dot notation to simulate multivariate normal asset return scenarios from data for a PortfolioCVaR or PortfolioMAD object.

```
obj = obj.simulateNormalScenariosByData(AssetReturns,NumScenarios,Name,Value);
```

Version History

Introduced in R2012b

R2023a: `fints` support for `AssetReturns` argument removed

Behavior changed in R2023a

The `AssetReturns` argument no longer supports a `fints` object as a datatype.

simulateNormalScenariosByMoments

Simulate multivariate normal asset return scenarios from mean and covariance of asset returns

Syntax

```
obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovar,NumScenarios)
obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovarNumScenarios,
NumAssets)
```

Description

`obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovar,NumScenarios)` simulates multivariate normal asset return scenarios from mean and covariance of asset returns for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see "PortfolioCVaR Object Workflow" on page 5-16, and "PortfolioMAD Object Workflow" on page 6-15.

`obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovarNumScenarios, NumAssets)` simulates multivariate normal asset return scenarios from mean and covariance of asset returns for PortfolioCVaR or PortfolioMAD objects using the optional input `NumScenarios`.

Note This function overwrites existing scenarios associated with `PortfolioCVaR` or `PortfolioMAD` objects, and also, possibly, `NumScenarios`.

If you want to use the function multiple times and you want to simulate identical scenarios each time the function is called, precede each function call with `rng`(*seed*) using a specified integer seed.

Examples

Simulate Multivariate Normal Asset Return Scenarios from Moments for a PortfolioCVaR Object

Given PortfolioCVaR object `p`, use the `simulateNormalScenariosByMoments` function to simulate multivariate normal asset return scenarios from moments.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);

Simulate Multivariate Normal Asset Return Scenarios from Moments for a PortfolioMAD Object

Given PortfolioMAD object `p`, use the `simulateNormalScenariosByMoments` function to simulate multivariate normal asset return scenarios from moments.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
    0.00408 0.0289 0.0204 0.0119;
    0.00192 0.0204 0.0576 0.0336;
    0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

AssetMean = [.5]
```

```
AssetMean = 0.5000
```

```

Input Arguments

obj — Object for portfolio
object

Object for portfolio, specified using a PortfolioCVaR or PortfolioMAD object.

For more information on creating a PortfolioCVaR or PortfolioMAD object, see

- PortfolioCVaR
- PortfolioMAD

Data Types: object

AssetMean — Mean of asset returns
vector

Mean of asset returns, specified as a vector.

Note If AssetMean is a scalar and the number of assets is known, scalar expansion occurs. If the number of assets cannot be determined, this function assumes that NumAssets = 1.

Data Types: double

AssetCovar — Covariance of asset returns
symmetric positive semidefinite matrix

Covariance of asset returns, specified as a symmetric positive semidefinite matrix.

Note

- If AssetCovar is a scalar and the number of assets is known, a diagonal matrix is formed with the scalar value along the diagonals. If it is not possible to determine the number of assets, this method assumes that NumAssets = 1.
- If AssetCovar is a vector, a diagonal matrix is formed with the vector along the diagonal.
- If AssetCovar is not a symmetric positive semidefinite matrix, use nearcorr to create a positive semidefinite matrix for a correlation matrix.

Data Types: double

NumScenarios — Number of scenarios to simulate
positive integer

Number of scenarios to simulate, specified as a positive integer.

Data Types: double

`NumAssets` — Number of assets

scalar

Number of assets, specified as a scalar.

Data Types: `double`

Output Arguments

`obj` — Updated portfolio object

object for portfolio

Updated portfolio object, returned as a `PortfolioCVaR` or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Tips

You can also use dot notation to simulate multivariate normal asset return scenarios from a mean and covariance of asset returns for a `PortfolioCVaR` or `PortfolioMAD` object.

```
obj = obj.simulateNormalScenariosByMoments(AssetMean, AssetCovar, NumScenarios, NumAssets);
```

Version History

Introduced in R2012b

sharpe

Compute Sharpe ratio for one or more assets

Syntax

```
sharpe(Asset)
sharpe(Asset,Cash)
Ratio = sharpe(Asset,Cash)
```

Description

`sharpe(Asset)` computes Sharpe ratio for each asset.

`sharpe(Asset,Cash)` computes Sharpe ratio for each asset including the optional argument `Cash`.

`Ratio = sharpe(Asset,Cash)` computes Sharpe ratio for each asset including the optional argument `Cash`.

Examples

Compute Sharpe Ratio

This example shows how to compute the Sharpe ratio using the mean return of a cash asset as the return for the riskless asset.

Given asset return data and the riskless asset return, the Sharpe ratio is calculated:

```
load FundMarketCash
Returns = tick2ret(TestData);
Riskless = mean(Returns(:,3))
```

```
Riskless = 0.0017
```

```
Sharpe = sharpe(Returns, Riskless)
```

```
Sharpe = 1×3

    0.0886    0.0315         0
```

The Sharpe ratio of the example fund is significantly higher than the Sharpe ratio of the market. As is demonstrated with `portalpha`, this translates into a strong risk-adjusted return. Since the `Cash` asset is the same as `Riskless`, it makes sense that its Sharpe ratio is `0`. The Sharpe ratio is calculated with the mean of cash returns. The Sharpe ratio can also be calculated with the cash return series as input for the riskless asset.

```
Sharpe = sharpe(Returns, Returns(:,3))
```

```
Sharpe = 1×3
```

```
    0.0886    0.0315         0
```

When using the `Portfolio` object, you can use the `estimateMaxSharpeRatio` function to estimate an efficient portfolio that maximizes the Sharpe ratio. For more information, see “Efficient Portfolio That Maximizes Sharpe Ratio” on page 4-107.

Input Arguments

`Asset` — Asset returns

matrix

Asset returns, specified as a `NUMSAMPLES x NUMSERIES` matrix with `NUMSAMPLES` observations of asset returns for `NUMSERIES` asset return series.

Data Types: `double`

`Cash` — Riskless asset

`0` (default) | numeric | vector

(Optional) Riskless asset, specified as a either a scalar return for a riskless asset or a vector of asset returns to be a proxy for a “riskless” asset. In either case, the periodicity must be the same as the periodicity of `Asset`. For example, if `Asset` is monthly data, then `Cash` must be monthly returns. If no value is supplied, the default value for `Cash` returns is `0`.

Data Types: `double`

Output Arguments

`Ratio` — Sharpe ratios

vector

Sharpe ratios, returned as a `1`-by-`NUMSERIES` row vector of Sharpe ratios for each series in `Asset`. Any series in `Asset` with standard deviation of returns equal to `0` has a `NaN` value for its Sharpe ratio.

Note If `Cash` is a vector, `Asset` and `Cash` need not have the same number of returns but must have the same periodicity of returns. The classic Sharpe ratio assumes that `Cash` is riskless. In reality, a short-term cash rate is not necessarily riskless. `NaN` values in the data are ignored.

Version History

Introduced in R2006b

stochosc

Stochastic oscillator

Syntax

```
percentKnD = stochosc(Data)
percentKnD = stochosc( ___ ,Name,Value)
```

Description

`percentKnD = stochosc(Data)` calculates the stochastic oscillator.

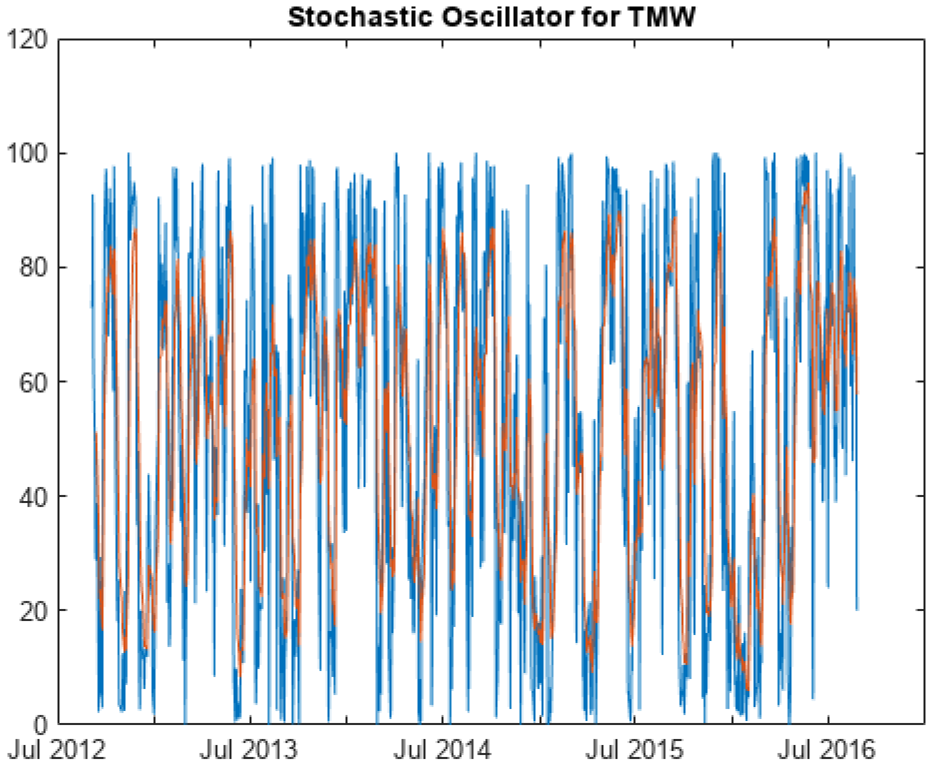
`percentKnD = stochosc( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Stochastic Oscillator for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
oscillator = stochosc(TMW,'NumPeriodsD',7,'NumPeriodsK',10,'Type','exponential');
plot(oscillator.Time,oscillator.FastPercentK,oscillator.Time,oscillator.FastPercentD)
title('Stochastic Oscillator for TMW')
```



Input Arguments

`Data` — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-`3` matrix of high, low, and closing prices stored in the corresponding columns, respectively. Timetables and tables with `M` rows must contain variables named `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `percentKnD = stochosc(TMW,'NumPeriodsD',10,'NumPeriodsK',3,'Type','exponential')`

`NumPeriodsK` — Period difference for PercentK

`10` (default) | positive integer

Period difference for PercentK, specified as the comma-separated pair consisting of `'NumPeriodsK'` and a scalar positive integer.

Data Types: `double`

`NumPeriodsD` — Length of moving average in periods for PercentD
`3` (default) | positive integer

Length of moving average in periods for PercentD, specified as the comma-separated pair consisting of `'NumPeriodsD'` and a scalar positive integer.

Data Types: `double`

Type — Moving average method for PercentD calculation
`'e'` (exponential) (default) | character vector with values `'exponential'` or `'triangular'`

Moving average method for PercentD calculation, specified as the comma-separated pair consisting of `'Type'` and a character vector with a value of:

- `'exponential'` – Exponential moving average is a weighted moving average. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10 period exponential moving average weights the most recent price by 18.18%.
- `'triangular'` – Triangular moving average is a double-smoothing of the data. The first simple moving average is calculated and then a second simple moving average is calculated on the first moving average with the same window size.

Data Types: `char`

Output Arguments

`percentKnD` — PercentK and PercentD
matrix | table | timetable

PercentK and PercentD, returned with the same number of rows (`M`) and type (matrix, table, or timetable) as the input `Data`.

More About

Stochastic Oscillator

The stochastic oscillator calculates the Fast PercentK (F%K), Fast PercentD (F%D), Slow PercentK (S %K), and Slow PercentD (S%D) from the series of high, low, and closing stock prices.

By default, the stochastic oscillator is based on 10-period difference for PercentK and a 3-period exponential moving average for PercentD.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument
Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

targetreturn

Portfolio weight accuracy

Syntax

```
return = targetreturn(Universe,Window,Offset,Weights)
```

Description

`return = targetreturn(Universe,Window,Offset,Weights)` computes target `return` values for each `Window` of data and given portfolio weights. These values should match the input target `return` used with `selectreturn`.

Input Arguments

`Universe` — Total return data for a group of securities

array

Total return data for a group of securities, specified as a number of observations (`NUMOBS`) by number of assets plus one (`NASSETS + 1`) array. Each row represents an observation. Column 1 contains MATLAB serial date numbers. The remaining columns contain the total return data for each security.

Data Types: `double`

`Window` — Number of data periods used to calculate frontier

integer

Number of data periods used to calculate frontier, specified as an integer.

Data Types: `double`

`Offset` — Number of periods to increment when each frontier is generated

integer

Number of periods to increment when each frontier is generated , specified as an integer.

Data Types: `double`

`Weights` — Asset allocation weights needed to obtain the target rate of return

matrix

Asset allocation weights needed to obtain the target rate of return, specified as a number of assets (NASSETS) by number of curves (NCURVES) matrix.

Data Types: `double`

Output Arguments

`return` — Target return

numeric

Target return, returned as a numeric value for each `Window` of data and given portfolio `Weights`.

Version History

Introduced before R2006a

taxedrr

After-tax rate of return

Syntax

`Return = taxedrr(PreTaxReturn,TaxRate)`

Description

`Return = taxedrr(PreTaxReturn,TaxRate)` calculates the after-tax rate of return.

Examples

Calculate the After-Tax Rate of Return

This example shows how to calculate the after-tax rate of return, given an investment that has a 12% nominal rate of return and is taxed at a 30% rate.

```
Return = taxedrr(0.12, 0.30)
```

```
Return = 0.0840
```

Input Arguments

`PreTaxReturn` — Normal rate of return
decimal

Normal rate of return, specified as a decimal.

Data Types: `double`

`TaxRate` — Tax rate
decimal

Tax rate, specified as a decimal.

Data Types: `double`

Output Arguments

`Return` — After-tax rate of return
decimal

After-tax rate of return, returned as a decimal.

Version History

Introduced before R2006a

tbilldisc2yield

Convert Treasury bill discount to equivalent yield

Syntax

```
[BEYield,MMYield] = tbilldisc2yield(Discount,Settle,Maturity)
```

Description

`[BEYield,MMYield] = tbilldisc2yield(Discount,Settle,Maturity)` converts the discount rate on Treasury bills into their respective money-market or bond-equivalent yields.

Examples

Convert the Discount Rate on Treasury Bills

This example shows how to convert the discount rate on Treasury bills into their respective money-market or bond-equivalent yields, given a Treasury bill with the following characteristics.

```
Discount = 0.0497;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';

[BEYield MMYield] = tbilldisc2yield(Discount, Settle, Maturity)
```

```
BEYield = 0.0517

MMYield = 0.0510
```

Convert the Discount Rate on Treasury Bills Using datetime Inputs

This example shows how to use `datetime` inputs to convert the discount rate on Treasury bills into their respective money-market or bond-equivalent yields, given a Treasury bill with the following characteristics.

```
Discount = 0.0497;
Settle = datetime(2002,10,1);
Maturity = datetime(2003,3,31);
[BEYield MMYield] = tbilldisc2yield(Discount, Settle, Maturity)
```

```
BEYield = 0.0517

MMYield = 0.0510
```

Input Arguments

`Discount` — Discount rate of Treasury bills

decimal

Discount rate of the Treasury bills, specified as a scalar of a `NTBILLS`-by-`1` vector of decimal values. The discount rate basis is actual/360.

Data Types: `double`

`Settle` — Settlement date of Treasury bill

datetime array | string array | date character vector

Settlement date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `tbilldisc2yield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of Treasury bill

datetime array | string array | date character vector

Maturity date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tbilldisc2yield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Output Arguments

`BEYield` — Bond equivalent yields of Treasury bills

numeric

Bond equivalent yields of the Treasury bills, returned as a `NTBILLS`-by-`1` vector. The bond-equivalent yield basis is actual/365.

`MMYield` — Money-market yields of Treasury bills

numeric

Money-market yields of the Treasury bills, returned as a `NTBILLS`-by-`1` vector. The money-market yield basis is actual/360.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although tbilldisc2yield supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

tbillprice

Price Treasury bill

Syntax

```
Price = tbillprice(Rate,Settle,Maturity)
Price = tbillprice( ___ ,Type)
```

Description

`Price = tbillprice(Rate,Settle,Maturity)` computes the price of a Treasury bill given a yield or discount rate.

`Price = tbillprice( ___ ,Type)` adds an optional argument for `Type`.

Examples

Compute the Price of a Treasury Bill Using the Bond-Equivalent Yield

Given a Treasury bill with the following characteristics, compute the price of the Treasury bill using the bond-equivalent yield (`Type` = 2) as input.

```
Rate = 0.045;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';

Type = 2;

Price = tbillprice(Rate, Settle, Maturity, Type)
```

```
Price = 97.8172
```

Price a Portfolio of Treasury Bills

Use `tbillprice` to price a portfolio of Treasury bills.

```
Rate = [0.045; 0.046];
Settle = {'02-Jan-02'; '01-Mar-02'};
Maturity = {'30-June-02'; '30-June-02'};
Type = [2 3];

Price = tbillprice(Rate, Settle, Maturity, Type)
```

```
Price = 2×1

   97.8408
   98.4539
```

Price a Portfolio of Treasury Bills Using `datetime` Input

Use `tbillprice` to price a portfolio of Treasury bills using `datetime` input.

```
Rate = [0.045; 0.046];
Type = [2 3];

Settle = [datetime(2002,1,2);datetime(2002,3,1)];
Maturity = [datetime(2002,6,30);datetime(2002,6,30)];
Price = tbillprice(Rate, Settle, Maturity, Type)
```

```
Price = 2×1

   97.8408
   98.4539
```

Input Arguments

`Rate` — Bond-equivalent yield, money-market yield, or discount rate

decimal

Bond-equivalent yield, money-market yield, or discount rate (defined by the input `Type`), specified as a scalar of a `NTBILLS`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date of Treasury bill

datetime array | string array | date character vector

Settlement date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tbillprice` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of Treasury bill

datetime array | string array | date character vector

Maturity date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tbillprice` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Type` — (Optional) Rate type

`2` (default) | numeric with values `1` = money market, `2` = bond-equivalent, `3` = discount rate

Rate type (determines how to interpret values entered in `Rate`), specified as a numeric value of `1`,`2`, or `3` using a scalar or a `NTBILLS`-by-`1` vector.

Note The bond-equivalent yield basis is actual/365. The money-market yield basis is actual/360. The discount rate basis is actual/360.

Data Types: double

Output Arguments

Price — Treasury bill price for every $100 face

numeric

Treasury bill prices for every $100 face, returned as a NTBILLS-by-1 vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although tbillprice supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

tbillrepo

Break-even discount of repurchase agreement

Syntax

```
TBEDiscount = tbillrepo(RepoRate,InitialDiscount,PurchaseDate,SaleDate,
Maturity)
```

Description

`TBEDiscount = tbillrepo(RepoRate,InitialDiscount,PurchaseDate,SaleDate, Maturity)` computes the true break-even discount of a repurchase agreement.

Examples

Compute the True Break-Even Discount

This example shows how to compute the true break-even discount of a Treasury bill repurchase agreement.

```
RepoRate = [0.045; 0.0475];
InitialDiscount = 0.0475;
PurchaseDate = '3-Jan-2002';
SaleDate = '3-Feb-2002';
Maturity = '3-Apr-2002';

TBEDiscount = tbillrepo(RepoRate, InitialDiscount,...
PurchaseDate, SaleDate, Maturity)
```

```
TBEDiscount = 2×1

    0.0491
    0.0478
```

Compute the True Break-Even Discount Using datetime Inputs

This example shows how to use `datetime` inputs to compute the true break-even discount of a Treasury bill repurchase agreement.

```
RepoRate = [0.045; 0.0475];
InitialDiscount = 0.0475;
PurchaseDate = datetime(2002,1,3);
SaleDate = datetime(2002,2,3);
Maturity = datetime(2002,4,3);
TBEDiscount = tbillrepo(RepoRate, InitialDiscount,...
PurchaseDate, SaleDate, Maturity)
```

```
TBEDiscount = 2×1

    0.0491
    0.0478
```

Input Arguments

`RepoRate` — Annualized, 360-day based repurchase rate
decimal

Annualized, 360-day based repurchase rate, specified as a scalar of a `NTBILLS`-by-`1` vector of decimal values.

Data Types: `double`

`InitialDiscount` — Discount on Treasury bill on day of purchase
decimal

Discount on the Treasury bill on the day of purchase, specified as a scalar of a `NTBILLS`-by-`1` vector of decimal values.

Data Types: `double`

`PurchaseDate` — Date Treasury bill is purchased
datetime array | string array | date character vector

Date the Treasury bill is purchased, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tbillrepo` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`SaleDate` — Date Treasury bill repurchase term is due
datetime array | string array | date character vector

Date the Treasury bill repurchase term is due, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tbillrepo` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of Treasury bill
datetime array | string array | date character vector

Maturity date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tbillrepo` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Output Arguments

`TBEDiscount` — True break-even discount of repurchase agreement
numeric

True break-even discount of a repurchase agreement, returned as a scalar or `NTBILLS`-by-`1` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although `tbillrepo` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

tbillval01

Value of one basis point

Syntax

```
[Val01Disc,Val01MMY,Val01BEY] = tbillval01(Settle,Maturity)
```

Description

`[Val01Disc,Val01MMY,Val01BEY] = tbillval01(Settle,Maturity)` calculates the value of one basis point of $100 Treasury bill face value on the discount rate, money-market yield, or bond-equivalent yield.

Examples

Compute the Value of One Basis Point

This example shows how to compute the value of one basis point, given a Treasury bill with the following settle and maturity dates.

```
Settle = '01-Mar-03';
Maturity = '30-June-03';
[Val01Disc, Val01MMY, Val01BEY] = tbillval01(Settle, Maturity)
```

```
Val01Disc = 0.0034

Val01MMY = 0.0034

Val01BEY = 0.0033
```

Compute the Value of One Basis Point Using datetime Inputs

This example shows how to use `datetime` inputs to compute the value of one basis point, given a Treasury bill with the following settle and maturity dates.

```
Settle = datetime(2003,3,1);
Maturity = datetime(2003,6,30);
[Val01Disc, Val01MMY, Val01BEY] = tbillval01(Settle, Maturity)
```

```
Val01Disc = 0.0034

Val01MMY = 0.0034

Val01BEY = 0.0033
```

Input Arguments

Settle — Settlement date of Treasury bill

datetime array | string array | date character vector

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector using a datetime array, string array, or date character vectors. Settle must be earlier than Maturity.

To support existing code, tbillval01 also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Maturity — Maturity date of Treasury bill

datetime array | string array | date character vector

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, tbillval01 also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

Val01Disc — Value of one basis point of discount rate for every $100 face

numeric

Value of one basis point of discount rate for every $100 face, returned as a NTBILLS-by-1 vector.

Val01MMY — Value of one basis point of money-market yield for every $100 face

numeric

Value of one basis point of money-market yield for every $100 face, returned as a NTBILLS-by-1 vector.

Val01BEY — Value of one basis point of bond-equivalent yield for every $100 face

numeric

Value of one basis point of bond-equivalent yield for every $100 face, returned as a NTBILLS-by-1 vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although tbillval01 supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

tbillyield

Yield on Treasury bill

Syntax

```
[MMYield,BEYield,Discount] = tbillyield(Price,Settle,Maturity)
```

Description

`[MMYield,BEYield,Discount] = tbillyield(Price,Settle,Maturity)` computes the yield of US Treasury bills given `Price`, `Settle`, and `Maturity`.

Examples

Compute the Yield of U.S. Treasury Bills

This example shows how to compute the yield of U.S. Treasury bills, given a Treasury bill with the following characteristics.

```
Price = 98.75;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';

[MMYield, BEYield, Discount] = tbillyield(Price, Settle,...
Maturity)
```

```
MMYield = 0.0252

BEYield = 0.0255

Discount = 0.0249
```

Compute the Yield of U.S. Treasury Bills Using datetime Inputs

This example shows how to use `datetime` inputs to compute the yield of U.S. Treasury bills, given a Treasury bill with the following characteristics.

```
Price = 98.75;
Settle = datetime('01-Oct-2002','Locale','en_US');
Maturity = datetime('31-Mar-2003','Locale','en_US');
[MMYield, BEYield, Discount] = tbillyield(Price, Settle,Maturity)
```

```
MMYield = 0.0252

BEYield = 0.0255

Discount = 0.0249
```

Input Arguments

`Price` — Price of Treasury bills for every $100 face value

numeric

Price of Treasury bills for every $100 face value, specified as a scalar of a `NTBILLS`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date of Treasury bill

datetime array | string array | date character vector

Settlement date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `tbillyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of Treasury bill

datetime array | string array | date character vector

Maturity date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tbillyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

Output Arguments

`MMYield` — Money-market yields of Treasury bills

numeric

Money-market yields of the Treasury bills, returned as a `NTBILLS`-by-`1` vector.

`BEYield` — Bond equivalent yields of Treasury bills

numeric

Bond equivalent yields of the Treasury bills, returned as a `NTBILLS`-by-`1` vector.

`Discount` — Discount rates of Treasury bills

numeric

Discount rates of the Treasury bills, returned as a `NTBILLS`-by-`1` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although tbillyield supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

tbillyield2disc

Convert Treasury bill yield to equivalent discount

Syntax

```
Discount = tbillyield2disc(Yield,Settle,Maturity)
Discount = tbillyield2disc( ___ ,Type)
```

Description

`Discount = tbillyield2disc(Yield,Settle,Maturity)` converts the yield on some Treasury bills into their respective discount rates.

`Discount = tbillyield2disc( ___ ,Type)` adds an optional argument for `Type`.

Examples

Compute the Discount Rate on a Money-Market Basis

Given a Treasury bill with these characteristics, compute the discount rate.

```
Yield = 0.0497;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';

Discount = tbillyield2disc(Yield,Settle,Maturity)
```

```
Discount = 0.0485
```

Compute the Discount Rate on a Money-Market Basis Using datetime Inputs

Given a Treasury bill with these characteristics, compute the discount rate using datetime inputs.

```
Yield = 0.0497;
Settle = datetime(2002,10,1);
Maturity = datetime(2003,3,31);

Discount = tbillyield2disc(Yield,Settle,Maturity)
```

```
Discount = 0.0485
```

Input Arguments

`Yield` — Yield of Treasury bills
decimal

Yield of Treasury bills, specified as a scalar of a `NTBILLS`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date of Treasury bill

datetime array | string array | date character vector

Settlement date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tbillyield2disc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of Treasury bill

datetime array | string array | date character vector

Maturity date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `tbillyield2disc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Type` — Yield type

`1` (default) | numeric with values `1` = money market, `2` = bond-equivalent

(Optional) Yield type (determines how to interpret values entered in `Yield`), specified as a numeric value of `1` or `2` using a scalar or a `NTBILLS`-by-`1` vector.

Note The bond-equivalent yield basis is actual/365. The money-market yield basis is actual/360.

Data Types: `double`

Output Arguments

`Discount` — Discount rates of Treasury bills

numeric

Discount rates of the Treasury bills, returned as a `NTBILLS`-by-`1` vector.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `tbillyield2disc` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

tbl2bond

Treasury bond parameters given Treasury bill parameters

Syntax

```
[TBondMatrix,Settle] = tbl2bond(TBillMatrix)
```

Description

`[TBondMatrix,Settle] = tbl2bond(TBillMatrix)` restates US Treasury bill market parameters in US Treasury bond form as zero-coupon bonds. This function makes Treasury bills directly comparable to Treasury bonds and notes.

Examples

Restate U.S. Treasury Bill in U.S. Treasury Bond Form

This example shows how to restate U.S. Treasury bill market parameters in U.S. Treasury bond form, given published Treasury bill market parameters for December 22, 1997.

```
TBill = [datenum('jan 02 1998')  10  0.0526  0.0522  0.0530
         datenum('feb 05 1998')  44  0.0537  0.0533  0.0544
         datenum('mar 05 1998')  72  0.0529  0.0527  0.0540];

TBond = tbl2bond(TBill)
```

```
TBond = 3×5
10^5 ×

         0    7.2976    0.0010    0.0010    0.0000
         0    7.2979    0.0010    0.0010    0.0000
         0    7.2982    0.0010    0.0010    0.0000
```

Restate U.S. Treasury Bill in U.S. Treasury Bond Form Using datetime Input

This example shows how to use `datetime` input to restate U.S. Treasury bill market parameters in U.S. Treasury bond form, given published Treasury bill market parameters for December 22, 1997.

```
TBill = [datenum('jan 02 1998')  10  0.0526  0.0522  0.0530
         datenum('feb 05 1998')  44  0.0537  0.0533  0.0544
         datenum('mar 05 1998')  72  0.0529  0.0527  0.0540];

dates = datetime(TBill(:,1), 'ConvertFrom', 'datenum','Locale','en_US');
data = TBill(:,2:end);
t=[table(dates) array2table(data)];
[TBond, Settle] = tbl2bond(t)
```

```
TBond=3×5 table
    CouponRate     Maturity       Bid      Asked     AskYield
    __________    ___________    ______    ______    ________

        0         02-Jan-1998    99.854    99.855      0.053
        0         05-Feb-1998    99.344    99.349     0.0544
        0         05-Mar-1998    98.942    98.946      0.054

Settle = 3x1 datetime
   22-Dec-1997
   22-Dec-1997
   22-Dec-1997
```

Input Arguments

TBillMatrix — Treasury bill parameters

table | matrix

Treasury bill parameters, specified as a 5-column table or a N-by-5 matrix of bond information where the table columns or matrix columns contains:

- Maturity (Required) Maturity date of Treasury bills, specified as a datetime, string, date character vector, or serial date number when using a matrix. Use datenum to convert date character vectors to serial date numbers. If the input TBillMatrix is a table, the Maturity dates can be a datetime array, string array, date character vectors, or serial date numbers.
- DaysMaturity (Required) Days to maturity, specified as an integer. Days to maturity are quoted on a skip-day basis; the actual number of days from settlement to maturity is DaysMaturity + 1.
- Bid (Required) Bid bank-discount rate (the percentage discount from face value at which the bill could be bought, annualized on a simple-interest basis), specified as a decimal fraction.
- Asked (Required) Asked bank-discount rate, specified as a decimal fraction.
- AskYield (Required) Asked yield (the bond-equivalent yield from holding the bill to maturity, annualized on a simple-interest basis and assuming a 365-day year), specified as a decimal fraction.

Data Types: double | char | string | datetime | table

Output Arguments

TBondMatrix — Treasury bond parameters

table | matrix

Treasury bond parameters, returned as a table or matrix depending on the TBillMatrix input.

When TBillMatrix is a table, TBondMatrix is also a table, and the variable type for the Maturity dates in TBondMatrix (column 1) matches the variable type for Maturity in TBillMatrix. For example, if Maturity dates are datetime arrays in TBillMatrix, they will also be datetime arrays in TBondMatrix.

When TBillMatrix input is a N-by-5 matrix, then each row describes a Treasury bond.

The parameters or columns returned for `TBondMatrix` are:

- `CouponRate` (Column 1) Coupon rate, which is always `0` since the Treasury bills are, by definition, a zero coupon instrument.

  .
- `Maturity` (Column 2) Maturity date for each bond. The format of the dates matches the format used for `Maturity` in `TBillMatrix` (datetime array, string array, date character vector, or serial date number).
- `Bid` (Column 3) Bid price based on $100 face value.
- `Asked` (Column 4) Asked price based on $100 face value.
- `AskYield` (Column 5) Asked yield to maturity: the effective return from holding the bond to maturity, annualized on a compound-interest basis.

`Settle` — Settlement dates implied by maturity dates and number of days to maturity quote

serial date number | datetime

Settlement dates implied by the maturity dates and the number of days to maturity quote, returned as a `N`-by-`5` vector containing serial date numbers, by default. Use the function `datestr` to convert serial date numbers to formatted date character vectors. `Settle` is returned as a datetime array only if the input `TBillMatrix` is a table containing datetime arrays for `Maturity` in the first column.

Version History

Introduced before R2006a

thirdwednesday

Find third Wednesday of month

Syntax

```
[BeginDates,EndDates] = thirdwednesday(Month,Year)
[BeginDates,EndDates] = thirdwednesday( ___ ,outputType)
```

Description

`[BeginDates,EndDates] = thirdwednesday(Month,Year)` computes the beginning and end period date for a LIBOR contract (third Wednesdays of delivery months).

`[BeginDates,EndDates] = thirdwednesday( ___ ,outputType)`, using optional input arguments, computes the beginning and end period date for a LIBOR contract (third Wednesdays of delivery months).

The type of the outputs depends on the input `outputType`. If this variable is `'datenum'`, `BeginDates` and `EndDates` are serial date numbers. If `outputType` is `'datetime'`, then `BeginDates` and `EndDates` are datetime arrays. By default, `outputType` is set to `'datenum'`.

Examples

Determine the Third Wednesday for Given Months and Years

Find the third Wednesday dates for swaps commencing in the month of October in the years 2002, 2003, and 2004.

```
Months = [10; 10; 10];
Year = [2002; 2003; 2004];
[BeginDates, EndDates] = thirdwednesday(Months, Year);
datestr(BeginDates)
```

```
ans = 3x11 char array
    '16-Oct-2002'
    '15-Oct-2003'
    '20-Oct-2004'
```

```
datestr(EndDates)
```

```
ans = 3x11 char array
    '16-Jan-2003'
    '15-Jan-2004'
    '20-Jan-2005'
```

Find the third Wednesday dates for swaps commencing in the month of October in the years 2002, 2003, and 2004 using an `outputType` of `'datetime'`.

```
Months = [10; 10; 10];
Year = [2002; 2003; 2004];
[BeginDates, EndDates] = thirdwednesday(Months, Year,'datetime')

BeginDates = 3x1 datetime
   16-Oct-2002
   15-Oct-2003
   20-Oct-2004

EndDates = 3x1 datetime
   16-Jan-2003
   15-Jan-2004
   20-Jan-2005
```

Input Arguments

`Month` — Month of delivery for Eurodollar futures

integer from 1 through 12 | vector of integers from 1 through 12

Month of delivery for Eurodollar futures, specified as an `N`-by-`1` vector of integers from `1` through `12`.

Duplicate dates are returned when identical months and years are supplied.

Data Types: `single` | `double`

`Year` — Delivery year for Eurodollar futures/Libor contracts corresponding to `Month`

four-digit nonnegative integer | vector of four-digit nonnegative integers

Delivery year for Eurodollar futures/Libor contracts corresponding to `Month`, specified as an `N`-by-`1` vector of our-digit nonnegative integers.

Duplicate dates are returned when identical months and years are supplied.

Data Types: `single` | `double`

`outputType` — Output date format

`'datenum'` (default) | character vector with values `'datenum'` or `'datetime'`

Output date format, specified as a character vector with values `'datenum'` or `'datetime'`. If `outputType` is `'datenum'`, then `BeginDates` and `EndDates` are serial date numbers. However, if `outputType` is `'datetime'`, then `BeginDates` and `EndDates` are datetime arrays.

Data Types: `char`

Output Arguments

`BeginDates` — Third Wednesday of given month and year

serial date number | date character vector

Third Wednesday of given month and year, returned as serial date numbers or date character vectors, or datetime arrays. This is also the beginning of the 3-month period contract.

The type of the outputs depends on the input `outputType`. If this variable is `'datenum'`, `BeginDates` and `EndDates` are serial date numbers. If `outputType` is `'datetime'`, then`BeginDates` and `EndDates` are datetime arrays. By default, `outputType` is set to `'datenum'`.

`EndDates` — End of three-month period contract for given month and year
serial date number | date character vector

End of three-month period contract for given month and year, returned as serial date numbers or date character vectors, or datetime arrays.

The type of the outputs depends on the input `outputType`. If this variable is `'datenum'`, `BeginDates` and `EndDates` are serial date numbers. If `outputType` is `'datetime'`, then`BeginDates` and `EndDates` are datetime arrays. By default, `outputType` is set to `'datenum'`.

thirtytwo2dec

Thirty-second quotation to decimal

Syntax

```
OutNumber = thirtytwo2dec(InNumber,InFraction)
```

Description

`OutNumber = thirtytwo2dec(InNumber,InFraction)` changes the price quotation for a bond or bond future from a fraction with a denominator of 32 to a decimal.

Examples

Change the Price Quotation for a Bond or Bond Future From a Fraction

This example shows how to change the price quotation for a bond or bond future from a fraction with a denominator of 32 to a decimal, given two bonds that are quoted as 101-25 and 102-31.

```
InNumber  = [101; 102];
InFraction = [25; 31];

OutNumber = thirtytwo2dec(InNumber, InFraction)
```

```
OutNumber = 2×1

  101.7812
  102.9688
```

Input Arguments

`InNumber` — Input number
integer

Input number, specified as a scalar or an `N`-by-`1` vector of integers representing price without the fractional components.

Data Types: `double`

`InFraction` — Fractional portions of each element in `InNumber`
numeric decimal fraction

Fractional portions of each element in `InNumber`, specified as a scalar or an `N`-by-`1` vector of numeric decimal fractions.

Data Types: `double`

Output Arguments

`OutNumber` — Output number that represents sum of `InNumber` and `InFraction`
decimal

Output number that represents sum of `InNumber` and `InFraction`, returned as a decimal.

Version History

Introduced before R2006a

`dec2thirtytwo`

tick2ret

Convert price series to return series

Syntax

```
[Returns,Intervals] = tick2ret(Data)
[Returns,Intervals] = tick2ret( ___ ,Name,Value)
```

Description

`[Returns,Intervals] = tick2ret(Data)` computes asset returns for `NUMOBS` price observations of `NASSETS` assets.

`[Returns,Intervals] = tick2ret( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Convert Price Series to Return Series

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock. Then convert a price series to a return series, given the first 10 periodic returns of `TMW`.

```
load SimulatedStock.mat

TMW_Close = TMW(1:10,'Close');
[Returns,Intervals] = tick2ret(TMW_Close)
```

```
Returns=9×1 timetable
       Time           Close

Convert Price Series to Return Series Using `datetime` Input

Use `datetime` input to convert a price series to a return series, given periodic returns of two stocks observed in the first, second, third, and fourth quarters.

```
TickSeries = [100 80
110 90
115 88
110 91];

TickTimes = datetime({'1/1/2015','1/7/2015','1/16/2015','1/28/2015'},'InputFormat','MM/dd/uuuu')
[Returns,Intervals] = tick2ret(TickSeries,'TickTimes',TickTimes)
```

```
Returns = 3×2

    0.1000    0.1250
    0.0455   -0.0222
   -0.0435    0.0341

Intervals = 3x1 duration
   144:00:00
   216:00:00
   288:00:00
```

Input Arguments

`Data` — Data for asset prices

matrix | table | timetable

Data for asset prices, specified as a `NUMOBSNASSETS` matrix, `table`, or `timetable`. Prices across a given row are assumed to occur at the same time for all columns, and each column is a price series of an individual asset.

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Returns,Intervals] = tick2ret(TickSeries,'TickTimes',TickTimes)`

`TickTimes` — Observation times associated with prices

sequential observation times from 1,2,...NUMOBS assumed for all assets (default) | vector

Observation times associated with prices, specified as the comma-separated pair consisting of 'TickTimes' and a NUMOBS element column vector of monotonically increasing observation times associated with the prices in Data. Times are taken either as serial date numbers (day units), date strings, datetime arrays, or as decimal numbers in arbitrary units (for example, yearly).

Note If the input Data type is a timetable, the row times information in the timetable overwrites the TickTimes input.

Data Types: double | datetime | string

Method — Method to convert asset prices to returns

'Simple' (default) | character vector with value of 'Simple' or 'Continuous' | string with value of "Simple" or "Continuous"

Method to convert asset prices to returns, specified as the comma-separated pair consisting of 'Method' and a string or character vector indicating the method to convert asset prices to returns.

If the method is 'Simple', then simple periodic returns at time *t* are computed as:

```
Returns(t) = Data(t)/Data(t-1) - 1.
```

If the method is 'Continuous', the continuous returns are computed as:

```
Returns(t) = log(Data(t)/Data(t-1)).
```

Data Types: char | string

Output Arguments

Returns — Time series array of asset returns

matrix | table | timetable

Time series array of asset returns, returned as a NUMOBS-1-by-NASSETS array of asset returns with the same type (matrix, table, or timetable) as the input Data. The first row contains the oldest returns and the last row contains the most recent. Returns across a given row are assumed to occur at the same time for all columns, and each column is a return series of an individual asset.

Intervals — Interval times between successive prices

vector

Interval times between successive prices, returned as a NUMOBS-1 length column vector where Intervals(*t*) = TickTimes(*t*) - TickTimes(*t* - 1).

Version History

Introduced before R2006a

R2022b: Support for negative price data

Behavior changed in R2022b

The Data input accepts negative prices.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports input `Data` that is specified as a tall column vector, a tall table, or a tall timetable. For more information, see `tall` and “Tall Arrays”.

“Returns with Negative Prices” on page 2-32

time2date

Dates from time and frequency

Syntax

```
Dates = time2date(Settle,TFactors)
Dates = time2date( ___ ,Compounding,Basis,EndMonthRule)
```

Description

`Dates = time2date(Settle,TFactors)` computes `Dates` corresponding to compounded rate quotes between `Settle` and `TFactors`. `time2date` is the inverse of `date2time`.

`Dates = time2date( ___ ,Compounding,Basis,EndMonthRule)` computes `Dates` corresponding to compounded rate quotes between `Settle` and `TFactors` using optional input arguments for `Compounding`, `Basis`, and `EndMonthRule`. `time2date` is the inverse of `date2time`.

Examples

Calculate Dates Using `time2date`

Show that `date2time` and `time2date` are the inverse of each other. First compute the time factors using `date2time`.

```
Settle = datetime(2002,9,1);
Dates = [datetime(2005,8,31) ; datetime(2006,2,28) ; datetime(2006,6,15) ; datetime(2006,12,31)]
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
TFactors = date2time(Settle, Dates, Compounding, Basis,...
EndMonthRule)
```

```
TFactors = 4×1

    5.9945
    6.9945
    7.5738
    8.6576
```

Now use the calculated `TFactors` in `time2date` and compare the calculated dates with the original set.

```
Dates_calc = time2date(Settle, TFactors, Compounding, Basis,...
EndMonthRule)
```

```
Dates_calc = 4x1 datetime
   31-Aug-2005
   28-Feb-2006
   15-Jun-2006
```

```
31-Dec-2006
```

Input Arguments

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `time2date` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`TFactors` — Time factors

vector

Time factors, corresponding to the compounding value, specified as a vector. `TFactors` must be equal to or greater than zero.

Data Types: `double`

`Compounding` — Rate at which input zero rates are compounded when annualized

2 (Semiannual compounding) (default) | scalar with numeric values of `0`, `1`, `2`, `3`, `4`, `5`, `6`, `12`, `365`, `–1`

Rate at which input zero rates are compounded when annualized, specified as a scalar with numeric values of: `0`, `1`, `2`, `3`, `4`, `5`, `6`, `12`, `365`, or `–1`. Allowed values are defined as:

- `0` — Simple interest (no compounding)
- `1` — Annual compounding
- `2` — Semiannual compounding (default)
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding
- `365` — Daily compounding
- `-1` — Continuous compounding

The optional `Compounding` argument determines the formula for the discount factors (`Disc`):

- `Compounding` = `1`, `2`, `3`, `4`, `6`, `12`
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units, for example, `T = F` is one year.
- `Compounding` = `365`
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- `Compounding` = `-1`

- Disc = exp(-T*Z), where T is time in years.

Basis — Day-count basis

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis, specified as an integer with a value of 0 through 13 or a N-by-1 vector of integers with values 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: single | double

EndMonthRule — End-of-month rule flag for month having 30 or fewer days

1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using a N-by-1 vector of values. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

Output Arguments

Dates — Dates corresponding to compounded rate quotes between Settle and TFactors

serial date number | datetime array

Dates corresponding to compounded rate quotes between Settle and TFactors, returned as a scalar or a N-by-1 vector using serial date numbers or a datetime array.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `time2date` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

"Handle and Convert Dates" on page 2-2

tmfactor

Time factors of arbitrary dates

Syntax

```
TMFactors = tmfactor(Settle,Maturity)
```

Description

`TMFactors = tmfactor(Settle,Maturity)` determines the time factors from a vector of Settlement dates to a vector of Maturity dates.

Examples

Find Time Factors of `Settle` and `Maturity` Dates

Find the `TFactors` for `Settle` and `Maturity` dates.

```
TFactors = tmfactor('1-Jan-2015','1-Jan-2016')
```

```
TFactors = 2
```

Find the `TFactors` for `Settle` and `Maturity` dates using a datetimes.

```
TFactors = tmfactor(datetime(2015,1,1),datetime(2016,1,1))
```

```
TFactors = 2
```

Input Arguments

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note `Settle` must be earlier than `Maturity`.

To support existing code, `tmfactor` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Data Types: char | string | datetime

Output Arguments

TMFactors — Time factors from a vector of Settle dates to a vector of Maturity dates

scalar numeric

Time factors from a vector of Settle dates to a vector of Maturity dates, returned as a scalar numeric.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although tmfactor supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

"Analyzing and Computing Cash Flows" on page 2-11

todecimal

Fractional to decimal conversion

Syntax

```
usddec = todecimal(quote)
usddec = todecimal( ___ ,fracpart)
```

Description

`usddec = todecimal(quote)` returns the decimal equivalent, `usddec`, of a security whose price is normally quoted as a whole number and a fraction (`quote`).

`usddec = todecimal( ___ ,fracpart)` returns the decimal equivalent, `usddec`, of a security whose price is normally quoted as a whole number and a fraction (`quote`). `fracpart` indicates the fractional base (denominator) with which the security is normally quoted (default = `32`).

Examples

Convert Stock Quote from Fractinal to Decimal

Often secuirty prices are quoted in fractional form based on a denominator of 32. For example, if you see the quoted price is 100:05 it means 100 5/32. To find the equivalent decimal value, enter:

```
usddec = todecimal(100.05)
```

```
usddec = 100.1562
```

You can change the defualt denominator of 32 by using the `fracpart` optional argument with a value of `16`.

```
usddec = todecimal(97.04, 16)
```

```
usddec = 97.2500
```

Input Arguments

`quote` — Quoted security price
scalar numeric

Quoted security price, specified as a scalar numeric or an `NPORTS`-by-`1` vector.

Note The convention of using `.` (period) as a substitute for `:` (colon) in the input is adopted from Excel software.

Data Types: `double`

`fracpart` — Fractional base (denominator) with which the security is normally quoted

32 (default) | scalar numeric

(Optional) Fractional base (denominator) with which the security is normally quoted, specified as a scalar numeric.

Data Types: `double`

Output Arguments

`usddec` — Fractional to decimal conversion

numeric

Fractional to decimal conversion, returned as a numeric decimal.

Version History

Introduced before R2006a

See Also

`toquoted`

toquoted

Decimal to fractional conversion

Syntax

```
quote = toquoted(usddec,fracpart)
```

Description

`quote = toquoted(usddec,fracpart)` returns the fractional equivalent, `quote`, of the decimal figure, `usddec`, based on the fractional base (denominator), `fracpart`. The fractional bases are the ones used for quoting equity prices in the United States (denominator 2, 4, 8, 16, or 32). If `fracpart` is not entered, the denominator 32 is assumed.

Examples

Convert Decimal to Fraction

A United States equity price in decimal form is 101.625. To convert this to fractional form in eighths of a dollar:

```
quote = toquoted(101.625, 8)
```

```
quote = 101.0500
```

The answer is interpreted as 101 5/8.

The convention of using . (period) as a substitute for : (colon) in the output is adopted from Excel ® software.

Input Arguments

`usddec` — Equity price
numeric

Equity price, specified as a numeric decimal.

Data Types: `double`

`fracpart` — Fractional bases used for quoting equity prices in the United States
32 (default) | numeric with denominator value of 2, 4, 8, 16, or 32

Fractional bases used for quoting equity prices in the United States, specified as a scalar numeric.

Data Types: `double`

Output Arguments

`quote` — Fractional equivalent
numeric

Fractional equivalent, returned as a numeric. For example, bond prices are quoted in fractional form based on a 32nd. If you see the quoted price is `100:05`, it means 100 5/32 which is equivalent to 100.15625.

Version History

Introduced before R2006a

`todecimal`

convert2daily

Aggregate timetable data to daily periodicity

Syntax

```
TT2 = convert2daily(TT1)
TT2 = convert2daily(TT1,Name,Value)
```

Description

`TT2 = convert2daily(TT1)` aggregates data (for example, high-frequency and intra-day data) to a daily periodicity.

`TT2 = convert2daily(TT1,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Aggregate Prices and Logarithmic Returns to Daily Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results for a daily periodicity.

Load a timetable (`TT`) of simulated stock price data and corresponding logarithmic returns. The data stored in `TT` is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable `TT` also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
            Time            Price     Log_Return
    ____________________    ______    __________

    02-Jan-2018 11:52:11    100.71     0.0070749
    02-Jan-2018 13:23:09    103.11      0.023551
    02-Jan-2018 14:45:30    100.24     -0.028229
    02-Jan-2018 15:30:48    101.37       0.01121
    03-Jan-2018 10:02:21    101.81     0.0043311
    03-Jan-2018 11:22:37    100.17      -0.01624
    03-Jan-2018 14:45:20     99.66    -0.0051043
    03-Jan-2018 14:55:39    100.12     0.0046051
```

Aggregate prices and logarithmic returns to a daily periodicity. To maintain consistency between prices and returns, for any given trading day, aggregate the prices by reporting the last recorded price by using `"lastvalue"` and aggregate the returns by summing all logarithmic returns by using `"sum"`.

```
tt = convert2daily(TT,'Aggregation',["lastvalue" "sum"]);
head(tt)

       Time        Price     Log_Return
    ___________    ______    __________

    02-Jan-2018    101.37     0.013607
    03-Jan-2018    100.12    -0.012408
    04-Jan-2018    106.76     0.064214
    05-Jan-2018    112.78     0.054856
    08-Jan-2018    119.07     0.054273
    09-Jan-2018    119.46      0.00327
    10-Jan-2018    124.44     0.040842
    11-Jan-2018    125.63    0.0095174
```

To verify consistency, examine the input and output timetables for January 2 and 3, 2018.

```
TT(1:8,:)  % Input data for 02-Jan-2018 and 03-Jan-2018

ans=8×2 timetable
            Time             Price     Log_Return
    ____________________    ______    __________

    02-Jan-2018 11:52:11    100.71     0.0070749
    02-Jan-2018 13:23:09    103.11      0.023551
    02-Jan-2018 14:45:30    100.24     -0.028229
    02-Jan-2018 15:30:48    101.37       0.01121
    03-Jan-2018 10:02:21    101.81     0.0043311
    03-Jan-2018 11:22:37    100.17      -0.01624
    03-Jan-2018 14:45:20     99.66    -0.0051043
    03-Jan-2018 14:55:39    100.12     0.0046051
```

```
tt(1:2,:)  % Return aggregated results

ans=2×2 timetable
       Time        Price     Log_Return
    ___________    ______    __________

    02-Jan-2018    101.37     0.013607
    03-Jan-2018    100.12    -0.012408
```

For each business day in `TT`, notice that the output aggregated price is the last price of the day and that the aggregated return is the sum of all logarithmic returns. Also, the aggregated returns are consistent with aggregated prices.

For example, the aggregated return for January 3, 2018, is `-0.012408`, which is the logarithmic return associated with the last prices recorded on January 2 and 3, 2018 (that is, `-0.012408` = `log(100.12)` - `log(101.37)`).

The dates of the aggregated results are whole dates that indicate the dates for which aggregated results are reported.

Input Arguments

TT1 — Data to aggregate to daily periodicity
timetable

Data to aggregate to a daily periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

Note

- NaNs indicate missing values.
- Timestamps must be in ascending or descending order.

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using addBusinessCalendar first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: timetable

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: TT2 = convert2daily(TT1,'Aggregation',["lastvalue" "sum"])

Aggregation — Intra-day aggregation method for data in TT1
"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for TT1 defining how data is aggregated over business days, specified as one of the following methods, a string vector of methods, or a length numVariables cell vector of methods, where numVariables is the number of variables in TT1.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.
- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.
- @customfcn — A custom aggregation method that accepts a timetable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs [].

If you specify a single method, convert2daily applies the specified method to all time series in TT1. If you specify a string vector or cell vector aggregation, convert2daily applies aggregation(*j*) to TT1(:,*j*); convert2daily applies each aggregation method one at a time (for more details, see retime). For example, consider a daily timetable representing TT1 with three variables.

```
        Time            AAA       BBB           CCC

01-Jan-2018 12:48:09    100.03    200.06    300.09    400.12
02-Jan-2018 10:27:32    100.07    200.14    300.21    400.28
02-Jan-2018 12:46:09    100.08    200.16    300.24    400.32
02-Jan-2018 14:14:13    100.25    200.50    300.75    401.00
02-Jan-2018 15:52:31    100.19    200.38    300.57    400.76
03-Jan-2018 09:47:11    100.54    201.08    301.62    402.16
03-Jan-2018 11:24:23    100.59    201.18    301.77    402.36
03-Jan-2018 14:41:17    101.40    202.80    304.20    405.60
03-Jan-2018 16:00:00    101.94    203.88    305.82    407.76
04-Jan-2018 09:55:51    102.53    205.06    307.59    410.12
04-Jan-2018 10:07:12    103.35    206.70    310.05    413.40
04-Jan-2018 14:26:23    103.40    206.80    310.20    413.60
05-Jan-2018 13:13:12    103.91    207.82    311.73    415.64
05-Jan-2018 14:57:53    103.89    207.78    311.67    415.56
```

The corresponding default daily results representing TT2 (where the 'lastvalue' is reported for each day) are as follows.

```
  Time         AAA       BBB           CCC
___________    ______    ______    ________________
01-Jan-2018    100.03    200.06    300.09    400.12
02-Jan-2018    100.19    200.38    300.57    400.76
03-Jan-2018    101.94    203.88    305.82    407.76
04-Jan-2018    103.40    206.80    310.20    413.60
05-Jan-2018    103.89    207.78    311.67    415.56
```

All methods omit missing data (NaNs) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of TT1, missing values can also appear in the aggregated results TT2. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: char | string | cell | function_handle

Output Arguments

TT2 — Daily data

timetable

Daily data, returned as a timetable. The time arrangement of TT1 and TT2 are the same.

If a variable of TT1 has no records for a business day within the sampling time span, convert2daily returns a NaN for that variable and business day in TT2.

The first date in TT2 is the first business date on or after the first date in TT1. The last date in TT2 is the last business date on or before the last date in TT1.

Version History

Introduced in R2021a

convert2weekly

Aggregate timetable data to weekly periodicity

Syntax

```
TT2 = convert2weekly(TT1)
TT2 = convert2weekly(___,Name,Value)
```

Description

`TT2 = convert2weekly(TT1)` aggregates data (for example, data recorded daily) to a weekly periodicity.

`TT2 = convert2weekly(___,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Aggregate Timetable Daily Data to Weekly Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting from a daily to a weekly periodicity. You can use `convert2weekly` to aggregate both intra-daily data and aggregated daily data. These methods result in equivalent weekly aggregates.

Load a timetable (`TT`) of simulated stock price data and corresponding logarithmic returns. The data stored in `TT` is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31,2020. The timetable `TT` also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
            Time            Price     Log_Return
    ____________________    ______    __________

    02-Jan-2018 11:52:11    100.71     0.0070749
    02-Jan-2018 13:23:09    103.11      0.023551
    02-Jan-2018 14:45:30    100.24     -0.028229
    02-Jan-2018 15:30:48    101.37       0.01121
    03-Jan-2018 10:02:21    101.81     0.0043311
    03-Jan-2018 11:22:37    100.17      -0.01624
    03-Jan-2018 14:45:20     99.66    -0.0051043
    03-Jan-2018 14:55:39    100.12     0.0046051
```

Use `convert2daily` to aggregate intra-daily prices and returns to daily periodicity. To maintain consistency between prices and returns, for any given trading day, aggregate prices by reporting the last recorded price with "lastvalue" and aggregate returns by summing all logarithmic returns with "sum".

```
TT1 = convert2daily(TT,'Aggregation',["lastvalue" "sum"]);
head(TT1)
```

```
       Time         Price     Log_Return
    ___________    ______    __________

    02-Jan-2018    101.37     0.013607
    03-Jan-2018    100.12    -0.012408
    04-Jan-2018    106.76     0.064214
    05-Jan-2018    112.78     0.054856
    08-Jan-2018    119.07     0.054273
    09-Jan-2018    119.46      0.00327
    10-Jan-2018    124.44     0.040842
    11-Jan-2018    125.63    0.0095174
```

Use convert2weekly to aggregate the data to a weekly periodicity and compare the results of two different aggregation approaches. The first approach computes weekly results by aggregating the daily aggregates and the second approach computes weekly results by directly aggregating the original intra-daily data.

```
tt1 = convert2weekly(TT1,'Aggregation',["lastvalue" "sum"]);   % Daily to weekly
tt2 = convert2weekly(TT ,'Aggregation',["lastvalue" "sum"]);   % Intra-daily to weekly

head(tt1)

    19-Jan-2018    117.67    -0.067842
    26-Jan-2018     118.8    0.0095573
    02-Feb-2018    120.85     0.017109
    09-Feb-2018    123.68     0.023147
    16-Feb-2018    124.33    0.0052417
    23-Feb-2018    127.09     0.021956
```

Notice that the results of the two approaches are the same and that convert2weekly reports on Fridays by default. For weeks in which Friday is not an NYSE trading day, the function reports results on the previous business day. In addition, you can use the convert2weekly optional name-value pair argument 'EndOfWeekDay' to specify a different day of the week that ends business weeks.

Input Arguments

TT1 — Data to aggregate to weekly periodicity
timetable

Data to aggregate to a weekly periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

Note

- NaNs indicate missing values.
- Timestamps must be in ascending or descending order.

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using addBusinessCalendar first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: timetable

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: TT2 = convert2weekly(TT1,'Aggregation',["lastvalue" "sum"])

Aggregation — Aggregation method for TT1 data for intra-week or inter-day aggregation
"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for TT1 defining how data is aggregated over business days in an intra-week or inter-day periodicity, specified as one of the following methods, a string vector of methods, or a length numVariables cell vector of methods, where numVariables is the number of variables in TT1.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.
- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.
- @customfcn — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs [].

If you specify a single method, `convert2weekly` applies the specified method to all time series in `TT1`. If you specify a string vector or cell vector `aggregation`, `convert2weekly` applies `aggregation(j)` to `TT1(:,j)`; `convert2weekly` applies each aggregation method one at a time (for more details, see `retime`). For example, consider a daily timetable representing `TT1` with three variables.

```
  Time           AAA       BBB            CCC

___________    _______    _______    _________________
01-Jan-2018    100.00    200.00    300.00    400.00
02-Jan-2018    100.03    200.06    300.09    400.12

06-Jan-2018    100.19    200.38    300.57    400.76
07-Jan-2018    100.54    201.08    301.62    402.16
08-Jan-2018    100.59    201.18    301.77    402.36
09-Jan-2018    101.40    202.80    304.20    405.60
10-Jan-2018    101.94    203.88    305.82    407.76
11-Jan-2018    102.53    205.06    307.59    410.12
12-Jan-2018    103.35    206.70    310.05    413.40
13-Jan-2018    103.40    206.80    310.20    413.60
14-Jan-2018    103.91    207.82    311.73    415.64
15-Jan-2018    103.89    207.78    311.67    415.56
16-Jan-2018    104.44    208.88    313.32    417.76
17-Jan-2018    104.44    208.88    313.32    417.76
18-Jan-2018    104.04    208.08    312.12    416.16
19-Jan-2018    104.94    209.88    314.82    419.76
```

The corresponding default weekly results representing `TT2` (in which all days are business days and the `'lastvalue'` is reported on Fridays) are as follows.

```
  Time         AAA       BBB            CCC

___________    _______    _______    _________________
05-Jan-2018    100.25    200.50    300.75    401.00
12-Jan-2018    103.35    206.70    310.05    413.40
19-Jan-2018    104.94    209.88    314.82    419.76
```

The default `'lastvalue'` returns the latest observed value in a given week for all variables in `TT1`.

All methods omit missing data (`NaN`s) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of `TT1`, missing values can also appear in the aggregated results `TT2`. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: `char` | `string` | `cell` | `function_handle`

`Daily` — Intra-day aggregation method for `TT1`
`"lastvalue"` (default) | `"sum"` | `"prod"` | `"mean"` | `"min"` | `"max"` | `"firstvalue"` | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for `TT1`, specified as an aggregation method, a string vector of methods, or a length `numVariables` cell vector of methods. For more details on supported methods and behaviors, see the `'Aggregation'` name-value argument.

Data Types: `char` | `string` | `cell` | `function_handle`

EndOfWeekDay — Day of week that ends business weeks
"Friday" (weeks end on Friday) (default) | scalar integer with value 1 through 7 | "Sunday" | "Monday" | "Tuesday" | "Wednesday" | "Thursday" | "Friday" | "Saturday" | character vector

Day of the week that ends business weeks, specified as a value in the table.

Value	Day Ending Each Week
"Sunday" or 1	Sunday
"Monday" or 2	Monday
"Tuesday" or 3	Tuesday
"Wednesday" or 4	Wednesday
"Thursday" or 5	Thursday
"Friday" or 6	Friday
"Saturday" or 7	Saturday

If the specified end-of-week day in a given week is not a business day, the preceding business day ends that week.

Data Types: double | char | string

Output Arguments

TT2 — Weekly data
timetable

Weekly data, returned as a timetable. The time arrangement of TT1 and TT2 are the same.

If a variable of TT1 has no business-day records during an annual period within the sampling time span, convert2weekly returns a NaN for that variable and annual period in TT2.

If the first week (week1) of TT1 contains at least one business day, the first date in TT2 is the last business date of week1. Otherwise, the first date in TT2 is the next end-of-week business date of TT1.

If the last week (weekT) of TT1 contains at least one business day, the last date in TT2 is the last business date of weekT. Otherwise, the last date in TT2 is the previous end-of-week business date of TT1.

convert2monthly

Aggregate timetable data to monthly periodicity

Syntax

```
TT2 = convert2monthly(TT1)
TT2 = convert2monthly(TT1,Name,Value)
```

Description

`TT2 = convert2monthly(TT1)` aggregates data (for example, data recorded daily or weekly) to monthly periodicity.

`TT2 = convert2monthly(TT1,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Aggregate Timetable Data to Monthly Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting to a monthly periodicity. You can use `convert2monthly` to aggregate both intra-daily data and aggregated daily data. These methods result in equivalent monthly aggregates. Lastly, you can aggregate results on a specific day of each month (for example, the 15th), rather than the default end of the month.

Load a timetable (TT) of simulated stock price data and corresponding logarithmic returns. The data stored in TT is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable TT also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
            Time            Price     Log_Return
    ____________________    ______    __________

    02-Jan-2018 11:52:11    100.71     0.0070749

    02-Jan-2018 15:30:48    101.37       0.01121
    03-Jan-2018 10:02:21    101.81     0.0043311
    03-Jan-2018 11:22:37    100.17      -0.01624
    03-Jan-2018 14:45:20     99.66    -0.0051043
    03-Jan-2018 14:55:39    100.12     0.0046051
```

First aggregate intra-daily prices and returns to daily periodicity. To maintain consistency between prices and returns, for any given trading day aggregate prices by reporting the last recorded price using `"lastvalue"` and aggregate returns by summing all logarithmic returns using `"sum"`.

```
TT1 = convert2daily(TT,'Aggregation',["lastvalue" "sum"]);
head(TT1)
```

```
       Time         Price     Log_Return
    ___________    ______    __________

    02-Jan-2018    101.37     0.013607
    03-Jan-2018    100.12    -0.012408
    04-Jan-2018    106.76     0.064214
    05-Jan-2018    112.78     0.054856
    08-Jan-2018    119.07     0.054273

    15-May-2018    110.47     -0.01438
    15-Jun-2018     99.06     -0.10902
    13-Jul-2018     95.74     -0.03409
    15-Aug-2018     99.94     0.042934
```

Notice that the results of the two approaches are the same. For months in which the 15th is not an NYSE trading day, the function reports results on the previous business day.

Use Custom Aggregation Method to Convert Timetable Daily Data to Monthly Periodicity

You can apply custom aggregation methods using function handles. Specify a function handle to aggregate related variables in a `timetable` while maintaining consistency between aggregated results when converting from a daily to a monthly periodicity.

Load a timetable (TT) of simulated stock price data and corresponding logarithmic returns. The data stored in TT is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31,2020. The timetable TT also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT')
head(TT)
```

```
            Time              Price     Log_Return
    ____________________    ______    __________

    02-Jan-2018 11:52:11    100.71     0.0070749
    02-Jan-2018 13:23:09    103.11      0.023551
    02-Jan-2018 14:45:30    100.24     -0.028229
    02-Jan-2018 15:30:48    101.37       0.01121
    03-Jan-2018 10:02:21    101.81     0.0043311
    03-Jan-2018 11:22:37    100.17      -0.01624
    03-Jan-2018 14:45:20     99.66    -0.0051043
    03-Jan-2018 14:55:39    100.12     0.0046051
```

First add another variable to TT that contains the simple (proportional) returns associated with the prices in TT and examine the first few rows.

```
TT.Simple_Return = exp(TT.Log_Return) - 1;  % Log returns to simple returns
head(TT)
```

```
            Time              Price     Log_Return    Simple_Return
    ____________________    ______    __________    _____________

    02-Jan-2018 11:52:11    100.71     0.0070749          0.0071
    02-Jan-2018 13:23:09    103.11      0.023551        0.023831
    02-Jan-2018 14:45:30    100.24     -0.028229       -0.027834
    02-Jan-2018 15:30:48    101.37       0.01121        0.011273
    03-Jan-2018 10:02:21    101.81     0.0043311       0.0043405
    03-Jan-2018 11:22:37    100.17      -0.01624       -0.016108
    03-Jan-2018 14:45:20     99.66    -0.0051043      -0.0050913
    03-Jan-2018 14:55:39    100.12     0.0046051       0.0046157
```

Create a function to aggregate simple returns and compute the monthly aggregates. To maintain consistency between prices and returns, for any given month, aggregate prices by reporting the last recorded price by using `"lastvalue"` and report logarithmic returns by summing all intervening logarithmic returns by using `"sum"`.

Notice that the aggregation function for simple returns operates along the first (row) dimension and omits missing data (NaNs). For more information on custom aggregation functions, see `timetable` and `retime`. When aggregation methods are a mix of supported methods and user-supplied functions, the `'Aggregation'` name-value pair argument must be specified as a cell vector of methods enclosed in curly braces.

```
f = @(x)(prod(1 + x,1,'omitnan') - 1);      % Aggregate simple returns
tt = convert2monthly(TT,'Aggregation',{'lastvalue' 'sum' f});
head(tt)
```

```
       Time         Price     Log_Return    Simple_Return
    ___________    ______    __________    _____________

    31-Jan-2018    122.96      0.20669            0.2296
    28-Feb-2018    121.92    -0.008494         -0.008458
    29-Mar-2018     108.9     -0.11294          -0.10679
    30-Apr-2018    110.38     0.013499           0.01359
    31-May-2018     99.02     -0.10861          -0.10292
    29-Jun-2018     96.24    -0.028477         -0.028075
    31-Jul-2018     97.15    0.0094111         0.0094555
    31-Aug-2018    101.51     0.043901          0.044879
```

Input Arguments

TT1 — Data to aggregate to monthly periodicity

timetable

Data to aggregate to a monthly periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

Note

- `NaN`s indicate missing values.
- Timestamps must be in ascending or descending order.

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `TT2 = convert2monthly(TT1,'Aggregation',["lastvalue" "sum"])`

Aggregation — Aggregation method for TT1

`"lastvalue"` (default) | `"sum"` | `"prod"` | `"mean"` | `"min"` | `"max"` | `"firstvalue"` | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for TT1 defining how to aggregate data over business days in an intra-month or inter-day periodicity, specified as one of the following methods, a string vector of methods, or a length numVariables cell vector of methods, where numVariables is the number of variables in TT1.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.
- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.
- @customfcn — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs [].

If you specify a single method, convert2monthly applies the specified method to all time series in TT1. If you specify a string vector or cell vector aggregation, convert2monthly applies aggregation(*j*) to TT1(:,*j*); convert2monthly applies each aggregation method one at a time (for more details, see retime). For example, consider a daily timetable representing TT1 with three variables.

```
   Time         AAA       BBB           CCC
___________    ______    ______    ________________

    .             .         .         .         .
    .             .         .         .         .
30-Apr-2018    171.72    343.44    515.16    686.88
    .             .         .         .         .
    .             .         .         .         .
    .             .         .         .         .
31-May-2018    201.24    402.48    603.72    804.96
    .             .         .         .         .
    .             .         .         .         .
    .             .         .         .         .
30-Jun-2018    223.22    446.44    669.66    892.88
```

The corresponding default monthly results representing TT2 (in which all days are business days and the 'lastvalue' is reported on the last business day of each month) are as follows.

```
       Time         AAA       BBB          CCC      
    ___________    ______    ______    ________________

    31-Jan-2018    114.65    229.30    343.95    458.60
    28-Feb-2018    129.19    258.38    387.57    516.76
    31-Mar-2018    162.93    325.86    488.79    651.72
    30-Apr-2018    171.72    343.44    515.16    686.88
    31-May-2018    201.24    402.48    603.72    804.96
    30-Jun-2018    223.22    446.44    669.66    892.88
```

All methods omit missing data (NaNs) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of TT1, missing values can also appear in the aggregated results TT2. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: char | string | cell | function_handle

Daily — Intra-day aggregation method for TT1
"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for TT1, specified as an aggregation method, a string vector of methods, or a length numVariables cell vector of methods. For more details on supported methods and behaviors, see the 'Aggregation' name-value argument.

Data Types: char | string | cell | function_handle

EndOfMonthDay — Day of the month that ends months
last business day of month (default) | integer with value 1 to 31

Day of the month that ends months, specified as a scalar integer with value 1 to 31. For months with fewer days than EndOfMonthDay, convert2monthly reports aggregation results on the last business day of the month.

Data Types: double

Output Arguments

TT2 — Monthly data
timetable

Monthly data, returned as a timetable. The time arrangement of TT1 and TT2 are the same.

If a variable of TT1 has no business-day records during a month within the sampling time span, convert2monthly returns a NaN for that variable and month in TT2.

If the first month (month1) of TT1 contains at least one business day, the first date in TT2 is the last business date of month1. Otherwise, the first date in TT2 is the next end-of-month business date of TT1.

If the last month (monthT) of TT1 contains at least one business day, the last date in TT2 is the last business date of monthT. Otherwise, the last date in TT2 is the previous end-of-month business date of TT1.

convert2quarterly

Aggregate timetable data to quarterly periodicity

Syntax

```
TT2 = convert2quarterly(TT1)
TT2 = convert2quarterly(TT1,Name,Value)
```

Description

`TT2 = convert2quarterly(TT1)` aggregates data (for example, data recorded daily or weekly) to a quarterly periodicity.

`TT2 = convert2quarterly(TT1,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Aggregate Timetable Data to Quarterly Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting to a quarterly periodicity. You can use `convert2quarterly` to aggregate both intra-daily data and aggregated monthly data. These methods result in equivalent quarterly aggregates.

Load a timetable (`TT`) of simulated stock price data and corresponding logarithmic returns. The data stored in `TT` is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable `TT` also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
            Time             Price     Log_Return
    ____________________    ______    __________

    02-Jan-2018 11:52:11    100.71     0.0070749
    02-Jan-2018 13:23:09    103.11      0.023551
    02-Jan-2018 14:45:30    100.24     -0.028229
    02-Jan-2018 15:30:48    101.37       0.01121
    03-Jan-2018 10:02:21    101.81     0.0043311
    03-Jan-2018 11:22:37    100.17      -0.01624
    03-Jan-2018 14:45:20     99.66    -0.0051043
    03-Jan-2018 14:55:39    100.12     0.0046051
```

Use `convert2monthly` to aggregate intra-daily prices and returns to a monthly periodicity. To maintain consistency between prices and returns for any given month, aggregate prices by reporting the last recorded price using "lastvalue" and aggregate returns by summing all logarithmic returns using "sum".

```
TT1 = convert2monthly(TT,'Aggregation',["lastvalue" "sum"]);
head(TT1)
```

```
       Time          Price     Log_Return
    ___________    ______    __________

    31-Jan-2018    122.96       0.20669
    28-Feb-2018    121.92     -0.008494
    29-Mar-2018     108.9      -0.11294
    30-Apr-2018    110.38      0.013499
    31-May-2018     99.02      -0.10861
    29-Jun-2018     96.24     -0.028477
    31-Jul-2018     97.15     0.0094111
    31-Aug-2018    101.51      0.043901
```

Use convert2quarterly to aggregate the data to a quarterly periodicity and compare the results of two different approaches. The first approach computes quarterly results by aggregating the monthly aggregates and the second approach computes quarterly results by directly aggregating the original intra-daily data. Note that convert2quaterly reports results on the last business day of each quarter.

```
tt1 = convert2quarterly(TT1,'Aggregation',["lastvalue" "sum"]);  % Monthly to quarterly
tt2 = convert2quarterly(TT ,'Aggregation',["lastvalue" "sum"]);  % Intra-daily to quarterly

head(tt1)
```

```

    29-Mar-2018     108.9       0.08526
    29-Jun-2018     96.24      -0.12358
    28-Sep-2018    111.37       0.14601
    31-Dec-2018     92.72      -0.18327
    29-Mar-2019      78.7      -0.16394
    28-Jun-2019    110.54       0.33973
    30-Sep-2019    180.13        0.4883
    31-Dec-2019    163.65     -0.095949
```

```
head(tt2)
```

```
       Time          Price     Log_Return
    ___________    ______    __________

    29-Mar-2018     108.9       0.08526
    29-Jun-2018     96.24      -0.12358
    28-Sep-2018    111.37       0.14601
    31-Dec-2018     92.72      -0.18327
    29-Mar-2019      78.7      -0.16394
    28-Jun-2019    110.54       0.33973
    30-Sep-2019    180.13        0.4883
    31-Dec-2019    163.65     -0.095949
```

The results of the two approaches are the same because each quarter contains exactly three calendar months.

Input Arguments

TT1 — Data to aggregate to quarterly periodicity
timetable

Data to aggregate to a quarterly periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

Note

- `NaN`s indicate missing values.
- Timestamps must be in ascending or descending order.

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `TT2 = convert2quarterly(TT1,'Aggregation',["lastvalue" "sum"])`

`Aggregation` — Aggregation method for TT1 data for intra-quarter or inter-day aggregation
`"lastvalue"` (default) | `"sum"` | `"prod"` | `"mean"` | `"min"` | `"max"` | `"firstvalue"` | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for `TT1` data defining how to aggregate data over business days in an intra-quarter or inter-day periodicity, specified as one of the following methods, a string vector of methods, or a length `numVariables` cell vector of methods, where `numVariables` is the number of variables in `TT1`.

- `"sum"` — Sum the values in each year or day.
- `"mean"` — Calculate the mean of the values in each year or day.
- `"prod"` — Calculate the product of the values in each year or day.
- `"min"` — Calculate the minimum of the values in each year or day.
- `"max"` — Calculate the maximum of the values in each year or day.
- `"firstvalue"` — Use the first value in each year or day.
- `"lastvalue"` — Use the last value in each year or day.
- `@customfcn` — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs `[]`.

If you specify a single method, `convert2quarterly` applies the specified method to all time series in `TT1`. If you specify a string vector or cell vector `aggregation`, `convert2quarterly` applies `aggregation(j)` to `TT1(:,j)`; `convert2quarterly` applies each aggregation method one at a time (for more details, see `retime`). For example, consider a daily timetable representing `TT1` with three variables.

```
   Time         AAA       BBB            CCC
___________    ______    ______    ________________
01-Jan-2018    100.00    200.00    300.00    400.00

    .             .         .         .         .
    .             .         .         .         .
    .             .         .         .         .
31-Dec-2018    243.17    486.34    729.51    972.68
```

The corresponding default quarterly results representing `TT2` (in which all days are business days and the `'lastvalue'` is reported on the last business day of each quarter) are as follows.

```
   Time         AAA       BBB            CCC
___________    ______    ______    ________________
31-Mar-2018    162.93    325.86    488.79    651.72
30-Jun-2018    223.22    446.44    669.66    892.88
30-Sep-2018    232.17    464.34    696.51    928.68
31-Dec-2018    243.17    486.34    729.51    972.68
```

All methods omit missing data (`NaN`s) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of `TT1`, missing values can also appear in the aggregated results `TT2`. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: `char` | `string` | `cell` | `function_handle`

`Daily` — Intra-day aggregation method for `TT1`
`"lastvalue"` (default) | `"sum"` | `"prod"` | `"mean"` | `"min"` | `"max"` | `"firstvalue"` | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for `TT1`, specified as an aggregation method, a string vector of methods, or a length `numVariables` cell vector of methods. For more details on supported methods and behaviors, see the `'Aggregation'` name-value argument.

Data Types: `char` | `string` | `cell` | `function_handle`

Output Arguments

TT2 — Quarterly data
timetable

Quarterly data, returned as a timetable. The time arrangement of TT1 and TT2 are the same.

convert2quarterly reports quarterly aggregation results on the last business day of March, June, September, and December.

If a variable of TT1 has no business-day records during a quarter within the sampling time span, convert2quarterly returns a NaN for that variable and quarter in TT2.

If the first quarter (Q1) of TT1 contains at least one business day, the first date in TT2 is the last business date of Q1. Otherwise, the first date in TT2 is the next end-of-quarter business date of TT1.

If the last quarter (QT) of TT1 contains at least one business day, the last date in TT2 is the last business date of QT. Otherwise, the last date in TT2 is the previous end-of-quarter business date of TT1.

convert2semiannual

Aggregate timetable data to semiannual periodicity

Syntax

```
TT2 = convert2semiannual(TT1)
TT2 = convert2semiannual(TT1,Name,Value)
```

Description

`TT2 = convert2semiannual(TT1)` aggregates data (for example, data recorded daily or weekly) to a semiannual periodicity.

`TT2 = convert2semiannual(TT1,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Aggregate Timetable Data to Semiannual Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting to a semiannual periodicity. You can use `convert2semiannual` to aggregate both intra-daily data and aggregated quarterly data. These methods result in equivalent semiannual aggregates.

Load a timetable (`TT`) of simulated stock price data and corresponding logarithmic returns. The data stored in `TT` is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018 to December 31,2020. The timetable `TT` also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
            Time             Price     Log_Return
    ____________________    ______    __________

    02-Jan-2018 11:52:11    100.71     0.0070749
    02-Jan-2018 13:23:09    103.11      0.023551
    02-Jan-2018 14:45:30    100.24     -0.028229
    02-Jan-2018 15:30:48    101.37       0.01121
    03-Jan-2018 10:02:21    101.81     0.0043311
    03-Jan-2018 11:22:37    100.17      -0.01624
    03-Jan-2018 14:45:20     99.66    -0.0051043
    03-Jan-2018 14:55:39    100.12     0.0046051
```

Use `convert2quarterly` to aggregate intra-daily prices and returns to a quarterly periodicity. To maintain consistency between prices and returns, for any given quarter, aggregate prices by reporting the last recorded price using "lastvalue" and aggregate returns by summing all logarithmic returns using "sum".

```
TT1 = convert2quarterly(TT,'Aggregation',["lastvalue" "sum"])
```

```
TT1=12×2 timetable
       Time        Price     Log_Return
    ___________    ______    __________

    29-Mar-2018     108.9      0.08526 
    29-Jun-2018     96.24     -0.12358 
    28-Sep-2018    111.37      0.14601 
    31-Dec-2018     92.72     -0.18327 
    29-Mar-2019      78.7     -0.16394 
    28-Jun-2019    110.54      0.33973 
    30-Sep-2019    180.13       0.4883 
    31-Dec-2019    163.65    -0.095949 
    31-Mar-2020    177.46     0.081015 
    30-Jun-2020    168.96    -0.049083 
    30-Sep-2020    260.77      0.43398 
    31-Dec-2020    274.75     0.052223 
```

Use convert2semiannual to aggregate the data to a semiannual periodicity and compare the results of two different approaches. The first approach computes semiannual results by aggregating the quarterly aggregates and the second approach computes semiannual results by directly aggregating the original intra-daily data. Note that convert2semiannual reports results on the last business day of June and December.

```
tt1 = convert2semiannual(TT1,'Aggregation',["lastvalue" "sum"])  % Quarterly to semiannual
```

```
tt1=6×2 timetable
       Time        Price     Log_Return
    ___________    ______    __________

    29-Jun-2018     96.24    -0.038325 
    31-Dec-2018     92.72    -0.037261 
    28-Jun-2019    110.54      0.17579 
    31-Dec-2019    163.65      0.39235 
    30-Jun-2020    168.96     0.031932 
    31-Dec-2020    274.75       0.4862 
```

```
tt2 = convert2semiannual(TT ,'Aggregation',["lastvalue" "sum"])  % Intra-daily to semiannual
```

```
tt2=6×2 timetable
       Time        Price     Log_Return
    ___________    ______    __________

    29-Jun-2018     96.24    -0.038325 
    31-Dec-2018     92.72    -0.037261 
    28-Jun-2019    110.54      0.17579 
    31-Dec-2019    163.65      0.39235 
    30-Jun-2020    168.96     0.031932 
    31-Dec-2020    274.75       0.4862 
```

The results of the two approaches are the same because each semiannual period contains exactly two calendar quarters.

Input Arguments

TT1 — Data to aggregate to semiannual periodicity

timetable

Data to aggregate to a semiannual periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

Note

- NaNs indicate missing values.
- Timestamps must be in ascending or descending order.

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using addBusinessCalendar first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: timetable

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: TT2 = convert2semiannual(TT1,'Aggregation',["lastvalue" "sum"])

Aggregation — Aggregation method for semiannual period to semiannual periodicity (inter-day aggregation)

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for TT1 defining how data is aggregated over business days in a semiannual period to semiannual periodicity (inter-day aggregation), specified as one of the following methods, a string vector of methods, or a length numVariables cell vector of methods, where numVariables is the number of variables in TT1.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.
- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.

- `@customfcn` — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs `[]`.

If you specify a single method, `convert2semiannual` applies the specified method to all time series in `TT1`. If you specify a string vector or cell vector `aggregation`, `convert2semiannual` applies `aggregation(j)` to `TT1(:,j)`; `convert2semiannual` applies each aggregation method one at a time (for more details, see `retime`). For example, consider a daily timetable representing `TT1` with three variables.

```
    Time         AAA       BBB            CCC
___________    ______    ______    _________________
01-Jan-2018    100.00    200.00    300.00     400.00
02-Jan-2018    100.02    200.04    300.06     400.08
03-Jan-2018     99.96    199.92    299.88     399.84
    .             .         .         .          .
    .             .         .         .          .
    .             .         .         .          .
28-Jun-2018     69.63    139.26    208.89     278.52
29-Jun-2018     70.15     140.3    210.45     280.60
30-Jun-2018     75.77    151.54    227.31     303.08
01-Jul-2018     75.68    151.36    227.04     302.72
02-Jul-2018     71.34    142.68    214.02     285.36
03-Jul-2018     69.25    138.50    207.75     277.00
    .             .         .         .          .
    .             .         .         .          .
    .             .         .         .          .
29-Dec-2018    249.16    498.32    747.48     996.64
30-Dec-2018    250.21    500.42    750.63    1000.84
31-Dec-2018    256.75    513.50    770.25    1027.00
```

The corresponding default semiannual results representing `TT2` (in which all days are business days and the `'lastvalue'` is reported on the last business day of each semiannual period) are as follows.

```
     Time         AAA       BBB           CCC
___________    ______    ______    ________________
30-Jun-2018     75.77    151.54    227.31    303.08
31-Dec-2018    256.75    513.50    770.25   1027.00
```

All methods omit missing data (`NaN`s) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of `TT1`, missing values can also appear in the aggregated results `TT2`. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: `char` | `string` | `cell` | `function_handle`

Daily — Intra-day aggregation method for TT1

`"lastvalue"` (default) | `"sum"` | `"prod"` | `"mean"` | `"min"` | `"max"` | `"firstvalue"` | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for `TT1`, specified as an aggregation method, a string vector of methods, or a length `numVariables` cell vector of methods. For more details on supported methods and behaviors, see the `'Aggregation'` name-value argument.

Data Types: `char` | `string` | `cell` | `function_handle`

Output Arguments

TT2 — Semiannual data
timetable

Semiannual data, returned as a timetable. `convert2semiannual` reports semiannual aggregation results on the last business day of June and December. The time arrangement of `TT1` and `TT2` are the same.

If a variable of `TT1` has no business-day records during an annual period within the sampling time span, `convert2semiannual` returns a `NaN` for that variable and annual period in `TT2`.

The first date in `TT2` is the last business date of the semiannual period in which the first date in `TT1` occurs, provided `TT1` has business dates in that semiannual period. Otherwise the first date in `TT2` is the next end-of-semiannual-period business date.

The last date in `TT2` is the last business date of the semiannual period in which the last date in `TT1` occurs, provided `TT1` has business dates in that semiannual period. Otherwise the last date in `TT2` is the previous end-of-semiannual-period business date.

convert2annual

Aggregate timetable data to annual periodicity

Syntax

```
TT2 = convert2annual(TT1)
TT2 = convert2annual(TT1,Name,Value)
```

Description

`TT2 = convert2annual(TT1)` aggregates data (for example, recorded daily or weekly data) to annual periodicity.

`TT2 = convert2annual(TT1,Name,Value)` uses additional options specified by one or more name-value arguments.

Examples

Aggregate Timetable Data to Annual Periodicity

Applyseparate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting to an annual periodicity. You can use `convert2annual` to aggregate both intra-daily data and aggregated monthly data. These methods result in equivalent annual aggregates.

Load a timetable (`TT`) of simulated stock price data and corresponding logarithmic returns. The data stored in `TT` is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable `TT` also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
            Time            Price     Log_Return
    ____________________    ______    __________

    02-Jan-2018 11:52:11    100.71     0.0070749
    02-Jan-2018 13:23:09    103.11      0.023551
    02-Jan-2018 14:45:30    100.24     -0.028229
    02-Jan-2018 15:30:48    101.37       0.01121
    03-Jan-2018 10:02:21    101.81     0.0043311
    03-Jan-2018 11:22:37    100.17      -0.01624
    03-Jan-2018 14:45:20     99.66    -0.0051043
    03-Jan-2018 14:55:39    100.12     0.0046051
```

First, aggregate intra-daily prices and returns to a monthly periodicity. To maintain consistency between prices and returns, for any given month aggregate prices by reporting the last recorded price using `"lastvalue"` and aggregate returns by summing all logarithmic returns using `"sum"`.

```
TT1 = convert2monthly(TT,'Aggregation',["lastvalue" "sum"]);
head(TT1)

       Time        Price     Log_Return
    ___________    ______    __________

    31-Jan-2018    122.96       0.20669
    28-Feb-2018    121.92     -0.008494
    29-Mar-2018     108.9      -0.11294
    30-Apr-2018    110.38      0.013499
    31-May-2018     99.02      -0.10861
    29-Jun-2018     96.24     -0.028477
    31-Jul-2018     97.15     0.0094111
    31-Aug-2018    101.51      0.043901
```

Use `convert2annual` to aggregate the data to an annual periodicity and compare the results of the two different aggregation approaches. The first approach computes annual results by aggregating the monthly aggregates and the second approach computes annual results by directly aggregating the original intra-daily data. Notice that by default, convert2annual reports results on the last business day of December. To change the month that ends annual periods, use the `'EndOfYearMonth'` name-value pair argument for `convert2annual`.

```
tt1 = convert2annual(TT1,'Aggregation',["lastvalue" "sum"])  % Monthly to annual

tt1=3×2 timetable
       Time        Price     Log_Return
    ___________    ______    __________

    31-Dec-2018     92.72     -0.075586
    31-Dec-2019    163.65       0.56815
    31-Dec-2020    274.75       0.51813
```

```
tt2 = convert2annual(TT ,'Aggregation',["lastvalue" "sum"])  % Intra-daily to semiannual

tt2=3×2 timetable
       Time        Price     Log_Return
    ___________    ______    __________

    31-Dec-2018     92.72     -0.075586
    31-Dec-2019    163.65       0.56815
    31-Dec-2020    274.75       0.51813
```

The results of the two approaches are the same because each annual period contains exactly 12 calendar months.

Input Arguments

TT1 — Data to aggregate to annual periodicity

timetable

Data to aggregate to an annual periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

Note

- NaNs indicate missing values.
- Timestamps must be in ascending or descending order.

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using addBusinessCalendar first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: timetable

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: TT2 = convert2annual(TT1,'Aggregation',["lastvalue" "sum"])

Aggregation — Aggregation method for TT1
"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for TT1 defining how to aggregate data over business days in a year to an annual periodicity, specified as one of the following methods, a string vector of methods, or a length numVariables cell vector of methods, where numVariables is the number of variables in TT1.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.
- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.
- @customfcn — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs [].

If you specify a single method, convert2annual applies the specified method to all time series in TT1. If you specify a string vector or cell vector aggregation, convert2annual applies aggregation(*j*) to TT1(:,*j*); convert2annual applies each aggregation method one at a time (for more details, see retime). For example, consider an input daily timetable with three variables.

```
    Time         AAA       BBB           CCC
_____________   ______    ______    ________________
01-Jan-2018     100.00    200.00    300.00    400.00
02-Jan-2018     100.03    200.06    300.09    400.12
03-Jan-2018     100.07    200.14    300.21    400.28
```

```
          .            .         .         .         .
          .            .         .         .         .
          .            .         .         .         .
      29-Dec-2018    249.16    498.32    747.48    996.64
      30-Dec-2018    250.21    500.42    750.63   1000.84
      31-Dec-2018    256.75    513.50    770.25   1027.00
```

By default, `convert2annual` applies the aggregation method `"lastvalue"`, which reports for each variable the values of the last business day of each year. The aggregated annual results are as follows:

```
TT2 = convert2annual(TT1)
```

```
TT2 =

  1×3 timetable

        Time          AAA       BBB             CCC
    ___________    ______    ______    ________________
    31-Dec-2018    256.75    513.50    770.25   1027.00
```

All methods omit missing data (`NaN`s) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of `TT1`, missing values can also appear in the aggregated results `TT2`. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: `char` | `string` | `cell` | `function_handle`

Daily — Intra-day aggregation method for TT1

`"lastvalue"` (default) | `"sum"` | `"prod"` | `"mean"` | `"min"` | `"max"` | `"firstvalue"` | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for `TT1`, specified as an aggregation method, a string vector of methods, or a length `numVariables` cell vector of methods. For more details on supported methods and behaviors, see the `'Aggregation'` name-value argument.

Data Types: `char` | `string` | `cell` | `function_handle`

EndOfYearMonth — Month that ends annual periods

`"December"` (weeks end on Friday) (default) | integer with value `1` to `12` | `"January"` | `"February"` | `"March"` | `"April"` | `"May"` | `"June"` | `"July"` | `"August"` | `"September"` | `"October"` | `"November"` | `"December"` | character vector

Month that ends annual periods, specified as a value in this table.

Value	Month Ending Each Year
`"January"` or `1`	January
`"February"` or `2`	February
`"March"` or `3`	March
`"April"` or `4`	April
`"May"` or `5`	May
`"June"` or `6`	June
`"July"` or `7`	July

Value	Month Ending Each Year
`"August"` or `8`	August
`"September"` or `9`	September
`"October"` or `10`	October
`"November"` or `11`	November
`"December"` or `12`	December

Data Types: `double` | `char` | `string`

Output Arguments

TT2 — Annual data
timetable

Annual data, returned as a timetable. The time arrangement of `TT1` and `TT2` are the same.

If a variable of `TT1` has no business-day records during an annual period within the sampling time span, `convert2annual` returns a `NaN` for that variable and annual period in `TT2`.

If the first annual period (`year1`) of `TT1` contains at least one business day, the first date in `TT2` is the last business date of `year1`. Otherwise, the first date in `TT2` is the next end-of-year-period business date of `TT1`.

If the last annual period (`yearT`) of `TT1` contains at least one business day, the last date in `TT2` is the last business date of `yearT`. Otherwise, the last date in `TT2` is the previous end-of-year-period business date of `TT1`.

totalreturnprice

Total return price time series

Syntax

```
Return = totalreturnprice(Price,Action,Dividend)
```

Description

`Return = totalreturnprice(Price,Action,Dividend)` generates a total return price time series given price data, action or split data, and dividend data. All input data is unadjusted.

Examples

Compute Return Using datetime Input for Price and Action

Compute `Return` returned as a table using datetime input in tables for `Price` and `Action`.

```
act = [732313, 2; 732314 ,2];
div = [732313, 0.0800; 732314, 0.0800];
prc = [732313, 12; 732314, 13];

prcTableDateTime=table(datetime(prc(:,1),'ConvertFrom','datenum'),prc(:,2));
acttableString=table(datestr(act(:,1)),act(:,2));
divTableNum = array2table(div);
Return = totalreturnprice(prcTableDateTime,acttableString,divTableNum)
```

```
Return=2×2 table
        Date        Return
    ___________    ______

    01-Jan-2005         1
    02-Jan-2005    1.0833
```

Input Arguments

Price — Price of security

matrix | table

Price of security, specified as a table or an `NUMOBS`-by-2 matrix. If `Price` is a table, the dates can either be a datetime array, string array, date character vectors, or serial date numbers. If `Price` is an `NUMOBS`-by-2 matrix of price data, column 1 contains MATLAB serial date numbers and column 2 contains price values.

Data Types: `double` | `char` | `string` | `datetime` | `table`

Action — Action or split data

matrix | table

Action or split data, specified as a table or an NUMOBS-by-2 matrix. If Action is a table, the dates can either be a datetime array, string array, date character vectors, or serial date numbers. If Action is an NUMOBS-by-2 matrix of price data, column 1 contains MATLAB serial date numbers and column 2 contains split ratios.

Data Types: double | char | string | datetime | table

Dividend — Dividend payouts

matrix | table

Dividend payouts, specified as a table or an NUMOBS-by-2 matrix. If Dividend is a table, the dates can either be serial date numbers, date character vectors, or datetime arrays. If Dividend is a NUMOBS-by-2 matrix of price data, column 1 contains MATLAB serial date numbers and column 2 contains dividend payouts.

Data Types: double | table

Output Arguments

Return — Total return price time series

matrix | table

Total return price time series, returned as a NUMOBS-by-2 matrix (if all inputs are matrices) or table (if any inputs are tables) of price data, where column 1 is dates and column 2 is total return price values. Dates in column 1 are in datetime format if any inputs specify dates in datetime format. Dates in column 1 are in date character vector format if no inputs specify dates in datetime format, but any of them use date character vector format. Otherwise, dates in column 1 are specified as serial date numbers. Use the function datestr to convert serial date numbers to formatted date character vectors.

tr2bonds

Term-structure parameters given Treasury bond parameters

Syntax

```
[Bonds,Prices,Yields] = tr2bonds(TreasuryMatrix,Settle)
[Bonds,Prices,Yields] = tr2bonds( ___ ,Settle)
```

Description

`[Bonds,Prices,Yields] = tr2bonds(TreasuryMatrix,Settle)` returns term-structure parameters (`Bonds`, `Prices`, and `Yields`) sorted by ascending maturity date, given Treasury bond parameters. The formats of the output matrix and vectors meet requirements for input to the `zbtprice` and `zbtyield` zero-curve bootstrapping functions.

`[Bonds,Prices,Yields] = tr2bonds( ___ ,Settle)` adds an optional argument for `Settle`.

Examples

Return Term-Structure Parameters Given Treasury Bond Parameters

This example shows how to return term-structure parameters (bond information, prices, and yields) sorted by ascending maturity date, given Treasury bond market parameters for December 22, 1997.

```
Matrix =[0.0650 datenum('15-apr-1999')  101.03125 101.09375 0.0564
         0.05125 datenum('17-dec-1998')  99.4375   99.5     0.0563
         0.0625 datenum('30-jul-1998')  100.3125  100.375   0.0560
         0.06125 datenum('26-mar-1998') 100.09375 100.15625 0.0546];

[Bonds, Prices, Yields] = tr2bonds(Matrix)
```

```
Bonds = 4×6

    0.0540
    0.0598
```

Input Arguments

`TreasuryMatrix` — Treasury bond parameters

table | matrix

Treasury bond parameters, specified as a 5-column table or a `NumBonds`-by-5 matrix of bond information where the table columns or matrix columns contains:

- CouponRate (Required) Coupon rate of the Treasury bond, specified as a decimal indicating the coupon rates for each bond in the portfolio.
- Maturity (Required) Maturity date of the Treasury bond, specified as a serial date number when using a matrix. Use datenum to convert date character vectors to serial date numbers. If the input TreasuryMatrix is a table, the Maturity dates can be a datetime array, string array, or date character vectors.
- Bid (Required) Bid prices, specified using an integer-decimal form for each bond in the portfolio.
- Asked (Required) Asked prices, specified using an integer-decimal form for each bond in the portfolio.
- AskYield (Required) Quoted ask yield, specified using a decimal form for each bond in the portfolio.

Data Types: double | char | string | datetime | table

Settle — Settlement date of Treasury bond

datetime array | string array | date character vector

(Optional) Settlement date of the Treasury bond, specified as a scalar or a NINST-by-1 vector using a datetime array, string array, or date character vectors. The Settle date must be before the Maturity date.

To support existing code, tr2bonds also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Output Arguments

Bonds — Coupon bond information

table | matrix

Coupon bond information, returned as a table or matrix depending on the TreasuryMatrix input.

When TreasuryMatrix is a table, Bonds is also a table, and the variable type for the Maturity dates in Bonds (column 1) matches the variable type for Maturity in TreasuryMatrix.

When TreasuryMatrix input is a n-by-5 matrix, then each row describes a bond.

The parameters or columns returned for Bonds are:

- Maturity (Column 1) Maturity date for each bond in the portfolio. The format of the dates matches the format used for Maturity in TreasuryMatrix (datetime array, string array, date character vector, or serial date number).
- CouponRate (Column 2) Coupon rate for each bond in the portfolio in decimal form.
- Face (Column 3, Optional) Face or par value for each bond in the portfolio. The default is 100.
- Period (Column 4, Optional) Number of coupon payments per year for each bond in the portfolio with allowed values: 1, 2, 3, 4, 6, and 12. The default is 2, unless you are dealing with zero coupons, then Period is 0 instead of 2.
- Basis (Column 5, Optional) Day-count basis for each bond in the portfolio with possible values:
  - 0 = actual/actual (default)

  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see "Basis" on page 2-16.
- `EndMonthRule` (Column 6, Optional) End-of-month rule flag for each bond in the portfolio. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. `0` = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. `1` = set rule on, meaning that a bond's coupon payment date is always the last actual day of the month. The default is `1`.

`Prices` — Bond prices
numeric

Bond prices, returned as a column vector containing the price of each bond in `Bonds`, respectively. The number of rows (*n*) matches the number of rows in `Bonds`.

`Yields` — Bond yields
numeric

Bond yields, returned as a column vector containing the yield to maturity of each bond in `Bonds`, respectively. The number of rows (*n*) matches the number of rows in `Bonds`.

If the optional input argument `Settle` is used, `Yields` is computed as a semiannual yield to maturity. If the input `Settle` is not used, the quoted input yields are used.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `tr2bonds` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

transprob

Estimate transition probabilities from credit ratings data

Syntax

```
[transMat,sampleTotals,idTotals] = transprob(data)
[transMat,sampleTotals,idTotals] = transprob( ___ ,Name,Value)
```

Description

`[transMat,sampleTotals,idTotals] = transprob(data)` constructs a transition matrix from historical data of credit ratings.

`[transMat,sampleTotals,idTotals] = transprob( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Construct a Transition Matrix From a Table of Historical Data of Credit Ratings

Using the historical credit rating table as input data from `Data_TransProb.mat` display the first ten rows and compute the transition matrix:

```
load Data_TransProb
data(1:10,:)
```

```
ans=10×3 table
         ID                Date           Rating
    ____________    _______________    _______

    {'00010283'}    {'10-Nov-1984'}    {'CCC'}
    {'00010283'}    {'12-May-1986'}    {'B'  }
    {'00010283'}    {'29-Jun-1988'}    {'CCC'}
    {'00010283'}    {'12-Dec-1991'}    {'D'  }
    {'00013326'}    {'09-Feb-1985'}    {'A'  }
    {'00013326'}    {'24-Feb-1994'}    {'AA' }
    {'00013326'}    {'10-Nov-2000'}    {'BBB'}
    {'00014413'}    {'23-Dec-1982'}    {'B'  }
    {'00014413'}    {'20-Apr-1988'}    {'BB' }
    {'00014413'}    {'16-Jan-1998'}    {'B'  }
```

```
% Estimate transition probabilities with default settings
transMat = transprob(data)
```

```
transMat = 8×8

   93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017

Create a Transition Matrix Using a Cell Array for Historical Data of Credit Ratings

Using a MATLAB® table containing the historical credit rating cell array input data (`dataCellFormat`) from `Data_TransProb.mat`, estimate the transition probabilities with default settings.

```
load Data_TransProb
transMat = transprob(dataCellFormat)
```

```
transMat = 8×8

   93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017
    1.6166   93.1518    4.3632    0.6602    0.1626    0.0055    0.0004    0.0396
    0.1237    2.9003   92.2197    4.0756    0.5365    0.0661    0.0028    0.0753
    0.0236    0.2312    5.0059   90.1846    3.7979    0.4733    0.0642    0.2193
    0.0216    0.1134    0.6357    5.7960   88.9866    3.4497    0.2919    0.7050
    0.0010    0.0062    0.1081    0.8697    7.3366   86.7215    2.5169    2.4399
    0.0002    0.0011    0.0120    0.2582    1.4294    4.2898   81.2927   12.7167
         0         0         0         0         0         0         0  100.0000
```

Using the historical credit rating cell array input data (`dataCellFormat`), compute the transition matrix using the `cohort` algorithm:

```
%Estimate transition probabilities with 'cohort' algorithm
transMatCoh = transprob(dataCellFormat,'algorithm','cohort')
```

```
transMatCoh = 8×8
```

```
   93.1345    5.9335    0.7456    0.1553    0.0311         0         0         0
    1.7359   92.9198    4.5446    0.6046    0.1560         0         0    0.0390
    0.1268    2.9716   91.9913    4.3124    0.4711    0.0544         0    0.0725
    0.0210    0.3785    5.0683   89.7792    4.0379    0.4627    0.0421    0.2103
    0.0221    0.1105    0.6851    6.2320   88.3757    3.6464    0.2873    0.6409
         0         0    0.0761    0.7230    7.9909   86.1872    2.7397    2.2831
         0         0         0    0.3094    1.8561    4.5630   80.8971   12.3743
         0         0         0         0         0         0         0  100.0000
```

Visualize Transitions Data for `transprob`

This example shows how to visualize credit rating transitions that are used as an input to the `transprob` function. The example also describes how the `transprob` function treats rating transitions when the company data starts after the start date of the analysis, or when the end date of the analysis is after the last transition observed.

Sample Data

Set up fictitious sample data for illustration purposes.

```
data = {'ABC','17-Feb-2015','AA';
    'ABC','6-Jul-2017','A';
    'LMN','12-Aug-2014','B';
    'LMN','9-Nov-2015','CCC';
    'LMN','7-Sep-2016','D';
    'XYZ','14-May-2013','BB';
    'XYZ','21-Jun-2016','BBB'};
data = cell2table(data,'VariableNames',{'ID','Date','Rating'});
disp(data)
```

```
       ID              Date            Rating
    _______    ________________    _______

    {'ABC'}    {'17-Feb-2015'}    {'AA' }
    {'ABC'}    {'6-Jul-2017' }    {'A'  }
    {'LMN'}    {'12-Aug-2014'}    {'B'  }
    {'LMN'}    {'9-Nov-2015' }    {'CCC'}
    {'LMN'}    {'7-Sep-2016' }    {'D'  }
    {'XYZ'}    {'14-May-2013'}    {'BB' }
    {'XYZ'}    {'21-Jun-2016'}    {'BBB'}
```

The `transprob` function understands that this panel-data format indicates the dates when a new rating is assigned to a given company. `transprob` assumes that such ratings remain unchanged, unless a subsequent row explicitly indicates a rating change. For example, for company `'ABC'`, `transprob` understands that the `'A'` rating is unchanged for any date after `'6-Jul-2017'` (indefinitely).

Compute Transition Matrix and Transition Counts

The `transprob` function returns a transition probability matrix as the primary output. There are also optional outputs that contain additional information for how many transitions occurred. For more information, see `transprob` for information on the optional outputs for both the `'cohort'` and the `'duration'` methods.

For illustration purposes, this example allows you to pick the `StartYear` (limited to `2014` or `2015` for this example) and the `EndYear` (`2016` or `2017`). This example also uses the `hDisplayTransitions` helper function (see the Local Functions on page 15-1534 section) to format the transitions information for ease of reading.

```
StartYear =  2014 ;

EndYear =  2017 ;
startDate = datetime(StartYear,12,31,'Locale','en_US');
endDate = datetime(EndYear,12,31,'Locale','en_US');
RatingLabels = ["AAA","AA","A","BBB","BB","B","CCC","D"];

[tm,st,it] = transprob(data,'startDate',startDate,'endDate',endDate,'algorithm','cohort','labels
```

The transition probabilities of the `TransMat` output indicate the probability of migrating between ratings. The probabilities are expressed in %, that is, they are multiplied by 100.

```
hDisplayTransitions(tm,RatingLabels,"Transition Matrix")
```

```
Transition Matrix

           AAA    AA     A     BBB    BB    B    CCC     D 
           ___    __    ___    ___    __    _    ___    ___

    AAA    100     0      0      0     0    0      0      0
    AA       0    50     50      0     0    0      0      0
    A        0     0    100      0     0    0      0      0
    BBB      0     0      0    100     0    0      0      0
    BB       0     0      0     50    50    0      0      0
    B        0     0      0      0     0    0    100      0
    CCC      0     0      0      0     0    0      0    100
    D        0     0      0      0     0    0      0    100
```

The transition counts are stored in the `sampleTotals` optional output and indicate how many transitions occurred between ratings for the entire sample (that is, all companies).

```
hDisplayTransitions(st.totalsMat,RatingLabels,"Transition counts, all companies")
```

```
Transition counts, all companies

           AAA    AA    A    BBB    BB    B    CCC    D
           ___    __    _    ___    __    _    ___    _

    AAA     0     0     0     0     0     0     0     0
    AA      0     1     1     0     0     0     0     0
    A       0     0     0     0     0     0     0     0
    BBB     0     0     0     1     0     0     0     0
    BB      0     0     0     1     1     0     0     0
    B       0     0     0     0     0     0     1     0
    CCC     0     0     0     0     0     0     0     1
    D       0     0     0     0     0     0     0     1
```

The third output of `transprob` is `idTotals` that contains information about transitions at an ID level, company by company (in the same order that the companies appear in the input data).

Select a company to display the transition counts and a corresponding visualization of the transitions. The `hPlotTransitions` helper function (see the Local Functions on page 15-1534 section) shows the transitions history for a company.

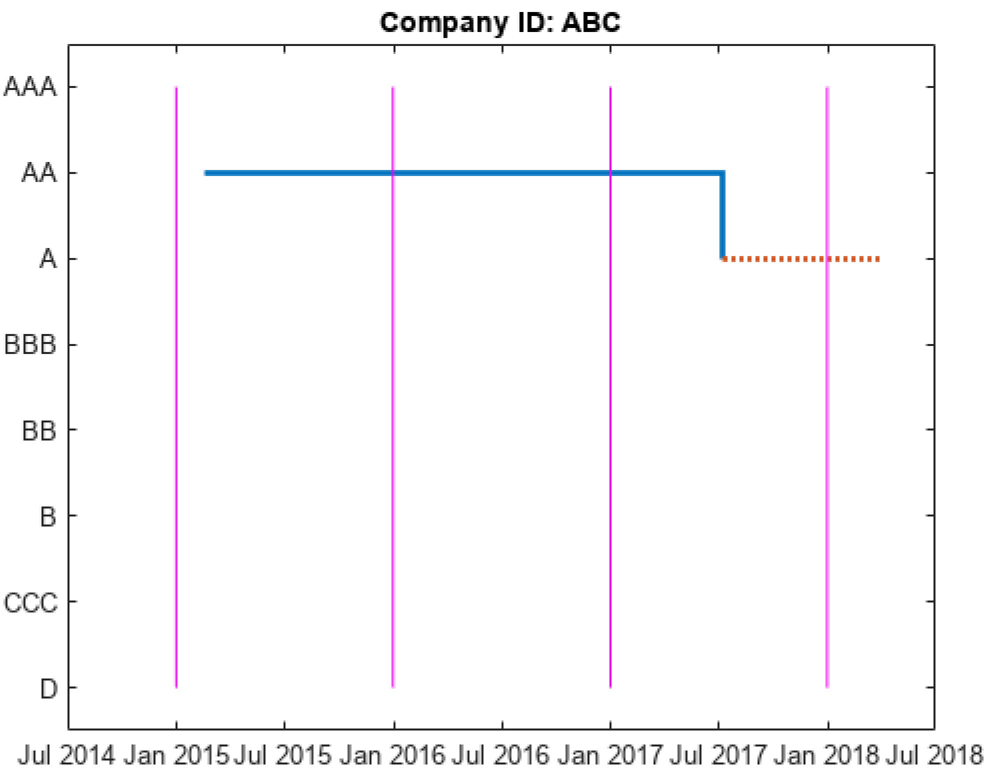
```
CompanyID = ABC ;
UniqueIDs = unique(data.ID,'stable');
[~,CompanyIndex] = ismember(CompanyID,UniqueIDs);
hDisplayTransitions(it(CompanyIndex).totalsMat,RatingLabels,strcat("Transition counts, company I
```

```
Transition counts, company ID: ABC

           AAA    AA    A    BBB    BB    B    CCC    D
           ___    __    _    ___    __    _    ___    _

    AAA     0     0     0     0     0     0     0     0
    AA      0     1     1     0     0     0     0     0
    A       0     0     0     0     0     0     0     0
    BBB     0     0     0     0     0     0     0     0
    BB      0     0     0     0     0     0     0     0
    B       0     0     0     0     0     0     0     0
    CCC     0     0     0     0     0     0     0     0
    D       0     0     0     0     0     0     0     0
```

```
hPlotTransitions(CompanyID,startDate,endDate,data,RatingLabels)
```



To understand how `transprob` handles data when the first observed date is after the start date of the analysis, or whose last observed date occurs before the end date of the analysis, consider the following example. For company `'ABC'` suppose that the analysis has a start date of `31-Dec-2014` and end date of `31-Dec-2017`. There are only two transitions reported for this company for that analysis time window. The first observation for `'ABC'` happened on `17-Feb-2015`. So the `31-Dec-2015` snapshot is the first time the company is observed. By `31-Dec-2016`, the company remained in the original 'AA' rating. By 31-Dec-2017, a downgrade to 'A' is recorded. Consistent with this, the transition counts show one transition from 'AA' to 'AA' (from the end of 2015 to the end of 2016), and one transition from 'AA' to 'A' (from the end of 2016 to the end of 2017). The plot shows the last rating as a dotted red line to emphasize that the last rating in the data is extrapolated indefinitely into the future. There is no extrapolation into the past; the company's history is ignored until a company rating is known for an entire transition period (31-Dec-2015 through 31-Dec-2016 in the case of 'ABC').

Compute Transition Matrix Containing NR (Not Rated) Rating

Consider a different sample data containing only a single company 'DEF'. The data contains transitions of company 'DEF' from 'A' to 'NR' rating and a subsequent transition from 'NR' to 'BBB'.

```
dataNR = {'DEF','17-Mar-2011','A';
    'DEF','24-Mar-2014','NR';
    'DEF','26-Sep-2016','BBB'};
dataNR = cell2table(dataNR,'VariableNames',{'ID','Date','Rating'});
disp(dataNR)
```

```
      ID            Date            Rating
    _______    _______________    _______

    {'DEF'}    {'17-Mar-2011'}    {'A'  }
    {'DEF'}    {'24-Mar-2014'}    {'NR' }
    {'DEF'}    {'26-Sep-2016'}    {'BBB'}
```

transprob treats 'NR' as another rating. The transition matrix below shows the estimated probability of transitioning into and out of 'NR'.

```
StartYearNR = 2010;
EndYearNR = 2018;
startDateNR = datetime(StartYearNR,12,31,'Locale','en_US');
endDateNR = datetime(EndYearNR,12,31,'Locale','en_US');
CompanyID_NR = "DEF";

RatingLabelsNR = ["AAA","AA","A","BBB","BB","B","CCC","D","NR"];

[tmNR,~,itNR] = transprob(dataNR,'startDate',startDateNR,'endDate',endDateNR,'algorithm','cohort
hDisplayTransitions(tmNR,RatingLabelsNR,"Transition Matrix")
```

```
Transition Matrix

           AAA    AA       A       BBB    BB      B     CCC     D       NR  
           ___    ___    ______    ___    ___    ___    ___    ___    ______

    AAA    100      0         0      0      0      0      0      0         0
    AA       0    100         0      0      0      0      0      0         0
    A        0      0    66.667      0      0      0      0      0    33.333
    BBB      0      0         0    100      0      0      0      0         0
    BB       0      0         0      0    100      0      0      0         0
    B        0      0         0      0      0    100      0      0         0
    CCC      0      0         0      0      0      0    100      0         0
    D        0      0         0      0      0      0      0    100         0
    NR       0      0         0     50      0      0      0      0        50
```

Display the transition counts and corresponding visualization of the transitions.

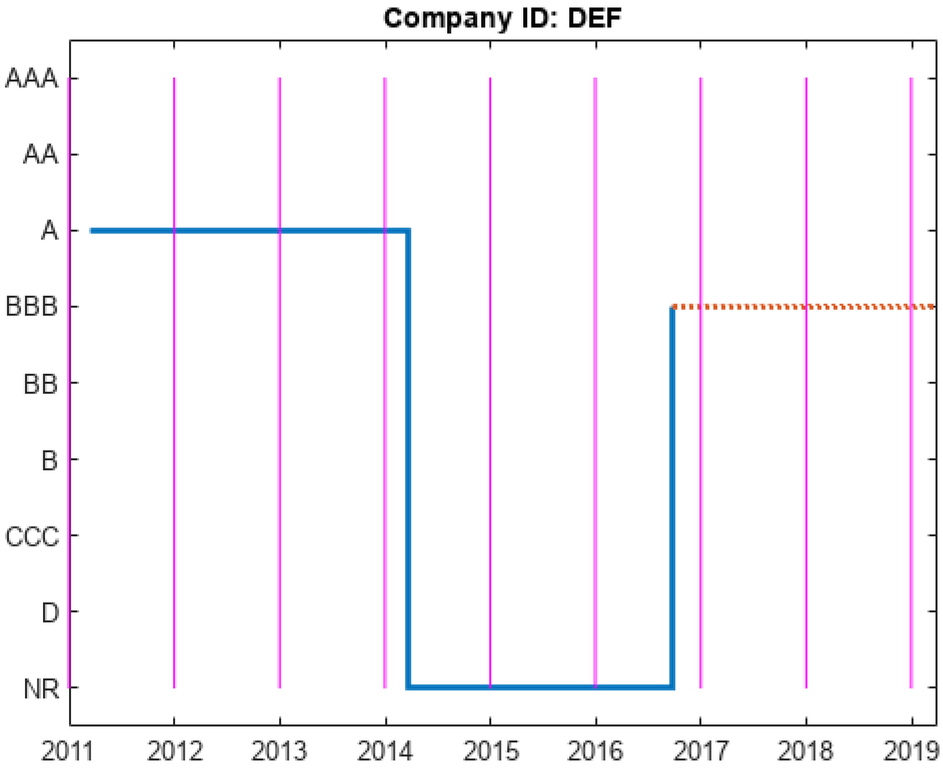
```
hDisplayTransitions(itNR.totalsMat,RatingLabelsNR,strcat("Transition counts, company ID: ",Compa
```

```
Transition counts, company ID: DEF

           AAA    AA    A    BBB    BB    B    CCC    D    NR
           ___    __    _    ___    __    _    ___    _    __

    AAA     0     0     0     0     0     0     0     0     0
    AA      0     0     0     0     0     0     0     0     0
    A       0     0     2     0     0     0     0     0     1
    BBB     0     0     0     2     0     0     0     0     0
    BB      0     0     0     0     0     0     0     0     0
    B       0     0     0     0     0     0     0     0     0
    CCC     0     0     0     0     0     0     0     0     0
    D       0     0     0     0     0     0     0     0     0
    NR      0     0     0     1     0     0     0     0     1
```

```
hPlotTransitions(CompanyID_NR,startDateNR,endDateNR,dataNR,RatingLabelsNR)
```



To remove the `'NR'` from the transition matrix, use the `'excludeLabels'` name-value input argument in `transprob`. The list of labels to exclude may or may not be specified in the name-value pair argument `labels`. For example, both `RatingLabels` and `RatingLabelsNR` generate the same output from `transprob`.

```
[tmNR,stNR,itNR] = transprob(dataNR,'startDate',startDateNR,'endDate',endDateNR,'algorithm','coh
hDisplayTransitions(tmNR,RatingLabels,"Transition Matrix")
```

```
Transition Matrix

           AAA    AA      A      BBB    BB      B      CCC     D
           ___    ___    ___    ___    ___    ___    ___    ___

    AAA    100      0      0      0      0      0      0      0
    AA       0    100      0      0      0      0      0      0
    A        0      0    100      0      0      0      0      0
    BBB      0      0      0    100      0      0      0      0
    BB       0      0      0      0    100      0      0      0
    B        0      0      0      0      0    100      0      0
    CCC      0      0      0      0      0      0    100      0
    D        0      0      0      0      0      0      0    100
```

Display the transition counts and corresponding visualization of the transitions.

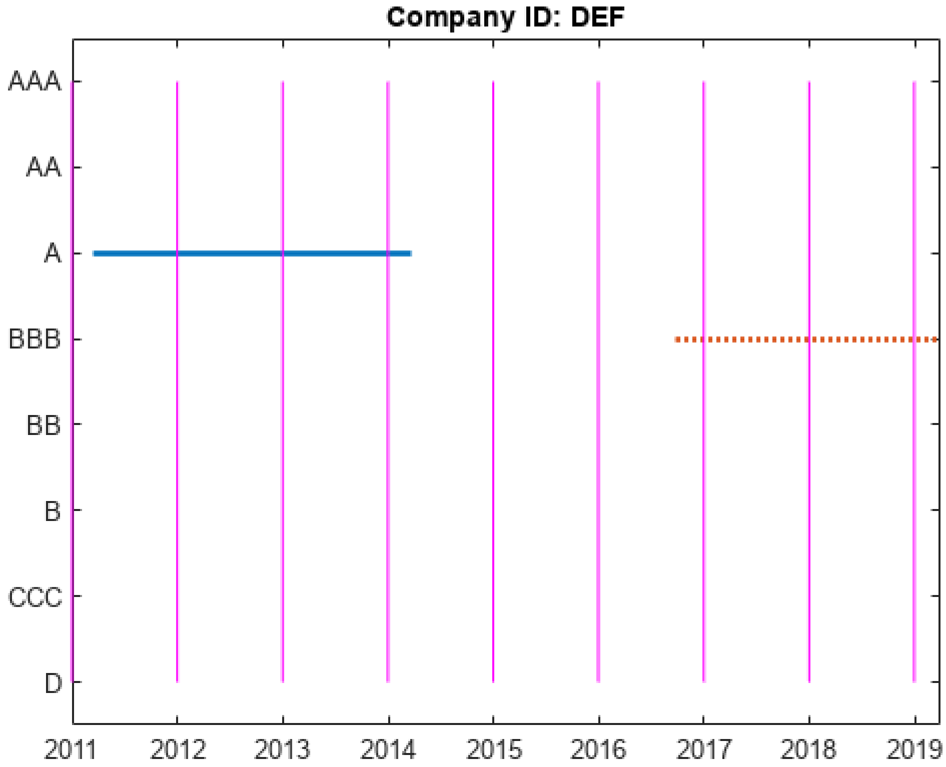
```
hDisplayTransitions(itNR.totalsMat,RatingLabels,strcat("Transition counts, company ID: ",CompanyI
```

```
Transition counts, company ID: DEF

           AAA    AA    A    BBB    BB    B    CCC    D
           ___    __    _    ___    __    _    ___    _

    AAA     0     0     0     0     0     0     0     0
    AA      0     0     0     0     0     0     0     0
    A       0     0     2     0     0     0     0     0
    BBB     0     0     0     2     0     0     0     0
    BB      0     0     0     0     0     0     0     0
    B       0     0     0     0     0     0     0     0
    CCC     0     0     0     0     0     0     0     0
    D       0     0     0     0     0     0     0     0
```

```
hPlotTransitions(CompanyID_NR,startDateNR,endDateNR,dataNR,RatingLabels)
```



Consistent with the previous plot, the transition counts still show two transitions from `'A'` to `'A'` (from the end of 2012 to the end of 2014), and two transitions from `'BBB'` to `'BBB'` (from the end of 2017 to the end of 2019).

However, different from the previous plot, specifying `'NR'` using the `'excludeLabels'` name-value input argument of `transprob` removes any transitions into and out of the `'NR'` rating.

Local Functions

```
function hDisplayTransitions(TransitionsData,RatingLabels,Title)
% Helper function to format transition information outputs

TransitionsAsTable = array2table(TransitionsData,...
   'VariableNames',RatingLabels,'RowNames',RatingLabels);

fprintf('\n%s\n\n',Title)
disp(TransitionsAsTable)

end

function hPlotTransitions(CompanyID,startDate,endDate,data,RatingLabels)
% Helper function to visualize transitions between ratings

   Ind = string(data.ID)==CompanyID;
   DatesOriginal = datetime(data.Date(Ind),'Locale','en_US');
   RatingsOriginal = categorical(data.Rating(Ind),flipud(RatingLabels(:)),flipud(RatingLabels(:)
   stairs(DatesOriginal,RatingsOriginal,'LineWidth',2)
   hold on;

   % Indicate rating extrapolated into the future (arbitrarily select 91
   % days after endDate as the last date on the plot)
   endDateExtrap = endDate+91;
   if endDateExtrap>DatesOriginal(end)
      DatesExtrap = [DatesOriginal(end); endDateExtrap];
      RatingsExtrap = [RatingsOriginal(end); RatingsOriginal(end)];
      stairs(DatesExtrap,RatingsExtrap,'LineWidth',2,'LineStyle',':')
   end
   hold off;

   % Add lines to indicate the snapshot dates
   % transprob uses 1 as the default for 'snapsPerYear', hardcoded here for simplicity
   % The call to cfdates generates the exact same snapshot dates that transprob uses
   snapsPerYear = 1;
   snapDates = cfdates(startDate-1,endDate,snapsPerYear)';
   yLimits = ylim;
   for ii=1:length(snapDates)
      line([snapDates(ii) snapDates(ii)],yLimits,'Color','m')
   end
   title(strcat("Company ID: ",CompanyID))
end
```

Input Arguments

data — Credit migration data

table | cell array of character vectors | preprocessed data structure

Using `transprob` to estimate transition probabilities given credit ratings historical data (that is, credit migration data), the `data` input can be one of the following:

- An `nRecords`-by-3 MATLAB table containing the historical credit ratings data of the form:

  ```
   ID            Date            Rating
  __________    _____________    ______
  '00010283'    '10-Nov-1984'    'CCC'
  '00010283'    '12-May-1986'    'B'
  '00010283'    '29-Jun-1988'    'CCC'
  '00010283'    '12-Dec-1991'    'D'
  '00013326'    '09-Feb-1985'    'A'
  '00013326'    '24-Feb-1994'    'AA'
  '00013326'    '10-Nov-2000'    'BBB'
  '00014413'    '23-Dec-1982'    'B'
  ```

  where each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). Column 3 is the rating assigned to the corresponding ID on the corresponding date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. When using a MATLAB table input, the names of the columns are irrelevant, but the ID, date and rating information are assumed to be in the first, second, and third columns, respectively. Also, when using a table input, the first and third columns can be categorical arrays, and the second can be a datetime array. The following summarizes the supported data types for table input:

Data Input Type	ID (1st Column)	Date (2nd Column)	Rating (3rd Column)
Table	• Numeric array • Cell array of character vectors • Categorical array	• Numeric array • Cell array of character vectors • Datetime array	• Numeric array • Cell array of character vectors • Categorical array

- An `nRecords`-by-`3` cell array of character vectors containing the historical credit ratings data of the form:

  ```
  '00010283'  '10-Nov-1984'  'CCC'
  '00010283'  '12-May-1986'  'B'
  '00010283'  '29-Jun-1988'  'CCC'
  '00010283'  '12-Dec-1991'  'D'
  '00013326'  '09-Feb-1985'  'A'
  '00013326'  '24-Feb-1994'  'AA'
  '00013326'  '10-Nov-2000'  'BBB'
  '00014413'  '23-Dec-1982'  'B'
  ```

  where each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). Column 3 is the rating assigned to the corresponding ID on the corresponding date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. IDs, dates, and ratings are stored in character vector format, but they can also be entered in numeric format. The following summarizes the supported data types for cell array input:

Data Input Type	ID (1st Column)	Date (2nd Column)	Rating (3rd Column)
Cell	• Numeric elements • Character vector elements	• Numeric elements • Character vector elements	• Numeric elements • Character vector elements

- A preprocessed data structure obtained using `transprobprep`. This data structure contains the fields`'idStart'`, `'numericDates'`, `'numericRatings'`, and `'ratingsLabels'`.

Data Types: `table` | `cell` | `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `transMat = transprob(data,'algorithm','cohort')`

`algorithm` — Estimation algorithm

`'duration'` (default) | character vector with values are `'duration'` or `'cohort'`

Estimation algorithm, specified as the comma-separated pair consisting of `'algorithm'` and a character vector with a value of `'duration'` or `'cohort'`.

Data Types: `char`

endDate — End date of the estimation time window

latest date in data (default) | datetime array | string array | date character vector | serial date number

End date of the estimation time window, specified as the comma-separated pair consisting of 'endDate' and a scalar datetime, string, date character vector, or serial date number. The endDate cannot be a date before the startDate.

Data Types: char | double | string | datetime

labels — Credit-rating scale

{'AAA','AA','A','BBB','BB','B','CCC','D'} (default) | cell array of character vectors

Credit-rating scale, specified as the comma-separated pair consisting of 'labels' and a nRatings-by-1, or 1-by-nRatings cell array of character vectors.

labels must be consistent with the ratings labels used in the third column of data. Use a cell array of numbers for numeric ratings, and a cell array for character vectors for categorical ratings.

Note When the input argument data is a preprocessed data structure obtained from a previous call to transprobprep, this optional input for 'labels is unused because the labels in the 'ratingsLabels' field of transprobprep take priority.

Data Types: cell

snapsPerYear — Number of credit-rating snapshots per year

1 (default) | numeric values are 1, 2, 3, 4, 6, or 12

Number of credit-rating snapshots per year to be considered for the estimation, specified as the comma-separated pair consisting of 'snapsPerYear' and a numeric value of 1, 2, 3, 4, 6, or 12.

Note This parameter is only used with the 'cohort' algorithm.

Data Types: double

startDate — Start date of the estimation time window

earliest date in data (default) | datetime array | string array | date character vector | serial date number

Start date of the estimation time window, specified as the comma-separated pair consisting of 'startDate' and a scalar datetime, string, date character vector, or serial date number.

Data Types: char | double | string | datetime

transInterval — Length of the transition interval in years

1 (one year transition probability) (default) | numeric

Length of the transition interval, in years, specified as the comma-separated pair consisting of 'transInterval' and a numeric value.

Data Types: double

excludeLabels — Label that is excluded from the transition probability computation

'' (do not exclude any label) (default) | numeric | character vector | string

Label that is excluded from the transition probability computation, specified as the comma-separated pair consisting of 'excludeLabels' and a character vector, string, or numerical rating.

If multiple labels are to be excluded, 'excludeLabels' must be a cell array containing all of the labels for exclusion. The type of the labels given in 'excludeLabels' must be consistent with the data type specified in the labels input.

The list of labels to exclude may or may not be specified in labels.

Data Types: double | char | string

Output Arguments

transMat — Matrix of transition probabilities in percent

matrix

Matrix of transition probabilities in percent, returned as a nRatings-by-nRatings transition matrix.

sampleTotals — Structure with sample totals

structure

Structure with sample totals, returned with fields:

- totalsVec — A vector of size 1-by-nRatings.
- totalsMat — A matrix of size nRatings-by-nRatings.
- algorithm — A character vector with values 'duration' or 'cohort'.

For the 'duration' algorithm, totalsMat(*i*,*j*) contains the total transitions observed out of rating *i* into rating*j* (all the diagonal elements are zero). The total time spent on rating *i* is stored in totalsVec(*i*). For example, if there are three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

```
Total time spent    IG       SG       D
in rating:       4859.09  1503.36  1162.05

Transitions             IG   SG    D
out of (row)       IG    0   89    7
into (column):     SG  202    0   32
                    D    0    0    0
```

Then

```
totals.totalsVec = [4859.09  1503.36  1162.05]
totals.totalsMat = [  0   89    7
                    202    0   32
                      0    0    0]
totals.algorithm = 'duration'
```

For the 'cohort' algorithm, totalsMat(*i*,*j*) contains the total transitions observed from rating *i* to rating *j*, and totalsVec(*i*) is the initial count in rating *i*. For example, given the following information:

```
Initial count       IG     SG     D
in rating:        4808   1572   1145

Transitions         IG     SG     D
from (row)    IG  4721     80      7
to (column):  SG   193   1347     32
               D     0      0   1145
```

Then

```
totals.totalsVec = [4808   1572   1145]
totals.totalsMat = [4721     80      7
                     193   1347     32
                       0      0   1145
totals.algorithm = 'cohort'
```

`idTotals` — IDs totals
struct array

IDs totals, returned as a struct array of size `nIDs`-by-`1`, where *n*IDs is the number of distinct IDs in column 1 of `data` when this is a table or cell array or, equivalently, equal to the length of the `idStart` field minus 1 when `data` is a preprocessed data structure from `transprobprep`. For each ID in the sample, `idTotals` contains one structure with the following fields:

- `totalsVec` — A sparse vector of size `1`-by-`nRatings`.
- `totalsMat` — A sparse matrix of size `nRatings`-by-`nRatings`.
- `algorithm` — A character vector with values `'duration'` or `'cohort'`.

These fields contain the same information described for the output `sampleTotals`, but at an ID level. For example, for `'duration'`, `idTotals(`*k*`).totalsVec` contains the total time that the *k*-th company spent on each rating.

More About

Cohort Estimation

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time.

If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates.

Duration Estimation

Unlike the cohort method, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur.

There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time.

Algorithms

Cohort Estimation

The algorithm first determines a sequence $t_0,...,t_K$ of snapshot dates. The elapsed time, in years, between two consecutive snapshot dates t_{k-1} and t_k is equal to 1 / *ns*, where *ns* is the number of snapshots per year. These K +1 dates determine K transition periods.

The algorithm computes N_i^n, the number of transition periods in which obligor *n* starts at rating *i*. These are added up over all obligors to get N_i, the number of obligors in the sample that start a period at rating *i*. The number periods in which obligor *n* starts at rating *i* and ends at rating *j*, or migrates from *i* to *j*, denoted byN_{ij}^n, is also computed. These are also added up to get N_{ij}, the total number of migrations from *i* to *j* in the sample.

The estimate of the transition probability from *i* to *j* in one period, denoted byP_{ij}, is

$$P_{ij} = \frac{Nij}{Ni}$$

These probabilities are arranged in a one-period transition matrix P_0, where the *i*,*j* entry in P_0 is P_{ij}.

If the number of snapshots per year *ns* is 4 (quarterly snapshots), the probabilities in P_0 are 3-month (or 0.25-year) transition probabilities. You may, however, be interested in 1-year or 2-year transition probabilities. The latter time interval is called the transition interval, Δ*t*, and it is used to convert P_0 into the final transition matrix, *P*, according to the formula:

$$P = P_0^{ns * \triangle t}$$

For example, if $ns = 4$ and $\Delta t = 2$, *P* contains the two-year transition probabilities estimated from quarterly snapshots.

Note For the cohort algorithm, optional output arguments `idTotals` and `sampleTotals` from `transprob` contain the following information:

- `idTotals(n).totalsVec` = $(N_i^n)\forall i$
- `idTotals(n).totalsMat` = $(N_{i,\,j}^n)\forall ij$
- `idTotals(n).algorithm` = `'cohort'`
- `sampleTotals.totalsVec` = $(N_i)\forall i$
- `sampleTotals.totalsMat` = $(N_{i,\,j})\forall ij$
- `sampleTotals.algorithm` = `'cohort'`

For efficiency, the vectors and matrices in `idTotals` are stored as sparse arrays.

When ratings must be excluded (see the `excludeLabels` name-value input argument), all transitions involving the excluded ratings are removed from the sample. For example, if the `‘NR’` rating must be excluded, any transitions into `‘NR’` and out of `‘NR’` are excluded from the sample. The total counts for all other ratings are adjusted accordingly. For more information, see “Visualize Transitions Data for transprob” on page 8-111.

Duration Estimation

The algorithm computes T_i^n, the total time that obligor n spends in rating i within the estimation time window. These quantities are added up over all obligors to get T_i, the total time spent in rating i, collectively, by all obligors in the sample. The algorithm also computes T_{ij}^n, the number times that obligor n migrates from rating i to rating j, with i not equal to j, within the estimation time window. And it also adds them up to get T_{ij}, the total number of migrations, by all obligors in the sample, from the rating i to j, with i not equal to j.

To estimate the transition probabilities, the duration algorithm first computes a generator matrix Λ. Each off-diagonal entry of this matrix is an estimate of the transition rate out of rating i into rating j, and is

$$\lambda_{ij} = \frac{T_{ij}}{T_i}, i \neq j$$

The diagonal entries are computed as:

$$\lambda_{ii} = -\sum_{j \neq i} \lambda_{ij}$$

With the generator matrix and the transition interval Δt (e.g., $\Delta t = 2$ corresponds to two-year transition probabilities), the transition matrix is obtained as $P = \exp(\Delta t \Lambda)$, where *exp* denotes matrix exponentiation (`expm` in MATLAB).

Note For the duration algorithm, optional output arguments `idTotals` and `sampleTotals` from `transprob` contain the following information:

- `idTotals(n).totalsVec` = $(T_i^n) \forall i$
- `idTotals(n).totalsMat` = $(T_{i,j}^n) \forall ij$
- `idTotals(n).algorithm` = `'duration'`
- `sampleTotals.totalsVec` = $(T_i) \forall i$
- `sampleTotals.totalsMat` = $(T_{i,j}) \forall ij$
- `sampleTotals.algorithm` = `'duration'`

For efficiency, the vectors and matrices in `idTotals` are stored as sparse arrays.

When ratings must be excluded (see the `excludeLabels` name-value input argument), all transitions involving the exclude ratings are removed from the sample. For example, if the `‘NR’` rating must be excluded, any transitions into `‘NR’` and out of `‘NR’` are excluded from the sample. The total time spent in `‘NR’` (or any other excluded rating) is also removed.

Version History

Introduced in R2010b

transprobbytotals

Estimate transition probabilities using `totals` structure input

Syntax

```
[transMat,sampleTotals] = transprobbytotals(totals)
[transMat,sampleTotals] = transprobbytotals( ___ ,Name,Value)
```

Description

`[transMat,sampleTotals] = transprobbytotals(totals)` estimates transition probabilities using a `totals` structure input. `transprobbytotals` is useful for removing outlier information, obtaining bootstrapped confidence intervals, or computing transition probability estimates for different periodicity parameters (1-year transitions, 2-year transitions, and so on) efficiently.

`[transMat,sampleTotals] = transprobbytotals( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Estimate Transition Probabilities Using a totals Structure Input

Use historical credit rating input data from `Data_TransProb.mat` and `transprob` to generate input for `transprobbytotals`:

```
load Data_TransProb

% Call TRANSPROB with three output arguments
[transMat, sampleTotals, idTotals] = transprob(data);
transMat
```

```
transMat = 8×8

   93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017
    1.6166   93.1518    4.3632    0.6602    0.1626    0.0055    0.0004    0.0396
    0.1237    2.9003   92.2197    4.0756    0.5365    0.0661    0.0028    0.0753
    0.0236    0.2312    5.0059   90.1846    3.7979    0.4733    0.0642    0.2193
    0.0216    0.1134    0.6357    5.7960   88.9866    3.4497    0.2919    0.7050
    0.0010    0.0062    0.1081    0.8697    7.3366   86.7215    2.5169    2.4399
    0.0002    0.0011    0.0120    0.2582    1.4294    4.2898   81.2927   12.7167
         0         0         0         0         0         0         0  100.0000
```

Suppose companies 4 and 27 are outliers and you want to remove them from the pre-processed `idTotals` struct array and estimate the new transition probabilities.

```
idTotals([4 27]) = [];
[transMat1, sampleTotals1] = transprobbytotals(idTotals);
transMat1
```

```
transMat1 = 8×8
```

```

Input Arguments

`totals` — Total transitions observed

structure | struct array

Total transitions observed, specified as a structure, or a struct array of length nTotals, with fields:

- `totalsVec` — A sparse vector of size `1`-by-`nRatings1`.
- `totalsMat` — A sparse matrix of size `nRatings1`-by-`nRatings2` with `nRatings1` ≤ `nRatings2`.
- `algorithm` — A character vector with values `'duration'` or `'cohort'`.

For the `'duration'` algorithm, `totalsMat`(*i*,*j*) contains the total transitions observed out of rating *i* into rating *j* (all the diagonal elements are 0). The total time spent on rating *i* is stored in `totalsVec`(*i*). For example, you have three rating categories, Investment Grade (`IG`), Speculative Grade (`SG`), and Default (`D`), and the following information:

```
Total time spent    IG       SG       D
in rating:       4859.09  1503.36  1162.05

Transitions             IG   SG    D
out of (row)       IG    0   89    7
into (column):     SG  202    0   32
                    D    0    0    0
```

Then:

```
totals.totalsVec = [4859.09  1503.36  1162.05]
totals.totalsMat = [  0   89    7
                    202    0   32
                      0    0    0]
totals.algorithm = 'duration'
```

For the `'cohort'` algorithm, `totalsMat`(*i*,*j*) contains the total transitions observed from rating *i* to rating *j*, and `totalsVec`(*i*) is the initial count in rating *i*. For example, given the following information:

```
Initial count       IG     SG     D
in rating:        4808   1572   1145

Transitions         IG     SG     D
from (row)    IG  4721     80      7
to (column):  SG   193   1347     32
               D     0      0   1145
```

Then:

```
totals.totalsVec = [4808   1572   1145]
totals.totalsMat = [4721     80      7
                    193   1347     32
                      0      0   1145
totals.algorithm = 'cohort'
```

Common totals structures are the optional output arguments from `transprob`:

- `sampleTotals` — A single structure summarizing the totals information for the whole dataset.
- `idTotals` — A struct array with the totals information at the ID level.

Data Types: `struct` | `structure`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `transMat = transprobbytotals(Totals1,'transInterval',5)`

`snapsPerYear` — Number of credit-rating snapshots per year

1 (default) | numeric values are 1, 2, 3, 4, 6, or 12

Number of credit-rating snapshots per year to be considered for the estimation, specified as the comma-separated pair consisting of `'snapsPerYear'` and a numeric value of 1, 2, 3, 4, 6, or 12.

Note This parameter is only used with the `'cohort' algorithm`.

Data Types: `double`

`transInterval` — Length of the transition interval in years

1 (one year transition probability) (default) | numeric

Length of the transition interval, in years, specified as the comma-separated pair consisting of `'transInterval'` and a numeric value.

Data Types: `double`

Output Arguments

`transMat` — Matrix of transition probabilities in percent
matrix

Matrix of transition probabilities in percent, returned as a `nRatings1`-by-`nRatings2` transition matrix.

`sampleTotals` — Structure with sample totals
structure

Structure with sample totals, returned with fields:

- `totalsVec` — A vector of size `1`-by-`nRatings1`.
- `totalsMat` — A matrix of size `nRatings1`-by-`nRatings2` with `nRatings1` ≤ `nRatings2`.
- `algorithm` — A character vector with values `'duration'` or `'cohort'`.

If `totals` is a struct array, `sampleTotals` contains the aggregated information. That is, `sampleTotals.totalsVec` is the sum of `totals`(*k*)`.totalsVec` over all *k*, and similarly for `totalsMat`. When `totals` is itself a single structure, `sampleTotals` and `totals` are the same.

More About

Cohort Estimation

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time.

If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates.

Duration Estimation

Unlike the cohort method, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur.

There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time.

Version History

Introduced in R2010b

transprobfromthresholds

Convert from credit quality thresholds to transition probabilities

Syntax

```
trans = transprobfromthresholds(thresh)
```

Description

`trans = transprobfromthresholds(thresh)` transforms credit quality thresholds into transition probabilities

Examples

Transform Credit Quality Thresholds Into Transition Probabilities

Use historical credit rating input data from `Data_TransProb.mat`, estimate transition probabilities with default settings.

```
load Data_TransProb

% Estimate transition probabilities with default settings
transMat = transprob(data)
```

```
transMat = 8×8

   93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017

```

Input Arguments

`thresh` — Credit quality thresholds

matrix

Credit quality thresholds, specified as a `M`-by-`N` matrix of credit quality thresholds.

In each row, the first element must be `Inf` and the entries must satisfy the following monotonicity condition:

```
 thresh(i,j) >= thresh(i,j+1), for 1<=j<N
```

The `M`-by-`N` input `thresh` and the `M`-by-`N` output `trans` are related as follows. The thresholds `thresh`(*i*,*j*) are critical values of a standard normal distribution *z*, such that:

```
trans(i,N) = P[z < thresh(i,N)],
```

```
trans(i,j) = P[z < thresh(i,j)] - P[z < thresh(i,j+1)], for 1<=j<N
```

Any given row in the output matrix `trans` determines a probability distribution over a discrete set of `N` ratings `'R1'`, `...`, `'RN'`, so that for any row *i* `trans`(*i*,*j*) is the probability of migrating into `'R`*j*`'`. `trans` can be a standard transition matrix, with `M` ≤ `N`, in which case row *i* contains the transition probabilities for issuers with rating `'R`*i*`'`. But `trans` does not have to be a standard transition matrix. `trans` can contain individual transition probabilities for a set of `M`-specific issuers, with `M` > `N`.

For example, suppose that there are only `N=3` ratings, `'High'`, `'Low'`, and `'Default'`, with these credit quality thresholds:

```
        High    Low    Default
High    Inf   -2.0814   -3.1214
Low     Inf    2.4044   -1.7530
```

The matrix of transition probabilities is then:

```
       High   Low   Default
High  98.13   1.78   0.09
Low    0.81  95.21   3.98
```

This means the probability of default for `'High'` is equivalent to drawing a standard normal random number smaller than −3.1214, or 0.09%. The probability that a `'High'` ends up the period with a rating of 'Low' or lower is equivalent to drawing a standard normal random number smaller than −2.0814, or 1.87%. From here, the probability of ending with a 'Low' rating is:

```
P[z<-2.0814] - P[z<-3.1214] = 1.87% - 0.09% = 1.78%
```

And the probability of ending with a 'High' rating is:

```
100%-1.87% = 98.13%
```

where 100% is the same as:

```
P[z<Inf]
```

Data Types: double

Output Arguments

trans — Matrix of transition probabilities in percent
matrix

Matrix of transition probabilities in percent, returned as a M-by-N matrix.

Version History

Introduced in R2011b

transprobgrouptotals

Aggregate credit ratings information into fewer rating categories

Syntax

```
totalsGrouped = transprobgrouptotals(totals,groupingEdges)
```

Description

`totalsGrouped = transprobgrouptotals(totals,groupingEdges)` aggregates the credit ratings information stored in the `totals` input into fewer ratings categories, which are defined by the `groupingEdges` argument.

Examples

Aggregate the Credit Ratings Information Stored in the totals Input

Use historical credit rating input data from `Data_TransProb.mat`. Load input data from file `Data_TransProb.mat`.

```
load Data_TransProb

% Call TRANSPROB with two output arguments
[transMat, sampleTotals] = transprob(data);
transMat
```

```
transMat = 8×8

   93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017

    3.1153    6.0157    8.7179   11.2373   13.5881
```

Input Arguments

`totals` — Total transitions observed

structure | struct array

Total transitions observed, specified as a structure, or a struct array of length nTotals, with fields:

- `totalsVec` — A sparse vector of size `1`-by-`nRatings1`.
- `totalsMat` — A sparse matrix of size `nRatings1`-by-`nRatings2` with `nRatings1` ≤ `nRatings2`.
- `algorithm` — A character vector with values `'duration'` or `'cohort'`.

For the `'duration'` algorithm, `totalsMat`(*i*,*j*) contains the total transitions observed out of rating *i* into rating *j* (all the diagonal elements are 0). The total time spent on rating *i* is stored in `totalsVec`(*i*). For example, you have three rating categories, Investment Grade (`IG`), Speculative Grade (`SG`), and Default (`D`), and the following information:

```
Total time spent    IG       SG       D
in rating:       4859.09  1503.36  1162.05

Transitions             IG   SG    D
out of (row)       IG    0   89    7
into (column):     SG  202    0   32
                    D    0    0    0
```

Then:

```
totals.totalsVec = [4859.09  1503.36  1162.05]
totals.totalsMat = [  0   89    7
                    202    0   32
                      0    0    0]
totals.algorithm = 'duration'
```

For the `'cohort'` algorithm, `totalsMat`(*i*,*j*) contains the total transitions observed from rating *i* to rating *j*, and `totalsVec`(*i*) is the initial count in rating *i*. For example, given the following information:

```
Initial count       IG     SG     D
in rating:        4808   1572   1145

Transitions         IG     SG     D
from (row)    IG  4721     80      7
to (column):  SG   193   1347     32
               D     0      0   1145
```

Then:

```
totals.totalsVec = [4808   1572   1145]
totals.totalsMat = [4721     80      7
                    193   1347     32
                      0      0   1145
totals.algorithm = 'cohort'
```

Common totals structures are the optional output arguments from `transprob`:

- `sampleTotals` — A single structure summarizing the totals information for the whole dataset.
- `idTotals` — A struct array with the totals information at the ID level.

Data Types: `struct` | `structure`

groupingEdges — Indicator for grouping credit ratings into categories
numeric array

Indicator for grouping credit ratings into categories, specified as a numeric array.

This table illustrates how to group a list of whole ratings into investment grade (`IG`) and speculative grade (`SG`) categories. Eight ratings are in the original list. Ratings `1` to `4` are `IG`, ratings `5` to `7` are `SG`, and rating `8` is a category of its own. In this example, the array of grouping edges is `[4 7 8]`.

```
Original ratings: 'AAA' 'AA'  'A'   'BBB' | 'BB'  'B'   'CCC' | 'D'
                                          |                   |
Relative ordering: (1)   (2)   (3)   (4)  |  (5)  (6)    (7)  | (8)
                                          |                   |
Grouped ratings:           'IG'           |      'SG'         | 'D'
                                          |                   |
Grouping edges:                      (4)  |              (7)  | (8)
```

In general, if `groupingEdges` has *K* elements `edge1` < `edge2` < `...` <`edge`*K*, ratings `1` to `edge1` (inclusive) are grouped in the first category, ratings `edge1+1` to `edge2` in the second category, and so forth.

Regarding the last element, `edge`*K*:

- If *n*`Ratings1` equals *n*`Ratings2`, then `edge`*K* must equal *n*`Ratings1`. This leads to *K* groups, and *n*`RatingsGrouped1` = *n*`RatingsGrouped2` = *K*.
- If *n*`Ratings1` < *n*`Ratings2`, then either:
  - `edge`*K* equals *n*`Ratings1`, in which case ratings `edge`*K*`+1`,...,`nRatings2` are treated as categories of their own. This results in *K*+(`nRatings2`-edge*K*) groups, with `nRatingsGrouped1` = *K* and `nRatingsGrouped2` = *K* + (`nRatings2` – `edge`*K*); or
  - `edge`*K* equals `nRatings2`, in which case there must be a *j*th edge element, `edge`*j*, such that `edge`*j* equals `nRatings1`. This leads to *K* groups, and `nRatingsGrouped1` = *j* and `nRatingsGrouped2` = *K*.

Data Types: `double`

Output Arguments

totalsGrouped — Aggregated information by categories
structure | struct array

Aggregated information by categories, returned as a structure, or a struct array of length nTotals, with fields:

- totalsVec — A vector of size 1-by-nRatingsGrouped1.
- totalsMat — A matrix of size nRatingsGrouped1-by-nRatingsGrouped2.
- algorithm — A character vector, 'duration' or 'cohort'.

nRatingsGrouped1 and nRatingsGrouped2 are defined in the description of groupingEdges. Each structure contains aggregated information by categories, based on the information provided in the corresponding structure in totals, according to the grouping of ratings defined by groupingEdges and consistent with the algorithm choice.

Following the examples in the description of the totals input, suppose IG and SG are grouped into a single ND (Not-Defaulted) category, using the edges[2 3]. For the 'cohort' algorithm, the output is:

```
totalsGrouped.totalsVec = [6380   1145]
totalsGrouped.totalsMat = [6341     39
                              0   1145]
totalsGrouped.algorithm = 'cohort'
```

and for the 'duration' algorithm:

```
totalsGrouped.totalsVec = [6362.45  1162.05]
totalsGrouped.totalsMat = [0  39
                           0   0]
totalsGrouped.algorithm = 'duration'
```

More About

Cohort Estimation

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time.

If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates. For more information, see the Algorithms section of transprob.

Duration Estimation

Unlike the cohort algorithm, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur.

There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time. For more information, see the Algorithms section of transprob.

Version History

Introduced in R2011b

transprobprep

Preprocess credit ratings data to estimate transition probabilities

Syntax

```
[prepData] = transprobprep(data)
[prepData] = transprobprep( ___ ,Name,Value)
```

Description

`[prepData] = transprobprep(data)` preprocesses credit ratings historical data (that is, credit migration data) for the subsequent estimation of transition probabilities.

`[prepData] = transprobprep( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Aggregate the Credit Ratings Information Stored in the totals Input

Load input data from the file `Data_TransProb.mat` and display the first ten rows. In this example, the inputs are provided in character vector format.

```
load Data_TransProb

% Preprocess credit ratings data.
prepData = transprobprep(data)
```

```
prepData = struct with fields:
          idStart: [1506x1 double]
     numericDates: [4315x1 double]
   numericRatings: [4315x1 double]
    ratingsLabels: {'AAA'  'AA'  'A'  'BBB'  'BB'  'B'  'CCC'  'D'}
```

Estimate transition probabilities with the default settings.

```
transMat = transprob(prepData)
```

```
transMat = 8×8

   93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017

         0         0         0         0         0         0         0  100.0000
```

Input Arguments

data — Historical data for credit ratings

table | cell array of character vectors

Historical input data for credit ratings, specified as one of the following:

- A MATLAB table of size nRecords-by-3 containing the credit ratings. Each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). The assigned credit rating corresponds to the associated ID on the associated date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. When using a MATLAB table input, the names of the columns are irrelevant, but the ID, date and rating information are assumed to be in the first, second, and third columns, respectively. Also, when using a table input, the first and third columns can be categorical arrays, and the second can be a datetime array. Here is an example with all the information in table format:

  ```
   ID            Date            Rating
  __________    _____________    ______
  '00010283'    '10-Nov-1984'    'CCC'
  '00010283'    '12-May-1986'    'B'
  '00010283'    '29-Jun-1988'    'CCC'
  '00010283'    '12-Dec-1991'    'D'
  '00013326'    '09-Feb-1985'    'A'
  '00013326'    '24-Feb-1994'    'AA'
  ```

  The following summarizes the supported data types for table input:

Data Input Type	ID (1st Column)	Date (2nd Column)	Rating (3rd Column)
Table	• Numeric array • Cell array of character vectors • Categorical array	• Numeric array • Cell array of character vectors • Datetime array	• Numeric array • Cell array of character vectors • Categorical array

- A cell array of size nRecords-by-3 containing the credit ratings. Each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). The assigned credit rating corresponds to the associated ID on the associated date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required but is recommended. IDs, dates, and ratings are stored in character vector format, but they can also be entered in numeric format. Here is an example with all the information in character vector format:

```
'00010283'    '10-Nov-1984'    'CCC'
'00010283'    '12-May-1986'    'B'
'00010283'    '29-Jun-1988'    'CCC'
'00010283'    '12-Dec-1991'    'D'
'00013326'    '09-Feb-1985'    'A'
'00013326'    '24-Feb-1994'    'AA'
```

The following summarizes the supported data types for cell array input:

Data Input Type	ID (1st Column)	Date (2nd Column)	Rating (3rd Column)
Cell	• Numeric elements • Character vector elements	• Numeric elements • Character vector elements	• Numeric elements • Character vector elements

Data Types: `table` | `cell`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `prepData = transprobprep(data,'labels', {'AAA','AA','A','BBB','BB','B','CCC','F'})`

`labels` — Credit-rating scale

`{'AAA','AA','A','BBB','BB','B','CCC','D'}` (default) | cell array of character vectors

Credit-rating scale, specified as the comma-separated pair consisting of `'labels'` and a `nRatings`-by-`1`, or `1`-by-`nRatings` cell array of character vectors.

`labels` must be consistent with the ratings labels used in the third column of `data`. Use a cell array of numbers for numeric ratings, and a cell array for character vectors for categorical ratings.

Data Types: `cell`

Output Arguments

`prepData` — Summary where credit ratings information corresponding to each company starts and ends

structure

Summary where the credit ratings information corresponding to each company starts and ends, returned as a structure with the following fields:

- `idStart` — Array of size (*n*IDs+1)-by-1, where *n*IDs is the number of distinct IDs in column 1 of `data`. This array summarizes where the credit ratings information corresponding to each company starts and ends. The dates and ratings corresponding to company *j* in `data` are stored from row `idStart`(*j*) to row `idStart`(*j*+1)−1 of `numericDates` and `numericRatings`.
- `numericDates` — Array of size *n*Records-by-`1`, containing the dates in column 2 of `data`, in numeric format.

- `numericRatings` — Array of size *n*Records-by-`1`, containing the ratings in column 3 of `data`, mapped into numeric format.
- `ratingsLabels` — Cell array of size`1`-by-`nRatings`, containing the credit rating scale.

transprobtothresholds

Convert from transition probabilities to credit quality thresholds

Syntax

```
thresh = transprobtothresholds(trans)
```

Description

`thresh = transprobtothresholds(trans)` transforms transition probabilities into credit quality thresholds.

Examples

Transform Transition Probabilities Into Credit Quality Thresholds

Use historical credit rating input data from `Data_TransProb.mat`. Load input data from file `Data_TransProb.mat`.

```
load Data_TransProb

% Estimate transition probabilities with default settings
transMat = transprob(data)
```

```
transMat = 8×8

```

Input Arguments

trans — Transition probabilities in percent

matrix

Transition probabilities in percent, specified as a M-by-N matrix. Entries cannot be negative and cannot exceed 100, and all rows must add up to 100.

Any given row in the M-by-N input matrix trans determines a probability distribution over a discrete set of N ratings. If the ratings are 'R1',...,'RN', then for any row *i* trans(i,j) is the probability of migrating into 'Rj'. If trans is a standard transition matrix, then M ≦ N and row *i* contains the transition probabilities for issuers with rating 'Ri'. But trans does not have to be a standard transition matrix. trans can contain individual transition probabilities for a set of M-specific issuers, with M > N.

The credit quality thresholds thresh(*i*,*j*) are critical values of a standard normal distribution *z*, such that:

```
trans(i,N) = P[z < thresh(i,N)],
```

```
trans(i,j) = P[z < thresh(i,j)] - P[z < thresh(i,j+1)], for 1<=j<N
```

This implies that thresh(*i*,1) = Inf, for all *i*. For example, suppose that there are only N=3 ratings, 'High', 'Low', and 'Default', with the following transition probabilities:

```
      High   Low   Default
High  98.13   1.78   0.09
Low    0.81  95.21   3.98
```

The matrix of credit quality thresholds is:

```
        High    Low    Default
High    Inf   -2.0814   -3.1214
Low     Inf    2.4044   -1.7530
```

This means the probability of default for 'High' is equivalent to drawing a standard normal random number smaller than −3.1214, or 0.09%. The probability that a 'High' ends up the period with a rating of 'Low' or lower is equivalent to drawing a standard normal random number smaller than −2.0814, or 1.87%. From here, the probability of ending with a 'Low' rating is:

```
P[z<-2.0814] - P[z<-3.1214] = 1.87% - 0.09% = 1.78%
```

And the probability of ending with a 'High' rating is:

```
100%-1.87% = 98.13%
```

where 100% is the same as:

```
P[z<Inf]
```

Data Types: double

Output Arguments

thresh — Credit quality thresholds

matrix

Credit quality thresholds, returned as a `M`-by-`N` matrix.

Version History

Introduced in R2011b

tsaccel

Acceleration between times

Syntax

```
acceleration = tsaccel(Data)
acceleration = tsaccel( ___ ,Name,Value)
```

Description

`acceleration = tsaccel(Data)` calculates the acceleration of a data series with time distance of *n* periods.

n periods.

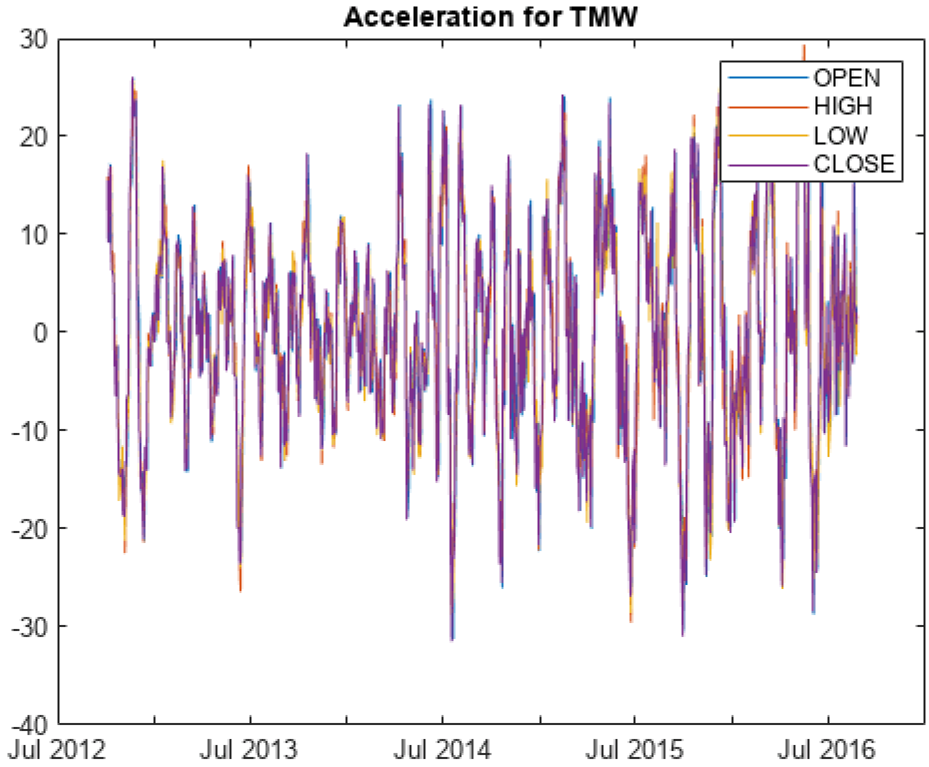
`acceleration = tsaccel( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Acceleration of a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
TMW.Volume = []; % remove VOLUME field
acceleration = tsaccel(TMW);
plot(acceleration.Time,acceleration.Variables)
legend('OPEN','HIGH','LOW','CLOSE')
title('Acceleration for TMW')
```



Input Arguments

`Data` — Data with high, low, open, close information

vector | matrix | table | timetable

Data with high, low, open, close information, specified as a vector, matrix, table, or timetable. For vector input, `Data` is a column vector of high, low, open, and closing prices stored in the corresponding columns. For matrix input, `Data` is an `M`-by-`N` column-oriented matrix of high, low, open, and closing prices stored in the corresponding columns. Timetables and tables with `M` rows must contain variables named `'High'`, `'Low'`, `'Open'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `accelearation = tsaccel(TMW,'NumPeriods',10,'Datatype',1)`

`NumPeriods` — Period difference for acceleration

`12` (default) | positive integer

Period difference for acceleration, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: `double`

`Datatype` — Indicates if `Data` contains the data itself or the momentum of the data
`0` (`Data` contains the data itself) (default) | integer with values `0` or `1`

Indicates if `Data` contains the data itself or the momentum of the data, specified as the comma-separated pair consisting of `'Datatype'` and a scalar integer with a value of:

- `0` – `Data` contains the data itself.
- `1` – `Data` contains the momentum of the data.

Data Types: `double`

Output Arguments

`acceleration` — Acceleration series
vector | matrix | table | timetable

Acceleration series, returned with the same number of rows (`M`) and columns (`N`) and the same type (vector, matrix, table, or timetable) as the input `Data`.

More About

Acceleration

Acceleration is defined as the difference of two momentum series separated by *n* periods.

Acceleration is the difference of the current momentum with the momentum *n* periods ago. By default, acceleration is based on 12-period difference.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument
Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

tsmom

Momentum between times

Syntax

```
momentum = tsmom(Data)
momentum = tsmom(___,Name,Value)
```

Description

`momentum = tsmom(Data)` calculates the momentum of a data series with time distance of *n* periods.

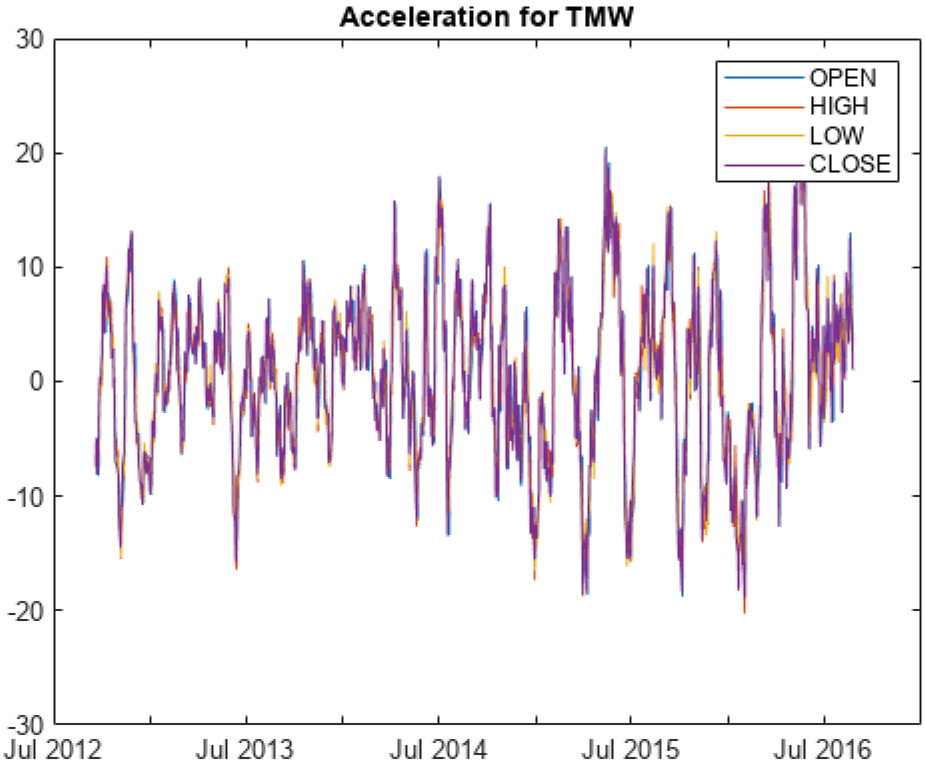
`momentum = tsmom(___,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Momentum for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
TMW.Volume = []; % remove VOLUME field
momentum = tsmom(TMW);
plot(momentum.Time,momentum.Variables)
legend('OPEN','HIGH','LOW','CLOSE')
title('Acceleration for TMW')
```



Input Arguments

`Data` — Data with high, low, open, close information

vector | matrix | table | timetable

Data with high, low, open, close information, specified as a vector, matrix, table, or timetable. For vector input, `Data` is a column vector. For matrix input, `Data` is an `M`-by-`N` column oriented matrix. Timetables and tables with `M` rows can contain variables named `'High'`, `'Low'`, `'Open'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `momentum = tsmom(TMW,'NumPeriods',15)`

`NumPeriods` — Period difference for momentum

`12` (default) | positive integer

Period difference for momentum, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`momentum` — Momentum series
matrix | table | timetable

Momentum series, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

More About

Momentum Series

Momentum series is the difference of the current data with the data *n* periods ago. By default, momentum is based on 12-period difference.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

typprice

Typical price

Syntax

```
TypicalPrice = typprice(Data)
```

Description

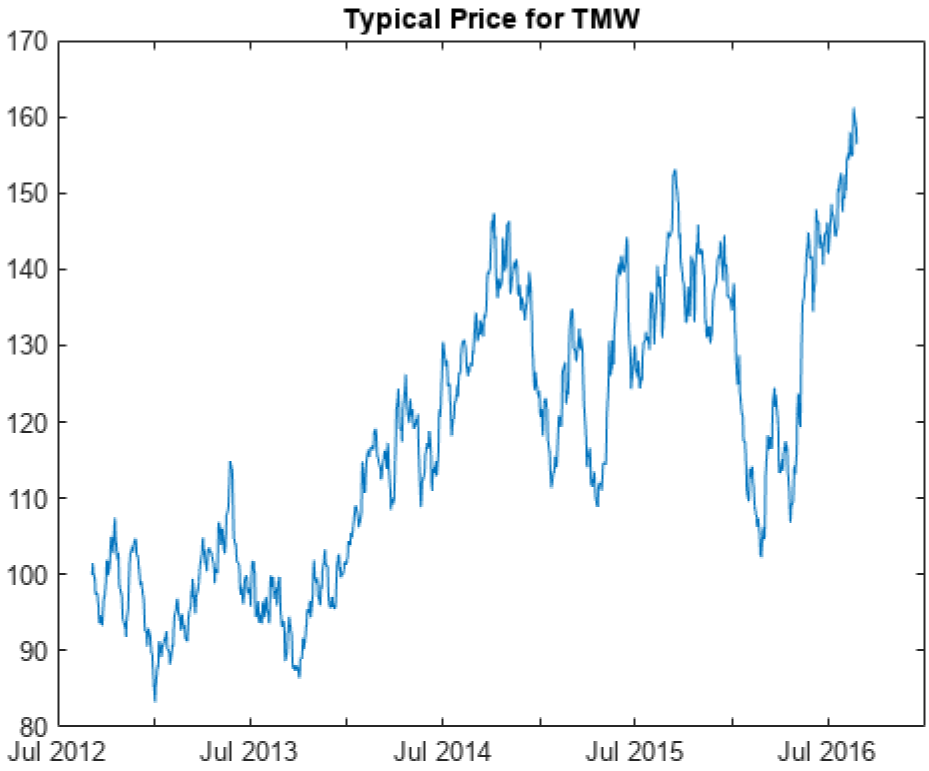
`TypicalPrice = typprice(Data)` calculates the typical prices from the series of high, low, and closing prices. The typical price is the average of the high, low, and closing prices for each period.

Examples

Calculate the Typical Price for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
TypicalPrice = typprice(TMW);
plot(TypicalPrice.Time,TypicalPrice.TypicalPrice)
title('Typical Price for TMW')
```



Input Arguments

`Data` — Data for high, low, and closing prices

matrix | table | timetable

Data for high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-3 matrix of high, low, and closing prices stored in the corresponding columns. Timetables and tables with `M` rows must contain variables named `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

`TypicalPrice` — Typical price series

matrix | table | timetable

Typical price series, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

uicalendar

Graphical calendar

Syntax

```
uicalendar(Name,Value)
```

Description

`uicalendar(Name,Value)` supports a customizable graphical calendar that interfaces with one or more `uicontrol`. `uicalendar` populates one or more `uicontrol` with user-selected dates.

Note As an alternative to `uicalendar`, you can use `uidatepicker`.

Examples

Use `uicalendar` with an `uicontrol`

Create an `uicontrol`:

```
textH1 = uicontrol('style', 'edit', 'position', [10 10 100 20])
```

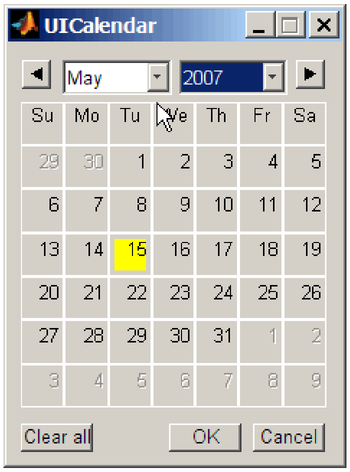
```
textH1 = 

  UIControl with properties:

              Style: 'edit'
             String: ''
    BackgroundColor: [0.9400 0.9400 0.9400]
           Callback: ''
              Value: 0
           Position: [10 10 100 20]
              Units: 'pixels'
```

Call UICalendar:

```
uicalendar('DestinationUI', {textH1, 'string'})
```

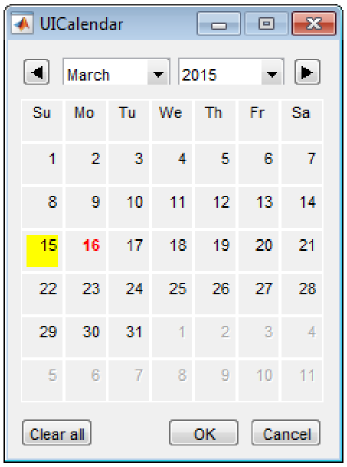


Su	Mo	Tu	We	Th	Fr	Sa
29	30	1	2	3	4	5
6	7	8	9	10	11	12
13	14	15	16	17	18	19
20	21	22	23	24	25	26
27	28	29	30	31	1	2
3	4	5	6	7	8	9

Select a date and click OK.

Alternatively, you can use datetime arrays for InitDate and Holiday.

```
uicalendar('InitDate',datetime('15-Mar-2015','Locale','en_US'),'Holiday',datetime('16-Mar-2015','Locale','en_US'))
```



Su	Mo	Tu	We	Th	Fr	Sa
1	2	3	4	5	6	7
8	9	10	11	12	13	14
15	16	17	18	19	20	21
22	23	24	25	26	27	28
29	30	31	1	2	3	4
5	6	7	8	9	10	11

Select a date and click OK. For more information on using uicalendar with an application, see "Example of Using UICalendar with an Application" on page 12-4.

Input Arguments

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: uicalendar('InitDate',datetime('15-Mar-2015','Locale','en_US'),'Holiday',datetime('16-Mar-2015','Locale','en_US'))

BusDays — Flag to indicate nonbusiness days
0 (Standard calendar without nonbusiness day indicators) (default) | numeric values of 0 or 1

Flag to indicate nonbusiness days, specified using numeric values of 0 or 1. The values are:

- 0 — (Default) Standard calendar without nonbusiness day indicators.
- 1 — Marks NYSE nonbusiness days in red.

Data Types: logical

BusDaySelect — Flag to indicate whether business and nonbusiness days
1 (Allows selections of business and nonbusiness days) (default) | numeric values of 0 or 1

Flag to indicate whether business and nonbusiness days, specified using numeric values of 0 or 1. The values are:

- 0 — Only allow selection of business days. Nonbusiness days are determined from the following parameters:
  - 'BusDays'
  - 'Holiday'
  - 'Weekend'
- 1 — (Default) Allows selections of business and nonbusiness days.

Data Types: logical

DateBoxColor — Color of date squares
[date R G B]

Color of date squares, specified using [date R G B], where [R G B] is the color.

Data Types: double

DateStrColor — Color of numeric date number in the date square
[date R G B]

Color of numeric date number in the date square, specified using [date R G B], where [R G B] is the color.

Data Types: double

DestinationUI — Destination object's handles
'string' (default UI property populated with dates) (default) | values are H or {H, {Prop}}

Destination object's handles, specified with values H or {H, {Prop}}. The values are:

- H — Scalar or vector of the destination object's handles. The default UI property that is populated with the dates is a character vector.
- {H, {Prop}} — Cell array of handles and the destination object's UI properties. H must be a scalar or vector and Prop must be a single property character vector or a cell array of property character vectors.

Data Types: char | cell

`Holiday` — Holiday dates in calendar
datetime array | string array | date character vector | serial date number

Holiday dates in calendar, specified using a scalar or vector using a datetime array, string array, date character vectors, or serial date numbers. The corresponding date of the holiday appears Red.

Data Types: `double` | `char` | `string` | `datetime`

`InitDate` — Initial start date when calendar is initialized
`TODAY` (default) | serial date number | datetime array | date character vector

Initial start date when calendar is initialized, specified with date values using a serial date number, datetime array, or date character vector. The values are:

- `Datenum` — Numeric or datetime array date value specifying the initial start date when the calendar is initialized. The default date is `TODAY`.

- `Datestr` — Date character vector value specifying the initial start date when the calendar is initialized. `Datestr` must include a Year, Month, and Day (for example, 01-Jan-2006).

Data Types: `double` | `char` | `datetime`

`InputDateFormat` — Format of initial start date
character vector

Format of initial start date (`InitDate`), specified using a character vector. See`datestr` for date format values.

Data Types: `double` | `datetime`

`OutputDateFormat` — Format of output date
character vector

Format of output date, specified using a character vector. See`datestr` for date format values.

Data Types: `double` | `datetime`

`OutputDateStyle` — Style for output date
`0` (default) | numeric value of `0`, `1`, `2`, or `3`

Style for output date, specified using a value of `0`, `1`, `2`, or `3`. The values are:

- `0` — (Default) Returns a single date character vector or a cell array (row) of date character vectors. For example, `{'01-Jan-2001, 02-Jan-2001, ...'}`.

- `1` — Returns a single date character vector or a cell (column) array of date character vectors. For example, `{'01-Jan-2001; 02-Jan-2001; ...'}`.

- `2` — Returns a character vector representation of a row vector of datenums. For example, `'[732758, 732759, 732760, 732761]'`.

- `3` — Returns a character vector representation of a column vector of datenums. For example, `'[732758; 732759; 732760; 732761]'`.

Data Types: `double`

`SelectionType` — Flag for date selection
`1` (default) | numeric value of `0` or `1`

Flag for date selection, specified with using a value of `0` or `1`. The values are:

- `0` — Allows multiple date selections.
- `1` — (Default) Allows only a single date selection.

Data Types: `logical`

`Weekend` — Define weekend days
`1` (default) | numeric values of `1` through `7`

Define weekend days, specified using a value of `1` through `7`. Weekend days are marked in red. `DayOfWeek` can be a vector containing the following numeric values:

- `1` — Sunday
- `2` — Monday
- `3` — Tuesday
- `4` — Wednesday
- `5` — Thursday
- `6` — Friday
- `7` — Saturday

Also this value can be a vector of length `7` containing `0`'s and `1`'s. The value `1` indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days then `WEEKEND = [1 0 0 0 0 0 1]`.

Data Types: `double`

`WindowStyle` — Window figure properties
`Normal` (default) | character vector with value of `Normal` or `Modal`

Window figure properties, specified with using a character vector with a value of `Normal` or `Modal`. The values are:

- `Normal` — (Default) Standard figure properties.
- `Modal` — Modal figures remain stacked above all normal figures and the MATLAB Command Window.

Data Types: `char`

Version History

Introduced before R2006a

volarea

Price and volume chart

Note volarea is updated to accept data input as a matrix, timetable, or table.

The syntax for volarea has changed. Previously, when using table input, the first column of dates could be a datetime array, date character vectors, or serial date numbers, and you were required to have specific number of columns.

When using table input, the new syntax for volarea supports:

- No need for time information. If you want to pass in date information, use timetable input.
- No requirement of specific number of columns. However, you must provide valid column names. volarea must contain a column named 'price' (case insensitive).

Syntax

```
volarea(Data)
h = volarea(ax,Data)
```

Description

volarea(Data) plots a chart from a series of price and traded volume of a security.

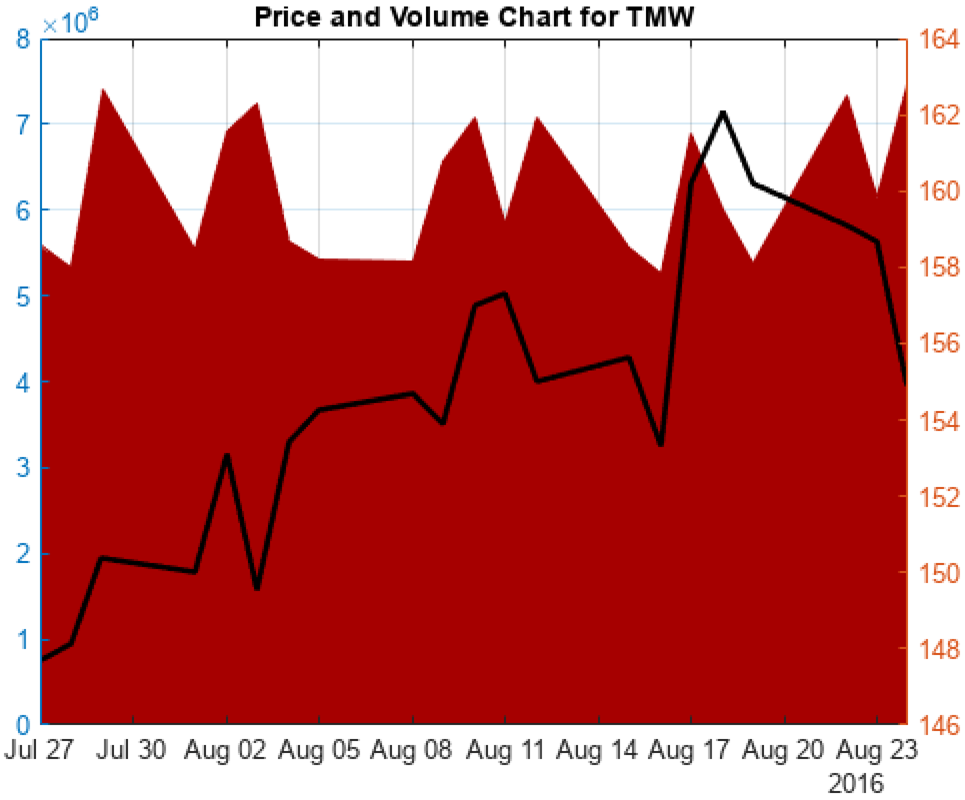
h = volarea(ax,Data) adds an optional argument for ax.

Examples

Plot Asset Date, Price, and Volume on a Single Axis for a Stock

Load the file SimulatedStock.mat, which provides a timetable (TMW) for financial data for TMW stock. This example shows how to plot asset date, price, and volume on a single axis, given asset TMW containing asset price and volume in most recent 21 days. Note that the variable name of asset price is be renamed to 'Price' (case insensitive).

```
load SimulatedStock.mat;
TMW.Properties.VariableNames{'Close'} = 'Price';
volarea(TMW(end-20:end,:))
title('Price and Volume Chart for TMW')
```



Input Arguments

`Data` — Data for prices and traded volume

matrix | table | timetable

Data for prices and traded volume, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-2 matrix of prices and traded volume. Timetables and tables with `M` rows must contain variables named `'Price'` and `'Volume'` (case insensitive).

Data Types: `double` | `table` | `timetable`

`ax` — Valid axis object

current axes (`ax = gca`) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The volarea plot is created in the axes specified by `ax` instead of in the current axes (`ax = gca`). The option `ax` can precede any of the input argument combinations.

Data Types: `object`

Output Arguments

`h` — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

Version History

Introduced in R2008a

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

volroc

Volume rate of change

Syntax

```
volumeChangeRate = volroc(Data)
volumeChangeRate = volroc( ___ ,Name,Value)
```

Description

`volumeChangeRate = volroc(Data)` calculates the volume rate-of-change from a data series of volume traded. The volume rate-of-change is calculated between the current volume and the volume *n* periods ago. By default, the Volume rate of change is based on a 12-period difference.

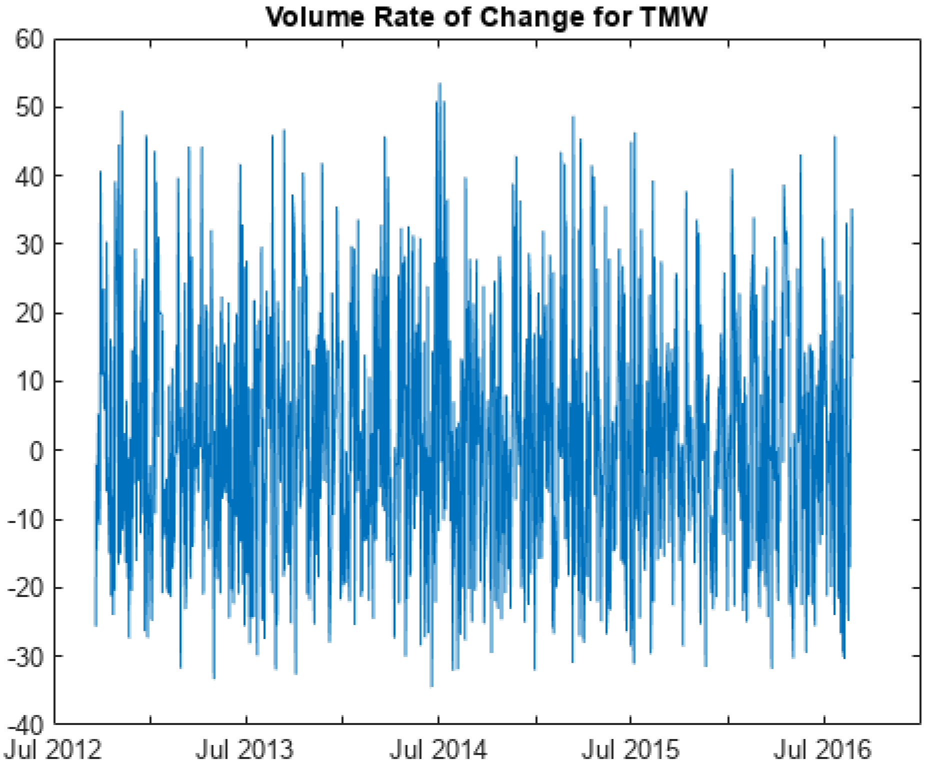
`volumeChangeRate = volroc( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Volume Rate of Change for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
volumeChangeRate = volroc(TMW);
plot(volumeChangeRate.Time,volumeChangeRate.VolumeChangeRate)
title('Volume Rate of Change for TMW')
```



Input Arguments

`Data` — Data for volume traded

vector | table | timetable

Data for volume traded, specified as a vector, table, or timetable. For vector input, `Data` is an `M`-by-`1` column vector of volume traded. Timetables and tables with `M` rows must contain a variable named `'Volume'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `volumeChangeRate = volroc(TMW,'NumPeriods',18)`

`NumPeriods` — Period difference for `volumeChangeRate`

`12` (default) | positive integer

Period difference for `volumeChangeRate`, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`volumeChangeRate` — Volume rate of change series
vector | table | timetable

Volume rate of change series, returned with the same number of rows (`M`) and the same type (vector, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument
Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

wclose

Weighted close

Syntax

```
WeightedClose = wclose(Data)
```

Description

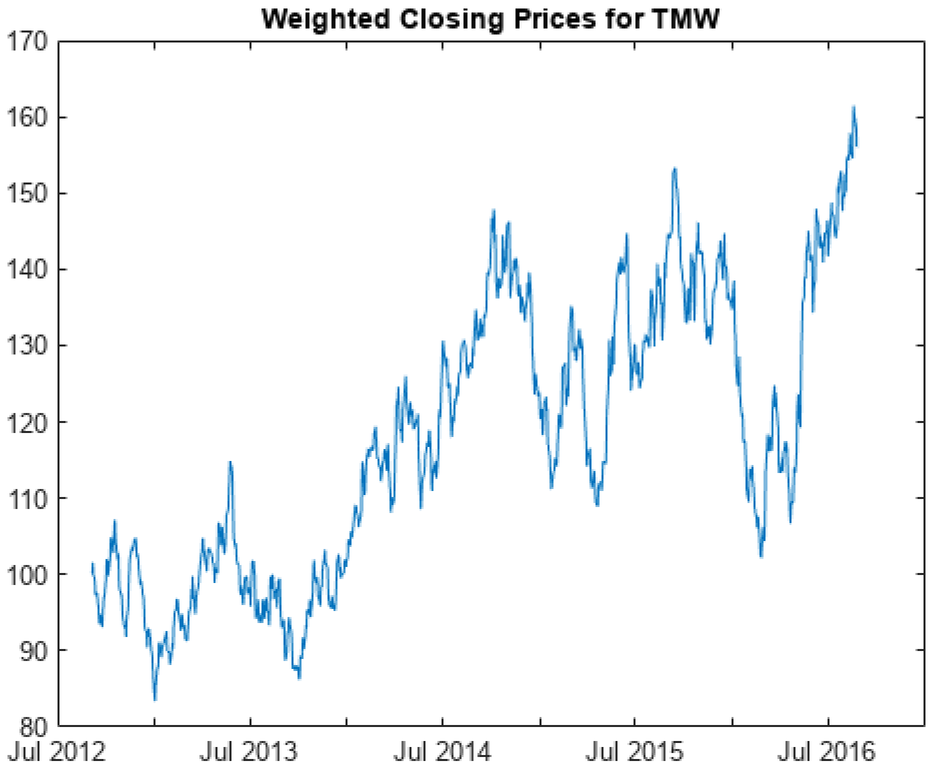
`WeightedClose = wclose(Data)` calculates the weighted closing prices from the series of high, low, and closing prices. The weighted closing price is the average of twice the closing price plus the high and low prices.

Examples

Calculate the Weighted Closing Prices for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
WeightedClose = wclose(TMW);
plot(WeightedClose.Time,WeightedClose.WeightedClose)
title('Weighted Closing Prices for TMW')
```



Input Arguments

`Data` — Data for high, low, and closing prices

matrix | table | timetable

Data for high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-`3` matrix of high, low, and closing prices stored in the corresponding columns. Timetables and tables with `M` rows must contain variables named `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

`WeightedClose` — Weighted closing price series

matrix | table | timetable

Weighted closing price series, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

weights2holdings

Portfolio values and weights into holdings

Syntax

```
Holdings = weights2holdings(Values,Weights,Prices)
```

Description

`Holdings = weights2holdings(Values,Weights,Prices)` converts portfolio values and weights into portfolio holdings.

Note `weights2holdings` does not create round-lot positions. The output `Holdings` are floating-point values.

Input Arguments

`Values` — Portfolio values

scalar numeric | vector

Portfolio values, specified as a scalar or an `NPORTS` vector.

Data Types: `double`

`Weights` — Portfolio weights

matrix

Portfolio weights, specified as an `NPORTS`-by-`NASSETS` matrix. The weights sum to the value of a `Budget` constraint, which is usually 1. (See `holdings2weights` for information about budget constraints.)

Data Types: `double`

`Prices` — Asset prices

vector

Asset prices, specified as an `NASSETS` vector.

Data Types: `double`

Output Arguments

`Holdings` — Holdings value

matrix

Holdings value, returned as an `NPORTS`-by-`NASSETS` matrix that contains the holdings of `NPORTS` portfolios that contain `NASSETS` assets.

Version History

Introduced before R2006a

See Also

`holdings2weights`

willad

Williams Accumulation/Distribution line

Syntax

```
WADLine = willad(Data)
```

Description

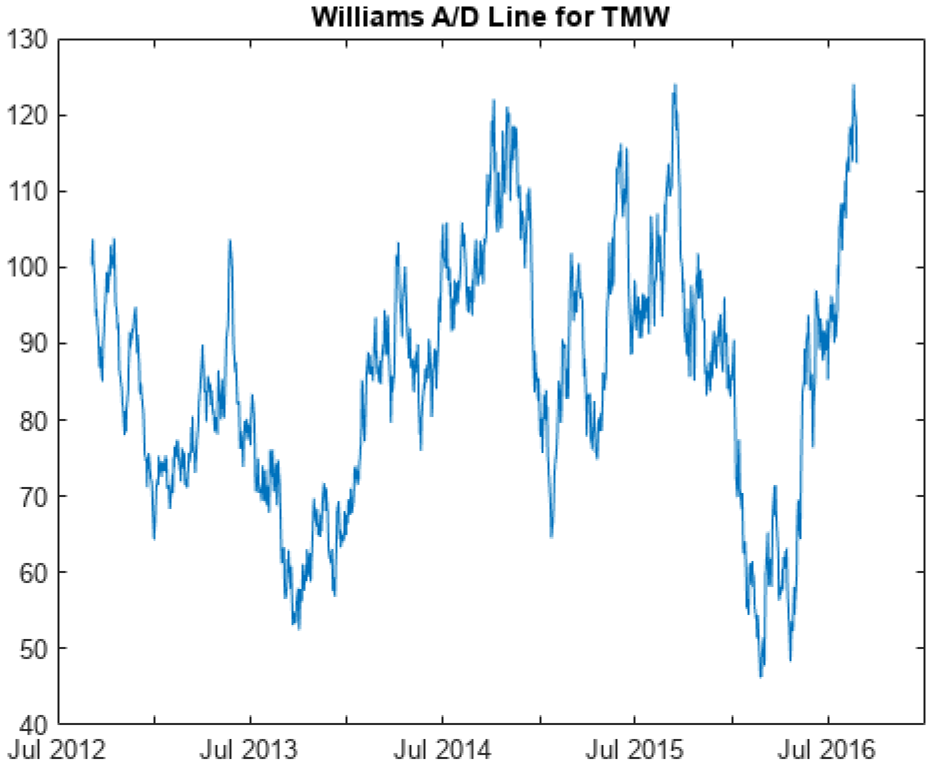
`WADLine = willad(Data)` calculates the Williams Accumulation/Distribution line from the series of high, low, and closing prices.

Examples

Calculate the Williams Accumulation/Distribution Line for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
WADLine = willad(TMW);
plot(WADLine.Time,WADLine.WillAD)
title('Williams A/D Line for TMW')
```



Input Arguments

`Data` — Data for high, low, and closing prices

matrix | table | timetable

Data for high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-`3` matrix of high, low, and closing prices stored in the corresponding columns. Timetables and tables with `M` rows must contain variables named `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Output Arguments

`WADLine` — Williams Accumulation/Distribution line

matrix | table | timetable

Williams Accumulation/Distribution line, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument

Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data

Behavior changed in R2022b

The `Data` input accepts negative prices.

willpctr

Williams %R

Syntax

```
PercentR = willpctr(Data)
PercentR = willpctr( ___ ,Name,Value)
```

Description

`PercentR = willpctr(Data)` calculates the Williams PercentR (%R) values for a data series of with high, low, and closing prices.

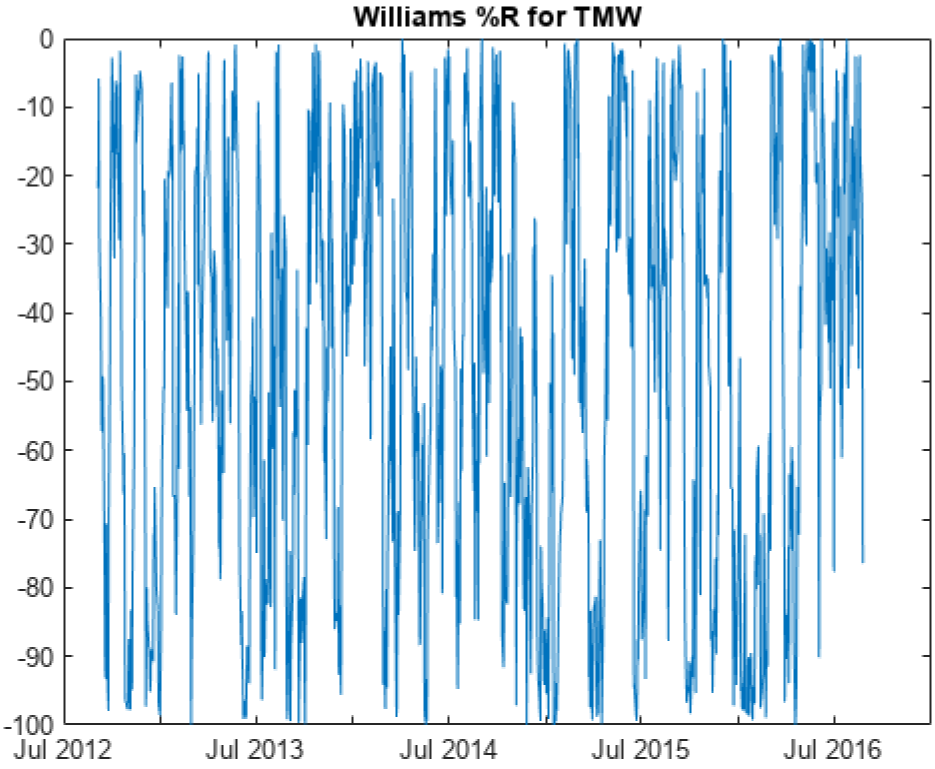
`PercentR = willpctr( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Williams %R for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for TMW stock.

```
load SimulatedStock.mat
PercentR = willpctr(TMW);
plot(PercentR.Time,PercentR.WillPercentR)
title('Williams %R for TMW')
```



Input Arguments

`Data` — Data with high, low, and close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-`3` with high, low, and closing prices stored in the corresponding columns. Timetables and tables with `M` rows must contain variables named `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: `double` | `table` | `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PercentR = willpctr(TMW,'NumPeriods',15)`

`NumPeriods` — Moving window for Williams PercentR

`14` (default) | positive integer

Moving window for Williams PercentR, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: `double`

Output Arguments

`PercentR` — Williams PercentR series
matrix | table | timetable

Williams PercentR series, returned with the same number of rows (`M`) and the same type (matrix, table, or timetable) as the input `Data`.

More About

Williams %R

Williams %R shows the current closing price in relation to the high and low of the past *n* days.

By default, Williams %R values are based on 14 periods.

Version History

Introduced before R2006a

R2023a: `fints` support removed for `Data` input argument
Behavior changed in R2023a

`fints` object support for the `Data` input argument is removed.

R2022b: Support for negative price data
Behavior changed in R2022b

The `Data` input accepts negative prices.

wrkdydif

Number of working days between dates

Syntax

```
Days = wrkdydif(StartDate,EndDate,Holidays)
```

Description

`Days = wrkdydif(StartDate,EndDate,Holidays)` returns the number of working days between dates `StartDate` and `EndDate` inclusive. `Holidays` is the number of holidays between the given dates, an integer.

Examples

Determine the Number of Working Days Between a `StartDate` and `EndDate`

Determine `Days` using date character vectors for `StartDate` and `EndDate`.

```
Days = wrkdydif('9/1/2000', '9/11/2000', 1)
```

```
Days = 6
```

Determine `Days` using a datetimes for array for `StartDate` and `EndDate`.

```
Days = wrkdydif(datetime(2000,9,1), datetime(2000,9,11), 1)
```

```
Days = 6
```

Input Arguments

`StartDate` — Start date

datetime array | string array | date character vector

Start date, specified as an `N`-by-`1` or `1`-by-`N` vector using a datetime array, string array, or date character vectors.

To support existing code, `wrkdydif` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`EndDate` — End date

datetime array | string array | date character vector

End date, specified as an `N`-by-`1` or `1`-by-`N` vector using a datetime array, string array, or date character vectors.

To support existing code, `wrkdydif` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

Holidays — Number of holidays between StartDate and EndDate
vector of integers

Number of holidays between the StartDate and EndDate, specified as an N-by-1 or 1-by-N vector of integers.

Data Types: double

Output Arguments

Days — Number of working days between dates StartDate and EndDate inclusive
integer

Number of working days between dates StartDate and EndDate inclusive, returned an N-by-1 or 1-by-N vector of integers.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although wrkdydif supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

xirr

Internal rate of return for nonperiodic cash flow

Syntax

```
Return = xirr(CashFlow,CashFlowDates)
Return = xirr( ___ ,Guess,MaxIterations,Basis)
```

Description

`Return = xirr(CashFlow,CashFlowDates)` returns the internal rate of return for a schedule of nonperiodic cash flows.

`Return = xirr( ___ ,Guess,MaxIterations,Basis)` adds optional arguments.

Examples

Find Internal Rate of Return for Nonperiodic Cash Flow

Find the internal rate of return for an investment of $10,000 that returns the following nonperiodic cash flow. The original investment is the first cash flow and is a negative number.

Cash Flow Dates

-10000 12-Jan-2007

2500 14-Feb-2008

2000 03-Mar-2008

3000 14-Jun-2008

4000 01-Dec-2008

Calculate the internal rate of return for this nonperiodic cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
CashFlowDates = ['01/12/2007'
                 '02/14/2008'
                 '03/03/2008'
                 '06/14/2008'
                 '12/01/2008'];
Return = xirr(CashFlow, CashFlowDates)
```

```
Return = 0.1006
```

Alternatively, you can use datetime input to calculate the internal rate of return for this nonperiodic cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
CashFlowDates = ['01/12/2007'
```

```
                 '02/14/2008'
                 '03/03/2008'
                 '06/14/2008'
                 '12/01/2008'];
CashFlowDates = datetime(CashFlowDates,'Locale','en_US')';
Return = xirr(CashFlow, CashFlowDates)
```

```
Return = 0.1006
```

Input Arguments

CashFlow — Cash flow

vector | matrix

Cash flow, specified as a vector or matrix. The first entry is the initial investment. If CashFlow is a matrix, each column represents a separate stream of cash flows whose internal rate of return is calculated. The first cash flow of each stream is the initial investment, usually entered as a negative number.

Data Types: double

CashFlowDates — Cash flow dates

datetime array | string array | date character vector

Cash flow dates, specified as a vector or matrix using a datetime array, string array, or date character vectors. The size of the input date numbers for CashFlowDates must the same size as CashFlow. Each column of CashFlowDate represents the dates of the corresponding column of CashFlow.

To support existing code, xirr also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | datetime | string

Guess — Initial estimate of the internal rate of return

0.1 (10%) (default) | numeric

(Optional) Initial estimate of the internal rate of return, specified as a scalar or vector. If Guess is a scalar, then it is applied to all streams, and if Guess is a vector, then it is the same length as the number of streams.

Data Types: double

MaxIterations — Number of iterations used by Newton's method to solve the internal rate of return

50 (default) | positive integer

(Optional) Number of iterations used by Newton's method to solve the internal rate of return, specified as a scalar or vector of positive integers. If MaxIterations is a scalar, then it is applied to all streams, and if MaxIterations is a vector, then it is the same length as the number of streams.

Data Types: double

Basis — Day-count basis

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

(Optional) Day-count basis, specified as a positive integer using scalar or a N-by-1 vector. If Basis is a scalar, then it is applied to all streams, and if Basis is a vector, then it is the same length as the number of streams.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: double

Output Arguments

Return — Annualized internal rate of return of each cash flow stream

numeric

Annualized internal rate of return of each cash flow stream, returned as a vector. A NaN indicates that a solution was not found.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although xirr supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

yeardays

Number of days in year

Syntax

```
Days = yeardays(Year)
Days = yeardays( ___ ,Basis)
```

Description

`Days = yeardays(Year)` returns the number of days in the given `Year`.

`Days = yeardays( ___ ,Basis)` returns the number of days in the given `Year`, based on the optional argument `Basis` for day-count.

Examples

Determine the Number of Days in a Given Year

Find the number of days in a given `Year`.

```
Days = yeardays(2000)
```

```
Days = 366
```

Find the number of days in a given `Year` using the optional argument `Basis`.

```
Days = yeardays(2000, 1)
```

```
Days = 360
```

Input Arguments

`Year` — Year to determine days
4 digit integer

Data Types: `single` | `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | vector of integers with values `0`,`1`,`2`,`3`,`4`,`5`,`6`,`7`,`8`,`9`,`10`,`11`,`12`,`13`

Day-count basis, specified as a vector of integers with values `0`,`1`,`2`,`3`,`4`,`5`,`6`,`7`,`8`,`9`,`10`,`11`,`12`,`13`.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `single` | `double`

Output Arguments

`Days` — Number of days in given `Year`
nonnegative integer

Number of days in given `Year`, returned as a nonnegative integer.

Version History

Introduced before R2006a

`days360` | `days365` | `daysact` | `yearfrac`

Topics
“Handle and Convert Dates” on page 2-2

yearfrac

Fraction of year between dates

Syntax

```
YearFraction = yearfrac(StartDate,EndDate,Basis)
```

Description

`YearFraction = yearfrac(StartDate,EndDate,Basis)` returns a fraction, in years, based on the number of days between dates `StartDate` and `EndDate` using the given day-count `Basis`.

The number of days in a year (365 or 366) is equal to the number of days in the calendar year after the `StartDate`. If `EndDate` is earlier than `StartDate`, `YearFraction` is negative.

All specified arguments must be `M`-by-`NUMINST` conforming matrices or scalar arguments.

Examples

Compute `yearfrac` When the Calendar Year After the StartDate is Not a Leap Year

Given a `Basis` of `0` and a `Basis` of `1`, compute `yearfrac`.

Define the `StartDate` and `EndDate` using a `Basis` of `0`.

```
YearFraction = yearfrac('14 mar 01', '14 sep 01', 0)
```

```
YearFraction = 0.5041
```

Define the `StartDate` and `EndDate` using a `Basis` of `1`.

```
YearFraction = yearfrac('14 mar 01', '14 sep 01', 1)
```

```
YearFraction = 0.5000
```

Compute `yearfrac` When the Calendar Year After the StartDate is a Leap Year

Given a `Basis` of `0`, compute `yearfrac` when the calendar after `StartDate` is in a leap year.

Define the `StartDate` and `EndDate` using a `Basis` of `0`.

```
yearFraction = yearfrac(' 14 mar 03', '14 sep 03', 0)
```

```
yearFraction = 0.5027
```

There are 184 days between March 14 and September 14, and the calendar year after the `StartDate` is a leap year, so `yearfrac` returns 184/366 = 0.5027.

Compute the Fraction of a Year Using an actual/actual Basis

To get the fraction of a year between '31-Jul-2015' and '30-Sep-2015' using the actual/actual basis:

```
yearfrac('31-Jul-2015', '30-Sep-2015', 0)*2
```

```
ans = 0.3333
```

For the actual/actual basis, the fraction of a year is calculated as:

```
(Actual Days between Start Date and End Date)/(Actual Days between Start Date
and exactly one year after Start Date)
```

There are 61 days between 31-Jul-2015 and 30-Sep-2015. Since the next year is a leap year, there are 366 days between 31-Jul-2015 and 31-Jul-2016. So, there is 61/366 which is exactly 1/6. So given this, exactly 2/6 is the expected result for the fraction of the six-month period.

Compute `yearfrac` When the Date Range Spans a Leap Year

Use a `Basis` of 12 to compute `yearfrac` when parts of the date range are in leap year and in a non-leap year. The output `YearFraction` is a fraction, in years, based on the number of days between the `StartDate` and `EndDate`.

```
YearFraction = yearfrac('1-Jan-2016','30-Jan-2017',12)
```

```
YearFraction = 1.0795
```

Compute `yearfrac` When Specifying datetimes

Given a `Basis` of `9`, compute `yearfrac` when the `StartDate` and `EndDate` are specified using datetimes.

```
yearfrac(datetime(2000,1,1), datetime(2001,1,1), 9)
```

```
ans = 1.0167
```

Input Arguments

`StartDate` — Start date
datetime array | string array | date character vector

Start date, specified as a scalar or an `M`-by-`N` vector using a datetime array, string array, or date character vectors.

Note The dimensions of the `StartDate`, `EndDate`, and `Basis` vectors must be consistent.

To support existing code, `yearfrac` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`EndDate` — End date
datetime array | string array | date character vector

End date, specified as a scalar or an `M`-by-`N` vector using a datetime array, string array, or date character vectors.

Note The dimensions of the `EndDate`, `StartDate`, and `Basis` vectors must be consistent.

To support existing code, `yearfrac` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Basis` — Day-count basis for each set of dates
`0` (actual/actual) (default) | vector of numerics with values `0` through `13`

Day-count basis for each set of dates, specified as a scalar or an `M`-by-`N` matrix of integers with values of `0` through `13`

Note The dimensions of the `Basis`, `StartDate`, and `EndDate` matrices must be consistent.

.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `single` | `double`

Output Arguments

YearFraction — Real numbers identifying interval, in years, between StartDate and EndDate

vector

Real numbers identifying the interval, in years, between StartDate and EndDate, returned as a scalar or an M-by-N matrix.

More About

Difference Between yearfrac and date2time

The difference between yearfrac and date2time is that date2time counts full periods as a whole integer, even if the number of actual days in the periods are different. yearfrac does not count full periods.

For example,

```
yearfrac('1/1/2000', '1/1/2001', 9)

ans =

    1.0167
```

yearfrac for Basis 9 (ACT/360 ICMA) calculates 366/360 = 1.0167. So, even if the dates have the same month and date, with a difference of 1 in the year, the returned value may not be exactly 1. On the other hand, date2time calculates one full year period:

```
date2time('1/1/2000', '1/1/2001', 1, 9)

ans =

     1
```

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although yearfrac supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

ylddisc

Yield of discounted security

Syntax

```
Yield = ylddisc(Settle,Maturity,Face,Price)
Yield = ylddisc(___,Basis)
```

Description

`Yield = ylddisc(Settle,Maturity,Face,Price)` returns the yield of a discounted security.

`Yield = ylddisc(___,Basis)` adds optional an argument for `Basis`.

Examples

Find the Yield of a Discounted Security

This example shows how to find the yield of the following discounted security.

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Price = 96.28;
Basis = 2;

Yield = ylddisc(Settle, Maturity, Face, Price, Basis)
```

```
Yield = 0.0903
```

Find the Yield of a Discounted Security Using datetime Inputs

This example shows how to use `datetime` inputs to find the yield of the following discounted security.

```
Settle = datetime(2000,10,14);
Maturity = datetime(2001,3,17);
Face = 100;
Price = 96.28;
Basis = 2;

Yield = ylddisc(Settle, Maturity, Face, Price, Basis)
```

```
Yield = 0.0903
```

Input Arguments

`Settle` — Settlement date of security

datetime array | string array | date character vector

Settlement date of the security, specified using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `ylddisc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of security

datetime array | string array | date character vector

Maturity date of the security, specified using a datetime array, string array, or date character vectors.

To support existing code, `ylddisc` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Redemption value of security

numeric

Redemption value (par value) of the security, specified as a scalar or vector using numeric values.

Data Types: `double`

`Price` — Discount price of security

numeric

Discount price of the security, specified as a scalar or vector using numeric values.

Data Types: `double`

`Basis` — (Optional) Day-count basis

`0` (actual/actual) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

Day-count basis for the security, specified as a scalar or vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`Yield` — Yield of discounted security
numeric

Yield of discounted security, returned as a scalar or vector of numeric values.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although `ylddisc` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

yldmat

Yield with interest at maturity

Syntax

```
Yield = yldmat(Settle,Maturity,Issue,Face,Price,CouponRate)
Yield = yldmat( ___ ,Basis)
```

Description

`Yield = yldmat(Settle,Maturity,Issue,Face,Price,CouponRate)` returns the yield of a security paying interest at maturity.

`Yield = yldmat( ___ ,Basis)` adds an optional argument for `Basis`.

Examples

Find the Yield of a Security Paying Interest at Maturity

This example shows how to find the yield of a security paying interest at maturity for the following.

```
Settle = '02/07/2000';
Maturity = '04/13/2000';
Issue = '10/11/1999';
Face = 100;
Price = 99.98;
CouponRate = 0.0608;
Basis = 1;

Yield = yldmat(Settle, Maturity, Issue, Face, Price,...
CouponRate, Basis)
```

```
Yield = 0.0607
```

Find the Yield of a Security Paying Interest at Maturity Using datetime Inputs

This example shows how to use `datetime` inputs find the yield of a security paying interest at maturity for the following:

```
Settle = datetime(2000,2,7);
Maturity = datetime(2000,4,13);
Issue = datetime(1999,10,11);
Face = 100;
Price = 99.98;
CouponRate = 0.0608;
Basis = 1;

Yield = yldmat(Settle, Maturity, Issue, Face, Price, CouponRate, Basis)
Yield = 0.0607
```

Input Arguments

`Settle` — Settlement date of security

datetime array | string array | date character vector

Settlement date of the security, specified using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `yldmat` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of security

datetime array | string array | date character vector

Maturity date of the security, specified using a datetime array, string array, or date character vectors.

To support existing code, `yldmat` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Issue` — Issue date of security

datetime array | string array | date character vector

Issue date of the security, specified using a datetime array, string array, or date character vectors.

To support existing code, `yldmat` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Redemption value of security

numeric

Redemption value (par value) of the security, specified as a scalar or vector using numeric values.

Data Types: `double`

`Price` — Price of security

numeric

Price of the security, specified as a scalar or vector using numeric values.

Data Types: `double`

`CouponRate` — Coupon rate of security

decimal fraction

Coupon rate of the security, specified as a scalar or a vector using decimal fractions.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integers of the set `[0...13]` | vector of integers of the set `[0...13]`

(Optional) Day-count basis for the security, specified as a scalar or vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`Yield` — Yield of a security paying interest at maturity

numeric

Yield of a security paying interest at maturity, returned as a scalar or vector of numeric values.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `yldmat` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

yldtbill

Yield of Treasury bill

Syntax

```
Yield = yldtbill(Settle,Maturity,Face,Price)
```

Description

`Yield = yldtbill(Settle,Maturity,Face,Price)` returns the yield for a Treasury bill.

Examples

Find the Yield for a Treasury Bill

This example shows how to return the yield for a Treasury bill, given the settlement date of a Treasury bill is February 10, 2000, the maturity date is August 6, 2000, the par value is $1000, and the price is $981.36.

```
Yield = yldtbill('2/10/2000', '8/6/2000', 1000, 981.36)
```

```
Yield = 0.0384
```

Find the Yield for a Treasury Bill Using datetime Inputs

This example shows how to use `datetime` inputs to return the yield for a Treasury bill, given the settlement date of a Treasury bill is February 10, 2000, the maturity date is August 6, 2000, the par value is $1000, and the price is $981.36.

```
Yield = yldtbill(datetime(2000,2,10), datetime(2000,8,6), 1000, 981.36)
```

```
Yield = 0.0384
```

Input Arguments

`Settle` — Settlement date of Treasury bill

datetime array | string array | date character vector

Settlement date of the Treasury bill, specified using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `yldtbill` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Maturity` — Maturity date of Treasury bill
datetime array | string array | date character vector

Maturity date of the Treasury bill, specified using a datetime array, string array, or date character vectors.

To support existing code, `yldtbill` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `char` | `string` | `datetime`

`Face` — Redemption value of Treasury bill
numeric

Redemption value (par value) of the Treasury bill, specified as a scalar or vector using numeric values.

Data Types: `double`

`Price` — Price of Treasury bill
numeric

Price of the Treasury bill, specified as a scalar or vector using numeric values.

Data Types: `double`

Output Arguments

`Yield` — Yield for Treasury bill
numeric

Yield for Treasury bill, returned as a scalar or vector of numeric values.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `yldtbill` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

zbtprice

Zero curve bootstrapping from coupon bond data given price

Syntax

```
[ZeroRates,CurveDates] = zbtprice(Bonds,Prices,Settle)
ZeroRates,CurveDates = zbtprice( ___ ,OutputCompounding)
```

Description

`[ZeroRates,CurveDates] = zbtprice(Bonds,Prices,Settle)` uses the bootstrap method to return a zero curve given a portfolio of coupon bonds and their prices.

A zero curve consists of the yields to maturity for a portfolio of theoretical zero-coupon bonds that are derived from the input `Bonds` portfolio. The bootstrap method that this function uses does *not* require alignment among the cash-flow dates of the bonds in the input portfolio. It uses theoretical par bond arbitrage and yield interpolation to derive all zero rates; specifically, the interest rates for cash flows are determined using linear interpolation. For best results, use a portfolio of at least 30 bonds evenly spaced across the investment horizon.

`ZeroRates,CurveDates = zbtprice( ___ ,OutputCompounding)` adds an optional argument for `OutputCompounding`.

Examples

Compute a Zero Curve Given a Portfolio of Coupon Bonds and Their Prices Using datetime Inputs

Given data and prices for 12 coupon bonds, two with the same maturity date, and given the common settlement date, use `datetime` inputs to compute a zero curve.

```
Bonds = [datenum('6/1/1998')   0.0475   100  2  0  0;
         datenum('7/1/2000')   0.06     100  2  0  0;
         datenum('7/1/2000')   0.09375  100  6  1  0;
         datenum('6/30/2001')  0.05125  100  1  3  1;
         datenum('4/15/2002')  0.07125  100  4  1  0;
         datenum('1/15/2000')  0.065    100  2  0  0;
         datenum('9/1/1999')   0.08     100  3  3  0;
         datenum('4/30/2001')  0.05875  100  2  0  0;
         datenum('11/15/1999') 0.07125  100  2  0  0;
         datenum('6/30/2000')  0.07     100  2  3  1;
         datenum('7/1/2001')   0.0525   100  2  3  0;
         datenum('4/30/2002')  0.07     100  2  0  0];

Prices = [99.375;
          99.875;
         105.75 ;
          96.875;
         103.625;
         101.125;
```

```
          103.125;
           99.375;

Input Arguments

Bonds — Coupon bond information to generate zero curve
table | matrix

Coupon bond information to generate zero curve, specified as a 6-column table or a n-by-2 to n-by-6 matrix of bond information, where the table columns or matrix columns contains:

- `Maturity` (Column 1, Required) Maturity date of the bond as a serial date number. Use `datenum` to convert date character vectors to serial date numbers. If the input `Bonds` is a table, the `Maturity` dates can be a datetime array, string array, or date character vectors.
- `CouponRate` (Column 2, Required) Decimal fraction indicating the coupon rate of the bond.

- `Face` (Column 3, Optional) Redemption or face value of the bond. Default = `100`.
- `Period` (Column 4, Optional) Coupons per year of the bond. Allowed values are `0`, `1`, `2` (default), `3`, `4`, `6`, and `12`.
- `Basis` (Column 5, Optional) Day-count basis of the bond. A vector of integers.
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see "Basis" on page 2-16.
- `EndMonthRule` (Column 6, Optional) End-of-month rule. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. `0` = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. `1` = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month

:

Note

- If `Bonds` is a table, the `Maturity` dates can be a datetime array, string array, or date character vectors.
- If `Bonds` is a matrix, is an `n`-by-`2` to `n`-by-`6` matrix where each row describes a bond, the first two columns (`Maturity` and `CouponRate`) are required. The remainder of the columns are optional but must be added in order. All rows in `Bonds` must have the same number of columns.

.

Data Types: `double` | `char` | `string` | `datetime` | `table`

`Prices` — Clean price (price without accrued interest) of each bond in `Bonds`
numeric

Clean price (price without accrued interest) of each bond in `Bonds`, specified as a `N`-by-`1` column vector. The number of rows (*n*) must match the number of rows in `Bonds`.

Data Types: `double`

Settle — Settlement date representing time zero in derivation of zero curve

datetime scalar | string scalar | date character vector

Settlement date representing time zero in derivation of zero curve, specified as scalar datetime, string, or date character vector. Settle represents time zero for deriving the zero curve, and it is normally the common settlement date for all the bonds.

To support existing code, zbtprice also accepts serial date numbers as inputs, but they are not recommended.

Data Types: char | string | datetime

OutputCompounding — Compounding frequency of output ZeroRates

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

(Optional) Compounding frequency of output ZeroRates, specified using the allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

Output Arguments

ZeroRates — Implied zero rates for each point along the investment horizon defined by maturity date

vector of decimal fractions

Implied zero rates for each point along the investment horizon defined by a maturity date, returned as a m-by-1 vector of decimal fractions where m is the number of bonds of unique maturity dates. In aggregate, the rates in ZeroRates constitute a zero curve.

If more than one bond has the same Maturity date, zbtprice returns the mean zero rate for that Maturity. Any rates before the first Maturity are assumed to be equal to the rate at the first Maturity, that is, the curve is assumed to be flat before the first Maturity.

CurveDates — Maturity dates that correspond to ZeroRates

datetime | serial date number

Maturity dates that correspond to the ZeroRates, returned as a m-by-1 vector of unique maturity dates, where m is the number of bonds of different maturity dates. These dates begin with the earliest Maturity date and end with the latest Maturitydate in the Bonds table or matrix.

If either inputs for Bonds or Settle have datetime values, then CurveDates is datetimes. Otherwise CurveDates is serial date numbers. Use the function datestr to convert serial date numbers to formatted date character vectors.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `zbtprice` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

zbtyield

Zero curve bootstrapping from coupon bond data given yield

Syntax

```
[ZeroRates,CurveDates] = zbtyield(Bonds,YieldsSettle)
ZeroRates,CurveDates = zbtyield( ___ ,OutputCompounding)
```

Description

`[ZeroRates,CurveDates] = zbtyield(Bonds,YieldsSettle)` uses the bootstrap method to return a zero curve given a portfolio of coupon bonds and their yields.

A zero curve consists of the yields to maturity for a portfolio of theoretical zero-coupon bonds that are derived from the input `Bonds` portfolio. The bootstrap method that this function uses does *not* require alignment among the cash-flow dates of the bonds in the input portfolio. It uses theoretical par bond arbitrage and yield interpolation to derive all zero rates; specifically, the interest rates for cash flows are determined using linear interpolation. For best results, use a portfolio of at least 30 bonds evenly spaced across the investment horizon.

`ZeroRates,CurveDates = zbtyield( ___ ,OutputCompounding)` adds an optional argument for `OutputCompounding`.

Examples

Compute a Zero Curve Given a Portfolio of Coupon Bonds and Their Yields Using datetime Inputs

Given data and yields to maturity for 12 coupon bonds (two with the same maturity date), and given the common settlement date, compute the zero curve using `datetime` inputs.

```
Bonds = [datenum('6/1/1998')   0.0475   100  2  0  0;
         datenum('7/1/2000')   0.06     100  2  0  0;
         datenum('7/1/2000')   0.09375  100  6  1  0;
         datenum('6/30/2001')  0.05125  100  1  3  1;
         datenum('4/15/2002')  0.07125  100  4  1  0;
         datenum('1/15/2000')  0.065    100  2  0  0;
         datenum('9/1/1999')   0.08     100  3  3  0;
         datenum('4/30/2001')  0.05875  100  2  0  0;
         datenum('11/15/1999') 0.07125  100  2  0  0;
         datenum('6/30/2000')  0.07     100  2  3  1;
         datenum('7/1/2001')   0.0525   100  2  3  0;
         datenum('4/30/2002')  0.07     100  2  0  0];

Input Arguments

Bonds — Coupon bond information to generate zero curve

table | matrix

Coupon bond information to generate zero curve, specified as a 6-column table or a n-by-2 to n-by-6 matrix of bond information, where the table columns or matrix columns contains:

- Maturity (Column 1, Required) Maturity date of the bond as a serial date number. Use datenum to convert date character vectors to serial date numbers. If the input Bonds is a table, the Maturity dates can be a datetime array, string array, or date character vectors.
- CouponRate (Column 2, Required) Decimal fraction indicating the coupon rate of the bond.
- Face (Column 3, Optional) Redemption or face value of the bond. Default = 100.
- Period (Column 4, Optional) Coupons per year of the bond. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
- Basis (Column 5, Optional) Day-count basis of the bond. A vector of integers.
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see “Basis” on page 2-16.
- EndMonthRule (Column 6, Optional) End-of-month rule. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month

:

Note

- If Bonds is a table, the Maturity dates can be a datetime array, string array, or date character vectors.

- If `Bonds` is a matrix, is an `n`-by-`2` to `n`-by-`6` matrix where each row describes a bond, the first two columns (`Maturity` and `CouponRate`) are required. The remainder of the columns are optional but must be added in order. All rows in `Bonds` must have the same number of columns.

.

Data Types: `double` | `char` | `string` | `datetime` | `table`

`Yields` — Yield to maturity of each bond in `Bonds`
numeric

Yield to maturity of each bond in `Bonds`, specified as a `N`-by-`1` column vector. The number of rows (*n*) must match the number of rows in `Bonds`.

Note Yield to maturity must be compounded semiannually.

Data Types: `double`

`Settle` — Settlement date representing time zero in derivation of zero curve
datetime scalar | string scalar | date character vector

Settlement date representing time zero in derivation of zero curve, specified as a scalar datetime, string, or date character vector. `Settle` represents time zero for deriving the zero curve, and it is normally the common settlement date for all the bonds.

To support existing code, `zbtyield` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `string` | `char` | `datetime`

`OutputCompounding` — Compounding frequency of output `ZeroRates`
2 (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `12`, `365`, `-1`

(Optional) Compounding frequency of output `ZeroRates`, specified using the allowed values:

- `0` — Simple interest (no compounding)
- `1` — Annual compounding
- `2` — Semiannual compounding (default)
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding
- `-1` — Continuous compounding

Data Types: `double`

Output Arguments

ZeroRates — Implied zero rates for each point along the investment horizon defined by maturity date
decimal fractions

Implied zero rates for each point along the investment horizon defined by a maturity date, returned as a m-by-1 vector of decimal fractions where m is the number of bonds with unique maturity dates. In aggregate, the rates in ZeroRates constitute a zero curve.

If more than one bond has the same Maturity date, zbtyield returns the mean zero rate for that Maturity. Any rates before the first Maturity are assumed to be equal to the rate at the first Maturity, that is, the curve is assumed to be flat before the first Maturity.

CurveDates — Maturity dates that correspond to ZeroRates
datetime | serial date number

Maturity dates that correspond to the ZeroRates, returned as a m-by-1 vector of unique maturity dates, where m is the number of bonds of different maturity dates. These dates begin with the earliest Maturity date and end with the latest Maturitydate in the Bonds table or matrix.

If either inputs for Bonds or Settle have datetime values, then CurveDatesCurveDates is datetimes. Otherwise CurveDates is serial date numbers. Use the function datestr to convert serial date numbers to formatted date character vectors.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended
Not recommended starting in R2022b

Although zbtyield supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

zero2disc

Discount curve given zero curve

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Compounding` and `Basis`.

Syntax

```
[DiscRates,CurveDates] = zero2disc(ZeroRates,CurveDates,Settle)
[DiscRates,CurveDates] = zero2disc( ___ ,Name,Value)
```

Description

`[DiscRates,CurveDates] = zero2disc(ZeroRates,CurveDates,Settle)` returns a discount curve given a zero curve and its maturity dates. If either inputs for or are`CurveDatesSettle` a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors. The `DiscRates` output is the same for any of these input data types.

`[DiscRates,CurveDates] = zero2disc( ___ ,Name,Value)` adds optional name-value pair arguments

Examples

Compute a Discount Curve Given a Zero Curve and Maturity Dates Using datetime Inputs

Given a zero curve over a set of maturity dates and a settlement date, compute a discount curve using `datetime` inputs.

```
ZeroRates = [0.0464
             0.0509
             0.0524
             0.0525
             0.0531
             0.0525
             0.0530
             0.0531
             0.0549
             0.0536];

CurveDates = [datetime(2000,11,6)
              datetime(2000,12,11)
              datetime(2001,1,15)
              datetime(2001,2,5)
              datetime(2001,3,4)
              datetime(2001,4,2)

Input Arguments

ZeroRates — Annualized zero rates

decimal fraction

Annualized zero rates, specified as a NUMBONDS-by-1 vector using decimal fractions. In aggregate, the zero rates constitute an implied zero curve for the investment horizon represented by CurveDates.

Data Types: double

CurveDates — Maturity dates

datetime array | string array | date character vector

Maturity dates that correspond to the input ZeroRates, specified as NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, zero2disc also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

Settle — Common settlement date for ZeroRates

datetime scalar | string scalar | date character vector

Common settlement date for ZeroRates, specified as a scalar datetime, string, or date character vector. Settle is the settlement date for the bonds from which the zero curve was bootstrapped.

To support existing code, zero2disc also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [DiscRates,CurveDates] = zero2disc(ZeroRates,CurveDates,Settle,'Compounding',4,'Basis',6)

Compounding — Rate at which input ZeroRateszero rates are compounded when annualized

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Rate at which the input ZeroRates are compounded when annualized, specified as the comma-separated pair consisting of 'Compounding' and allowed numeric values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

Data Types: double

Basis — Day-count basis used for annualizing input ZeroRates

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis used for annualizing the input ZeroRates, specified as the comma-separated pair consisting of 'Basis' and allowed numeric values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Data Types: `double`

Output Arguments

`DiscRates` — Discount factors

decimal

Discount factors, returned as a `NUMBONDS`-by-`1` vector of decimal fractions. In aggregate, the discount factors constitute a discount curve for the investment horizon represented by `CurveDates`.

`CurveDates` — Maturity dates that correspond to `DiscRates`

serial date number | datetime

Maturity dates that correspond to the `DiscRates`, returned as a `NUMBONDS`-by-`1` vector of maturity dates that correspond to the discount factors. This vector is the same as the input vector `CurveDates`, but is sorted by ascending maturity.

If either inputs for `CurveDates` or `Settle` are a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `zero2disc` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

zero2fwd

Forward curve given zero curve

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: InputCompounding, InputBasis, OutputCompounding, and OutputBasis.

Syntax

```
[ForwardRates,CurveDates] = zero2fwd(ZeroRates,CurveDates,Settle)
[ForwardRates,CurveDates] = zero2fwd( ___ ,Name,Value)
```

Description

[ForwardRates,CurveDates] = zero2fwd(ZeroRates,CurveDates,Settle) returns an implied forward rate curve given a zero curve and its maturity dates. If either input for CurveDates or Settle is a datetime array, CurveDates is returned as a datetime array. Otherwise, CurveDates is returned as a serial date number. Use the function datestr to convert serial date numbers to formatted date character vectors. ForwardRates is the same for any of these input data types.

[ForwardRates,CurveDates] = zero2fwd(___ ,Name,Value) adds optional name-value pair arguments

Examples

Compute an Implied Forward Rate Curve Given a Zero Curve and Maturity Dates Using datetime Inputs

Given a zero curve over a set of maturity dates, a settlement date, and a compounding rate, use datetime compute the forward rate curve.

```
ZeroRates = [0.0458
             0.0502
             0.0518
             0.0519
             0.0524
             0.0519
             0.0523
             0.0525
             0.0541
             0.0529];

```

Input Arguments

ZeroRates — Annualized zero rates

decimal fraction

Annualized zero rates, specified as a NUMBONDS-by-1 vector using decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by CurveDates. The first element pertains to forward rates from the settlement date to the first curve date.

Data Types: double

CurveDates — Maturity dates

datetime array | string array | date character vector

Maturity dates, specified as a NUMBONDS-by-1 vector using a datetime array, string array, or date character vectors that correspond to the ZeroRates.

To support existing code, zero2fwd also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

Settle — Common settlement date for ZeroRates

datetime scalar | string scalar | date character vector

Common settlement date for input ZeroRates, specified as scalar datetime, string, or date character vector.

To support existing code, zero2fwd also accepts serial date numbers as inputs, but they are not recommended.

Data Types: datetime | string | char

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [ForwardRates,CurveDates] = zero2fwd(ZeroRates,CurveDates,Settle,'InputCompounding',3,'InputBasis',5,'OutputCompounding',4,'OutputBasis',5)

InputCompounding — Compounding frequency of input zero rates

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input zero rates, specified as the comma-separated pair consisting of 'InputCompounding' and allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

Note If InputCompounding is not specified, then InputCompounding is assigned the value specified for OutputCompounding. If either InputCompounding or OutputCompounding are not specified, the default is 2 (semiannual) for both.

Data Types: double

InputBasis — Day-count basis of input zero rates

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of input zero rates, specified as the comma-separated pair consisting of 'InputBasis' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If InputBasis is not specified, then InputBasis is assigned the value specified for OutputBasis. If either InputBasis or Outputbasis are not specified, the default is 0 (actual/actual) for both.

Data Types: double

OutputCompounding — Compounding frequency of output forward rates

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of output forward rates, specified as the comma-separated pair consisting of 'OutputCompounding' and allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

Note If OutputCompounding is not specified, then OutputCompounding is assigned the value specified for InputCompounding. If either InputCompounding or OutputCompounding are not specified, the default is 2 (semiannual) for both.

Data Types: double

OutputBasis — Day-count basis of output forward rates

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of output forward rates, specified as the comma-separated pair consisting of 'OutputBasis' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If OutputBasis is not specified, then OutputBasis is assigned the value specified for InputBasis. If either InputBasis or OutputBasis are not specified, the default is 0 (actual/actual) for both.

Data Types: double

Output Arguments

ForwardRates — Forward curve for investment horizon represented by CurveDates

numeric

Forward curve for the investment horizon represented by CurveDates, returned as a NUMBONDS-by-1 vector of decimal fractions. In aggregate, the rates in ForwardRates constitute a forward curve over the dates in CurveDates. ForwardRates are ordered by ascending maturity.

CurveDates — Maturity dates that correspond to ForwardRates

datetime | serial date number

Maturity dates that correspond to the `ForwardRates`, returned as a `NUMBONDS`-by-`1` vector of maturity dates that correspond to the `ForwardRates`.

`ForwardRates` are expressed as serial date numbers (default) or datetimes (if `CurveDates` or `Settle` are datetime arrays), representing the maturity dates for each rate in `ForwardRates`. These dates are the same dates as those associated with the input `ZeroRates`, but are ordered by ascending maturity.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although `zero2fwd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

zero2pyld

Par yield curve given zero curve

Note In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

Syntax

```
[ParRates,CurveDates] = zero2pyld(ZeroRates,CurveDates,Settle)
[ParRates,CurveDates] = zero2pyld( ___ ,Name,Value)
```

Description

`[ParRates,CurveDates] = zero2pyld(ZeroRates,CurveDates,Settle)` returns a par yield curve given a zero curve and its maturity dates. If either input for `CurveDates` or `Settle` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number. Use the function `datestr` to convert serial date numbers to formatted date character vectors. `ParRates` is the same for any of these input data types.

`[ParRates,CurveDates] = zero2pyld( ___ ,Name,Value)` adds optional name-value pair arguments

Examples

Compute Par Yield Curve Given a Zero Curve and Maturity Dates Using datetime Inputs

Given a zero curve over a set of maturity dates, a settlement date, and annual compounding for the input zero curve and monthly compounding for the output par rates, use `datetime` inputs to compute a par yield curve.

```
ZeroRates = [0.0457
0.0487
0.0506
0.0507
0.0505
0.0504
0.0506
0.0516
0.0539
0.0530];
CurveDates = [datetime(2000,11,6)
              datetime(2000,12,11)
              datetime(2001,1,15)
              datetime(2001,2,5)
              datetime(2001,3,4)
              datetime(2001,4,2)
              datetime(2001,4,30)
              datetime(2001,6,25)
              datetime(2001,9,4)
              datetime(2001,11,12)];

Settle = datetime(2000,11,3);
InputCompounding = 12;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;

[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates,...
Settle, 'InputCompounding',12,'InputBasis',2,'OutputCompounding',1,'OutputBasis',2)

```

Demonstrate a Roundtrip From `zero2pyld` to `pyld2zero`

Given the following zero curve and its maturity dates, return the `ParRates`.

```
Settle = datetime(2013,2,1);

CurveDates = [datetime(2014,2,1)
             datetime(2015,2,1)
             datetime(2016,2,1)
             datetime(2018,2,1)
             datetime(2020,2,1)
             datetime(2023,2,1)
             datetime(2033,2,1)
             datetime(2043,2,1) ];
```

```
OriginalZeroRates = [.11 0.30 0.64 1.44 2.07 2.61 3.29 3.55]'/100;

OutputCompounding = 1;
OutputBasis = 0;
InputCompounding = 1;
InputBasis = 0;

ParRates = zero2pyld(OriginalZeroRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
```

```
ParRates = 8×1

    0.0011
    0.0030
    0.0064
    0.0142
    0.0202
    0.0251
    0.0310
    0.0331
```

For the `ParRates`, use the `pyld2zero` function to return the `ZeroRatesOut` and determine the roundtrip error.

```
ZeroRatesOut = pyld2zero(ParRates, CurveDates, Settle, ...
'OutputCompounding', OutputCompounding, 'OutputBasis', OutputBasis, ...
'InputCompounding', InputCompounding, 'InputBasis', InputBasis)
```

```
ZeroRatesOut = 8×1

    0.0011
    0.0030
    0.0064
    0.0144
    0.0207
    0.0261
    0.0329
    0.0355
```

```
max(abs(OriginalZeroRates - ZeroRatesOut)) % Roundtrip error
```

```
ans = 1.4919e-16
```

Input Arguments

ZeroRates — Annualized zero rates

decimal fraction

Annualized zero rates, specified as a `NUMBONDS`-by-`1` vector using decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by `CurveDates`.

Data Types: `double`

`CurveDates` — Maturity dates

datetime array | string array | date character vector

Maturity dates which correspond to the input `ZeroRates`, specified as a `NUMBONDS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `zero2pyld` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `datetime` | `string` | `char`

`Settle` — Common settlement date for `ZeroRates`

datetime scalar | string scalar | date character vector

Common settlement date for input `ZeroRates`, specified as a scalar datetime, string, or date character vector.

To support existing code, `zero2pyld` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `datetime` | `string` | `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[ParRates,CurveDates] = zero2pyld(ZeroRates,CurveDates, Settle,'OutputCompounding',3,'OutputBasis',5,'InputCompounding',4,'InputBasis',5)`

`OutputCompounding` — Compounding frequency of output `ParRates`

2 (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `12`, `365`, `-1`

Compounding frequency of output `ParRates`, specified as the comma-separated pair consisting of `'OutputCompounding'` and allowed values:

- `1` — Annual compounding
- `2` — Semiannual compounding (default)
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

Note

- If `InputCompounding` is `1`, `2`, `3`, `4`, `6`, or `12` and `OutputCompounding` is not specified, the value of `InputCompounding` is used.
- If `InputCompounding` is `0` (simple), `-1` (continuous), or `365` (daily), a valid `OutputCompounding` value must also be specified.

- If either InputCompounding or OutputCompounding are not specified, the default is 2 (semiannual) for both.

Data Types: double

OutputBasis — Day-count basis of output ParRates
0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of output ParRates, specified as the comma-separated pair consisting of 'OutputBasis' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If OutputBasis is not specified, then OutputBasis is assigned the value specified for InputBasis. If either InputBasis or OutputBasis are not specified, the default is 0 (actual/actual) for both.

Data Types: double

InputCompounding — Compounding frequency of input ZeroRates
2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input ZeroRates, specified as the comma-separated pair consisting of 'InputCompounding' and allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding

- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

Note

- If InputCompounding is set to 0 (simple), -1 (continuous), or 365 (daily), the OutputCompounding must also be specified using a valid value.
- If InputCompounding is not specified, then InputCompounding is assigned the value specified for OutputCompounding.
- If either InputCompounding or OutputCompounding are not specified, the default is 2 (semiannual) for both.

Data Types: double

InputBasis — Day-count basis of input ZeroRates

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of the input ZeroRates, specified as the comma-separated pair consisting of 'InputBasis' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-16.

Note If InputBasis is not specified, then InputBasis is assigned the value specified for OutputBasis. If either InputBasis or Outputbasis are not specified, the default is 0 (actual/actual) for both.

Data Types: double

Output Arguments

ParRates — Par bond coupon rates

numeric

Par bond coupon rates, returned as a NUMBONDS-by-1 numeric vector. ParRates are ordered by ascending maturity.

CurveDates — Maturity dates that correspond to ParRates

datetime | serial date number

Maturity dates that correspond to the ParRates, returned as a NUMBONDS-by-1 vector of maturity dates that correspond to each par rate contained in ParRates.

ParRates are expressed as serial date numbers (default) or datetimes (if CurveDates or Settle are datetime arrays). CurveDates are ordered by ascending maturity.

Version History

Introduced before R2006a

R2022b: Serial date numbers not recommended

Not recommended starting in R2022b

Although zero2pyld supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

compact

Create compact credit scorecard

Syntax

```
csc = compact(sc)
```

Description

`csc = compact(sc)` converts an existing `creditscorecard` object to a `compactCreditScorecard` object (`csc`).

Note To use this function, you must have a license for Risk Management Toolbox.

Examples

Convert `creditscorecard` Object into `compactCreditScorecard` Object

Convert a `creditscorecard` object into a `compactCreditScorecard` object to use `displaypoints` (Risk Management Toolbox), `score` (Risk Management Toolbox), and `probdefault` (Risk Management Toolbox) from Risk Management Toolbox™ with the object.

First, create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData.mat
sc = creditscorecard(data)
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustID'  'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBala
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: ''
            PredictorVars: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
                     Data: [1200x11 table]
```

Before creating a `compactCreditScorecard` object, you must use `autobinning` and `fitmodel` with the `creditscorecard` object.

```
sc = autobinning(sc);
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:
    logit(status) ~ 1 + CustAge + ResStatus + EmpStatus + CustIncome + TmWBank + OtherCC + AMBala
    Distribution = Binomial

Estimated Coefficients:
                   Estimate       SE       tStat       pValue  
                   ________    ________    ______    __________

    (Intercept)    0.70239     0.064001    10.975    5.0538e-28
    CustAge        0.60833      0.24932      2.44      0.014687
    ResStatus        1.377      0.65272    2.1097      0.034888
    EmpStatus      0.88565        0.293    3.0227     0.0025055
    CustIncome     0.70164      0.21844    3.2121     0.0013179
    TmWBank         1.1074      0.23271    4.7589    1.9464e-06
    OtherCC         1.0883      0.52912    2.0569      0.039696
    AMBalance        1.045      0.32214    3.2439     0.0011792

1200 observations, 1192 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 89.7, p-value = 1.4e-16
```

Convert the `creditscorecard` object into a `compactCreditScorecard` object by using the `compact` function. To use `compact`, you must have a Risk Management Toolbox™ license.

```
csc = compact(sc)
```

```
csc = 
  compactCreditScorecard with properties:

              Description: ''
                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
        NumericPredictors: {'CustAge'  'CustIncome'  'TmWBank'  'AMBalance'}
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
            PredictorVars: {'CustAge'  'ResStatus'  'EmpStatus'  'CustIncome'  'TmWBank'  'OtherC
```

You can then use `displaypoints` (Risk Management Toolbox), `score` (Risk Management Toolbox), and `probdefault` (Risk Management Toolbox) from Risk Management Toolbox™ with the `compactCreditScorecard` object.

Input Arguments

`sc` — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object.

Note You must use a creditscorecard object (sc) for input that has been previously processed with autobinning and fitmodel, or fitConstrainedModel. Optionally, you can use formatpoints in addition to these functions.

Output Arguments

csc — Compact credit scorecard

compactCreditScorecard object

Compact credit scorecard, returned as a compactCreditScorecard object. You can then use displaypoints, score, and probdefault from the Risk Management Toolbox with this csc object.

Version History

Introduced in R2019a

score

Compute credit scores for given data

Syntax

```
Scores = score(sc)
Scores = score(sc, data)
```

```
[Scores,Points] = score(sc)
[Scores,Points] = score(sc,data)
```

Description

`Scores = score(sc)` computes the credit scores for the `creditscorecard` object’s training data. This data can be a “training” or a “live” dataset. If the `data` input argument is not explicitly provided, the `score` function determines scores for the existing `creditscorecard` object’s data.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into `NaN` values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

`Scores = score(sc, data)` computes the credit scores for the given input `data`. This data can be a “training” or a “live” dataset.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into `NaN` values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

`[Scores,Points] = score(sc)` computes the credit scores and points for the given data. If the `data` input argument is not explicitly provided, the `score` function determines scores for the existing `creditscorecard` object’s data.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into `NaN` values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

`[Scores,Points] = score(sc,data)` computes the credit scores and points for the given input `data`. This data can be a “training” or a “live” dataset.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into `NaN` values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

Examples

Obtain Scores for Training Data

This example shows how to use `score` to obtain scores for the training data.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:
    logit(status) ~ 1 + CustAge + ResStatus + EmpStatus + CustIncome + TmWBank + OtherCC + AMBala

                   Estimate       SE       tStat       pValue  
                   ________    ________    ______    __________

    (Intercept)    0.70239     0.064001    10.975    5.0538e-28
    CustAge        0.60833      0.24932      2.44      0.014687
    ResStatus        1.377      0.65272    2.1097      0.034888
    EmpStatus      0.88565        0.293    3.0227     0.0025055
    CustIncome     0.70164      0.21844    3.2121     0.0013179
    TmWBank         1.1074      0.23271    4.7589    1.9464e-06
    OtherCC         1.0883      0.52912    2.0569      0.039696
    AMBalance        1.045      0.32214    3.2439     0.0011792

1200 observations, 1192 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 89.7, p-value = 1.4e-16
```

Score training data using the `score` function without an optional input for `data`. By default, it returns unscaled scores. For brevity, only the first ten scores are displayed.

```
Scores = score(sc);
disp(Scores(1:10))
```

```
    1.0968
    1.4646
    0.7662
    1.5779
    1.4535
    1.8944
   -0.0872
    0.9207
    1.0399
    0.8252
```

Scale scores and display both points and scores for each individual in the training data (for brevity, only the first ten rows are displayed). For other scaling methods, and other options for formatting points and scores, use the `formatpoints` function.

```
sc = formatpoints(sc,'WorstAndBestScores',[300 850]);
[Scores,Points] = score(sc);
disp(Scores(1:10))
```

```
  602.0394

Scores for Missing or Out-of-Range Data When Using the 'BinMissingData' Option

This example describes the assignment of points for missing data when the `'BinMissingData'` option is set to `true`.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values.

- Predictors with no missing data in the training set have no <missing> bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to NaN, and this leads to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes.

Create a creditscorecard object using the CreditCardData.mat file to load the dataMissing with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus     EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ____

      1          53          62         <undefined>    Unknown        50000         55         Ye
      2          61          22         Home Owner     Employed       52000         25         Ye
      3          47          30         Tenant         Employed       37000         61         No
      4         NaN          75         Home Owner     Employed       53000         20         Ye
      5          68          56         Home Owner     Employed       53000         14         Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

```

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the `'PointsOddsAndPDO'` argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc,'PointsOddsAndPDO',[500 2 50]);
PointsInfo = displaypoints(sc)
```

```
PointsInfo=38×3 table

    {'EmpStatus'}    {'Employed'  }    86.937
    {'EmpStatus'}    {'<missing>' }       NaN
      ⋮
```

Notice that points for the `<missing>` bin for `CustAge` and `ResStatus` are explicitly shown (as `64.9836` and `74.1250`, respectively). These points are computed from the WOE value for the `<missing>` bin, and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit `<missing>` bin. By default the points are set to `NaN` for missing data and they lead to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument `'Missing'` in `formatpoints` to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall `'MinValue'` was earlier set to `0` for `CustAge` and `CustIncome`). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

```
tdata = dataMissing(11:18,mdl.PredictorNames); % Keep only the predictors retained in the model
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
```

```
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)
```

```
    CustAge     ResStatus      EmpStatus      CustIncome    TmWBank    OtherCC    AMBalance
    _______    ___________    ___________    __________    _______    _______    _________

```

Use the name-value argument `'Missing'` in `formatpoints` to choose how to assign points to missing values for predictors that do not have an explicit `<missing>` bin. In this example, use the `'MinPoints'` option for the `'Missing'` argument. The minimum points for `EmpStatus` in the scorecard displayed above are `58.8072`, and for `CustIncome` the minimum points are `29.3753`.

```
sc = formatpoints(sc,'Missing','MinPoints');
[Scores,Points] = score(sc,tdata);
disp(Scores)

Score a New Dataset

This example shows how to use `score` to obtain scores for a new dataset (for example, a validation or a test dataset) using the optional `'data'` input in the `score` function.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601

    1.4401
      ⋮
```

Input Arguments

`sc` — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

`data` — Dataset to be scored

table

(Optional) Dataset to be scored, specified as a MATLAB table where each row corresponds to individual observations. The `data` must contain columns for each of the predictors in the `creditscorecard` object.

Output Arguments

`Scores` — Scores for each observation

vector

Scores for each observation, returned as a vector.

`Points` — Points per predictor for each observation
table

Points per predictor for each observation, returned as a table.

Algorithms

The score of an individual *i* is given by the formula

```
Score(i) = Shift + Slope*(b0 + b1*WOE1(i) + b2*WOE2(i)+ ... +bp*WOEp(i))
```

where *bj* is the coefficient of the *j*-th variable in the model, and WOE*j*(*i*) is the Weight of Evidence (WOE) value for the *i*-th individual corresponding to the *j*-th model variable. `Shift` and `Slope` are scaling constants that can be controlled with `formatpoints`.

If the data for individual *i* is in the *i*-th row of a given dataset, to compute a score, the data(*i*,*j*) is binned using existing binning maps, and converted into a corresponding Weight of Evidence value `WOE`*j*(*i*). Using the model coefficients, the unscaled score is computed as

```
 s = b0 + b1*WOE1(i) + ... +bp*WOEp(i).
```

For simplicity, assume in the description above that the *j*-th variable in the model is the *j*-th column in the data input, although, in general, the order of variables in a given dataset does not have to match the order of variables in the model, and the dataset could have additional variables that are not used in the model.

The formatting options can be controlled using `formatpoints`.

Version History

Introduced in R2014b

formatpoints

Format scorecard points and scaling

Syntax

```
sc = formatpoints(sc,Name,Value)
```

Description

`sc = formatpoints(sc,Name,Value)` modifies the scorecard points and scaling using optional name-value pair arguments. For example, use optional name-value pair arguments to change the scaling of the scores or the rounding of the points.

Examples

Scale Points Using Points, Odds Levels, and PDO

This example shows how to use `formatpoints` to scale by providing the points, odds levels, and PDO (points to double the odds). By using `formatpoints` to scale, you can put points and scores in a desired range that is more meaningful for practical purposes. Technically, this involves a linear transformation from the unscaled to the scaled points by the `formatpoints` function.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

MinScore = 300.0000

MaxScore = 850
```

As expected, the values of `MinScore` and `MaxScore` correspond to the desired worst and best scores.

Scale Points Using Shift and Slope

This example shows how to use `formatpoints` to scale by providing the `Shift` and `Slope` values. By using `formatpoints` to scale, you can put points and scores in a desired range that is more meaningful for practical purposes. Technically, this involves a linear transformation from the unscaled to the scaled points by the `formatpoints` function.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

Round Points

This example shows how to use `formatpoints` to round points. Rounding is usually applied after scaling, otherwise, if the points for a particular predictor are all in a small range, rounding could cause the rounded points for different bins to be the same. Also, rounding all the points may slightly change the minimum and maximum total points.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

Rounding and Default Probabilities

This example shows that rounding scorecard points can modify the original risk ranking of a credit scorecard. You can control rounding by using `formatpoints` with the optional name-value pair argument for `'Rounding'`.

Credit scores rank customers by risk. If higher scores are given to better, less risky customers, then higher scores must correspond to lower default probabilities. When you use the name-value pair argument for `'Rounding'`, depending on the value for `'Rounding'`, the rounding behavior is:

- When `'Rounding'` is set to `'None'` (default option), no rounding is applied to points or scores, and the risk ranking is completely consistent with the calibrated model.
- When `'Rounding'` is set to `'FinalScore'`, rounding is only applied to the final scores. In this case: a) Customers with different scores (different risk) may have the same rounded score. b) Customers with the same rounded score may have different default probabilities. c) Customer with higher rounded scores will always have lower default probability than customers with lower scores.
- When `'Rounding'` is set to `'AllPoints'`, rounding is applied to all points in the scorecard (all bins, all predictors). In this case: a) Customers with different scores (different risk) may have the same rounded score, or their ranking may even be reversed (the customer with the lower original score may have a higher rounded score). b) Customers with the same rounded score may have different default probabilities. c) Customer with higher rounded scores may in some cases have *higher* default probabilities than customers with lower scores.

Create a `creditscorecard`

To demonstrate the rounding behavior, first create a `creditscorecard` object.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID','ResponseVar','status');
sc = autobinning(sc);
sc = modifybins(sc,'CustIncome','CutPoints',20000:5000:60000);
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1487.9719, Chi2Stat = 35.469392, PValue = 2.5909009e-09
2. Adding TmWBank, Deviance = 1465.7998, Chi2Stat = 22.172089, PValue = 2.4927133e-06
3. Adding AMBalance, Deviance = 1455.206, Chi2Stat = 10.593833, PValue = 0.0011346548
4. Adding EmpStatus, Deviance = 1446.3918, Chi2Stat = 8.8142314, PValue = 0.0029889009
5. Adding CustAge, Deviance = 1440.6825, Chi2Stat = 5.709236, PValue = 0.016875883
6. Adding ResStatus, Deviance = 1436.1363, Chi2Stat = 4.5462043, PValue = 0.032991806
7. Adding OtherCC, Deviance = 1431.9546, Chi2Stat = 4.1817827, PValue = 0.040860699

Generalized linear regression model:
    logit(status) ~ 1 + CustAge + ResStatus + EmpStatus + CustIncome + TmWBank + OtherCC + AMBala
    Distribution = Binomial

Estimated Coefficients:

1200 observations, 1192 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.5, p-value = 6.12e-17
```

Apply the 'Rounding' Options

Apply each of the three 'Rounding' options to the creditscorecard object.

```
sc = formatpoints(sc,'PointsOddsAndPDO',[500 2 50]); % No Rounding
points1  = displaypoints(sc);
[S1,P1]  = score(sc);
defProb1 = probdefault(sc);

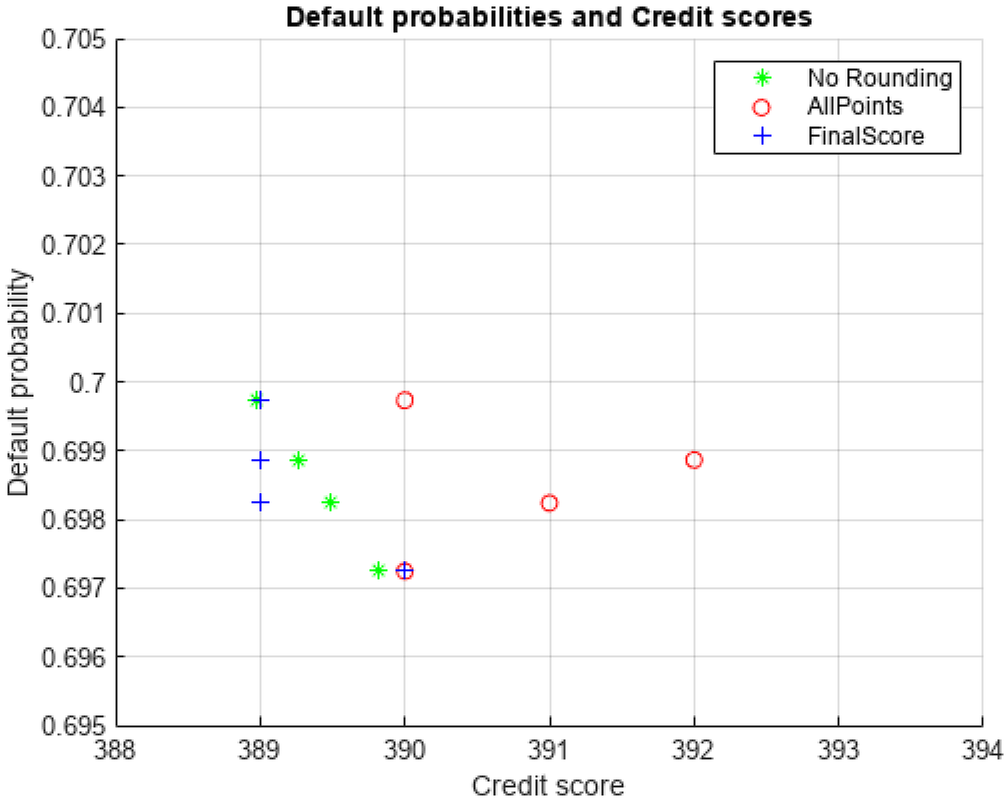
sc = formatpoints(sc,'Round','AllPoints'); % 'AllPoints' Rounding
points2  = displaypoints(sc);
[S2,P2]  = score(sc);
defProb2 = probdefault(sc);

sc = formatpoints(sc,'Round','FinalScore'); % 'FinalScore' Rounding
points3  = displaypoints(sc);
[S3,P3]  = score(sc);
defProb3 = probdefault(sc);
```

Compare the 'Rounding' Options

Visualize the default probabilities versus the scores.

```
figure
hold on
scatter(S1, defProb1, 'g*')
scatter(S2, defProb2, 'ro')
scatter(S3, defProb3, 'b+')
legend('No Rounding','AllPoints','FinalScore')
axis([388 394 0.695 0.705])
xlabel('Credit score')
ylabel('Default probability')
title('Default probabilities and Credit scores')
grid
```



Inspect the points and total scores for each `'Rounding'` option, in table format.

```
ind = [208 363 694 886];
ProbDefault = defProb1(ind)
```

```
ProbDefault = 4×1

```

The original `creditscorecard` model, without rounding, was calibrated to the data with a logistic regression. The ranking and probabilities have a statistical foundation.

Rounding, however, effectively modifies the `creditscorecard` model. When only the final score is rounded, this leads to some "ties" in rounded scores, but at least the risk ranking *across* scores is preserved (because if *s1* <= *s2*, then round(*s1*) <= round(*s2*)).

However, when you round all points, a score may gain extra points by chance. For example, in the second row in the table (row 363 of original data), the points for all predictors are rounded up by almost `0.5`. The original score is `389.27`. Rounding the final score makes it `389`. However, rounding all points makes it `392`, that is three points higher than rounding the final score.

Scores for Missing or Out-of-Range Data

This example shows how to use `formatpoints` to score missing or out-of-range data. When data is scored, some observations can be either missing (`NaN`, or `undefined`) or out of range. You will need to decide whether or not points are assigned to these cases. Use the name-value pair argument `Missing` to do so.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Indicate that the minimum allowed value for `'CustAge'` is zero. This makes any negative values for age invalid or out-of-range.

```
sc = modifybins(sc,'CustAge','MinValue',0);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Scores for Missing or Out-of-Range Data When Using the 'BinMissingData' Option

This example describes the assignment of points for missing data when the 'BinMissingData' option is set to true.

- Predictors that have missing data in the training set have an explicit bin for <missing> with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the <missing> bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values.
- Predictors with no missing data in the training set have no <missing> bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to NaN, and this leads to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes.

Create a creditscorecard object using the CreditCardData.mat file to load the dataMissing with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus     EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ____

      1          53          62         <undefined>    Unknown        50000         55         Ye
      2          61          22         Home Owner     Employed       52000         25         Ye
      3          47          30         Tenant         Employed       37000         61         No
      4         NaN          75         Home Owner     Employed       53000         20         Ye
      5          68          56         Home Owner     Employed       53000         14         Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))

```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

```

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the `'PointsOddsAndPDO'` argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc,'PointsOddsAndPDO',[500 2 50]);
PointsInfo = displaypoints(sc)
```

```
PointsInfo=38×3 table
     Predictors            Bin            Points
    ____________    ______________    ______

    {'CustAge'  }    {'[0,33)'    }    54.062
    {'CustAge'  }    {'[33,37)'   }    56.282
    {'CustAge'  }    {'[37,40)'   }    60.012
    {'CustAge'  }    {'[40,46)'   }    69.636
    {'CustAge'  }    {'[46,48)'   }    77.912
    {'CustAge'  }    {'[48,51)'   }     78.86
    {'CustAge'  }    {'[51,58)'   }     80.83
    {'CustAge'  }    {'[58,Inf]'  }     96.76
    {'CustAge'  }    {'<missing>' }    64.984
    {'ResStatus'}    {'Tenant'    }    62.138
    {'ResStatus'}    {'Home Owner'}    73.248
    {'ResStatus'}    {'Other'     }    90.828
    {'ResStatus'}    {'<missing>' }    74.125
    {'EmpStatus'}    {'Unknown'   }    58.807
    {'EmpStatus'}    {'Employed'  }    86.937
    {'EmpStatus'}    {'<missing>' }       NaN
       ⋮
```

Notice that points for the `<missing>` bin for `CustAge` and `ResStatus` are explicitly shown (as `64.9836` and `74.1250`, respectively). These points are computed from the WOE value for the `<missing>` bin, and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit `<missing>` bin. By default the points are set to `NaN` for missing data and they lead to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument `'Missing'` in `formatpoints` to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall `'MinValue'` was earlier set to `0` for `CustAge` and `CustIncome`). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

```
tdata = dataMissing(11:18,mdl.PredictorNames); % Keep only the predictors retained in the model
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)
```

```
    CustAge     ResStatus      EmpStatus      CustIncome    TmWBank    OtherCC    AMBalance
    _______    ___________    ___________    __________    _______    _______    _________

      NaN      Tenant         Unknown          34000         44         Yes        119.8  
       48      <undefined>    Unknown          44000         14         Yes       403.62  
       65      Home Owner     <undefined>      48000          6         No        111.88  
       44      Other          Unknown            NaN         35         No        436.41  
     -100      Other          Employed         46000         16         Yes       162.21  
       33      House          Employed         36000         36         Yes       845.02  
    39      Tenant         Freelancer       34000          40          Yes        756.26
    24      Home Owner     Employed            -1          19          Yes        449.61
```

Score the new data and see how points are assigned for missing `CustAge` and `ResStatus`, because we have an explicit bin with points for `<missing>`. However, for `EmpStatus` and `CustIncome` the `score` function sets the points to `NaN`.

```
[Scores,Points] = score(sc,tdata);
disp(Scores)
```

```
  481.2231
  520.8353
       NaN
       NaN

    _______     _________     _________     __________     _______     _______     _________

    64.984       62.138        58.807         67.893       61.858      75.622       89.922
     78.86       74.125        58.807         82.439       61.061      75.622       89.922
     96.76       73.248           NaN         96.969       51.132      50.914       89.922
    69.636       90.828        58.807            NaN       61.858      50.914       89.922
    64.984       90.828        86.937         82.439       61.061      75.622       89.922
    56.282       74.125        86.937         70.107       61.858      75.622       63.028
    60.012       62.138           NaN         67.893       61.858      75.622       63.028
    54.062       73.248        86.937            NaN       61.061      75.622       89.922
```

Use the name-value argument `'Missing'` in `formatpoints` to choose how to assign points to missing values for predictors that do not have an explicit `<missing>` bin. In this example, use the `'MinPoints'` option for the `'Missing'` argument. The minimum points for `EmpStatus` in the scorecard displayed above are `58.8072`, and for `CustIncome` the minimum points are `29.3753`.

```
sc = formatpoints(sc,'Missing','MinPoints');
[Scores,Points] = score(sc,tdata);
disp(Scores)
```

```

Input Arguments

sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a creditscorecard object. Use creditscorecard to create a creditscorecard object.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: sc = formatpoints(sc,'BasePoints',true,'Round','AllPoints','WorstAndBestScores',[100, 700])

Note ShiftAndSlope, PointsOddsAndPDO, and WorstAndBestScores are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (BasePoints, Missing, and Round) are not scaling methods and can be used together or with any one of the three scaling methods.

BasePoints — Indicator for separating base points

false (default) | logical scalar

Indicator for separating base points, specified as the comma-separated pair consisting of 'BasePoints' and a logical scalar. If true, the scorecard explicitly separates base points. If false, the base points are spread across all variables in the creditscorecard object.

Data Types: char

Missing — Indicator for points assigned to missing or out-of-range information when scoring

NoScore (default) | character vector with values NoScore, ZeroWOE, MinPoints, and MaxPoints

Indicator for points assigned to missing or out-of-range information when scoring, specified as the comma-separated pair consisting of 'Missing' and a character vector with a value for NoScore, ZeroWOE, MinPoints, or MaxPoints, where:

- NoScore — Missing and out-of-range data do not get points assigned and points are set to NaN. Also, the total score is set to NaN.
- ZeroWOE — Missing or out-of-range data get assigned a zero Weight-of-Evidence (WOE) value.

- `MinPoints` — Missing or out-of-range data get the minimum possible points for that predictor. This penalizes the score if higher scores are better.
- `MaxPoints` — Missing or out-of-range data get the maximum possible points for that predictor. This penalizes the score if lower scores are better.

Note When using the `creditscorecard` name-value argument `'BinMissingData'` with a value of `true`, missing data for numeric and categorical predictors is binned in a separate bin labeled `<missing>`. The `<missing>` bin only contains missing values for a predictor and does not contain invalid or out-of-range values for a predictor.

Data Types: `char`

Round — Indicator whether to round points or scores
`'None'` (default) | character vector with values`'AllPoints'`, `'FinalScore'`

Indicator whether to round points or scores, specified as the comma-separated pair consisting of `'Round'` and a character vector with values `'AllPoints'`, `'FinalScore'` or `'None'`, where:

- `None` — No rounding is applied.
- `AllPoints` — Apply rounding to each predictor's points before adding up the total score.
- `FinalScore` — Round the final score only (rounding is applied after all points are added up).

For more information and an example of using the `'Round'` name-value pair argument, see “Rounding and Default Probabilities” on page 15-1674.

Data Types: `char`

ShiftAndSlope — Indicator for shift and slope scaling parameters
`[0,1]` (default) | numeric array with two elements `[Shift,Slope]`

Indicator for shift and slope scaling parameters for the credit scorecard, specified as the comma-separated pair consisting of `'ShiftAndSlope'` and a numeric array with two elements `[Shift, Slope]`. `Slope` cannot be zero. The `ShiftAndSlope` values are used scale the scoring model.

Note `ShiftAndSlope`, `PointsOddsAndPDO`, and `WorstAndBestScores` are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (`BasePoints`, `Missing`, and `Round`) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set `ShiftAndSlope` to`[0,1]`.

Data Types: `double`

PointsOddsAndPDO — Indicator for target points for given odds and double odds level
numeric array with three elements `[Points,Odds,PDO]`

Indicator for target points (`Points`) for a given odds level (`Odds`) and the desired number of points to double the odds (`PDO`), specified as the comma-separated pair consisting of `'PointsOddsAndPDO'` and a numeric array with three elements `[Points,Odds,PDO]`. `Odds` must be a positive number. The `PointsOddsAndPDO` values are used to find scaling parameters for the scoring model.

Note The points to double the odds (PDO) may be positive or negative, depending on whether higher scores mean lower risk, or vice versa.

ShiftAndSlope, PointsOddsAndPDO, and WorstAndBestScores are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (BasePoints, Missing, and Round) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set ShiftAndSlope to[0,1].

Data Types: double

WorstAndBestScores — Indicator for worst (highest risk) and best (lowest risk) scores in scorecard

numeric array with two elements [WorstScore,BestScore]

Indicator for worst (highest risk) and best (lowest risk) scores in the scorecard, specified as the comma-separated pair consisting of 'WorstAndBestScores' and a numeric array with two elements [WorstScore,BestScore]. WorstScore and BestScore must be different values. These WorstAndBestScores values are used to find scaling parameters for the scoring model.

Note WorstScore means the riskiest score, and its value could be lower or higher than the ‘best’ score. In other words, the ‘minimum’ score may be the ‘worst‘ score or the 'best' score, depending on the desired scoring scale.

ShiftAndSlope, PointsOddsAndPDO, and WorstAndBestScores are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (BasePoints, Missing, and Round) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set ShiftAndSlope to[0,1].

Data Types: double

Output Arguments

sc — Credit scorecard model

creditscorecard object

Credit scorecard model returned as an updated creditscorecard object. For more information on using the creditscorecard object, see creditscorecard.

Algorithms

The score of an individual *i* is given by the formula

```
Score(i) = Shift + Slope*(b0 + b1*WOE1(i) + b2*WOE2(i)+ ... +bp*WOEp(i))
```

where *bj* is the coefficient of the *j*th variable in the model, and WOE*j*(*i*) is the Weight of Evidence (WOE) value for the *i*th individual corresponding to the *j*th model variable. Shift and Slope are scaling constants further discussed below. The scaling constant can be controlled with formatpoints.

If the data for individual *i* is in the *i*-th row of a given dataset, to compute a score, the data(*i*,*j*) is binned using existing binning maps, and converted into a corresponding Weight of Evidence value `WOE`*j*(*i*). Using the model coefficients, the unscaled score is computed as

```
 s = b0 + b1*WOE1(i) + ... +bp*WOEp(i).
```

For simplicity, assume in the description above that the *j*-th variable in the model is the *j*-th column in the data input, although, in general, the order of variables in a given dataset does not have to match the order of variables in the model, and the dataset could have additional variables that are not used in the model.

The formatting options can be controlled using `formatpoints`. When the base points are reported separately (see the `formatpoints` parameter `BasePoints`), the base points are given by

```
Base Points = Shift + Slope*b0,
```

and the points for the *j*-th predictor, *i*-th row are given by

```
Points_ji = Slope*(bj*WOEj(i))).
```

By default, the base points are not reported separately, in which case

```
Points_ji = (Shift + Slope*b0)/p + Slope*(bj*WOEj(i)),
```

where *p* is the number of predictors in the scorecard model.

By default, no rounding is applied to the points by the `score` function (`Round` is `None`). If `Round` is set to `AllPoints` using `formatpoints`, then the points for individual *i* for variable *j* are given by

```
 points if rounding is 'AllPoints': round( Points_ji )
```

and, if base points are reported separately, the are also rounded. This yields integer-valued points per predictor, hence also integer-valued scores. If `Round` is set to `FinalScore` using `formatpoints`, then the points per predictor are not rounded, and only the final score is rounded

```
 score if rounding is 'FinalScore': round(Score(i)).
```

Regarding the scaling parameters, the `Shift` parameter, and the `Slope` parameter can be set directly with the `ShiftAndSlope` parameter of `formatpoints`. Alternatively, you can use the `formatpoints` parameter for `WorstAndBestScores`. In this case, the parameters `Shift` and `Slope` are found internally by solving the system

```
Shift + Slope*smin = WorstScore,
Shift + Slope*smax = BestScore,
```

where `WorstScore` and `BestScore` are the first and second elements in the `formatpoints` parameter for `WorstAndBestScores` and *smin* and *smax* are the minimum and maximum possible unscaled scores:

```
smin = b0 + min(b1*WOE1) + ... +min(bp*WOEp),
smax = b0 + max(b1*WOE1) + ... +max(bp*WOEp).
```

A third alternative to scale scores is the `PointsOddsAndPDO` parameter in `formatpoints`. In this case, assume that the unscaled score *s* gives the log-odds for a row, and the `Shift` and `Slope` parameters are found by solving the following system

```
Points = Shift + Slope*log(Odds)
Points + PDO = Shift + Slope*log(2*Odds)
```

where `Points`, `Odds`, and `PDO` ("points to double the odds") are the first, second, and third elements in the `PointsOddsAndPDO` parameter.

Whenever a given dataset has a missing or out-of-range value data (*i*,*j*), the points for predictor *j*, for individual *i*, are set to `NaN` by default, which results in a missing score for that row (a `NaN` score). Using the `Missing` parameter for `formatpoints`, you can modify this behavior and set the corresponding Weight-of-Evidence (WOE) value to zero, or set the points to the minimum points, or the maximum points for that predictor.

Version History

Introduced in R2014b

displaypoints

Return points per predictor per bin

Syntax

```
PointsInfo = displaypoints(sc)
[PointsInfo,MinScore,MaxScore] = displaypoints(sc)
[PointsInfo,MinScore,MaxScore] = displaypoints( ___ ,Name,Value)
```

Description

`PointsInfo = displaypoints(sc)` returns a table of points for all bins of all predictor variables used in the `creditscorecard` object after a linear logistic regression model is fit using `fitmodel` to the Weight of Evidence data. The `PointsInfo` table displays information on the predictor name, bin labels, and the corresponding points per bin.

`[PointsInfo,MinScore,MaxScore] = displaypoints(sc)` returns a table of points for all bins of all predictor variables used in the `creditscorecard` object after a linear logistic regression model is fit (`fitmodel`) to the Weight of Evidence data. The `PointsInfo` table displays information on the predictor name, bin labels, and the corresponding points per bin and `displaypoints`. In addition, the optional `MinScore` and `MaxScore` values are returned.

`[PointsInfo,MinScore,MaxScore] = displaypoints( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Display Unscaled Points

This example shows how to use `displaypoints` after a model is fitted to compute the unscaled points per bin, for a given predictor in the `creditscorecard` model.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
```

```
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

    {'EmpStatus' }    {'Unknown'     }    -0.076317
    {'EmpStatus' }    {'Employed'    }      0.31449
    {'EmpStatus' }    {'<missing>'   }          NaN
    {'CustIncome'}    {'[-Inf,29000)'}     -0.45716
      ⋮
```

`displaypoints` always displays a `'<missing>'` bin for each predictor. The value of the `'<missing>'` bin comes from the initial `creditscorecard` object, and the `'<missing>'` bin is set to `NaN` whenever the scorecard model has no information on how to assign points to missing data.

To configure the points for the `'<missing>'` bin, you must use the initial `creditscorecard` object. For predictors that have missing values in the training set, the points for the `'<missing>'` bin are estimated from the data if the `'BinMissingData'` name-value pair argument is set to `true` using `creditscorecard`. When the `'BinMissingData'` parameter is set to `false`, or when the data contains no missing values in the training set, use the `'Missing'` name-value pair argument in `formatpoints` to indicate how to assign points to the missing data.

Display Unscaled Points When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus     EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ____

      1          53          62         <undefined>    Unknown        50000         55         Ye
      2          61          22         Home Owner     Employed       52000         25         Ye
      3          47          30         Tenant         Employed       37000         61         No
      4         NaN          75         Home Owner     Employed       53000         20         Ye
      5          68          56         Home Owner     Employed       53000         14         Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);

disp(sc)
```

```

```

```
plotbins(sc,'ResStatus')
```

For the `'CustAge'` and `'ResStatus'` predictors, there is missing data (`NaN`s and `<undefined>`) in the training data, and the binning process estimates a WOE value of `-0.15787` and `0.026469` respectively for missing data in these predictors, as shown above.

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the <missing> bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

```

    {'EmpStatus'}    {'Employed'  }      0.31401
    {'EmpStatus'}    {'<missing>' }          NaN
      ⋮
```

Notice that points for the <missing> bin for CustAge and ResStatus are explicitly shown. These points are computed from the WOE value for the <missing> bin and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin, and by default the points are set to NaN for missing data, and they lead to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes.

Display Scaled Points

This example shows how to use formatpoints after a model is fitted to format scaled points, and then use displaypoints to display the scaled points per bin, for a given predictor in the creditscorecard model.

Points become scaled when a range is defined. Specifically, a linear transformation from the unscaled to the scaled points is necessary. This transformation is defined either by supplying a shift and slope or by specifying the worst and best scores possible. (For more information, see formatpoints.)

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the creditscorecard function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

    {'EmpStatus' }    {'Unknown'     }    56.765
    {'EmpStatus' }    {'Employed'    }    105.81
    {'EmpStatus' }    {'<missing>'   }       NaN
    {'CustIncome'}    {'[-Inf,29000)'}    8.9706
       ⋮

MinScore = 300.0000

MaxScore = 850
```

Notice that, as expected, the values of `MinScore` and `MaxScore` correspond to the worst and best possible scores.

Separate the Base Points From the Total Points

This example shows how to use `displaypoints` after a model is fitted to separate the base points from the rest of the points assigned to each predictor variable. The name-value pair argument `'BasePoints'` in the `formatpoints` function is a boolean that serves this purpose. By default, the base points are spread across all variables in the scorecard.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

```

Display Points After Modifying Bin Labels

This example shows how to use `displaypoints` after a model is fitted and the `modifybins` function is used to provide user-defined bin labels for a numeric predictor.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06

Compute the Predictor Weights

This example shows how to use a credit scorecard to compute the weights of the predictors. The weights of the predictors are determined from the range of points of each predictor, divided by the total range of points for the scorecard. The points for the scorecard not only take into consideration the betas, but also implicitly the binning of the predictor values and the corresponding weights of evidence.

Create a scorecard.

```
load CreditCardData.mat
sc = creditscorecard(data,'IDVar','CustID');
sc = autobinning(sc);
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

    {'ResStatus'}    {'Home Owner'}    73.444
```

```
 fprintf('Min points: %g, Max points: %g\n',MinPts,MaxPts);
```

```
Min points: 355.505, Max points: 671.64
```

Compute the predictor weights.

```
Predictor = unique(PointsTable.Predictors,'stable');
NumPred = length(Predictor);
Weight = zeros(NumPred,1);
for ii=1:NumPred
   Ind = cellfun(@(x)strcmpi(Predictor{ii},x),PointsTable.Predictors);
   MaxPtsPred = max(PointsTable.Points(Ind));
   MinPtsPred = min(PointsTable.Points(Ind));
   Weight(ii) = 100*(MaxPtsPred-MinPtsPred)/PtsRange;
end

PredictorWeights = table(Predictor,Weight);
PredictorWeights(end+1,:) = PredictorWeights(end,:);
PredictorWeights.Predictor{end} = 'Total';
PredictorWeights.Weight(end) = sum(Weight);
disp(PredictorWeights)
```

```
      Predictor       Weight
    _____________    ______
    {'CustAge'   }    14.556
    {'ResStatus' }     9.302
    {'EmpStatus' }    8.9174
    {'CustIncome'}    20.401
    {'TmWBank'   }    25.884
    {'OtherCC'   }    7.9885
    {'AMBalance' }    12.951
    {'Total'     }       100
```

The weights are defined as the range of points for the predictor divided by the range of points for the scorecard.

Display Points for `creditscorecard` Object That Contains Missing Data

To create a `creditscorecard` object using the `CreditCardData.mat` file, load the `data` (using a dataset from Refaat 2011). Using the `dataMissing` dataset, set the `'BinMissingData'` indicator to `true`.

```
load CreditCardData.mat
sc = creditscorecard(dataMissing,'BinMissingData',true);
```

Use `autobinning` with the `creditscorecard` object.

```
sc = autobinning(sc);
```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor `ResStatus`.

```
[bi,cg] = bininfo(sc,'ResStatus')
```

```
bi=5×6 table
         Bin           Good    Bad      Odds        WOE        InfoValue 
    ______________     ____    ___     ______    _________    __________

    {'Tenant'    }     296     161     1.8385    -0.095463     0.0035249
    {'Home Owner'}     352     171     2.0585     0.017549    0.00013382
    {'Other'     }     128      52     2.4615      0.19637     0.0055808
    {'<missing>' }      27      13     2.0769     0.026469    2.3248e-05
    {'Totals'    }     803     397     2.0227          NaN     0.0092627

cg=3×2 table
       Category        BinNumber
    ______________     _________

    {'Tenant'    }         1    
    {'Home Owner'}         2    
    {'Other'     }         3    
```

To group categories `'Tenant'` and `'Other'`, modify the category grouping table `cg`, so the bin number for `'Other'` is the same as the bin number for `'Tenant'`. Then use `modifybins` to update the `creditscorecard` object.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc,'ResStatus','Catg',cg);
```

Display the updated bin information using `bininfo`. Note that the bin labels has been updated and that the bin membership information is contained in the category grouping `cg`.

```
[bi,cg] = bininfo(sc,'ResStatus')
```

```
bi=4×6 table
         Bin         Good    Bad      Odds         WOE       InfoValue 
    _____________    ____    ___    ______    _________    __________

    {'Group1'   }    296     161    1.8385    -0.095463     0.0035249
    {'Group2'   }    480     223    2.1525     0.062196     0.0022419
    {'<missing>'}     27      13    2.0769     0.026469    2.3248e-05
    {'Totals'   }    803     397    2.0227          NaN       0.00579

cg=3×2 table
       Category         BinNumber
    ______________    _________

    {'Tenant'    }        1    
    {'Home Owner'}        2    
    {'Other'     }        2    
```

Use `formatpoints` with the `'Missing'` name-value pair argument to indicate that missing data is assigned `'maxpoints'`.

```
sc = formatpoints(sc,'BasePoints',true,'Missing','maxpoints','WorstAndBest',[300 800]);
```

Use `fitmodel` to fit the model.

```
sc = fitmodel(sc,'VariableSelection','fullmodel','Display','Off');
```

Then use `displaypoints` (Risk Management Toolbox) with the `creditscorecard` object to return a table of points for all bins of all predictor variables used in the `compactCreditScorecard` object. By setting the `displaypoints` (Risk Management Toolbox) name-value pair argument for '`ShowCategoricalMembers`' to `true`, all the members contained in each individual group are displayed.

```
[PointsInfo,MinScore,MaxScore] = displaypoints(sc,'ShowCategoricalMembers',true)
```

```

```

Input Arguments

`sc` — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[PointsInfo,MinScore,MaxScore] = displaypoints(sc, ‘ShowCategoricalMembers’,true)`

`ShowCategoricalMembers` — Indicator for how to display bins labels of categories that were grouped together

`false` (default) | `true` or `false`

Indicator for how to display bins labels of categories that were grouped together, specified as the comma-separated pair consisting of `'ShowCategoricalMembers'` and a logical scalar with a value of `true` or `false`.

By default, when `'ShowCategoricalMembers'` is `false`, bin labels are displayed as `Group1`, `Group2`,...,`Group`*n*, or if the bin labels were modified in `creditscorecard`, then the user-defined bin label names are displayed.

If `'ShowCategoricalMembers'` is `true`, all the members contained in each individual group are displayed.

Data Types: `logical`

Output Arguments

`PointsInfo` — One row per bin, per predictor, with the corresponding points

table

One row per bin, per predictor, with the corresponding points, returned as a table. For example:

Predictors	Bin	Points
Predictor_1	Bin_11	Points_11
Predictor_1	Bin_12	Points_12
Predictor_1	Bin_13	Points_13
	...	...
Predictor_1	`'<missing>'`	`NaN` (Default)
Predictor_2	Bin_21	Points_21
Predictor_2	Bin_22	Points_22
Predictor_2	Bin_23	Points_23
	...	...
Predictor_2	`'<missing>'`	`NaN` (Default)
Predictor_*j*	Bin_*ji*	Points_*ji*
	...	...
Predictor_*j*	`'<missing>'`	`NaN` (Default)

`displaypoints` always displays a `'<missing>'` bin for each predictor. The value of the `'<missing>'` bin comes from the initial `creditscorecard` object, and the `'<missing>'` bin is set to `NaN` whenever the scorecard model has no information on how to assign points to missing data.

To configure the points for the `'<missing>'` bin, you must use the initial `creditscorecard` object. For predictors that have missing values in the training set, the points for the `'<missing>'` bin are estimated from the data if the `'BinMissingData'` name-value pair argument for is set to `true` using `creditscorecard`. When the `'BinMissingData'` parameter is set to `false`, or when the data contains no missing values in the training set, use the `'Missing'` name-value pair argument in `formatpoints` to indicate how to assign points to the missing data.

Another option is to use `fillmissing` to specify replacement "fill" values for predictors with a `NaN` or `<undefined>` value. If you use `fillmissing`, then the `displaypoints` `'<missing>'` row has the same points as the bin associated with the fill value.

When base points are reported separately (see `formatpoints`), the first row of the returned `PointsInfo` table contains the base points.

`MinScore` — Minimum possible total score

scalar

Minimum possible total score, returned as a scalar.

Note Minimum score is the lowest possible total score in the mathematical sense, independently of whether a low score means high risk or low risk.

`MaxScore` — Maximum possible total score

scalar

Maximum possible total score, returned as a scalar.

Note Maximum score is the highest possible total score in the mathematical sense, independently of whether a high score means high risk or low risk.

Algorithms

The points for predictor *j* and bin *i* are, by default, given by

```
Points_ji = (Shift + Slope*b0)/p + Slope*(bj*WOEj(i))
```

where *bj* is the model coefficient of predictor *j*, *p* is the number of predictors in the model, and WOE*j*(*i*) is the Weight of Evidence (WOE) value for the *i*-th bin corresponding to the j-th model predictor. `Shift` and `Slope` are scaling constants.

When the base points are reported separately (see the `formatpoints` name-value pair argument `BasePoints`), the base points are given by

```
Base Points = Shift + Slope*b0,
```

and the points for the *j*-th predictor, *i*-th row are given by

```
Points_ji = Slope*(bj*WOEj(i))).
```

By default, the base points are not reported separately.

The minimum and maximum scores are:

```
MinScore = Shift + Slope*b0 + min(Slope*b1*WOE1) + ... +min(Slope*bp*WOEp)),
MaxScore = Shift + Slope*b0 + max(Slope*b1*WOE1) + ... +max(Slope*bp*WOEp)).
```

Use `formatpoints` to control the way points are scaled, rounded, and whether the base points are reported separately. See `formatpoints` for more information on format parameters and for details and formulas on these formatting options.

fitmodel

Fit logistic regression model to Weight of Evidence (WOE) data

Syntax

```
sc = fitmodel(sc)
```

```
[sc,mdl] = fitmodel(sc)
[sc,mdl] = fitmodel( ___ ,Name,Value)
```

Description

`sc = fitmodel(sc)` fits a logistic regression model to the Weight of Evidence (WOE) data and stores the model predictor names and corresponding coefficients in the `creditscorecard` object.

`fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic or manual binning process. The response variable is mapped so that "Good" is `1`, and "Bad" is `0`. This implies that higher (unscaled) scores correspond to better (less risky) individuals (smaller probability of default).

Alternatively, you can use `setmodel` to provide names of the predictors that you want in the logistic regression model, along with their corresponding coefficients.

`[sc,mdl] = fitmodel(sc)` fits a logistic regression model to the Weight of Evidence (WOE) data and stores the model predictor names and corresponding coefficients in the `creditscorecard` object. `fitmodel` returns an updated `creditscorecard` object and a `GeneralizedLinearModel` object containing the fitted model.

`fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic or manual binning process. The response variable is mapped so that "Good" is `1`, and "Bad" is `0`. This implies that higher (unscaled) scores correspond to better (less risky) individuals (smaller probability of default).

Alternatively, you can use `setmodel` to provide names of the predictors that you want in the logistic regression model, along with their corresponding coefficients.

`[sc,mdl] = fitmodel( ___ ,Name,Value)` fits a logistic regression model to the Weight of Evidence (WOE) data using optional name-value pair arguments and stores the model predictor names and corresponding coefficients in the `creditscorecard` object. Using name-value pair arguments, you can select which Generalized Linear Model to fit the data. `fitmodel` returns an updated `creditscorecard` object and a `GeneralizedLinearModel` object containing the fitted model.

Examples

Fit a Stepwise Logistic Model

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'T
                     Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc)
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'T
                     Data: [1200x11 table]
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default).

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601

```

Fit a Stepwise Logistic Model For a creditscorecard Object Containing Weights

Use the `CreditCardData.mat` file to load the data (`dataWeights`) that contains a column (`RowWeights`) for the weights (using a dataset from Refaat 2011).

```
load CreditCardData
```

Create a `creditscorecard` object using the optional name-value pair argument for `'WeightsVar'`.

```
sc = creditscorecard(dataWeights,'IDVar','CustID','WeightsVar','RowWeights')
```

```
sc = 
  creditscorecard with properties:

              GoodLabel: 0
            ResponseVar: 'status'
             WeightsVar: 'RowWeights'
               VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
      NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
  CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
         BinMissingData: 0
                  IDVar: 'CustID'
          PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'T
                   Data: [1200x12 table]
```

Perform automatic binning.

```
sc = autobinning(sc)
```

```
sc = 
  creditscorecard with properties:

              GoodLabel: 0
            ResponseVar: 'status'
             WeightsVar: 'RowWeights'
               VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
      NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
  CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
         BinMissingData: 0
```

```
                   IDVar: 'CustID'
           PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                    Data: [1200x12 table]
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). When the optional name-value pair argument `'WeightsVar'` is used to specify observation (sample) weights, the `mdl` output uses the weighted counts with `stepwiseglm` and `fitglm`.

```
[sc,mdl] = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 764.3187, Chi2Stat = 15.81927, PValue = 6.968927e-05
2. Adding TmWBank, Deviance = 751.0215, Chi2Stat = 13.29726, PValue = 0.0002657942
3. Adding AMBalance, Deviance = 743.7581, Chi2Stat = 7.263384, PValue = 0.007037455

Generalized linear regression model:
    logit(status) ~ 1 + CustIncome + TmWBank + AMBalance
    Distribution = Binomial

Estimated Coefficients:
                   Estimate       SE       tStat       pValue  
                   ________    ________    _____    __________

    (Intercept)    0.70642     0.088702    7.964    1.6653e-15
    CustIncome      1.0268      0.25758    3.9862    6.7132e-05
    TmWBank         1.0973      0.31294    3.5063     0.0004543
    AMBalance       1.0039      0.37576    2.6717     0.0075464

1200 observations, 1196 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 36.4, p-value = 6.22e-08
```

Fit a Logistic Model with All Predictors

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
```

```
            PredictorVars: {'CustAge'    'TmAtAddress'    'ResStatus'    'EmpStatus'    'CustIncome'    'Tr
                     Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc,'Algorithm','EqualFrequency')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'    'CustAge'    'TmAtAddress'    'ResStatus'    'EmpStatus'    'CustI
        NumericPredictors: {'CustAge'    'TmAtAddress'    'CustIncome'    'TmWBank'    'AMBalance'    'Uti
    CategoricalPredictors: {'ResStatus'    'EmpStatus'    'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'    'TmAtAddress'    'ResStatus'    'EmpStatus'    'CustIncome'    'Tr
                     Data: [1200x11 table]
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. Set the `VariableSelection` name-value pair argument to `FullModel` to specify that all predictors must be included in the fitted logistic regression model.

```
sc = fitmodel(sc,'VariableSelection','FullModel');
```

```
Generalized linear regression model:
    logit(status) ~ 1 + CustAge + TmAtAddress + ResStatus + EmpStatus + CustIncome + TmWBank + O
    Distribution = Binomial

Estimated Coefficients:
                   Estimate       SE        tStat       pValue

1200 observations, 1190 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 85.6, p-value = 1.25e-14
```

Fit a Stepwise Logistic Model When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus     EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ___

      1          53          62         <undefined>    Unknown        50000         55         Ye
      2          61          22         Home Owner     Employed       52000         25         Ye
      3          47          30         Tenant         Employed       37000         61         No
      4         NaN          75         Home Owner     Employed       53000         20         Ye
      5          68          56         Home Owner     Employed       53000         14         Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
disp(sc)
```

```
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 1
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'T
                     Data: [1200×11 table]
```

Display and plot bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

```
         Bin         Good    Bad     Odds       WOE       InfoValue

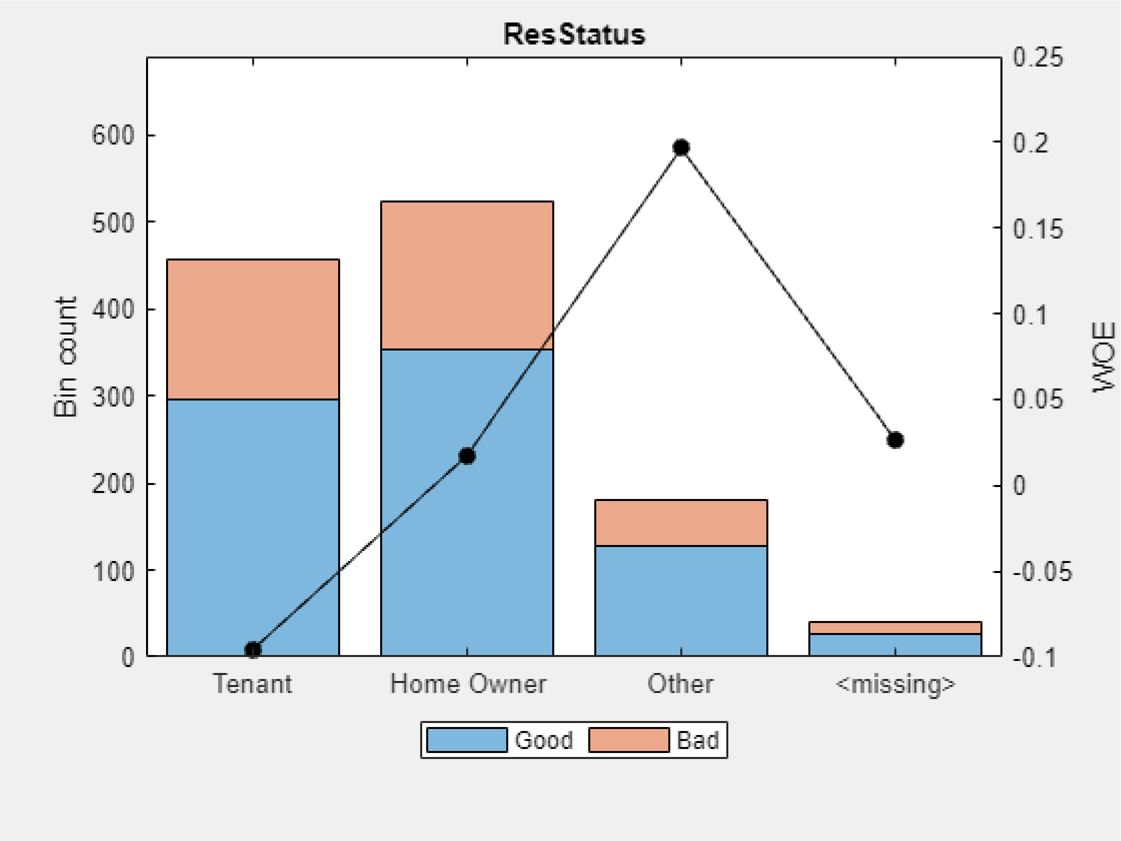
plotbins(sc,'ResStatus')
```



Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the <missing> bin is applied when performing the WOE transformation. For example, a missing value for customer age (`CustAge`) is replaced with `-0.15787` which is the WOE value for the `<missing>` bin for the `CustAge` predictor. However, when `'BinMissingData'` is false, a missing value for `CustAge` remains as missing (`NaN`) when applying the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

Input Arguments

`sc` — Credit scorecard model
`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[sc,mdl] = fitmodel(sc,'VariableSelection','FullModel')`

`PredictorVars` — Predictor variables for fitting `creditscorecard` object
all predictors in the `creditscorecard` object (default) | cell array of character vectors

Predictor variables for fitting the `creditscorecard` object, specified as the comma-separated pair consisting of `'PredictorVars'` and a cell array of character vectors. When provided, the `creditscorecard` object property `PredictorsVars` is updated. Note that the order of predictors in the original dataset is enforced, regardless of the order in which `'PredictorVars'` is provided. When not provided, the predictors used to create the `creditscorecard` object (by using `creditscorecard`) are used.

Data Types: `cell`

`VariableSelection` — Variable selection method to fit logistic regression model
`'Stepwise'` (default) | character vector with values `'Stepwise'`, `'FullModel'`

The variable selection method to fit the logistic regression model, specified as the comma-separated pair consisting of `'VariableSelection'` and a character vector with values `'Stepwise'` or `'FullModel'`:

- `Stepwise` — Uses a stepwise selection method which calls the Statistics and Machine Learning Toolbox function `stepwiseglm`. Only variables in `PredictorVars` can potentially become part of the model and uses the `StartingModel` name-value pair argument to select the starting model.

- `FullModel` — Fits a model with all predictor variables in the `PredictorVars` name-value pair argument and calls `fitglm`.

Note Only variables in the `PredictorVars` property of the `creditscorecard` object can potentially become part of the logistic regression model and only linear terms are included in this model with no interactions or any other higher-order terms.

The response variable is mapped so that “Good” is `1` and “Bad” is `0`.

Data Types: `char`

`StartingModel` — Initial model for `Stepwise` variable selection
`'Constant'` (default) | character vector with values `'Constant'`, `'Linear'`

Initial model for the `Stepwise` variable selection method, specified as the comma-separated pair consisting of `'StartingModel'` and a character vector with values `'Constant'` or `'Linear'`. This option determines the initial model (constant or linear) that the Statistics and Machine Learning Toolbox function `stepwiseglm` starts with.

- `Constant` — Starts the stepwise method with an empty (constant only) model.
- `Linear` — Starts the stepwise method from a full (all predictors in) model.

Note `StartingModel` is used only for the `Stepwise` option of `VariableSelection` and has no effect for the `FullModel` option of `VariableSelection`.

Data Types: `char`

`Display` — Indicator to display model information at command line
`'On'` (default) | character vector with values `'On'`, `'Off'`

Indicator to display model information at command line, specified as the comma-separated pair consisting of `'Display'` and a character vector with value `'On'` or `'Off'`.

Data Types: `char`

Output Arguments

`sc` — Credit scorecard model
`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object. The `creditscorecard` object contains information about the model predictors and coefficients used to fit the WOE data. For more information on using the `creditscorecard` object, see `creditscorecard`.

`mdl` — Fitted logistic model
`GeneralizedLinearModel` object

Fitted logistic model, retuned as an object of type `GeneralizedLinearModel` containing the fitted model. For more information on a `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

Note When creating the `creditscorecard` object with `creditscorecard`, if the optional name-value pair argument `WeightsVar` was used to specify observation (sample) weights, then `mdl` uses the weighted counts with `stepwiseglm` and `fitglm`.

More About

Using `fitmodel` with Weights

When observation weights are provided in the credit scorecard `data`, the weights are used to calibrate the model coefficients.

The underlying Statistics and Machine Learning Toolbox functionality for `stepwiseglm` and `fitglm` supports observation weights. The weights also affect the logistic model through the WOE values. The WOE transformation is applied to all predictors before fitting the logistic model. The observation weights directly impact the WOE values. For more information, see “Using bininfo with Weights” on page 15-1807 and “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

Therefore, the credit scorecard points and final score depend on the observation weights through both the logistic model coefficients and the WOE values.

Models

A logistic regression model is used in the `creditscorecard` object.

For the model, the probability of being “Bad” is defined as: `ProbBad = exp(-s) / (1 + exp(-s))`.

Version History

Introduced in R2014b

fitConstrainedModel

Fit logistic regression model to Weight of Evidence (WOE) data subject to constraints on model coefficients

Syntax

```
[sc,mdl] = fitConstrainedModel(sc)
```

```
[sc,mdl] = fitConstrainedModel( ___ ,Name,Value)
```

Description

`[sc,mdl] = fitConstrainedModel(sc)` fits a logistic regression model to the Weight of Evidence (WOE) data subject to equality, inequality, or bound constraints on the model coefficients. `fitConstrainedModel` stores the model predictor names and corresponding coefficients in an updated `creditscorecard` object `sc` and returns the `GeneralizedLinearModel` object `mdl` which contains the fitted model.

`[sc,mdl] = fitConstrainedModel( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Credit Scorecards with Constrained Logistic Regression Coefficients

To compute scores for a `creditscorecard` object with constraints for equality, inequality, or bounds on the coefficients of the logistic regression model, use `fitConstrainedModel`. Unlike `fitmodel`, `fitConstrainedModel` solves for both the unconstrained and constrained problem. The current solver used to minimize an objective function for `fitConstrainedModel` is `fmincon`, from the Optimization Toolbox™.

This example has three main sections. First, `fitConstrainedModel` is used to solve for the coefficients in the unconstrained model. Then, `fitConstrainedModel` demonstrates how to use several types of constraints. Finally, `fitConstrainedModel` uses bootstrapping for the significance analysis to determine which predictors to reject from the model.

Create the `creditscorecard` Object and Bin data

```
load CreditCardData.mat
sc = creditscorecard(data,'IDVar','CustID');
sc = autobinning(sc);
```

Unconstrained Model Using `fitConstrainedModel`

Solve for the unconstrained coefficients using `fitConstrainedModel` with default values for the input parameters. `fitConstrainedModel` uses the internal optimization solver `fmincon` from the Optimization Toolbox™. If you do not set any constraints, `fmincon` treats the model as an unconstrained optimization problem. The default parameters for the `LowerBound` and `UpperBound` are `-Inf` and `+Inf`, respectively. For the equality and inequality constraints, the default is an empty numeric array.

```
[sc1,mdl1] = fitConstrainedModel(sc);
coeff1 = mdl1.Coefficients.Estimate;
disp(mdl1.Coefficients);
```

```
                   Estimate 
                   _________

    (Intercept)      0.70246
    CustAge           0.6057
    TmAtAddress       1.0381
    ResStatus         1.3794
    EmpStatus        0.89648
    CustIncome       0.70179
    TmWBank           1.1132
    OtherCC           1.0598
    AMBalance         1.0572
    UtilRate       -0.047597
```

Unlike `fitmodel` which gives *p*-values, when using `fitConstrainedModel`, you must use bootstrapping to find out which predictors are rejected from the model, when subject to constraints. This is illustrated in the "Significance Bootstrapping" section.

Using `fitmodel` to Compare the Results and Calibrate the Model

`fitmodel` fits a logistic regression model to the Weight-of-Evidence (WOE) data and there are no constraints. You can compare the results from the "Unconstrained Model Using fitConstrainedModel" section with those of `fitmodel` to verify that the model is well calibrated.

Now, solve the unconstrained problem by using `fitmodel`. Note that `fitmodel` and `fitConstrainedModel` use different solvers. While `fitConstrainedModel` uses `fmincon`, `fitmodel` uses `stepwiseglm` by default. To include all predictors from the start, set the `'VariableSelection'` name-value pair argument of `fitmodel` to `'fullmodel'`.

```
[sc2,mdl2] = fitmodel(sc,'VariableSelection','fullmodel','Display','off');
coeff2 = mdl2.Coefficients.Estimate;
disp(mdl2.Coefficients);
```

```
                   Estimate       SE         tStat        pValue  
                   _________    ________    _________    __________

As both the tables and the plot show, the model coefficients match. You can be confident that this implementation of `fitConstrainedModel` is well calibrated.

Constrained Model

In the constrained model approach, you solve for the values of the coefficients b_i of the logistic model, subject to constraints. The supported constraints are bound, equality, or inequality. The coefficients maximize the likelihood-of-default function defined, for observation i, as:

$$L_i = p(\text{Default}_i)^{y_i} \times (1 - p(\text{Default}_i))^{1 - y_i}$$

where:

- $p(\text{Default}_i) = \dfrac{1}{1 + e^{-b\text{x}_i}}$
- $\boldsymbol{b} = [b_1\, b_2\, .\, .\, .\, b_K]$ is an unknown model coefficient
- $\boldsymbol{x_i} = [x_{\text{i}1}\, x_2\, .\, .\, .\, x_{\text{iK}}]$ is the predictor values at observation i
- y_i is the response value; a value of 1 represents default and a value of 0 represents non-default

This formula is for non-weighted data. When observation i has weight w_i, it means that there are w_i as many observations i. Therefore, the probability that default occurs at observation i is the product of the probabilities of default:

$$p_i \;=\; \underbrace{p(\text{Default}_i)^{y_i} * p(\text{Default}_i)^{y_i} * \ldots * p(\text{Default}_i)^{y_i}}_{w_i\,\text{times}} = p(\text{Default}_i)^{w_i * y_i}$$

Likewise, the probability of non-default for weighted observation i is:

$$\widehat{p}_i \;=\; \underbrace{p(\sim\text{Default}_i)^{1-y_i} * p(\sim\text{Default}_i)^{1-y_i} * \ldots * p(\sim\text{Default}_i)^{1-y_i}}_{w_i\,\text{times}} = (1 - p(\text{Default}_i))^{w_i * (1-y_i)}$$

For weighted data, if there is default at a given observation i whose weight is w_i, it is as if there was a w_i count of that one observation, and all of them either all default, or all non-default. w_i may or may not be an integer.

Therefore, for the weighted data, the likelihood-of-default function for observation i in the first equation becomes

$$L_i = p(\text{Default}_i)^{w_i * y_i} \times (1 - p(\text{Default}_i))^{w_i * (1-y_i)}$$

By assumption, all defaults are independent events, so the objective function is

$$L = L_1 \times L_2 \times \ldots \times L_N$$

or, in more convenient logarithmic terms:

$$\log(L) = \sum_{i=1}^{N} w_i * [y_i \log(p(\text{Default}_i)) + (1 - y_i)\log(1 - p(\text{Default}_i))]$$

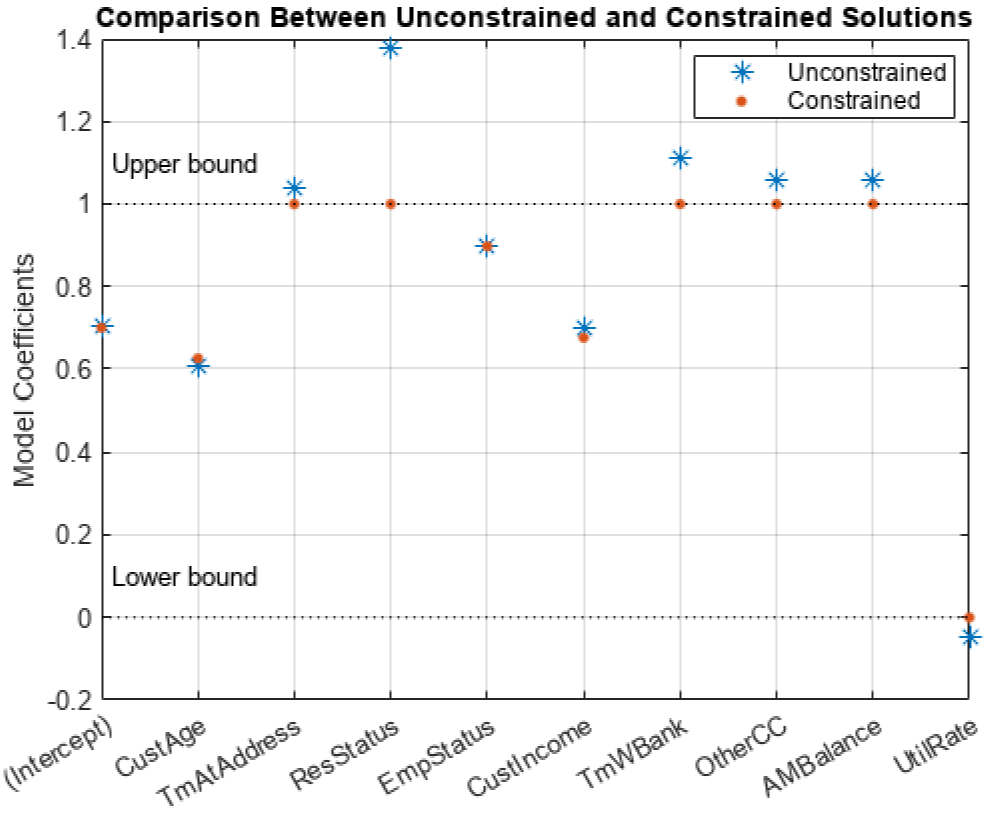
Apply Constraints on the Coefficients

After calibrating the unconstrained model as described in the "Unconstrained Model Using fitConstrainedModel" section, you can solve for the model coefficients subject to constraints. You can choose lower and upper bounds such that $0 \le b_i \le 1, \forall i = 1\ldots K$, except for the intercept. Also, since the customer age and customer income are somewhat correlated, you can also use additional constraints on their coefficients, for example, $|b_{CusAge} - b_{CustIncome}| < 0.1$. The coefficients corresponding to the predictors `'CustAge'` and `'CustIncome'` in this example are b_2 and b_6, respectively.

```
K  = length(sc.PredictorVars);
lb = [-Inf;zeros(K,1)];
ub = [Inf;ones(K,1)];
AIneq = [0 -1 0 0 0 1 0 0 0 0;0 -1 0 0 0 -1 0 0 0 0];
bIneq = [0.05;0.05];
Options = optimoptions('fmincon','SpecifyObjectiveGradient',true,'Display','off');
[sc3,mdl] = fitConstrainedModel(sc,'AInequality',AIneq,'bInequality',bIneq,...
    'LowerBound',lb,'UpperBound',ub,'Options',Options);

figure
plot(coeff1,'*','MarkerSize',8)
hold on
plot(mdl.Coefficients.Estimate,'.','MarkerSize',12)
line(xlim,[0 0],'color','k','linestyle',':')
line(xlim,[1 1],'color','k','linestyle',':')
text(1.1,0.1,'Lower bound')
text(1.1,1.1,'Upper bound')
grid on

xticklabels(mdl.Coefficients.Properties.RowNames)
ylabel('Model Coefficients')
title('Comparison Between Unconstrained and Constrained Solutions')
legend({'Unconstrained','Constrained'},'Location','best')
```



Significance Bootstrapping

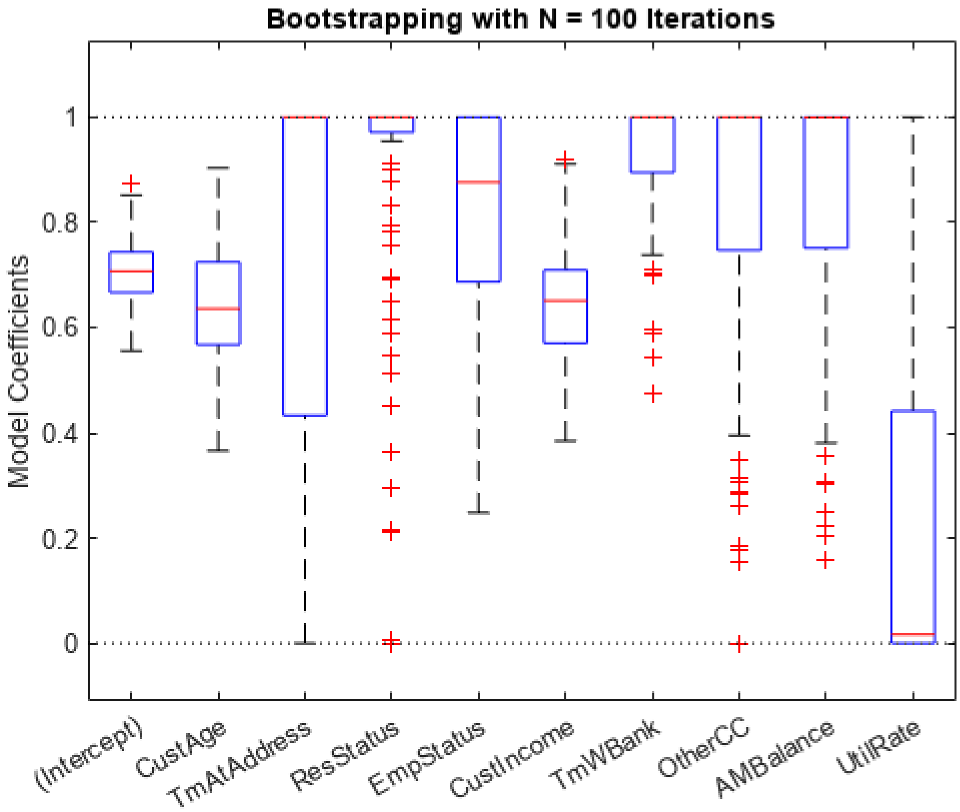
For the unconstrained problem, standard formulas are available for computing *p*-values, which you use to evaluate which coefficients are significant and which are to be rejected. However, for the constrained problem, standard formulas are not available, and the derivation of formulas for significance analysis is complicated. A practical alternative is to perform significance analysis through *bootstrapping*.

In the bootstrapping approach, when using `fitConstrainedModel`, you set the name-value argument `'Bootstrap'` to `true` and chose a value for the name-value argument `'BootstrapIter'`. Bootstrapping means that *NIter* samples (with replacement) from the original observations are selected. In each iteration, `fitConstrainedModel` solves for the same constrained problem as the "Constrained Model" section. `fitConstrainedModel` obtains several values (solutions) for each coefficient b_i and you can plot these as a `boxplot` or `histogram`. Using the boxplot or histogram, you can examine the median values to evaluate whether the coefficients are away from zero and how much the coefficients deviate from their means.

```
lb = [-Inf;zeros(K,1)];
ub = [Inf;ones(K,1)];
AIneq = [0 -1 0 0 0 1 0 0 0 0;0 1 0 0 0 -1 0 0 0 0];
bIneq = [0.05;0.05];
c0 = zeros(K,1);
NIter = 100;
Options = optimoptions('fmincon','SpecifyObjectiveGradient',true,'Display','off');
rng('default')

[sc,mdl] = fitConstrainedModel(sc,'AInequality',AIneq,'bInequality',bIneq,...
    'LowerBound',lb,'UpperBound',ub,'Bootstrap',true,'BootstrapIter',NIter,'Options',Options);

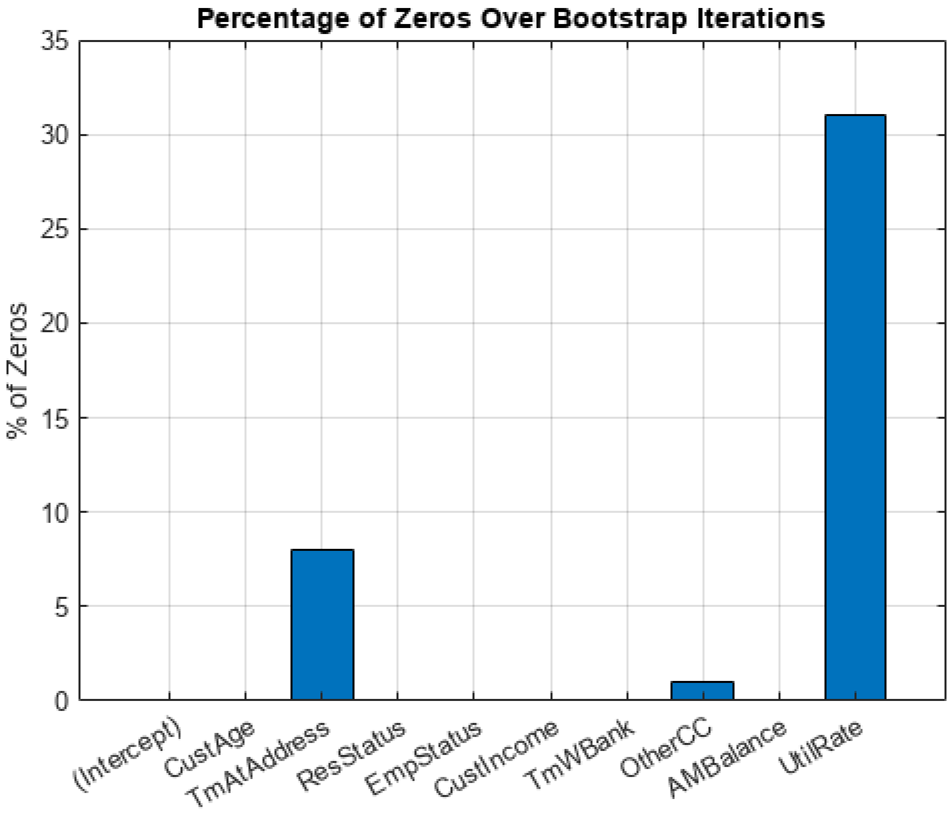
figure
boxplot(mdl.Bootstrap.Matrix,mdl.Coefficients.Properties.RowNames)
hold on
line(xlim,[0 0],'color','k','linestyle',':')
line(xlim,[1 1],'color','k','linestyle',':')
title('Bootstrapping with N = 100 Iterations')
ylabel('Model Coefficients')
```



The solid red lines in the boxplot indicate that the median values and the bottom and top edges are for the 25th and 75th percentiles. The "whiskers" are the minimum and maximum values, not including outliers. The dotted lines represent the lower and upper bound constraints on the coefficients. In this example, the coefficients cannot be negative, by construction.

To help decide which predictors to keep in the model, assess the proportion of times each coefficient is zero.

```
Tol = 1e-6;
figure
bar(100*sum(mdl.Bootstrap.Matrix<= Tol)/NIter)
ylabel('% of Zeros')
title('Percentage of Zeros Over Bootstrap Iterations')
xticklabels(mdl.Coefficients.Properties.RowNames)
grid on
```



Based on the plot, you can reject `'UtilRate'` since it has the highest number of zero values. You can also decide to reject `'TmAtAddress'` since it shows a peak, albeit small.

Set the Corresponding Coefficients to Zero

To set the corresponding coefficients to zero, set their upper bound to zero and solve the model again using the original data set.

```
ub(3) = 0;
ub(end) = 0;
[sc,mdl] = fitConstrainedModel(sc,'AInequality',AIneq,'bInequality',bIneq,'LowerBound',lb,'Upper
Ind = (abs(mdl.Coefficients.Estimate) <= Tol);
ModelCoeff = mdl.Coefficients.Estimate(~Ind);
ModelPreds = mdl.Coefficients.Properties.RowNames(~Ind)';

Set Constrained Coefficients Back Into the creditscorecard

Now that you have solved for the constrained coefficients, use setmodel to set the model's coefficients and predictors. Then you can compute the (unscaled) points.

```
ModelPreds = ModelPreds(2:end);
sc = setmodel(sc,ModelPreds,ModelCoeff);
p = displaypoints(sc);

disp(p)
```

```

```

Using the unscaled points, you can follow the remainder of the “Credit Scorecard Modeling Workflow” on page 8-51 to compute scores and probabilities of default and to validate the model.

Input Arguments

`sc` — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[sc,mdl] = fitConstrainedModel(sc,'LowerBound',2,'UpperBound',100)`

`PredictorVars` — Predictor variables for fitting `creditscorecard` object

all predictors in the `creditscorecard` object (default) | cell array of character vectors

Predictor variables for fitting the `creditscorecard` object, specified as the comma-separated pair consisting of `'PredictorVars'` and a cell array of character vectors. If you provide predictor variables, then the function updates the `creditscorecard` object property `PredictorsVars`. The order of predictors in the original dataset is enforced, regardless of the order in which

'PredictorVars' is provided. When not provided, the predictors used to create the creditscorecard object (by using creditscorecard) are used.

Data Types: cell

LowerBound — Lower bound
-Inf (default) | scalar | vector

Lower bound, specified as the comma-separated pair consisting of 'LowerBound' and a scalar or a real vector of length N+1, where N is the number of model coefficients in the creditscorecard object.

Data Types: double

UpperBound — Upper bound
Inf (default) | scalar | vector

Upper bound, specified as the comma-separated pair consisting of 'UpperBound' and a scalar or a real vector of length N+1, where N is the number of model coefficients in the creditscorecard object.

Data Types: double

AInequality — Matrix of linear inequality constraints
[] (default) | matrix

Matrix of linear inequality constraints, specified as the comma-separated pair consisting of 'AInequality' and a real M-by-N+1 matrix, where M is the number of constraints and N is the number of model coefficients in the creditscorecard object.

Data Types: double

bInequality — Vector of linear inequality constraints
[] (default) | vector

Vector of linear inequality constraints, specified as the comma-separated pair consisting of 'bInequality' and a real M-by-1 vector, where M is the number of constraints.

Data Types: double

AEquality — Matrix of linear equality constraints
[] (default) | matrix

Matrix of linear equality constraints, specified as the comma-separated pair consisting of 'AEquality' and a real M-by-N+1 matrix, where M is the number of constraints and N is the number of model coefficients in the creditscorecard object.

Data Types: double

bEquality — Vector of linear equality constraints
[] (default) | vector

Vector of linear equality constraints, specified as the comma-separated pair consisting of 'bEquality' and a real M-by-1 vector, where M is the number of constraints.

Data Types: double

Bootstrap — Indicator that bootstrapping defines the solution accuracy

false (default) | logical with a value of true or false

Indicator that bootstrapping defines the solution accuracy, specified as the comma-separated pair consisting of 'Bootstrap' and a logical with a value of true or false.

Data Types: logical

BootstrapIter — Number of bootstrapping iterations

100 (default) | positive integer

Number of bootstrapping iterations, specified as the comma-separated pair consisting of 'BootstrapIter' and a positive integer.

Data Types: double

Options — optimoptions object

optimoptions('fmincon','SpecifiedObjectiveGradient',true,'Display','off') (default) | object

optimoptions object, specified as the comma-separated pair consisting of 'Options' and an optimoptions object. You can create the object by using optimoptions from Optimization Toolbox.

Data Types: object

Output Arguments

sc — Credit scorecard model

creditscorecard object

Credit scorecard model, returned as an updated creditscorecard object. The creditscorecard object contains information about the model predictors and coefficients that fit the WOE data. For more information on using the creditscorecard object, see creditscorecard.

mdl — Fitted logistic model

GeneralizedLinearModel object

Fitted logistic model, retuned as a GeneralizedLinearModel object containing the fitted model. For more information on a GeneralizedLinearModel object, see GeneralizedLinearModel.

Note If you specify the optional WeightsVar argument when creating a creditscorecard object, then mdl uses the weighted counts with stepwiseglm and fitglm.

The mdl structure has the following fields:

- Coefficients is a table in which the RowNames property contains the names of the model coefficients and has a single column, 'Estimate', containing the solution.
- Bootstrap exists when 'Bootstrap' is set to true, and has two fields:
  - CI contains the 95% confidence interval for the solution.
  - Matrix an NIter-by-N matrix of coefficients, where NIter is the number of bootstrap iterations and N is the number of model coefficients.

- Solver has three fields:
  - Options additional information on the algorithm and solution.
  - ExitFlag contains an integer that codes the reason why the solver stopped. For more information, see fmincon.
  - Output is a structure with additional information on the optimization process.

More About

Model Coefficients

When you use fitConstrainedModel to solve for the model coefficients, the function solves for the same number of parameters as predictor variables you specify, plus one additional coefficient for the intercept.

The first coefficient corresponds to the intercept. If you provide predictor variables using the 'PredictorVars' optional input argument, then fitConstrainedModel updates the creditscorecard object property PredictorsVars. The order of predictors in the original dataset is enforced, regardless of the order in which 'PredictorVars' is provided. When not provided, the predictors used to create the creditscorecard object (by using creditscorecard) are used.

Calibration

The constrained model is first calibrated such that, when unconstrained, the solution is identical, within a certain tolerance, to the solution given by fitmodel, with the'fullmodel' choice for the name-value argument 'VariableSelection'.

As an exercise, you can test the calibration by leaving all name-value parameters of fitConstrainedModel to their default values. The solutions are identical to within a 10^{-6} to 10^{-5} tolerance.

Calibration with Weights and Missing Data

If the credit scorecard data contains observation weights, the fitConstrainedModel function uses the weights to calibrate the model coefficients.

For credit scorecard data with no missing data and no weights, the likelihood function for observation i is

$$L_i = p(^{\text{Default}_i} \times (^1$$

$$\text{where } p(\text{Default}_i) = \frac{1}{(1 + e^{-bx_i})}$$

where:

- $b = [b_1\ b_2 \ldots b_K]$ is for unknown model coefficients
- $x_i = [x_{i1}\ x_{i2} \ldots x_{iK}]$ is the predictor values at observation i
- y_i is the response value of 1 (the default) or a value of 0.

When observation i has weight w_i, it means that there are w_i observations. Because of the independence of defaults between observations, the probability that there is default at observation i is the product of the probabilities of default

$$p_i = p(^{\mathrm{Default}_i} * p(^{\mathrm{Default}_i} * \ldots * p(^{\mathrm{Default}_i} = p(^{\mathrm{Default}_i}$$

$$w_i \text{ times}$$

Likewise, the probability of non-default for weighted observation *i* is

$$\widehat{p}_i = p(^{\sim} * p(^{\sim} * \ldots * p(^{\sim} = (1 - p(^{\mathrm{Default}_i}$$

$$w_i \text{ times}$$

For weighted data, if there is default at a given observation *i* whose weight is w_i, it is as if there was w_i defaults of that one observation, and all of them either all default, or all non-default. w_i may or may not be an integer. Therefore, the likelihood function for observation *i* becomes

$$L_i = p(\mathrm{Default}_i)^{w_i * y_i} \times (1 - p(\mathrm{Default}_i))^{w_i * (1 - y_i)}$$

Likewise, for data with missing observations (`NaN`, `<undefined>`, or “`Missing`”), the model is calibrated by comparing the unconstrained case with results given by `fitglm`. Where the data contains missing observations, the WOE input matrix has `NaN` values. The `NaN` values do not pose any issue for `fitglm` (unconstrained), or `fmincon` (constrained). The only edge case is if all observations of a given predictor are missing, in which case, that predictor is discarded from the model.

Bootstrapping

Bootstrapping is a method for estimating the accuracy of the solution obtained after iterating the objective function `NI`ter times.

When `'Bootstrap'` is set to `true`, the `fitConstrainedModel` function performs sampling with replacement of the WOE values and is passed to the objective function. At the end of the iterative process, the solutions are stored in a `NI`ter-by-`N+1` matrix, where `N` is the number of model coefficients.

The 95% confidence interval (CI) returned in the output structure `mdl.Bootstrap` contains the values of the coefficients at the 25th and 97.5th percentiles.

Models

A logistic regression model is used in the `creditscorecard` object.

For the model, the probability of being “Bad” is given by `ProbBad = exp(-s) / (1 + exp(-s))`.

Version History

Introduced in R2019a

setmodel

Set model predictors and coefficients

Syntax

```
sc = setmodel(sc,ModelPredictors,ModelCoefficients)
```

Description

`sc = setmodel(sc,ModelPredictors,ModelCoefficients)` sets the predictors and coefficients of a linear logistic regression model fitted outside the `creditscorecard` object and returns an updated `creditscorecard` object. The predictors and coefficients are used for the computation of scorecard points. Use `setmodel` in lieu of `fitmodel`, which fits a linear logistic regression model, because `setmodel` offers increased flexibility. For example, when a model fitted with `fitmodel` needs to be modified, you can use `setmodel`. For more information, see “Workflows for Using setmodel” on page 15-1744.

Note When using `setmodel`, the following assumptions apply:

- The model coefficients correspond to a linear logistic regression model (where only linear terms are included in the model and there are no interactions or any other higher-order terms).
- The model was previously fitted using Weight of Evidence (WOE) data with the response mapped so that ‘Good’ is `1` and ‘Bad’ is `0`.

Examples

Modify a GLM Model Fitted with `fitmodel`

This example shows how to use `setmodel` to make modifications to a logistic regression model initially fitted using the `fitmodel` function, and then set the new logistic regression model predictors and coefficients back into the `creditscorecard` object.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
```

```
          BinMissingData: 0
                   IDVar: 'CustID'
           PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                    Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

The standard workflow is to use the `fitmodel` function to fit a logistic regression model using a stepwise method. However, `fitmodel` only supports limited options regarding the stepwise procedure. You can use the optional `mdl` output argument from `fitmodel` to get a copy of the fitted `GeneralizedLinearModel` object, to later modify.

```
[sc,mdl] = fitmodel(sc);
```

```

```

Suppose you want to include, or "force," the predictor `'UtilRate'` in the logistic regression model, even though the stepwise method did not include it in the fitted model. You can add `'UtilRate'` to the logistic regression model using the `GeneralizedLinearModel` object `mdl` directly.

```
mdl = mdl.addTerms('UtilRate')
```

```
mdl = 
Generalized linear regression model:
    logit(status) ~ 1 + CustAge + ResStatus + EmpStatus + CustIncome + TmWBank + OtherCC + AMBala
    Distribution = Binomial
```

```
Estimated Coefficients:
                   Estimate       SE        tStat        pValue  
                   ________    ________    ________    __________

    (Intercept)     0.70239    0.064001      10.975    5.0538e-28

1200 observations, 1191 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 89.7, p-value = 5.26e-16
```

Use `setmodel` to update the model predictors and model coefficients in the `creditscorecard` object. The `ModelPredictors` input argument does not explicitly include a string for the intercept. However, the `ModelCoefficients` input argument does have the intercept information as its first element.

```
ModelPredictors = mdl.PredictorNames
```

```
ModelPredictors = 8x1 cell
    {'CustAge'   }
    {'ResStatus' }
    {'EmpStatus' }
    {'CustIncome'}
    {'TmWBank'   }
    {'OtherCC'   }
    {'AMBalance' }
    {'UtilRate'  }
```

```
ModelCoefficients = mdl.Coefficients.Estimate
```

```
ModelCoefficients = 9×1

    0.7024

      ⋮
```

Fit a Logistic Regression Model Outside of the `creditscorecard` Object

This example shows how to use `setmodel` to fit a logistic regression model directly, without using the `fitmodel` function, and then set the new model predictors and coefficients back into the `creditscorecard` object. This approach gives more flexibility regarding options to control the stepwise procedure. This example fits a logistic regression model with a nondefault value for the `'PEnter'` parameter, the criterion to admit a new predictor in the logistic regression model during the stepwise procedure.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

The logistic regression model needs to be fit with Weight of Evidence (WOE) data. The WOE transformation is a special case of binning, since the data first needs to be binned, and then the binned information is mapped to the corresponding WOE values. This transformation is done using the `bindata` function. `bindata` has an argument that prepares the data for the model fitting step. By setting the `bindata` name-value pair argument for `'OutputType'` to `WOEModelInput'`:

- All predictors are converted to WOE values.
- The output contains only predictors and response (no `'IDVar'` or any unused variables).
- Predictors with infinite or undefined (`NaN`) WOE values are discarded.
- The response values are mapped so that "Good" is `1` and "Bad" is `0` (this implies that higher unscaled scores correspond to better, less risky customers).

```
bd = bindata(sc,'OutputType','WOEModelInput');
```

For example, the first ten rows in the original data for the variables `'CustAge'`, `'ResStatus'`, `'CustIncome'`, and `'status'` (response variable) look like this:

```
data(1:10,{'CustAge' 'ResStatus' 'CustIncome' 'status'})
```

```
ans=10×4 table
    CustAge    ResStatus     CustIncome    status
    _______    __________    __________    ______

      53       Tenant          50000         0   
      61       Home Owner      52000         0   
      47       Tenant          37000         0   
      50       Home Owner      53000         0   
      68       Home Owner      53000         0   
      65       Home Owner      48000         0   
      34       Home Owner      32000         1   
      50       Other           51000         0   
      50       Tenant          52000         1   
      49       Home Owner      53000         1   
```

Here is how the same ten rows look after calling `bindata` with the name-value pair argument `'OutputType'` set to `'WOEModelInput'`:

```
bd(1:10,{'CustAge' 'ResStatus' 'CustIncome' 'status'})
```

```
ans=10×4 table
    CustAge     ResStatus    CustIncome    status
    ________    _________    __________    ______

     0.21378    -0.095564      0.47972       1

     0.18758    -0.095564    -0.026696       1   
     0.21378     0.019329      0.47972       1   
     0.62245     0.019329      0.47972       1   
     0.62245     0.019329      0.47972       1   
    -0.39568     0.019329     -0.29217       0   
     0.21378      0.20049      0.47972       1   
     0.21378    -0.095564      0.47972       0   
     0.21378     0.019329      0.47972       0   
```

Fit a logistic linear regression model using a stepwise method with the Statistics and Machine Learning Toolbox™ function `stepwiseglm`, but use a nondefault value for the `'PEnter'` and `'PRemove'` optional arguments. The predictors `'ResStatus'` and `'OtherCC'` would normally be included in the logistic linear regression model using default options for the stepwise procedure.

```
mdl = stepwiseglm(bd,'constant','Distribution','binomial',...
'Upper','linear','PEnter',0.025,'PRemove',0.05)
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306

mdl = 
Generalized linear regression model:
    logit(status) ~ 1 + CustAge + EmpStatus + CustIncome + TmWBank + AMBalance
    Distribution = Binomial

Estimated Coefficients:
                   Estimate       SE        tStat       pValue  
                   ________    ________    ______    __________

    (Intercept)    0.70263     0.063759     11.02    3.0544e-28
    CustAge        0.57265       0.2482    2.3072      0.021043
    EmpStatus      0.88356      0.29193    3.0266      0.002473
    CustIncome     0.70399      0.21781    3.2321      0.001229
    TmWBank            1.1      0.23185    4.7443    2.0924e-06
    AMBalance       1.0313      0.32007    3.2221     0.0012724

1200 observations, 1194 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 81.4, p-value = 4.18e-16
```

Use `setmodel` to update the model predictors and model coefficients in the `creditscorecard` object. The `ModelPredictors` input argument does not explicitly include a string for the intercept. However, the `ModelCoefficients` input argument does have the intercept information as its first element.

```
ModelPredictors = mdl.PredictorNames
```

```
ModelPredictors = 5x1 cell
    {'CustAge'   }
    {'EmpStatus' }
    {'CustIncome'}
    {'TmWBank'   }
    {'AMBalance' }
```

```
ModelCoefficients = mdl.Coefficients.Estimate
```

```
ModelCoefficients = 6×1

    0.7026
    0.5726
    0.8836
    0.7040
    1.1000
    1.0313
```

```
sc = setmodel(sc,ModelPredictors,ModelCoefficients);
```

Verify that the desired model predictors are part of the scorecard predictors by displaying the scorecard points.

```
pi = displaypoints(sc)
```

```
pi=30×3 table

Input Arguments

sc — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

ModelPredictors — Predictor names included in fitted model

cell array of character vectors with predictor values `{'PredictorName1','PredictorName2',...}`

Predictor names included in the fitted model, specified as a cell array of character vectors as `{'PredictorName1','PredictorName2',...}`. The predictor names must match predictor variable names in the `creditscorecard` object.

Note Do not include a character vector for the constant term in `ModelPredictors`, `setmodel` internally handles the `'(Intercept)'` term based on the number of model coefficients (see `ModelCoefficients`).

Data Types: `cell`

`ModelCoefficients` — Model coefficients corresponding to model predictors
numeric array with values `[coeff1,coeff2,..]`

Model coefficients corresponding to the model predictors, specified as a numeric array of model coefficients, `[coeff1,coeff2,..]`. If *N* is the number of predictor names provided in `ModelPredictors`, the size of `ModelCoefficients` can be *N* or *N*+1. If `ModelCoefficients` has *N*+1 elements, then the first coefficient is used as the `'(Intercept)'` of the fitted model. Otherwise, the `'(Intercept)'` is set to `0`.

Data Types: `double`

Output Arguments

`sc` — Credit scorecard model
`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object. The `creditscorecard` object contains information about the model predictors and coefficients of the fitted model. For more information on using the `creditscorecard` object, see `creditscorecard`.

More About

Workflows for Using `setmodel`

When using `setmodel`, there are two possible workflows to set the final model predictors and model coefficients into a `creditscorecard` object.

The first workflow is:

- Use `fitmodel` to get the optional output argument `mdl`. This is a `GeneralizedLinearModel` object and you can add and remove terms, or modify the parameters of the stepwise procedure. Only linear terms can be in the model (no interactions or any other higher-order terms).
- Once the `GeneralizedLinearModel` object is satisfactory, set the final model predictors and model coefficients into the `creditscorecard` object using the `setmodel` input arguments for `ModelPredictors` and `ModelCoefficients`.

An alternate workflow is:

- Obtain the Weight of Evidence (WOE) data using `bindata`. Use the `'WOEModelInput'` option for the `'OutputType'` name-value pair argument in `bindata` to ensure that:
  - The predictors data is transformed to WOE.
  - Only predictors whose bins have finite WOE values are included.
  - The response variable is placed in the last column.
  - The response variable is mapped (“Good” is `1` and “Bad” is `0`).
- Use the data from the previous step to fit a linear logistic regression model (only linear terms in the model, no interactions, or any other higher-order terms). See, for example, `stepwiseglm`.
- Once the `GeneralizedLinearModel` object is satisfactory, set the final model predictors and model coefficients into the `creditscorecard` object using the `setmodel` input arguments for `ModelPredictors` and `ModelCoefficients`.

bindata

Binned predictor variables

Syntax

```
bdata = bindata(sc)
bdata = bindata(sc,data)
bdata = bindata(sc,Name,Value)
```

Description

`bdata = bindata(sc)` binned predictor variables returned as a table. This is a table of the same size as the data input, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

`bdata = bindata(sc,data)` returns a table of binned predictor variables. `bindata` returns a table of the same size as the `creditscorecard` data, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

`bdata = bindata(sc,Name,Value)` binned predictor variables returned as a table using optional name-value pair arguments. This is a table of the same size as the data input, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

Examples

Bin `creditscorecard` Data as Bin Numbers, Categories, or WOE Values

This example shows how to use the `bindata` function to simply bin or discretize data.

Suppose bin ranges of

- '0 to 30'
- '31 to 50'
- '51 and up'

are determined for the age variable (via manual or automatic binning). If a data point with age 41 is given, binning this data point means placing it in the bin for 41 years old, which is the second bin, or the '31 to 50' bin. Binning is then the mapping from the original data, into discrete groups or bins. In this example, you can say that a 41-year old is mapped into bin number 2, or that it is binned into the '31 to 50' category. If you know the Weight of Evidence (WOE) value for each of the three bins, you could also replace the data point 41 with the WOE value corresponding to the second bin. `bindata` supports the three binning formats just mentioned:

- Bin number (where the `'OutputType'` name-value pair argument is set to `'BinNumber'`); this is the default option, and in this case, 41 is mapped to bin 2.

- Categorical (where the `'OutputType'` name-value pair argument is set to `'Categorical'`); in this case, 41 is mapped to the '31 to 50' bin.
- WOE value (where the `'OutputType'` name-value pair argument is set to `'WOE'`); in this case, 41 is mapped to the WOE value of bin number 2.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

Show the bin information for `'CustAge'`.

```
bininfo(sc,'CustAge')
```

```

Bin Additional "Test" Data

This example shows how to use the `bindata` function's optional input for the data to bin. If not provided, `bindata` bins the `creditscorecard` training data. However, if a different dataset needs to be binned, for example, some "test" data, this can be passed into `bindata` as an optional input.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''

      12         48         NaN         Other          Unknown          44000          14
      13         65          63         <undefined>    Unknown          48000           6
      14         44          75         Other          <undefined>      41000          35
```

Convert the test data to WOE values. To do this, set the bindata name-value pair argument for 'OutputType' to 'WOE', passing the test data tdata as an optional input.

```
bdata = bindata(sc,tdata,'OutputType','WOE');
disp(bdata)
```

```
    CustID    CustAge     TmAtAddress    ResStatus    EmpStatus    CustIncome    TmWBank     Othe
    ______    ________    ___________    _________    _________    __________    ________    ___

      11    -0.15787      0.02263    -0.095463    -0.19947     -0.06843    -0.12109    0.05
      12     0.17713          NaN      0.19637    -0.19947      0.20579    -0.13107    0.05
      13     0.60931      0.02263     0.026469    -0.19947      0.47972    -0.25547    -0.2
      14    -0.04556      0.02263      0.19637         NaN    -0.011271    -0.12109    -0.2
```

For the `'CustAge'` and `'ResStatus'` predictors, because there is missing data in the training data, the missing values in the test data get mapped to the WOE value estimated for the `<missing>` bin. Therefore, a missing value for `'CustAge'` is replaced with `-0.15787`, and a missing value for `'ResStatus'` is replaced with `0.026469`.

For `'TmAtAddress'` and `'EmpStatus'`, the training data has no missing values, therefore there is no bin for missing data, and there is no way to estimate a WOE value for missing data. Therefore, for these predictors, the WOE transformation leaves missing values as missing (that is, sets a WOE value of `NaN`).

These rules apply when `'OutputType'` is set to `'WOE'` or `'WOEModelInput'`. The rationale is that if a data-based WOE value exists for missing data, it should be used for the WOE transformation and for subsequent steps (for example, fitting a logistic model or scoring).

On the other hand, when `'OutputType'` is set to `'BinNumber'` or `'Categorical'`, `bindata` leaves missing values as missing, since this allows you to subsequently treat the missing data as you see fit.

For example, when `'OutputType'` is set to `'BinNumber'`, missing values are set to `NaN`:

```
bdata = bindata(sc,tdata,'OutputType','BinNumber');
disp(bdata)
```

```
    CustID    CustAge    TmAtAddress    ResStatus    EmpStatus    CustIncome    TmWBank    Other
    ______    _______    ___________    _________    _________    __________    _______    ____

      11        NaN            2             1            1           3            3          2
      12          6          NaN             3            1           6            2          2
      13          8            2           NaN            1           7            1          1
      14          4            2             3          NaN           5            3          1
```

And when `'OutputType'` is set to `'Categorical'`, missing values are set to `'<undefined>'`:

```
bdata = bindata(sc,tdata,'OutputType','Categorical');
disp(bdata)
```

```
    CustID      CustAge      TmAtAddress      ResStatus      EmpStatus      CustIncome       TmWBa
    ______    ___________    ___________    ___________    ___________    _____________    _____

      11      <undefined>    [23,83)        Tenant         Unknown        [33000,35000)    [23,45
      12      [48,51)        <undefined>    Other          Unknown        [42000,47000)    [12,23
      13      [58,Inf]       [23,83)        <undefined>    Unknown        [47000,Inf]      [-Inf
      14      [40,46)        [23,83)        Other          <undefined>    [40000,42000)    [23,45
```

Apply a Weight of Evidence (WOE) Transformation to Data

`bindata` supports the following types of WOE transformation:

- When the `'OutputType'` name-value argument is set to `'WOE'`, `bindata` simply applies the WOE transformation to all predictors and keeps the rest of the variables in the original data in place and unchanged.
- When the `'OutputType'` name-value pair argument is set to `'WOEModelInput'`, `bindata` returns a table that can be used directly as an input for fitting a logistic regression model for the scorecard. In this case, `bindata`:
- Applies WOE transformation to all predictors.
- Returns predictor variables, but no `IDVar` or unused variables are included in the output.
- Includes the mapped response variable as the last column.
- The `fitmodel` function calls `bindata` internally using the `'WOEModelInput'` option to fit the logistic regression model for the `creditscorecard` model.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Use the `'IDVar'` argument to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

Show the bin information for `'CustAge'`.

```
bininfo(sc,'CustAge')
```

```

     0.21378
     0.21378
     0.21378
```

The size of the original data and the size of `bdata` output are the same because `bindata` leaves unused variables (such as `'IDVar'`) unchanged and in place.

```
whos data bdata
```

```
  Name          Size              Bytes  Class    Attributes

  bdata      1200x11             108987  table              
  data       1200x11              84603  table              
```

The response values are the same in the original data and in the binned data because, by default, `bindata` does not modify response values.

```
disp([data.status(1:10) bdata.status(1:10)])
```

```
     0     0
     0     0
     0     0
     0     0
     0     0
     0     0
     1     1
     0     0
     1     1
     1     1
```

When fitting a logistic regression model with WOE data, set the `'OutputType'` name-value pair argument to `'WOEModelInput'`.

```
bdata = bindata(sc,'OutputType','WOEModelInput');
```

The binned predictor data is the same as when the `'OutputType'` name-value pair argument is set to `'WOE'`.

```
bdata(1:10,'CustAge')
```

```
ans=10×1 table
    CustAge 
    ________

     0.21378
     0.62245
     0.18758
     0.21378
     0.62245
     0.62245
    -0.39568
     0.21378
     0.21378
     0.21378
```

However, the size of the original data and the size of `bdata` output are different. This is because `bindata` removes unused variables (such as `'IDVar'`).

```
whos data bdata
```

```
  Name          Size             Bytes  Class    Attributes

  bdata      1200x10             99167  table              
  data       1200x11             84603  table              
```

The response values are also modified in this case and are mapped so that "Good" is `1` and "Bad" is `0`.

```
disp([data.status(1:10) bdata.status(1:10)])
```

```
     0     1
     0     1

     0     1
     1     0
     0     1
     1     0
     1     0
```

Input Arguments

sc — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

data — Data to bin given the rules set in `creditscorecard` object

table

Data to bin given the rules set in the `creditscorecard` object, specified using a table. By default, `data` is set to the `creditscorecard` object's raw data.

Before creating a `creditscorecard` object, perform a data preparation task to have an appropriately structured `data` as input to a `creditscorecard` object.

Data Types: `table`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `bdata = bindata(sc,'OutputType','WOE','ResponseFormat','Mapped')`

OutputType — Output format

`'BinNumber'` (default) | character vector with values `'BinNumber'`, `'Categorical'`, `'WOE'`

Output format, specified as the comma-separated pair consisting of `'OutputType'` and a character vector with the following values:

- `BinNumber` — Returns the bin numbers corresponding to each observation.
- `Categorical` — Returns the bin label corresponding to each observation.
- `WOE` — Returns the Weight of Evidence (WOE) corresponding to each observation.
- `WOEModelInput` — Use this option when fitting a model. This option:
  - Returns the Weight of Evidence (WOE) corresponding to each observation.
  - Returns predictor variables, but no `IDVar` or unused variables are included in the output.
  - Discards any predictors whose bins have `Inf` or `NaN` WOE values.
  - Includes the mapped response variable as the last column.

Note When the `bindata` name-value pair argument `'OutputType'` is set to `'WOEModelInput'`, the `bdata` output only contains the columns corresponding to predictors whose bins do not have `Inf` or `NaN` Weight of Evidence (WOE) values, and `bdata` includes the mapped response as the last column.

Missing data (if any) are included in the `bdata` output as missing data as well, and do not influence the rules to discard predictors when `'OutputType'` is set to `'WOEModelInput'`.

Data Types: `char`

`ResponseFormat` — Response values format
`'RawData'` (default) | character vector with values `'RawData'`, `'Mapped'`

Response values format, specified as the comma-separated pair consisting of `'ResponseFormat'` and a character vector with the following values:

- `RawData` — The response variable is copied unchanged into the `bdata` output.
- `Mapped` — The response values are modified (if necessary) so that "Good" is mapped to `1`, and "Bad" is mapped to `0`.

Data Types: `char`

Output Arguments

`bdata` — Binned predictor variables
table

Binned predictor variables, returned as a table. This is a table of the same size (see exception in the following Note) as the data input, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

Note When the `bindata` name-value pair argument `'OutputType'` is set to `'WOEModelInput'`, the `bdata` output only contains the columns corresponding to predictors whose bins do not have `Inf` or `NaN` Weight of Evidence (WOE) values, and `bdata` includes the mapped response as the last column.

Missing data (if any) are included in the `bdata` output as missing data as well, and do not influence the rules to discard predictors when `'OutputType'` is set to `'WOEModelInput'`.

Version History

Introduced in R2014b

plotbins

Plot histogram counts for predictor variables

Syntax

```
plotbins(sc,PredictorName)
hFigure = plotbins(sc,PredictorName)
hFigure = plotbins( ___ ,Name,Value)
```

Description

`plotbins(sc,PredictorName)` plots histogram counts for given predictor variables. When a predictor's bins are modified using `modifybins` or `autobinning`, rerun `plotbins` to update the figure to reflect the change.

`hFigure = plotbins(sc,PredictorName)` returns a handle to the figure. `plotbins` plots histogram counts for given predictor variables. When a predictor's bins are modified using `modifybins` or `autobinning`, rerun `plotbins` to update the figure to reflect the change.

`hFigure = plotbins( ___ ,Name,Value)` returns a handle to the figure. `plotbins` plots histogram counts for given predictor variables using optional name-value pair arguments. When a predictor's bins are modified using `modifybins` or `autobinning`, rerun `plotbins` to update the figure to reflect the change.

Examples

Plot a Histogram for Bin Information

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the `PredictorName` input argument for `CustIncome` using the defaults for the algorithm `Monotone`.

```
sc = autobinning(sc, 'CustIncome')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustID'  'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBala
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: ''
```

```
         PredictorVars: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
                  Data: [1200x11 table]
```

Use `bininfo` to display the autobinned data.

```
[bi, cp] = bininfo(sc, 'CustIncome')
```

```
bi=8×6 table
           Bin            Good    Bad     Odds        WOE       InfoValue

       35000
       40000
       42000
       47000
```

Manually remove the second cut point (the boundary between the second and third bins) to merge bins two and three. Use the `modifybins` function to update the scorecard and then display updated bin information.

```
cp(2) = [];
sc = modifybins(sc,'CustIncome','CutPoints',cp);
bi = bininfo(sc,'CustIncome')
```

```
bi=7×6 table

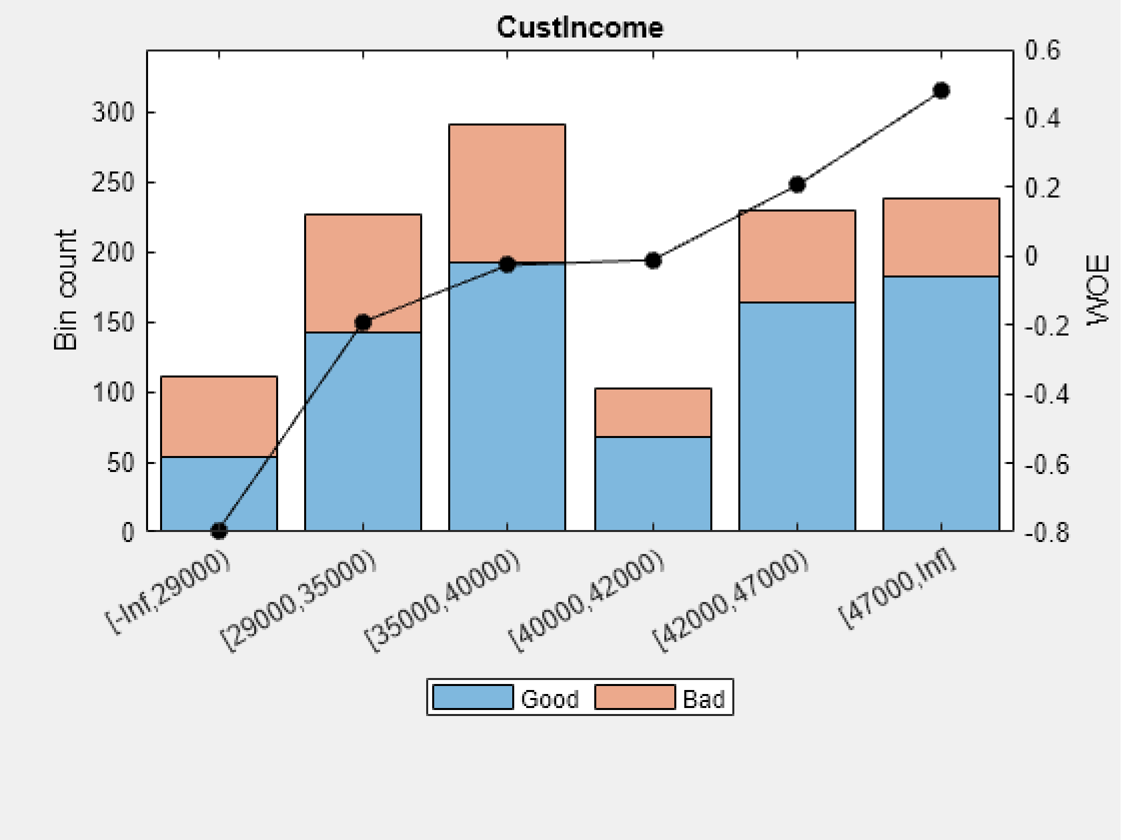
    {'Totals'       }    803     397      2.0227          NaN       0.12043
```

Plot the histogram count for updated bin information for the `PredictorName` called `CustIncome`.

```
plotbins(sc,'CustIncome')
```



Plot a Histogram for Bin Information Using Name-Value Pair Arguments

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the `PredictorName` input argument for `CustIncome` using the defaults for the algorithm `Monotone`.

```
sc = autobinning(sc, 'CustIncome')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustID'  'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBala
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: ''
            PredictorVars: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
```

```
                        Data: [1200x11 table]
```

Use `bininfo` to display the autobinned data.

```
[bi, cp] = bininfo(sc, 'CustIncome')
```

```
bi=8×6 table
           Bin             Good    Bad      Odds          WOE       InfoValue 
    _________________    _____    ___    _______    _________    __________

    {'[-Inf,29000)' }      53      58    0.91379     -0.79457       0.06364
    {'[29000,33000)'}      74      49     1.5102     -0.29217     0.0091366
    {'[33000,35000)'}      68      36     1.8889     -0.06843    0.00041042
    {'[35000,40000)'}     193      98     1.9694    -0.026696    0.00017359
    {'[40000,42000)'}      68      34          2    -0.011271    1.0819e-05
    {'[42000,47000)'}     164      66     2.4848      0.20579     0.0078175
    {'[47000,Inf]'  }     183      56     3.2679      0.47972      0.041657
    {'Totals'       }     803     397     2.0227          NaN       0.12285

cp = 6×1

       29000

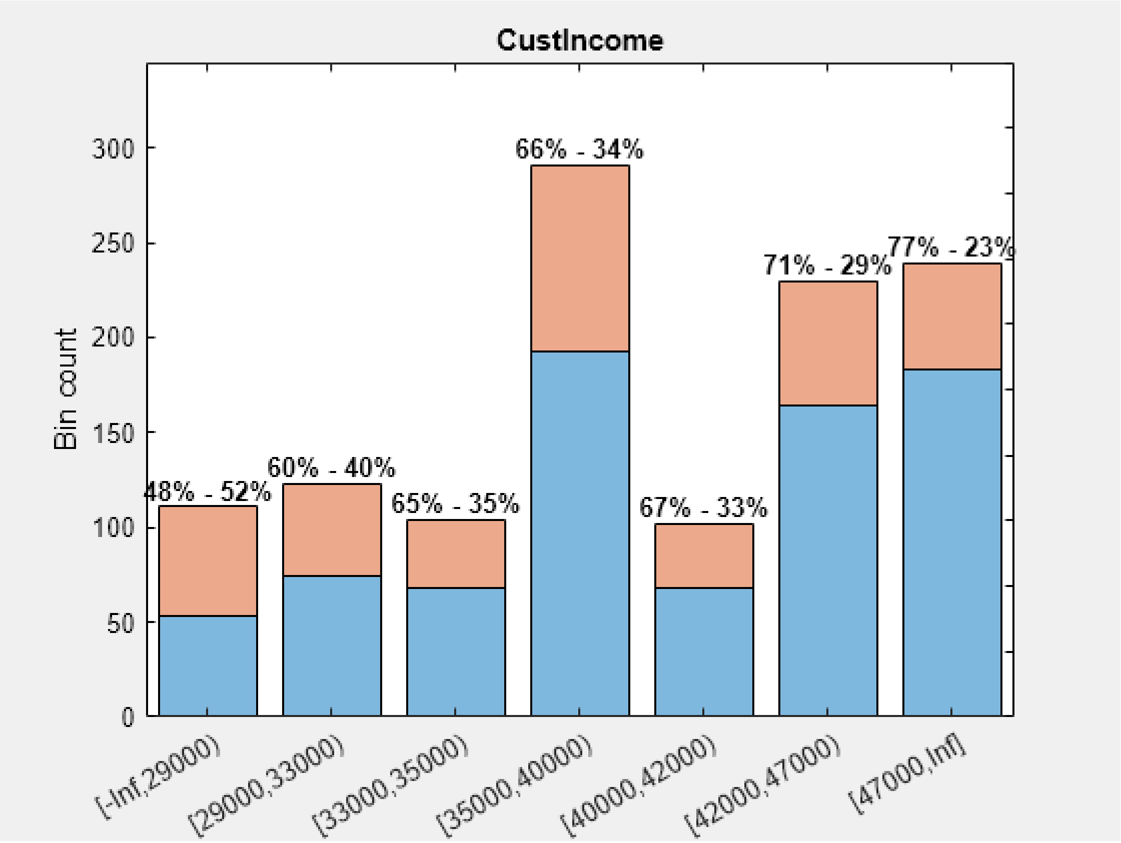
       35000
       40000
       42000
       47000
```

Plot the bin information for `CustIncome` without the Weight of Evidence (WOE) line and without a legend by setting the `'WOE'` and `'Legend'` name-value arguments to `'Off'`. Also, set the `'BinText'` name-value pair argument to `'PercentRows'` to show as text over the plot bars for the proportion of "Good" and "Bad" within each bin, that is, the probability of "Good" and "Bad" within each bin.

```
plotbins(sc,'CustIncome','WOE','Off','Legend','Off','BinText','PercentRows')
```



Plot Bin Information When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus     EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ____

      1          53          62         <undefined>    Unknown        50000         55         Ye
      2          61          22         Home Owner     Employed       52000         25         Ye
      3          47          30         Tenant         Employed       37000         61         No
      4         NaN          75         Home Owner     Employed       53000         20         Ye
      5          68          56         Home Owner     Employed       53000         14         Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);

disp(sc)
```

```
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn

```

```
plotbins(sc,'ResStatus')
```

Input Arguments

`sc` — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

`PredictorName` — Name of one or more predictors to plot

character vector with predictor name | cell array of character vectors with predictor names

Name of one or more predictors to plot, specified using a character vector or cell array of character vectors containing one or more names of the predictors.

Data Types: `char` | `cell`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `plotbins(sc,PredictorName,'BinText','Count','WOE','On')`

`BinText` — Information to display on top of plotted bin counts

`'None'` (default) | character vector with values `'None'`, `'Count'`, `'PercentRows'`, `'PercentCols'`, `'PercentTotal'`

Information to display on top of plotted bin counts, specified as the comma-separated pair consisting of `'BinText'` and a character vector with values:

- `None` — No text is displayed on top of the bins.
- `Count` — For each bin, displays the count for “Good” and “Bad.”
- `PercentRows` — For each bin, displays the count for “Good” and “Bad” as a percentage of the number of observations in the bin.
- `PercentCols` — For each bin, displays the count for “Good” and “Bad” as a percentage of the total “Good” and total “Bad” in the entire sample.
- `PercentTotal` — For each bin, displays the count for “Good” and “Bad” as a percentage of the total number of observations in the entire sample.

Data Types: `char`

`WOE` — Indicator for Weight of Evidence (WOE)

`'On'` (default) | character vector with values `'On'`, `'Off'`

Indicator for Weight of Evidence (WOE) line, specified as the comma-separated pair consisting of `'WOE'` and a character vector with values `On` or `Off`. When set to `On`, the WOE line is plotted on top of the histogram.

Data Types: `char`

Legend — Indicator for legend on plot

`'On'` (default) | character vector with values `'On'`, `'Off'`

Indicator for legend on the plot, specified as the comma-separated pair consisting of `'Legend'` and a character vector with values `On` or `Off`.

Data Types: `char`

Output Arguments

`hFigure` — Figure handle for histogram plot for predictor variables

figure object

Figure handle for histogram plot for predictor variables, returned as figure object or array of figure objects if more than one `PredictorName` is specified as an input.

Version History

Introduced in R2014b

modifybins

Modify predictor’s bins

Syntax

```
sc = modifybins(sc,PredictorName,Name,Value)
```

Description

`sc = modifybins(sc,PredictorName,Name,Value)` manually modifies predictor bins for numeric predictors or categorical predictors using optional name-value pair arguments. For numeric predictors, minimum value, maximum value, and cut points can be specified. For categorical predictors, category groupings can be specified. Bin labels can be specified for both types of predictors.

Examples

Modify Predictor Bins for Numeric Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The predictor `CustIncome` is numeric. By default, each value of a predictor is placed in a separate bin.

```
bi = bininfo(sc,'CustIncome')
```

```
bi=46×6 table

    {'[30000,40000)'}      324     173     1.8728    -0.076967    0.0024846
    {'[40000,50000)'}      304     123     2.4715      0.20042     0.013781
    {'[50000,60000)'}      103      32     3.2188      0.46457     0.022144
    {'[60000,Inf]'  }        8       1          8        1.375     0.010235
    {'Totals'       }      803     397     2.0227          NaN      0.12035

cp = 5×1

       20000
       30000
       40000
       50000
       60000
```

The first and last bins contain very few points. To merge the first bin into the second one, remove the first cut point. Similarly, to merge the last bin into the second-to-last one, remove the last cut point. Then use `modifybins` to update the scorecard, and display updated bin information.

```
cp(1)=[];
cp(end)=[];
sc = modifybins(sc,'CustIncome','CutPoints',cp);
bi = bininfo(sc,'CustIncome')
```

```
bi=5×6 table
           Bin             Good    Bad      Odds          WOE       InfoValue
    _________________      ____    ___    _______    _________    _________

    {'[0,30000)'    }       64      68    0.94118     -0.76504     0.070065
    {'[30000,40000)'}      324     173     1.8728    -0.076967    0.0024846
    {'[40000,50000)'}      304     123     2.4715      0.20042     0.013781
    {'[50000,Inf]'  }      111      33     3.3636       0.5086     0.028028
    {'Totals'       }      803     397     2.0227          NaN      0.11436
```

Modify Predictor Bins for Categorical Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor `ResStatus`.

```
[bi,cg] = bininfo(sc,'ResStatus')
```

```
bi=4×6 table
         Bin           Good    Bad     Odds         WOE       InfoValue
    ______________    ____    ___    ______    _________    _________

    {'Home Owner'}    365     177    2.0621     0.019329    0.0001682
    {'Tenant'    }    307     167    1.8383    -0.095564    0.0036638
    {'Other'     }    131      53    2.4717      0.20049    0.0059418
    {'Totals'    }    803     397    2.0227          NaN    0.0097738

cg=3×2 table
       Category       BinNumber
    ______________    _________

    {'Home Owner'}        1
    {'Tenant'    }        2
    {'Other'     }        3
```

To group categories `'Tenant'` and `'Other'`, modify the category grouping table `cg`, so the bin number for `'Other'` is the same as the bin number for `'Tenant'`. Then use `modifybins` to update the scorecard.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc,'ResStatus','CatGrouping',cg);
```

Display the updated bin information. Note that the bin labels has been updated and that the bin membership information is contained in the category grouping `cg`.

```
[bi,cg] = bininfo(sc,'ResStatus')
```

```
bi=3×6 table
       Bin         Good    Bad     Odds         WOE        InfoValue
    __________    ____    ___    ______    _________    __________

    {'Group1'}    365     177    2.0621     0.019329     0.0001682

    {'Other'     }        2
```

Merge Bins for Numerical and Categorical Predictors

Create a `creditscorecard` object (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID','GoodLabel',0);
```

For the numerical predictor `CustAge`, use the `modifybins` function to set the following cut points:

```
cp = [25 37 49 65];
sc = modifybins(sc,'CustAge','CutPoints',cp,'MinValue',0,'MaxValue',75);
bininfo(sc,'CustAge')
```

```
ans=6×6 table
        Bin         Good    Bad     Odds         WOE       InfoValue 
    ____________    ____    ___    ______    _________    _________

    {'[0,25)' }       9       8     1.125     -0.58664    0.0052464
    {'[25,37)'}     125      92    1.3587     -0.39789     0.030268
    {'[37,49)'}     340     183    1.8579    -0.084959    0.0031898
    {'[49,65)'}     298     108    2.7593      0.31054     0.030765
    {'[65,75]'}      31       6    5.1667      0.93781     0.022031
    {'Totals' }     803     397    2.0227          NaN       0.0915
```

Use the `modifybins` function to merge the 2nd and 3rd bins.

```
sc = modifybins(sc,'CustAge','CutPoints',cp([1 3 4]));
bininfo(sc,'CustAge')
```

```
ans=5×6 table
        Bin         Good    Bad     Odds        WOE       InfoValue 
    ____________    ____    ___    ______    ________    _________

    {'[0,25)' }       9       8     1.125    -0.58664    0.0052464
    {'[25,49)'}     465     275    1.6909    -0.17915     0.020355
    {'[49,65)'}     298     108    2.7593     0.31054     0.030765
    {'[65,75]'}      31       6    5.1667     0.93781     0.022031
    {'Totals' }     803     397    2.0227         NaN     0.078397
```

Display bin information for the categorical predictor `ResStatus`.

```
[bi,cg] = bininfo(sc,'ResStatus');
disp(bi)
```

```
          Bin           Good    Bad     Odds        WOE       InfoValue 
    ______________    ____    ___    ______    _________    _________

    {'Home Owner'}     365     177    2.0621     0.019329    0.0001682
    {'Tenant'    }     307     167    1.8383    -0.095564    0.0036638
    {'Other'     }     131      53    2.4717      0.20049    0.0059418
    {'Totals'    }     803     397    2.0227          NaN    0.0097738
```

Use the `modifybins` function to merge categories 2 and 3.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc,'ResStatus','CatGrouping',cg);
bininfo(sc,'ResStatus')
```

```
ans=3×6 table
       Bin          Good     Bad      Odds         WOE         InfoValue

```

Split Bins for Numerical and Categorical Predictors

Create a `creditscorecard` object (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID','GoodLabel',0)
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'

    {'50k and more'}      111      33     3.3636       0.5086     0.028028
    {'Totals'      }    803     397     2.0227         NaN     0.099836
```

Bin labels should be the last bin-modification step. As in this example, user-defined bin labels often contain information about the cut points, minimum, or maximum values for numeric data, or information about category groupings for categorical data. To prevent situations where user-defined labels and cut points are inconsistent (and labels are misleading), the `creditscorecard` object overrides user-defined labels every time the bins are modified using `modifybins`.

To illustrate `modifybins` overriding user-defined labels every time the bins are modified, reset the first cut point to 31000 and display updated bin information. Note that the bin labels are reset to their default format and accurately reflect the change in the cut points.

```
sc = modifybins(sc,'CustIncome','CutPoints',[31000 50000]);
bi = bininfo(sc,'CustIncome')
```

```
bi=4×6 table
           Bin             Good    Bad      Odds         WOE        InfoValue
    _________________    ____    ___    _______    ________    _________

    {'[0,31000)'    }     82      84    0.97619    -0.72852     0.079751
    {'[31000,50000)'}    610     280     2.1786    0.074251    0.0040364
    {'[50000,Inf]'  }    111      33     3.3636      0.5086     0.028028
    {'Totals'       }    803     397     2.0227         NaN      0.11182
```

Modify Bin Information When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus     EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ____

      1          53          62         <undefined>    Unknown        50000         55         Ye
      2          61          22         Home Owner     Employed       52000         25         Ye
      3          47          30         Tenant         Employed       37000         61         No
      4         NaN          75         Home Owner     Employed       53000         20         Ye
      5          68          56         Home Owner     Employed       53000         14         Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);

disp(sc)
```

```
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'

```

Input Arguments

`sc` — Credit scorecard model
`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

`PredictorName` — Name of predictor
character vector

Name of predictor, specified as a character vector containing the name of the predictor. `PredictorName` is case-sensitive.

Data Types: `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `sc = modifybins(sc,PredictorName,'MinValue',10,'CutPoints',[23, 44, 66, 88])`

`MinValue` — Minimum acceptable value (numeric predictors only)
`-Inf` (default) | numeric

Minimum acceptable value, specified as the comma-separated pair consisting of `'MinValue'` and a numeric value (for numeric predictors only). Values below this number are considered out of range.

Data Types: `double`

`MaxValue` — Maximum acceptable value (numeric predictors only)
`Inf` (default) | numeric

Maximum acceptable value, specified as the comma-separated pair consisting of `'MaxValue'` and a numeric value (for numeric predictors only). Values above this number are considered out of range.

Data Types: `double`

`CutPoints` — Split points between bins
each observed value of the predictor is placed in a separate bin (default) | nondecreasing numeric array

Split points between bins, specified as the comma-separated pair consisting of `'CutPoints'` and a nondecreasing numeric array. If there are `NumBins` bins, there are *n* = `NumBins – 1` cut points so that C1, C2,..., C*n* describe the bin boundaries with the following convention:

- The first bin includes any values >= `MinValue`, but < C1.
- The second bin includes any values >= C1, but < C2.
- The last bin includes any values >= C*n*, and <= `MaxValue`.

Note Cut points do not include `MinValue` or `MaxValue`.

By default, cut points are defined so that each observed value of the predictor is placed in a separate bin. If the sorted observed values are V1, …, V*M*, the default cut points are V2, …, V*M*, which define *M* bins.

Data Types: `double`

`CatGrouping` — Table with two columns named `Category` and `BinNumber`
each category is placed in a separate bin (default) | table with two columns named `Category` and `BinNumber`

Table with two columns named `Category` and `BinNumber`, specified as the comma-separated pair consisting of `'CatGrouping'` and a table, where the first column contains an exhaustive list of categories for the predictor, and the second column contains the bin number to which each category belongs.

By default, each category is placed in a separate bin. If the observed categories are `'`Cat1`'`…,`'`Cat*M*`'`, the default category grouping is as follows.

Category	BinNumber
`'`Cat1`'`	1
`'`Cat2`'`	2
…	…
`'`Cat*M*’`'`	*M*

Data Types: `double`

`BinLabels` — Bin labels for each bin
automatically generated bin labels depending on the predictor’s type (default) | cell array of character vectors

Bin labels for each bin, specified as the comma-separated pair consisting of `'BinLabels'` and a cell array of character vectors with bin label names.

Note `'BinLabels'` does not support a value of `<missing>`.

Bin labels are used to tag the bins in different object functions such as `bininfo`, `plotbins`, and `displaypoints`. A `creditscorecard` object automatically sets default bins whenever bins are modified. The default format for bin labels depends on the predictor’s type.

The format for `BinLabels` is:

- Numeric data — Before any manual or automatic modification of the predictor bins, there is a bin for each observed predictor value by default. In that case, the bin labels simply show the predictor values. Once the predictor bins have been modified, there are nondefault values for `MinValue` or `MaxValue`, or nondefault cut points C1, C2,..., C*n*. In that case, the bin labels are:
  - Bin 1 label: `'[MinValue, C1)'`
  - Bin 2 label: `'[C1, C2)'`

- Last bin label: `'[Cn, MaxValue]'`

  For example, if there are three bins, `MinValue` is 0 and `MaxValue` is 40, and cut point 1 is 20 and cut point 2 is 30, then the corresponding three bin labels are:

  ```
  '[0,20)'
  '[20,30)'
  '[30,40]'
  ```

- Categorical data — For categorical data, before any modification of the predictor bins, there is one bin per category. In that case, the bin labels simply show the predictor categories. Once the bins have been modified, the labels are set to `'Group1'`, `'Group2'`, and so on, for bin 1, bin 2, and so on, respectively. For example, suppose that we have the following category grouping

Category	BinNumber
'Cat1'	1
'Cat2'	2
'Cat3'	2

  Bin 1 contains `'Cat1'` only and its bin label is set to `'Group1'`. Bin 2 contains `'Cat2'` and `'Cat3'` and its bin label is set to `'Group2'`.

Tip Using `BinLabels` should be the last step (if needed) in modifying bins. `BinLabels` definitions are overridden each time that the bins are modified using the `modifybins` or `autobinning` functions.

Data Types: `cell`

Output Arguments

`sc` — Credit scorecard model

`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object. For more information on using the `creditscorecard` object, see `creditscorecard`.

Version History

Introduced in R2014b

modifypredictor

Set properties of credit scorecard predictors

Syntax

```
sc = modifypredictor(sc,PredictorName)
sc = modifypredictor( ___ ,Name,Value)
```

Description

`sc = modifypredictor(sc,PredictorName)` sets the properties of the credit scorecard predictors.

`sc = modifypredictor( ___ ,Name,Value)` sets the properties of the credit scorecard predictors using optional name-value pair arguments.

Examples

Modify a Predictor to Change the Predictor Type from Numeric to Categorical

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). In practice, categorical data many times is represented with numeric values. To show the case where categorical data is given as numeric data, the data for the variable `'ResStatus'` is intentionally converted to numeric values.

```
load CreditCardData
data.ResStatus = double(data.ResStatus);
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustAge'  'TmAtAddress'  'ResStatus'  'CustIncome'  'TmWBank'  'AMBa
    CategoricalPredictors: {'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

```
[T,Stats] = predictorinfo(sc,'ResStatus')
```

```
T=1×4 table
                 PredictorType     LatestBinning      LatestFillMissingType    LatestFillMissin
                 _____________    _________________    _____________________    ________________
```

```
    ResStatus     {'Numeric'}     {'Original Data'}       {'Original'}              {0x0 double
```

```
Stats=4×1 table
             Value 
            _______

    Min           1
    Max           3
    Mean     1.7017
    Std     0.71833
```

Note that `'ResStatus'` appears as part of the `NumericPredictors` property. Assume that you want `'ResStatus'` to be treated as categorical data. For example, you may want to allow automatic binning algorithms to reorder the categories. Use `modifypredictor` to change the `'PredictorType'` of the `PredictorName` `'ResStatus'` from numeric to categorical.

```
sc = modifypredictor(sc,'ResStatus','PredictorType','Categorical')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

```
[T,Stats] = predictorinfo(sc,'ResStatus')
```

```
T=1×5 table
                 PredictorType     Ordinal      LatestBinning      LatestFillMissingType    Late
                _______________    _______    _________________    _____________________    ____

    ResStatus    {'Categorical'}     false     {'Original Data'}        {'Original'}
```

```
Stats=3×1 table
          Count
          _____

    C1     542 
    C2     474 
    C3     184 
```

Notice that `'ResStatus'` now appears as part of the `'Categorical'` predictors.

Input Arguments

`sc` — Credit scorecard model
`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

`PredictorName` — Predictor name
character vector | cell array of character vectors

Predictor name, specified using a character vector or cell array of character vectors containing the names of the credit scorecard predictors. `PredictorName` is case-sensitive.

Data Types: `char` | `cell`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `sc = modifypredictor(sc, {'CustAge','CustIncome'},'PredictorType','Categorical','Ordinal',true)`

`PredictorType` — Predictor type that one or more predictors are converted to
`''` no conversion occurs (default) | character vector with values `'Numeric'`, `'Categorical'`

Predictor type that one or more predictors are converted to, specified as the comma-separated pair consisting of `'PredictorType'` and a character vector. Possible values are:

- `''` — No conversion occurs.
- `'Numeric'` — The predictor data specified by `PredictorName` is converted to numeric.
- `'Categorical'` — The predictor data specified by `PredictorName` is converted to categorical.

Data Types: `char`

`Ordinal` — Indicator for whether predictors being converted to categorical are ordinal
`false` (default) | logical with values `true`, `false`

Indicator for whether predictors being converted to categorical or existing categorical predictors are treated as ordinal data, specified as the comma-separated pair consisting of `'Ordinal'` and a logical with values `true` or `false`.

Note This optional input parameter is only used for predictors of type `'Categorical'`.

Data Types: `logical`

Output Arguments

`sc` — Credit scorecard model

`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object.

Version History

Introduced in R2015b

predictorinfo

Summary of credit scorecard predictor properties

Syntax

```
[T,Stats] = predictorinfo(sc,PredictorName)
```

Description

`[T,Stats] = predictorinfo(sc,PredictorName)` returns a summary of credit scorecard predictor properties and some basic predictor statistics.

Examples

Obtain Information for a Specified PredictorName

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

Obtain the predictor statistics for the `PredictorName` of `CustAge`.

```
[T,Stats] = predictorinfo(sc,'CustAge')
```

```
T=1×4 table
               PredictorType      LatestBinning       LatestFillMissingType    LatestFillMissingVa

    Tenant         474
    Other          184
```

Obtain Information for a Specified `PredictorName` After Using `fillmissing`

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(dataMissing,'BinMissingData',true,'IDVar','CustID');
sc = autobinning(sc);
```

Use `fillmissing` to replace missing values for the `CustAge` predictor with a value of `38`.

```
sc = fillmissing(sc,'CustAge','constant',38);
```

Obtain the predictor statistics for the `PredictorName` of `CustAge`.

```
[T,Stats] = predictorinfo(sc,'CustAge')
```

```

    Home Owner     563
    Other          180
```

Input Arguments

sc — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

PredictorName — Predictor name

character vector

Predictor name, specified using a character vector containing the names of the credit scorecard predictor of interest. `PredictorName` is case-sensitive.

Data Types: `char`

Output Arguments

T — Summary information for specified predictor

table

Summary information for specified predictor, returned as table with the following columns:

- `'PredictorType'` — `'Numeric'` or `'Categorical'`.
- `'Ordinal'` — For categorical predictors, a boolean indicating whether it is ordinal.
- `'LatestBinning'` — Character vector indicating the last applied algorithm for the input argument `PredictorName`. The values are:

  - `'Original Data'` — When no binning is applied to the predictor.
  - `'Automatic / BinningName'` — Where `'BinningName'` is one of the following: `Monotone`, `Equal Width`, or `Equal Frequency`.
  - `'Manual'` — After each call of `modifybins`, where either `'CutPoints'`, `'CatGrouping'`, `'MinValue'`, or `'MaxValue'` are modified.
- `'LatestFillMissingType'` — If `fillmissing` has been applied to the predictor, the value of the `Statistics` argument for `fillmissing` is displayed. If the predictor does not have any missing data, then the fill type is `'Original'`.
- `'LatestFillMissingValue'` — If `fillmissing` has been applied to the predictor, the fill value is displayed. If the predictor does not have any missing data, then the fill value is `[ ]`.

The predictor's name is used as a row name in the table that is returned.

`Stats` — Summary statistics for the input `PredictorName`
table

Summary statistics for the input `PredictorName`, returned as a table. The corresponding value is stored in the `'Value'` column.

The table's row names indicate the relevant statistics for numeric predictors:

- `'Min'` — Minimum value in the sample.
- `'Max'` — Maximum value in the sample.
- `'Mean'` — Mean value in the sample.
- `'Std'` — Standard deviation of the sample.

Note For data types other than 'double' or 'single', numeric precision may be lost for the standard deviation. Data types other than 'double' or 'single' are cast as 'double' before computing the standard deviation.

For categorical predictors, the row names contain the names of the categories, with corresponding total count in the `'Count'` column.

Version History

Introduced in R2015b

`creditscorecard` | `modifybins` | `modifypredictor` | `bininfo` | `fillmissing`

bininfo

Return predictor’s bin information

Syntax

```
bi = bininfo(sc,PredictorName)
bi = bininfo( ___ ,Name,Value)

[bi,bm] = bininfo(sc,PredictorName,Name,Value)

[bi,bm,mv] = bininfo(sc,PredictorName,Name,Value)
```

Description

`bi = bininfo(sc,PredictorName)` returns information at bin level, such as frequencies of “Good,” “Bad,” and bin statistics for the predictor specified in `PredictorName`.

`bi = bininfo( ___ ,Name,Value)` adds optional name-value arguments.

`[bi,bm] = bininfo(sc,PredictorName,Name,Value)` adds optional name-value arguments.`bininfo` also optionally returns the binning map (`bm`) or bin rules in the form of a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors.

`[bi,bm,mv] = bininfo(sc,PredictorName,Name,Value)` returns information at bin level, such as frequencies of “Good,” “Bad," and bin statistics for the predictor specified in `PredictorName` using optional name-value pair arguments. `bininfo` optionally returns the binning map or bin rules in the form of a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors. In addition, optional name-value pair arguments `mv` returns a numeric array containing the minimum and maximum values, as set (or defined) by the user. The `mv` output argument is set to an empty array for categorical predictors.

Examples

Display Bin Information Using Default Options

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Display bin information for the categorical predictor `ResStatus`.

```
bi = bininfo(sc,'ResStatus')
```

```
bi=4×6 table
          Bin            Good    Bad      Odds        WOE         InfoValue
    ________________    ____    ___    ______    __________    __________

    {'Home Owner'}      365     177    2.0621      0.019329    0.0001682
    {'Tenant'    }    307     167    1.8383    -0.095564    0.0036638
    {'Other'     }    131      53    2.4717      0.20049    0.0059418
    {'Totals'    }    803     397    2.0227          NaN    0.0097738
```

Display Bin Information For a creditscorecard Object Containing Weights

Use the `CreditCardData.mat` file to load the data (`dataWeights`) that contains a column (`RowWeights`) for the weights (using a dataset from Refaat 2011).

```
load CreditCardData
```

Create a `creditscorecard` object using the optional name-value pair argument for `'WeightsVar'`.

```
sc = creditscorecard(dataWeights,'WeightsVar','RowWeights')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: 'RowWeights'
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustID'  'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalan
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: ''
            PredictorVars: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
                     Data: [1200x12 table]
```

Display bin information for the numerical predictor `'CustIncome'`. When the optional name-value pair argument `'WeightsVar'` is used to specify observation (sample) weights, the `bi` table contains weighted counts.

```
bi = bininfo(sc,'CustIncome');
bi(1:10,:)
```

```
ans=10×6 table
       Bin          Good        Bad        Odds         WOE        InfoValue

    {'25000'}     2.2333     6.1383    0.36383     -1.7186      0.042642
    {'26000'}     2.1246     4.4754    0.47474     -1.4525      0.024526
    {'27000'}     3.1058      3.528    0.88032    -0.83501     0.0082144
```

Display Bin Information Using Name-Value Arguments

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Display customized bin information for the categorical predictor `ResStatus`, keeping only the `WOE` column. The Weight-of-Evidence (WOE) is defined bin by bin, but there is no concept of "total WOE", therefore the last element in the `'Totals'` row is set to `NaN`.

```
bi = bininfo(sc,'ResStatus','Statistics','WOE');
disp(bi)
```

```
         Bin           Good    Bad       WOE    
    ______________     ____    ___    _________

    {'Home Owner'}     365     177     0.019329
    {'Tenant'    }     307     167    -0.095564
    {'Other'     }     131      53      0.20049
    {'Totals'    }     803     397          NaN
```

Display customized bin information for the categorical predictor `ResStatus`, keeping only the `Odds` and `WOE` columns, without the `Totals` row.

```
bi = bininfo(sc,'ResStatus','Statistics',{'Odds','WOE'},'Totals','Off');
disp(bi)
```

```
         Bin           Good    Bad     Odds        WOE    
    ______________     ____    ___    ______    _________

    {'Home Owner'}     365     177    2.0621     0.019329
    {'Tenant'    }     307     167    1.8383    -0.095564
    {'Other'     }     131      53    2.4717      0.20049
```

Display information value, entropy, Gini, and chi square statistics. For more information on these statistics, see “Statistics for a Credit Scorecard” on page 15-1806.

For information value, entropy and Gini, the value reported at a bin level is the contribution of the bin to the total value. The total information value, entropy, and Gini measures are in the `'Totals'` row.

For chi square, if there are *N* bins, the first *N-1* values in the `'Chi2'` column report pairwise chi square statistics for contiguous bins. For example, this pairwise measure is also used by the `'Merge'` algorithm in `autobinning` to determine if two contiguous bins should be merged. In this example, the first value in the `'Chi2'` column (`1.0331`) is the chi square statistic of bins 1 and 2 (`'Home Owner'` and `'Tenant'`), and the second value in the column (`2.5103`) is the chi square statistic of bins 2 and 3 (`'Tenant'` and `'Other'`). There are no more pairwise chi square values to compute in this example, so the third element of the `'Chi2'` column is set to `NaN`. The chi square value reported in the `'Totals'` row is the chi square statistic computed over all bins.

```
bi = bininfo(sc,'ResStatus','Statistics',{'InfoValue','Entropy','Gini','Chi2'});
disp(bi)
```

```
         Bin           Good    Bad    InfoValue    Entropy      Gini       Chi2 
    ______________     ____    ___    _________    _______    _______    ______
    {'Home Owner'}    365     177    0.0001682    0.91138    0.43984    1.0331
    {'Tenant'    }    307     167    0.0036638    0.93612    0.45638    2.5103
    {'Other'     }    131      53    0.0059418    0.86618    0.41015       NaN
    {'Totals'    }    803     397    0.0097738    0.91422    0.44182    2.5549
```

Display Bin Information and Binning Map for Categorical Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor `ResStatus`.

```
[bi,cg] = bininfo(sc,'ResStatus')
```

```
bi=4×6 table
         Bin          Good    Bad     Odds        WOE        InfoValue
    ______________    ____    ___    ______    _________    _________

    {'Home Owner'}    365     177    2.0621     0.019329    0.0001682
    {'Tenant'    }    307     167    1.8383    -0.095564    0.0036638
    {'Other'     }    131      53    2.4717      0.20049    0.0059418
    {'Totals'    }    803     397    2.0227          NaN    0.0097738

cg=3×2 table

    {'Home Owner'}        1
    {'Tenant'    }        2
    {'Other'     }        3
```

To group categories `Tenant` and `Other`, modify the category grouping table `cg` so that the bin number for `Other` is the same as the bin number for `Tenant`. Then use the `modifybins` function to update the scorecard.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc,'ResStatus','CatGrouping',cg);
```

Display the updated bin information. The bin labels have been updated and that the bin membership information is contained in the category grouping `cg`.

```
[bi,cg] = bininfo(sc,'ResStatus')
```

```
bi=3×6 table

    {'[35000,40000)'}    193      98     1.9694    -0.026696    0.00017359
    {'[40000,42000)'}     68      34          2    -0.011271    1.0819e-05
    {'[42000,47000)'}    164      66     2.4848      0.20579     0.0078175
    {'[47000,Inf]'  }    183      56     3.2679      0.47972      0.041657
    {'Totals'       }    803     397     2.0227          NaN       0.12043

cp = 5×1

       29000
       35000
       40000
       42000
       47000

mv = 1×2
```

```
    0   Inf
```

Note, it is recommended to avoid having bins with frequencies of zero because they lead to infinite or undefined (`NaN`) statistics. Use the `modifybins` or `autobinning` functions to modify bins.

Display Bin Information for Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus     EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ____

      1          53          62         <undefined>    Unknown        50000         55         Ye
      2          61          22         Home Owner     Employed       52000         25         Ye
      3          47          30         Tenant         Employed       37000         61         No
      4         NaN          75         Home Owner     Employed       53000         20         Ye
      5          68          56         Home Owner     Employed       53000         14         Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);

disp(sc)
```

```
  creditscorecard with properties:

              GoodLabel: 0
            ResponseVar: 'status'
             WeightsVar: ''

```

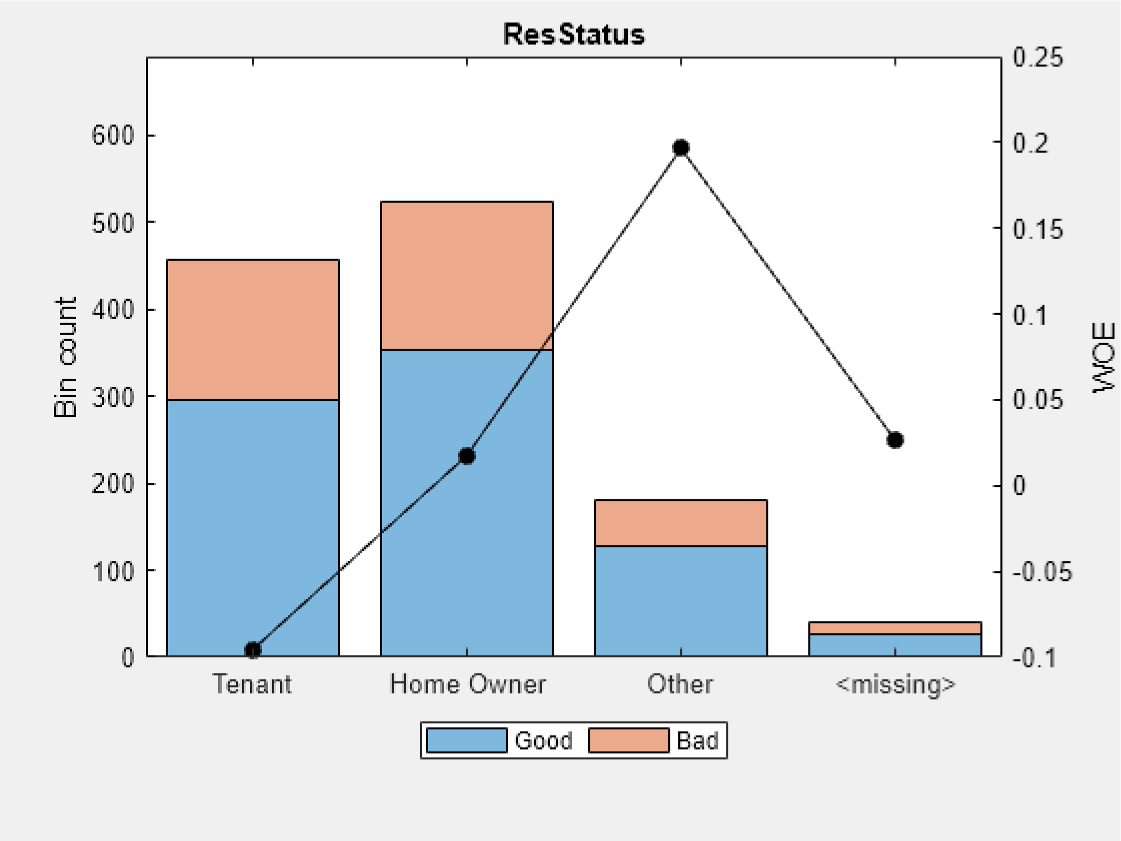
Note that the category grouping table does not include `<missing>` because this is a reserved bin and users cannot interact directly with the `<missing>` bin.

```
plotbins(sc,'ResStatus')
```



Input Arguments

sc — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

`PredictorName` — Predictor name

character vector

Predictor name, specified using a character vector containing the name of the predictor. `PredictorName` is case-sensitive.

Data Types: `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `bi = bininfo(sc, PredictorName,'Statistics','WOE','Totals','On')`

`Statistics` — List of statistics to include for bin information

`{'Odds','WOE','InfoValue'}` (default) | character vector with values `'Odds'`, `'WOE'`, `'InfoValue'`,`'Entropy'`, `'Gini'`, `'Chi2'` | cell array of character vectors with values `'Odds'`, `'WOE'`, `'InfoValue'`, `'Entropy'`,`'Gini'`, `'Chi2'`

List of statistics to include in the bin information, specified as the comma-separated pair consisting of `'Statistics'` and a character vector or a cell array of character vectors. For more information, see “Statistics for a Credit Scorecard” on page 15-1806. Possible values are:

- `'Odds'` — Odds information is the ratio of “Goods” over “Bads.”
- `'WOE'` — Weight of Evidence. The WOE Statistic measures the deviation between the distribution of “Goods” and “Bads.”
- `'InfoValue'` — Information value. Closely tied to the WOE, it is a statistic used to determine how strong a predictor is to use in the fitting model. It measures how strong the deviation is between the distributions of “Goods” and “Bads.” However, bins with only “Good” or only “Bad” observations do lead to an infinite Information Value. Consider modifying the bins in those cases by using `modifybins` or `autobinning`.
- `'Entropy'` — Entropy is a measure of unpredictability contained in the bins. The more the number of “Goods” and “Bads” differ within the bins, the lower the entropy.
- `'Gini'` — Measure of statistical dispersion or inequality within a sample of data.
- `'Chi2'` — Measure of statistical difference and independence between groups.

Note Avoid having bins with frequencies of zero because they lead to infinite or undefined (`NaN`) statistics. Use `modifybins` or `autobinning` to modify bins.

Data Types: `char` | `cell`

`Totals` — Indicator to include row of totals at bottom information table

`'On'` (default) | character vector with values `'On'`, `'Off'`

Indicator to include a row of totals at the bottom of the information table, specified as the comma-separated pair consisting of `'Totals'` and a character vector with values `On` or `Off`.

Data Types: `char`

Output Arguments

`bi` — Bin information

table

Bin information, returned as a table. The bin information table contains one row per bin and a row of totals. The columns contain bin descriptions, frequencies of “Good” and “Bad,” and bin statistics. Avoid having bins with frequencies of zero because they lead to infinite or undefined (`NaN`) statistics. Use `modifybins` or `autobinning` to modify bins.

Note When creating the `creditscorecard` object with `creditscorecard`, if the optional name-value pair argument `WeightsVar` was used to specify observation (sample) weights, then the `bi` table contains weighted counts.

`bm` — Binning map or rules

vector of cut points for numeric predictors | table of category groupings for categorical predictors

Binning map or rules, returned as a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors. For more information, see `modifybins`.

`mv` — Binning minimum and maximum values

numeric array

Binning minimum and maximum values (as set or defined by the user), returned as a numeric array. The `mv` output argument is set to an empty array for categorical predictors.

More About

Statistics for a Credit Scorecard

Weight of Evidence (WOE) is a measure of the difference of the distribution of “Goods” and “Bads” within a bin.

Suppose the predictor's data takes on *M* possible values b1, ..., b*M*. For binned data, *M* is a small number. The response takes on two values, “Good” and “Bad.” The frequency table of the data is given by:

	Good	Bad	Total
b1:	n11	n12	n1
b2:	n21	n22	n2
b*M*:	n*M*1	n*M*2	n*M*
Total:	nGood	nBad	nTotal

The Weight of Evidence (WOE) is defined for each data value b*`i`* as

```
WOE(i) = log((ni1/nGood)/(ni2/nBad)).
```

If you define

```
 pGood(i) = ni1/nGood, pBad(i) = ni2/nBad
```

then `pGood`(*i*) is the proportion of “Good” observations that take on the value `bi`, and similarly for `pBad`(*i*). In other words, `pGood`(*i*) gives the distribution of good observations over the *M* observed values of the predictor, and similarly for `pBad`(*i*). With this, an equivalent formula for the WOE is

```
WOE(i) = log(pGood(i)/pBad(i)).
```

Using the same frequency table, the odds for row *i* are defined as

```
Odds(i) = ni1 / ni2,
```

and the odds for the sample are defined as

```
OddsTotal = nGood / nBad.
```

For each row *i*, you can also compute its contribution to the total Information Value, given by

```
InfoValue(i) = (pGood(i) - pBad(i)) * WOE(i),
```

and the total Information Value is simply the sum of all the `InfoValuel`(*i*) terms. (A `nansum` is returned to discard contributions from rows with no observations at all.)

Likewise, for each row *i*, we can compute its contribution to the total Entropy, given by

```
 Entropy(i) = -1/log(2)*(ni1/ni*log(ni1/ni)+ni2/ni*log(ni2/ni),
```

and the total Entropy is simply the weighted sum of the row entropies,

```
Entropy = sum(ni/nTotal * Entropy(i)), i = 1...M.
```

Chi2 is computed pairwise for each pair of bins and measures the statistical difference between two groups when splitting or merging bins and is defined as:

```
 Chi2 = sum(sum((Aij - Eij)^2/Eij , j=1..k), i=m,m+1).
```

For more information on splitting and merging bins, see Split on page 15-1830 and Merge on page 15-1833.

Gini ratio is a measure of the parent node, that is, of the given bins/categories prior to splitting or merging. The Gini ratio is defined as:

```
Gr = 1-G_hat/Gp
```

`G_hat` is the weighted Gini measure for the current split or merge:

```
G_hat = Sum((nj/N) * Gj, j=1..m).
```

For more information on splitting and merging bins, see Split on page 15-1830 and Merge on page 15-1833.

Using `bininfo` with Weights

When observation weights are defined using the optional `WeightsVar` argument when creating a `creditscorecard` object, instead of counting the rows that are good or bad in each bin, the `bininfo` function accumulates the weight of the rows that are good or bad in each bin.

The “frequencies” reported are no longer the basic “count” of rows, but the “cumulative weight” of the rows that are good or bad and fall in a particular bin. Once these “weighted frequencies” are known, all other relevant statistics (`Good`, `Bad`, `Odds`, `WOE`, and `InfoValue`) are computed with the usual formulas. For more information, see “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

Version History

Introduced in R2014b

autobinning

Perform automatic binning of given predictors

Syntax

```
sc = autobinning(sc)
sc = autobinning(sc,PredictorNames)
sc = autobinning( ___ ,Name,Value)
```

Description

`sc = autobinning(sc)` performs automatic binning of all predictors.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the `creditscorecard` object. To apply the binning rules to the `creditscorecard` object data, or to a new dataset, use `bindata`.

`sc = autobinning(sc,PredictorNames)` performs automatic binning of the predictors given in `PredictorNames`.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the `creditscorecard` object. To apply the binning rules to the `creditscorecard` object data, or to a new dataset, use `bindata`.

`sc = autobinning( ___ ,Name,Value)` performs automatic binning of the predictors given in `PredictorNames` using optional name-value pair arguments. See the name-value argument `Algorithm` for a description of the supported binning algorithms.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the `creditscorecard` object. To apply the binning rules to the `creditscorecard` object data, or to a new dataset, use `bindata`.

Examples

Perform Automatic Binning Using the Defaults

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning using the default options. By default, `autobinning` bins all predictors and uses the `Monotone` algorithm.

```
sc = autobinning(sc);
```

Use `bininfo` to display the binned data for the predictor `CustAge`.

```
bi = bininfo(sc, 'CustAge')
```

```
bi=8×6 table

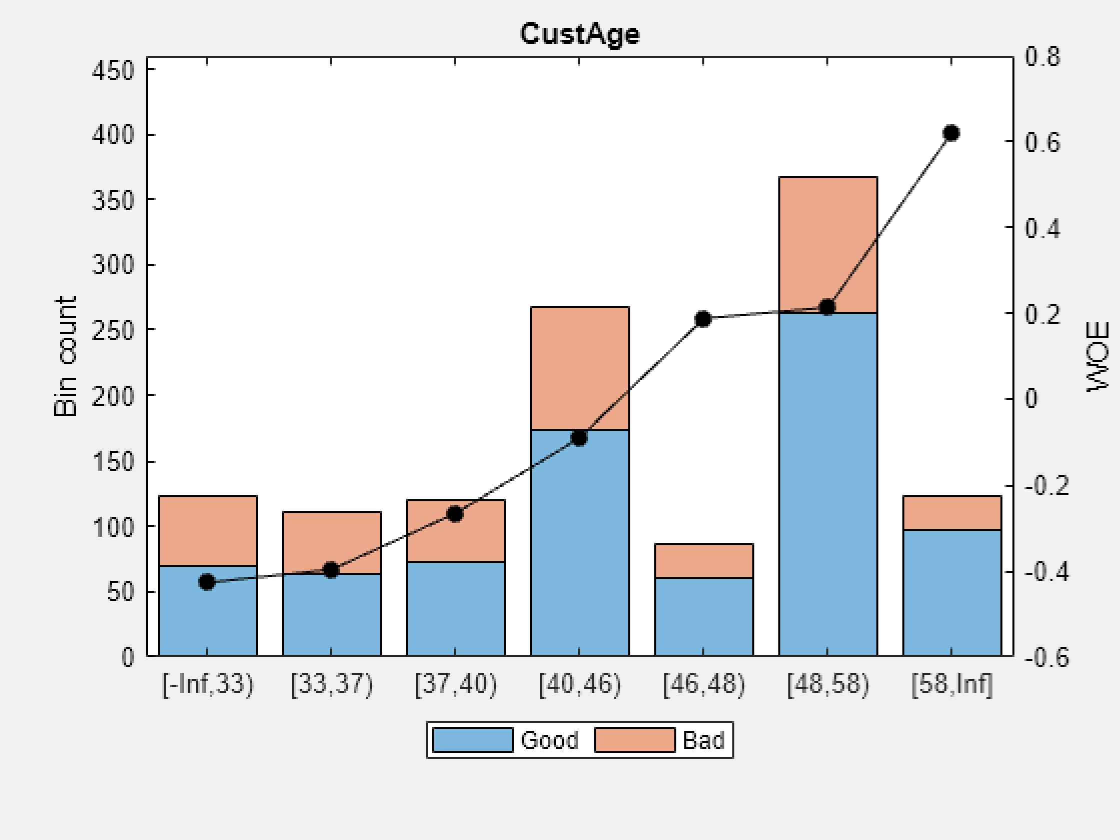
    {'Totals'   }    803     397    2.0227          NaN     0.095205
```

Use `plotbins` to display the histogram and WOE curve for the predictor `CustAge`.

```
plotbins(sc,'CustAge')
```



Perform Automatic Binning with a Named Predictor Using the Defaults

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the predictor CustIncome using the default options. By default, autobinning uses the Monotone algorithm.

```
sc = autobinning(sc,'CustIncome');
```

Use bininfo to display the binned data.

```
bi = bininfo(sc, 'CustIncome')
```

```

    {'[42000,47000)'}      164      66     2.4848      0.20579     0.0078175
    {'[47000,Inf]'  }      183      56     3.2679      0.47972      0.041657
    {'Totals'       }      803     397     2.0227          NaN       0.12285
```

Perform Automatic Binning Using Two Name-Value Pair Arguments

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the predictor CustIncome using the Monotone algorithm with the initial number of bins set to 20. This example explicitly sets both the Algorithm and the AlgorithmOptions name-value arguments.

```
AlgoOptions = {'InitialNumBins',20};
sc = autobinning(sc,'CustIncome','Algorithm','Monotone','AlgorithmOptions',...
     AlgoOptions);
```

Use bininfo to display the binned data. Here, the cut points, which delimit the bins, are also displayed.

```
[bi,cp] = bininfo(sc,'CustIncome')
```

```

```

Perform Automatic Binning Using Multiple Name-Value Pair Arguments

This example shows how to use the `autobinning` default `Monotone` algorithm and the `AlgorithmOptions` name-value pair arguments associated with the `Monotone` algorithm. The `AlgorithmOptions` for the `Monotone` algorithm are three name-value pair parameters: `‘InitialNumBins'`, `'Trend'`, and `'SortCategories'`. `'InitialNumBins'` and `'Trend'` are applicable for numeric predictors and `'Trend'` and `'SortCategories'` are applicable for categorical predictors.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning for the numeric predictor `CustIncome` using the `Monotone` algorithm with 20 bins. This example explicitly sets both the `Algorithm` argument and the `AlgorithmOptions` name-value arguments for `'InitialNumBins'` and `'Trend'`.

```
AlgoOptions = {'InitialNumBins',20,'Trend','Increasing'};

sc = autobinning(sc,'CustIncome','Algorithm','Monotone',...
    'AlgorithmOptions',AlgoOptions);
```

Use `bininfo` to display the binned data.

```
bi = bininfo(sc,'CustIncome')
```

```
bi=11×6 table
           Bin             Good    Bad      Odds          WOE        InfoValue
    _________________    ____    ___    _______    _________    __________

    {'[-Inf,19000)' }      2       3    0.66667      -1.1099     0.0056227
    {'[19000,29000)'}     51      55    0.92727     -0.77993      0.058516
    {'[29000,31000)'}     29      26     1.1154     -0.59522      0.017486
    {'[31000,34000)'}     80      42     1.9048    -0.060061     0.0003704
    {'[34000,35000)'}     33      17     1.9412    -0.041124     7.095e-05
    {'[35000,40000)'}    193      98      1.9694    -0.026696    0.00017359
    {'[40000,42000)'}     68      34           2    -0.011271    1.0819e-05
    {'[42000,43000)'}     39      16      2.4375      0.18655      0.001542
    {'[43000,47000)'}    125      50         2.5      0.21187     0.0062972
    {'[47000,Inf]'  }    183      56      3.2679      0.47972      0.041657
    {'Totals'       }    803     397      2.0227          NaN       0.13175
```

Perform Automatic Binning for Multiple Predictors

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning for the predictor `CustIncome` and `CustAge` using the default `Monotone` algorithm with `AlgorithmOptions` for `InitialNumBins` and `Trend`.

```
AlgoOptions = {'InitialNumBins',20,'Trend','Increasing'};

sc = autobinning(sc,{'CustAge','CustIncome'},'Algorithm','Monotone',...
    'AlgorithmOptions',AlgoOptions);
```

Use `bininfo` to display the binned data.

```
bi1 = bininfo(sc, 'CustIncome')
```

```
bi1=11×6 table
           Bin             Good    Bad      Odds         WOE        InfoValue
    _________________    ____    ___    _______    _________    __________

    {'[-Inf,19000)' }       2       3    0.66667      -1.1099     0.0056227
    {'[19000,29000)'}      51      55    0.92727     -0.77993      0.058516
    {'[29000,31000)'}      29      26     1.1154     -0.59522      0.017486

```

Perform Automatic Binning for a Categorical Predictor Using the Defaults

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the predictor that is a categorical predictor called `ResStatus` using the default options. By default, `autobinning` uses the `Monotone` algorithm.

```
sc = autobinning(sc,'ResStatus');
```

Use `bininfo` to display the binned data.

```
bi = bininfo(sc, 'ResStatus')
```

```
bi=4×6 table
         Bin           Good    Bad     Odds         WOE       InfoValue

    {'Tenant'     }    307     167    1.8383    -0.095564    0.0036638
    {'Home Owner'}     365     177    2.0621     0.019329    0.0001682
    {'Other'      }    131      53    2.4717      0.20049    0.0059418
    {'Totals'     }    803     397    2.0227          NaN    0.0097738
```

Perform Automatic Binning for a Categorical Predictor Using Name-Value Pair Arguments

This example shows how to modify the data (for this example only) to illustrate binning categorical predictors using the `Monotone` algorithm.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
```

Add two new categories and updating the response variable.

```
newdata = data;
rng('default'); %for reproducibility
Predictor = 'ResStatus';
Status    = newdata.status;
NumObs    = length(newdata.(Predictor));
Ind1 = randi(NumObs,100,1);
Ind2 = randi(NumObs,100,1);
newdata.(Predictor)(Ind1) = 'Subtenant';
newdata.(Predictor)(Ind2) = 'CoOwner';
```

```
Status(Ind1) = randi(2,100,1)-1;
Status(Ind2) = randi(2,100,1)-1;

newdata.status = Status;
```

Update the `creditscorecard` object using the `newdata` and plot the bins for a later comparison.

```
scnew = creditscorecard(newdata,'IDVar','CustID');
[bi,cg] = bininfo(scnew,Predictor)
```

```
bi=6×6 table
         Bin           Good    Bad     Odds        WOE       InfoValue

```
plotbins(sc,'ResStatus')
```

Perform Automatic Binning Using the Split Algorithm

This example demonstrates using the `'Split'` algorithm with categorical and numeric predictors. Load the `CreditCardData.mat` dataset and modify so that it contains four categories for the predictor '`ResStatus'` to demonstrate how the split algorithm works.

```
load CreditCardData.mat
x = data.ResStatus;
Ind = find(x == 'Tenant');
Nx  = length(Ind);
x(Ind(1:floor(Nx/3))) = 'Subletter';
data.ResStatus = x;
```

Create a `creditscorecard` and use `bininfo` to display the `'Statistics'`.

```
sc = creditscorecard(data,'IDVar','CustID');
[bi1,cg1] = bininfo(sc,'ResStatus','Statistics',{'Odds','WOE','InfoValue'});
disp(bi1)
```

```
        Bin            Good    Bad     Odds        WOE        InfoValue
    ______________     ____    ___    ______    _________    _________

    {'Home Owner'}     365     177    2.0621     0.019329    0.0001682
    {'Tenant'    }     204     112    1.8214      -0.1048    0.0029415
    {'Other'     }     131      53    2.4717      0.20049    0.0059418
    {'Subletter' }    103      55     1.8727    -0.077023    0.00079103
    {'Totals'    }    803     397     2.0227          NaN     0.0098426
```

```
disp(cg1)
```

```
       Category       BinNumber
    ______________    _________

    {'Home Owner'}        1    
    {'Tenant'    }        2    
    {'Other'     }        3    
    {'Subletter' }        4    
```

Using the Split Algorithm with a Categorical Predictor

Apply presorting to the `'ResStatus'` category using the default sorting by `'Odds'` and specify the `'Split'` algorithm.

```
sc = autobinning(sc,'ResStatus', 'Algorithm', 'split','AlgorithmOptions',...
    {'Measure','gini','SortCategories','odds','Tolerance',1e4});
[bi2,cg2] = bininfo(sc,'ResStatus','Statistics',{'Odds','WOE','InfoValue'});
disp(bi2)
```

```
       Bin        Good    Bad     Odds     WOE    InfoValue
    __________    ____    ___    ______    ___    _________

    {'Group1'}    803     397    2.0227      0        0    
    {'Totals'}    803     397    2.0227    NaN        0    
```

```
disp(cg2)
```

```
       Category       BinNumber
    ______________    _________

    {'Tenant'    }        1    
    {'Subletter' }        1    
    {'Home Owner'}        1    
    {'Other'     }        1    
```

Using the Split Algorithm with a Numeric Predictor

To demonstrate a split for the numeric predictor, 'TmAtAddress', first use `autobinning` with the default `'Monotone'` algorithm.

```
sc = autobinning(sc,'TmAtAddress');
bi3 = bininfo(sc,'TmAtAddress','Statistics',{'Odds','WOE','InfoValue'});
disp(bi3)
```

```
         Bin          Good    Bad     Odds        WOE        InfoValue 
    _____________    ____    ___    ______    _________    __________

    {'[-Inf,23)'}    239     129    1.8527    -0.087767     0.0023963
    {'[23,83)'  }    480     232     2.069      0.02263    0.00030269
    {'[83,Inf]' }     84      36    2.3333      0.14288       0.00199
    {'Totals'   }    803     397    2.0227          NaN      0.004689
```

Then use `autobinning` with the `'Split'` algorithm.

```
sc = autobinning(sc,'TmAtAddress','Algorithm', 'Split');
bi4 = bininfo(sc,'TmAtAddress','Statistics',{'Odds','WOE','InfoValue'});
disp(bi4)
```

```
        Bin          Good    Bad      Odds         WOE         InfoValue 
    ____________     ____    ___    _______    _________    __________

    {'[-Inf,4)'}      20      12     1.6667     -0.19359     0.0010299
    {'[4,5)'   }       4       7    0.57143       -1.264      0.015991
    {'[5,23)'  }     215     110     1.9545    -0.034261    0.00031973
    {'[23,33)' }     130      39     3.3333      0.49955        0.0318
    {'[33,Inf]'}     434     229     1.8952    -0.065096     0.0023664
    {'Totals'  }     803     397     2.0227          NaN      0.051507
```

Perform Automatic Binning Using the Merge Algorithm

Load the `CreditCardData.mat` dataset. This example demonstrates using the `'Merge'` algorithm with categorical and numeric predictors.

```
load CreditCardData.mat
```

Using the Merge Algorithm with a Categorical Predictor

To merge a categorical predictor, create a `creditscorecard` using default sorting by `'Odds'` and then use `bininfo` on the categorical predictor `'ResStatus'`.

```
sc = creditscorecard(data,'IDVar','CustID');
[bi1,cg1] = bininfo(sc,'ResStatus','Statistics',{'Odds','WOE','InfoValue'});
disp(bi1);
```

```
         Bin           Good    Bad     Odds        WOE        InfoValue
    ______________     ____    ___    ______    _________    _________

    {'Home Owner'}     365     177    2.0621     0.019329    0.0001682
    {'Tenant'    }     307     167    1.8383    -0.095564    0.0036638
    {'Other'     }     131      53    2.4717      0.20049    0.0059418
    {'Totals'    }     803     397    2.0227          NaN    0.0097738
```

    {'Other'     }        2    
```

Using the Merge Algorithm with a Numeric Predictor

To demonstrate a merge for the numeric predictor, 'TmAtAddress', first use `autobinning` with the default `'Monotone'` algorithm.

```
sc = autobinning(sc,'TmAtAddress');
bi3 = bininfo(sc,'TmAtAddress','Statistics',{'Odds','WOE','InfoValue'});
disp(bi3)
```

```
         Bin         Good    Bad     Odds        WOE        InfoValue 
    _____________    ____    ___    ______    _________    __________

    {'[-Inf,23)'}    239     129    1.8527    -0.087767     0.0023963
    {'[23,83)'  }    480     232     2.069      0.02263    0.00030269
    {'[83,Inf]' }     84      36    2.3333      0.14288       0.00199
    {'Totals'   }    803     397    2.0227          NaN      0.004689
```

Then use `autobinning` with the `'Merge'` algorithm.

```
sc = autobinning(sc,'TmAtAddress','Algorithm', 'Merge');
bi4 = bininfo(sc,'TmAtAddress','Statistics',{'Odds','WOE','InfoValue'});
disp(bi4)
```

```
         Bin         Good    Bad     Odds         WOE        InfoValue 
    _____________    ____    ___    _______    _________    __________

    {'[-Inf,28)'}    303     152     1.9934    -0.014566    8.0646e-05
    {'[28,30)'  }     27       2       13.5       1.8983      0.054264
    {'[30,98)'  }    428     216     1.9815    -0.020574    0.00022794
    {'[98,106)' }     11      13    0.84615     -0.87147      0.016599
    {'[106,Inf]'}     34      14     2.4286      0.18288     0.0012942
    {'Totals'   }    803     397     2.0227          NaN      0.072466
```

Input Arguments

sc — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

PredictorNames — Predictor or predictors names to automatically bin

character vector | cell array of character vectors

Predictor or predictors names to automatically bin, specified as a character vector or a cell array of character vectors containing the name of the predictor or predictors. `PredictorNames` are case-sensitive and when no `PredictorNames` are defined, all predictors in the `PredictorVars` property of the `creditscorecard` object are binned.

Data Types: `char` | `cell`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `sc = autobinning(sc,'Algorithm','EqualFrequency')`

`Algorithm` — Algorithm selection

`'Monotone'` (default) | character vector with values `'Monotone'`, `'Split'`, `'Merge'`, `'EqualFrequency'`, `'EqualWidth'`

Algorithm selection, specified as the comma-separated pair consisting of `'Algorithm'` and a character vector indicating which algorithm to use. The same algorithm is used for all predictors in `PredictorNames`. Possible values are:

- `'Monotone'` — (default) Monotone Adjacent Pooling Algorithm (MAPA), also known as Maximum Likelihood Monotone Coarse Classifier (MLMCC). Supervised optimal binning algorithm that aims to find bins with a monotone Weight-Of-Evidence (WOE) trend. This algorithm assumes that only neighboring attributes can be grouped. Thus, for categorical predictors, categories are sorted before applying the algorithm (see `'SortCategories'` option for `AlgorithmOptions`). For more information, see “Monotone” on page 15-1828.
- `'Split'` — Supervised binning algorithm, where a measure is used to split the data into bins. The measures supported by `'Split'` are `gini`, `chi2`, `infovalue`, and `entropy`. The resulting split must be such that the gain in the information function is maximized. For more information on these measures, see `AlgorithmOptions` and “Split” on page 15-1830.
- `'Merge'` — Supervised automatic binning algorithm, where a measure is used to merge bins into buckets. The measures supported by `'Merge'` are `chi2`, `gini`, `infovalue`, and `entropy`. The resulting merging must be such that any pair of adjacent bins is statistically different from each other, according to the chosen measure. For more information on these measures, see `AlgorithmOptions` and “Merge” on page 15-1833.
- `'EqualFrequency'` — Unsupervised algorithm that divides the data into a predetermined number of bins that contain approximately the same number of observations. This algorithm is also known as “equal height” or “equal depth.” For categorical predictors, categories are sorted before applying the algorithm (see `'SortCategories'` option for `AlgorithmOptions`). For more information, see “Equal Frequency” on page 15-1835.
- `'EqualWidth'` — Unsupervised algorithm that divides the range of values in the domain of the predictor variable into a predetermined number of bins of “equal width.” For numeric data, the width is measured as the distance between bin edges. For categorical data, width is measured as the number of categories within a bin. For categorical predictors, categories are sorted before applying the algorithm (see `'SortCategories'` option for `AlgorithmOptions`). For more information, see “Equal Width” on page 15-1836.

Data Types: `char`

AlgorithmOptions — Algorithm options for selected Algorithm

{'InitialNumBins',10,'Trend','Auto','SortCategories','Odds'} for Monotone (default) | cell array with {'OptionName',*OptionValue*} for Algorithm options

Algorithm options for the selected Algorithm, specified as the comma-separated pair consisting of 'AlgorithmOptions' and a cell array. Possible values are:

- For Monotone algorithm:
  - {'InitialNumBins',*n*} — Initial number (*n*) of bins (default is 10). 'InitialNumBins' must be an integer > 2. Used for numeric predictors only.
  - {'Trend','TrendOption'} — Determines whether the Weight-Of-Evidence (WOE) monotonic trend is expected to be increasing or decreasing. The values for 'TrendOption' are:
    - 'Auto' — (Default) Automatically determines if the WOE trend is increasing or decreasing.
    - 'Increasing' — Look for an increasing WOE trend.
    - 'Decreasing' — Look for a decreasing WOE trend.

    The value of the optional input parameter 'Trend' does not necessarily reflect that of the resulting WOE curve. The parameter 'Trend' tells the algorithm to “look for” an increasing or decreasing trend, but the outcome may not show the desired trend. For example, the algorithm cannot find a decreasing trend when the data actually has an increasing WOE trend. For more information on the 'Trend' option, see “Monotone” on page 15-1828.
  - {'SortCategories','SortOption'} — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
    - 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
    - 'Goods' — The categories are sorted by order of increasing values of “Good.”
    - 'Bads' — The categories are sorted by order of increasing values of “Bad.”
    - 'Totals' — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
    - 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from bininfo.)

    For more information, see Sort Categories on page 15-1836
- For Split algorithm:
  - {'InitialNumBins',*n*} — Specifies an integer that determines the number (*n* >0) of bins that the predictor is initially binned into before splitting. Valid for numeric predictors only. Default is 50.
  - {'Measure',*MeasureName*} — Specifies the measure where '*MeasureName*' is one of the following:'Gini' (default), 'Chi2', 'InfoValue', or 'Entropy'.
  - {'MinBad',*n*} — Specifies the minimum number *n* (*n*>=0) of Bads per bin. The default value is 1, to avoid pure bins.
  - {'MaxBad',*n*} — Specifies the maximum number *n* (*n*>=0) of Bads per bin. The default value is Inf.

  - `{'MinGood',n}` — Specifies the minimum number *n* (*n*`>=0`) of Goods per bin. The default value is `1`, to avoid pure bins.
  - `{'MaxGood',n}` — Specifies the maximum number *n* (*n*`>=0`) of Goods per bin. The default value is `Inf`.
  - `{'MinCount',n}` — Specifies the minimum number *n* (*n*`>=0`) of observations per bin. The default value is `1`, to avoid empty bins.
  - `{'MaxCount',n}` — Specifies the maximum number *n* (*n*`>=0`) of observations per bin. The default value is `Inf`.
  - `{'MaxNumBins',n}` — Specifies the maximum number *n* (*n*`>=2`) of bins resulting from the splitting. The default value is `5`.
  - `{'Tolerance',Tol}` — Specifies the minimum gain (>0) in the information function, during the iteration scheme, to select the cut-point that maximizes the gain. The default is `1e4`.
  - `{'Significance',n}` — Significance level threshold for the chi-square statistic, above which splitting happens. Values are in the interval `[0,1]`. Default is `0.9` (90% significance level).
  - `{'SortCategories','SortOption'}` — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of `'SortOption'` are:

    - `'Goods'` — The categories are sorted by order of increasing values of “Good.”
    - `'Bads'` — The categories are sorted by order of increasing values of “Bad.”
    - `'Odds'` — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
    - `'Totals'` — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
    - `'None'` — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

    For more information, see Sort Categories on page 15-1836

- For `Merge` algorithm:

  - `{'InitialNumBins',n}` — Specifies an integer that determines the number (*n* >0) of bins that the predictor is initially binned into before merging. Valid for numeric predictors only. Default is `50`.
  - `{'Measure',MeasureName}` — Specifies the measure where '*MeasureName*' is one of the following:`'Chi2'` (default), `'Gini'`, `'InfoValue'`, or `'Entropy'`.
  - `{'MinNumBins',n}` — Specifies the minimum number *n* (*n*`>=2`) of bins that result from merging. The default value is `2`.
  - `{'MaxNumBins',n}` — Specifies the maximum number *n* (*n*`>=2`) of bins that result from merging. The default value is `5`.
  - `{'Tolerance',n}` — Specifies the minimum threshold below which merging happens for the information value and entropy statistics. Valid values are in the interval `(0.1)`. Default is `1e3`.
  - `{'Significance',n}` — Significance level threshold for the chi-square statistic, below which merging happens. Values are in the interval `[0,1]`. Default is `0.9` (90% significance level).
  - `{'SortCategories','SortOption'}` — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of `'SortOption'` are:

    - `'Goods'` — The categories are sorted by order of increasing values of “Good.”
    - `'Bads'` — The categories are sorted by order of increasing values of “Bad.”
    - `'Odds'` — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
    - `'Totals'` — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
    - `'None'` — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

  For more information, see Sort Categories on page 15-1836
- For `EqualFrequency` algorithm:

  - `{'NumBins',`*`n`*`}` — Specifies the desired number (*n*) of bins. The default is `{'NumBins',5}` and the number of bins must be a positive number.
  - `{'SortCategories','SortOption'}` — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of `'SortOption'` are:

    - `'Odds'` — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
    - `'Goods'` — The categories are sorted by order of increasing values of “Good.”
    - `'Bads'` — The categories are sorted by order of increasing values of “Bad.”
    - `'Totals'` — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
    - `'None'` — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

  For more information, see Sort Categories on page 15-1836
- For `EqualWidth` algorithm:

  - `{'NumBins',`*`n`*`}` — Specifies the desired number (*n*) of bins. The default is `{'NumBins',5}` and the number of bins must be a positive number.
  - `{'SortCategories','SortOption'}` — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of `'SortOption'` are:

    - `'Odds'` — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
    - `'Goods'` — The categories are sorted by order of increasing values of “Good.”
    - `'Bads'` — The categories are sorted by order of increasing values of “Bad.”
    - `'Totals'` — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
    - `'None'` — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

  For more information, see Sort Categories on page 15-1836

Example: `sc = autobinning(sc,'CustAge','Algorithm','Monotone','AlgorithmOptions',{'Trend','Increasing'})`

Data Types: `cell`

`Display` — Indicator to display information on status of the binning process at command line
`'Off'` (default) | character vector with values `'On'`, `'Off'`

Indicator to display the information on status of the binning process at command line, specified as the comma-separated pair consisting of `'Display'` and a character vector with a value of `'On'` or `'Off'`.

Data Types: `char`

Output Arguments

`sc` — Credit scorecard model
`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object containing the automatically determined binning maps or rules (cut points or category groupings) for one or more predictors. For more information on using the `creditscorecard` object, see `creditscorecard`.

Note If you have previously used the `modifybins` function to manually modify bins, these changes are lost when running `autobinning` because all the data is automatically binned based on internal autobinning rules.

More About

Monotone

The `'Monotone'` algorithm is an implementation of the Monotone Adjacent Pooling Algorithm (MAPA), also known as Maximum Likelihood Monotone Coarse Classifier (MLMCC); see Anderson or Thomas in the “References” on page 15-1837.

Preprocessing

During the preprocessing phase, preprocessing of numeric predictors consists in applying equal frequency binning, with the number of bins determined by the `'InitialNumBins'` parameter (the default is 10 bins). The preprocessing of categorical predictors consists in sorting the categories according to the `'SortCategories'` criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the “Sort Categories” on page 15-1836 definition or the description of `AlgorithmOptions` option for `'SortCategories'` for more information.

Main Algorithm

The following example illustrates how the `'Monotone'` algorithm arrives at cut points for numeric data.

Bin	Good	Bad	Iteration1	Iteration2	Iteration3	Iteration4
'[-Inf,33000)'	127	107	0.543			
'[33000,38000)'	194	90	0.620	0.683		
'[38000,42000)'	135	78	0.624	0.662		
'[42000,47000)'	164	66	0.645	0.678	0.713	
'[47000,Inf]'	183	56	0.669	0.700	0.740	0.766

Initially, the numeric data is preprocessed with an equal frequency binning. In this example, for simplicity, only the five initial bins are used. The first column indicates the equal frequency bin ranges, and the second and third columns have the “Good” and “Bad” counts per bin. (The number of observations is 1,200, so a perfect equal frequency binning would result in five bins with 240 observations each. In this case, the observations per bin do not match 240 exactly. This is a common situation when the data has repeated values.)

Monotone finds break points based on the cumulative proportion of “Good” observations. In the`'Iteration1'` column, the first value (0.543) is the number of “Good” observations in the first bin (127), divided by the total number of observations in the bin (127+107). The second value (0.620) is the number of “Good” observations in bins 1 and 2, divided by the total number of observations in bins 1 and 2. And so forth. The first cut point is set where the minimum of this cumulative ratio is found, which is in the first bin in this example. This is the end of iteration 1.

Starting from the second bin (the first bin after the location of the minimum value in the previous iteration), cumulative proportions of “Good” observations are computed again. The second cut point is set where the minimum of this cumulative ratio is found. In this case, it happens to be in bin number 3, therefore bins 2 and 3 are merged.

The algorithm proceeds the same way for two more iterations. In this particular example, in the end it only merges bins 2 and 3. The final binning has four bins with cut points at 33,000, 42,000, and 47,000.

For categorical data, the only difference is that the preprocessing step consists in reordering the categories. Consider the following categorical data:

Bin	Good	Bad	Odds
'Home Owner'	365	177	2.062
'Tenant'	307	167	1.838
'Other'	131	53	2.474

The preprocessing step, by default, sorts the categories by `'Odds'`. (See the “Sort Categories” on page 15-1836 definition or the description of `AlgorithmOptions` option for `'SortCategories'` for more information.) Then, it applies the same steps described above, shown in the following table:

Bin	Good	Bad	Odds	Iteration1	Iteration2	Iteration3
'Tenant'	307	167	1.838	0.648		
'Home Owner'	365	177	2.062	0.661	0.673	
'Other'	131	53	2.472	0.669	0.683	0.712

In this case, the Monotone algorithm would not merge any categories. The only difference, compared with the data before the application of the algorithm, is that the categories are now sorted by `'Odds'`.

In both the numeric and categorical examples above, the implicit `'Trend'` choice is `'Increasing'`. (See the description of `AlgorithmOptions` option for the `'Monotone'` `'Trend'` option.) If you set the trend to `'Decreasing'`, the algorithm looks for the maximum (instead of the minimum) cumulative ratios to determine the cut points. In that case, at iteration 1, the maximum would be in the last bin, which would imply that all bins should be merged into a single bin. Binning into a single bin is a total loss of information and has no practical use. Therefore, when the chosen trend leads to a single bin, the Monotone implementation rejects it, and the algorithm returns the bins found after the preprocessing step. This state is the initial equal frequency binning for numeric data and the sorted categories for categorical data. The implementation of the Monotone algorithm by default uses a heuristic to identify the trend (`'Auto'` option for `'Trend'`).

Split

Split is a supervised automatic binning algorithm, where a measure is used to split the data into buckets. The supported measures are `gini`, `chi2`, `infovalue`, and `entropy`.

Internally, the split algorithm proceeds as follows:

1. All categories are merged into a single bin.
2. At the first iteration, all potential cutpoint indices are tested to see which one results in the maximum increase in the information function (`Gini`, `InfoValue`, `Entropy`, or `Chi2`). That cutpoint is then selected, and the bin is split.
3. The same procedure is reiterated for the next sub-bins.
4. The algorithm stops when the maximum number of bins is reached or when the splitting does not result in any additional change in the information change function.

The following table for a categorical predictor summarizes the values of the change function at each iteration. In this example, `'Gini'` is the measure of choice, such that the goal is to see a decrease of the Gini measure at each iteration.

Iteration 0 Bin Number	Member	Gini	Iteration 1 Bin Number	Member	Gini	Iteration 2 Bin Number	Member	Gini
1	'Tenant'		1	'Tenant'		1	'Tenant'	0.45638
1	'Subletter '		1	'Subletter '	0.44789	1	'Subletter '	
1	'Home Owner'		1	'Home Owner'		2	'Home Owner'	0.43984
1	'Other'		2	'Other'	0.41015	3	'Other'	0.41015

Iteration 0 Bin Number	Member	Gini	Iteration 1 Bin Number	Member	Gini	Iteration 2 Bin Number	Member	Gini
Total Gini		0.442765			0.442102			0.441822
Relative Change		0			0.001498			0.002128

The relative change at iteration *i* is with respect to the Gini measure of the entire bins at iteration *i*-1. The final result corresponds to that from the last iteration which, in this example, is iteration 2.

The following table for a numeric predictor summarizes the values of the change function at each iteration. In this example, `'Gini'` is the measure of choice, such that the goal is to see a decrease of the Gini measure at each iteration. Since most numeric predictors in datasets contain many bins, there is a preprocessing step where the data is pre-binned into 50 equal-frequency bins. This makes the pool of valid cutpoints to choose from for splitting smaller and more manageable.

Iteration 0 Bin Number	Member	Gini	Iteration 1 Bin Number	Gini	Iteration 2 Bin Number	Gini	Iteration 3 Bin Number	Gini
1	`'21'`		`'[-Inf,47]'`	0.473897	`'[-Inf,47]'`	0.473897	`'[-Inf,35]'`	0.494941
1	`'22'`		`'[47,Inf]'`	0.385238	`'[47,61]'`	0.407072	`'[35,47]'`	0.463201
1	`'23'`				`'[61,Inf]'`	0.208795	`'[47,61]'`	0.407072
1	`'74'`			0			`'[61,Inf]'`	0.208795
Total Gini		0.442765		0.435035		0.432048		0.430511
Relative Change		0		0.01746		0.006867		0.0356

The resulting split must be such that the information function (content) increases. As such, the best split is the one that results in the maximum information gain. The information functions supported are:

- Gini: Each split results in an increase in the Gini Ratio, defined as:

  ```
  G_r = 1- G_hat/G_p
  ```

  `G_p` is the Gini measure of the parent node, that is, of the given bins/categories prior to splitting. `G_hat` is the weighted Gini measure for the current split:

  ```
  G_hat = Sum((nj/N) * Gini(j), j=1..m)
  ```

  where

  `nj` is the total number of observations in the *j*th bin.

  `N` is the total number of observations in the dataset.

`m` is the number of splits for the given variable.

`Gini(j)` is the Gini measure for the *j*th bin.

The Gini measure for the split/node *j* is:

```
Gini(j) = 1 - (Gj^2+Bj^2) / (nj)^2
```

where `Gj`, `Bj` = Number of Goods and Bads for bin *j*.

- `InfoValue`: The information value for each split results in an increase in the total information. The split that is retained is the one which results in the maximum gain, within the acceptable gain tolerance. The Information Value (IV) for a given observation *j* is defined as:

  ```
  IV = sum( (pG_i-pB_i) * log(pG_i/pB_i), i=1..n)
  ```

  where

  `pG_i` is the distribution of Goods at observation `i`, that is `Goods(i)/Total_Goods`.

  `pB_i` is the distribution of Bads at observation `i`, that is `Bads(i)/Total_Bads`.

  `n` is the total number of bins.

- `Entropy`: Each split results in a decrease in entropy variance defined as:

  ```
   E = -sum(ni * Ei, i=1..n)
  ```

  where

  `ni` is the total count for bin `i`, that is `(ni = Gi + Bi)`.

  `Ei` is the entropy for row (or bin) `i`, defined as:

  ```
   Ei = -sum(Gi*log2(Gi/ni) + Bi*log2(Bi/ni))/N,
  i=1..n
  ```

- `Chi2`: Chi2 is computed pairwise for each pair of bins and measures the statistical difference between two groups. Splitting is selected at a point (cutpoint or category indexing) where the maximum Chi2 value is:

  ```
   Chi2 = sum(sum((Aij - Eij)^2/Eij , j=1..k), i=m,m+1)
  ```

  where

  `m` takes values from `1 ... n-1`, where `n` is the number of bins.

  `k` is the number of classes. Here `k = 2` for the (Goods, Bads).

  `Aij` is the number of observations in bin `i`, `j`th class.

  `Eij` is the expected frequency of `Aij`, which is equal to `(Ri*Cj)/N`.

  `Ri` is the number of observations in bin `i`, which is equal to `sum(Aij, j=1..k)`.

  `Cj` is the number of observations in the `j`th class, which is equal to `sum(Aij, I = m,m+1)`.

  `N` is the total number of observations, which is equal to `sum(Cj, j=1..k)`.

The Chi2 measure for the entire sample (as opposed to the pairwise Chi2 measure for adjacent bins) is:

```
Chi2 = sum(sum((Aij - Eij)^2/Eij , j=1..k), i=1..n)
```

Merge

Merge is a supervised automatic binning algorithm, where a measure is used to merge bins into buckets. The supported measures are chi2, gini, infovalue, and entropy.

Internally, the merge algorithm proceeds as follows:

1. All categories are initially in separate bins.
2. The user selected information function (Chi2, Gini, InfoValue or Entropy) is computed for any pair of adjacent bins.
3. At each iteration, the pair with the smallest information change measured by the selected information function is merged.
4. The merging continues until either:

   a. All pairwise information values are greater than the threshold set by the significance level or the relative change is smaller than the tolerance.

   b. If at the end, the number of bins is still greater than the MaxNumBins allowed, merging is forced until there are at most MaxNumBins bins. Similarly, merging stops when there are only MinNumBins bins.
5. For categorical, original bins/categories are pre-sorted according to the sorting of choice set by the user. For numeric data, the data is preprocessed to get IntialNumBins bins of equal frequency before the merging algorithm starts.

The following table for a categorical predictor summarizes the values of the change function at each iteration. In this example, 'Chi2' is the measure of choice. The default sorting by Odds is applied as a preprocessing step. The Chi2 value reported below at row *i* is for bins *i* and *i*+1. The significance level is 0.9 (90%), so that the inverse Chi2 value is 2.705543. This is the threshold below which adjacent pairs of bins are merged. The minimum number of bins is 2.

Iteration 0 Bin Number	Member	Chi2	Iteration 1 Bin Number	Member	Chi2	Iteration 2 Bin Number	Member	Chi2
1	'Tenant'	1.007613	1	'Tenant'	0.795920	1	'Tenant'	
2	'Subletter'	0.257347	2	'Subletter'		1	'Subletter'	
3	'Home Owner'	1.566330	2	'Home Owner'	1.522914	1	'Home Owner'	1.797395
4	'Other'		3	'Other'		2	'Other'	
Total Chi2		2.573943			2.317717			1.797395

The following table for a numeric predictor summarizes the values of the change function at each iteration. In this example, 'Chi2' is the measure of choice.

Iteration 0 Bin Number	Chi2	Iteration 1 Bins	Chi2		Final Iteration Bins	Chi2
'[-Inf,22]'	0.11814	'[-Inf,22]'	0.11814		'[-Inf,33]'	8.4876
'[22,23]'	1.6464	'[22,23]'	1.6464		'[33, 48]'	7.9369
...		...			'[48,64]'	9.956
'[58,59]'	0.311578	'[58,59]'	0.27489		'[64,65]'	9.6988
'*[59,60]*'	*0.068978*	'*[59,61]*'	1.8403		'[65,Inf]'	NaN
'[60,61]'	1.8709	'[61,62]'	5.7946	...		
'[61,62]'	5.7946	...				
...		'[69,70]'	6.4271			
'[69,70]'	6.4271	'[70,Inf]'	NaN			
'[70,Inf]'	NaN					
Total Chi2	67.467		67.399			23.198

The resulting merging must be such that any pair of adjacent bins is statistically different from each other, according to the chosen measure. The measures supported for `Merge` are:

- `Chi2`: Chi2 is computed pairwise for each pair of bins and measures the statistical difference between two groups. Merging is selected at a point (cutpoint or category indexing) where the maximum Chi2 value is:

  ```
  Chi2 = sum(sum((Aij - Eij)^2/Eij , j=1..k), i=m,m+1)
  ```

  where

  `m` takes values from `1 ... n-1`, and `n` is the number of bins.

  `k` is the number of classes. Here `k = 2` for the (Goods, Bads).

  `Aij` is the number of observations in bin `i`, `j`th class.

  `Eij` is the expected frequency of `Aij`, which is equal to `(Ri*Cj)/N`.

  `Ri` is the number of observations in bin `i`, which is equal to `sum(Aij, j=1..k)`.

  `Cj` is the number of observations in the `j`th class, which is equal to `sum(Aij, I = m,m+1)`.

  `N` is the total number of observations, which is equal to `sum(Cj, j=1..k)`.

  The `Chi2` measure for the entire sample (as opposed to the pairwise `Chi2` measure for adjacent bins) is:

  ```
  Chi2 = sum(sum((Aij - Eij)^2/Eij , j=1..k), i=1..n)
  ```
- Gini: Each merge results in a decrease in the Gini Ratio, defined as:

  `G_r = 1- G_hat/G_p`

`G_p` is the Gini measure of the parent node, that is, of the given bins/categories prior to merging. `G_hat` is the weighted Gini measure for the current merge:

```
G_hat = Sum((nj/N) * Gini(j), j=1..m)
```

where

`nj` is the total number of observations in the *j*th bin.

`N` is the total number of observations in the dataset.

`m` is the number of merges for the given variable.

`Gini(j)` is the Gini measure for the *j*th bin.

The Gini measure for the merge/node *j* is:

```
Gini(j) = 1 - (Gj^2+Bj^2) / (nj)^2
```

where `Gj`, `Bj` = Number of Goods and Bads for bin *j*.

- `InfoValue`: The information value for each merge will result in a decrease in the total information. The merge that is retained is the one which results in the minimum gain, within the acceptable gain tolerance. The Information Value (IV) for a given observation *j* is defined as:

  ```
  IV = sum( (pG_i-pB_i) * log(pG_i/pB_i), i=1..n)
  ```

  where

  `pG_i` is the distribution of Goods at observation `i`, that is `Goods(i)/Total_Goods`.

  `pB_i` is the distribution of Bads at observation `i`, that is `Bads(i)/Total_Bads`.

  `n` is the total number of bins.
- `Entropy`: Each merge results in an increase in entropy variance defined as:

  ```
   E = -sum(ni * Ei, i=1..n)
  ```

  where

  `ni` is the total count for bin `i`, that is `(ni = Gi + Bi)`.

  `Ei` is the entropy for row (or bin) `i`, defined as:

  ```
   Ei = -sum(Gi*log2(Gi/ni) + Bi*log2(Bi/ni))/N,
  i=1..n
  ```

Note When using the Merge algorithm, if there are pure bins (bins that have either zero count of `Goods` or zero count of `Bads`), the statistics such as Information Value and Entropy have non-finite values. To account for this, a frequency shift of `.5` is applied for computing various statistics whenever the algorithm finds pure bins.

Equal Frequency

Unsupervised algorithm that divides the data into a predetermined number of bins that contain approximately the same number of observations.

EqualFrequency is defined as:

Let v[1], v[2],..., v[N] be the sorted list of different values or categories observed in the data. Let f[*i*] be the frequency of v[*i*]. Let F[*k*] = f[1]+...+f[*k*] be the cumulative sum of frequencies up to the *k*th sorted value. Then F[*N*] is the same as the total number of observations.

Define AvgFreq = F[*N*] / *NumBins*, which is the ideal average frequency per bin after binning. The *n*th cut point index is the index *k* such that the distance abs(F[*k*] - *n**AvgFreq) is minimized.

This rule attempts to match the cumulative frequency up to the *n*th bin. If a single value contains too many observations, equal frequency bins are not possible, and the above rule yields less than *NumBins* total bins. In that case, the algorithm determines *NumBins* bins by breaking up bins, in the order in which the bins were constructed.

The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the “Sort Categories” on page 15-1836 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.

Equal Width

Unsupervised algorithm that divides the range of values in the domain of the predictor variable into a predetermined number of bins of “equal width.” For numeric data, the width is measured as the distance between bin edges. For categorical data, width is measured as the number of categories within a bin.

The EqualWidth option is defined as:

For numeric data, if MinValue and MaxValue are the minimum and maximum data values, then

```
Width = (MaxValue - MinValue)/NumBins
```

and the CutPoints are set to MinValue + Width, MinValue + 2*Width, ... MaxValue – Width. If a MinValue or MaxValue have not been specified using the modifybins function, the EqualWidth option sets MinValue and MaxValue to the minimum and maximum values observed in the data.

For categorical data, if there are *NumCats* numbers of original categories, then

```
Width = NumCats / NumBins,
```

and set cut point indices to the rounded values of Width, 2*Width, ..., *NumCats* – Width, plus 1.

The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the “Sort Categories” on page 15-1836 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.

Sort Categories

As a preprocessing step for categorical data, 'Monotone', 'EqualFrequency', and 'EqualWidth' support the 'SortCategories' input. This serves the purpose of reordering the categories before applying the main algorithm. The default sorting criterion is to sort by 'Odds'. For example, suppose that the data originally looks like this:

Bin	Good	Bad	Odds
'Home Owner'	365	177	2.062
'Tenant'	307	167	1.838
'Other'	131	53	2.472

After the preprocessing step, the rows would be sorted by `'Odds'` and the table looks like this:

Bin	Good	Bad	Odds
'Tenant'	307	167	1.838
'Home Owner'	365	177	2.062
'Other'	131	53	2.472

The three algorithms only merge adjacent bins, so the initial order of the categories makes a difference for the final binning. The `'None'` option for `'SortCategories'` would leave the original table unchanged. For a description of the sorting criteria supported, see the description of the `AlgorithmOptions` option for `'SortCategories'`.

Upon the construction of a scorecard, the initial order of the categories, before any algorithm or any binning modifications are applied, is the order shown in the first output of `bininfo`. If the bins have been modified (either manually with `modifybins` or automatically with `autobinning`), use the optional output (`cg`,`'category grouping'`) from `bininfo` to get the current order of the categories.

The `'SortCategories'` option has no effect on categorical predictors for which the `'Ordinal'` parameter is set to true (see the `'Ordinal'` input parameter in MATLAB categorical arrays for `categorical`. Ordinal data has a natural order, which is honored in the preprocessing step of the algorithms by leaving the order of the categories unchanged. Only categorical predictors whose `'Ordinal'` parameter is false (default option) are subject to reordering of categories according to the `'SortCategories'` criterion.

Using autobinning with Weights

When observation weights are defined using the optional `WeightsVar` argument when creating a `creditscorecard` object, instead of counting the rows that are good or bad in each bin, the `autobinning` function accumulates the weight of the rows that are good or bad in each bin.

The “frequencies” reported are no longer the basic “count” of rows, but the “cumulative weight” of the rows that are good or bad and fall in a particular bin. Once these “weighted frequencies” are known, all other relevant statistics (`Good`, `Bad`, `Odds`, `WOE`, and `InfoValue`) are computed with the usual formulas. For more information, see “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

probdefault

Likelihood of default for given data set

Syntax

```
pd = probdefault(sc)
pd = probdefault(sc,data)
```

Description

`pd = probdefault(sc)` computes the probability of default for `sc`, the data used to build the `creditscorecard` object.

`pd = probdefault(sc,data)` computes the probability of default for a given data set specified using the optional argument `data`.

By default, the data used to build the `creditscorecard` object are used. You can also supply input data, to which the same computation of probability of default is applied.

Examples

Compute Probability for Default Using Credit ScoreCard Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Util
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tm
                     Data: [1200x11 table]
```

Perform automatic binning using the default options. By default, `autobinning` uses the `Monotone` algorithm.

```
sc = autobinning(sc);
```

Fit the model.

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

Compute Probability for Default Using Credit ScoreCard Data When Using the 'BinMissingData' Option

This example describes both the assignment of points for missing data when the 'BinMissingData' option is set to true, and the corresponding computation of probabilities of default.

- Predictors that have missing data in the training set have an explicit bin for <missing> with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the <missing> bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values, and the final score is mapped to a probability of default when using probdefault.
- Predictors with no missing data in the training set have no <missing> bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to NaN, and this leads to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes. The final score is then mapped to a probability of default when using probdefault.

Create a creditscorecard object using the CreditCardData.mat file to load the dataMissing with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus     EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ____

      1          53          62         <undefined>    Unknown        50000         55         Ye
      2          61          22         Home Owner     Employed       52000         25         Ye
      3          47          30         Tenant         Employed       37000         61         No
      4         NaN          75         Home Owner     Employed       53000         20         Ye
      5          68          56         Home Owner     Employed       53000         14         Ye
```

Use creditscorecard with the name-value argument 'BinMissingData' set to true to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);

disp(sc)
```

```
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 1
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

Set a minimum value of 0 for CustAge and CustIncome. With this, any negative age or income information becomes invalid or "out-of-range". For scoring and probability of default computations, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc,'CustAge','MinValue',0);
sc = modifybins(sc,'CustIncome','MinValue',0);
```

Display bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
bi = bininfo(sc,'CustAge');
disp(bi)
```

```

    {'Totals'     }      803     397    2.0227          NaN     0.0092627
```

For the `'CustAge'` and `'ResStatus'` predictors, there is missing data (`NaN`s and `<undefined>`) in the training data, and the binning process estimates a WOE value of -0.15787 and 0.026469 respectively for missing data in these predictors, as shown above.

For `EmpStatus` and `CustIncome` there is no explicit bin for missing values because the training data has no missing values for these predictors.

```
bi = bininfo(sc,'EmpStatus');
disp(bi)
```

```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the <missing> bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

```

```

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the `'PointsOddsAndPDO'` argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc,'PointsOddsAndPDO',[500 2 50]);
PointsInfo = displaypoints(sc)
```

```
PointsInfo=38×3 table

    {'EmpStatus'}    {'<missing>' }       NaN
          ⋮
```

Notice that points for the `<missing>` bin for `CustAge` and `ResStatus` are explicitly shown (as `64.9836` and `74.1250`, respectively). These points are computed from the WOE value for the <missing> bin and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin. By default the points are set to `NaN` for missing data, and they lead to a score of `NaN` when running `score`. For predictors that have no explicit <missing> bin, use the name-value argument `'Missing'` in `formatpoints` to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range, values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall `'MinValue'` was earlier set to 0 for `CustAge` and `CustIncome`). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

```
tdata = dataMissing(11:18,mdl.PredictorNames); % Keep only the predictors retained in the model
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)
```

```
    CustAge     ResStatus       EmpStatus      CustIncome    TmWBank    OtherCC    AMBalance
    _______    ___________    ___________    __________    _______    _______    _________

      NaN      Tenant         Unknown          34000         44         Yes        119.8
```

```
     48      <undefined>    Unknown          44000         14          Yes        403.62
     65      Home Owner     <undefined>      48000          6          No         111.88
     44      Other          Unknown            NaN         35          No         436.41
   -100      Other          Employed         46000         16          Yes        162.21
     33      House          Employed         36000         36          Yes        845.02
     39      Tenant         Freelancer       34000         40          Yes        756.26
     24      Home Owner     Employed            -1         19          Yes        449.61
```

Score the new data and see how points are assigned for missing `CustAge` and `ResStatus`, because we have an explicit bin with points for `<missing>`. However, for `EmpStatus` and `CustIncome` the `score` function sets the points to `NaN`. The corresponding probabilities of default are also set to `NaN`.

Use the name-value argument `'Missing'` in `formatpoints` to choose how to assign points to missing values for predictors that do not have an explicit `<missing>` bin. In this example, use the `'MinPoints'` option for the `'Missing'` argument. The minimum points for `EmpStatus` in the scorecard displayed above are `58.8072`, and for `CustIncome` the minimum points are `29.3753`. All rows now have a score and a corresponding probability of default.

```
sc = formatpoints(sc,'Missing','MinPoints');

Input Arguments

sc — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. To create this object, use `creditscorecard`.

data — Dataset to apply probability of default rules

table

(Optional) Dataset to apply probability of default rules, specified as a MATLAB table, where each row corresponds to individual observations. The data must contain columns for each of the predictors in the `creditscorecard` object.

Data Types: `table`

Output Arguments

pd — Probability of default

array

Probability of default, returned as a `NumObs`-by-`1` numerical array of default probabilities.

More About

Default Probability

After the unscaled scores are computed (see “Algorithms for Computing and Scaling Scores” on page 15-1662), the probability of the points being “Good” is represented by the following formula:

```
ProbGood = 1./(1 + exp(-UnscaledScores))
```

Thus, the probability of default is

```
pd = 1 - ProbGood
```

Version History

Introduced in R2015a

validatemodel

Validate quality of credit scorecard model

Syntax

```
Stats = validatemodel(sc)
Stats = validatemodel(sc,data)
[Stats,T] = validatemodel(sc,Name,Value)
[Stats,T,hf] = validatemodel(sc,Name,Value)
```

Description

`Stats = validatemodel(sc)` validates the quality of the `creditscorecard` model.

By default, the data used to build the `creditscorecard` object is used. You can also supply input data to which the validation is applied.

`Stats = validatemodel(sc,data)` validates the quality of the `creditscorecard` model for a given data set specified using the optional argument `data`.

`[Stats,T] = validatemodel(sc,Name,Value)` validates the quality of the `creditscorecard` model using the optional name-value pair arguments, and returns `Stats` and `T` outputs.

`[Stats,T,hf] = validatemodel(sc,Name,Value)` validates the quality of the `creditscorecard` model using the optional name-value pair arguments, and returns the figure handle `hf` to the CAP, ROC, and KS plots.

Examples

Validate a Credit Scorecard Model

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar','CustID')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

Perform automatic binning using the default options. By default, `autobinning` uses the `Monotone` algorithm.

```
sc = autobinning(sc);
```

Fit the model.

```
sc = fitmodel(sc);
```

```

Validate a Credit Score Card Model With Weights

Use the `CreditCardData.mat` file to load the data (`dataWeights`) that contains a column (`RowWeights`) for the weights (using a dataset from Refaat 2011).

```
load CreditCardData
```

Create a `creditscorecard` object using the optional name-value pair argument for `'WeightsVar'`.

```
sc = creditscorecard(dataWeights,'IDVar','CustID','WeightsVar','RowWeights')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: 'RowWeights'
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'T
                     Data: [1200x12 table]
```

Perform automatic binning.

```
sc = autobinning(sc)
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: 'RowWeights'
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'T
                     Data: [1200x12 table]
```

Fit the model.

```
sc = fitmodel(sc);
```

```
1. Adding CustIncome, Deviance = 764.3187, Chi2Stat = 15.81927, PValue = 6.968927e-05
2. Adding TmWBank, Deviance = 751.0215, Chi2Stat = 13.29726, PValue = 0.0002657942
3. Adding AMBalance, Deviance = 743.7581, Chi2Stat = 7.263384, PValue = 0.007037455
```

```
Generalized linear regression model:
    logit(status) ~ 1 + CustIncome + TmWBank + AMBalance
    Distribution = Binomial

Estimated Coefficients:
                   Estimate       SE        tStat       pValue  
                   ________    ________    ______    __________

    AMBalance       1.0039      0.37576    2.6717     0.0075464

1200 observations, 1196 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 36.4, p-value = 6.22e-08
```

Format the unscaled points.

```
sc = formatpoints(sc, 'PointsOddsAndPDO',[500,2,50]);
```

Score the data.

```
scores = score(sc);
```

Validate the credit scorecard model by generating the CAP, ROC, and KS plots. When the optional name-value pair argument `'WeightsVar'` is used to specify observation (sample) weights, the `T` table uses statistics, sums, and cumulative sums that are weighted counts.

```
[Stats,T] = validatemodel(sc,'Plot',{'CAP','ROC','KS'});

```

Validate a Credit Score Card Model When Using the 'BinMissingData' Option

This example describes both the assignment of points for missing data when the `'BinMissingData'` option is set to `true`, and the corresponding computation of model validation statistics.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values, and the final score is used to compute model validation statistics with `validatemodel`.
- Predictors with no missing data in the training set have no `<missing>` bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to `NaN`, and this leads to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument `'Missing'` in `formatpoints` to indicate how missing data should be treated for scoring purposes. The final score is used to compute model validation statistics with `validatemodel`.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus     EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ____

      1          53           62        <undefined>    Unknown        50000          55        Ye
      2          61           22        Home Owner     Employed       52000          25        Ye
      3          47           30        Tenant         Employed       37000          61        No
      4         NaN           75        Home Owner     Employed       53000          20        Ye
      5          68           56        Home Owner     Employed       53000          14        Ye
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);

disp(sc)
```

```
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 1
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

Set a minimum value of zero for `CustAge` and `CustIncome`. With this, any negative age or income information becomes invalid or "out-of-range". For scoring and probability of default computations, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc,'CustAge','MinValue',0);
sc = modifybins(sc,'CustIncome','MinValue',0);
```

Display bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
bi = bininfo(sc,'CustAge');
disp(bi)
```

```

    {'Totals'     }     803     397    2.0227          NaN     0.0092627
```

For the `'CustAge'` and `'ResStatus'` predictors, there is missing data (`NaN`s and `<undefined>`) in the training data, and the binning process estimates a WOE value of `-0.15787` and `0.026469` respectively for missing data in these predictors, as shown above.

For `EmpStatus` and `CustIncome` there is no explicit bin for missing values, because the training data has no missing values for these predictors.

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the <missing> bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the `'PointsOddsAndPDO'` argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc,'PointsOddsAndPDO',[500 2 50]);
PointsInfo = displaypoints(sc)
```

```
PointsInfo=38×3 table

    {'EmpStatus'}    {'Employed'  }   86.937
    {'EmpStatus'}    {'<missing>' }      NaN
      ⋮
```

Notice that points for the `<missing>` bin for `CustAge` and `ResStatus` are explicitly shown (as `64.9836` and `74.1250`, respectively). These points are computed from the WOE value for the `<missing>` bin, and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit `<missing>` bin. By default the points are set to `NaN` for missing data, and they lead to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument `'Missing'` in `formatpoints` to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range, values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall `'MinValue'` was earlier set to 0 for `CustAge` and `CustIncome`). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

This is a very small validation data set, only used to illustrate the scoring of rows with missing and out-of-range values, and its relationship with model validation.

```
tdata = dataMissing(11:18,mdl.PredictorNames); % Keep only the predictors retained in the model
tdata.status = dataMissing.status(11:18); % Copy the response variable value, needed for validat
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)
```

```

Score the new data and see how points are assigned for missing CustAge and ResStatus, because we have an explicit bin with points for <missing>. However, for EmpStatus and CustIncome the score function sets the points to NaN.

The validation results are unreliable, the scores with NaN values are kept (see the validation table ValTable below), but it is unclear what impact these NaN values have in the validation statistics (ValStats). This is a very small validation data set, but NaN scores could still influence the validation results on a larger data set.

```

Use the name-value argument `'Missing'` in `formatpoints` to choose how to assign points to missing values for predictors that do not have an explicit `<missing>` bin. In this example, use the `'MinPoints'` option for the `'Missing'` argument. The minimum points for `EmpStatus` in the scorecard displayed above are `58.8072` and for `CustIncome` the minimum points are `29.3753`.

The validation results are no longer influenced by `NaN` values, since all rows now have a score.

```

Input Arguments

`sc` — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object. To create this object, use `creditscorecard`.

`data` — Validation data

table

(Optional) Validation data, specified as a MATLAB table, where each table row corresponds to individual observations. The `data` must contain columns for each of the predictors in the credit scorecard model. The columns of data can be any one of the following data types:

- Numeric
- Logical
- Cell array of character vectors
- Character array
- Categorical
- String
- String array

In addition, the table must contain a binary response variable.

Note When observation weights are defined using the optional `WeightsVar` name-value pair argument when creating a `creditscorecard` object, the weights stored in the `WeightsVar` column are used when validating the model on the training data. If a different validation data set is provided using the optional `data` input, observation weights for the validation data must be included in a column whose name matches `WeightsVar`, otherwise unit weights are used for the validation data. For more information, see “Using validatemodel with Weights” on page 15-1868.

Data Types: `table`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `sc = validatemodel(sc,data,'AnalysisLevel','Deciles','Plot','CAP')`

`AnalysisLevel` — Type of analysis level

`'Scores'` (default) | character vector with values `'Deciles'`, `'Scores'`

Type of analysis level, specified as the comma-separated pair consisting of `'AnalysisLevel'` and a character vector with one of the following values:

- `'Scores'` — Returns the statistics (`Stats`) at the observation level. Scores are sorted from riskiest to safest, and duplicates are removed.
- `'Deciles'` — Returns the statistics (`Stats`) at decile level. Scores are sorted from riskiest to safest and binned with their corresponding statistics into 10 deciles (10%, 20%, ..., 100%).

Data Types: `char`

`Plot` — Type of plot

`'None'` (default) | character vector with values `'None'`, `'CAP'`, `'ROC'`,`'KS'` | cell array of character vectors with values `'None'`, `'CAP'`, `'ROC'`,`'KS'`

Type of plot, specified as the comma-separated pair consisting of `'Plot'` and a character vector with one of the following values:

- `'None'` — No plot is displayed.
- `'CAP'` — Cumulative Accuracy Profile. Plots the fraction of borrowers up to score “s” versus the fraction of defaulters up to score “s” (`'PctObs'` versus `'Sensitivity'` columns of `T` optional output argument). For more details, see “Cumulative Accuracy Profile (CAP)” on page 15-1867.
- `'ROC'` — Receiver Operating Characteristic. Plots the fraction of non-defaulters up to score “s” versus the fraction of defaulters up to score “s” (`'FalseAlarm'` versus `'Sensitivity'` columns of `T` optional output argument). For more details, see “Receiver Operating Characteristic (ROC)” on page 15-1867.
- `'KS'` — Kolmogorov-Smirnov. Plots each score “s” versus the fraction of defaulters up to score “s,” and also versus the fraction of non-defaulters up to score “s” (`'Scores'` versus both `'Sensitivity'` and `'FalseAlarm'` columns of the optional output argument `T`). For more details, see “Kolmogorov-Smirnov statistic (KS)” on page 15-1867.

> **Tip** For the Kolmogorov-Smirnov statistic option, you can enter `'KS'` or `'K-S'`.

Data Types: `char` | `cell`

Output Arguments

`Stats` — Validation measures

table

Validation measures, returned as a `4`-by-`2` table. The first column, `'Measure'`, contains the names of the following measures:

- Accuracy ratio (AR)
- Area under the ROC curve (AUROC)
- The KS statistic
- KS score

The second column, `'Value'`, contains the values corresponding to these measures.

`T` — Validation statistics data

array

Validation statistics data, returned as an `N`-by-`9` table of validation statistics data, sorted, by score, from riskiest to safest. When `AnalysisLevel` is set to `'Deciles'`, `N` is equal to `10`. Otherwise, `N` is equal to the total number of unique scores, that is, scores without duplicates.

The table `T` contains the following nine columns, in this order:

- `'Scores'` — Scores sorted from riskiest to safest. The data in this row corresponds to all observations up to, and including the score in this row.
- `'ProbDefault'` — Probability of default for observations in this row. For deciles, the average probability of default for all observations in the given decile is reported.
- `'TrueBads'` — Cumulative number of “bads” up to, and including, the corresponding score.
- `'FalseBads'` — Cumulative number of “goods” up to, and including, the corresponding score.
- `'TrueGoods'` — Cumulative number of “goods” above the corresponding score.
- `'FalseGoods'` — Cumulative number of “bads” above the corresponding score.
- `'Sensitivity'` — Fraction of defaulters (or the cumulative number of “bads” divided by total number of “bads”). This is the distribution of “bads” up to and including the corresponding score.
- `'FalseAlarm'` — Fraction of non-defaulters (or the cumulative number of “goods” divided by total number of “goods”). This is the distribution of “goods” up to and including the corresponding score.
- `'PctObs'` — Fraction of borrowers, or the cumulative number of observations, divided by total number of observations up to and including the corresponding score.

Note When creating the `creditscorecard` object with `creditscorecard`, if the optional name-value pair argument `WeightsVar` was used to specify observation (sample) weights, then the `T` table uses statistics, sums, and cumulative sums that are weighted counts.

`hf` — Handle to the plotted measures

figure handle

Figure handle to plotted measures, returned as a figure handle or array of handles. When `Plot` is set to `'None'`, `hf` is an empty array.

More About

Cumulative Accuracy Profile (CAP)

CAP is generally a concave curve and is also known as the Gini curve, Power curve, or Lorenz curve.

The scores of given observations are sorted from riskiest to safest. For a given fraction M (0% to 100%) of the total borrowers, the height of the CAP curve is the fraction of defaulters whose scores are less than or equal to the maximum score of the fraction M, also known as “Sensitivity.”

The area under the CAP curve, known as the AUCAP, is then compared to that of the perfect or “ideal” model, leading to the definition of a summary index known as the accuracy ratio (*AR*) or the Gini coefficient:

$$AR = \frac{A_R}{A_P}$$

where A_R is the area between the CAP curve and the diagonal, and A_P is the area between the perfect model and the diagonal. This represents a “random” model, where scores are assigned randomly and therefore the proportion of defaulters and non-defaulters is independent of the score. The perfect model is the model for which all defaulters are assigned the lowest scores, and therefore, perfectly discriminates between defaulters and nondefaulters. Thus, the closer to unity *AR* is, the better the scoring model.

Receiver Operating Characteristic (ROC)

To find the receiver operating characteristic (ROC) curve, the proportion of defaulters up to a given score “s,” or “Sensitivity,” is computed.

This proportion is known as the true positive rate (TPR). Additionally, the proportion of nondefaulters up to score “s,“ or “False Alarm Rate,” is also computed. This proportion is also known as the false positive rate (FPR). The ROC curve is the plot of the “Sensitivity” vs. the “False Alarm Rate.” Computing the ROC curve is similar to computing the equivalent of a confusion matrix at each score level.

Similar to the CAP, the ROC has a summary statistic known as the area under the ROC curve (AUROC). The closer to unity, the better the scoring model. The accuracy ratio (*AR*) is related to the area under the curve by the following formula:

$$AR = 2(AUROC) - 1$$

Kolmogorov-Smirnov statistic (KS)

The Kolmogorov-Smirnov (KS) plot, also known as the fish-eye graph, is a common statistic used to measure the predictive power of scorecards.

The KS plot shows the distribution of defaulters and the distribution of non-defaulters on the same plot. For the distribution of defaulters, each score “s” is plotted versus the proportion of defaulters up to “s," or “Sensitivity." For the distribution of non-defaulters, each score “s” is plotted versus the proportion of non-defaulters up to “s," or “False Alarm." The statistic of interest is called the KS statistic and is the maximum difference between these two distributions (“Sensitivity” minus “False Alarm”). The score at which this maximum is attained is also of interest.

Using validatemodel with Weights

Model validation statistics incorporate observation weights when these are provided by the user.

Without weights, the validation statistics are based on how many good and bad observations fall below a particular score. On the other hand, when observation weights are provided, the weight (not the count) is accumulated for the good and the bad observations that fall below a particular score.

When observation weights are defined using the optional `WeightsVar` name-value pair argument when creating a `creditscorecard` object, the weights stored in the `WeightsVar` column are used when validating the model on the training data. When a different validation data set is provided using the optional `data` input, observation weights for the validation data must be included in a column whose name matches `WeightsVar`, otherwise unit weights are used for the validation data set.

Not only the validation statistics, but also the credit scorecard scores themselves depend on the observation weights of the training data. For more information, see “Using fitmodel with Weights” on page 15-1722 and “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

fillmissing

Replace missing values for credit scorecard predictors

Syntax

```
sc = fillmissing(sc,PredictorNames,Statistics)
sc = fillmissing( ___ ,ConstantValue)
```

Description

`sc = fillmissing(sc,PredictorNames,Statistics)` replaces missing values of the predictor `PredictorNames` with values defined by `Statistics` and returns an updated credit scorecard object (`sc`). Standard missing data is defined as follows:

- `NaN` for numeric arrays
- `<undefined>` for categorical arrays

Note If you run `fillmissing` after binning a predictor, the existing cutpoints and bin edges are preserved and the "Good" and "Bad" counts from the `<missing>` bin are added to the corresponding bin.

`sc = fillmissing( ___ ,ConstantValue)` uses arguments from the previous syntax and a value for a `ConstantValue` to replace missing values.

Examples

Fill Missing Data in a `creditscorecard` Object

This example shows how to use `fillmissing` to replace missing values in the `CustAge` and `ResStatus` predictors with user-defined values. For additional information on alternative approaches for "treating" missing data, see “Credit Scorecard Modeling with Missing Values” on page 8-56.

Load the credit scorecard data and use `dataMissing` for the training data.

```
load CreditCardData.mat
disp(head(dataMissing));
```

```

      ⋮
```

When a validation data set has missing values and you use `fillmissing` with the training dataset, the missing values in the validation data set are assigned the same points as the corresponding bins containing the filled values.

As the table shows, the `'<missing>'` bin for the `CustAge` predictor is assigned the same points as the `'[40,46)'` bin because the missing data is filled with the median value `45`.

The points assigned to the `'<missing>'` bin for the `EmpStatus` predictor are `NaN` because `fillmissing` is not used for that predictor. The assigned points are decided by the default `'NoScore'` for the `'Missing'` name-value pair argument in `formatpoints`.

Create a test validation data set (`tdata`) and add missing values.

```
tdata = data(1:10,:);
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
[scr,pts] = score(sc,tdata)
```

```
scr = 10×1

Handling of Missing Values in Validation Data Sets

This example shows different possibilities for handling missing data in validation data.

When scoring data from a validation data set, you have several options. If you choose to do nothing, the points assigned to the missing data are `NaN`, which comes from the default `'NoScore'` for the `'Missing'` name-value pair argument in `formatpoints`.

If you want to score missing values of all the predictors with one consistent metric, you can use the options `'ZeroWOE'`, `'MinPoints'`, or `'MaxPoints'` for the `'Missing'` name-value pair argument in `formatpoints`.

```
load CreditCardData.mat
sc = creditscorecard(data);
predictorinfo(sc,'CustAge')
```

```

Input Arguments

`sc` — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object.

`PredictorNames` — Name of `creditscorecard` predictor whose missing data is filled

character vector | string | cell array of character vectors | string array

Name of `creditscorecard` predictor to fill missing data for, specified as a scalar character vector, scalar string, cell array of character vectors, or string array.

Data Types: `char` | `string` | `cell`

`Statistics` — Statistic to use to fill missing data for predictors

character vector with a value of `'mean'`, `'median'`, `'mode'`, `'original'`, or `'constant'` | string with a value of `"mean"`, `"median"`, `"mode"`, `"original"`, or `"constant"`

Statistic to use to fill missing data for the predictors, specified as a character vector or string with one of the following values.

- `'mean'` — Replace missing data with the average or mean value. The option is valid only for numeric data. The `'mean'` calculates the weighted mean of the predictor by referring to the predictor column and the `Weights` column from the `creditscorecard` object. For more information, see “Weighted Mean” on page 15-1879.

- `'median'` — Replace missing data with the median value. Valid for numeric and ordinal data. The `'median'` calculates the weighted median of the predictor by referring to the predictor column and the `Weights` column from the `creditscorecard` object. For more information, see “Weighted Median” on page 15-1880.
- `'mode'` — Replace missing data with the mode. Valid for numeric and both nominal and ordinal categorical data. The `'mode'` calculates the weighted `mode` of the predictor by referring to the predictor column and the `Weights` column from the `creditscorecard` object. For more information, see “Weighted Mode” on page 15-1880.
- `'original'` — Set the missing data for numeric and categorical predictors back to its original value: `NaN` if numeric, `<undefined>` or `<missing>` if categorical.
- `'constant'` — Set the missing data for numeric and categorical predictors to a constant value that you specify in the optional argument for `ConstantValue`.

Data Types: `char` | `string`

`ConstantValue` — Value to fill missing entries in predictors specified in `PredictorNames`
`[ ]` (default) | numeric | character vector | string | cell array of character vectors | string array

(Optional) Value to fill missing entries in predictors specified in `PredictorNames`, specified as a numeric value, character vector, string, or cell array of character vectors.

Note You can use `ConstantValue` only if you set the `Statistics` argument to `'constant'`.

Data Types: `char` | `double` | `string` | `cell`

Output Arguments

`sc` — Updated `creditscorecard`
`creditscorecard` object

Updated `creditscorecard` object, returned as an object.

More About

Weighted Mean

The weighted mean is similar to an ordinary mean except that instead of each of the data points contributing equally to the final average, some data points contribute more than others.

The weighted mean for a nonempty finite multiset of data (x) with corresponding nonnegative weights (w) is

$$\bar{x} = \frac{\sum_{i=1}^{n} w_i x_i}{\sum_{i=1}^{n} w_i}$$

Weighted Median

The weighted median is the 50% weighted percentile, where the percentage in the total weight is counted instead of the total number.

For n distinct ordered elements (x) positive weights (w) such that $\sum_{i=1}^{n} w_i = 1$, the weighted median is the element x_k:

$$\sum_{i=1}^{k-1} w_i \leq \frac{1}{2} \text{ and } \sum_{i=k+1}^{n} w_i \leq \frac{1}{2}$$

In the case where the respective weights of both elements border the midpoint of the set of weights without encapsulating it, each element defines a partition equal to 1/2. These elements are referred to as the lower weighted median and upper weighted median. The weighted median is chosen based on which element keeps the partitions most equal. This median is always the weighted median with the lowest weight. In the event that the upper and lower weighted medians are equal, the lower weighted median is accepted.

Weighted Mode

The weighted mode of a set of weighted data values is the value that appears most often.

The mode of a sample is the element that occurs most often in the collection. For example, the mode of the sample [1, 3, 6, 6, 6, 6, 7, 7, 12, 12, 17] is 6.

creditscorecard

Create `creditscorecard` object to build credit scorecard model

Description

Build a credit scorecard model by creating a `creditscorecard` object and specify input data in a table format.

After creating a `creditscorecard` object, you can use the associated object functions to bin the data and perform logistic regression analysis to develop a credit scorecard model to guide credit decisions. This workflow shows how to develop a credit scorecard model.

1. Use `screenpredictors` from Risk Management Toolbox to pare down a potentially large set of predictors to a subset that is most predictive of the credit score card response variable. Use this subset of predictors when creating the `creditscorecard` object.
2. Create a `creditscorecard` object (see “Create creditscorecard” on page 15-1881 and “Properties” on page 15-1884).
3. Bin the data using `autobinning`.
4. Fit a logistic regression model using `fitmodel` or `fitConstrainedModel`.
5. Review and format the credit scorecard points using `displaypoints` and `formatpoints`. At this point in the workflow, if you have a license for Risk Management Toolbox, you have the option to create a `compactCreditScorecard` object (`csc`) using the `compact` function. You can then use the following functions `displaypoints`, `score`, and `probdefault` from the Risk Management Toolbox with the `csc` object.
6. Score the data using `score`.
7. Calculate the probabilities of default for the data using `probdefault`.
8. Validate the quality of the credit scorecard model using `validatemodel`.

For more detailed information on this workflow, see “Credit Scorecard Modeling Workflow” on page 8-51.

Creation

Syntax

```
sc = creditscorecard(data)
sc = creditscorecard( ___ ,Name,Value)
```

Description

`sc = creditscorecard(data)` creates a `creditscorecard` object by specifying `data`. The credit scorecard model, returned as a `creditscorecard` object, contains the binning maps or rules (cut points or category groupings) for one or more predictors.

`sc = creditscorecard( ___ ,Name,Value)` sets Properties on page 15-1884 using name-value pairs and any of the arguments in the previous syntax. For example, `sc =`

`creditscorecard(data,'GoodLabel',0,'IDVar','CustID','ResponseVar','status','PredictorVars', {'CustAge','CustIncome'},'WeightsVar','RowWeights','BinMissingData',true)`. You can specify multiple name-value pairs.

Note To use observation (sample) weights in the credit scorecard workflow, when creating a `creditscorecard` object, you must use the optional name-value pair `WeightsVar` to define which column in the `data` contains the weights.

Input Arguments

`data` — Data for `creditscorecard` object
table

Data for the `creditscorecard` object, specified as a MATLAB table, where each column of data can be any one of the following data types:

- Numeric
- Logical
- Cell array of character vectors
- Character array
- Categorical
- String

In addition, the table must contain a binary response variable. Before creating a `creditscorecard` object, perform a data preparation task to have appropriately structured `data` as input to a `creditscorecard` object. The `data` input sets the Data on page 15-0 property.

Data Types: `table`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `sc = creditscorecard(data,'GoodLabel',0,'IDVar','CustAge','ResponseVar','status','PredictorVars', {'CustID','CustIncome'},'WeightsVar','RowWeights','BinMissingData',true)`

`GoodLabel` — Indicator for which of two possible values in response variable correspond to “Good” observations
set to the response value with the highest count (default) | character vector | numeric scalar | logical

Indicator for which of the two possible values in the response variable correspond to “Good” observations, specified as the comma-separated pair consisting of `'GoodLabel'` and a numeric scalar, logical, or character vector. The `GoodLabel` name-value pair argument sets the GoodLabel on page 15-0 property.

When specifying `GoodLabel`, follow these guidelines.

If Response Variable is...	GoodLabel Must be...
numeric	numeric
logical	logical or numeric
cell array of character vectors	character vector
character array	character vector
categorical	character vector

If not specified, GoodLabel is set to the response value with the highest count. However, if the optional WeightsVar argument is provided when creating the creditscorecard object, then counts are replaced with weighted frequencies. For more information, see "Credit Scorecard Modeling Using Observation Weights" on page 8-54.

GoodLabel can only be set when creating the creditscorecard object. This parameter cannot be set using dot notation.

Data Types: char | double

IDVar — Variable name used as ID or tag for observations

empty character vector '' (default) | character vector

Variable name used as ID or tag for the observations, specified as the comma-separated pair consisting of 'IDVar' and a character vector. The IDVar data could be an ordinal number (for example, 1,2,3...), a Social Security number. This is provided as a convenience to remove this column from the predictor variables. IDVar is case-sensitive. The IDVar name-value pair argument sets the IDVar on page 15-0 property.

You can set this optional parameter using the creditscorecard function or by using dot notation at the command line, as follows.

Example: sc.IDVar = 'CustID'

Data Types: char

ResponseVar — Response variable name for "Good" or "Bad" indicator

last column of the data input (default) | character vector

Response variable name for the "Good" or "Bad" indicator, specified as the comma-separated pair consisting of 'ResponseVar' and a character vector. The response variable data must be binary. The ResponseVar name-value pair argument sets the ResponseVar on page 15-0 property.

If not specified, ResponseVar is set to the last column of the data input. ResponseVar can only be set when creating the creditscorecard object using the creditscorecard function. ResponseVar is case-sensitive.

Data Types: char

WeightsVar — Weights variable name

empty character vector '' (default) | character vector

Weights variable name, specified as the comma-separated pair consisting of 'WeightsVar' and a character vector to indicate which column name in the data table contains the row weights. WeightsVar is case-sensitive. The WeightsVar name-value pair argument sets the WeightsVar on page 15-0 property, and this property can only be set at the creation of a creditscorecard object. If the name-value pair argument WeightsVar is not specified when creating a creditscorecard object, then observation weights are set to unit weights by default.

The WeightsVar values are used in the credit scorecard workflow by autobinning, bininfo, fitmodel, and validatemodel. For more information, see “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

Data Types: char

BinMissingData — Indicates if missing data is removed or displayed in a separate bin
false (missing data removed) (default) | logical with value true or false

Indicates if missing data is removed or displayed in a separate bin, specified as the comma-separated pair consisting of 'BinMissingdata' and a logical scalar with a value of true or false. If BinMissingData is true, the missing data for a predictor is displayed in a separate bin labeled <missing>.

Data Types: logical

Properties

Data — Data used to create the creditscorecard object
table

Data used to create the creditscorecard object, specified as a table when creating a creditscorecard object. In the Data property, categorical predictors are stored as categorical arrays.

Example: sc.Data(1:10,:)

Data Types: table

IDVar — Name of the variable used as ID or tag for the observations
empty character vector '' (default) | character vector

Name of the variable used as ID or tag for the observations, specified as a character vector. This property can be set as an optional parameter when creating a creditscorecard object or by using dot notation at the command line. IDVar is case-sensitive.

Example: sc.IDVar = 'CustID'

Data Types: char

VarNames — All variable names from the data input
VarNames come directly from data input to creditscorecard object (default)

This property is read-only.

VarNames is a cell array of character vectors containing the names of all variables in the data. The VarNames come directly from the data input to the creditscorecard object. VarNames is case-sensitive.

Data Types: cell

ResponseVar — Name of the response variable, “Good” or “Bad” indicator
last column of the data input (default) | character vector

Name of the response variable, “Good” or “Bad” indicator, specified as a character vector. The response variable data must be binary. If not specified, `ResponseVar` is set to the last column of the data input. This property can only be set with an optional parameter when creating a `creditscorecard` object. `ResponseVar` is case-sensitive.

Data Types: `char`

`WeightsVar` — Name of the variable used as ID or tag for weights
empty character vector `''` (default) | character vector

Name of the variable used as ID or tag to indicate which column name in the `data` table contains the row weights, specified as a character vector. This property can be set as an optional parameter (`WeightsVar`) when creating a `creditscorecard` object. `WeightsVar` is case-sensitive.

Data Types: `char`

`GoodLabel` — Indicator for which of the two possible values in the response variable correspond to “Good” observations
set to the response value with the highest count (default) | character vector | numeric scalar | logical

Indicator for which of the two possible values in the response variable correspond to “Good” observations. When specifying `GoodLabel`, follow these guidelines:

If Response Variable is...	`GoodLabel` must be:
numeric	numeric
logical	logical or numeric
cell array of character vectors	character vector
character array	character vector
categorical	character vector

If not specified, `GoodLabel` is set to the response value with the highest count. This property can only be set with an optional parameter when creating a `creditscorecard` object. This property cannot be set using dot notation.

Data Types: `char` | `double`

`PredictorVars` — Predictor variable names
set difference between `VarNames` and `{IDVar,ResponseVar}` (default) | cell array of character vectors containing names

Predictor variable names, specified using a cell array of character vectors containing names. By default, when you create a `creditscorecard` object, all variables are predictors except for `IDVar` and `ResponseVar`. This property can be modified using a name-value pair argument for the `fitmodel` function or by using dot notation. `PredictorVars` is case-sensitive and the predictor variable name cannot be the same as the `IDVar` or `ResponseVar`.

Example: `sc.PredictorVars = {'CustID','CustIncome'}`

Data Types: `cell`

`NumericPredictors` — Name of numeric predictors
empty character vector `''` (default) | character vector

Name of numeric predictors, specified as a character vector. This property cannot be set by using dot notation at the command line. It can only be modified using the `modifypredictor` function.

Data Types: `char`

`CategoricalPredictors` — Name of categorical predictors

empty character vector `''` (default) | character vector

Name of categorical predictors, specified as a character vector. This property cannot be set by using dot notation at the command line. It can only be modified using the `modifypredictor` function.

Data Types: `char`

`BinMissingData` — Indicates if missing data is removed or displayed in a separate bin

`false` (missing data removed) (default) | logical with value `true` or `false`

Indicates if missing data is removed or displayed in a separate bin, specified as the comma-separated pair consisting of `'BinMissingdata'` and a logical scalar with a value of `true` or `false`. If `BinMissingData` is `true`, the missing data for a predictor is displayed in a separate bin labeled `<missing>`. For more information on working with missing data, see “Credit Scorecard Modeling with Missing Values” on page 8-56.

Data Types: `logical`

`creditscorecard` Property	Set/Modify Property from Command Line Using `creditscorecard` Function	Modify Property Using Dot Notation	Property Not User-Defined and Value Is Defined Internally
`Data`	No	No	Yes, copy of `data` input
`IDVar`	Yes	Yes	No, but the user specifies this
`VarNames`	No	No	Yes
`ResponseVar`	Yes	No	If not specified, set to last column of `data` input
`WeightsVar`	No	No	Yes
`GoodLabel`	Yes	No	If not specified, set to response value with highest count
`PredictorVars`	Yes (also modifiable using `fitmodel` function)	Yes	Yes, but the user can modify this
`NumericPredictors`	No (can only be modified using `modifypredictor` function)	No	Yes, but the user can modify this
`CategoricalPredictors`	No (can only be modified using `modifypredictor` function)	No	Yes, but the user can modify this

`creditscorecard` Property	Set/Modify Property from Command Line Using `creditscorecard` Function	Modify Property Using Dot Notation	Property Not User-Defined and Value Is Defined Internally
`BinMissingData`	Yes	No	False by default, but the user can modify this

Object Functions

autobinning	Perform automatic binning of given predictors
bininfo	Return predictor’s bin information
predictorinfo	Summary of credit scorecard predictor properties
modifypredictor	Set properties of credit scorecard predictors
fillmissing	Replace missing values for credit scorecard predictors
modifybins	Modify predictor’s bins
bindata	Binned predictor variables
plotbins	Plot histogram counts for predictor variables
fitmodel	Fit logistic regression model to Weight of Evidence (WOE) data
fitConstrainedModel	Fit logistic regression model to Weight of Evidence (WOE) data subject to constraints on model coefficients
setmodel	Set model predictors and coefficients
displaypoints	Return points per predictor per bin
formatpoints	Format scorecard points and scaling
score	Compute credit scores for given data
probdefault	Likelihood of default for given data set
validatemodel	Validate quality of credit scorecard model
compact	Create compact credit scorecard

Examples

Create a `creditscorecard` Object

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data)
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
        NumericPredictors: {'CustID'  'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalan
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: ''
            PredictorVars: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIn
                     Data: [1200x11 table]
```

Create a creditscorecard Object Containing Weights

Use the CreditCardData.mat file to load the data (dataWeights) that contains a column (RowWeights) for the weights (using a dataset from Refaat 2011).

```
load CreditCardData
```

Create a creditscorecard object using the optional name-value pair argument for 'WeightsVar'.

```
sc = creditscorecard(dataWeights,'WeightsVar','RowWeights')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: 'RowWeights'
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustID'  'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBala
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: ''
            PredictorVars: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
                     Data: [1200x12 table]
```

Display creditscorecard Object Properties

Create a creditscorecard object using the CreditCardData.mat file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data)
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustID'  'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBala
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: ''
            PredictorVars: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
                     Data: [1200x11 table]
```

To display the creditscorecard object properties, use dot notation.

```
sc.PredictorVars
```

```
ans = 1x10 cell
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}    {'EmpStatus'}    {'CustInco
```

```
sc.VarNames
```

```
ans = 1x11 cell
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}    {'EmpStatus'}    {'CustInco
```

Change a Property Value for a creditscorecard Object

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data)
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustID'  'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBala
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: ''
            PredictorVars: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
                     Data: [1200x11 table]
```

Since the `IDVar` property has public access, you can change its value at the command line.

```
sc.IDVar = 'CustID'
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'T
                     Data: [1200x11 table]
```

Create a creditscorecard Object

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data)
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustID'  'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBala
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 0
                    IDVar: ''
            PredictorVars: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
                     Data: [1200x11 table]
```

In this example, the default values for the properties `ResponseVar`, `PredictorVars` and `GoodLabel` are assigned when this object is created. By default, the property `ResponseVar` is set to the variable name that is in the last column of the input data (`'status'` in this example). The property `PredictorVars` contains the names of all the variables that are in `VarNames`, but excludes `IDVar` and `ResponseVar`. Also, by default in the previous example, `GoodLabel` is set to `0`, since it is the value in the response variable (`ResponseVar`) with the highest count.

Display the `creditscorecard` object properties using dot notation.

```
sc.PredictorVars
```

```
ans = 1x10 cell
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}    {'EmpStatus'}    {'CustInco
```

```
sc.VarNames
```

```
ans = 1x11 cell
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}    {'EmpStatus'}    {'CustInco
```

Since `IDVar` and `PredictorVars` have public access, you can change their values at the command line.

```
sc.IDVar = 'CustID'
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
```

```
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tr
                     Data: [1200x11 table]
```

```
sc.PredictorVars = {'CustIncome','ResStatus','AMBalance'}
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustIncome'  'AMBalance'}
    CategoricalPredictors: {'ResStatus'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'ResStatus'  'CustIncome'  'AMBalance'}
                     Data: [1200x11 table]
```

```
disp(sc)
```

```
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustIncome'  'AMBalance'}
    CategoricalPredictors: {'ResStatus'}
           BinMissingData: 0
                    IDVar: 'CustID'
            PredictorVars: {'ResStatus'  'CustIncome'  'AMBalance'}
                     Data: [1200x11 table]
```

Create a creditscorecard Object and Set GoodLabel and ResponseVar

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `data` (using a dataset from Refaat 2011). Then use name-value pair arguments for `creditscorecard` to define `GoodLabel` and `ResponseVar`.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID','GoodLabel',0,'ResponseVar','status')
```

```
sc = 
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustI
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
```

```
          BinMissingData: 0
                   IDVar: 'CustID'
           PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tı
                    Data: [1200x11 table]
```

`GoodLabel` and `ResponseVar` can only be set (enforced) when creating a `creditscorecard` object using `creditscorecard`.

Create a `creditscorecard` Object and Set the `'BinMissingData'` Property

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData
head(dataMissing,5)
```

```
    CustID    CustAge    TmAtAddress     ResStatus      EmpStatus    CustIncome    TmWBank    Othe
    ______    _______    ___________    ___________    _________    __________    _______    ____

      1         53           62         <undefined>    Unknown        50000          55         Ye
      2         61           22         Home Owner     Employed       52000          25         Ye
      3         47           30         Tenant         Employed       37000          61         No
      4        NaN           75         Home Owner     Employed       53000          20         Ye
      5         68           56         Home Owner     Employed       53000          14         Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
disp(sc)
```

```
  creditscorecard with properties:

                GoodLabel: 0
              ResponseVar: 'status'
               WeightsVar: ''
                 VarNames: {'CustID'  'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIı
        NumericPredictors: {'CustAge'  'TmAtAddress'  'CustIncome'  'TmWBank'  'AMBalance'  'Uti
    CategoricalPredictors: {'ResStatus'  'EmpStatus'  'OtherCC'}
           BinMissingData: 1
                    IDVar: 'CustID'
            PredictorVars: {'CustAge'  'TmAtAddress'  'ResStatus'  'EmpStatus'  'CustIncome'  'Tı
                     Data: [1200x11 table]
```

Display bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
bi = bininfo(sc,'CustAge');
disp(bi)
```

```
         Bin           Good    Bad     Odds        WOE       InfoValue 
    ______________     ____    ___    ______    ________    ___________

    {'[-Inf,33)'}       69     52     1.3269    -0.42156       0.018993
    {'[33,37)'  }       63     45        1.4    -0.36795       0.012839

addBusinessCalendar

Add business calendar awareness to timetables

Syntax

```
TT = addBusinessCalendar(TT)
TT = addBusinessCalendar( ___ ,Name=Value)
```

Description

`TT = addBusinessCalendar(TT)` adds business calendar awareness to an input timetable `TT` by setting a custom property for the output timetable `TT`.

`TT = addBusinessCalendar( ___ ,Name=Value)` sets additional options specified by one or more name-value arguments, using any of the input arguments in the previous syntax. For example, `TT = addBusinessCalendar(TT,Holidays=H)` replaces the default holidays stored in `Data_NYSE_Closures.mat` with the list of holidays `H`.

Examples

Add Business Calendar for Calculating Period-Over-Period Rolling Returns

This example shows how to add a business calendar when you calculate period-over-period (PoP) rolling differences for 5 years of simulated daily prices. For each date in timetable `TT`, the difference represents the PoP difference of the corresponding price compared to the price one period earlier.

Use `holidays` to indicate the holidays in `holidays.m` for the simulation period.

```
H = holidays(datetime(2014,1,1),datetime(2018,12,31));
```

Simulate daily prices for three assets.

```
t = (datetime(2014,1,1):caldays:datetime(2018,12,31))';
rng(200,"twister")
Price = 100 + 0.1*(0:numel(t) - 1)'.*cumsum(randn(numel(t),1)/100);
Price = round(Price*100)/100;
Price2 = round(Price*94)/100;
Price3 = round(Price*88)/100;

TT    = timetable(Price,Price2,Price3,RowTimes=t);
head(TT,15)
```

```
       Time        Price     Price2    Price3
    ___________    ______    ______    ______

    01-Jan-2014       100        94        88
    02-Jan-2014       100        94        88
    03-Jan-2014       100        94        88
    04-Jan-2014       100        94        88

    12-Jan-2014    100.11     94.1      88.1
    13-Jan-2014    100.11     94.1      88.1
    14-Jan-2014    100.12    94.11     88.11
    15-Jan-2014    100.12    94.11     88.11
```

Use `addBusinessCalendar` to indicate the holidays for the simulation period in the timetable TT.

```
TT = addBusinessCalendar(TT,Holidays=H);
```

Use `rollingreturns` with the `'Method'` name-value pair argument set to "`difference`" to compute the differences, that is, the period-over-period changes.

```
deltas = rollingreturns(TT,Period=calweeks(1),Method="difference");
head(deltas,15)
```

```

```

Input Arguments

TT — Input timetable to update with business calendar awareness

timetable

Input timetable to update with business calendar awareness, specified as a `timetable`.

Data Types: `timetable`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `TT = addBusinessCalendar(TT,Holidays=H)` replaces the default holidays stored in `Data_NYSE_Closures.mat` with the list of holidays `H`

`Holidays` — Alternate holidays and market closure dates
datetime vector

Alternate holidays and market closure dates, specified as a datetime vector. The dates in `Holidays` must be whole dates without `HH:MM:SS` components. No business is conducted on the dates in `Holidays`.

By default, `Holidays` is the New York Stock Exchange (NYSE) holidays and market closure dates. For more details, load the default holidays in `Data_NYSE_Closures.mat` and inspect the `NYSE` variable, or, if you have a Financial Toolbox license, see `holidays` and `isbusday`.

Tip If you have a Financial Toolbox license, you can generate alternate holiday schedules by using the `createholidays` function and performing this procedure:

1. Generate a new `holidays` function using `createholidays`.
2. Call the new `holidays` function to get the list of holidays.
3. Specify the alternate holidays to `addBusinessCalendar` by using the `Holidays` name-value argument.

Data Types: `datetime`

`Weekends` — Alternate weekend days on which no business is conducted
`[1 0 0 0 0 0 1]` or `["Sunday" "Saturday"]` (default) | logical vector | string vector

Alternate weekend days on which no business is conducted, specified as a length 7 logical vector or a string vector.

For a logical vector, `true` (`1`) entries indicate a weekend day and `false` (`0`) entries indicate a weekday, where entries correspond to Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday.

Example: `Weekends=[1 0 0 0 0 1 1]` specifies that business is not conducted on Fridays through Sundays.

For a string vector, entries explicitly list the weekend days.

Example: `Weekends=["Friday" "Saturday" "Sunday"]`

Tip If business is conducted seven days per week, set `Weekends` to `[0 0 0 0 0 0 0]`.

Data Types: `logical`

Output Arguments

`TT` — Updated timetable `TT` with added business calendar awareness by a custom property
timetable

Updated timetable `TT` with added business calendar awareness by the custom property `BusinessCalendar`, returned as a `timetable`.

The custom property `BusinessCalendar` contains a data structure that contains a field `IsBusinessDay` that stores a callable function (`F`). The function `F` accepts a datetime matrix (`D`) and returns a logical indicator matrix (`I`) of the same size: `I = F(D)`. `true` (`1`) elements of `I` indicate that the corresponding element of `D` occurs on a business day; `false` (`0`) elements of `I` indicate otherwise.

Access the callable function `F` by using `F = TT.Properties.CustomProperties.BusinessCalendar.IsBusinessDay`.

Version History

Introduced in R2020b

See Also

`isbusday` | `rollingreturns` | `timetable`

rollingreturns

Period-over-period rolling returns or differences from prices

Syntax

```
returns = rollingreturns(TT)
returns = rollingreturns(___,Name,Value)
```

Description

`returns = rollingreturns(TT)` calculates period-over-period (PoP) returns or differences from corresponding prices. For each date in timetable `TT`, the return represents the PoP return of the corresponding price compared to the price one `Period` earlier.

`returns = rollingreturns(___,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Year-over-Year Returns from Daily Prices with Business Calendar Awareness

This example shows how to compute year-over-year rolling returns for five years of simulated daily prices and also includes business calendar awareness.

Simulate five years of daily prices and store the result in the timetable `TT`. Then, use `isbusday` to retain only data for New York Stock Exchange (NYSE) business dates.

```
rng(200,'twister')
time = (datetime(2014,1,1):caldays:datetime(2018,12,31))';
price = 100 + 0.1*(0:numel(time) - 1)'.*cumsum(randn(numel(time),1)/100);
price = round(price*100)/100;                  % Round prices to the nearest penny
TT = timetable(price,'RowTimes',time,'VariableNames',{'Prices'});
TT = TT(isbusday(TT.Properties.RowTimes),:);  % Retain only NYSE business days
head(TT,10)
```

```
       Time         Prices
    ___________     ______

    02-Jan-2014        100
    03-Jan-2014        100
    06-Jan-2014     100.01
    07-Jan-2014     100.02
    08-Jan-2014     100.02
    09-Jan-2014     100.04
    10-Jan-2014     100.06
    13-Jan-2014     100.11
    14-Jan-2014     100.12
    15-Jan-2014     100.12
```

Use `addBusinessCalendar` to add NYSE business calendar awareness. The business calendar logic determines if the date of the previous period is a business date, and if it is not, then the most recent business day preceding that date is found. For example, since 21-May-2016 is a Saturday and 22-May-2016 is a Sunday, year-over-year prices for Monday 22-May-2017 are compared to Friday 20-May-2016.

```
TT = addBusinessCalendar(TT);  % Add NYSE business calendar
```

Compute the year-over-year returns and display the last few prices and corresponding returns.

```
returns = rollingreturns(TT, 'Period', calyears);
tail([TT returns])
```

```
       Time        Prices    Prices_Return_1y

    21-Dec-2018    217.66        0.18648
    24-Dec-2018    221.42        0.20882
    26-Dec-2018    224.81        0.21473
    27-Dec-2018    222.17        0.19897
    28-Dec-2018    224.63        0.19142
    31-Dec-2018    224.37        0.19206
```

Year-over-Year Returns from Monthly Prices with End-of-Month Dates

Economic data is often reported on the last day of each month or quarter. So end-of-month ambiguities can arise when computing period-over-period returns for periods that exceed the periodicity at which data is reported.

Simulate five years of daily prices and store the result in the timetable TT.

```
rng(200,'twister')
time = (datetime(2014,1,1):caldays:datetime(2018,12,31))';
price = 100 + 0.1*(0:numel(time) - 1)'.*cumsum(randn(numel(time),1)/100);
price = round(price*100)/100;         % Round prices to the nearest penny
TT = timetable(price,'RowTimes',time,'VariableNames',{'Prices'});
head(TT,10)
```

```
       Time        Prices
    ___________    ______

    01-Jan-2014       100
    02-Jan-2014       100
    03-Jan-2014       100
    04-Jan-2014       100
    05-Jan-2014    100.01
    06-Jan-2014    100.01
    07-Jan-2014    100.02
    08-Jan-2014    100.02
    09-Jan-2014    100.04
    10-Jan-2014    100.06
```

Create a new timetable by sampling TT on the last day of each month to mimic monthly reporting.

```
monthEndDates = dateshift(TT.Time(1):calmonths:TT.Time(end),'end','month');
TT = TT(monthEndDates,:);   % Sample TT at end-of-month dates
head(TT,10)

       Time        Prices

```

Display a subset of the dates and compare a direct calculation of the dates in previous months to those shifted to the end of the month in which the previous period occurs.

```
dates = timerange(datetime(2016,2,29),datetime(2017,2,28),'month');
[TT.Time(dates) (TT.Time(dates) - calyears) dateshift(TT.Time(dates) - calyears,'end','month')]

ans = 13x3 datetime
   29-Feb-2016   28-Feb-2015   28-Feb-2015
   31-Mar-2016   31-Mar-2015   31-Mar-2015
   30-Apr-2016   30-Apr-2015   30-Apr-2015
   31-May-2016   31-May-2015   31-May-2015
   30-Jun-2016   30-Jun-2015   30-Jun-2015
   31-Jul-2016   31-Jul-2015   31-Jul-2015
   31-Aug-2016   31-Aug-2015   31-Aug-2015
   30-Sep-2016   30-Sep-2015   30-Sep-2015
   31-Oct-2016   31-Oct-2015   31-Oct-2015
   30-Nov-2016   30-Nov-2015   30-Nov-2015
   31-Dec-2016   31-Dec-2015   31-Dec-2015
   31-Jan-2017   31-Jan-2016   31-Jan-2016
   28-Feb-2017   28-Feb-2016   29-Feb-2016
```

Examine these results and notice that the dates in the second and third columns of the last row differ. Specifically, when the current date in the first column is `28-Feb-2017` the dates in the second and third columns differ because 2016 is a leap year. More generally, the dates differ whenever the month of the previous period has more days than the current month for which returns are computed. In this example, end-of-months dates present the following ambiguity. When the current date of interest is `28-Feb-2017`, should subtracting one calendar year produce `28-Feb-2016` or `29-Feb-2016`?

The correct answer depends on the application, and both approaches are valid use cases. This problem is exacerbated, for example, when working with end-of-monthly price data and computing month-over-month returns. To address the end-of-month ambiguity, the `rollingreturns` function supports an `EndOfMonth` flag.

```
returns = rollingreturns(TT, 'Period', calyears, 'EndOfMonth', true);
```

The `EndOfMonth` flag ensures that the `rollingreturns` function uses the correct end-of-month date of each calendar month. In this example, the return on `28-Feb-2017` is correctly computed from the price reported `29-Feb-2016` rather than `28-Feb-2016`.

```

Input Arguments

TT — Input timetable of prices

timetable

Input timetable of prices, specified as a `timetable`. The timetable `TT` must satisfy the following conditions:

- All observations in `TT` must be associated with whole dates specified as datetimes with no `HH:MM:SS` time component (no time-of-day component).
- `TT` dates must be sorted in ascending order.
- `TT` must have no duplicate dates.
- Each variable in `TT` must contain either a single numeric vector or a numeric matrix of prices. For example, suppose `TT` contains three variables of daily prices.

```
   Time         Price1    Price2          Prices
___________     ______    ______    ________________
24-Dec-2018     221.42    442.84    221.42    442.84
25-Dec-2018     220.62    441.24    220.62    441.24
26-Dec-2018     224.81    449.62    224.81    449.62
27-Dec-2018     222.17    444.34    222.17    444.34
28-Dec-2018     224.63    449.26    224.63    449.26

```

Note To include business-calendar-awareness and account for nonbusiness days (for example, weekends, holidays, market closures), you must first use the `addBusinessCalendar` function to populate a custom property for the input `TT`. For example, to add business calendar logic to include only NYSE business days, you can use `TT = addBusinessCalendar(TT)`.

Data Types: `timetable`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `returns = rollingreturns(TT,'Period',calweeks(1),'EndOfMonth',true,'Method','continuous')`

`Period` — Period to compute period-over-period returns

`TT.Properties.TimeStep` (default) | scalar calendar duration

Period to compute period-over-period returns, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar calendar duration (for example, `caldays`, `calweeks`, or `calmonths`).

The default is the time step defined in `TT` (`TT.Properties.TimeStep`), but only when `TT.Properties.TimeStep` is not `NaN`. If `TT.Properties.TimeStep` is `NaN`, then `Period` is required.

Data Types: `double`

`EndOfMonth` — End-of-month flag indicates whether prices at current date are compared to last date of month for previous `Period`

`false` (default) | value of `true` or `false`

End-of-month flag indicates whether the prices at the current date are compared to last date of month for the previous `Period`, specified as the comma-separated pair consisting of `'EndOfMonth'` and a scalar logical value of `true` or `false`.

- If you set `EndOfMonth` to `true` (logical `1`), meaning that the current prices are compared to end-of-month prices of the previous `Period`.
- If you set `EndOfMonth` to `false` (logical `0`), meaning that the current prices are compared to prices recorded on the actual date of the previous `Period`.

Note The `EndOfMonth` flag is intended to address end-of-month date calculations when computing the dates of a previous `Period` one or more months in the past.

For example, suppose you have monthly prices reported at the end of each month and want to compute year-over-year returns (that is, `Period = calyears(1)`). When the current date of interest is `28-Feb-2017`, setting `EndOfMonth = true` (logical 1) ensures that returns computed for `28-Feb-2017` compare the prices on `28-Feb-2017` to those on `29-Feb-2016` rather than `28-Feb-2016`.

Similarly, suppose you have monthly prices reported at the end of each month and want to compute month-over-month returns (that is, `Period = calmonths(1)`). When the current date of interest is `30-Apr-2020`, setting `EndOfMonth = true` (logical 1) ensures that returns computed for `30-Apr-2020` compare the prices on `30-Apr-2020` to those on `31-Mar-2020` rather than `30-Mar-2020`.

Data Types: `logical`

`Method` — Method for computing `returns` from prices

`'simple'` (default) | character vector with value `'simple'`, `'continuous'`, or `'difference'`

Method for computing `returns` from prices, specified as the comma-separated pair consisting of `'Method'` and a scalar character vector.

- `'simple'` — Compute simple (proportional) returns: `R(t) = P(t)/P(t-period) - 1`.
- `'continuous'` — Compute continuous (logarithmic) returns: `R(t) = log(P(t)/P(t-period))`.
- `'difference'` — Compute differences (period-over-period changes): `R(t) = P(t) - P(t-period)`

Data Types: `char`

Output Arguments

`returns` — Period-over-period decimal returns or differences

timetable

Period-over-period decimal returns or differences, returned as a timetable of the same size and format as the input argument `TT`. The returns or differences in row *t* are associated with the *t*th date in `TT` and represent the return or difference of the *t*th price *P*(*t*) relative to the price in the previous period *P*(*t*-period). If the date in the previous period is not found in `TT`, then the result is `NaN` to indicate a missing value.

Variable names in the output append `_Return` or `_Difference` to the variable names in `TT` for returns and differences, respectively, followed by the period used in the period-over-period results. For example, if `TT` has a variable named `ABC` and week-over-week returns are computed for a `Period` of `calweeks(1)`, the corresponding output variable is named `ABC_Returns_1w`.

`rollingreturns` is an aggregation function in which the frequency at which prices are recorded must equal or exceed that at which `returns` or differences are computed. For example, daily prices can be used to compute daily, weekly, or monthly `returns`, but computing daily `returns` from weekly or monthly prices generally makes no sense.

Algorithms

Period-over-period results are computed for every date in `TT` as follows:

1. For each date *t* in TT, the date *t*-period is computed.

   - If date *t*-period is a business date, then this date is the date "one period ago"
   - If date *t*-period is not a business date, then each calendar day preceding *t*-period is examined repeatedly until a business date is found, at which point this date is the date "one period ago," or the preceding date occurs prior to the first date in TT, at which point no previous business date exists in TT.
2. If the date "one period ago" is found in TT, then the corresponding price *P*(*t*-period) is recorded and the return *R*(*t*) is computed. However, if the date "one period ago" is not found in TT, then the previous price *P*(*t*-period) is assumed missing (that is, an implicit NaN), and the return *R*(*t*) = NaN.
3. The previous steps are repeated until the date *t*-period precedes the first date found in TT, at which point the algorithm terminates.

simByMilstein

Simulate BM, GBM, CEV, HWV, SDEDDO, SDELD, SDEMRD sample paths by Milstein approximation

Syntax

```
[Paths,Times,Z] = simByMilstein(MDL,NPeriods)
[Paths,Times,Z] = simByMilstein( ___ ,Name=Value)
```

Description

[Paths,Times,Z] = simByMilstein(MDL,NPeriods) simulates NTrials sample paths of NVARS state variables driven by the BM, GBM, CEV, HWV, SDEDDO, SDELD, or SDEMRD process sources of risk over NPeriods consecutive observation periods, approximating continuous-time by the Milstein method.

simByMilstein provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as DeltaTimes approaches zero.

[Paths,Times,Z] = simByMilstein(___ ,Name=Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for MonteCarloMethod, QuasiSequence, and BrownianMotionMethod. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Quasi-Monte Carlo Simulation with Milstein Scheme Using GBM Model

This example shows how to use simByMilstein with a GBM model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead of pseudo random numbers.

Create a univariategbm object to represent the model: $dX_t = 0.25X_tdt + 0.3X_tdW_t$.

```
GBM_obj = gbm(0.25, 0.3)  % (B = Return, Sigma)
```

```
GBM_obj = 
   Class GBM: Generalized Geometric Brownian Motion
   ------------------------------------------------
     Dimensions: State = 1, Brownian = 1
   ------------------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
```

```
         Return: 0.25
          Sigma: 0.3
```

gbm objects display the parameter B as the more familiar Return.

Perform a quasi-Monte Carlo simulation by using simByMilstein with the optional name-value arguments for MonteCarloMethod, QuasiSequence, and BrownianMotionMethod.

```
[paths,time,z] = simByMilstein(GBM_obj,10,ntrials=4096,montecarlomethod="quasi",quasisequence="so
```

Input Arguments

MDL — Stochastic differential equation model

BM object | GBM object | CEV object | HWV object | SDEDDO object | SDELD object | SDEMRD object

Stochastic differential equation model, specified as a BM, GBM, CEV, HWV, SDEDDO, SDELD, or SDEMRD object. You can use the following to create a MDL object:

- bm
- gbm
- cev
- hwv
- sdeddo
- sdeld
- sdemrd

Data Types: object

NPeriods — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of NPeriods determines the number of rows of the simulated output series.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: [Paths,Times,Z] = simByMilstein(GBM_obj,NPeriods,DeltaTime=dt,Method="reflection")

Method — Method to handle negative values

'basic' (default) | character vector with values'basic', 'absorption', 'reflection', 'partial-truncation', 'full-truncation', or 'higham-mao' | string with values "basic", "absorption", "reflection", "partial-truncation", "full-truncation", or "higham-mao"

Method to handle negative values, specified as Method and a character vector or string with a supported value.

Note The `Method` argument is only supported when using a `CIR` object. For more information on creating a `CIR` object, see `cir`.

Data Types: `char` | `string`

`NTrials` — Simulated trials (sample paths) of `NPeriods` observations each

`1` (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as `NTrials` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations

`1` (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of `'DeltaTimes'` and a scalar or a `NPeriods`-by-`1` column vector.

`DeltaTime` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps within each time increment *dt* (specified as `DeltaTime`)

`1` (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as `DeltaTime`), specified as `NSteps` and a positive scalar integer.

The `simByMilestein` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps − 1` intermediate points. Although `simByMilstein` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`Antithetic` — Flag to indicate whether `simByMilstein` uses antithetic sampling to generate the Gaussian random variates

`False` (no antithetic sampling) (default) | logical with values `True` or `False`

Flag indicates whether `simByMilstein` uses antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes). This argument is specified as `Antithetic` and a scalar logical flag with a value of `True` or `False`.

When you specify `True`, `simByMilstein` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials `(1,3,5,...)` correspond to the primary Gaussian paths.
- Even trials `(2,4,6,...)` are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see `Z`), `simByMilstein` ignores the value of `Antithetic`.

Data Types: `logical`

Z — Direct specification of the dependent random noise process used to generate the Brownian motion vector
generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process used to generate the Brownian motion vector (Wiener process) that drives the simulation. This argument is specified as `Z` and a function or as an `(NPeriods □ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify `Z` as a function, it must return an `NBrowns`-by-`1` column vector, and you must call it with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function`

`StorePaths` — Flag that indicates how the output array `Paths` is stored and returned
`True` (default) | logical with values `True` or `False`

Flag that indicates how the output array `Paths` is stored and returned, specified as `StorePaths` and a scalar logical flag with a value of `True` or `False`.

If `StorePaths` is `True` (the default value) or is unspecified, `simByMilstein` returns `Paths` as a three-dimensional time series array.

If `StorePaths` is `False` (logical `0`), `simByMilstein` returns the `Paths` output array as an empty matrix.

Data Types: `logical`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes
`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as `MonteCarloMethod` and a string or character vector with one of the following values:

- `"standard"` — Monte Carlo using pseudo random numbers.
- `"quasi"` — Quasi-Monte Carlo using low-discrepancy sequences.
- `"randomized-quasi"` — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see `Z`), `simByMilstein` ignores the value of `MonteCarloMethod`.

Data Types: `string` | `char`

`QuasiSequence` — Low discrepancy sequence to drive the stochastic processes
`"sobol"` (default) | string with value `"sobol"` | character vector with value `'sobol'`

Low discrepancy sequence to drive the stochastic processes, specified as `QuasiSequence` and a string or character vector with one of the following values:

- `"sobol"` — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If `MonteCarloMethod` option is not specified or specified as`"standard"`, `QuasiSequence` is ignored.

If you specify an input noise process (see `Z`), `simByMilstein` ignores the value of `QuasiSequence`.

Data Types: `string` | `char`

`BrownianMotionMethod` — Brownian motion construction method
`"standard"` (default) | string with value `"brownian-bridge"` or `"principal-components"` | character vector with value `'brownian-bridge'` or `'principal-components'`

Brownian motion construction method, specified as `BrownianMotionMethod` and a string or character vector with one of the following values:

- `"standard"` — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- `"brownian-bridge"` — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- `"principal-components"` — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the `Z` input argument, `BrownianMotionMethod` is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the `MonteCarloMethod` using pseudo random numbers. However, the performance differs between the two when the `MonteCarloMethod` option `"quasi"` is introduced, with faster convergence seen for `"brownian-bridge"` construction option and the fastest convergence when using the `"principal-components"` construction option.

Data Types: `string` | `char`

`Processes` — Sequence of end-of-period processes or state vector adjustments
`simByEuler` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments of the form, specified as `Processes` and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simByMilstein` function runs processing functions at each interpolation time. They must accept the current interpolation time t, and the current state vector X_t, and return a state vector that may be an adjustment to the input state.

If you specify more than one processing function, `simByMilstein` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as a `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When the input flag `StorePaths` = `False`, `simByEuler` returns `Paths` as an empty matrix.

`Times` — Observation times associated with the simulated paths

column vector

Observation times associated with the simulated paths, returned as a `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates used to generate the Brownian motion vector

array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as a `(NPeriods □ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional time series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

This function simulates any vector-valued SDE of the form

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- X is an *NVars*-by-1 state vector of process variables (for example, short rates or equity prices) to simulate.
- W is an *NBrowns*-by-1 Brownian motion vector.
- F is an *NVars*-by-1 vector-valued drift-rate function.
- G is an *NVars*-by-*NBrowns* matrix-valued diffusion-rate function.

`simByEuler` simulates `NTrials` sample paths of `NVars` correlated state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, using the Euler approach to approximate continuous-time stochastic processes.

- This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as `DeltaTime` approaches zero.
- The input argument `Z` allows you to directly specify the noise-generation process. This process takes precedence over the `Correlation` parameter of the `sde` object and the value of the `Antithetic` input flag. If you do not specify a value for `Z`, `simByEuler` generates correlated Gaussian variates, with or without antithetic sampling as requested.
- The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simByEuler` tests the state vector X_t for an all-`NaN` condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be `NaN`. This test enables a user-defined `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

simByMilstein

Simulate CIR sample paths by Milstein approximation

Syntax

```
[Paths,Times,Z] = simByMilstein(MDL,NPeriods)
[Paths,Times,Z] = simByMilstein( ___ ,Name=Value)
```

Description

[Paths,Times,Z] = simByMilstein(MDL,NPeriods) simulates NTrials sample paths of NVARS state variables driven by the CIR process sources of risk over NPeriods consecutive observation periods, approximating continuous-time Cox-Ingersoll-Ross (CIR) by the Milstein method.

simByMilstein provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as DeltaTimes approaches zero.

[Paths,Times,Z] = simByMilstein(___ ,Name=Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for MonteCarloMethod, QuasiSequence, and BrownianMotionMethod. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Quasi-Monte Carlo Simulation with simByMilstein Scheme Using CIR Model

This example shows how to use simByMilstein with a CIR model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead of pseudo random numbers.

The Cox-Ingersoll-Ross (CIR) short rate class derives directly from SDE with mean-reverting drift (SDEMRD): $dX_t = S(t)[L(t) - X_t]dt + D(t, X_t^{\frac{1}{2}})V(t)dW$

where D is a diagonal matrix whose elements are the square root of the corresponding element of the state vector.

Create a cir object to represent the model: $dX_t = 0.2(0.1 - X_t)dt + 0.05X_t^{\frac{1}{2}}dW$.

```
cir_obj = cir(0.2, 0.1, 0.05)  % (Speed, Level, Sigma)
```

```
cir_obj = 
   Class CIR: Cox-Ingersoll-Ross
   ----------------------------------------
```

```
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 1
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.05
          Level: 0.1
          Speed: 0.2
```

Define the quasi-Monte Carlo simulation using the optional name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`.

```
[paths,time,z] = simByMilstein(cir_obj,10,ntrials=4096,method="basic",montecarlomethod="quasi",q
```

Input Arguments

`MDL` — Stochastic differential equation model

CIR object

Stochastic differential equation model, specified as a `cir` object. You can create a `bates` object using `cir`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `[Paths,Times,Z] = simByMilstein(CIR_obj,NPeriods,DeltaTime=dt,Method="reflection")`

`Method` — Method to handle negative values

`'basic'` (default) | character vector with values`'basic'`, `'absorption'`, `'reflection'`, `'partialtruncation'`, `'fulltruncation'`, or `'higham-mao'` | string with values `"basic"`, `"absorption"`, `"reflection"`, `"partialtruncation"`, `"fulltruncation"`, or `"higham-mao"`

Method to handle negative values, specified as `Method` and a character vector or string with a supported value.

Note The `Method` argument is only supported when using a `CIR` object. For more information on creating a `CIR` object, see `cir`.

Data Types: char | string

NTrials — Simulated trials (sample paths) of NPeriods observations each
1 (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of NPeriods observations each, specified as NTrials and a positive scalar integer.

Data Types: double

DeltaTimes — Positive time increments between observations
1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTimes' and a scalar or a NPeriods-by-1 column vector.

DeltaTime represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

NSteps — Number of intermediate time steps within each time increment *dt* (specified as DeltaTime)
1 (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as DeltaTime), specified as NSteps and a positive scalar integer.

The simByMilestein function partitions each time increment *dt* into NSteps subintervals of length *dt*/NSteps, and refines the simulation by evaluating the simulated state vector at NSteps - 1 intermediate points. Although simByMilstein does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

Antithetic — Flag to indicate whether simByMilstein uses antithetic sampling to generate the Gaussian random variates
False (no antithetic sampling) (default) | logical with values True or False

Flag indicates whether simByMilstein uses antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes). This argument is specified as Antithetic and a scalar logical flag with a value of True or False.

When you specify True, simByMilstein performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials (1,3,5,...) correspond to the primary Gaussian paths.
- Even trials (2,4,6,...) are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see Z), simByMilstein ignores the value of Antithetic.

Data Types: logical

Z — Direct specification of the dependent random noise process used to generate the Brownian motion vector
generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process used to generate the Brownian motion vector (Wiener process) that drives the simulation. This argument is specified as `Z` and a function or as an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify `Z` as a function, it must return an `NBrowns`-by-`1` column vector, and you must call it with two inputs:

- A real-valued scalar observation time *t*.
- An `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function`

`StorePaths` — Flag that indicates how the output array `Paths` is stored and returned
`True` (default) | logical with values `True` or `False`

Flag that indicates how the output array `Paths` is stored and returned, specified as `StorePaths` and a scalar logical flag with a value of `True` or `False`.

If `StorePaths` is `True` (the default value) or is unspecified, `simByMilstein` returns `Paths` as a three-dimensional time series array.

If `StorePaths` is `False` (logical `0`), `simByMilstein` returns the `Paths` output array as an empty matrix.

Data Types: `logical`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes
`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as `MonteCarloMethod` and a string or character vector with one of the following values:

- `"standard"` — Monte Carlo using pseudo random numbers.
- `"quasi"` — Quasi-Monte Carlo using low-discrepancy sequences.
- `"randomized-quasi"` — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see `Z`), `simByMilstein` ignores the value of `MonteCarloMethod`.

Data Types: `string` | `char`

`QuasiSequence` — Low discrepancy sequence to drive the stochastic processes
`"sobol"` (default) | string with value `"sobol"` | character vector with value `'sobol'`

Low discrepancy sequence to drive the stochastic processes, specified as `QuasiSequence` and a string or character vector with one of the following values:

- `"sobol"` — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If `MonteCarloMethod` option is not specified or specified as`"standard"`, `QuasiSequence` is ignored.

If you specify an input noise process (see `Z`), `simByMilstein` ignores the value of `QuasiSequence`.

Data Types: `string` | `char`

`BrownianMotionMethod` — Brownian motion construction method
`"standard"` (default) | string with value `"brownian-bridge"` or `"principal-components"` | character vector with value `'brownian-bridge'` or `'principal-components'`

Brownian motion construction method, specified as `BrownianMotionMethod` and a string or character vector with one of the following values:

- `"standard"` — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- `"brownian-bridge"` — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- `"principal-components"` — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the `Z` input argument, `BrownianMotionMethod` is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the `MonteCarloMethod` using pseudo random numbers. However, the performance differs between the two when the `MonteCarloMethod` option `"quasi"` is introduced, with faster convergence seen for `"brownian-bridge"` construction option and the fastest convergence when using the `"principal-components"` construction option.

Data Types: `string` | `char`

`Processes` — Sequence of end-of-period processes or state vector adjustments
`simByEuler` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments of the form, specified as `Processes` and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simByMilstein` function runs processing functions at each interpolation time. They must accept the current interpolation time t, and the current state vector X_t, and return a state vector that may be an adjustment to the input state.

If you specify more than one processing function, `simByMilstein` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as a `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When the input flag `StorePaths` = `False`, `simByEuler` returns `Paths` as an empty matrix.

`Times` — Observation times associated with the simulated paths

column vector

Observation times associated with the simulated paths, returned as a `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates used to generate the Brownian motion vector

array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as a `(NPeriods  NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional time series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another of the same expected value, but smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent of any other pair, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

This function simulates any vector-valued SDE of the form

$$dX_t = F(t, X_t)dt + G(t, X_t)dW_t$$

where:

- X is an *NVars*-by-1 state vector of process variables (for example, short rates or equity prices) to simulate.
- W is an *NBrowns*-by-1 Brownian motion vector.
- F is an *NVars*-by-1 vector-valued drift-rate function.
- G is an *NVars*-by-*NBrowns* matrix-valued diffusion-rate function.

`simByEuler` simulates `NTrials` sample paths of `NVars` correlated state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, using the Euler approach to approximate continuous-time stochastic processes.

- This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as `DeltaTime` approaches zero.
- The input argument `Z` allows you to directly specify the noise-generation process. This process takes precedence over the `Correlation` parameter of the `sde` object and the value of the `Antithetic` input flag. If you do not specify a value for `Z`, `simByEuler` generates correlated Gaussian variates, with or without antithetic sampling as requested.
- The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simByEuler` tests the state vector X_t for an all-`NaN` condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be `NaN`. This test enables a user-defined `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

simByMilstein

Simulate Heston sample paths by Milstein approximation

Syntax

```
[Paths,Times,Z] = simByMilstein(MDL,NPeriods)
[Paths,Times,Z] = simByMilstein( ___ ,Name=Value)
```

Description

[Paths,Times,Z] = simByMilstein(MDL,NPeriods) simulates NTrials sample paths of Heston bivariate models driven by two NBrowns Brownian motion sources of risk approximating continuous-time stochastic processes by Milstein scheme.

simByMilstein provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as DeltaTimes approaches zero.

[Paths,Times,Z] = simByMilstein(___ ,Name=Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for MonteCarloMethod, QuasiSequence, and BrownianMotionMethod. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Quasi-Monte Carlo Simulation with Milstein Scheme Using Heston Model

This example shows how to use simByMilstein with a Heston model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Define the parameters for the heston object.

```
Return = 0.03;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;

AssetPrice = 80;
V0 = 0.04;
Rho = -0.7;
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];
```

Create a heston object.

```
Heston = heston(Return,Speed,Level,Volatility,startstate=StartState,correlation=Correlation)
Heston = 
   Class HESTON: Heston Bivariate Stochastic Volatility
   ----------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   ----------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
    Correlation: 2x2 double array
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.03
          Speed: 1
          Level: 0.05
     Volatility: 0.2
```

Perform a quasi-Monte Carlo simulation by using `simByMilstein` with the optional name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`.

```
[paths,time] = simByMilstein(Heston,10,ntrials=4096,MonteCarloMethod="quasi",QuasiSequence="sobo
```

Input Arguments

`MDL` — Stochastic differential equation model

`Heston` object

Stochastic differential equation model, specified as a `heston` object. You can create a `heston` object using `heston`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `[Paths,Times,Z] = simByMilstein(Heston_obj,NPeriods,NTrials=10,DeltaTimes=dt)`

`NTrials` — Simulated trials (sample paths)

`1` (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as `NTrials` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations

`1` (default) | scalar | column vector

Positive time increments between observations, specified as `DeltaTimes` and a scalar or an `NPeriods`-by-`1` column vector.

`DeltaTimes` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps within each time increment *dt*

`1` (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as `DeltaTimes`), specified as `NSteps` and a positive scalar integer.

The `simByMilstein` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps − 1` intermediate points. Although `simByMilstein` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`Antithetic` — Flag to use antithetic sampling to generate the Gaussian random variates

`false` (no antithetic sampling) (default) | logical with values `true` or `false`

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as `Antithetic` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

When you specify `true`, `simByEuler` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials `(1,3,5,...)` correspond to the primary Gaussian paths.
- Even trials `(2,4,6,...)` are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see `Z`), `simByMilstein` ignores the value of `Antithetic`.

Data Types: `logical`

`Z` — Direct specification of the dependent random noise process for generating Brownian motion vector

generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as `Z` and a function or as an `(NPeriods □ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify Z as a function, it must return an NBrowns-by-1 column vector, and you must call it with two inputs:

- A real-valued scalar observation time t
- An NVars-by-1 state vector X_t

Data Types: double | function

StorePaths — Flag that indicates how Paths is stored and returned
true (default) | logical with values true or false

Flag that indicates how the output array Paths is stored and returned, specified as StorePaths and a scalar numeric or logical 1 (true) or 0 (false).

If StorePaths is true (the default value) or is unspecified, simByMilstein returns Paths as a three-dimensional time-series array.

If StorePaths is false (logical 0), simByMilstein returns Paths as an empty matrix.

Data Types: logical

MonteCarloMethod — Monte Carlo method to simulate stochastic processes
"standard" (default) | string with values "standard", "quasi", or "randomized-quasi" | character vector with values 'standard', 'quasi', or 'randomized-quasi'

Monte Carlo method to simulate stochastic processes, specified as MonteCarloMethod and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see Z), simByMilstein ignores the value of MonteCarloMethod.

Data Types: string | char

QuasiSequence — Low discrepancy sequence to drive the stochastic processes
"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as QuasiSequence and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If MonteCarloMethod option is not specified or specified as"standard", QuasiSequence is ignored.

If you specify an input noise process (see Z), simByMilstein ignores the value of QuasiSequence.

Data Types: `string` | `char`

`BrownianMotionMethod` — Brownian motion construction method

`"standard"` (default) | string with value `"brownian-bridge"` or `"principal-components"` | character vector with value `'brownian-bridge'` or `'principal-components'`

Brownian motion construction method, specified as `BrownianMotionMethod` and a string or character vector with one of the following values:

- `"standard"` — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- `"brownian-bridge"` — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- `"principal-components"` — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the `Z` input argument, `BrownianMotionMethod` is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the `MonteCarloMethod` using pseudo random numbers. However, the performance differs between the two when the `MonteCarloMethod` option `"quasi"` is introduced, with faster convergence seen for `"brownian-bridge"` construction option and the fastest convergence when using the `"principal-components"` construction option.

Data Types: `string` | `char`

`Processes` — Sequence of end-of-period processes or state vector adjustments

`simByMilstein` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as `Processes` and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simByMilstein` function runs processing functions at each interpolation time. The functions must accept the current interpolation time t, and the current state vector X_t and return a state vector that can be an adjustment to the input state.

If you specify more than one processing function, `simByMilstein` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simByMilstein` tests the state vector X_t for an all-`NaN` condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be `NaN`. This test enables you to define a `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as a `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When `StorePaths` is set to `false`, `simByMilstein` returns `Paths` as an empty matrix.

`Times` — Observation times associated with simulated paths

column vector

Observation times associated with the simulated paths, returned as an `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates for generating Brownian motion vector

array

Dependent random variates for generating the Brownian motion vector (Wiener processes) that drive the simulation, returned as an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional time-series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another that has the same expected value but a smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent other pairs, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

Heston models are bivariate composite models. Each Heston model consists of two coupled univariate models:

- A geometric Brownian motion (`gbm`) model with a stochastic volatility function.

  $$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.

- A Cox-Ingersoll-Ross (`cir`) square root diffusion model.

  $$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

  This model describes the evolution of the variance rate of the coupled GBM price process.

This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as `DeltaTimes` approaches zero.

simByMilstein

Simulate `Bates` sample paths by Milstein approximation

Syntax

```
[Paths,Times,Z,N] = simByMilstein(MDL,NPeriods)
[Paths,Times,Z,N] = simByMilstein( ___ ,Name=Value)
```

Description

`[Paths,Times,Z,N] = simByMilstein(MDL,NPeriods)` simulates `NTrials` sample paths of Bates or Heston bivariate models driven by `NBrowns` Brownian motion sources of risk and `NJUMPS` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods, approximating continuous-time stochastic processes by Milstein scheme.

`simByMilstein` provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion; the discrete-time process approaches the true continuous-time process only in the limit as `DeltaTimes` approaches zero.

`[Paths,Times,Z,N] = simByMilstein( ___ ,Name=Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Quasi-Monte Carlo Simulation with Milstein Scheme Using Bates Model

This example shows how to use `simByMilstein` with a Bates model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead of pseudo random numbers.

Define the parameters for the `bates` object.

```
AssetPrice = 80;
Return = 0.03;
JumpMean = 0.02;
JumpVol = 0.08;
JumpFreq = 0.1;

V0 = 0.04;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;
Rho = -0.7;
```

```
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];
```

Create a `bates` object.

```
Bates = bates(Return, Speed, Level, Volatility, ...
                JumpFreq, JumpMean, JumpVol,startstate=StartState,correlation=Correlation)
```

```
Bates =
   Class BATES: Bates Bivariate Stochastic Volatility
   --------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   --------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
    Correlation: 2x2 double array
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.03
          Speed: 1
          Level: 0.05
     Volatility: 0.2
       JumpFreq: 0.1
       JumpMean: 0.02
        JumpVol: 0.08
```

Perform a quasi-Monte Carlo simulation by using `simByMilstein` with the optional name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`.

```
[paths,time,z,n] = simByMilstein(Bates,10,ntrials=4096,montecarlomethod="quasi",quasisequence="so
```

Input Arguments

`MDL` — Stochastic differential equation model

`Bates` object

Stochastic differential equation model, specified as a `bates` object. You can create a `bates` object using `bates`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `[Paths,Times,Z,N] = simByMilstein(Bates_obj,NPeriods,NTrials=10,DeltaTimes=dt)`

`NTrials` — Simulated trials (sample paths)

`1` (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as `NTrials` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations

`1` (default) | scalar | column vector

Positive time increments between observations, specified as `DeltaTimes` and a scalar or an `NPeriods`-by-`1` column vector.

`DeltaTimes` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps within each time increment *dt*

`1` (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as `DeltaTimes`), specified as `NSteps` and a positive scalar integer.

The `simByMilstein` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps − 1` intermediate points. Although `simByMilstein` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`Antithetic` — Flag to use antithetic sampling to generate the Gaussian random variates

`false` (no antithetic sampling) (default) | logical with values `true` or `false`

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as `Antithetic` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

When you specify `true`, `simByEuler` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials `(1,3,5,...)` correspond to the primary Gaussian paths.
- Even trials `(2,4,6,...)` are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see `Z`), `simByMilstein` ignores the value of `Antithetic`.

Data Types: `logical`

Z — Direct specification of the dependent random noise process for generating Brownian motion vector

generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as `Z` and a function or as an `(NPeriods  NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify `Z` as a function, it must return an `NBrowns`-by-`1` column vector, and you must call it with two inputs:

- A real-valued scalar observation time t
- An `NVars`-by-`1` state vector X_t

Data Types: `double` | `function`

N — Dependent random counting process for generating number of jumps

random numbers from Poisson distribution with parameter `JumpFreq` from a `bates` object (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as `N` and a function or an (`NPeriods` `NSteps`) -by-`NJumps`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify a function, `N` must return an `NJumps`-by-`1` column vector, and you must call it with two inputs: a real-valued scalar observation time t followed by an `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function`

`StorePaths` — Flag that indicates how `Paths` is stored and returned

`true` (default) | logical with values `true` or `false`

Flag that indicates how the output array `Paths` is stored and returned, specified as `StorePaths` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

If `StorePaths` is `true` (the default value) or is unspecified, `simByMilstein` returns `Paths` as a three-dimensional time-series array.

If `StorePaths` is `false` (logical `0`), `simByMilstein` returns `Paths` as an empty matrix.

Data Types: `logical`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes

`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as `MonteCarloMethod` and a string or character vector with one of the following values:

- "standard" — Monte Carlo using pseudo random numbers.
- "quasi" — Quasi-Monte Carlo using low-discrepancy sequences.
- "randomized-quasi" — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see Z), simByMilstein ignores the value of MonteCarloMethod.

Data Types: string | char

QuasiSequence — Low discrepancy sequence to drive the stochastic processes
"sobol" (default) | string with value "sobol" | character vector with value 'sobol'

Low discrepancy sequence to drive the stochastic processes, specified as QuasiSequence and a string or character vector with one of the following values:

- "sobol" — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If MonteCarloMethod option is not specified or specified as"standard", QuasiSequence is ignored.

If you specify an input noise process (see Z), simByMilstein ignores the value of QuasiSequence.

Data Types: string | char

BrownianMotionMethod — Brownian motion construction method
"standard" (default) | string with value "brownian-bridge" or "principal-components" | character vector with value 'brownian-bridge' or 'principal-components'

Brownian motion construction method, specified as BrownianMotionMethod and a string or character vector with one of the following values:

- "standard" — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- "brownian-bridge" — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- "principal-components" — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the Z input argument, BrownianMotionMethod is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the MonteCarloMethod using pseudo random numbers. However, the performance differs between the two when the `MonteCarloMethod` option `"quasi"` is introduced, with faster convergence seen for `"brownian-bridge"` construction option and the fastest convergence when using the `"principal-components"` construction option.

Data Types: `string` | `char`

`Processes` — Sequence of end-of-period processes or state vector adjustments
`simByMilstein` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as `Processes` and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The `simByMilstein` function runs processing functions at each interpolation time. The functions must accept the current interpolation time t, and the current state vector X_t and return a state vector that can be an adjustment to the input state.

If you specify more than one processing function, `simByMilstein` invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

The end-of-period `Processes` argument allows you to terminate a given trial early. At the end of each time step, `simByMilstein` tests the state vector X_t for an all-`NaN` condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be `NaN`. This test enables you to define a `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables
array

Simulated paths of correlated state variables, returned as a `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When `StorePaths` is set to `false`, `simByMilstein` returns `Paths` as an empty matrix.

`Times` — Observation times associated with simulated paths
column vector

Observation times associated with the simulated paths, returned as an `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates for generating Brownian motion vector
array

Dependent random variates for generating the Brownian motion vector (Wiener processes) that drive the simulation, returned as an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional time-series array.

`N` — Dependent random variates for generating jump counting process vector

array

Dependent random variates used to generate the jump counting process vector, returned as an `(NPeriods  NSteps)`-by-`NJumps`-by-`NTrials` three-dimensional time series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another that has the same expected value but a smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent other pairs, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

Bates models are bivariate composite models. Each Bates model consists of two coupled univariate models.

- One model is a geometric Brownian motion (`gbm`) model with a stochastic volatility function and jumps.

  $$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t} + Y(t)X_{1t}dN_t$$

  This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.
- The other model is a Cox-Ingersoll-Ross (`cir`) square root diffusion model.

  $$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

  This model describes the evolution of the variance rate of the coupled Bates price process.

This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as `DeltaTimes` approaches zero.

simByMilstein

Simulate `Merton` sample paths by Milstein approximation

Syntax

```
[Paths,Times,Z,N] = simByMilstein(MDL,NPeriods)
[Paths,Times,Z,N] = simByMilstein(___,Name=Value)
```

Description

`[Paths,Times,Z,N] = simByMilstein(MDL,NPeriods)` simulates `NTrials` sample paths of `NVars` correlated state variables driven by `NBrowns` Brownian motion sources of risk and `NJumps` compound Poisson processes representing the arrivals of important events over `NPeriods` consecutive observation periods. The simulation approximates the continuous-time Merton jump diffusion process by the Euler approach.

`[Paths,Times,Z,N] = simByMilstein(___,Name=Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Quasi-Monte Carlo Simulation with Milstein Scheme Using Merton Model

This example shows how to use `simByMilstein` with a Merton model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Define the parameters for the `merton` object.

```
AssetPrice = 80;
Return = 0.03;
Sigma = 0.16;
JumpMean = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

Create a `merton` object.

```
mertonObj = merton(Return,Sigma,JumpFreq,JumpMean,JumpVol,StartState=AssetPrice)
```

```
mertonObj = 
   Class MERTON: Merton Jump Diffusion
   ----------------------------------------
     Dimensions: State = 1, Brownian = 1
   ----------------------------------------
      StartTime: 0
     StartState: 80
    Correlation: 1
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
          Sigma: 0.16
         Return: 0.03
       JumpFreq: 2
       JumpMean: 0.02
        JumpVol: 0.08
```

Perform a quasi-Monte Carlo simulation by using `simByMilstein` with the optional name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`.

```
[paths,times] = simByMilstein(mertonObj,10,Ntrials=4096,MonteCarloMethod="quasi",QuasiSequence="
```

Input Arguments

`MDL` — Stochastic differential equation model

`Merton` object

Stochastic differential equation model, specified as a `merton` object. You can create a `merton` object using `merton`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `[Paths,Times,Z,N] = simByMilstein(Merton_obj,NPeriods,NTrials=1000,DeltaTimes=dt,NSteps=10)`

`NTrials` — Simulated trials (sample paths)

`1` (single path of correlated state variables) (default) | positive scalar integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of `'NTrials'` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations

`1` (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of `'DeltaTimes'` and a scalar or a `NPeriods`-by-`1` column vector.

`DeltaTimes` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps within each time increment
`1` (indicating no intermediate evaluation) (default) | positive scalar integer

Number of intermediate time steps within each time increment *dt* (specified as `DeltaTimes`), specified as the comma-separated pair consisting of `'NSteps'` and a positive scalar integer.

The `simByEuler` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps - 1` intermediate points. Although `simByEuler` does not report the output state vector at these intermediate points, the refinement improves accuracy by allowing the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`Antithetic` — Flag to use antithetic sampling to generate the Gaussian random variates
`false` (no antithetic sampling) (default) | logical with values `true` or `false`

Flag to use antithetic sampling to generate the Gaussian random variates that drive the Brownian motion vector (Wiener processes), specified as the comma-separated pair consisting of `'Antithetic'` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

When you specify `true`, `simByEuler` performs sampling such that all primary and antithetic paths are simulated and stored in successive matching pairs:

- Odd trials `(1,3,5,...)` correspond to the primary Gaussian paths.
- Even trials `(2,4,6,...)` are the matching antithetic paths of each pair derived by negating the Gaussian draws of the corresponding primary (odd) trial.

Note If you specify an input noise process (see `Z`), `simByEuler` ignores the value of `Antithetic`.

Data Types: `logical`

`Z` — Direct specification of the dependent random noise process for generating Brownian motion vector
generates correlated Gaussian variates based on the `Correlation` member of the `SDE` object (default) | function | three-dimensional array of dependent random variates

Direct specification of the dependent random noise process for generating the Brownian motion vector (Wiener process) that drives the simulation, specified as the comma-separated pair consisting of `'Z'` and a function or as an `(NPeriods ∗ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional array of dependent random variates.

Note If you specify `Z` as a function, it must return an `NBrowns`-by-`1` column vector, and you must call it with two inputs:

- A real-valued scalar observation time *t*
- An `NVars`-by-`1` state vector X_t

Data Types: `double` | `function`

`N` — Dependent random counting process for generating number of jumps
random numbers from Poisson distribution with parameter `JumpFreq` from `merton` object (default) | three-dimensional array | function

Dependent random counting process for generating the number of jumps, specified as the comma-separated pair consisting of `'N'` and a function or an (`NPeriods` □ `NSteps`) -by-`NJumps`-by-`NTrials` three-dimensional array of dependent random variates.

If you specify a function, `N` must return an `NJumps`-by-`1` column vector, and you must call it with two inputs: a real-valued scalar observation time *t* followed by an `NVars`-by-`1` state vector X_t.

Data Types: `double` | `function`

`StorePaths` — Flag that indicates how `Paths` is stored and returned
`true` (default) | logical with values `true` or `false`

Flag that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of `'StorePaths'` and a scalar numeric or logical `1` (`true`) or `0` (`false`).

If `StorePaths` is `true` (the default value) or is unspecified, `simByEuler` returns `Paths` as a three-dimensional time series array.

If `StorePaths` is `false` (logical `0`), `simByEuler` returns `Paths` as an empty matrix.

Data Types: `logical`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes
`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of `'MonteCarloMethod'` and a string or character vector with one of the following values:

- `"standard"` — Monte Carlo using pseudo random numbers.
- `"quasi"` — Quasi-Monte Carlo using low-discrepancy sequences.
- `"randomized-quasi"` — Randomized quasi-Monte Carlo.

Note If you specify an input noise process (see `Z` and `N`), `simByEuler` ignores the value of `MonteCarloMethod`.

Data Types: `string` | `char`

`QuasiSequence` — Low discrepancy sequence to drive the stochastic processes
`"sobol"` (default) | string with value `"sobol"` | character vector with value `'sobol'`

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of `'QuasiSequence'` and a string or character vector with one of the following values:

- `"sobol"` — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If MonteCarloMethod option is not specified or specified as"standard", QuasiSequence is ignored.

Data Types: string | char

BrownianMotionMethod — Brownian motion construction method
"standard" (default) | string with value "brownian-bridge" or "principal-components" | character vector with value 'brownian-bridge' or 'principal-components'

Brownian motion construction method, specified as the comma-separated pair consisting of 'BrownianMotionMethod' and a string or character vector with one of the following values:

- "standard" — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- "brownian-bridge" — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- "principal-components" — The Brownian motion path is calculated by minimizing the approximation error.

Note If an input noise process is specified using the Z input argument, BrownianMotionMethod is ignored.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the MonteCarloMethod using pseudo random numbers. However, the performance differs between the two when the MonteCarloMethod option "quasi" is introduced, with faster convergence seen for "brownian-bridge" construction option and the fastest convergence when using the "principal-components" construction option.

Data Types: string | char

Processes — Sequence of end-of-period processes or state vector adjustments
simByEuler makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

The simByEuler function runs processing functions at each interpolation time. The functions must accept the current interpolation time t, and the current state vector X_t and return a state vector that can be an adjustment to the input state.

If you specify more than one processing function, simByEuler invokes the functions in the order in which they appear in the cell array. You can use this argument to specify boundary conditions, prevent negative prices, accumulate statistics, plot graphs, and more.

The end-of-period Processes argument allows you to terminate a given trial early. At the end of each time step, simByEuler tests the state vector X_t for an all-NaN condition. Thus, to signal an early termination of a given trial, all elements of the state vector X_t must be `NaN`. This test enables you to define a `Processes` function to signal early termination of a trial, and offers significant performance benefits in some situations (for example, pricing down-and-out barrier options).

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as an `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When `StorePaths` is set to `false`, `simByEuler` returns `Paths` as an empty matrix.

`Times` — Observation times associated with simulated paths

column vector

Observation times associated with the simulated paths, returned as an `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates for generating Brownian motion vector

array

Dependent random variates used to generate the Brownian motion vector (Wiener processes) that drive the simulation, returned as an `(NPeriods ⨉ NSteps)`-by-`NBrowns`-by-`NTrials` three-dimensional time-series array.

`N` — Dependent random variates used for generating jump counting process vector

array

Dependent random variates for generating the jump counting process vector, returned as an `(NPeriods ⨉ NSteps)`-by-`NJumps`-by-`NTrials` three-dimensional time-series array.

More About

Antithetic Sampling

Simulation methods allow you to specify a popular *variance reduction* technique called *antithetic sampling*.

This technique attempts to replace one sequence of random observations with another that has the same expected value but a smaller variance. In a typical Monte Carlo simulation, each sample path is independent and represents an independent trial. However, antithetic sampling generates sample paths in pairs. The first path of the pair is referred to as the *primary path*, and the second as the *antithetic path*. Any given pair is independent other pairs, but the two paths within each pair are highly correlated. Antithetic sampling literature often recommends averaging the discounted payoffs of each pair, effectively halving the number of Monte Carlo trials.

This technique attempts to reduce variance by inducing negative dependence between paired input samples, ideally resulting in negative dependence between paired output samples. The greater the extent of negative dependence, the more effective antithetic sampling is.

Algorithms

This function simulates any vector-valued SDE of the following form:

$$dX_t = B(t, X_t)X_t dt + D(t, X_t)V(t, x_t)dW_t + Y(t, X_t, N_t)X_t dN_t$$

Here:

- X_t is an `NVars`-by-`1` state vector of process variables.
- $B(t,X_t)$ is an `NVars`-by-`NVars` matrix of generalized expected instantaneous rates of return.
- $D(t,X_t)$ is an `NVars`-by-`NVars` diagonal matrix in which each element along the main diagonal is the corresponding element of the state vector.
- $V(t,X_t)$ is an `NVars`-by-`NVars` matrix of instantaneous volatility rates.
- dW_t is an `NBrowns`-by-`1` Brownian motion vector.
- $Y(t,X_t,N_t)$ is an `NVars`-by-`NJumps` matrix-valued jump size function.
- dN_t is an `NJumps`-by-`1` counting process vector.

`simByEuler` simulates `NTrials` sample paths of `NVars` correlated state variables driven by `NBrowns` Brownian motion sources of risk over `NPeriods` consecutive observation periods, using the Euler approach to approximate continuous-time stochastic processes.

This simulation engine provides a discrete-time approximation of the underlying generalized continuous-time process. The simulation is derived directly from the stochastic differential equation of motion. Thus, the discrete-time process approaches the true continuous-time process only as `DeltaTimes` approaches zero.

simByTransition

Simulate `Bates` sample paths with transition density

Syntax

```
[Paths,Times] = simByTransition(MDL,NPeriods)
[Paths,Times] = simByTransition( ___ ,Name,Value)
```

Description

`[Paths,Times] = simByTransition(MDL,NPeriods)` simulates `NTrials` of Bates bivariate models driven by two Brownian motion sources of risk and one compound Poisson process representing the arrivals of important events over `NPeriods` consecutive observation periods. `simByTransition` approximates continuous-time stochastic processes by the transition density.

`[Paths,Times] = simByTransition( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`. For more information, see "Quasi-Monte Carlo Simulation" on page 14-62.

Examples

Use `simByTransition` with bates Object

Simulate Bates sample paths with transition density.

Define the parameters for the `bates` object.

```
AssetPrice = 80;
Return = 0.03;
JumpMean = 0.02;
JumpVol = 0.08;
JumpFreq = 0.1;
V0 = 0.04;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;
Rho = -0.7;
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];
```

Create a `bates` object.

```
batesObj = bates(Return, Speed, Level, Volatility,...
                JumpFreq, JumpMean, JumpVol,'startstate',StartState,...
                'correlation',Correlation)
```

```
batesObj = 
   Class BATES: Bates Bivariate Stochastic Volatility
```

```
  --------------------------------------------------
    Dimensions: State = 2, Brownian = 2
  --------------------------------------------------
     StartTime: 0
    StartState: 2x1 double array
   Correlation: 2x2 double array
         Drift: drift rate function F(t,X(t))
     Diffusion: diffusion rate function G(t,X(t))
    Simulation: simulation method/function simByEuler
        Return: 0.03
         Speed: 1
         Level: 0.05
    Volatility: 0.2
      JumpFreq: 0.1
      JumpMean: 0.02
       JumpVol: 0.08
```

Define the simulation parameters.

```
nPeriods = 5;   % Simulate sample paths over the next five years
Paths = simByTransition(batesObj,nPeriods);
Paths
```

```
Paths = 6×2

   80.0000    0.0400
   99.5724    0.0201
  124.2066    0.0176
   56.5051    0.1806
   80.4545    0.1732
   94.7887    0.1169
```

Quasi-Monte Carlo Simulation Using Bates Model

This example shows how to use `simByTransition` with a Bates model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Define the parameters for the `bates` object.

```
AssetPrice = 80;
Return = 0.03;
JumpMean = 0.02;
JumpVol = 0.08;
JumpFreq = 0.1;
V0 = 0.04;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;
Rho = -0.7;
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];
```

Create a `bates` object.

```
Bates = bates(Return, Speed, Level, Volatility,...
                JumpFreq, JumpMean, JumpVol,'startstate',StartState,...
                'correlation',Correlation)
```

```
Bates = 
   Class BATES: Bates Bivariate Stochastic Volatility
   --------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   --------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
    Correlation: 2x2 double array
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.03
          Speed: 1
          Level: 0.05
     Volatility: 0.2
       JumpFreq: 0.1
       JumpMean: 0.02
        JumpVol: 0.08
```

Perform a quasi-Monte Carlo simulation by using `simByTransition` with the optional name-value argument for `'MonteCarloMethod'`, `'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time] = simByTransition(Bates,10,'ntrials',4096,'MonteCarloMethod','quasi','QuasiSequence
```

Input Arguments

`MDL` — Stochastic differential equation model

`bates` object

Stochastic differential equation model, specified as a `bates` object. For more information on creating a `bates` object, see `bates`.

Data Types: `object`

`NPeriods` — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Paths,Times] = simByTransition(Bates,NPeriods,'DeltaTimes',dt)`

`NTrials` — Simulated trials (sample paths)

`1` (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of `'NTrials'` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations

`1` (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of `'DeltaTimes'` and a scalar or `NPeriods`-by-`1` column vector.

`DeltaTime` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps

`1` (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment *dt* (defined as `DeltaTimes`), specified as the comma-separated pair consisting of `'NSteps'` and a positive scalar integer.

The `simByTransition` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps - 1` intermediate points. Although `simByTransition` does not report the output state vector at these intermediate points, the refinement improves accuracy by enabling the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`StorePaths` — Flag for storage and return method

`True` (default) | logical with values `True` or `False`

Flag for storage and return method that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of `'StorePaths'` and a scalar logical flag with a value of `True` or `False`.

- If `StorePaths` is `True` (the default value) or is unspecified, then `simByTransition` returns `Paths` as a three-dimensional time series array.
- If `StorePaths` is `False` (logical `0`), then `simByTransition` returns the `Paths` output array as an empty matrix.

Data Types: `logical`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes

`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of `'MonteCarloMethod'` and a string or character vector with one of the following values:

- `"standard"` — Monte Carlo using pseudo random numbers.
- `"quasi"` — Quasi-Monte Carlo using low-discrepancy sequences.
- `"randomized-quasi"` — Randomized quasi-Monte Carlo.

Data Types: `string` | `char`

`QuasiSequence` — Low discrepancy sequence to drive the stochastic processes
`"sobol"` (default) | string with value `"sobol"` | character vector with value `'sobol'`

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of `'QuasiSequence'` and a string or character vector with one of the following values:

- `"sobol"` — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If `MonteCarloMethod` option is not specified or specified as`"standard"`, `QuasiSequence` is ignored.

Data Types: `string` | `char`

`BrownianMotionMethod` — Brownian motion construction method
`"standard"` (default) | string with value `"brownian-bridge"` or `"principal-components"` | character vector with value `'brownian-bridge'` or `'principal-components'`

Brownian motion construction method, specified as the comma-separated pair consisting of `'BrownianMotionMethod'` and a string or character vector with one of the following values:

- `"standard"` — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.
- `"brownian-bridge"` — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- `"principal-components"` — The Brownian motion path is calculated by minimizing the approximation error.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the `MonteCarloMethod` using pseudo random numbers. However, the performance differs between the two when the `MonteCarloMethod` option `"quasi"` is introduced, with faster convergence seen for `"brownian-bridge"` construction option and the fastest convergence when using the `"principal-components"` construction option.

Data Types: `string` | `char`

`Processes` — Sequence of end-of-period processes or state vector adjustments
`simByTransition` makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of `'Processes'` and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

`simByTransition` applies processing functions at the end of each observation period. The processing functions accept the current observation time t and the current state vector X_t, and return a state vector that might adjust the input state.

If you specify more than one processing function, `simByTransition` invokes the functions in the order in which they appear in the cell array.

Data Types: `cell` | `function`

Output Arguments

`Paths` — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as an `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When the input flag `StorePaths` = `False`, `simByTransition` returns `Paths` as an empty matrix.

`Times` — Observation times associated with the simulated paths

column vector

Observation times associated with the simulated paths, returned as an `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

More About

Transition Density Simulation

The CIR SDE has no solution such that $r(t) = f(r(0),\cdots)$.

In other words, the equation is not explicitly solvable. However, the transition density for the process is known.

The exact simulation for the distribution of $r(t\_1\ ),\cdots,r(t\_n)$ is that of the process at times $t\_1,\cdots,t\_n$ for the same value of $r(0)$. The transition density for this process is known and is expressed as

$$r(t) = \frac{\sigma^2(1 - e^{-\alpha(t - u)}}{4\alpha} x_d^2 \left(\frac{4\alpha e^{-\alpha(t - u)}}{\sigma^2(1 - e^{-\alpha(t - u)})} r(u) \right), t > u$$

where

$$d \equiv \frac{4b\alpha}{\sigma^2}$$

Bates Model

Bates models are bivariate composite models.

Each Bates model consists of two coupled univariate models:

- A geometric Brownian motion (`gbm`) model with a stochastic volatility function and jumps.

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t} + Y(t)X_{1t}dN_t$$

This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.

- A Cox-Ingersoll-Ross (`cir`) square root diffusion model.

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

This model describes the evolution of the variance rate of the coupled Bates price process.

Version History

Introduced in R2020b

R2022a: Perform Quasi-Monte Carlo simulation

Behavior changed in R2022a

Perform Quasi-Monte Carlo simulation using the name-value arguments `MonteCarloMethod` and `QuasiSequence`.

R2022b: Perform Brownian bridge and principal components construction

Behavior changed in R2022b

Perform Brownian bridge and principal components construction using the name-value argument `BrownianMotionMethod`.

simByTransition

Simulate Heston sample paths with transition density

Syntax

```
[Paths,Times] = simByTransition(MDL,NPeriods)
[Paths,Times] = simByTransition( ___ ,Name,Value)
```

Description

`[Paths,Times] = simByTransition(MDL,NPeriods)` simulates `NTrials` sample paths of Heston bivariate models driven by two Brownian motion sources of risk. `simByTransition` approximates continuous-time stochastic processes by the transition density.

`[Paths,Times] = simByTransition( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

You can perform quasi-Monte Carlo simulations using the name-value arguments for `MonteCarloMethod`, `QuasiSequence`, and `BrownianMotionMethod`. For more information, see “Quasi-Monte Carlo Simulation” on page 14-62.

Examples

Use simByTransition with heston Object

Simulate Heston sample paths with transition density.

Define the parameters for the `heston` object.

```
Return = 0.03;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;

AssetPrice = 80;
V0 = 0.04;
Rho = -0.7;
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];
```

Create a `heston` object.

```
hestonObj = heston(Return,Speed,Level,Volatility,'startstate',StartState,'correlation',Correlatio
```

```
hestonObj = 
   Class HESTON: Heston Bivariate Stochastic Volatility
   ----------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   ----------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
```

```
    Correlation: 2x2 double array
          Drift: drift rate function F(t,X(t))
      Diffusion: diffusion rate function G(t,X(t))
     Simulation: simulation method/function simByEuler
         Return: 0.03
          Speed: 1
          Level: 0.05
     Volatility: 0.2
```

Define the simulation parameters.

```
nPeriods = 5;   % Simulate sample paths over the next five years
Paths = simByTransition(hestonObj,nPeriods);
Paths
```

```
Paths = 6×2

   80.0000    0.0400
   99.7718    0.0201
  124.7044    0.0176
   52.7914    0.1806
   75.3173    0.1732
   76.7572    0.1169
```

Quasi-Monte Carlo Simulation Using Heston Model

This example shows how to use `simByTransition` with a Heston model to perform a quasi-Monte Carlo simulation. Quasi-Monte Carlo simulation is a Monte Carlo simulation that uses quasi-random sequences instead pseudo random numbers.

Define the parameters for the `heston` object.

```
Return = 0.03;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;

AssetPrice = 80;
V0 = 0.04;
Rho = -0.7;
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];
```

Create a `heston` object.

```
Heston = heston(Return,Speed,Level,Volatility,'startstate',StartState,'correlation',Correlation)
```

```
Heston = 
   Class HESTON: Heston Bivariate Stochastic Volatility
   ----------------------------------------------------
     Dimensions: State = 2, Brownian = 2
   ----------------------------------------------------
      StartTime: 0
     StartState: 2x1 double array
    Correlation: 2x2 double array
```

```
       Drift: drift rate function F(t,X(t))
   Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
      Return: 0.03
       Speed: 1
       Level: 0.05
  Volatility: 0.2
```

Perform a quasi-Monte Carlo simulation by using `simByTransition` with the optional name-value argument for `'MonteCarloMethod'`, `'QuasiSequence'`, and `'BrownianMotionMethod'`.

```
[paths,time] = simByTransition(Heston,10,'ntrials',4096,'MonteCarloMethod','quasi','QuasiSequence
```

Input Arguments

`MDL` — Stochastic differential equation model
`heston` object

Stochastic differential equation model, specified as a `heston` object. For more information on creating a `heston` object, see `heston`.

Data Types: `object`

`NPeriods` — Number of simulation periods
positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Paths,Times] = simByTransition(Heston,NPeriods,'DeltaTimes',dt)`

`NTrials` — Simulated trials (sample paths)
`1` (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of `'NTrials'` and a positive scalar integer.

Data Types: `double`

`DeltaTimes` — Positive time increments between observations
`1` (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of `'DeltaTimes'` and a scalar or `NPeriods`-by-`1` column vector.

`DeltaTime` represents the familiar *dt* found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

`NSteps` — Number of intermediate time steps

`1` (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment *dt* (defined as `DeltaTimes`), specified as the comma-separated pair consisting of `'NSteps'` and a positive scalar integer.

The `simByTransition` function partitions each time increment *dt* into `NSteps` subintervals of length *dt*/`NSteps`, and refines the simulation by evaluating the simulated state vector at `NSteps - 1` intermediate points. Although `simByTransition` does not report the output state vector at these intermediate points, the refinement improves accuracy by enabling the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

`MonteCarloMethod` — Monte Carlo method to simulate stochastic processes

`"standard"` (default) | string with values `"standard"`, `"quasi"`, or `"randomized-quasi"` | character vector with values `'standard'`, `'quasi'`, or `'randomized-quasi'`

Monte Carlo method to simulate stochastic processes, specified as the comma-separated pair consisting of `'MonteCarloMethod'` and a string or character vector with one of the following values:

- `"standard"` — Monte Carlo using pseudo random numbers.
- `"quasi"` — Quasi-Monte Carlo using low-discrepancy sequences.
- `"randomized-quasi"` — Randomized quasi-Monte Carlo.

Data Types: `string` | `char`

`QuasiSequence` — Low discrepancy sequence to drive the stochastic processes

`"sobol"` (default) | string with value `"sobol"` | character vector with value `'sobol'`

Low discrepancy sequence to drive the stochastic processes, specified as the comma-separated pair consisting of `'QuasiSequence'` and a string or character vector with one of the following values:

- `"sobol"` — Quasi-random low-discrepancy sequences that use a base of two to form successively finer uniform partitions of the unit interval and then reorder the coordinates in each dimension

Note If `MonteCarloMethod` option is not specified or specified as`"standard"`, `QuasiSequence` is ignored.

Data Types: `string` | `char`

`BrownianMotionMethod` — Brownian motion construction method

`"standard"` (default) | string with value `"brownian-bridge"` or `"principal-components"` | character vector with value `'brownian-bridge'` or `'principal-components'`

Brownian motion construction method, specified as the comma-separated pair consisting of `'BrownianMotionMethod'` and a string or character vector with one of the following values:

- `"standard"` — The Brownian motion path is found by taking the cumulative sum of the Gaussian variates.

- "brownian-bridge" — The last step of the Brownian motion path is calculated first, followed by any order between steps until all steps have been determined.
- "principal-components" — The Brownian motion path is calculated by minimizing the approximation error.

The starting point for a Monte Carlo simulation is the construction of a Brownian motion sample path (or Wiener path). Such paths are built from a set of independent Gaussian variates, using either standard discretization, Brownian-bridge construction, or principal components construction.

Both standard discretization and Brownian-bridge construction share the same variance and therefore the same resulting convergence when used with the MonteCarloMethod using pseudo random numbers. However, the performance differs between the two when the MonteCarloMethod option "quasi" is introduced, with faster convergence seen for "brownian-bridge" construction option and the fastest convergence when using the "principal-components" construction option.

Data Types: string | char

StorePaths — Flag for storage and return method
True (default) | logical with True or False

Flag for storage and return method that indicates how the output array Paths is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar logical flag with a value of True or False.

- If StorePaths is True (the default value) or is unspecified, then simByTransition returns Paths as a three-dimensional time series array.
- If StorePaths is False (logical 0), then simByTransition returns the Paths output array as an empty matrix.

Data Types: logical

Processes — Sequence of end-of-period processes or state vector adjustments
simByTransition makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

simByTransition applies processing functions at the end of each observation period. The processing functions accept the current observation time t and the current state vector X_t, and return a state vector that might adjust the input state.

If you specify more than one processing function, simByTransition invokes the functions in the order in which they appear in the cell array.

Data Types: cell | function

Output Arguments

Paths — Simulated paths of correlated state variables
array

Simulated paths of correlated state variables, returned as an `(NPeriods + 1)`-by-`NVars`-by-`NTrials` three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector X_t at time t. When the input flag `StorePaths` = `False`, `simByTransition` returns `Paths` as an empty matrix.

`Times` — Observation times associated with simulated paths
column vector

Observation times associated with the simulated paths, returned as an `(NPeriods + 1)`-by-`1` column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

More About

Transition Density Simulation

The CIR SDE has no solution such that $r(t) = f(r(0),\cdots)$.

In other words, the equation is not explicitly solvable. However, the transition density for the process is known.

The exact simulation for the distribution of *r*(*t*_1),···,*r*(*t*_*n*) is that of the process at times *t*_1,···,*t*_*n* for the same value of $r(0)$. The transition density for this process is known and is expressed as

$$r(t) = \frac{\sigma^2(1 - e^{-\alpha(t-u)}}{4\alpha}x_d^2\left(\frac{4\alpha e^{-\alpha(t-u)}}{\sigma^2(1 - e^{-\alpha(t-u)})}r(u)\right), t > u$$

where

$$d \equiv \frac{4b\alpha}{\sigma^2}$$

Heston Model

Heston models are bivariate composite models.

Each Heston model consists of two coupled univariate models:

- A geometric Brownian motion (`gbm`) model with a stochastic volatility function.

  $$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

  This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.
- A Cox-Ingersoll-Ross (`cir`) square root diffusion model.

  $$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

  This model describes the evolution of the variance rate of the coupled GBM price process.

Bibliography

Note For the well-known algorithms and formulas used in Financial Toolbox software (such as how to compute a loan payment given principal, interest rate, and length of the loan), no references are given here. The references here pertain to less common formulas.

Bond Pricing and Yields

The pricing and yield formulas for fixed-income securities come from:

[1] Golub, B.W. and L.M. Tilman. *Risk Management: Approaches for Fixed Income Markets.* Wiley, 2000.

[2] Martellini, L., P. Priaulet, and S. Priaulet. *Fixed Income Securities.* Wiley, 2003.

[3] Mayle, Jan. *Standard Securities Calculation Methods.* New York: Securities Industry Association, Inc. Vol. 1, 3rd ed., 1993, ISBN 1-882936-01-9. Vol. 2, 1994, ISBN 1-882936-02-7.

[4] Tuckman, B. *Fixed Income Securities: Tools for Today's Markets.* Wiley, 2002.

In many cases these formulas compute the price of a security given yield, dates, rates, and other data. These formulas are nonlinear, however; so when solving for an independent variable within a formula, Financial Toolbox software uses Newton's method. See any elementary numerical methods textbook for the mathematics underlying Newton's method.

Term Structure of Interest Rates

The formulas and methodology for term structure functions come from:

[5] Fabozzi, Frank J. "The Structure of Interest Rates." Ch. 6 in Fabozzi, Frank J. and T. Dessa Fabozzi, eds. *The Handbook of Fixed Income Securities.* 4th ed. New York, Irwin Professional Publishing, 1995, ISBN 0-7863-0001-9.

[6] McEnally, Richard W. and James V. Jordan. "The Term Structure of Interest Rates." Ch. 37 in Fabozzi and Fabozzi, *ibid*.

[7] Das, Satyajit. "Calculating Zero Coupon Rates." *Swap and Derivative Financing.* Appendix to Ch. 8, pp. 219–225, New York, Irwin Professional Publishing., 1994, ISBN 1-55738-542-4.

Derivatives Pricing and Yields

The pricing and yield formulas for derivative securities come from:

[8] Chriss, Neil A. *Black-Scholes and Beyond: Option Pricing Models.* Chicago, Irwin Professional Publishing, 1997, ISBN 0-7863-1025-1.

[9] Cox, J., S. Ross, and M. Rubenstein. “Option Pricing: A Simplified Approach.” *Journal of Financial Economics.* Vol. 7, Sept. 1979, pp. 229–263.

[10] Hull, John C. *Options, Futures, and Other Derivatives. 5th edition*, Prentice Hall, 2003, ISBN 0-13-009056-5.

Portfolio Analysis

The Markowitz model is used for portfolio analysis computations. For a discussion of this model see Chapter 7 of:

[11] Bodie, Zvi, Alex Kane, and Alan J. Marcus. *Investments.* 2nd. Edition. Burr Ridge, IL, Irwin Professional Publishing, 1993, ISBN 0-256-08342-8.

Investment Performance Metrics

The risk and ratio formulas for investment performance metrics come from:

[12] Daniel Bernoulli. "Exposition of a New Theory on the Measurement of Risk." *Econometrica.* Vol. 22, No 1, January 1954, pp. 23–36 (English translation of "Specimen Theoriae Novae de Mensura Sortis." *Commentarii Academiae Scientiarum Imperialis Petropolitanae.* Tomus V, 1738, pp. 175–192).

[13] Martin Eling and Frank Schuhmacher. *Does the Choice of Performance Measure Influence the Evaluation of Hedge Funds?* Working Paper, November 2005.

[14] John Lintner. "The Valuation of Risk Assets and the Selection of Risky Investments in Stocks Portfolios and Capital Budgets." *Review of Economics and Statistics.* Vol. 47, No. 1, February 1965, pp. 13–37.

[15] Malik Magdon-Ismail, Amir F. Atiya, Amrit Pratap, and Yaser S. Abu-Mostafa. "On the Maximum Drawdown of a Brownian Motion." *Journal of Applied Probability.* Volume 41, Number 1, March 2004, pp. 147–161.
