“Optimizations that Overclock Resources” on page 28-23

“How to Use Constrained Overclocking” on page 28-23

“Constrained Overclocking Limitations” on page 28-24

Why Constrain Overclocking?

Area and timing optimizations that you specify can result in upsampled rates in your design. For example, when you use the resource sharing optimization, the code generator overclocks the shared resources by an overclocking factor (OCF). The OCF depends on the number of shareable resources, N , and the **SharingFactor**, SF , that you specify. If your clock rate is high, overclocking can cause your design clock rate to exceed the maximum clock rate of your target hardware. To constrain overclocking, use the **Oversampling factor** in conjunction with clock-rate pipelining to constrain the overclocking of your design.

Optimizations that Overclock Resources

Area and speed optimizations, and certain block implementations that you specify result in overclocking the resources in your design. For example, the following optimizations and implementations can result in upsampled rates in your design:

- RAM mapping
- Streaming
- Resource sharing
- Loop streaming
- Specific block implementations, such as cascade architectures, Newton-Raphson architectures, and some filter implementations

How to Use Constrained Overclocking

When using area and speed optimizations, you can specify constraints on overclocking using the **oversampling** parameter. If you want a single-rate design, you can use these parameters to prevent overclocking, or limit overclocking within a range.

Suppose that you have a design that does not currently fit in the target hardware, but is already running at the target device maximum clock frequency, and you know that the inputs to your design can change at most every N cycles. You can enable area optimizations, such as resource sharing, and specify a single-rate implementation using the **Oversampling factor**. You can specify the **Oversampling factor** in the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box.

By default, the clock-rate pipelining optimization is enabled, and it works in conjunction with the **Oversampling factor** to make the DUT sample time slower than the actual clock rate. You can design your model at the base sample time and then set the **Oversampling factor** to N . This setting gives HDL Coder a latency budget of N cycles to perform the computation. In this situation, HDL

Coder can reuse the shared resource at the original clock rate over N cycles, instead of implementing the sharing optimization by overclocking the shared resource.

Constrained Overclocking Limitations

When you constrain overclocking by specifying an **Oversampling factor** greater than 1, **Clock inputs** must be set to `Single`.

Resolve Numeric Mismatch with Delay Balancing

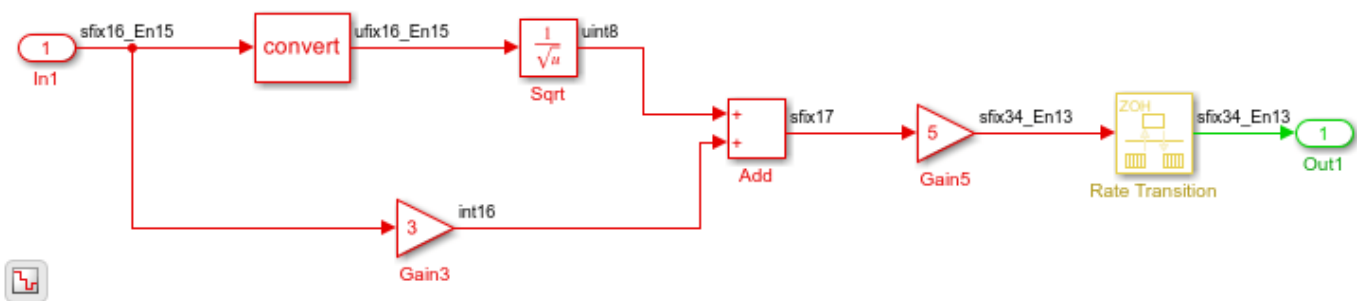

This example shows how to use delay balancing to resolve a numeric mismatch between the generated model and original model after HDL code generation.

Problem

The issue is that simulating the validation model results in a numeric mismatch between the original model and the generated model after HDL code generation. To illustrate this issue:

1. Open the `hdlcoder_resolve_delaybalancing` model. The DUT is a simple multirate design.

```
modelname = 'hdlcoder_resolve_delaybalancing';
dutname = 'hdlcoder_resolve_delaybalancing/Subsystem';
load_system(modelname)
open_system(dutname)
set_param(modelname, 'SimulationCommand', 'update');
```

2. Generate HDL code and validation model for the DUT.

```
makehdl(dutname, 'TreatBalanceDelaysOffAs', 'None', 'GenerateValidationModel', 'on', ...
        'TargetDirectory', 'C:/Temp/hdlsrc')
```

```
### Generating HDL for 'hdlcoder_resolve_delaybalancing/Subsystem'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('hdlcoder_resolve
### Running HDL checks on the model 'hdlcoder_resolve_delaybalancing'.
### Begin compilation of the model 'hdlcoder_resolve_delaybalancing'...
### Working on the model 'hdlcoder_resolve_delaybalancing'...
### Working on... <a href="matlab:configset.internal.open('hdlcoder_resolve_delaybalancing', 'Gen
### Begin model generation 'gm_hdlcoder_resolve_delaybalancing' ...
### Rendering DUT with optimization related changes (IO, Area, Pipelining)...
### Model generation complete.
### Generating new validation model: <a href="matlab:open_system('C:\Temp\hdlsrc\hdlcoder_resolve
### Validation model generation complete.
### Begin VHDL Code Generation for 'hdlcoder_resolve_delaybalancing'.
### MESSAGE: The design requires 3 times faster clock with respect to the base rate = 0.1.
### Begin VHDL Code Generation for 'Subsystem_tc'.
### Working on Subsystem_tc as C:\Temp\hdlsrc\hdlcoder_resolve_delaybalancing\Subsystem_tc.vhd.
### Code Generation for 'Subsystem_tc' completed.
### Working on hdlcoder_resolve_delaybalancing/Subsystem/Sqrt/Sqrt_iv as C:\Temp\hdlsrc\hdlcode
### Working on hdlcoder_resolve_delaybalancing/Subsystem/Sqrt/Sqrt_core as C:\Temp\hdlsrc\hdlcode
### Working on hdlcoder_resolve_delaybalancing/Subsystem/Sqrt as C:\Temp\hdlsrc\hdlcoder_resolve
### Working on hdlcoder_resolve_delaybalancing/Subsystem as C:\Temp\hdlsrc\hdlcoder_resolve_delay
### Generating package file C:\Temp\hdlsrc\hdlcoder_resolve_delaybalancing\Subsystem_pkg.vhd.
```

```

### Code Generation for 'hdlcoder_resolve_delaybalancing' completed.
### Creating HDL Code Generation Check Report file:///C:/Temp/hdlsrc/hdlcoder_resolve_delaybalancing
### HDL check for 'hdlcoder_resolve_delaybalancing' complete with 0 errors, 0 warnings, and 5 messages
### HDL code generation complete.

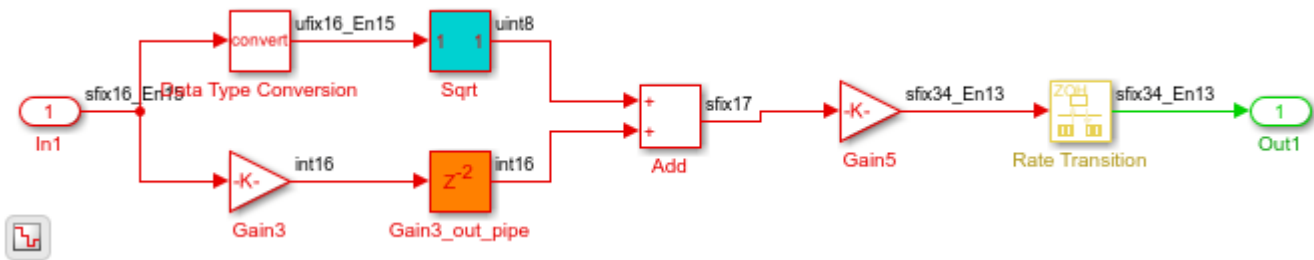

```

3. View the validation model. The validation model compares the generated model with the original model. The generated model displays the effect of optimizations and block-specific architectures that you specify. Use the validation model to verify that the DUT in the generated model is bit-true to the numeric results produced by the original DUT.

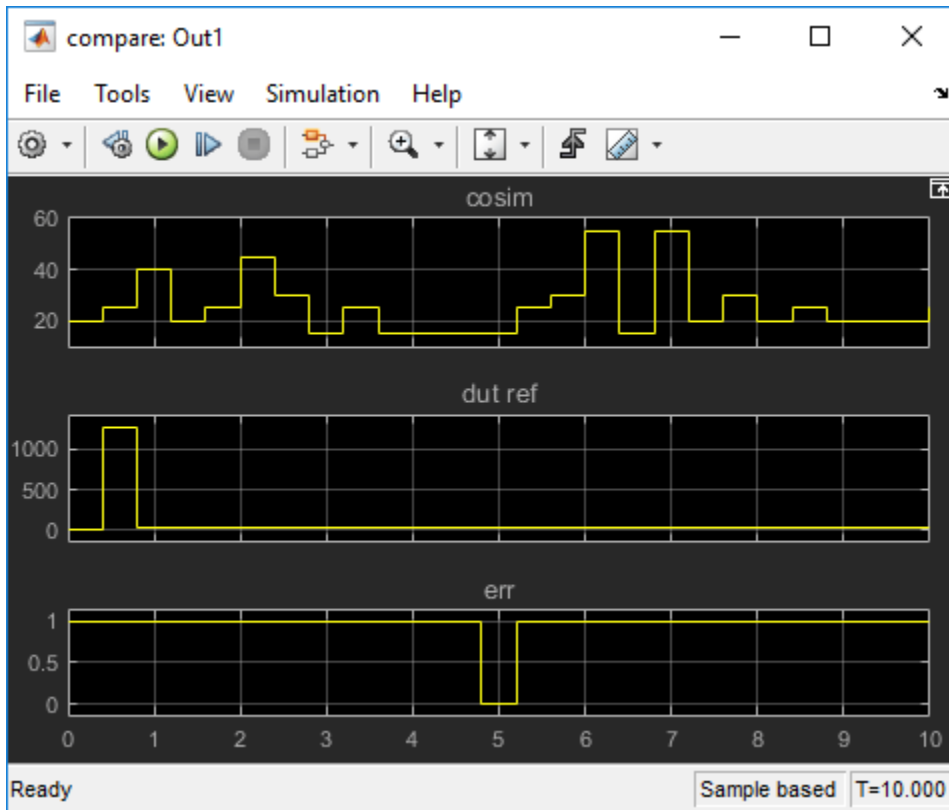

```

valmodelName = 'gm_hdlcoder_resolve_delaybalancing_vnl';
valmodelsys = 'gm_hdlcoder_resolve_delaybalancing_vnl/Subsystem';
load_system(valmodelName)
open_system(valmodelsys)
set_param(valmodelName, 'SimulationCommand', 'update');

```

4. Simulate the validation model. HDL Coder™ generates warnings that indicate an assertion detected at various time stamps. If you navigate through the validation model by double-clicking the Compare Subsystem and then the Assert_Out1 Subsystem, you see a compare: Out1 Scope block. This Scope block compares the output of the original model DUT with the generated model DUT and displays numeric differences as an error signal. When you double-click the Scope block, you see a nonzero error, which indicates a numerical mismatch.

Cause

To diagnose this issue:

1. Observe the parameters saved on the original model. You see that `BalanceDelays` is set to off on the model.

```
hdlsaveparams(modelname)
```

```
% Set Model 'hdlcoder_resolve_delaybalancing' HDL parameters
hdlset_param('hdlcoder_resolve_delaybalancing', 'BalanceDelays', 'off');
hdlset_param('hdlcoder_resolve_delaybalancing', 'GenerateHDLTestBench', 'off');
hdlset_param('hdlcoder_resolve_delaybalancing', 'GenerateValidationModel', 'on');
hdlset_param('hdlcoder_resolve_delaybalancing', 'HDLSubsystem', 'hdlcoder_resolve_delaybalancing');
```

```
% Set Gain HDL parameters
```

```
hdlset_param('hdlcoder_resolve_delaybalancing/Subsystem/Gain3', 'OutputPipeline', 2);
```

```
hdlset_param('hdlcoder_resolve_delaybalancing/Subsystem/Sqrt', 'Architecture', 'RecipSqrtNewton');
```

2. Inspect the validation model. Inside the DUT Subsystem, you see that the code generator implemented the reciprocal square root operation as a Subsystem. If you double-click the `Sqrt` Subsystem, you see that the implementation has a latency. This latency arises due to the Newton-Raphson implementation of reciprocal square root.

```
open_system('gm_hdlcoder_resolve_delaybalancing_vnl/Subsystem/Sqrt')
```

The simulation mismatch occurred because the Newton-Raphson choice for implementing the Reciprocal Sqrt block results in a latency difference between the original model and the generated model. In addition, the downsampling introduced by the Rate Transition block drops samples. As delay balancing is disabled on the model, the code generator did not add matching delays to account for this latency.

Solution

To fix this issue, enable delay balancing on the model. In the original model, set `BalanceDelays` to on. When you enable delay balancing, the code generator detects introduction of delays along one path and adds matching delays on other, parallel signal paths.

1. Enable `BalanceDelays` on the model and generate HDL code and validation model.

```
load_system(modelname)
makehdl(dutname, 'TreatBalanceDelaysOffAs', 'Error', 'BalanceDelays', 'on', ...
        'GenerateValidationModel', 'on', ...
        'TargetDirectory', 'C:/Temp/hdlsrc')

### Generating HDL for 'hdlcoder_resolve_delaybalancing/Subsystem'.

### HDL check for 'hdlcoder_resolve_delaybalancing' complete with 0 errors, 0 warnings, and 4 mes
### HDL code generation complete.
```

2. Open the validation model. You see that the code generator introduced matching delays to balance the latency introduced by the Sqrt block and to offset the effect of downsampling. The additional delays account for the latency difference.

```
load_system(valmodelName)
open_system(valmodelsys)
set_param(valmodelName, 'SimulationCommand', 'update');
```

3. Simulate the validation model and open the compare: Out1 Scope block. You see that the numerical mismatch has been resolved.

Resolve Simulation Mismatch when Pipelining with a Feedback Loop Outside the DUT

This example shows how to use pipelining optimizations to resolve a simulation mismatch between the generated model and original model after HDL code generation.

Issue

If you have a feedback loop around your device under test (DUT) subsystem and pipeline optimizations enabled in the DUT, you might have a simulation mismatch between your generated and original model. This mismatch is due to added latency from delays or pipeline registers in the DUT of the generated model that are not present in the original model DUT. A simulation mismatch shows that your original and generated model, and your original model and generated HDL code, are not functionally equivalent.

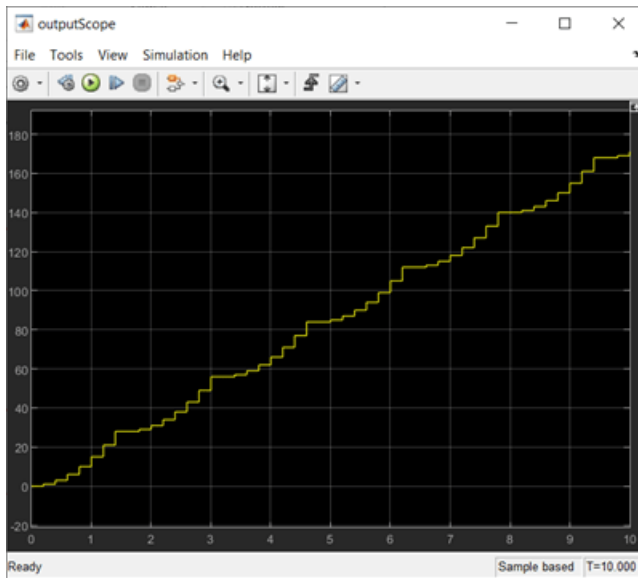

HDL Coder™ generates code only for your DUT and nothing outside of that in your model. As a result, the simulation mismatch does not cause code generation errors. The mismatch is also not seen in the validation model because it is comparing only the original model DUT to the generated model DUT.

This issue can be seen in the `feedback_loop_outsideDUT` model. In the model, the feedback delay is outside of the DUT subsystem that HDL Coder generates code for.

```
modelName = "feedback_loop_outsideDUT";
dutname = "feedback_loop_outsideDUT/DUT";
open_system(modelname);
sim(modelname);
```

Open the `outputScope` of the original model.

In the model, the HDL Block properties `InputPipeline` and `OutputPipeline` are set to 1 for the `Add` block. These properties place a delay block, which acts as a pipeline register, before and after the `Add` block to add pipelines in the combinatorial path and increase the clock frequency of your design. Because there are options enabled to add pipelines in the generated model and HDL code, delay balancing is enabled (its default) for the model. It is recommended to keep delay balancing enabled to balance delays added in your design. For more information, see “Delay Balancing” on page 28-81.

```
hdlsaveparams(modelname)
```

```
%% Set Model 'feedback_loop_outsideDUT' HDL parameters
hdlset_param('feedback_loop_outsideDUT', 'GenerateHDLCode', 'off');
hdlset_param('feedback_loop_outsideDUT', 'GenerateValidationModel', 'on');
hdlset_param('feedback_loop_outsideDUT', 'HDLSubsystem', 'feedback_loop_outsideDUT/DUT');

% Set SubSystem HDL parameters
hdlset_param('feedback_loop_outsideDUT/DUT', 'ClockRatePipelining', 'off');

% Set Sum HDL parameters
hdlset_param('feedback_loop_outsideDUT/DUT/Add', 'InputPipeline', 1);
hdlset_param('feedback_loop_outsideDUT/DUT/Add', 'OutputPipeline', 1);
```

Generate HDL code. In the MATLAB Command Window, a message during code generation shows that two cycles of latency have been introduced in the generated model. The latency is not compensated for during code generation because the feedback loop is outside of the DUT. Because of the latency introduced, the original model and generated model have a simulation mismatch.

```
makehdl(dutname);
```

```
### Generating HDL for 'feedback_loop_outsideDUT/DUT'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('feedback_loop_outsideDUT')">feedback_loop_outsideDUT</a>.

```

Open and run the generated model.

```

open_system("gm_feedback_loop_outsideDUT");
sim("gm_feedback_loop_outsideDUT");
    
```

In the `outputScope` of the generated model, compare the scopes of the original and generated model to see the simulation mismatch between the two scopes.

Potential Solutions

Use Clock-Rate Pipelining

To fix this issue, it is recommended to bring the design delay inside of the DUT subsystem so it can be taken into account during HDL code generation. The feedback delay is brought into the DUT in the model `feedback_loop_inDUT`. HDL Coder then takes the entire feedback loop into account during code generation.

```
modelName = "feedback_loop_inDUT";
load_system(modelname);
dutname = "feedback_loop_inDUT/DUT";
open_system(dutname);
```

When you generate code for this DUT by using the `makehdl` command, this delay balancing error is displayed in the MATLAB Command Window:

```
Delay balancing unsuccessful because Delay introduced in feedback loop cannot
be path balanced. Offending Block:feedback_loop_inDUT/DUT/Add_out_pipe.
```

While the error in the HDL code generation is about unsuccessful delay balancing, the delay balancing issue is a result of pipelining in feedback loops that introduce latency and break functional equivalence between the original and generated model. To pipeline your design inside a feedback loop by using optimization options, such as the HDL Block properties `InputPipeline` and `OutputPipeline` for blocks in your DUT, use a faster clock rate and enable the clock-rate pipelining optimization. For more information, see “Clock-Rate Pipelining” on page 28-149.

In the `feedback_loop_inDUT` model, to use clock-rate pipelining:

- Set an oversampling factor of 10 to increase the clock rate to be 10x the model base rate, or data rate.
- Enable clock-rate pipelining for the DUT.

```
hdlset_param(modelname, "Oversampling", 10)
hdlset_param(dutname, "ClockRatePipelining", "on");
```

Now, when you generate code, there are no errors and the latency decreases from two data rate cycles to one cycle. The latency that remains is a result of the feedback loop in the DUT. The latency is not added during code generation.

```
makehdl(dutname);
```

```
### Generating HDL for 'feedback_loop_inDUT/DUT'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('feedback_loop_in
```

```

### Running HDL checks on the model 'feedback_loop_inDUT'.
### Begin compilation of the model 'feedback_loop_inDUT'...
### Working on the model 'feedback_loop_inDUT'...
### The code generation and optimization options you have chosen have introduced additional pipe
### The delay balancing feature has automatically inserted matching delays for compensation.
### The DUT requires an initial pipeline setup latency. Each output port experiences these addit
### Output port 1: 1 cycles.
### Working on... <a href="matlab:configset.internal.open('feedback_loop_inDUT', 'GenerateModel'
### Begin model generation 'gm_feedback_loop_inDUT' ....
### Rendering DUT with optimization related changes (IO, Area, Pipelining)...
### Model generation complete.
### Generating new validation model: <a href="matlab:open_system('hdlsrc\feedback_loop_inDUT\gm_
### Validation model generation complete.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_7084/ib967011/9/tp
### HDL check for 'feedback_loop_inDUT' complete with 0 errors, 0 warnings, and 2 messages.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_7084/ib967011/9/tp
### HDL check for 'feedback_loop_inDUT' complete with 0 errors, 0 warnings, and 2 messages.

```

Open and run the generated model.

```

open_system("gm_feedback_loop_inDUT");
sim("gm_feedback_loop_inDUT");

```

You can now compare the original model `feedback_loop_inDUT` to the generated model `gm_feedback_loop_inDUT` by using the output scopes of the original and generated models. The simulation of the original model with the feedback loop inside or outside the DUT is the same simulation. The generated model with the feedback loop inside the DUT now has a functionally matching output scope, delayed by one data rate cycle of latency.

The output scope shows that the original and generated model are now functionally equivalent. This functional equivalence can also be seen by using the validation model because the feedback loop is inside the DUT and you can directly compare the two DUTs.

Now that the issue is fixed by using clock-rate pipelining, for design purposes, you can move the feedback loop wire outside of the DUT while keeping the delay inside the DUT. This option enables you to maintain your original design as much as possible, while fixing the simulation mismatch with clock-rate pipelining.

```
modelname = "delay_inDUT";
load_system(modelname);
dutname = "delay_inDUT/DUT";
open_system(modelname);
```

Applying this solution means that the delay balancing error during code generation is not generated. As a result, the simulation issue is not indicated during code generation when you move only the delay inside the DUT and have disabled clock-rate pipelining.

```
makehdl(dutname);
```

```
### Generating HDL for 'delay_inDUT/DUT'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('delay_inDUT', {
### Running HDL checks on the model 'delay_inDUT'.
### Begin compilation of the model 'delay_inDUT'...
### Working on the model 'delay_inDUT'...
### The code generation and optimization options you have chosen have introduced additional pipe
### The delay balancing feature has automatically inserted matching delays for compensation.
### The DUT requires an initial pipeline setup latency. Each output port experiences these addit
### Output port 1: 1 cycles.
### Working on... <a href="matlab:configset.internal.open('delay_inDUT', 'GenerateModel')">Genera
### Begin model generation 'gm_delay_inDUT' ....
### Rendering DUT with optimization related changes (IO, Area, Pipelining)...
### Model generation complete.
### Generating new validation model: <a href="matlab:open_system('hdlsrc\delay_inDUT\gm_delay_in
### Validation model generation complete.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_7084/ib967011/9/tp
### HDL check for 'delay_inDUT' complete with 0 errors, 0 warnings, and 1 messages.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_7084/ib967011/9/tp
### HDL check for 'delay_inDUT' complete with 0 errors, 0 warnings, and 1 messages.
```

Even though there is no delay balancing error to fix during code generation, the simulation mismatch still needs to be fixed. This requires the same solution of setting the oversampling factor and enabling clock-rate pipelining. Removing the feedback loop from the DUT but keeping the design delay inside allows the design delay to be absorbed and reduces the latency to zero.

```

hdlset_param(modelname, "Oversampling", 10)
hdlset_param(dutname, "ClockRatePipelining", "on");

makehdl(dutname);

### Generating HDL for 'delay_inDUT/DUT'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('delay_inDUT', {
### Running HDL checks on the model 'delay_inDUT'.
### Begin compilation of the model 'delay_inDUT'...
### Working on the model 'delay_inDUT'...
### Working on... <a href="matlab:configset.internal.open('delay_inDUT', 'GenerateModel')">Generate
### Begin model generation 'gm_delay_inDUT' ....
### Rendering DUT with optimization related changes (IO, Area, Pipelining)...
### Model generation complete.
### Generating new validation model: <a href="matlab:open_system('hdlsrc\delay_inDUT\gm_delay_in
### Validation model generation complete.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_7084/ib967011/9/tp
### HDL check for 'delay_inDUT' complete with 0 errors, 0 warnings, and 1 messages.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_7084/ib967011/9/tp
### HDL check for 'delay_inDUT' complete with 0 errors, 0 warnings, and 1 messages.

```

Open and run the generated model. You can compare the output scopes of the original and generated model after code generation to see the issue is resolved and there is no added latency during code generation.

```

open_system("gm_delay_inDUT");
sim("delay_inDUT");

```

This is the output scope of the original model `delay_inDUT`.

This is the output scope of the generated model gm_delay_inDUT.

Disable Optimizations That Add Latency

To keep the feedback loop outside of the DUT with no added latency to the generated model, remove all optimizations that add pipelines to your generated model and HDL code. In this example, remove the input and output pipelines optimization options that are specified for the Add block in your DUT subsystem in the feedback_loop_outsideDUT model.

```

modelname = "feedback_loop_outsideDUT";
dutname = "feedback_loop_outsideDUT/DUT";
open_system(modelname);

hdlset_param("feedback_loop_outsideDUT/DUT/Add", "InputPipeline", 0);
hdlset_param("feedback_loop_outsideDUT/DUT/Add", "OutputPipeline", 0);

```

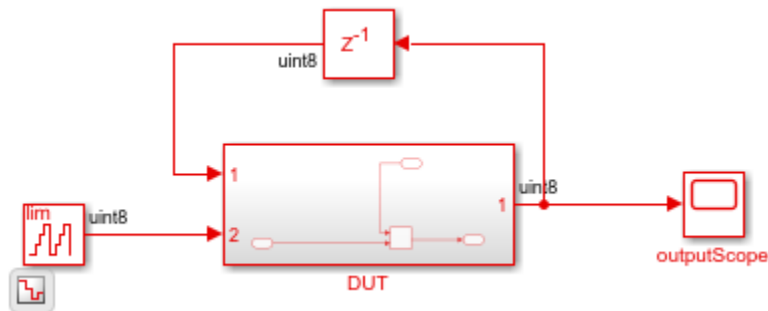

Removing the input and output pipelines removes the added latency to the generated model. The original and generated model are now functionally equivalent with no simulation mismatch. To compare the original and generated model scope outputs, generate HDL code.

```
makehdl(dutname)
```

```
### Generating HDL for 'feedback_loop_outsideDUT/DUT'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('feedback_loop_outsideDUT')">feedback_loop_outsideDUT</a>.
### Running HDL checks on the model 'feedback_loop_outsideDUT'.
### Begin compilation of the model 'feedback_loop_outsideDUT'...
### Working on the model 'feedback_loop_outsideDUT'...
### Working on... <a href="matlab:configset.internal.open('feedback_loop_outsideDUT', 'GenerateModel')">GenerateModel</a>.
### Begin model generation 'gm_feedback_loop_outsideDUT' ....
### Copying DUT to the generated model....
### Model generation complete.
### Generating new validation model: <a href="matlab:open_system('hdlsrc\feedback_loop_outsideDUT_validation')">feedback_loop_outsideDUT_validation</a>.
### Validation model generation complete.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_7084/ib967011/9/tp:
### HDL check for 'feedback_loop_outsideDUT' complete with 0 errors, 0 warnings, and 1 messages.

### HDL check for 'feedback_loop_outsideDUT' complete with 0 errors, 0 warnings, and 1 messages.
```

Open and run the generated model.

```
open_system("gm_feedback_loop_outsideDUT");
sim("gm_feedback_loop_outsideDUT");
```

This is the output scope of the original model feedback_loop_outsideDUT.

This is the output scope of the generated model `gm_feedback_loop_outsideDUT`.

Redesign the Model to Handle Added Latency

If you prefer to keep the pipeline optimization in your design, you can redesign your model to handle the added latency in order to remove the simulation mismatch. For example, you can redesign your model to no longer contain a feedback loop. If you remove the feedback loop, HDL Coder can balance delays to handle the added latency and maintain functional equivalence between the original and generated model to avoid a simulation mismatch.

“Determine Blocks That Support Streaming” on page 28-43

“Requirements for Streaming Subsystems” on page 28-43

“Streaming Report” on page 28-44

What Is Streaming?

Streaming is an area optimization in which HDL Coder transforms a vector data path to a scalar data path (or to several smaller-sized vector data paths). By default, HDL Coder generates fully parallel implementations for vector computations. For example, the code generator realizes a vector sum as several adders, executing in parallel during a single clock cycle. This technique can consume many hardware resources. With streaming, the generated code saves chip area by multiplexing the data over a smaller number of shared hardware resources.

By specifying a streaming factor for a subsystem, you can control the degree to which such resources are shared within that subsystem. When the ratio of streaming factor (N_{st}) to subsystem data path width (V_{dim}) is 1:1, HDL Coder implements an entirely scalar data path. A streaming factor of 0 (the default) produces a fully parallel implementation (that is, without sharing) for vector computations.

If you know the maximal vector dimensions and the sample rate for a subsystem, you can compute the possible streaming factors and resulting sample rates for the subsystem. However, even if the requested streaming factor is mathematically possible, the subsystem must meet other criteria for streaming.

By default, when you apply the streaming optimization, HDL Coder oversamples the shared hardware resource to generate an area-optimized implementation with the original latency. If the streamed data path is operating at a rate slower than the base rate, the code generator implements the data path at the base rate. You can also limit the oversampling ratio to meet target hardware clock constraints. To learn more, see “Clock-Rate Pipelining” on page 28-149.

You can generate and use the validation model to verify that the output of the optimized DUT is bit-true to the results produced by the original DUT. To learn more about the validation model, see “Generated Model and Validation Model” on page 28-10.

Specify Streaming

To specify streaming from the UI:

- In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select the subsystem, model reference, or MATLAB Function block and then click **HDL Block Properties**. In the **StreamingFactor** field, enter the number of resources that you want to stream.

Note For MATLAB Function blocks, to specify the **StreamingFactor**, in the HDL Block Properties dialog box, you must set the HDL architecture of the block to MATLAB Datapath.

- Right-click the subsystem, model reference, or MATLAB Function block and select **HDL Code > HDL Block Properties**. In the **StreamingFactor** field, enter the number of resources that you want to stream.

At the command-line, you can set `StreamingFactor` using the `hdlset_param` function, as in the following example.

```
modelName = 'sfir_fixed'
dut = 'sfir_fixed/symmetric_fir';
open_system(modelName)
hdlset_param(dut, 'StreamingFactor', 4);
```

How to Determine Streaming Factor and Sample Time

In a given subsystem, if N_{st} is the streaming factor, and V_{dim} is the maximum vector dimension, then the data path of the resultant streamed subsystem is one of the following:

- Of width $V_{stream} = (V_{dim}/N_{st})$, if $V_{dim} > N_{st}$.
- Of width $V_{stream} = (N_{st}/V_{dim})$, if $N_{st} > V_{dim}$.
- Scalar.

If the original data path operated with a sample time, S , that is equal to the base sample time, then the streamed subsystem operates with a sample time of:

- S / N_{st} , if $V_{dim} > N_{st}$.
- S / V_{dim} , if $N_{st} > V_{dim}$.

If the original data path operated with a sample time, S , that is greater than the base sample time, S_{base} , then the streamed subsystem operates with a sample time of $S_{base} / \text{Oversampling}$. Notice that the streamed sample time is independent of the original sample time, S .

Determine Blocks That Support Streaming

HDL Coder supports many blocks for streaming. If you initiate streaming code generation for a subsystem that contains incompatible blocks, the coder works around those blocks and generates non-streaming code for them.

HDL Coder cannot apply the streaming optimization to a model reference.

Requirements for Streaming Subsystems

Before applying streaming, HDL Coder performs a series of checks on the subsystems to be streamed. You can stream a subsystem if:

- The streaming factor N_{st} is a perfect divisor of the vector width V_{dim} , or the vector width must be a perfect divisor of the streaming factor.
- All inputs to the subsystem have the same vector size. If the inputs have different vector sizes, you can stream the subsystem by flattening the subsystem hierarchy. When you flatten the hierarchy, the streaming optimization identifies regions with different vector sizes and creates streaming groups for these regions. These groups have different streaming factors that are inferred from the vector sizes.

Streaming Report

To see the streaming information in the report, before you generate code for each subsystem or model reference, enable the optimization report. To enable this report, in the **HDL Code** tab, select **Report Options**, and then select **Generate optimization report**.

When you generate an optimization report, in the **Streaming and Sharing** section, you see the effect of the streaming optimization. If streaming is unsuccessful, the report shows diagnostic messages and offending blocks that caused streaming to fail. When the requested streaming factor cannot be implemented, HDL Coder generates non-streaming code.

If streaming is successful, the report displays the **StreamingFactor** that was inferred, and a table that specifies:

- **Group:** A unique group ID for a group of Simulink blocks that belong to a streaming group.
- **Inferred Streaming Factor:** Streaming factor inferred by HDL Coder with the **Streaming Factor** that you specify in the HDL Block Properties.

To see groups of blocks that belong to a streaming group in your Simulink model and in the generated model, click the **Highlight streaming groups and diagnostics** link in the report.

Resource Sharing

In this section...

“How Resource Sharing Works” on page 28-45
 “Benefits and Costs of Resource Sharing” on page 28-45
 “Shareable Resources in Different Blocks” on page 28-46
 “Specify Resource Sharing” on page 28-46
 “Limitations for Resource Sharing” on page 28-46
 “Block Requirements for Resource Sharing” on page 28-47
 “Resource Sharing Report” on page 28-47

Resource sharing is an area optimization in which HDL Coder identifies multiple functionally equivalent resources and replaces them with a single resource. The data is time-multiplexed over the shared resource to perform the same operations.

How Resource Sharing Works

You can specify a sharing factor `SF` for a subsystem or a MATLAB Function block. HDL Coder tries to identify a certain number of identical, shareable resources `N` up to `SF`. How the code generator shares these resources depends on `N`, `SF`, and the `Oversampling` factor.

By default, the `Oversampling` factor is 1, and resource sharing overclocks the shared resources by an overclocking factor (OCF) that depends on the remainder of `SF` and `N`.

```

if rem(SF,N) == 0
    OCF = N;
else
    OCF = SF;
end
  
```

If you specify an `Oversampling` factor greater than 1, your design operates a faster clock rate on the target hardware because clock-rate pipelining is enabled by default. When you specify a **SharingFactor**, the resource sharing optimization tries to share up to `N` resources, and overclocks the shared resources by a factor given by:

$$\text{Overclocking factor} = (\text{block_rate} \div \text{DUT_base_rate}) \times \text{Oversampling}$$

You can use the validation model to verify that the output of the optimized DUT is bit-true to the results produced by the original DUT. To learn more about the validation model, see “Generated Model and Validation Model” on page 28-10.

Benefits and Costs of Resource Sharing

Resource sharing can substantially reduce your chip area. For example, the generated code can use one multiplier to perform the operations of several identically configured multipliers from the original model. However, resource sharing has the following costs:

- Uses more multiplexers and can use more registers.

- Reduces opportunities for distributed pipelining or retiming, because HDL Coder does not pipeline across clock rate boundaries.
- Multiplies the clock rate of the target hardware by the sharing factor.

Shareable Resources in Different Blocks

If you specify a nonzero sharing factor for a MATLAB Function block, HDL Coder identifies and shares functionally equivalent multipliers.

If you specify a nonzero sharing factor for a Subsystem, HDL Coder identifies and shares functionally equivalent instances of the following types of blocks:

- Gain
- Product
- Multiply-Add
- Add or Sum with two inputs
- Atomic Subsystem
- MATLAB Function

The code generator shares functionally equivalent MATLAB Function blocks with fixed-point types. When you use floating-point types or use the MATLAB Datapath architecture for MATLAB Function blocks with fixed-point types, HDL Coder treats the MATLAB Function block as a regular Subsystem. You can then share functionally equivalent resources inside the MATLAB Function block. To learn more, see “Use MATLAB Datapath Architecture for Sharing with MATLAB Function Blocks” on page 25-132.

Specify Resource Sharing

To specify resource sharing from the UI:

- In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select the subsystem, model reference, or MATLAB Function block and then click **HDL Block Properties**. In the **SharingFactor** field, enter the number of shareable resources.
- Right-click the subsystem, model reference, or MATLAB Function block and select **HDL Code > HDL Block Properties**. In the **SharingFactor** field, enter the number of shareable resources.

At the command-line, set the `SharingFactor` using `hdlset_param`, as in the following example.

```
modelName = 'sfir_fixed'
dut = 'sfir_fixed/symmetric_fir';
open_system(modelname)
hdlset_param(dut, 'SharingFactor', 4);
```

Limitations for Resource Sharing

- Multirate sharing cannot share resources that have different number of pipelines inserted from adaptive pipelining.
- Model references are not supported for resource sharing.

Block Requirements for Resource Sharing

Blocks to be shared must have the following requirements:

- Single rate.
- No infinite sample rate. The DUT must not contain blocks with `inf` sample time. During HDL code generation, HDL Coder only resolves `inf` sample times when the sample times do not propagate to the DUT output. For more information, see “Use Discrete and Finite Sample Time for Constant Block” on page 25-94.
- No bus inputs or outputs.
- No tunable mask parameters. To share these blocks, in the Mask Editor, clear the **Tunable** check box.
- If the block is within a feedback loop, at least one Unit Delay or Delay block must be connected to each output port.

To learn about block-specific settings and requirements for resource sharing, see:

- “Resource Sharing Settings for Various Blocks” on page 25-127
- “Resource Sharing of Subsystems and Floating-Point IPs” on page 25-131

Resource Sharing Report

To see the resource sharing information in the report, before you generate code for each subsystem or model reference, enable the optimization report. To enable this report, in the **HDL Code** tab, select **Report Options**, and then select **Generate optimization report**.

When you generate the optimization report, in the **Streaming and Sharing** section, you see the effect of the resource sharing optimization. If resource sharing is unsuccessful, the report shows diagnostic messages and offending blocks that cause resource sharing to fail.

If resource sharing is successful, the report displays the **SharingFactor**, and a table that contains groups of blocks that shared resources. The table contains:

- **Group Id:** A unique ID for a group of similar Simulink blocks, such as add or product blocks, that share resources.
- **Resource Type:** The type of Simulink block in a sharing group.
- **I/O Wordlengths:** Word lengths of inputs to and output from the block in a sharing group.
- **Group size:** Number of blocks of the same type in a sharing group.
- **Block name:** Name of a block that belongs to a sharing group.
- **Color Legend:** Color that highlights all the blocks in a sharing group.

To see the shared resources in your Simulink model and in the generated model, click the **Highlight shared resources and diagnostics** link.

Streaming: Area Optimization

This example shows how to use the subsystem level streaming optimization in HDL Coder™.

Introduction

Streaming is a subsystem-wide optimization supported by HDL Coder for implementing area-efficient hardware. By default, the coder implements hardware that is bit-accurate and cycle-accurate to the Simulink® model. This implies that vector datapaths in Simulink map inefficiently to hardware. Consider a product block in Simulink that operates on two 64-element vector inputs and generates a 64-element vector output. This block executes 64 multiplications in a single Simulink time step. To remain cycle-accurate, HDL Coder maps this block to 64 parallel multipliers in the generated HDL code. Given that multipliers are expensive on FPGAs, this is an inefficient hardware implementation.

Streaming is an optimization that flattens a vector datapath to either a scalar or a smaller sized vector datapath. The idea is to serialize the execution of parallel hardware, so that resources can be shared and the vector data can be time-multiplexed over the shared resources.

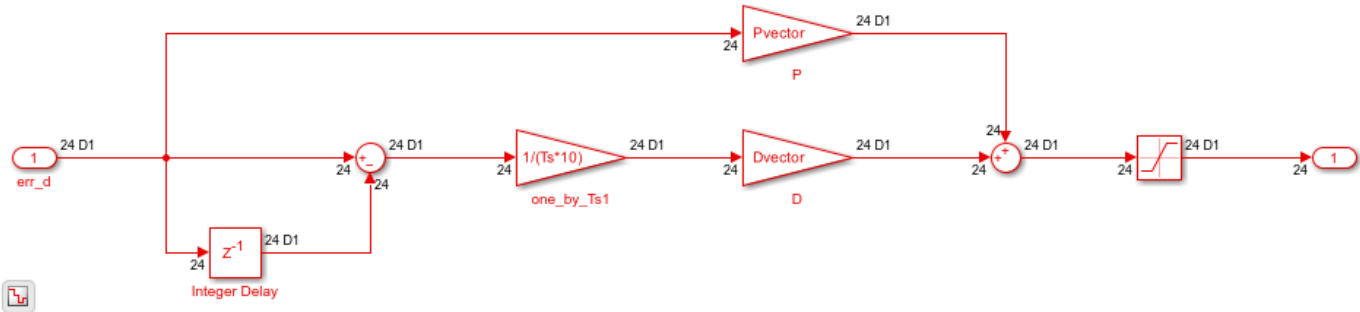

Consider the following example model that operates on a 24-element vector datapath. This model contains three vector gains and two vector adds, resulting in a hardware implementation containing 72 multipliers and 24 adders. This can be confirmed by generating the resource utilization report when generating HDL code.

```

bdclose all;
load_system('hdl_areaopt1');
open_system('hdl_areaopt1/Controller');
hdlset_param('hdl_areaopt1/Controller', 'StreamingFactor', 0);
hdlset_param('hdl_areaopt1', 'ResourceReport', 'on');
makehdl('hdl_areaopt1/Controller');

```

Streaming to Scalarize the Datapath

An efficient area implementation of the same model can be realized by setting a positive integer value to the `StreamingFactor` implementation parameter on the subsystem. This parameter specifies the extent to which the datapath is scalarized - the higher the value, the greater the area savings. In this example, we have a 24-element vector datapath; to fully scalarize it, specify a `StreamingFactor` value of 24. This can be done either through the HDL block properties dialog (opened by right-clicking on the Controller subsystem) or through the command `hdlset_param`.

Generating HDL code with `StreamingFactor` set to 24, generates HDL that uses only three multipliers and two adders (see the resource report after HDL code generation). The streamed architecture is implemented as local multi-rate or in single-rate mode depending on the context of the subsystem being streamed. If the subsystem logic is operating at a slower sample rate or if the “Oversampling factor” on page 21-15 is set to a value greater than one, then clock-rate pipelining kicks in and a streamed subsystem is implemented as a multi-cycle, single-rate architecture. See “Single-Rate Resource Sharing Architecture” on page 28-65 for more details. In all other cases, a local multi-rate implementation is created, as described in this example. The elements of the vector datapath are streamed at a faster rate (in this case 24 times faster and denoted in red) and all computations operate on a scalar datapath. At the output, the vector is reconstructed using a deserializer and the output is sampled at the slower rate (as seen in the generated model in green).

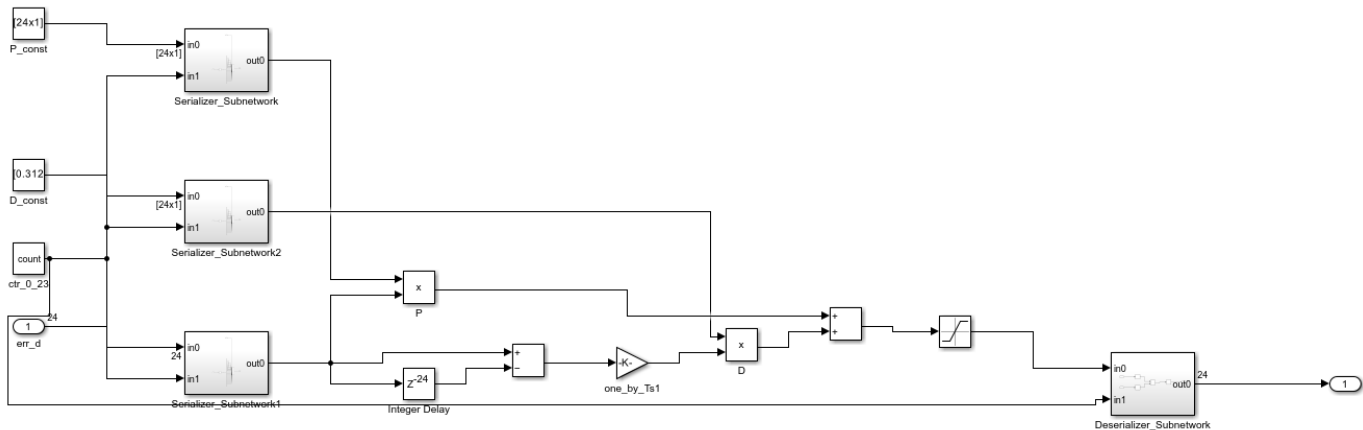

```
hdlset_param('hdl_areaopt1/Controller', 'StreamingFactor', 24);
hdlset_param('hdl_areaopt1', 'GenerateValidationModel', 'on');
makehdl('hdl_areaopt1/Controller');

```

Delay Balancing and Functional Equivalence

The rate transitions that implement time-multiplexing in the streaming architecture introduce a cycle of additional latency. To maintain functional fidelity, this delay must be balanced across all cut-sets that this path is a member of. When the streaming option is turned on, the coder automatically also turns on the delay balancing option (`BalanceDelays`) to automatically balance this additional delay. The coder also automatically turns on the validation model generation option so the user can verify that functional equivalence is maintained with respect to the original model.

```

sim('gm_hdl_areaopt1_vnl');
open_system('gm_hdl_areaopt1_vnl/Compare/Assert_Out1/compare: Out1')

```

Parameterizability for More Flexibility

By tuning the `StreamingFactor` parameter, one can explore the design space along the datapath size dimension. A value of 1 implies no streaming (or fully parallel implementation), and a value of 24 (or the full vector length) implies maximal streaming (or fully serial implementation). By picking values between these two extremes, one can explore the design space from fully parallel to fully serial implementations.

If we set `StreamingFactor` to 6 in this example model, we get a four-element vector datapath in the generated HDL. This results in the use of 12 multipliers and 8 adders as shown in the resource report.

```
hdlset_param('hdl_areaopt1/Controller', 'StreamingFactor', 6);
makehdl('hdl_areaopt1/Controller');
open_system('gm_hdl_areaopt1/Controller');
%set_param('gm_hdl_areaopt1', 'SimulationCommand', 'update');
```

Resource Sharing for Area Optimization

This example shows how to use the subsystem level sharing optimization in HDL Coder™.

Introduction

To implement area-efficient hardware, use resource sharing, which is a subsystem-level optimization supported by HDL Coder.

By default, HDL Coder implements hardware that is a one-to-one mapping of Simulink® blocks to hardware module implementations. The resource sharing optimization enables you to share hardware resources by enabling an N-to-1 mapping of N functionally equivalent Simulink blocks to a single hardware module. The user specifies N by using the `SharingFactor` implementation parameter.

Because a time-multiplexed architecture incurs a longer latency to complete the area optimization, HDL Coder manages the timing discrepancy depending on what resources are being shared. Suppose that the shared resources are operating at the base sample rate, and then resource sharing is implemented as a local multirate architecture, which is described in this example. If the shared resources are operating at a slower sample rate than the base sample rate, then HDL Coder invokes clock-rate pipelining to synthesize an implementation that uses the latency budget defined in the rate differential. In this case, the resource shared architecture is a single rate implementation and takes multiple time steps to complete all the shared operations. “Single-Rate Resource Sharing Architecture” on page 28-65 describes the details of this implementation.

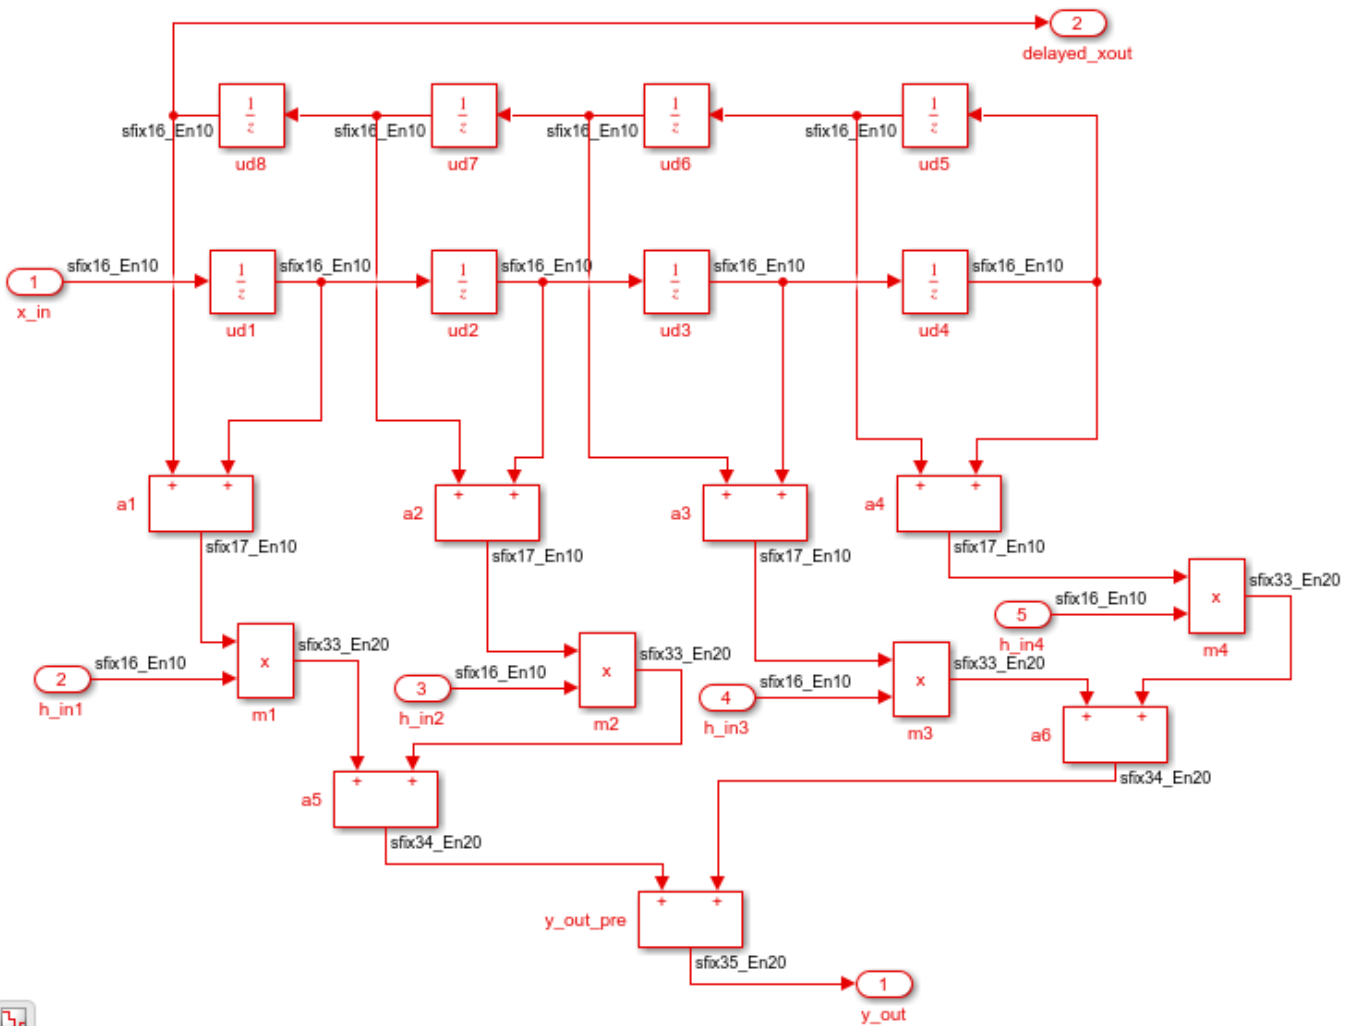

This example also illustrates the local multirate architecture of resource sharing. Consider the following symmetric FIR filter model. It contains four product blocks that are functionally equivalent and that map to four multipliers in hardware. The Resource Utilization Report lists the hardware resources used.

```

bdclose all;
load_system('sfir_fixed');
open_system('sfir_fixed/symmetric_fir');
hdlset_param('sfir_fixed', 'ResourceReport', 'on');
makehdl('sfir_fixed/symmetric_fir');

```

Share Resources for an N-to-1 Mapping

To reduce area resources, you can invoke the sharing optimization by setting the `SharingFactor` parameter on the subsystem to a positive integer value. This parameter specifies N in the N -to-1 hardware mapping. In this example, there are four product blocks, so generating HDL with `SharingFactor` set to 4 generates HDL code that has one multiplier.

The code generation model reflects the sharing architecture. The inputs to the shared blocks are time-multiplexed over the shared resource at a faster rate (in this case 4x faster, shown in red). The outputs are then routed to the respective consumers at a slower rate (shown in green).

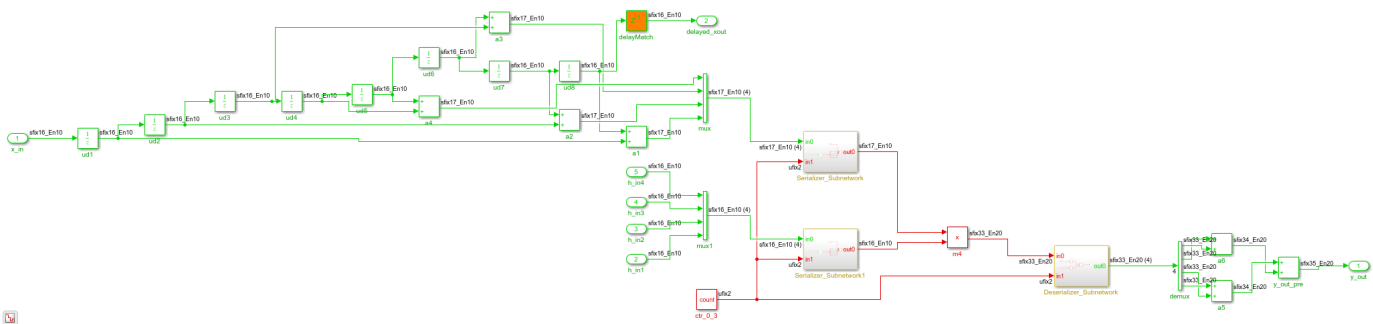

```
hdlset_param('sfir_fixed/symmetric_fir', 'SharingFactor', 4);
hdlset_param('sfir_fixed', 'GenerateValidationModel', 'on');
makehdl('sfir_fixed/symmetric_fir');
open_system('gm_sfir_fixed/symmetric_fir');
set_param('gm_sfir_fixed', 'SimulationCommand', 'update');
```

```

### HDL code generation complete.

```

The sharing optimization is implemented by using time-division multiplexing. Simulink requires the outputs of the shared resource to be sampled at the predefined sample rate. HDL Coder overclocks the shared resource at a faster rate than the data rate. In the preceding example, the shared architecture, which includes the shared resources multiplexer-serializer at the inputs, and demultiplexer-deserializer at the outputs, operates at four times the rate of the input data, because the Sharingfactor is set to 4.

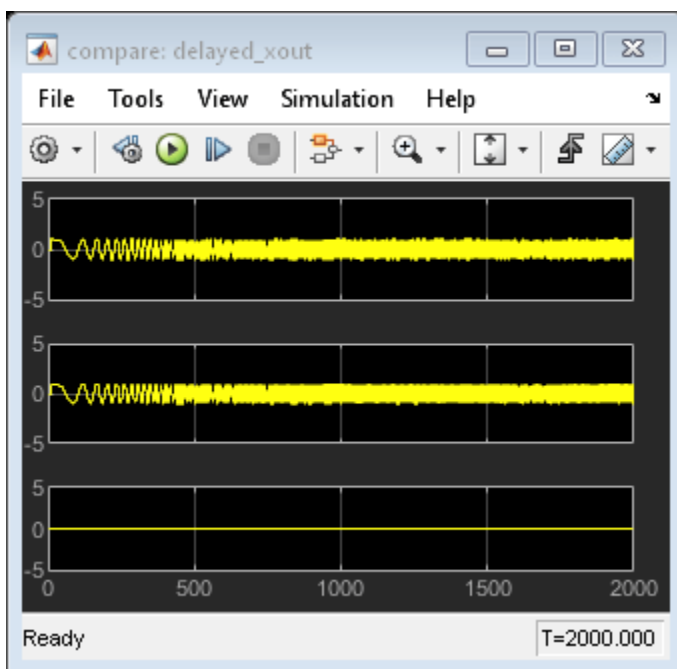

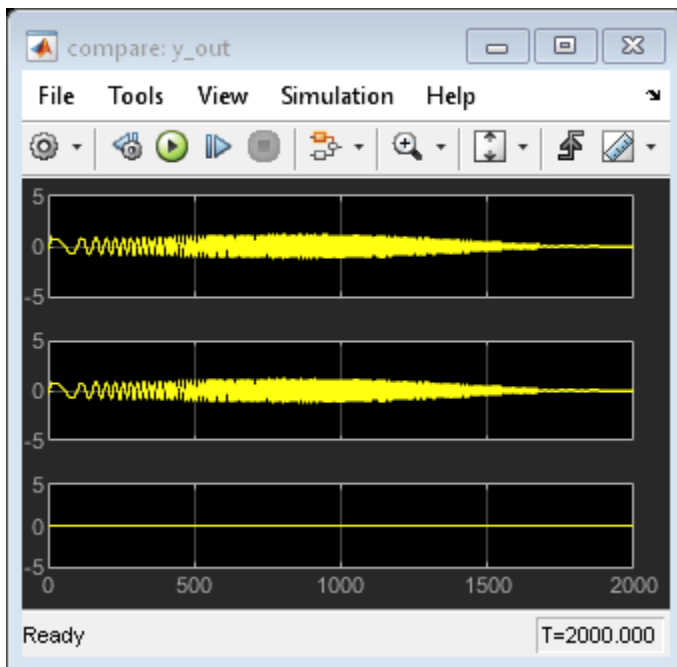

Delay Balancing and Functional Equivalence

The rate transitions that implement time-multiplexing in the resource sharing architecture introduce additional latency. To maintain functional equivalence, delay balancing inserts matching delays in parallel merging paths. The generated validation model enables you to verify functional equivalence by comparing the operation of the shared hardware architecture to the original model.

```

sim('gm_sfir_fixed_vnl');
open_system('gm_sfir_fixed_vnl/Compare/Assert_y_out/compare: y_out');
open_system('gm_sfir_fixed_vnl/Compare/Assert_delayed_xout/compare: delayed_xout');

```

Control Multiplicative Oversampling Through SharingFactor

The net oversampling for the whole design is equivalent to the LCM of all SharingFactor values set on the model. Consider the example `hdlcoder_uniform_oversampling.slx`. It has two subsystems: subsystem `Share3` has three gain blocks that can be shared and `Share4` has four gain blocks that can be shared.

```
saved_warning_state = warning('off', 'hdlcoder:makehdl:DeprecateMaxOverSampling');
warning('off', 'hdlcoder:makehdl:DeprecateMaxComputationLatency');
```

```

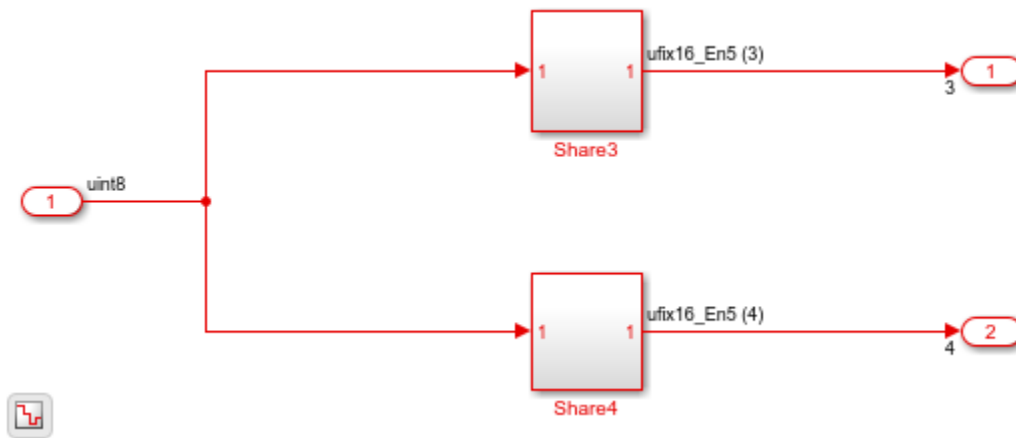

bdclose('all');
load_system('hdlcoder_uniform_oversampling');
open_system('hdlcoder_uniform_oversampling/Subsystem');
set_param('hdlcoder_uniform_oversampling', 'SimulationCommand', 'update');
hdlsaveparams('hdlcoder_uniform_oversampling/Subsystem');

%% Set Model 'hdlcoder_uniform_oversampling' HDL parameters
hdlset_param('hdlcoder_uniform_oversampling', 'GenerateValidationModel', 'on');
hdlset_param('hdlcoder_uniform_oversampling', 'HDLSubsystem', 'hdlcoder_uniform_oversampling');

% Set SubSystem HDL parameters
hdlset_param('hdlcoder_uniform_oversampling/Subsystem/Share3', 'SharingFactor', 3);

% Set SubSystem HDL parameters
hdlset_param('hdlcoder_uniform_oversampling/Subsystem/Share4', 'SharingFactor', 4);

```

Share3 sets its SharingFactor to 3 and Share4 sets its SharingFactor to 4. HDL Coder applies local resource sharing to each subsystem and as a result, the HDL implementation requires $\text{LCM}(3, 4) = 12x$ oversampling. This oversampling is reported during HDL code generation.

```

makehdl('hdlcoder_uniform_oversampling/Subsystem');

### HDL code generation complete.

```

One way to circumvent this multiplicative effect of oversampling is to set the `SharingFactor` of all subsystems to the available oversampling budget. In the above example, if the oversampling budget is only 4x, then set `SharingFactor` set to 4 for both `Share3` and `Share4`. In this case, HDL Coder can share fewer resources than the `SharingFactor` and stay idle for the remaining cycles.

```

hdlset_param('hdlcoder_uniform_oversampling/Subsystem/Share3', 'SharingFactor', 4);
makehdl('hdlcoder_uniform_oversampling/Subsystem');

```

The oversampling factor is now $\text{LCM}(4,4) = 4$. This value is the value reported during code generation. It is a best practice to set the `SharingFactor` values to the available oversampling budget. If your design contains fewer shareable resources than the `SharingFactor` value you specify, HDL Coder shares the shareable resources available and overclocks them by the `SharingFactor` value. If you want to apply resource sharing and other optimizations that use overclocking, such as streaming, or apply resource sharing in multiple nested subsystems, this general guideline might result in a higher oversampling factor.

Block Support, Atomic Subsystems, and Extensions

HDL Coder supports resource sharing of four block types: Product, Gain, Atomic Subsystem, and MATLAB Function. For MATLAB Function blocks, use the MATLAB Datapath architecture with fixed-

point types. This architecture is the default setting for floating-point types. You can specify the **HDL Architecture** in the HDL Block Properties dialog box of the MATLAB Function block.

Sharing functionally equivalent Product and Gain blocks means that the multipliers in the HDL implementation are shared. Two Product blocks are functionally equivalent if:

- The data types of their inputs and outputs are identical.
- Their block parameter settings are identical.
- Their HDL block properties are identical.

For a Gain block, functional equivalence additionally requires that the constant value and data types are also identical. If the gain constant data types are identical for two Gain blocks that have different gain constant values, HDL Coder can share them. Similarly, if a Gain block can be implemented as a Product block that has constant input, and it has the same data types as another Product block in the design, HDL Coder can share them.

The third block type, Atomic Subsystem, is useful for sharing functionally equivalent logic encapsulated inside atomic subsystems. Two atomic subsystems are functionally equivalent and can be shared if:

- Their Simulink checksums are identical.
- Their HDL block properties are identical.

Share Atomic Subsystems

The following example demonstrates an audio filtering model that applies the same filter on the left and right channels. By default, HDL Coder generates two filter modules in hardware.

```
bdclose all;
load_system('hdlcoder_audiofiltering');
open_system('hdlcoder_audiofiltering/Audio filter');
```

The filters on the two audio channels can be shared by specifying a `SharingFactor` value of 2 on the encompassing subsystem. This generates an architecture that uses only one filter, as shown below.

```
hdlset_param('hdlcoder_audiofiltering/Audio filter', 'SharingFactor', 2);
makehdl('hdlcoder_audiofiltering/Audio filter');
open_system('gm_hdlcoder_audiofiltering/Audio filter');
set_param('gm_hdlcoder_audiofiltering', 'SimulationCommand', 'update');
```

```

Opportunities to Resource Share Across Hierarchies

Because `SharingFactor` is a subsystem-level parameter, different subsystems at different levels of the hierarchy can specify different sharing values. In the audio filter example, the filters on each channel use three gain blocks respectively.

```
open_system('hdlcoder_audiofiltering/Audio filter/Filter_left');
```

Share Resources at Higher Level of Hierarchy

You can specify a `SharingFactor` value of 2 at the top-level of the DUT to share the filters on the two channels. You can specify a `SharingFactor` value of 3 on each of the filter subsystems to enable sharing of the three gain blocks in each channel. When HDL code is now generated, the left and right filters have been shared. Only one filter is at the top-level of the hierarchy.

```
hdlset_param('hdlcoder_audiofiltering/Audio filter', 'SharingFactor', 2);
hdlset_param('hdlcoder_audiofiltering/Audio filter/Filter_left', 'SharingFactor', 3);
hdlset_param('hdlcoder_audiofiltering/Audio filter/Filter_right', 'SharingFactor', 3);
makehdl('hdlcoder_audiofiltering/Audio filter');
open_system('gm_hdlcoder_audiofiltering/Audio filter');
set_param('gm_hdlcoder_audiofiltering', 'SimulationCommand', 'update');
```

### HDL code generation complete.

```

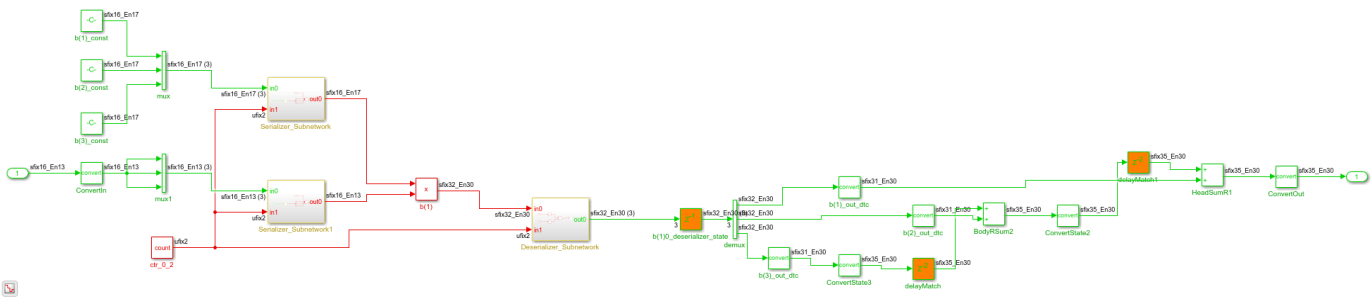

Share Resources at Lower Level of Hierarchy

The three gain blocks in the lower level of the hierarchy (within the filter subsystem) have also been shared. You have reduced the resource usage from six multipliers to just one.

```

open_system('gm_hdlcoder_audiofiltering/Audio filter/Filter_left');
set_param('gm_hdlcoder_audiofiltering', 'SimulationCommand', 'update');

```

Combine Optimizations and Sharing

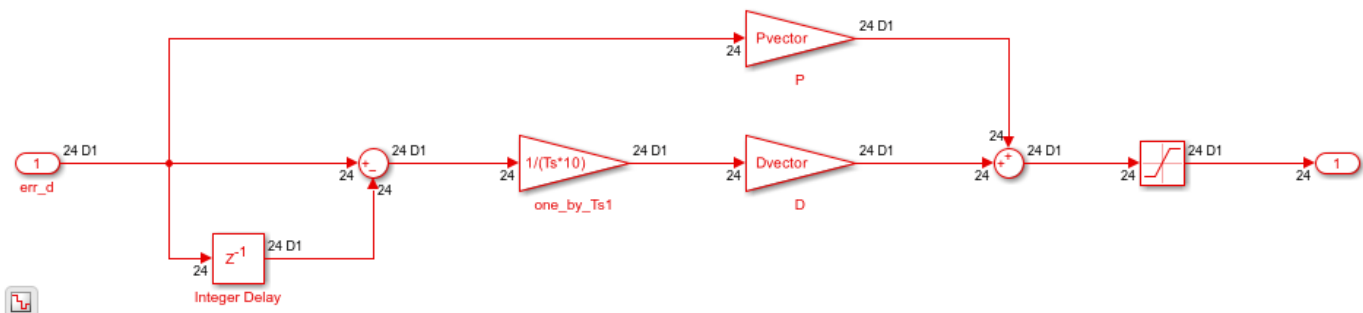

Resource sharing can be combined with other optimizations, such as the streaming optimization.

Consider this model. It contains a 24-element vector datapath and three vector gain blocks, which map to 72 multipliers, by default. Streaming can scalarize the vector datapath while sharing can share the three Gain blocks.

```

bdclose all;
load_system('hdl_areaopt1');
open_system('hdl_areaopt1/Controller');
set_param('hdl_areaopt1', 'SimulationCommand', 'update');

```

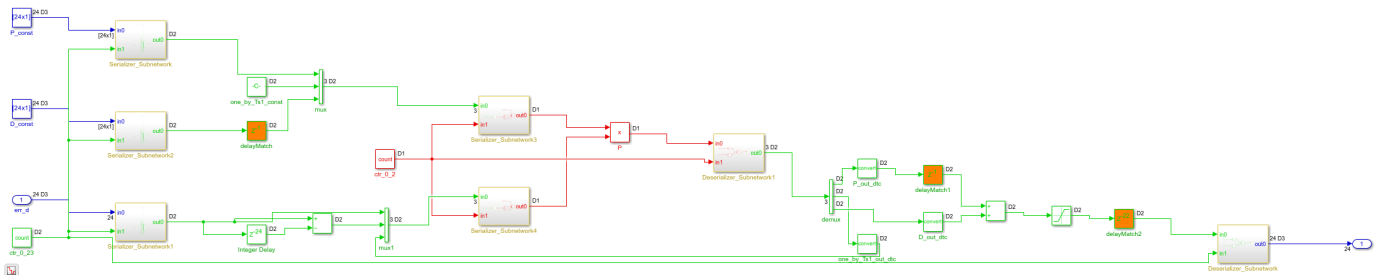

Streaming and Sharing to Reduce Design to Use One Multiplier

To invoke both optimizations, set `StreamingFactor` to 24 and `SharingFactor` to 3. The former reduces the number of multipliers from 72 to 3. The latter reduces the 3 scalar multipliers to 1.

```
hdlset_param('hdl_areaopt1/Controller', 'StreamingFactor', 24);
hdlset_param('hdl_areaopt1/Controller', 'SharingFactor', 3);
makehdl('hdl_areaopt1/Controller');
open_system('gm_hdl_areaopt1/Controller');
set_param('gm_hdl_areaopt1', 'SimulationCommand', 'update');
```

```

Single-Rate Resource Sharing Architecture

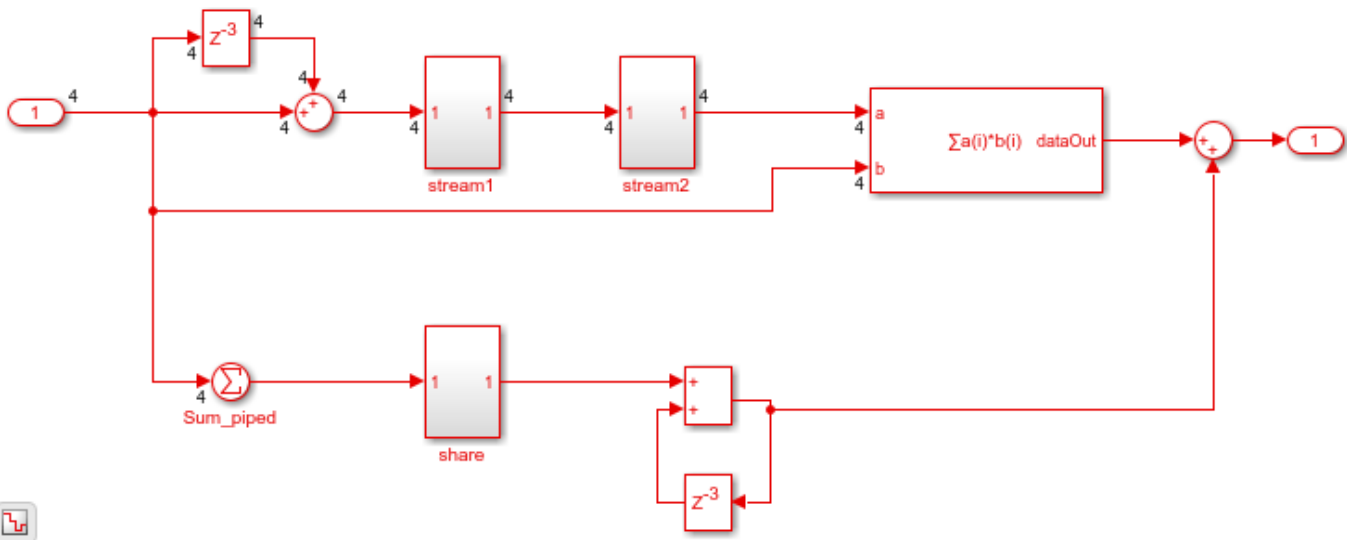

This example shows how HDL Coder™ generates a single-rate architecture from a model to manage the execution of operations in the context of clock-rate pipelining and resource sharing. When you apply resource sharing to blocks in your design, HDL Coder decides the architecture to use based on the sample rate of the regions where sharing occurs. If resource sharing occurs in a region of the design that operates at the fastest base sample rate, then HDL Coder synthesizes a local multi-rate architecture, as described in “Resource Sharing for Area Optimization” on page 28-54. In this example, the shared resources are in a region that operates at a slower sample rate, so HDL Coder applies clock-rate pipelining and synthesizes a single-rate architecture.

Clock-rate pipelining is an optimization that finds separate regions of logic in a design that operate on data at a slower sample rate and inserts pipelining and resource sharing logic at the faster clock rate. In these cases, resource sharing is implemented as a time-multiplexed architecture that operates at a single rate and incurs a latency. In order to execute dependent operations and manage the additional latency, HDL Coder synthesizes appropriate scheduling logic.

Inspect Model

Open and update the model `hdlcoder_singlerate_sharing`.

```
bdclose('all');
load_system('hdlcoder_singlerate_sharing');
open_system('hdlcoder_singlerate_sharing/Subsystem');
set_param('hdlcoder_singlerate_sharing', 'SimulationCommand', 'update');
```

This model has an oversampling constraint defined by the “Oversampling factor” on page 21-15 property, which specifies how much faster the FPGA clock rate runs with respect to the Simulink base sample time. This model sets the oversampling factor to 30 by using the command-line to set the property `Oversampling`, which means that the clock-rate pipelined region can consume 30 clock cycles to complete execution.

Generate HDL Code and Inspect Validation Model

List the optimization options for individual blocks and subsystems by using the function `hdlsaveparams`. Generate code and a validation model to see single-rate sharing architecture.

```
hdlsaveparams('hdlcoder_singlerate_sharing/Subsystem');
makehdl('hdlcoder_singlerate_sharing/Subsystem');

%% Set Model 'hdlcoder_singlerate_sharing' HDL parameters
hdlset_param('hdlcoder_singlerate_sharing', 'GenerateValidationModel', 'on');

```

At the global level in the generated validation model, HDL Coder schedules each of these locally shared and streamed subsystems according to their latency. The unit of scheduling is a clock-rate pipelined region that has been automatically identified by HDL Coder. For each region, a Counter Limited block is used as a sequencer for the scheduling logic. In order to avoid generating identical counters, HDL Coder generates one global scheduling counter per model for all clock-rate pipelining regions that require the same size counter. The counter counts from zero to $clockratebudget - 1$, where the budget is the ratio of the shared resource sample rate to the FPGA clock rate.

In this example, the budget is 30 because the Oversampling property is 30. HDL Coder assigns a time interval that each streamed and shared subsystem executes within. The subsystem is encapsulated in an enabled subsystem so that it is only active during that time interval. The counter or sequencer value specifies the current time step, and the logic that computes the time interval drives the enable inputs to these subsystems.

For each subsystem in the validation model that specifies resource sharing or streaming, a single-rate resource-shared architecture implements the time-division multiplexing. For example, see the validation model subsystem `gm_hdlcoder_singlerate_sharing_vnl/Subsystem/share`. If `SharingFactor = N`, it takes $N - 1$ cycles to execute the shared architecture per cycle of the original computation.

Open the validation model subsystem `gm_hdlcoder_singlerate_sharing_vnl/Subsystem/share`.

```

open_system('gm_hdlcoder_singlerate_sharing_vnl/Subsystem/share');
set_param('gm_hdlcoder_singlerate_sharing_vnl', 'SimulationCommand', 'update');

```

The subsystem `gm_hdlcoder_singlerate_sharing_vnl/Subsystem/share` is assigned the time interval $[2, 3]$ because the Sum of Elements block, `hdlcoder_singlerate_sharing/Subsystem/Sum_piped` has the HDL block property **OutputPipeline** set to 2 and is on the path between the DUT inputs and the inputs to this subsystem. The shared subsystem starts execution in time step two, and because the resource sharing property `SharingFactor` is set to 3, takes $3 - 1 = 2$ cycles to complete. The enable input to `gm_hdlcoder_singlerate_sharing_vnl/`

Subsystem/share/crp_temp_shared is asserted only when the global counter is greater than or equal to two and less than or equal to three.

In addition to streamed and shared subsystems, HDL Coder also schedules any blocks or subsystems that contain state or implement multi-cycle operations. For example, the design uses Multiply-Accumulate block in the gm_hdlcoder_singlerate_sharing_vnl/Subsystem/crp_temp_MAC subsystem that computes the dot-product on two four-element vectors. This logic takes four cycles to execute and is scheduled in the time interval [4, 7] because there are two streaming regions on the path from the inputs to the Multiply-Accumulate block. The first streaming region, gm_hdlcoder_singlerate_sharing_vnl/Subsystem/stream1, is scheduled in time interval [0, 1] due to a streaming factor of two. The second streaming region, gm_hdlcoder_singlerate_sharing_vnl/Subsystem/stream2, is scheduled in time interval [1, 4] due to a streaming factor of four.

The generated validation model has non-trivial changes from the original model, but models the single-rate sharing architecture that HDL Coder synthesizes and generates for the HDL code. This model also compares the numerics of the synthesized architecture with the original model except for differences accounted for by added latency. For more details, see “Delay Balancing and Validation Model Workflow in HDL Coder” on page 28-96. Run the validation model to compare the numerics between the generated and the original model in each time step. The model throws an error on mismatches.

Improve Resource Sharing with Design Modifications

This example shows how to improve opportunities for resource sharing to optimize your model design by making certain modifications to your design. Resource sharing is an HDL Coder optimization that improves area utilization in the design on the target FPGA device. The optimization identifies multiple functionally equivalent resources and replaces them with a single resource. For more information, see “Resource Sharing” on page 28-45.

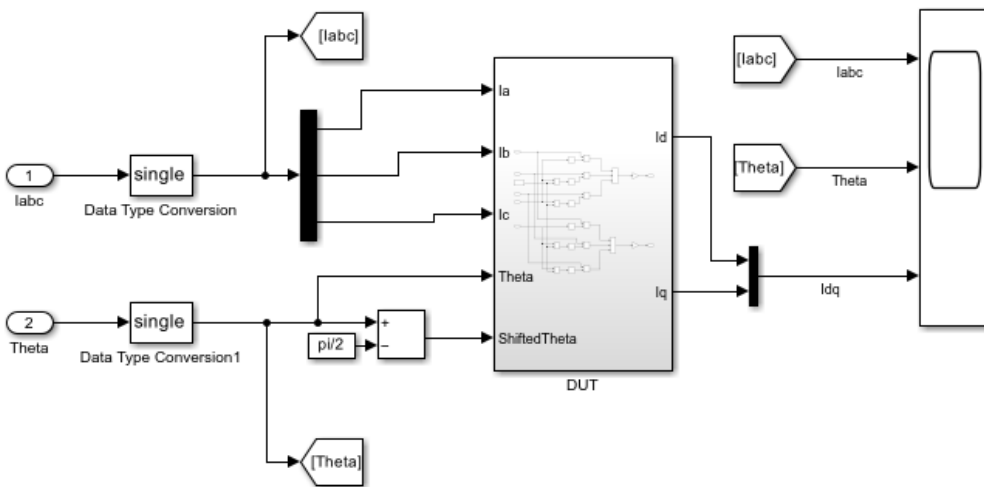

Analyze the Current Model

Execute the following lines of code to copy the necessary example files into a temporary folder.

```
design_name = 'hdlcoderParkTransform';
design_new_name = 'hdlcoderParkTransformCopy';

copyfile(fullfile([design_name, '.slx']), fullfile([design_new_name, '.slx']), 'f');

% Open the model.
open_system(design_new_name);
```

Copyright 2020-2021 The MathWorks, Inc.

```
% Set a SharingFactor of 6 on the subsystem of interest and generate
% HDL along with the corresponding reports from the model.
```

```
subsystem = [design_new_name '/DUT'];
hdlset_param(subsystem, 'SharingFactor', 6);
makehdl(subsystem);

In the generated Streaming and Sharing report, notice that there are specific groups that were identified to be eligible for sharing:

Resource Type	Group Size	Block Name
Trigonometry	6	sine
Sum	2	AddSub2
Sum	2	AddSub1
Product	6	Product
Product	2	Gain

The Native Floating-Point Resource Report shows the operators needed:

Resource	Usage
Adders	4
Multipliers	2
Sin	1
Subtractors	2

The High-level Resource Report shows that the resource utilization for the design was estimated to be:

Resource	Usage
Multipliers	9
Adders/Subtractors	152
Registers	1121
Total 1-Bit Registers	15896
RAMs	0
Multiplexers	857

I/O Bits	228
Static Shift operators	5
Dynamic Shift operators	13

You can also run synthesis workflow on the model. The synthesis results for this model are:

Resource	Usage
Slice LUTs	29381
Slice Registers	24140
DSPs	50
Block Ram Tile	0
URAM	0

For more details regarding synthesis workflow, see “HDL Code Generation and FPGA Synthesis from Simulink Model”.

Detect Patterns in Model

Upon further analysis of the model, you can see that there are a few patterns that can be modified to improve resource sharing.

The first such pattern is with the Add and Subtract blocks whose names start with AddSub and whose output goes to Sin blocks.

The second pattern corresponds to a Sum (as an addition or subtraction) block followed by a Gain block.

In both of these patterns, there are some dissimilarities in the highlighted blocks that prevent resource sharing from happening optimally. The dissimilarities are as follows:

First, the signs of the Sum blocks in the region near the Gain blocks are different. Going from top to bottom, the signs are +++ and ---.

You can fix this inconsistency with the following changes:

- 1 Switch the signs of the bottom Sum block from --- to +++
- 2 Make the three bottom Sin blocks to Cos blocks.
- 3 Change the input to the Cos block and the two bottom Sum blocks from Inport 5 ShiftedTheta to Inport 4 Theta.

Second, the signs of the Sum blocks in the different regions are different. Going from the top to bottom, the signs are +-, ++, +- and ++.

The blocks with both positive signs are being shared separately from the blocks with alternating signs. This separation between the blocks with both positive signs and the blocks with alternating signs requires more resources. You can simplify your model further to reduce the number of Sum blocks in your model while improving resource sharing. The input to the Sum blocks are the same, and you can reduce the number of Sum blocks you need to two. Then, the inconsistency between the signs is easily fixed by introducing a Unary Minus block.

The discrepancy is then resolved, and this model now shares more resources than the original.

This edited model is saved as `hdlcoderParkTransformShare.slx`. Copy this version of the model into the temporary directory using the following commands:

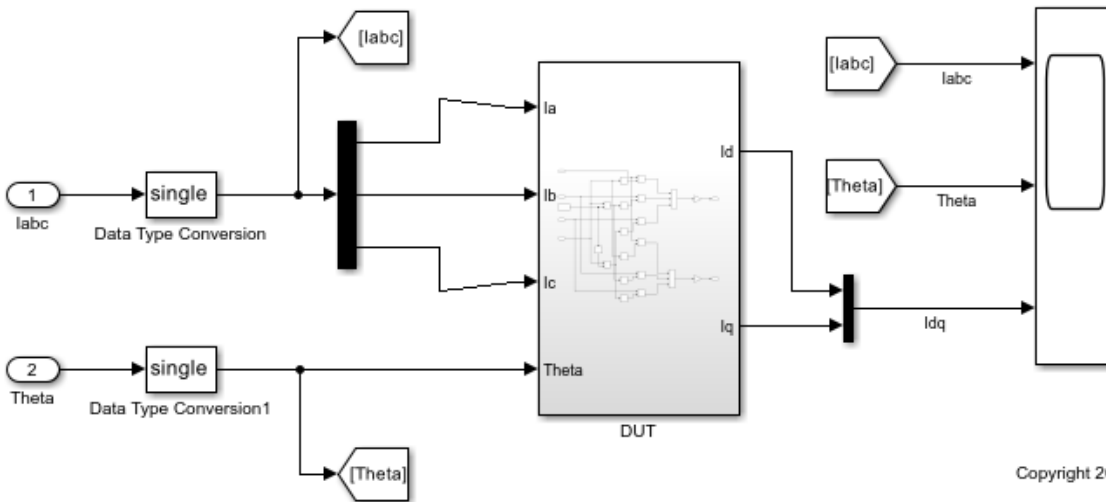

```

design_name = 'hdlcoderParkTransformShare';
design_new_name = 'hdlcoderParkTransformShareCopy';

copyfile(fullfile([design_name, '.slx']), fullfile([design_new_name, '.slx']), 'f');

% Open the model.
open_system(design_new_name);

```

Compare Results from Optimized Model

Since this model has been improved for resource sharing, more blocks are shared and results in an improvement in resource utilization. Set a **SharingFactor** of 3 on the subsystem of interest and generate HDL along with the corresponding reports from the optimized model

```
subsystem = [design_new_name '/DUT'];
```

```
hdlset_param(subsystem, 'SharingFactor', 6);
makehdl(subsystem);
```

```

```

After making those design modifications, the Native Floating-Point Resource Report shows the updated operators needed:

Resource	Usage
Adders	2
Multipliers	2
SinCos	1
Subtractors	1
Unary Minus	1

Notice that the **Adders**, **Multipliers**, and **Subtractors** count have reduced after sharing.

After sharing, the High-level Resource Report shows that the resource utilization for the design was estimated to be:

Resource	Usage
Multipliers	13
Adders/Subtractors	178
Registers	1012
Total 1-Bit Registers	16888
RAMs	0
Multiplexers	610
I/O Bits	196
Static Shift operators	8
Dynamic Shift operators	8

After running synthesis on the model, you can see the following results:

Resource	Usage
Slice LUTs	8792
Slice Registers	8419
DSPs	13
Block Ram Tile	0
URAM	0

Notice that the **Slice LUTs**, **Slice Registers**, and **DSPs** counts have reduced after sharing.

To learn how you can further improve resource sharing with automatic replacement of recurring patterns using the Clone Detection application, see “Improve Resource Sharing with Clone Detection and Replacement” on page 28-75.

Improve Resource Sharing with Clone Detection and Replacement

This example shows how you can automatically identify and replace recurring patterns by using the Clone Detector App. Consequently, it also improves opportunities for optimizing the model by using resource sharing. The Clone Detector App refactors models by identifying clones in a design and replacing clones with links to subsystem blocks in a library. This example uses a model that has already been modified for optimal resource sharing by using the Clone Detector App. To learn more about these modifications, see "Improve Resource Sharing with Design Modifications."

Clone Detection

Clone Detection is a tool that can be used to identify modeling patterns in a design that are similar to a few sample patterns provided as inputs through a custom library file. Once the Clone Detector App identifies these patterns, it replaces the patterns with atomic subsystems. This enables the generation of optimal code through code reuse and results in better resource utilization through sharing of resources among the atomic subsystems. For more information regarding Clone Detection, please refer to "Enable Component Reuse by Using Clone Detection" (Simulink Check).

Set Up Model for Resource Sharing

This edited model is saved as `hdlcoderParkTransformShare.slx`. Copy this version of the model into the temporary directory using the following commands:

```
design_name = 'hdlcoderParkTransformShare';
design_new_name = 'hdlcoderParkTransformShareCopy';

copyfile(fullfile([design_name, '.slx']), fullfile([design_new_name, '.slx']), 'f');

% Open the model.
open_system(design_new_name);
```

Set a **SharingFactor** of 6 on the subsystem of interest and generate HDL along with the corresponding reports from the model.

```

subsystem = [design_new_name '/DUT'];
hdlset_param(subsystem, 'SharingFactor', 6);
makehdl(subsystem);

```

The High-level Resource Report shows that the resource utilization for the design was estimated to be:

Resource	Usage
Multipliers	13
Adders/Subtractors	178
Registers	1012
Total 1-Bit Registers	16888
RAMs	0
Multiplexers	610
I/O Bits	196
Static Shift operators	8
Dynamic Shift operators	8

You can also run synthesis workflow on the model. The synthesis results for this model are:

Resource	Usage
Slice LUTs	8792

Slice Registers	8419
DSPs	13
Block Ram Tile	0
URAM	0

For more details regarding synthesis workflow, see “HDL Code Generation and FPGA Synthesis from Simulink Model”.

Use Clone Detection to Optimize the Model for Resource Sharing

Before you use the Clone Detector App, create a customer library that contains each repeating pattern in the model as an Atomic Subsystem. For this example, you are given a custom library called `hdlcoderParkTransformShareLib.slx`.

```
% Copy the library into the temporary directory
lib_name = 'hdlcoderParkTransformShareLib';
lib_new_name = 'hdlcoderParkTransformShareLibCopy';

copyfile([lib_name, '.slx'], fullfile([lib_new_name, '.slx']), 'f');

% Open the custom library
open_system('hdlcoderParkTransformShareLibCopy');
```

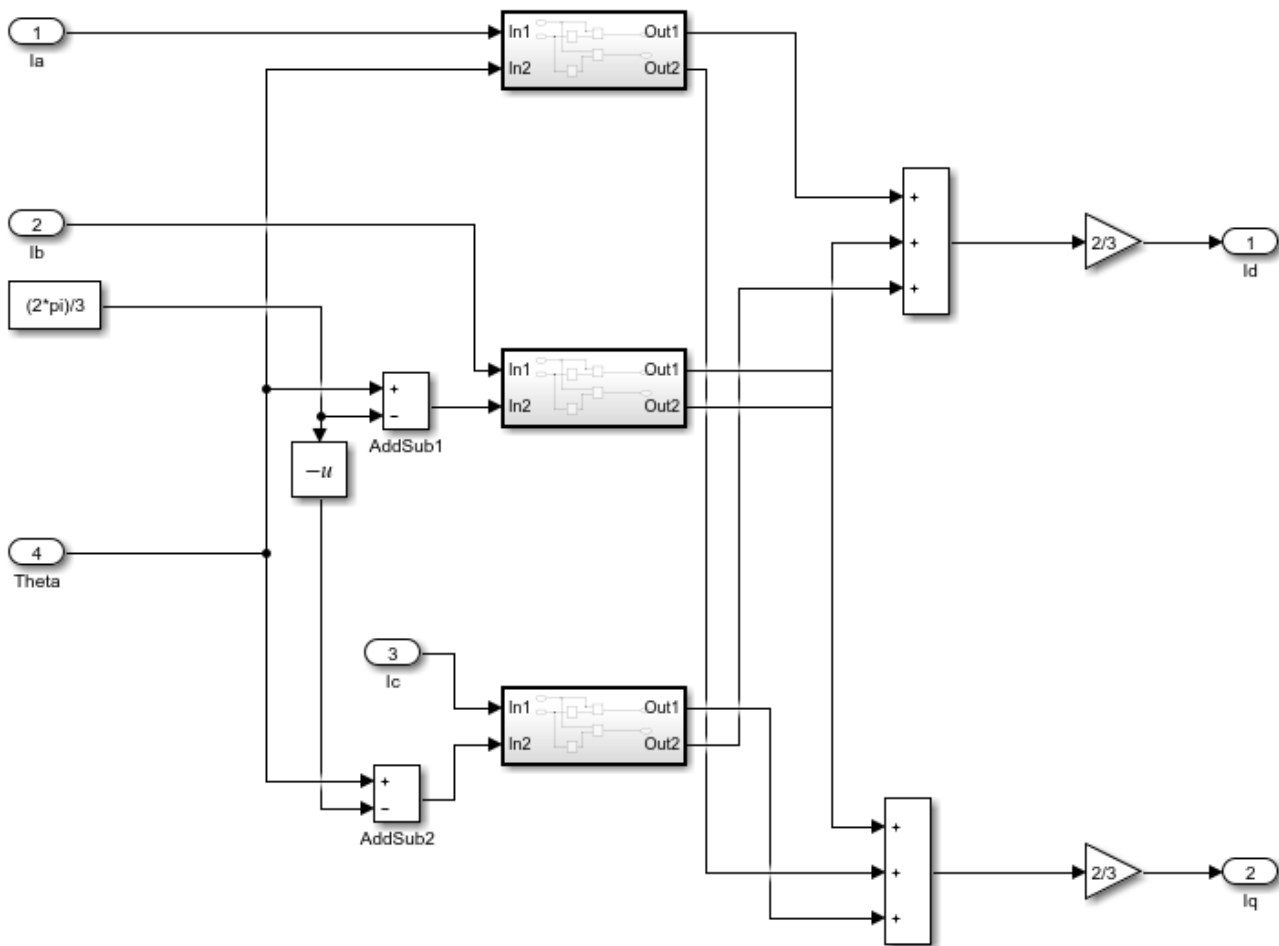

Copyright 2020-2021 The MathWorks, Inc.

Replace patterns of the model with the library containing the Atomic Subsystem. To configure the Clone Detector App and replace the clones, refer to “Enable Component Reuse by Using Clone Detection” (Simulink Check). Specifically, follow the instructions in the *Set the Parameters for Clone Detection* section to link the library for clone detection, and set the **Maximum number of different parameters** value to 0.

Then, follow the *Replace Clones* section to apply this library to the model for exact clone replacement.

Notice that all the patterns in the original model has been replaced with atomic subsystems from the library as shown below:

Save the changes made to this system. In the Simulink Editor, on the **Simulation** tab, click **Save**.

Compare Results from Optimized Model

Since this model contains the Sin, Cos, and Product blocks inside atomic subsystems, they can now be shared and results in an improvement in resource utilization.

```
subsystem = [design_new_name '/DUT'];
hdlset_param(subsystem, 'SharingFactor', 3);
```

```
% Generate HDL code and the corresponding reports for the optimized model
makehdl(subsystem);

```

After sharing, the High-level Resource Report shows that the resource utilization for the design was estimated to be:

Resource	Usage
Multipliers	13
Adders/Subtractors	177
Registers	1004
Total 1-Bit Registers	16657
RAMs	0
Multiplexers	610
I/O Bits	196
Static Shift operators	8
Dynamic Shift operators	8

Notice that the **Adders/Subtractors**, **Registers**, and **Total 1-Bit Registers** counts have reduced after the atomic subsystems are shared.

You can also run synthesis workflow on the model. The synthesis results for this model are:

Resource	Usage
----------	-------

Slice LUTs	8848
Slice Registers	8308
DSPs	13
Block Ram Tile	0
URAM	0

Notice that the **Slice Registers** count has reduced after sharing.

Delay Balancing

In this section...

“Specify Delay Balancing” on page 28-81

“Delay Balancing Considerations” on page 28-83

“Delay Absorption During Delay Balancing” on page 28-84

“Delay Balancing Limitations” on page 28-85

“Delay Balancing Report” on page 28-85

To achieve more efficient hardware usage and higher clock rates in your model, HDL Coder has several optimizations, block implementations, and options that introduce discrete delays into your model. Optimizations such as output pipelining, streaming, or resource sharing can introduce delays. Some block implementations, such as the Newton-Raphson and CORDIC architecture, inherently introduce delays in the generated code.

When optimizations or block implementation options introduce delays along the critical path in a model, the numerics of the original model and generated model or HDL code can differ from each other because equivalent delays are not introduced on other, parallel signal paths. Manual insertion of compensating delays along other paths is possible, but is prone to error and does not scale well to large models that have many signal paths or multiple sample rates.

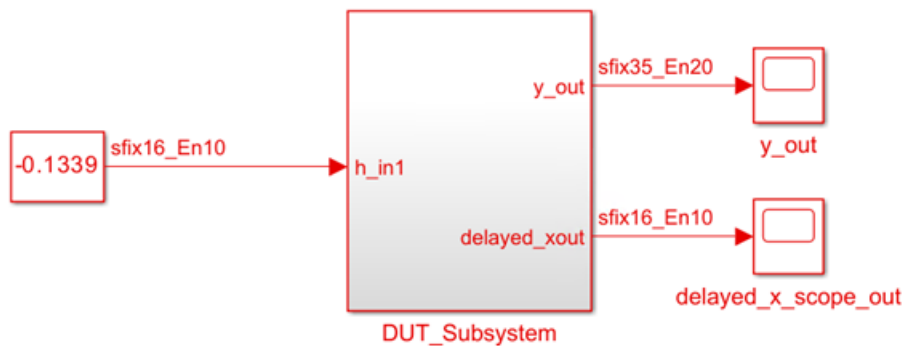

To avoid this issue, HDL Coder provides delay balancing. By default, delay balancing is enabled on the model. HDL Coder detects introduction of new delays along one path, and then inserts matching delays on the other paths. When you enable delay balancing, the generated model is functionally equivalent to the original model. It is not recommended that you disable delay balancing on the model. If you disable this setting, HDL Coder generates a warning that numeric differences can occur in the validation model. To fix this warning, enable delay balancing on the model or run the model check “Check delay balancing setting” on page 44-11.

Specify Delay Balancing

You can set delay balancing for the ports in your device under test (DUT) subsystem, subsystems within the top-level DUT subsystem, or an entire model. Disabling delay balancing for an entire model is not recommended. You can disable delay balancing for specific parts of your design by using the HDL block property **BalanceDelays** for input and outputs ports and subsystems. See “Delay Balancing Considerations” on page 28-83.

Disable Delay Balancing for Constant Sources

A stable path is a path where the initial source to the path is constant. If your model contains a stable path outside the DUT and connected to the top-level DUT subsystem and you want to reduce the amount of resources needed, you can disable delay balancing for the stable path by disabling the HDL block property **BalanceDelays** on the DUT-level Inport block. The **BalanceDelays** property affects only DUT-level Inport blocks. For example, in this model, you can disable **BalanceDelays** for the DUT_Subsystem Inport block and input port h_in1 because the input to the Inport block is a Constant block.

To disable the HDL block property **BalanceDelays** for an Inport block using the HDL Block Properties dialog box:

- 1 Right-click the Inport block.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 Set **BalanceDelays** to off.

To disable delay balancing for an Inport block from the command line, use the `hdlset_param` function.

If you have a subsystem hierarchy in your DUT and you disable **BalanceDelays** on the DUT-level Inport block, delay balancing on the stable path does not occur at lower-level hierarchy if the stable path propagates to the lower-level hierarchy. For an example, see the Constrain Delay Balancing to the Data Path section in “Control the Scope of Delay Balancing” on page 28-104.

When you disable delay balancing for a subsystem, that setting takes precedence over the on setting for the **BalanceDelays** property of Inport blocks in the subsystem. For example, if you disable delay balancing for a model or subsystem that contains an Inport block with **BalanceDelays** set to on, you do not need to disable delay balancing for that Inport block.

Note When you disable **BalanceDelays** on DUT-level Inport blocks for stable paths and distributed pipelining is enabled for the model, change the **Distributed pipelining priority** configuration parameter from **Numerical Integrity** to **Performance** if you see delays inserted on stable paths in the generated model. For more information, see “Distributed pipelining priority” on page 19-13.

If your model contains a stable path that originates in the DUT, meaning that there is a Constant block as an input in the DUT, and a parallel path to the stable path has latency introduced from optimizations, delay balancing does not insert a matching delay on the stable path that contains the Constant block because the output value of the block is a constant. Not inserting the delay results in less resources needed for the design, but also results in an initial simulation mismatch. To resolve the simulation mismatch, add matching delays to the Constant block path by setting the HDL block property **OutputPipeline** to the number of matching delays needed at the output of the Constant block.

Disable Delay Balancing for a Subsystem

You can disable delay balancing for a specific subsystem in your model to localize delay balancing. Disabling delay balancing for a subsystem is only recommended in advanced use cases and can result

in a mismatch in the validation model. To disable delay balancing for a subsystem, use the subsystem HDL block property `BalanceDelays`.

Delay Balancing Considerations

When you generate HDL code, delay balancing is an essential part of code optimizations. If any optimizations are enabled, you must balance pipelines introduced as a part of those optimizations. Failure to balance automatically inserted pipeline delays causes issues in generated code deployed in hardware. The recommended way to balance these delays is to keep `BalanceDelays` enabled for the model.

When you disable delay balancing for the model, HDL Coder does not compensate for latency inserted due to optimizations or block implementations. Unbalanced delays can lead to a mismatch in simulation results between HDL code and your Simulink model and unexpected and untested behavior of hardware implementation. It is recommended that you generate the validation model and observe effects of such unbalanced delays. To generate a validation model, see the configuration parameter **Validation model**. For examples of delay balancing and the validation model, see “Delay Balancing and Validation Model Workflow in HDL Coder” on page 28-96 and “Resolve Numeric Mismatch with Delay Balancing” on page 28-25.

For multirate models, HDL Coder might generate a large number of pipeline registers that can prevent the HDL design from fitting onto an FPGA. Before you disable delay balancing for the model, see “Delay Balancing on Multirate Designs” on page 28-109 and “Optimize Generated HDL Code for Multirate Designs with Large Rate Differentials” on page 14-84.

Resolving Delay Balancing Errors in a Feedback Loop Design

When you enable delay balancing on a model and that model contains a feedback loop in the DUT subsystem, during HDL code generation, you may see this error:

```
Delay balancing unsuccessful because an extra 3 cycles of latency introduced
in the feedback loop cannot be absorbed. Consider increasing the latency
budget by adding more design delays in the feedback loop or using clock-rate
pipelining. If clock-rate pipelining is already enabled, refer to
"highlightClockRatePipelining.m" for further diagnostics.
```

In this situation, the error is a result of pipelining in feedback loops that introduces latency and breaks the functional equivalence between the original and generated model. However, disabling delay balancing for the entire model results in a simulation mismatch between your original model and the generated model. To resolve this issue, either:

- Use clock-rate pipelining. See the Use Clock-Rate Pipelining section in “Resolve Simulation Mismatch when Pipelining with a Feedback Loop Outside the DUT” on page 28-31.
- Increase the latency budget by adding more design delays. See the Model with Latency in a Feedback Loop section in “Use Delay Absorption While Modeling with Latency” on page 28-87.

Disable Global Delay Balancing

If you must disable global delay balancing, you can disable the model setting by:

- Disabling the `BalanceDelays` option for the model at the command line. See the “Command-Line Information” on page 19-5 section for the **Balance delays** parameter. Starting in R2021b, you cannot disable this parameter from the Configuration Parameters window.

- Changing the diagnostic option `TreatBalanceDelaysOffAs` to `Warning` or `None`. This option highlights when disabling `BalanceDelays` results in unbalanced delays in the model. For more information, see “Check for presence of unbalanced delays in generated HDL code” on page 21-107.

When you disable delay balancing for your model:

- Turn off features that generate pipelines or add latency, such as optimizations like resource sharing, streaming, pipelining, or enabling the `MapToRAM` HDL block property of a lookup table (LUT) block. Manually balance the delays instead. For more information, see “Resource Sharing for Area Optimization” on page 28-54, “Streaming: Area Optimization” on page 28-49, “Distributed Pipelining: Speed Optimization” on page 28-140, and “MapToRAM” on page 26-19.
- Use local delay balancing where possible to save time on manually balancing delays for your entire DUT. For more information on how to apply local delay balancing to specific parts of your model, see “Control the Scope of Delay Balancing” on page 28-104 and “Set Delay Balancing For a Subsystem” on page 26-5.
- Check for the command-line messages about additional latency, such as `The code generation and optimization options you have chosen have introduced additional pipeline delays`, and remove optimization settings that insert latency. For an example, see “Delay Balancing and Validation Model Workflow in HDL Coder” on page 28-96.
- Run the `Check for blocks that have nonzero output latency` Model Advisor check. For more information, see “Check for blocks that have nonzero output latency” on page 44-21.

Delay Absorption During Delay Balancing

The delay balancing optimization applies delay absorption to your model, which uses design delays in place of pipeline delays introduced from optimizations to prevent unused latency from being added in your design. Similar to other pipeline optimizations, such as distributed pipelining, delay absorption moves existing delays to the point where an optimization introduces latency. Delay absorption allows you to model with latency, which means that you can add design delays in the original design to simulate the extra delays introduced by optimizations in the generated design. If there are enough design delays, the extra delays introduced by optimizations are absorbed and no additional cycles of latency are reported at the DUT output ports. Modeling with latency prevents timing differences between the original model and generated model and allows HDL Coder to generate a functionally equivalent model to the generated HDL code. Modeling with latency at the clock rate is useful for high-frequency, high-throughput applications, such as signal processing and wireless system design. For more information, see “Use Delay Absorption While Modeling with Latency” on page 28-87.

For delay absorption to run during HDL code generation:

- Delay balancing must be on for the model.
- Place a `Delay` block with a delay length equal to or greater than the block latency after the block that introduces latency. You can place the `Delay` block anywhere downstream on the data path from the block that introduces latency. For example, if you have a series of floating-point operators that accumulate to create a large amount of latency, you can place a single `Delay` block with a delay length equal to the total latency from the operators at the end of the series of operators.
- For delay absorption to take place inside of a triggered subsystem, enable the model parameter **Use trigger signal as clock**.

For more information on floating-point operations and delay absorption, see “Latency Considerations with Native Floating Point” on page 14-109.

Delay Balancing Limitations

Subsystem-Level Restrictions

HDL Coder does not support delay balancing if:

- The “BalanceDelays” on page 26-5 block property for all instances of an Atomic Subsystem or Model Reference resolves to a different value.

To fix this error, enable `BalanceDelays` for all instances of the Atomic Subsystem or Model Reference.

- A subsystem with `BlackBox Architecture` has the `ImplementationLatency` block property set to a negative value.

To fix this error, for `ImplementationLatency`, enter a nonnegative integer.

Sample Time Restrictions

HDL Coder does not support delay balancing if you introduce latency from optimizations and:

- The sample time is continuous.
- Your design has an infinite sample time output.

Delay Balancing Report

To see the delay balancing information in the report, before you generate code for each subsystem or model reference, enable the optimization report. In the **HDL Code Generation** tab, select **Report**, and then select **Generate optimization report**.

When you generate code for each subsystem, model reference, or MATLAB Function block, HDL Coder produces the optimization report. Select the **Delay Balancing** section of the report.

The Delay Balancing Report shows latency changes, pipeline and phase delay at the output ports, and the number of pipelines added at the output ports to match the delays. If delay balancing fails, the report displays the criteria that was violated and the link to any block or subsystem that caused delay balancing to fail.

Use Delay Absorption While Modeling with Latency

Learn how to model your design with latency to apply the delay absorption optimization that runs when you generate HDL code with delay balancing.

Delay absorption is part of the delay balancing optimization. Delay absorption uses design delays in place of pipeline delays introduced from optimizations to prevent unused latency from being added to your design. You can use delay absorption by modeling with latency, which means that you add design delays to your model to take the place of introduced latency from optimizations. By modeling your design with latency, HDL Coder™ can use delay absorption to absorb the design delays and not introduce extra pipeline delays that add latency to your model, which prevents timing differences between the original model and generated model and allows HDL Coder to generate a functionally equivalent model to the generated HDL code.

Delays in your design can either be design delays or pipeline delays. Design delays are delays that you manually insert in your design by using Delay blocks, or other blocks that have state, including Queue, HDL FIFO, or Buffer blocks. Pipeline delays are delays that are generated by optimization settings, such as input or output pipelining options or block implementation settings, such as the `ShiftAdd` implementation for a Divide block and the CORDIC approximation for a Trigonometric Function block.

Certain block implementations, floating-point operations, and optimization settings, such as input pipelining or resource sharing, introduce latency to the generated HDL code and generated model. The additional latency results in a timing difference between the original model and the generated model. To avoid this timing difference, such as when you are using a control system with a feedback loop, you can add design delays to your model. For delay absorption to absorb the design delays:

- Place a Delay block after the block that is introducing latency. You can place the Delay block anywhere downstream on the data path from the block that introduces latency.
- Set the Delay block **Delay length** parameter to a value equal to the block latency.

By adding Delay blocks to your original model, you can simulate your original model with latency.

These blocks can introduce latency:

- Divide, Sqrt, and Reciprocal blocks that have custom latency value greater than zero
- Trigonometric Function blocks that have **Function** set to `sin`, `cos`, `sincos`, `cos+jsin`, or `atan2` and **Approximation method** set to CORDIC
- Native floating-point operators that have the HDL block property **LatencyStrategy** set to `Max`, `Min`, or a custom value greater than zero

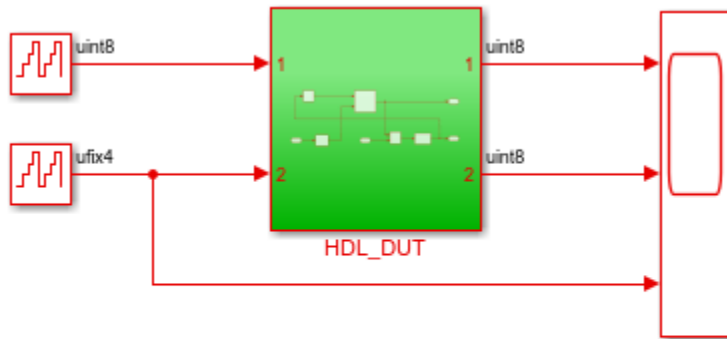

To learn about blocks that have custom latency with fixed-point types, open the `HDLMathLib` library. The library contains fixed-point blocks that have control signals.

```
open_system('HDLMathLib')
```

Model with Latency When Blocks Introduce Latency

To learn how HDL Coder absorbs delays, open the model `hdlcoder_absorb_delay_timing`.

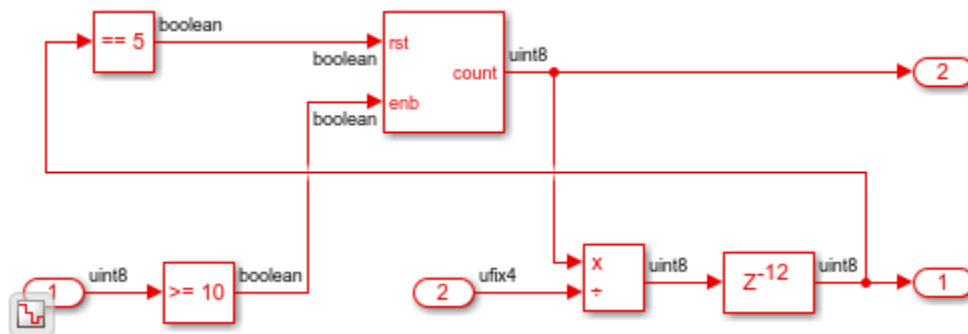

```
open_system('hdlcoder_absorb_delays')
set_param('hdlcoder_absorb_delays', 'SimulationCommand', 'Update')
```

Copyright 2020 The MathWorks, Inc.

Inside the HDL_DUT subsystem, you see a Delay block that has **Delay length** equal to 12 beside the Divide block. This **Delay length** corresponds to the latency of the division operation for fixed-point data types. In this case, the required **Delay length** is the sum of the bitwidth, 8, and 4, which is equal to 12.

```
load_system('hdlcoder_absorb_delays')
open_system('hdlcoder_absorb_delays/HDL_DUT')
```

To generate HDL code for the DUT subsystem, use the `makehdl` function.

```
makehdl('hdlcoder_absorb_delays/HDL_DUT')
```

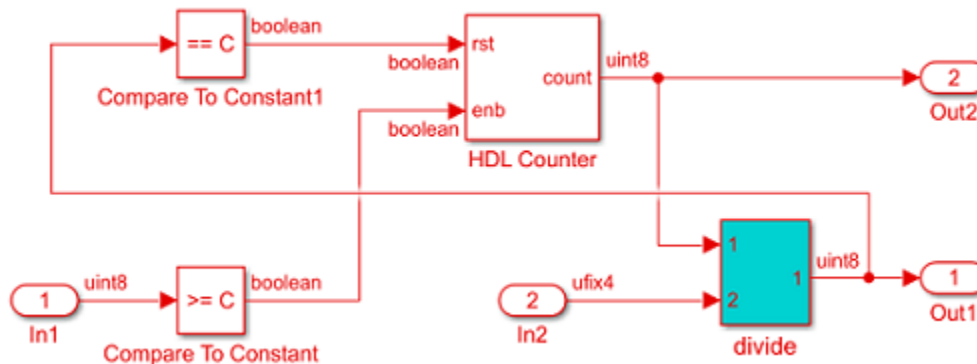

```

```

In the generated model, the delays beside the Divide block are absorbed into the block latency. When you double-click this Divide block, you see the original Divide block and the Delay block with **Delay length** of 12.

For an example that shows delay absorption for floating-point operations, see “Latency Considerations with Native Floating Point” on page 14-109.

Model with Latency When Optimizations Introduce Latency

Optimizations such as distributed pipelining can introduce latency. For example, open this model `hdlcoder_absorb_delay_sharing`. The DUT subsystem contains two subsystems `sub_scalar` and `sub_add`.

```

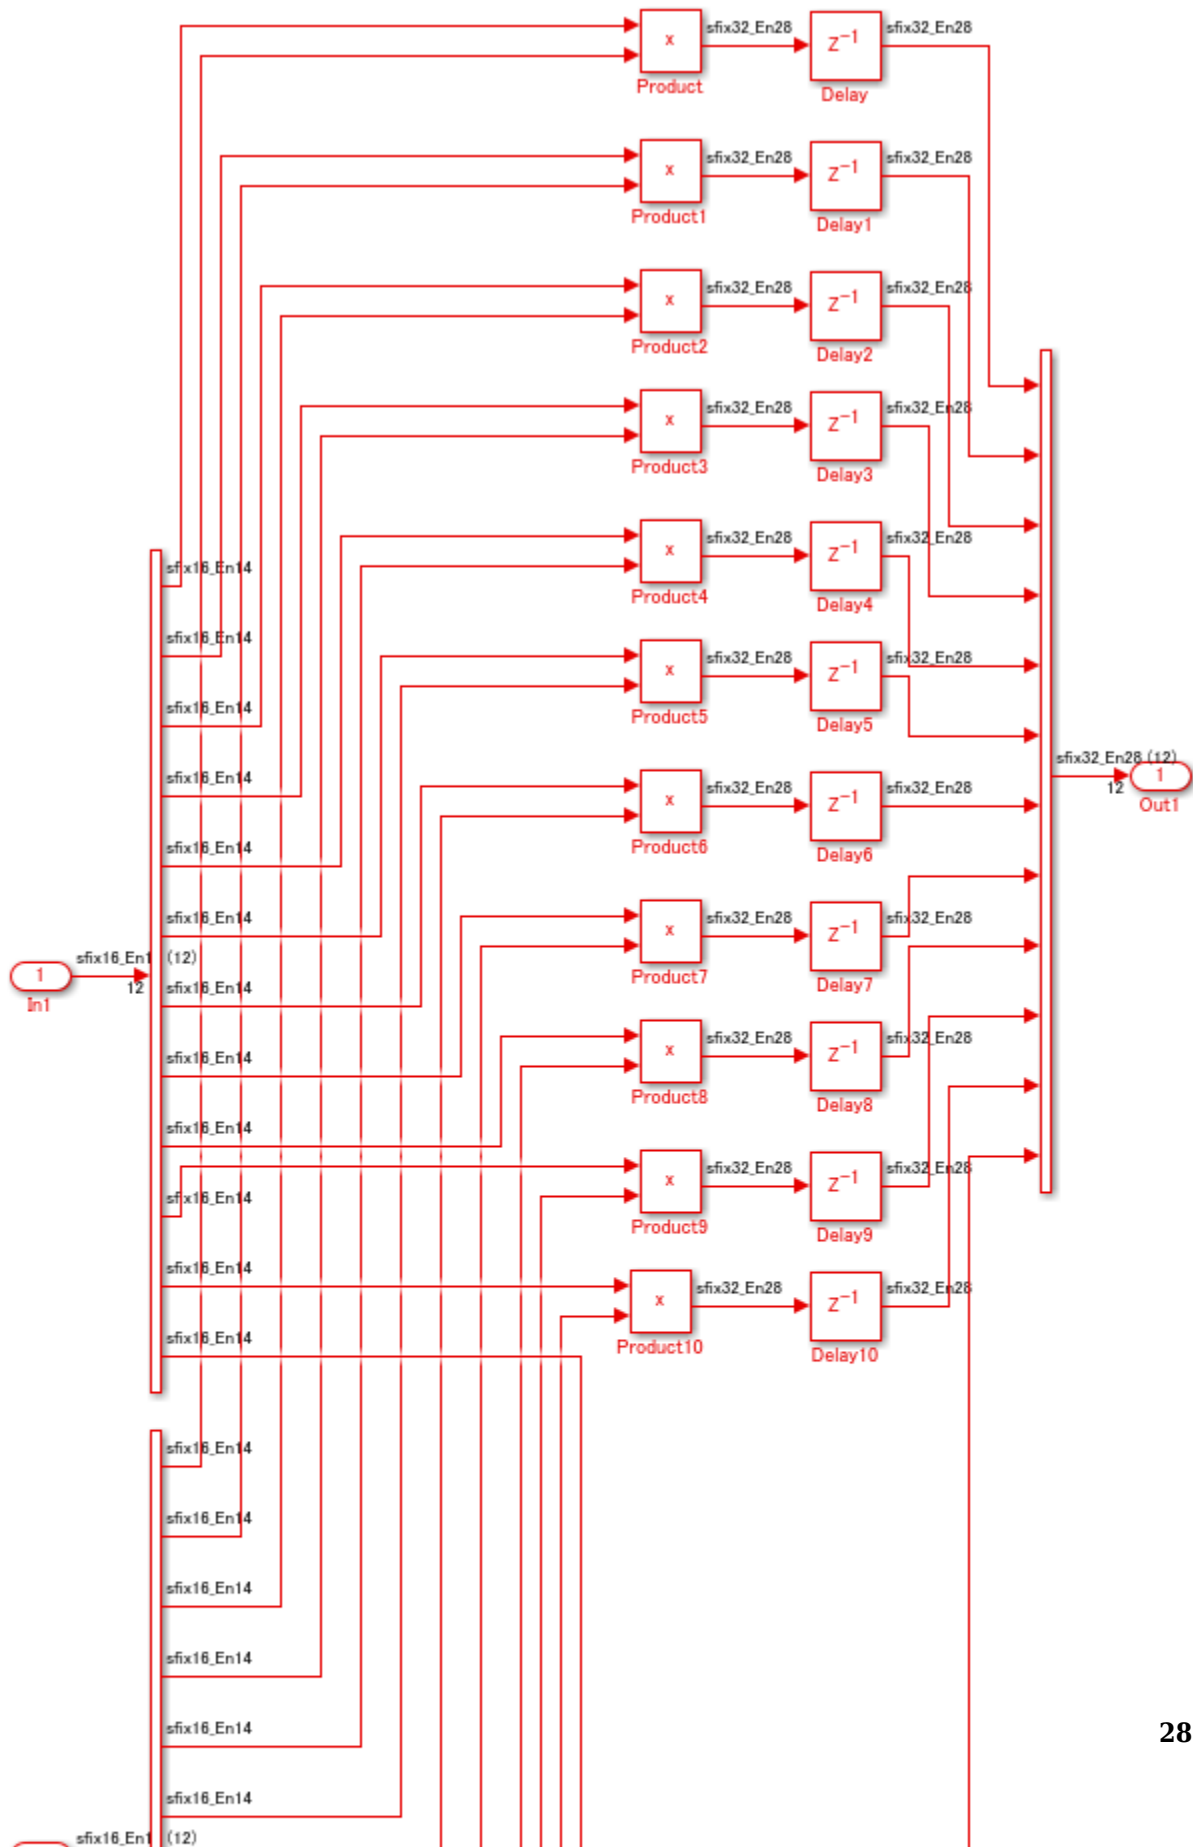

load_system('hdlcoder_absorb_delay_sharing')
open_system('hdlcoder_absorb_delay_sharing')
set_param('hdlcoder_absorb_delay_sharing', 'SimulationCommand', 'Update')

```

The `sub_scalar` subsystem consists of 12 Product blocks that have a unit delay beside them. To share these Product blocks, a **SharingFactor** of 12 is specified on the `sub_scalar` subsystem.

```
open_system('hdlcoder_absorb_delay_sharing/DUT/sub_scalar')
```

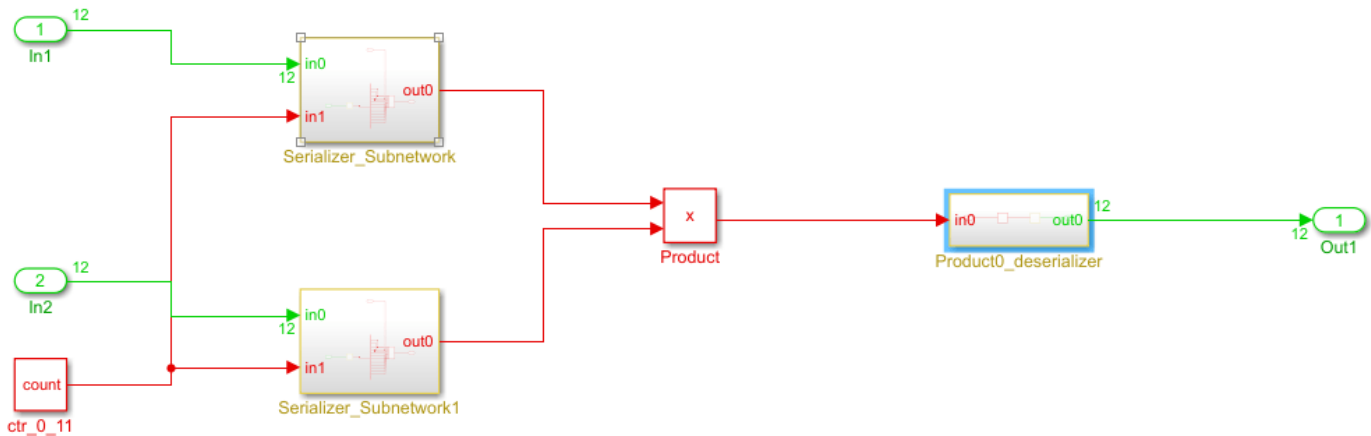

To generate HDL code for the DUT subsystem, use the `makehdl` function.

```
makehdl('hdlcoder_absorb_delay_sharing/DUT')

### Generating HDL for 'hdlcoder_absorb_delay_sharing/DUT'.

```

When you specify a value greater than 1 for the **SharingFactor**, Deserializer blocks that have 1 sample delay are inserted after HDL code generation. By adding the unit Delay blocks beside the Product blocks in the original model, these delays are absorbed into the Product block after you perform the sharing optimization.

In the generated model, the delays are absorbed in the Deserializer block.

Model with Latency in a Feedback Loop

When you model with latency in a feedback loop, you can either:

- Use clock-rate pipelining. For more information see “Clock-Rate Pipelining” on page 28-149.
- Use delay absorption. For example, you can model a feedback loop at the clock rate with some amount of latency expressed as design delays to absorb the latency introduced from native floating-point operators or pipeline optimizations.

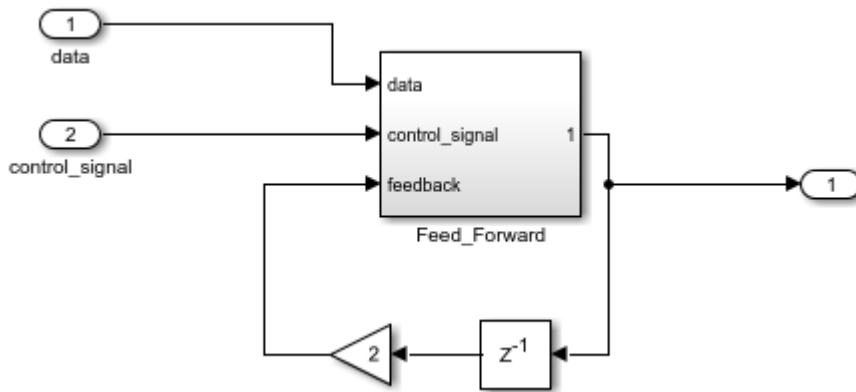

In this example, use delay absorption to model with latency in a feedback loop.

This example contains output pipelines to help optimize the speed of the design, but at the cost of introducing an extra cycle of latency for each pipeline. This additional latency is balanced during delay balancing so that the numerics and functionality of the algorithm are preserved. However, in a feedback loop, delay balancing requires you to model with latency in order to absorb the design delays to prevent a timing mismatch as a result of the pipeline optimizations.

For example, if you generate code with output pipelines added in a feedback loop without modeling with latency, HDL Coder generates a delay balancing error. You can observe this in the `delay_absorption_feedback_loop` model, where the subsystem `delay_absorption_feedback_loop/DUT/Subsystem` is in a feedback loop and the `delay_absorption_feedback_loop/DUT/Feed_Forward/Sum` block has the HDL block property `OutputPipeline` set to 2.

Load and open the model to its DUT subsystem.

```
load_system('delay_absorption_feedback_loop');
open_system('delay_absorption_feedback_loop/DUT');
```

View the non-default parameters by using `hdlsaveparams` to see the `OutputPipeline` setting for the Sum block.

```
hdlsaveparams('delay_absorption_feedback_loop');
```

```
%% Set Model 'delay_absorption_feedback_loop' HDL parameters
hdlset_param('delay_absorption_feedback_loop', 'GenerateValidationModel', 'on');
hdlset_param('delay_absorption_feedback_loop', 'HDLSubsystem', 'delay_absorption_feedback_loop/DUT');
hdlset_param('delay_absorption_feedback_loop', 'OptimizationReport', 'on');
```

```
% Set Sum HDL parameters
```

```
hdlset_param('delay_absorption_feedback_loop/DUT/Feed_Forward/Sum', 'OutputPipeline', 2);
```

If you generate code by using the `makehdl` function, there is a delay balancing error in the HDL Code Generation Report. To fix this error, you need to add enough latency in your design to match the amount of latency added from the output pipelining optimization.

In this example, you need two unit delays total, or a single design delay with a **Delay Length** of two. The error mentions only one extra cycle of latency because the current Delay block in the feedback path is absorbed to handle one of the two extra cycles of latency. Increase the feedback delay block from a **Delay Length** of one to a **Delay Length** of two. You can do this by setting the parameter in the Delay block or by using this command:

```
set_param('delay_absorption_feedback_loop/DUT/Delay', 'DelayLength', '2');
```

Generate HDL code by using the `makehdl` function.

```
makehdl('delay_absorption_feedback_loop/DUT');
```

```

### HDL code generation complete.

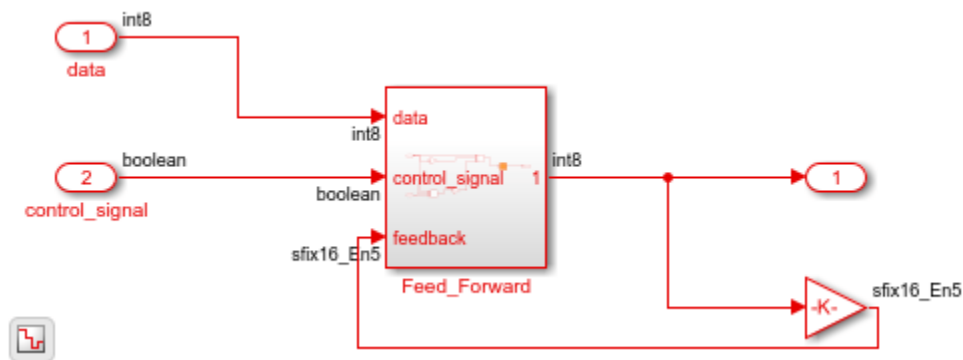

```

Open the generated model to view the absorbed design delays. The feedback delays were absorbed and moved into the `Feed_Forward` subsystem to handle the latency added from output pipelining. No extra latency is introduced as a result of delay absorption.

```

open_system('gm_delay_absorption_feedback_loop/DUT');
set_param('gm_delay_absorption_feedback_loop', 'SimulationCommand', 'update');

```

When applying delay absorption in a feedback loop, follow these guidelines:

- Add the design delays to be absorbed at the same subsystem level as the feedback loop.
- Delay absorption cannot absorb upstream latency from a feedback loop, which means that if there are design delays placed before a feedback loop in your model, delay absorption does not absorb those upstream design delays. If you do have upstream latency that is not absorbed, HDL code generation produces a delay balancing error message in the HDL code generation report. Use clock-rate pipelining to model with latency when there is upstream latency in your design.
- Delay absorption cannot absorb design delays separated from the block that introduces latency by a component that takes in a zero-input value and outputs a non-zero value, such as a NOT Logical Operator block.

Delay Balancing and Validation Model Workflow in HDL Coder

This example shows how HDL Coder™ can automatically balance delays within a model. HDL Coder may introduce additional delays in the HDL implementation for a given model. These delays may be introduced by either certain block implementations or by optimizations for the purpose of improving the efficiency of the hardware implementations. However, introducing delays on only certain paths can result functional behavior that is different from the original intent of the user model, thereby violating functional equivalence between the original user model and the HDL implementation.

Delay Balancing is a feature supported by HDL Coder for automatically balancing such newly introduced delays across all parallel paths, ensuring that functional integrity is preserved with reference to the original model. This equivalence relationship can be confirmed by invoking the validation model workflow that enables the user to visualize the HDL Code-generation model, the delays introduced by implementations and those introduced by delay balancing and verify the equivalence relationship with the original model.

Implementations and Optimizations introduce Latency

Some of the arithmetic blocks in Simulink® require complex hardware algorithms. Consider, for example, the reciprocal square root block. This block computes its answer in a single time step in Simulink. If the corresponding hardware implementation should stay cycle-accurate with Simulink, the hardware algorithm for this block must compute in a single clock cycle. However, this results in a long critical path that degrades the clock frequency and efficiency of hardware. Thus, HDL Coder implements this block with a 5-cycle latency, which means that every path containing this block will introduce a 5-cycle delay.

Certain optimizations supported by HDL Coder may also introduce additional delays. For example, specifying `InputPipeline` or `OutputPipeline` as an implementation parameter on a block introduces additional pipeline delays in the generated HDL. This is again unmatched across parallel paths and will result in functional differences with the original model.

Consider an example model that contains a square root block implementing the `rSqrt` function and the `Gain3` block along the parallel path has the `OutputPipeline` HDL Block property set to 2.

```
bdclose all;
load_system('hdl_delaybalancing');
open_system('hdl_delaybalancing/Subsystem');
set_param('hdl_delaybalancing', 'SimulationCommand', 'update');
```

Validation Model Generation

Due to changes in latency, the HDL Coder always generates a Code Generation model that captures the added delays during implementation. The RTL verification and automatic co-simulation model

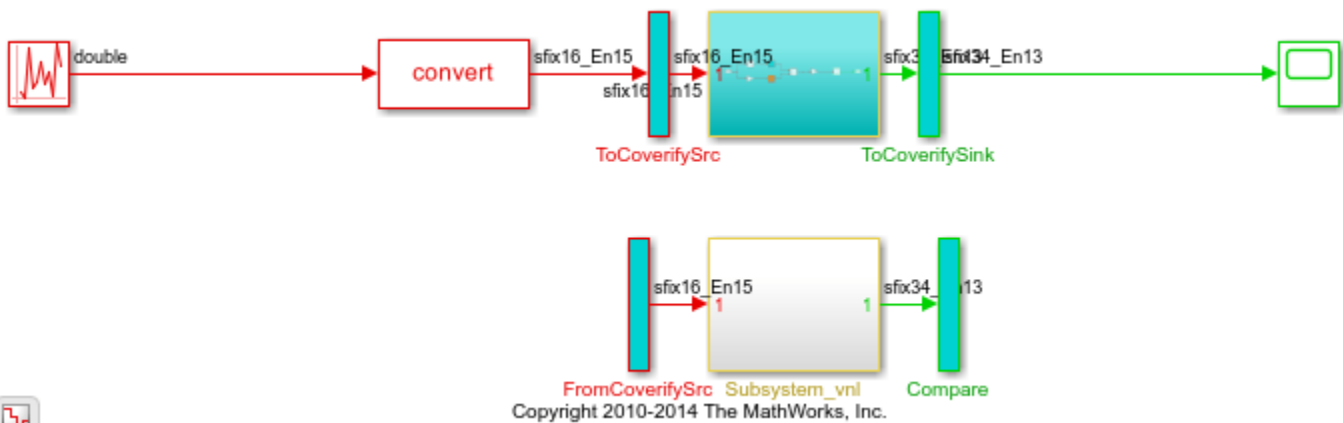

generation features validate that the RTL simulation of the generated HDL code is bit-accurate and cycle-accurate with the Simulink simulation of the Code-generation model. However, this does not say anything about the functional relationship with the original, user model.

The Validation model enables the user to verify that the functional equivalence of the original, user model with the Code-generation model. This feature is turned on by the model-level parameter, `GenerateValidationModel`. This parameter can be set by either the `hdlset_param` command or can be supplied as a `makehdl` argument. Then, during code generation, notice a message that says that validation model has been generated.

The Validation Model consists of two parts: the DUT from the original model (`gm_hdl_delaybalancing_vnl/Subsystem_vnl`) and the DUT from the Code-generation model (`gm_hdl_delaybalancing_vnl/Subsystem`).

```
hdlset_param('hdl_delaybalancing', 'GenerateValidationModel', 'on');
hdlset_param('hdl_delaybalancing', 'BalanceDelays', 'off');
makehdl('hdl_delaybalancing/Subsystem');
open_system('gm_hdl_delaybalancing_vnl');
set_param('gm_hdl_delaybalancing_vnl', 'SimulationCommand', 'update');

Code Generation DUT: Output Pipeline Insertion

The top subsystem (`gm_hdl_delaybalancing_vnl/Subsystem`) in the Validation model is the DUT as implemented for HDL code generation and this is reference DUT when performing RTL testbench verification and Cosimulation block based verification. Notice that `OutputPipeline` parameter on the `Gain3` block is implemented by an integer delay of length 2.

```
open_system('gm_hdl_delaybalancing_vnl/Subsystem');
```

Code Generation DUT: Sqrt Block Implementation

Implementing the square root function in on clock cycle is not efficient for hardware. The coder implements a pipelined architecture and this is reflected in the Code-Generation DUT model (under the square root subsystem) by the five additional delays.

```
open_system('gm_hdl_delaybalancing_vnl/Subsystem/Sqrt');
```

Equivalence Checking with the Validation Model

Validation model performs equivalence checking by routing the same inputs to both (the original and code-generation) DUTs using `From` and `Goto` blocks. This is encapsulated in the `ToCoverifySrc` and `FromCoverifySrc` subsystems. Both DUTs now respond to the same stimuli in each time step. The outputs from both DUTs are then sampled in each time step and their equivalence is checked. This is

done by comparing the outputs from each output port, computing their difference, which should always be zero for functional equivalence.

In the current example, however, notice that functional equivalence is violated. The difference between the two outputs is non-zero in several time steps. This results in mismatch assertions and is also reflected in the last panel of the comparison scope.

Automatic Delay Balancing

To solve the functional equivalence problem, you can turn on the delay balancing feature by setting the model-level `BalanceDelays` option to on. This can be done through either the `hdlset_param` command or as a `makehdl` argument.

With `BalanceDelays` turned on, HDL Coder automatically identifies the locations where matching delays need to be added to guarantee functional equivalence. After taking into account all of the

delays introduced from implementation and optimizations, BalanceDelays adds delays that cover regular cut-sets, multi-rate boundaries, and subsystem boundaries.

Now when we observe the Code-generation DUT from the validation model notice that several additional delays have been added for matching delays introduced by the Sqrt block and OutputPipeline option. The names of these delays are typically prefixed with delayMatch. Notice that the coder also automatically computes the appropriate delays needed when crossing rate boundaries.

```
hdlset_param('hdl_delaybalancing', 'BalanceDelays', 'on');
makehdl('hdl_delaybalancing/Subsystem');
open_system('gm_hdl_delaybalancing_vnl/Subsystem')
set_param('gm_hdl_delaybalancing_vnl', 'SimulationCommand', 'update');

Initial Latency and Functional Validation

The delays introduced by implementations essentially construct a pipelined hardware architecture to improve clock frequency and hardware efficiency. The pipeline however introduces an initial latency and the first output sample is generated after this initial latency. While these pipeline delays are

automatically balanced inside the DUT, it is important to manually balance delays outside the DUT in the rest of the model. The amount of delay (or initial latency) is communicated to the user during code generation as follows:

```
### Some latency changes occurred in the DUT. Each output port experiences these additional de
### Output port 0: 2 cycles
```

The equivalence checking in the Validation model uses this initial latency information for delaying the output from the original DUT. This is an example of balancing the delay outside DUT, since the balancing occurs at the inputs of the equivalence checking subsystem. Now, when we simulate the Validation model, note that there are no assertions and thus functional equivalence is preserved. While the pipeline delays are automatically balanced inside the DUT, it is important to manually balance delays outside the DUT in the rest of the model.

Control the scope of delay balancing

The examples above describe the delay balancing feature as applied to the whole DUT. Sometimes, the design may explicitly model control and data paths, and you may not want to insert matching

delays on the control path during delay balancing. The examples in “Control the Scope of Delay Balancing” on page 28-104 show how this option can be applied locally to individual subsystems instead of the entire DUT.

Control the Scope of Delay Balancing

This example shows how to balance delays in specific parts of a design, without balancing delays on the entire design.

You can programmatically balance delays by using the `BalanceDelays` HDL block property to balance the additional delays introduced by HDL Coder™ for certain block implementations and optimizations. You can enable or disable this property on individual subsystems or certain blocks in your model. For example, in a design containing a data path and a control path, you can apply delay balancing only on the data path of the design, such as on the paths that require data synchronization. You can use `BalanceDelays` at the block or subsystem level to control how and where HDL Coder balances delays. `hdlcoder_localdelaybalancing.slx` shows how to disable delay balancing on user-defined stable control paths.

Constrain Delay Balancing to the Data Path

The example model `hdlcoder_localdelaybalancing.slx` has two subsystems under the device under test (DUT) subsystem, `hdlcoder_localdelaybalancing/Subsystem`, `param_control` and `symmetric_fir`, which contain the control logic and the data path, respectively.

```
bdclose('all');
open_system('hdlcoder_localdelaybalancing');
open_system('hdlcoder_localdelaybalancing/Subsystem');
```

To the optimize timing results, each subsystem has one block that has one output pipeline register.

```

open_system('gm_hdlcoder_localdelaybalancing_vnl/Subsystem/param_control');

```

Delay balancing is enabled globally by default and inserts matching delays on both the control path and the data path, as shown in the validation model. For more information on the validation model, see “Generated Model and Validation Model” on page 28-10.

In this example, only the data path, `symmetric_fir`, requires data synchronization. The inputs `u1` through `u4` to the `param_control` subsystem are constant inputs that are coefficients to the FIR filter. The input paths through the DUT subsystem for these coefficients are stable and do not have to synchronize with each other or with the processed data. As a result, you can disable delay balancing for the input ports with constant inputs to the control logic to save on hardware resources. To achieve this, set the HDL block property `BalancedDelays` for Inport blocks `u1` through `u4` of the DUT subsystem to `off`. Because the stable paths propagate through to the lower-level hierarchy in the

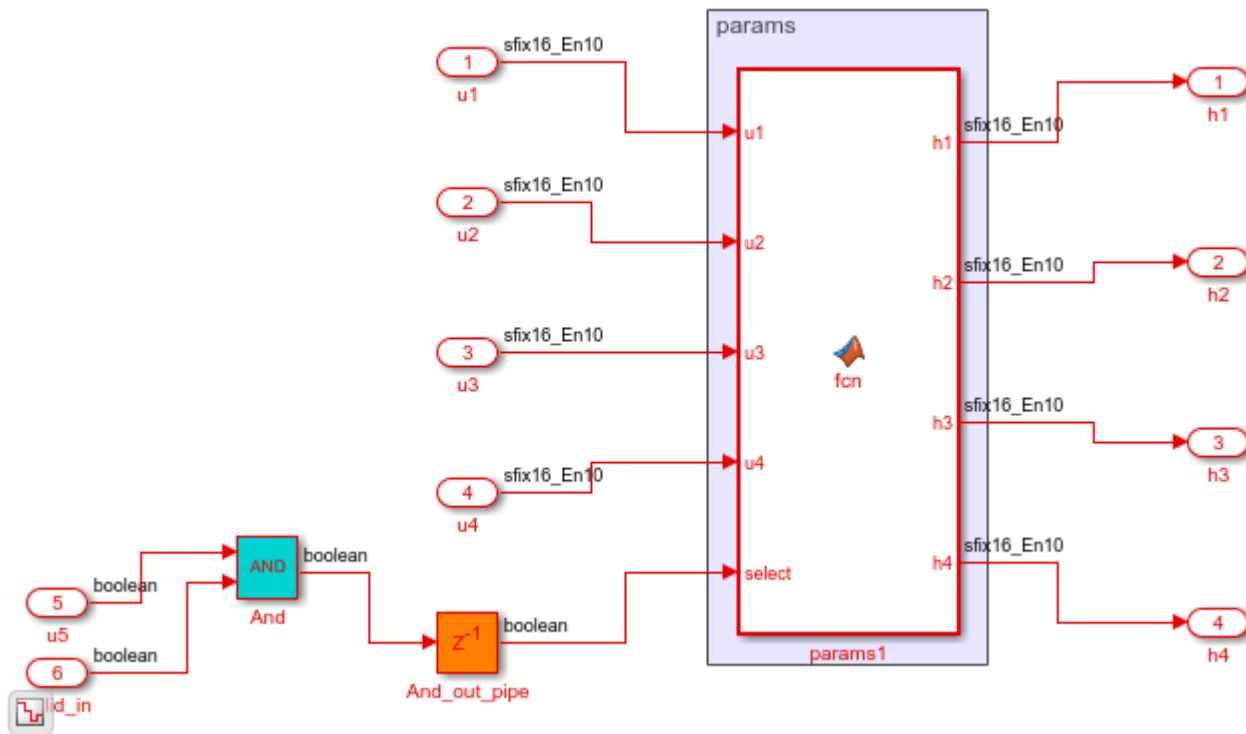

DUT subsystem, you do not need to disable this property for lower-level Inport blocks inside the `param_control` or `symmetric_fir` subsystems.

```
hdlset_param('hdlcoder_localdelaybalancing/Subsystem/u1', 'BalanceDelays', 'off');
hdlset_param('hdlcoder_localdelaybalancing/Subsystem/u2', 'BalanceDelays', 'off');
hdlset_param('hdlcoder_localdelaybalancing/Subsystem/u3', 'BalanceDelays', 'off');
hdlset_param('hdlcoder_localdelaybalancing/Subsystem/u4', 'BalanceDelays', 'off');
```

Close the validation model, generate HDL code using the `makehdl` function, and open the new validation model to the `param_control` subsystem.

```
bdclose('gm_hdlcoder_localdelaybalancing_vnl');
hdlset_param('hdlcoder_localdelaybalancing', 'ValidationModelNameSuffix', '_vnl_DBoff')
makehdl('hdlcoder_localdelaybalancing/Subsystem');
load_system('gm_hdlcoder_localdelaybalancing_vnl_DBoff');
set_param('gm_hdlcoder_localdelaybalancing_vnl_DBoff', 'SimulationCommand', 'update');
Simulink.BlockDiagram.expandSubsystem('gm_hdlcoder_localdelaybalancing_vnl_DBoff/Subsystem/param_control');
open_system('gm_hdlcoder_localdelaybalancing_vnl_DBoff/Subsystem/param_control');
```

```
### Generating HDL for 'hdlcoder_localdelaybalancing/Subsystem'.

Delay Balancing on Multirate Designs

This example shows how an indiscrete usage of Simulate rates on a multirate design can generate an undesirable HDL code, and provides few recommendations for optimal code generation.

Introduction

This example model contains 3 subsystems, the first one demonstrates the issue and the others provide practical ways of resolving the issue.

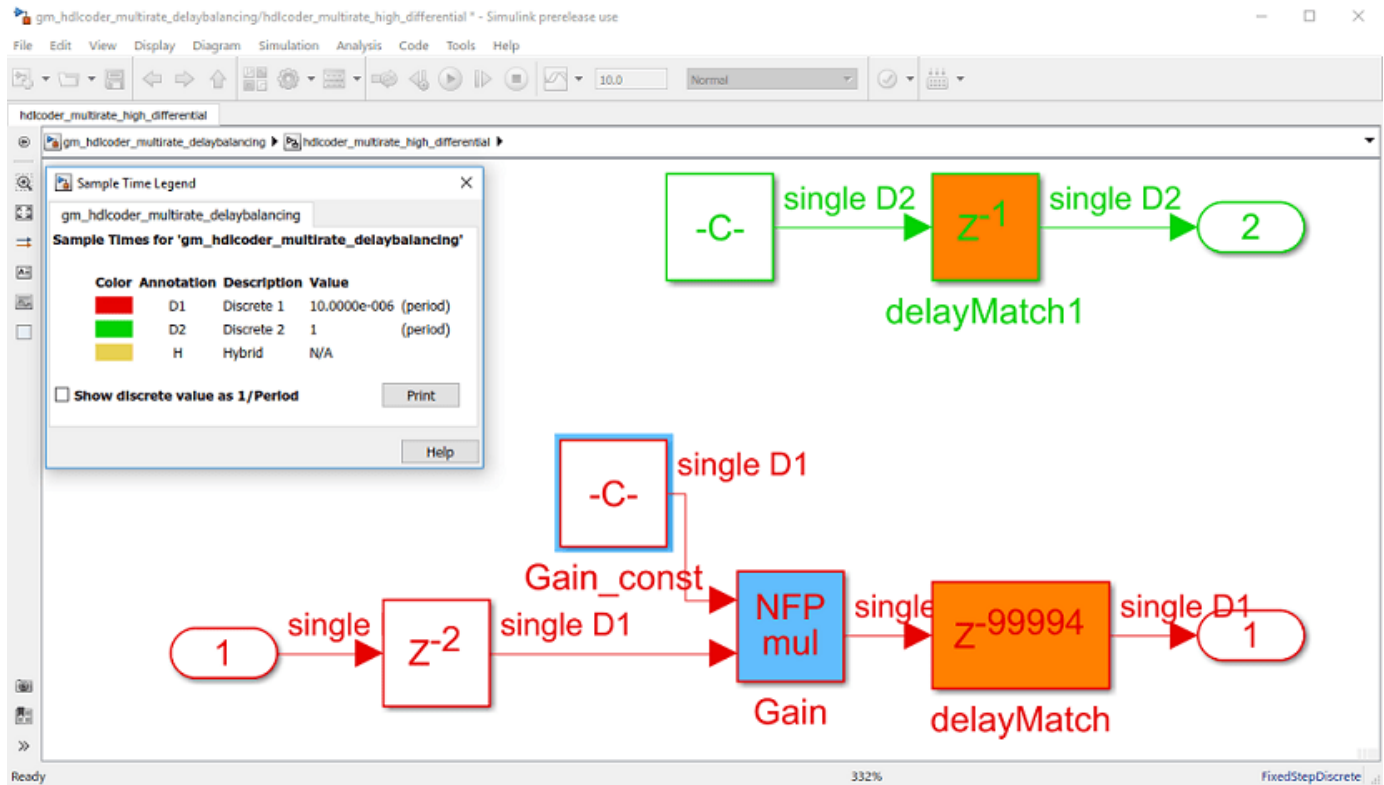

Note in the below design there are two islands of logics, both running at different rates. The rate differential between the two rates is $10E-06$, which is a very high number and possibly unrealistic for practical FPGA design. This model has a floating-point Gain block, a multi-cycle operator, in the fast-clock region.

Running code generation on this model, we get:

```
>> makehdl (gob)
### Generating HDL for 'hdlocoder_multirate_delaybalancing/hdlocoder_multirate_high_differential'.
### Using the config set for model hdlocoder_multirate_delaybalancing for HDL code generation parameters.
### Starting HDL check.
### The code generation and optimization options you have chosen have introduced additional pipeline delays.
### The delay balancing feature has automatically inserted matching delays for compensation.
### The DUT requires an initial pipeline setup latency. Each output port experiences these additional delays.
### Output port 0: 100000 cycles.
### Output port 1: 1 cycles.
### Begin VHDL Code Generation for 'hdlocoder_multirate_delaybalancing'.
### Working on hdlocoder_multirate_delaybalancing/hdlocoder_multirate_high_differential/nfp_mul_comp as hdlocoder_multirate_delaybalancing/nfp_mul_comp.vhd.
### Working on hdlocoder_multirate_high_differential_tc as hdlocoder_multirate_delaybalancing/hdlocoder_multirate_high_differential_tc.vhd.
### Working on hdlocoder_multirate_delaybalancing/hdlocoder_multirate_high_differential as hdlocoder_multirate_delaybalancing/hdlocoder_multirate_high_differential.vhd.
### Generating package file hdlocoder_multirate_delaybalancing/hdlocoder_multirate_high_differential_pkg.vhd.
### Creating HDL Code Generation Check Report hdlocoder_multirate_high_differential_report.html
### HDL check for 'hdlocoder_multirate_delaybalancing' complete with 0 errors, 0 warnings, and 0 messages.
### HDL code generation complete.
```

The compiled generated model looks as below. Note that the high output latency on the fast clock rate region of the design are added to balance delays across multiple output paths of the system.

The high number of registers in the fast clock rate region has an undesired effect post HDL-code generation:

- 1 Generated HDL files are by itself very large.
- 2 The large number of pipeline registers will make fitting the design into an FPGA improbable.

The following sections of this document create a general awareness of the resource constraint that multi-rate models can create when used in the presence of multi-cycle operations, and provides a few recommendations for optimum resource usage.

```
open_system('hdlcoder_multirate_delaybalancing');
```

Recommended Guidelines

Your Simulink models might have different clock-rate paths due to different modeling reasons. In the presence of optimizations, like I/O pipelining, distributed pipelining, streaming and/or sharing, or multi-cycle operations, like floating-point IPs, fixed-point math functions like sqrt or divide, pipelines are introduced which are applied at the same rate at which the signal path operates.

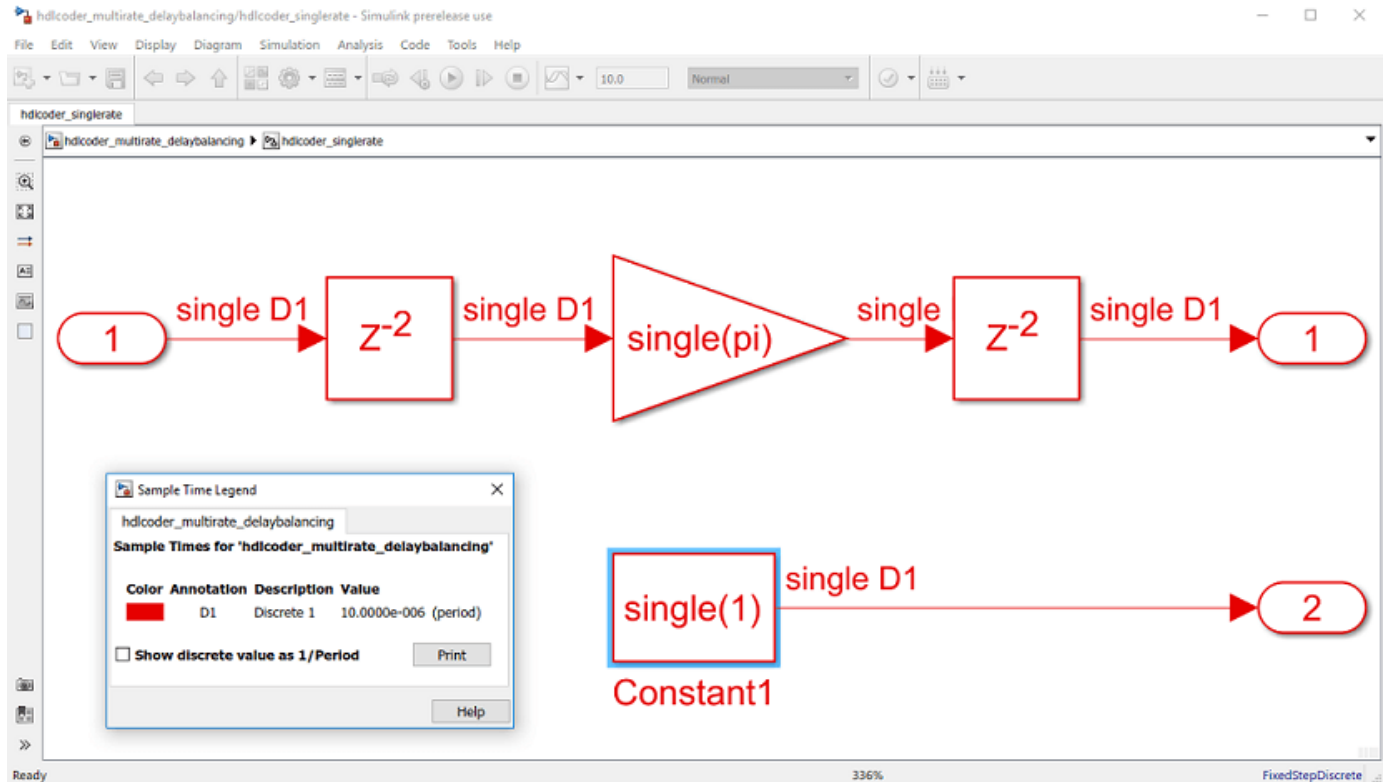

Introducing any additional pipelining introduces undesirable latency overhead that needs to be balanced across multiple output paths, operating at different rates. If the ratio difference between the fastest and slowest clock rate in the Simulink model is very large, it causes a large number of registers to be generated in the final HDL code. The HDL files become large and the design may not even fit into an FPGA.

Recommendation #1: Remove unintentional multirates

There might be an undesirable effect that the rate differential of the model has on the generated HDL code. For instance, in the above model, the sample rate specified on the constant block was not given

consideration and set to a value that caused a rate differential of 10E06 with the base model rate. Such a high rate differential appears unintentional.

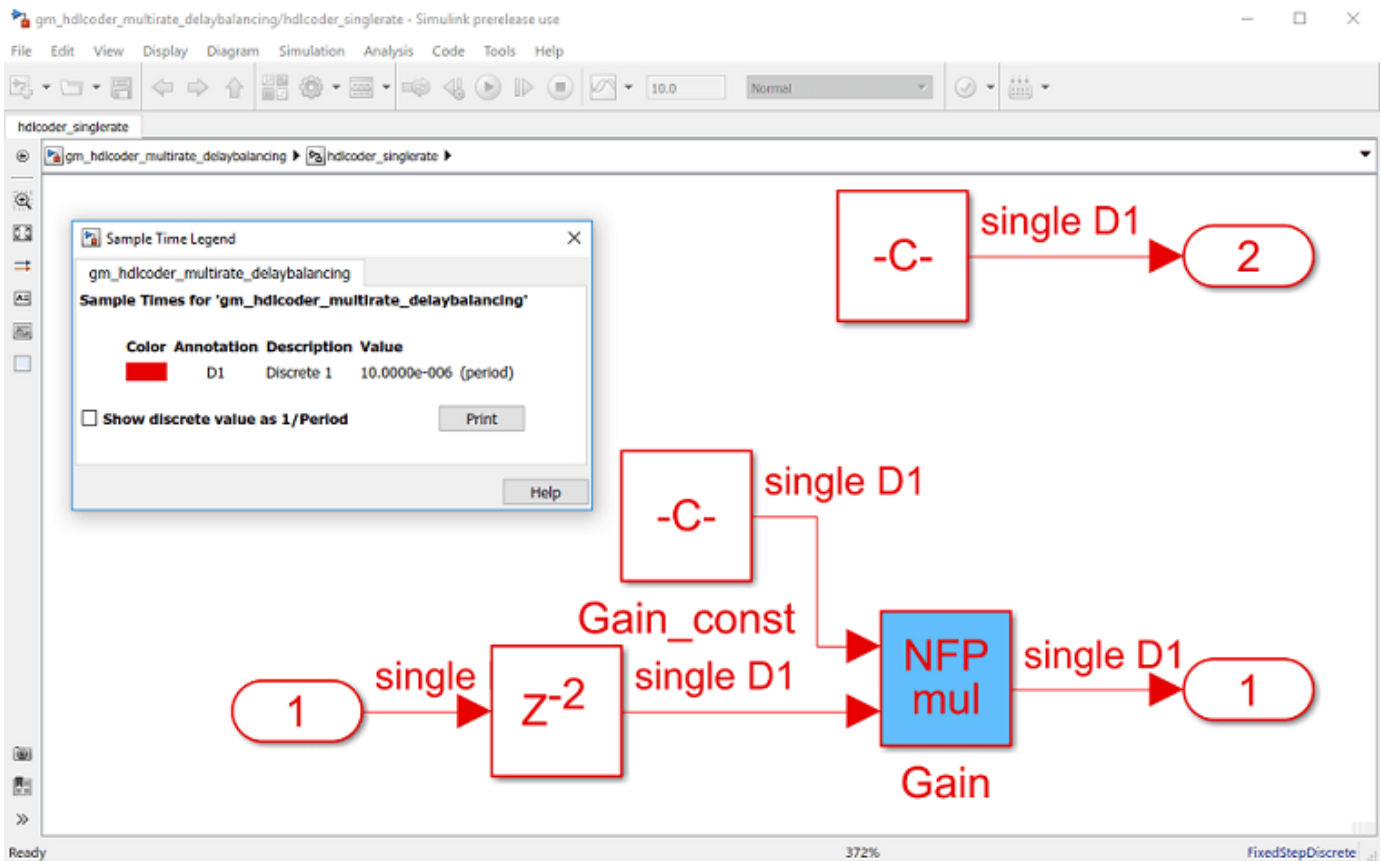

A recommendation is to change the sample rate of the constant block to run at the same rate as the base model, for such a situation.

Running code generation on this model, you get:

```
>> makehdl(gcb)
### Generating HDL for 'hdlcoder_multirate_delaybalancing/hdlcoder_singlerate'.
### Using the config set for model hdlcoder_multirate_delaybalancing for HDL code generation parameters.
### Starting HDL check.
### The code generation and optimization options you have chosen have introduced additional pipeline delays.
### The delay balancing feature has automatically inserted matching delays for compensation.
### The DUT requires an initial pipeline setup latency. Each output port experiences these additional delays.
### Output port 0: 6 cycles.
### Output port 1: 6 cycles.
### Begin VHDL Code Generation for 'hdlcoder_multirate_delaybalancing'.
### Working on hdlcoder_multirate_delaybalancing/hdlcoder_singlerate/nfp_mul_comp as hdlsrc/hdlcoder_multirate_delaybalancing/nfp_mul_comp.vhd.
### Working on hdlcoder_multirate_delaybalancing/hdlcoder_singlerate as hdlsrc/hdlcoder_multirate_delaybalancing/hdlcoder_singlerate.vhd.
### Generating package file hdlsrc/hdlcoder_multirate_delaybalancing/hdlcoder_singlerate_pkg.vhd.
### Creating HDL Code Generation Check Report hdlcoder_singlerate_report.html
### HDL check for 'hdlcoder_multirate_delaybalancing' complete with 0 errors, 0 warnings, and 0 messages.
### HDL code generation complete.
```

Note that the output latency numbers have decreased significantly. The compiled generated model looks like the image below.

There is no undesirable high number of registers.

Recommendation #2: Keep rate differential practical

If multi-rate is a desirable property that you need, consider making the rate differential as practical as possible.

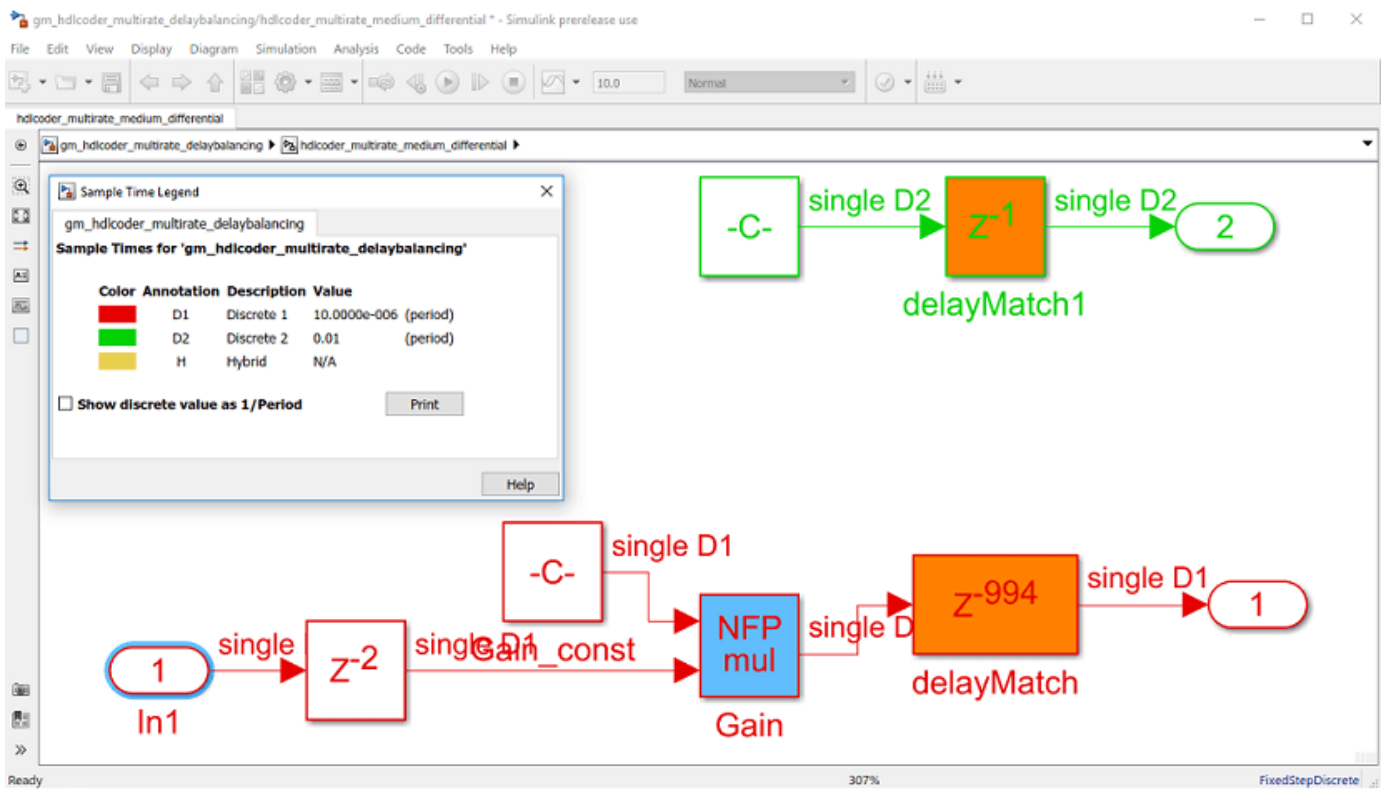

For example, if one path of the design running at 'ns' and other path of your design is at 'us' and is a desirable feature of the design, you can still choose to have multi-rate paths in his model with the awareness that delay balancing may cause high number of registers.

Running code generation on this model, we get:

```
>> makehdl(gcb)
### Generating HDL for 'hdlcoder_multirate_delaybalancing/hdlcoder_multirate_medium_differential'.
### Using the config set for model hdlcoder_multirate_delaybalancing for HDL code generation parameters.
### Starting HDL check.
### The code generation and optimization options you have chosen have introduced additional pipeline delays.
### The delay balancing feature has automatically inserted matching delays for compensation.
### The DUT requires an initial pipeline setup latency. Each output port experiences these additional delays.
### Output port 0: 1000 cycles.
### Output port 1: 1 cycles.
### Begin VHDL Code Generation for 'hdlcoder_multirate_delaybalancing'.
### Working on hdlcoder_multirate_delaybalancing/hdlcoder_multirate_medium_differential/nfp_mul_comp as hdlsrc\hdlcoder_multirate_delaybalancing\nfp_mul_comp.vhd.
### Working on hdlcoder_multirate_medium_differential_tc as hdlsrc\hdlcoder_multirate_delaybalancing\hdlcoder_multirate_medium_differential_tc.vhd.
### Working on hdlcoder_multirate_delaybalancing/hdlcoder_multirate_medium_differential as hdlsrc\hdlcoder_multirate_delaybalancing\hdlcoder_multirate_medium_differential.vhd.
### Generating package file hdlsrc\hdlcoder_multirate_delaybalancing\hdlcoder_multirate_medium_differential_pkg.vhd.
### Creating HDL Code Generation Check Report hdlcoder_multirate_medium_differential_report.html
### HDL check for 'hdlcoder_multirate_delaybalancing' complete with 0 errors, 0 warnings, and 0 messages.
### HDL code generation complete.
```

The compiled generated model looks like the figure below. In the generated model and HDL code, we will have close to 1000 registers in the fast clock rate output path. The additional cost of registers is **not unusual** for control logics that are running 1000x faster than the system. It is important to be aware of the hardware resource constraints for such a model.

To optimize on the total number of registers in FPGA, you can also use the model parameter **Map pipeline delays to RAM**. Doing this can tradeoff RAM resources to save on logic area.

```
>> hdlset_param(gcs, 'MapPipelineDelaysToRAM', 'on');
```

Find Feedback Loops

In this section...

“Specify Highlighting of Feedback Loops” on page 28-117

“Remove Highlighting” on page 28-117

“Limitations” on page 28-118

Feedback loops in your Simulink design can inhibit delay balancing and optimizations such as resource sharing and streaming.

To find feedback loops in your design that are inhibiting optimizations, you can generate and run a MATLAB script that highlights one or more feedback loops in your original model and the generated model. When you run the script, different feedback loops are highlighted in different colors. The feedback loop highlighting script is saved in the same target folder as the HDL code.

After you generate code, if feedback loops are inhibiting optimizations, the command window shows a link that you can click to highlight feedback loops. If you generate an Optimization Report, the report also contains a link you can click to highlight feedback loops.

The script can highlight feedback loops that are inhibiting the following optimizations:

- Resource sharing
- Streaming
- MATLAB variable pipelining
- Delay balancing

Specify Highlighting of Feedback Loops

By default, highlighting of feedback loops is enabled. This setting is available:

- In the Configuration Parameters dialog box, on the **HDL Code Generation > Global Settings > Advanced** tab, select **Highlight feedback loops inhibiting delay balancing and optimizations**.
- To generate a feedback loop highlighting script programmatically, use the `HighlightFeedbackLoops` property with `makehdl` or `hdlset_param`. For example, to generate a feedback loop highlight script for a model, *myModel*, enter:

```
hdlset_param ('myModel', 'HighlightFeedbackLoops', 'on');
```

Remove Highlighting

By default, HDL Coder generates a script to highlight feedback loops and a script to clear the highlighting of feedback loops in your model. You can turn off highlighting using either of these ways:

- Click the `clearhighlighting` script in the MATLAB Command Window
- In the Simulink Toolstrip, select **Debug > Trace Signal**.

Limitations

- Feedback loop highlighting cannot highlight blocks that have names that contain a single quote (').
- In some cases, feedback loop highlighting might highlight a subsystem or one block instead of the lowest-level block.

Hierarchy Flattening

In this section...

“What Is Hierarchy Flattening?” on page 28-119

“When to Flatten Hierarchy” on page 28-119

“Considerations” on page 28-119

“How to Flatten Hierarchy” on page 28-120

“Limitations for Hierarchy Flattening” on page 28-120

“Hierarchy Flattening Report” on page 28-121

What Is Hierarchy Flattening?

Hierarchy flattening enables you to remove subsystem hierarchy from the HDL code generated from your design.

HDL Coder considers blocks within a flattened subsystem to be at the same level of hierarchy, and no longer grouped into separate subsystems. This consideration allows the coder to reorganize blocks for optimization across the original hierarchical boundaries, while preserving functionality.

When to Flatten Hierarchy

To preserve the modularity of the design and have a one-to-one mapping from subsystem name to corresponding HDL module or entity name, do not flatten the hierarchy. The generated HDL code is more readable when you don't flatten the hierarchy.

Flatten hierarchy to:

- Enable more extensive area and speed optimization.
- Reduce the number of HDL output files. For every subsystem that you flatten, HDL Coder generates one less HDL output file.

Considerations

- Before you flatten the hierarchy, you must have the `MaskParameterAsGeneric` property set to `off`. For more information, see “Generate Parameterized HDL Code from Masked Subsystem” on page 21-61.
- When you use optimizations such as resource sharing or streaming with hierarchy flattening, in certain cases, HDL Coder might retain the subsystem hierarchy in the generated model. However, the HDL code generated for the flattened subsystems is inlined, which reduces the number of HDL files.
- When you use floating-point data types in `Native Floating Point` mode, HDL Coder might not flatten the hierarchy. This is because floating-point designs generate hundreds of lines of code and inlining the HDL files makes the generated code less readable.

How to Flatten Hierarchy

By default, a subsystem inherits its hierarchy flattening setting from the parent subsystem. However, you can enable or disable flattening for individual subsystems. This table lists options you can specify for hierarchy flattening options for a subsystem are listed in the following table.

Hierarchy Flattening Setting	Description
inherit (default)	Use the hierarchy flattening setting of the parent subsystem. If this subsystem is the highest-level subsystem, do not flatten.
on	Flatten this subsystem.
off	Do not flatten this subsystem, even if the parent subsystem is flattened.

To set hierarchy flattening using the HDL Block Properties dialog box:

- In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select the Subsystem and then click **HDL Block Properties**. For **FlattenHierarchy**, select **on**, **off**, or **inherit**.
- Right-click the Subsystem and select **HDL Code > HDL Block Properties**. For **FlattenHierarchy**, select **on**, **off**, or **inherit**.

To set hierarchy flattening from the command line, use `hdlset_param`. For example, to turn on hierarchy flattening for a subsystem, `my_dut`:

```
hdlset_param('my_dut', 'FlattenHierarchy', 'on')
```

See also `hdlset_param`.

Limitations for Hierarchy Flattening

A subsystem cannot be flattened if the subsystem is:

- A Synchronous Subsystem or uses the State Control block in Synchronous mode.
- A model reference implementation.
- A Triggered Subsystem when “Use trigger signal as clock” on page 21-41 is enabled.
- A masked subsystem that contains any of the following:
 - Bus.
 - Enumerated data type.
 - Lookup table blocks: 1-D Lookup Table, 2-D Lookup Table, Cosine HDL Optimized, Direct LookupTable (n-D), Prelookup, Sine HDL Optimized, n-D Lookup Table.
 - MATLAB System block.
 - Stateflow blocks: Chart, State Transition Table, Sequence Viewer.
 - Blocks with a pass-through or no-op implementation. See “Pass through, No HDL, and Cascade Implementations” on page 26-57.

Note This option removes subsystem boundaries before code generation. It does not necessarily generate HDL code with a completely flat hierarchy.

Hierarchy Flattening Report

To see the hierarchy flattening information in the report, before you generate code for each subsystem or model reference, enable the optimization report. To enable this report, in the **HDL Code** tab, select **Report Options**, and then select **Generate optimization report**.

The report displays subsystems in your model that have **FlattenHierarchy** set to **on** and **off**, hierarchy flattening status, and the HDL files that are inlined. You can use the report to more effectively flatten the subsystem hierarchy and improve opportunities for optimizations such as clock-rate pipelining on the model.

If hierarchy flattening is unsuccessful, the report shows a table that contains subsystems that are not flattened, and reasons for not flattening the subsystem. Subsystems that have a * highlighted beside it indicates whether the HDL files are inlined though hierarchy flattening failed.

Apply RAM Mapping to Optimize Area

In this section...

“RAM Mapping for a Simulink Model” on page 28-122

“RAM Mapping for a MATLAB Design” on page 28-123

“Use the RAM Mapping Threshold” on page 28-123

“Exclude Inefficient RAM Mapping” on page 28-124

RAM mapping is an area optimization that maps storage and delay elements in your Simulink model or MATLAB code to random access memory (RAM) rather than to individual registers on hardware. RAM mapping can reduce the amount of area that your design uses in the target hardware by reducing the number of registers that elements consume and store those elements in RAM blocks.

RAM Mapping for a Simulink Model

You can map these Simulink model elements to RAM:

- Delay blocks. To map delays to RAM, set the HDL block property UseRAM. For guidelines, see “Map Large Delays to Block RAM” on page 25-98.
- Persistent variables in MATLAB Function blocks. To map persistent arrays in a MATLAB Function block to RAM, set the HDL block property MapPersistentVarsToRAM. For an example, see “RAM Mapping With the MATLAB Function Block” on page 28-126.
- Lookup tables. To map lookup tables to RAM, set the HDL block property MapToRAM.
- RAM blocks from the HDL Operations library:
 - Single Port RAM
 - Single Port RAM System
 - Dual Port RAM
 - Dual Port RAM System
 - Simple Dual Port RAM
 - Simple Dual Port RAM System
 - Dual Rate Dual Port RAM
- Blocks with a RAM implementation.

Specify RAM Mapping for a Simulink Model

To specify RAM mapping for persistent arrays in a MATLAB Function block or Delay blocks:

- 1 Set the associated RAM mapping property for the elements that you want to map to RAM. For example, to map a Delay block to RAM, set the **UseRAM** HDL block property to on. To map persistent arrays, set the MATLAB Function block HDL block property **MapPersistentVarsToRAM** to on.
- 2 Specify a minimum RAM mapping threshold by using the **RAM mapping threshold** configuration parameter. See “RAM Mapping Parameters” on page 19-6.

RAM Mapping for a MATLAB Design

You can map these MATLAB code elements to RAM:

- Persistent array variables.
- Pipeline registers in the generated HDL code.
- `dsp.Delay` System object.
- `hdl.RAM` System object.

Specify RAM Mapping for a MATLAB Design

To specify RAM mapping for delays or persistent arrays in a MATLAB function, in the **Optimizations** section of the **HDL Code Generation** tab of the MATLAB HDL Workflow Advisor:

- 1 Set the associated RAM mapping property for the elements that you want to map to RAM. For example, to map persistent arrays, select the **Map persistent array variables to RAMs** option. For more information, see “Map Persistent Arrays and `dsp.Delay` Objects to RAM” on page 8-6. To map pipeline delays to RAM, select the **Map pipeline delays to RAM** option.
- 2 Specify a value for the **RAM mapping threshold** option. For more information, see “RAMThreshold”.

For an example, see “Map Matrices to Block RAMs to Reduce Area” on page 8-2.

Use the RAM Mapping Threshold

When you use the configuration parameter **RAM mapping threshold (bits)**, you can specify a single integer to define the mapping threshold that maps any delay or persistent array greater than that threshold bit size to RAM. For example, if your design contains a Delay block with a delay length of 1024 cycles and a word length of 28 bits and you set the HDL block property **UseRAM** to on and the **RAM mapping threshold** parameter to 256 total bits, the total RAM size of 28672 bits of the Delay block exceeds the threshold and HDL Coder maps 1024x28 bits to the RAM on hardware. To calculate the total RAM size, use this formula:

$$\text{RAMSize} = \text{Delay length} * \text{Word length} * \text{Vector length} * \text{Complexity}$$

In this case, the input vector length is 1 and the complexity of a real data type is 1, so the total RAM size equation is:

$$\text{RAMSize} = \text{Delay length} * \text{Word length} = 1024 * 28$$

With a block RAM (BRAM) size on the target hardware of 1024x32 bits, the delay is mapped with 4 bits of unused width for each row of RAM. As a result, depending on the shape of the data defined by delay length and word length, RAM mapping might be inefficient.

RAM Merging

RAM merging is a process that merges several delays and maps them to RAM together. During HDL code generation, RAM merging occurs when you have multiple Delay blocks with the same delay length in the same subsystem. RAM merging fuses the delays into a single delay that has a RAM size equal to the sum of the original RAM sizes. If this new RAM size is greater than the **RAM mapping threshold** value, the merged delays are mapped to RAM. For example, if you have three Delay blocks in a subsystem that each have a total RAM size of 40 bits and the **RAM mapping threshold** is 100, all three delays map to RAM because they have a total of $3 \times 40 = 120$ bits when they merge.

Exclude Inefficient RAM Mapping

To exclude inefficient mapping, you can specify two thresholds to define the shape of the data to map to RAM, one for delay length (for delays) or array size (for persistent array variables) and one for word length or bit width of the data type. Setting both thresholds maps delays or persistent arrays more efficiently to RAM by excluding delays or persistent arrays that inefficiently map to block RAM on the target hardware for your design. These thresholds allow you to selectively map data that has a shape similar to specific block RAM configuration on your target hardware.

Set Total RAM Size for RAM Mapping Threshold

For example, for a model with **RAM Mapping Threshold** set to 256, both of these subsystems in the DUT in the generated model are mapped to block RAM on the Xilinx RAMB36E1 because both subsystems contain delays with a total bit size of 32768 bits, which is greater than the threshold, even with different delay lengths and bit widths.

To determine how many block RAMs are used from the design, run synthesis on the model. For more information on how to run synthesis, “HDL Code Generation and FPGA Synthesis from Simulink Model”. This is the Resource summary report from synthesis:

Resource summary			
Resource	Usage	Available	Utilization (%)
Slice LUTs	52	303600	0.02
Slice Registers	356	607200	0.06
DSPs	0	2800	0.00
Block RAM Tile	3	1030	0.29
URAM	0	0	

Because the BRAM on the Xilinx RAMB36E1 can be configured for both 512x64 bits and 1024x32 bits size, the first subsystem inefficiently maps to block RAM and takes up two BRAM of size 512x64 bits, while the second subsystem maps more efficiently to one BRAM of size 1024x32 bits for a total of 3 block RAM.

Set Delay Length and Word Length for RAM Mapping Threshold

For this example, the **RAM Mapping Threshold** is changed to 1024x1, where 1024 is the delay length threshold and 1 is the word length threshold. To determine how many block RAMs are used, run synthesis on the model. This is the Resource summary report from synthesis:

Resource summary			
Resource	Usage	Available	Utilization (%)
Slice LUTs	1118	303600	0.37
Slice Registers	595	607200	0.10
DSPs	0	2800	0.00
Block RAM Tile	1	1030	0.10
URAM	0	0	

Now, only the second subsystem is mapped to BRAM because the first subsystem has a delay length of 256 cycles, which is less than the delay length threshold of 1024. As a result, only one BRAM is used to map the second subsystem. The first subsystem is mapped to LUTs and registers.

RAM Mapping With the MATLAB Function Block

This example shows how to map persistent arrays to RAM by using the `MapPersistentVarsToRAM` block-level parameter. The RAM size must be greater than or equal to the `RAMMappingThreshold`. The resource report shows the difference in area improvements resulting from RAM mapping.

Line Buffer Model

Open the model `hdlcoder_ram_mapping_matlab_function`.

```
open_system('hdlcoder_ram_mapping_matlab_function')
set_param('hdlcoder_ram_mapping_matlab_function', 'SimulationCommand', 'Update')
```

Copyright 2019-2021 The MathWorks, Inc.

The DUT Subsystem in the model drives a Line Buffer MATLAB Function block.

```
open_system('hdlcoder_ram_mapping_matlab_function/HDL_DUT')
```

To see the MATLAB® code implementation of the line buffer, open the MATLAB Function block.

```
open_system('hdlcoder_ram_mapping_matlab_function/HDL_DUT/Line Buffer')
```

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Line buffer: Uses a presistent array to store the image
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

function y = line_buffer(u)
%3codegen

persistent u_d ctr;

if isempty(u_d)
    u_d = uint8(zeros(1,80)); % You can map this to RAM
    ctr = uint8(1);
end

y = u_d(ctr);
u_d(ctr) = u;

if ctr == uint8(80)
    ctr = uint8(1);
else
    ctr = ctr + 1;
end

end

```

Generate HDL Code

1. Enable generation of the resource utilization report. The report displays the number of adders, subtractors, multipliers, registers, and RAMs that the design consumes.

```
hdlset_param('hdlcoder_ram_mapping_matlab_function', 'resourcereport', 'on')
```

2. Generate HDL code for the HDL_DUT Subsystem.

```
makehdl('hdlcoder_ram_mapping_matlab_function/HDL_DUT')
```

HDL Coder™ displays the Code Generation Report. In the report, select the **High-Level Resource Report** section. The design consumes 81 registers and 648 1-bit registers. By default, the MapPersistentVarsToRAM property is disabled and the code generator does not infer or consume RAM resources.

Multipliers	0
Adders/Subtractors	3
Registers	81
Total 1-Bit Registers	648
RAMs	0
Multiplexers	1
I/O Bits	20
Static Shift operators	0
Dynamic Shift operators	0

Enable RAM Mapping and Generate HDL Code

1. Enable the MapPersistentVarsToRAM HDL parameter on the MATLAB Function block.

```
ml_subsys = 'hdlcoder_ram_mapping_matlab_function/HDL_DUT/Line Buffer';
hdlset_param(ml_subsys, 'MapPersistentVarsToRAM', 'on')
```

2. Generate HDL code for the HDL_DUT Subsystem.

```
makehdl('hdlcoder_ram_mapping_matlab_function/HDL_DUT')
```

In the Code Generation Report, select the **High-Level Resource Report** section. The design consumes one register, eight 1-bit registers, and one RAM. The number of RAMs inferred depends on the RAMMappingThreshold that you specify. See “RAM Mapping Parameters” on page 19-6.

Multipliers	0
Adders/Subtractors	3
Registers	1
Total 1-Bit Registers	8
RAMs	1
Multiplexers	3
I/O Bits	20
Static Shift operators	0
Dynamic Shift operators	0

RAM Mapping with MATLAB Datapath Architecture

The MATLAB Datapath architecture treats the MATLAB Function block like a regular Subsystem. The architecture converts the MATLAB code that you wrote to a dataflow representation in

Simulink®. HDL Coder can then more widely use optimizations across the MATLAB Function block with other Simulink blocks in your model.

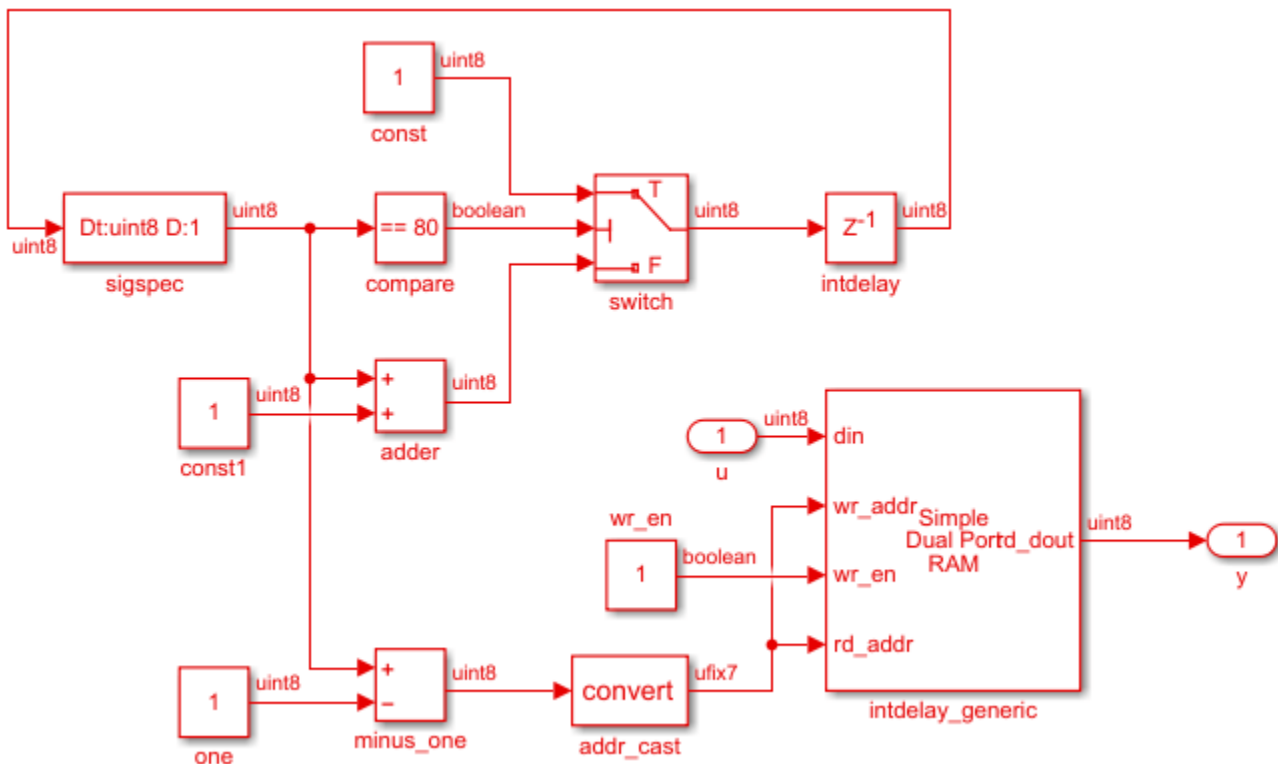

1. Enable the MATLAB Datapath HDL architecture and then set the MapPersistentVarsToRAM parameter on the MATLAB Function block.

```
hdlset_param(m_l_subsys, 'Architecture', 'MATLAB Datapath')
hdlset_param(m_l_subsys, 'MapPersistentVarsToRAM', 'on')
```

2. Generate HDL code for the HDL_DUT Subsystem.

```
makehdl('hdlcoder_ram_mapping_matlab_function/HDL_DUT')
```

The **High-Level Resource Report** indicates that the design consumes the same number of resources as the design that used the default architecture of the MATLAB Function block. To see how MATLAB Datapath architecture modifies the MATLAB code to a Simulink dataflow representation, open the generated model `gm_hdlcoder_ram_mapping_matlab_function` and navigate to the HDL_DUT Subsystem. There is a Line Buffer Subsystem in place of the MATLAB Function block. Inside the Subsystem block is the dataflow representation that displays a RAM block inferred.

To learn about design patterns that enable efficient RAM mapping of persistent arrays in MATLAB Function blocks, see the `eml_hdl_design_patterns/RAMs` library.

What Is Distributed Pipelining?

Distributed pipelining, or register retiming, is a speed optimization that moves existing delays in a design to reduce the critical path while preserving functional behavior. This optimization moves the delays within a subsystem while preserving the hierarchy.

The HDL Coder software uses an adaptation of the Leiserson-Saxe retiming algorithm.

For example, in this model, there is a delay of 2 at the output.

The diagram shows the generated model after distributed pipelining redistributes the delay to reduce the critical path.

Benefits and Costs of Distributed Pipelining

Distributed pipelining can reduce your design's critical path, enabling you to use a higher clock rate and increase throughput.

However, distributed pipelining requires your design to contain a number of delays. If you need to insert additional delays in your design to enable distributed pipelining, this increases the area and the initial latency of your design.

How Distributed Pipelining Works

HDL Coder applies distributed pipelining with other optimization options to move the existing delays in your design to reduce the critical path. The existing delays in your design can either be design delays or pipeline delays. Design delays are delays that you manually insert in your design by using Delay blocks, or other blocks that have state, including Queue, HDL FIFO, or Buffer blocks. Pipeline

delays are delays that are generated by optimization settings, such as input or output pipelining options, or block implementation settings, such as the `ShiftAdd` implementation for a Divide block and the `CORDIC` approximation for a Trigonometric Function block. See “InputPipeline” on page 26-14 and “OutputPipeline” on page 26-19.

When you generate code, before distributed pipelining runs, the input and output pipelines you specify are inserted at the input and outputs ports in your design. HDL Coder uses these pipelines to determine latency requirements and an outline for ideal pipelining for your design.

HDL Coder begins distributed pipelining by calculating the propagation delay for the components in your design by assigning each component an equal weight, except for wire components, such as Selector blocks and Bit Concat blocks, that are assigned zero-propagation delay. Distributed pipelining then redistributes the design delays and pipeline delays based on the weight assigned to each component in your design. Distributed pipelining takes into consideration all of the pipeline stages and distributes them as evenly as possible in order to obtain the shortest critical path. The inserted pipelines might not appear in the place you originally requested them because distributed pipelining can move these to improve the critical path.

If pipelines are required at specific point after a block, you can set the HDL Block Property **ConstrainedOutputPipeline** on the block at the specified point to the number of pipelines that you want to keep as output pipelines after that block. Constrained output pipelining does not insert extra pipelines, but instead provides information to distributed pipelining to first prioritize pipelines moved to or left at that specific point in your design. This option is used only to prevent distributed pipelining from moving specified pipelines or to require distributed pipelining to move pipelines to that specified point. For more information, see “Constrained Output Pipelining” on page 28-147.

Note If you want to disable distributed pipelining from running on your subsystem and you have set constrained output pipelining on blocks in your design, disable distributed pipelining for your subsystem and reset the **ConstrainedOutputPipeline** property on the blocks to zero.

If you do not want the design delays you have in your design to be moved by distributed pipelining, enable **Preserve design delays**. See “Preserve design delays” on page 19-14.

Requirements for Distributed Pipelining

Distributed pipelining requires your design to contain delays or registers that can be redistributed. You can use input pipelining or output pipelining to insert more registers. You can insert these delays manually or insert them by setting the HDL block properties **InputPipeline** or **OutputPipeline** for the subsystem or block that you plan to set distributed pipelining. For more information, see “InputPipeline” on page 26-14 and “OutputPipeline” on page 26-19.

If your design does not meet your timing requirements at first, try adding more delays or registers to improve your results.

Specify Distributed Pipelining

You can set distributed pipelining on a model or the top-level DUT subsystem. For finer control, you can set distributed pipelining on subsystems, Stateflow charts, and MATLAB Function blocks in the top-level DUT subsystem. See “Use Distributed Pipelining Optimization in Models with MATLAB Function Blocks” on page 34-32.

To enable distributed pipelining for the model from the UI:

- 1 In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
- 2 Click **Settings**. In the **HDL Code Generation > Optimization** pane, in the **Pipelining** tab, select **Distributed pipelining** and click **OK**.

To enable distributed pipelining for a model, on the command line, enter:

```
hdlset_param('modelname', 'DistributedPipelining', 'on')
```

If you have a top-level device under test (DUT) that contains a subsystem hierarchy, such as lower-level subsystems, and you want distributed pipelining to run throughout the DUT and the lower-level subsystems, enable the model configuration parameter **Distributed pipelining** and leave the HDL block property **DistributedPipelining** as `inherit` for the DUT and all lower-level subsystems.

To prevent distributed pipelining from running in a specific lower-level subsystem in the DUT, set the HDL block property **DistributedPipelining** to `off` for that subsystem.

Note If you insert pipeline registers, output data can be in an invalid state initially. To avoid test bench errors resulting from initial invalid samples, disable output checking for those samples. For more information, see “Ignore output data checking (number of samples)” on page 23-21.

Limitations of Distributed Pipelining

The distributed pipelining optimization has these limitations:

- Your pipelining results might not be optimal in hardware because the operator latencies in your target hardware might differ from the estimated operator latencies used by the distributed pipelining algorithm.
- HDL Coder generates pipeline registers at the outputs instead of distributing the registers to reduce critical path in these situations:
 - Stateflow chart containing a state, local variable, or a matrix with statically unresolvable index.
- HDL Coder distributes pipeline registers around these blocks instead of within them:
 - Model
 - Sum (Cascade implementation)
 - Divide
 - Reciprocal
 - Sqrt
 - Sine HDL Optimized and Cosine HDL Optimized
 - Product (Cascade implementation)
 - MinMax
 - Upsample
 - Downsample
 - Rate Transition
 - Zero-Order Hold

- Reciprocal Sqrt (RecipSqrtNewton implementation)
- Trigonometric Function (CORDIC Approximation)
- Single Port RAM
- Dual Port RAM
- Simple Dual Port RAM
- Blocks with floating-point IP (i.e. native floating-point)
- If you enable distributed pipelining for a subsystem that contains these blocks, HDL Coder generates a warning message during code generation in the HDL Code Generation Check Report. This message identifies blocks that act as barriers for distributed pipelining in the subsystem. HDL Coder distributes pipeline registers around nested subsystems.

Distributed Pipelining Report

To see the distributed pipelining information in the report, before you generate code for each subsystem or model reference, enable the optimization report. In the **HDL Code** tab, select **Report Options**, and then select **Generate optimization report**.

When you generate the optimization report, in the **Distributed Pipelining** section, you see the effect of the distributed pipelining optimization for the subsystems that have distributed pipelining enabled in the generated model and in the **Distributed Pipelining Summary**. If distributed pipelining is unsuccessful, the report shows diagnostic messages and blocks that caused distributed pipelining to fail.

If you set the HDL block property **ConstrainedOutputPipeline** for a block in your design, the **Constrained Output Pipeline Summary** displays the requested constrained output pipelines and if those requests are met during code generation.

If distributed pipelining is successful, the **Detailed Report** in the **Distributed Pipelining** section displays comparative listings of registers before and after you apply the distributed pipelining transform.

Distributed Pipelining Using Synthesis Timing Estimates

Distributed pipelining is a speed optimization that increases clock frequency for your target device by distributing pipelines in your generated HDL code. For more information, see “Distributed Pipelining” on page 28-131. Synthesis timing estimates can more accurately reflect how components function on hardware. You can use them for distributed pipelining to more effectively maximize the clock frequency for your specific target device.

Synthesis Timing Estimates in Distributed Pipelining

When applying distributed pipelining to a subsystem, HDL Coder calculates an approximate propagation delay for each component in your design to determine where to place the added delays. Synthesis timing estimates are propagation delay estimates for each component in your design.

Without synthesis timing estimates, HDL Coder calculates propagation delay for the components in your design by assigning each component an equal weight, except for wire components, such as Selector blocks and Bit Concat blocks, that are assigned zero propagation delay.

Using synthesis timing estimates, HDL Coder calculates propagation delays for the components in your design by assigning different weights to varying components, based on how the components function on hardware. This information is derived from a target-specific timing database that HDL Coder supports, or that you create by using the `genhdltdb` function. Critical path estimation uses the same timing databases to estimate the critical path in a design. See “Critical Path Estimation Without Running Synthesis” on page 28-192. Using synthesis timing estimates for distributed pipelining is typically applied when you specify a synthesis tool for the model because the optimization option is platform-specific.

How Distributed Pipelining Works By Using Synthesis Timing Estimates

For an example of how distributed pipelining works using by synthesis timing estimates, in the following model, there is a delay of 2 at the output. Multipliers on hardware take longer to compute than adders, meaning their actual propagation delay is longer than adder propagation delay. To simplify the calculations for this example, assume adders have a propagation delay of one nanosecond and multipliers have twice as long of a propagation delay as adders, two nanoseconds.

Without using synthesis timing estimates for distributed pipelining, the adders and multipliers are given equal weights for their propagation delays and the distributed pipelining algorithm cannot tell the difference between the components. The pipelines are distributed as shown in the figure. The critical path length then becomes the delay of the first adder and multiplier, three nanoseconds.

Using synthesis timing estimates for distributed pipelining, the adders and multiplier are now given weights for their propagation delays that more accurately reflect how the components function on hardware. The delays are redistributed so that the critical path contains just the multiplier, making the critical path length the propagation delay of just the multiplier, two nanoseconds.

Using synthesis timing estimates for distributed pipelining most effectively minimizes the critical path to maximize the clock frequency for your design when:

- Your synthesis tool and target hardware have been characterized by using a timing database that HDL Coder supports or by using a timing database that you create by using the `genhdltdb` function.
- All of the blocks in your design are characterized, meaning the blocks are part of the timing database for each supported target device. See “Characterized Blocks” on page 28-195.

Requirements for Synthesis Timing Estimates for Distributed Pipelining

To use synthesis timing estimates for distributed pipelining, specify distributed pipelining for at least one subsystem or MATLAB Function block in your design.

If you specify a synthesis tool using the model parameter `SynthesisTool`, HDL Coder sets default values for the model parameters `SynthesisToolChipFamily` and `SynthesisToolSpeedValue`. If you do not specify a value for `SynthesisTool` or for `SynthesisToolChipFamily` and `SynthesisToolSpeedValue`, HDL Coder generates a warning when generating HDL code. HDL Coder sets the default values for `SynthesisToolChipFamily` and `SynthesisToolSpeedValue` as `virtex7` and `-1` respectively. To prevent the warning, specify the `SynthesisToolChipFamily` and `SynthesisToolSpeedValue` parameters.

Specify Distributed Pipelining to Use Synthesis Timing Estimates

To use synthesis timing estimates for distributed pipelining, you can:

- In the Configuration Parameters dialog box, enable the parameter **Use synthesis estimates for distributed pipelining**, located in **HDL Code Generation > Optimization > Pipelining** tab.
- Use the `hdlset_param` function. Set the parameter to `on` at the command line. For example, to enable this parameter for the model `sfir_fixed`, use this command:

```
hdlset_param('sfir_fixed','UseSynthesisEstimatesForDistributedPipelining','on')
```

For more information, see the Use Synthesis Timing Estimates for Distributed Pipelining section in the “Distributed Pipelining: Speed Optimization” on page 28-140 example.

Limitations

- The run time to generate HDL code from your model is approximately 10x more than the run time of using equal weights to calculate the propagation delays of the components in your design.

- If there are uncharacterized blocks in the model that are not supported, the distributed pipelining results might be less optimal than not using synthesis timing estimates for distributed pipelining. The uncharacterized blocks in the model appear as a message in the HDL Code Generation Check Report and the Resource Utilization Report, and as a link to a script to highlight the blocks in the MATLAB Command Window.
- If you have a MATLAB function block in your design with the HDL Block Property **Architecture** set to `MATLAB Function`, when using synthesis timing estimates for distributed pipelining, you might see the MATLAB function block appear as an uncharacterized block in the reports. To characterize the MATLAB function block, set the **Architecture** to `MATLAB Datapath`.

Distributed Pipelining: Speed Optimization

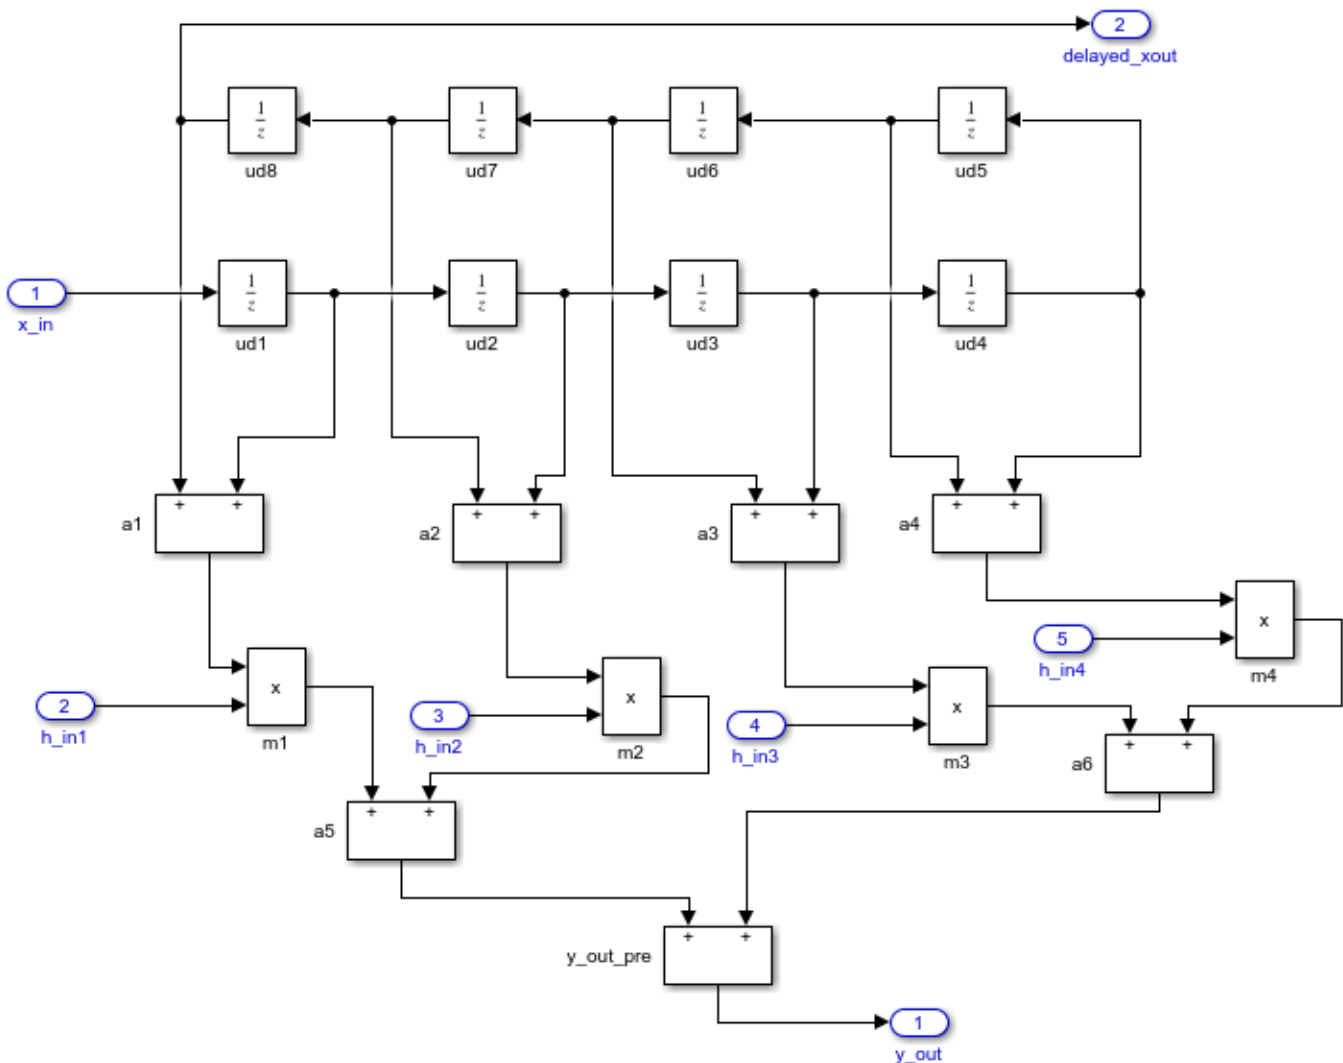

This example shows how to use distributed pipelining to optimize a design for speed in HDL Coder™.

Introduction

Distributed pipelining is a subsystem-wide optimization supported by HDL Coder for reducing the critical path and achieving high clock speed hardware. By turning on distributed pipelining, HDL Coder redistributes the input pipeline registers, output pipeline registers of the subsystem, and the registers in the subsystem to positions that minimize the combinatorial logic between registers and maximize the clock speed of the chip synthesized from the generated HDL code. For more information on distributed pipelining, see “Distributed Pipelining” on page 28-131.

Consider the following example model of a symmetric FIR filter. The combinatorial logic from an input or a register to an output or another register contains a product block and an adder tree. Distributed pipelining moves the output registers set at the subsystem level to reduce the levels of the combinatorial logic.

```
bdclose all;  
load_system('sfir_fixed');  
open_system('sfir_fixed/symmetric_fir');
```

Set Output Pipeline Stage

To increase the clock speed, you can set a number of pipeline stages for any subsystem. Without turning on distributed pipelining, the specified number of registers are added to each of the output ports of the subsystem. Some synthesis tools support optimizations, such as retiming, that optimize the position of the registers during synthesis.

To see the effects of distributed pipelining in reducing the critical path and increasing the clock frequency, enable `CriticalPathEstimation` to estimate a critical path for your design. When you enable critical path estimation, HDL Coder uses a target-specific timing database to estimate the critical path. If you do not set a Synthesis Tool Chip Family and Synthesis Tool Speed Value to specify the specific target timing database, HDL Coder sets default values for both parameters for critical path estimation, and generates a warning when generating HDL code. To prevent the warning, specify the Synthesis Tool Chip Family and Synthesis Tool Speed Value. You can do this with or without a Synthesis Tool specified. For more information, see “Critical Path Estimation Without Running Synthesis” on page 28-192.

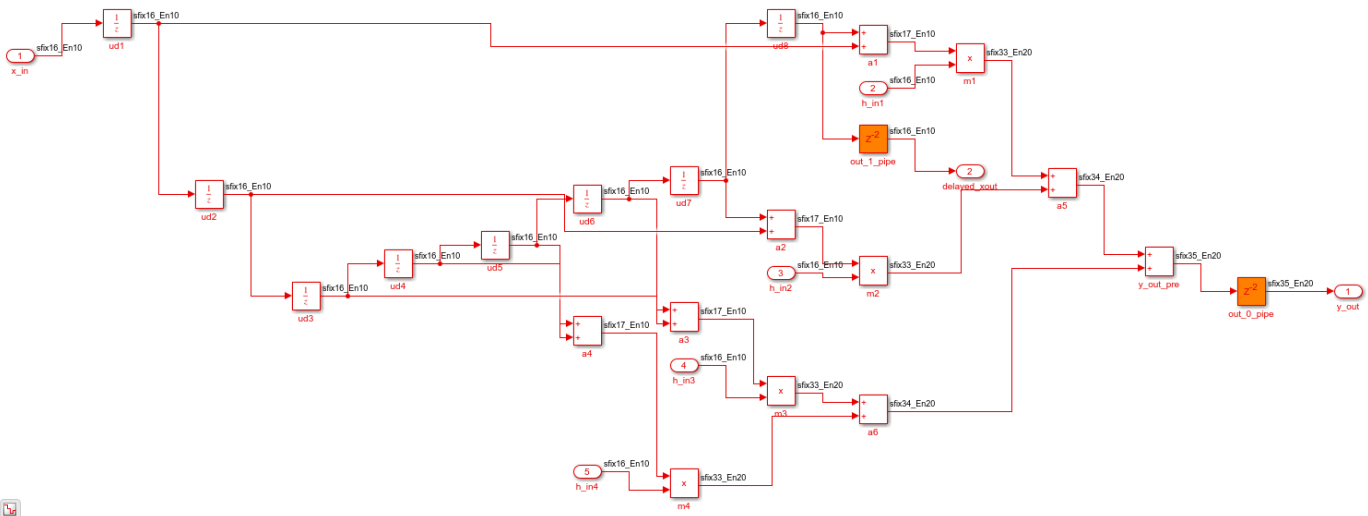

```
hdlset_param('sfir_fixed', 'CriticalPathEstimation', 'on');
hdlset_param('sfir_fixed', 'SynthesisToolChipFamily', 'virtex7', 'SynthesisToolSpeedValue', '-1');
```

In this example, the subsystem output pipeline register is set to 2.

The code generation model explicitly reflects the inserted register at output ports of the subsystem (highlighted in orange).

```
hdlset_param('sfir_fixed/symmetric_fir', 'OutputPipeline', 2);
makehdl('sfir_fixed/symmetric_fir');
open_system('gm_sfir_fixed/symmetric_fir');
set_param('gm_sfir_fixed', 'SimulationCommand', 'update');
```

### HDL code generation complete.
```

The critical path estimated with distributed pipelining on is now 7.443 ns.

Use Synthesis Timing Estimates for Distributed Pipelining

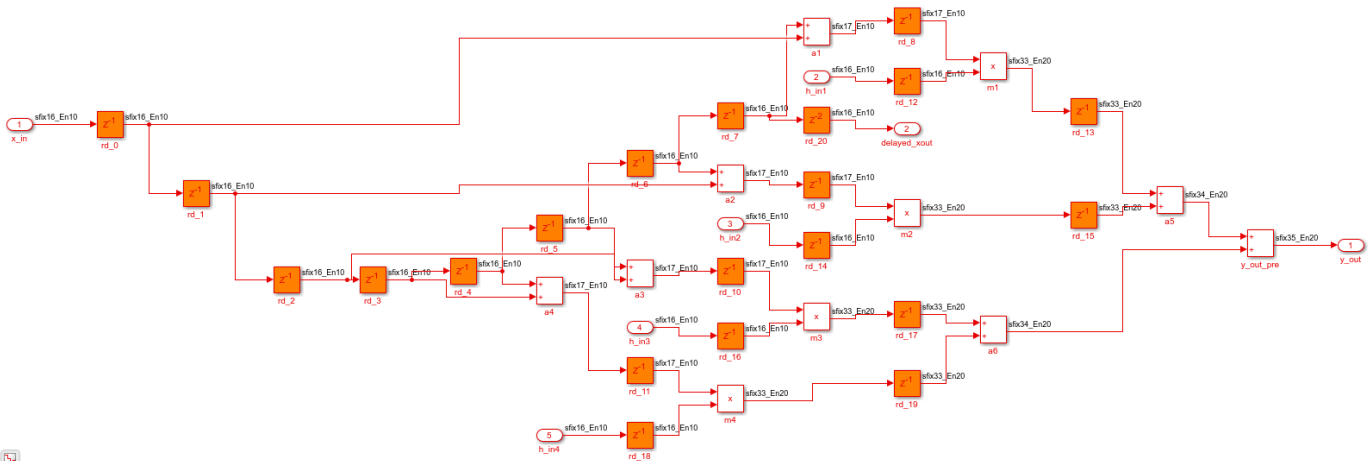

To more accurately reflect how components function on hardware to better distribute pipelines in your design and maximize the clock frequency for your target device, enable synthesis timing estimates for distributed pipelining using the model configuration parameter **Use synthesis estimates for Distributed Pipelining** or through the command-line.

```
hdlset_param('sfir_fixed', 'UseSynthesisEstimatesForDistributedPipelining', 'on');
```

Generate HDL code with a specified generated model name, and open the generated model.

```
makehdl('sfir_fixed/symmetric_fir', 'GeneratedModelNamePrefix', 'gm3_');
open_system('gm3_sfir_fixed/symmetric_fir');
set_param('gm3_sfir_fixed', 'SimulationCommand', 'update');
```

```

### HDL code generation complete.
```

Using synthesis timing estimates causes an increase in run time of the function `makehdl`, but it can reduce the critical path and increase the clock frequency of your design. For more information, see “Distributed Pipelining Using Synthesis Timing Estimates” on page 28-137.

The critical path estimation report shows that critical path is now 6.320 ns. The critical path estimation is just an estimated critical path based on a target-specific timing database. If you want the actual critical path on your target hardware, you must run the model through synthesis.

Synthesis Comparison of Distributed Pipelining With and Without Synthesis Timing Estimates

In the HDL Workflow Advisor, generate HDL code and perform FPGA synthesis using the Generic ASIC/FPGA workflow with these settings:

- **Synthesis tool** set to Xilinx Vivado
- **Family** of the synthesis tool set to virtex7
- **Speed** of the synthesis tool set to -1
- **Target Frequency (MHz)** set to 120

For more information on the code generation and synthesis steps, see “HDL Code Generation and FPGA Synthesis from Simulink Model”.

The synthesis results without distributed pipelining enabled are:

Timing summary	
	Value
Requirement	8.3333 ns
Data Path Delay	7.368 ns
Slack	-0.764 ns
Clock Frequency	

The synthesis results shows negative slack, indicating that timing constraints are not met. The clock frequency is not calculated when timing constraints are not met.

The synthesis results with distributed pipelining enabled are:

Timing summary	
	Value
Requirement	8.3333 ns
Data Path Delay	1.35 ns
Slack	2.717 ns
Clock Frequency	178.05 MHz

The synthesis results show positive slack and a clock frequency of 178.05 MHz, indicating that the timing constraints are met and the target clock frequency of 120 MHz is met.

The synthesis results with distributed pipelining using synthesis timing estimates are:

Timing summary	
	Value
Requirement	8.3333 ns
Data Path Delay	1.273 ns
Slack	3.837 ns
Clock Frequency	222.40 MHz

The synthesis results show a clock frequency of 222.40 MHz, indicating that the timing constraints are met. The clock speed has increased by using synthesis timing estimates for distributed pipelining.

Distributed Pipelining Across Subsystem Hierarchies

If your DUT subsystem has subsystem hierarchy, meaning it contains lower-level subsystems, set the model parameter **Distributed pipelining** to `on` to have distributed pipelining run through the entire DUT without needing to enable `DistributedPipelining` for the DUT and each subsystem inside the DUT. The subsystem HDL block property **DistributedPipelining** is set to `inherit` by default, which means that each subsystem takes the **DistributedPipelining** value of its parent subsystem. The top-level DUT subsystem takes the value specified by the model parameter **Distributed pipelining**.

You can specifically enable or disable distributed pipelining for a lower-level subsystem if you set the HDL block property **DistributedPipelining** to `On` or `Off` for the subsystem. For more information, “DistributedPipelining” on page 26-9.

Constrained Output Pipelining

In this section...

“What Is Constrained Output Pipelining?” on page 28-147
 “When to Use Constrained Output Pipelining” on page 28-147
 “Requirements for Constrained Output Pipelining” on page 28-147
 “Specify Constrained Output Pipelining” on page 28-147
 “Limitations of Constrained Output Pipelining” on page 28-148

What Is Constrained Output Pipelining?

With constrained output pipelining, you can specify a nonnegative number of registers at the outputs of a block.

Constrained output pipelining does not add registers, but instead redistributes existing delays within your design to try to meet the constraint. If HDL Coder cannot meet the constraint with existing delays, it reports the difference between the number of desired and actual output registers in the timing report.

Distributed pipelining does not move registers you specify with constrained output pipelining.

When to Use Constrained Output Pipelining

Use constrained output pipelining when you want to place registers at specific locations in your design. This can enable you to optimize the speed of your design.

For example, if you know where the critical path is in your design and want to reduce it, you can use constrained output pipelining to place registers at specific locations along the critical path.

Requirements for Constrained Output Pipelining

Your design must contain existing delays or registers. When there are fewer registers than HDL Coder needs to satisfy your constraint, the coder reports the difference between the number of desired and actual output registers.

You can add registers to your design using input or output pipelining.

Specify Constrained Output Pipelining

To specify constrained output pipelining for a block using the UI:

- In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select the Subsystem and then click **HDL Block Properties**. For **ConstrainedOutputPipeline**, enter the number of registers you want at the output ports.
- Right-click the block and select **HDL Code > HDL Block Properties**. For **ConstrainedOutputPipeline**, enter the number of registers you want at the output ports.

To specify constrained output pipelining, on the command line, enter:

```
hdlset_param(path_to_block,...  
             'ConstrainedOutputPipeline',number_of_output_registers)
```

For example, to constrain six registers at the output ports of a subsystem, *subsys*, in your model, *mymodel*, enter:

```
hdlset_param('mymodel/subsys','ConstrainedOutputPipeline', 6)
```

Limitations of Constrained Output Pipelining

HDL Coder does not constrain output pipeline register placement:

- Within a DUT subsystem, if the DUT contains a subsystem, model reference, or model reference with black box implementation.
- At the outputs of any type of delay block or the top-level DUT subsystem.

Clock-Rate Pipelining

In this section...

“Specify Clock-Rate Pipelining” on page 28-151

“Limitations for Clock-Rate Pipelining” on page 28-152

When you enable speed and area optimizations that insert pipeline registers, use the clock-rate pipelining optimization to identify multicycle paths in your design. Clock-rate pipelining inserts pipeline registers at the faster clock rate, which improves clock frequency without introducing additional latency or by adding minimal latency. You can use clock-rate pipelining with a Simulink model or a MATLAB function.

Rationale for Clock-Rate Pipelining

HDL Coder introduces pipelines when you specify certain block implementations or enable some optimizations on the Simulink model or MATLAB function, such as:

- Multi-cycle block implementations
- Input and output pipelining
- Distributed pipelining
- Floating-point library mapping
- Native floating-point HDL code generation
- Resource sharing
- Streaming

By default, in slow paths, these pipeline registers operate at the slow data rate. When you enable clock-rate pipelining, the pipeline registers operate at the faster clock rate. Clock-rate pipelining does not affect existing design delays in your model. It is an alternative to using multicycle path constraints with your synthesis tool.

How Clock-Rate Pipelining Works in a Simulink Model

The clock-rate pipelining optimization identifies slow paths or regions in the model by analyzing the block sample times. Blocks that have a sample time greater than the device under test (DUT) base sample time are part of the slow path, and are potential candidates for clock-rate pipelining. In these slow paths, HDL Coder enables optimizations to introduce pipeline delays at the clock rate.

If you specify an “Oversampling factor” on page 21-15 greater than one, the DUT sample time becomes slower than the actual clock rate. HDL Coder determines the maximum number of clock-rate pipelines that it can insert based on the DUT-to-block sample time ratio and the oversampling factor.

Maximum number of clock-rate delays = $(block_rate \div DUT_base_rate) \times Oversampling$

Clock-rate pipelining identifies regions in the model that have the same slow data rate, and are delimited by either Delay blocks or blocks that introduce a rate transition. HDL Coder converts these regions to the faster clock rate by introducing Repeat blocks at the input of the region and Rate Transition blocks at the output of the region. If the output of a clock-rate region is a Delay block at the data rate, HDL Coder absorbs that Delay block. To accommodate the delay, HDL Coder introduces several clock-rate pipelines corresponding to the ratio of the data rate to the clock rate.

HDL Coder generates a script that highlights blocks in your model that are obstacles to clock-rate pipelining and a script to clear the highlighting. Sometimes, if HDL Coder is unable to implement resource sharing or streaming at the clock rate, it displays a code generation error with a recommendation for changing the `Oversampling` value. To clear highlighting, click the `clearhighlighting` script in the MATLAB Command Window.

How Clock-Rate Pipelining Works in a MATLAB Function

A MATLAB function, which is the DUT when generating HDL code from MATLAB, runs at a single data rate. If you want a clock rate that is faster than the data rate, you can use clock-rate pipelining. You specify how much faster you want your clock rate to be than the DUT data rate by specifying an oversampling factor greater than one. The maximum number of clock-rate delays that HDL Coder can insert is equal to the oversampling factor.

You can also use clock-rate pipelining to optimize speed if you have other code generation options that introduce latency in a feedback loop, such as the use of persistent variables or native floating point.

Clock-Rate Pipelining and Hierarchy Flattening

You can use the clock-rate pipelining optimization with or without flattening the subsystem hierarchy. Flatten the subsystem hierarchy when you want to maximize opportunities for sharing resources in your design. To flatten the subsystem hierarchy, enable **FlattenHierarchy** on the top-level Subsystem. By default, all Subsystem blocks inside the top-level subsystem inherit this **FlattenHierarchy** setting. Hierarchy flattening brings several clock-rate regions to the same level in the hierarchy and combines them, which increases opportunities for clock-rate pipelining. However, it breaks the modularity of your design and affects the readability of the generated HDL code. See also “Hierarchy Flattening” on page 28-119.

To apply clock-rate pipelining without flattening the hierarchy, on the top-level subsystem in your model, disable **FlattenHierarchy**. If your design uses fixed-point data types, enable some optimizations on the underlying subsystems. In this case, HDL Coder introduces clock-rate pipelines in your design while preserving the subsystem hierarchy, which:

- Improves the modularity of your design and makes navigation through the generated model easier especially in large designs with complex hierarchies.
- Improves readability of the generated HDL code by creating multiple Verilog or VHDL files for the various Subsystem blocks in your design.

Clock-Rate Pipelining for DUT Output Ports

To produce DUT outputs as soon as possible by passing the outputs from the DUT at the clock rate rather than the data rate, select the **Allow clock-rate pipelining of DUT output ports** configuration parameter or use the `ClockRatePipelineOutputPorts` property. This property

changes the timing of your DUT interface by changing the sample time of the DUT output ports from a slower data rate to the clock rate. To adjust for the difference in timing, HDL Coder generates messages that provide the phase offset of each output port. For example, this message means that the output data from *portname* is valid after 31 clock cycles: `Phase of output port portname: 31 clock cycles`. To set this parameter, see “Allow clock-rate pipelining of DUT output ports” on page 19-10.

The validation model adjusts for the timing difference by inserting a Rate Transition block at the DUT output and comparing the output of the Rate Transition block with the original output. The RTL test bench logs the output data at the input of the Rate Transition block and compares it with the DUT output in the RTL simulation.

When producing DUT outputs at the clock rate, the outputs are ready as soon as possible, even if one output is ready before another. For example, this is useful if you run a hardware-in-the-loop simulation with a control system and have a plant model running at a slow rate and discrete logic such as control signals in the DUT that need to run at a faster rate or with a short response delay time. To synchronize the outputs while still satisfying the highest-latency requirements of the outputs, you can balance clock-rate pipelined DUT output ports by selecting the **Balance clock-rate pipelined DUT output ports** configuration parameter or using the `BalanceClockRateOutputPorts` property. You can apply this property when interfacing your logic with a valid signal interface to align the output of your logic path and the output of the valid signal path. To set this parameter, see “Balance clock-rate pipelined DUT output ports” on page 19-11.

Specify Clock-Rate Pipelining

You can generate HDL code with the clock-rate pipelining optimization from a Simulink model or MATLAB function.

Specify Clock-Rate Pipelining for a Simulink Model

You can set clock-rate pipelining on a model or, for finer control, on subsystems within the top-level DUT subsystem. By default, clock-rate pipelining is enabled on the model. To disable clock-rate pipelining from the UI:

- 1 In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
- 2 Click **Settings**. In the **HDL Code Generation > Optimization > Pipelining** tab, clear **Clock-rate pipelining** and click **OK**.

At the command line, use the `makehdl` or `hdlset_param` function to set the `ClockRatePipelining` property to `off`.

You can use clock-rate pipelining for a subsystem within the top-level DUT subsystem. To model a control path in your design at the data rate instead of the clock rate, put the control path in a subsystem, and disable clock-rate pipelining for that subsystem. To disable clock-rate pipelining for a subsystem within the top-level DUT subsystem, set **ClockRatePipelining** to `off` for that subsystem. See also “Set Clock-Rate Pipelining For a Subsystem” on page 26-6.

Specify Clock-Rate Pipelining for a MATLAB Function

To enable the clock-rate pipelining for a MATLAB function:

- 1 Open the MATLAB HDL Workflow Advisor. To get started with the MATLAB HDL Workflow Advisor, see “Basic HDL Code Generation and FPGA Synthesis from MATLAB”.

- 2 In the left pane, click the **HDL Code Generation** task. In the right pane, navigate to the **Optimization** tab and select **Clock Rate Pipelining**.
- 3 Click the **Clocks & Ports** tab and set **Oversampling factor** to a value greater than one.

Limitations for Clock-Rate Pipelining

These blocks inhibit clock-rate pipelining, and therefore delimit clock-rate pipelining regions:

- Counter Free-Running
- Counter Limited
- Deserializer1D
- Discrete PID Controller
- Dual Port RAM
- Dual Rate Dual Port RAM
- FFT HDL Optimized
- HDL Cosimulation
- HDL FIFO
- HDL Counter
- Hit Crossing
- HDL Minimum Resource FFT
- HDL Streaming FFT
- MATLAB System, if it uses persistent variables
- Reusable Subsystem, if FlattenHierarchy is not enabled
- Serializer1D
- Simple Dual Port RAM
- Single Port RAM
- Upsample
- Model Reference. Use a Subsystem Reference instead.

HDL Coder does not support clock-rate pipelining for:

- Black box subsystem or black box model reference blocks.
- Subsystems that contain blocks not supported for clock-rate pipelining.
- Altera DSP Builder subsystems.
- Xilinx System Generator subsystems
- Communications Toolbox blocks.
- DSP System Toolbox blocks, except for Delay and Discrete FIR Filter.
- Stateflow blocks.

HDL Coder does not support applying both the streaming and sharing optimizations on the same resource when you use the clock-rate pipelining optimization. Either disable clock-rate pipelining or use either the streaming optimization or the sharing optimization on the same resource when clock-rate pipelining is enabled.

HDL Coder does not support clock-rate pipelining when **Clock inputs** is set to **Multiple**.

Increase Clock Frequency Using Clock-Rate Pipelining

This example shows how to apply clock-rate pipelining to optimize slow paths in your design and thereby reduce latency, increase clock frequency and decrease area usage. For more information on how to use clock-rate pipelining, see “Clock-Rate Pipelining” on page 28-149.

Introduction

Algorithmic design with Simulink may introduce many slow-rate datapaths in the generated HDL design. These slow paths correspond to slower Simulink sample time operations because the algorithmic data rate operates at a slower rate than the HDL clock rate.

Clock-rate pipelining identifies the maximal subregions in the model operating at the same data rate, and are delimited either by rate-change blocks or Delay blocks. These subregions are called *clock-rate regions* because they are good candidates for clock-rate pipelining. If the output of a clock-rate region is a Delay block at the data rate, HDL Coder absorbs that Delay block, which results in a budget of several clock-rate pipelines equal to the ratio of data rate to the clock rate.

Consider the field-oriented control example “Field-Oriented Control of a Permanent Magnet Synchronous Machine” on page 14-66, which describes a motor-control design mapped to an FPGA. The input samples in this design arrive every $20 \mu\text{s}$ or 50 KHz. In a closed control loop, the controller latency must be within the desired response time. In this model, there is a delay on the output port that results in a latency of $20 \mu\text{s}$.

To meet design constraints like timing and area, you can apply several optimizations like input and output pipelining, distributed pipelining, streaming, and/or sharing. Additionally, you can implement non-trivial math functions like `sqrt` or `divide` as multi-cycle pipelined operations. Because the pipelines introduced by any of the above optimizations are applied at the same rate at which the signal path operates, which is $20 \mu\text{s}$, introducing additional pipelining creates undesirable latency overhead and can violate the closed loop latency budget.

However, the FPGA can implement this controller in the order of MHz, which means that the introduced pipelines can then operate at the MHz rate thereby minimizing the impact on latency. Clock-rate pipelining leverages this rate differential and pipelines the controller to improve its area and timing characteristics on the FPGA. This example shows how to incrementally apply timing and area optimizations using clock-rate pipelining.

Preparing the Model

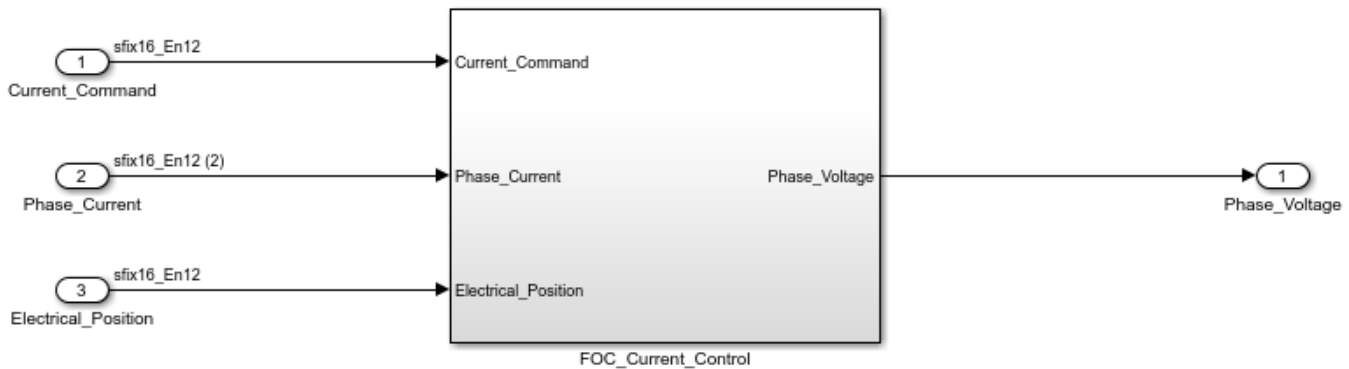

Prepare the model so that it is ready for clock-rate pipelining.

Open the `hdlcoderFocCurrentFixptHdl` model, then define the rate differential. Signal paths in Simulink end up on slow paths in HDL either because the signal path operates at a slower sample time than the base sample time of the model, or because the Simulink base sample time corresponds to the data rate instead of the clock rate. The base sample time in this model is 20μ secs. The final FPGA implementation of the controller targets 40 MHz (or 25 ns).

```
open_system('hdlcoderFocCurrentFixptHdl')
```

FOC Current Control

Copyright 2014-2017 The MathWorks, Inc.

Setting the model sample time to 25 ns slows down Simulink simulation performance. Use the “Oversampling factor” on page 21-15 to specify how much faster the FPGA clock rate runs with respect to the Simulink base sample time. In this case, the design requires a 800x oversampling factor. This is calculated by dividing the target frequency of the FPGA 40MHz by the model base frequency 50KHz.

Set optimizations on subsystems. For fixed-point designs, HDL Coder applies clock-rate pipelining to subsystems only when it needs to insert pipelining. The HDL Coder options that introduce pipelining are distributed pipelining, sharing, streaming, input/output pipelining, constrained output pipeline, adaptive pipelining and any block implementations that introduce multi-cycle implementations including floating point implementations. You can apply optimizations either locally, to maintain the subsystem hierarchies, or globally, if the underlying subsystems are flattened. In the local case, apply pipelining and optimization settings on individual subsystems. In the global case, these settings should be on the top-level subsystem. For more information on prerequisites for Hierarchy Flattening, see “Hierarchy Flattening” on page 28-119.

Apply Clock-Rate Pipelining

Create a copy of the original model `hdlcoderFocCurrentFixptHdl` and save it as a new model `hdlcoderFocClockRatePipelining` to apply clock-rate pipelining optimizations and compare it to the original model.

```
srcHdlModel = 'hdlcoderFocCurrentFixptHdl';
dstHdlModel = 'hdlcoderFocClockRatePipelining';
dstHdlDut   = [dstHdlModel '/FOC_Current_Control'];
gmHdlModel  = ['gm_' dstHdlModel];
gmHdlDut    = ['gm_' dstHdlDut];

open_system(srcHdlModel);
save_system(srcHdlModel,dstHdlModel);
```

FOC Current Control

Copyright 2014-2017 The MathWorks, Inc.

The subsystem `FOC_Current_Control` that contains the algorithm for which HDL code is generated is referred to as the device under test (DUT). Open the DUT subsystem.

```
open_system(dstHdlDut);
```

Apply clock-rate pipelining. Clock-rate pipelining is enabled by default and automatically finds clock-rate regions when you generate HDL code. For more information, see “Clock-Rate Pipelining” on page 28-149.

```
hdlset_param(dstHdlModel, 'ClockRatePipelining', 'on');
```

Configure the model to increase clock speed by setting the oversampling factor for clock-rate pipelining and enabling distributed pipelining for the model. The subsystems inherit the top-level distributed pipelining setting by default.

```
hdlset_param(dstHdlModel, 'Oversampling', 800);
hdlset_param(dstHdlModel, 'DistributedPipelining', 'on');
```

```
set_param([dstHdlDut '/DQ_Current_Control/D_Current_Control'], 'TreatAsAtomicUnit', 'off');
set_param([dstHdlDut '/DQ_Current_Control/Q_Current_Control'], 'TreatAsAtomicUnit', 'off');
```

```
save_system(dstHdlModel);
```

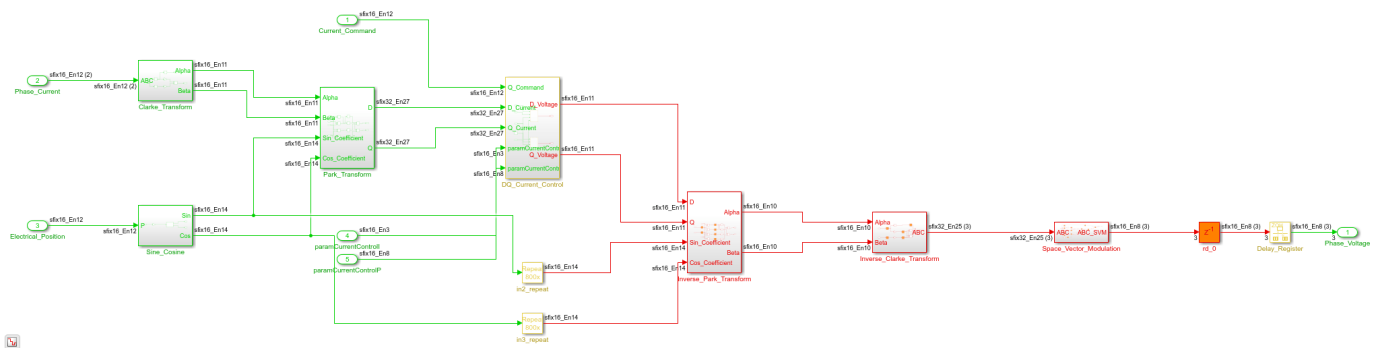

To see the impact of clock-rate pipelining, generate HDL code and look inside the top-level subsystem of the generated model.

```
makehdl(dstHdlDut);
```

```

```

The generated model shows that the design has been clock-rate pipelined and is running at the fast rate. If there are subsystems in the generated model that are not clock-rate pipelined, then check if there were optimizations set on the subsystem in the original model.

```
open_system(gmHdlDut);
set_param(gmHdlModel, 'SimulationCommand', 'update');
set_param(gmHdlDut, 'ZoomFactor', 'FitSystem');
```

Rate transitions are introduced on the design inputs to bring them to the clock rate, which is determined as the original base sample time divided by the oversampling factor, which is $2e-5/800 = 2.5e-8$ or 25 ns. All pipelines are introduced at this rate and are operating at the clock rate. Finally, observe that the output-side delay has been replaced by a down-sampling rate transition, which brings the signal back to the data rate. The clock frequency of the design was improved by inserting pipelines at the clock rate, without incurring any additional sample time delays.

Verify that the functional behavior of the design is unchanged by using the validation model and co-simulation model. For more information, see “Verification”.

Apply Local Area Optimizations to Subsystems

The rate differential on the slow path implies that computation along this path can take several clock cycles. Specifically, the allowed latency is defined by the clock-rate budget. Apart from adding pipelines to improve clock frequency, you can reuse hardware resources by leveraging the latency budget. Apply resource sharing optimizations, such as setting the `StreamingFactor` and `SharingFactor` options in a slow-path region. This section demonstrates how resource sharing is applied within clock-rate regions.

When resource sharing is applied to a clock-rate path, HDL Coder oversamples the shared resource architecture for time-multiplexing as illustrated in “Resource Sharing for Area Optimization” on page 28-54. However, if sharing or streaming is requested in a slow datapath, then HDL Coder implements resource sharing without oversampling.

The `Park_Transform` subsystem and `Inverse_Park_Transform` subsystem each use four multipliers within them that can be potentially shared. Additionally, the `Clarke_Transform` subsystem and `Inverse_Clarke_Transform` subsystem each use two gains, which may be potentially shared, unless they are simply power-of-2 gains, which results in shifts instead of multiplications. As a result, the gain in `Inverse_Clarke_Transform` cannot be shared. Open the current model and highlight the subsystems where sharing can be applied.

```
srcHdlModel = 'hdlcoderFocClockRatePipelining';
dstHdlModel = 'hdlcoderFocSharing';
dstHdlDut   = [dstHdlModel '/FOC_Current_Control'];
gmHdlModel  = ['gm_' dstHdlModel];
gmHdlDut    = ['gm_' dstHdlDut];
```

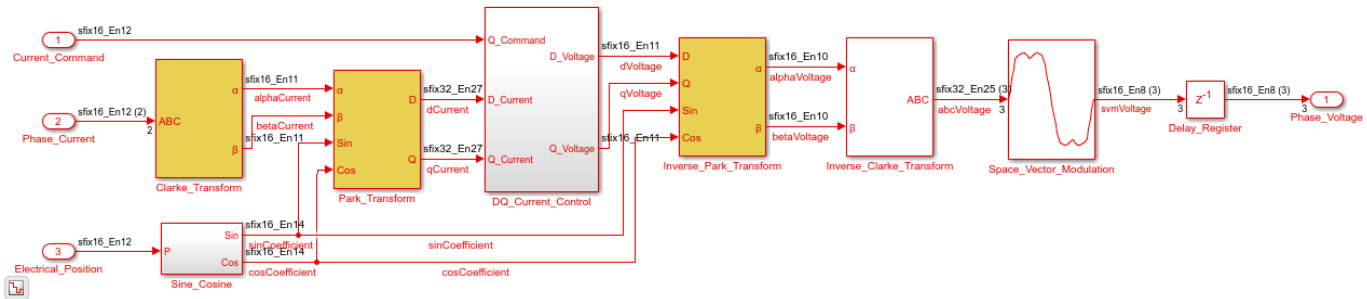

```
open_system(srcHdlModel);
save_system(srcHdlModel,dstHdlModel);
```

```
open_system(dstHdlDut);
hilite_system([dstHdlDut '/Park_Transform']);
```

```

hilite_system([dstHdlDut '/Inverse_Park_Transform']);
hilite_system([dstHdlDut '/Clarke_Transform']);

```

Set the sharing factors to the number of multipliers to share for each of the subsystems in order to apply resource sharing.

```

hdlset_param([dstHdlDut '/Park_Transform'], 'SharingFactor', 4);
hdlset_param([dstHdlDut '/Inverse_Park_Transform'], 'SharingFactor', 4);
hdlset_param([dstHdlDut '/Clarke_Transform'], 'SharingFactor', 2);

```

```
save_system(dstHdlModel);
```

Generate HDL code using the makehdl command.

```
makehdl(dstHdlDut);
```

```

```

Review the generated model and observe that HDL Code implements time-multiplexing at the clock rate using knowledge of the available latency budget due to the slow datapath.

```

load_system(gmHdlDut);
set_param(gmHdlModel, 'SimulationCommand', 'update');
set_param(gmHdlDut, 'ZoomFactor', 'FitSystem');
hilite_system([gmHdlDut '/ctr_799']);
hilite_system([gmHdlDut '/Clarke_Transform/Clarke_Transform_shared']);
hilite_system([gmHdlDut '/Park_Transform/Park_Transform_shared']);
hilite_system([gmHdlDut '/Inverse_Park_Transform/Inverse_Park_Transform_shared']);
open_system(gmHdlDut);
Simulink.BlockDiagram.arrangeSystem(gmHdlDut);

```

The time-multiplexing architecture, also known as the single-rate sharing architecture is described in “Single-Rate Resource Sharing Architecture” on page 28-65. A global scheduler is created to enable and disable different regions of the design using enabled subsystems. The enable/disable control is implemented using a Limited Counter block `ctr_799` that counts to the latency budget (0 to 799). The shared regions are implemented as enabled subsystems that are enabled according to an automatically determined schedule order. In this design, there are two subsystems containing groups of multipliers that are shared in four places and one subsystem containing a group of multipliers that are shared in two places. As a result of resource sharing, the multiplier count for the design has reduced from 20 to 13 without any latency penalties.

Apply Global Optimizations by Flattening the Model

Global cross-subsystem optimizations can be applied by leveraging the subsystem-flattening feature. With flattening, there are more number of resources that can be shared at the same level of hierarchy. To trigger such sharing, set either sharing or streaming on the top-level subsystem. The sharing factor value chosen must be an upper bound. To determine a good value, the resource usage of the design must be analyzed.

```

srcHdlModel = 'hdlcoderFocCurrentFixptHdl';
dstHdlModel = 'hdlcoderFocSharingWithFlattening';

```

```

dstHdlDut = [dstHdlModel '/FOC_Current_Control'];
gmHdlModel = ['gm_' dstHdlModel];
gmHdlDut = ['gm_' dstHdlDut];

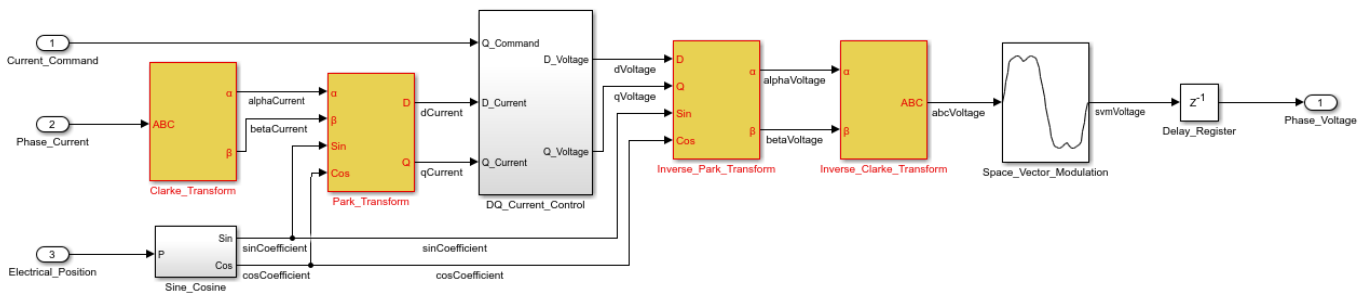

open_system(srcHdlModel);
save_system(srcHdlModel,dstHdlModel);

open_system(dstHdlDut);

hdlset_param(dstHdlModel, 'ClockRatePipelining', 'on');
hdlset_param(dstHdlModel, 'Oversampling', 800);
hdlset_param(dstHdlModel, 'DistributedPipelining', 'on');
hdlset_param(dstHdlDut, 'FlattenHierarchy', 'on');

hilite_system([dstHdlDut '/Park_Transform']);
hilite_system([dstHdlDut '/Inverse_Park_Transform']);
hilite_system([dstHdlDut '/Clarke_Transform']);
hilite_system([dstHdlDut '/Inverse_Clarke_Transform']);

```

The Park_Transform subsystem and the Inverse_Park_Transform subsystem each use four multipliers within them that can be potentially shared. Additionally, the Clarke_Transform subsystem and the Inverse_Clarke_Transform subsystem each use two gains, which may be potentially shared, unless they are simply power-of-2 gains, which results in shifts instead of multiplications. Choose the upper-bound value of four as the SharingFactor and generate HDL code.

```

hdlset_param(dstHdlDut, 'SharingFactor', 4);
save_system(dstHdlModel);

```

```
makehdl(dstHdlDut);
```

```

### HDL code generation complete.

```

Review the generated model and observe that HDL Coder implements time-multiplexing at the clock rate using knowledge of the available latency budget due to the slow datapath.

```

open_system(gmHdlDut);
set_param(gmHdlModel, 'SimulationCommand', 'update');
set_param(gmHdlDut, 'ZoomFactor', 'FitSystem');
hilite_system([gmHdlDut '/ctr_799']);
hilite_system([gmHdlDut '/crp_temp_shared']);
hilite_system([gmHdlDut '/crp_temp_shared1']);
hilite_system([gmHdlDut '/crp_temp_shared2']);
hilite_system([gmHdlDut '/crp_temp_shared3']);
hilite_system([gmHdlDut '/crp_temp_shared4']);

```

In this design, there are five subsystems containing groups of multipliers that are shared in four places or less across the model. These five subsystems have `crp_temp_shared` as part of their names.

In summary, with the design flattened, the multiplier count for the design has reduced from 20 to 7 without any latency penalties.

Minimize Latency

As an advanced maneuver, it is possible to reduce the output latency by removing the output `Delay_Register` and instead using the option to allow clock-rate pipelining of DUT output ports.

Create a new model as a copy of the `hdlcoderFocSharing` model and remove the output `Delay_Register`.

```

srcHdlModel = 'hdlcoderFocSharing';
dstHdlModel = 'hdlcoderFocMinLatency';
dstHdlDut = [dstHdlModel '/FOC_Current_Control'];
gmHdlModel = ['gm_' dstHdlModel];

```

```

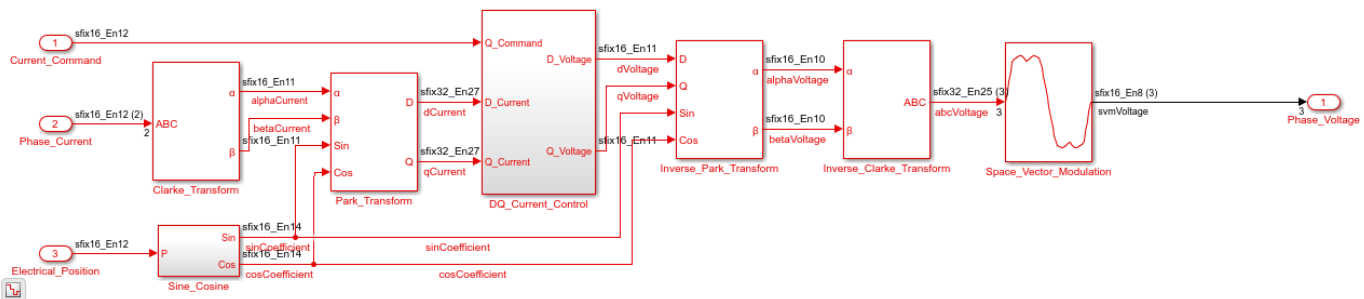

gmHdlDut    = ['gm_' dstHdlDut];

open_system(srcHdlModel);
save_system(srcHdlModel,dstHdlModel);

delete_line(dstHdlDut,'Space_Vector_Modulation/1','Delay_Register/1');
delete_line(dstHdlDut,'Delay_Register/1','Phase_Voltage/1');
delete_block([dstHdlDut,'/Delay_Register'])
add_line(dstHdlDut,'Space_Vector_Modulation/1','Phase_Voltage/1');

open_system(dstHdlDut);

```

The clock-rate pipelining for output ports option is available in the configuration parameters dialog under the **HDL Code Generation > Optimization > Pipelining** tab: check the **Allow clock-rate pipelining of DUT output ports** option. The command-line property name for this option is `ClockRatePipelineOutputPorts`. When the `ClockRatePipelineOutputPorts` option is turned on and the output register is removed, the generated HDL code does not wait for the full sample step to generate the output. It instead generates the output within a few clock cycles as soon as the data is ready. The generated HDL code generates the output at the clock rate without waiting for the next sample step.

```

hdlset_param(dstHdlModel, 'ClockRatePipelineOutputPorts', 'on');
save_system(dstHdlModel);

makehdl(dstHdlDut);

```

```

```

Notice that the `makehdl` command has generated a message, `### Phase of output port 1:`, explaining how to sample the DUT outputs. The number of clock cycles specified in this message is how quickly the DUT outputs can be sampled and, in essence, is the latency of the design. The total latency of the design is down from a data-rate sample step of $20\ \mu\text{s}$ to a few nanoseconds.

Review the generated model to observe that a new DUT subsystem is created whose output operates at the clock rate, which is 25 ns.

```

open_system(gmHdlDut);
set_param(gmHdlModel, 'SimulationCommand', 'update');
set_param(gmHdlDut, 'ZoomFactor', 'FitSystem');

```

This option introduces additional latency into the generated HDL code that was not in the original simulation model. In doing this, the sample time of the output port has changed to the clock rate. This introduces a possible discrepancy in results during the validation and verification flow since the test-harness expects the design to generate outputs at the data rate. The validation model addresses this problem by inserting a down-sampling rate-transition to bring the output back to the data rate. Thus, the validation model still compares outputs at the data rate. The HDL testbench compares the new DUT outputs at the clock rate because the generated HDL outputs are emitted at the clock rate.

Fine-tune for Performance

While this example illustrates the basic workflow to use clock-rate pipelining to minimize design latency, there are many other options available for fine-tuning HDL performance. The following are tips to leverage the feature's full potential. Note that these guidelines may not correspond to good modeling practices, but rather they are good practices for preparing your implementation model for HDL code generation and optimization.

- **Multi-rate designs:** In this example, the source model is operating at a single rate, which is the data rate. The **Oversampling factor** option specifies its relationship to the clock rate. This setup works best for minimizing design latency. Clock-rate pipelining also works well in multi-rate designs by optimizing the slow-paths, but can introduce sample delays at the rate-transition boundaries. Thus, for minimizing latency, use a single rate (the data rate) for the whole design.
- **Clock frequency:** In this design, distributed pipelining did not pipeline the whole datapath. This is because HDL Coder takes into account the consequences of moving pipelines across certain blocks that can cause a numerical mismatch. Often, these numerical integrity issues occur at boundary conditions. If your design does not hit these boundary conditions, you can set the **Distributed pipelining priority** parameter to **Performance**. In this case, go through validation to confirm that the design is working properly and is robust to all operating conditions. For more information, see the Distributed pipelining priority section in “Pipelining Parameters” on page 19-9.

- Flatten hierarchy: You can turn on hierarchy flattening to either maximize global cross-subsystem optimizations and/or to improve the effectiveness of clock-rate pipelining in the presence of feedback loops. In particular, when there are feedback loops that cross subsystem boundaries, turn on hierarchy flattening in the highest-level subsystem that contains the feedback loop. However, to be effective, check that all the requirements for “Hierarchy Flattening” on page 28-119 are satisfied for the lower-level subsystems.
- Provide sufficient budget: When the total number of clock-rate pipelines applied is equal to or more than the available oversampling budget, understanding the timing impact can be hard. Therefore, provide sufficient budget, or value of **Oversampling factor**, for clock-rate pipelining. The only drawback of too big of an oversampling value is that the counters used by the timing controller and scheduler can be larger. The area overhead is, therefore, quite small.

Summary

Clock-rate pipelining is a technique to optimize and pipeline slow paths in your design. Clock-rate pipelining ensures that pipelines are introduced at the clock rate for these HDL Coder constructs and optimizations:

- Pipelined math operations: Several math blocks implement a multi-cycle, pipelined HDL implementation, e.g., Newton-Rhapson method for sqrt or recip, CORDIC algorithm for trigonometric functions. These pipelines are introduced at clock rate if the block operates on a slow path.
- Floating point mapping: As described above, floating point library mapping utilizes clock-rate pipelines when implementing floating point math.
- Pipelining optimizations: All pipelining optimizations including input/output pipelining, adaptive pipelining and distributed pipelining use clock-rate registers on slow paths.
- Resource sharing and streaming: Time-multiplexing of resource-shared architectures are implemented at the clock rate.

Slow paths are identified as paths using a slower Simulink sample time or when **Oversampling factor** is set in the HDL Coder settings. Using clock-rate pipelining, the design speed and area properties can be improved without compromising the total latency of the design.

Iteratively Maximize Clock Frequency by Using Speed Optimizations

This example shows how to iteratively maximize the clock frequency for a model by using various speed optimizations and minimize the resources needed for the design. In this example, you first apply speed optimizations to achieve a desired target frequency, then apply area optimizations to reduce the resources needed for your design on hardware.

The algorithm in this model detects a peak pulse in a noisy signal. The model is designed for deployment onto hardware but it is not yet optimized for speed.

To optimize the model:

- 1 You use Simulink® HDL optimizations to generate optimized HDL code from the model. These optimizations can increase the clock speed of your design and reduce the amount of hardware components needed for the design.
- 2 For each iteration of optimizations that you apply, you use the HDL Workflow Advisor to run synthesis on your model and to generate a Resource and Timing summary to determine the clock frequency achieved and the resources used.
- 3 From the summary, you can determine which optimizations to apply next. The target clock frequency in this example is 230 MHz.

Prerequisites

This example requires Xilinx Vivado® as the synthesis tool. Set up the synthesis tool before beginning this example by using the function `hdlsetuptoolpath`.

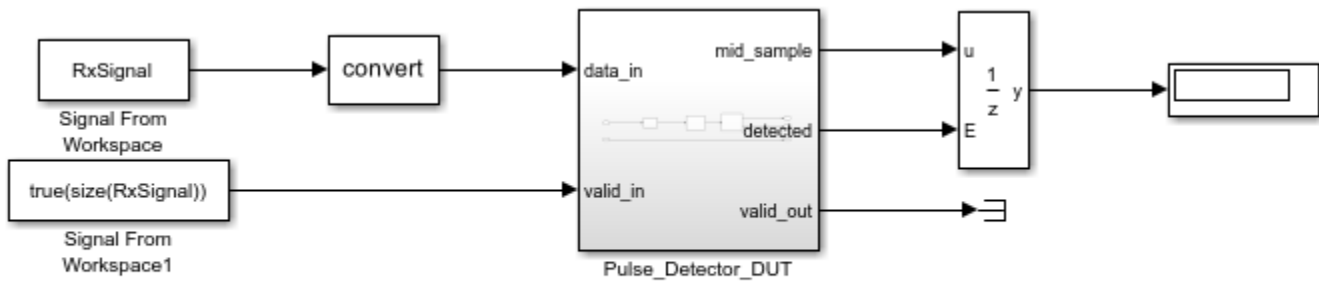

This example targets the Xilinx Zynq® hardware with a speed grade of -1. HDL Coder™ has a default timing database for Xilinx Zynq with a speed grade -1. If you are targeting an FPGA that HDL Coder does not have a characterized timing database for, use the function `genhdltdb` to create your own database. To see the list of characterized timing databases, see “Critical Path Estimation Without Running Synthesis” on page 28-192.

If you generate your own timing database, you can use the model parameter `TimingDatabaseDirectory` to set the timing database for the model to your custom timing database created. See “Custom Timing Database Directory” on page 22-9.

Open and Simulate the Model

Open and simulate the model to see the peak found using the peak detection algorithm.

```
modelName = 'pulse_detector';  
DUTname = [modelName '/Pulse_Detector_DUT'];  
open_system(modelname);
```

© 2022 The MathWorks, Inc.

```
sim(modelname);
```

Set the `Pulse_Detector_DUT` as the HDL subsystem so you generate HDL code for the `Pulse_Detector_DUT` subsystem and not the entire model.

```
hdlset_param(modelname, 'HDLSubsystem', DUTname);
```

Apply Base Speed Optimizations

When you want to deploy a model to an FPGA, it is a best practice to apply some base speed optimizations. For this example, enable adaptive pipelining and add I/O pipeline registers. Applying an input and output pipeline enables you to clock the I/O for the FPGA. Adaptive pipelining enables you to pipeline and target DSPs. For more information, see “Adaptive Pipelining” on page 28-181.

```
hdlset_param(modelname, 'AdaptivePipelining', 'on');
hdlset_param(DUTname, 'OutputPipeline', 1);
hdlset_param(DUTname, 'InputPipeline', 1);
```

When you apply optimizations that can affect timing or numerical changes in the model, such as adaptive pipelining, it is a best practice to generate a validation model. Enable the generation of the validation model. The validation model compares the generated model and original model and displays any numerical mismatches between the two.

```
hdlset_param(modelname, 'GenerateValidationModel', 'on');
```

To view the nondefault HDL code generation parameters for the model, use the function `hdlsaveparams`.

```
hdlsaveparams(modelname)
```

```
%% Set Model 'pulse_detector' HDL parameters
hdlset_param('pulse_detector', 'AdaptivePipelining', 'on');
hdlset_param('pulse_detector', 'Backannotation', 'on');
hdlset_param('pulse_detector', 'CriticalPathEstimation', 'on');
hdlset_param('pulse_detector', 'GenerateHDLTestBench', 'off');
hdlset_param('pulse_detector', 'GenerateValidationModel', 'on');
hdlset_param('pulse_detector', 'HDLSubsystem', 'pulse_detector/Pulse_Detector_DUT');
hdlset_param('pulse_detector', 'MinimizeClockEnables', 'on');
hdlset_param('pulse_detector', 'OptimizationReport', 'on');
hdlset_param('pulse_detector', 'ResetType', 'Synchronous');
hdlset_param('pulse_detector', 'ResourceReport', 'on');
hdlset_param('pulse_detector', 'SynthesisTool', 'Xilinx Vivado');
hdlset_param('pulse_detector', 'SynthesisToolChipFamily', 'Zynq');
```

```
hdlset_param('pulse_detector', 'SynthesisToolDeviceName', 'xc7z045');
hdlset_param('pulse_detector', 'SynthesisToolPackageName', 'ffg900');
hdlset_param('pulse_detector', 'SynthesisToolSpeedValue', '-1');
hdlset_param('pulse_detector', 'TargetDirectory', 'hdl_prj\hdlsrc');
hdlset_param('pulse_detector', 'TargetFrequency', 230);
hdlset_param('pulse_detector', 'TargetLanguage', 'Verilog');
hdlset_param('pulse_detector', 'Traceability', 'on');

% Set SubSystem HDL parameters
hdlset_param('pulse_detector/Pulse_Detector_DUT', 'InputPipeline', 1);
hdlset_param('pulse_detector/Pulse_Detector_DUT', 'OutputPipeline', 1);

hdlset_param('pulse_detector/Pulse_Detector_DUT/Discrete FIR Filter', 'Architecture', 'Fully Parallel');
```

Note that the Discrete FIR Filter block has the HDL block property **Architecture** set to **Fully Parallel**. This option enables subsystem level optimizations to be applied to the filter block. For more information, see “Subsystem Optimizations for Filters” on page 28-214.

Generate code by using the `makehdl` command.

`makehdl(DUTname)`

Because the `Traceability` parameter for this model is on, the Code Generation Report window opens after the `makehdl` function completes. This report summarizes the generated code and the

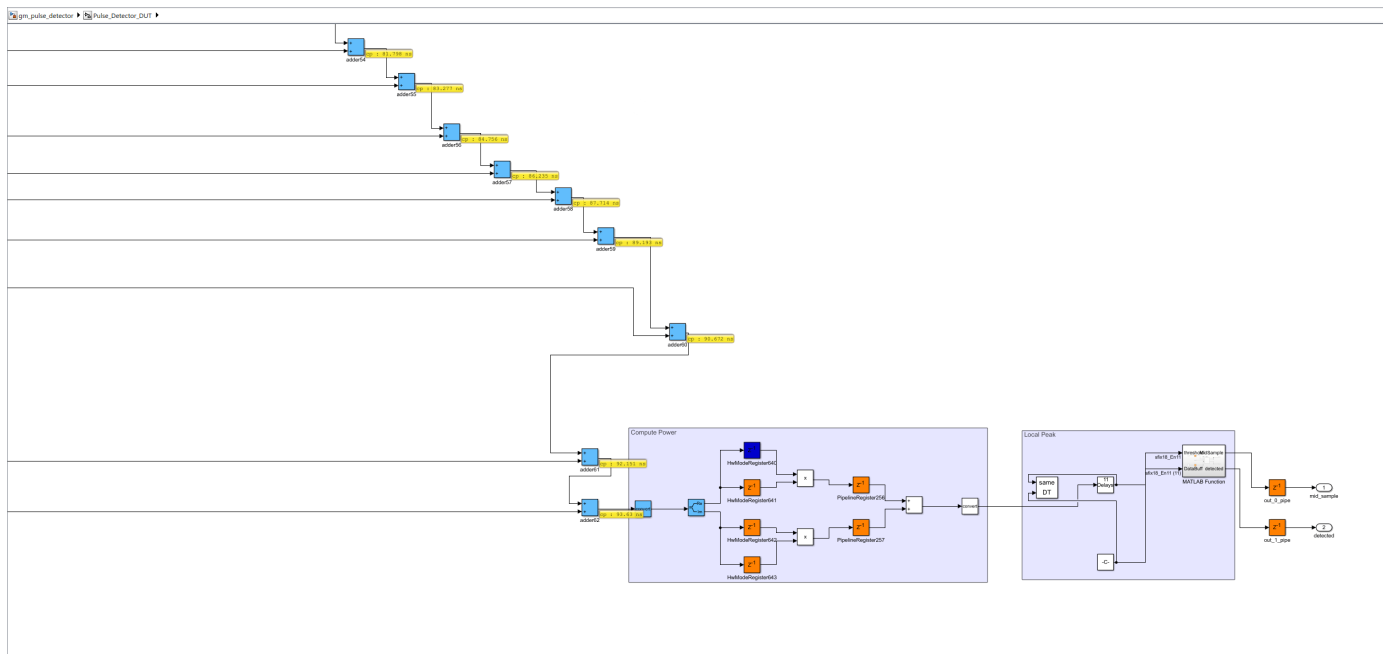

HDL code options applied to the model. For more information, see “Create and Use Code Generation Reports” on page 30-2.

In the left pane, click **Delay Balancing**. The pipelines added from the base speed optimizations applied add 9 cycles of latency to the generated model.

You can find out more information about the optimizations applied in the **Optimization Report** section. Each link in this section characterizes an optimization applied to the model. Click **High-level resource report** to see the initial estimate of resources needed to deploy the model to your target hardware.

Open the generated model `gm_pulse_detector` to see the optimizations applied to the model. The generated model is located in the `hdl_prj\hdlsrc\pulse_detector` folder.

Click on the highlighting script `hdl_prj\hdlsrc\pulse_detector\criticalPathEstimated.m` in the output of the `makehdl` command to highlight the estimated critical path of the design. This image shows a snippet of the generated model with part of estimated critical path highlighted and the subsystems expanded. The critical path estimation shows the critical path running through a long chain of adders from the Discrete FIR Filter block.

You can also see the estimated critical path in the Code Generation Report by clicking **Critical Path Estimation**. For this example, the critical path estimated is 93.872 ns. The critical path estimation is an estimation of the critical path of your model when it is implemented on hardware. To accurately capture the critical path, you must run synthesis on your model.

In the **Critical Path Estimation** pane, you can also click scripts to highlight the estimated critical path of your design and the blocks not characterized by the critical path estimation in both the original model and generated model. Click the script that highlights the uncharacterized blocks, `highlightCriticalPathEstimationOffendingBlocks.m`. The script highlights the MATLAB Function block. When the HDL block property **Architecture** is set to MATLAB Function, critical path estimation cannot characterize the MATLAB Function block. While you can still generate code, to most accurately capture the critical path of your design and apply subsystem level optimizations to

your MATLAB Function block, consider changing the **Architecture** of your MATLAB Function block to MATLAB Datapath. This option is explored in the next set of optimizations applied to the model.

To determine if the speed optimizations applied to the model achieve the target frequency, run synthesis on the model to check if the timing constraints are met.

To run synthesis on the model:

- 1 In Simulink, the in **HDL Code** tab, click **Workflow Advisor**.
- 2 In the left pane, click **4. FPGA Synthesis and Analysis > 4.2 Perform Synthesis and P/R > 4.2.2. Run Implementation**. Clear **Skip This Task**.
- 3 Right-click **4.2.2 Run Implementation** and click **Run to Selected Task**.

The HDL Workflow Advisor runs through synthesis and implementation for the model. The Result section displays the Resource and Timing summary from synthesis. The Timing summary shows that there is negative slack, which indicates that the timing constraint, the target clock frequency, is not met. When timing is not met, the clock frequency is not calculated in this report.

Timing summary	
	Value
Requirement	4.3478 ns
Data Path Delay	8.615 ns
Slack	-4.731 ns
Clock Frequency	

For reference, you can calculate the clock frequency manually by using this equation:

$$\text{ClockFrequency} = 1/(\text{Requirement} - \text{Slack})$$

The calculated clock frequency is 110 MHz.

For more information on the code generation and synthesis steps, see “HDL Code Generation and FPGA Synthesis from Simulink Model”.

Apply Distributed Pipelining

To apply Simulink HDL optimizations to the MATLAB Function block, set the HDL block property **Architecture** to MATLAB Datapath. This option characterizes the MATLAB Function block for critical path estimation, which helps you get a more accurate estimate of your critical path. For more

information on when to set this property to MATLAB Datapath, see “HDL Optimizations Across MATLAB Function Block Boundary Using MATLAB Datapath Architecture” on page 28-203.

```
hdlset_param([DUTname '/Local Peak/MATLAB Function'], 'Architecture', 'MATLAB Datapath');
```

To increase the clock frequency and reduce the critical path, you can enable the HDL optimization distributed pipelining. In order to use distributed pipelining, there already needs to be pipelines in the design that distributed pipelining can move to minimize the critical path. In this example, to break up the long chain of adders causing a long critical path, increase the number of pipeline stages for distributed pipelining to move by increasing the number of output pipelines. For more information on distributed pipelining, see “Distributed Pipelining” on page 28-131.

Increase the number of output pipeline stages in the DUT to 23 and enable distributed pipelining for the model.

```
hdlset_param(DUTname, 'OutputPipeline', 23);
hdlset_param(modelname, 'DistributedPipelining', 'on');
```

Distributed pipelining priority is by default set as Numerical Integrity. Set the **Distributed pipelining priority** to Performance to allow distributed pipelining to move pipelines with the goal of trying to maximize clock speed. If you do not change this parameter and generate HDL code, the Code Generation Report window displays this message in the **Distributed Pipelining** pane:

```
'DistributedPipeliningPriority' set to 'Numerical Integrity' is
preventing movement of pipelines around certain blocks. Consider
changing the priority to 'Performance' if numerical inaccuracies can be
ignored. Note that this can lead to validation model mismatches during
the initialization cycles or whole simulation time if the model has feedback loops.
```

It is important to note that when you set **Distributed pipelining priority** to Performance, the model behavior might not strictly match the generated code behavior. If strict numerical integrity is a requirement, keep **Distributed pipelining priority** set to Numerical Integrity. Instead, consider moving the placement of initial pipelines set in the design, in this case the output pipeline stages, to locations where the pipelines are not blocked by distributed pipelining barriers. For more information on distributed pipelining priority, see “Pipelining Parameters” on page 19-9. For more information on distributed pipelining barriers, see “Highlight blocks inhibiting distributed pipelining” on page 21-103.

```
hdlset_param(modelname, 'DistributedPipeliningPriority', 'Performance');
```

To apply distributed pipelining across all subsystems in the DUT and see all blocks at the same level in the generated model, enable the FlattenHierarchy parameter on the DUT subsystem. Alternatively, to keep the subsystem hierarchy while still applying distributed pipelining across subsystems, enable **Distributed pipelining** for the model.

```
hdlset_param(DUTname, 'FlattenHierarchy', 'on')
```

The optimization options applied to the model add 31 cycles of latency to the generated model. This increase in latency is due to the large number of output pipelines, which reduced the critical path.

Below is a snippet of the generated model with the estimated critical path highlighted. The estimated critical path is now only through a single multiplier block because distributed pipelining broke up the long chain of adders in the Discrete FIR Filter by inserting pipelines throughout the original critical path. As a result, the adder chain with pipelines now has a shorter path than the multiplier block by itself.

gm_pulse_detector Pulse_Detector_DUT

The estimated critical path is now 5.971 ns, which is much smaller than the initial value of 93.872 ns. This decrease in estimated critical path is a result of the speed optimizations applied across the entire DUT, including its subsystems and the MATLAB Function block.

Check if your timing constraints have been met by running the HDL Workflow Advisor through step 4.2.2. The synthesis results show that there is positive slack, indicating that the timing constraint is met. The clock frequency is now 255 MHz and is higher than the target frequency of 230 MHz and the initial clock frequency of 110 MHz.

The optimizations applied to the model add 31 cycles of latency to the generated model.

The estimated critical path is 5.971 ns, which is the same as the previous model. Because critical path estimation is an estimate, you need to run synthesis to determine how this option changed your clock frequency and resources.

Depending on your design, using synthesis timing estimates for distributed pipelining can improve your clock speed or keep it similar to the clock frequency when using synthesis estimates for distributed pipelining is not enabled.

Using synthesis timing estimates for distributed pipelining can increase your clock speed if your design has different types of components with nonzero propagation delay, and the delays of each type of block are different from one another. For example, if you have Add and Multiply blocks in your

design that have nonzero propagation delays, but the numerical value of the delays are significantly different, using synthesis timing estimates for distributed pipelining can increase your clock frequency.

Using synthesis timing estimates for distributed pipelining might not improve your clock frequency if there is such a large number of delays in the model that regardless of how distributed pipelining moves the delays, they are placed in the same or similar locations in the design.

Check if your timing constraints have been met by running the HDL Workflow Advisor through step 4.2.2. The synthesis results show that there is positive slack, which indicates that the timing constraint is met. The clock frequency is now 236 MHz and is higher than the target frequency of 230 MHz.

Apply Area Optimizations

The target frequency is now met due the applied speed optimizations, but the model uses significant resources. The **Resource summary** table displays the resource usage for the model.

To reduce the area used by the design, apply sharing to the DUT. If you look at the generated model you can see a significant portion of the FIR Filter block uses adders. Ensure resource sharing is applied to the adders by enabling the sharing of adders. You can increase or decrease the sharing factor depending on the area requirements for your design. For this example, set the `SharingFactor` to 8 to reduce the DSP usage by about a factor of eight.

```
hdlset_param(DUTname, 'SharingFactor', 8);
hdlset_param(modelname, 'ShareAdders', 'on');
```

Resource sharing creates a multirate model due to the serializer subnetworks added in the generated model. Synthesis tools require a constraint file to indicate if a path is using a slower clock enable where it can tolerate multiple clock cycles. If a synthesis tool does not have a constraint file when there are multiple clock rates, the synthesis tool might report that the critical path is in a slow part of the logic that does not need to be executed every single clock cycle. You can generate this constraint file by enabling the generation of a multicycle path constraint for your model. Generating this constraint file can also improve the timing of your design and reduce synthesis time. For more

information, see “Meet Timing Requirements Using Enable-Based Multicycle Path Constraints” on page 27-37.

```

The optimizations add 96 cycles of latency to the generated model. This increase in added latency is due to the resource sharing area optimizations. Sharing resources for multiple operations serializes the design and as a result, the optimized design requires more clock cycles to produce the output. In this example because there is no requirement to maximize throughput, reducing the area consumed at the cost of added latency is a good trade-off.

The critical path estimated is 6.213 ns, which is slightly larger than without area optimizations applied.

Check if your timing constraints have been met by running the HDL Workflow Advisor through step 4.2.2. The synthesis results show that there is positive slack, which indicates that the timing constraint is met. The clock frequency is now 234 MHz and is higher than the target frequency of 230 MHz.

As indicated by the resource summary, the DSP usage decreased significantly from 28.67% of the DSPs used to 3.67% used. The trade-off for this decrease in area is a minor decrease in clock frequency and a slight increase in the usage of slice LUTs and slice Registers.

Parsed resource report file: [Pulse_Detector_DUT_utilization_placed.rpt](#).

- “Pipeline Insertion for MATLAB Function Blocks” on page 28-186
- “Adaptive Pipelining Report” on page 28-186

Certain patterns or combination of blocks with registers can improve the achievable clock frequency and reduce the area usage on the FPGA boards. The adaptive pipelining optimization creates these patterns by inserting pipeline registers to the blocks in your design. To determine the optimal number of pipeline registers to insert in your design, the optimization considers the target device, target frequency, multiplier word lengths, and the settings in the HDL Block Properties. Use adaptive pipelining with:

- Clock-rate pipelining to insert pipeline registers at a faster clock-rate instead of the slower data-rate. With clock-rate pipelining, you can design your DUT at one rate, and then specify the **Oversampling factor**.
- Resource sharing which saves area and timing because the code generator shares resources and inserts adaptive pipeline registers.

By default, the adaptive pipelining optimization is disabled on the model. In certain situations, you must enable this optimization before generating HDL code. See “Design Patterns That Require Adaptive Pipelining” on page 28-188.

Requirements

- For HDL Coder to insert adaptive pipelines, specify the target device. When your design has multipliers, specify the target device and the target frequency.

Note If you use a target device that is not characterized for adaptive pipelining, the optimization uses Xilinx Virtex®-7 when Xilinx Vivado is specified as the **Synthesis Tool**, and uses Intel Stratix® V when the **Synthesis Tool** is Altera Quartus II or Intel Quartus Pro.

- Make sure that delay balancing is enabled for the subsystem that you want HDL Coder to insert adaptive pipelines for. If you disable delay balancing, the code generator does not insert adaptive pipelines.
- Make sure that your design does not have floating-point data types or operations.

Note In some cases, when you have blocks inside a feedback loop, adaptive pipelining is unable to insert the required number of pipeline registers at the output. Delay balancing can then fail.

Specify Adaptive Pipelining

You can set adaptive pipelining for an entire model or, for finer control, you can set adaptive pipelining for subsystems within the top-level DUT subsystem.

Enable Adaptive Pipelining for a Model

By default, adaptive pipelining is disabled at the model level. You can enable adaptive pipelining in one of the following ways:

- In the HDL Workflow Advisor, on the **HDL Code Generation > Set Code Generation Options > Set Optimization Options > Pipelining** tab, select **Adaptive pipelining**.
- In the Configuration Parameters dialog box, on the **HDL Code Generation > Optimization > Pipelining** tab, select **Adaptive pipelining** and click **OK**.
- At the command line, use the `makehdl` or `hdlset_param` function to set “Adaptive pipelining” on page 19-15 to on.

```
hdlset_param(gcs, 'AdaptivePipelining', 'on')
```

Enable Adaptive Pipelining for a Subsystem

By default, subsystems in your model inherit the model-level adaptive pipelining setting. If you want HDL Coder to selectively enable adaptive pipelines for a subsystem in your model, set **AdaptivePipelining** to on for that subsystem.

To learn how to set adaptive pipelining for a subsystem, see “Set Adaptive Pipelining For a Subsystem” on page 26-4.

Supported Blocks

Adaptive pipelining supports these multipliers, multiply accumulate, and rate transition blocks for automatic pipeline insertion.

- Downsample
- Rate Transition
- Product
- Gain
- Multiply-Add
- Multiply-Accumulate
- MATLAB Function

Pipeline Insertion for Rate Transition and Downsample Blocks

To insert adaptive pipelines for the Rate Transition and Downsample blocks:

- 1 Specify the target device.
- 2 Make sure that Downsample blocks have a **Downsample factor** greater than two.

When generating code, HDL Coder inserts a pipeline register at the output port of the Downsample block. Addition of the pipeline register can avoid the bypass register logic, which saves area on the target FPGA.

This figure is the generated model for the blocks with Xilinx Virtex7 as the target FPGA device.

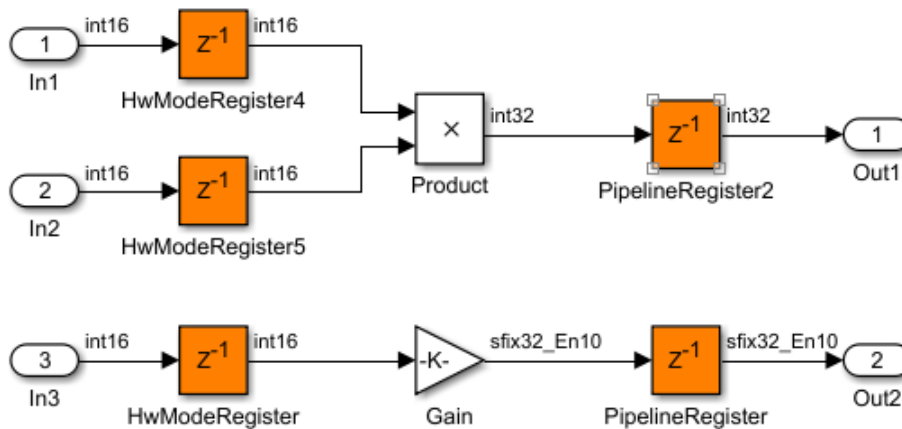

Pipeline Insertion for Product and Gain Blocks

To insert adaptive pipelines for these blocks:

- 1 Specify the target device.
- 2 Specify a target frequency greater than zero.

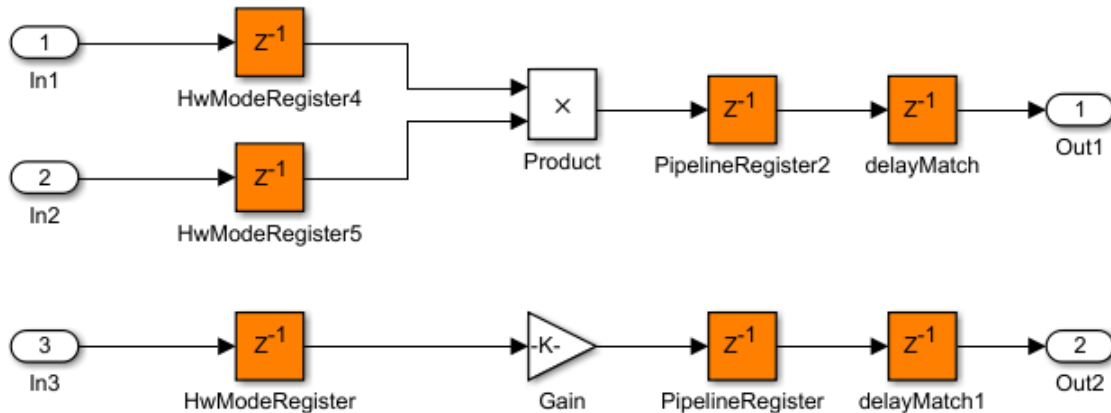

When generating code, HDL Coder inserts registers at the input and output ports of the blocks. The combination of multipliers with the registers can potentially map to DSP units on the target device.

This figure is the generated model for the Product, Gain, and Multiply-Add blocks with Intel Arria10 as the target FPGA device and a target frequency of 500 MHz. The inputs to the blocks are of type `int16`.

The pattern and number of pipeline registers that HDL Coder inserts can vary depending on the target device, target frequency, and the multiplier word lengths.

This figure is the generated model for the blocks with Xilinx Virtex7 as the target FPGA device and a target frequency of 1500 MHz. The inputs are of type `int8`.

The blocks have a different number of pipeline registers at the output ports. To match the delays, HDL Coder adds a delay at the output of the Product and Gain blocks.

Pipeline Insertion for Multiply-Add and Multiply-Accumulate Blocks

To insert adaptive pipelines for these blocks:

- 1 Specify the target device.
- 2 Specify a target frequency greater than zero.
- 3 Use the `Parallel` HDL architecture for the Multiply-Accumulate block. For an input vector of size N , this architecture uses N Multiply-Add blocks in series to compute the result.

Caution The Multiply-Add block with `PipelineDepth` set to `auto` or a value greater than zero and the Multiply-Accumulate block with HDL architecture specified as `Parallel` ignore the adaptive pipelining setting. If you specify the target FPGA device and a target frequency greater than zero, the code generator inserts pipeline registers at the inputs and outputs of the block even when adaptive pipelining is disabled.

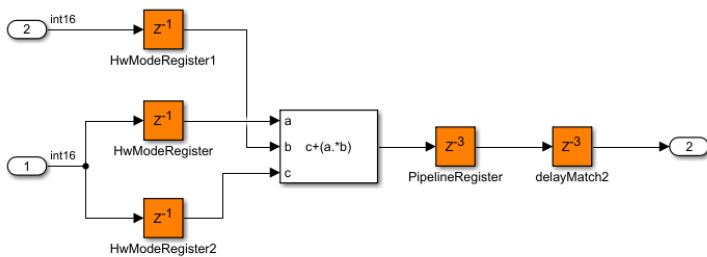

When generating code, HDL Coder inserts registers at the input and output ports of the blocks. The combination of the blocks with the registers can potentially map to DSP units on the target device.

This figure is the generated model for the Multiply-Add and Multiply-Accumulate with Intel Arria10 as the target FPGA device and a target frequency of 500 MHz. The inputs to the blocks are of type `int8`.

The pattern and number of pipeline registers that HDL Coder inserts can vary depending on the target device, target frequency, and the multiplier word lengths.

This figure is the generated model for the blocks with Xilinx Virtex7 as the target FPGA device and a target frequency of 1500 MHz. The inputs are of type int16.

Pipeline Insertion for MATLAB Function Blocks

To insert adaptive pipelines for MATLAB Function blocks:

- 1 Specify the target device.
- 2 Specify a target frequency greater than zero.
- 3 Set the HDL architecture for the MATLAB Function blocks to **MATLAB Datapath**.

HDL Coder treats MATLAB Function blocks that have their architecture set to **MATLAB Datapath** like regular Subsystems. The code generator converts the MATLAB algorithm to a Simulink block diagram. If the Simulink diagram uses blocks that are supported by adaptive pipelining, such as Product or Add blocks, the code generator inserts pipeline registers at the input and output ports of the blocks. The combination of multipliers with the registers can potentially map to DSP units on the target device.

Consider a MATLAB Function block that uses the **MATLAB Datapath** architecture. This code is the algorithm inside the MATLAB Function block.

```
function y = fcn(u)
y = u*5;
```

This figure is the generated model for the MATLAB Function block that has Intel Arria10 as the target FPGA device and a target frequency of 500 MHz. The inputs to the blocks are of type `int16`. The code generator inferred the algorithm as a multiplication by a constant and inserted adaptive pipelines at the input and output.

See “HDL Applications for the MATLAB Function Block” on page 34-2.

Adaptive Pipelining Report

To see the adaptive pipelining information in the report, before you generate code for each Subsystem or model reference, enable the Code Generation report. In the Configuration Parameters dialog box, on the **HDL Code Generation** pane, select **Generate optimization report**.

When you generate HDL code, the Code Generation report opens when code generation is complete. Select the **Adaptive Pipelining** section of the Optimization report.

The Adaptive Pipelining report displays the status of the adaptive pipelining optimization and whether adaptive pipelines were inserted in your design.

When you enable adaptive pipelining and generate HDL code, the report displays:

- The blocks that have inserted pipeline registers. To see the pipeline registers inserted to the blocks in your design, click the link to the block.
- The number of pipeline registers inserted.
- Additional notes.
- If adaptive pipelining is not completed, the criteria that caused it to fail.

- “Iteratively Maximize Clock Frequency by Using Speed Optimizations” on page 28-167

Design Patterns That Require Adaptive Pipelining

Certain patterns or combination of blocks with registers can improve the achievable clock frequency and reduce the area usage on FPGAs. The adaptive pipelining optimization creates these patterns by inserting pipeline registers to the blocks in your design. To determine the optimal number of pipeline registers to insert in your design, the optimization considers the target device, target frequency, multiplier word lengths, and the settings in the HDL Block Properties. See “Adaptive Pipelining” on page 28-181.

By default, the adaptive pipelining optimization is disabled on a model. If you decide to use this optimization, you must enable it.

In many situations, you can selectively insert pipelines in your model and generate efficient HDL code without enabling the adaptive pipelining optimization. For example, you can selectively add pipelines next to a multiplier.

For certain design patterns, you must enable the adaptive pipelining optimization before generating code. For example, you might not be able to selectively add pipelines to the internal logic of a Discrete-Time Integrator block.

Guidelines on whether to enable adaptive pipelining:

- For releases previous to R2021a, the adaptive pipelining report for your model showed that the code generator inserted adaptive pipelines. Enable adaptive pipelining when you generate code for that model.
- If your model uses the blocks that are supported by the adaptive pipelining optimization and you do not selectively insert pipeline registers for these blocks, enable adaptive pipelining.
- If your model uses the blocks that are supported by the adaptive pipelining optimization and you enable any of the following optimizations, also enable adaptive pipelining:
 - Resource sharing
 - Streaming
 - Clock-rate pipelining.

See “Adaptive Pipelining Report” on page 28-186 and “Supported Blocks” on page 28-182.

The examples “Audio System That Uses Low Pass, Band Pass, and High Pass Filters” on page 28-188 and “Discrete FIR Filter That Uses Resource Sharing” on page 28-188 illustrate some situations in which you must enable adaptive pipelining before generating code.

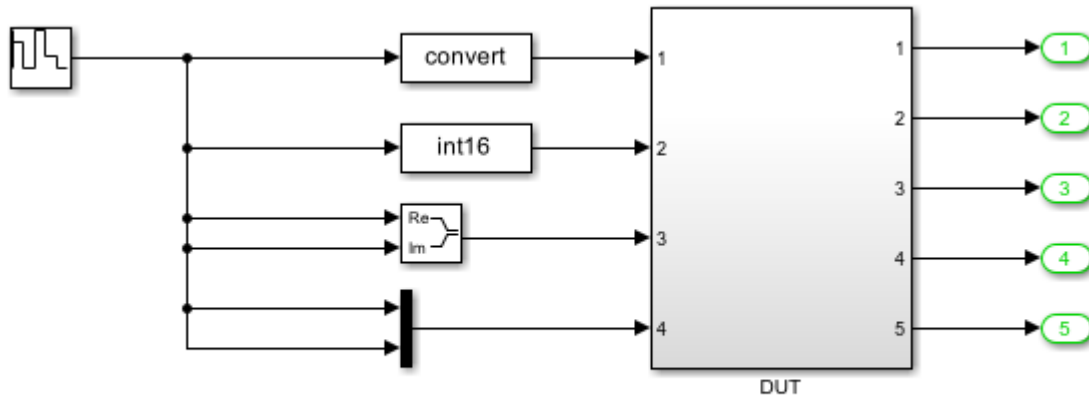

Audio System That Uses Low Pass, Band Pass, and High Pass Filters

See “Running an Audio Filter on Live Audio Input Using a Zynq Board” on page 47-161.

The model in this example has adaptive pipelining enabled. If you disable adaptive pipelining, the generated HDL code does not meet the timing constraints.

Discrete FIR Filter That Uses Resource Sharing

Open and explore this model for a Discrete FIR filter.

Copyright 2017 The MathWorks, Inc.

For the DUT Subsystem block, the HDL block property **SharingFactor** is set to 8. So, this subsystem uses the resource sharing optimization.

Generate Code With Adaptive Pipelining Disabled

In the Configuration Parameters dialog box, on the **HDL Code Generation > Optimization > Pipelining** tab, clear **Adaptive pipelining**.

In the HDL Workflow Advisor, set **Target Frequency (MHz)** to 200 and **Synthesis tool** to Xilinx Vivado. Generate HDL code and perform FPGA synthesis. For more information on the code generation and synthesis steps, see “HDL Code Generation and FPGA Synthesis from Simulink Model”.

In the generated model, no adaptive pipelines are inserted.

The synthesis result shows a negative slack, indicating that timing constraints are not met.

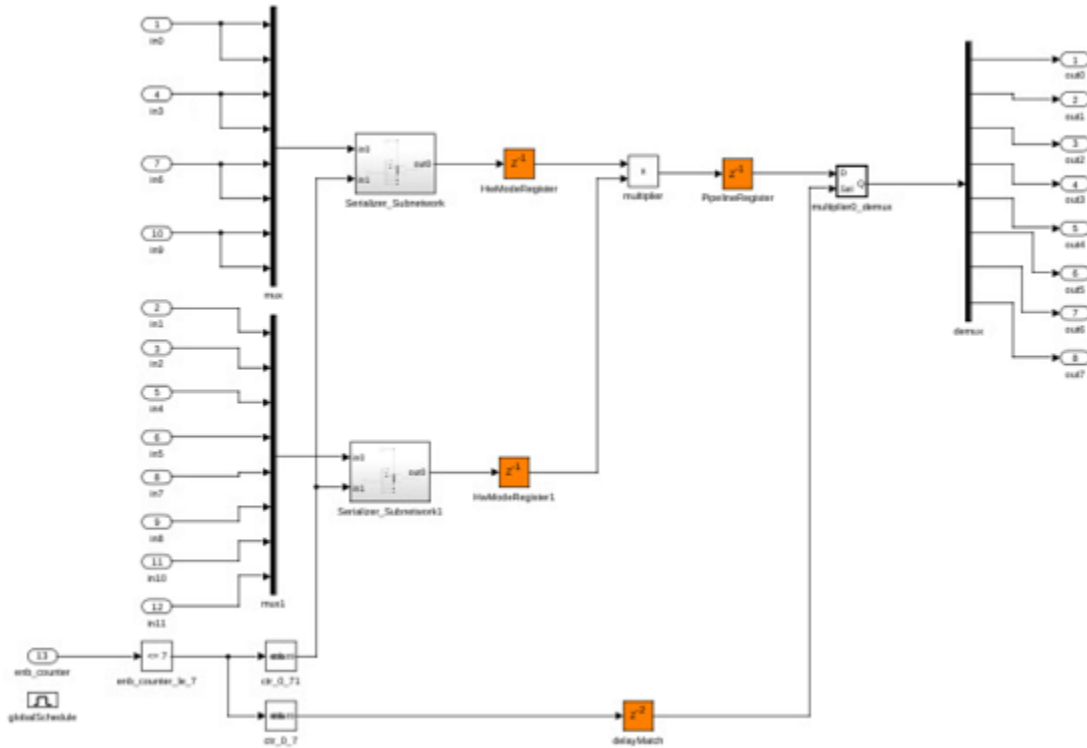

Resource summary	
Resource	Usage
Slice LUTs	5241
Slice Registers	4550
DSPs	7
Block RAM Tile	0
URAM	0

Timing summary	
	Value (ns)
Requirement	5
Data Path Delay	8.841
Slack	-3.855

Generate Code With Adaptive Pipelining Enabled

In the Configuration Parameters dialog box, on the **HDL Code Generation > Optimization > Pipelining** tab, select **Adaptive pipelining**. Generate HDL code and perform FPGA synthesis as before.

In the generated model, you can see that the code generator has inserted adaptive pipelines for the multiplier blocks.

The synthesis result shows a positive slack, indicating that timing constraints are satisfied.

Resource summary	
Resource	Usage
Slice LUTs	5062
Slice Registers	4951
DSPs	7
Block RAM Tile	0
URAM	0

Timing summary	
	Value (ns)
Requirement	5
Data Path Delay	4.528
Slack	0.41

Critical Path Estimation Without Running Synthesis

In this section...

“Critical Path Estimation Process” on page 28-192

“Use Critical Path Estimation” on page 28-194

“Characterized Blocks” on page 28-195

“Considerations” on page 28-201

Critical path is a combinational path between an input and output that has the maximum timing delay. To find the critical path in your design, use HDL Coder. To make the critical path timing meet the target frequency that you want your design to achieve, break the critical path by adding delays. The additional delays increase the latency and register usage on the target FPGA.

To quickly identify the most likely critical path in your design, use critical path estimation. You then do not have to run synthesis or generate HDL code. Critical path estimation speeds up this iterative process of finding the critical path. It optimizes the critical path until your design timing meets the target frequency that you want.

Critical path estimation speeds up the design iteration process. Critical path estimation is an alternative to annotating the critical path by performing **FPGA Synthesis and Analysis** with the HDL Workflow Advisor.

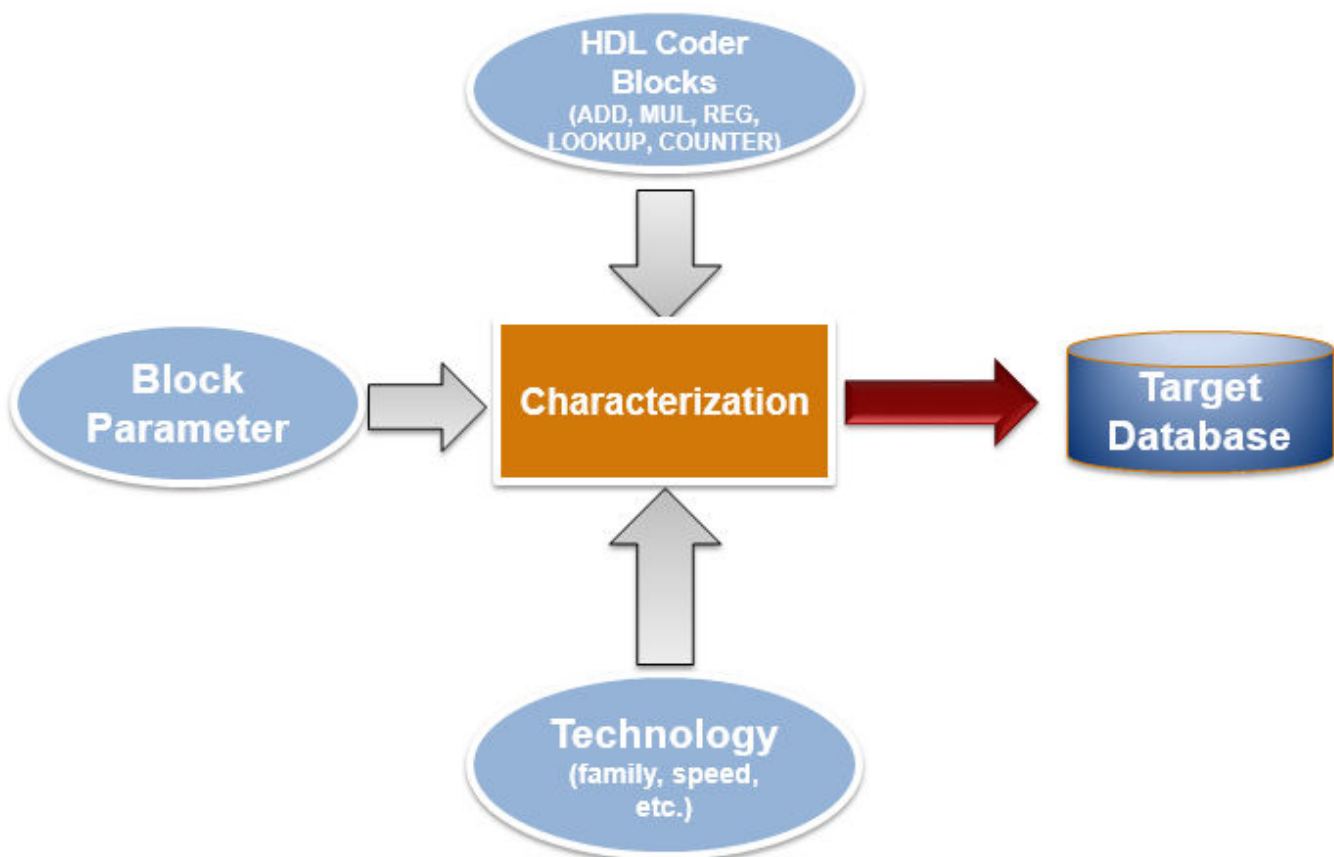

Critical Path Estimation Process

HDL Coder finds the estimated critical path by performing static timing analysis with timing data from target-specific timing databases. Generate timing databases for a specified target device family, target device speed grade, and target tool by using the `genhdl_tdb` function. By default, HDL Coder has timing databases for these target devices:

- Altera Cyclone V
- Intel Stratix V
- Xilinx Artix[®]-7, speed grade -1

- Xilinx Kintex[®]-7, speed grade -1
- Xilinx Kintex UltraScale[™], speed grade -1
- Xilinx Virtex-4, speed grade -10
- Xilinx Virtex-7, speed grade -1
- Xilinx Zynq, speed grade -1
- Xilinx Zynq UltraScale+[™], speed grade -1

To create timing databases, HDL Coder characterizes basic design components, such as Simulink blocks, block architectures, and subcomponents of those blocks, for specific target devices.

The code generator analyzes your model design to decompose it into the blocks and subcomponents in the timing databases. If your design consists of blocks or subcomponents in the timing databases, the code generator can estimate the timing critical path more accurately. If your design uses components that are not in the timing databases, a separate highlighting script is generated to show the uncharacterized blocks. If the timing data is incomplete for parts of your design, it is possible that the estimated critical path does not match your actual critical path.

If your target hardware is one of the target devices supported for critical path estimation, the timing numbers and estimated critical path are more accurate. If your target hardware is not a supported device, or is not in the same device family, you can estimate the critical path, but it is possible that the timing numbers are not accurate.

Use Critical Path Estimation

You can estimate the critical path for your design in the Configuration Parameters dialog box or at the command line. To estimate the critical path in the Configuration Parameters dialog box:

- 1 Enable generation of critical path estimation report.
 - a In the **Apps** tab, select **HDL Coder**.
 - b In the HDL Code tab, select **Settings > Report Options**, and then select **Generate high-level timing critical path report**.
- 2 Disable HDL code generation for your model. In the **HDL Code Generation > Global Settings > Advanced** tab, clear the **Generate HDL Code** check box.

To estimate the critical path in your design, you do not have to run the complete code generation process. When you disable HDL code generation, you run the process until HDL Coder creates the generated model and displays the critical path estimation script. You avoid running a larger portion of the code generation process, which saves time in estimating the critical path, especially for large models.

- 3 If your design contains floating-point data types, enable the **Native Floating Point** mode. In the Configuration Parameters dialog box, on the **HDL Code Generation > Floating Point** pane, select **Use Floating Point**.
- 4 Set the path of the generated timing databases for your target device. In the Configuration Parameters dialog box, on the **HDL Code Generation > Report** pane, select the **Generate high-level timing critical path report** parameter, and then set the path of your generated timing databases by clicking **Browse** and selecting the target folder.

By default, the target folder shows some of the saved timing database folders based on your target configuration. If the **Custom Timing Database Directory** box is empty or the target configuration has no timing databases, by default, HDL Coder uses timing databases for the Xilinx Artix-7, speed grade -1 device to generate the critical path estimation report.

You can also generate timing databases for a specified target device family, target device speed grade, and target tool by using the `genhdltdb` function.

- 5 Generate a critical path estimation report. In the **HDL Code Generation** pane, click **Apply**, and then click **Generate**.

HDL Coder generates a critical path estimation report and displays messages in the MATLAB Command Window that include a link to a highlighting script and a script that clears the highlighting.

To generate the report at the command line, use this code. Specify the `modelName` and `dutname` variables based on the design for which you want to estimate the critical path. Set the path of the generated timing databases for your target device by using the `hdlset_param` function. When you enable the generation of the critical path estimation report and do not set the timing database path for a target device, HDL Coder searches for the default timing databases for the specified target device family and target device speed grade. If timing databases for the specified target device are not available, by default, HDL Coder uses timing databases for the Xilinx Artix-7, speed grade -1 device to generate the critical path estimation report. This example uses the `sfir_single` model.

```
% Specify model and subsystem names
modelName = 'sfir_single';
dutname = 'sfir_single/symmetric_fir';
open_system(modelName)

% Disable HDL code generation for faster generation
```

```

% of critical path estimation report
hdlset_param(modelname,'CriticalPathEstimation','on');
hdlset_param(modelname,'GenerateHDLCode','off');

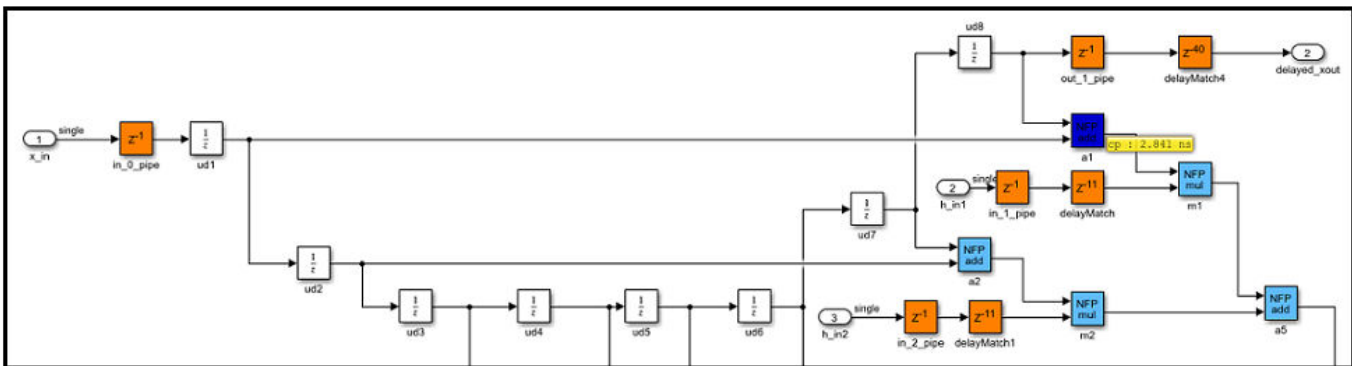

% If design contains single data types,
% enable native floating-point support
fpconfig = hdlcoder.createFloatingPointTargetConfig('NativeFloatingPoint');
hdlset_param(modelname,'FloatingPointTargetConfig',fpconfig);

% Set path of generated timing databases for target device
hdlset_param(modelname,'TimingDatabaseDirectory','C:\Work\Database');

% Generate report
makehdl(dutname)

```

When you click the link to the `criticalpathestimated` script, the code generator highlights the critical path in the generated model. In the generated model, you see the critical path timing information and blocks that are on this path. This figure shows a section of a Simulink model that has the critical path annotated. The native floating-point operators are highlighted in light blue and the delays are highlighted in orange. The block that is part of the critical path is highlighted in dark blue with the critical path value annotated beside the block. For more information, see “Generated Model and Validation Model” on page 28-10.

You can clear the highlighting by clicking the link to the `clearhighlighting` script.

To optimize the critical path, break the critical path by adding pipeline registers. If you select **Use Floating Point** to use native floating point, set the **LatencyStrategy** to **Max** to improve timing. Regenerate the critical path estimation report and the script that highlights the critical path in your design. You can repeat this process until your design timing meets the target frequency that you want.

Characterized Blocks

This table lists blocks that are characterized with fixed-point and single-precision native floating-point types. These blocks are part of the timing database for each supported target device.

If you have a MATLAB function block in your design and the HDL Block Property **Architecture** is set to **MATLAB Function**, when estimating the critical path and generating HDL code, you might see the MATLAB function block appear as an uncharacterized block in the code generation reports. To characterize the MATLAB function block, set the **Architecture** to **MATLAB Datapath**.

When you use MATLAB Function blocks and generate code by using the **MATLAB Datapath** architecture, HDL Coder converts the MATLAB algorithm to a Simulink block diagram in the generated model. In the generated model, critical path estimation can annotate the critical path inside the MATLAB Function block and across the MATLAB Function block boundary with other Simulink blocks. See also “HDL Optimizations Across MATLAB Function Block Boundary Using MATLAB Datapath Architecture” on page 28-203.

Considerations

Critical Path Estimation for Multirate Models

Critical path estimation does not consider the clock-gating information to different sequential elements in your design.

If your model contains multiple sample rates or uses speed and area optimizations that insert pipeline registers, your design becomes multirate and can have multicycle paths. For multirate models, critical path estimation treats the slow and fast data paths as running at the same rate. A data path that has a faster clock rate might be highlighted as the critical path when the design has another data path at a slower rate. This issue might cause critical path estimation to report inaccurate timing results.

To verify the estimated critical path information, open the HDL Workflow Advisor and run the Generic ASIC/FPGA workflow for your target device to the **Annotate model with synthesis result** task.

Critical Path Estimation in Native Floating Point Mode

If you have single data types in your design and you use the Native Floating Point mode by selecting **Use Floating Point**, the critical path estimation script sometimes highlights a single floating-point operator in the generated model. The code generator highlights a single block because floating-point algorithms are computation-intensive. The critical path can be an internal register-to-register path within the floating-point operator.

In this case, to optimize the critical path timing, set the **LatencyStrategy** to Max for the Simulink block corresponding to that operator.

Simulink blocks that uses half-precision data types do not participate in critical path estimation. These blocks are highlighted by using the 0 ns timing delay.

HDL Code Generation Behavior

When you enable critical path estimation, it is possible that the generated HDL code is different from the report for a Delay block that has an external reset or an enable port. For blocks such as MinMax, the number of generated HDL files might differ when you enable critical path estimation. This change occurs due to certain optimizations performed by the code generator when you enable this optimization. The optimization changes only how the code appears and does not affect the functionality.

Following are the Simulink blocks for which the generated HDL code can potentially be different.

- Delay block that has external reset or enable port
- MinMax
- Unit Delay Enabled Synchronous
- Unit Delay Resettable Synchronous
- Unit Delay Enabled Resettable Synchronous
- Enabled Delay
- Resettable Delay
- Tapped Delay

- Discrete FIR Filter
- Biquad Filter
- MATLAB Function

Inaccuracy in Critical Path Estimation

- Critical path estimation tries to account for routing delays by using an estimation factor. Without running place and route, it is difficult to accurately account for routing delays.
- HDL Coder infers uncharacterized blocks that are combinational in nature as zero-delay combinational blocks. The code generator treats other blocks as registers.
- If your target device does not have timing characteristics that are similar to one of the supported target devices, critical path estimation cannot accurately compute your critical path.

HDL Optimizations Across MATLAB Function Block Boundary Using MATLAB Datapath Architecture

This example shows how to use various optimizations inside the MATLAB Function block and across the MATLAB Function block boundary with other blocks in your Simulink® model. The example also illustrates the difference in area and timing when you use different HDL architecture settings of the MATLAB Function block.

Why Use MATLAB Datapath Architecture?

HDL code generation for a MATLAB Function block supports two HDL architectures: MATLAB Function and MATLAB Datapath. Specify the **HDL Architecture** in the HDL Block Properties dialog box of the MATLAB Function block.

Use the MATLAB Datapath architecture to:

- Model complex fixed-point and floating-point MATLAB algorithms inside MATLAB Function blocks and interface this algorithm with other Simulink blocks in your model.
- Improve area and timing of your design significantly by optimizing the algorithm inside the MATLAB Function block and across the MATLAB Function block boundary with other Simulink blocks in your model.

The MATLAB Datapath architecture is the default setting for MATLAB Function blocks with floating-point types. By enabling this architecture for fixed-point operations, you can use various optimizations that include:

- Hierarchy flattening
- Resource sharing and streaming
- Clock-rate pipelining
- Adaptive pipelining
- Distributed pipelining
- Critical path estimation

How MATLAB Datapath Architecture Works

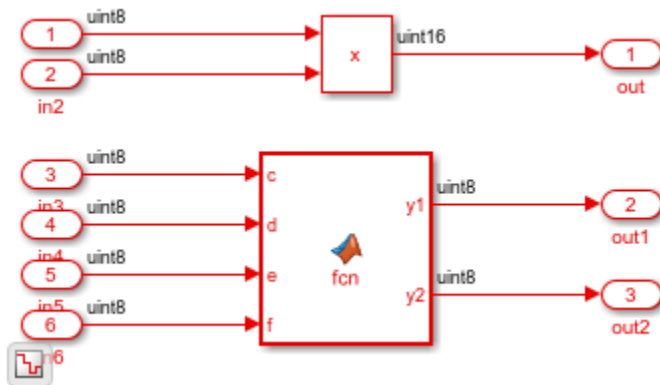

Fixed-point Simulink models use the MATLAB Function architecture by default. Certain HDL optimizations such as resource sharing and distributed pipelining that you enable with this architecture optimize the blocks surrounding the MATLAB Function block and the algorithm inside the MATLAB Function block. To see the effect of the optimizations inside the MATLAB Function block, examine the generated HDL code for the block. This architecture does not apply the optimizations across the MATLAB Function block boundary with other Simulink blocks.

Floating-point Simulink models use the MATLAB Datapath architecture even if you specify MATLAB Function as the architecture setting for the block. When you use floating-point types, specify the native floating-point mode. With this architecture, the code generator treats the block like a regular Subsystem block. HDL Coder transforms the control flow algorithm of the MATLAB code inside the MATLAB Function block to a dataflow representation that uses Simulink blocks. The MATLAB Datapath architecture unrolls loops in your code due to this transformation. If you want to stream loops, either use the loop streaming optimization with the MATLAB Function architecture or use the streaming optimization with MATLAB Datapath as the HDL architecture.

By using the MATLAB Datapath architecture, you can more effectively perform various HDL Coder optimizations with the MATLAB Function block that you would otherwise perform with a Subsystem block. The MATLAB Datapath architecture applies the optimization settings that you specify on the algorithm inside the MATLAB Function block and across the MATLAB Function block boundary with other blocks in your Simulink model.

For example, consider this model with a DUT Subsystem that consists of a Product block and a MATLAB Function block.

```
open_system('hdlcoder_MLFB_simple_datapath')
set_param('hdlcoder_MLFB_simple_datapath', 'SimulationCommand', 'Update')
open_system('hdlcoder_MLFB_simple_datapath/HDL_DUT')
```

The MATLAB Function block implements two multiplications.

```
open_system('hdlcoder_MLFB_simple_datapath/HDL_DUT/MATLAB Function')
```

```
function [y1, y2] = fcn(c, d, e, f)
%#codegen

y1 = c * d;
y2 = e * f;
```

The HDL architecture of the MATLAB Function block is set to MATLAB Datapath. To generate HDL code for the HDL_DUT Subsystem, run this command:

```
makehdl('hdlcoder_MLFB_simple_datapath/HDL_DUT')
```

When you generate HDL code, the code generator replaces the MATLAB Function block with a subsystem that performs the multiplications $c * d$ and $e * f$.

With the MATLAB Datapath architecture, you can perform optimizations inside the MATLAB Function block and across the MATLAB Function block with other Simulink blocks. In this example, you can share the two multipliers inside the MATLAB Function block. To optimize the blocks, set the **SharingFactor** to 2 on the MATLAB Function block.

```
mldsubsys = 'hdlcoder_MLFB_simple_datapath/HDL_DUT/MATLAB Function';
hdlset_param(mldsubsys, 'SharingFactor', 2)
```

When you generate HDL code, the code generator shares the multiplications inside the MATLAB Function block. The sharing group is displayed in the Optimization Report. When you click the links in the sharing group, HDL Coder displays the shared multipliers inside the MATLAB Function block in the generated model and the original model.

Sharing Report

Subsystem: [MATLAB Function](#)

SharingFactor: 2

[Highlight shared resources and diagnostics](#)

Group Id	Resource Type	I/O Wordlengths	Group Size	Block Name	Color Legend
1	Product	8x8 -> 16	2	multiplier	

You can apply the optimization across the MATLAB Function block with other Simulink blocks. In this example, you can share the Product block outside the MATLAB Function block with the multipliers inside the MATLAB Function block. To share these resources, remove the **SharingFactor** on the MATLAB Function block, and on the parent subsystem, HDL_DUT, enable **FlattenHierarchy** and set **SharingFactor** to 3.

```
hdlset_param(mldsubsys, 'SharingFactor', 0)
hdlset_param('hdlcoder_MLFB_simple_datapath/HDL_DUT', ...
             'FlattenHierarchy', 'on', 'SharingFactor', 3)
```

Note: Do not use the InlineMATLABCode property with the MATLAB Datapath architecture of the block. Use FlattenHierarchy instead.

When you generate HDL code, the code generator shares the multiplications inside the MATLAB Function block with the Product block outside. You see the sharing group of three multipliers in the

Optimization Report. When you click the links in the sharing group, the shared multipliers are highlighted in the generated model and the original model.

MATLAB Function Block Model With Default MATLAB Function Architecture

For an example model that illustrates the MATLAB Datapath architecture and how it differs from the MATLAB Function architecture, open the model `hdlcoder_MLFB_share_pipeline`. The model uses integer types. For an example that illustrates how you use the MATLAB Datapath architecture with floating-point types, see “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116.

```
open_system('hdlcoder_MLFB_share_pipeline')
set_param('hdlcoder_MLFB_share_pipeline', 'SimulationCommand', 'Update')
```

Copyright 2019-2021 The MathWorks, Inc.

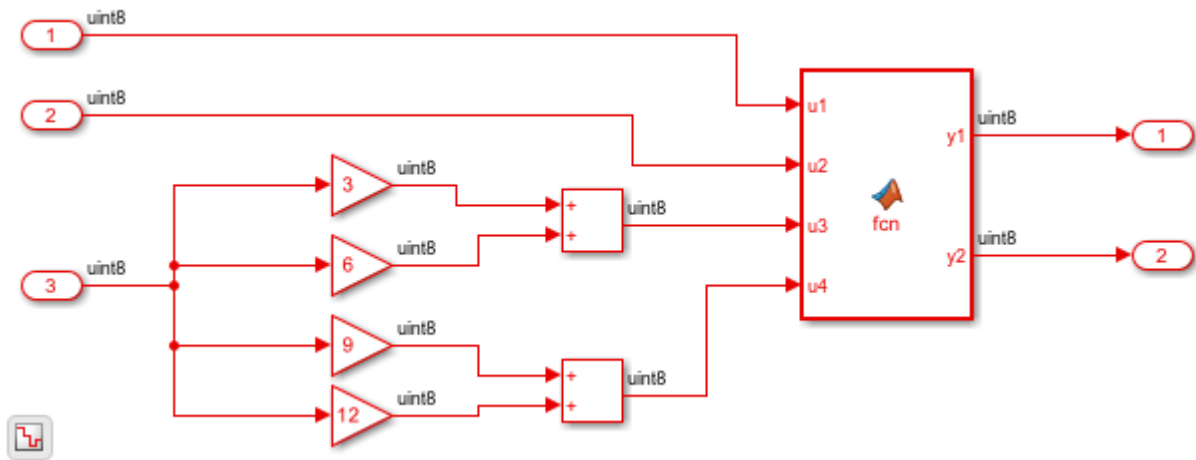

The model contains two DUT subsystems at the top level `HDL_DUT_sharing` and `HDL_DUT_distpipe`. The subsystems illustrate how you can use resource sharing and distributed pipelining optimizations across the MATLAB Function block boundary with other blocks. Both subsystems perform basic additions and multiplications inside and outside the MATLAB Function block.

```
open_system('hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing')
```

```
open_system('hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing/Subsystem')
```

```
open_system('hdlcoder_MLFB_share_pipeline/HDL_DUT_distpipe')
```

To see the HDL parameters that are saved on the model, run the `hdlsaveparams` function.

```
hdlsaveparams('hdlcoder_MLFB_share_pipeline')
```

```

%% Set Model 'hdlcoder_MLFB_share_pipeline' HDL parameters
hdlset_param('hdlcoder_MLFB_share_pipeline', 'CriticalPathEstimation', 'on');
hdlset_param('hdlcoder_MLFB_share_pipeline', 'HDLSubsystem', 'hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing/Subsystem');
hdlset_param('hdlcoder_MLFB_share_pipeline', 'OptimizationReport', 'on');
hdlset_param('hdlcoder_MLFB_share_pipeline', 'Oversampling', 40);
hdlset_param('hdlcoder_MLFB_share_pipeline', 'ResourceReport', 'on');
hdlset_param('hdlcoder_MLFB_share_pipeline', 'ShareAdders', 'on');
hdlset_param('hdlcoder_MLFB_share_pipeline', 'TargetDirectory', 'hdl_prj\hdlsrc');
hdlset_param('hdlcoder_MLFB_share_pipeline', 'Traceability', 'on');
    
```

```
% Set SubSystem HDL parameters
hdlset_param('hdlcoder_MLFB_share_pipeline/HDL_DUT_distpipe', 'DistributedPipelining', 'on');
hdlset_param('hdlcoder_MLFB_share_pipeline/HDL_DUT_distpipe', 'FlattenHierarchy', 'on');

% Set SubSystem HDL parameters
hdlset_param('hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing', 'FlattenHierarchy', 'on');
hdlset_param('hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing', 'SharingFactor', 8);
```

You see that the default MATLAB Function HDL architecture is saved on the model.

Generate HDL Code using MATLAB Function Architecture

To generate HDL code for the sharing DUT, run this command:

```
makehdl('hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing')
```

When you open the Streaming and Sharing Report, the report displays four multipliers and three adders as shared resources.

Sharing Report

Subsystem: [HDL DUT sharing](#)

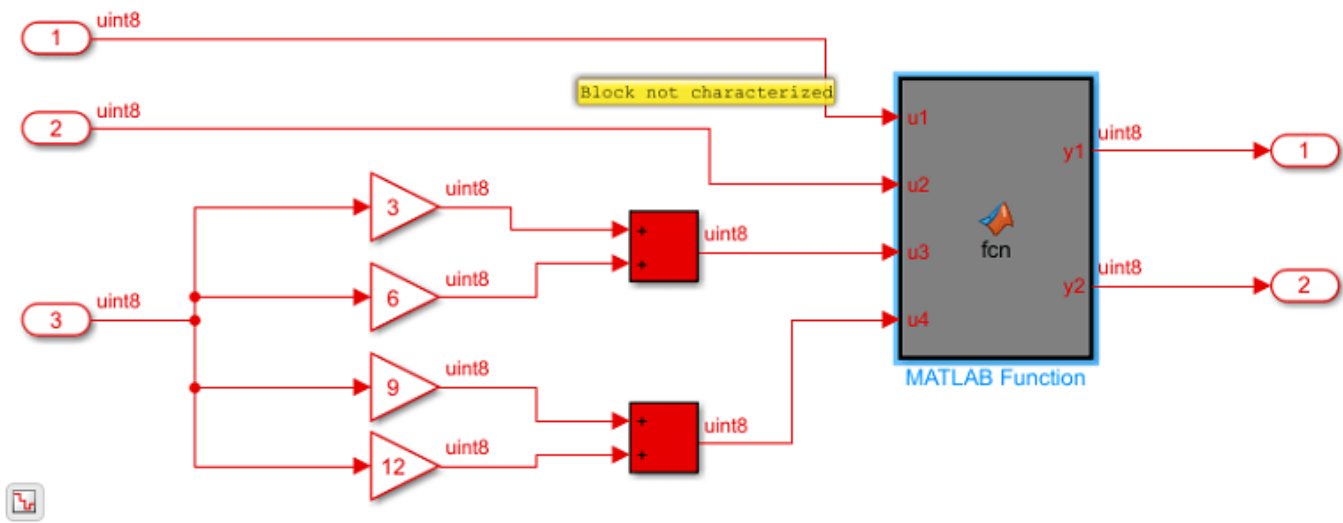

SharingFactor: 8

[Highlight shared resources and diagnostics](#)

Group Id	Resource Type	I/O Wordlengths	Group Size	Block Name	Color Legend
1	Product	8x8 -> 16	4	Gain2	
2	Sum	8+8 -> 8	3	Add1	

When you click the second sharing group, the code generator highlights three adders surrounding the MATLAB Function block. The sharing group includes the two adders inside the Subsystem and the Add block outside. The code generator did not share the multipliers and adders that are inside the MATLAB Function block.

Critical path estimation is enabled on the model. When you annotate the critical path, the MATLAB Function block acts as a barrier to this optimization. If the critical path is inside the MATLAB Function block and if you want to highlight the critical path, use the MATLAB Datapath architecture.

To generate HDL code for HDL_DUT_distpipe, run this command:

```
makehdl('hdlcoder_MLFB_share_pipeline/HDL_DUT_distpipe')
```

When you open the Distributed Pipelining Report, you see that the code generator moved pipelines inside the HDL_DUT_distpipe subsystem but did not distribute pipelines inside the MATLAB Function block.

16-bit	6

This figure displays how distributed pipelining moved pipeline registers inside the subsystem.

Apply Optimizations Across MATLAB Function Block and Other Simulink Blocks

To improve area and timing of your design, use the MATLAB Datapath architecture. For the HDL_DUT_sharing subsystem, you can combine resource sharing with clock-rate pipelining and share the resources inside the MATLAB Function block and across the MATLAB Function block with other blocks.

To share resources:

1. Enable **FlattenHierarchy** and specify a **SharingFactor** on the parent subsystem HDL_DUT_sharing. Set the **SharingFactor** to 8.

```
share_subsys = 'hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing';
hdlset_param(share_subsys, 'FlattenHierarchy', 'on', 'SharingFactor', 8);
```

2. Specify the MATLAB Datapath architecture for the MATLAB Function blocks inside the HDL_DUT_sharing subsystem.

```
share_mlfcn1 = 'hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing/MATLAB Function';
share_mlfcn2 = 'hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing/Subsystem/MATLAB Function';
hdlset_param(share_mlfcn1, 'architecture', 'MATLAB Datapath');
hdlset_param(share_mlfcn2, 'architecture', 'MATLAB Datapath');
```

To generate HDL code for HDL_DUT_distpipe, run this command:

```
makehdl('hdlcoder_MLFB_share_pipeline/HDL_DUT_sharing')
```

When you open the Streaming and Sharing report, the report displays a sharing group of eight multipliers and two sharing groups of adders.

Sharing Report

Subsystem: [HDL_DUT_sharing](#)

SharingFactor: 8

[Highlight shared resources and diagnostics](#)

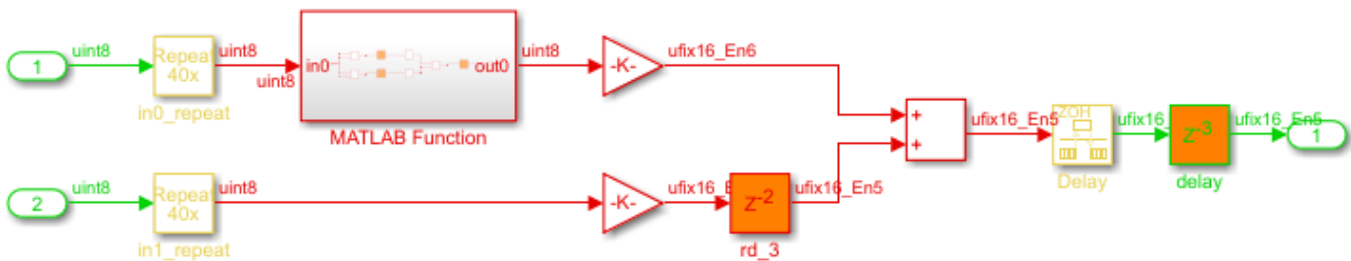

Group Id	Resource Type	I/O Wordlengths	Group Size	Block Name	Color Legend
1	Product	9x9 -> 17	8	multiplier	
2	Sum	8+8 -> 8	4	adder	
3	Sum	8+8 -> 8	2	Add1	

When you select the first sharing group, you see that the optimization shared the multipliers inside the MATLAB Function with the four Gain blocks outside. The second sharing group consists of adders inside each of the two MATLAB Function blocks.

You can use the distributed pipelining optimization with the `Distributedpipe_MLFB` subsystem. Enable distributed pipelining at the top level and set the HDL architecture of the MATLAB Function to MATLAB Datapath with **DistributedPipelining** set to on.

```
dist_subsys = 'hdlcoder_MLFB_share_pipeline/HDL_DUT_distpipe/MATLAB Function';
hdlset_param(dist_subsys, 'architecture', 'MATLAB Datapath');
hdlset_param(dist_subsys, 'DistributedPipelining', 'on');
```

After you generate HDL code, open the generated model. The code generator uses distributed pipelining and distributed pipelining to move the pipeline registers across the blocks and inside the MATLAB Function Subsystem.

This figure displays how distributed pipelining moved pipeline registers inside the MATLAB Function Subsystem.

Subsystem Optimizations for Filters

The Discrete FIR Filter (when used with scalar or multichannel input data) and Biquad Filter blocks participate in subsystem-level optimizations. To set optimization properties, right-click on the subsystem and open the **HDL Properties** dialog box.

For these blocks to participate in subsystem-level optimizations, you must leave the block-level **Architecture** set to the default, **Fully parallel**.

You cannot use these subsystem optimizations when using the Discrete FIR Filter in frame-based input mode.

Sharing

These filter blocks support sharing resources within the filter and across multiple blocks in the subsystem. When you specify a **SharingFactor**, the optimization tools generate a filter implementation in HDL that shares resources using time-multiplexing. To generate an HDL implementation that uses the minimum number of multipliers, set the **SharingFactor** to a number greater than or equal to the total number of multipliers. The sharing algorithm shares multipliers that have the same input and output data types. To enable sharing between blocks, you may need to customize the internal data types of the filters. Alternatively, you can target a particular system clock rate with your choice of **SharingFactor**.

Resource sharing applies to multipliers by default. To share adders, select the check box under **Resource sharing** on the **Configuration Parameters > HDL Code Generation > Global Settings > Optimizations** dialog box.

For more information, see “Resource Sharing” on page 28-45 and the “Area Reduction of Multichannel Filter Subsystem” on page 28-215 example.

You can also use a **SharingFactor** with multichannel filters. See “Area Reduction of Filter Subsystem” on page 28-220.

Streaming

Streaming refers to sharing an atomic part of the design across multiple channels. To generate a streaming HDL implementation of a multichannel subsystem, set **StreamingFactor** to the number of channels in your design.

If the subsystem contains a single filter block, the block-level **ChannelSharing** option and the subsystem-level **StreamingFactor** option result in similar HDL implementations. Use **StreamingFactor** when your subsystem contains either more than one filter block or additional multichannel logic that can participate in the optimization. You must set block-level **ChannelSharing** to off to use **StreamingFactor** at the subsystem level.

See “Streaming” on page 28-42 and the “Area Reduction of Filter Subsystem” on page 28-220 example.

Pipelining

You can enable **DistributedPipelining** at the subsystem level to allow the filter to participate in pipeline optimizations. The optimization tools operate on the **InputPipeline** and **OutputPipeline**

pipeline stages specified at subsystem level. The optimization tools also operate on these block-level pipeline stages:

- **InputPipeline** and **OutputPipeline**
- **MultiplierInputPipeline** and **MultiplierOutputPipeline**
- **AddPipelineRegisters**

The optimization tools do not move design delays within the filter architecture. See “Distributed Pipelining” on page 8-14.

The filter block also participates in clock-rate pipelining, if enabled in **Configuration Parameters**. This feature is enabled by default. See “Clock-Rate Pipelining” on page 28-149.

Area Reduction of Multichannel Filter Subsystem

To reduce the number of multipliers in the HDL implementation of a multichannel filter and surrounding logic, use the **StreamingFactor** HDL Coder™ optimization.

Copyright 2016 The MathWorks, Inc.

The model includes a two-channel sinusoidal signal source feeding a filter subsystem targeted for HDL code generation.

The subsystem contains a Discrete FIR Filter block and a constant multiplier. The multiplier is included to show the optimizations operating over all eligible logic in a subsystem.

The filter has 44 symmetric coefficients. With no optimizations enabled, the generated HDL code takes advantage of symmetry. The nonoptimized HDL implementation uses 46 multipliers: 22 for each channel of the filter and 1 for each channel of the Product block.

To enable streaming optimization for the Multichannel FIR Filter Subsystem, right-click the subsystem and select **HDL Code > HDL Block Properties**.

Set the **StreamingFactor** to 2, because this design is a two-channel system.

To observe the effect of the optimization, under **Configuration Parameters > HDL Code Generation**, select **Generate resource utilization report** and **Generate optimization report**. Then, to generate HDL code, right-click the Multichannel FIR Filter Subsystem and select **HDL Code > Generate HDL for Subsystem**.

With the streaming factor applied, the logic for one channel is instantiated once and run at twice the rate of the original model.

In the **Code Generation Report** window, click **High-level Resource Report**. The generated HDL code now uses 23 multipliers, compared to 46 in the nonoptimized code. The multipliers in the filter kernel and subsequent scaling are shared between the channels.

Multipliers	23
Adders/Subtractors	44
Registers	92
RAMs	0
Multiplexers	28

To apply **SharingFactor** to multichannel filters, set the **SharingFactor** to 23.

The optimized HDL now uses only 2 multipliers. The optimization tools do not share multipliers of different sizes.

Summary

Multipliers	2
Adders/Subtractors	47
Registers	166
Total 1-Bit Registers	3566

Area Reduction of Filter Subsystem

To reduce the number of multipliers in the HDL implementation of a multifilter design, use the **SharingFactor** HDL Coder™ optimization.

Copyright 2016 The MathWorks, Inc.

The model includes a sinusoidal signal source feeding a filter subsystem targeted for HDL code generation.

The subsystem contains a Discrete FIR Filter block and a Biquad Filter block. This design demonstrates how the optimization tools share resources between multiple filter blocks.

The Discrete FIR Filter block has 43 symmetric coefficients. The Biquad Filter block has 6 coefficients, two of which are unity. With no optimizations enabled, the generated HDL code takes advantage of symmetry and unity coefficients. The nonoptimized HDL implementation of the subsystem uses 27 multipliers.

Multipliers	27
Adders/Subtractors	46
Registers	49
Total 1-Bit Registers	800
RAMs	0
Multiplexers	0
I/O Bits	52

To enable streaming optimization for the **Multi-Filter Subsystem**, right-click the subsystem and select **HDL Code > HDL Block Properties**.

Set the **SharingFactor** to 27 to reduce the design to a single multiplier. The optimization tools attempt to share multipliers with matching data types. To reduce to a single multiplier, you must set the internal data types of the filter blocks to match each other.

To observe the effect of the optimization, under **Configuration Parameters > HDL Code Generation**, select **Generate resource utilization report** and **Generate optimization report**. Then, to generate HDL code, right-click the Multi-Filter Subsystem and select **HDL Code > Generate HDL for Subsystem**.

With the **SharingFactor** applied, the subsystem upsamples the rate by 27 to share a single multiplier for all the coefficients.

In the **Code Generation Report** window, click **High-level Resource Report**. The generated HDL code now uses one multiplier.

Multipliers	1
Adders/Subtractors	48
Registers	102
Total 1-Bit Registers	2457
RAMs	0
Multiplexers	7
I/O Bits	52

Remove Redundant Logic and Unused Blocks in Generated HDL Code

If your design contains redundant logic or unused blocks, HDL Coder™ removes the blocks, components, or part of the HDL code that does not contribute to the output.

Redundant Logic Considerations

Components that do not contribute to the output in the design are removed during HDL code generation. Removing redundant logic reduces code size and avoids potential synthesis failures with downstream tools when deploying your code onto a target platform. If a component or logic is preserved during HDL code generation, that component or logic is considered *active*. This optimization improves the performance of your design on the target hardware. The optimization does not affect the traceability support.

Redundant logic in your design is removed in conjunction with unused port deletion optimization. To learn about this optimization, see “Optimize Unconnected Ports in HDL Code for Simulink Models” on page 28-246.

HDL Coder does not treat a component or logic as redundant in these cases:

- The component has at least one output port that contributes to the evaluation of the DUT output.
- The component has at least one output port that contributes to the evaluation of the control port of a Subsystem block that is active.
- The component has at least one output port that contributes to the evaluation of input of a component that is preserved during HDL code generation.
- The component is an active black box subsystem, or contains an active black box subsystem, or is connected to an active black box subsystem, as described below.
- The component is an FPGA Data Capture block.

In other cases, the code generator treats the logic as redundant and removes the associated blocks or components during code generation. In addition, blocks that have HDL architecture set to **No HDL**, such as Scope, Assertion, Terminator, and To Workspace blocks are considered redundant, and are removed during code generation.

How Redundant Logic Removal Works

During code generation, HDL Coder removes the redundant logic or blocks that do not contribute to the DUT output. Open the model `hdlcoder_remove_redundant_logic`.

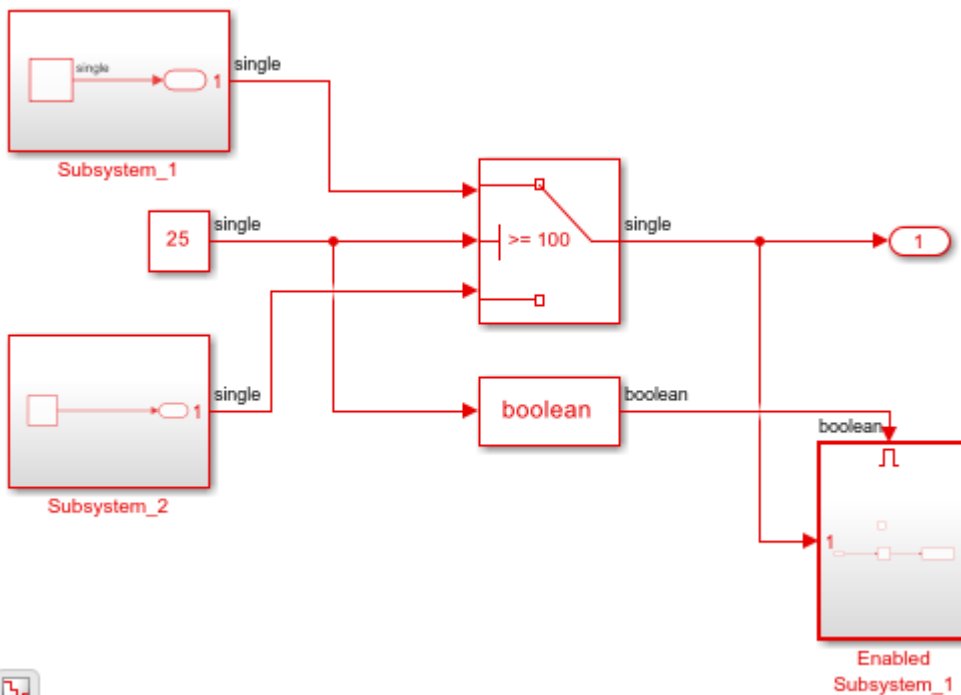

```
open_system('hdlcoder_remove_redundant_logic')
set_param('hdlcoder_remove_redundant_logic', 'SimulationCommand', 'update');
```

Copyright 2020 The MathWorks, Inc.

The DUT subsystem block contains a Switch block and an Enabled Subsystem block. Based on the control input to the Switch block, the false path from `Subsystem_2` is passed to the output. The `EnabledSubsystem_1` block output is terminated by a Display block and does not actively contribute to the output.

```
open_system('hdlcoder_remove_redundant_logic/DUT')
```

To generate HDL code for the design, at the MATLAB® command prompt, enter:

```
makehdl('hdlcoder_remove_redundant_logic/DUT')
```

The generated VHDL® code shows that HDL Coder evaluated the Switch block condition at compile time to pass the input from `Subsystem_2` to the output, and eliminated `Subsystem_1` input branch. The `EnabledSubsystem_1` block is removed during HDL code generation since it does not have an active output.

ARCHITECTURE rtl OF DUT IS

```

FOR ALL : Subsystem_2
  USE ENTITY work.Subsystem_2(rtl);

-- Signals
SIGNAL Subsystem_2_out1   : std_logic_vector(31 DOWNT0 0); -- ufix32

BEGIN
  u_Subsystem_2 : Subsystem_2
    PORT MAP( Out1 => Subsystem_2_out1  -- single
              );

  Out1 <= Subsystem_2_out1;

END rtl;

```

Redundant Logic in Black Box Subsystems

Black box subsystems are subsystem blocks that have HDL architecture set to `BlackBox`. A black box interface for a subsystem is the generated VHDL component or Verilog® module that includes only the HDL input and output port definitions for the subsystem. Use the generated interface to integrate existing manually written HDL code, third-party IP, or other code generated by HDL Coder. See “Generate Black Box Interface for Subsystem” on page 32-4.

Black box subsystems that have at least one input port are considered valid and preserved during HDL code generation. The input port can be unconnected. In this case, Simulink® inserts a virtual signal that has a constant zero value as input to the block. In the case of output ports, the black box subsystems must have at least one output port that is connected to a downstream block. When the output port is connected, the code generator identifies the black box subsystem as a source that contributes to the output value computation, and preserves it during code generation.

Open the model `hdlcoder_blackbox_redundant_logic`.

```

open_system('hdlcoder_blackbox_redundant_logic')
sim('hdlcoder_blackbox_redundant_logic');

```

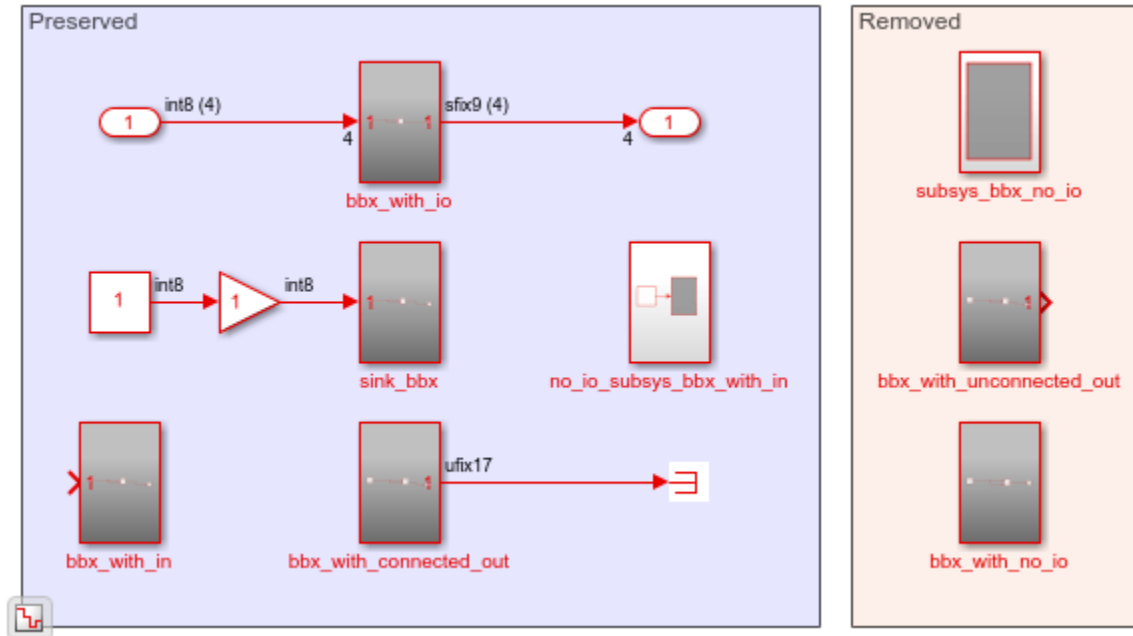

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains black box subsystems inside boxes labeled `Preserved` and `Removed`. Black box subsystems inside `Preserved` are not removed during code generation because they have

at least one input port. The other black box subsystems that do not have an input port or have an unconnected output port are removed during code generation.

```
open_system('hdlcoder_blackbox_redundant_logic/DUT')
```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_blackbox_redundant_logic/DUT')
```

The generated HDL code shows the subsystems in the Preserved section. The unconnected input port is automatically connected to a constant zero.

...

END rtl;

```

Redundant Logic in Subsystem Blocks

Subsystem blocks are preserved in the generated HDL code if the blocks have at least one output port that contributes to the evaluation of a DUT output. The Subsystem blocks are also preserved if they contain a black box subsystem that is valid. A black box subsystem is valid if it contains an input port, or an output port that is connected, as described above.

The different kinds of subsystem blocks follow this convention.

- Subsystem
- Atomic Subsystem
- Model References
- Variant Subsystem
- ForEach Subsystem
- Triggered Subsystem
- Enabled Subsystem
- Synchronous subsystems
- Masked subsystems

For individual subsystem ports, the removal of redundant logic also varies depending on whether you specify the **Remove Unused Ports** setting in the Configuration Parameters dialog box. See “Remove Unused Ports” on page 19-4.

Open the model `hdlcoder_subsys_redundant_logic`.

```

open_system('hdlcoder_subsys_redundant_logic')
sim('hdlcoder_subsys_redundant_logic');

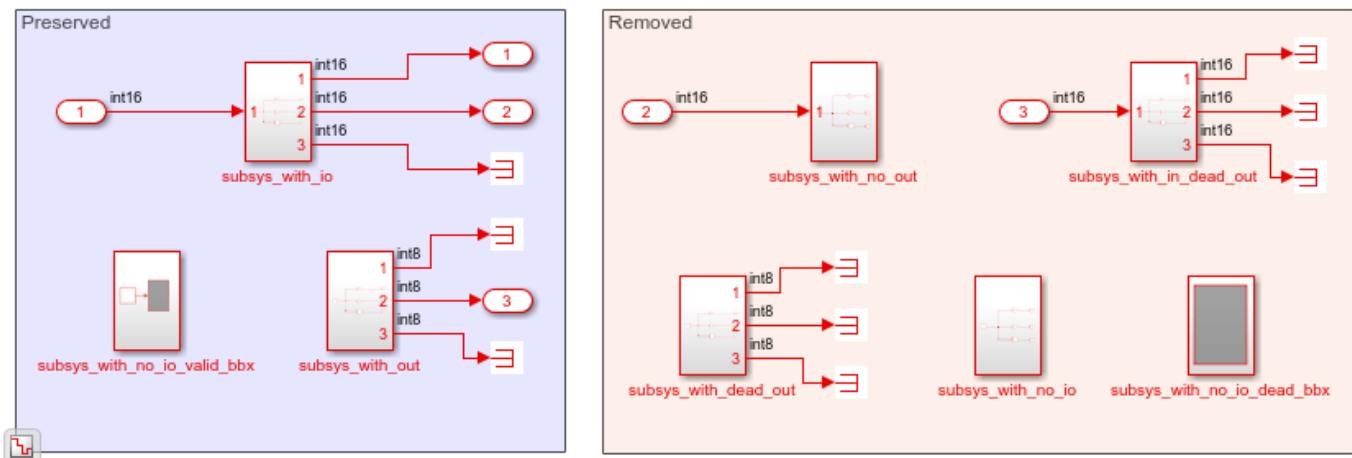

```

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains subsystem blocks inside boxes labeled Preserved and Removed. Subsystem blocks inside Preserved are not removed during code generation because they have at least one output port that contributes to the evaluation of the DUT output, or have a valid black box subsystem. The other black box subsystems that do not have an active output port are removed during code generation.

```
open_system('hdlcoder_subsys_redundant_logic/DUT')
```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_subsys_redundant_logic/DUT')
```

The generated HDL code shows the subsystems in the Preserved section.

```
ARCHITECTURE rtl OF DUT IS
```

```
-- Component Declarations
```

```
COMPONENT subsys_with_io
```

```
  PORT( In1      : IN   std_logic_vector(15 DOWNT0 0); -- int16
        Out1     : OUT  std_logic_vector(15 DOWNT0 0); -- int16
        Out2     : OUT  std_logic_vector(15 DOWNT0 0); -- int16
        );
```

```
END COMPONENT;
```

```

COMPONENT subsys_with_out
  PORT( Out2      : OUT  std_logic_vector(7 DOWNTO 0)  -- int8
        );
END COMPONENT;

COMPONENT subsys_with_no_io_valid_bbx
  PORT( clk      : IN   std_logic;
        reset    : IN   std_logic;
        enb      : IN   std_logic
        );
END COMPONENT;

...

END rtl;

```

Redundant Logic in Subsystem Ports

For subsystem data ports, the removal of redundant logic also depends on whether you specify the **Remove Unused Ports** setting. See “Optimize Unconnected Ports in HDL Code for Simulink Models” on page 28-246.

Control ports are not affected by the **Remove Unused Ports** setting. The control ports and components that contribute to evaluation of the control ports are preserved in the generated HDL code only if the entire subsystem instance is considered active.

```

open_system('hdlcoder_control_redundant_logic')
sim('hdlcoder_control_redundant_logic');

```

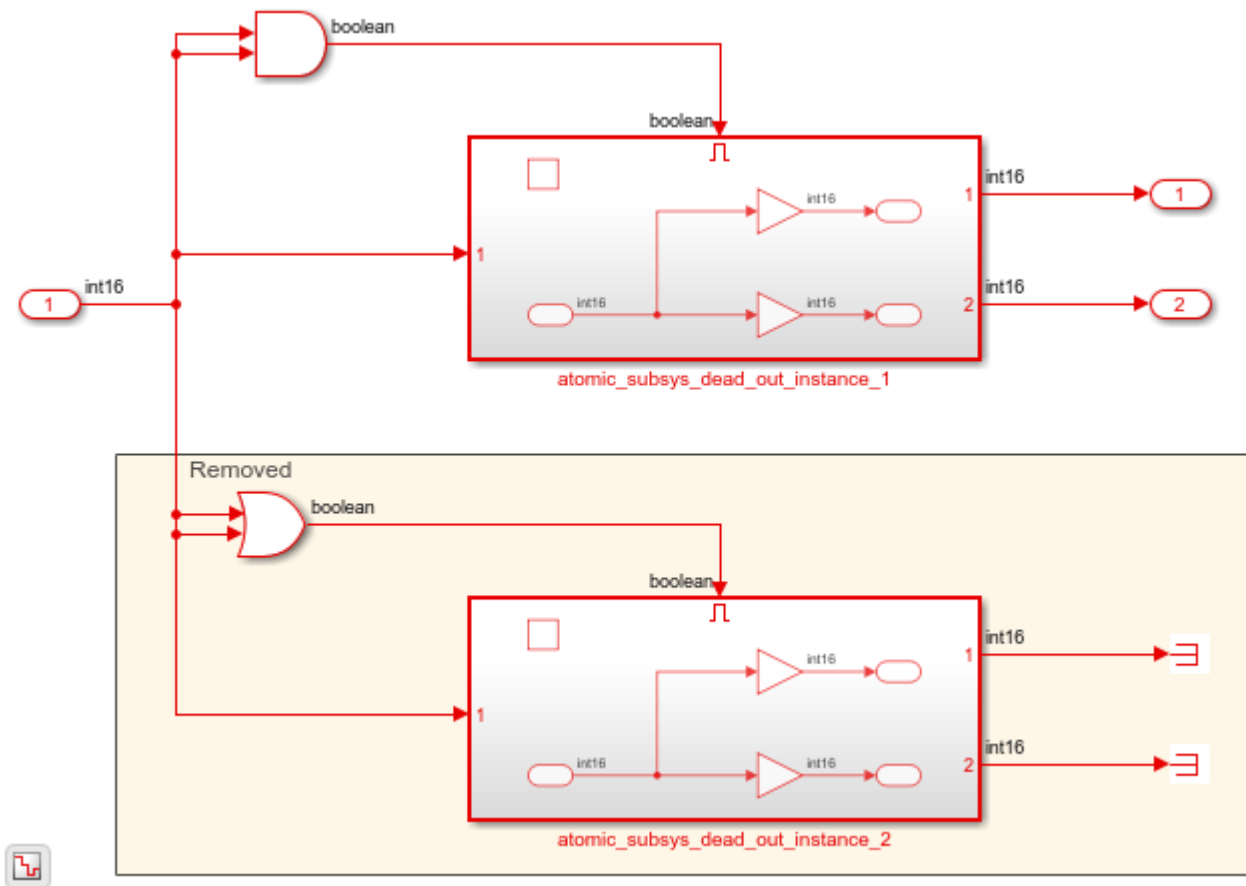

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains two atomic subsystems with an input that drives the Enable port. The subsystem `atomic_subsys_dead_out_instance_2` is not active as the outputs are terminated.

```

open_system('hdlcoder_control_redundant_logic/DUT')

```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_control_redundant_logic/DUT')
```

The `atomic_subsys_dead_out_instance_2` including the control port and input signal is removed in the generated HDL code.

```
ENTITY DUT IS
  PORT( clk      : IN    std_logic;
         reset    : IN    std_logic;
         clk_enable : IN    std_logic;
         In1      : IN    std_logic_vector(15 DOWNTO 0); -- int16
         ce_out   : OUT   std_logic;
         Out1     : OUT   std_logic_vector(15 DOWNTO 0); -- int16
         Out2     : OUT   std_logic_vector(15 DOWNTO 0); -- int16
  );
END DUT;
```

```
ARCHITECTURE rtl OF DUT IS
```

```
-- Component Declarations
```

```
COMPONENT atomic_subsys_dead_out_instance_1
  PORT( clk      : IN    std_logic;
         reset    : IN    std_logic;
         enb     : IN    std_logic;
         In1     : IN    std_logic_vector(15 DOWNTO 0); -- int16
```

```

        Enable      : IN    std_logic;
        Out1       : OUT   std_logic_vector(15 DOWNTO 0); -- int16
        Out2       : OUT   std_logic_vector(15 DOWNTO 0) -- int16
    );
END COMPONENT;

...

END rtl;

```

Redundant Logic in Atomic Subsystems and Model References

Redundant logic in atomic subsystems, model references, and ForEach subsystem blocks are treated in the same manner during HDL code generation. Redundant logic at the boundary of atomic subsystems are removed during HDL code generation.

Open the model `hdlcoder_atomic_subsys2_redundant`.

```

open_system('hdlcoder_atomic_subsys2_redundant')
sim('hdlcoder_atomic_subsys2_redundant');

```

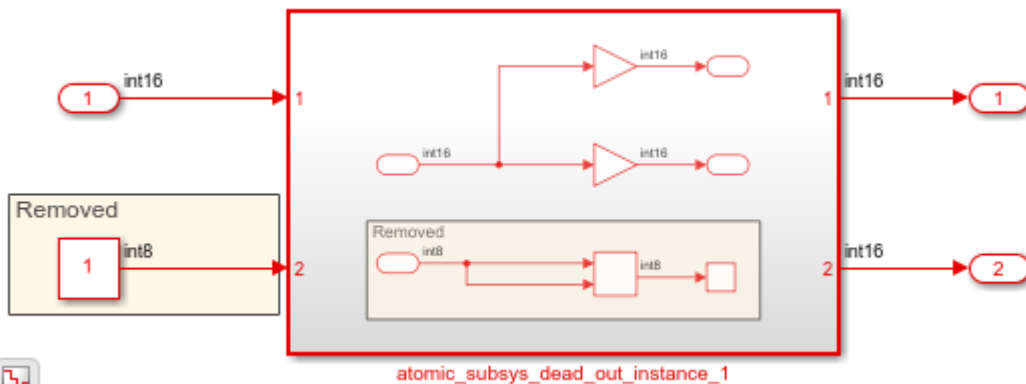

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains a single Atomic Subsystem block. The Constant block is input to the subsystem that has an Add block connected to a Terminator block.

```

open_system('hdlcoder_atomic_subsys2_redundant/DUT')

```

To generate HDL code for the DUT subsystem, run this command:

```

makehdl('hdlcoder_atomic_subsys2_redundant/DUT')

```

When you generate HDL code, the Add block and the input port are removed because the blocks do not contribute to the evaluation of a DUT output.

```

ENTITY atomic_subsys_dead_out_instance_1 IS
  PORT( In1      : IN    std_logic_vector(15 DOWNTO 0); -- int16
        Out1     : OUT   std_logic_vector(15 DOWNTO 0); -- int16
        Out2     : OUT   std_logic_vector(15 DOWNTO 0); -- int16
        );
END atomic_subsys_dead_out_instance_1;

ARCHITECTURE rtl OF atomic_subsys_dead_out_instance_1 IS
  ...

  In1_signed <= signed(In1);

  Gain_mul_temp <= to_signed(16#000A#, 16) * In1_signed;
  Gain_out1 <= Gain_mul_temp(15 DOWNTO 0);

  Out1 <= std_logic_vector(Gain_out1);

  Gain1_mul_temp <= to_signed(16#0014#, 16) * In1_signed;
  Gain1_out1 <= Gain1_mul_temp(15 DOWNTO 0);

  Out2 <= std_logic_vector(Gain1_out1);

END rtl;

```

If there are more than one active instances of the Atomic Subsystem blocks, the redundant logic computation does not cross the subsystem boundary, and the blocks are preserved in the generated HDL code.

Open the model `hdlcoder_atomic_subsys1_redundant`.

```

open_system('hdlcoder_atomic_subsys1_redundant')
sim('hdlcoder_atomic_subsys1_redundant');

```

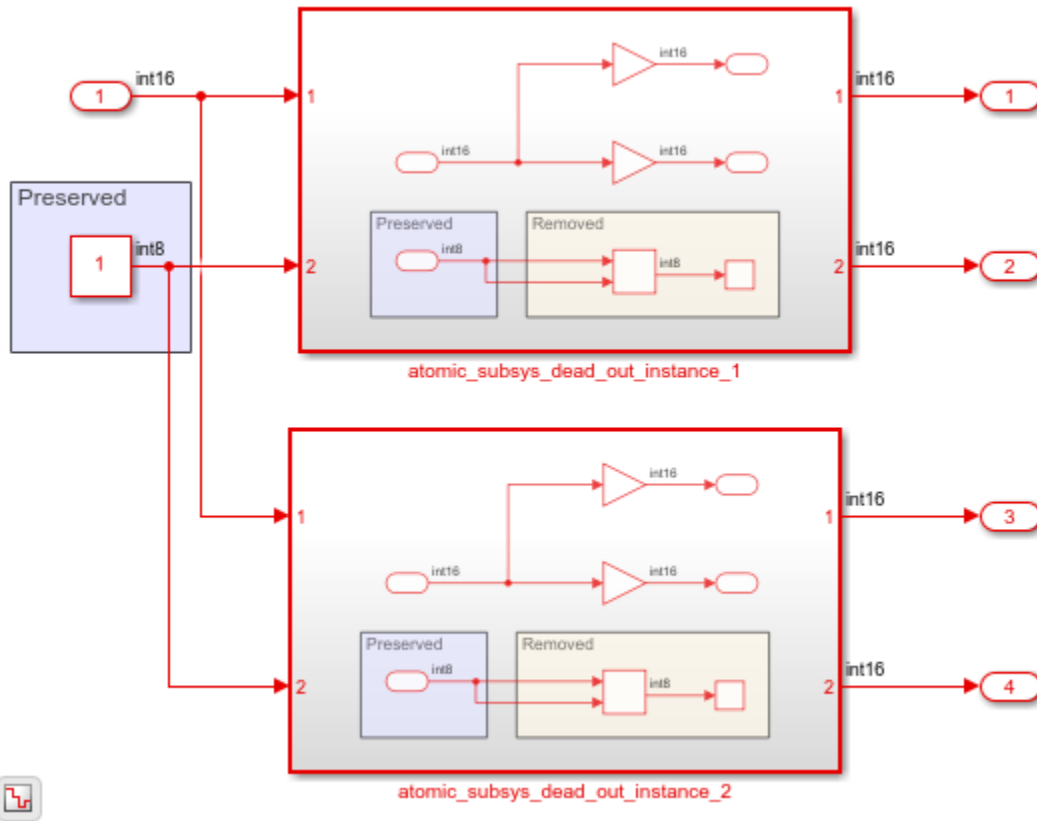

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains two atomic subsystems. Inside these subsystems, an Add block is connected to a Terminator block.

```

open_system('hdlcoder_atomic_subsys1_redundant/DUT')

```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_atomic_subsys1_redundant/DUT')
```

When you generate HDL code, the Add block is removed because it does not contribute to the evaluation of a DUT output. As there are two atomic subsystem instances that are active, the input port to the Add block is preserved during HDL code generation.

A single HDL file `atomic_subsys_dead_out_instance_1` is generated for the atomic subsystems. This file contains the `In2` port declaration but is unused in the HDL code. At the DUT level, `DUT.vhd`, the Constant block is preserved though it is feeding into an input port that does not drive any component inside the Atomic Subsystem.

```
ENTITY atomic_subsys_dead_out_instance_1 IS
  PORT( In1      : IN    std_logic_vector(15 DOWNT0 0); -- int16
        In2      : IN    std_logic_vector(7 DOWNT0 0); -- int8
        Out1     : OUT   std_logic_vector(15 DOWNT0 0); -- int16
        Out2     : OUT   std_logic_vector(15 DOWNT0 0) -- int16
        );
END atomic_subsys_dead_out_instance_1;

ARCHITECTURE rtl OF atomic_subsys_dead_out_instance_1 IS

  -- Signals
  SIGNAL In1_signed      : signed(15 DOWNT0 0); -- int16
  SIGNAL Gain_mul_temp   : signed(31 DOWNT0 0); -- sfix32
  SIGNAL Gain_out1      : signed(15 DOWNT0 0); -- int16
```

```

SIGNAL Gain1_mul_temp    : signed(31 DOWNTO 0); -- sfix32
SIGNAL Gain1_out1       : signed(15 DOWNTO 0); -- int16
...
END rtl;

```

When you have multiple instances of Atomic Subsystem blocks that are active, these instances are preserved in the generated code.

Open the model `hdlcoder_atomic_subsys1_ports_redundant`.

```

open_system('hdlcoder_atomic_subsys1_ports_redundant')
sim('hdlcoder_atomic_subsys1_ports_redundant');

```

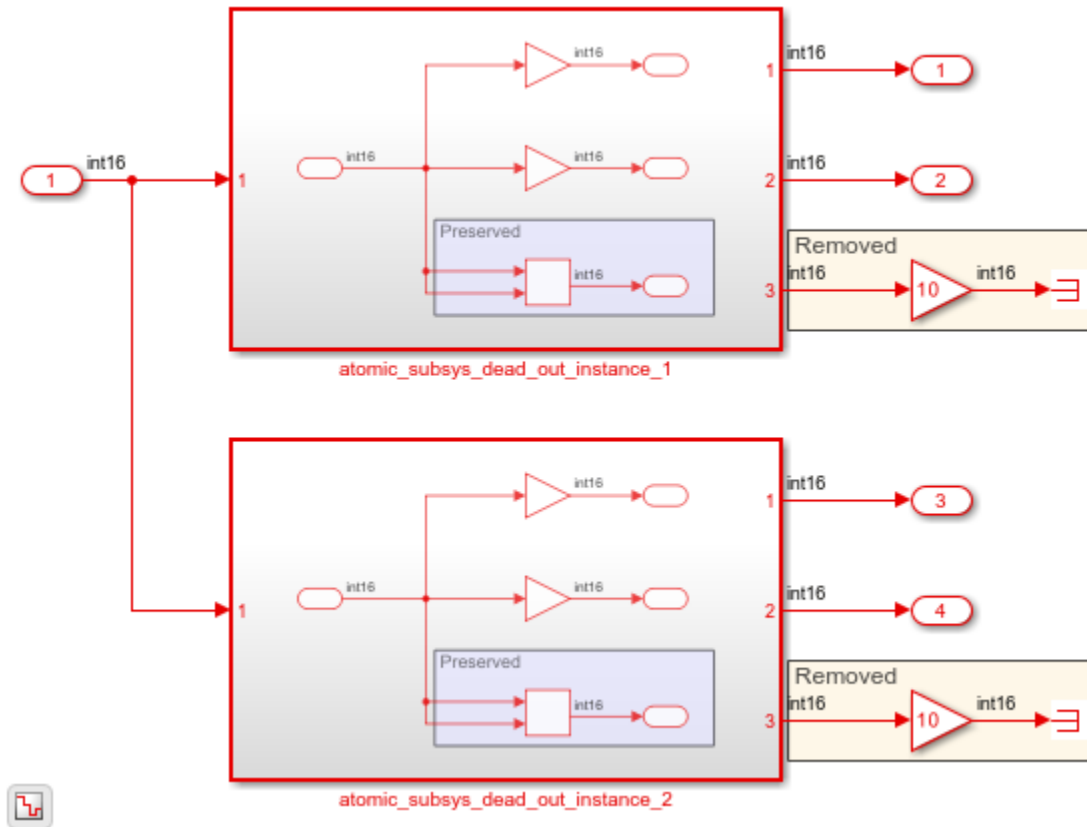

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains two atomic subsystems that are active.

```

open_system('hdlcoder_atomic_subsys1_ports_redundant/DUT')

```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_atomic_subsys1_ports_redundant/DUT')
```

The atomic subsystems are preserved in the generated HDL code but the Gain block calculation is removed from the code. In this case, the multiple atomic subsystem instances are active and thus the redundant logic is not removed across the port boundary.

```
ENTITY DUT IS
  PORT( In1      :   IN      std_logic_vector(15 DOWNTO 0); -- int16
        Out1     :   OUT     std_logic_vector(15 DOWNTO 0); -- int16
        Out2     :   OUT     std_logic_vector(15 DOWNTO 0); -- int16
        Out3     :   OUT     std_logic_vector(15 DOWNTO 0); -- int16
        Out4     :   OUT     std_logic_vector(15 DOWNTO 0); -- int16
  );
END DUT;

ARCHITECTURE rtl OF DUT IS

  -- Component Declarations
  COMPONENT atomic_subsys_dead_out_instance_1
    PORT( In1      :   IN      std_logic_vector(15 DOWNTO 0); -- int16
          Out1     :   OUT     std_logic_vector(15 DOWNTO 0); -- int16
          Out2     :   OUT     std_logic_vector(15 DOWNTO 0); -- int16
          Out3     :   OUT     std_logic_vector(15 DOWNTO 0); -- int16
    );
  END COMPONENT;
END COMPONENT;
```

```

...
Out1 <= atomic_subsys_dead_out_instance_1_out1;
Out2 <= atomic_subsys_dead_out_instance_1_out2;
Out3 <= atomic_subsys_dead_out_instance_2_out1;
Out4 <= atomic_subsys_dead_out_instance_2_out2;
END rtl;

```

When at least one instance of Atomic Subsystem block is not active and when there are unused output ports outside the Atomic Subsystem blocks, the generated HDL code varies depending on the **Remove Unused Port** setting. See “Optimize Unconnected Ports in HDL Code for Simulink Models” on page 28-246.

Redundant Logic in Masked Subsystems

Redundant logic in masked subsystems are removed in the same manner as for regular Subsystem blocks. When generating mask parameters as generics in the HDL code by setting MaskParameterAsGeneric to on, the generic ports are preserved in the code.

Open the model `hdlcoder_masked_subsys_redundant`.

```

open_system('hdlcoder_masked_subsys_redundant')
sim('hdlcoder_masked_subsys_redundant');

```

Copyright 2020 The MathWorks, Inc.

The model contains a masked subsystem that has two mask parameters Gain and Gain1. Gain has the value 10 and Gain1 has the value 20.

```

open_system('hdlcoder_masked_subsys_redundant/DUT')

```

To generate HDL code for the DUT subsystem, run this command:

```

makehdl('hdlcoder_masked_subsys_redundant/DUT')

```

The generated code shows that generic ports Gain and Gain1 are preserved but the output port Out2 is removed.

```

ENTITY Subsystem IS
  GENERIC( Gain      : integer := 10;
           Gain1     : integer := 20
         );
  PORT( In1         : IN   std_logic_vector(15 DOWNTO 0); -- int16
        Out1        : OUT  std_logic_vector(15 DOWNTO 0)  -- int16
      );
END Subsystem;

ARCHITECTURE rtl OF Subsystem IS
  ...

  kconst <= to_signed(Gain, 16);

  In1_signed <= signed(In1);

  Gain_mul_temp <= kconst * In1_signed;
  Gain_out1 <= Gain_mul_temp(15 DOWNTO 0);

  Out1 <= std_logic_vector(Gain_out1);

END rtl;

```

Redundant Logic in DocBlock and Annotations

Annotations or DocBlock blocks that are inside active subsystems are preserved in the generated HDL code. A subsystem is active if it contains at least one output port that leads to the evaluation of the DUT output, or has an active black box subsystem, as described above. If HDL Coder determines that a subsystem containing an annotation or DocBlock is redundant, then that annotation or DocBlock is also removed from the generated code.

Open the model `hdlcoder_annotations_redundant_logic`.

```

open_system('hdlcoder_annotation_redundant_logic')
sim('hdlcoder_annotation_redundant_logic');

```

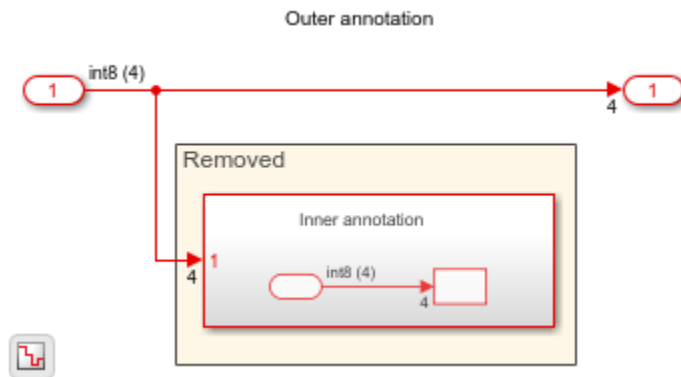

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains an Inner annotation subsystem. This subsystem is redundant because it does not have an active output port.

```

open_system('hdlcoder_annotation_redundant_logic/DUT')

```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_annotation_redundant_logic/DUT')
```

The generated HDL code shows the Inner annotation subsystem including the annotation Inner annotation removed from the generated HDL code.

```
ENTITY DUT IS
  PORT( In1  :   IN   vector_of_std_logic_vector8(0 TO 3); -- int8 [4]
        Out2 :   OUT  vector_of_std_logic_vector8(0 TO 3) -- int8 [4]
        );
END DUT;

ARCHITECTURE rtl OF DUT IS

BEGIN
  -- Removed
  --
  -- Outer annotation

  Out2 <= In1;

END rtl;
```

Redundant Logic in Bus Signals and Bus Element Ports

Redundant logic and unused blocks are removed from the model when it contains buses. The redundant logic optimization applies in the same manner to virtual buses, nonvirtual buses, and bus element ports.

Open the model `hdlcoder_virtual_bus_redundant`.

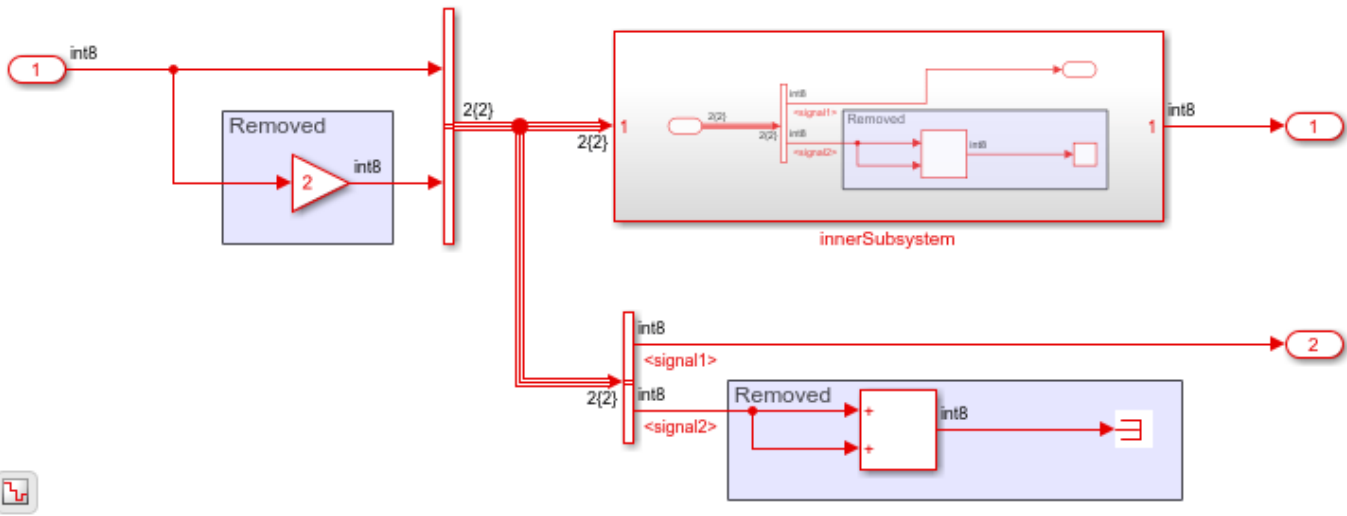

```
open_system('hdlcoder_virtual_bus_redundant')
sim('hdlcoder_virtual_bus_redundant');
```

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains a virtual bus that drives an innerSubsystem block and an Add block. One of the bus signals is connected to Terminator blocks at the output.

```
open_system('hdlcoder_virtual_bus_redundant/DUT')
```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_virtual_bus_redundant/DUT')
```

The generated HDL code shows that the redundant logic is removed in the design and the input port and output ports that are active are preserved.

```
ENTITY DUT IS
  PORT( In1          : IN   std_logic_vector(7 DOWNT0 0); -- int8
        Out1         : OUT  std_logic_vector(7 DOWNT0 0); -- int8
        Out2         : OUT  std_logic_vector(7 DOWNT0 0); -- int8
  );
END DUT;

ARCHITECTURE rtl OF DUT IS
  -- Component Declarations
  COMPONENT innerS
    PORT( In1_signal1 : IN   std_logic_vector(7 DOWNT0 0); -- int8
          Out1        : OUT  std_logic_vector(7 DOWNT0 0); -- int8
  );

```

```

    );
END COMPONENT;

...

END rtl;

```

Inside the innerSubsystem block, the Add block connected to the Terminator block is removed.

```

ENTITY innerSubsystem IS
  PORT( In1_signal1      : IN    std_logic_vector(7 DOWNTO 0); -- int8
        Out1            : OUT   std_logic_vector(7 DOWNTO 0) -- int8
        );
END innerSubsystem;

ARCHITECTURE rtl OF innerSubsystem IS

  -- Signals
  SIGNAL signal1        : signed(7 DOWNTO 0); -- int8

BEGIN
  -- Removed

  signal1 <= signed(In1_signal1);

  Out1 <= std_logic_vector(signal1);

END rtl;

```

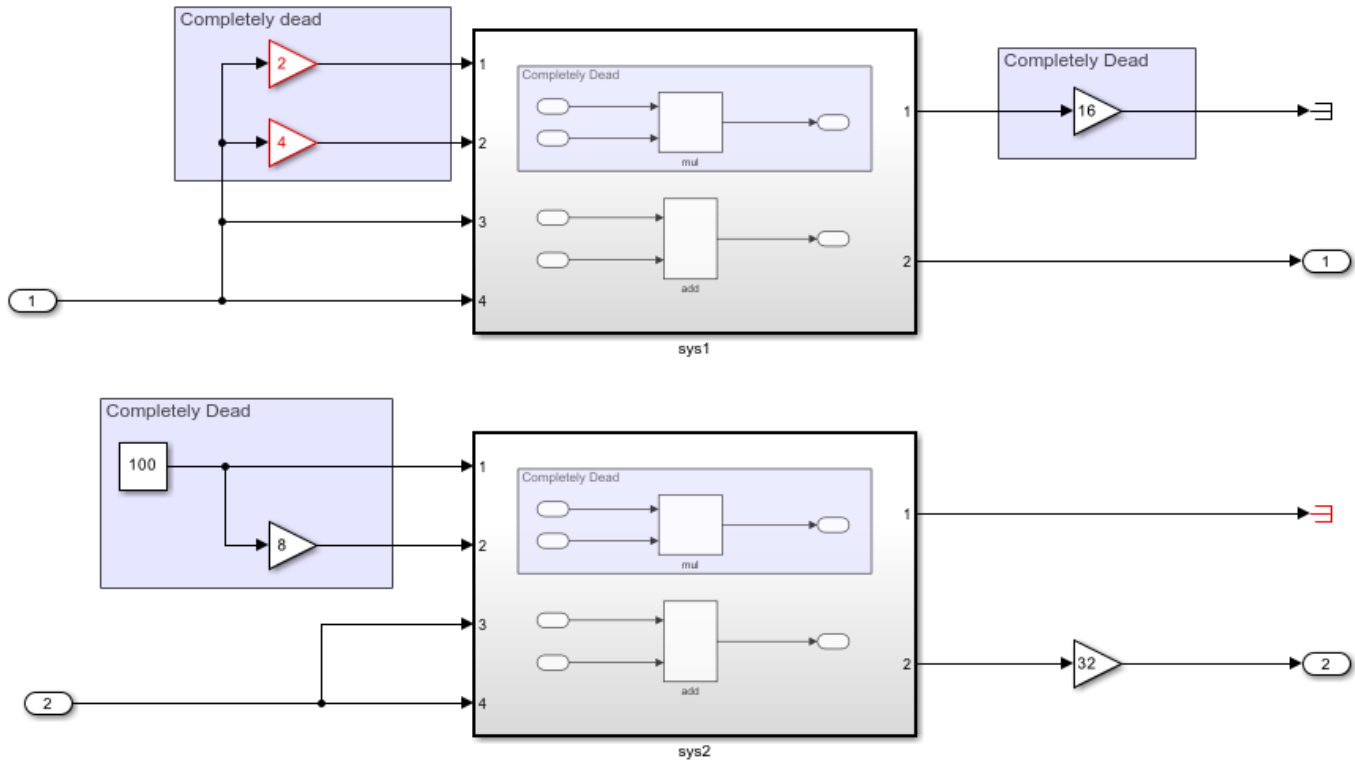

Block Connectivity Definition

HDL Coder classifies block connectivity as completely unconnected or partially connected to detect and removed unused logic. Completely unconnected: For modules generated from identical atomic subsystems, model blocks, or ForEach subsystem blocks that are reused across multiple instances, the internal module logic and logic for blocks connected to the module are classified as completely unconnected only if all instances of the module do not use the logic. For example, open the model `atomic_complete_unconnected.slx`.

```

open_system('atomic_complete_unconnected')
open_system('atomic_complete_unconnected/DUT')

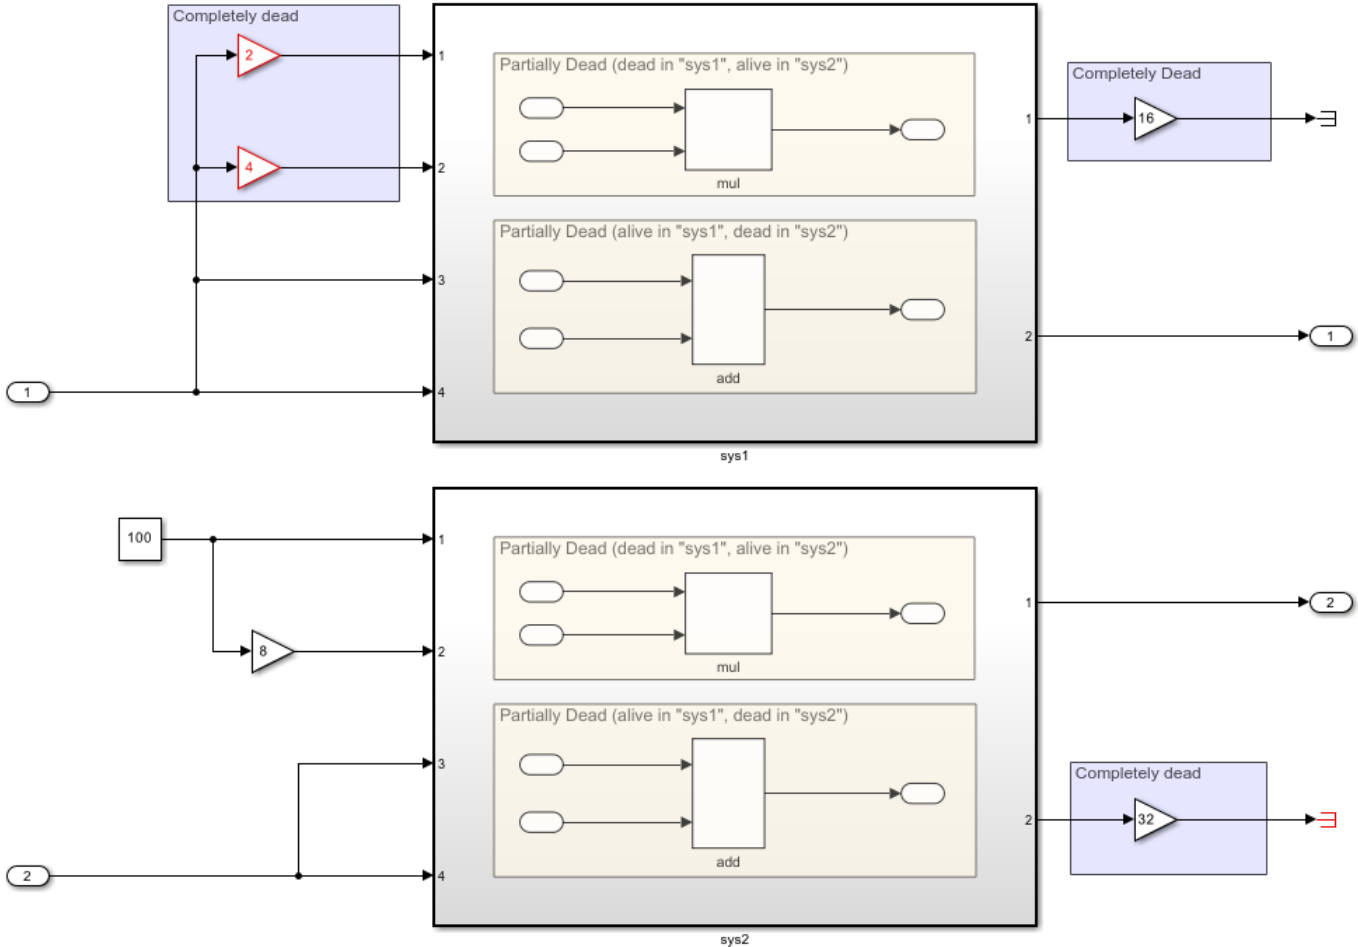

```

The `mul` block is unused in both `sys1` and `sys2` subsystems and is eliminated from the generated code. Inputs to the `mul` block are completely unconnected as well and are eliminated from the generated code.

Partially connected: For modules generated from identical atomic subsystems, model blocks, or `ForEach` subsystem blocks that are reused across multiple instances, the internal module logic and logic for blocks connected to the module are classified as partially connected even if one instance of the module uses the repeated logic. For example, open the model `atomic_partial_connected.slx`.

```
open_system('atomic_partial_connected')
```

The `mul` block is used in `sys2`, classifying the block as partially connected and the block logic is retained in the generated code. The inputs to the `mul` block are completely unused and eliminated from the generated code.

Limitations

1. When your model contains multiple instances of atomic subsystems, model references, or ForEach subsystem blocks, if these blocks are determined to be partially connected during HDL code generation, then all ports are preserved in the generated code.
2. For models that have vector signals, Demux blocks act as boundaries for the redundant logic optimization. Redundant logic and components that are downstream of the Demux block are removed during HDL code generation. The optimization does not cross the Demux block boundary and therefore preserves components that are upstream of the Demux block. This limitation when using vectors also applies when you convert buses to vectors.

Open the model `hdlcoder_vector_redundant_logic`.

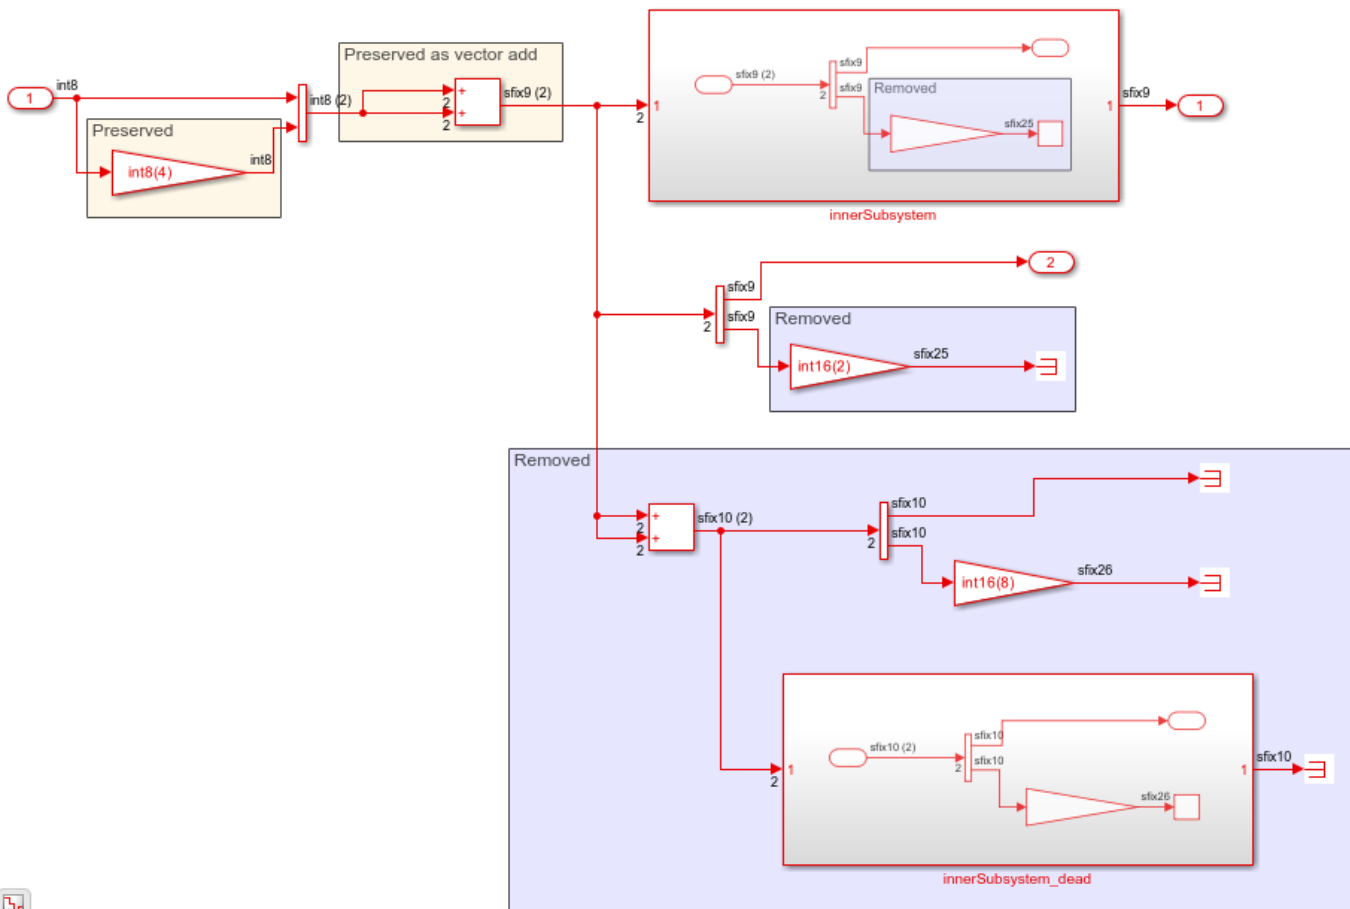

```
open_system('hdlcoder_vector_redundant_logic')
sim('hdlcoder_vector_redundant_logic');
```

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains an innerSubsystem block. This subsystem has one active output port and the other port is terminated.

```
open_system('hdlcoder_vector_redundant_logic/DUT')
```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_vector_redundant_logic/DUT')
```

The generated HDL code shows that the Add block performs a vector Add calculation. Both the Gain block and Add block are preserved in the generated HDL code as the redundant logic optimization does not cross the Demux block boundary.

```

ENTITY DUT IS
  PORT( In1      : IN    std_logic_vector(7 DOWNTO 0); -- int8
        Out1     : OUT   std_logic_vector(8 DOWNTO 0); -- sfix9
        Out2     : OUT   std_logic_vector(8 DOWNTO 0) -- sfix9
        );
END DUT;

ARCHITECTURE rtl OF DUT IS

Optimize Unconnected Ports in HDL Code for Simulink Models

HDL code generation improves code readability, reduces code size, and reduces area usage by removing unconnected ports from the generated code. This improvement includes removing unconnected vector and scalar ports, bus element ports, and bus ports. Unconnected port removal can help avoid synthesis failure caused by unused ports in the generated code.

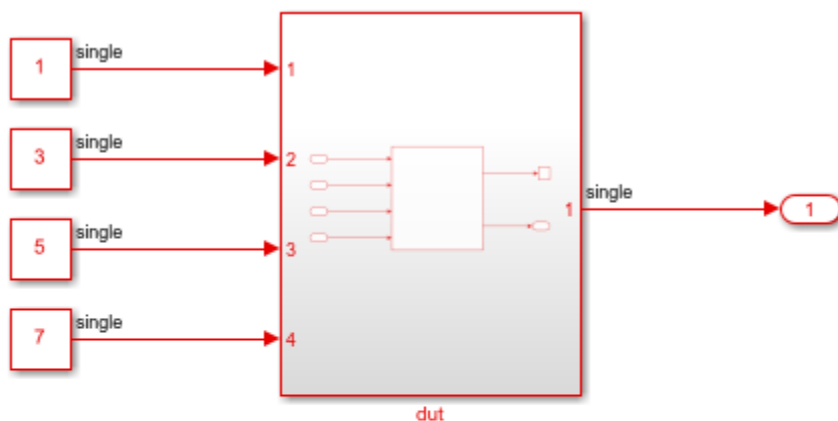

Unused Port Removal

Unused port removal works in conjunction with removal of unused blocks in your design. See “Remove Redundant Logic and Unused Blocks in Generated HDL Code” on page 28-224.

You can see the effect of unused port removal in the generated HDL code. Ports are not removed from top-level DUT models or subsystems, implementation models, or validation models.

Open the model `hdlcoder_RemoveUnconnectedPorts` containing Bus Element ports and a port connected to an inactive output.

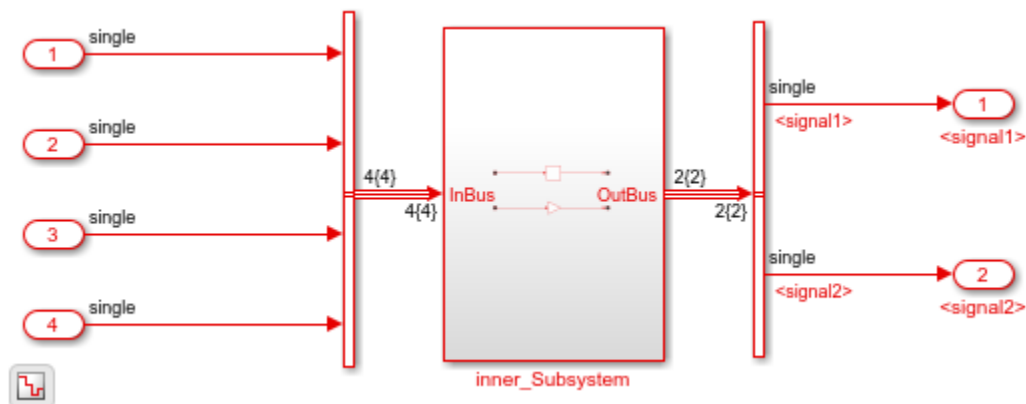

```
open_system('hdlcoder_RemoveUnconnectedPorts')
set_param('hdlcoder_RemoveUnconnectedPorts', 'SimulationCommand', 'update');
```

Copyright 2019-2021 The MathWorks, Inc.

Open the `dut` Subsystem block, and then open the `mid_Subsystem` block. The `mid_Subsystem` contains the Bus Element ports. One of the output signals is connected to a Terminator block.

```
open_system('hdlcoder_RemoveUnconnectedPorts/dut/mid_Subsystem')
```

To generate HDL code for the design, at the MATLAB® command prompt, enter:

```
makehdl('hdlcoder_RemoveUnconnectedPorts/dut')
```

The generated code `mid_Subsystem.vhd` shows that unconnected ports are removed during HDL code generation. The input `InBus_signal3` at the DUT input port is multiplied by a Gain block, and then connected to the output port `OutBus_signal2`, which is then passed to the DUT output port. Because the other input and output ports are unused at the DUT level, these ports are removed from the generated HDL code.

```
ARCHITECTURE rtl OF mid_Subsystem IS
```

```
-- Component Declarations
```

```
COMPONENT inner_Subsystem
```

```
  PORT( clk          : IN    std_logic;
        reset       : IN    std_logic;
        enb         : IN    std_logic;
        InBus_signal3 : IN    std_logic_vector(31 DOWNTO 0); -- single
        OutBus_signal2 : OUT  std_logic_vector(31 DOWNTO 0) -- single
        );
```

```
END COMPONENT;
```

```
...
```

```
END rtl;
```

Disable Unused Port Deletion Optimization

By default, the optimization is enabled and unused ports are removed in the generated HDL code.

If you do not want unconnected ports to be removed from your design:

- 1 In the Configuration Parameters dialog box, clear the “Remove Unused Ports” on page 19-4 check box.
- 2 When you run the HDL Workflow Advisor, in the **Set Code Generation Options > Set Optimization Options** task, clear the **Remove Unused Ports** check box.
- 3 At the command line, set `DeleteUnusedPorts` to off with `hdlset_param` or `makehdl`. For example, to specify that you want to preserve the unused ports in the `hdlcoder_RemoveUnconnectedPorts` model, run this command:

```
makehdl('hdlcoder_RemoveUnconnectedPorts/dut', 'DeleteUnusedPorts', 'off')
```

The generated HDL code preserves the unused Bus Elements ports.

```

ARCHITECTURE rtl OF mid_Subsystem IS
-- Component Declarations
COMPONENT inner_Subsystem
  PORT( clk          : IN    std_logic;
        reset       : IN    std_logic;
        enb         : IN    std_logic;
        InBus_signal1 : IN    std_logic_vector(31 DOWNTO 0); -- single
        InBus_signal2 : IN    std_logic_vector(31 DOWNTO 0); -- single
        InBus_signal3 : IN    std_logic_vector(31 DOWNTO 0); -- single
        InBus_signal4 : IN    std_logic_vector(31 DOWNTO 0); -- single
        OutBus_signal1 : OUT   std_logic_vector(31 DOWNTO 0); -- single
        OutBus_signal2 : OUT   std_logic_vector(31 DOWNTO 0) -- single
      );
END COMPONENT;

...

END rtl;

```

Unused Port Deletion for Subsystem Ports

This optimization can remove unused subsystem data ports. Control ports and ports of a referenced model are not removed.

A subsystem data port is considered to be active when it contributes to a DUT output port downstream or is connected to an active black box subsystem, or a component that is preserved during HDL code generation.

Open the model `hdlcoder_subsys_ports_unused`.

```

open_system('hdlcoder_subsys_ports_unused')
sim('hdlcoder_subsys_ports_unused');

```

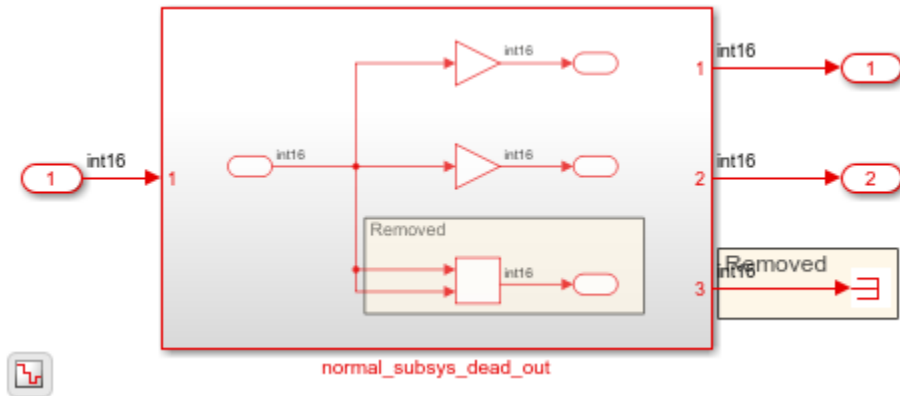

Copyright 2020 The MathWorks, Inc.

The model contains a `normal_subsys_dead_out` subsystem that contains an output port `out3` that is terminated and does not contribute to the DUT output.

```

open_system('hdlcoder_subsys_ports_unused/DUT')

```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_subsys_ports_unused/DUT')
```

By default, when DeleteUnusedPorts is on, the Add block calculation and output port Out3 are removed in the generated HDL code.

```
ENTITY normal_subsys_dead_out IS
  PORT( In1      : IN   std_logic_vector(15 DOWNT0 0); -- int16
        Out1     : OUT  std_logic_vector(15 DOWNT0 0); -- int16
        Out2     : OUT  std_logic_vector(15 DOWNT0 0) -- int16
      );
END normal_subsys_dead_out;

ARCHITECTURE rtl OF normal_subsys_dead_out IS
  ...
  Out1 <= std_logic_vector(Gain_out1);
  ...
  Out2 <= std_logic_vector(Gain1_out1);
END rtl;
```

To disable DeleteUnusedPorts optimization, run this command:

```
makehdl('hdlcoder_subsys_ports_unused/DUT', 'DeleteUnusedPorts', 'off')
```

When you set DeleteUnusedPorts to off, this port and the Add block calculation are preserved in the generated HDL code.

```
ENTITY normal_subsys_dead_out IS
  PORT( In1      : IN   std_logic_vector(15 DOWNT0 0); -- int16
        Out1     : OUT  std_logic_vector(15 DOWNT0 0); -- int16
        Out2     : OUT  std_logic_vector(15 DOWNT0 0); -- int16
        Out3     : OUT  std_logic_vector(15 DOWNT0 0) -- int16
      );
END normal_subsys_dead_out;

ARCHITECTURE rtl OF normal_subsys_dead_out IS
  ...
```

```

    Out1 <= std_logic_vector(Gain_out1);
...
    Out2 <= std_logic_vector(Gain1_out1
    Add_out1 <= to_signed(16#0000#, 16);
    Out3 <= std_logic_vector(Add_out1);
END rtl;

```

Unused Port Deletion for Atomic Subsystems

For unused ports outside atomic subsystems, atomic subsystem instances are removed from the generated HDL code.

Open the model `hdlcoder_atomic_subsys3_redundant`

```

open_system('hdlcoder_atomic_subsys3_redundant')
sim('hdlcoder_atomic_subsys3_redundant');

```

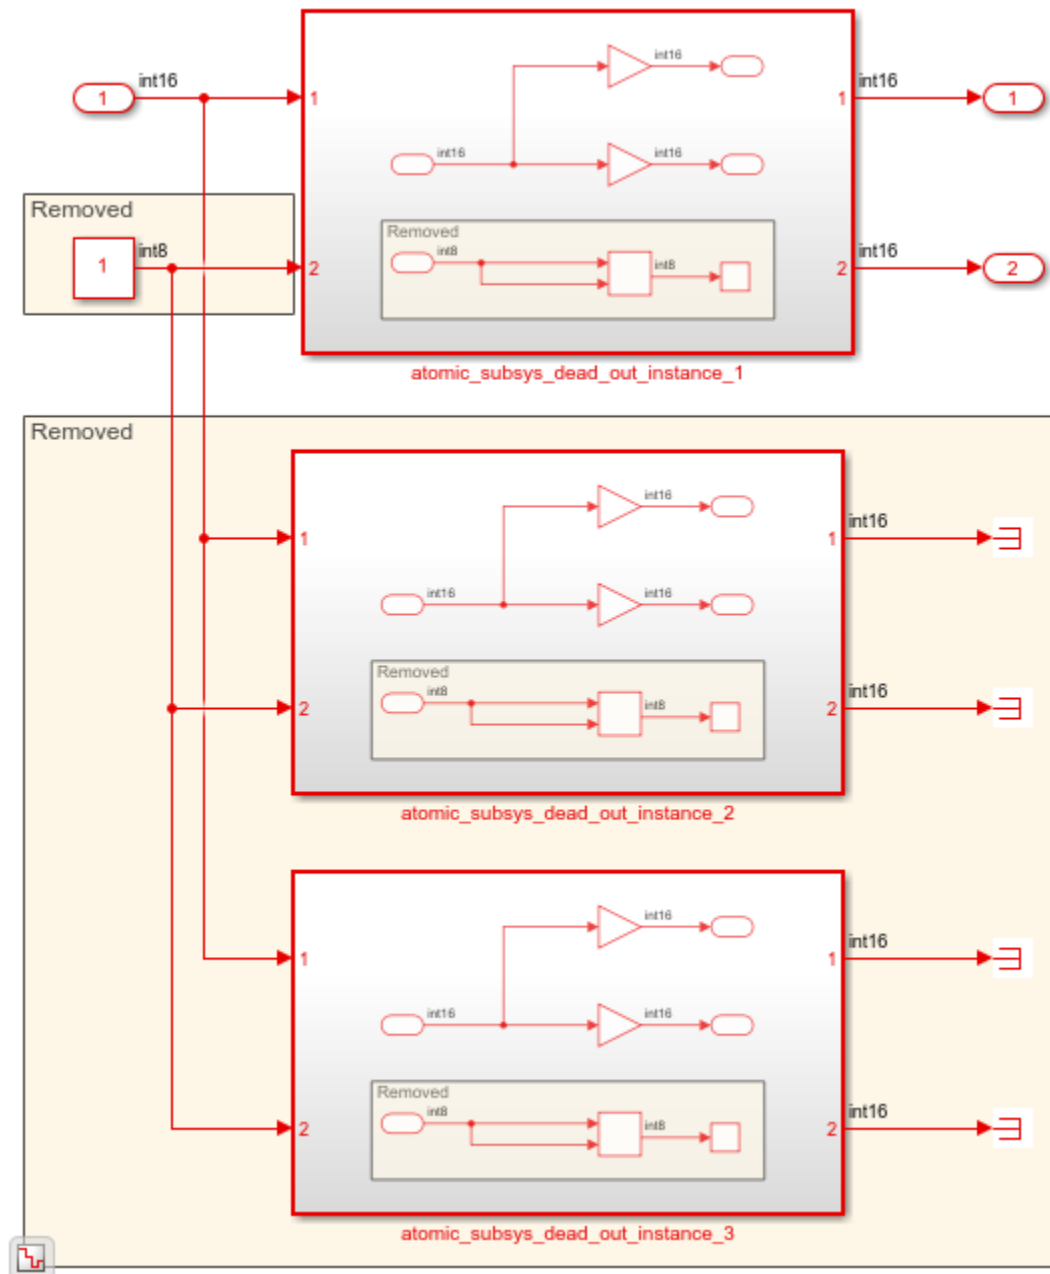

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains three atomic subsystem instances. The outputs of two of the atomic subsystem instances are connected to Terminator blocks.

```

open_system('hdlcoder_atomic_subsys3_redundant/DUT')

```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_atomic_subsys3_redundant/DUT')
```

```
ENTITY DUT IS
  PORT( In1      : IN    std_logic_vector(15 DOWNTO 0); -- int16
         Out1     : OUT   std_logic_vector(15 DOWNTO 0); -- int16
         Out2     : OUT   std_logic_vector(15 DOWNTO 0) -- int16
        );
END DUT;
```

```
ARCHITECTURE rtl OF DUT IS
```

```

-- Component Declarations
COMPONENT atomic_subsys_dead_out_instance_1
  PORT( In1      : IN    std_logic_vector(15 DOWNT0 0); -- int16
        Out1     : OUT   std_logic_vector(15 DOWNT0 0); -- int16
        Out2     : OUT   std_logic_vector(15 DOWNT0 0) -- int16
      );
END COMPONENT;

...

END rtl;

```

To set DeleteUnusedPorts to off, run this command:

```
makehdl('hdlcoder_atomic_subsys3_redundant/DUT', 'DeleteUnusedPorts', 'off')
```

If you set DeleteUnusedPorts to off, the input port In2 is preserved in the generated HDL code but it is feeding into an input port that is driving an unused component.

```

ENTITY DUT IS
  PORT( In1      : IN    std_logic_vector(15 DOWNT0 0); -- int16
        Out1     : OUT   std_logic_vector(15 DOWNT0 0); -- int16
        Out2     : OUT   std_logic_vector(15 DOWNT0 0) -- int16
      );
END DUT;

ARCHITECTURE rtl OF DUT IS

        In2      : IN    std_logic_vector(7 DOWNT0 0);  -- int8
        Out1     : OUT   std_logic_vector(15 DOWNT0 0); -- int16
        Out2     : OUT   std_logic_vector(15 DOWNT0 0) -- int16
      );
END COMPONENT;

...

END rtl;

```

Unused Port Deletion for Output Ports of Atomic Subsystems

When you have multiple active atomic subsystem instances, the redundant logic across the boundary including any ports is preserved in the HDL code independent of the DeleteUnusedPorts setting. When you have only one Atomic Subsystem instance, by default, when DeleteUnusedPorts is on, any redundant logic and ports across the subsystem boundary are removed. If you set DeleteUnusedPorts to off, any unused port is preserved though the logic is redundant.

Open the model hdlcoder_atomic_subsys2_ports_redundant.

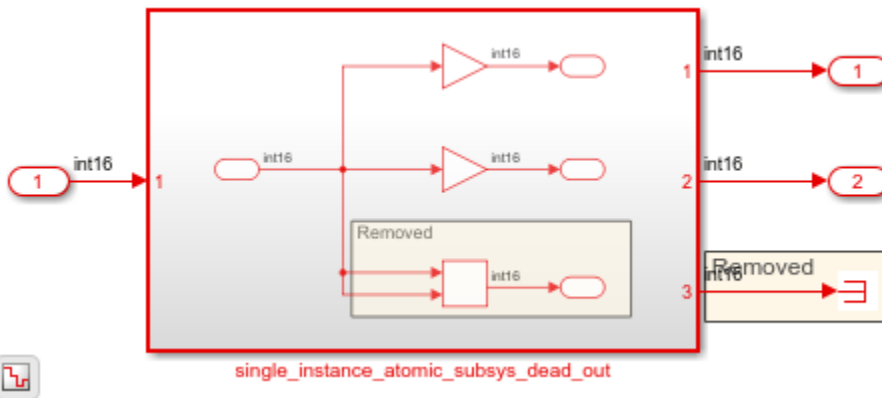

```
open_system('hdlcoder_atomic_subsys2_ports_redundant')
sim('hdlcoder_atomic_subsys2_ports_redundant');
```

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains an Atomic Subsystem block that contains an Add block connected to an output port terminated outside the subsystem.

```
open_system('hdlcoder_atomic_subsys2_ports_redundant/DUT')
```

To generate HDL code for the DUT subsystem, run this command:

```
makehdl('hdlcoder_atomic_subsys2_ports_redundant/DUT')
```

In the generated HDL code, the Add block and corresponding output port Out3 is removed because it does not contribute to an active output.

```
ENTITY DUT IS
  PORT( In1   :   IN    std_logic_vector(15 DOWNTO 0); -- int16
        Out1  :   OUT   std_logic_vector(15 DOWNTO 0); -- int16
        Out2  :   OUT   std_logic_vector(15 DOWNTO 0); -- int16
        );
END DUT;

ARCHITECTURE rtl OF DUT IS
  -- Component Declarations

Upstream Logic Preservation of Unused Port

You can preserve logic upstream from a Terminator block, its unused logic, while still removing other unconnected ports and unused logic. You can choose specific unused logic that you want to preserve for generated HDL code while still optimizing the rest of your model. Enable the HDL block property `PreserveUpstreamLogic` for the Terminator block for which you want to preserve the logic upstream. See “`PreserveUpstreamLogic`” on page 26-20.

Open the model `hdlcoder_subsys_port_preserve`.

```

open_system('hdlcoder_subsys_ports_preserved')
sim('hdlcoder_subsys_ports_preserved');

```

Copyright 2020 The MathWorks, Inc.

The model contains a DUT subsystem that has two Terminator blocks as output ports for the subsystem. The Terminator block `TermPres` has the HDL block property `PreserveUpstreamLogic` set to on. The Terminator block `TermRem` does not (the default setting). The model property `DeleteUnusedPorts` is enabled by default.

```

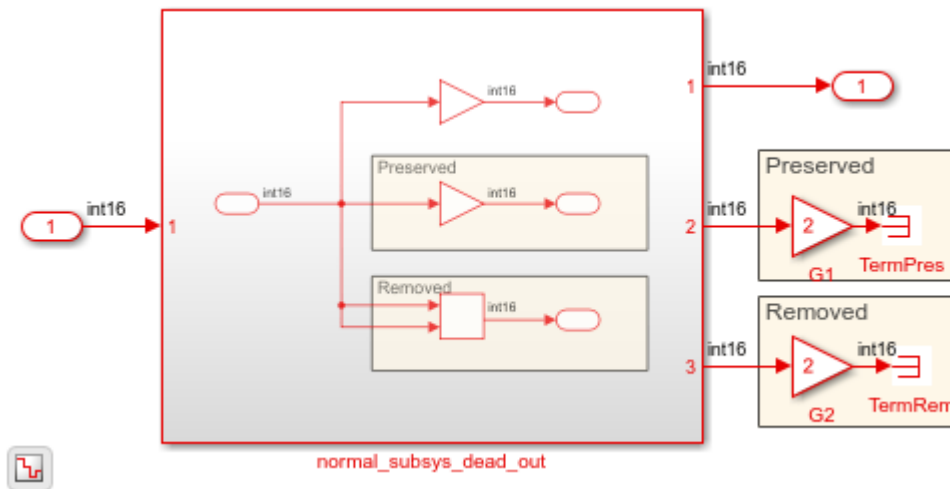

open_system('hdlcoder_subsys_ports_preserved/DUT')
hdlget_param('hdlcoder_subsys_ports_preserved/DUT/TermPres', 'PreserveUpstreamLogic')

```

```

ans =
    'on'

```

When you generate HDL code, the logic connected upstream from the TermPres block is preserved in the HDL code, including the outport Out2 from the `normal_subsys_dead_out` subsystem. Enabling `PreserveUpstreamLogic` for a Terminator block takes priority over the enabled `DeleteUnusedPorts` option. The logic connected upstream from the TermRem block is not preserved, including not preserving the outport from the `normal_subsys_dead_out` subsystem.

To generate HDL code for the DUT subsystem, run this command:

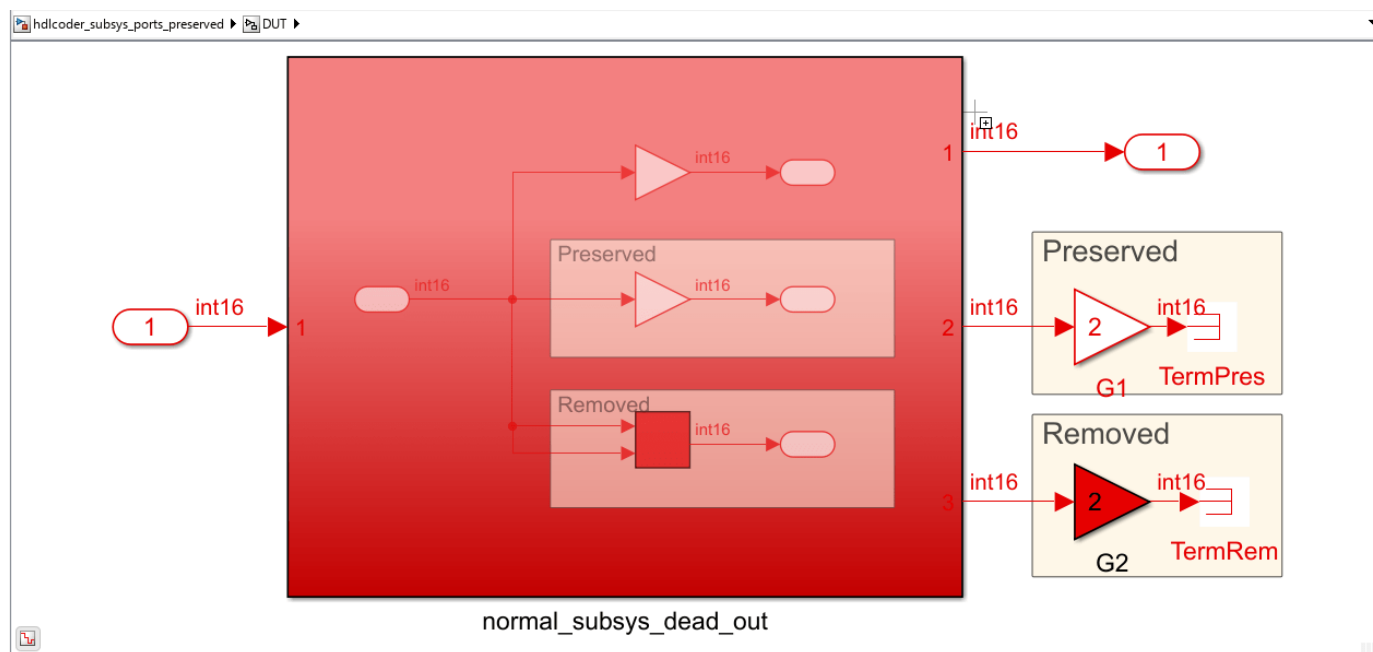

```
makehdl('hdlcoder_subsys_ports_preserved/DUT')
```

In the code traceability report, click the G1 gain connected to TermPres. The corresponding HDL code shows that the logic connected upstream from TermPres, such as G1, is preserved. No corresponding HDL code exists for the logic upstream from TermRem.

```

G1
51 SIGNAL normal_subsys_dead_out_out1 : std_logic_vector(15 DOWNTO 0); -- ufix16
52 SIGNAL normal_subsys_dead_out_out2 : std_logic_vector(15 DOWNTO 0); -- ufix16
53 SIGNAL normal_subsys_dead_out_out2_signed : signed(15 DOWNTO 0); -- int16
54 SIGNAL G1_cast : signed(31 DOWNTO 0); -- sfix32
55 SIGNAL G1_out1 : signed(15 DOWNTO 0); -- int16
56
57 BEGIN
58 -- Removed
59 --
60 -- Preserved
61
62 u_normal_subsys_dead_out : normal_subsys_dead_out
63 PORT MAP( In1 => In1, -- int16
64 out1 => normal_subsys_dead_out_out1, -- int16
65 out2 => normal_subsys_dead_out_out2 -- int16
66 );
67
68 normal_subsys_dead_out_out2_signed <= signed(normal_subsys_dead_out_out2);
69
70 G1_cast <= resize(normal_subsys_dead_out_out2_signed & '0', 32);
71 G1_out1 <= G1_cast(15 DOWNTO 0);
72
73
74 Out1 <= normal_subsys_dead_out_out1;
75
76 END rtl;
77
78
hdlsrc\hdlcoder_subsys_ports_preserved\DUT\DUT.vhd Ln 63 Col 9
  
```

You can highlight the removed logic blocks upstream from TermRem by clicking the script `highlightRemovedDeadBlocks.m` in the output of the `makehdl` command. The removed blocks appear in red in the model. To clear the highlighting, click the script `clearHighlightingRemovedDeadBlocks.m`. For more information, see “Highlight dead blocks removed in generated code” on page 21-104.

You can also view all eliminated and virtual blocks in the code generation report. Click **Traceability Report**, then view the **Eliminated / Virtual Blocks** section.

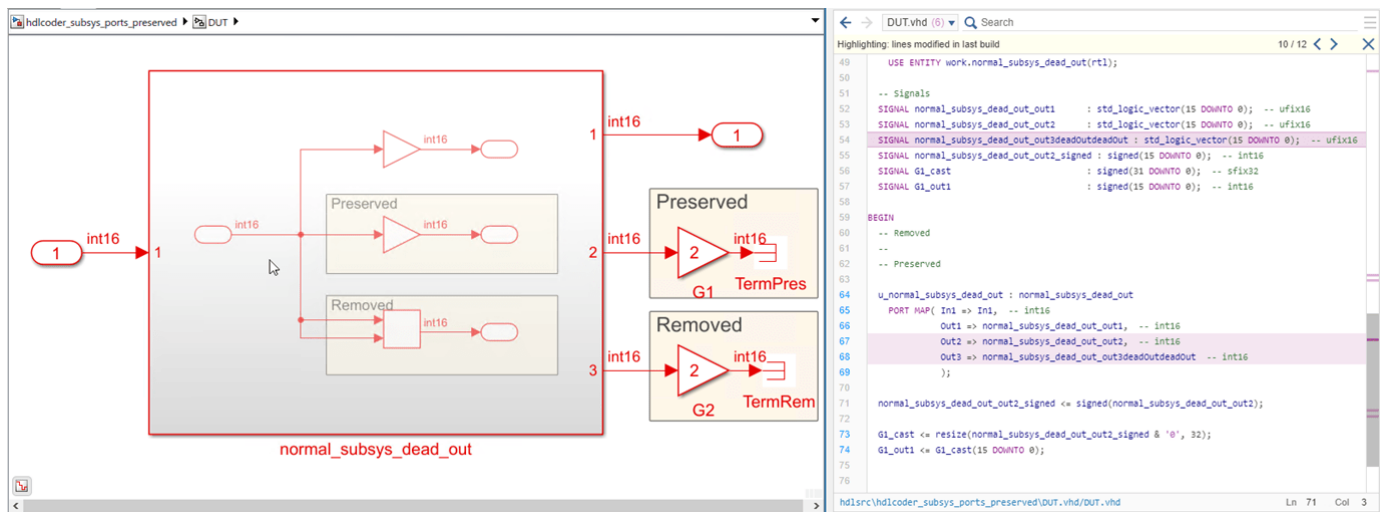

You can preserve the output port from the `normal_subsys_dead_out` subsystem connected to `TermRem` but still remove any upstream logic by disabling `DeleteUnusedPorts` for the model.

```
hdlset_param('hdlcoder_subsys_ports_preserved', 'DeleteUnusedPorts', 'off')
```

Generate HDL code for the DUT subsystem:

```
makehdl('hdlcoder_subsys_ports_preserved/DUT');
```

The traceability report now highlights the difference between the last HDL code generated and this HDL code. The logic upstream from `TermRem`, such as the gain block `G2`, is still removed because `PreserveUpstreamLogic` is off. The output `Out3` is now in the generated HDL code because `DeleteUnusedPorts` is set to off for the model.

Limitations

If your model contains multiple instances of atomic subsystems, model references, or ForEach Subsystem blocks, and these blocks are active during HDL code generation, then ports are preserved in the generated code. Components connected upstream to these ports are also considered active. The ports are preserved independently of whether you enable or disable the `DeleteUnusedPorts` setting.

This limitation also applies to bus signals. In this case, the entire bus is preserved in the generated HDL code. For an example, see “Remove Redundant Logic and Unused Blocks in Generated HDL Code” on page 28-224.

HDL Code Generation from Frame-Based Algorithms

Platforms that have limited I/O like FPGA or ASIC devices typically process large datasets as streaming pixels or samples. To deploy a frame-based model onto these devices, you must manually translate your algorithms to operate on streams of data. You can automate this process and generate HDL code from frame-based models or MATLAB functions with matrix inputs by using the frame-to-sample optimization in HDL Coder. This optimization converts frame-based vector or matrix inputs to smaller-sized samples or pixels for HDL code generation to target stream-based hardware and reduce the FPGA I/O needed to handle large input and output signals. You can optimize designs for hardware while reducing algorithm development time for various use cases in domains that have large inputs, such as image processing, digital signal processing, radar applications, and audio processing.

When you use the frame-to-sample optimization, HDL Coder generates hardware-ready HDL code from frame-based algorithms that has the necessary logic to store samples inside the DUT in line buffers, align streams, and balance data paths. You can use multiple modeling patterns, such as element-wise operations, neighborhood operations, and iterative and reduction operations, to author frame-based algorithms supported by the frame-to-sample optimization.

Generating HDL Code from a Frame-based Algorithm

When you use the frame-to-sample conversion to generate HDL code from a frame-based algorithm, HDL Coder transforms your frame-based algorithm into synthesizable HDL code with sample-based logic that has valid and ready control signals and the logic to handle and align the data streams directly from the frame-based algorithm. You can use the frame-to-sample conversion with a Simulink model or a MATLAB function.

When you generate HDL code from a frame-based algorithm, the stream-based HDL code and generated model contain sample-based logic, which includes data signals, valid and ready control signals. This timing diagram maps the relationship between the Valid, Data, and Ready signals.

A Valid signal indicates when data is available. The Ready signal indicates that the DUT can accept and process data. Transfer of data occurs only when both the Valid and Ready signals are high. This is represented by data packets A, B, and C in the image. When the Ready signal is low, the DUT cannot process more data. If you send a Valid and Data signal before the Ready signal assertion, the Data signal is dropped. You can de-assert the Valid signal and not send data while the Ready signal is high. If the Ready signal de-asserts and the Valid signal is high, the Data signal is dropped. This is represented by data packet D in the image.

You can create matrix or frame-based algorithms by using element-wise operations, neighborhood operations, and iterative and reduction operations supported for HDL code generation. You can create:

- Neighborhood operations by using the `hdl.npufun` function in a MATLAB function or the Neighborhood Processing Subsystem block in a Simulink model. You can use `hdl.npufun` in a MATLAB Function block in your DUT to apply neighborhood processing and element-wise operations to an incoming image or matrix, such as filtering with a kernel.
- Iterative operations using the `hdl.iteratorfun` function. For example, you can use `hdl.iteratorfun` in a MATLAB Function block in your DUT to loop over arrays to produce a single output to an incoming image or matrix for histogram equalization and to compute statistics such as `min` and `max`.
- Element-wise operations by using element-wise functions or blocks such as the Gain, Product, Sum, Subtract, and Divide blocks.

In vision or image processing, you can use these frame operations to model 2-D based algorithms, such as filtering, histogram creation, histogram equalization, and edge detection. In signal processing, you can calculate a moving average computation on a large input signal.

Specify the Frame-to-Sample Conversion Optimization

You can generate HDL code with the frame-to-sample conversion optimization from a Simulink model or MATLAB function.

Specify the Frame-to-Sample Conversion Optimization from Simulink

To enable the frame-to-sample conversion optimization for a Simulink model:

- 1 Individually enable the HDL block property **ConvertToSamples** for Inport blocks on the DUT to convert the incoming vector or matrix input signal to samples by using the frame to sample conversion optimization. To specify an Inport block as an input signal for the frame-to-sample conversion, enter:

```
hdlset_param("<path/to/Inport>", ConvertToSamples = "on")
```

- 2 Select the **Enable frame to sample conversion** parameter in the Configuration Parameters window. Use the frame-to-sample conversion parameters to apply frame-to-sample optimization options to your design. To enable frame-to-sample conversion on a Simulink model, on the command line, enter:

```
hdlset_param("<model_name>", FrameToSampleConversion = "on")
```

For more information, see “Frame to Sample Conversion Parameters” on page 19-34.

- 3 If you design your frame-based algorithm using a MATLAB Function block, set the HDL block property **Architecture** of the MATLAB Function block to **MATLAB Datapath**.

After generating HDL code, you can check the generated model and HDL code to see that each of the matrix inputs streamed contain a sample, valid, and ready bundle. You can use the validation model to compare the original frame-based model and the generated sample-based model. You can also deploy the generated HDL code to an FPGA using the IP core generation workflow. For an example, see “Deploy a Frame-Based Model with AXI4-Stream Interfaces” on page 47-356.

Specify Frame-to-Sample Conversion from MATLAB

To enable the frame-to-sample conversion optimization for a MATLAB function:

- 1 Open the MATLAB HDL Workflow Advisor. To get started with the MATLAB HDL Workflow Advisor, see “Basic HDL Code Generation and FPGA Synthesis from MATLAB”.
- 2 In the left pane, click the **HDL Code Generation** task. In the right pane, navigate to the **Optimization** tab and select **Aggressive Dataflow Conversion**.
- 3 Click the **Frame to Sample Conversion** tab and select **Enable Frame to Sample Conversion**. Use the frame-to-sample conversion parameters in this tab to apply optimization options to your design.

Generate HDL Code from a Frame-Based Model Example

The Simulink model `hdlFrame_Blur_2D_MLFB` models a common image-processing frame-based blurring algorithm which uses a neighborhood processing pattern.

Open the model to view the frame-based blurring algorithm. The model applies an image-blurring kernel to the image `cameraman.tif`.

```
open_system("hdlFrame_Blur_2D_MLFB");
set_param(gcs, 'SimulationCommand', 'Update');
```

The DUT contains a MATLAB function called `image_blur` in the MATLAB Function block. The `image_blur` function calls the frame-to-sample supported function `hdl.npufun` that applies the blurring kernel in the `blur` function to the input image. For more information, see `hdl.npufun`.

```
open_system("hdlFrame_Blur_2D_MLFB/DUT/MATLAB Function")
```

```
function I_out = image_blur(I)
% Blur input image

I_out = hdl.npufun(@blur, [3 3], I);

end

function y = blur(N)

y = sum(N(:), 'native')/9;

end
```

Apply the frame-to-sample conversion optimization by setting the model configuration parameter `FrameToSampleConversion` to `on` from the command line.

```
hdlset_param("hdlFrame_Blur_2D_MLFB", FrameToSampleConversion = "on");
```

Specify which incoming frame-based signal to be convert to a sample-based signal by setting the HDL Inport block property `ConvertToSamples` of the input to `on`. In this example, set the `ConvertToSamples` property to `on` for the only Inport block to the DUT subsystem, `I`.

```
hdlset_param("hdlFrame_Blur_2D_MLFB/DUT/I", ConvertToSamples = "on");
```

To see the conversion from the frame-based model to the sample-based version, enable model generation. Generate HDL code and the generated model from the DUT subsystem.

```
hdlset_param("hdlFrame_Blur_2D_MLFB", GenerateModel = "on");
makehdl('hdlFrame_Blur_2D_MLFB/DUT');
```

```
bdclose('hdlFrame_Blur_2D_MLFB/Original');
bdclose('hdlFrame_Blur_2D_MLFB/Equalized1');
```

```

### HDL code generation complete.

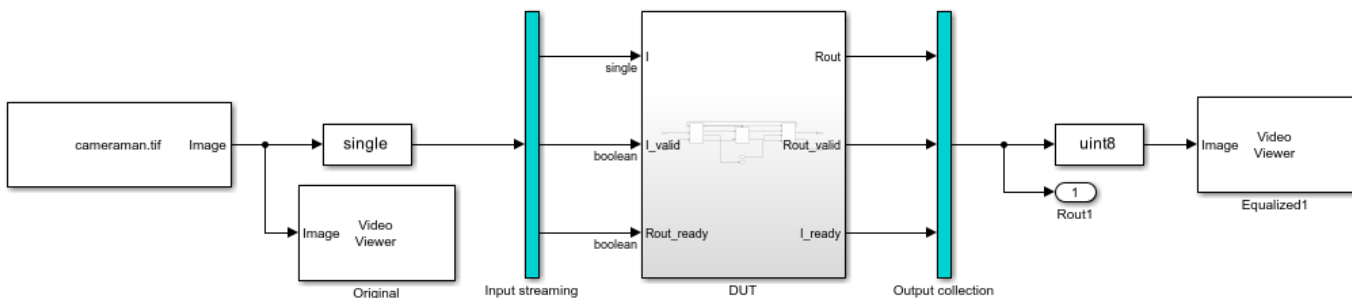

```

Open the generated model, `gm_hdlFrame_Blur_2D_MLFB`. This model contains the sample-based version of the DUT and contains Valid, Ready, and Data signals.

```

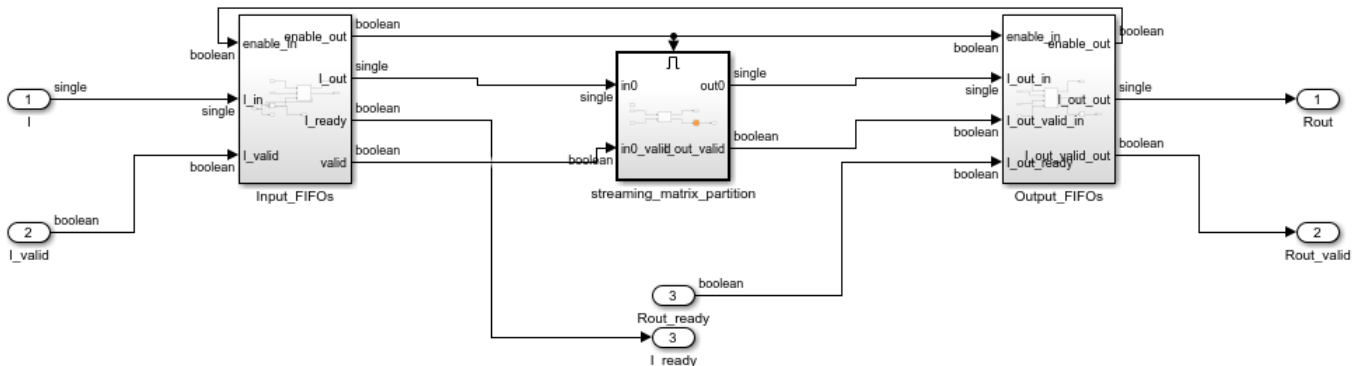

open_system('gm_hdlFrame_Blur_2D_MLFB');
Simulink.BlockDiagram.arrangeSystem('gm_hdlFrame_Blur_2D_MLFB');

```

Open the generated model DUT. There is significantly more hardware detail in the sampled-based generated model than in the original frame-based model. In the DUT subsystem, there is an input and output FIFO that handles and stores the data from the generated streaming matrix partition. The streaming matrix partition contains the blurring algorithm and other sample-based logic needed to deploy the algorithm to stream-based hardware.

```
open_system('gm_hdlFrame_Blur_2D_MLFB/DUT');
```

If you run the generated model, notice that the time it takes to get the output image is longer than the original model. Converting a frame-based algorithm to a sample-based algorithm that streams pixels of the image one at a time requires more time to process each pixel than the frame-based version. The latency to process a valid output pixel for a valid input pixel from the original input frame depends on a few factors, such as size of the input image, the samples per cycle, and the algorithm. The output of the `makehdl` command displays the added latency in the MATLAB command window. In this example, the first valid output is accessible after an initial latency of 257 valid inputs.

The sampling rate, latency, and image size determine the simulation stop time needed for the generated model. To generate the blurred output image from the sample-based algorithm in the generated model, the original and subsequent generated model have stop times of 2 seconds, which is the time needed to display the entire output image after latency is introduced.

Hardware Considerations

Prior to generating HDL code from frame-based algorithms for hardware deployment:

- Check that the target hardware should have enough memory to store frames in memory before and after the stream-based algorithm is applied. Sample-based algorithms require more memory, but use significantly less I/O.
- Ensure your design can handle some latency. Sample-based algorithms add latency and delay depending on your algorithm, design, and input data size.

Supported Blocks and Operations

Frame-to-sample conversion supports these blocks and operations:

- MATLAB Function block with the HDL block property **Architecture** set to **MATLAB Datapath**. In the MATLAB function, you can use:
 - Frame-to-sample-focused functions, such as `hdl.npufun` and `hdl.iteratorfun`.

- Element-wise operations between streamed data.
- Operations between a scalar and streamed data.
- Neighborhood Processing Subsystem block.
- Element-wise operations. For example, you can use blocks that support element-wise operations such as the Gain, Product, Sum, Subtract, and Divide blocks.
- Square matrix product operations. For example, you can use the Matrix Multiply block with square input matrices.
- Constant inputs or sources.
- Saturation.
- Trigonometric operations.
- Bit-wise operations, such as bit-slice, bit-and, and bit-or.
- Comparison operations.
- Bias block.
- Abs block.
- Complex to Real-Imag block and Real-Imag to Complex block.
- Sqrt block.
- Data type conversion block.
- Switch block.

Limitations

Frame-to-sample conversion does not support:

- 3-D matrices.
- Column vectors.
- Persistent variables.
- Non-square matrix product operations.
- Matrix operations on streamed data. For example, frame-to-sample conversion in Simulink does not support using the Selector, Assignment, or Reshape block on streamed data.
- Sum of elements operations.
- Product of elements operations.
- MATLAB System Objects such as `hdl.RAM`.
- For Each Subsystems.
- Delay blocks.
- Blocks that contain design delays.
- Bus objects as a datatype.
- IP core generation from a MATLAB function.

Use Neighborhood, Reduction, and Iterator Patterns with a Frame-Based Model or Function for HDL Code Generation

In this example, you use frame-based modeling to model an image processing algorithm that rectifies fog in an image. You then generate synthesizable HDL code by using the HDL Coder™ frame-to-sample conversion optimization to generate pixel-based code from the frame-based model.

The fog rectification model uses neighborhood, reduction, and iterator patterns. You can model neighborhood patterns by using the `hdl.npufun` function in a MATLAB® Function block or the Neighborhood Processing Subsystem block. You can implement reduction and iterator patterns by using `hdl.iteratorfun` in a MATLAB Function block.

Additionally, as an alternative from generating HDL code from a Simulink® model, you can use a MATLAB function to generate HDL code that contains the frame-based fog rectification algorithm.

Model Algorithm by Using a MATLAB Function Block

In the `hdlFrame_FogRectification_2D_MLFB` model, the device under test (DUT) contains a MATLAB Function block that includes the neighborhood processing, reduction, and iterator operations needed for fog rectification. To generate synthesizable HDL code from the frame-based model, the neighborhood processing algorithm uses the frame-to-sample conversion supported function `hdl.npufun`. The iterator and reduction algorithms use the frame-to-sample conversion supported function `hdl.iteratorfun`. For more information, see `hdl.npufun` and `hdl.iteratorfun`. Using these two functions in a frame-based model enables you to contain an entire fog rectification algorithm in a single MATLAB Function block.

Open the `hdlFrame_FogRectification_2D_MLFB/DUT/MATLAB Function` subsystem to see the fog rectification algorithm.

```
load_system("hdlFrame_FogRectification_2D_MLFB");
open_system("hdlFrame_FogRectification_2D_MLFB/DUT/MATLAB Function");

function [r_out,g_out,b_out] = fog_rectification(Ru, Gu, Bu)

[im_gray, restoreR, restoreG, restoreB] = fog_stage1(Ru, Gu, Bu);

[r_out,g_out,b_out] = fog_rectification_m(im_gray, restoreR, restoreG, restoreB);

end

function [im_gray, restoreR, restoreG, restoreB] = fog_stage1(Ru, Gu, Bu)
coder.inline('never')

%% Dark channel Estimation from input
darkChannel = hdl.npufun(@min_kernel, [1 1], Ru, Gu, Bu);

count(pix+1) = count(pix+1) +1;
end

function cdf = cdf_compute(hist, cdf, idx)
if idx > 1
    cdf(idx) = cdf(idx-cast(1,'like',idx)) + hist;
else
    cdf(1) = hist;
end
end

function ili2 = find_break_points(cdf, ili2, idx, p1, p2)
    if (cdf <= p1)
        ili2(1) = ili2(1) + 1;
    end

    if (cdf >= p2)
        ili2(2) = ili2(2) + 1;
    end
end

function T = createTable(UNUSED, T, idx, i1, i2, t1f, t2f, t3f, o1, o2)

    is = uint16(idx);
    if is <= i1+1
        T(idx) = uint8(t1f*(is-1));
    elseif is >= i1+2 && is <= i2+1
        T(idx) = uint8(((t2f)*(is-1))-((t2f)*i1)+o1);
    else
        T(idx) = uint8(((t3f)*(is-1))-((t3f)*i2)+o2);
    end
end

function [r_out, g_out, b_out] = table_lookup(r, g, b, T)
    out1=T(r);
    out2=T(g);
    out3=T(b);

    r_out = uint8(out1);
    g_out = uint8(out2);
    b_out = uint8(out3);
end

```

Run the Model

The model uses 2-D matrices as inputs to the DUT. These inputs signals are the separated R, G, and B components of the input image. Each input signal is a frame input matrix composed of 240x320 pixels. Simulate the model to see the frame size and simulation results.

```
sim("hdlFrame_FogRectification_2D_MLFB");
```

Generate HDL Code

Generate synthesizable HDL code by using the frame-to-sample conversion. Set the HDL block property `ConvertToSamples` on the Inport blocks of the DUT that connect to the R, G, B input signals to convert the input signals from frame-based to sample-based inputs.

```
hdlset_param('hdlFrame_FogRectification_2D_MLFB/DUT/r_in', 'ConvertToSamples', 'on');
hdlset_param('hdlFrame_FogRectification_2D_MLFB/DUT/g_in', 'ConvertToSamples', 'on');
hdlset_param('hdlFrame_FogRectification_2D_MLFB/DUT/b_in', 'ConvertToSamples', 'on');
```

For the MATLAB Function block that contains the fog rectification algorithm, set the HDL block property `Architecture` to `MATLAB Datapath`. Enable the frame-to-sample conversion optimization and generate HDL code using the `makehdl` command. For more information on the frame-to-sample conversion optimization, see “HDL Code Generation from Frame-Based Algorithms” on page 29-2.

```
hdlset_param('hdlFrame_FogRectification_2D_MLFB/DUT/MATLAB Function', 'Architecture', 'MATLAB Datapath');
hdlset_param('hdlFrame_FogRectification_2D_MLFB', 'FrameToSampleConversion', 'on');
```

```
makehdl('hdlFrame_FogRectification_2D_MLFB/DUT')
```

The frame-to-sample conversion separates the frame-based inputs into sample, valid, and ready signals for a sample-based hardware-targeted interface.

Model Algorithm by Using Neighborhood Processing Subsystem and MATLAB Function Blocks

In the `hdlFrame_FogRectification_2D_SLBlock` model, the DUT models the fog rectification algorithm using multiple Neighborhood Processing Subsystem and MATLAB Function blocks that use the `hdl.npufun` function. The MATLAB Function block `fogStage2` and the `hdl.iteratorfun` function model the reduction and iterator functions. Separating the fog rectification algorithm into various Simulink blocks enables you to visualize and model the different aspects of the fog rectification in a more modular way than with a single MATLAB Function block.

Open the `hdlFrame_FogRectification_2D_SLBlock/DUT` subsystem to see the fog rectification algorithm.

```
load_system("hdlFrame_FogRectification_2D_SLBlock");
open_system("hdlFrame_FogRectification_2D_SLBlock/DUT");
```

Run the Model

The model uses 2-D matrices as inputs to the DUT. These inputs signals are the separated R, G, and B components of the input image. Each input signal is a frame input matrix composed of 240x320 pixels. Simulate the model to see the frame size and simulation results.

```
sim("hdlFrame_FogRectification_2D_SLBlock");
```

Although the `hdlFrame_FogRectification_2D_SLBlock` and `hdlFrame_FogRectification_2D_MLFB` models differ in design, the output is the same. Both models can also generate synthesizable HDL code for sample-based hardware.

Generate HDL Code

Generate synthesizable HDL code by using the frame-to-sample conversion. Set the HDL block property `ConvertToSamples` on the Inport blocks of the DUT that connect to the R, G, B input signals to convert the input signals from frame-based to sample-based inputs.

```
hdlset_param('hdlFrame_FogRectification_2D_SLBlock/DUT/R_in', 'ConvertToSamples', 'on');
hdlset_param('hdlFrame_FogRectification_2D_SLBlock/DUT/G_in', 'ConvertToSamples', 'on');
hdlset_param('hdlFrame_FogRectification_2D_SLBlock/DUT/B_in', 'ConvertToSamples', 'on');
```

Enable the frame-to-sample conversion optimization and generate HDL code using the `makehdl` command.

```
hdlset_param('hdlFrame_FogRectification_2D_SLBlock', 'FrameToSampleConversion', 'on')
makehdl('hdlFrame_FogRectification_2D_SLBlock/DUT')
```

The frame-to-sample conversion separates the frame-based inputs into sample, valid, and ready signals for a sample-based hardware-targeted interface.

Model Algorithm and Generate HDL Code by Using a MATLAB Function

You can also generate HDL code directly from MATLAB functions by using the MATLAB-to-HDL workflow. For more information on the MATLAB-to-HDL workflow, see “Generate HDL Code from MATLAB Code Using the Command Line Interface”. In this example, the MATLAB function `fog_rectification` contains the MATLAB code from the MATLAB Function block in the `hdlFrame_FogRectification_2D_MLFB/DUT` subsystem.

```
open("fog_rectification");
```

Open the test bench function, `fog_rectification_tb`, to see the input fog rectification image separated into the R,G, and B components.

```
open("fog_rectification_tb");
```

The `fog_rectification_tb` script tests the function by inputting the original fog rectification image and splitting the input signal into the R, G, and B frame-based components of the image.

The test bench uses code generation to run the algorithm faster. To specify the input types and generate HDL code quickly without running the test bench, use the `-args` option.

To generate HDL code from a MATLAB function, create a `coder.HdlConfig` object, `hdlcfg`. Set the `DesignFunctionName` property to the `fog_rectification` function.

```
hdlcfg = coder.config('hdl');
hdlcfg.DesignFunctionName = 'fog_rectification';
```

To enable frame-to-sample conversion, first enable `AggressiveDataflowConversion`. This property transforms the control flow algorithm of the MATLAB code in the MATLAB function to a dataflow representation that is used for the frame-to-sample conversion optimization.

```
hdlcfg.AggressiveDataflowConversion = true;
```

Enable frame-to-sample conversion for the `coder.HdlConfig` object.

```
hdlcfg.FrameToSampleConversion = true;
```

Specify the input image and separate the image into its R, G, and B frame-based input components.

```
I = imread('inputFogRectification.png');  
R = I(:,:,1);  
G = I(:,:,2);  
B = I(:,:,3);
```

Generate HDL code by using the `codegen` function. Specify the input arguments in the `codegen` command by using the `-args` option.

```
codegen -config hdlcfg -args { R,G,B }
```

Generate HDL Code from Frame-Based Models by Using Neighborhood Modeling Methods

If you have a frame-based model, you can model an optical flow algorithm by using multiple neighborhood processing methods. In this example, you use the HDL Coder™ frame-to-sample conversion optimization to generate synthesizable pixel-based HDL code from two frame-based models that demonstrate different modeling patterns.

This example shows two different modeling patterns for a neighborhood processing algorithm for optical flow. One of the patterns uses a MATLAB Function block with the neighborhood processing function `hdl.npufun`. The other pattern uses the Neighborhood Processing Subsystem block.

Model Algorithm with MATLAB Function Block

In the `hdlFrame_OpticalFlow_LK_MLFB` model, there is a single MATLAB Function block inside the device under test (DUT) that contains neighborhood processing operations needed for the Lucas Kanade method for optical flow. To generate synthesizable HDL code from the frame-based model, HDL Coder uses the frame-to-sample conversion supported function, `hdl.npufun` to create a streaming sample-based neighborhood processing algorithm. Using this function in a frame-based model enables you to contain the entire image processing algorithm in a single MATLAB Function block.

Open the `hdlFrame_OpticalFlow_LK_MLFB/DUT_LK/MATLAB Function LK` subsystem to see the optical flow algorithm.

```
load_system("hdlFrame_OpticalFlow_LK_MLFB");
open_system("hdlFrame_OpticalFlow_LK_MLFB/DUT_LK/MATLAB Function LK");

function flowVector = opticalFlowForHDL_lk(I, Idelay)
% Lucas Kanade

% Copyright 2021 The MathWorks, Inc.

Ix = hdl.npufun(@imfilter_ComputIx, [1 5], I);
Iy = hdl.npufun(@imfilter_ComputIy, [5 1], I);
It = I - Idelay;

Wlxx = hdl.npufun(@imfilter_kernel, [5 5], Ix.*Ix);
Wlxy = hdl.npufun(@imfilter_kernel, [5 5], Ix.*Iy);
Wlyy = hdl.npufun(@imfilter_kernel, [5 5], Iy.*Iy);
Wlxt = hdl.npufun(@imfilter_kernel, [5 5], Ix.*It);
Wlyt = hdl.npufun(@imfilter_kernel, [5 5], Iy.*It);

[Vx, Vy] = hdl.npufun(@calc_roots_pixel, [1 1], Wlxx, Wlxy, Wlyy, Wlxt, Wlyt);
flowVector = complex(Vx,Vy);

end

function WI_1x1 = imfilter_ComputIx(I_1x5)

coder.inline('always');

d5 = [-1 8 0 -8 1]/12;
```

```
d5 = fliplr(d5(:)');
[WI_1x1] = sum(d5 .* I_1x5);

end

function WI_1x1 = imfilter_ComputIy(I_5x1)

coder.inline('always');

d5 = [-1 8 0 -8 1]/12;
d5 = flipud(d5(:));
[WI_1x1] = sum(d5(:) .* I_5x1);

end

function WI_1x1 = imfilter_kernel(I_5x5)

coder.inline('always');

p5 = [1 4 6 4 1]/16;
W = p5(:)*p5(:)';
[WI_1x1] = sum(W(:) .* I_5x5(:));

end

function [VxPix, VyPix] = calc_roots_pixel(aPix, bPix, cPix, ...
    txPix, tyPix)

coder.inline('always');

r = aPix + cPix;
s = sqrt(single(4 * bPix * bPix + (aPix - cPix) * (aPix - cPix)));
eig1 = (single(r) + s);
eig2 = (single(r) - s);

vx = single(0);
vy = single(0);
% thresh = single(196.6); %98.3040*2
thresh = 0.0039;
% thresh2 = single(98.304);
thresh2 = 0;

if (eig1 > thresh && eig2 > thresh)
    d = bPix * bPix - aPix * cPix;
    iDelta = 1/d;
    vx = single( -(tyPix * bPix - txPix * cPix)*iDelta);
    vy = single( -(txPix * bPix - aPix * tyPix)*iDelta);
elseif (eig1 > thresh && eig2 < thresh)
    rr = bPix+aPix;
    cc = cPix+bPix;
    norm = cc*cc + rr*rr;

    if (norm > thresh2)
        invnorm = 1/norm;
        tmp = -(txPix + tyPix) * invnorm;
        vx = single(rr * tmp);
        vy = single(cc * tmp);
    end
end
```

```

end

VxPix = vx;
VyPix = vy;

end

```

Run the Model

The input video is split into a previous frame and current frame. The input ports of the DUT, CurrFrame and PrevFrame, connect to the 2-D matrices that contain the data for the current frame and previous frame. Each input signal is a frame composed of 360x640 pixels. Simulate the model to see the frame size and simulation results of the optical flow output.

```
sim("hdlFrame_OpticalFlow_LK_MLFB");
```

Generate HDL Code

Generate synthesizable HDL code by using the frame-to-sample conversion. Set the HDL block property ConvertToSamples on the Inport blocks of the DUT that connect to the frame-input signals to convert the input signals from frame-based to sample-based inputs.

```
hdlset_param('hdlFrame_OpticalFlow_LK_MLFB/DUT_LK/PrevFrame','ConvertToSamples','on');
hdlset_param('hdlFrame_OpticalFlow_LK_MLFB/DUT_LK/CurrFrame','ConvertToSamples','on');
```

For the MATLAB Function block that contains the optical flow algorithm, set the HDL block property Architecture to MATLAB Datapath. Enable the frame-to-sample conversion optimization and generate HDL code using the makehdl command. For more information on the frame-to-sample conversion optimization, see “HDL Code Generation from Frame-Based Algorithms” on page 29-2.

```
hdlset_param('hdlFrame_OpticalFlow_LK_MLFB/DUT_LK/MATLAB Function LK','Architecture','MATLAB Datapath');
hdlset_param('hdlFrame_OpticalFlow_LK_MLFB','FrameToSampleConversion','on');

makehdl('hdlFrame_OpticalFlow_LK_MLFB/DUT_LK');
```

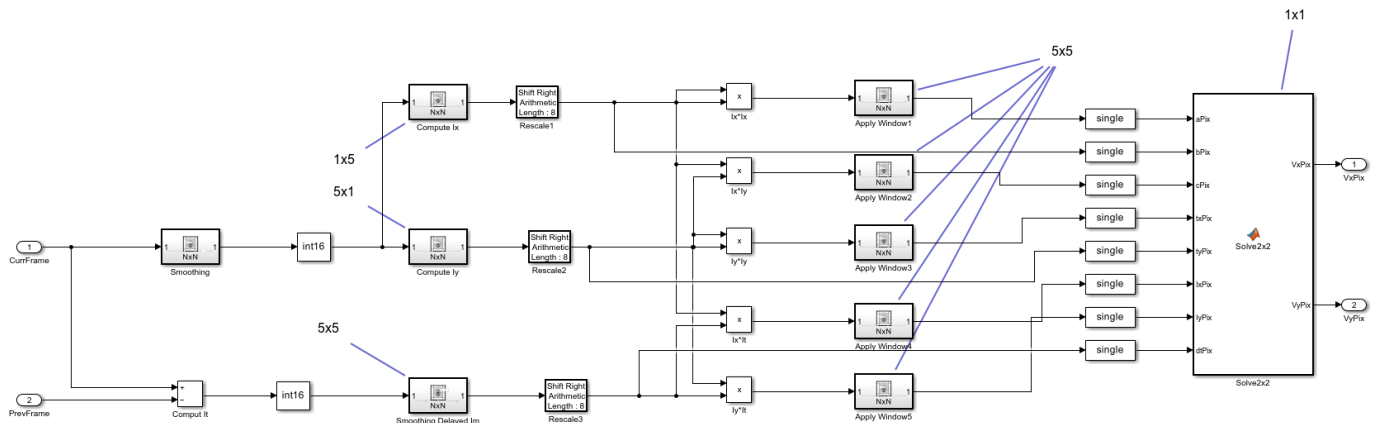

The frame-to-sample conversion separates the frame-based inputs into sample, valid, and ready signals for a sample-based hardware-targeted interface.

Model Algorithm with the Neighborhood Processing Subsystem Block

In the hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem model, the DUT contains multiple Neighborhood Processing Subsystem blocks that contain the neighborhood processing operations needed for the Lucas Kanade optical flow algorithm. Separating the optical flow algorithm into various Simulink blocks enables you to visualize and model the different aspects of the algorithm in a more modular way than with a single MATLAB Function block.

Open the hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem/DUT subsystem to see the optical flow algorithm.

```
load_system("hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem");
open_system("hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem/DUT");
```

Run the Model

The input video is split into a previous frame and current frame. The input ports of the DUT, CurrFrame and PrevFrame, connect to the 2-D matrices that contain the data for the current frame and previous frame. Each input signal is a frame composed of 360x640 pixels. Simulate the model to see the frame size and simulation results of the optical flow output.

```
sim("hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem");
```

Although the hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem and hdlFrame_OpticalFlow_LK_MLFB models differ in design, the output is the same. Both models can also generate synthesizable HDL code for sample-based hardware.

Generate HDL Code

Generate synthesizable HDL code by using the frame-to-sample conversion. Set the HDL block property ConvertToSamples on the Inport blocks of the DUT that connect to the frame-input signals to convert the input signals from frame-based to sample-based inputs.

```
hdlset_param('hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem/DUT/PrevFrame','ConvertToSamples');
hdlset_param('hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem/DUT/CurrFrame','ConvertToSamples');
```

Enable the frame-to-sample conversion optimization and generate HDL code using the makehdl command.

```
hdlset_param('hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem','FrameToSampleConversion','on');
makehdl('hdlFrame_OpticalFlow_LK_NeighborProcessingSubsystem/DUT');
```

The frame-to-sample conversion separates the frame-based inputs into sample, valid, and ready signals for a sample-based hardware-targeted interface.

Use Sample-Based Inputs and Frame-Based Inputs in an Algorithm

You can use matrix or frame-based signals with scalar or sample-based signals in the same algorithm when you use the frame-to-sample conversion operation. You can use non-streamed scalar inputs with streamed frame inputs to generate synthesizable HDL code for algorithms where you apply a threshold value or gain to an incoming streamed signal. This example uses an RGB image as an input and applies a color filter based on the threshold signals.

Model Frame Input and Sample Input Interaction

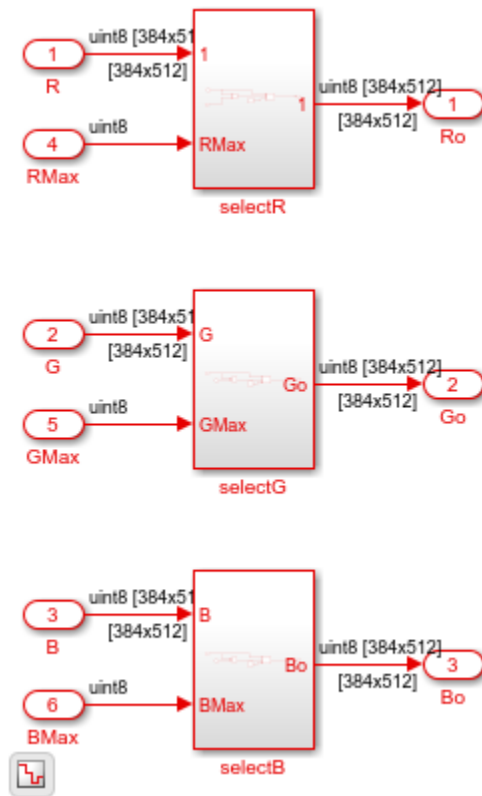

This example takes an RGB input image, splits the image into three individual RGB inputs signals, and applies a color filter on each signal based on the threshold signals specific to each color input. The threshold signals are inputs to the DUT as non-streamed scalar values.

```
open_system("hdlFrame_RGBFilter");
set_param('hdlFrame_RGBFilter', 'SimulationCommand', 'update');
```

Open the DUT subsystem to see the blocks that perform the filtering operation on the RGB frame inputs.

```
open_system('hdlFrame_RGBFilter/DUT');
```

Run the Model

The model uses 2-D matrices as inputs to the DUT. These inputs signals are the separated R,G,B components of the input image. Each streamed-input signal is a frame input matrix composed of 384x512 pixels. Each non-streamed threshold input is a `uint8` scalar value. Simulate the model to see the color-filtered output image.

```
sim("hdlFrame_RGBFilter");
```

Generate HDL Code

Generate synthesizable HDL code by using the frame-to-sample conversion. Set the HDL block property `ConvertToSamples` on the Inport blocks of the DUT that connect to the R, G, B input signals to convert the input signals from frame-based to sample-based inputs. You do not need to enable the `ConvertToSamples` property on the threshold inputs because they are scalar sample-based values.

```
hdlset_param('hdlFrame_RGBFilter/DUT/R', 'ConvertToSamples', 'on');
hdlset_param('hdlFrame_RGBFilter/DUT/G', 'ConvertToSamples', 'on');
hdlset_param('hdlFrame_RGBFilter/DUT/B', 'ConvertToSamples', 'on');
```

Enable the frame-to-sample conversion optimization and generate HDL code using the `makehdl` command. For more information on the frame-to-sample conversion optimization, see “HDL Code Generation from Frame-Based Algorithms” on page 29-2.

```
hdlset_param('hdlFrame_RGBFilter', 'FrameToSampleConversion', 'on')
makehdl('hdlFrame_RGBFilter/DUT')
```

The frame-to-sample conversion separates the frame-based inputs into sample, valid, and ready signals for a sample-based hardware-targeted interface.

Perform FPGA Synthesis and Analysis

In the HDL Workflow Advisor, perform FPGA synthesis using the generic ASIC/FPGA workflow. To generate HDL code and run synthesis on your design using the HDL Workflow Advisor, see “HDL Code Generation and FPGA Synthesis from Simulink Model”.

Use these settings located in the **HDL Code Generation > Target** pane in the Model Configuration Parameters dialog box:

- **Synthesis tool** set to Xilinx Vivado
- **Family** set to Zynq
- **Device** set to xc7z045
- **Package** set to ffg900
- **Speed** set to -2
- **Target Frequency (MHz)** set to 200

This table shows the synthesis results for the DUT subsystem in `hdlFrame_RBFilter`. The results report the frames per seconds (FPS) for each individual RGB channel, which assumes that each RGB input is streamed independently of one another.

Subsystem	r	c	FPSMax	FPSTgtFreq	Fmax	Slices	SliceRegs	LUTs	DSPs	RAMs	URAMs	Latency	DataPathDelay	Slack	LogicLevels	LogicDelay	RouteDelay
DUT	384	512	1710	1017	336.4	136	450	370	0	0	0	6	2.638	2.03	3	0.552	2.086

The synthesis results show a positive slack of 2.03 ns, which indicates that the timing constraints are met. The *r* and *c* columns correspond to the number of rows and columns of the frame, respectively. The *FPSMax* and *FPSTgtFreq* columns correspond to the average FPS at the output when using the maximum achievable frequency *Fmax* and the Target Frequency 200 MHz, respectively. To calculate the average FPS, use this equation:

$$\text{FPS} = \frac{\text{Frequency (Hz)}}{r \cdot c}$$

Synthesize Code for Frame-Based Model

This example shows how you can generate HDL code for a Sobel edge detection frame algorithm and calculate the frames per second of your design by synthesizing the generated code with the Simulink® HDL Workflow Advisor.

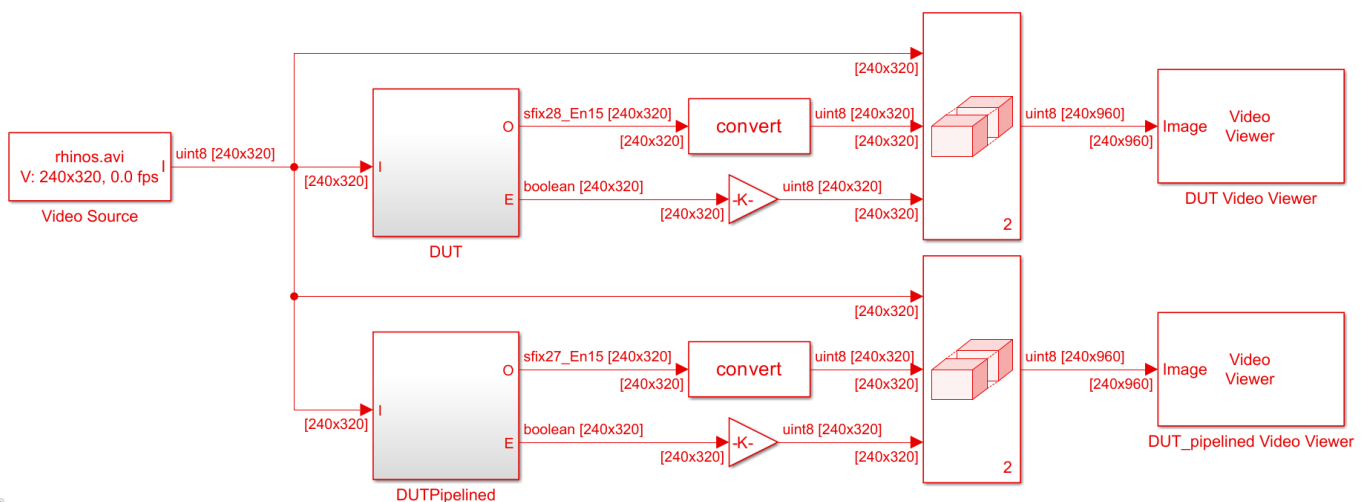

In this example, you can optimize the speed of the design by either manually pipelining the algorithm or by applying distributed pipelining.

Sobel Edge Detection Model

Open the model to see a frame-based implementation of the Sobel edge detection algorithm.

```
open_system('FrameBasedEdgeDetectionForHDLCodeGenExample')
set_param('FrameBasedEdgeDetectionForHDLCodeGenExample', 'SimulationCommand', 'Update')
```

Edge Detection and Image Overlay

The model consists of two designs under test (DUT) and a testbench. The DUT subsystem contains a MATLAB® Function block that implements a Sobel edge detection algorithm using `hdl.npufun`.

```
function [O, E] = edgeDetectionAndOverlay(I)

E = hdl.npufun(@sobel_kernel, [3 3], I);
O = hdl.npufun(@mix_kernel, [1 1], E, I);

end

function e = sobel_kernel(in)

u = fi(in);
hGrad = u(1) + fi(2)*u(2) + u(3) - (u(7) + fi(2)*u(8) + u(9));
vGrad = u(1) + fi(2)*u(4) + u(7) - (u(3) + fi(2)*u(6) + u(9));

hGrad = bitshift(hGrad, -3); % Divide by 8
vGrad = bitshift(vGrad, -3); % Divide by 8
```

```
thresholdValueSq = fi(49); % Threshold parameter
e = (hGrad*hGrad + vGrad*vGrad) > thresholdValueSq;
```

```
end
```

```
function O = mix_kernel(E, I)
```

```
alpha = fi(0.8); % Parameter for combining images
scaleE = E*fi(255,0,8,0);
O = scaleE * (fi(1)-alpha) + I*alpha;
```

```
end
```

The DUTPipelined subsystem contains a MATLAB Function block with a manually pipelined version of the previous algorithm that uses the `coder.hdl.pipeline` pragma. For example, you can modify the `mix_kernel` function to insert pipeline registers for the overlay operation.

```
function O = mix_kernel(E, I)
```

```
alpha = fi(0.8); % Parameter for combining images
scaleE = E*fi(255,0,8,0);
scaleEdelay = coder.hdl.pipeline(scaleE,2);
O1 = scaleEdelay*(1-alpha);
O1delay = coder.hdl.pipeline(O1,2);
O2 = I*alpha;
O2delay = coder.hdl.pipeline(O2,4);
O = O1delay + O2delay;
```

```
end
```

Perform FPGA Synthesis and Analysis

Use the HDL Workflow Advisor to synthesize the DUTs and compare the resources and timing achieved by each of the implementations. To generate HDL code and run synthesis on your design using the HDL Workflow Advisor, see “HDL Code Generation and FPGA Synthesis from Simulink Model”.

This table shows the results achieved for each DUT subsystem when you use these settings in the HDL Workflow Advisor:

- **Synthesis Tool:** Xilinx Vivado
- **Family:** Zynq
- **Device:** xc7z045
- **Package:** ffg900
- **Speed:** -2
- **Target Frequency:** 200

The FPSMax and FPStgtFreq columns correspond to the average frames per second (FPS) at the output when using the maximum achievable frequency (Fmax) and the Target Frequency (200 MHz), respectively, and *r* and *c* correspond to the number of rows and columns of the frame. To calculate the average frames per second, you can use this equation:

$$\text{FPS} = \frac{\text{Frequency (Hz)}}{r \cdot c}.$$

DUT	r	c	FPSMax	FPSGtgtFreq	Fmax	Slices	SliceRegs	LUTs	DSPs	RAMs	Latency	DataPathDelay	Slack	LogicLevels	LogicDelay	RouteDelay
DUT	240	320	926	NA	72.84	274	530	712	10	1.5	8	12.541	-9.058	25	7.01	5.531
DUT_pipelined	240	320	3549	2604	272.63	302	1006	724	10	1.5	23	3.316	1.332	4	0.496	2.82

Converting a frame-based algorithm to a sample-based algorithm requires more time to process each pixel than the frame-based version. This conversion adds additional latency between the input and output frames. In this example, the first pixel of the manually pipelined DUT output frame is available after an initial latency of 321 valid input pixels, plus the latency of 23 clock cycles reported in the table. For more information, see “HDL Code Generation from Frame-Based Algorithms” on page 29-2.

Optimized Speed by Using Speed Optimizations

You can use the distributed pipelining and the adaptive pipelining optimizations from HDL Coder™ with the frame-to-sample optimization to reduce the critical path of the design and achieve higher clock speed hardware for the DUT subsystem. Distributed pipelining moves existing design delays and pipeline registers in your design to reduce the critical path and adaptive pipelining inserts pipeline registers to blocks in the design that could result in area or speed optimizations. For this example, add input and output pipelines for distributed pipelining to redistribute and enable adaptive pipelining to obtain an optimal result. For more information on distributed pipelining and adaptive pipelining, see “Distributed Pipelining” on page 28-131 and “Adaptive Pipelining” on page 28-181 respectively.

Enable distributed pipelining, adaptive pipelining, and set the MATLAB Function block input and output pipeline registers to 16 by entering:

```
hdlset_param('FrameBasedEdgeDetectionForHDLCodeGenExample', 'DistributedPipelining', 'on');
hdlset_param('FrameBasedEdgeDetectionForHDLCodeGenExample', 'AdaptivePipelining', 'on');
hdlset_param('FrameBasedEdgeDetectionForHDLCodeGenExample/DUT/MATLAB Function', 'DistributedPipe');
hdlset_param('FrameBasedEdgeDetectionForHDLCodeGenExample/DUT/MATLAB Function', 'OutputPipeline');
hdlset_param('FrameBasedEdgeDetectionForHDLCodeGenExample/DUT/MATLAB Function', 'InputPipeline');
```

This table shows the resources and timing achieved when using distributed pipelining for different video formats. The highlighted row corresponds to the video format used in the previous section.

Format	r	c	FPSMax	FPSGtgtFreq	Fmax	Slices	SliceRegs	LUTs	DSPs	RAMs	Latency	DataPathDelay	Slack	LogicLevels	LogicDelay	RouteDelay
8KUHDV	4320	7680	7	6	246.43	412	1155	847	10	10	23	3.001	0.942	0	3.001	0
4KUHDV	2160	3840	29	24	246.43	403	1133	848	10	5	23	3.001	0.942	0	3.001	0
2KCinema	1080	2048	111	90	246.43	377	1118	829	10	3	23	3.001	0.942	0	3.001	0
1200p	1200	1600	118	96	246.43	377	1111	819	10	2.5	23	3.001	0.942	0	3.001	0
1080p	1080	1920	128	104	246.43	381	1111	850	10	2.5	23	3.001	0.942	0	3.001	0
1024p	1024	1280	188	152	246.43	380	1107	842	10	2.5	23	3.001	0.942	0	3.001	0
768p	768	1024	267	217	246.43	389	1104	843	10	2.5	23	3.001	0.942	0	3.001	0
720p	720	1280	313	254	246.43	360	1096	851	10	1.5	23	3.001	0.942	0	3.001	0
576p	576	720	594	482	246.43	378	1089	888	10	1.5	23	3.001	0.942	0	3.001	0
480pH	480	720	713	578	246.43	356	1085	885	10	1.5	23	3.001	0.942	0	3.001	0
480p	480	640	802	651	246.43	356	1085	869	10	1.5	23	3.001	0.942	0	3.001	0
240p	240	320	3208	2604	246.43	362	1282	923	10	1.5	45	3.001	0.942	0	3.001	0

For all video formats, the synthesis results show a clock frequency of 246.43 MHz, indicating that the timing constraints are met.

Optimized Speed by Modifying the Samples per Cycle

You can vary the video size and achieve higher FPS by using the **SamplesPerCycle** parameter in the Configuration Parameters window:

$$\text{FPS} = \frac{\text{Frequency (Hz)}}{r \cdot \left(\frac{c}{\text{SamplesPerCycle}} \right)}$$

This table shows the FPS obtained for the DUT`pipelined` subsystem (manually pipelined) when you vary the size of the frames and the **Samples Per Cycle** parameter. For more information on the **Samples Per Cycle** parameter, see “Frame to Sample Conversion Parameters” on page 19-34.

Video Format	r	c	FPS @ 1,2,4,8 pixels per cycle			
			1	2	4	8
8KUHD TV	4320	7680	7	15	29	57
4KUHD TV	2160	3840	29	63	119	233
2KCinema	1080	2048	111	226	451	853
1200p	1200	1600	118	253	473	912
1080p	1080	1920	128	270	501	1033

Offload Large Delays from Frame-Based Models to External Memory

Frame-based algorithms often require storing large amounts of data in external memory for future processing. When you use the frame-to-sample conversion, HDL Coder™ transforms your frame-based algorithm into sample-based HDL code and generates additional ports to offload the delays that the design needs for pipeline computations. During the IP core generation, HDL Coder can map these ports to an AXI4 Master interface to store the data in external memory.

Offloading a large delay is also useful in signal processing algorithms that require a large amount of data to process the input signal. A common image processing application is histogram equalization, which requires building a histogram from an entire input frame in order to equalize the image. This example shows how to leverage the frame-to-sample optimization to generate a sample-based IP core with AXI4-Stream interfaces from a frame-based histogram equalization model.

To run this example, you must have the following software and hardware boards:

- HDL Coder Support Package for Xilinx® Zynq® Platform.
- Xilinx Vivado®. To view the supported versions, see “HDL Language Support and Supported Third-Party Tools and Hardware”.
- Xilinx Zynq ZC706 Evaluation Kit.

Model a Histogram Equalization Algorithm Using Iterative Operations

Open the HistogramEq MATLAB Function block in the hdlFrame_Zynq_Histogram/DUT subsystem to see the histogram equalization algorithm.

```
load_system('hdlFrame_Zynq_Histogram')
open_system('hdlFrame_Zynq_Histogram/DUT/HistogramEq')

function im_out = histeq(im_gray)

% Histogram calculation
hist = zeros(1, 256, 'uint16');
hist = hdl.iteratorfun(@hist_kernel_fcn, im_gray, hist);

[row,col] = size(im_gray);
factor = coder.const(fi(255/(row*col)));

% Cumulative distribution function calculation
cdf_init = zeros(1,256,'uint8');
cdf = hdl.iteratorfun(@cdf_compute, hist, cdf_init, factor);

% Equalize input frame: replace the value from look up table
im_out = hdl.npufun(@table_lookup, [1,1], im_gray, 'NonSampleInput', cdf);

end

function count = hist_kernel_fcn(pix, count, idx) %#ok<INUSD>

count(pix+1) = count(pix+1) +1;

end

function cdf = cdf_compute(hist, cdf, idx, factor)

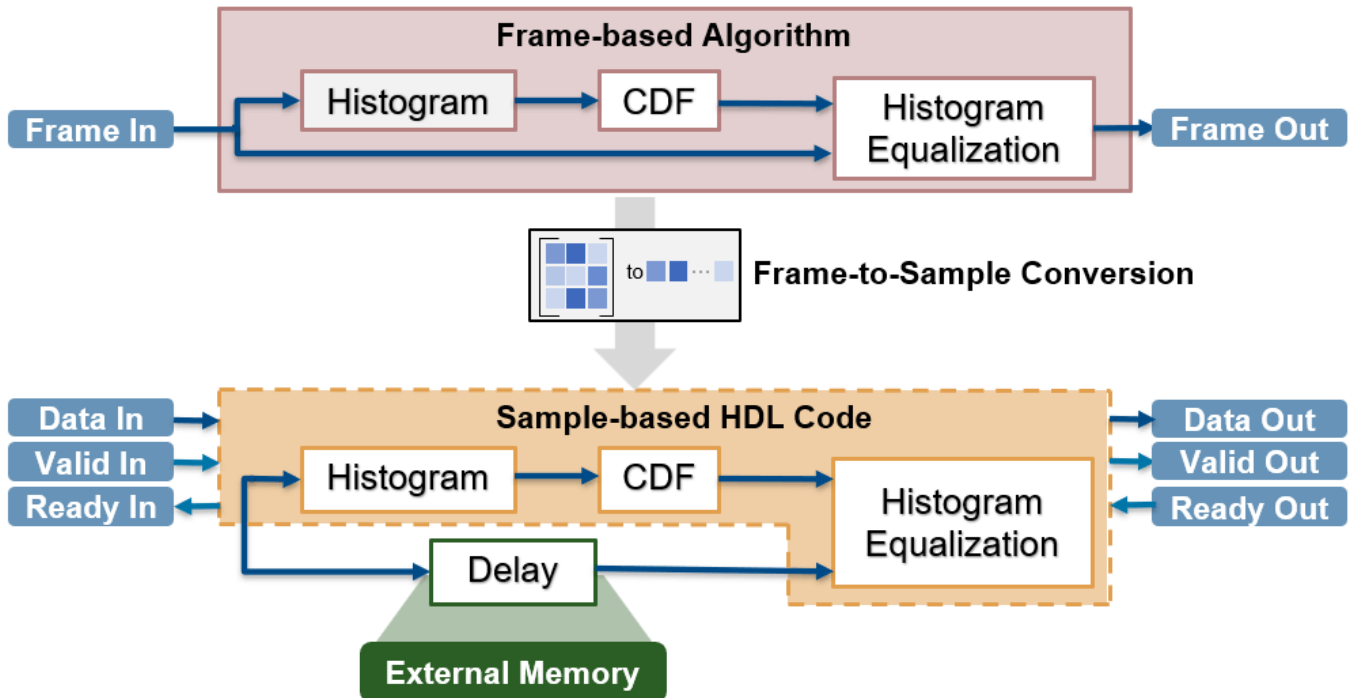

if idx > 1
    cdf(idx) = uint8(cdf(idx-cast(1,'like'),idx)) + hist*factor);
else
    cdf(1) = uint8(hist*factor);
end

end

function out = table_lookup(in, cdf)
    out = cdf(in);
end
```

In the hdlFrame_Zynq_Histogram model, there is a single MATLAB® Function block inside the device under test (DUT) that uses the hdl.iteratorfun function to compute the cumulative distribution function (CDF) of the incoming frame, and the hdl.npufun function to equalize the frame using the CDF result. For more information on modeling iterative and neighborhood operations in frame-based models, see “HDL Code Generation from Frame-Based Algorithms” on page 29-2.

When you use the frame-to-sample optimization and set the “Delay size threshold for external memory” on page 19-38 configuration parameter to a specified threshold in bits, HDL Coder generates sample-based HDL code from the frame-based algorithm and offloads the largest delay greater than the threshold to external memory.

Generate HDL IP Core

When you generate an IP core for this model, you can connect the streaming I/O of your algorithm to a streaming interface. HDL Coder handles the external memory mapping process by generating the frame management logic and read and write controllers to write the delay to external memory using an AXI4 Master interface. The IP core can then write the incoming frame data to DDR memory and read the data to perform the equalization once the histogram has been calculated. This process reduces modeling and development time because HDL Coder handles the complex frame management of multiple delays in external memory and does not require you to model the simplified AXI4 master protocol to connect the IP core to external memory.

To generate an IP core from the frame-based DUT and deploy this design on the Zynq hardware:

1. Enable the frame-to-sample conversion:

```
hdlset_param('hdlFrame_Zynq_Histogram', 'FrameToSampleConversion', 'on');
```

2. Enable the HDL block property `ConvertToSamples` for the input image to be streamed, `ImageIn`:

```
hdlset_param('hdlFrame_Zynq_Histogram/DUT/ImageIn', 'ConvertToSamples', 'on');
```

3. To offload a large delay to external memory outside of the FPGA, set the `DelaySizeThreshold` parameter to a delay size threshold in bits. For this example, the delay needed for the histogram equalization algorithm is of similar size to the image, which is $262 \times 216 \times 8$ or 452736 bits. To map the

large delay to external memory, set the parameter to a value lower than the image size in bits. In this case, set the `DelaySizeThreshold` to 10000 bits.

```
hdlset_param('hdlFrame_Zynq_Histogram', 'DelaySizeThreshold', 10000)
```

4. Set up the Xilinx Vivado synthesis tool path by using the `hdlsetuptoolpath` command. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2022.1\bin\vivado.bat')
```

5. Open the HDL Workflow Advisor and generate an IP core from the DUT subsystem, `hdlFrame_Zynq_Histogram/DUT`. In task **1.1 Set Target Device and Synthesis Tool**, set **Target workflow** to IP Core Generation and **Target platform** to Xilinx Zynq ZC706 evaluation kit. In task **1.2 Set Target Reference Design**, set **Reference Design** to Default System with External DDR3 memory access. In task **1.3 Set Target Interface**, set **Target platform interface table** to the settings shown in this image.

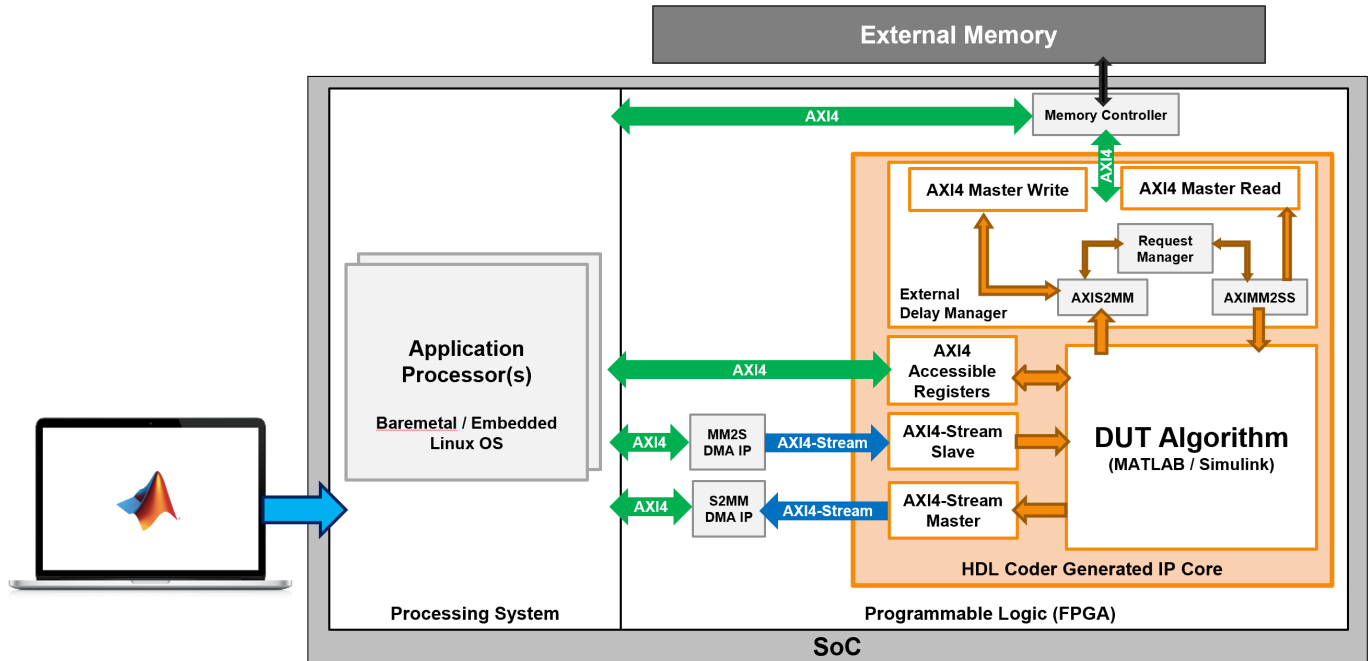

6. Right-click task **3.2 Generate RTL Code and IP Core** and select **Run to Selected Task** to generate the IP core. Because the frame-to-sample optimization is enabled, HDL Coder generates additional DUT ports to offload the necessary delays needed for the histogram calculation. During the IP core generation, HDL Coder maps these ports to an AXI4 Master interface to store the data in the DDR memory. You can find the register address mapping, the necessary frame size for the external delay, and other information about the IP core generated in the IP core report.

7. In task **4.2 Generate Software Interface**, select the **Generate host interface script** check box and click **Run this Task**. The HDL Workflow Advisor generates two MATLAB files in your current folder that you can use to prototype the generated IP core.

8. Right-click task **4.3 Build FPGA Bitstream** and select **Run to Selected Task** to generate the Vivado project and build the FPGA bitstream.

During the project creation, the generated DUT IP core is integrated into the `Default System with External DDR3 Memory Access` reference design. This reference design contains a Xilinx Memory Interface Generator IP, which communicates with the on-board external DDR3 memory on the ZC706 platform, and the MATLAB as AXI Master IP, which enables MATLAB to control the DUT IP and initialize and verify the DDR memory content. The DMA IPs transfer AXI4-Stream data between the processing system and the FPGA.

To view the generated Vivado project, click the link in the result window in task **4.1 Create Project**. Open the Vivado block design. The generated reference design project looks similar to this architecture diagram.

9. After the bitstream generates, right-click task **4.4 Program Target Device** and click **Run this Task** to program the target device.

For a more information on IP core generation for Xilinx hardware, see “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

Run FPGA Implementation on Xilinx Zynq ZC706 Evaluation Kit

You can interact with the FPGA design by reading and writing data from MATLAB on the host computer as described in the Interact with FPGA Design from Host Computer section in “Prototype FPGA Design on Hardware with Live Data by Using MATLAB Commands” on page 46-234.

You can use these commands as a starting point to test the frame-based model deployed on the FPGA.

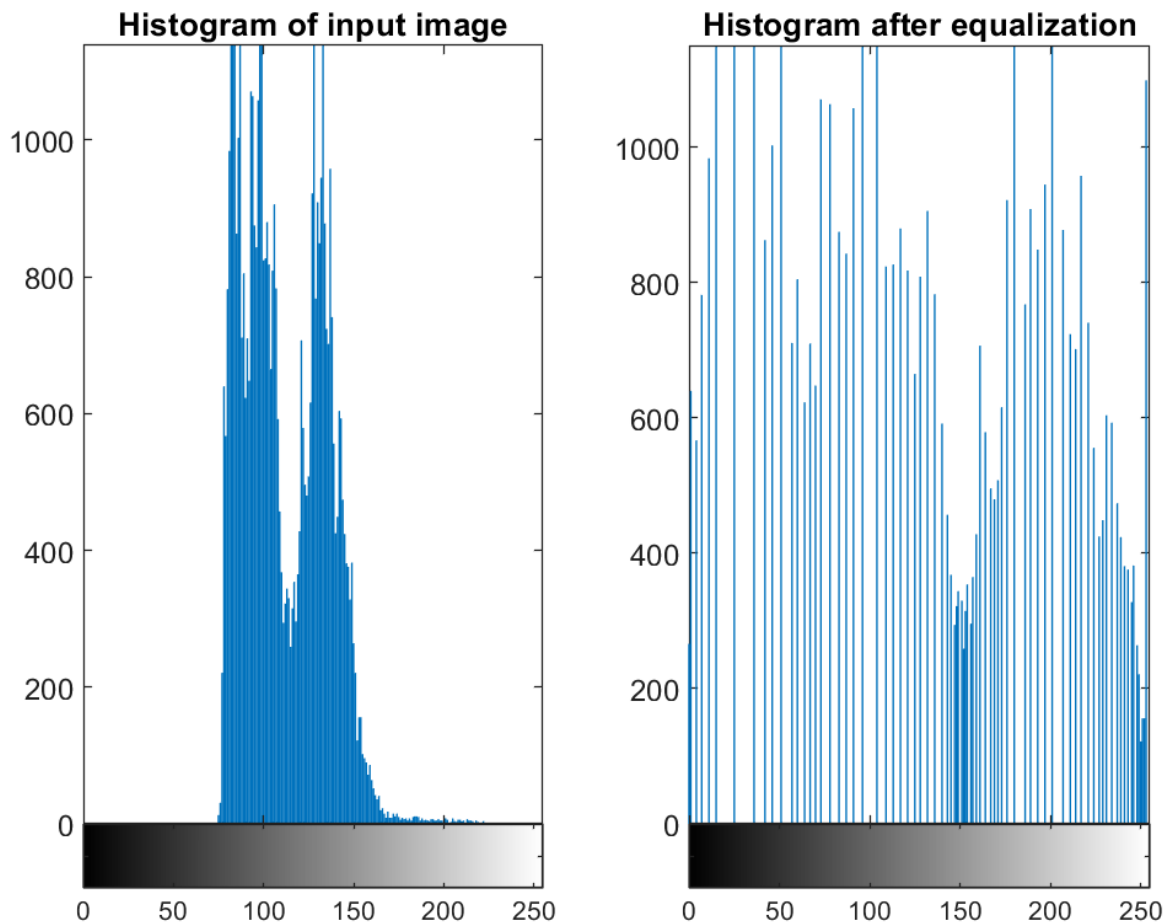

```
% load image
I = imread('hdlc_pout.tif');

%Write image to FPGA
wrValid1 = writePort(hFPGA, "ImageIn", I);
wrValid2 = writePort(hFPGA, "ImageIn", I);
% Read result from FPGA
[outputFrame1, rdValid1] = readPort(hFPGA, "ImageOut");
% Display result
figure
imagesc([I outputFrame1],[0 255]); colormap(gray)
title('(left) Input image, (right) Output image read from FPGA')
% Display histograms
figure
subplot(1,2,1);imhist(I,256);
```

```
title('Histogram of input image')  
subplot(1,2,2);imhist(outputFrame1,256);  
title('Histogram after equalization')
```

(left) Input image, (right) Output image read from FPGA

Limitations

When you generate an IP core from a frame-based algorithm and enable delay mapping to external memory, these limitations apply:

- You can map at most one large delay to external memory. If there are multiple large delays over the threshold set by the **Delay size threshold for external memory** parameter, the largest delay is mapped to external memory while the rest of the delays are mapped to memory on the FPGA.
- HDL Coder only maps FIFO blocks as delays generated during HDL code generation to external memory. Delay blocks created from optimizations that add pipelines to the generated model and code cannot be moved outside the DUT and mapped to external memory.

Deploy Frame-Based Models with AXI4-Stream Video Interfaces in Zynq-Based Hardware

You can use the HDL Coder™ frame-to-sample optimization to design and deploy frame-based algorithms that use AXI4-Stream Video interfaces to enable high-speed video streaming.

In this example, you:

- 1 Model a frame-based edge detection algorithm by using neighborhood processing functions.
- 2 Generate an HDL IP core with an AXI4-Stream Video interface.
- 3 Integrate the generated IP core into a Xilinx® Zynq® ZC706 reference design with access to HDMI interfaces.

Prerequisites

To run this example, you must have the following software and hardware boards setup:

- HDL Coder™ Support Package for Xilinx Zynq Platform
- Embedded Coder® Support Package for Xilinx Zynq Platform
- Vision HDL Toolbox™ Support Package for Xilinx-Zynq-Based Hardware
- Xilinx Vivado® Design Suite
- Xilinx Zynq ZC706 evaluation kit with FMC HDMI I/O card (FMC-HDMI-CAM or FMC-IMAGEON)

Set Up Hardware

1. Install the HDL Coder and Embedded Coder Support Packages for Xilinx Zynq Platform, and Vision HDL Toolbox Support Package for Xilinx Zynq-Based Hardware. To install the support packages, in MATLAB®, in the **Home** tab, click **Add-Ons > Get Hardware Support Packages**.

2. Use the SD card image provided by the Embedded Coder Support Package for Xilinx Zynq Platform.

3. Set up the Xilinx Zynq ZC706 board and the FMC HDMI I/O card as shown in the figure below. Follow these instructions for connecting the hardware:

- 1** Remove the SD card from the host computer and insert it into the Zynq board.
- 2** Plug the HDMI FMC card into the FMC connector on the Zynq board.
- 3** Connect an Ethernet cable to the board.
- 4** Connect the power cable.
- 5** Connect an HDMI video source to the FMC HDMI I/O card. The video source must be able to provide 1080p video output, such as a video camera, smart phone, tablet, or the HDMI output of your computer.
- 6** Connect a monitor to the FMC HDMI I/O card. The monitor must be able to support 1080p display.

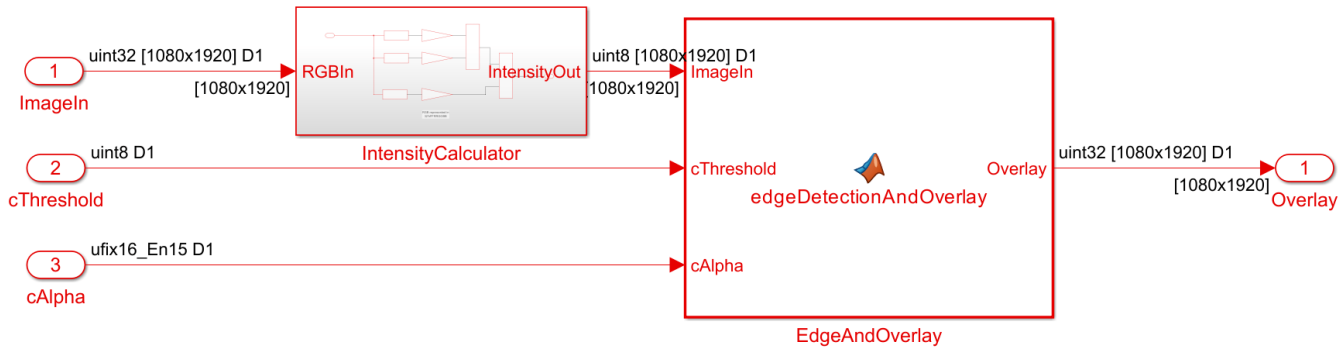

To learn more about the ZC706 hardware setup, see Xilinx ZC706 Evaluation Board User Guide.

Model a Frame-Based Algorithm to Integrate with the Default Video System Reference Design

Open the frame-based model, `hdlcoder_frame_video_edge`, which contains an edge detection and image overlay algorithm in the device under test (DUT), `EdgeDUT`.

```
load_system('hdlcoder_frame_video_edge')
open_system('hdlcoder_frame_video_edge/EdgeDUT')
```

In the example model, the DUT subsystem, `hdlcoder_frame_video_edge/EdgeDUT`, uses the `hdl.npufun` function to implement the Sobel Edge detection algorithm and the `code.hdl.pipeline` function to pipeline the design to achieve the frequency needed to perform edge detection on live video. For more information on modeling the algorithm, see “Synthesize Code for Frame-Based Model” on page 29-26. When using the frame-to-sample optimization, you do not need to model additional control signals. The ports `ImageIn` and `Overlay` are the pixel data ports for video streams. The additional input ports, `cThreshold` and `cAlpha`, are control ports that adjust the parameters of the Sobel edge detection algorithm. You can enable the frame-to-sample conversion for this model using these commands:

```
hdlset_param('hdlcoder_frame_video_edge', 'FrameToSampleConversion', 'on');
hdlset_param('hdlcoder_frame_video_edge/EdgeDUT/ImageIn', 'ConvertToSamples', 'on');
```

Generate HDL IP Core with AXI4-Stream Video Interface

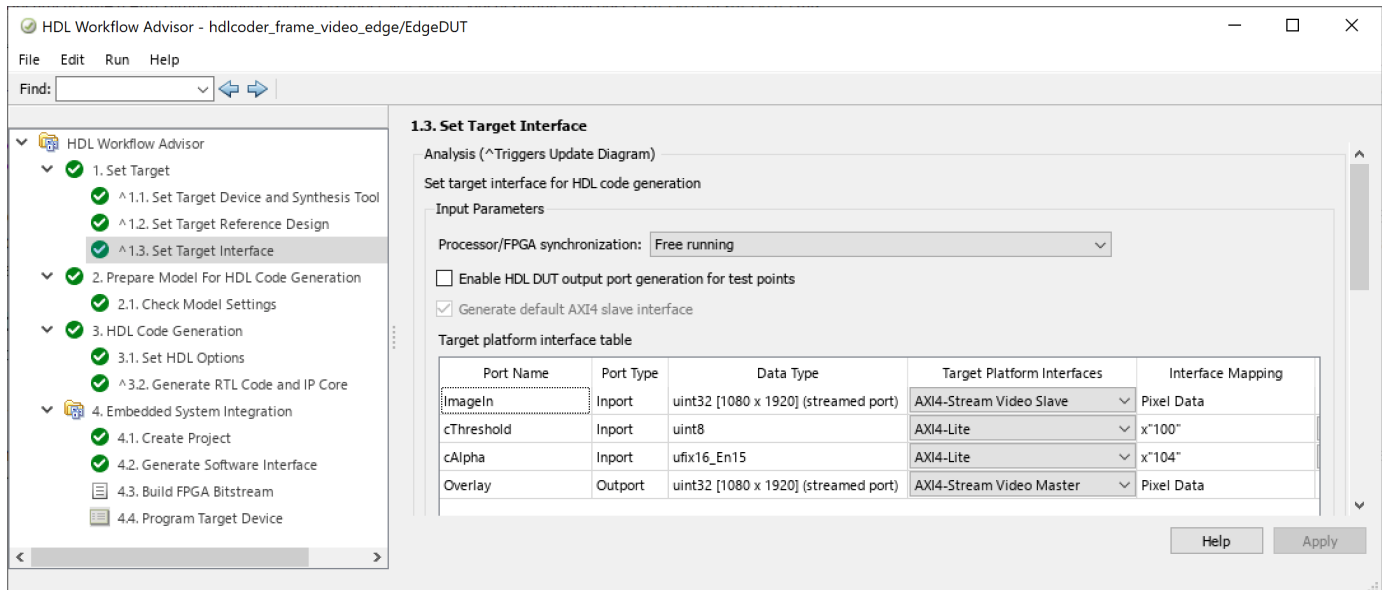

When you generate an IP core that is integrated into the Default Video System Reference Design, the video stream signals are encoded into a 32-bit representation `32'hFFRRGGBB`. To account for the data format, the subsystem `hdlcoder_frame_video_edge/EdgeDUT/IntensityCalculator` decodes the RGB 32-bit representation of the video stream to get the intensity of the frame. Additionally, the subsystem encodes the output into the same format when it calculates the overlay. For more information on the architecture of the reference design see “Default Video System Reference Design” (HDL Coder Support Package for Xilinx Zynq Platform).

To generate an IP core with the AXI4-Stream Video interface from a frame-based model:

1. Set up the Xilinx Vivado synthesis tool path by using the `hdlsetuptoolpath` command. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2022.1\bin\vivado.bat')
```

2. In the **1.1 Set Target Device and Synthesis Tool Task**, set **Target workflow** to IP Core Generation and set **Target platform** to Xilinx Zynq ZC706 evaluation kit. In task 1.2, set the **Reference Design** to Default video system (requires HDMI FMC module). In task 1.3, **Target Platform Interface Table** section, set the cells to these settings:

The AXI4-Stream video interface contains data (TDATA) and control signals such as TVALID, back pressure (READY), and data boundary (TDATA and TLAST). TDATA indicates the start of a video frame and TLAST indicates the end of a line. The timing diagram shows the timing for a 2x4 frame.

To use the frame-to-sample optimization, you must map your frame inputs and outputs as Pixel Data. The TVALID, READY, and TLAST control signals are automatically generated. In this example, the frame ports ImageIn and Overlay are mapped to the AXI4-Stream Video interface. The scalar ports cAlpha and cThreshold are mapped to the AXI4-Lite interface. HDL Coder generates AXI4 interface accessible registers for these ports.

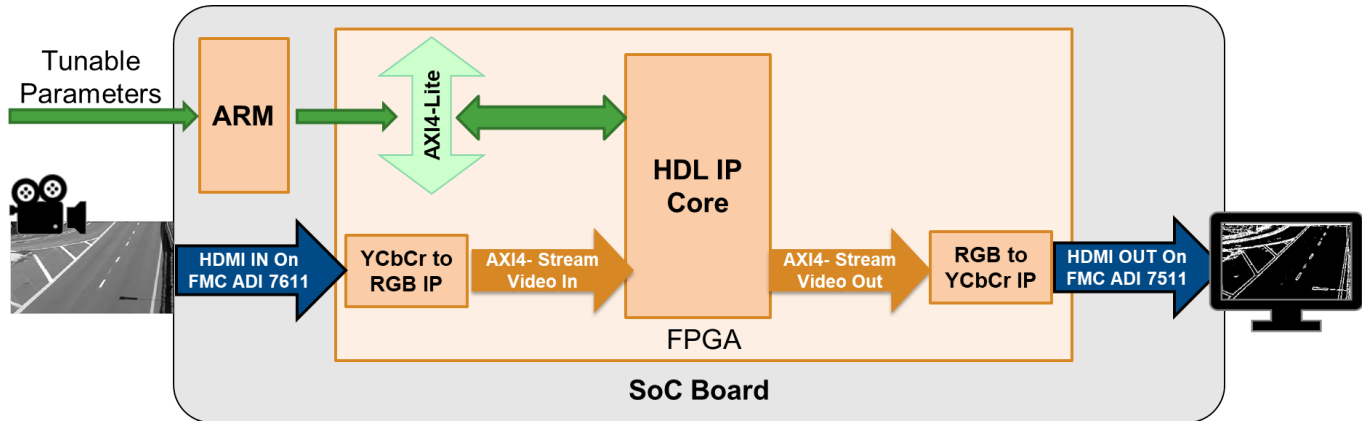

3. Right-click task 3.2, **Generate RTL Code and IP Core**, and select **Run to Selected Task** to generate the IP core. You can find the register address mapping and other information for the IP core in the generated IP Core Report.

4. Right-click task 4.2 **Build FPGA Bitstream**, and select **Run to Selected Task** to generate the Vivado project and build the FPGA bitstream.

5. Run task 4.3, **Program Target Device**, to program the FPGA board.

System Architecture with the Generated IP Core

The high-level architecture of the complete Zynq design is shown below.

The generated DUT IP core is integrated into the Default Video System reference design. The AXI4-Stream Video interface processes the video stream from the HDMI input and sends the output video stream to the HDMI output. The host computer can tune parameters by writing to AXI4-Lite registers within the algorithm IP core.

- “HDL Code Generation from Frame-Based Algorithms” on page 29-2

Optimize Area Usage For Frame-Based Algorithms with Tall Array Inputs

This example shows how to generate area-efficient HDL code from a frame-based algorithm that has input data with significantly more rows than columns. This type of input data is common in audio and digital signal processing algorithms. You can use the frame-to-sample conversion optimization and adjust the order in which the input data is processed for your target hardware to reduce the amount of area needed for the algorithm. For more information on the frame-to-sample conversion optimization, see “HDL Code Generation from Frame-Based Algorithms” on page 29-2.

The “Input processing order” on page 19-37 configuration parameter allows you to select the order in which the frame-to-sample optimization processes an incoming matrix. By selecting the input processing order, you can align the way your algorithm is processed with the type of hardware you are using or the application you are targeting. For example, if you have an input hardware sensor or an upstream component that requires the column-major ordering, you do not need to use an extra transpose. Similarly, if you have a digital signal processing algorithm that requires column-major ordering, you do not need to transpose the matrix to make the algorithm compatible with the frame-to-sample optimization.

Inspect the Model

For this example, the input data is daily data of average temperature over the course of 10 years, stored as 365 rows for each day by 10 columns for the 10 years. The algorithm calculates a moving average within each year, which requires computing the moving average along each column.

Load the input data `inputTemp` from the `inputData.mat` file.

```
load('inputData.mat');
```

Load the model and open the MATLAB Function block that contains the moving average algorithm.

```
mdl = 'moving_avg_col_major';
dut = [mdl '/DUT'];
```

```
load_system(mdl);
open_system([dut '/MATLAB Function'])
```

```
function out_data = movingAvgfcn(inp_data)
out_data = hdl.npufun(@kernelAdd, [5 1], inp_data);
end
```

```
function y = kernelAdd(x)
y = single(1/5)*sum(x(:), 'native');
end
```

The `hdl.npufun` function computes the moving average algorithm and is compatible with the frame-to-sample conversion optimization. You could also use the Neighboring Processing Subsystem block to apply the same algorithm and generate HDL code with the frame-to-sample optimization. For an example, see “Generate HDL Code from Frame-Based Models by Using Neighborhood Modeling Methods” on page 29-17.

Run Model and Plot Output

Run the model to save the output data to your MATLAB workspace as `outputTemp`.

```
sim mdl
```

Plot the first year of input temperature data against the output temperature data to see the moving average filter applied to the data.

```
dayLength = 1:size(inputTemp,1);
yearofChoice = 1;
```

```
figure;
plot(dayLength,inputTemp(:,1));
title('Temp vs. Moving Avg Temp')
hold on;
plot(dayLength,outputTemp(:,1));
legend('Temp', 'Moving Avg Temp')
```

Generate HDL Code and View Area Usage

To generate HDL code using the frame-to-sample conversion optimization, first set the HDL subsystem to the DUT you want to generate code from.

```
hdlset_param mdl, 'HDLSubsystem', dut;
```

To convert the input matrix from a frame-based to a sample-based input, set the HDL block property `ConvertToSamples` to `on` on the Inport block of the DUT that connects to the frame-input signal.

```
hdlset_param([dut '/in_sig'], 'ConvertToSamples', 'on');
```

Enable the frame-to-sample conversion optimization and generate HDL code using the `makehdl` command.

```
hdlset_param mdl, 'FrameToSampleConversion', 'on');
```

```
makehdl(dut)
```

```

Run Synthesis

By default, the **Input Processing Order** parameter is set to `RowMajor`. Run synthesis to determine the initial area usage from the model without applying column-major ordering for optimization. To run synthesis on the model, you need to have a synthesis tool installed and on the MATLAB™ path. For more information, see “Tool Setup”.

To run synthesis on the model:

1. In Simulink, in the **HDL Code** tab, click **Workflow Advisor**.
2. In the left pane, click **1. Set Target > 1.1 Set Target Device and Synthesis Tool**. Set:
 - **Target workflow** to Generic ASIC/FPGA
 - **Synthesis tool** to Xilinx Vivado
 - **Family** to Virtex7
 - **Device** to xc7vx485t
 - **Package** to ffg1761
 - **Speed** to -2
3. Click **1.2 Set Target Frequency**, and set **Target Frequency (MHz)** to 300.
4. In the left pane, click **4. FPGA Synthesis and Analysis > 4.2 Perform Synthesis and P/R > 4.2.2. Run Implementation**. Clear **Skip This Task**.
5. Right-click **4.2.2 Run Implementation** and click **Run to Selected Task**.

The HDL Workflow Advisor runs through synthesis and implementation for the model. The synthesis results display the **Resource summary** and **Timing summary**.

Resource summary			
Resource	Usage	Available	Utilization (%)
Slice LUTs	3046	0	
Slice Registers	3740	0	
DSPs	1	0	
Block RAM Tile	0	0	
URAM	0	0	

Parsed timing report file: [timing_post_map.rpt](#).

Timing summary	
	Value
Requirement	3.3333 ns (300 MHz)
Data Path Delay	0.715 ns
Slack	-0.183 ns
Clock Frequency	284.39 MHz

For more information on the code generation and synthesis steps, see “HDL Code Generation and FPGA Synthesis from Simulink Model”.

Optimize Area Usage

Typically, for incoming frame data that has a significantly larger number of rows than columns, also called a *tall matrix*, you can use column-major ordering to optimize the area used on hardware. For incoming frame data that has a significantly larger number of columns than rows, also called a *long matrix*, you can use row-major ordering to optimize the area used on hardware. The output of either ordering method is the same, but the ordering can generate less or more efficient mapping onto the target FPGA hardware.

For this example, to optimize the area, you either change the input processing order to column-major ordering or manually transpose the data. It is less time consuming and requires no extra manual

effort to use the **Input Processing Order** parameter instead of manually transposing the data. Set the input processing order to column major by using the command-line.

```
hdlset_param mdl, 'InputProcessingOrder', 'ColumnMajor');
```

Generate HDL code using the `makehdl` command and run through synthesis with the same settings as you did before.

```
makehdl(dut)
```

```

Compute Image Characteristics with a Frame-Based Model for HDL Code Generation

In this example, you use frame-based modeling to model an image processing algorithm that detects an object based on color. The model takes 2-D images as input and produces a two-element location for the detected object. You then generate synthesizable HDL code by using the HDL Coder™ frame-to-sample conversion optimization, which generates pixel-based code from a frame-based model. For more info on the frame-to-sample conversion optimization, see “HDL Code Generation from Frame-Based Algorithms” on page 29-2.

The object detection model uses neighborhood, iterator, and element-wise operator patterns. You can model neighborhood patterns by using the `hdl.npufun` function in a MATLAB® Function block or the Neighborhood Processing Subsystem block. You can implement iterator patterns by using `hdl.iteratorfun` in a MATLAB Function block. You can model element-wise operations using Simulink® blocks. Neighborhood processing operations, element-wise operations using Simulink blocks, and iterator operations support the generation of synthesizable HDL code by using the frame-to-sample conversion optimization. This model uses Sum, Abs, Relational, and Logical Operator blocks for element-wise operations. The input to the model is a frame-based RGB video signal. The output from the model is the sample-based location of the detected object.

Inspect and Run the Model

In the `hdlFrame_ObjectDetecting` model, the device under test (DUT) contains a MATLAB Function block `rgb2hsv` that uses neighborhood processing to convert the input RGB color space to the HSV color space. The HSV color space output is passed into the `FindTarget` subsystem that contains Simulink blocks that detect the target color area. Finally, the `Compute Centroid` MATLAB Function block computes a centroid value from the detected area in the image by using `hdl.iteratorfun`.

Open the `hdlFrame_ObjectDetecting/DUT` subsystem to see the object detection algorithm.

```
load_system('hdlFrame_ObjectDetecting');
open_system('hdlFrame_ObjectDetecting/DUT');
```

Open the `hdlFrame_ObjectDetecting/DUT/rgb2hsv` MATLAB Function block to see the RGB to HSV color space conversion algorithm.

```
open_system('hdlFrame_ObjectDetecting/DUT/rgb2hsv');
```

```
function [H, S, V] = rgb2hsv_frame(R, G, B)
[H, S, V] = hdl.npufun(@rgb2hsvKernel, [1 1], R, G, B);
end
```

```

function [h, s, v] = rgb2hsvKernel(r, g, b)

maxVal = max([r g b]);
minVal = min([r g b]);
delta = maxVal - minVal;

h = single(0.0);
if (r == maxVal)
    h = (g - b) / delta;
end

if (g == maxVal)
    h = (b - r) / delta + 2.0;
end

if (b == maxVal)
    h = (r - g) / delta + 4.0;
end

h = h/6.0;
if h < 0.0
    h = h + 1;
end

tmp = delta / maxVal;
if (delta == 0.0)
    h = single(0.0);
end

if (maxVal ~= 0.0)
    s = tmp;
else
    s = single(0.0);
end

v = maxVal;

end
    
```

Open the `hdlFrame_ObjectDetecting/DUT/Compute Centroid` block to see the centroid computation algorithm.

```
open_system('hdlFrame_ObjectDetecting/DUT/Compute Centroid');
```

```

function centroid = myCentroid_frame(BW)

C = coder.const(int32(size(BW, 2)));
sumRC = int32([0 0 0 0]); % centroidR, centriC, RowCounter, ColCounter totalPoints

centRC = hdl.iteratorfun(@kernel, BW, sumRC, C);
recip = single(1)/single(centRC(5));
centR = int32(single(centRC(1))*recip);
centC = int32(single(centRC(2))*recip);
centroid = [centR, centC];
    
```

```
end

function sumRC = kernel(bw, sumRC, idx, C)
sumRC(3) = sumRC(3) + 1; % counter 1 rows

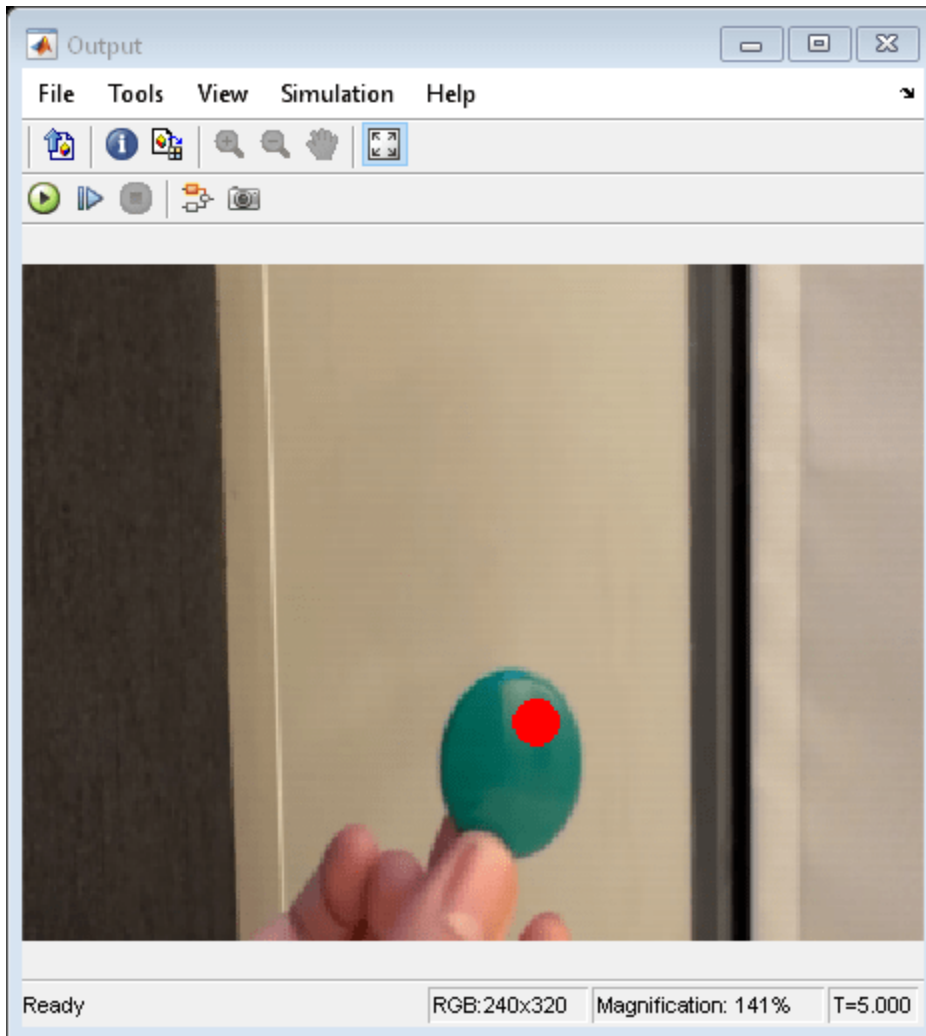

% check for boundaries
if sumRC(3) > C
    sumRC(3) = 1;
    sumRC(4) = sumRC(4) + 1; % counter 2 cols
end

if bw
    sumRC(1) = sumRC(1) + sumRC(3);
    sumRC(2) = sumRC(2) + sumRC(4);
    sumRC(5) = sumRC(5) + 1;
end

end
```

The model uses 2-D matrices as inputs to the DUT. These inputs signals are the separated R, G, and B components of the input image. Each input signal is a frame input matrix composed of 240x320 pixels. To see the frame size and simulation results, open the `hdlFrame_ObjectDetecting/Output` block and simulate the model.

```
open_system('hdlFrame_ObjectDetecting/Output')
sim("hdlFrame_ObjectDetecting");
```

Identify Streamed Signals

To generate synthesizable HDL code using the frame-to-sample conversion, identify the signals to be converted from frames to samples during HDL code generation. For this example, you convert the R, G, and B input signals. The R, G, and B input signals are streamed signals in this example because they go through the frame-to-sample conversion optimization during HDL code generation. The frame-to-sample conversion detects if the output of the DUT is a streamed output signal, which is a converted frame-to-sample signal, or a non-streamed signal, which is any output that does not get transformed from frame to samples. In this example, the centroid value is a characteristic of the image, and is characterized as a non-streamed signal.

Close the `hdlFrame_ObjectDetecting/Output` block and set the HDL block property `ConvertToSamples` on the Inport blocks of the DUT that connect to the R, G, and B input signals to convert the input signals from frame-based to sample-based inputs during HDL code generation.

```
close_system('hdlFrame_ObjectDetecting/Output')
hdlset_param('hdlFrame_ObjectDetecting/DUT/R', 'ConvertToSamples', 'on');
hdlset_param('hdlFrame_ObjectDetecting/DUT/G', 'ConvertToSamples', 'on');
hdlset_param('hdlFrame_ObjectDetecting/DUT/B', 'ConvertToSamples', 'on');
```

```

Create and Use Code Generation Reports

Report Generation

The HDL Coder software creates and displays an HTML code generation report when you select one or more options listed in the table. In the Configuration Parameters dialog box, you can specify the UI options in the **HDL Code Generation > Report** pane.

GUI option	makehdl Property	Dependency
Generate traceability report	Traceability	"Generate HDL code" on page 21-109 must be enabled.
Generate resource utilization report	ResourceReport	"Generate HDL code" on page 21-109 and "Generated model" on page 21-93 must be enabled.
Generate high-level timing critical path report	CriticalPathEstimation	"Generate HDL code" on page 21-109 and "Generated model" on page 21-93 must be enabled.
Generate optimization report	OptimizationReport	"Generate HDL code" on page 21-109 and "Generated model" on page 21-93 must be enabled.
Generate model Web view	HDLGenerateWebview	"Generate HDL code" on page 21-109 must be enabled.

When you generate code, the Code Generation Report appears in a separate window.

Code Generation Report

The Code Generation Report is an HTML file that includes a **Summary**, a **Clock Summary**, a **Code Interface Report**, and one or more of these optional sections:

- Traceability report
- Resource utilization report
- High-level timing critical path report
- Optimization report
- Model web view

The **Summary** lists information about the model, the DUT, the date of code generation, and top-level coder settings. The **Summary** also lists model properties that have nondefault values.

The **Code Interface Report** shows the DUT input and output port names, data types, and bit widths. The report displays links corresponding to each input port and output port in your Simulink model.

Timing and Area Report

When you select **Generate resource utilization report**, HDL Coder adds a **Timing and Area Report** section to the Code Generation Report. This section of the report contains these subsections:

- **High-level Resource Report:** The **Summary** section summarizes multipliers, adders and subtractors, and registers consumed by the device under test (DUT).

The **Detailed Report** section contains more information on the resources that each subsystem uses. Wherever possible, the detailed report links back to corresponding blocks in your model. The **Detailed Report** section also contains:

- A **Registers** section that displays the total 1-bit register that is calculated as the sum of products over the bit widths of the registers and their frequency of occurrence.
- A **Static Shift operators** section and a **Dynamic Shift operators** section. A static shift is a shift value that is a mask constant. The shift logic does not change. A dynamic shift is a shift value specified as input to a block. Dynamic shifts are more resource-expensive than static shifts and should be used sparingly.
- **Target-Specific Report:** When you request target-specific code generation on the model, this subsection shows the resource utilization report.

Optimization Report

When you select **Generate optimization report**, HDL Coder adds an Optimization Report section, that contains these subsections:

- **Distributed Pipelining:** If a subsystem has the `DistributedPipelining` option enabled, this subsection displays comparative listings of registers before and after you apply the distributed pipelining transform.
- **Streaming and Sharing:** Summary and detailed information about the subsystems for which you specify sharing or streaming optimizations and the delay balancing summary.
- **Target Code Generation:** Displays target device summary and target mapping status for the subsystem that has floating-point data types.
- **Delay Balancing:** Provides detailed information on pipeline latency and phase delays added at the output ports to match delays along the parallel paths.
- **Adaptive Pipelining:** Displays status of the adaptive pipelining optimization, blocks for which pipeline registers are inserted, and the number of pipeline registers.
- **Hierarchy Flattening:** Displays hierarchy flattening status, subsystems that have `FlattenHierarchy` set to on or off, and the inline HDL files.

 “Traceability Report Limitations” on page 30-12

Even a relatively small model can generate hundreds of lines of HDL code. To identify the mapping between your source model and the generated HDL code more easily, use the traceability support in HDL Coder.

How Traceability Works

When you enable traceability support and generate HDL code for your model, the code generator creates and displays an HTML code generation report.

By default, the code generator uses the line-level style to generate a traceability report. The report generated by using this style contains hyperlinks for each line of HDL code to navigate between code and model. You can customize the traceability style to generate a comment-based report. This style contains hyperlinked comments above a block of code that correspond to a searchable tag for a certain block in your model. To learn more about the two traceability styles, see “Traceability style” on page 22-4.

You can generate reports for the root-level model or for subsystems, blocks, Stateflow charts, or MATLAB Function blocks. By default, HDL Coder generates a report for the top-level model.

After you generate the report, you can navigate from:

- Model to code: Select a certain block in your model and navigate to corresponding lines of HDL code in the report.
- Code to model: Select a line of code in the report and navigate to Simulink blocks corresponding to that line of code.

HDL Coder provides this two-way navigation or bidirectional traceability. With traceability support, you can:

- Verify that the generated code is as you expect. You can identify which model elements correspond to a line of code, and track code from different model elements that you have or have not reviewed.
- Verify whether the generated code meets the design requirements. You can assign the requirements to model elements and include the requirements as hyperlinks in the traceability report.

Generate Traceability Report

You can generate the report in the Configuration Parameters dialog box or at the command-line.

- 1 Enable generation of the traceability report.
 - In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select **Settings > Report Options**, and then select **Generate traceability report**.
 - At the command line, use `hdlset_param` to set the `Traceability` property on the model.

To learn more about this parameter, see “Generate traceability report” on page 22-3.
- 2 Specify the traceability style. To generate a line-level traceability report, leave this setting as the default. To generate a comment-based traceability report:
 - On the **HDL Code Generation > Report** pane, specify the **Traceability style**.
 - At the command line, use `hdlset_param` to specify the `TraceabilityStyle` property on the model.

To learn more about this parameter, see “Traceability style” on page 22-4.
- 3 Generate HDL code and the traceability report. Either select the DUT Subsystem and click **Generate HDL Code** on the Simulink Toolstrip, or run `makehdl` on the DUT Subsystem at the command line.

When HDL code generation is complete, the HTML code generation report appears in a new window.

Report Location

By default, HDL Coder writes the code generation report files to a folder in the `hdlsrc\html\` folder of the build folder. If you close the report, you can navigate to this folder to reopen the report.

Before generating code, you can customize the target folder that stores the HDL code and the report files.

- In the Configuration Parameters dialog box, specify the target folder by using the **Target** setting.
- At the command line, use the `TargetDirectory` property.

To learn how to specify this parameter, see “Folder” on page 17-4.

To keep your traceability report up to date, regenerate the HDL code and report after modifying the source model.

View the Traceability Report

In the HTML code generation report window, select the **Traceability Report** section. In the left pane of the report, click the names of **Generated Source Files** to view their contents in a MATLAB web browser window.

This figure shows a typical traceability report.

Eliminated / Virtual Blocks

Block Name	Comment
<S2>/x_in	Inport
<S2>/h_in1	Inport
<S2>/h_in2	Inport
<S2>/h_in3	Inport
<S2>/h_in4	Inport
<S2>/y_out	Outport
<S2>/delayed_xout	Outport

Traceable Simulink Blocks / Stateflow Objects / MATLAB Functions

Subsystem: [sfir_fixed/symmetric_fir](#)

Object Name	Code Location
<S2>/a1	symmetric_fir.vhd:208, 209, 210
<S2>/a2	symmetric_fir.vhd:212, 213, 214

The traceability report has several subsections that indicate the blocks or subsystems from which the code was generated:

- The **Eliminated / Virtual Blocks** section accounts for blocks that are untraceable because they are not included in the generated HDL code.
- The **Traceable Simulink Blocks / Stateflow Objects / MATLAB Functions** section provides a complete mapping between model elements and code.

If you assigned block requirements, you can see the requirements as hyperlinked comments in the traceability report. For more information, see “Include Requirements in Block Comments” on page 21-69.

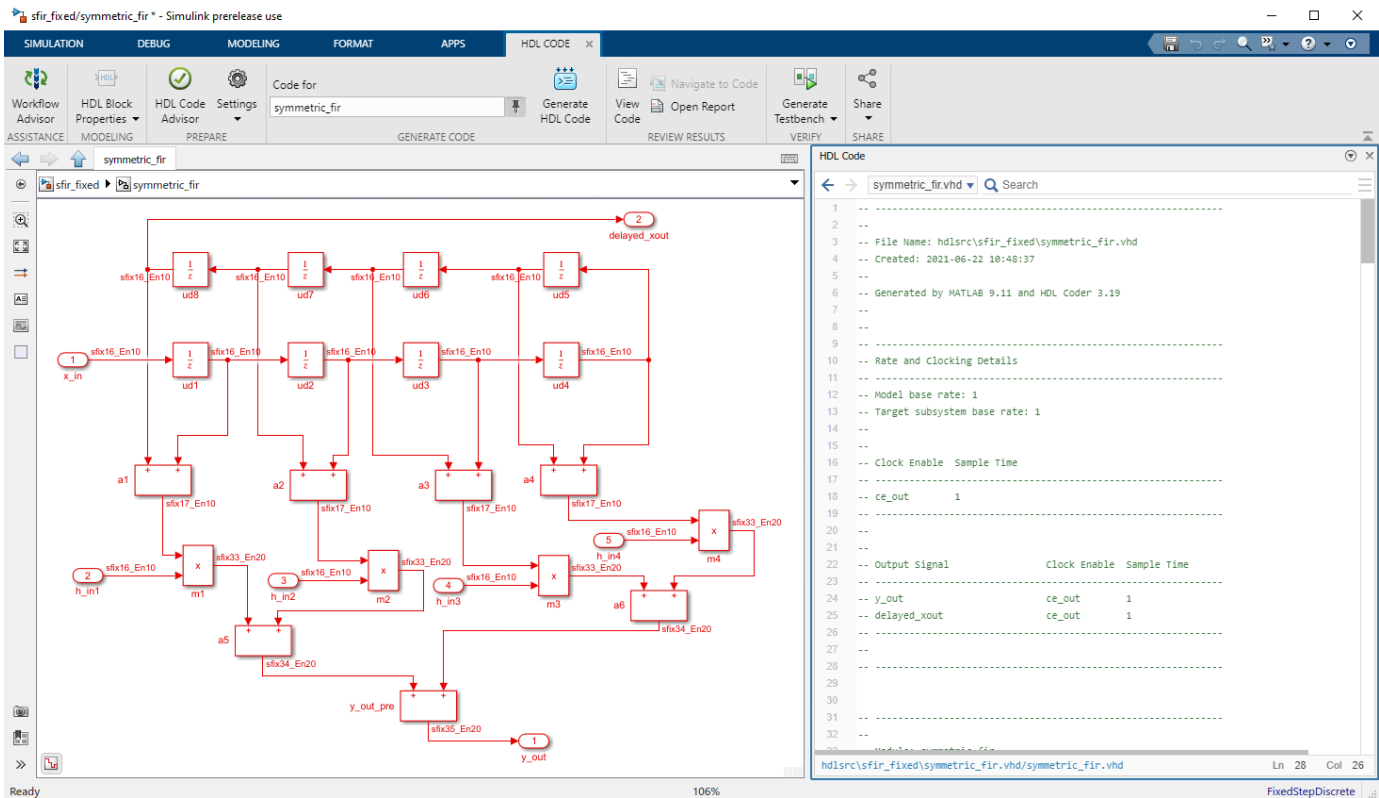

Traceability by Using Code View

By default, after you enable generation of the traceability report and generate HDL code for your model, the Code view displays the generated code to the right of your model. You can use the Code view to trace generated HDL code to your model and your model to the generated HDL code.

To manually open the Code view, open the **HDL Coder** app. On the Simulink toolstrip, click the **View Code** button. Select the file that you want to display by using the drop-down list at the top of the

Code view. You can dock or undock the Code view from the editor and minimize or expand the Code view using the down arrow in the upper right corner of the Code view. You can also use rich text capabilities, such as code folding and hiding comments.

This figure shows the Code view opened from the **View Code** button on the Simulink toolstrip in **HDL Coder** app.

Code-to-Model Navigation

To navigate from the HDL code to the model, follow either of these workflows:

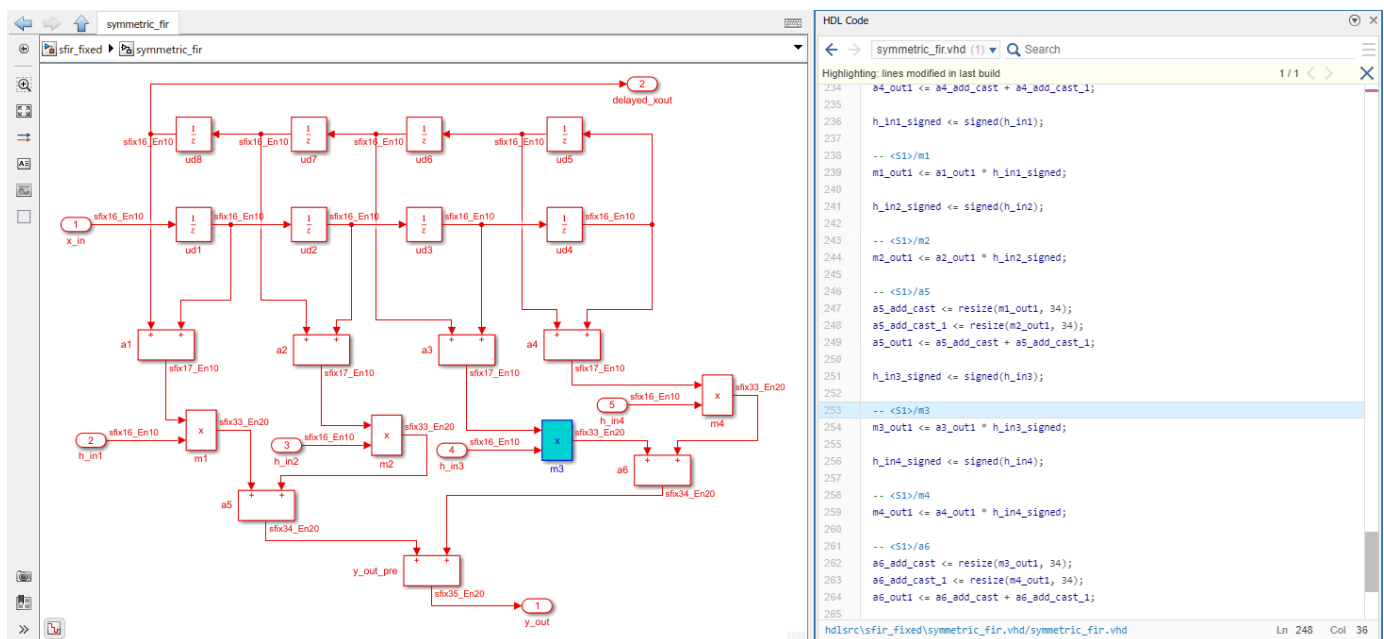

Use the Code view:

- 1 Navigate to the Code view by clicking the automatically generated Code view panel on the right or by clicking the **View Code** button on the Simulink toolstrip in the **HDL Coder** app.
- 2 In the Code view, click the line number hyperlink or code comment link to highlight the block that the code line traces to. You can trace lines of code to the model elements from which they were generated.

This figure shows how the generated HDL code on line 238 in `symmetric_fir.vhd` in the Code view maps to the block highlighted in blue in the model when the **Traceability style** is specified as **Line Level**.

This figure shows how the comment <S1>/m3 generated in HDL code on line 253 in symmetric_fir.vhd in the Code view maps to the block highlighted in blue in the model when the **Traceability style** is specified as Comment Based.

Use the Code Generation Report:

- 1 In the traceability report, on the **Code Location** column, click any hyperlink.
The code generator highlights that line of HDL code in the generated source file.
- 2 Select the link corresponding to that line of code in the source file.

The code generator opens a separate window that displays the highlighted Simulink block corresponding to that line of code.

This figure shows how to navigate from the HDL code to the model by using the traceability report when you specify Line Level as the **Traceability style**.

Traceable Simulink Blocks / Stateflow Objects / MATLAB Functions

Subsystem: [sfir_fixed/symmetric_fir](#)

Object Name	Code Location
<S2>/a1	symmetric_fir.vhd:208, 209, 210
<S2>/a2	symmetric_fir.vhd:212, 213, 214
<S2>/a3	symmetric_fir.vhd:216, 217, 218

```

206
207
208 a1_add_cast <= resize(ud8_out1, 17);
209 a1_add_cast_1 <= resize(ud1_out1, 17);
210 a1_out1 <= a1_add_cast + a1_add_cast_1;
211
212 a2_add_cast <= resize(ud7_out1, 17);
213 a2_add_cast_1 <= resize(ud2_out1, 17);
214 a2_out1 <= a2_add_cast + a2_add_cast_1;
215
    
```

In the traceability report, you see that HDL Coder generates line-level hyperlinks to the HDL code in the **Code Location** column. Click the link to highlight that line of code in the HDL source file, and then click the hyperlink for that line of code in the source file to highlight the corresponding block in your model.

This figure shows how to navigate from the HDL code to the model using the traceability report when you specify Comment Based as the **Traceability style**.

Traceable Simulink Blocks / Stateflow Objects / MATLAB Functions

Subsystem: [sfir_fixed/symmetric_fir](#)

Object Name	Code Location
<S2>/a1	symmetric_fir.vhd:216
<S2>/a2	symmetric_fir.vhd:221
<S2>/a3	symmetric_fir.vhd:226

```

214
215
216 -- <S2>/a1
217 a1_add_cast <= resize(ud8_out1, 17);
218 a1_add_cast_1 <= resize(ud1_out1, 17);
219 a1_out1 <= a1_add_cast + a1_add_cast_1;
220
221 -- <S2>/a2
222 a2_add_cast <= resize(ud7_out1, 17);
223 a2_add_cast_1 <= resize(ud2_out1, 17);
224 a2_out1 <= a2_add_cast + a2_add_cast_1;
225
    
```

In the traceability report, when you select a hyperlink in the **Code Location** column, you see that HDL Coder highlights a hyperlinked comment [<S2>/a1](#) in the HDL code. When you click the hyperlinked comment in the HDL source file, the code generator highlights the corresponding block [a1](#) in your model.

Model-to-Code Navigation

Use model-to-code traceability to select a component at any level of the model and view the code references to that component in the traceability report. For tracing, you can select these objects:

- Subsystem
- Simulink block
- MATLAB Function block
- Stateflow chart, or these elements of a Stateflow chart:
 - State
 - Transition
 - Truth table
 - MATLAB function inside a chart

You can navigate from a certain block in the model to the HDL code generated for that block by using any of these approaches.

- Click that block in the model. The Code view highlights the code for the block and scrolls to the highlighted code lines.

This figure shows an example of how a block highlighted in the model maps to the corresponding highlighted HDL code in the script `symmetric_fir.vhd` when the **Traceability style** is specified as **Line Level**.

The screenshot displays a Simulink model window titled 'symmetric_fir' on the left and an HDL Code window titled 'symmetric_fir.vhd (10)' on the right. The model shows a complex signal flow with blocks labeled 'sfix16_En10', 'ud8', 'ud7', 'ud6', 'ud5', 'ud4', 'a1', 'a2', 'a3', 'a4', 'a5', 'a6', 'm1', 'm2', 'm3', 'm4', 'm3', 'a6', 'y_out_pre', and 'y_out'. A block labeled 'ud3' is highlighted in blue. The HDL code window shows the corresponding code for 'ud3', with lines 129-132 highlighted in purple. The code is as follows:

```

129 IF enb = '1' THEN
130     ud2_out1 <= ud1_out1;
131 END IF;
132 END IF;
133 END PROCESS ud2_process;
134
135
136 ud3_process : PROCESS (clk, reset)
137 BEGIN
138 IF reset = '1' THEN
139     ud3_out1 <= to_signed(16#0000#, 16);
140 ELSEIF clk'EVENT AND clk = '1' THEN
141     IF enb = '1' THEN
142         ud2_out1 <= ud2_out1;
143     END IF;
144 END IF;
145 END PROCESS ud3_process;
146
147
148 ud4_process : PROCESS (clk, reset)
149 BEGIN
150 IF reset = '1' THEN
151     ud4_out1 <= to_signed(16#0000#, 16);
152 ELSEIF clk'EVENT AND clk = '1' THEN
153     IF enb = '1' THEN
154         ud4_out1 <= ud3_out1;
155     END IF;
156 END IF;
157 END PROCESS ud4_process;
  
```

This figure shows an example of how a block highlighted in the model maps to the corresponding highlighted comment in the HDL code in the script `symmetric_fir.vhd` when the **Traceability style** is specified as **Comment Based**.

- Select that block and click **Navigate to Code** on the **HDL Code** tab.
- Right-click that block in your Simulink model and select **HDL Code > Navigate to Code**.

This figure shows the model-to-code navigation for both line-level and comment-based traceability style.

```

207
208 a1_add_cast <= resize(ud8_out1, 17);
209 a1_add_cast_1 <= resize(ud1_out1, 17);
210 a1_out1 <= a1_add_cast + a1_add_cast_1;
211
212 a2_add_cast <= resize(ud7_out1, 17);
213 a2_add_cast_1 <= resize(ud2_out1, 17);
214 a2_out1 <= a2_add_cast + a2_add_cast_1;
215
    
```

**HDL Source Code
(Line-Level Traceability)**

```

214
215
216 -- <S2>/a1
217 a1_add_cast <= resize(ud8_out1, 17);
218 a1_add_cast_1 <= resize(ud1_out1, 17);
219 a1_out1 <= a1_add_cast + a1_add_cast_1;
220
221 -- <S2>/a2
222 a2_add_cast <= resize(ud7_out1, 17);
223 a2_add_cast_1 <= resize(ud2_out1, 17);
224 a2_out1 <= a2_add_cast + a2_add_cast_1;
225
    
```

**HDL Source Code
(Comment-Based Traceability)**

If you use **Line Level** as the **Traceability style** and navigate from the model to the HDL code, the traceability report highlights all lines of HDL code corresponding to that block.

If you use Comment Based as the **Traceability style** and navigate from the model to the HDL code, the traceability report highlights the traceable block comment in the HDL code.

Traceability Report Limitations

- If a block name in your model contains a single quote ('), code-to-model and model-to-code traceability are disabled for that block.
- If an asterisk (*) in a block name in your model causes a name-mangling ambiguity relative to other names in the model, code-to-model highlighting and model-to-code highlighting are disabled for that block. This is most likely to occur if an asterisk precedes or follows a slash (/) in a block name or appears at the end of a block name.
- If a block name in your model contains the character `ÿ` (`char(255)`), code-to-model highlighting and model-to-code highlighting are disabled for that block.
- If you use certain subsystem types, the Subsystem block is not traceable from the model to the HDL code at the subsystem level. It is possible that you can trace individual blocks within the Subsystem block. You cannot trace from the model to the code for these subsystem types:
 - Virtual
 - Masked
 - Nonvirtual for which code has been optimized away
- Traceability does not support Model Reference as the top-level Subsystem block.

Web View of Model in Code Generation Report

In this section...
“Generate HTML Code Generation Report with Model Web View” on page 30-13
“Model Web View Limitations” on page 30-14

To review and analyze the generated code, it is helpful to navigate between the code and model. If you have a Simulink Report Generator license, you can include a Web view of the model within the HTML code generation report. You can then share your model and generated code outside of the MATLAB environment. When you generate the report, the Web view includes the block diagram attributes displayed in the Simulink Editor, such as, block sorted execution order, signal properties, and port data types. You can display the generated Web views in a supported Web browser. See “Web Views” (Simulink Report Generator) for browser requirements and to read more about Web views.

Generate HTML Code Generation Report with Model Web View

This example shows how to create an HTML code generation report which includes a Web view of the model diagram.

- 1 Open the mcombo model.
- 2 Open the **Configuration Parameters** dialog box or **Model Explorer** and navigate to the **HDL Code Generation** pane.
- 3 Under **Code generation report**, select **Generate model Web view**.
- 4 Click the **Generate** button.

After building the model and generating code, the code generation report opens in a MATLAB Web browser.

- 5 In the left navigation pane, select a source code file. The corresponding source code is displayed in the right pane and includes hyperlinks.

- 6 Click a link in the code. The model Web view displays and highlights the corresponding block in the model.
- 7 To highlight the generated code for a block in your model, click the block. The corresponding code is highlighted in the source code pane.
- 8 To go back to the code generation report for the top model, at the top of the left navigation pane, click the **Back** button until the top model's report is displayed.

For more information about exploring a model in a Web view, see "Explore Web Views" (Simulink Report Generator).

Model Web View Limitations

The HTML code generation report includes the following limitations when using the model Web view:

- Code is not generated for virtual blocks. In the model Web view of the code generation report, when tracing between the model and the code, when you click a virtual block, it is highlighted yellow.

- In the model Web view, you cannot open a referenced model diagram by double-clicking the Model block in the top model. Instead, open the code generation report for the referenced model by using the drop-down menu at the top of the report.
- Stateflow truth tables, events, and links to library charts are not supported in the model Web view.
- Searching in the code generation report does not find or highlight text in the model Web view.
- If you navigate from the actual model diagram (not the model Web view in the report), to the source code in the HTML code generation report, the model Web view is disabled and not visible. To enable the model Web view, open the report again.
- For a subsystem build, the traceability hyperlinks of the root level inport and outport blocks are disabled.
- “Traceability Limitations” (Embedded Coder) that apply to tracing between the code and the actual model diagram.

Generate Code with Annotations or Comments

In this section...

“Simulink Annotations” on page 30-16

“Signal Descriptions” on page 30-16

“Text Comments” on page 30-16

“Requirements Comments and Hyperlinks” on page 30-17

The following sections describe how to use the HDL Coder software to add text annotations to generated code, in the form of model annotations, text comments or requirements comments.

Simulink Annotations

You can enter text directly on the block diagram as Simulink annotations. HDL Coder renders text from Simulink annotations as plain text comments in generated code. The comments are generated at the same level in the model hierarchy as the subsystem(s) that contain the annotations, as if they were Simulink blocks.

For Constant blocks, to reflect the annotations as comments in the HDL code, clear the “Minimize Intermediate Signals” on page 21-59 check box and set “Traceability style” on page 22-4 to **Comment Based**.

See “Annotate Models” for general information on annotations.

Signal Descriptions

You can provide a description for the signals in your Simulink model. The generated HDL code displays these descriptions as comments above the signal declaration statements. To specify a description for the signal, right-click the signal, and select **Properties** to open the Signal Properties dialog box. Then, select the **Documentation** tab, and in the **Description** section, enter a description for the signal. For the signal description, use ASCII characters because non-ASCII characters in the generated code can potentially interfere with downstream synthesis and lint tools. In some cases, due to certain optimizations that act on the signals, the generated code may not translate all signal descriptions to HDL comments or may create replicas of HDL comments for certain signal descriptions.

Text Comments

You can enter text comments at any level of the model by placing a DocBlock at the desired level and entering text comments. HDL Coder renders text from the DocBlock in generated code as plain text comments. The comments are generated at the same level in the model hierarchy as the subsystem that contains the DocBlock.

Set the **Document type** parameter of the DocBlock to **Text**. HDL Coder does not support the HTML or RTF options.

See DocBlock for general information on the DocBlock.

Requirements Comments and Hyperlinks

You can assign requirement comments to blocks.

If your model includes requirements comments, you can choose to render the comments in one of the following formats:

- *Text comments in generated code:* To include requirements as text comments in code, use the defaults for **Include requirements in block comments** (on) and **Generate traceability report** (off) in the Configuration Parameters dialog box.

If you generate code from the command line, set the `Traceability` and `RequirementComments` properties. This code shows the text requirements comments generated for a Gain block from the `mcombo` model:

```
open_system('mcombo')
makehdl(gcb, 'Traceability', 'off', 'RequirementComments', 'on');

BEGIN
    In1_signed <= signed(In1);

    --
    -- Block requirements for <S10>/Gain
    -- 1. Gain Requirements Sect 1
    -- 2. Gain Requirements Sect 2
    Gain_gainparam <= to_signed(16384, 16);

    Gain_out1 <= resize(In1_signed(15 DOWNT0 0) & '0'

    Out1 <= std_logic_vector(Gain_out1);

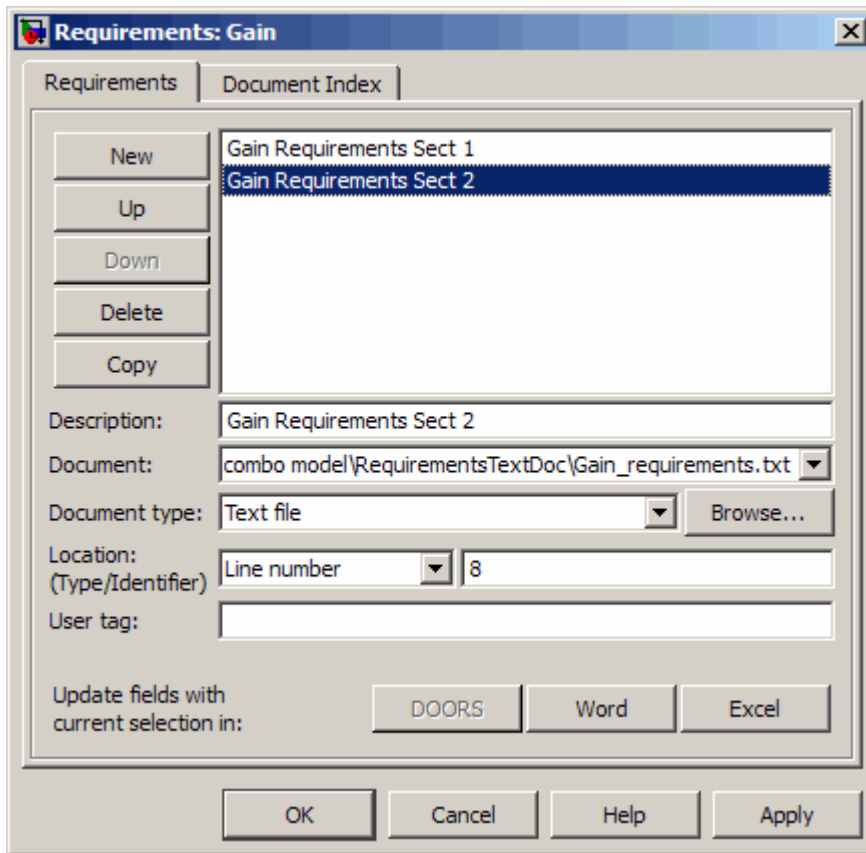

END rtl;
```

- *Hyperlinked comments:* To include requirements comments as hyperlinked comments in an HTML code generation report, select both **Generate traceability report** and **Include requirements in block comments** in the Configuration Parameters dialog box.

If you generate code from the command line, set the `Traceability` and `RequirementComments` properties:

```
makehdl(gcb, 'Traceability', 'on', 'RequirementComments', 'on');
```

The comments include links back to a requirements document associated with the block and to the block within the original model. For example, the following figure shows two requirements links assigned to a Gain block. The links point to sections of a text requirements file.

The following code shows hyperlinked requirements comments generated for the Gain block.

```

BEGIN
  In1_signed <= signed(In1);

  -- <S10>/Gain
  --
  --
  -- Block requirements for <S10>/Gain
  -- 1. Gain Requirements Sect 1
  -- 2. Gain Requirements Sect 2
  Gain_gainparam <= to_signed(16384, 16);

  Gain_out1 <= resize(In1_signed(15 DOWNT0 0) & '0'
  Out1 <= std_logic_vector(Gain_out1);

END rtl;

```

Check Your Model for HDL Compatibility

This example shows how to check whether a subsystem or model is compatible for HDL code generation by using the HDL compatibility checker. The HDL compatibility checker examines the specified system for compatibility problems, such as use of unsupported blocks, illegal data type usage, and so on. The HDL compatibility checker generates an HDL Code Generation Check Report. The report is stored in the target `hdlsrc` folder. The report file naming convention is `system_report.html`, where `system` is the name of the subsystem or model that is passed to the HDL compatibility checker. The HDL Code Generation Check Report is displayed in a MATLAB™ web browser window. Each entry in the HDL Code Generation Check Report has hyperlinks to the block or subsystem that is not compatible for HDL code generation.

Open this Simulink™ model that has a Product block inside a DUT Subsystem. The inputs to the block are a mix of double and integer data types.

```
load_system('hdlcoder_product_mixed_types')
open_system('hdlcoder_product_mixed_types/DUT')
```

To check whether the DUT Subsystem is compatible for HDL code generation, run the compatibility checker. To run the checker from the command line, use the `checkhdl` function. To learn more about the `checkhdl` function, see `checkhdl`.

```
checkhdl('hdlcoder_product_mixed_types/DUT', ...
         'TargetDirectory','C:/HDL_Checks/hdlsrc')
```

```
### Running HDL checks on the model 'hdlcoder_product_mixed_types'.
### Begin compilation of the model 'hdlcoder_product_mixed_types'...
### Creating HDL Code Generation Check Report file:///home/jdirner/Documents/MATLAB/Examples/hdl
### HDL check for 'hdlcoder_product_mixed_types' complete with 2 errors, 0 warnings, and 0 messa
```

HDL check for 'hdlcoder_product_mixed_types' complete with 1 errors, 1 warnings, and 0 messages.

The following table describes blocks for which errors, warnings or messages were reported.

Simulink Blocks and resources	Level	Description
hdlcoder_product_mixed_types/DUT/Product	Error	Unhandled mixed double, single, and non-real datatypes at ports of block.
hdlcoder_product_mixed_types/DUT	Warning	Signals of type 'Double' will not generate synthesizable HDL. Consider enabling native floating-point mode and retyping all 'Double' typed signals to 'Single' to generate synthesizable code. More information

Click the [hdlcoder_product_mixed_types/DUT/Product](#) link to highlight the Product block inside the DUT Subsystem.

To run the compatibility checker from the UI:

- 1 Open the Configuration Parameters dialog box or the Model Explorer. Select the **HDL Code Generation** pane.
- 2 From the **Generate HDL for** dropdown, select the DUT Subsystem you want to check.
- 3 Click the **Run Compatibility Checker** button.

For a Subsystem that passes the HDL compatibility check, the HDL Code Generation Check Report contains a hyperlink to that subsystem.

Display Blocks for HDL Code Generation in Library Browser

The `hdlLib` function displays the blocks that are compatible with HDL code generation in the Library Browser in standalone mode. If you construct models by using blocks from this Library Browser, your models are compatible with HDL code generation.

In the Library Browser, parameter settings for blocks are compatible with HDL code generation, and therefore can differ from the default settings.

To display the blocks that are compatible with HDL code generation:

- In the **Apps** tab, select **HDL Coder**. In the **HDL Code** tab, select **HDL Block Properties > Open HDL Block Library**.
- Alternatively, at the command prompt, enter:

```
hdlLib
```

The Library Browser opens in standalone mode showing blocks compatible with HDL code generation.

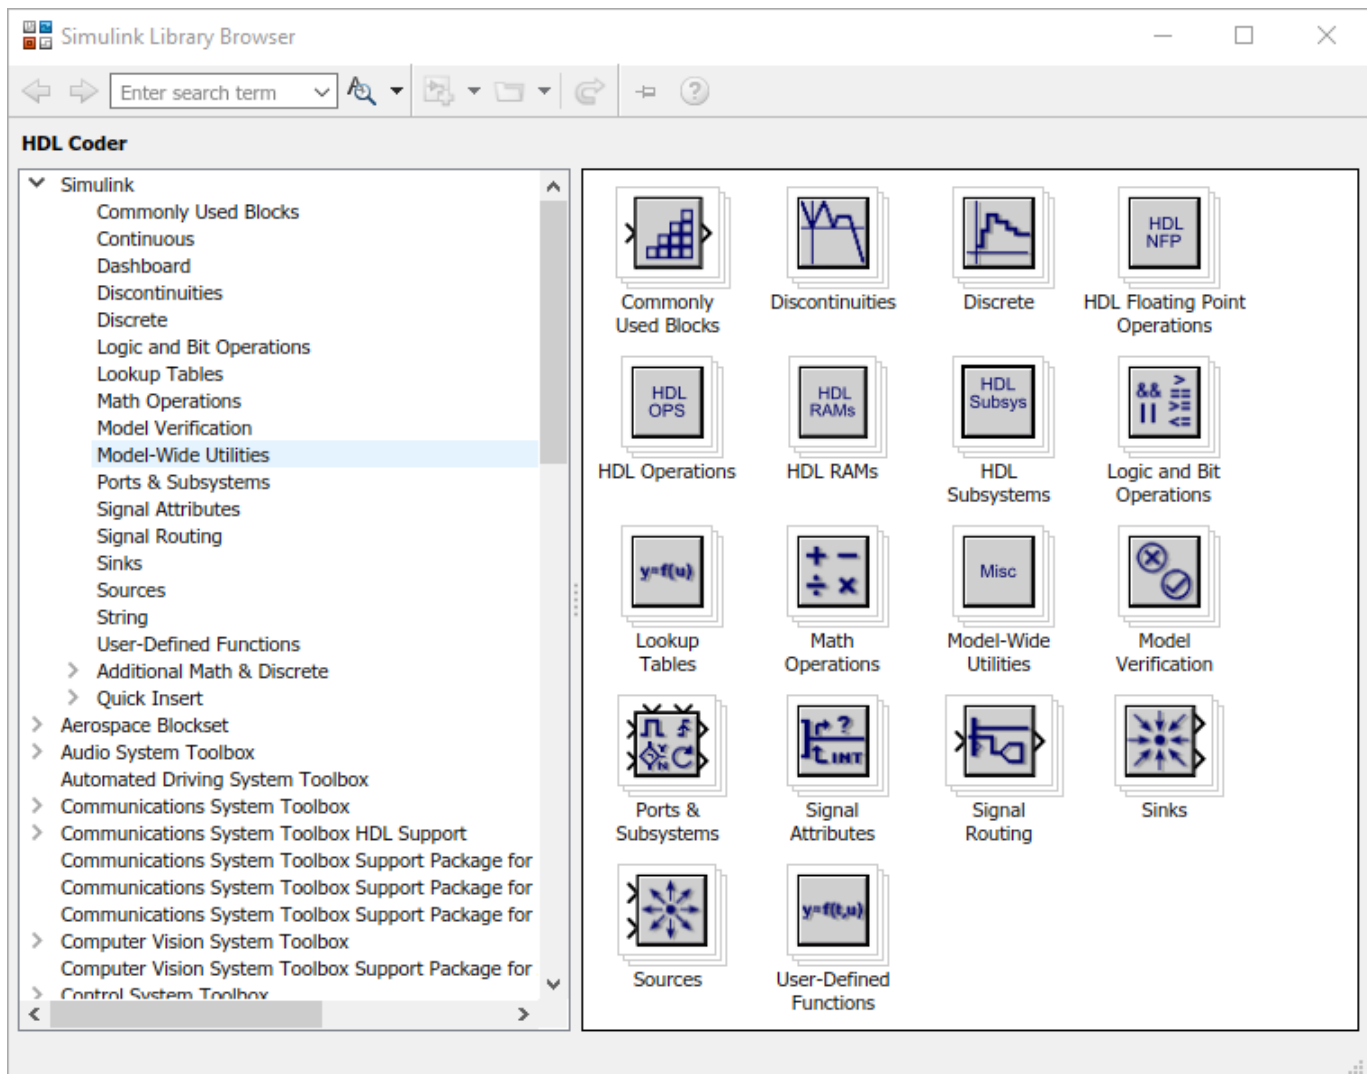

You can drag the blocks from the Library Browser into your model.

If you close and reopen the Library Browser in the same MATLAB session, you continue to see only the blocks that are compatible with HDL code generation.

To reset the Library Browser to display all blocks, regardless of HDL code generation compatibility, click the  button.

Alternatively, at the command prompt, enter:

```
hdlLib('off')
```

To change the Library Browser to display only those blocks that are compatible with HDL code generation, click the  button.

Generate Table of Supported Blocks

To generate an HTML table that lists the blocks that are compatible with HDL Code generation:

- 1 At the command prompt, enter:

```
hdllib('html')
```

hdllib creates the `hdlsupported` library and these HTML reports:

```
### HDL supported block list hdlblklist.html  
### HDL implementation list hdlsupported.html
```

- 2 To see the generated list of blocks, click the `hdlblklist.html` link.

Trace Code Using the Mapping File

Note This section refers to generated VHDL entities or Verilog modules generically as “entities.”

A mapping file is a text report file generated by `makehdl`. Mapping files are generated as an aid in tracing generated HDL entities back to the corresponding systems in the model.

A mapping file shows the relationship between systems in the model and the VHDL entities or Verilog modules that were generated from them. A mapping file entry has the form

```
path --> HDL_name
```

where *path* is the full path to a system in the model and *HDL_name* is the name of the VHDL entity or Verilog module that was generated from that system. The mapping file contains one entry per line.

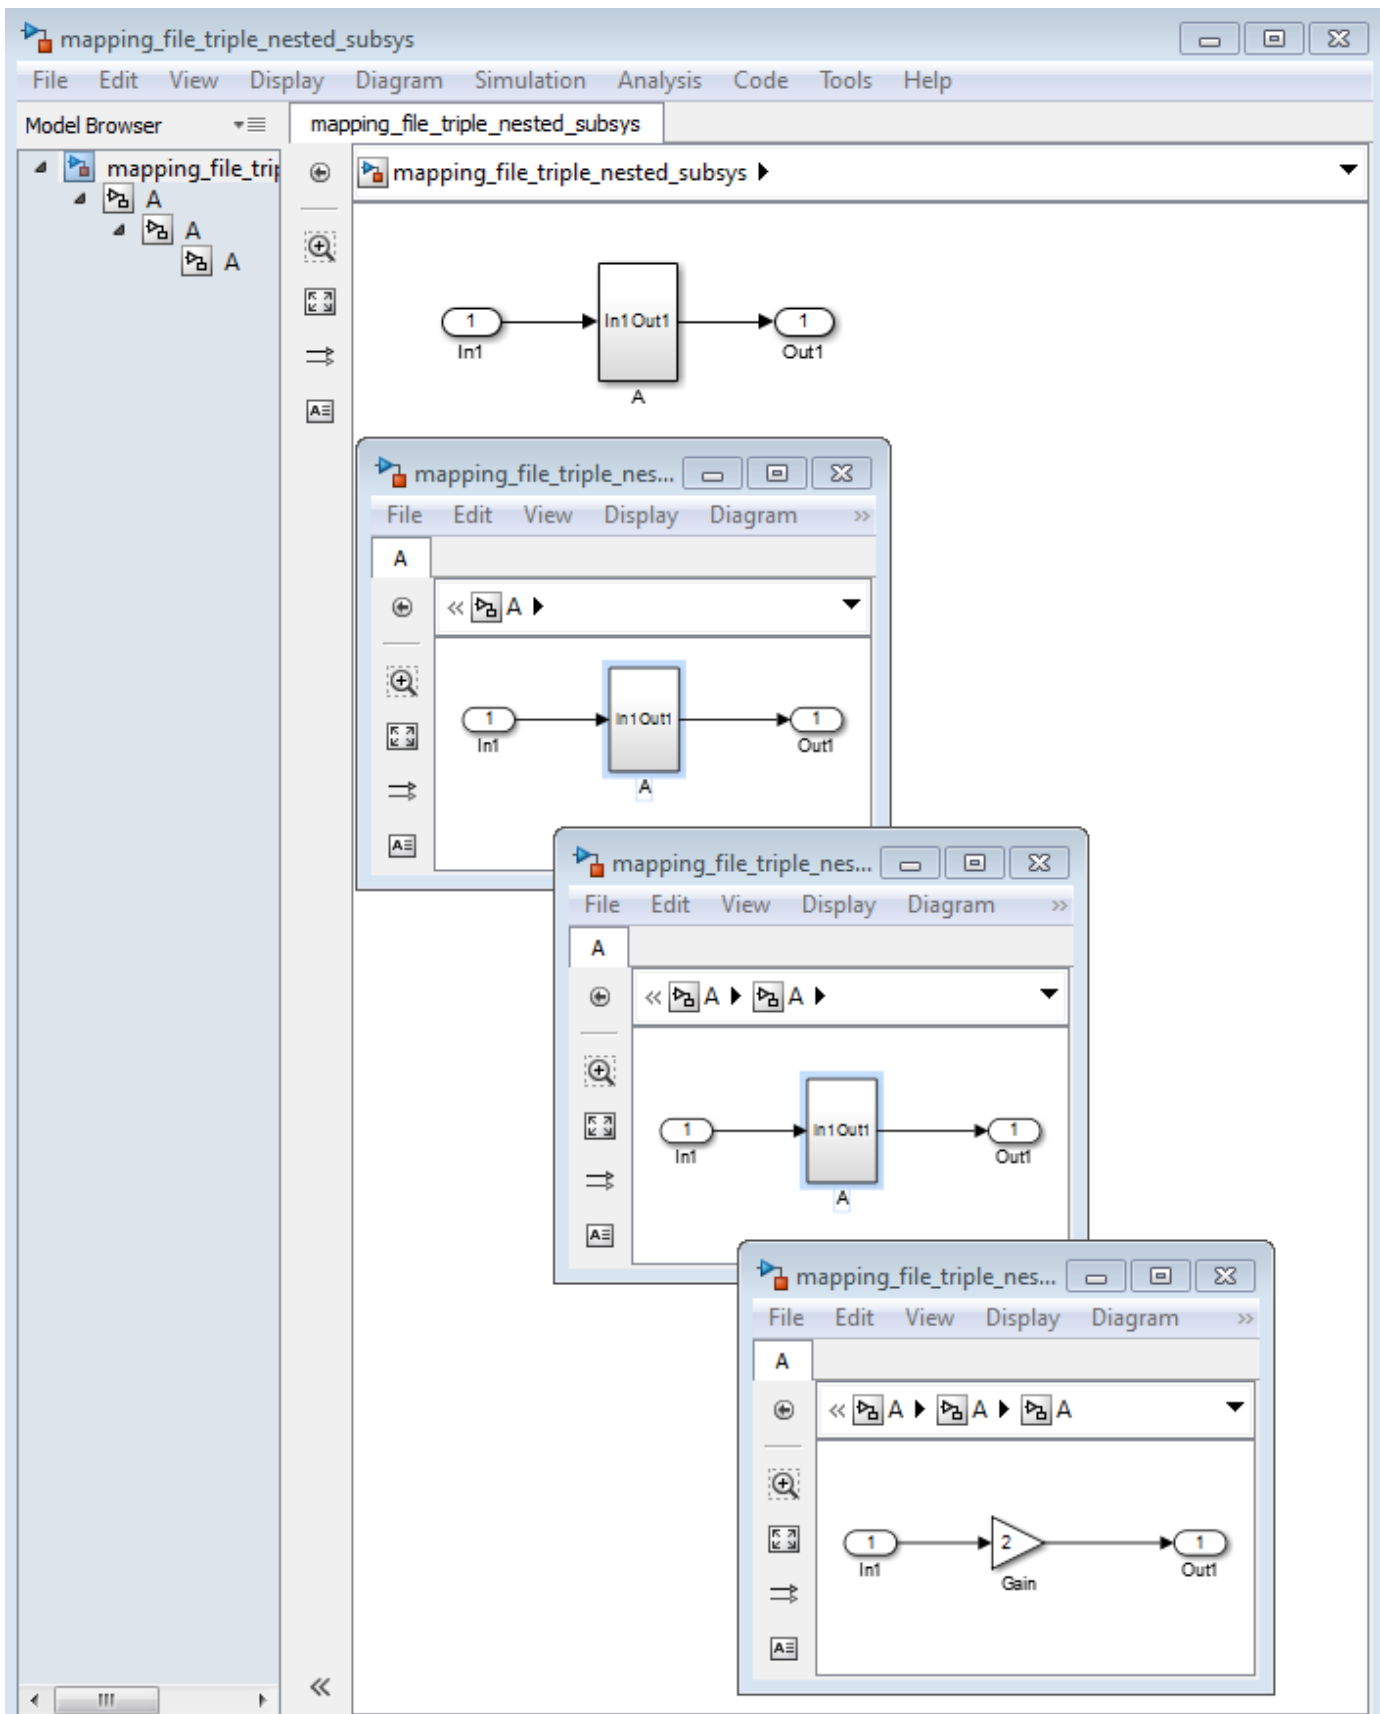

In simple cases, the mapping file may contain only one entry. For example, the `symmetric_fir` subsystem of the `sfir_fixed` model generates the following mapping file:

```
sfir_fixed/symmetric_fir --> symmetric_fir
```

Mapping files are more useful when HDL code is generated from complex models where multiple subsystems generate many entities, and in cases where conflicts between identically named subsystems are resolved by HDL Coder.

If a subsystem name is unique within the model, HDL Coder simply uses the subsystem name as the generated entity name. Where identically named subsystems are encountered, the coder attempts to resolve the conflict by appending a postfix string (by default, `'_entity'`) to the conflicting subsystem. If subsequently generated entity names conflict in turn with this name, incremental numerals (`1, 2, 3, . . . n`) are appended.

As an example, consider the model shown in the following figure. The top-level model contains subsystems named A nested to three levels.

When code is generated for the top-level subsystem A, `makehdl` works its way up from the deepest level of the model hierarchy, generating unique entity names for each subsystem.

```
makehdl('mapping_file_triple_nested_subsys/A')  
### Working on mapping_file_triple_nested_subsys/A/A/A as A_entity1.vhd  
### Working on mapping_file_triple_nested_subsys/A/A as A_entity2.vhd  
### Working on mapping_file_triple_nested_subsys/A as A.vhd  
  
### HDL Code Generation Complete.
```

The following example lists the contents of the resultant mapping file.

```
mapping_file_triple_nested_subsys/A/A/A --> A_entity1  
mapping_file_triple_nested_subsys/A/A --> A_entity2  
mapping_file_triple_nested_subsys/A --> A
```

Given this information, you can trace a generated entity back to its corresponding subsystem by using the `open_system` command, for example:

```
open_system('mapping_file_triple_nested_subsys/A/A')
```

Each generated entity file also contains the path for its corresponding subsystem in the header comments at the top of the file, as in the following code excerpt.

```
-- Module: A_entity2  
-- Simulink Path: mapping_file_triple_nested_subsys/A  
-- Hierarchy Level: 0
```

Add or Remove the HDL Configuration Component

In this section...
“What Is the HDL Configuration Component?” on page 30-27
“Adding the HDL Coder Configuration Component To a Model” on page 30-27
“Removing the HDL Coder Configuration Component From a Model” on page 30-27

What Is the HDL Configuration Component?

The HDL configuration component is an internal data structure that HDL Coder creates and attaches to a model. This component lets you view the **HDL Code Generation** pane in the Configurations Parameters dialog box and set HDL code generation options. Normally, you do not need to interact with the HDL configuration component. However, there are situations where you might want to add or remove the HDL configuration component:

- A model that was created on a system that did not have HDL Coder installed does not have the HDL configuration component attached. In this case, you might want to add the HDL configuration component to the model.
- If a previous user removed the HDL configuration component, you might want to add the component back to the model.
- If a model will be running on some systems that have HDL Coder installed, and on other systems that do not, you might want to keep the model consistent between both environments. If so, you might want to remove the HDL configuration component from the model.

Adding the HDL Coder Configuration Component To a Model

To add the HDL Coder configuration component to a model, In the Simulink Toolstrip, on the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. On the **HDL Code** tab, select **Settings > Add HDL Coder Configuration to Model**.

Removing the HDL Coder Configuration Component From a Model

To remove the HDL Coder configuration component from a model, on the **HDL Code** tab, select **Settings > Remove HDL Configuration from Model**.

HDL Coding Standards

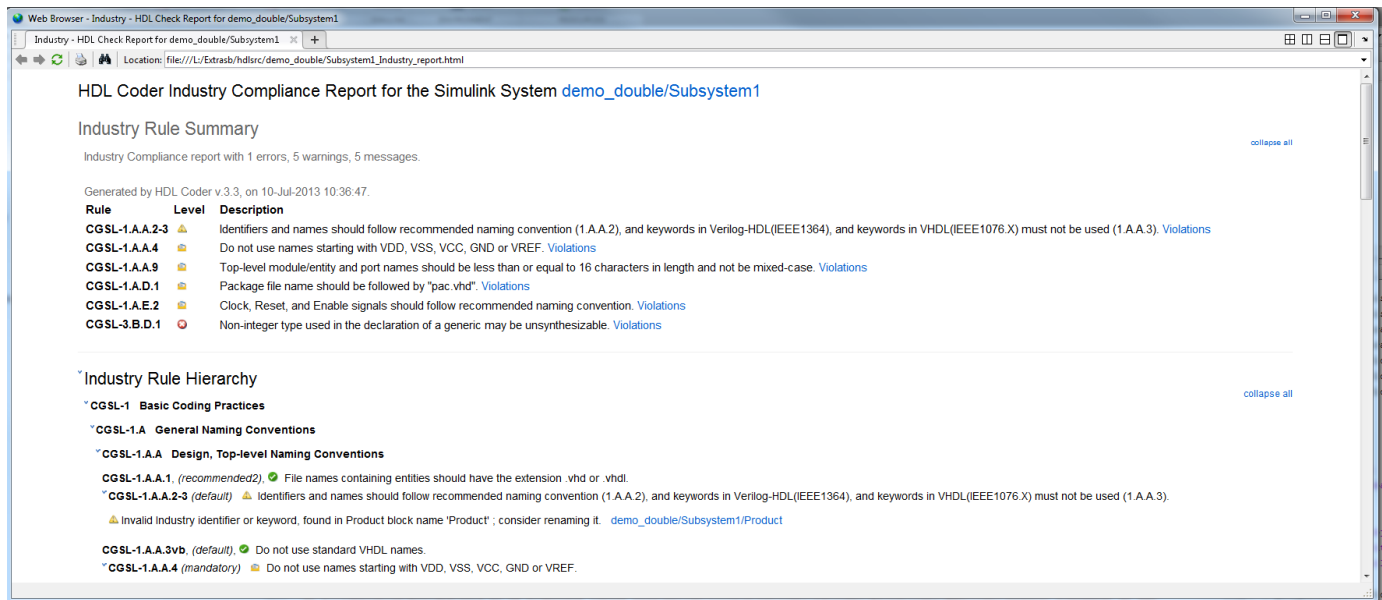

- “HDL Coding Standard Report” on page 31-2
- “HDL Coding Standards” on page 31-4
- “Generate HDL Coding Standard Report from Simulink” on page 31-5
- “Basic Coding Practices” on page 31-7
- “RTL Description Rules and Checks” on page 31-17
- “RTL Design Methodology Guidelines” on page 31-41
- “Generate HDL Lint Tool Script” on page 31-45
- “Cascaded Conditional Region Variable Assignments” on page 31-47

HDL Coding Standard Report

The HDL coding standard report shows how your generated HDL code conforms to an industry coding standard you select when generating code.

The report can contain errors, warnings, and messages. Errors and warnings in the report link to elements in your original design so you can fix problems, then regenerate code. Messages show where HDL Coder automatically corrected the code to conform to the coding standard.

The report also lists the rules in the coding standard with which the generated code complies. You can inspect the report to see which coding standard rules the coder checks.

To learn more about HDL coding standards, see "HDL Coding Standards" on page 31-4.

Rule Summary

The rule summary section shows the total numbers of errors, warnings, and messages, and lists the corresponding rules. Each rule shown in the summary links to the rule in the detailed rule hierarchy section.

Rule Hierarchy

The rule hierarchy section lists every rule HDL Coder checks, within three categories:

- Basic coding practices, including rules for names, clocks, and reset.
- RTL description techniques, including rules for combinatorial and synchronous logic, operators, and finite state machines.
- RTL design methodology guidelines, including rules for ports, function libraries, files, and comments.

If your HDL code does not conform to a specific rule, the rule shows either the automated correction, or a link to the original design element causing the error or warning. When you click a link, the

design opens with the design element highlighted. You can fix the problem in your design, then regenerate code.

Rule and Report Customization

You can configure the report so that it does not display passing rules by using the `ShowPassingRules` property of the HDL coding standard customization object. You can also disable or customize coding standard rules. See HDL Coding Standard Customization.

How to Fix Warnings and Errors

To learn more about warnings and errors you can fix by modifying your design, see:

- “Basic Coding Practices” on page 31-7
- “RTL Description Rules and Checks” on page 31-17
- “RTL Design Methodology Guidelines” on page 31-41

HDL Coding Standards

Industry coding standards recommend using certain HDL coding guidelines. HDL Coder generates code that follows industry standard rules and generates a report that shows how well your generated HDL code conforms to industry coding standards. See “HDL Coding Standard Report” on page 31-2.

HDL Coder checks for conformance of your Simulink model or MATLAB algorithm to the HDL coding standard rules.

The coder can also generate third-party lint tool scripts to use to check your generated HDL code. The industry standard rules fall under the following three sections:

- Section 1: “Basic Coding Practices” on page 31-7.
- Section 2: “RTL Description Rules and Checks” on page 31-17.
- Section 3: “RTL Design Methodology Guidelines” on page 31-41.

When generating a coding standard report, HDL Coder adds a prefix to the rules. The rule prefix depends on whether you generate the report from MATLAB or Simulink. The rule prefix for MATLAB is CGML and for Simulink is CGSL.

To fix errors or warnings related to these rules, update your model design. You can customize some of the coding standard rules. See HDL Coding Standard Customization.

HDL coding standards provide language-specific code usage rules to help you generate more efficient, portable, and synthesizable HDL code, such as coding guidelines for:

- Names
- Ports, reset, and clocks
- Combinatorial and synchronous logic
- Finite state machines
- Conditional statements and operators

Generate HDL Coding Standard Report from Simulink

In this section...

“Using the Configuration Parameters Dialog Box” on page 31-5

“Using the Command Line” on page 31-5

You can generate an HDL coding standard report that shows how well your generated code follows industry standards. You can optionally customize the coding standard report and the coding standard rules.

Using the Configuration Parameters Dialog Box

To generate an HDL coding standard report using the Configuration Parameters dialog box:

- 1 To open the Configuration Parameters dialog box, in the Apps gallery, click **HDL Coder**. The **HDL Code** tab in the Simulink toolstrip appears. In the **Prepare** section, click **Settings**.
- 2 In the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box, select the **Coding standards** tab.
- 3 For the **HDL coding standard** parameter, select **Industry** and click **Apply**.
- 4 Optionally, use the other options in the **Coding standards** tab to customize the coding standard rules and click **Apply**.
- 5 You can then generate HDL code by clicking the **Generate HDL Code** button in the **HDL Code** tab in the Simulink toolstrip.

After you generate code, the message window shows a link to the HTML compliance report. To open the report, click the report link.

Using the Command Line

To generate an HDL coding standard report using the command-line interface, set the `HDLCodingStandard` property to `Industry` by using `makehdl` or `hdlset_param`.

For example, to generate HDL code and an HDL coding standard report for a subsystem, `sfir_fixed/symmetric_sfir`, enter the following command:

```
makehdl('sfir_fixed/symmetric_fir','HDLCodingStandard','Industry')

### Generating HDL for 'sfir_fixed/symmetric_fir'.
### Starting HDL check.
### HDL check for 'sfir_fixed' complete with 0 errors, 0 warnings, and 0 messages.
### Begin VHDL Code Generation for 'sfir_fixed'.
### Working on sfir_fixed/symmetric_fir as hdlsrc\sfir_fixed\symmetric_fir.vhd
### Industry Compliance report with 4 errors, 18 warnings, 5 messages.
### Generating Industry Compliance Report symmetric_fir_Industry_report.html
### Generating SpyGlass script file sfir_fixed_symmetric_fir_spyglass.prj
### HDL code generation complete.
```

To open the report, click the report link.

You can customize the coding standard report and coding standard rule checks by specifying an HDL coding standard customization object. For example, for a subsystem, `sfir_fixed/`

`symmetric_sfir`, you can create an HDL coding standard customization object, `cso`, set the maximum if-else statement chain length to 5 by using the `IfElseChain` property, and generate code:

```
cso = hdlcoder.CodingStandard('Industry');  
cso.IfElseChain.length = 5;  
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard', 'Industry', ...  
        'HDLCodingStandardCustomizations', cso)
```

Basic Coding Practices

In this section...
"1.A General Naming Conventions" on page 31-8
"1.B General Guidelines for Clocks and Resets" on page 31-13
"1.C Guidelines for Initial Reset" on page 31-14
"1.D Guidelines for Clocks" on page 31-15
"1.F Guidelines for Hierarchical Design" on page 31-16

HDL Coder conforms to the following naming conventions and basic coding guidelines and checks for modeling constructs that violate these rules. HDL Coder reports potential rule violations in the HDL coding standard report. To avoid these violations, see the rule recommendations.

1.A General Naming Conventions

1.A.A Design and Top-Level Naming Conventions

Rule / Severity	Message	Problem	Recommendations
1.A.A.1 Warning	Verilog: Source file name should be same as the name of the module in the file.	By default, HDL Coder generates code that has the same module and file name. If you use BlackBox architecture for your subsystem and generate code, the source names and file names can be different.	If you use BlackBox architecture for your subsystem, make sure that the source file name and module name are the same.
	VHDL: File names containing entities should have the extension .vhd or .vhdl.	Source file name has to use certain recommended naming conventions and file extensions.	Use the VHDL file extension option in the HDL Workflow Advisor, or the VHDLFileExtension property from the command line.
1.A.A.2 Message	Verilog/VHDL: Identifiers and names should follow recommended naming convention.	A name in the design does not start with a letter or contains a character other than a number, letter, or underscore.	Update the names in your design so that they start with a letter of the alphabet (a - z, A - Z), and contain only alphanumeric characters (a - z, A - Z, 0 - 9) and underscores (_).
1.A.A.3 Message	Verilog/VHDL: Keywords in Verilog-HDL (IEEE1364), SystemVerilog(v3.1a), and keywords in VHDL (IEEE1076.X) must not be used.	There are Verilog, SystemVerilog, or VHDL keywords within the names in your design.	Update the names in your design so that they do not contain Verilog, SystemVerilog, or VHDL keywords. You can disable this rule checking by using the HDLKeywords property of the HDL coding standard customization object.
1.A.A.3vb Message	VHDL: Do not use standard VHDL names.	HDL Coder does not use standard VHDL names.	No action required.
1.A.A.4 Error	Verilog/VHDL: Do not use names starting with VDD, VSS, VCC, GND or VREF.	A name or names in the design are not using the standard naming convention.	Update the names in your design so that they start with a letter of the alphabet (a - z, A - Z), and contain only alphanumeric characters (a - z, A - Z, 0 - 9) and underscores (_).

Rule / Severity	Message	Problem	Recommendations
1.A.A.5 Error	Verilog/VHDL: Do not use case variants of name in the same scope.	Two or more names in your design, within the same scope, are identical except for case. For example, the names <code>foo</code> and <code>Foo</code> cannot be in the same scope.	Update the names in your design so that no two names within the same scope differ only in case. You can disable this rule checking by using the <code>DetectDuplicateNamesCheck</code> property of the HDL coding standard customization object.
1.A.A.6 Warning	Verilog: Primary port names or module names must follow recommended naming convention. VHDL: Component name should be same as its corresponding entity name.	HDL Coder generates code that complies with this rule for Verilog and VHDL.	No action required.
1.A.A.9 Warning	Verilog/VHDL: Top-level module/entity and port names should be less than or equal to 16 characters in length and not be mixed-case.	A top-level module, entity, or port name in the generated code is longer than 16 characters, or uses letters with mixed case.	Update the indicated name in your design so that it is less than or equal to 16 characters long, and all letters are lowercase. all letters must be either all uppercase or all lowercase. You can customize this rule by using the <code>ModuleInstanceEntityNameLength</code> property of the HDL coding standard customization object.

1.A.B Module Naming Conventions

Rule / Severity	Message	Problem	Recommendations
1.A.B.1-1b Error	Verilog: Module and Instance names should be between 2 and 32 characters in length. The instance names including hierarchy should be less than or equal to 128 characters in length.	A module, instance, or entity name in the generated code is fewer than 2 characters or more than 32 characters in length.	Update the indicated name in your design so that it is from 2 through 32 characters in length. You can customize this rule by using the <code>ModuleInstanceEntityNameLength</code> property of the HDL coding standard customization object.
	VHDL: Entity names and instance names should be between 2 and 32 characters in length. The instance names including hierarchy should be less than or equal to 128 characters in length.		

1.A.C Signal Naming Conventions

Rule / Severity	Message	Problem	Recommendations
1.A.C.3 Error	Verilog: Signal names, port names, parameter names, define names and function names should be between 2 and 40 characters in length.	A signal, port, parameter, define, or function name in the generated code is fewer than 2 characters, or more than 40 characters in length.	Update function names or subsystem names in your design to be from 2 through 40 characters in length. You can customize this rule by using the <code>SignalPortParamNameLength</code> property of the HDL coding standard customization object.
	VHDL: Signal names, variable names, type names, label names, and function names should be between 2 and 40 characters in length.		

1.A.D File, Package, and Parameter Naming Conventions

Rule / Severity	Message	Problem	Recommendations
1.A.D.1 Warning	Verilog: Include files must have extensions that match ".h", ".vh", ".inc", and ".h", ".inc", ".ht", ".tsk" for testbench.	The generated include files match these extensions for the testbench.	No action required.
	VHDL: Package file name should be followed by "pac.vhd".	By default, the generated package file postfix is _pkg.	In the Configuration Parameters dialog box, on the HDL Code Generation > Global Settings > General pane, specify the Package postfix to _pac.
1.A.D.4 Warning	Verilog: Macros defined outside a module must not be used in the module.	HDL Coder does not generate macros in the Verilog code, or redefine constants in the VHDL code.	No action required.
	VHDL: Constants should not be redefined.		
1.A.D.9 Warning	Verilog: Bit-width must be specified for parameters with more than 32 bits.	HDL Coder does not specify a bit-width greater than 32 bits in the generated code.	No action required.
	VHDL: Generic must not be used at top-level module.	If you use generics at top-level module or if you have mask parameters in your design and set the MaskParameterAsGeneric property, HDL Coder reports this violation.	If you have mask parameters in your design, set the MaskParameterAsGeneric to off.

1.A.E Register and Clock Naming Conventions

Rule / Severity	Message	Problem	Recommendations
1.A.E.2 Warning	Verilog/VHDL: Clock, Reset, and Enable signals should follow recommended naming convention.	The clock, reset, and enable signals are not using the recommended naming convention.	<p>In the Configuration Parameters dialog box, on the HDL Code Generation > Global Settings pane, using the clock input port, reset input port, and clock enable input port options, update the names for the clock, reset, and enable signals respectively. Follow these naming conventions:</p> <ul style="list-style-type: none">• Clock signal names must be <code>clk</code> or <code>ck</code>.• Clock enable signal names must be <code>en</code>.• For 'active-high' reset, reset signal names must be <code>rst</code> or <code>reset</code>.• For 'active-low' reset, reset signal names must be <code>rst</code>, <code>reset</code>, <code>rst_n</code>, <code>reset_n</code>, <code>rst_x</code>, or <code>reset_x</code>.

1.A.F Architecture Naming Conventions

Rule / Severity	Message	Problem	Recommendations
1.A.F.1 Warning	VHDL: Architecture name must contain RTL.	In the generated VHDL code, the architecture name does not contain RTL.	In HDL Code Generation > Global Settings > General tab, update the VHDL architecture name to use an architecture name that contains RTL.
1.A.F.4 Warning	VHDL: An entity and its architecture must be described in the same file.	By default, HDL Coder describes the entity and architecture of the VHDL code in the same file. If you set the SplitEntityArch property to on, the generated VHDL code describes the entity and architecture in separate files, so HDL Coder reports a warning.	Set SplitEntityArch to off so that HDL Coder describes the entity and architecture of the VHDL code in the same file.

1.B General Guidelines for Clocks and Resets

1.B.A Clock Constraints

Rule / Severity	Message	Problem	Recommendations
1.B.A.1 Message	VHDL: Design should have only a single clock and use only one edge of the clock.	Your design uses multiple edges of the clock or contains more than one clock signals. If you set the ClockInputs property to multiple or use TriggerAsClock to use the trigger signal for a triggered subsystem as clock, HDL Coder generates this message.	Update your design to use a single clock signal. In the HDL Code Generation > Global Settings panel, set Clock inputs to Single, and Clock edge to Rising or Falling.
1.B.A.2 Error	Verilog/VHDL: Do not create an RS latch or flip-flop using primitive cells such as AND, OR.	HDL Coder does not create latches, and complies with this rule.	No action required.
1.B.A.3 Error	Verilog/VHDL: Remove combinational loops.	HDL Coder does not create combinational loops.	No action required.

1.C Guidelines for Initial Reset

1.C.A Flip-Flop Clock Constraints

Rule / Severity	Message	Problem	Recommendations
1.C.A.3 Warning	Verilog/VHDL: Do not use asynchronous set/reset signals other than initial reset.	HDL Coder does not use asynchronous reset signals as non-reset or synchronous reset signals.	No action required.
1.C.A.6 Error	Verilog/VHDL: Signals must not be used as both asynchronous reset and synchronous reset.	HDL Coder adds the reset control logic outside the DUT and does not generate both asynchronous reset and synchronous reset signals.	No action required.
1.C.A.7 Warning	Verilog/VHDL: A flip-flop must not have both asynchronous set and asynchronous reset.	HDL Coder does not generate code with both asynchronous set and reset signals.	No action required.

1.C.B Reset Conventions

Rule / Severity	Message	Problem	Recommendations
1.C.B.1a Message	Verilog/VHDL: Asynchronous resets or sets must not be gated.	HDL Coder does not gate asynchronous set or reset signals.	No action required.
1.C.B.1b Message	Verilog/VHDL: Reset must be generated in separate module instantiated at top-level.	The generated code complies with this rule, because the DUT does not contain reset instantiation.	No action required.
1.C.B.2 Warning	Verilog/VHDL: Do not use signals other than initial reset for asynchronous reset input of flip-flop.	HDL Coder uses only initial reset signals for asynchronous reset input of flip-flop.	No action required.

1.D Guidelines for Clocks

1.D.A Clock Packaging Constraints

Rule / Severity	Message	Problem	Recommendations
1.D.A.1 Warning	Verilog/VHDL: Clock should be generated in separate module or entity instantiated at top-level.	HDL Coder generates code that complies with this rule, because the DUT does not contain clock instantiation.	No action required.

1.D.C Clock Gating Constraints

Rule / Severity	Message	Problem	Recommendations
1.D.C.2-4 Message	Verilog/VHDL: Do not use flip-flop outputs as clocks of other flip-flops and flip-flop clock signals as non-clock signals.	HDL Coder does not use the output of flip-flops as clocks of other flip-flops, or flip-flop clock signals as nonclock signals.	No action required.
1.D.C.6 Message	Verilog/VHDL: Do not use flip-flops with inverted edges.	If your Simulink model uses a Triggered Subsystem block with rising and falling triggers and has TriggerAsClock enabled, HDL Coder violates this rule.	Disable TriggerAsClock or do not use Triggered Subsystem blocks with both rising and falling triggers in your Simulink model.

1.D.D Clock Hierarchy Constraints

Rule / Severity	Message	Problem	Recommendations
1.D.D.2 Message	Verilog: One hierarchical level should have a single clock only.	Your Simulink model uses multiple clock signals.	Update your design to use a single clock signal. In the HDL Code Generation > Global Settings panel, set Clock inputs to Single.

1.F Guidelines for Hierarchical Design

1.F.A Basic Block Size Guidelines

Rule / Severity	Message	Problem	Recommendations
1.F.A.4 Error	Verilog/VHDL: Clock generation, reset generation, RAM, Setup/Hold ensure buffers, and I/O cells must be a module at top-level.	HDL Coder generates separate modules for the DUT, RAM, timing controller, so that it complies with this rule.	No action required.

RTL Description Rules and Checks

In this section...
"2.A Guidelines for Combinational Logic" on page 31-17
"2.B Guidelines for "Always" Constructs of Combinational Logic" on page 31-22
"2.C Guidelines for Flip-Flop Inference" on page 31-24
"2.D Guidelines for Latch Description" on page 31-27
"2.E Guidelines for Tristate Buffer" on page 31-28
"2.F Guidelines for Always/Process Construct with Circuit Structure into Account" on page 31-29
"2.G Guidelines for "IF" Statement Description" on page 31-30
"2.H Guidelines for "CASE" Statement Description" on page 31-32
"2.I Guidelines for "FOR" Statement Description" on page 31-35
"2.J Guidelines for Operator Description" on page 31-36
"2.K Guidelines for Finite State Machine Description" on page 31-39

HDL Coder conforms to the following RTL description rules and checks for modeling constructs that violate these rules. HDL Coder reports potential rule violations in the HDL coding standard report. To avoid these violations, see the rule recommendations.

2.A Guidelines for Combinational Logic

2.A.A Combinatorial Logic Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.A.1 Reference	VHDL: Package IEEE.std_logic_1164 must be included in each entity.	HDL Coder includes the package in each entity in the generated VHDL code.	No action required.
2.A.A.2 Warning	Verilog: A function description must assign return values to all possible states of the function.	HDL Coder does not generate functions for DUT.	No action required.
2.A.A.3 Warning	Verilog: Check using RTL parsing tool for error prevention.	HDL Coder generates VHDL and Verilog code with the correct syntax and complies with this rule.	No action required.

2.A.B Function Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.B.1 Error	Verilog: Function statement should not be used for asynchronous reset line logic in an always construct for FF inference.	HDL Coder does not generate functions for DUT.	No action required.
	VHDL: Use <code>std_logic</code> or <code>std_logic_vector</code> data types to describe ports of an entity.	At the inputs and outputs, HDL Coder uses <code>std_logic</code> or <code>std_logic_vector</code> to describe the ports.	No action required.
2.A.B.2-3 Error	Verilog: Do not use nonblocking assignment, or input argument as input in function description.	The generated HDL code complies with this rule for Verilog.	No action required.
	VHDL: Use range specification for integer types.	By default, HDL Coder specifies the range for integer types in the generated code.	No action required.
2.A.B.4 Error	Verilog: Task constructs should not be used in the design.	HDL Coder does not use tasks or fork-join constructs in the Verilog code.	No action required.
	VHDL: Do not use bit and bit vector data types in the design.	HDL Coder does not use bit or bit vector data types in the generated code.	No action required.
2.A.B.5 Error	Verilog: Clock edges should not be used in a task description.	When generating Verilog code, HDL Coder does not use clock edges in a task description.	No action required.
2.A.B.6 Error	VHDL: Specify range for <code>std_logic_vector</code> .	HDL Coder complies with this rule, because the generated VHDL code specifies the range that <code>std_logic_vector</code> uses.	No action required.

2.A.C Bit Width Matching Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.C.1-2 Error	Verilog: Ensure that bitwidth of function arguments matches that of corresponding function inputs, and bitwidth of function return value matches that of assignment destination signal.	At module instantiation, HDL Coder enforces type matching, so that it complies with this rule.	No action required.
	VHDL: Use only 'in', 'out', and 'inout' ports. Do not use buffer and linkage.	When generating VHDL code, HDL Coder specifies 'IN', 'OUT', or 'INOUT' ports, and does not use buffer or linkage.	No action required.
2.A.C.3 Error	Verilog: Use concatenation when assigning to multiple signals.	HDL Coder complies with this rule.	No action required.
	VHDL: Port mode must be explicitly specified.	When generating VHDL code, HDL Coder specifies 'IN', 'OUT', or 'INOUT' ports and does not use buffer or linkage.	No action required.
2.A.C.4-5 Error	Verilog: In function description, do not assign global signals, and return value assignment must be the last statement.	HDL Coder generates Verilog code that complies with this rule.	No action required.
	VHDL: Input port must not be described with initial value.	In the generated VHDL code, HDL Coder does not specify an initial value to the input port.	No action required.

2.A.D Operators Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.D.5 Message	Verilog: Bit-wise operators must be used instead of logical operators in multi-bit operations.	In the generated Verilog code, HDL Coder complies with this rule for multibit operators.	No action required.
2.A.D.6 Message	Verilog: Reduction of a single-bit or large expression should not be performed.	By default, HDL Coder does not reduce a single-bit or a large expression. If your design performs bit-reduction operations, the resulting HDL code can perform reduction of a large expression.	Update your design so that there are no calls to bit reduction operations.

2.A.E Conditional Statement Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.E.3 Message	Verilog: Ensure that conditional expressions evaluate to a scalar.	HDL Coder complies with this rule.	No action required.

2.A.F Array, Vector, Matrix Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.F.2 Warning	Verilog/VHDL: LSB of vectors/memory should be zero.	Your design contains vectors whose LSB has a nonzero value.	Update your design so that the generated code contains vectors or memory whose LSB value is zero.
2.A.F.4 Warning	Verilog/VHDL: Index variable width should not be too short.	HDL Coder enforces type matching and ensures that the index variable width is not too short.	No action required.
2.A.F.5 Error	Verilog/VHDL: Do not use x and z for an array index.	In the generated code, HDL Coder does not use x or z for an array index.	No action required.

2.A.G Assignment Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.G.1 Error	VHDL: Direct assignment must be used for aggregates.	HDL Coder directly assigns aggregates in the generated code without performing any intervening operations.	No action required.

2.A.H Function Return Value Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.H.1 Reference	VHDL: Constrained arrays should not be used as sub-program description.	In the generated code, HDL Coder does not use constrained arrays in subprogram description.	No action required.
2.A.H.2 Reference	VHDL: Specify range for return values in function description when return type is array.	In function description, when the return type is array, HDL Coder specifies the range for return values in function in the generated code.	No action required.
2.A.H.4-6 Error	VHDL: In a sub-program description, use only OTHERS clause when specifying aggregates, not use or call a nested subprogram description, and not read Global signals.	HDL Coder complies with this rule.	No action required.
2.A.H.9-10 Warning	VHDL: A function must have a return statement, return a valid value in all possible states, and not have any other statement following the return statement.	HDL Coder complies with this rule.	No action required.

2.A.I Built-in Attribute Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.I.4-5 Error	VHDL: Do not use user-defined attributes, or built-in attributes except range, length, left, right, high, low, reverse_range, and event.	By default, HDL Coder does not use user-defined attributes in the generated code. If you set HDL block properties, such as DSPStyle in your design, the generated code uses synthesis directives.	To fix this error, in your design, clear the HDL block property that you have set for using synthesis directives in the generated code.

2.A.J VHDL Specific Conventions

Rule / Severity	Message	Problem	Recommendations
2.A.J.1-6 Warning	VHDL: In a design, do not use block statements, objects of type record, shared variables, while-loop statements, procedures, or selected signal assignments.	If your design uses loop statements, HDL Coder generates this warning.	To avoid this warning, update your design so that there are no looping statements.
2.A.J.8-13 Error	VHDL: In a design, do not use access types, alias declarations, bus and register signals, disconnect specifications, waveforms, and attributes that are defined in Synopsys library.	HDL Coder complies with this rule.	No action required.

2.B Guidelines for “Always” Constructs of Combinational Logic**2.B.A Latch Constraints**

Rule / Severity	Message	Problem	Recommendations
2.B.A.2 Reference	Verilog/VHDL: Check latch creation from RTL lint checker and synthesis tools; Design should not have latches.	HDL Coder does not create latches.	No action required.

2.B.B Signal Constraints - I

Rule / Severity	Message	Problem	Recommendations
2.B.B.2-3 Message	Verilog/VHDL: In the sensitivity list of a process or always block, do not define constants, use wait statements, or include a signal that is not read inside that block.	HDL Coder generates code that complies with the use of these constructs inside a process block (VHDL) or an always block (Verilog).	No action required.
	Verilog: Do not describe multiple event expressions with always constructs.	HDL Coder does not describe more than one event expression in an always construct.	No action required.

2.B.C Signal Constraints - II

Rule / Severity	Message	Problem	Recommendations
2.B.C.1-2 Error	Verilog: Do not use nonblocking assignments in combinational always blocks, or when assigning initial values in always constructs of sequential blocks.	Your design uses constructs that generate Verilog code with nonblocking assignments in combinational always blocks or assigns initial values in always constructs of sequential blocks.	Update your MATLAB algorithm or Stateflow design so that the generated Verilog code does not use these constructs.
2.B.C.3 Message	Verilog/VHDL: Do not assign a signal more than once in an always construct for sequential circuits.	In an always construct for sequential circuits, HDL Coder does not perform multiple assignments to a signal.	No action required.

2.C Guidelines for Flip-Flop Inference

2.C.A Assignment Constraints

Rule / Severity	Message	Problem	Recommendations
2.C.A.1-2c Error	Verilog/VHDL: In flip-flop description, do not use quasi-continuous assignments, deassign statements, blocking assignments, variable assignment statements, or stable attribute.	HDL Coder does not introduce any additional data or add these constructs when generating flip-flops in process blocks (VHDL) or always blocks. (Verilog)	No action required.
2.C.A.4-5b Warning	Verilog/VHDL: Only flip-flop data paths can have delays. The delay values must be integral and non-negative.	HDL Coder does not generate code that uses DELAY attributes for the DUT. The generated testbench can contain DELAY attributes.	No action required.
2.C.A.6 Error	Verilog/VHDL: Check the logic level of the reset signal as specified in the sensitivity list of the always block.	HDL Coder uses <code>posedge</code> or <code>negedge</code> to denote transitions at clock edges in the generated code.	No action required.
2.C.A.7 Message	Verilog/VHDL: A flip-flop should not have two asynchronous resets. Do not use functions in the asynchronous reset description.	HDL Coder does not generate multiple asynchronous resets. The generated code can contain multiple synchronous resets.	No action required.
2.C.A.8 Error	VHDL: Do not use wait constructs.	HDL Coder does not use wait constructs.	No action required.
2.C.A.9 Error	VHDL: Functions <code>'rising_edge'</code> or <code>'falling_edge'</code> should not be used in the design.	By default, HDL Coder uses the event syntax for clock events. By using the <code>UseRisingEdge</code> property, you can specify whether to use the <code>rising_edge</code> or <code>falling_edge</code> to detect clock transitions.	To fix this error, you can control the <code>UseRisingEdge</code> property such that the generated code uses the event syntax.

2.C.B Blocking Statement Constraints

Rule / Severity	Message	Problem	Recommendations
2.C.B.1-2 Warning	Verilog/VHDL: Use blocking assignment in flip-flop description. Do not use blocking and nonblocking assignments together in the same always block.	HDL Coder complies with this rule.	No action required.
2.C.B.4 Error	VHDL: Variables, if used, must be assigned to a signal before the end of the process.	The generated HDL code does not contain dead code, so HDL Coder complies with this rule.	No action required.

2.C.C Clock Constraints

Rule / Severity	Message	Problem	Recommendations
2.C.C.1-2b Error	Verilog/VHDL: Do not use edges of multiple clocks or both edges of the same clock in an always block. Do not describe multiple clock edges in a single process/always block for same edge of a single clock.	HDL Coder uses the rising edge or falling edge of the clock, but does not use both edges of the clock.	No action required.
2.C.C.4-5 Error	Verilog/VHDL: Minimize, and if possible, remove clock enable signals and reset signal on networks.	If your design generates code that uses clock enables and reset signals on networks, HDL Coder generates an error.	To minimize clock enables in the generated HDL code, in the HDL coding standard customization properties, enable the MinimizeClockEnableCheck property. To remove reset signals on the networks, in the HDL coding standard customization properties, enable the RemoveResetCheck setting.
2.C.C.6 Warning	Verilog/VHDL: Do not use asynchronous reset signals.	Your Simulink model design or MATLAB code uses asynchronous reset signals.	To avoid this violation, use synchronous reset signals for your design. In the Configuration Parameters dialog box, set Reset type to Synchronous.

2.C.D Initial Value Constraints

Rule / Severity	Message	Problem	Recommendations
2.C.D.1 Error	Verilog/VHDL: Do not specify flip-flop or RAM initial value using initial construct.	The generated HDL code for your design contains an unsynthesizable initial statement.	Disable the Initialize block RAM or Initialize all RAM blocks option in the HDL Workflow Advisor. You can disable this rule checking by using the <code>InitialStatements</code> property of the HDL coding standard customization object.

2.C.F Mixed Timing Constraints

Rule / Severity	Message	Problem	Recommendations
2.C.F.1-2a Warning	Verilog/VHDL: Do not use multiple resets or mix descriptions of flip-flops with and without asynchronous reset in the same process/always block.	HDL Coder complies with this rule.	No action required.

2.D Guidelines for Latch Description**2.D.A Module Constraints**

Rule / Severity	Message	Problem	Recommendations
2.D.A.2-3 Warning	Verilog/VHDL: Latch descriptions should not have asynchronous set or asynchronous reset, or be mixed with other descriptions in the same module.	HDL Coder does not create latches in the generated code.	No action required.
2.D.A.4-5 Error	Verilog/VHDL: Do not use combinational loops that contain latches or level two latches in the same phase clock.	By default, HDL Coder does not create combinational loops. If your MATLAB algorithm contains combinational loops, the generated HDL code can use combinational loops.	Update your MATLAB code so that the generated HDL code does not contain any combinational loops.

2.E Guidelines for Tristate Buffer

2.E.A Module Constraints

Rule / Severity	Message	Problem	Recommendations
2.E.A.1-2 Warning	Verilog/VHDL: Tristate descriptions must not be mixed with other descriptions in the same module and should not contain logic in tristate enable conditions.	HDL Coder does not create latches or tristate buffers in the generated code.	No action required.
2.E.A.4-5b Reference	Verilog/VHDL: Tristate bus must not be driven by more than specified number of drivers. A net that is not tristated or a signal without a resolution function must not have multiple drivers.	HDL Coder does not create latches or tristate buffers in the generated code.	No action required.
2.E.A.6-9 Error	Verilog/VHDL: Inout port should not be directly connected to input/output. Do not use tristate output in an if conditional expression or in the selection expression of a case statement that assigns a fixed value in others choice.	By default, HDL Coder does not connect input or output ports directly to bidirectional ports. In your Simulink model, on the HDL block properties for the input or output port, if you set BidirectionalPort to on, the generated HDL code can directly connect inout to input or output ports.	In your Simulink model, on the HDL block properties for the input or output port, set BidirectionalPort to off.

2.E.B Connectivity Constraints

Rule / Severity	Message	Problem	Recommendations
2.E.B.1 Warning	Verilog/VHDL: Logic directly driven by tristate nets should be in a separate module.	HDL Coder does not have tristate nets in the generated HDL code.	No action required.

2.F Guidelines for Always/Process Construct with Circuit Structure into Account

2.F.B Constraints on Number of Conditional Statements

Rule / Severity	Message	Problem	Recommendations
2.F.B.1 Error	Verilog/VHDL: Do not describe more than one statement (if/case/while/for/loop) separately within a single always or process block.	The generated HDL code for your design contains more than one conditional statement (if-else, case, and loops) that is described separately within a process block for VHDL code or an always block for Verilog code.	Update your design so that there is not more than one conditional statement that is described separately in a process block. You can customize this rule by using the <code>ConditionalRegionCheck</code> property of the HDL coding standard customization object.
2.F.B.1.a Error	Verilog/VHDL: Do not write to same signal for VHDL or register for Verilog in multiple cascaded conditional (if/case) regions within the same process block for VHDL code or always construct for Verilog code.	The generated HDL code for your design contains the same signal for VHDL code or register for Verilog code written to in multiple cascaded conditional regions (such as if/case regions) in the same process block for VHDL code or always construct for Verilog code.	Update your design so that the signal or register is not written to more than once in cascaded conditional regions in the same process block or always construct. For more information, see "Cascaded Conditional Region Variable Assignments" on page 31-47. You can customize this rule by using the <code>CascadedConditionalAssignmentCheck</code> property of the HDL coding standard customization object.
2.F.B.2 Error	Verilog/VHDL: A variable in the sensitivity list is modified inside the same process or always block.	HDL Coder does not modify the variables in the sensitivity list, including clock, reset, and enable signals.	No action required.

2.G Guidelines for “IF” Statement Description

2.G.B Common Sub-Expression Constraints

Rule / Severity	Message	Problem	Recommendations
2.G.B.2 Warning	Verilog/VHDL: Avoid describing conditions that will not be executed.	The generated HDL code does not contain dead code, or result in conditions that are not executed.	No action required.

2.G.C Nesting Depth Constraints

Rule / Severity	Message	Problem	Recommendations
2.G.C.1a-b Message	Verilog/VHDL: Nesting in if-else constructs should not be deeper than N levels. Where feasible case statements should be used, rather than if-else statements, if performance is important.	The MATLAB code contains an if-elseif statement with more than N levels of nesting. By default, N is 3.	<p>Modify if-elseif statements in your MATLAB code so there are N or fewer levels of nesting.</p> <p>For example, the following if-elseif pseudocode contains three levels of nesting:</p> <pre>if ... if ... if ... else else else</pre> <p>You can customize this rule by using the IfElseNesting property of the HDL coding standard customization object.</p>
2.G.C.1c Message	Verilog/VHDL: Chain of if...else if constructs must not be exceed default number of levels.	The generated HDL code contains an if-elseif statement with more than seven branches.	<p>Modify if-elseif statements in your MATLAB code so that the number of branches is seven or fewer.</p> <p>For example, the following if-elseif pseudocode contains three branches:</p> <pre>if ... elseif ... elseif ... else</pre> <p>You can customize this rule by using the IfElseChain property of the HDL coding standard customization object.</p>

2.G.D Begin-End Decorator Constraints

Rule / Severity	Message	Problem	Recommendations
2.G.D.2-3 Message	Verilog/VHDL: Attach begin-end to "if" statements.	The generated HDL code complies with these code constructs.	No action required.
	Verilog: Do not use fork-join constructs.		

2.H Guidelines for "CASE" Statement Description**2.H.A CASE Structure Constraints**

Rule / Severity	Message	Problem	Recommendations
2.H.A.3-5 Reference	Verilog/VHDL: case constructs should not have overlapping clause conditions. Do not use full_case directive.	The generated HDL code complies with these constructs for case statements and does not use the full_case directive.	No action required.

2.H.C Default Value Constraints

Rule / Severity	Message	Problem	Recommendations
2.H.C.3 Warning	Verilog: Do not use //synposys full_case pragma when all conditions are not described as case clause or the default clause is missing.	HDL Coder describes all possible cases in a case statement so that the synthesis tool does not infer a latch.	No action required.
2.H.C.4 Message	Verilog/VHDL: A signal that is assigned don't care value in a case default clause should not be used in if conditions, ternary and case constructs.	HDL Coder does not use a signal that is assigned a <i>don't care</i> value in the default clause.	No action required.
2.H.C.5 Warning	Verilog/VHDL: Default clause in case construct must be the last clause.	To avoid latch inference, HDL Coder describes all possible cases, including the default clause.	No action required.
2.H.C.6-7 Message	Verilog/VHDL: Do not use a signal to which don't care is assigned for selection expression of casex statements or case statements that do not assign 'X' in default clause.	HDL Coder does not use <i>don't care</i> values, and explores the entire space of an n-bit select signal.	No action required.

2.H.D Don't Care Constraints

Rule / Severity	Message	Problem	Recommendations
2.H.D.1-4 Message	Verilog: Design should not use casex or casez constructs. casex or casez constructs must contain a dont-care condition, and not have complex clause conditions. The don't care condition in casex or casez branches must follow proper coding style.	HDL Coder does not generate casex or casez constructs, so that it complies with this rule.	No action required.

2.H.E Additional CASE Constraints

Rule / Severity	Message	Problem	Recommendations
2.H.E.1-4 Message	Verilog: Do not use parallel_case directive. In a case clause condition, do not use fixed values, variables, expressions, and logical, arithmetic, bitwise, or reduction operations.	HDL Coder does not use the parallel_case directive and generates code that complies with these constructs.	No action required.

2.1 Guidelines for “FOR” Statement Description

2.1.A Loop Body Constraints

Rule / Severity	Message	Problem	Recommendations
2.1.A.2a-b Message	Verilog: Loop variable and terminating condition of "for" construct must have constant initial value.	HDL Coder does not generate casex or casez constructs so that it complies with this rule.	No action required.
2.1.A.2c-e Message	Verilog: Loop variable of "for" construct must have a constant value inside the construct and must not be used outside the construct. Verilog: The loop termination condition must not be a constant.	HDL Coder generates the right loop constructs and complies with this rule.	No action required.

2.1.B Non-Constant Operation Constraints

Rule / Severity	Message	Problem	Recommendations
2.1.B.4 Error	Verilog/VHDL: Separate for loops must be used in reset and logic parts of flip-flop descriptions.	HDL Coder uses separate for loops in the reset and logic parts of flip-flop descriptions.	No action required.

2.1.C Exit Constraints

Rule / Severity	Message	Problem	Recommendations
2.1.C.1 Error	VHDL: Exit or next statement must not be used in a for loop.	The generated code contains for loops only when HDL Coder knows the number of iterations. When the loop is executing, HDL Coder does not exit from the for loop,	No action required.

2.J Guidelines for Operator Description

2.J.A Comparison and Precedence Constraints

Rule / Severity	Message	Problem	Recommendations
2.J.A.4a-c Message	Verilog: Signals must not be compared with X or Z, or values containing X or Z.	By default, HDL Coder does not generate code that contains these constructs. If your Simulink model design uses Constant blocks with Architecture set to Logic Value and uses these constructs, the coder displays this message.	Update your Simulink model design so that the Constant blocks do not use these constructs when Architecture is set to Logic Value . Alternatively, change the Architecture to Constant .
2.J.A.4v Error	Verilog/VHDL: Do not assign X except for the others clause of case statements.	By default, HDL Coder does not use X in the others clause of case statements. In certain cases, if the generated code does not comply with 2.J.A.4a-c , HDL Coder can assign X in the others clause.	Update your Simulink model design so that the generated HDL code does not use constructs that rule 2.J.A.4a-c specifies.
2.J.A.5-6 Warning	Verilog: Do not use values containing 'X' or 'Z'. VHDL: Do not use values including 'X', 'Z', 'U'-'', 'W', 'H', 'L', or constants that contain the values 'X', 'Z', 'U'-'', 'W', 'H', 'L'.	If your design uses unknown or high-impedance constants, HDL Coder displays a warning.	Update your Simulink model or MATLAB algorithm so that there are no high-impedance constants.
2.J.A.7-8 Message	Verilog: Do not use RAM output signals for a conditional expression of if statements, or selection expression of case statements that assign 'x' in the default clause.	By default, HDL Coder complies with this rule. If your Simulink model uses RAM output signals with a Switch or Multiport switch block, the generated HDL code can use these constructs.	Update your Simulink model so that there are no RAM output signals to Switch or Multiport switch blocks.

2.J.B Vector Operator Constraints

Rule / Severity	Message	Problem	Recommendations
2.J.B.3 Message	Verilog/VHDL: Do not perform logical negation on vectors.	HDL Coder does not perform logical negation on vectors.	No action required.

2.J.C Relational Operator Constraints

Rule / Severity	Message	Problem	Recommendations
2.J.C.1-6 Error	Verilog/VHDL: Bitwidths of operands of a relational or logical operator must match.	HDL Coder ensures that the data types of the operands match in a relational or logical expression.	No action required.
	Verilog/VHDL: Bitwidths should be specified for conditional expression.		

2.J.D Signed Signal, Data Type Constraints

Rule / Severity	Message	Problem	Recommendations
2.J.D.3-5 Warning	Verilog/VHDL: Take care when assigning integer to reg or wire, and when comparing negative value reg and integer variables. Integer objects must not be assigned negative values.	HDL Coder complies with this rule.	No action required.
2.J.D.6 Warning	VHDL: Signed data type must be used in signed operation and std_logic_vector calling std_logic_unsigned package must be used in unsigned operation.	HDL Coder complies with this rule.	No action required.
2.J.D.8 Warning	VHDL: Function To_stdlogicvector should not be used in the design.	HDL Coder does not use the function To_stdlogicvector in the code.	No action required.

2.J.E Number of Operator Repetition Constraints

Rule / Severity	Message	Problem	Recommendations
2.J.E.5 Warning	Verilog: Do not describe arithmetic operators with conditional operators(?) in assign statement.	HDL Coder complies with this rule.	No action required.

2.J.F Precision Constraints

Rule / Severity	Message	Problem	Recommendations
2.J.F.5 Warning	Verilog/VHDL: Large multipliers must not be described using the multiplication operator with RTL.	The generated HDL code contains a multiplication operator (*) where the output of the multiplication has a bitwidth of 16 or greater.	In your design, implement multiplications by using a shift-and-add algorithm, or ensure that the data size of the output of a multiplication does not require a bitwidth of 16 or greater. You can customize this rule by using the <code>MultiplierBitWidth</code> property of the HDL coding standard customization object.

2.J.G Common Sub-Expression Constraints

Rule / Severity	Message	Problem	Recommendations
2.J.G.2 Warning	Verilog/VHDL: common operational expressions should be described separately.	HDL Coder identifies the common operational expressions and describes them separately.	No action required.

2.J.H Division Operator Constraints

Rule / Severity	Message	Problem	Recommendations
2.J.H.1 Message	Verilog/VHDL: Do not use arithmetic and logical expressions in the right and left sides of the division or modulus operator.	HDL Coder homogenizes the division operator into a separate statement and complies with this rule.	No action required.
2.J.H.2-3 Message	Verilog/VHDL: Keep the left side of the division or modulus operator within 12 bits. If right side of the division or modulus operator is not a power of two, keep it within 8 bits.	In your design, the left side of the modulus or division operation is greater than 12 bits, or the right side is not a power of two and greater than eight bits.	Update your design so that the number of bits in the operands of the division or modulus operation are within the bounds that the rule specifies.

2.K Guidelines for Finite State Machine Description**2.K.A State Transition Constraints**

Rule / Severity	Message	Problem	Recommendations
2.K.A.4 Warning	Verilog/VHDL: Number of states of an FSM should be within 40.	Your model design contains a Stateflow Chart or State Transition Table that uses more than 40 states.	Update your model design so that there are not more than 40 states.

2.K.C Logic Separation Constraints

Rule / Severity	Message	Problem	Recommendations
2.K.C.1 Reference	Verilog/VHDL: Ensure that sequential and combinational parts of an FSM are in separate always block.	By default, HDL Coder puts the sequential and combinational parts of a Finite State Machine (FSM) in separate always blocks.	No action required.

2.K.E Encoding Constraints

Rule / Severity	Message	Problem	Recommendations
2.K.E.2 Warning	VHDL: Do not assign state encoding by attaching attributes to the state variable which is declared as a type.	HDL Coder does not attach attributes to state variables in the generated code.	No action required.

RTL Design Methodology Guidelines

In this section...
“3.A Guidelines for Creating Function Libraries” on page 31-41
“3.B Guidelines for Using Function Libraries” on page 31-42
“3.C Guidelines for Test Facilitation Design” on page 31-43

HDL Coder conforms to the following RTL design methodology guidelines, and checks for modeling constructs that violate these rules. HDL Coder reports potential rule violations in the HDL coding standard report. To avoid these violations, see the rule recommendations.

3.A Guidelines for Creating Function Libraries

3.A.C Signal, Port Constraints - I

Rule / Severity	Message	Problem	Recommendations
3.A.C.1 Warning	Verilog: The order of module port declarations and instance port connections lists should be same as the order in the module port map.	HDL Coder preserves the order of module port declarations and instance port connections as they appear in the original Simulink DUT.	No action required.
3.A.C.4a Message	Verilog/VHDL: Define only one port or signal per line in I/O, reg, and wire declaration.	HDL Coder complies with this rule.	No action required.

3.A.D Signal, Port Constraints - II

Rule / Severity	Message	Problem	Recommendations
3.A.D.4-5 Warning	Verilog/VHDL: Multiple assignments should not be made in one line.	The generated HDL code contains multiple assignments in one line or lines greater than N characters. You have a name or identifier in your original design that contains more than N characters.	Shorten names in your design that are longer than N characters. You can also customize N by using the LineLength property of the HDL coding standard customization object. HDL Coder folds the long lines in the design only so far as the HDL code syntax is not broken.
	Verilog/VHDL: The maximum number of characters in one line should not be more than N.		

3.A.F Generic Usage Constraints

Rule / Severity	Message	Problem	Recommendations
3.A.F.1 Reference	Verilog: Generic should be used in conditional expression of if generate statement.	HDL Coder does not generate if-generate statements, but can generate for-generate statements in the generated HDL code.	No action required.

3.B Guidelines for Using Function Libraries**3.B.B Parameters, Constant Constraints**

Rule / Severity	Message	Problem	Recommendations
3.B.B.2b-4 Message	Verilog: Define macros should be read using include files. Include files must be specified with more than 1 level higher relative path.	HDL Coder does not generate macros in the HDL code.	No action required.
3.B.B.5-7 Message	Verilog: Text macros should not be nested, and constants should be defined using parameters only.	HDL Coder does not generate macros in the HDL code.	No action required.

3.B.C Port Constraints

Rule / Severity	Message	Problem	Recommendations
3.B.C.1 Message	Verilog/VHDL: Port/Generic connections in instantiations must be made by named association rather than position association.	HDL Coder preserves the association of ports, so that it complies with this rule.	No action required.
3.B.C.2 Message	Verilog: Bit-width of the component port and its connected net must match.	HDL Coder enforces type and bit-width matching, so that it complies with this rule.	No action required.
3.B.C.3 Message	VHDL: Do not use entity instantiation in the design.	HDL Coder does not use entity instantiation in the design. The generated HDL code is generic and reusable.	No action required.

3.B.D Generic Constraints

Rule / Severity	Message	Problem	Recommendations
3.B.D.1 Error	Verilog/VHDL: Non-integer type used in the declaration of a generic may be unsynthesizable.	The generated HDL code contains a noninteger data type.	<p>If you have floating-point data types in your design, you can map them to HDL Coder native floating-point libraries so that the generated code does not use floating-point data types.</p> <p>Alternatively, modify your design so that it does not use floating-point data types.</p> <p>You can disable this rule checking by using the NonIntegerTypes property of the HDL coding standard customization object.</p>
3.B.D.3 Error	Verilog: Do not use defparam statements.	HDL Coder complies with this rule.	No action required.

3.C Guidelines for Test Facilitation Design

3.C.A Clock Constraints - I

Rule / Severity	Message	Problem	Recommendations
3.C.A.1-4 Error	Verilog/VHDL: Internal clocks and asynchronous sets/resets must be controllable from external pins.	<p>In the generated HDL code, you can control clocks from external pins. If you have a triggered subsystem and enable TriggerAsClock, then the trigger signal becomes a clock signal that you can control from external pins.</p> <p>For reset signals that you model in Simulink, the generated VHDL code can have a load port, which is a primary input in the generated code.</p>	To avoid this rule violation, disable the TriggerAsClock .

3.C.B Black Box Constraints

Rule / Severity	Message	Problem	Recommendations
3.C.B.3 Error	Verilog/VHDL: Do not connect the outputs of a black box to clock, reset, or tristate enable pins.	HDL Coder connects the clock bundle to the entity or blackbox and does not modify it, so the generated code complies with this rule.	No action required.

3.C.C Clock Constraints - II

Rule / Severity	Message	Problem	Recommendations
3.C.C.1 Error	Verilog/VHDL: A clock must not be connected to the D input of a flip-flop.	HDL Coder does not use clock as data.	No action required.

3.C.F Clock Constraints - III

Rule / Severity	Message	Problem	Recommendations
3.C.F.2 Error	Verilog/VHDL: Do not mix clock and reset lines.	HDL Coder connects the clock bundle to the entity or blackbox and does not modify it, so the generated code complies with this rule.	No action required.

Generate HDL Lint Tool Script

You can generate a lint tool script to use with a third-party lint tool to check your generated HDL code.

HDL Coder can generate Tcl scripts for the following lint tools:

- Ascent Lint
- HDL Designer
- Leda
- SpyGlass
- Custom

If you specify one of the supported third-party lint tools, you can either generate a default tool-specific script, or customize the script by specifying the initialization, command, and termination names as a character vector. If you want to generate a script for a custom lint tool, you must specify the initialization, command, and termination names.

HDL Coder writes the initialization, command, and termination names to a Tcl script that you can use to run the third-party tool.

How to Generate an HDL Lint Tool Script

Using the Configuration Parameters Dialog Box

- 1 In the Configuration Parameters dialog box, select **HDL Code Generation > EDA Tool Scripts**.
- 2 Select the **Lint script** option.
- 3 For **Choose lint tool**, select **Ascent Lint**, **HDL Designer**, **Leda**, **SpyGlass**, or **Custom**.
- 4 Optionally, enter text to customize the **Lint initialization**, **Lint command**, and **Lint termination** strings. For a custom tool, specify these fields.

After you generate code, the message window shows a link to the lint tool script.

Using the Command Line

To generate an HDL lint tool script from the command line, set the `HDLLintTool` parameter to `AscentLint`, `HDLDesigner`, `Leda`, `SpyGlass`, or `Custom` using `makehdl` or `hdlset_param`.

To disable HDL lint tool script generation, set the `HDLLintTool` parameter to `None`.

For example, to generate HDL code and a default SpyGlass lint script for a DUT subsystem, `sfir_fixed\symmetric_fir`, enter the following:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLLintTool', 'SpyGlass')
```

After you generate code, the message window shows a link to the lint tool script.

To generate an HDL lint tool script with custom initialization, command, and termination names, use the `HDLLintTool`, `HDLLintInit`, `HDLLintTerm`, and `HDLLintCmd` parameters.

For example, you can use the following command to generate a custom Leda lint script for a DUT subsystem, `sfir_fixed\symmetric_fir`, with custom initialization, command, and termination names:

```
makehdl('sfir_fixed/symmetric_fir','HDLLintTool','Leda',...
        'HDLLintInit','myInitialization','HDLLintCmd','myCommand %s',...
        'HDLLintTerm','myTermination')
```

Custom Lint Tool Command Specification

If you want to generate a lint tool script for a custom lint tool, you must use `%s` as a placeholder for the HDL file name in the generated Tcl script.

Specify the **Lint command** or `HDLLintCmd` using the following format:

```
hdlset_param ('HDLLintCmd', 'custom_lint_tool_command -option1 -option2 %s')
```

For example, to set `HDLLintCmd`, where the lint command is `custom_lint_tool_command -option1 -option2`, at the command line, enter:

```
hdlset_param ('HDLLintCmd', 'custom_lint_tool_command -option1 -option2 %s')
```

Cascaded Conditional Region Variable Assignments

In R2021b, HDL Coder provides a coding standard (Guideline 2.F.B.1.a in “RTL Description Rules and Checks” on page 31-17) to check for assignments to the same variable in multiple cascaded control regions within the same process block. HDL Coder points to the blocks that generate such a coding style. If the style is not recommended for use in your production workflow, consider an alternative coding style or replace the block pointed to by the rule. The check displays an error if the generated HDL code for your design contains the same variable/signal for VHDL or register/wire for Verilog written to in multiple cascaded conditional regions, such as `switch case` or `if/else` cascaded regions, within the same process block. To turn on this check for your model, see “Check for assignments to the same variable in multiple cascaded control regions” on page 21-85.

Example Patterns that Fail the Check for Guideline 2.F.B.1.a

These examples show HDL Code patterns that fail the check for the presence of assignments to the same variable in multiple cascaded conditional regions.

Parallel Cascaded 'if' Regions

```
always @(u) begin
    if(u < 8'sd4) begin
        y = -8'sd1;
    end
    if(u == 8'sd1) begin
        y = 8'sd10;
    end
    else
        y =8'sd2;
    end
end
```

Parallel Cascaded 'if' Regions with Nesting

```
always @(u, k) begin
    if (u < 8'sd4) begin
        if(k == 8'sd1) begin
            y = 8'sd10;
        end
    end
    if (u < 8'sd2) begin
        y = 8'sd1;
    end
    else
        y = 8'sd2;
    end
end
```

Parallel Cascaded 'if' and 'switch' Regions

```
always @(u) begin
    if (u < 8'sd4) begin
        y = 8'sd10;
    end
    case (u)
        8'sd1:
            y = 8'sd11;
        default:
            y = 8'sd4;
    end
end
```

```
    endcase
end
```

Parallel Cascaded 'switch' Regions

```
always @(u) begin
    case (u)
        8'sd2:
            y = 8'sd15;
        default:
            y = 8'sd4;
    endcase
    case (u)
        8'sd1:
            y = 8'sd11;
        default:
            y = 8'sd4;
    endcase
end
```

Parallel Cascaded Region Inside Nested Region

```
always @(u) begin
    case (u)
        8'sd2:
            y = 8'sd15;
        default:
            if (u < 8'sd4) begin
                y = 8'sd10;
            end
            if (u == 8'sd1) begin
                y = 8'sd10;
            else
                y = 8'sd2;
            end
    endcase
end
```

Example Patterns that Pass the Check for Guideline 2.F.B.1.a

These examples show HDL Code patterns that pass the check for the presence of assignments to the same variable in multiple cascaded conditional regions if you enable the check.

Default Value and Conditional Assignment

```
always @(u) begin
    y = 8'sd1;
    if (u < 8'sd4) begin
        y = 8'sd10;
    end
end
```

Parallel cascaded "if" Regions Writing to Different Outputs

```
always @(u) begin
    if (u < 8'sd4) begin
        y1 = -8'sd1;
    end
end
```

```

else
    y1 = 8'sd3;
end
if (u == 8'sd1) begin
    y2 = 8'sd10;
else
    y2 = 8'sd2;
end
end
end

```

Assignment in All Paths of Condition Regions

```

always @(u) begin
    if (u == 8'sd1) begin
        y = 8'sd10;
    else
        y = 8'sd2;
    end
end
end

```

Simulink Blocks and Modeling Patterns that Fail the Check for Guideline 2.F.B.1.a

Some Simulink blocks and modeling patterns can fail this check (guideline 2.F.B.1.a) and cause an error during HDL code generation. If a block or modeling pattern you use in your code fails this check, consider disabling the check if it is not needed in your production workflow or changing the block or modeling pattern producing the code failure.

MATLAB Function Block

In some cases, MATLAB code written inside MATLAB Function blocks might generate HDL Code that fails this check.

Conditional Initialization of Persistent Variables

If the persistent variables in a MATLAB Function block are conditionally initialized and then overwritten in a conditional region elsewhere in the code, the generated code might fail this check.

For example, if you have a MATLAB Function block in your DUT with the MATLAB code:

```

function y = fcn(u)

persistent loc;

if(isempty(loc) || u == int8(2))
    loc = int8(-1);
end

% persistent variable overwritten in conditional code region
if(u<int8(4))
    loc = int8(10);
end

y = loc;

```

This Verilog code snippet demonstrates the violation of a value assignment to the variable *loc_temp* in two parallel conditional if statements.

```
always @(loc, loc_not_empty, u) begin
    loc_temp = loc;
    loc_not_empty_next = loc_not_empty;
    if ( ! loc_not_empty || (u == 8'sd2)) begin
        loc_temp = -8'sd1;
        loc_not_empty_next = 1'b1;
    end
    // persistent variable overwritten in conditional code region
    if (u < 8'sd4) begin
        loc_temp = 8'sd10;
    end
    ...
end
```

Explicit modeling in the MATLAB Function block

If you set the **HDL Architecture** in the HDL Block Properties dialog box of the MATLAB Function block as **MATLAB Function** and design your MATLAB code in a coding style that assigns multiple values to the same variable in cascading conditional regions, an error might occur from the resulting violating patterns in the generated HDL code.

For example, if you have a MATLAB Function block in your DUT with the MATLAB code:

```
function y = fcn(u)

% if region 1
if(u<4)

    % if region 1-1
    if(u==1)
        y = int8(0);
    else
        y = int8(4);
    end

    % if region 1-2
    if(u==2)
        y = int8(5);
    end
else
    y = int8(6);
end

...

end
```

Region 1 in the preceding code contains two `if` statements that assign different values to the same output variable `y`. This pattern causes a violation in the generated Verilog code.

```
module mlfb
    (u,
     y);
    ...
    always @(u) begin
```

```

// if region 1
if (u < 8'sd4) begin
  // if region 1-1
  if (u == 8'sd1) begin
    y_1 = 8'sd0;
  end
  else begin
    y_1 = 8'sd4;
  end
  // if region 1-2
  if (u == 8'sd2) begin
    y_1 = 8'sd5;
  end
end
else begin
  y_1 = 8'sd6;
end

...

end

assign y = y_1;

endmodule // mlfb

```

Conditional Assignments of Matrix Variables

If you assign different indices of a single matrix in multiple cascading conditional regions in a MATLAB Function block, a violation can occur.

For example, if you have a MATLAB Function block in your DUT with the MATLAB code:

```

function y = fcn(u)
y = int8(zeros(1,2));

% if region 1
if(u==1)
  y(1) = int8(2);
end

% if region 2
if(u==2)
  y(2) = int8(5);
end

```

Although two different indices of the matrix *y* are being assigned values in cascading *if* statements, this code generates Verilog code that causes a violation.

```

ARCHITECTURE rtl OF mlfb IS
  -- Signals
  SIGNAL u_signed : signed(7 DOWNT0 0); -- int8
  SIGNAL y_tmp : vector_of_signed8(0 TO 1); -- int8 [2]

BEGIN
  u_signed <= signed(u);

```

```
m_lfb_1_output : PROCESS (u_signed)
BEGIN
  FOR t_0 IN 0 TO 1 LOOP
    y_tmp(t_0) <= to_signed(16#00#, 8);
  END LOOP;

  -- if region 1
  IF u_signed = to_signed(16#00000001#, 8) THEN
    y_tmp(0) <= to_signed(16#02#, 8);
  END IF;
  -- if region 2
  IF u_signed = to_signed(16#00000002#, 8) THEN
    y_tmp(1) <= to_signed(16#05#, 8);
  END IF;
END PROCESS m_lfb_1_output;

outputgen: FOR k IN 0 TO 1 GENERATE
  y(k) <= std_logic_vector(y_tmp(k));
END GENERATE;

END rtl;
```

Workarounds

- Design MATLAB code in your MATLAB Function block in a way that avoids patterns that assign multiple values to the same variable in multiple cascaded conditional regions.
- Consider specifying the HDL Block property of the MATLAB Function block **HDL Architecture** to be MATLAB Datapath.

Stateflow Charts

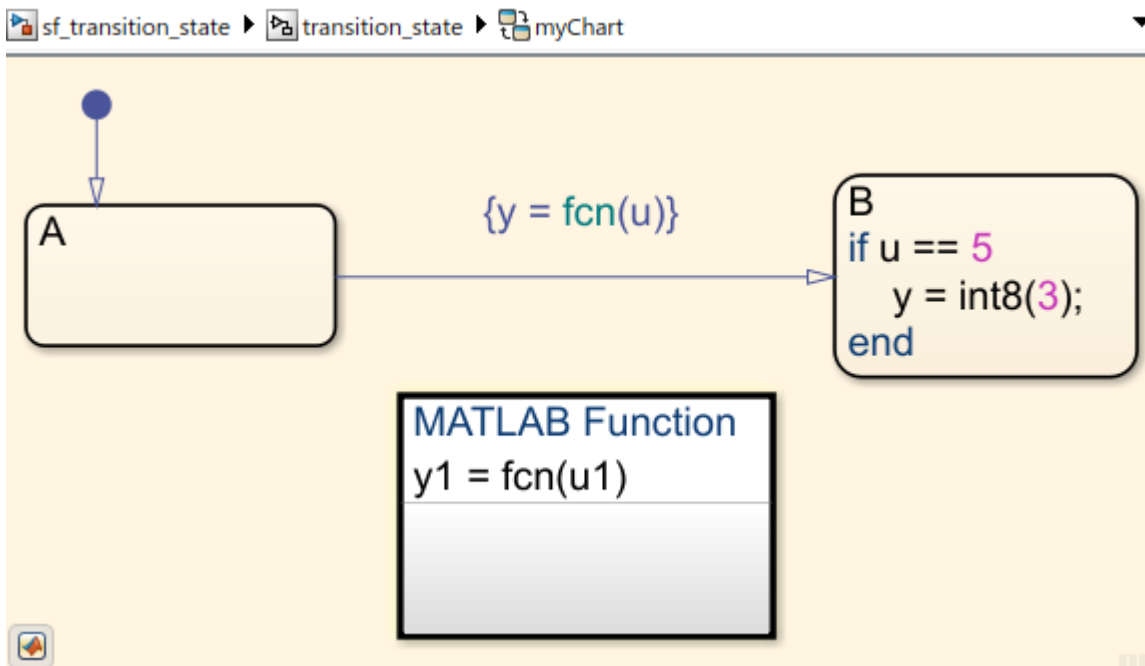

In some cases, MATLAB code written in Stateflow chart can generate HDL code that violates this check.

Explicit Chart Patterns

Cascaded if regions containing assignments to the same variable in a Stateflow chart can produce the equivalent pattern in the generated HDL code.

One if region in a transition followed by another if region in a destination state can cause a violation in the generated HDL code. This pattern is seen in this Stateflow Chart:

With the MATLAB Function block in the transition containing the code:

```

function y1 = fcn(u1)
    if(u1<4)
        y1 = int8(5);
    end
end

```

```

else
    y1 = int8(6);
end
end

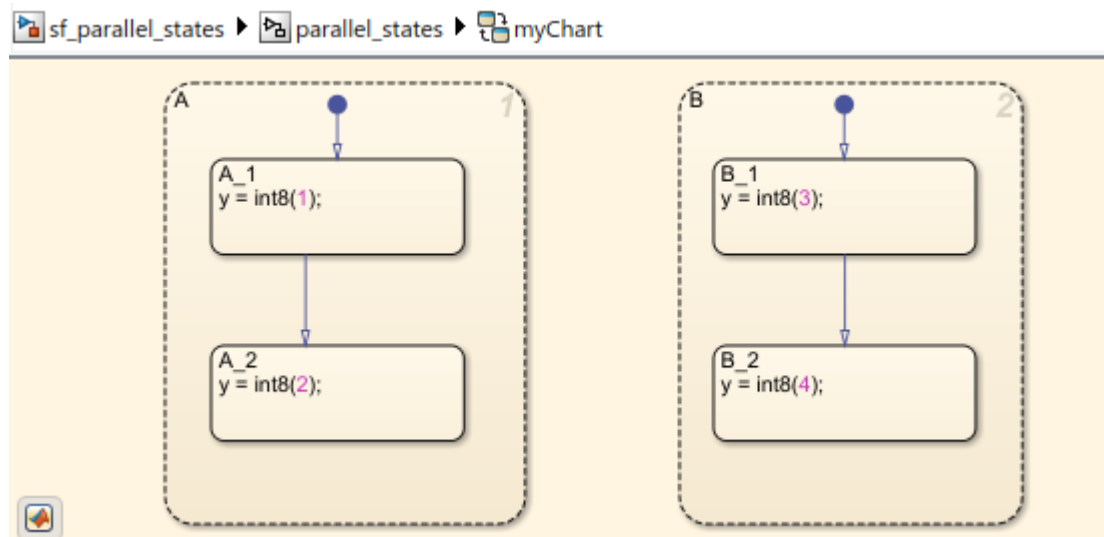

```

The workaround for both of these explicit chart pattern violations is to change the design pattern used in creating the Stateflow charts. Avoid using explicit `if/else` or `switch/case` regions in your Stateflow charts. Instead, redesign the required control flows by using Stateflow chart semantics, such as transitions and states.

Parallel Decomposition

In Stateflow charts, you have an option to choose **Parallel (AND)** mode for the **Decomposition** property of the chart that changes the chart execution to parallel style. For more information, see “Execution Order for Parallel States” (Stateflow).

For example, when you specify parallel decomposition in a chart, it results in the generation of cascaded `switch` regions in the same `always` process.

If the same output variable is assigned a value in multiple parallel states, a violation occurs in the generated HDL code. This Verilog code snippet demonstrates the violation of a value assignment to the variable `y_1` in two parallel conditional case statements in the same `always` process, generated as a result of parallel decomposition.

```

always @(is_A, is_B) begin
    is_A_next = is_A;
    is_B_next = is_B;
    case ( is_A )
        state_type_is_A_IN_A_1 :
            begin
                is_A_next = state_type_is_A_IN_A_2;
                y_1 = 8'sd2;
            end
        default :
            begin
                //case IN_A_2:
                y_1 = 8'sd2;
            end
    endcase
end

```

```

        end
    endcase
    case ( is_B)
        state_type_is_B_IN_B_1 :
            begin
                is_B_next = state_type_is_B_IN_B_2;
                y_1 = 8'sd4;
            end
        default :
            begin
                //case IN_B_2:
                y_1 = 8'sd4;
            end
    endcase
end

```

Temporal Logic

Use of temporal logic in your Stateflow chart generally results in violations. Under some conditions, generated code does not violate the coding guideline. Avoid using temporal logic to generate code that does not result in a violation.

LUT-Based Sine, Cosine Block

When using the LUT-based Sine, Cosine block in your model to generate HDL code, a violation of this check might occur in the generated HDL code. This Verilog code snippet generated from a Simulink model containing a LUT-based Sine, Cosine block demonstrates the violation of a value assignment to the variable *Look_Up_Table_k* in multiple parallel conditional *if* statements.

```

always @(QuadHandle2_out1) begin

    Look_Up_Table_t_0_0[0] = 16'sb0000000000000000;
    ...
    Look_Up_Table_t_0_0[31] = 16'sb0011111111101100;
    Look_Up_Table_t_0_0[32] = 16'sb0100000000000000;
    Look_Up_Table_in0_0 = 18'sb000000000000000000;
    Look_Up_Table_in0_0_0 = 18'sb000000000000000000;

    if (QuadHandle2_out1 <= 18'sb000000000000000000) begin
        Look_Up_Table_k = 6'b000000;
    end
    else if (QuadHandle2_out1 >= 18'sb000100000000000000) begin
        Look_Up_Table_k = 6'b100000;
    end
    else begin
        Look_Up_Table_in0_0 = QuadHandle2_out1 >>> 8'd9;
        Look_Up_Table_k = Look_Up_Table_in0_0[5:0];
    end

    ...

    Look_Up_Table_dout_low = Look_Up_Table_t_0_0[Look_Up_Table_k];
    if ( ! (Look_Up_Table_k == 6'b100000)) begin
        Look_Up_Table_k = Look_Up_Table_k + 6'b000001;
    end
    ...
end

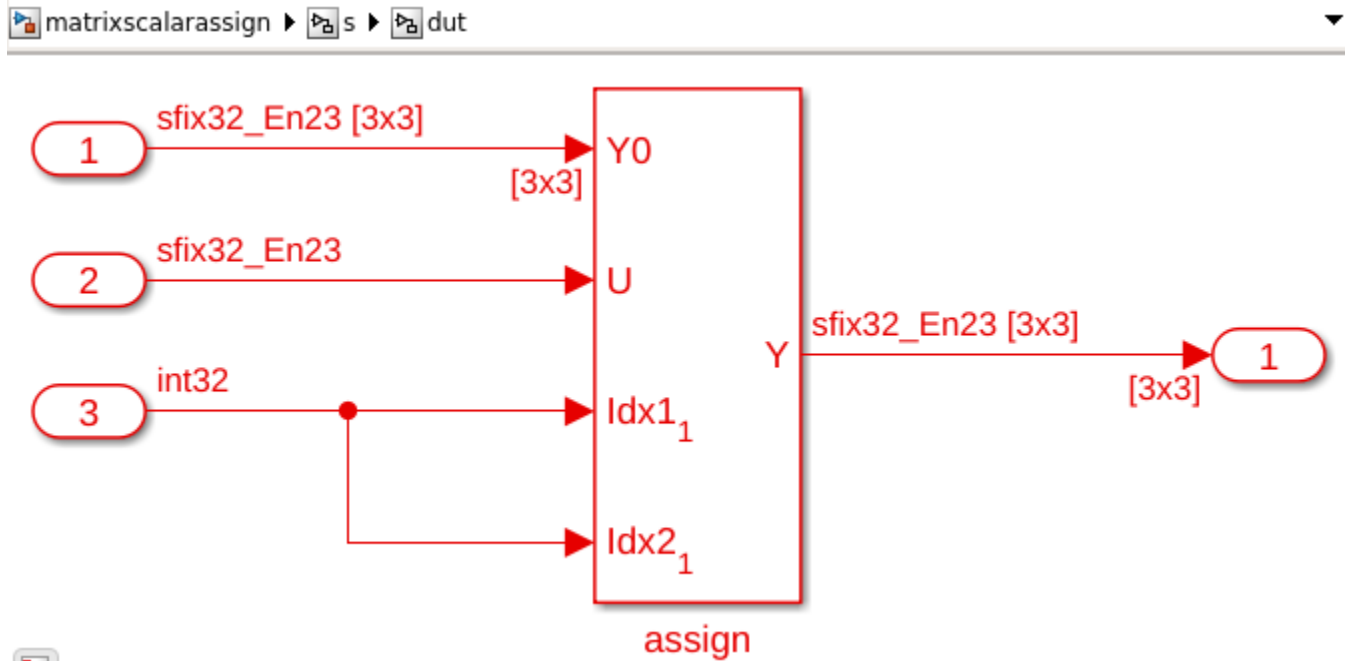

```

For more information, see Sine, Cosine.

Assignment Block

Similar to the violation caused by conditional assignments of matrix variables in MATLAB Function blocks, the Assignment block might cause a similar violation in the generated HDL code.

For example, a model containing an Assignment block in the DUT with the Assignment block property **Index Option** having more than one dimension and set to Index vector (port):

produces this Verilog code snippet:

```
always @* begin
  if ((In3 == 32'sb00000000000000000000000000000001) && (In3 == 32'sb00000000000000000000000000000000))
  begin
    assign_out1[0][0] = In2;
  end
  else begin
    assign_out1[0][0] = In1[0][0];
  end
  if ((In3 == 32'sb00000000000000000000000000000010) && (In3 == 32'sb00000000000000000000000000000000))
  begin
    assign_out1[1][0] = In2;
  end
  else begin
    assign_out1[1][0] = In1[1][0];
  end
  ...
  if ((In3 == 32'sb00000000000000000000000000000011) && (In3 == 32'sb00000000000000000000000000000000))
  begin
    assign_out1[2][2] = In2;
  end
end
```

```

        Selector_out1[1] = Bias_out1[1][0];
        Selector_out1[2] = Bias_out1[2][0];
        Selector_out1[3] = Bias_out1[3][0];
    end
end

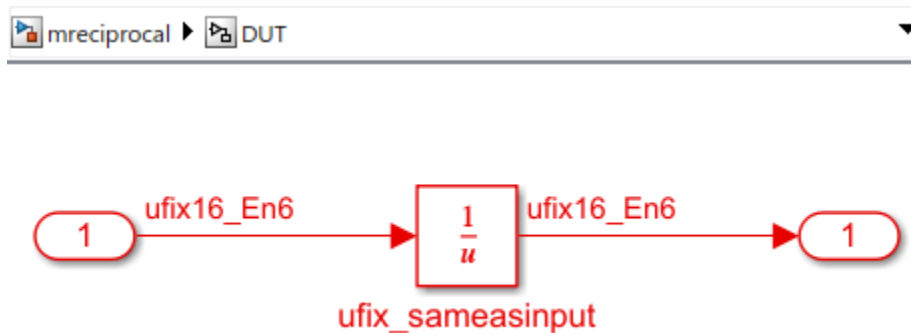

```

For more information on the Selector block, see Selector.

Math Function Block Set as Reciprocal

If a Math Function block with the **Function** set as reciprocal, the **Algorithm method** set as Exact, and the **Saturate on integer overflow** selected as on is in a DUT in a model that generates HDL code, a violation of this check might occur.

For example, a model containing the Math Function block with the preceding settings

produces this Verilog Code snippet that demonstrates the violation of a value assignment to the variable `ufix_sameasinput_out1` in two parallel conditional if statements:

```

always @(In1) begin
    ufix_sameasinput_div_temp = 16'b0000000000000000;
    if (In1 == 16'b0000000000000000) begin
        ufix_sameasinput_out1 = 16'b1111111111111111;
    end
    else begin
        ufix_sameasinput_div_temp = 13'b1000000000000 / In1;
        ufix_sameasinput_out1 = ufix_sameasinput_div_temp;
    end
    if (In1 == 16'b0000000000000000) begin
        ufix_sameasinput_out1 = 16'b1111111111111111;
    end
end
end

```

For more information on the Math Function block, see Math Function.

Model Referencing for HDL Code Generation

In this section...

“Benefits of Model Referencing for Code Generation” on page 32-2

“How To Generate Code for a Referenced Model” on page 32-2

“Generate Code for Model Arguments” on page 32-3

“Generate Comments” on page 32-3

“Limitations” on page 32-3

Benefits of Model Referencing for Code Generation

Model referencing in your DUT subsystem enables you to:

- Partition a large design into a hierarchy of smaller designs for reuse, modular development, and accelerated simulation.
- Incrementally generate and test code.

HDL Coder incrementally generates code for referenced models according to the **Configuration Parameters dialog box > Model Referencing pane > Rebuild** options.

However, HDL Coder treats `If changes detected` and `If changes in known dependencies detected` as the same. For example, if you set **Rebuild** to either `If changes detected` or `If changes in known dependencies detected`, HDL Coder regenerates code for referenced models only when the referenced models have changed.

How To Generate Code for a Referenced Model

By default, “Generate VHDL code for model references into a single library” on page 21-31 is enabled. The VHDL code is generated in a single library instead of separate libraries. In this case, set the `ScalarizePorts` property to `off` before generating HDL code.

When generating code, if you encounter typing or naming conflicts between vector ports when interfacing two or more generated VHDL code modules, use the `ScalarizePorts` property to generate non-conflicting port definitions. For more information, see “Scalarize ports” on page 21-45.

Use of vector or matrix ports at the model reference boundary requires ports to be scalarized in generated VHDL code, or the type definition or code to be placed in single library. When generating VHDL code, either set “Scalarize ports” on page 21-45 to on or enable “Generate VHDL code for model references into a single library” on page 21-31 option.

You can generate HDL code for the referenced model using the UI or the command line.

Using the UI

- 1 Right-click the Model block and select **HDL Code > HDL Block Properties**.
- 2 For **Architecture**, select **ModelReference**.
- 3 Generate HDL code from your DUT subsystem.

Using the Command Line

- 1 Set the `Architecture` property of the Model block to `ModelReference`. For example, for a DUT subsystem, `mydut`, that includes a model reference, `referenced_model`, enter this command:

```
hdlset_param ('mydut/referenced_model', ...
             'Architecture', 'ModelReference');
```

- 2 Generate HDL code for your DUT subsystem.

```
makehdl ('mydut');
```

Generate Code for Model Arguments

To generate a single Verilog module or VHDL entity for instances of a referenced model with different model argument values, see “Generate Parameterized Code for Referenced Models” on page 14-21.

Generate Comments

If you enter text in the Model Block Properties dialog box **Description** field, HDL Coder generates a comment in the HDL code.

Limitations

- Model block must have default values for the Block parameters.
- Multiple model references that refer to the same model must have the same HDL block properties.
- Referenced models cannot be protected models.

HDL Coder cannot move registers across a model reference. Therefore, referenced models can inhibit these optimizations:

- Distributed pipelining
- Constrained output pipelining
- Streaming

To use these optimizations, consider using subsystem references instead of model references. For more information, see “Subsystem Reference”.

When you have model references and generate HDL code, the generated model, validation model, and cosimulation model can fail to compile or simulate. To fix compilation or simulation errors, make sure that the referenced models are loaded or are on the search path.

The coder can apply the resource sharing optimization to share referenced model instances. However, you can apply this optimization only when all model references that point to the same referenced model have the same rate after optimizations and rate propagation. The model reference final rate may differ from the original rate, but all model references that point to the same referenced model must have the same final rate.

Generate Black Box Interface for Subsystem

In this section...

“What Is a Black Box Interface?” on page 32-4

“Requirements” on page 32-4

“Generate a Black Box Interface for a Subsystem” on page 32-4

“Generate Code for a Black Box Subsystem Implementation” on page 32-6

What Is a Black Box Interface?

A *black box* interface for a subsystem is a generated VHDL component or Verilog module that includes only the HDL input and output port definitions for the subsystem. By generating such a component, you can use a subsystem in your model to generate an interface to existing manually written HDL code, third-party IP, or other code generated by HDL Coder.

Requirements

- The black box implementation is available only for subsystem blocks below the level of the DUT. Virtual and atomic subsystem blocks of custom libraries that are below the level of the DUT also work with black box implementations.
- You can generate at most one clock port and one clock enable port for a black box subsystem. Therefore, the black box subsystem must be single-rate even if it is in a multirate DUT.

Generate a Black Box Interface for a Subsystem

To generate the interface, select the `BlackBox` implementation for one or more Subsystem blocks. Consider the following model that contains a subsystem `top`, which is the device under test.

The subsystem `top` contains two lower-level subsystems:

Suppose that you want to generate HDL code from **top**, with a black box interface from the **Interface** subsystem. To specify a black box interface:

- 1 Right-click the **Interface** subsystem and select **HDL Code > HDL Block Properties**.

The HDL Properties dialog box appears.

- 2 Set **Architecture** to **BlackBox**.

The following parameters are available for the black box implementation:

The HDL block parameters available for the black box implementation enable you to customize the generated interface. See “Customize Black Box or HDL Cosimulation Interface” on page 32-12 for information about these parameters.

- 3 Change parameters as desired, and click **Apply**.
- 4 Click **OK** to close the HDL Properties dialog box.

Generate Code for a Black Box Subsystem Implementation

When you generate code for the DUT in the `ex_blackbox_subsys` model, the following messages appear:

```
>> makehdl('ex_blackbox_subsys/top')
### Generating HDL for 'ex_blackbox_subsys/top'
```

```

### Starting HDL Check.
### HDL Check Complete with 0 errors, 0 warnings and 0 messages.

### Begin VHDL Code Generation
### Working on ex_blackbox_subsys/top/gencode as hdlsrc\gencode.vhd
### Working on ex_blackbox_subsys/top as hdlsrc\top.vhd
### HDL Code Generation Complete.

```

In the progress messages, observe that the `gencode` subsystem generates a separate file, `gencode.vhd`, for its VHDL entity definition. The Interface subsystem does not generate such a file. The interface code for this subsystem is in `top.vhd`, generated from `ex_blackbox_subsys/top`. The following code listing shows the component definition and instantiation generated for the Interface subsystem.

```

COMPONENT Interface
  PORT( clk      : IN    std_logic;
        clk_enable : IN    std_logic;
        reset     : IN    std_logic;
        In1      : IN    std_logic_vector(7 DOWNT0 0); -- uint8
        In2      : IN    std_logic_vector(15 DOWNT0 0); -- uint16
        In3      : IN    std_logic_vector(31 DOWNT0 0); -- uint32
        Out1     : OUT   std_logic_vector(31 DOWNT0 0) -- uint32
        );
END COMPONENT;

...
u_Interface : Interface
  PORT MAP( clk => clk,
            clk_enable => enb,
            reset => reset,
            In1 => gencode_out1, -- uint8
            In2 => gencode_out2, -- uint16
            In3 => gencode_out3, -- uint32
            Out1 => Interface_out1 -- uint32
            );

enb <= clk_enable;

ce_out <= enb;

Out1 <= Interface_out1;

```

By default, the black box interface generated for subsystems includes clock, clock enable, and reset ports. “Customize Black Box or HDL Cosimulation Interface” on page 32-12 describes how you can rename or suppress generation of these signals, and customize other aspects of the generated interface.

Generate Black Box Interface for Referenced Model

In this section...
“When to Generate a Black Box Interface” on page 32-8
“How to Generate a Black Box Interface” on page 32-8
“Caveats and Limitations” on page 32-8

When to Generate a Black Box Interface

Specify a black box implementation for the Model block when you already have legacy or manually-written HDL code. HDL Coder generates the HDL code that is required to interface to the referenced HDL code.

Code is generated with the following assumptions:

- Every HDL entity or module requires clock, clock enable, and reset ports. Therefore, these ports are defined for each generated entity or module.
- Use of Simulink data types is assumed. For VHDL code, port data types are assumed to be `STD_LOGIC` or `STD_LOGIC_VECTOR`.

If you want to generate code for a multirate, multiclock DUT that includes a referenced model, see “Model Referencing for HDL Code Generation” on page 32-2.

How to Generate a Black Box Interface

To instantiate an HDL wrapper, or black box interface, for a referenced model:

- 1 Right-click the Model block and select **HDL Code > HDL Block Properties**.

In the HDL Block Properties dialog box:

- For **Architecture**, select **BlackBox**.
- Customize the ports and other implementation parameters. To learn more about customizing the ports, see “Customize Black Box or HDL Cosimulation Interface” on page 32-12.

- 2 Generate HDL code for your DUT subsystem.

Caveats and Limitations

- If you run the `checkhdl` function to check the compatibility of your model for HDL code generation, the function does not check the port data types within the referenced model.
- If you encounter typing or naming conflicts between vector ports when interfacing two or more generated VHDL code modules, use the `ScalarizePorts` property to generate nonconflicting port definitions. For more information, see “Scalarize ports” on page 21-45.

Integrate Custom HDL Code by Using DocBlock

In this section...

“When to Use DocBlock for Integrating Custom Code” on page 32-10

“Use DocBlock to Integrate Custom Code” on page 32-10

“Restrictions” on page 32-10

“Include Custom HDL Code Using Doc Block” on page 32-11

You can use one or more DocBlock blocks to integrate custom HDL code into your design.

When to Use DocBlock for Integrating Custom Code

If you want to keep the HDL code in your model, instead of as a separate file, use a DocBlock to integrate custom HDL code. The text in the DocBlock is your custom VHDL or Verilog code.

You include each DocBlock that contains custom HDL code by placing it in a black box subsystem, and then including the black box subsystem in your design under test (DUT). One HDL file is generated for each black box subsystem.

Alternatives for Custom Code Integration

If you want to keep your custom HDL code separate from your model, such as when the custom code is intellectual property (IP) or a library from a third party vendor, use a black box subsystem on page 32-4 or black box model reference on page 32-8.

Use DocBlock to Integrate Custom Code

- 1 In your DUT, at any level of hierarchy, add a Subsystem block.
- 2 For the Subsystem block, in the HDL Block Properties dialog box:
 - Set **Architecture** to `BlackBox`.
 - Customize the black box subsystem interface so that it matches your custom HDL code interface. See “Customize Black Box or HDL Cosimulation Interface” on page 32-12.
- 3 In the subsystem, add a DocBlock block.
- 4 For the DocBlock, in the HDL Block Properties dialog box:
 - Set **Architecture** to `HDLText`.
 - Set **TargetLanguage** to your target language, either `Verilog` or `VHDL`.
- 5 In the DocBlock, enter the HDL code for your custom Verilog module or VHDL entity.

The language must match the DocBlock **TargetLanguage** setting.

Restrictions

- The black box subsystem that contains the DocBlock cannot be the top-level DUT.
- You can have a maximum of two DocBlock blocks in the black box subsystem. If you have two DocBlock blocks, one must have **TargetLanguage** set to `VHDL` and the other must have **TargetLanguage** set to `Verilog`.

When generating code, HDL Coder integrates the code from the DocBlock that matches the target language for code generation.

- When a black box subsystem that contains the DocBlock is placed in another black box subsystem, HDL Coder does not integrate the HDL code from this DocBlock during code generation.

Include Custom HDL Code Using Doc Block

The `hdlcoderIncludeCustomHdlUsingDocBlockExample` model shows how to integrate custom VHDL and Verilog code into your design with the DocBlock block.

To open `hdlcoderIncludeCustomHdlUsingDocBlockExample` model, run these commands:

```
load_system('hdlcoderIncludeCustomHdlUsingDocBlockExample.slx');
open_system('hdlcoderIncludeCustomHdlUsingDocBlockExample/DUT');
```

Set appropriate HDL Block properties within the BlackBox architecture for subsystem

The `LegacyCodeSubs` subsystem has two DocBlock blocks which contains legacy VHDL and Verilog code. You can generate the HDL code of the DUT subsystem by using `makehdl` command.

- “Generate Black Box Interface for Referenced Model” on page 32-8

Customize Black Box or HDL Cosimulation Interface

You can customize port names and set attributes of the external component when you generate an interface from the following blocks:

- Model with black box implementation
- Subsystem with black box implementation
- HDL Cosimulation

Interface Parameters

Open the HDL Block Properties dialog box to see the interface generation parameters.

The following table summarizes the names, value settings, and purpose of the interface generation parameters.

Note You cannot specify clock, reset, and clock enable signals explicitly in your Simulink model by using the **AddClockEnablePort**, **AddClockPort**, and **AddResetPort** parameters. Instead, use these parameters to add a clock, reset, or clock enable port in the generated HDL code.

Parameter Name	Values	Description
AddClockEnablePort	on off Default: on	If on, add a clock enable input port to the interface generated for the block. The name of the port is specified by ClockEnableInputPort .
AddClockPort	on off Default: on	If on, add a clock input port to the interface generated for the block. The name of the port is specified by ClockInputPort .
AddResetPort	on off Default: on	If on, add a reset input port to the interface generated for the block. The name of the port is specified by ResetInputPort .
AllowDistributedPipelining	on off Default: off	If on, allow HDL Coder to move registers across the block, from input to output or output to input.
ClockEnableInputPort	Default: clk_enable	Specifies HDL name for block's clock enable input port.
ClockInputPort	Default: clk	Specifies HDL name for block's clock input signal.
ConstrainedOutputPipeline	Default: 0	Specifies the number of delays that you want the code generator to insert at the output of the interface by redistributing existing delays in your design.

Parameter Name	Values	Description
EntityName	Default: Entity name string is derived from the block name, and modified when necessary to generate a legal VHDL entity name.	Specifies VHDL entity or Verilog module name generated for the block.
GenericList	<p>Pass a cell array variable that contains cell arrays each with two or three strings, or enter a cell array of cell arrays that each contain two or three strings. The strings represent the name, value, and optional data type of a VHDL generic or Verilog parameter. The default data type is integer.</p> <p>Default: none</p>	<p>Specifies a list of VHDL generic or Verilog parameter name-value pairs, each with an optional data type specification, to pass to a subsystem with a BlackBox implementation.</p> <p>For example, in the HDL Block Properties dialog box, enter <code>{'name', 'value', 'type'}</code>, or, if the data type is integer, enter <code>{'name', 'value'}</code>.</p> <p>To set GenericList using <code>hdlset_param</code>, at the command line, enter:</p> <pre>hdlset_param (blockname, 'GenericList', {' 'na me ' ', 'value ' ', 'type ' '});</pre> <p>If the data type is integer, at the command line, enter:</p> <pre>hdlset_param (blockname, 'GenericList', {' 'na me ' ', 'value ' '});</pre>
ImplementationLatency	-1 0 positive integer Default: -1	<p>Specifies the additional latency of the external component in time steps, relative to the Simulink block.</p> <p>If 0 or greater, this value is used for delay balancing. Your inputs and outputs must operate at the same rate.</p> <p>If -1, latency is unknown. This disables delay balancing.</p>
InlineConfigurations (VHDL only)	on off Default: If this parameter is unspecified, defaults to the value of the global <code>InlineConfigurations</code> property.	If off, suppress generation of a configuration for the block, and require a user-supplied external configuration.

Parameter Name	Values	Description
InputPipeline	Default: 0	Specifies the number of input pipeline stages (pipeline depth) in the generated code.
OutputPipeline	Default: 0	Specifies the number of output pipeline stages (pipeline depth) in the generated code.
ResetInputPort	Default: reset	Specifies HDL name for block's reset input.
VHDLArchitectureName (VHDL only)	Default: rtl	Specifies RTL architecture name generated for the block. The architecture name is generated only if InlineConfigurations is on.
VHDLComponentLibrary (VHDL only)	Default: work	Specifies the library from which to load the VHDL component.

Specify Bidirectional Ports

You can specify bidirectional ports for Subsystem blocks with black box implementation. In the generated code, the bidirectional ports have the Verilog or VHDL `inout` keyword.

In the FPGA Turnkey workflow, you can use the bidirectional ports to connect to external RAM.

In this section...

“Requirements” on page 32-15

“How To Specify a Bidirectional Port” on page 32-15

“Limitations” on page 32-15

Requirements

- The bidirectional port must be a black box subsystem port.
- There must be no logic between the bidirectional port and the corresponding top-level DUT subsystem port. Otherwise, the generated code does not compile.

How To Specify a Bidirectional Port

To specify a bidirectional port using the UI:

- 1 In the black box Subsystem, right-click the Inport or Outport block that represents the bidirectional port. Select **HDL Code > HDL Block Properties**.
- 2 For **BidirectionalPort**, select on.

To specify a bidirectional port at the command line, set the `BidirectionalPort` property to 'on' using `hdlset_param` or `makehdl`.

For example, suppose you have a model, `my_model`, that contains a DUT subsystem, `dut_subsys`, and the DUT subsystem contains a black box subsystem, `blackbox_subsys`. If `blackbox_subsys` has an Inport, `input_A`, specify `input_A` as bidirectional by entering:

```
hdlset_param('my_model/dut_subsys/blackbox_subsys/input_A','BidirectionalPort','on');
```

Limitations

- In the FPGA Turnkey workflow, in the **Target platform interfaces table**, you must map a bidirectional port to either `Specify FPGA Pin { 'LSB', ..., 'MSB' }` or one of the other interfaces where the interface bitwidth exactly matches your bidirectional port bitwidth.

For example, you can map a 32-bit bidirectional port to the `Expansion Headers J6 Pin 2-64[0:31]` interface.

- You cannot generate a Verilog test bench if there is a bidirectional port within your DUT subsystem.
- HDL Coder does not support bidirectional ports for masked subsystems that use `BlackBox` as the **HDL Architecture**.
- Simulink does not support bidirectional ports, so you cannot simulate the bidirectional behavior in Simulink.

Generate Reusable Code for Subsystems

In this section...

“Requirements for Generating Reusable Code for Atomic Subsystems” on page 32-17

“Requirements for Generating Reusable Code for Virtual Subsystems” on page 32-17

“Generate Reusable Code for Atomic Subsystems” on page 32-18

“Generate Reusable Code for Atomic Subsystems with Tunable Mask Parameters” on page 32-20

HDL Coder can detect atomic subsystems that are identical, or identical except for their mask parameter values, at any level of the model hierarchy, and generate a single reusable HDL module or entity. The reusable HDL code is generated as a single file and instantiated multiple times.

Requirements for Generating Reusable Code for Atomic Subsystems

- The `DefaultParameterBehavior` Simulink Configuration Parameter must be `Inlined`. You can set this parameter at the command line by using the `set_param` or `hdlsetup` function. To specify this setting in the Configuration Parameters dialog box, you must have Simulink Coder.

Note Using `hdlsetup` sets `InlineParams` property to `on`. Enabling this parameter is the same as setting `DefaultParameterBehavior` to `Inlined`. Setting `InlineParams` to `off` changes `DefaultParameterBehavior` value to `Tunable`.

- Do not use functionality such as signal logging or using blocks like `To Workspace` or `To File`.
- The atomic subsystems must be identical, or identical except for their mask parameter values.
 - `MaskParameterAsGeneric` must be `on`. For more information, see “Generate Parameterized HDL Code from Masked Subsystem” on page 21-61.
 - Mask parameters must be nontunable. The code generator does not share atomic subsystems with mask parameters that are tunable.
 - Mask parameters must be scalar.
 - Mask parameter data types must be integer or fixed-point with a word length of less than or equal to 32.
 - The tunable parameter must be used in only `Constant`, `Gain`, or `Compare To Constant` blocks.
 - Port data types must match.

If you change the value of the tunable mask parameter, the output port data type can change. If one of the atomic subsystems has a different port data type, the code generated for that subsystem also differs.

Requirements for Generating Reusable Code for Virtual Subsystems

- The `DefaultParameterBehavior` Simulink Configuration Parameter must be `Inlined`. You can set this parameter at the command line by using the `set_param` or `hdlsetup` function. To specify this setting in the Configuration Parameters dialog box, you must have Simulink Coder.

Note Using `hdlsetup` sets `InlineParams` property to on. Enabling this parameter is the same as setting `DefaultParameterBehavior` to `Inlined`. Setting `InlineParams` to off changes `DefaultParameterBehavior` value to `Tunable`.

- Do not use logging functionality such as signal logging or blocks like To Workspace or To File.
- The virtual subsystems must be identical, or identical except for their mask parameter values.
 - `SubsystemReuse` must be set to 'Atomic and Virtual'.
 - Setting `SubsystemReuse` to 'Atomic and Virtual' reduces artificial algebraic errors and improves the recognition of identical subsystems, irrespective of their topology within the rest of the design. Identification of similar subsystems can help resource sharing.
 - To set these values to your required setting, in the MATLAB Command Window, enter:

```
hdlset_param('myHDLModel', 'SubsystemReuse', 'Atomic and Virtual')
```
 - Alternatively, you can set this option from the top-level **HDL Code Generation** pane in the Configuration Parameters dialog box. Under **Global Settings > Coding style**, you can change the **Code reuse** setting to the required option.
 - The previous commands set the `SubsystemReuse` option for your project. To set this option for only the current code generation session, enter:

```
makehdl(<DUT system>, 'SubsystemReuse', 'Atomic and Virtual')
```
- `MaskParameterAsGeneric` must be on. For more information, see “Generate Parameterized HDL Code from Masked Subsystem” on page 21-61.
- Mask parameters must be nontunable. The code generator does not share atomic subsystems with mask parameters that are tunable.
- Mask parameters must be scalar.
- Mask parameter data types must be integer or fixed-point with a word length of less than or equal to 32.
- The tunable parameter must be used in only Constant, Gain, or Compare To Constant blocks.
- Port data types must match.

If you change the value of the tunable mask parameter, the output port data type can change. If one of the atomic subsystems has a different port data type, the code generated for that subsystem also differs.

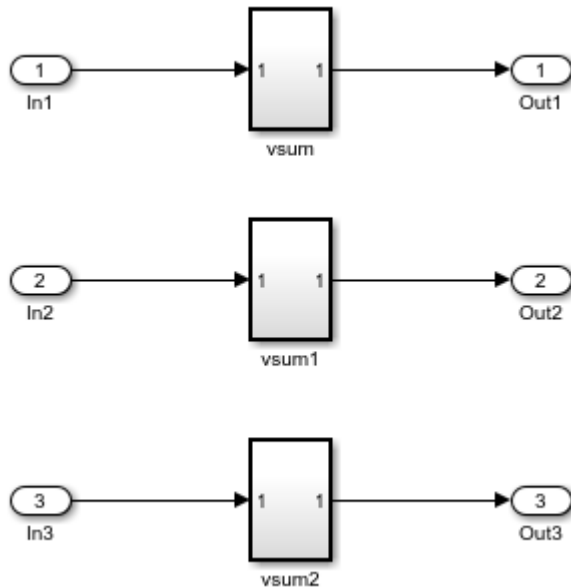

Generate Reusable Code for Atomic Subsystems

This example shows HDL code generation of a model that has identical atomic subsystems. If your design contains identical atomic subsystems, the coder generates one HDL module or entity for the subsystem and instantiates it multiple times.

Open Model

Open the `hdlcoder_reusable_code_identical_subsystem` model to see an example of a DUT subsystem containing three identical atomic subsystems.

```
load_system('hdlcoder_reusable_code_identical_subsystem');
open_system('hdlcoder_reusable_code_identical_subsystem/DUT');
```

Generate HDL Code

You can generate the HDL code for the model by using `makehdl` function. To generate HDL code for DUT subsystem, run this command:

```
makehdl('hdlcoder_reusable_code_identical_subsystem/DUT')
```

```
### Generating HDL for 'hdlcoder_reusable_code_identical_subsystem/DUT'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('hdlcoder_reusabl
### Running HDL checks on the model 'hdlcoder_reusable_code_identical_subsystem'.
### Begin compilation of the model 'hdlcoder_reusable_code_identical_subsystem'...
### Working on the model 'hdlcoder_reusable_code_identical_subsystem'...
### Working on... <a href="matlab:configset.internal.open('hdlcoder_reusable_code_identical_subsy
### Begin model generation 'gm_hdlcoder_reusable_code_identical_subsystem' ....
### Rendering DUT with optimization related changes (IO, Area, Pipelining)...
### Model generation complete.
### Generating new validation model: <a href="matlab:open_system('hdl_prj\hdlsrc\hdlcoder_reusabl
### Validation model generation complete.
### Begin VHDL Code Generation for 'hdlcoder_reusable_code_identical_subsystem'.
### Working on hdlcoder_reusable_code_identical_subsystem/DUT/vsum as hdl_prj\hdlsrc\hdlcoder_reu
### Working on hdlcoder_reusable_code_identical_subsystem/DUT as hdl_prj\hdlsrc\hdlcoder_reusabl
### Generating package file hdl_prj\hdlsrc\hdlcoder_reusable_code_identical_subsystem\DUT_pkg.vhd
### Code Generation for 'hdlcoder_reusable_code_identical_subsystem' completed.

### HDL check for 'hdlcoder_reusable_code_identical_subsystem' complete with 0 errors, 0 warnings
### HDL code generation complete.
```

HDL Coder generates a single VHDL® file, `vsum.vhd`, for the three subsystems. The generated code for the DUT subsystem, `DUT.vhd`, contains three instantiations of the `vsum` component.

```
ARCHITECTURE rtl OF DUT IS
```

```
-- Component Declarations
```

```
COMPONENT vsum
```

```
  PORT( In1
```

```
        : IN    vector_of_std_logic_vector16(0 TO 9); -- int16
```

```

        Out1
    );
END COMPONENT;

-- Component Configuration Statements
FOR ALL : vsum
    USE ENTITY work.vsum(rtl);

-- Signals
SIGNAL vsum_out1           : std_logic_vector(19 DOWNTO 0); -- ufix20
SIGNAL vsum1_out1         : std_logic_vector(19 DOWNTO 0); -- ufix20
SIGNAL vsum2_out1         : std_logic_vector(19 DOWNTO 0); -- ufix20

BEGIN
u_vsum : vsum
    PORT MAP( In1 => In1, -- int16 [10]
              Out1 => vsum_out1 -- sfix20
    );

u_vsum1 : vsum
    PORT MAP( In1 => In2, -- int16 [10]
              Out1 => vsum1_out1 -- sfix20
    );

u_vsum2 : vsum
    PORT MAP( In1 => In3, -- int16 [10]
              Out1 => vsum2_out1 -- sfix20
    );

Out1 <= vsum_out1;
Out2 <= vsum1_out1;
Out3 <= vsum2_out1;

END rtl;

```

Generate Reusable Code for Atomic Subsystems with Tunable Mask Parameters

Using this example, you can generate HDL code for your design containing atomic subsystems that are identical except for their tunable mask parameter values. You can generate one HDL module or entity for the subsystem. In the generated code, the module or entity is instantiated multiple times.

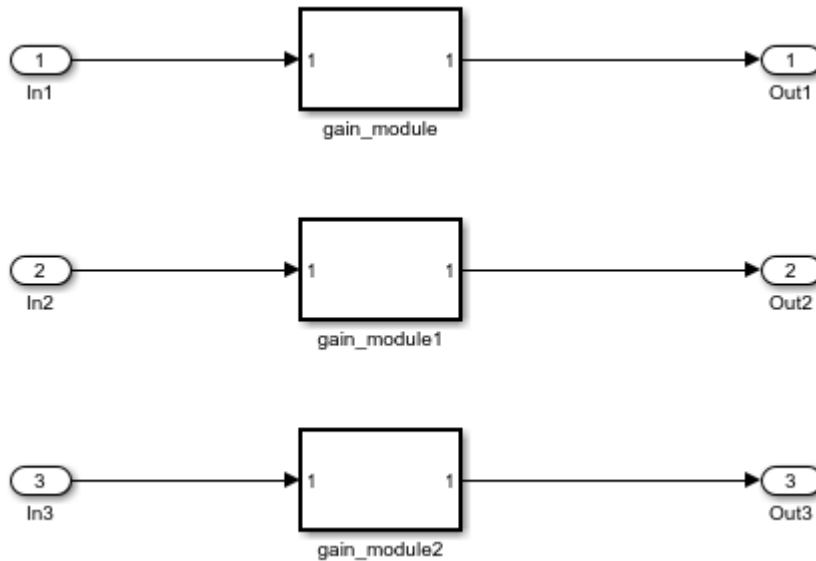

Open Model

The `hdlcoder_reusable_code_parameterized_subsystem` model shows an example of a DUT subsystem containing atomic subsystems that are identical except for their tunable mask parameter values.

```

load_system('hdlcoder_reusable_code_parameterized_subsystem');
open_system('hdlcoder_reusable_code_parameterized_subsystem/DUT');

```

In `hdlcoder_reusable_code_parameterized_subsystem/DUT`, the gain modules are subsystems with gain values represented by tunable mask parameters. Gain values are: 4 for `gain_module`, 5 for `gain_module1`, and 7 for `gain_module2`.

Generate HDL Code

To generate reusable code for identical atomic subsystems, enable `MaskParameterAsGeneric` for the model. By default, `MaskParameterAsGeneric` is disabled.

To enable the generation of reusable code for the atomic subsystems with tunable parameters, set `MaskParameterAsGeneric` option to "on" for a model by using `hdlset_param` function.

```
hdlset_param('hdlcoder_reusable_code_parameterized_subsystem', 'MaskParameterAsGeneric', 'on');
```

Alternatively, in the Configuration Parameters dialog box, in the **HDL Code Generation > Global Settings > Coding Style** tab, enable the **Generate parameterized HDL code from masked subsystem** option.

You can also enable `MaskParameterAsGeneric` option by using `makehdl` function and generate HDL code for a DUT subsystem.

```
makehdl('hdlcoder_reusable_code_parameterized_subsystem/DUT', 'MaskParameterAsGeneric', 'on', ...
        'TargetLanguage', 'Verilog')
```

```
### Generating HDL for 'hdlcoder_reusable_code_parameterized_subsystem/DUT'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('hdlcoder_reusab
### Running HDL checks on the model 'hdlcoder_reusable_code_parameterized_subsystem'.
### Begin compilation of the model 'hdlcoder_reusable_code_parameterized_subsystem'...
### Working on the model 'hdlcoder_reusable_code_parameterized_subsystem'...
### Working on... <a href="matlab:configset.internal.open('hdlcoder_reusable_code_parameterized_s
### Begin model generation 'gm_hdlcoder_reusable_code_parameterized_subsystem' ....
### Copying DUT to the generated model....
### Model generation complete.
### Begin Verilog Code Generation for 'hdlcoder_reusable_code_parameterized_subsystem'.
### Working on hdlcoder_reusable_code_parameterized_subsystem/DUT/gain_module as hdlsrc\hdlcoder_
```

```

### Working on hdlcoder_reusable_code_parameterized_subsystem/DUT as hdlsrc\hdlcoder_reusable_co
### Code Generation for 'hdlcoder_reusable_code_parameterized_subsystem' completed.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_10220/ib17334E/0/tp
### HDL check for 'hdlcoder_reusable_code_parameterized_subsystem' complete with 0 errors, 0 warn
### HDL code generation complete.

```

With MaskParameterAsGeneric enabled, HDL Coder generates a single source file, `gain_module.v`, for the three gain module subsystems. The generated code for the DUT subsystem, `DUT.v`, contains three instantiations of the `gain_module` component.

```

module DUT
(
    In1,
    In2,
    In3,
    Out1,
    Out2,
    Out3
);

input  [7:0] In1; // uint8
input  [7:0] In2; // uint8
input  [7:0] In3; // uint8
output [31:0] Out1; // uint32
output [31:0] Out2; // uint32
output [31:0] Out3; // uint32

wire [31:0] gain_module_out1; // uint32
wire [31:0] gain_module1_out1; // uint32
wire [31:0] gain_module2_out1; // uint32

gain_module # (.myGain(4)
)
    u_gain_module (.In1(In1), // uint8
                  .Out1(gain_module_out1) // uint32
                  );

assign Out1 = gain_module_out1;

gain_module # (.myGain(5)
)
    u_gain_module1 (.In1(In2), // uint8
                   .Out1(gain_module1_out1) // uint32
                   );

assign Out2 = gain_module1_out1;

gain_module # (.myGain(7)
)
    u_gain_module2 (.In1(In3), // uint8
                   .Out1(gain_module2_out1) // uint32
                   );

assign Out3 = gain_module2_out1;
endmodule // DUT

```

In `gain_module.v`, the `myGain` Verilog® parameter is generated for the tunable mask parameter.

```

module gain_module
(

```

```
        In1,  
        Out1  
    );  
  
input  [7:0] In1; // uint8  
output [31:0] Out1; // uint32  
  
parameter [31:0] myGain = 4; // ufix32  
  
wire [31:0] kconst; // ufix32  
wire [39:0] Gain_mul_temp; // ufix40  
wire [31:0] Gain_out1; // uint32  
  
assign kconst = myGain;  
  
assign Gain_mul_temp = kconst * In1;  
assign Gain_out1 = Gain_mul_temp[31:0];  
  
assign Out1 = Gain_out1;  
  
endmodule // gain_module
```

If the input model has subsystems that contains mask information such as mask variables and mask initialization code, the mask information of those subsystems is preserved in the generated model. If you do not need this information, you can remove it.

Scalarization of Vector Ports in Generated VHDL Code

This example shows how to flatten the vector signals in a Simulink® model into a structure of scalar signals in the generated VHDL® code.

Specify Scalarization of Vector Ports

When you generate Verilog code, by default, the vector signals are flattened into scalars by default. When you generate VHDL code, you can specify whether to flatten the vector signals on the entire model or at the DUT level. Flattening the vector ports at only the DUT level speeds up code generation, especially for large models that have many vector inputs.

When generating HDL code from MATLAB® and Simulink, you can scalarize the vector ports into scalars. For the MATLAB® to HDL workflow, in the **HDL Code Generation** task, on the **Clocks & Ports** tab, set **Scalarize ports** to `dutlevel` or `on`.

To scalarize the vector ports when generating HDL code for a Simulink model:

- In the Configuration Parameters dialog box, on the **HDL Code Generation > Global Settings > Ports** tab, set **Scalarize Ports** parameter to `dutlevel` or `on`.
- In the HDL Workflow Advisor, on the **HDL Code Generation > Set Code Generation Options > Set Advanced Options > Ports** tab, set **Scalarize Ports** parameter to `dutlevel` or `on`.
- At the MATLAB command prompt, set the `ScalarizePorts` property to `on` or `dutlevel` by using `hdlset_param` or `makehdl`.

See “Scalarize ports” on page 21-45.

Vector Sum Model

To see the flattening of vector ports, open the model `hdlcoder_hdlcoder_vector_sum_nested`. The model is driven by a vector input of width 10 and has a scalar output.

```
open_system('hdlcoder_vector_sum_nested')
set_param('hdlcoder_vector_sum_nested','SimulationCommand','update')
```

Copyright 2020-2021 The MathWorks, Inc.

This model is the same as the `simplevectorsum` model and consists of a Subsystem, `vsum_mid`, inside the `vsum` subsystem.

```
open_system('hdlcoder_vector_sum_nested/vsum')
```

The `vsum_mid` subsystem contains a Sum of Elements block that is configured for vector summation. The model is configured to use the Tree implementation when generating HDL code for the Sum of Elements block within the `vsum` subsystem. This implementation is optimized for minimal latency, generates a tree-shaped structure of adders for the block.

```
open_system('hdlcoder_vector_sum_nested/vsum/vsum_mid')
```

Scalarize Vector Ports

By default, the `ScalarizePorts` property is off. HDL Coder™ generates a type definition and port declaration for the vector port `In1`, as shown in this code.

```
PACKAGE simplevectorsum_pkg IS
  TYPE vector_of_std_logic_vector16 IS ARRAY (NATURAL RANGE <>)
    OF std_logic_vector(15 DOWNTO 0);
  TYPE vector_of_signed16 IS ARRAY (NATURAL RANGE <>) OF signed(15 DOWNTO 0);
END simplevectorsum_pkg;
```

...

```
ENTITY vsum IS
  PORT( In1      : IN   vector_of_std_logic_vector16(0 TO 9); -- int16 [10]
        Out1     : OUT  std_logic_vector(19 DOWNTO 0)  -- sfix20
      );
END vsum;
```

To scalarize the vector ports when generating HDL code, either set the **Scalarize ports** parameter in the Configuration Parameters dialog box or set the `ScalarizePorts` property to `on` or `outlevel` by using the `hdlset_param` or `makehdl` functions. When you set `ScalarizePorts` to `outlevel`, only the vector signals at the DUT are flattened into scalars. The scalars are input to the `vsum_mid` subsystem as vectors.

```
makehdl('hdlcoder_vector_sum_nested/vsum', 'ScalarizePorts', 'outlevel')
```

```
ENTITY vsum IS
  PORT( In1_0      : IN   std_logic_vector(15 DOWNTO 0); -- int16
        In1_1      : IN   std_logic_vector(15 DOWNTO 0); -- int16
        In1_2      : IN   std_logic_vector(15 DOWNTO 0); -- int16
        In1_3      : IN   std_logic_vector(15 DOWNTO 0); -- int16
        In1_4      : IN   std_logic_vector(15 DOWNTO 0); -- int16
        In1_5      : IN   std_logic_vector(15 DOWNTO 0); -- int16
        In1_6      : IN   std_logic_vector(15 DOWNTO 0); -- int16
        In1_7      : IN   std_logic_vector(15 DOWNTO 0); -- int16
        In1_8      : IN   std_logic_vector(15 DOWNTO 0); -- int16
        In1_9      : IN   std_logic_vector(15 DOWNTO 0); -- int16
```

```

        Out1          :   OUT   std_logic_vector(19 DOWNT0 0) -- sfix20
    );
END vsum;

ENTITY vsum_mid IS
    PORT( In1          :   IN    vector_of_std_logic_vector16(0 TO 9); -- in
          Out1         :   OUT   std_logic_vector(19 DOWNT0 0) -- sfix20
    );
END vsum_mid;

```

You can change the starting index for the names of scalarized vector ports from Zero-based to One-based by setting the model configuration parameter **Indexing for scalarized port naming** to One-based. For more information, see “Indexing for Scalarized Port Naming” on page 21-63.

To flatten the vector ports on the entire model, set `ScalarizePorts` to `on`. The vector ports at `vsum_mid` and the inputs to the Sum of Elements block are also flattened into scalars.

```
makehdl('hdlcoder_vector_sum_nested/vsum', 'ScalarizePorts', 'on')
```

```

ENTITY vsum_mid IS
    PORT( In1_0        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          In1_1        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          In1_2        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          In1_3        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          In1_4        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          In1_5        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          In1_6        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          In1_7        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          In1_8        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          In1_9        :   IN    std_logic_vector(15 DOWNT0 0); -- int16
          Out1         :   OUT   std_logic_vector(19 DOWNT0 0) -- sfix20
    );
END vsum_mid;

```

Usage Notes and Restrictions

- When you use the `ScalarizePorts` property for a protected model, you must use the same value for this property as the value specified for this parameter in the top model from which it is referenced.
- When you use the IP Core Generation and FPGA-in-the-Loop workflows, vector ports are not supported. Set `ScalarizePorts` as `on` or `dutlevel`. For faster code generation, set `ScalarizePorts` to `dutlevel`.
- Vector or matrix ports as input to a model reference interface must be scalarized before generating HDL code. Set `ScalarizePorts` to `dutlevel`.
- By default, **Generate VHDL code for model references into a single library** is enabled. The VHDL code is generated in a single library instead of separate libraries. In this case, set the `ScalarizePorts` property to `off` before generating HDL code.
- When generating code, if you encounter typing or naming conflicts between vector ports when interfacing two or more generated VHDL code modules, use the `ScalarizePorts` property to generate non-conflicting port definitions.

Create a Xilinx System Generator Subsystem

In this section...

“Why Use Xilinx System Generator Subsystems” on page 32-28

“Requirements for Xilinx System Generator Subsystems” on page 32-28

“Create a Xilinx System Generator Subsystem” on page 32-28

“Limitations for Code Generation from Xilinx System Generator Subsystems” on page 32-29

Why Use Xilinx System Generator Subsystems

You can generate HDL code from a model with both Simulink and Xilinx blocks using Xilinx System Generator (XSG) subsystems. Using Simulink and Xilinx blocks in your model provides:

- A single platform for combined Simulink and Xilinx System Generator simulation, code generation, and synthesis.
- Targeted code generation: Xilinx System Generator for DSP generates code from Xilinx blocks and HDL Coder generates code from Simulink blocks.
- HDL Coder area and speed optimizations for Simulink components.

Requirements for Xilinx System Generator Subsystems

Group your Xilinx blocks into one or more Xilinx System Generator (XSG) subsystems for code generation. An XSG subsystem can contain a hierarchy of subsystems.

To generate code from a Xilinx System Generator subsystem:

- Use Vivado or ISE Design Suite 13.4 or later.
- If your design uses Boolean data types, select the **Use STD_LOGIC type for Boolean or 1 bit wide gateways** setting in the Xilinx System Generator window. By default, Xilinx System Generator uses `std_logic_vector` to represent Boolean types whereas HDL Coder uses `std_logic`, which can result in a mismatch.

An XSG subsystem is a Subsystem block that has:

- Architecture set to **Module**.
- One System Generator token, placed at the top level of the XSG subsystem hierarchy.
- Xilinx blocks.
- Simulink blocks not requiring code generation.
- Input and output ports connected directly to Gateway In or Gateway Out blocks.
- **Propagate data type to output** option enabled on Gateway Out blocks.
- Matching input and output data types on Gateway In blocks. See “Limitations for Code Generation from Xilinx System Generator Subsystems” on page 32-29.

Create a Xilinx System Generator Subsystem

- 1 Create a subsystem containing the Xilinx blocks and set its architecture to **Module**.

- 2 Add a System Generator token at the top level of the subsystem.

You can have subsystem hierarchy in a Xilinx System Generator subsystem, but there must be a System Generator token at the top level of the hierarchy.

- 3 Connect each subsystem input or output port directly to a Gateway In or Gateway Out block.
- 4 On each Gateway Out block, select the **Propagate data type to output** option.

Limitations for Code Generation from Xilinx System Generator Subsystems

Code generation from Xilinx System Generator (XSG) subsystems has these limitations:

- `ConstrainedOutputPipeline`, `InputPipeline`, and `OutputPipeline` are the only valid block properties for an XSG subsystem.
- HDL Coder does not generate code for blocks within an XSG subsystem, including Simulink blocks.
- Gateway In blocks must not do nontrivial data type conversion. For example, a Gateway In block can convert between the `sfixed_en6` and `Fix_8_6` data types, but changing data sign, word length, or fraction length is not allowed.
- For Verilog code generation, Simulink block names in your design cannot be the same as Xilinx names. Similarly, Xilinx blocks in your design cannot have the same name as other Xilinx blocks. HDL Coder cannot resolve these name conflicts and generates an error late in the code generation process.

“How to Create an Altera DSP Builder Subsystem” on page 32-30

“Determine Clocking Requirements for Altera DSP Builder Subsystems” on page 32-31

“Limitations for Code Generation from Altera DSP Builder Subsystems” on page 32-31

Why Use Altera DSP Builder Subsystems?

You can generate HDL code from a model with both Simulink and Altera DSP Builder Advanced blocks using Altera DSP Builder (DSPB) subsystems.

Using both Simulink and Altera blocks in your model provides the following benefits:

- A single platform for combined Simulink and Altera DSP Builder simulation, code generation, and synthesis.
- Targeted code generation: Altera DSP Builder generates code from Altera blocks; HDL Coder generates code from Simulink blocks.
- HDL Coder area and speed optimizations for Simulink components.

Requirements for Altera DSP Builder Subsystems

You must group your Altera blocks into one or more Altera DSP Builder (DSPB) subsystems for code generation. A DSPB subsystem can contain a hierarchy of subsystems.

To generate code from a Altera DSP Builder subsystem, you must use Quartus II 13.0 or later.

A DSPB subsystem is a Subsystem block with:

- Architecture set to **Module**.
- A valid DSP Builder Advanced Blockset design, including a top-level Device block and DSP Builder Advanced blocks, as defined in the Altera DSP Builder documentation.

How to Create an Altera DSP Builder Subsystem

- 1 Create an Altera DSP Builder Advanced Blockset design as defined in the Altera DSP Builder documentation.
- 2 Create a subsystem containing the Altera DSP Builder Advanced Blockset design, and set its **Architecture** to **Module**.

To see an example that shows HDL code generation for an Altera DSP Builder subsystem, see “Using Altera DSP Builder Advanced Blockset with HDL Coder” on page 32-32.

Determine Clocking Requirements for Altera DSP Builder Subsystems

DSPB subsystems must either run at the DUT subsystem base rate, or you can provide a custom clock.

Determining the DUT subsystem base rate can be an iterative process. Area optimizations, such as RAM mapping or resource sharing, may cause HDL Coder to oversample area-optimized parts of the design. Therefore, the DUT subsystem initial base rate may differ from the final base rate, and you may not know the model base rate until you generate code.

To determine the model base rate, iteratively generate code until your model converges on a base rate:

- 1 Generate code for the DUT subsystem that contains your DSPB subsystem.
- 2 If HDL Coder displays an error message that says that your DSPB subsystem rate is slower than the base rate, modify the DSPB subsystem inputs so that the DSPB subsystem runs at the base rate in the message.

For example, you can insert an Upsample block.

- 3 Repeat these steps until your DSPB subsystem rate matches the base rate.

To provide a custom clock for your DSPB subsystem:

- 1 In the HDL Workflow Advisor, for **HDL Code Generation > Set Code Generation Options > Set Advanced Options > Clock inputs**, select **Multiple**.
- 2 In the generated HDL code, connect your custom clocks to the DUT clock input ports that corresponds to your DSPB subsystems clock.

Limitations for Code Generation from Altera DSP Builder Subsystems

Code generation for Altera DSP Builder (DSPB) subsystems has the following limitations:

- The DUT subsystem cannot be a DSPB subsystem.
- DSPB subsystems must run at the Simulink model base rate. You may need to iteratively generate code to determine the base rate, because area optimizations can cause local multirate. See “Determine Clocking Requirements for Altera DSP Builder Subsystems” on page 32-31 for a workflow.
- Altera blocks with bus interfaces are not supported.
- Altera DSP Builder does not generate Verilog code.
- Test bench simulation mismatches can occur because the Simulink data comparison does not take Altera valid signals into account. For an example and workaround, see “Using Altera DSP Builder Advanced Blockset with HDL Coder” on page 32-32.

Using Altera DSP Builder Advanced Blockset with HDL Coder

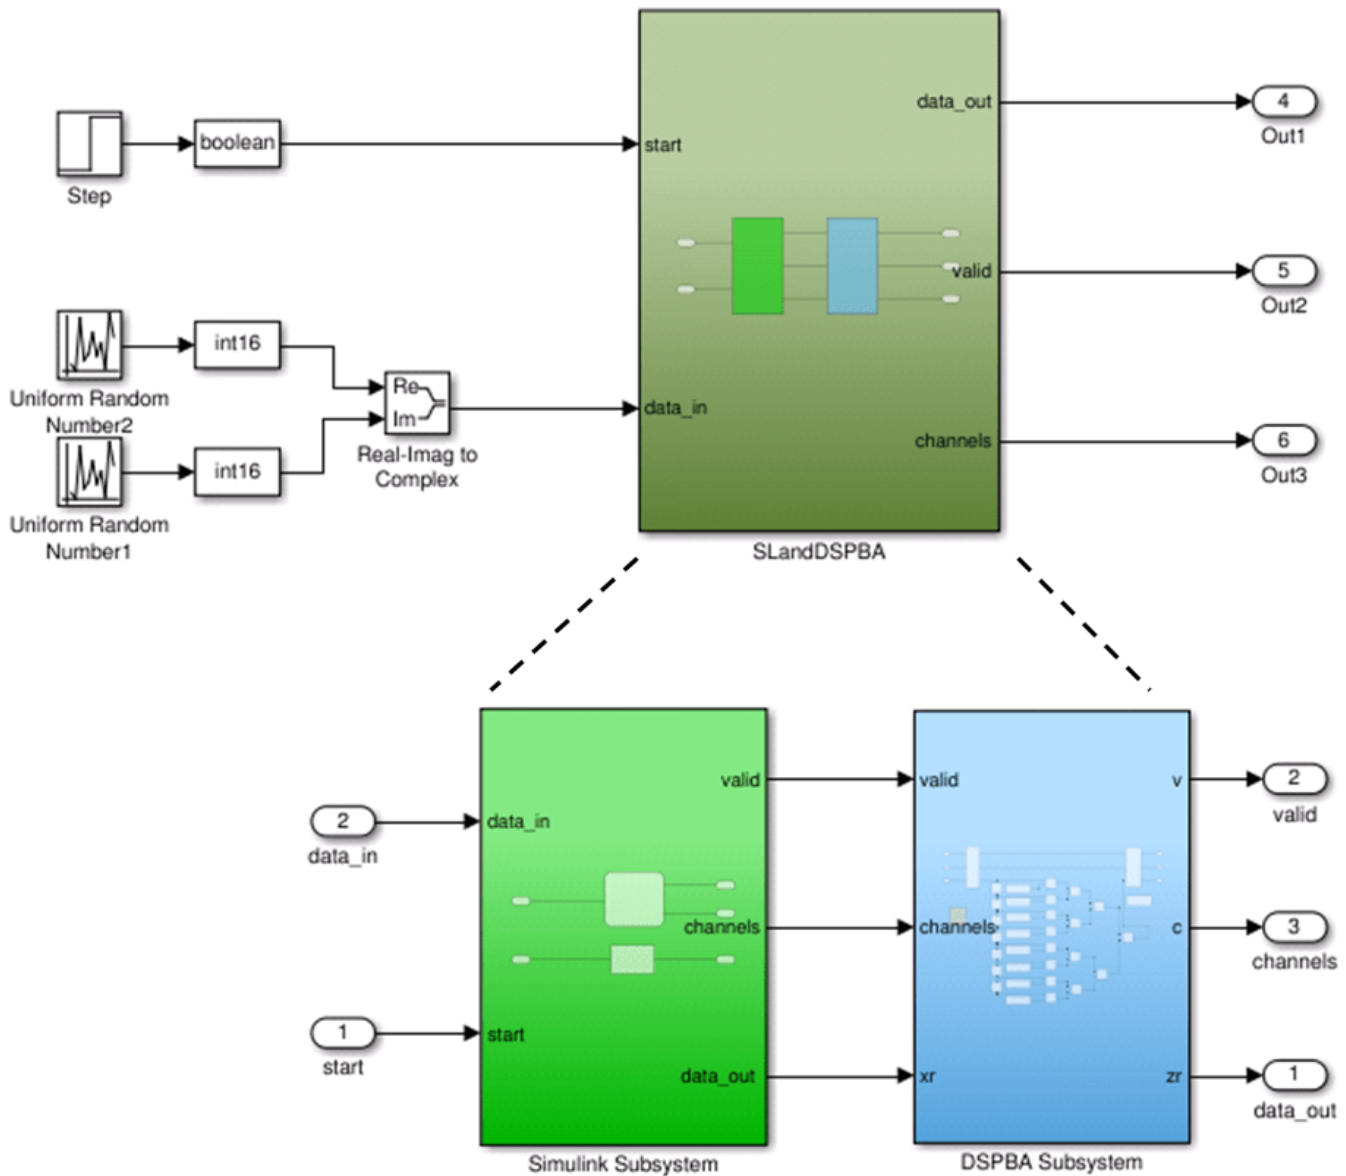

This example shows how to use the Altera® DSP Builder Advanced Blockset with HDL Coder™.

Introduction

Using the Altera® DSP Builder Advanced Blockset Subsystem block, or DSPBA Subsystem block, enables you to model designs using blocks from both Simulink® and Altera®, and to automatically generate integrated HDL code. HDL Coder™ generates HDL code from the Simulink® blocks, and uses Altera® DSP Builder to generate HDL code from the DSPBA Subsystem blocks.

In this example, the design, or code generation subsystem, contains two parts: one with Simulink® native blocks, and one with Altera® DSP Builder Advanced blocks. The Altera® blocks are grouped in a DSPBA Subsystem (hdlcoder_sldspba/SLandDSPBA/DSPBA Subsystem). Altera® DSP Builder optimizes these blocks for Altera® FPGAs. In the rest of the design, Simulink® blocks and HDL Coder™ offer many model-based design features, such as distributed pipelining and delay balancing, to perform model-level optimizations.

```
open_system('hdlcoder_sldspba');  
open_system('hdlcoder_sldspba/SLandDSPBA');
```

Setup for Altera® DSP Builder Advanced Blockset

In order to use the Altera® DSP Builder Advanced Blockset Subsystem block, you must have Altera® Quartus II set up with Simulink®. For version compatibility, see “HDL Language Support and Supported Third-Party Tools and Hardware”.

Create Altera® DSP Builder Advanced Blockset Subsystem

To create a DSPBA Subsystem:

- 1 Put the Altera® blocks in one subsystem and set its architecture to "Module" (the default value).
- 2 Place a Device block at the top level of the subsystem. You can have subsystem hierarchy in a DSPBA Subsystem, but there must be a Device block at the top level of the hierarchy.

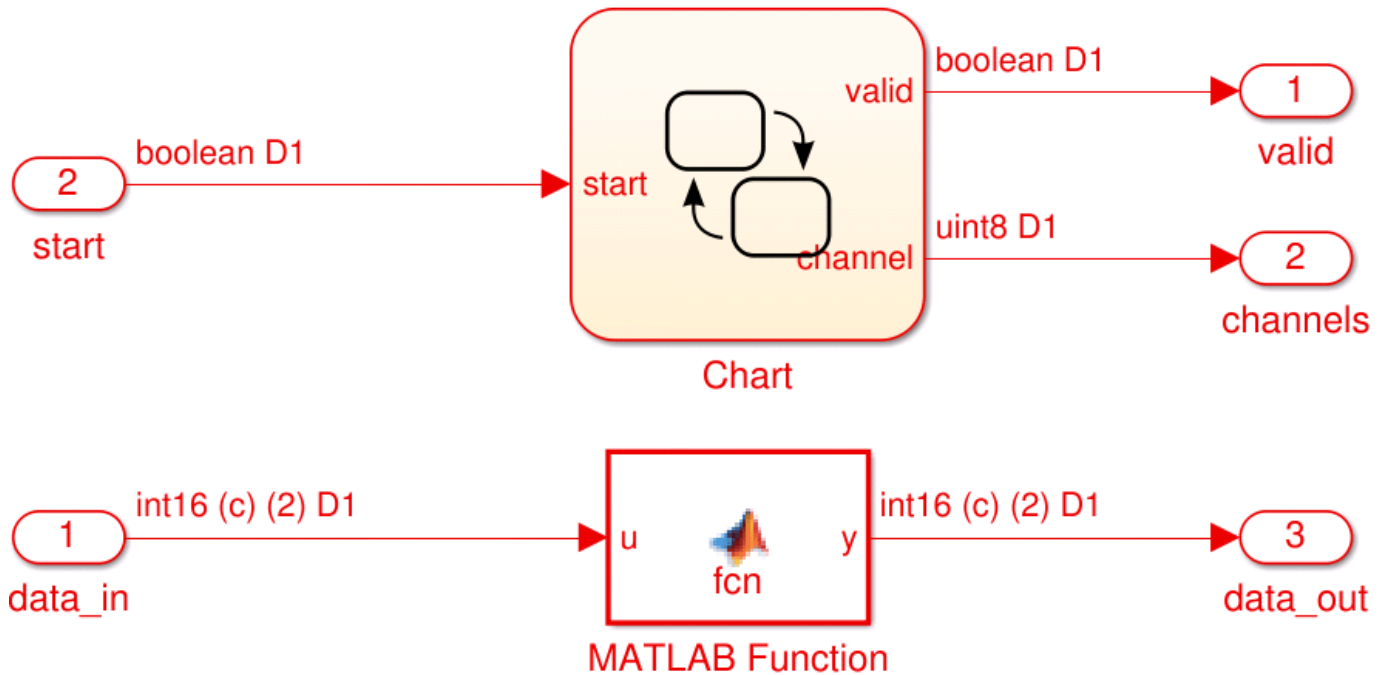

```
open_system('hdlcoder_sldspba/SLDSPBA/DSPBA Subsystem');
```

Simulink® Components

In this example, a Stateflow chart generates the channel and valid signals to drive the DSPBA subsystem.

```
open_system('hdlcoder_sldspba/SLandDSPBA/Simulink Subsystem');
```

Generate HDL Code

You can use either `makehdl` at the command line or HDL Workflow Advisor to generate HDL code. To use `makehdl`:

```
makehdl('hdlcoder_sldspba/SLandDSPBA');
```

You can also generate a testbench, simulate, and synthesize the design as you would for any other model.

Handle Simulation Mismatch When Valid Signal Not Asserted

The DSPBA Subsystem simulation may not match its generated code's behavior when the valid signal is not asserted under certain circumstances, such as when the folding option in both `hdlcoder_sldspba/SLandDSPBA/DSPBA Subsystem/ChannelIn` and `hdlcoder_sldspba/SLandDSPBA/DSPBA Subsystem/ChannelOut` are turned on. The mismatch affects the downstream Simulink design and causes a test bench simulation failure.

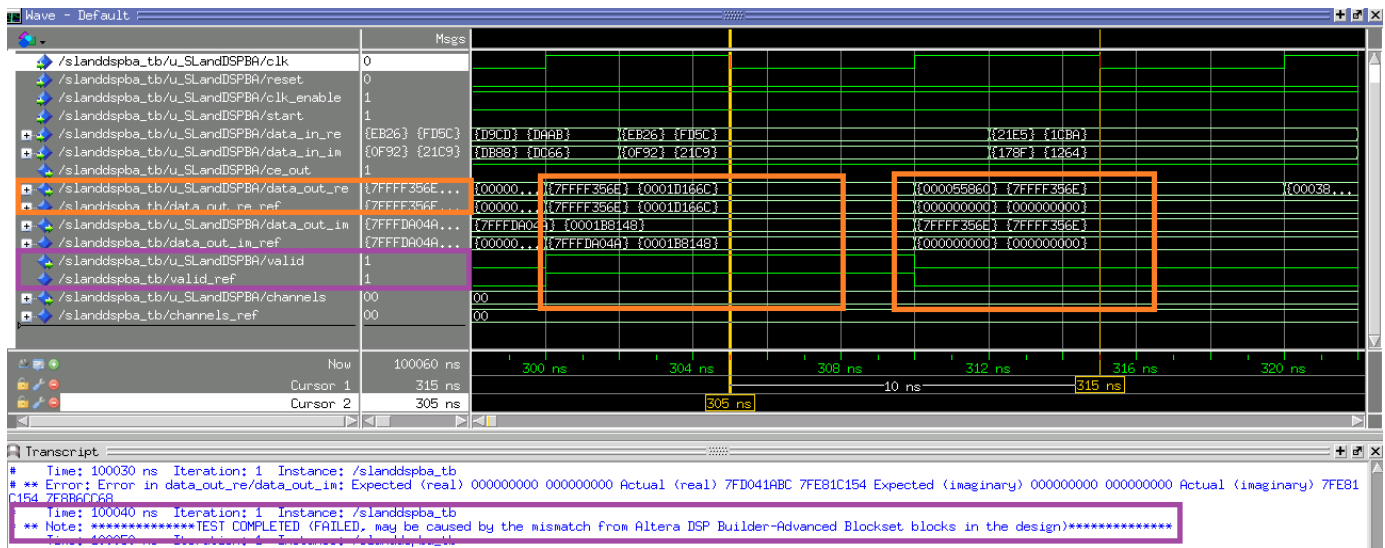

To see the mismatch, you can turn the folding setting on the ChannelIn and ChannelOut blocks:

```
set_param('hdlcoder_sldspba/SLandDSPBA/DSPBA Subsystem/ChannelIn', 'FoldingEnabled', 1);
set_param('hdlcoder_sldspba/SLandDSPBA/DSPBA Subsystem/ChannelOut', 'FoldingEnabled', 1);
```

Then, generate the HDL code and test bench again:

```
makehdl('hdlcoder_sldspba/SLandDSPBA');
makehdl('hdlcoder_sldspba/SLandDSPBA');
```

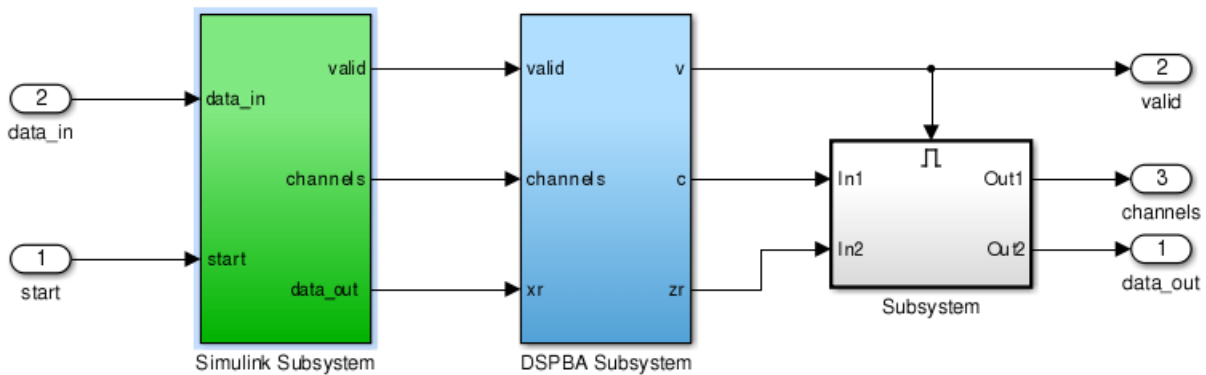

After simulating the generated code and test bench, you can see that the outputs from HDL coder match the reference data only when the valid signal is asserted.

As the message from the test bench indicates, the mismatch is expected.

To avoid this simulation mismatch, insert an enabled subsystem at the DSPBA Subsystem output signals, before they reach the Simulink part of your design or the output ports of the overall design. The following subsystem shows how to connect signals to the enabled subsystem.

```
open_system('hdlcoder_sldspba/SLandDSPBA2');
```

Using Xilinx System Generator for DSP with HDL Coder

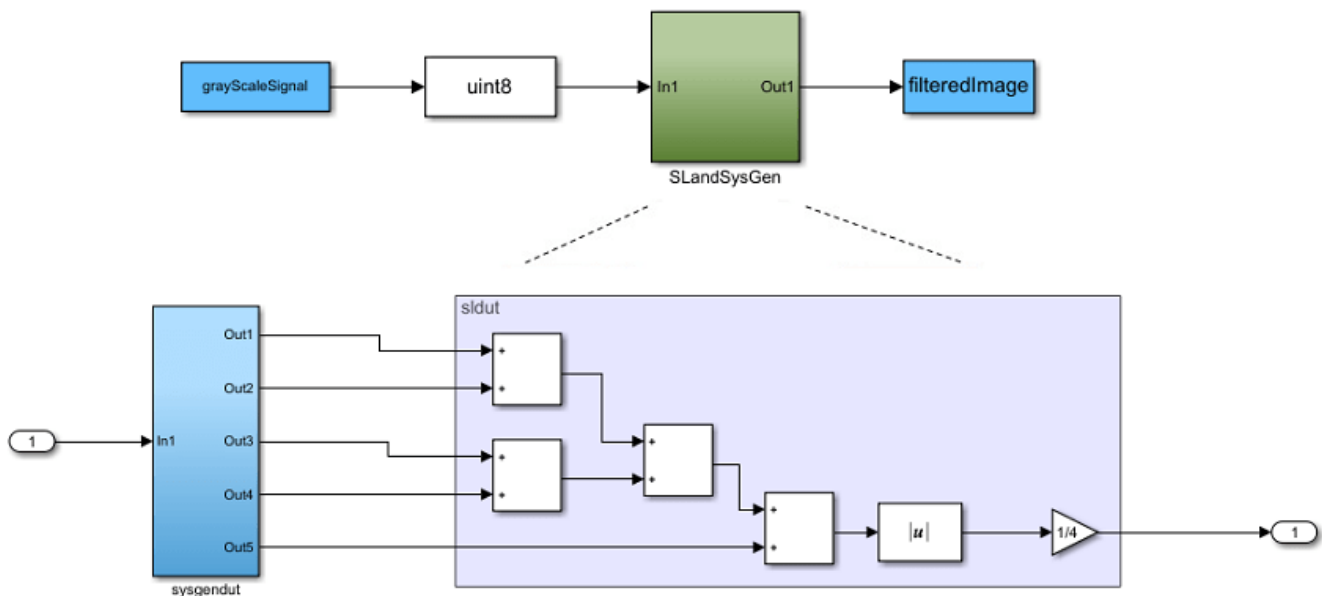

This example shows how to use Xilinx® System Generator for DSP with HDL Coder™.

Introduction

Using the Xilinx System Generator Subsystem block enables you to model designs using blocks from both Simulink® and Xilinx, and to automatically generate integrated HDL code. HDL Coder™ generates HDL code from the Simulink blocks, and uses Xilinx System Generator to generate HDL code from the Xilinx System Generator Subsystem blocks.

In this example, the design, or code generation subsystem, contains two parts: one with Simulink native blocks, and one with Xilinx blocks. The Xilinx blocks are grouped into a Xilinx System Generator Subsystem `sysgendut` that is inside a `SLandSysGen` Subsystem at the top level of the model `hdlcoder_slsysgen`. System Generator optimizes these blocks for Xilinx FPGAs. In the rest of the design, Simulink blocks and HDL Coder offer model-based design capabilities and HDL optimizations, such as distributed pipelining and delay balancing.

```
open_system('hdlcoder_slsysgen');
open_system('hdlcoder_slsysgen/SLandSysGen');
```

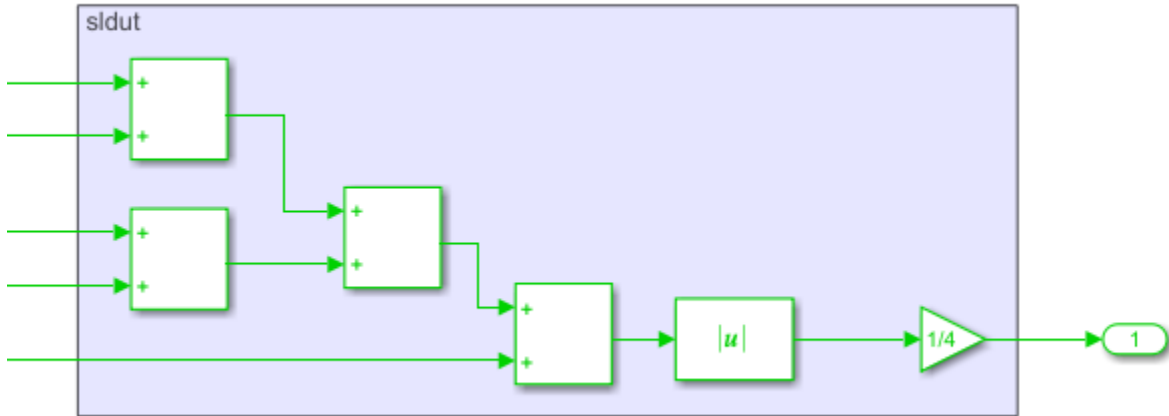

Perform Model-Level Optimizations for Simulink® Components

In this example, a sum tree indicated by the `sldut` section inside the `SLandSysGen` Subsystem is modeled with Simulink blocks. You can use distributed pipelining feature to take care of the speed optimization.

Distributed pipelining can move pipeline registers into the sum tree to reduce the critical path without changing the model function. Other optimizations, such as resource sharing, are also available, but not used in this example.

```
open_system('hdlcoder_slsysgen/SLandSysGen');
```

Create Xilinx System Generator Subsystem

To create a Xilinx System Generator subsystem:

- 1 Put the Xilinx blocks in one subsystem and leave the HDL architecture set to default value of Module.
- 2 Place a System Generator token at the top level of the subsystem. You can have subsystem hierarchy in a Xilinx System Generator Subsystem, but there must be a System Generator token at the top level of the hierarchy.

```
open_system('hdlcoder_slsysgen/SLandSysGen/sysgendut');
```

Configure Gateway In and Gateway Out Blocks

In each Xilinx System Generator subsystem, you must connect input and output ports directly to Gateway In and Gateway Out blocks.

Gateway In blocks must not do non-trivial data type conversion. For example, a Gateway In block can convert between `uint8` and `UFix_8_0`, but changing data sign, word length, or fraction length is not allowed.

Generate HDL Code

You can use either `makehdl` at the command line or HDL Workflow Advisor to generate HDL code. To use `makehdl`:

```
makehdl('hdlcoder_slsysgen/SLandSysGen');
```

You can also generate a testbench, simulate, and synthesize the design as you would for any other model.

Choose a Test Bench for Generated HDL Code

When you generate HDL code with HDL Coder, you can optionally generate a test bench as well. The coder also generates build-and-run scripts for the HDL simulator you specify. The test bench options are:

- **HDL test bench** — An HDL test bench that includes the generated HDL DUT and files containing input and output data vectors. This test bench verifies the generated HDL DUT against test vectors generated from your Simulink model. See “Test Bench Generation” on page 41-15.
- **Cosimulation model** — A Simulink model that includes an HDL Cosimulation block that runs your generated HDL code in an HDL simulator. The model also includes your original Simulink stimulus generation, your behavioral model, and any blocks for display or analysis of the output data. The model compares the output of the HDL Cosimulation block against the output of the source subsystem. See “Generate a Cosimulation Model” on page 32-42.
- **SystemVerilog DPI test bench** — An HDL test bench that includes the generated HDL DUT and a generated C-language component. The C component creates input stimuli and runs a behavioral model of the DUT subsystem. The test bench uses a direct programming interface (DPI) to run the C component inside an HDL simulation. This test bench verifies the generated HDL DUT against a C representation of the source Simulink model. See “Verify HDL Design Using SystemVerilog DPI Test Bench” on page 32-66.
- **FPGA-in-the-loop** — A Simulink model that includes an FPGA-in-the-Loop block that communicates with your HDL design while it runs on the FPGA board. The model also includes your original Simulink stimulus generation, your behavioral model, and any blocks for display or analysis of the output data. The model compares the output of the FPGA-in-the-Loop block against the output of the source subsystem. See “FIL Simulation with HDL Workflow Advisor for Simulink” (HDL Verifier).

Select test bench options in HDL Workflow Advisor under **HDL Code Generation > Set Testbench Options**, or in the Model Configuration Parameters dialog box, under **HDL Code Generation > Test Bench**. Alternatively, for command-line access, select your test bench using the properties of `makehdltb`.

For FPGA-in-the-loop, select the target workflow in HDL Workflow Advisor under **Set Target > Set Target Device and Synthesis Tool**. Then select your FPGA and synthesis tool. You can also generate an FPGA-in-the-loop model for existing HDL code by using **FPGA-in-the-Loop Wizard**.

Requirements

- To use this feature, your installation must include an HDL Verifier license.
- Make sure the DUT subsystem has no unconnected output ports. See “Terminate Unconnected Block Outputs and Usage of Commenting Blocks” on page 25-26.

What Is A Cosimulation Model?

A cosimulation model is an automatically generated Simulink model configured for both Simulink simulation and cosimulation of your design with an HDL simulator. HDL Coder supports automatic generation of a cosimulation model as a part of the test bench generation process.

The cosimulation model includes:

- A behavioral model of your design, realized in a Simulink subsystem.
- A corresponding HDL Cosimulation block, configured to cosimulate the design using HDL Verifier. HDL Coder configures the HDL Cosimulation block for use with either Mentor Graphics ModelSim, Cadence Incisive, or Xilinx Vivado simulator.
- Test input data, calculated from the test bench stimulus that you specify.
- Scope blocks, which let you observe and compare the DUT and HDL cosimulation outputs, and any error between these signals.
- Goto and From blocks that capture the stimulus and response signals from the DUT and use these signals to drive the cosimulation.
- A comparison/assertion mechanism that reports discrepancies between the original DUT output and the cosimulation output .

In addition to the generated model, HDL Coder generates a TCL script that launches and configures your cosimulation tool. Comments in the script file document clock, reset, and other timing signal information defined by the coder for the cosimulation tool.

Generating a Cosimulation Model using the Model Configuration Parameters

This example demonstrates the process for generating a cosimulation model. The example model, `hdl_cosim_demo1`, implements a simple multiply and accumulate (MAC) algorithm. Open the model by entering the name at the MATLAB command line:

```
hdl_cosim_demo1
```

The following figure shows the top-level model.

The DUT is the MAC subsystem.

Cosimulation model generation takes place during generation of the test bench. As a best practice, generate HDL code before generating a test bench, as follows:

- 1 Open the Configuration Parameters dialog box . Right-click on the white space of the Simulink model and select **Model Configuration Parameters**.
- 2 In the **HDL Code Generation** pane of the Configuration Parameters dialog box, set **Generate HDL for** to `hdl_cosim_demo1/MAC`.
- 3 Click **Apply**.
- 4 Click **Generate**. HDL Coder displays progress messages, as shown in the following listing:

```
### Applying HDL Code Generation Control Statements
### Starting HDL Check.
### HDL Check Complete with 0 error, 0 warning and 0 message.

### Begin VHDL Code Generation
```

```
### Working on hdl_cosim_demo1/MAC as hdlsrc\MAC.vhd
### HDL Code Generation Complete.
```

Next, configure the test bench options to include generation of a cosimulation model:

- 1 Select the **HDL Code Generation > Test Bench** pane of the Configuration Parameters dialog box.
- 2 Select the **Cosimulation model** check box. Then select your **Simulation tool** in the drop-down menu.
- 3 Configure required test bench options. HDL Coder records option settings in a generated script file (see “The Cosimulation Script File” on page 32-51).
- 4 Click **Apply**.

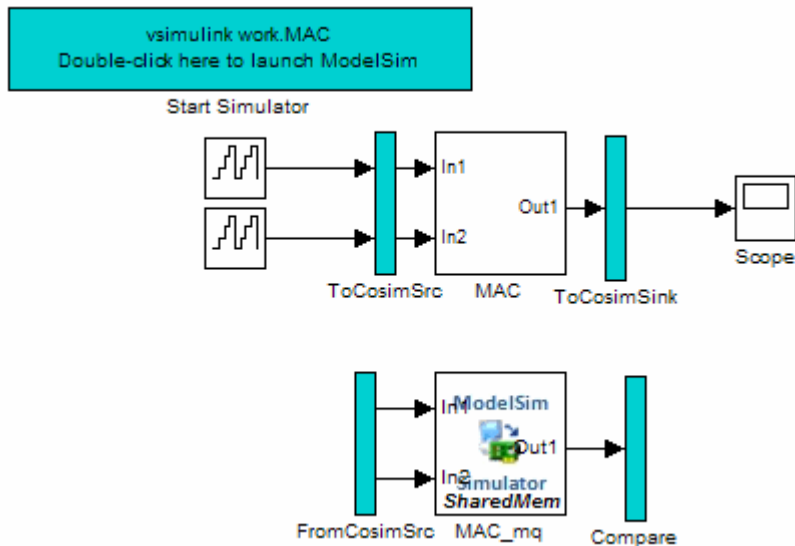

Next, generate test bench code and the cosimulation model:

- 1 At the bottom of the **Test Bench** pane, click **Generate Test Bench**. HDL Coder displays progress messages as shown in the following listing:

```
### Begin TestBench Generation
### Generating new cosimulation model: gm_hdl_cosim_demo1_mq0.mdl
### Generating new cosimulation tcl script: hdlsrc/gm_hdl_cosim_demo1_mq0_tcl.m
### Cosimulation Model Generation Complete.

### Generating Test bench: hdlsrc\MAC_tb.vhd
### Please wait ...
### HDL TestBench Generation Complete.
```

When test bench generation completes, HDL Coder opens the generated cosimulated model. The following figure shows the generated model.

- 2 Save the generated model. The generated model exists only in memory unless you save it.

As indicated by the code generation messages, HDL Coder generates the following files in addition to the usual HDL test bench file:

- A cosimulation model (gm_hdl_cosim_demo1_mq)
- A file that contains a TCL cosimulation script and information about settings of the cosimulation model (gm_hdl_cosim_demo1_mq_tcl.m)

Generated file names derive from the model name, as described in “Naming Conventions for Generated Cosimulation Models and Scripts” on page 32-54.

The next section, “Structure of the Generated Model” on page 32-45, describes the features of the model. Before running a cosimulation, become familiar with these features.

Structure of the Generated Model

You can set up and launch a cosimulation using controls located in the generated model. This section examines the model generated from the example MAC subsystem.

Simulation Path

The model comprises two parallel signal paths. The simulation path, located in the upper half of the model window, is nearly identical to the original DUT. The purpose of the simulation path is to execute a normal Simulink simulation and provide a reference signal for comparison to the cosimulation results. The following figure shows the simulation path.

The two subsystems labelled ToCosimSrc and ToCosimSink do not change the performance of the simulation path. Their purpose is to capture stimulus and response signals of the DUT and route them to and from the HDL cosimulation block (see “Signal Routing Between Simulation and Cosimulation Paths” on page 32-47).

Cosimulation Path

The cosimulation path, located in the lower half of the model window, contains the generated HDL Cosimulation block. The following figure shows the cosimulation path.

The FromCosimSrc subsystem receives the same input signals that drive the DUT. In the gm_hdl_cosim_demo1_mq0 model, the subsystem simply passes the inputs on to the HDL Cosimulation block. Signals of some other data types require further processing at this stage (see “Signal Routing Between Simulation and Cosimulation Paths” on page 32-47).

The Compare subsystem at the end of the cosimulation path compares the cosimulation output to the reference output produced by the simulation path. If the comparison detects a discrepancy, an Assertion block in the Compare subsystem displays a warning message. If desired, you can disable

assertions and control other operations of the Compare subsystem. See “Controlling Assertions and Scope Displays” on page 32-48 for details.

HDL Coder populates the HDL Cosimulation block with the compiled I/O interface of the DUT. The following figure shows the **Ports** pane of the Mac_mq HDL Cosimulation block.

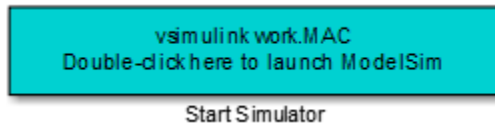

HDL Coder sets the **Full HDL Name**, **Sample Time**, **Data Type**, and other fields as required by the model. HDL Coder also configures other HDL Cosimulation block parameters under the **Timescales** and **Tcl** panes.

Tip HDL Coder configures the generated HDL Cosimulation block for the Shared Memory connection method.

Start Simulator Control

ModelSim or Incisive® users — When you double-click the Start Simulator control, it launches the selected cosimulation tool and passes in a startup command to the tool. The Start Simulator icon displays the startup command, as shown in the following figure.

The commands executed when you double-click the Start Simulator icon launch and set up the cosimulation tool, but they do not start the actual cosimulation. "Launching a Cosimulation" on page 32-49 describes how to run a cosimulation with the generated model.

Vivado simulator users — When you double-click the Start Simulator control, it regenerates a shared library (DLL file). The Start Simulator icon displays that information, as shown in the following figure.

Signal Routing Between Simulation and Cosimulation Paths

The generated model routes signals between the simulation and cosimulation paths using Goto and From blocks. For example, the Goto blocks in the ToCosimSrc subsystem route each DUT input signal to a corresponding From block in the FromCosimSrc subsystem. The following figures show the Goto and From blocks in each subsystem.

gm_hdl_cosim_demo1_mq ▶ ToCosimSrc

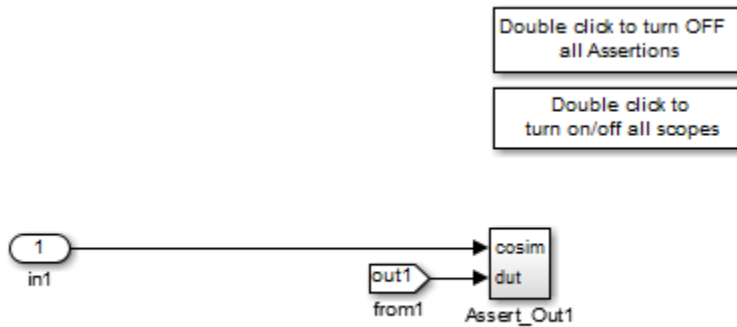

gm_hdl_cosim_demo1_mq ▶ FromCosimSrc

The preceding figures show simple scalar inputs. Signals of complex and vector data types require further processing. See “Complex and Vector Signals in the Generated Cosimulation Model” on page 32-53 for further information.

Controlling Assertions and Scope Displays

The Compare subsystem lets you control the display of signals on scopes, and warning messages from assertions. The following figure shows the Compare subsystem for the gm_hdl_cosim_demo1_mq0 model.

For each output of the DUT, HDL Coder generates an assertion checking subsystem (`Assert_OutN`). The subsystem computes the difference (`err`) between the original DUT output (`dut_ref`) and the corresponding cosimulation output (`cosim`). The subsystem routes the comparison result to an Assertion block. If the comparison result is not zero, the Assertion block reports the discrepancy.

The following figure shows the `Assert_Out1` subsystem for the `gm_hdl_cosim_demo1_mq0` model.

This subsystem also routes the `dut_ref`, `cosim`, and `err` signals to a Scope for display at the top level of the model.

By default, the generated cosimulation model enables all assertions and displays all Scopes. Use the buttons on the Compare subsystem to disable assertions or hide Scopes.

Tip Assertion messages are warnings and do not stop simulation.

Launching a Cosimulation

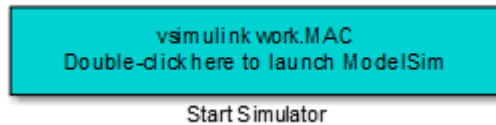

To run a cosimulation with the generated model:

- 1 Double-click the Compare subsystem to configure Scopes and assertion settings.

If you want to disable Scope displays or assertion warnings before starting your cosimulation, use the buttons on the Compare subsystem (shown in the following figure).

- 2 Double-click the Start Simulator control.

The Start Simulator control launches your HDL simulator (in this case, HDL Verifier for use with Mentor Graphics ModelSim).

The HDL simulator in turn executes a startup script. In this case the startup script consists of the TCL commands located in `gm_hdl_cosim_demo1_mq0_tcl.m`. When the HDL simulator finishes executing the startup script, it displays a message like the following.

```
# Ready for cosimulation...
```

- 3 In the Simulink Editor for the generated model, start simulation.

As the cosimulation runs, the HDL simulator displays messages like the following.

```
# Running Simulink Cosimulation block.
# Chip Name: --> hdl_cosim_demo1/MAC
# Target language: --> vhdl
# Target directory: --> hdlsrc
# Fri Jun 05 4:26:34 PM Eastern Daylight Time 2009
# Simulation halt requested by foreign interface.
# done
```

At the end of the cosimulation, if you have enabled Scope displays, the compare scope displays the following signals:

- `cosim`: The result signal output by the HDL Cosimulation block.
- `dut ref`: The reference output signal from the DUT.
- `err`: The difference (error) between these two outputs.

The following figure shows these signals.

The Cosimulation Script File

The generated script file has two sections:

- A comment section that documents model settings that are relevant to cosimulation.
- A function that stores several lines of TCL code into a variable, `tclCmds`. The cosimulation tools execute these commands when you launch a cosimulation.

Header Comments Section

The following listing shows the comment section of a script file generated for the `hdl_cosim_demo1` model:

```

The comments section comprises the following subsections:

- *Header comments*: This section documents the files names for the source and generated models and the source and generated DUT.
- *Test bench settings*: This section documents the `makehdl.tb` property values that affect cosimulation model generation. The generated TCL script uses these values to initialize the cosimulation tool.
- *Sample time information*: The next two sections document the base sample time and oversampling factor of the model. HDL Coder uses `ModelBaseSampleTime` and `OverClockFactor` to map the clock period of the model to the HDL cosimulation clock period.
- *Clock, clock enable, and reset waveforms*: This section documents the computations of the duty cycle of the `clk`, `clk_enable`, and `reset` signals.

TCL Commands Section

The following listing shows the TCL commands section of a script file generated for the `hdl_cosim_demo1` model:

```

function tclCmds = gm_hdl_cosim_demo1_mq_tcl
tclCmds = {
    'do MAC_compile.do',...% Compile the generated code
    'vsimulink work.MAC',...% Initiate cosimulation
    'add wave /MAC/clk',...% Add wave commands for chip input signals
    'add wave /MAC/reset',...
    'add wave /MAC/clk_enable',...
    'add wave /MAC/In1',...

```

```

'add wave /MAC/In2',...
'add wave /MAC/ce_out',...% Add wave commands for chip output signals
'add wave /MAC/Out1',...
'set UserTimeUnit ns',...% Set simulation time unit
'puts "",...
'puts "Ready for cosimulation...","",...
};
end

```

Complex and Vector Signals in the Generated Cosimulation Model

Input signals of complex or vector data types require insertion of additional elements into the cosimulation path. this section describes these elements.

Complex Signals

The generated cosimulation model automatically breaks complex inputs into real and imaginary parts. The following figure shows a `FromCosimSrc` subsystem that receives two complex input signals. The subsystem breaks the inputs into real and imaginary parts before passing them to the subsystem outputs.

The model maintains the separation of real and imaginary components throughout the cosimulation path. The Compare subsystem performs separate comparisons and separate scope displays for the real and imaginary signal components.

Vector Signals

The generated cosimulation model flattens vector inputs. The following figure shows a `FromCosimSrc` subsystem that receives two vector input signals of dimension 2. The subsystem flattens the inputs into scalars before passing them to the subsystem outputs.

Generating a Cosimulation Model from the Command Line

To generate a cosimulation model from the command line, pass the `GenerateCosimModel` property to the `makehdltb` function. `GenerateCosimModel` takes one of the following property values:

- `'ModelSim'`: generate a cosimulation model configured for HDL Verifier for use with Mentor Graphics ModelSim.
- `'Incisive'`: generate a cosimulation model configured for HDL Verifier for use with Cadence Incisive.
- `'Vivado Simulator'`: generate a cosimulation model configured for HDL Verifier for use with Xilinx Vivado.

In the following command, `makehdltb` generates a cosimulation model configured for HDL Verifier for use with Mentor Graphics ModelSim.

```
makehdltb('hdl_cosim_demo1/MAC','GenerateCosimModel','ModelSim');
```

Naming Conventions for Generated Cosimulation Models and Scripts

The naming convention for generated cosimulation models is

prefix_modelname_toolid_suffix, where:

- *prefix* is the string `gm`.
- *modelname* is the name of the generating model.
- *toolid* is an identifier indicating the HDL simulator chosen by the **Cosimulation model for use with**: option. Valid *toolid* strings are `'mq'`, `'in'`, or `'vs'`.
- *suffix* is an integer that provides each generated model with a unique name. The suffix increments with each successive test bench generation for a given model. For example, if the original model name is `test`, then the sequence of generated cosimulation model names is `gm_test_toolid_0`, `gm_test_toolid_1`, and so on.

The naming convention for generated cosimulation scripts is the same as that for models, except that the file name extension is `.m`.

Limitations for Cosimulation Model Generation

When you configure a model for cosimulation model generation, observe the following limitations:

- Explicitly specify the sample times of source blocks to the DUT in the simulation path. Use of the default sample time (-1) in the source blocks may cause sample time propagation problems in the cosimulation path of the generated model.
- The HDL Coder software does not support continuous sample times for cosimulation model generation. Do not use sample times 0 or Inf in source blocks in the simulation path.
- If you set **Clock Inputs** to **Multiple**, HDL Coder does not support generation of a cosimulation model.
- Combinatorial output paths (caused by absence of registers in the generated code) have a latency of one extra cycle in cosimulation. To avoid discrepancy in the comparison between the simulation and cosimulation outputs, the **Allow direct feedthrough** option on the **Ports** pane of the HDL Cosimulation block is automatically selected.

Alternatively, you can avoid the latency by specifying output pipelining (see “OutputPipeline” on page 26-19). This will fully register outputs during code generation.

- Double data types are not supported for the HDL Cosimulation block. Avoid use of double data types in the simulation path when generating HDL code and a cosimulation model.

HDL Verifier Cosimulation Model Generation in HDL Coder

This example shows how to reuse an existing Simulink® model to verify HDL Coder™ generated hardware designs using an HDL Verifier™ cosimulation test bench.

Introduction

Cosimulation is a challenging task, especially with automatically generated code. It is important to keep in-sync various aspects of the source model including sample rates, feedforward/feedthrough systems, and other various parameters and settings used during code generation, while setting up the HDL Verifier cosimulation block and the target HDL simulator.

The automated cosimulation model generation takes the guess-work out of the HDL cosimulation block and simulator setup by deciphering all the compiled model and code generation information. All of the automated settings are documented in the generated scripts. The end result is a cosimulation model that is ready to verify the generated code.

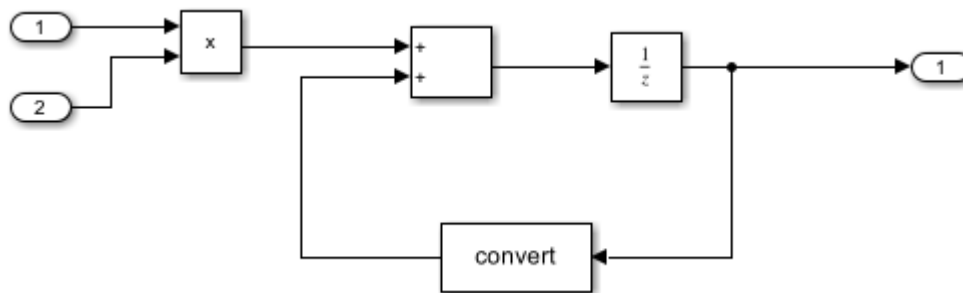

The main examples show using Mentor Graphics® ModelSim®/Questa®, but other supported simulators include Cadence® Xcelium™ (formerly Incisive®) and Xilinx® Vivado™ Simulator. Specific `makehdl tb` examples are given for those simulators at the end.

Generating HDL and the Cosimulation Model

This sections shows a basic multiply-accumulate design in Simulink. We generate the HDL design and generate a cosimulation test bench model. We then go through some details of how the test bench model operates.

Generate the HDL Design

Take a simple accumulator design in Simulink and automatically generate a cosimulation model for it as a part of test bench generation.

```
% Generate VHDL code using the |makehdl| function.
makehdl('hdl_cosim_demo1/MAC', 'targetlang', 'vhdl')
```

```
### Generating HDL for 'hdl_cosim_demo1/MAC'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('hdl_cosim_demo1">
### Running HDL checks on the model 'hdl_cosim_demo1'.
### Begin compilation of the model 'hdl_cosim_demo1'...
### Working on the model 'hdl_cosim_demo1'...
### Working on... <a href="matlab:configset.internal.open('hdl_cosim_demo1', 'GenerateModel')">G
### Begin model generation 'gm_hdl_cosim_demo1' ....
```

```

### Copying DUT to the generated model....
### Model generation complete.
### Begin VHDL Code Generation for 'hdl_cosim_demo1'.
### Working on hdl_cosim_demo1/MAC as hdlsrc\hdl_cosim_demo1\MAC.vhd.
### Code Generation for 'hdl_cosim_demo1' completed.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_10220/ib17334E/0/t/
### HDL check for 'hdl_cosim_demo1' complete with 0 errors, 0 warnings, and 0 messages.
### HDL code generation complete.

```

Generate the Cosimulation Model as an HDL Test Bench

Using the model used for creating the Simulink design as a starting point, generate a cosimulation model to use as an HDL test bench. Set the makehdl parameter `GenerateCosimModel` to choose the HDL simulator. Supported values include `ModelSim`, `Incisive`, or `Vivado Simulator`.

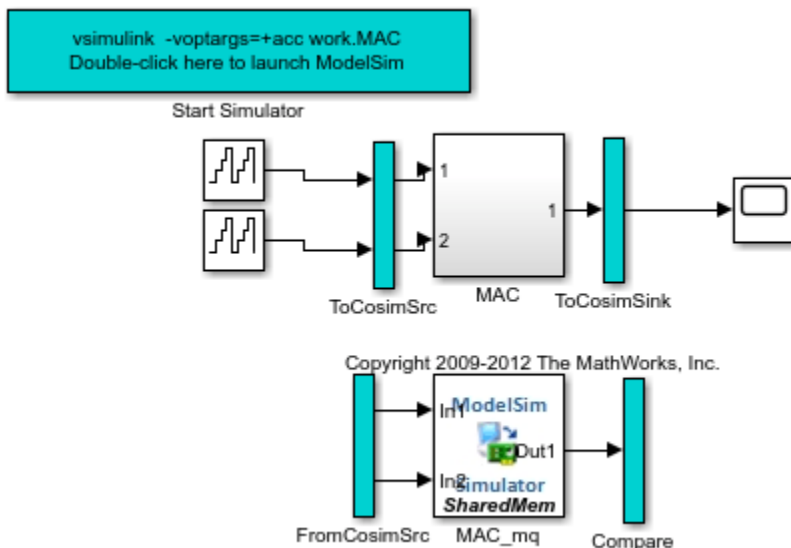

```

% Generate the cosimulation test bench for the MAC HDL
makehdltb('hdl_cosim_demo1/MAC', 'targetlang', 'vhdl', 'GenerateCosimModel', 'ModelSim')

### Begin TestBench generation.
### Generating HDL TestBench for 'hdl_cosim_demo1/MAC'.
### Begin compilation of the model 'hdl_cosim_demo1'...
### Begin compilation of the model 'gm_hdl_cosim_demo1'...
### Generating new cosimulation model: <a href="matlab:open_system('gm_hdl_cosim_demo1_mq')">gm_hdl_cosim_demo1_mq.m
### Generating new cosimulation tcl script: hdlsrc\hdl_cosim_demo1\gm_hdl_cosim_demo1_mq_tcl.m.
### Generating new cosimulation tcl script: hdlsrc\hdl_cosim_demo1\gm_hdl_cosim_demo1_mq_batch_tcl.m.
### Note: Option 'Allow direct feedthrough' has been set to 'on' on 'gm_hdl_cosim_demo1_mq/MAC_mq'.
### Begin simulation of the model 'gm_hdl_cosim_demo1'...

### Collecting data...
### Generating test bench data file: hdlsrc\hdl_cosim_demo1\In1.dat.
### Generating test bench data file: hdlsrc\hdl_cosim_demo1\In2.dat.
### Generating test bench data file: hdlsrc\hdl_cosim_demo1\Out1_expected.dat.
### Working on MAC_tb as hdlsrc\hdl_cosim_demo1\MAC_tb.vhd.
### Generating package file hdlsrc\hdl_cosim_demo1\MAC_tb_pkg.vhd.
### HDL TestBench generation complete.

```

New Code Generation Messages

As seen from the additional code generation messages in the command window a cosimulation model `gm_hdl_cosim_demo1_mq` is generated; In addition to the code generated in the target directory, `hdlsrc`, an additional cosimulation script `gm_hdl_cosim_demo1_mq_tcl.m` is generated to prepare the target simulator for cosimulation with Simulink.

```
### Generating new cosimulation model: gm_hdl_cosim_demo1_mq
### Generating new cosimulation tcl script: hdlsrc/gm_hdl_cosim_demo1_mq_tcl.m
### Cosimulation Model Generation Complete.
```

(Optional) Generate HDL Code Coverage Report and Database

To instrument the HDL Simulator to generate a code coverage database, either:

a) On the **HDL Code Generation > Test Bench** pane, select the check box labeled **HDL code coverage**.

b) When you call `makehdltb`, set `HDLCodeCoverage` to on. For example:

```
makehdltb('hdl_cosim_demo1/MAC', 'targetlang', 'vh', 'GenerateCosimModel', 'ModelSim', 'HDLCodeCov
```

The HDL code coverage artifacts are generated in the source directory after the test bench is simulated.

Examining the Cosimulation Model Test Bench Features

Stimulus and Response Capture

As you can see from the cosimulation model the original device under test (DUT) is intercepted by two subsystems `ToCosimSrc` and `ToCosimSink`. The purpose of these two subsystems is to capture the stimulus and the response of the DUT and use it for driving the cosimulation using `Goto` blocks. The number of `Goto` blocks in each of the following subsystems match the number of inputs and outputs of the DUT.

`ToCosimSrc`:

`ToCosimSink`:

Stimulus to the HDL Cosimulation Block

The stimulus that is originally driving the DUT is fed to the fully configured HDL cosimulation block using the From block as shown below. In some cases input stimulus signals cannot be directly fed to the HDL Cosimulation block. For example, the HDL design might have flattened structured datatypes such as complex signals and vectored signals and the HDL cosimulation block reflects the RTL interface. In such cases further transformation of the input stimulus signals is done automatically. In the current model, the From blocks directly feed the contents of corresponding Goto blocks.

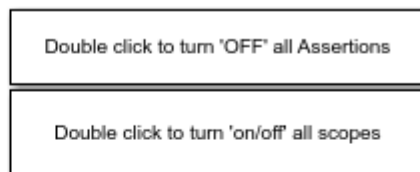

FromCosimSrc:

Comparison of the Results

The response from the original DUT is compared with the response from the HDL Cosimulation block in HDL Verifier using the Sink blocks provided by Simulink for visualization of the response data.

Compare:

Assertion Checking in the Generated Model

For each output of the device under test subsystem the following assertion-checking model is generated that checks the original output (`dut_ref`) with cosimulation output (`cosim`) and generates assertion messages when the input to the assertion block detects a mismatch.

Assert_Out1:

Using Assertion Blocks

Assertions are enabled in the Assertion block but do not stop simulation. If as a part of cosimulation there are any assertions from the following block you should see a warning from the Assertion block:

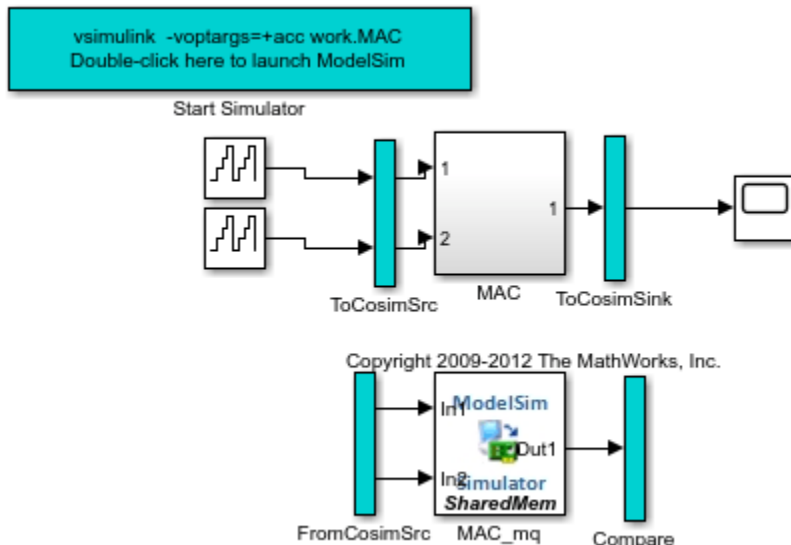

Warning: Assertion detected in 'gm_hdl_cosim_demo1_mq/Compare/Assert_Out1/AssertEq' at time 1.000

Examining the HDL Simulator Specific Support

HDL Cosimulation Block Setup

The HDL Cosimulation block is automatically populated with the compiled input output interface of the DUT. The **Ports** panel is fully populated with **Full HDL Name**, **Sample Time** and **Data type** information. Similarly, various HDL Cosimulation block setup parameters such as **Timescale** and **tcl port** panes are automatically populated. Note that **Connection method** of the cosimulation model is always configured as Shared Memory.

MAC_mq:

Target Simulator Launch and Setup

Now look at the automation associated with the launch and setup of the target simulator (ModelSim/ Questa, Incisive/Xcelium, or Vivado Simulator). As can be seen in the top level of the generated

model, a subsystem with the name `Start Simulator` is generated with the following callback function. This subsystem is used to launch the target simulator of choice.

OpenFcn:

```
ans =
    'try
      cosimDirName = pwd;
      cd 'hdlsrc\hdl_cosim_demo1';
      vsim('tclstart',gm_hdl_cosim_demo1_mq_tcl);
      cd (cosimDirName);
      clear cosimDirName;
    catch me
      disp('Failed to launch cosimulator with "vsim"');
      disp (me.message);
      cd (cosimDirName);
      clear cosimDirName;
    end'
```

Simulation of the Cosimulation Model

The code associated with the callback is simulator specific and executes the necessary commands to get the HDL simulator up and running. For ModelSim/Quarta an invocation of `vsim` is made. For Incisive/Xcelium, an invocation of `nclaunch` is made. For Vivado Simulator, there is no separate process or debug environment; instead a system command compiles the design into a shared-library for the cosimulation.

The following show the details for ModelSim/Quarta.

```
vsim('tclstart',gm_hdl_cosim_demo1_mq_tcl)
```

The MATLAB command `vsim` for ModelSim launches the target simulator from within MATLAB environment with the necessary setup for cosimulation. The `vsim` command is invoked with the `tclstart` option that accepts a tcl string that configures the simulator on its launch. The file `gm_hdl_cosim_demo1_mq_tcl` is also automatically generated by HDL Coder along with the cosimulation model.

Contents of the Generated tclstart Command File

The generated `tclstart` file contains commands for configuring the launched simulator as well as comments about how various settings of Cosimulation model are generated.

`hdlsrc/hdl_cosim_demo1/gm_hdl_cosim_demo1_mq_tcl:`

};
end

```

Header Comments in the tclstart File

The comments in the `tclstart` file specify the source model, generated model, cosimulation model, and the source and cosimulation DUT subsystems. The cosimulation DUT is placed in parallel with the source model DUT in the cosimulation model to capture any differences between the generated HDL code and the source model DUT. The cosimulation model validates the cycle-accurate and bit-true behavior of the generated code.

Visualizing HDL Signals

Wave commands are added for all top-level interface signals.

Pre-simulation Commands

In the HDL Cosimulation block, the **Pre-simulation Tcl commands** parameter contains force commands that drive the clock bundle (clock, clock-enable, reset). The **Time to run HDL simulator before cosimulation starts** parameter initiates simulation with a run time necessary to bring the chip out of reset.

Cosim block TclPreSimCommand:

```

ans =

    'puts "Running Simulink Cosimulation block.";
      puts "Chip Name: --> hdl_cosim_demo1/MAC";
      puts "Target language: --> vhdl";
      puts "Target directory: --> hdlsrc\hdl_cosim_demo1";
      puts [clock format [clock seconds]];
      # Clock force command;
      force /MAC/clk 0 0ns, 1 5ns -r 10ns;
      # Clock enable force command;
      force /MAC/clk_enable 0 0ns, 1 37ns;
      # Reset force command;
      force /MAC/reset 1 0ns, 0 27ns;
    '

```

Test Bench Options Affecting Cosimulation Model Generation

The next part of the `tclstart` script file shows all the `makehdltb` test bench parameters supported by HDL Coder and their initial values used in cosimulation scripts.

```

ClockName, ResetName, ClockEnableName
ClockLowTime, ClockHighTime, ClockPeriod
ResetLength, ClockEnableDelay, HoldTime

```

Model Sample Times and Mapping of DutBaseSampleTime to ClockPeriod

The next part of the comment section covers sample times in the model and how they influenced clocking of the HDL Cosimulation block in HDL Verifier.

```
N = (ClockPeriod / DutBaseSampleTime) * OverClockFactor
1 sec in Simulink corresponds to 10ns in the HDL Simulator(N = 10)
```

Generated tclstart Script Output

The function in `gm_hdl_cosim_demo1_mq_tcl` generates the necessary tcl command string (`tclCmds`).

If the `EDAScriptGeneration` option is turned on and compilation `do` files are generated for ModelSim as part of `makehdl`, then a single `do` command is generated. If the `EDAScriptGeneration` option is turned off, then explicit compilation commands are added for compiling the generated HDL code for the DUT.

Launching the Simulator and Running the Cosimulation Test Bench

Double clicking the Start Simulator block launches the simulator with the tcl commands in the generated `tclstart` MATLAB script. Once the simulator is launched all the generated code is compiled and the HDL Cosimulation block is ready for simulation.

To run the test bench, press the **Run** button. Any data value or cycle timing differences between the original Simulink design and the HDL design are flagged via assertions.

Support for Other HDL Interface Translations

Support for Complex Signals

The model `hdl_cosim_demo2` contains a MAC subsystem using complex data types. The cosimulation test bench generation automatically handles translating the Simulink types to match the HDL port interface.

```
% Generate the HDL for a MAC design using complex data types and its
% corresponding cosimulation test bench model:
bdclose all;
load_system('hdl_cosim_demo2');
open_system('hdl_cosim_demo2/Complex MAC');
makehdl('hdl_cosim_demo2/Complex MAC', 'targetlang', 'vh');
makehdltb('hdl_cosim_demo2/Complex MAC', 'targetlang', 'vh', 'GenerateCosimModel', 'ModelSim')
```

Observe the `FromCosimSrc` subsystems: the input complex signal is automatically broken into real and imaginary pieces before driving the HDL Cosimulation block.

Observe that the comparison section checks the results for real and imaginary parts of complex outputs separately.

Support for Vector Signals

The model `hdl_cosim_demo3` contains a MAC subsystem using vectored data signals. The cosimulation test bench generation automatically handles translating the Simulink types to match the flattened HDL port interface.

```
% Generate the HDL for a MAC design using vectored signals and its
% corresponding cosimulation test bench model:
bdclose all;
load_system('hdl_cosim_demo3');
open_system('hdl_cosim_demo3/Vector MAC');
makehdl('hdl_cosim_demo3/Vector MAC', 'targetlang', 've');
makehdltb('hdl_cosim_demo3/Vector MAC', 'targetlang', 've', 'GenerateCosimModel', 'ModelSim')
```

Observe how vectored signals are handled in the FromCosimSrc and Compare subsystems.

Support for Local Multi-Rate

The model `hdl_cosim_demo4` contains a MAC subsystem with a Sum of Elements block that is configured with a Cascade implementation and requires overclocking as can be seen in the code generation messages. The cosimulation test bench generation automatically handles translating the timing interface in Simulink to that required of the HDL implementation.

```
% Generate the HDL for a MAC design with 5x overclocking and its
% corresponding cosimulation test bench model:
bdclose all;
load_system('hdl_cosim_demo4');
open_system('hdl_cosim_demo4/LocalMR MAC');
makehdl('hdl_cosim_demo4/LocalMR MAC', 'targetlang', 'vh');
makehdltb('hdl_cosim_demo4/LocalMR MAC', 'targetlang', 'vh', 'GenerateCosimModel', 'ModelSim');
```

Note how the time-scale settings change to offset the overclocking in the multi-rate system.

The code generation messages show an overclocking that require a five times faster clock with respect to base rate of the model. This info is encapsulated in the cosimulation model as a part of the time scale setting as per the following message:

```
N = (ClockPeriod / DutBaseSampleTime) * OverClockFactor
1 sec in Simulink corresponds to 50ns in the HDL Simulator(N = 50)
```

Support for Incisive/Xcelium

The following are the concrete commands to create an Incisive/Xcelium cosimulation test bench for the first model.

```
% Generate the HDL and cosimulation model for Incisive/Xcelium
bdclose all;
load_system('hdl_cosim_demo1')
makehdl('hdl_cosim_demo1/MAC', 'targetlang', 'vh')
makehdltb('hdl_cosim_demo1/MAC', 'targetlang', 'vh', 'GenerateCosimModel', 'Incisive')
type hdlsrc/hdl_cosim_demo1/gm_hdl_cosim_demo1_in_tcl
```

Support for Vivado Simulator

The following are the concrete commands to create a Vivado Simulator cosimulation test bench for the first model.

```
% Generate the HDL and cosimulation model for Vivado Simulator
bdclose all;
load_system('hdl_cosim_demo1')
makehdl('hdl_cosim_demo1/MAC', 'targetlang', 'vh')
makehdltb('hdl_cosim_demo1/MAC', 'targetlang', 'vh', 'GenerateCosimModel', 'Vivado Simulator')
type hdlsrc/hdl_cosim_demo1/gm_hdl_cosim_demo1_vs.tcl
```

Verify HDL Design Using SystemVerilog DPI Test Bench

This example shows how to use SystemVerilog DPI test bench for verification of HDL code where a large data set is required.

In certain applications, simulation of a large number of samples is required to verify the HDL code generated by HDL Coder™ for your algorithm. For instance, these applications require a large number of samples for algorithm verification:

- a) Calculation of radar astronomy frequency channels using a polyphase filter bank.
- b) Obtaining the Bit Error Rate (BER) from a Viterbi decoder in a communications system.
- c) Pixel-streaming video processing algorithms on high-resolution video.

Generating an HDL test bench to verify such a design is time consuming because the coder must simulate the model in Simulink® to capture the test bench data.

A faster generated test bench alternative is the HDL Verifier™ SystemVerilog DPI test bench. The SystemVerilog DPI test bench does not require a Simulink simulation, so for large data sets it generates a test bench in a shorter time than the HDL test bench.

HDL Verifier SystemVerilog DPI test bench integrates with Simulink Coder™ to export a Simulink system as generated C code inside a SystemVerilog component with a Direct Programming Interface (DPI). Within the DPI-C component the stimuli is generated and applied to the C subsystem and also applied to the generated HDL code for the Simulink system. The test bench compares the output of the HDL simulation with the output of the DPI-C component to verify the HDL design.

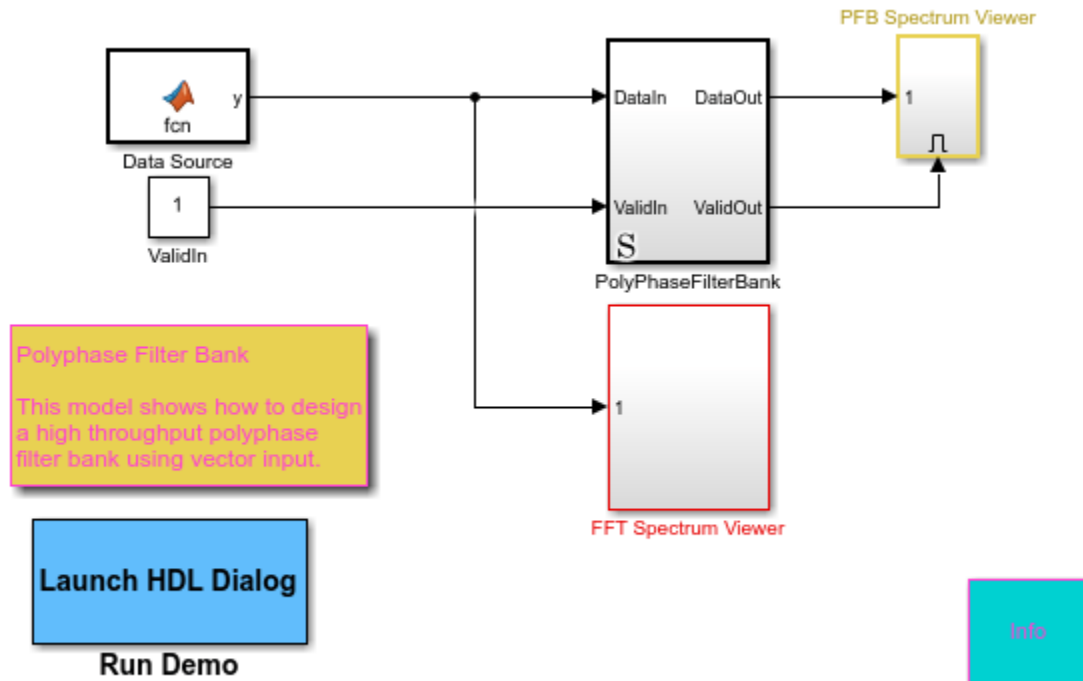

Polyphase Filter Bank

Polyphase filter bank is a widely used technique to reduce inaccuracy in FFT due to leakage and scalloping losses. Polyphase filter bank produces a flatter response as compared to a normal DFT by suppressing out-of-band signals significantly.

The model is a Polyphase Filter Bank which consists of a filter and an FFT that processes 16 samples at a time. For more information about the polyphase filter bank see "High-Throughput Channelizer for FPGA" on page 15-10.

```
modelName = 'hdlcoder_DPIC_testbench';
open_system(modelname);
```

Copyright 2016 The MathWorks, Inc.

Set Up the Model

The InitFcn callback(Model Properties > Callbacks > InitFcn) sets up the model. In this example, a 512-point FFT with a four tap filter for each band is used. The dsp.Channelizer object is used to generate the coefficients.

The algorithm requires 512 filters (one filter for each band). For a vector input of 16 samples the filter implementation shares 16 filters, 32 times. The input data consists of two sine waves, 200KHz and 250 KHz.

Generate HDL Code, HDL Test Bench, and SystemVerilog DPI Test Bench

Use a temporary directory for the generated files:

```
workingdir = tempname;
```

Check the PolyphaseFilterBank subsystem for HDL code generation compatibility:

```
checkhdl('hdlcoder_DPIC_testbench/PolyPhaseFilterBank', 'TargetDirectory', workingdir);
```

Run the following command to generate HDL code:

```
makehdl('hdlcoder_DPIC_testbench/PolyPhaseFilterBank', 'TargetDirectory', workingdir);
```

Run the following command to generate the test bench:

```
makehdltb('hdlcoder_DPIC_testbench/PolyPhaseFilterBank', 'TargetDirectory', workingdir);
```

This will generate an HDL test bench by simulating the model in Simulink and then capturing the test bench data.

Run the following command to generate SystemVerilog DPI test bench:

```
HDLsimulator = 'ModelSim'; % Supported Simulator Options = 'ModelSim', 'Incisive', 'VCS', 'Vivado'
makehdltb('hdlcoder_DPIC_testbench/PolyPhaseFilterBank', 'TargetDirectory', workingdir, 'GenerateSV');
```

This command generates a SystemVerilog test bench without running a Simulink simulation. Instead of a simulation, the code exports the Simulink system as generated C code inside a SystemVerilog component. The test bench verifies the output data by comparing it with the output of the HDL design. The makehdltb function also generates simulator-specific scripts for compilation and simulation.

SystemVerilog DPI test bench can be used to verify HDL designs of both target languages - VHDL® and Verilog®.

Alternatively, you can set SystemVerilog DPI test bench options on the 'HDL Code Generation > Test Bench' pane in Configuration Parameters.

Generated SystemVerilog DPI Test Bench Artifacts

When you request a SystemVerilog DPI test bench, the coder generates the following artifacts:

- PolyPhaseFilterBank_dpi_tb.sv - This is the SystemVerilog test bench that verifies the HDL code.
- PolyPhaseFilterBank_dpi_tb.do - This is the macro file that Mentor Graphics ModelSim® uses to compile the HDL code and run the test bench simulation.

Based on the selected simulator, the coder generates a different file for compilation and test bench simulation. For instance, if you select 'Incisive', the coder generates 'PolyPhaseFilterBank_dpi_tb.sh' for compilation and simulation on Cadence® Incisive®.

(Optional) Generate HDL Code Coverage Report and Database

To instrument the HDL Simulator to generate a HDL code coverage report and database, either:

a.) On the 'HDL Code Generation > Test Bench' pane, select the check box labeled 'HDL code coverage'.

b.) When you call 'makehdltb', set 'HDLCodeCoverage' to 'on'. For example:

```
makehdltb('hdlcoder_DPIC_testbench/PolyPhaseFilterBank','TargetDirectory',workingdir, 'GenerateS
```

The HDL code coverage artifacts are generated in the source directory after the test bench is simulated.

Generation Time Comparison of HDL Test Bench and SystemVerilog DPI Test Bench

The simulation time of the model is set in the pre-load callback (Model Properties > Callbacks > PreLoadFcn)

```
simTime = 1000;
```

The sampling frequency is 2e+6 Hz, which means that the simulation to generate the HDL testbench collects 2e+9 samples.

For certain applications, it takes more samples to obtain the right frequency from the polyphase filter. An increase in required simTime would also increase the time required to generate an HDL test bench.

A solution for such applications is to use the SystemVerilog DPI test bench. The generation time for the test bench remains the same no matter how many samples your test scenario requires.

You can increase the Simulation Time by changing the 'simTime' variable. For instance to generate an HDL test bench for 2e+12 samples, set:

```
simTime = 1000000;
```

The table shows a comparison of time taken (in seconds) for generation of HDL test bench and SystemVerilog DPI test bench for increasing numbers of samples (from 2e+9 to 2e+15) :

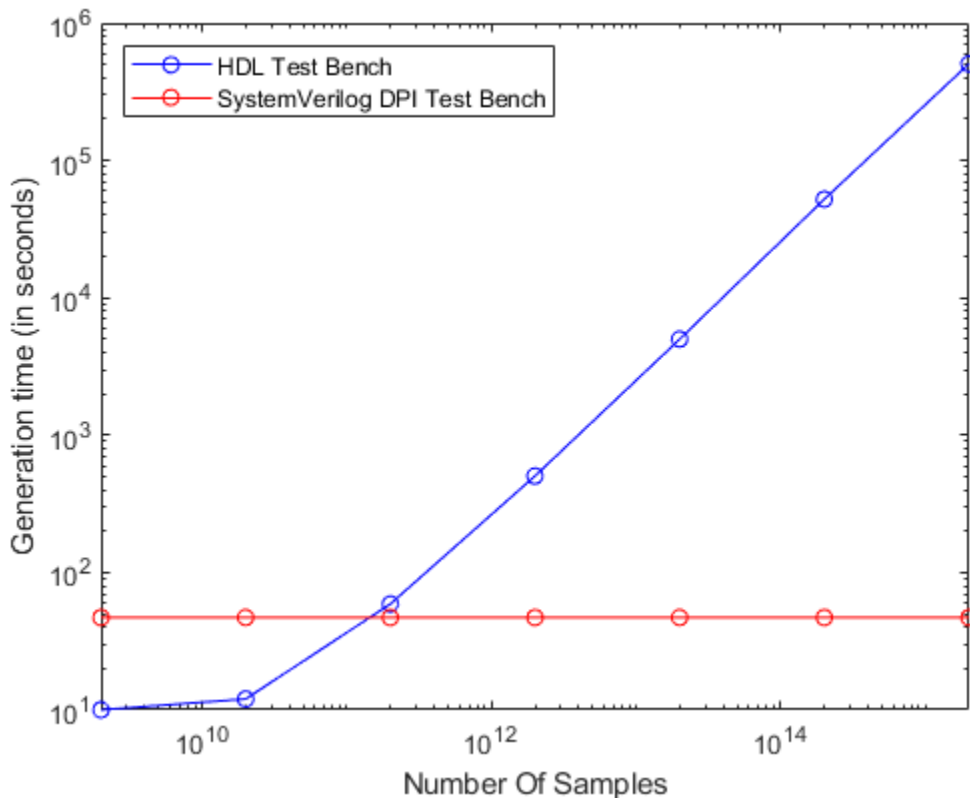

```
columns = {'NumberOfSamples','GenerationTimeHDLTestBench','GenerationTimeSystemVerilogDPITestben
numSamples = [2e9;2e10;2e11;2e12;2e13;2e14;2e15];
HDLTBtime= [10;12;59;504;4994;52200;505506];
DPICBtime=[47;47;47;47;47;47;47];
CompareTestBenchTimes = table(numSamples,HDLTBtime,DPICBtime,'VariableNames',columns);
disp(CompareTestBenchTimes);
```

NumberOfSamples	GenerationTimeHDLTestBench	GenerationTimeSystemVerilogDPITestbench
2e+09	10	47
2e+10	12	47
2e+11	59	47
2e+12	504	47

2e+13	4994	47
2e+14	52200	47
2e+15	5.0551e+05	47

A log plot of generation time for both these test bench types with respect to the Number of samples, shows that while HDL test bench requires more generation time with an increase in the number of samples, generation time for the SystemVerilog DPI test bench remains constant irrespective of the number of samples.

```
loglog(numSamples,HDLTBtime,'b-o', numSamples,DPICTBtime, 'r-o' );
xlim([2e09 2e15]);
legend('HDL Test Bench','SystemVerilog DPI Test Bench','Location','northwest');
xlabel('Number Of Samples');
ylabel('Generation time (in seconds)');
close_system(modelname,0);
```

Conclusion

While HDL test bench is very efficient for a small number of samples, if your test scenario requires a large number of samples, HDL Verifier SystemVerilog DPI test bench provides faster test bench generation.

Pass-Through and No-Op Implementations

HDL Coder provides a pass-through or no-op implementation for some blocks. A pass-through implementation generates a wire in the HDL; a no-op implementation omits code generation for the block or subsystem. These implementations are useful in cases where you need a block for simulation, but do not need the block or subsystem in your generated HDL code.

The pass-through and no-op implementations are summarized in the following table.

Implementation	Description
Pass-through implementations	Provides a pass-through implementation in which the block's inputs are passed directly to its outputs. HDL Coder supports the following blocks with a pass-through implementation: <ul style="list-style-type: none"> • Convert 1-D to 2-D • Reshape • Signal Conversion • Signal Specification
No HDL	This implementation completely removes the block from the generated code. This enables you to use the block in simulation but treat it as a “no-op” in the HDL code. This implementation is used for many blocks (such as Scopes and Assertions) that are significant in simulation but are meaningless in HDL code.

Synchronous Subsystem Behavior with the State Control Block

In this section...

“What Is a State Control Block?” on page 32-72

“State Control Block Modes” on page 32-72

“Synchronous Badge for Subsystems by Using Synchronous Mode” on page 32-73

“Generate HDL Code with the State Control Block” on page 32-74

What Is a State Control Block?

When you have blocks with state, and have enable or reset ports inside a subsystem, use the Synchronous mode of the State Control block to:

- Provide efficient enable and reset simulation behavior on hardware.
- Generate cleaner HDL code and use fewer resources on hardware.

You can add the State Control block to your Simulink model at any level in the model hierarchy. How you set the State Control block affects the simulation behavior of other blocks inside the subsystem that have state.

- For synchronous hardware simulation behavior, set **State control** to **Synchronous**.
- For default Simulink simulation behavior, set **State control** to **Classic**.

State Control Block Modes

Functionality	Synchronous mode	Classic mode
State Control block setting	Default block setting when you add the block from the HDL Subsystems block library.	The simulation behavior is the same as a subsystem that does not use the State Control block.
Simulink simulation behavior <ul style="list-style-type: none"> • Initialize method: Initializes states. • Update method: Updates states. • Output method: Computes output values. 	The update method only updates states. The output method computes the output values at each time step. For example, when you have enabled subsystems, the output value changes when the enable signal is low as it processes new input values. The output value matches the output from Classic mode when enable signal becomes high.	The update method updates states and computes the output values. For example, when you have enabled subsystems, the output value is held steady when the enable signal is low and changes only when the enable signal becomes high.
HDL simulation behavior	More efficient on hardware.	Less efficient on hardware.

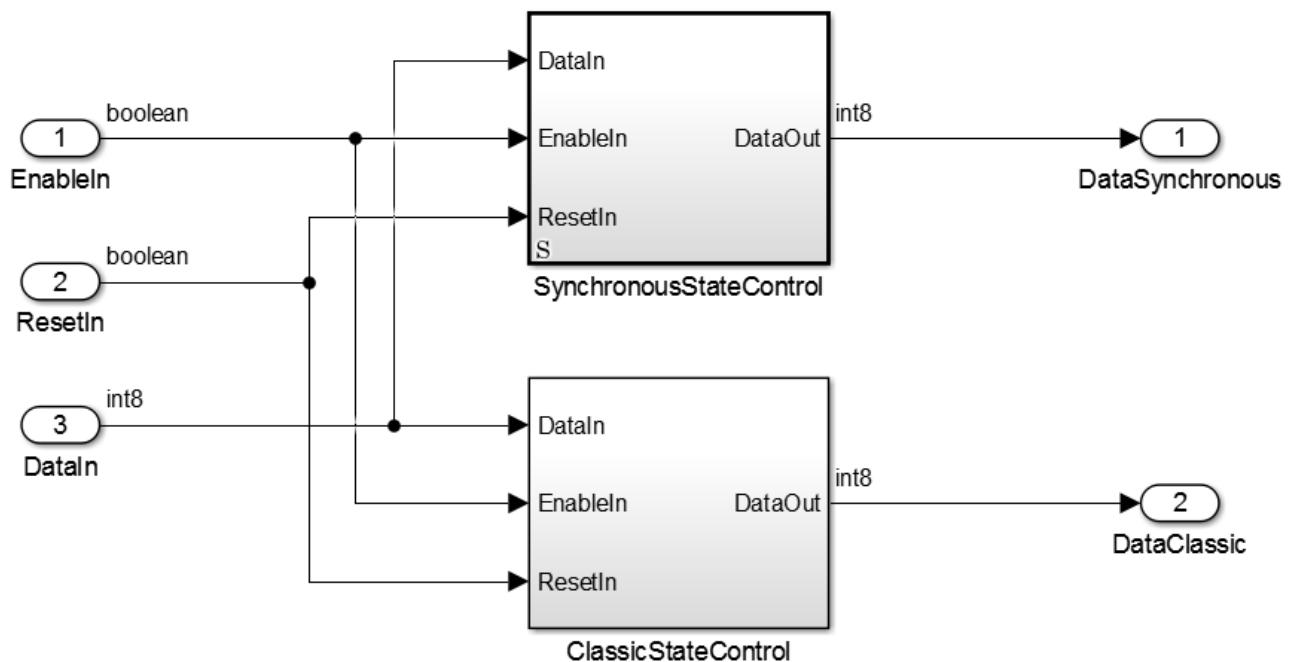

Functionality	Synchronous mode	Classic mode
HDL code generation behavior	Generated HDL code is cleaner and uses fewer resources on hardware. For example, when you have enabled subsystems, HDL Coder does not generate bypass registers for each state update and uses fewer hardware resources.	Generated HDL code is not as clean and uses more hardware resources. For example, when you have enabled subsystems, HDL Coder generates bypass registers for each state update and uses more resources.

To learn more about when you can use the State Control block, see [State Control](#).

Synchronous Badge for Subsystems by Using Synchronous Mode

To see if a subsystem in your Simulink model uses synchronous semantics:

- A symbol **S** is displayed on the subsystem to indicate synchronous behavior.

- If you double-click the **SynchronousStateControl** subsystem, a badge **S** is displayed in the Simulink editor to indicate that blocks inside the subsystem are using synchronous hardware semantics.

The **SynchronousStateControl** and **ClassicStateControl** subsystems use a Delay block with an external reset and an enable port in Synchronous and Classic modes respectively.

Generate HDL Code with the State Control Block

The following table shows a comparison of the HDL code generated from the Delay block for Classic and Synchronous modes of the State Control block.

Functionality	Synchronous mode	Classic mode
<p>HDL code generation. Settings applied:</p> <ul style="list-style-type: none"> • Language: Verilog • Reset type: Synchronous 	<pre> `timescale 1 ns / 1 ns module SynchronousStateControl (clk, reset, enb, DataIn, EnableIn, ResetIn, DataOut); input clk; input reset; input enb; input signed [7:0] DataIn; // int8 input EnableIn; input ResetIn; output signed [7:0] DataOut; // int8 reg signed [7:0] Delay_Synchronous_reg [0:1]; wire signed [7:0] Delay_Synchronous_reg_next [0:1]; wire signed [7:0] Delay_Synchronous_out1; always @(posedge clk) begin : Delay_Synchronous_process if (reset == 1'b1 ResetIn == 1'b1) begin Delay_Synchronous_reg[0] <= 8'sb00000000; Delay_Synchronous_reg[1] <= 8'sb00000000; end else begin if (enb && EnableIn) begin Delay_Synchronous_reg[0] <= Delay_Synchronous_reg_next[0]; Delay_Synchronous_reg[1] <= Delay_Synchronous_reg_next[1]; end end end assign Delay_Synchronous_out1 = Delay_Synchronous_reg[1]; assign Delay_Synchronous_reg_next[0] = DataIn; end assign Delay_Synchronous_reg_next[1] = Delay_Synchronous_reg[0]; assign DataOut = Delay_Synchronous_out1; endmodule // SynchronousStateControl </pre> <ul style="list-style-type: none"> • Generated HDL code is cleaner and requires fewer hardware resources as HDL Coder does not generate bypass registers. • The update method only updates the states. 	<pre> `timescale 1 ns / 1 ns module ClassicStateControl (clk, reset, enb, DataIn, EnableIn, ResetIn, DataOut); input clk; input reset; input enb; input signed [7:0] DataIn; // int8 input EnableIn; input ResetIn; output signed [7:0] DataOut; // int8 reg signed [7:0] Delay_Synchronous_reg [0:1]; reg signed [7:0] Delay_Synchronous_bypass; // sfix8 wire signed [7:0] Delay_Synchronous_reg_next [0:1]; wire signed [7:0] Delay_Synchronous_bypass_next; // wire signed [7:0] Delay_Synchronous_reg_next [0:1]; wire signed [7:0] Delay_Synchronous_delay_out; // sf wire signed [7:0] Delay_Synchronous_out1; // int8 always @(posedge clk) begin : Delay_Synchronous_process if (reset == 1'b1 ResetIn == 1'b1) begin Delay_Synchronous_bypass <= 8'sb00000000; Delay_Synchronous_reg[0] <= 8'sb00000000; Delay_Synchronous_reg[1] <= 8'sb00000000; end else begin if (enb && EnableIn) begin Delay_Synchronous_bypass <= Delay_Synchronous_bypass_next; Delay_Synchronous_reg[0] <= Delay_Synchronous_reg_next[0]; Delay_Synchronous_reg[1] <= Delay_Synchronous_reg_next[1]; end end assign Delay_Synchronous_delay_out = (ResetIn == 1'b1 ? State Control

Using the State Control Block to Generate More Efficient Code with HDL Coder

This example shows how to use the State Control block to generate hardware-friendly HDL code using HDL Coder™.

Introduction to the State Control block

The State Control block is a block that modifies the Simulink® simulation behavior for its containing subsystem and all subsystems nested beneath it. Its purpose is to more closely model the synchronous behavior of clocked digital hardware, particularly with respect to blocks that have state and use explicit enable and reset signals.

When a State Control block is placed in a subsystem and has its parameter set to **Synchronous**, the generated HDL code will be more hardware friendly. When a subsystem is in the Synchronous mode it is marked with a graphic **S** in its lower left corner. A State Control block with its parameter set to **Classic** behaves identically to when there is no State Control block in the subsystem.

The simulation behavior difference between the two modes is small, but significant to generating efficient HDL code. The differences focus around the simulation behavior involving explicit reset and enable signals. For example, in Synchronous mode, the explicit block reset input has priority over the block enable input signal.

Classic mode behavior for Delay with explicit enable input port

HDL code generated by HDL Coder simulates identically to the model that it is generated from. In Classic State Control mode, the generated code for certain constructs implements sub-optimal hardware due to this requirement. For example, a Delay block with explicit enable input will generate a bypass register, comprised of a register and a multiplexer, in addition to the modeled register, to capture the Simulink Classic mode behavior.

Examine the contents of `Enabled_Delay.vhd` to observe the additional register signals and the bypass register.

Enabled Subsystems

When a model has an Enabled subsystem in Synchronous mode, the code generated for it will also be improved. A Synchronous mode Enabled subsystem will no longer generate bypass registers on the subsystem outputs. In addition, any registers inside the Enabled subsystem that have explicit enable inputs will also show the same improvements as discussed previously.

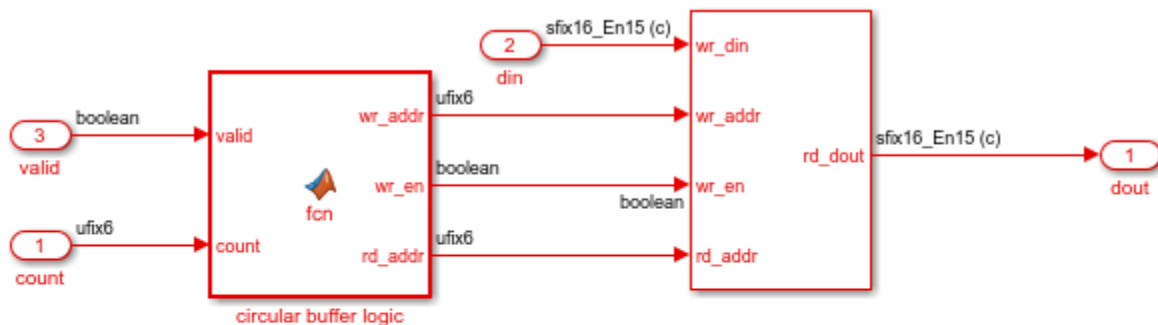

MATLAB Function Blocks and Synchronous Mode

MATLAB Function Blocks require more precise configuration in order to be used in Synchronous mode. If the block contains a direct combinatorial path from block input to output, you must enable direct feedthrough:

- 1 Open the Property Inspector. In the **Modeling** tab, in the **Design** section, click the **Property Inspector**.
- 2 Click the MATLAB Function block.
- 3 Expand the **Advanced** section. Select **Allow direct feedthrough** for each block containing a combinatorial output path.

This setting allows the code to be generated in Synchronous mode from a MATLAB Function block, when that block has both combinatorial and sequential paths in its code.

```
open_system('hdlcoder_statecontrol_model/MAC FIR Block Sync/RAM delay line')
% open_system('hdlcoder_statecontrol_model/MAC FIR Block Sync/RAM delay line/circular buffer logic')
```

The RAM based delay line has 2 latency:
 - 1 from count to rd_addr
 - 1 from rd_addr to rd_dout

Resettable Subsystem Support in HDL Coder

This example shows how to use Resettable Subsystems in HDL Coder™.

Introduction to Resettable Subsystems

A Resettable Subsystem is a subsystem that will reset all states within the subsystem hierarchy based on a boolean control signal. It does this without requiring wiring the reset signal to each stateful block in Simulink®. This feature allows resetting blocks such as the MATLAB Function Block, which does not have an available reset port. For support in HDL Coder, a Resettable Subsystem is supported only within a Synchronous State Control region.

```
load_system('hdlcoder_resettable_subsystem');
open_system('hdlcoder_resettable_subsystem/DUT/Resettable Subsystem');
set_param('hdlcoder_resettable_subsystem', 'SimulationCommand', 'update');
```

The Reset Block

A Resettable Subsystem looks similar to an Enabled Subsystem or any other Simulink conditionally executed subsystem in that it has a specialized Reset Port block inside it. This control port block has several trigger types available. HDL Coder supports the "level hold" trigger type.

```
open_system('hdlcoder_resettable_subsystem/DUT/Resettable Subsystem/LocalReset');
```

Resettable Subsystem Effects on Generated HDL code

Resettable Subsystems allow resetting the state of all blocks with state inside the subsystem to their initial value. In the generated HDL code, each design delay, a delay modeled explicitly in Simulink, has a reset added. Hardware implementation delays such as pipeline delays are not reset. The reset signal is a synchronous signal and is entirely independent from the global reset signal.

```
close_system('hdlcoder_resettable_subsystem/DUT/Resettable Subsystem/LocalReset');
makehdl('hdlcoder_resettable_subsystem/DUT');
type hdlsrc/hdlcoder_resettable_subsystem/DUT.vhd
```

Introduction to Stateflow HDL Code Generation

In this section...

“Example” on page 33-2

“Chart Initialization” on page 33-2

“Tunable Parameters” on page 33-3

“Comments in Stateflow Charts” on page 33-3

“Restrictions” on page 33-3

Stateflow charts provide concise descriptions of complex system behavior by using hierarchical finite state machine (FSM) theory, flow diagram notation, and state-transition diagrams.

You use a chart to model a finite state machine or a complex control algorithm intended for realization as an ASIC or FPGA. When the model meets design requirements, you then generate HDL code (VHDL or Verilog) that implements the design embodied in the model. You can simulate and synthesize generated HDL code by using industry standard tools, and then map your system designs into FPGAs and ASICs. For more information on how to generate HDL code for finite state machines, see “Generate HDL for Mealy and Moore Finite State Machines” on page 33-7.

Generation of VHDL or Verilog code from a model containing a chart does not differ greatly from HDL code generation from other models. The HDL code generator is designed to:

- Support the largest possible subset of chart semantics consistent with HDL code. This broad subset means that you can generate HDL code from existing models without significant remodeling.
- Generate bit-true, cycle-accurate HDL code that is fully compatible with Stateflow simulation semantics.

Example

Using the `hdlcodercfir` model, the example shows how to generate HDL code for a subsystem that includes Stateflow charts.

To open the model, at the command line, enter:

```
hdlcodercfir
```

Chart Initialization

Enabling the **Execute (enter) Chart at Initialization** property executes the update chart function immediately following chart initialization. You can keep the chart property **Execute (enter) Chart at Initialization** disabled. This property can significantly alter the Stateflow Chart behavior and the generated HDL Code. “Execution of a Chart at Initialization” (Stateflow) describes the effect of this property on a Stateflow Chart.

You cannot perform arithmetic in initialization actions because reset actions cannot handle the delay of combinatorial logic.

You can select or clear **Initialize Outputs Every Time Chart Wakes Up**. If you clear it, the generated HDL code includes an additional register for the state machine output values.

Tunable Parameters

You can use a tunable parameter in a Stateflow Chart intended for HDL code generation.

For more information, see “Generate DUT Ports for Tunable Parameters” on page 14-18.

Comments in Stateflow Charts

When your Simulink model contains a Stateflow Chart that uses comments, HDL Coder generates the comments in the HDL code.

When you generate Verilog code from the model, HDL Coder displays the comments in the Stateflow Chart inline beside the corresponding Stateflow object.

Restrictions

HDL Coder does not support Stateflow blocks that contain messages for HDL code generation.

Location of Charts in the Model

A chart intended for HDL code generation must be part of a Simulink subsystem. If the chart for which you want to generate code is at the root level of your model, embed the chart in a subsystem. Connect the relevant signals to the subsystem inputs and outputs.

Data Types

The code generator supports a subset of MATLAB data types in charts that include:

- Signed and unsigned integer
- Fixed point
- Boolean
- Enumeration

Note Except for data types assigned to ports, multidimensional arrays of these types are supported. Port data types must be either scalar or vector.

If you use single and double data types, HDL Coder generates real data types in the HDL code. You can simulate and verify the code by using third-party simulators such as ModelSim.

Real types are not synthesizable on the target FPGA device. The code generator does not support generation of HDL code for the Stateflow Chart in **Native Floating Point** mode. To generate synthesizable HDL code when you use floating-point data types, develop an algorithm by using MATLAB Function on page 14-119 blocks or other “Simulink Blocks Supported by Using Native Floating Point” on page 14-142.

Imported Code

A chart intended for HDL code generation must be entirely self-contained. These restrictions apply:

- Do not call MATLAB functions other than `min` or `max`.

- Do not use MATLAB System objects in a Chart block.
- Do not use MATLAB workspace data.
- Do not call C math functions. HDL does not have a counterpart to the C math library.
- If the **Enable C-bit operations** property is disabled, do not use the exponentiation operator (^). The exponentiation operator is implemented with the C Math Library function `pow`.
- Do not include custom code. Information entered on the **Simulation Target > Custom Code** pane in the Configuration Parameters dialog box is ignored.
- Do not share data (through Data Store Memory blocks) between charts. HDL Coder does not map such global data to HDL because HDL does not support global data.

Vector of Tunable Parameters

Vector of Tunable Parameters as data types for Chart blocks is not supported.

Input and Output Events

HDL Coder supports the use of input and output events with Stateflow charts, subject to these constraints:

- You can define and use only one input event per Stateflow chart. There is no restriction on the number of output events that you can use.
- The coder does not support HDL code generation for charts that have a single input event, and which also have nonzero initial values on the chart's output ports.
- All input and output events must be edge-triggered.

For detailed information on input and output events, see “Activate a Stateflow Chart by Sending Input Events” (Stateflow) and “Activate a Simulink Block by Sending Output Events” (Stateflow).

Messages

Stateflow messages are not supported for HDL code generation.

Loops

Other than `for` loops, do not explicitly use loops in a chart intended for HDL code generation. Observe the following restrictions on `for` loops:

- The data type of the loop counter variable must be `int32`.
- HDL Coder supports only constant-bounded loops.

The `for` loop example, `sf_for`, shows a design pattern for a `for` loop that uses a graphical function.

Additional Restrictions

HDL Coder imposes additional restrictions on the use of classic chart features. These limitations exist because HDL does not support some features of general-purpose sequential programming languages.

- Do not define local events in a chart from which HDL code is generated.

Do not use these implicit events:

- `enter`

- `exit`
- `change`

You can use these implicit events:

- `wakeup`
- `tick`

If the base events are limited to these types of implicit events, you can use temporal logic.

- Do not use recursion through graphical functions. HDL Coder does not support recursion.
- Avoid unstructured code. Although charts allow unstructured code through transition flow diagrams and graphical functions, this usage results in `goto` statements and multiple function return statements. HDL does not support either `goto` statements or multiple function return statements. Therefore, do not use unstructured flow diagrams.
- If you have not selected the **Initialize Outputs Every Time Chart Wakes Up** chart option, do not read from output ports.
- Do not use Data Store Memory objects.
- Do not use pointer (&) or indirection (*) operators. See “Pointer and Address Operations” (Stateflow).
- If a chart gets a run-time overflow error during simulation, it is possible to disable data range error checking and generate HDL code for the chart. In such cases, some results obtained from the generated HDL code might not be bit-true to results from the simulation. The recommended practice is to enable overflow checking and eliminate overflow conditions from the model during simulation.

More About

- “Hardware Realization of Stateflow Semantics” on page 33-6

Hardware Realization of Stateflow Semantics

A mapping from Stateflow semantics to an HDL implementation has the following requirements:

- **Requirement 1:** Hardware designs require separability of output and state update functions.
- **Requirement 2:** HDL is a concurrent language. To achieve the goal of bit-true simulation, execution must be in order.

To meet Requirement 1, an FSM is coded in HDL as two concurrent blocks that execute under different conditions. One block evaluates the transition conditions, computes outputs and computes the next state variables. The other block updates the current state variables from the available next state and performs the actual state transitions. This second block is activated only on the trigger edge of the clock signal, or an asynchronous reset signal.

Stateflow sequential semantics map to HDL sequential statements, and local chart variables in function scope map to VHDL variables in process scope. In VHDL, variable assignment is sequential. Therefore, statements in a Stateflow function that uses local variables can map to statements in a VHDL process that uses corresponding variables. The VHDL assignments execute in the same order as the assignments in the Stateflow function.

Generate HDL for Mealy and Moore Finite State Machines

In this section...

“Generate HDL Code for Moore Finite State Machine” on page 33-7

“Generate HDL for Mealy Finite State Machine” on page 33-8

“Initialize Outputs Every Time Chart Wakes Up” on page 33-10

Stateflow charts support modeling of three types of state machines:

- Classic (default)
- Mealy
- Moore

For HDL code generation, use Mealy or Moore type state machines. Mealy and Moore state machines differ in these ways.

- The output of a Mealy state machine is a function of the current state and inputs.
- The output of a Moore state machine is a function of the current state only.

The principal advantages of using Mealy or Moore charts as an alternative to Classic charts are:

- Moore charts can generate more efficient code than Classic charts.
- At compile time, Mealy and Moore charts are validated for conformance to their formal definitions and semantic rules, and violations are reported.

To learn more about HDL code generation guidelines for charts, see the Chart block.

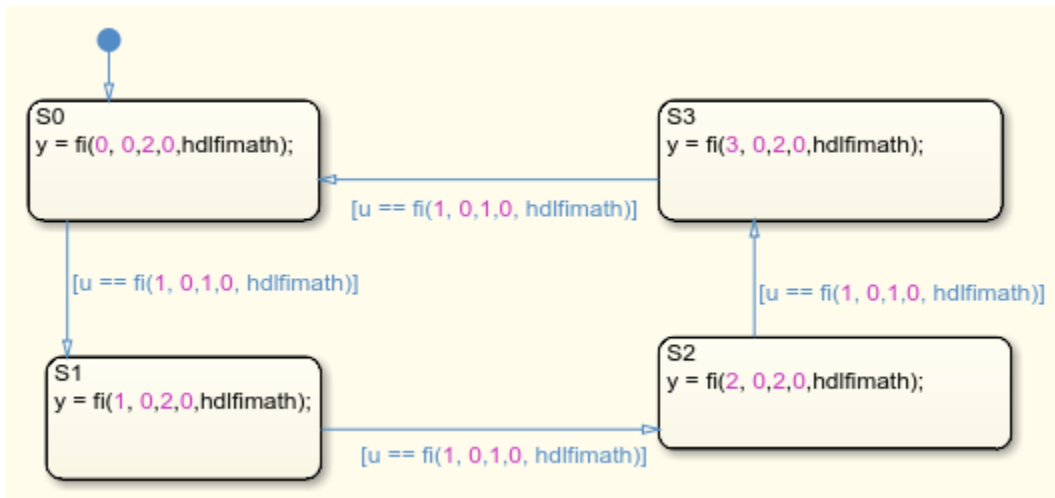

Generate HDL Code for Moore Finite State Machine

This example shows Stateflow chart of a Moore state machine that uses MATLAB® as the action language.

Open model

Load `hdlcoder_fsm_mealy_moore` model. The Moore subsystem in `hdlcoder_fsm_mealy_moore` contains the Stateflow chart `Moore_Chart` that models a Moore state machine. To open the `Moore_Chart`, run these commands:

```
load_system('hdlcoder_fsm_mealy_moore.slx');
open_system('hdlcoder_fsm_mealy_moore/Moore/Moore_Chart');
```

When generating HDL code for a chart that models a Moore state machine, these conditions apply.

- The chart must meet the general code generation requirements as described in the Chart block.
- Actions must occur in states only. These actions must be unlabeled. Moore actions must be associated with states, because the output computation is dependent only on states, not input. The configuration of active states at time step t determines the output. If state S is active when a chart wakes up at time t , then state S contributes to the output whether or not the state remains active into time $t+1$.
- Do not call Simulink® functions. This restriction prevents the output from depending on the input in ways that are difficult for the HDL code generator to verify.
- If you disable the **Initialize Outputs Every Time Chart Wakes Up** parameter, the generated HDL code includes additional registers of the state machine output values.
- You can enable clock-driven outputs for a Moore chart by setting the Stateflow chart HDL block property **ClockDrivenOutput** to on. For more information, see “Guidelines for HDL Code Generation Using Stateflow Charts” on page 25-114.

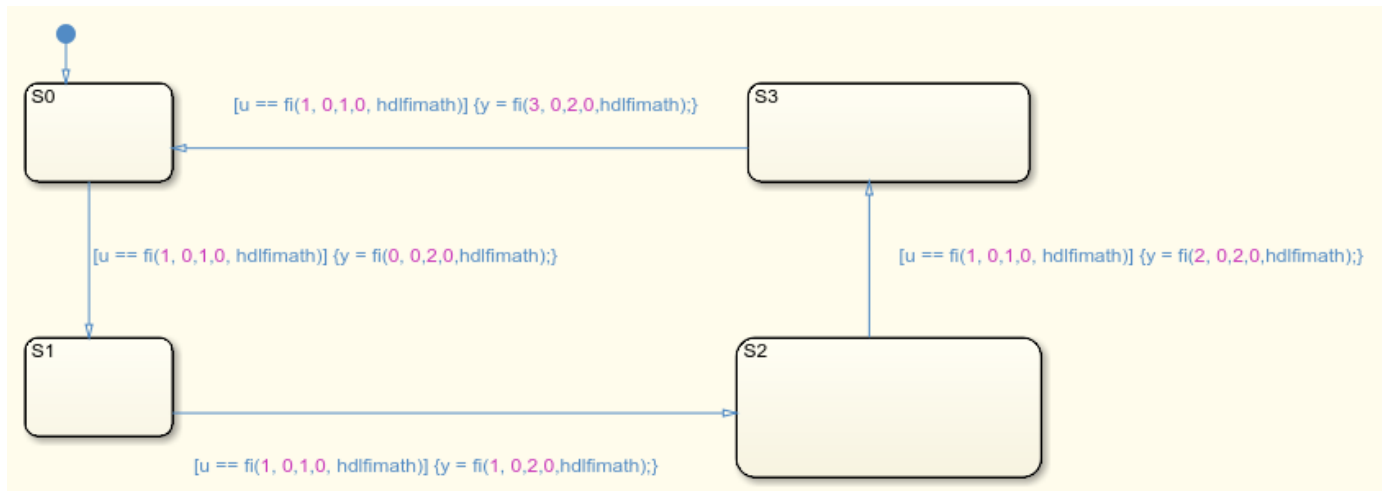

Generate HDL for Mealy Finite State Machine

This example shows Stateflow chart that models a Mealy state machine using MATLAB as the action language. You can also generate the HDL code for Stateflow using HDL Coder™.

Open model

Load `hdlcoder_fsm_mealy_moore` model. The Mealy subsystem in `hdlcoder_fsm_mealy_moore` contains the Stateflow chart `Mealy_Chart` that model a Mealy state machine. To open the `Mealy_Chart`, run these commands:

```
load_system('hdlcoder_fsm_mealy_moore.slx');
open_system('hdlcoder_fsm_mealy_moore/Mealy/Mealy_Chart');
```

When generating HDL code for a chart that models a Mealy state machine, these conditions apply.

- The chart must meet the general code generation requirements as described in the Chart block.
- Actions must be associated with inner and outer transitions only.
- If you disable the **Initialize Outputs Every Time Chart Wakes Up** parameter, the generated HDL code includes additional registers of the state machine output values.

Mealy actions are associated with transitions. In Mealy machines, the output computation is driven by a change of input values. The dependence of the output on the input is the fundamental distinguishing factor between the formal definitions of Mealy and Moore machines. The requirement that actions result from transitions is to some degree stylistic, rather than required, to enforce Mealy semantics. Because transition conditions are primarily input conditions in any machine type, the output computation ultimately follows input conditions in either type.

Generated HDL Code of the Mealy Chart

This code is the Verilog® code generated for the Mealy chart.

```
always @(posedge clk or posedge reset)
  begin : Mealy_Chart_1_process
    if (reset == 1'b1) begin
      is_Mealy_Chart <= is_Mealy_Chart_IN_S0;
    end
    else begin
      if (enb) begin
        is_Mealy_Chart <= is_Mealy_Chart_next;
      end
    end
  end

always @(is_Mealy_Chart, u) begin
  is_Mealy_Chart_next = is_Mealy_Chart;
  y_1 = 2'b00;
  case ( is_Mealy_Chart)
    is_Mealy_Chart_IN_S0 :
      begin
        if (u == 8'sb00000001) begin
```

```
        y_1 = 2'b00;
        is_Mealy_Chart_next = is_Mealy_Chart_IN_S1;
    end
end
is_Mealy_Chart_IN_S1 :
begin
    if (u == 8'sb00000001) begin
        y_1 = 2'b01;
        is_Mealy_Chart_next = is_Mealy_Chart_IN_S2;
    end
end
is_Mealy_Chart_IN_S2 :
begin
    if (u == 8'sb00000001) begin
        y_1 = 2'b10;
        is_Mealy_Chart_next = is_Mealy_Chart_IN_S3;
    end
end
default :
begin
    if (u == 8'sb00000001) begin
        y_1 = 2'b11;
        is_Mealy_Chart_next = is_Mealy_Chart_IN_S0;
    end
end
endcase
end
assign y = y_1;
```

Initialize Outputs Every Time Chart Wakes Up

Mealy and Moore charts have an option to return the output signals to their initial values when the signals are not driven by a state or transition. Select the **Initialize Outputs Every Time Chart Wakes Up** parameter to enable this behavior. If you clear this parameter, the generated HDL code includes additional registers to store the state machine output values.

This figure shows a simple Moore chart with two states and one output. The output is set to 1 in state A, and the initial value of the output is 4.

Symbols			
TYPE	NAME	VALUE	PORT
	in		1
	out	int32(4)	1

When you select the **Initialize Outputs Every Time Chart Wakes Up** parameter, the output value returns to 4 unless the state machine is in state A. State A sets the output to 1. When you clear the **Initialize Outputs Every Time Chart Wakes Up** parameter, the output value remains at 1 after the machine passes through state A, and does not return to 4.

This figure shows the Verilog code generated for this Moore chart, with **Initialize Outputs Every Time Chart Wakes Up** selected and then with it cleared.

Initialize outputs every time chart wakes up

```

always @(posedge clk or posedge reset)
begin : MooreChart_1_process
  if (reset == 1'b1) begin
    is_MooreChart <= is_MooreChart_IN_A;
  end
  else begin
    if (enb) begin
      is_MooreChart <= is_MooreChart_next;
    end
  end
end

always @(in, is_MooreChart) begin
  is_MooreChart_next = is_MooreChart;
  case ( is_MooreChart)
  is_MooreChart_IN_A :
    begin
      if (in > 32'sb00000000000000000000000000000000) begin
        is_MooreChart_next = is_MooreChart_IN_B;
      end
    end
  default :
    begin
      //case IN_B:
      if (in < 32'sb00000000000000000000000000000000) begin
        is_MooreChart_next = is_MooreChart_IN_A;
      end
    end
  endcase
end

always @(is_MooreChart) begin
  out_l = 32'sd4;
  case ( is_MooreChart)
  is_MooreChart_IN_A :
    begin
      out_l = 32'sd1;
    end
  default :
    begin
      //case IN_B:
    end
  endcase
end

```

Initialize outputs every time chart wakes up

```

always @(posedge clk or posedge reset)
begin : MooreChart_1_process
  if (reset == 1'b1) begin
    out_reg <= 32'sd4;
    is_MooreChart <= is_MooreChart_IN_A;
  end
  else begin
    if (enb) begin
      is_MooreChart <= is_MooreChart_next;
      out_reg <= out_reg_next;
    end
  end
end

always @(in, is_MooreChart) begin
  is_MooreChart_next = is_MooreChart;
  case ( is_MooreChart)
  is_MooreChart_IN_A :
    begin
      if (in > 32'sb00000000000000000000000000000000) begin
        is_MooreChart_next = is_MooreChart_IN_B;
      end
    end
  default :
    begin
      //case IN_B:
      if (in < 32'sb00000000000000000000000000000000) begin
        is_MooreChart_next = is_MooreChart_IN_A;
      end
    end
  endcase
end

always @(is_MooreChart, out_reg) begin
  out_reg_next = out_reg;
  case ( is_MooreChart)
  is_MooreChart_IN_A :
    begin
      out_reg_next = 32'sd1;
    end
  default :
    begin
      //case IN_B:
    end
  endcase
end

assign out = out_reg_next;

```

This table shows the resource usage of these two Moore machines synthesized for a Xilinx Vivado Virtex 7 device. When you clear **Initialize Outputs Every Time Chart Wakes Up**, the generated HDL code includes additional registers for the output state.

Resource	Initialize Outputs Every Time Chart Wakes UpSelected	Initialize Outputs Every Time Chart Wakes UpCleared
LUTs	18	20
Registers	1	3
DSPs	0	0

Temporal Logic

Stateflow temporal logic operators (such as `after`, `before`, or `every`) are Boolean operators that operate on recurrence counts of Stateflow events. Temporal logic operators can appear only in conditions on transitions that originate from states, and in state actions. Although temporal logic does not introduce new events into a Stateflow model, it is useful to think of the change of value of a temporal logic condition as an event. You can use temporal logic operators in many cases where a counter is required. A common use case would be to use temporal logic to implement a time-out counter.

For detailed information, see “Control Chart Execution by Using Temporal Logic” (Stateflow).

The chart shown in the following figure uses temporal logic in a design for a debouncer. Instead of instantaneously switching between on and off states, the chart uses two intermediate states and temporal logic to ignore transients. The transition is committed based on a time-out.

By default, states in a Stateflow Chart are ordered alphabetically. The ordering of states in the HDL code can potentially vary if you enable active state output port generation in the HDL code. To enable this setting, open the Chart properties and select the **Create output port for monitoring** check box. See also “Simplify Stateflow Charts by Incorporating Active State Output” (Stateflow).

When you generate VHDL code, the recently added state is selected as the OTHERS state in the HDL code. The following code excerpt shows VHDL code generated from this Chart.

```
Chart_1_output : PROCESS (is_Chart, u, temporalCounter_i1, y_reg)
  VARIABLE temporalCounter_i1_temp : unsigned(7 DOWNTO 0);
  BEGIN
    temporalCounter_i1_temp := temporalCounter_i1;
    is_Chart_next <= is_Chart;
    y_reg_next <= y_reg;
    IF temporalCounter_i1 < 7 THEN
      temporalCounter_i1_temp := temporalCounter_i1 + 1;
    END IF;

    CASE is_Chart IS
      WHEN IN_tran1 =>
        IF u = 1.0 THEN
          is_Chart_next <= IN_on;
          y_reg_next <= 1.0;
        ELSIF temporalCounter_i1_temp >= 3 THEN
          is_Chart_next <= IN_off;
          y_reg_next <= 0.0;
        END IF;
      WHEN IN_tran2 =>
        IF temporalCounter_i1_temp >= 5 THEN
          is_Chart_next <= IN_on;
          y_reg_next <= 1.0;
        ELSIF u = 0.0 THEN
          is_Chart_next <= IN_off;
          y_reg_next <= 0.0;
        END IF;
      WHEN IN_off =>
        IF u = 1.0 THEN
          is_Chart_next <= IN_tran2;
          temporalCounter_i1_temp := to_unsigned(0, 8);
        END IF;
      WHEN OTHERS =>
        IF u = 0.0 THEN
          is_Chart_next <= IN_tran1;
          temporalCounter_i1_temp := to_unsigned(0, 8);
        END IF;
    END CASE;

    temporalCounter_i1_next <= temporalCounter_i1_temp;
  END PROCESS Chart_1_output;
```

Graphical Function

A graphical function is a function defined graphically by a flow diagram. Graphical functions reside in a chart along with the diagrams that invoke them. Like MATLAB functions and C functions, graphical functions can accept arguments and return results. Graphical functions can be invoked in transition and state actions.

The following figure shows a graphical function that implements a 64-by-64 counter.

The following code excerpt shows VHDL code generated for this graphical function.

```

x64_counter_sf : PROCESS (x, y, outx_reg, outy_reg)
-- local variables
  VARIABLE x_temp : unsigned(7 DOWNTO 0);
  VARIABLE y_temp : unsigned(7 DOWNTO 0);
BEGIN
  outx_reg_next <= outx_reg;
  outy_reg_next <= outy_reg;
  x_temp := x;
  y_temp := y;
  x_temp := tmw_to_unsigned(tmw_to_unsigned(tmw_to_unsigned(x_temp, 9), 10)
    + tmw_to_unsigned(to_unsigned(1, 9), 10), 8);

  IF x_temp < to_unsigned(64, 8) THEN
    NULL;
  ELSE
    x_temp := to_unsigned(0, 8);
    y_temp := tmw_to_unsigned(tmw_to_unsigned(tmw_to_unsigned(y_temp, 9), 10)
      + tmw_to_unsigned(to_unsigned(1, 9), 10), 8);

    IF y_temp < to_unsigned(64, 8) THEN
      NULL;
    ELSE
      y_temp := to_unsigned(0, 8);
    END IF;
  END IF;

  outx_reg_next <= x_temp;
  outy_reg_next <= y_temp;
  x_next <= x_temp;
  y_next <= y_temp;
END PROCESS x64_counter_sf;

```

Hierarchy and Parallelism

Stateflow charts support both hierarchy (states containing other states) and parallelism (multiple states that can be active simultaneously).

In Stateflow semantics, parallelism is not synonymous with concurrency. Parallel states can be active simultaneously, but they are executed sequentially according to their execution order. (Execution order is displayed on the upper right corner of a parallel state).

For detailed information on hierarchy and parallelism, see “Overview of Stateflow Objects” (Stateflow) and “Execution Order for Parallel States” (Stateflow).

For HDL code generation, an entire chart maps to a single output computation process. Within the output computation process:

- The execution of parallel states proceeds sequentially.
- Nested hierarchical states map to nested CASE statements in the generated HDL code.

Stateless Charts

Charts consisting of pure flow diagrams (i.e., charts without states) are useful in capturing `if-then-else` constructs used in procedural languages like C.

As an example, consider the following logic, expressed in C-like pseudocode.

```
if(U1==1) {
    if(U2==1) {
        Y = 1;
    }else{
        Y = 2;
    }
}else{
    if(U2<2) {
        Y = 3;
    }else{
        Y = 4;
    }
}
```

The following figure shows the flow diagram that implements the `if-then-else` logic.

The following generated VHDL code excerpt shows the nested IF-ELSE statements obtained from the flow diagram.

```
Chart : PROCESS (Y1_reg, Y2_reg, U1, U2)
  -- local variables
  BEGIN
    Y1_reg_next <= Y1_reg;
    Y2_reg_next <= Y2_reg;

    IF unsigned(U1) = to_unsigned(1, 8) THEN
      IF unsigned(U2) = to_unsigned(1, 8) THEN
        Y1_reg_next <= to_unsigned(1, 8);
      ELSE
        Y1_reg_next <= to_unsigned(2, 8);
      END IF;

      ELSIF unsigned(U2) < to_unsigned(2, 8) THEN
        Y1_reg_next <= to_unsigned(3, 8);
      ELSE
        Y1_reg_next <= to_unsigned(4, 8);
      END IF;

      Y2_reg_next <= tmw_to_unsigned(tmw_to_unsigned(tmw_to_unsigned(unsigned(U1), 9), 10)
        + tmw_to_unsigned(tmw_to_unsigned(unsigned(U2), 9), 10), 8);
    END PROCESS Chart;
```

Truth Tables

HDL Coder supports HDL code generation for:

- Truth Table functions within a Stateflow chart
- Truth Table blocks in Simulink models

This section examines a Truth Table function in a chart, and the VHDL code generated for the chart.

Truth Tables are well-suited for implementing compact combinatorial logic. A typical application for Truth Tables is to implement nonlinear quantization or threshold logic. Consider the following logic:

Y = 1 when $0 \leq U \leq 10$
Y = 2 when $10 < U \leq 17$
Y = 3 when $17 < U \leq 45$
Y = 4 when $45 < U \leq 52$
Y = 5 when $52 < U$

A stateless chart with a single call to a Truth Table function can represent this logic succinctly.

The following figure shows the quantizer chart, containing the Truth Table.

The following figure shows the threshold logic, as displayed in the Truth Table Editor.

The screenshot shows the Stateflow software interface for a truth table. The window title is "Stateflow (truth table) sf_truth_table/quantizer/quantizer.quantize". The menu bar includes "File", "Edit", "Settings", "Add", and "Help". The toolbar contains icons for file operations and navigation.

The interface is divided into two main sections: "Condition Table" and "Action Table".

Condition Table

	Description	Condition	D1	D2	D3	D4	D5
1		U <= 10	T	-	-	-	-
2		U <= 17	-	T	-	-	-
3		U <= 45	-	-	T	-	-
4		U <= 52	-	-	-	T	-
		Actions: Specify a row from the Action Table	1	2	3	4	5

Action Table

#	Description	Action
1		Y = 1
2		Y = 2
3		Y = 3
4		Y = 4
5		Y = 5

The following code excerpt shows VHDL code generated for the quantizer chart.

```

quantizer : PROCESS (Y_reg, U)
-- local variables
VARIABLE aVarTruthTableCondition_1 : std_logic;
VARIABLE aVarTruthTableCondition_2 : std_logic;

```

```

VARIABLE aVarTruthTableCondition_3 : std_logic;
VARIABLE aVarTruthTableCondition_4 : std_logic;
BEGIN
  Y_reg_next <= Y_reg;
  -- Condition #1
  aVarTruthTableCondition_1 := tmw_to_stdlogic(unsigned(U) <= to_unsigned(10, 8));
  -- Condition #2
  aVarTruthTableCondition_2 := tmw_to_stdlogic(unsigned(U) <= to_unsigned(17, 8));
  -- Condition #3
  aVarTruthTableCondition_3 := tmw_to_stdlogic(unsigned(U) <= to_unsigned(45, 8));
  -- Condition #4
  aVarTruthTableCondition_4 := tmw_to_stdlogic(unsigned(U) <= to_unsigned(52, 8));

  IF tmw_to_boolean(aVarTruthTableCondition_1) THEN
    -- D1
    -- Action 1
    Y_reg_next <= to_unsigned(1, 8);
  ELSIF tmw_to_boolean(aVarTruthTableCondition_2) THEN
    -- D2
    -- Action 2
    Y_reg_next <= to_unsigned(2, 8);
  ELSIF tmw_to_boolean(aVarTruthTableCondition_3) THEN
    -- D3
    -- Action 3
    Y_reg_next <= to_unsigned(3, 8);
  ELSIF tmw_to_boolean(aVarTruthTableCondition_4) THEN
    -- D4
    -- Action 4
    Y_reg_next <= to_unsigned(4, 8);
  ELSE
    -- Default
    -- Action 5
    Y_reg_next <= to_unsigned(5, 8);
  END IF;
END PROCESS quantizer;

```

Note When generating code for a Truth Table block in a Simulink model, HDL Coder writes a separate entity/architecture file for the Truth Table code. The file is named `Truth_Table.vhd` (for VHDL) or `Truth_Table.v` (for Verilog).

Initialize Persistent Variables in MATLAB Functions

A persistent variable is a local variable in a MATLAB function that retains its value in memory between calls to the function. If you generate code from your model, you must initialize a persistent variable for your MATLAB functions. For more information, see `persistent`.

When using MATLAB functions that contain persistent variables in Simulink models, you should follow these guidelines:

- Initialize the persistent variables in functions only by accessing constants.
- Ensure the control flow of the function does not depend on whether the initialization occurs.

If you do not follow these guidelines, several conditions produce an initialization error:

- MATLAB Function blocks with persistent variables where the **Allow direct feedthrough** property is cleared
- MATLAB Function blocks with persistent variables in models with State Control blocks where **State control** is set to Synchronous
- Stateflow charts that implement Moore machine semantics and that use MATLAB functions with persistent variables

For example, the function `fcn` below uses a persistent variable, `n`. `fcn` violates both guidelines. The initial value of `n` depends on the input `u` and the `return` statement interrupts the normal control flow of the function. Consequently, this code produces an error when used in a model that has one of the conditions described above.

```
function y = fcn(u)
    persistent n

    if isempty(n)
        n = u;
        y = 1;
        return
    end

    y = n;
    n = n + u;
end
```

To prevent the error, initialize the persistent variable by setting it to a constant value and removing the `return` statement. This modified version of `fcn` initializes the persistent variable without producing an error:

```
function y = fcn(u)
    persistent n

    if isempty(n)
        n = 1;
    end

    y = n;
    n = n + u;
end
```

MATLAB Function Block with No Direct Feedthrough

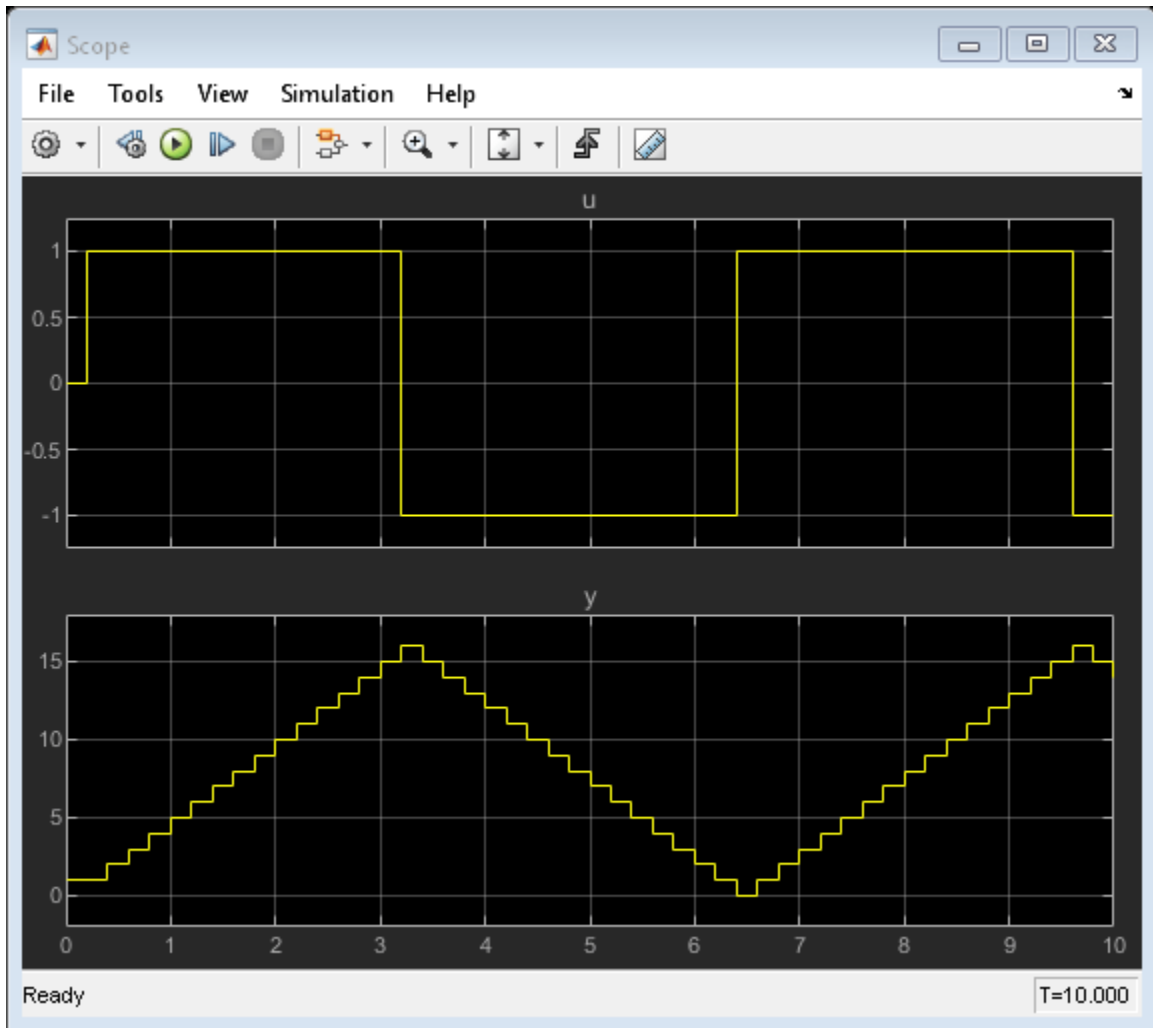

This model contains a MATLAB Function block that uses the first version of `fcn`, described previously. The MATLAB Function block input is a square wave, which is provided by a Sign and Sine Wave block. The MATLAB Function block adds the value of `u` to the persistent variable `n` at each time step.

Simulate the model. The simulation returns an error because:

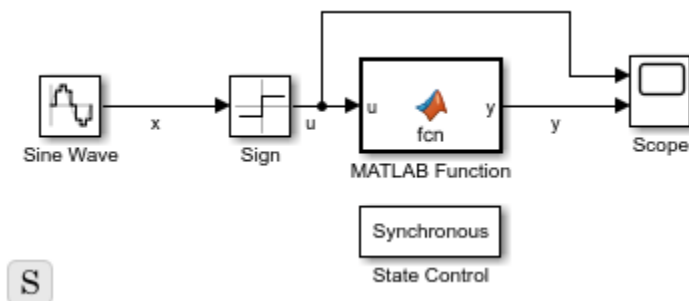

- The initial value of the persistent variable `n` depends on the input `u`.
- The `return` statement interrupts the normal control flow of the function.
- The **Allow direct feedthrough** property of the MATLAB Function block is cleared.

Modify the MATLAB Function block code, as shown in the corrected version of `fcn`. Simulate the model again.

State Control Block in Synchronous Mode

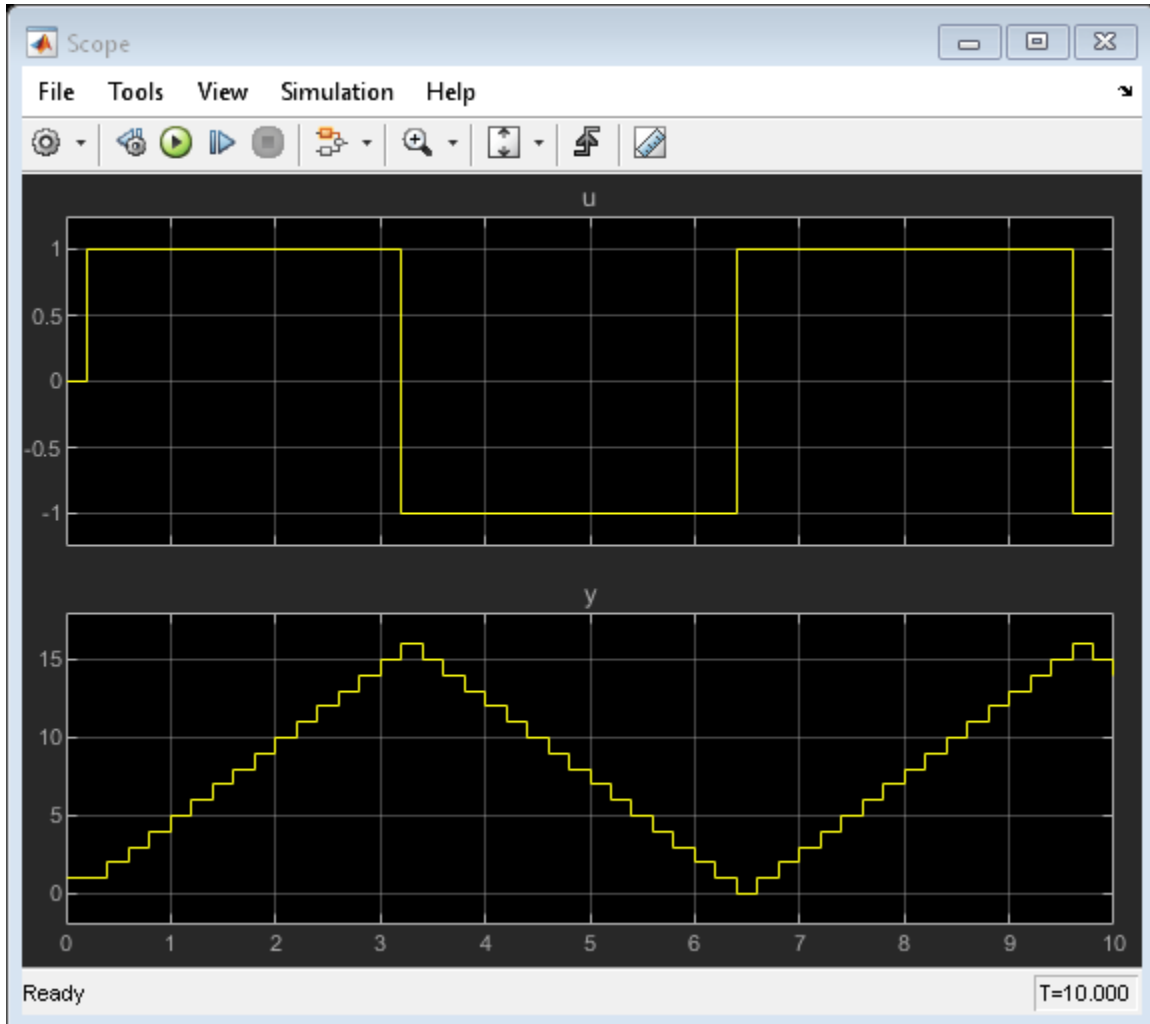

This model contains a MATLAB Function block that uses the first version of `fcn`, described previously. The MATLAB Function block input is a square wave, which is provided by a Sign and Sine Wave block. The MATLAB Function block adds the value of `u` to the persistent variable `n` at each time step. The model contains a State Control block where **State control** is set to Synchronous.

Simulate the model. The simulation returns an error because:

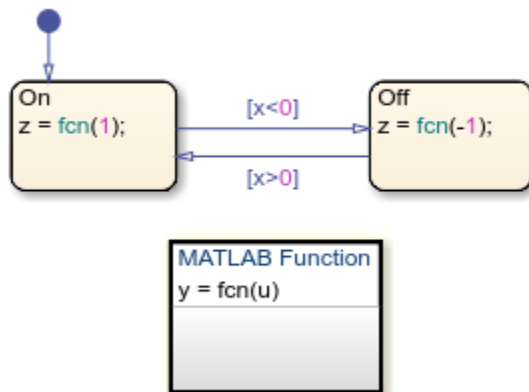

- The initial value of the persistent variable n depends on the input u .
- The return statement interrupts the normal control flow of the function.
- The model contains a State Control block where **State control** is set to **Synchronous**.

Modify the MATLAB Function block code, as shown in the corrected version of `fcn`. Simulate the model again.

Stateflow Chart Implementing Moore Semantics

This model contains a Stateflow Chart with a MATLAB function that uses the first version of `fcn`, described previously. The MATLAB function adds the value (1 or -1) determined by the active state to the persistent variable n at each time step.

Simulate the model. The simulation returns an error because:

- The initial value of the persistent variable `n` depends on the input `u`.
- The return statement interrupts the normal control flow of the function.
- The chart implements Moore semantics.

Modify the MATLAB function code, as shown in the corrected version of `fcn`. Simulate the model again.

“HDL Applications” on page 34-2

Structure of Generated HDL Code

The MATLAB Function block contains a MATLAB function in a model. The inputs and outputs of the function are represented by the ports on the block, which allow you to interface your model to the function code. When you generate HDL code for a MATLAB Function block, HDL Coder generates two HDL files:

- A file containing entity and architecture code that implement the actual algorithm or computations generated for the MATLAB Function block.
- A file containing an entity definition and RTL architecture that provide a black box interface to the algorithmic code generated for the MATLAB Function block.

The structure of these code files is analogous to the structure of the model, in which a subsystem provides an interface between the root model and the function in the MATLAB Function block.

HDL Applications

The MATLAB Function block supports a subset of the MATLAB language that is well-suited to HDL implementation of various DSP and telecommunications algorithms, such as:

- Sequence and pattern generators
- Encoders and decoders
- Interleavers and de-interleavers
- Modulators and demodulators
- Multipath channel models; impairment models
- Timing recovery algorithms
- Viterbi algorithm; Maximum Likelihood Sequence Estimation (MLSE)
- Adaptive equalizer algorithms

You can also use the MATLAB Function block in a wide variety of floating-point applications. Both `single` and `double` types are supported. To learn more, see “HDL Optimizations Across MATLAB Function Block Boundary Using MATLAB Datapath Architecture” on page 28-203.

Counter Model Using the MATLAB Function block

In this tutorial, you construct and configure a simple model, `eml_hdl_incrementer_tut`, and then generate VHDL code from the model. `eml_hdl_incrementer_tut` includes a MATLAB Function block that implements a simple fixed-point counter function, `incrementer`. The `incrementer` function is invoked once during each sample period of the model. The function maintains a persistent variable `count`, which is either incremented or reinitialized to a preset value (`ctr_preset_val`), depending on the value passed in to the `ctr_preset` input of the MATLAB Function block. The function returns the counter value (`counter`) at the output of the MATLAB Function block.

The MATLAB Function block resides in a subsystem, `DUT_eML_Block`. The subsystem functions as the device under test (DUT) from which you generate HDL code.

The root-level model drives the subsystem and includes Display and To Workspace blocks for use in simulation. (The Display and To Workspace blocks do not generate HDL code.)

Tip If you do not want to construct the model step by step, or do not have time, you can open the completed model by entering the name at the command prompt:

```
eml_hdl_incrementer
```

After you open the model, save a copy of it to your local folder as `eml_hdl_incrementer_tut`.

The Incrementer Function Code

The following code listing gives the complete incrementer function definition:

```
function counter = incrementer(ctr_preset, ctr_preset_val)
% The function incrementer implements a preset counter that counts
% how many times this block is called.
%
% This example function shows how to model memory with persistent variables,
% using fimath settings suitable for HDL. It also demonstrates MATLAB
% operators and other language features that HDL Coder supports
% for code generation from Embedded MATLAB Function block.
%
% On the first call, the result 'counter' is initialized to zero.
% The result 'counter' saturates if called more than 2^14-1 times.
% If the input ctr_preset receives a nonzero value, the counter is
% set to a preset value passed in to the ctr_preset_val input.

persistent current_count;
if isempty(current_count)
    % zero the counter on first call only
    current_count = uint32(0);
end

counter = getfi(current_count);

if ctr_preset
    % set counter to preset value if input preset signal is nonzero
    counter = ctr_preset_val;
else
    % otherwise count up
    inc = counter + getfi(1);
```

```

    counter = getfi(inc);
end

% store counter value for next iteration
current_count = uint32(counter);

function hdl_fi = getfi(val)
nt = numerictype(0,14,0);
fm = hdlfimath;
hdl_fi = fi(val, nt, fm);

```

Setting Up

Before you begin building the example model, set up a working folder for your model and generated code.

Setting Up a folder

- 1 Start MATLAB.
- 2 Create a folder named `eml_tut`, for example:

```
mkdir D:\work\eml_tut
```

The `eml_tut` folder stores the model you create, and also contains sub-folders and generated code. The location of the folder does not matter, except that it should not be within the MATLAB tree.

- 3 Make the `eml_tut` folder your working folder, for example:

```
cd D:\work\eml_tut
```

Creating the Model and Configuring General Model Settings

In this section, you create a model and set some parameters to values recommended for HDL code generation `hdlsetup` command. The `hdlsetup` command uses the `set_param` function to set up models for HDL code generation quickly and consistently. See “Customize `hdlsetup` Function Based on Target Application” on page 25-19 for further information about `hdlsetup`.

To set the model parameters:

- 1 Create a new model.
- 2 Save the model as `eml_hdl_incrementer_tut`.
- 3 At the MATLAB command prompt, type:

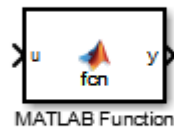

```
hdlsetup('eml_hdl_incrementer_tut');
```
- 4 Open the Configuration Parameters dialog box.
- 5 Set the following **Solver** options, which are useful in simulating this model:

- **Fixed step size:** 1
- **Stop time:** 5

- 6 Click **OK** to save your changes and close the Configuration Parameters dialog box.
- 7 Save your model.

Adding a MATLAB Function Block to the Model

- 1 Open the Simulink Library Browser. Then, select the Simulink/User-Defined Functions library.
- 2 Select the MATLAB Function block from the library window and add it to the model.

- 3 Change the block label from MATLAB Function to eml_inc_block.

- 4 Save the model.
- 5 Close the Simulink Library Browser.

Set Fixed-Point Options for the MATLAB Function Block

This section describes how to set up the `fimath` specification and other fixed-point options that are recommended for efficient HDL code generation from the MATLAB Function block. The recommended settings are:

- ProductMode property of the `fimath` specification: 'FullPrecision'
- SumMode property of the `fimath` specification: 'FullPrecision'
- **Treat these inherited signal types as fi objects** option: Fixed-point (This is the default setting.)

Configure the options as follows:

- 1 Open the `eml_hdl_incrementer_tut` model that you created in “Adding a MATLAB Function Block to the Model” on page 34-8.
- 2 Double-click the MATLAB Function block to open it for editing. The MATLAB Function Block Editor appears.
- 3 In the **Modeling** tab, in the **Design** section, click the **Property Inspector**. The Property Inspector displays the default `fimath` specification and other properties for the MATLAB Function block.

- 4 Open the **Fixed-point properties** section and select **Specify Other**. Selecting this option enables the **MATLAB Function block fimath** text entry field.
- 5 The `hdlfimath` function is a utility that defines a FIMATH specification that is optimized for HDL code generation. Replace the default **MATLAB Function block fimath** specification with a call to `hdlfimath` as follows:

```
hdlfimath;
```

- 6 Save the model.

Programming the MATLAB Function Block

The next step is add code to the MATLAB Function block to define the `incrementer` function, and then use diagnostics to check for errors.

- 1 Open the `eml_hdl_incrementer_tut` model that you created in “Adding a MATLAB Function Block to the Model” on page 34-8.
- 2 Double-click the MATLAB Function block to open it for editing.
- 3 In the MATLAB Function Block Editor, delete the default code.
- 4 Copy the complete `incrementer` function definition from the listing given in “The Incrementer Function Code” on page 34-6, and paste it into the editor.
- 5 Save the model. Doing so updates the model window, redrawing the MATLAB Function block.

Changing the function header of the MATLAB Function block makes the following changes to the block icon:

- The function name in the middle of the block changes to `incrementer`.
 - The arguments `ctr_preset` and `ctr_preset_val` appear as input ports to the block.
 - The return value `counter` appears as an output port from the block.
- 6 Resize the block to make the port labels more legible.

- 7 Save the model again.

Constructing and Connecting the DUT_eML_Block Subsystem

This section assumes that you have completed “Programming the MATLAB Function Block” on page 34-9 without encountering an error. In this section, you construct a subsystem containing the `incrementer` function block, to be used as the device under test (DUT) from which to generate HDL code. You then set the port data types and connect the subsystem ports to the model.

Constructing the DUT_eML_Block Subsystem

Construct a subsystem containing the `incrementer` function block as follows:

- 1 Click the `incrementer` function block.
- 2 On the **Modeling** tab of the Simulink Toolstrip, select **Create Subsystem**.

A subsystem, labeled `Subsystem`, is created in the model window.

- 3 Change the Subsystem label to `DUT_eML_Block`.

Setting Port Data Types for the MATLAB Function Block

- 1 Double-click the subsystem to view its interior. As shown in the following figure, the subsystem contains the `incrementer` function block, with input and output ports connected.

- 2 Double-click the `incrementer` function block to open the MATLAB Function Block Editor.
- 3 In the **Modeling** tab, in the **Design** section, open the **Model Explorer**.
- 4 Click on the `eml_inc_block`, select the `ctr_preset` entry in the Content list. Click the Show data type assistant button to display the Data Type Assistant parameters. Set **Mode** for this port to `Built in`. Set **Data type** to `boolean`. Click the button labeled `<<` to close the Data Type Assistant. Click **Apply**.
- 5 Select the `ctr_preset_val` entry in the Content list. Open the Data Type Assistant. Set **Mode** for this port to `Fixed point`. Set **Signedness** to `Unsigned`. Set **Word length** to 14. Click the button labeled `<<` to close the Data Type Assistant. Click **Apply**.
- 6 Select the `counter` entry in the Content list. Open the Data Type Assistant. Verify that **Mode** for this port is set to `Inherit: Same as Simulink`. Click the button labeled `<<` to close the Data Type Assistant. Click **Apply**.
- 7 Close the Model Explorer and the MATLAB Function Block Editor.
- 8 Save the model and close the `DUT_eML_Block` subsystem.

Connecting Subsystem Ports to the Model

Next, connect the ports of the `DUT_eML_Block` subsystem to the model as follows:

- 1 From the Sources library, add a Constant block to the model. Set the value of the Constant block to 1, and the **Output data type** to `boolean`. Change the block label to `Preset`.

- 2 Make a copy of the Preset Constant block. Set its value to 0, and change its block label to Increment.
- 3 From the Signal Routing library, add a Manual Switch block to the model. Change its label to Control. Connect its output to the In1 port of the DUT_eML_Block subsystem.
- 4 Connect the Preset Constant block to the upper input of the Control switch block. Connect the Increment Constant block to the lower input of the Control switch block.
- 5 Add a third Constant block to the model. Set the value of the Constant to 15, and the **Output data type** to Inherit via back propagation. Change the block label to Preset Value.
- 6 Connect the Preset Value Constant block to the In2 port of the DUT_eML_Block subsystem.
- 7 From the Sinks library, add a Display block to the model. Connect it to the Out1 port of the DUT_eML_Block subsystem.
- 8 From the Sinks library, add a To Workspace block to the model. Route the output signal from the DUT_eML_Block subsystem to the To Workspace block.
- 9 Save the model.

Checking the Function for Errors

Use the built-in diagnostics of MATLAB Function blocks to test for syntax errors:

- 1 Open the eml_hdl_incrementer_tut model.
- 2 Double-click the MATLAB Function block incrementer to open it for editing.
- 3 In the MATLAB Function Block Editor, select **Build Model > Build** to compile and build the MATLAB Function block code.

The build process displays some progress messages. These messages include some warnings, because the ports of the MATLAB Function block are not yet connected to signals. You can ignore these warnings.

The build process builds an S-function for use in simulation. The build process includes generation of C code for the S-function. The code generation messages you see during the build process refer to generation of C code, not HDL code generation.

When the build concludes without encountering an error, a message window appears indicating that parsing was successful. If errors are found, the Diagnostics Manager lists them. See the MATLAB Function block documentation for information on debugging MATLAB Function block build errors.

Compiling the Model and Displaying Port Data Types

In this section you enable the display of port data types and then compile the model. Model compilation verifies the model structure and settings, and updates the model display.

- 1 In the **Debug** tab of the Simulink Toolstrip, on the **Information Overlays > Ports** section, select **Base data types**.
- 2 Press **Ctrl+D** to compile and update the model. This triggers a rebuild of the code. After the model compiles, the block diagram updates to show the port data types.

- 3 Save the model.

Simulating the `eml_hdl_incrementer_tut` Model

Start simulation. If required, the code rebuilds before the simulation starts.

After the simulation completes, the Display block shows the final output value returned by the `incrementer` function block. For example, given a **Start time** of 0, a **Stop time** of 5, and a zero value at the `ctr_preset` port, the simulation returns a value of 6:

You might want to experiment with the results of toggling the **Control** switch, changing the **Preset Value** constant, and changing the total simulation time. You might also want to examine the workspace variable `simout`, which is bound to the **To Workspace** block.

Generating HDL Code

In this section, you select the `DUT_eML_Block` subsystem for HDL code generation, set basic code generation options, and then generate VHDL code for the subsystem.

Selecting the Subsystem for Code Generation

Select the `DUT_eML_Block` subsystem for code generation:

- 1 Open the Configuration Parameters dialog box and click the **HDL Code Generation** pane.
- 2 Select `eml_hdl_incrementer_tut/DUT_eML_Block` from the **Generate HDL for** list.
- 3 Click **Apply**.

Generating VHDL Code

In the Configuration Parameters dialog box, the top-level **HDL Code Generation** options should now be set as follows:

- The **Generate HDL for** field specifies the `eml_hdl_incrementer_tut/DUT_eML_Block` subsystem for code generation.
- The **Language** field specifies (by default) generation of VHDL code.
- The **Folder** field specifies (by default) that the code generation target folder is a subfolder of your working folder, named `hdlsrc`.

Before generating code, select **Current Folder** from the **Layout** menu in the MATLAB Command Window. This displays the Current Folder browser, which lets you easily access your working folder and the files that are generated within it.

To generate code:

- 1 Click the **Generate** button.

HDL Coder compiles the model before generating code. Depending on model display options (such as port data types), the appearance of the model might change after code generation.

- 2 As code generation proceeds, the coder displays progress messages. The process should complete with a message like the following:

```
### HDL Code Generation Complete.
```

The names of generated VHDL files in the progress messages are hyperlinked. After code generation completes, you can click these hyperlinks to view the files in the MATLAB Editor.

- 3 A folder icon for the `hdlsrc` folder is now visible in the Current Folder browser. To view generated code and script files, double-click the `hdlsrc` folder icon.
- 4 Observe that two VHDL files were generated. The structure of HDL code generated for MATLAB Function blocks is similar to the structure of code generated for Stateflow charts and Digital Filter blocks. The VHDL files that were generated in the `hdlsrc` folder are:
 - `eml_inc_blk.vhd`: VHDL code. This file contains entity and architecture code implementing the actual computations generated for the MATLAB Function block.
 - `DUT_eML_Block.vhd`: VHDL code. This file contains an entity definition and RTL architecture that provide a black box interface to the code generated in `eml_inc_blk.vhd`.

The structure of these code files is analogous to the structure of the model, in which the `DUT_eML_Block` subsystem provides an interface between the root model and the `incrementer` function in the MATLAB Function block.

The other files generated in the `hdlsrc` folder are:

- `DUT_eML_Block_compile.do`: Mentor Graphics ModelSim compilation script (`vcom` command) to compile the VHDL code in the two `.vhd` files.
 - `DUT_eML_Block_map.txt`: Mapping file. This report file maps generated entities (or modules) to the subsystems that generated them (see “Trace Code Using the Mapping File” on page 30-24).
- 5 To view the generated VHDL code in the MATLAB Editor, double-click the `DUT_eML_Block.vhd` or `eml_inc_blk.vhd` file icons in the Current Folder browser.

Generate Instantiable Code for Functions

In this section...

“How To Generate Instantiable Code for Functions” on page 34-16

“Generate Code Inline for Specific Functions” on page 34-16

“Limitations for Instantiable Code Generation for Functions” on page 34-16

For the MATLAB Function block, you can use the **InstantiateFunctions** parameter to generate a VHDL entity or Verilog module for each function. HDL Coder generates code for each entity or module in a separate file.

The **InstantiateFunctions** options for the MATLAB Function block are listed in the following table.

InstantiateFunctions Setting	Description
'off' (default)	Generate code for functions inline.
'on'	Generate a VHDL entity or Verilog module for each function, and save each module or entity in a separate file.

How To Generate Instantiable Code for Functions

To set the **InstantiateFunctions** parameter using the HDL Block Properties dialog box:

- 1 Right-click the MATLAB Function block.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 For **InstantiateFunctions**, select **on**.

To set the **InstantiateFunctions** parameter from the command line, use `hdlset_param`. For example, to generate instantiable code for functions in a MATLAB Function block, `myMatlabFcn`, in your DUT subsystem, `myDUT`, enter:

```
hdlset_param('my_DUT/my_MATLABFcnBlk', 'InstantiateFunctions', 'on')
```

Generate Code Inline for Specific Functions

If you want to generate instantiable code for some functions but not others, enable the option to generate instantiable code for functions, and use `coder.inline`. See `coder.inline` for details.

Limitations for Instantiable Code Generation for Functions

The software generates code inline when:

- Function calls are within conditional code or `for` loops.
- Any function is called with a nonconstant `struct` input.
- The function has state, such as a persistent variable, and is called multiple times.
- There is an enumeration anywhere in the design function.

MATLAB Function Block Design Patterns for HDL

In this section...
“HDL Design Pattern Blocks” on page 34-20
“Using Blocks in this Library for HDL Code Generation” on page 34-21
“Fixed-Point Algorithm Support” on page 34-21

You can use MATLAB Function blocks to write algorithms for implementation in Simulink and Stateflow, then use this code for HDL code generation. You can use the HDL design patterns library `eml_hdl_design_patterns` to implement common hardware modeling algorithms using the MATLAB Function block. The library contains examples that demonstrate hardware-friendly applications of the MATLAB Function block for HDL code generation.

To open the library, at the MATLAB command prompt, enter:

```
eml_hdl_design_patterns
```

You can use the blocks in the library to model various hardware elements by:

- Copying a block from the library to your model and using it as a computational unit.
- Copying the code from the block and using it as a local function in an existing MATLAB Function block.

When you create custom blocks, you can control whether to inline or instantiate the HDL code generated from MATLAB Function blocks. To inline or instantiate the HDL code, in the Configuration

Parameters dialog box, click **HDL Code Generation > Global Settings**. In the right pane, in the **Coding style** tab, select **Inline MATLAB Function block code**.

Note Do not use the **Inline MATLAB Function block code** setting when you set the **Architecture** HDL block property of the MATLAB Function block to **MATLAB Datapath**. Enable **FlattenHierarchy** instead. For more information, see “HDL Optimizations Across MATLAB Function Block Boundary Using MATLAB Datapath Architecture” on page 28-203.

HDL Design Pattern Blocks

This table summarizes some of the categories of HDL design patterns in the `eml_hdl_design_patterns` library. For more information on the different blocks, see “Create Hardware Design Patterns Using the MATLAB Function Block For HDL Code Generation” on page 34-27.

Library Subsystem	Purpose
Combinatorics	Combinatorial fixed-point algorithms, such as expressions containing addition, subtraction, and multiplication operators with different fixed-point data types.
Adders	Algorithms that model different adder logic.
Delays	Algorithms to model integer delay, tap delay, and tap delay vector blocks by using vectors of persistent variables. Use these design patterns to implement sequential algorithms that carry state between executions of the MATLAB Function block in a model.
Comparators	Algorithms for finding the minimum value of a vector.
FSMs	MATLAB Function block control constructs such as <code>switch/case</code> and <code>if-else</code> , coupled with fixed point arithmetic operations to model control logic quickly. The <code>FSMs/mealy_fsm_blk</code> and <code>FSMs/moore_fsm_blk</code> blocks provide example implementations of Mealy and Moore finite state machines in the MATLAB Function block.
Counters	Counter logic that shows how to model state and quantize data elements within loops.

Library Subsystem	Purpose
Shift Registers	<p>Algorithms that model shift register hardware elements.</p> <p>The <code>shift_reg_1by32</code> block shows how to model shift registers by using the <code>bitsliceget</code> and <code>bitconcat</code> functions. This function implements a serial input and output shifters with a 32-bit fixed-point operand input.</p> <p>The <code>shift_reg_1by64</code> block shows a 64 bit shifter. In this case, the shifter uses two fixed-point words to represent the operand, overcoming the 32-bit word length limitation for fixed-point integers.</p>
Word Twiddlers	Algorithms that perform word conversions, such as conversions from an integer to bits and bits to an integer.

Using Blocks in this Library for HDL Code Generation

To build models using blocks in this library and generate HDL code:

- Create or open a model.
- Copy a block from `eml_hdl_design_patterns` library to your model.
- Place the block in the device under test (DUT) subsystem.
- Run the `hdlsetup` command to set up your model for HDL code generation.
- Run the `makehdl` function to generate HDL code for the DUT subsystem.

For more information on generating HDL code from a MATLAB Function block, see “Code Generation from a MATLAB Function Block” on page 34-5.

Fixed-Point Algorithm Support

The MATLAB Function block supports floating-point arithmetic and fixed-point arithmetic by using the Fixed-Point Designer `fi` function. This function supports rounding and saturation modes that you can use to code algorithms that manipulate arbitrary word and fraction lengths. HDL Coder supports all `fi` rounding and overflow modes. HDL code generated from the MATLAB Function block is bit-true to MATLAB semantics. Generated code uses bit manipulation and bit access operators, such as `slice`, `extend`, `reduce`, and `concatenate` that are native to VHDL and Verilog. The `eml_hdl_design_patterns` library includes example blocks that use the `fi` object, such as the blocks in the `Adders` subsystem.

Use Compiled External Functions With MATLAB Function Blocks

The HDL Coder software supports HDL code generation from MATLAB Function blocks that include compiled external functions. This feature enables you to write reusable MATLAB code and call it from multiple MATLAB Function blocks.

Such functions must be defined in files that are on the MATLAB Function block path. Use the `%#codegen` compilation directive to indicate that the MATLAB code is suitable for code generation. See “Function Definition” for information on how to create, compile, and invoke external functions.

Build the MATLAB Function Block Code First

Before generating HDL code for a subsystem containing a MATLAB Function block, build the MATLAB Function block code to check for errors. To build the code, click the **Build Model** button in the function editor.

Use the hdlfimath Utility for Optimized FIMATH Settings

The `hdlfimath` function is a utility that defines a FIMATH specification that is optimized for HDL code generation.

The following listing shows the `fimath` setting defined by `hdlfimath`.

```
hdlfm = fimath(...
    'RoundMode', 'floor',...
    'OverflowMode', 'wrap',...
    'ProductMode', 'FullPrecision', 'ProductWordLength', 32,...
    'SumMode', 'FullPrecision', 'SumWordLength', 32,...
    'CastBeforeSum', true);
```

The HDL division operator does not support 'floor' rounding mode. Use 'round' mode or change the signed integer division operations to unsigned integer division.

When the `fimath OverflowMode` property of the `fimath` specification is set to 'Saturate', HDL code generation is disallowed for the following cases:

- `SumMode` is set to 'SpecifyPrecision'
- `ProductMode` is set to 'SpecifyPrecision'

Use Optimal Fixed-Point Option Settings

Use the default (Fixed-point) setting for the **Treat these inherited signal types as fi objects** option.

Clear the **Saturate on integer overflow** setting for the MATLAB Function block.

Set the Output Data Type of MATLAB Function Blocks Explicitly

By setting the output data type of a MATLAB Function block explicitly, you enable optimizations for RAM mapping and pipelining. Avoid inheriting the output data type for a MATLAB Function block for which you want to enable optimizations.

Using Tunable Parameters

HDL Coder supports both tunable and non-tunable parameters with the following data types:

- Scalar
- Vector
- Complex
- Structure
- Enumeration

When using tunable parameters with the MATLAB Function block:

- The tunable parameter should be a Simulink.Parameter object with the `StorageClass` set to `ExportedGlobal`.

```
x = Simulink.Parameter
x.Value = 1
x.CoderInfo.StorageClass = 'ExportedGlobal'
```

- Double-click the MATLAB Function block and open the **Symbols** pane and **Property Inspector** in the **Design** section in the **Modeling** tab. In the Symbols Pane, select the tunable parameter. In the Property Inspector, select the **Tunable** check box.

For details, see “Generate DUT Ports for Tunable Parameters” on page 14-18.

Run HDL Model Check for MATLAB Function Blocks

When your design contains MATLAB Function blocks, before you generate HDL code, you can run the check “Check for MATLAB Function block settings” on page 44-18 in the HDL Code Advisor. This check verifies whether you use the recommended MATLAB Function blocks for HDL code generation. The settings include whether `fi` settings are defined as per `hdlfimath` and **Saturate on integer overflow** check box is cleared.

See also “Check HDL Compatibility of Simulink Model Using HDL Code Advisor” on page 45-2.

Use MATLAB Datapath Architecture for Enhanced HDL Optimizations

In the HDL Block Properties dialog box for the MATLAB Function blocks, you can specify whether to use MATLAB Function or MATLAB Datapath as the HDL architecture. Floating-point models use

the MATLAB Datapath architecture even if you specify the HDL architecture as MATLAB Function on the block. Fixed-point models use the MATLAB Function architecture by default.

To perform various speed and area optimizations such as sharing and distributed pipelining inside the MATLAB Function block and across the MATLAB Function block boundary with other Simulink blocks, use the MATLAB Datapath architecture. When you use this architecture, the code generator treats the MATLAB Function block like a regular Subsystem block. This capability enables you to optimize the algorithm inside the MATLAB Function block and across the MATLAB Function block with other blocks in your model.

See “HDL Optimizations Across MATLAB Function Block Boundary Using MATLAB Datapath Architecture” on page 28-203.

CORDIC Algorithm Using the MATLAB Function Block

This example shows how to use HDL Coder to check, generate and verify HDL for a fixed-point CORDIC model implementing sin and cos trigonometric functions using the MATLAB Function Block.

```
open_system("hdlcordic_eml.slx");
```

Create Hardware Design Patterns Using the MATLAB Function Block For HDL Code Generation

You can use the HDL design patterns library `em_hdl_design_patterns` to implement patterns that use the MATLAB Function block to solve common hardware modeling problems. For more information on the `em_hdl_design_patterns` library, see “MATLAB Function Block Design Patterns for HDL” on page 34-18.

HDL Coder™ supports a subset of MATLAB Function block features that you can use in HDL implementations of various digital signal processing (DSP) and telecommunication applications, such as sequence detectors, pattern generators, encoders, and decoders. Some of the features supported by the MATLAB Function block in HDL Coder are:

- Numeric classes, including `int`, `uint`, `logical`, `single`, and `double`
- Fixed-point arithmetic using the `fi` object
- Arithmetic, logical, relational, and bitwise operator support
- MATLAB® expressions that use the preceding operators
- 1-D and 2-D matrix operations
- Matrix subscripting
- Control flow using `if`, `switch`, and `for` statements
- Subfunctions
- Persistent variables that model state
- Fixed point and integer MATLAB library functions

Open the Pattern Library

The MATLAB Function block expresses algorithm behavior in a concise and textual way, which enables you to model hardware algorithms at a high level. You can use HDL Coder to implement these MATLAB Function block hardware-friendly algorithms. The sample patterns library `em_hdl_design_patterns` shows how to model common, HDL-supported hardware modeling constructs using MATLAB Function blocks. Open this sample library model at the MATLAB command prompt by entering:

```
open_system('eml_hdl_design_patterns')
```

Model Arithmetic Expressions Using MATLAB Function Blocks

In the `em_hdl_design_patterns` library, you can use the blocks in the `Adders` and `Misc` subsystems to model arithmetic expressions. To model arbitrary length arithmetic operations using signed and unsigned logic vectors, use the `fi` object. When using `fi` objects in a MATLAB Function block, the `fi` function helps you to define a fixed-point object with a customized `numericType` object and `fimath` object. The `numericType` object defines the sign, word length, and fraction length attributes of the `fi` object and the `fimath` object defines rounding and saturation modes. For more information, see `fi`. To generate HDL code using the `fi` function, use these `fimath` settings:

```
fimath(...
    'RoundMode', 'floor',...
    'OverflowMode', 'wrap',...
    'ProductMode', 'FullPrecision', 'ProductWordLength', 32,...
    'SumMode', 'FullPrecision', 'SumWordLength', 32);
```

When modeling algorithms that require more complicated rounding and saturation logic, you can use other `fimath` modes for rounding, such as `floor`, `ceil`, `fix`, or `nearest`, and overflow, such as `wrap`, or `saturate`.

To see the affect of `fimath` properties on generated HDL code, generate HDL code for `eml_hdl_design_patterns/Adders/add_with_carry` and `eml_hdl_design_patterns/Misc/eml_expr`.

Model Combinatorics Using Fixed-Point Algorithms

Open the `eml_hdl_design_patterns` library and select the `Combinatorics/eml_expr` block. The `eml_expr` MATLAB Function block implements a simple expression that contains addition, subtraction, and multiplication operators with different fixed-point data types. Generate HDL code for the MATLAB Function block by following the process in “Code Generation from a MATLAB Function Block” on page 34-5.

This is the generated VHDL code:

```
BEGIN
  --MATLAB Function 'Subsystem/eml_expr': '<S2>:1'
  -- fixpt arithmetic expression
  -- '<S2>:1:4'
  mul_temp <= signed(a) * signed(b);
  sub_cast <= resize(mul_temp, 11);
  add_cast <= resize(signed(a & '0'), 7);
  add_cast_0 <= resize(signed(b), 7);
  add_temp <= add_cast + add_cast_0;
  sub_cast_0 <= resize(add_temp & '0' & '0', 11);
  expr <= sub_cast - sub_cast_0;
  -- cast the result to correct output type
  -- '<S2>:1:7'

  y <= "0111111" WHEN ((expr(10) = '0') AND (expr(9 DOWNTO 7) /= "000"))
    OR ((expr(10) = '0') AND (expr(7 DOWNTO 1) = "0111111"))
    ELSE
    "1000000" WHEN (expr(10) = '1') AND (expr(9 DOWNTO 7) /= "111")
    ELSE
    std_logic_vector(expr(7 DOWNTO 1) + ("0" & expr(0)));
END fsm_SFHDL;
```

This is the generated Verilog code from the `eml_expr` MATLAB Function block:

```
//MATLAB Function 'Subsystem/eml_expr': '<S2>:1'
// fixpt arithmetic expression
// '<S2>:1:4'
assign mul_temp = a * b;
assign sub_cast = mul_temp;
assign add_cast = {a[4], {a, 1'b0}};
assign add_cast_0 = b;
assign add_temp = add_cast + add_cast_0;
assign sub_cast_0 = {{2{add_temp[6]}}, {add_temp, 2'b00}};
assign expr = sub_cast - sub_cast_0;
// cast the result to correct output type
// '<S2>:1:7'
assign y = (((expr[10] == 0) && (expr[9:7] != 0))
  || ((expr[10] == 0) && (expr[7:1] == 63)) ? 7'sb0111111 :
  ((expr[10] == 1) && (expr[9:7] != 7) ? 7'sb1000000 :
  expr[7:1] + $signed({1'b0, expr[0]})));
```

The generated HDL code shows the conversion of this expression with fixed-point operands. The default `fimath` specification for the blocks determines the behavior of arithmetic expressions using fixed-point operands inside the MATLAB Function block. You can see the `fimath` settings in the block comments of the `eml_expr` block.

Model State Using Persistent Variables

To model complex control logic, your model must be able to model registers. When generating code, you can represent state-holding elements as persistent variables. A persistent variable retains its value across function calls in the MATLAB code and across sample times steps during simulation. State-holding elements in hardware such as registers and flip-flops have similar behavior. Consequently, persistent variables in MATLAB Function blocks map to registers in hardware.

The `Delays` subsystem in the `em_hdl_design_patterns` library contains MATLAB Function blocks that show how you can use global and local reset conditions to change the values of persistent variables and how you can use vectors of persistent variables to model integer delay, tap delay, and tap delay vector blocks. You can use these design patterns to implement sequential algorithms that carry state between executions of the MATLAB Function block in a model.

Note that the MATLAB code must read the persistent variable before it is written in order for HDL Coder to map the persistent variable to a register in the HDL code. When generating code, HDL Coder displays a warning message if the MATLAB code does not follow this convention.

Model Control Logic and Finite State Machines

You can use conditional statements such as `switch`, `case`, `if`, and `else` together with fixed-point arithmetic operations and delay elements to model control logic. In the `em_hdl_design_patterns` library, the MATLAB Function blocks in the `FSMs` subsystems show how to use these conditional statements. The `mealy_fsm_blk` and `moore_fsm_blk` blocks provide example implementations of Mealy and Moore finite state machines in a MATLAB Function block.

The MATLAB Function block can model simple state machines and other control-based hardware algorithms, such as pattern matchers or synchronization-related controllers, by using control statements and persistent variables. For modeling more complex and hierarchical state machines with complicated temporal logic, use a Stateflow® chart to model the state machine.

Model Counters

The MATLAB Function blocks in the `Counters` subsystem show how to model state and quantize data elements in loops. You can use counters for global reset control of persistent state variables and local reset control. To implement arithmetic and control logic algorithms in MATLAB Function blocks intended for HDL code generation, ensure that:

- The top-level MATLAB Function block is called once per time step.
- It is possible to fully unroll program loops.
- Persistent variables with reset values and update logic are used to hold values across simulation time steps.
- Quantized data variables are used inside loops.

Model Bitwise and Bit Conversion Operations

The MATLAB Function block supports a variety of bitwise operations useful for hardware bit manipulation operations, such as bits-to-integer conversion, integer-to-bits conversion, bit concatenation, bit packing and unpacking, and pn-sequence generation and bit-scramblers.

These bitwise functions are supported by HDL Coder:

- `bitget`, `bitsliceget`, `bitconcat`, `bitset`, `bitcmp`
- `bitand`, `bitor`, `bitxor`
- `bitandreduce`, `bitorreduce`, `bitxorreduce`
- `bitshift`, `bitsll`, `bitsrl`, `bitsra`, `bitrol`, `bitror`

When modeling pure logic and no math operations in the MATLAB Function block, use:

- Unsigned instead of signed input operands.
- Non-saturating `fimath` options to generate less hardware.
- `wrap` as the `OverflowMode` setting.
- `floor` as the `RoundMode` setting.

In the `em_hdl_design_patterns` library, the MATLAB Function block `hdl_bit_ops` in the `Bit Twiddlers` subsystem and the `signal_distance` and `nibble_swap_with_slice_concat` MATLAB Function blocks in the `Word Twiddlers` subsystem show how to apply these settings.

For an example model that shows how you can perform a conversion from integer-to-bits and bits-to-integer, open the model `hdlcoder_int2bits_bits2int`, by entering:

```
open_system('hdlcoder_int2bits_bits2int')
```

You can also open the model by double-clicking on the black text box `hdlcoder_int2bits_bits2int` in the `Word Twiddlers` subsystem.

The `hdlcoder_int2bits_bits2int` model uses these MATLAB Function blocks from the `Word Twiddlers` subsystem in the `em_hdl_design_patterns` library:

- `Bits2Int`
- `Int2Bits`
- `Integer to Bits`
- `Bits to Integer`

Model Hardware Elements

You can use the MATLAB Function block to model various hardware elements like barrel shifters, rotators, and carry-save adders by using MATLAB scripts. In the `em_hdl_design_patterns` library, see the `Shift Registers` subsystem for MATLAB Function blocks that model various shift register hardware elements, such as 32-bit and 64-bit shift registers.

Use Distributed Pipelining Optimization in Models with MATLAB Function Blocks

This example shows how to optimize the generated HDL code for MATLAB Function blocks by using the distributed pipelining optimization. Distributed pipelining is an HDL Coder™ optimization that improves the generated HDL code from MATLAB Function blocks, Simulink® models, or Stateflow® charts. By using distributed pipelining, your design achieves higher clock rates on the FPGA device. For more information, see “Distributed Pipelining” on page 28-131.

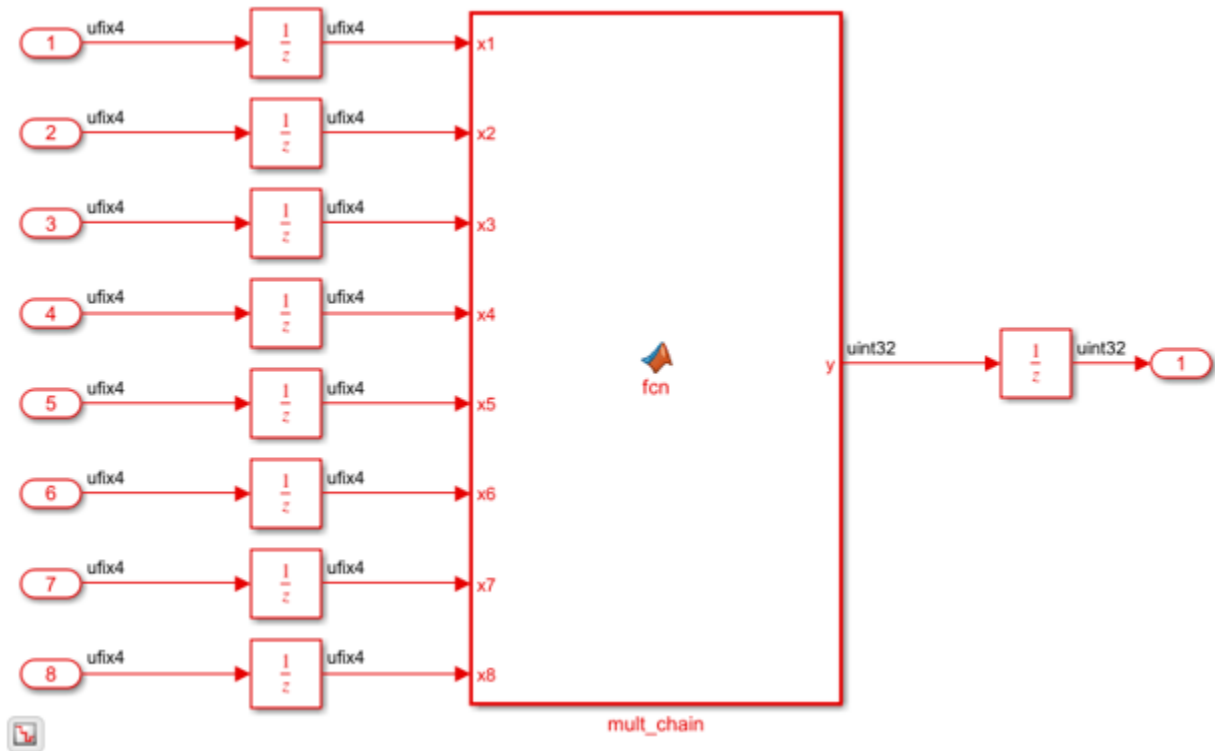

Open Multiplier Chain Model

This example shows how to distribute pipeline registers in a model that chains five multiplications.

Copyright 2019-2023 The MathWorks, Inc.

The HDL_DUT subsystem is the DUT for which you want to generate HDL code. The subsystem drives a MATLAB Function block `mult_chain`.

To see the chain of multiplications, open the MATLAB Function block. The block contains this MATLAB code:

```
function y = fcn(x1,x2,x3,x4,x5,x6,x7,x8)
% A chained multiplication:
% y = (x1*x2)*(x3*x4)*(x5*x6)*(x7*x8)

y1 = x1 * x2;
y2 = x3 * x4;
y3 = x5 * x6;
y4 = x7 * x8;

y5 = y1 * y2;
y6 = y3 * y4;

y = y5 * y6;
```

Apply Distributed Pipelining Optimization

1. Specify generation of two pipeline stages for the MATLAB Function block. Right-click the `mult_chain` MATLAB Function block. Select **HDL Code > HDL Block Properties**. In the HDL Properties window, set **OutputPipeline** to 2.
2. Set **Architecture** to **MATLAB Datapath**. This architecture treats the MATLAB Function block like a regular subsystem. You can then apply various HDL Coder optimizations on MATLAB Function blocks along with other blocks in your Simulink model.
3. To enable the distributed pipelining optimization across hierarchies in your model, in the Configuration Parameters dialog box, click **HDL Code Generation > Optimization**. Click the **Pipelining** tab, then select the model configuration parameter **Distributed pipelining**.

4. To see the results of the optimization in the code generation report, click **HDL Code Generation > Report**. Then, enable the parameter **Generate optimization report**.

5. Optionally, when you use the MATLAB datapath architecture for a MATLAB Function block, you can enable synthesis timing estimates for distributed pipelining. Synthesis timing estimates calculate the propagation delays of the components in your design for distributed pipelining. Using this parameter, you can more accurately reflect how components function on hardware to better distribute pipelines in your design and maximize the clock frequency for your specific target device. For more information, see “Distributed Pipelining Using Synthesis Timing Estimates” on page 28-137.

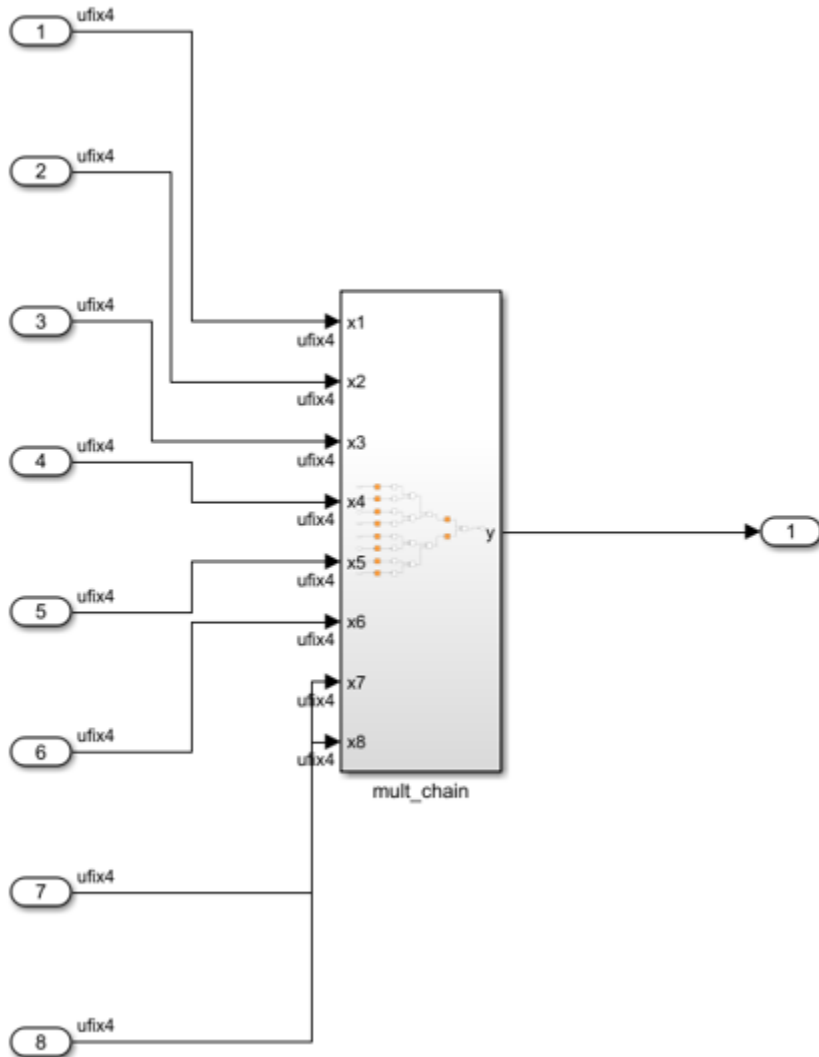

To enable synthesis timing estimates, click **HDL Code Generation > Optimization**, then select the **Pipelining** tab. Enable the **Use synthesis estimates for distributed pipelining** parameter.

6. Generate HDL Code for the HDL_DUT subsystem. In the **Apps** tab, click **HDL Coder**. In the **HDL Code** tab, click **Generate HDL Code**.

By default, HDL Coder generates VHDL code in the `hdlsrc` folder.

Analyze Results of Optimization

In the Code Generation Report window, in the **Distributed Pipelining** section, you see that the code generator moved the pipeline registers. To see the effects of the optimization, open the generated model `gm_hdlcoder_distpipe_multiplier_chain` and navigate to the HDL_DUT subsystem.

The MATLAB datapath architecture replaces the MATLAB Function block with a subsystem. The optimization can then distribute the pipeline registers and the unit delay inside the subsystem to optimize the multiplier chain and improve timing. Open the `mult_chain` subsystem to view this optimization.

Generating Scripts for HDL Simulators and Synthesis Tools

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Structure of Generated Script Files” on page 35-3
- “Properties for Controlling Script Generation” on page 35-4
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7
- “Add Synthesis Attributes” on page 35-18
- “Configure Synthesis Project Using Tcl Script” on page 35-19

Generate Scripts for Compilation, Simulation, and Synthesis

You can enable or disable script generation and customize the names and content of generated script files using either of the following methods:

- Use the `makehdl` or `makehdl tb` functions, and pass in property name/property value arguments, as described in “Properties for Controlling Script Generation” on page 35-4.
- Set script generation options in the **HDL Code Generation > EDA Tool Scripts** pane of the Configuration Parameters dialog box, as described in “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7.

Structure of Generated Script Files

A generated EDA script consists of three sections, generated and executed in the following order:

- 1** An initialization (`Init`) phase. The `Init` phase performs the required setup actions, such as creating a design library or a project file. Some arguments to the `Init` phase are implicit, for example, the top-level entity or module name.
- 2** A command-per-file phase (`Cmd`). This phase of the script is called iteratively, once per generated HDL file or once per signal. On each call, a different file or signal name is passed in.
- 3** A termination phase (`Term`). This is the final execution phase of the script. One application of this phase is to execute a simulation of HDL code that was compiled in the `Cmd` phase. The `Term` phase does not take arguments.

The HDL Coder software generates scripts by passing format strings to the `fprintf` function. Using the GUI options (or `makehdl` and `makehdltb` properties) summarized in the following sections, you can pass in customized format names to the script generator. Some of these format names take arguments, such as the top-level entity or module name, or the names of the VHDL or Verilog files in the design.

You can use valid `fprintf` formatting characters. For example, `'\n'` inserts a newline into the script file.

Properties for Controlling Script Generation

This section describes how to set properties in the `makehdl` or `makehdl tb` functions to enable or disable script generation and customize the names and content of generated script files.

Enabling and Disabling Script Generation

The `EDAScriptGeneration` property controls the generation of script files. By default, `EDAScriptGeneration` is set on. To disable script generation, set `EDAScriptGeneration` to `off`, as in the following example.

```
makehdl('sfir_fixed/symmetric_fir','EDAScriptGeneration','off')
```

Customizing Script Names

When you generate HDL code, HDL Coder appends a postfix string to the model or subsystem name *system* in the generated script name.

When you generate test bench code, HDL Coder appends a postfix string to the test bench name *testbench_tb*.

The postfix string depends on the type of script (compilation, simulation, or synthesis) being generated. The default postfix strings are shown in the following table. For each type of script, you can define your own postfix using the associated property.

Script Type	Property	Default Value
Compilation	<code>HDLCompileFilePostfix</code>	<code>_compile.do</code>
Simulation	<code>HDLSimFilePostfix</code>	<code>_sim.do</code>
Synthesis	<code>HDLSynthFilePostfix</code>	Depends on the selected synthesis tool. See “Choose synthesis tool” on page 24-11.

The following command generates VHDL code for the subsystem `system`, specifying a custom postfix for the compilation script. The name of the generated compilation script will be `system_test_compilation.do`.

```
makehdl('mymodel/system', 'HDLCompileFilePostfix', '_test_compilation.do')
```

Customizing Script Code

Using the property name/property value pairs summarized in the following table, you can pass in customized format names as character vectors to `makehdl` or `makehdl tb`. The properties are named according to the following conventions:

- Properties that apply to the initialization (`Init`) phase are identified by the `Init` character vector in the property name.
- Properties that apply to the command-per-file phase (`Cmd`) are identified by the `Cmd` character vector in the property name.
- Properties that apply to the termination (`Term`) phase are identified by the `Term` character vector in the property name.

Property Name and Default	Description
Name: HDLCompileInit Default: 'vlib %s\n'	Format name passed to <code>fprintf</code> to write the Init section of the compilation script. The implicit argument is the contents of the <code>VHDLLibraryName</code> property, which defaults to 'work'. You can override the default Init string ('vlib work\n') by changing the value of <code>VHDLLibraryName</code> .
Name: HDLCompileVHDLCmd Default: 'vcom %s %s\n'	Format name passed to <code>fprintf</code> to write the Cmd section of the compilation script for VHDL files. The two implicit arguments are the contents of the <code>SimulatorFlags</code> property and the file name of the current entity or module. To omit the flags, set <code>SimulatorFlags</code> to '' (the default).
Name: HDLCompileVerilogCmd Default: 'vlog %s %s\n'	Format name passed to <code>fprintf</code> to write the Cmd section of the compilation script for Verilog files. The two implicit arguments are the contents of the <code>SimulatorFlags</code> property and the file name of the current entity or module. To omit the flags, set <code>SimulatorFlags</code> to '' (the default).
Name: HDLCompileTerm Default: ''	Format name passed to <code>fprintf</code> to write the termination portion of the compilation script.
Name: HDLSimInit Default: ['onbreak resume\n',... 'onerror resume\n']	Format name passed to <code>fprintf</code> to write the initialization section of the simulation script.
Name: HDLSimCmd Default: 'vsim -voptargs==+acc %s.%s\n'	Format name passed to <code>fprintf</code> to write the simulation command. If your target language is VHDL, the first implicit argument is the value of the <code>VHDLLibraryName</code> property. If your target language is Verilog, the first implicit argument is 'work'. The second implicit argument is the top-level module or entity name.
Name: HDLSimViewWaveCmd Default: 'add wave sim:%s\n'	Format name passed to <code>fprintf</code> to write the simulation script waveform viewing command. The implicit argument adds the signal paths for the DUT top-level input, output, and output reference signals.
Name: HDLSimTerm Default: 'run -all\n'	Format name passed to <code>fprintf</code> to write the Term portion of the simulation script. The string is a synthesis project creation command. The content of the string is specific to the selected synthesis tool. See "Choose synthesis tool" on page 24-11.
Name: HDLSynthInit	Format name passed to <code>fprintf</code> to write the Init section of the synthesis script. The content of the format name is specific to the selected synthesis tool. See "Choose synthesis tool" on page 24-11.

Property Name and Default	Description
Name: HDLSynthCmd	Format name passed to <code>fprintf</code> to write the <code>Cmd</code> section of the synthesis script. The content of the format name is specific to the selected synthesis tool. See “Choose synthesis tool” on page 24-11.
Name: HDLSynthTerm	Format name passed to <code>fprintf</code> to write the <code>Term</code> section of the synthesis script. The content of the format name is specific to the selected synthesis tool. See “Choose synthesis tool” on page 24-11.

Examples

The following example specifies a custom VHDL library name for the Mentor Graphics ModelSim compilation script for code generated from the subsystem, `system`.

```
makehdl(system, 'VHDLLibraryName', 'mydesignlib')
```

The resultant script, `system_compile.do`, is:

```
vlib mydesignlib
vcom system.vhd
```

The following example specifies that HDL Coder generate a Xilinx ISE synthesis file for the subsystem `sfir_fixed/symmetric_fir`.

```
makehdl('sfir_fixed/symmetric_fir', 'HDLSynthTool', 'ISE')
```

The following listing shows the resultant script, `symmetric_fir_ise.tcl`.

```
set src_dir "./hdlsrc"
set prj_dir "synprj"
file mkdir ../$prj_dir
cd ../$prj_dir
project new symmetric_fir.ise
xfile add ../$src_dir/symmetric_fir.vhd
project set family Virtex4
project set device xc4vsx35
project set package ff668
project set speed -10
process run "Synthesize - XST"
```

Configure Compilation, Simulation, Synthesis, and Lint Scripts

You set options that configure script file generation on the **EDA Tool Scripts** pane. These options correspond to the properties described in “Properties for Controlling Script Generation” on page 35-4.

To view and set **EDA Tool Scripts** options:

- 1 Open the Configuration Parameters dialog box.
- 2 Select the **HDL Code Generation > EDA Tool Scripts** pane.

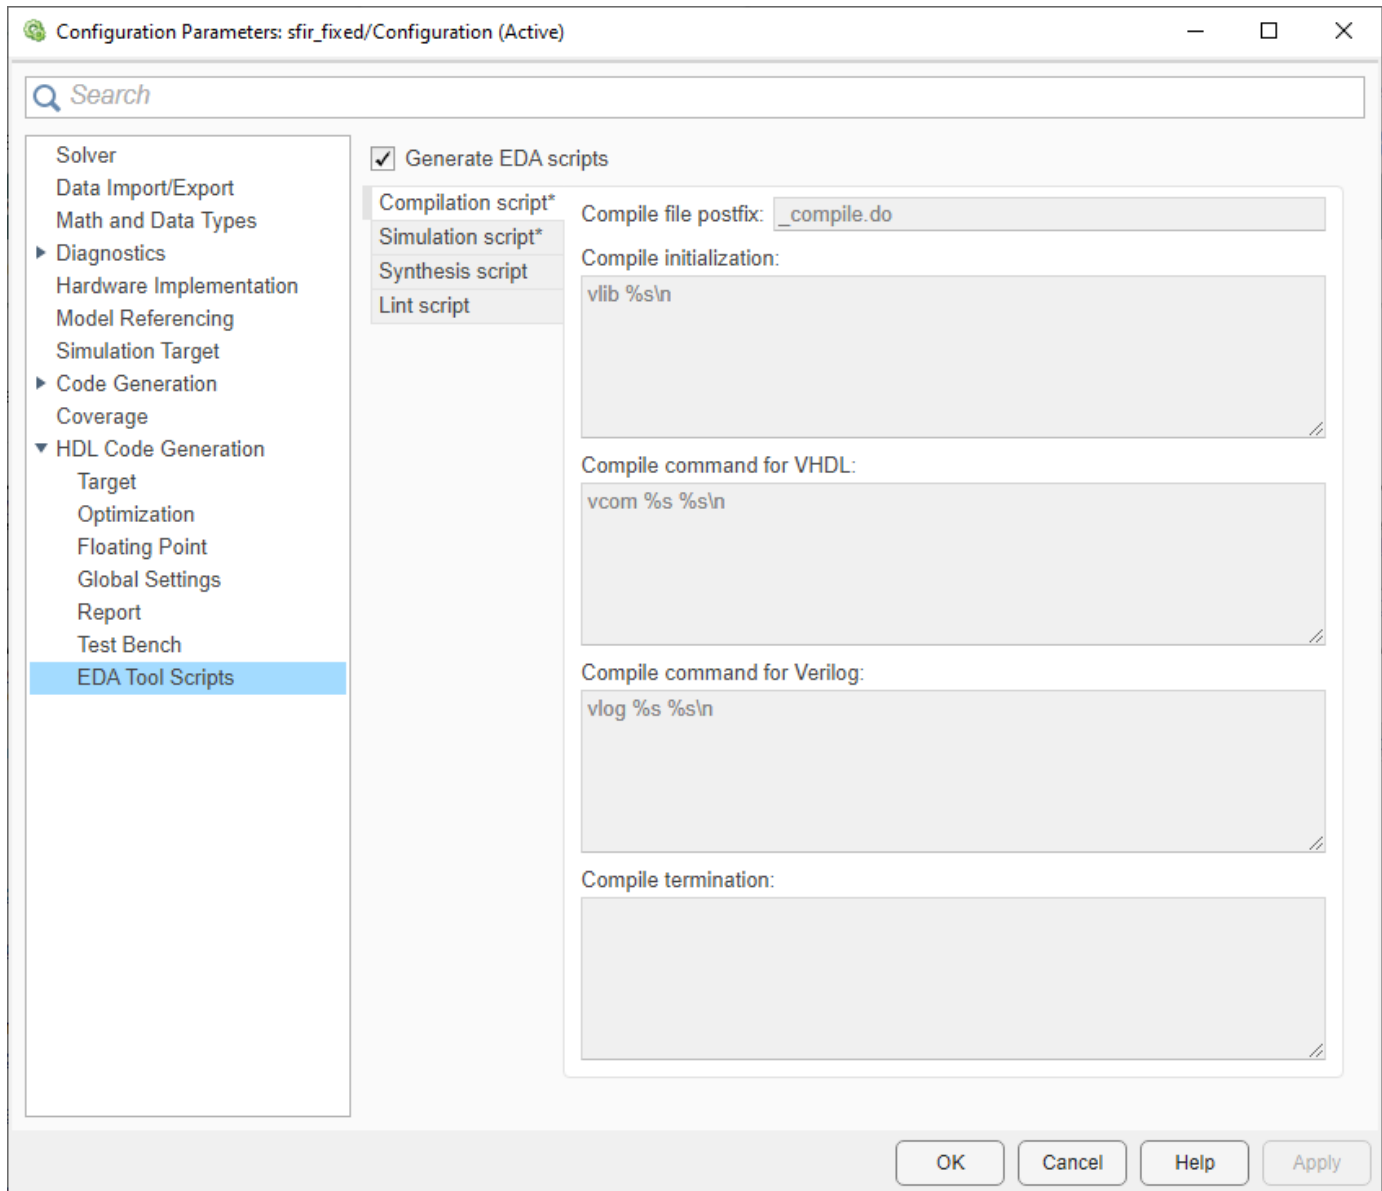

- 3 The **Generate EDA scripts** option controls the generation of script files. By default, this option is selected.

If you want to disable script generation, clear this check box and click **Apply**.

- 4** The list on the left of the **EDA Tool Scripts** pane lets you select from several categories of options. Select a category and set the options as desired. The categories are:
- **Compilation script:** Options related to customizing scripts for compilation of generated VHDL or Verilog code. For more information, see “Compilation Script Options” on page 35-8.
 - **Simulation script:** Options related to customizing scripts for HDL simulators. For more information, see “Simulation Script Options” on page 35-10.
 - **Synthesis script:** Options related to customizing scripts for synthesis tools. For more information, see “Synthesis Script Options” on page 35-12.
 - **Lint script:** Options related to customizing scripts for HDL lint tools. For more information, see “Lint Script Options” on page 35-15.

Compilation Script Options

The following figure shows the **Compilation script** pane, with options set to their default values.

The following table summarizes the **Compilation script** options.

Option and Default	Description
Compile file postfix' '_compile.do'	Postfix appended to the DUT name or test bench name to form the script file name. For more information, see "Compile file postfix" on page 24-4.
Name: Compile initialization Default: 'vlib %s\n'	Format name passed to fprintf to write the Init section of the compilation script. The argument is the contents of the VHDLLibraryName property, which defaults to 'work'. You can override the default Init 'vlib work\n' by changing the value of VHDLLibraryName. For more information, see "Compile initialization" on page 24-4.

Option and Default	Description
Name: Compile command for VHDL Default: 'vcom %s %s\n'	Format name passed to <code>fprintf</code> to write the <code>Cmd</code> section of the compilation script for VHDL files. The two arguments are the contents of the <code>SimulatorFlags</code> property option and the filename of the current entity or module. To omit the flags, set <code>SimulatorFlags</code> to '' (the default). For more information, see “Compile command for VHDL” on page 24-5.
Name: Compile command for Verilog Default: 'vlog %s %s\n'	Format name passed to <code>fprintf</code> to write the <code>Cmd</code> section of the compilation script for Verilog files. The two arguments are the contents of the <code>SimulatorFlags</code> property and the filename of the current entity or module. To omit the flags, set <code>SimulatorFlags</code> to '' (the default). For more information, see “Compile command for Verilog” on page 24-5.
Name: Compile termination Default: ''	Format name passed to <code>fprintf</code> to write the termination portion of the compilation script. For more information, see “Compile termination” on page 24-6.

See also

“Compilation Script Parameters” on page 24-4

Simulation Script Options

The following figure shows the **Simulation script** pane, with options set to their default values.

The following table summarizes the **Simulation script** options.

Option and Default	Description
Simulation file postfix '_sim.do'	Postfix appended to the model name or test bench name to form the simulation script file name. For more information, see "Simulation file postfix" on page 24-7.
Simulation initialization Default: ['onbreak resume\nnonerror resume\n']	Format name passed to fprintf to write the initialization section of the simulation script. For more information, see "Simulation initialization" on page 24-7.

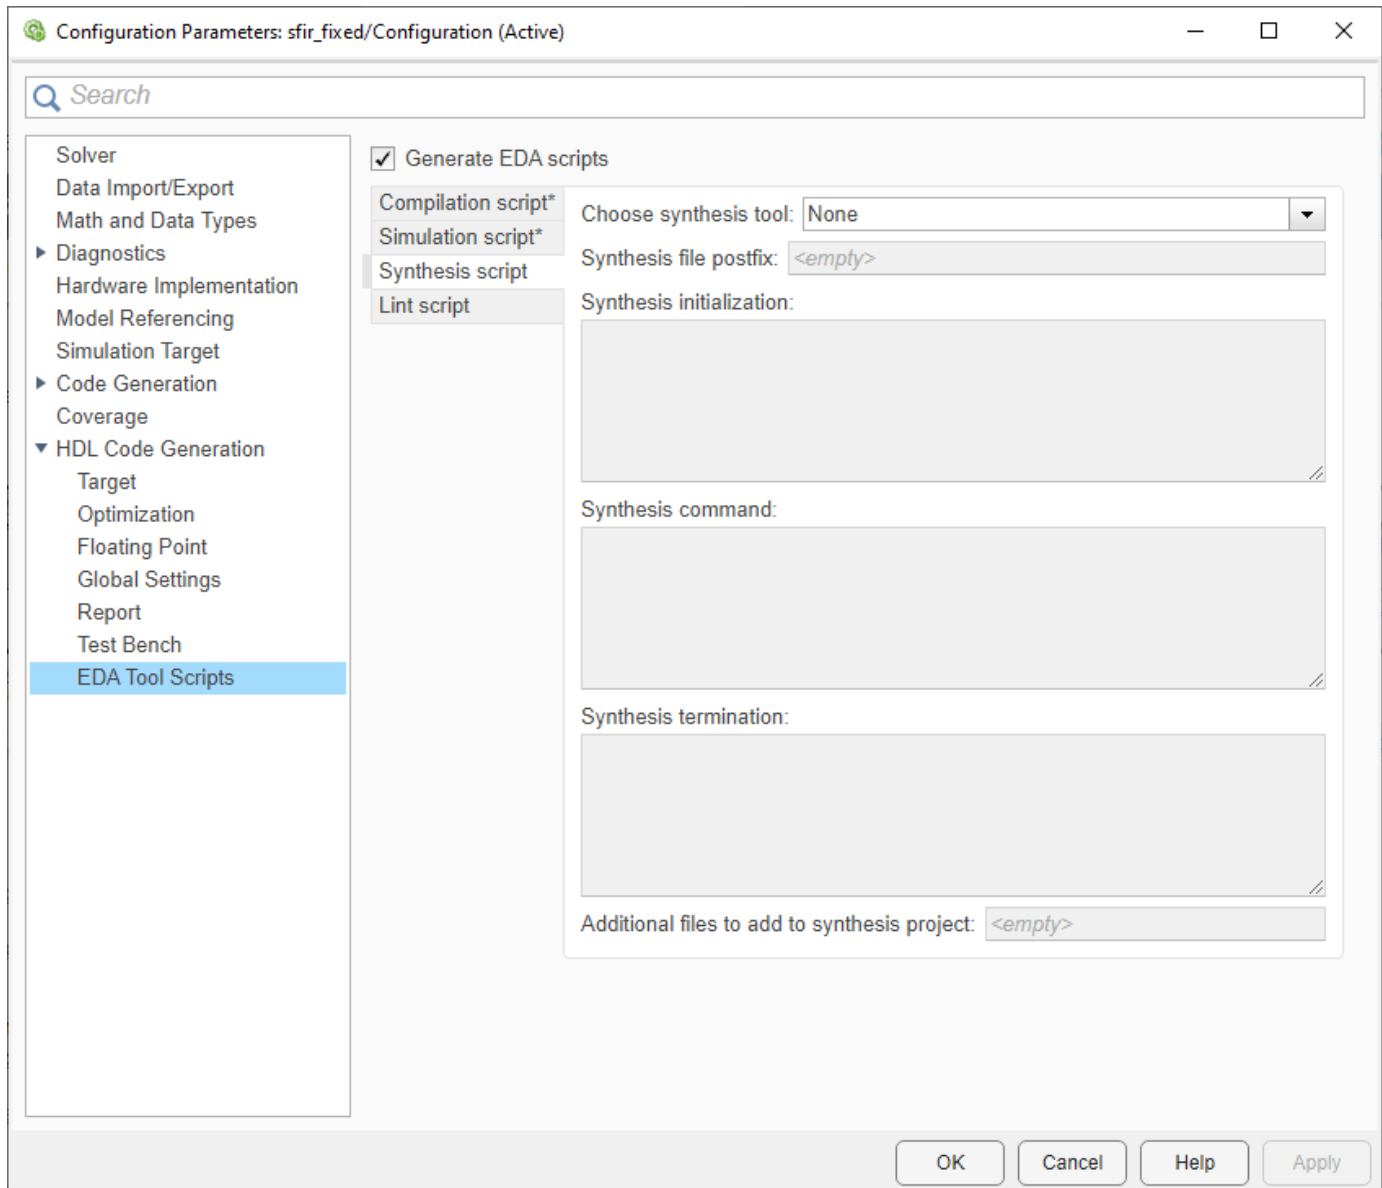

Option and Default	Description
Simulation command Default: 'vsim -voptargs=+acc %s.%s\n'	Format name passed to fprintf to write the simulation command. If your TargetLanguage is 'VHDL', the first implicit argument is the value of VHDLLibraryName. If your TargetLanguage is 'Verilog', the first implicit argument is 'work'. The second implicit argument is the top-level module or entity name. For more information, see "Simulation command" on page 24-8.
Simulation waveform viewing command Default: 'add wave sim:%s\n'	Format name passed to fprintf to write the simulation script waveform viewing command. The top-level module or entity signal names are implicit arguments. For more information, see "Simulation waveform viewing command" on page 24-8.
Simulation termination Default: 'run -all\n'	Format name passed to fprintf to write the Term portion of the simulation script. For more information, see "Simulation termination" on page 24-9.
Simulator flags Default: <empty>	Specify options that are specific to your application and the simulator you are using. For example, if you use the 1076-1993 VHDL compiler, specify the flag -93. The coder adds the flags you specify with this option to the compilation command in the generated EDA tool scripts. For more information, see "Simulator flags" on page 24-9.

"Simulation Script Parameters" on page 24-7

Synthesis Script Options

The following figure shows the **Synthesis script** pane, with options set to their default values. The **Choose synthesis tool** property defaults to None, which disables generation of a synthesis script.

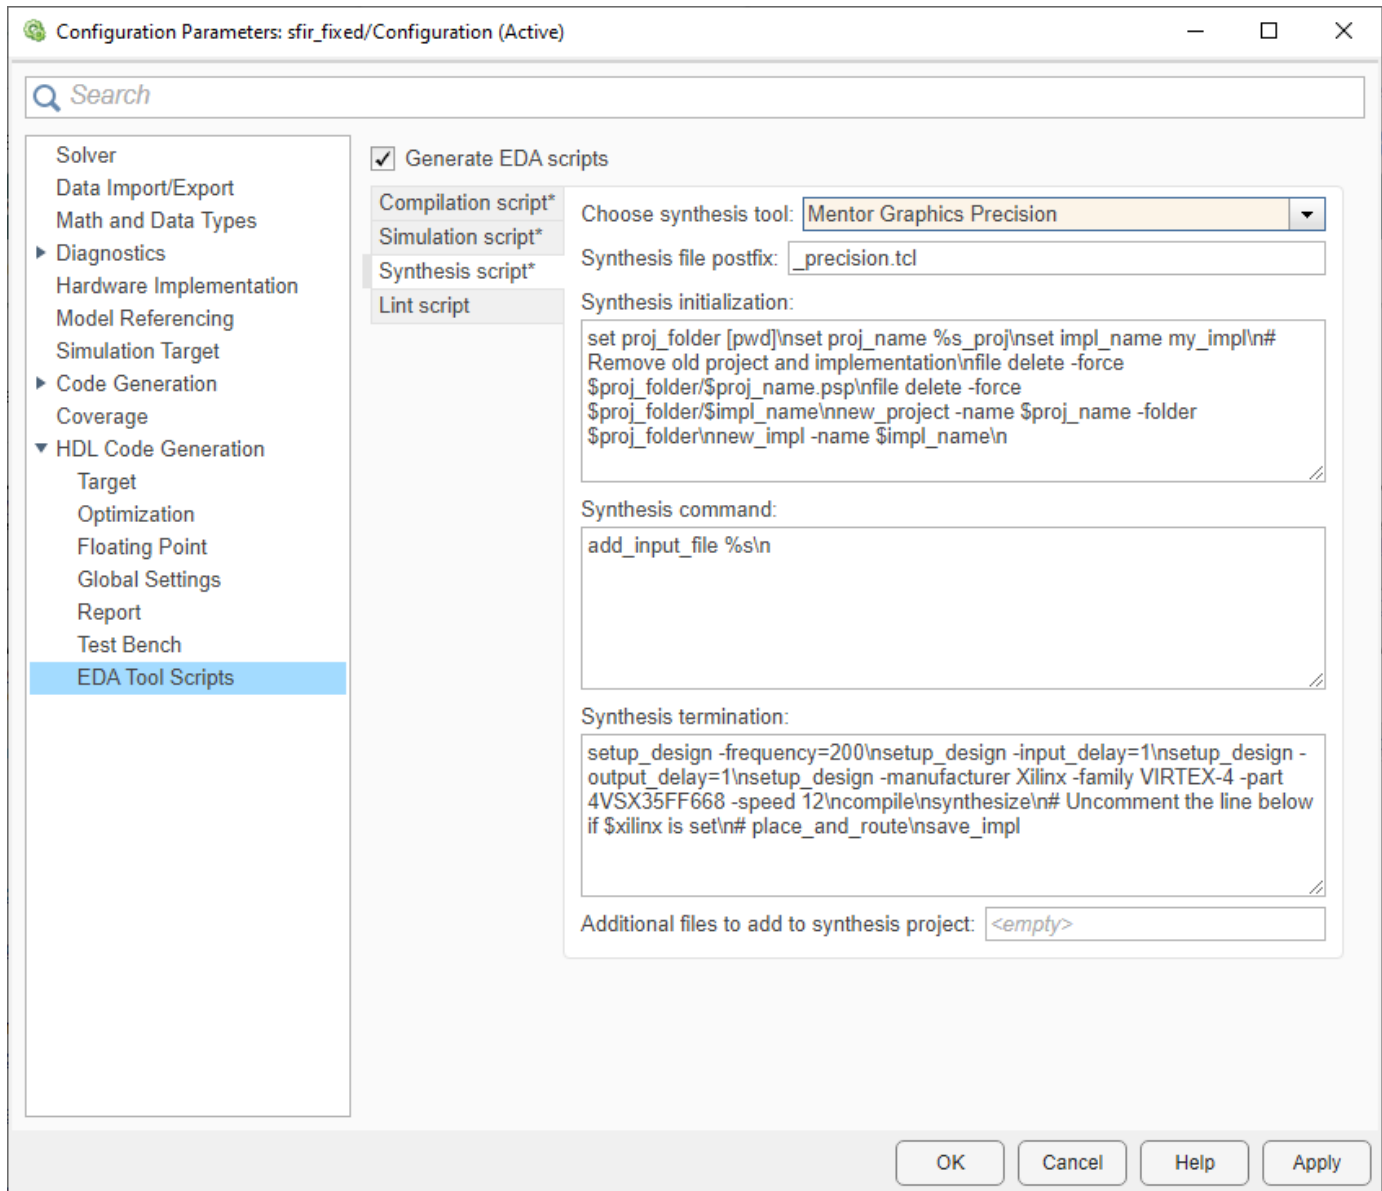

To enable synthesis script generation, select a synthesis tool from the **Choose synthesis tool** menu.

When you select a synthesis tool, HDL Coder:

- Enables synthesis script generation.
- Enters a file name postfix (specific to the chosen synthesis tool) into the **Synthesis file postfix** field.
- Enters strings (specific to the chosen synthesis tool) into the initialization, command, and termination fields.

The following figure shows the default option values entered for the Mentor Graphics Precision tool.

The following table summarizes the **Synthesis script** options.

Option Name	Description
Choose synthesis tool	<p>None (default): do not generate a synthesis script Xilinx ISE: generate a synthesis script for Xilinx ISE Microchip Libero: generate a synthesis script for Microchip Libero Mentor Graphics Precision: generate a synthesis script for Mentor Graphics Precision Altera Quartus II: generate a synthesis script for Altera Quartus II Synopsys Synplify Pro: generate a synthesis script for Synopsys Synplify Pro Xilinx Vivado: generate a synthesis script for Xilinx Vivado Custom: generate a custom synthesis script</p> <p>For more information, see “Choose synthesis tool” on page 24-11.</p>
Synthesis file postfix	<p>Your choice of synthesis tool sets the postfix for generated synthesis file names to one of the following:</p> <pre>_ise.tcl _libero.tcl _precision.tcl _quartus.tcl _synplify.tcl _vivado.tcl _custom.tcl</pre> <p>For more information, see “Synthesis file postfix” on page 24-12.</p>
Synthesis initialization	<p>Format name passed to <code>fprintf</code> to write the <code>Init</code> section of the synthesis script. The default string is a synthesis project creation command. The implicit argument is the top-level module or entity name.</p> <p>The content of the string is specific to the selected synthesis tool. For more information, see “Synthesis initialization” on page 24-13.</p>
Synthesis command	<p>Format name passed to <code>fprintf</code> to write the <code>Cmd</code> section of the synthesis script. The implicit argument is the file name of the entity or module.</p> <p>The content of the string is specific to the selected synthesis tool. For more information, see “Synthesis command” on page 24-14.</p>
Synthesis termination	<p>Format name passed to <code>fprintf</code> to write the <code>Term</code> section of the synthesis script.</p> <p>The content of the string is specific to the selected synthesis tool. For more information, see “Synthesis termination” on page 24-14.</p>

See also

“Synthesis Script Parameters” on page 24-11

Lint Script Options

The following figure shows the **Lint script** pane, with options set to their default values.

The following table summarizes the **Lint script** options.

Option	Description
Choose HDL lint tool	Enable or disable generation of an HDL lint script, and select the HDL lint tool for which HDL Coder generates a script. For more information, see “Choose HDL lint tool” on page 24-17.
Lint initialization	Enter an initialization text for your HDL lint script. For more information, see “Lint initialization” on page 24-18.
Lint command	Enter the command for your HDL lint script. For more information, see “Lint command” on page 24-18.
Lint termination	Enter a termination character vector for your HDL lint script. For more information, see “Lint termination” on page 24-18.

To enable lint script generation, select a HDL lint tool from the **Choose HDL lint tool** menu.

When you select the HDL lint tool, HDL Coder:

- Enables lint script generation.
- Enters strings (specific to the chosen HDL lint tool) into the initialization, command, and termination fields.

You can also generate the custom lint script. Select Custom from the **Choose HDL lint tool** and enter strings into the initialization, command, and termination fields.

“Lint Script Parameters” on page 24-17

“Generate HDL Lint Tool Script” on page 31-45

Add Synthesis Attributes

To learn how to add synthesis attributes in the generated HDL code for multiplier mapping, see “DSPStyle” on page 26-10.

Configure Synthesis Project Using Tcl Script

You can add a Tcl script that configures your synthesis project.

To configure your synthesis project using a Tcl script:

- 1 Create a Tcl script that contains commands to customize your synthesis project.

For example, to specify the finite state machine style:

- For Xilinx ISE, create a Tcl script that contains the following line:

```
project set "FSM Encoding Algorithm" "Gray" -process "Synthesize - XST"
```

- For Xilinx Vivado, create a Tcl script that contains the following line:

```
set_property STEPS.SYNTH_DESIGN.ARGS.FSM_EXTRACTION gray [get_runs synth_1]
```

- 2 In the HDL Workflow Advisor, in the **FPGA Synthesis and Analysis > Create Project** task, in the **Additional source files** field, enter the full path to the Tcl file manually, or by using the **Add** button.

When HDL Coder creates the project, the Tcl script is executed to apply the synthesis project settings.

Workflows in HDL Workflow Advisor

The HDL Workflow Advisor offers various workflows to check your algorithm for HDL compatibility, generate HDL code, verify the code, and then deploy the code to your target platform.

You can run the Workflow Advisor for your MATLAB algorithm or Simulink model. Before you deploy the code to a target hardware platform, install the synthesis tool and specify the path to that synthesis tool by using the `hdlsetuptoolpath` function. See “Tool Setup”.

HDL Workflow Advisor is not available in Simulink Online.

Set Up HDL Workflow Advisor in MATLAB

Before you specify the target workflow, when you run the Workflow Advisor from MATLAB, specify the design and test bench files, define the input types, and run fixed-point conversion.

To specify the target workflow for code generation:

- 1 On the MATLAB toolstrip, from the **Apps** tab, select the **HDL Coder** app.
- 2 Select the MATLAB design and test bench files and click the **Workflow Advisor** button.
- 3 In the **HDL Workflow Advisor**, select **Code Generation Workflow** as **MATLAB to HDL** or **MATLAB to SystemC**.
- 4 In the **Select Code Generation Target** task, select the **Workflow** for code generation.

Note The steps after code generation workflow selection change depending on your target workflow.

Set Up HDL Workflow Advisor in Simulink

When you run the Workflow Advisor from your Simulink model, irrespective of the target workflow, you run the steps to prepare the model for HDL code generation, and then generate code.

Open the Simulink model for which you want to run the workflow.

- 1 On the Simulink toolstrip, from the **Apps** tab, select the **HDL Coder** app.
- 2 On the **HDL Code** tab, click the **Workflow Advisor** button.
- 3 In the HDL Workflow Advisor, on the **Set Target Device and Synthesis Tool** task, select the **Target workflow**.

The steps in the Workflow Advisor change depending on the **Target workflow**, **Target platform**, and **Synthesis tool**.

Generic ASIC/FPGA

Generate HDL code from your Simulink model or MATLAB algorithm, verify the HDL code, and deploy the code to a generic ASIC or FPGA device. You can select from a family of devices that belong to these synthesis tools, as listed in “Generic ASIC/FPGA Hardware”.

By using this workflow, you can:

- Generate HDL code for your fixed-point MATLAB algorithm or your HDL-compatible Simulink model.
- Generate an HDL test bench and cosimulation test bench (requires HDL Verifier), and scripts to build and run the code and test bench. You can also generate a SystemVerilog DPI test benches and code coverage when running the Simulink HDL Workflow Advisor (requires HDL Verifier).
- Perform FPGA synthesis and timing analysis and rapidly prototype your design on generic FPGA platforms through integration with third-party synthesis tools.
- Back-annotate the model with critical path information and other information obtained during synthesis, and then optimize your design for area and speed.

Note If you select Intel Quartus Pro or Microchip Libero SoC as the **Synthesis tool**, the **Annotate Model with Synthesis Result** task is not available. To see the critical path, run the workflow to synthesis, and then open the timing reports.

To learn more, see:

- “HDL Code Generation and FPGA Synthesis from Simulink Model”
- “Basic HDL Code Generation and FPGA Synthesis from MATLAB”

FPGA Turnkey

Deploy your Simulink model or MATLAB algorithm onto standalone FPGA boards and SoC platforms. To use this workflow, you must select VHDL as the **Language**. You can select from one of these synthesis tools, as listed in “FPGA Turnkey Hardware”.

Use this workflow to:

- Choose boards from the FPGA Board Manager that are **Turnkey Enabled** or create your own custom boards for deployment.
- Generate HDL code for the entire FPGA design, the DUT algorithm, and the FPGA wrapper top-level HDL code. You can also specify the pin mapping constraints.
- Perform FPGA synthesis and timing analysis. Rapidly prototype your design on FPGA and SoC platforms through integration with third-party synthesis tools.

For an example, see “Getting Started with FPGA Turnkey Workflow” on page 36-72.

IP Core Generation

Generate RTL code and a custom HDL IP core from your Simulink model or MATLAB algorithm. Before you run the workflow, partition your design into components that run on software and components that run on hardware. See “Hardware-Software Co-Design Workflow for SoC Platforms” on page 46-8.

The IP core is a shareable and reusable HDL component that consists of IP core definition files, HDL code generated for your algorithm, C header file with the register address map, and the IP core report. See:

- “Custom IP Core Report” on page 46-19
- “Custom IP Core Generation” on page 46-16

You can select from one of these synthesis tools, as listed in “IP Core Generation Hardware”.

Use this workflow to:

- Generate a generic board-independent Xilinx or Intel HDL IP core.
- Integrate the IP core into a reference design to target standalone FPGA boards or SoC platforms with Xilinx Vivado IP integrator or Intel Qsys.
- Communicate with the generated HDL IP core by using embedded ARM processor or, from MATLAB, by using the HDL Verifier AXI Manager. See “Set Up AXI Manager” (HDL Verifier).

You can integrate the HDL IP core into HDL Coder provided reference designs such as the `default system reference design` or into a reference design that you created. To learn more, see:

- “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231
- “Define Custom Board and Reference Design for Intel SoC Workflow” on page 47-249

Simulink Real-Time FPGA I/O

Generate HDL code from your Simulink model and deploy the code onto Speedgoat® FPGA I/O modules. This workflow requires Xilinx Vivado and uses the `IP Core Generation` workflow infrastructure, as mentioned in “Simulink Real-Time FPGA I/O: Speedgoat Target Computer”.

To run the `Simulink Real-Time FPGA I/O` workflow, install the Speedgoat I/O Blockset and the Speedgoat HDL Coder Integration Packages. After you install the integration packages, you can choose the **Target platform**, and then run the workflow to:

- Generate a reusable and shareable IP core.
- Integrate the IP core into the Speedgoat reference design.
- Generate an FPGA bitstream and download the bitstream to the target hardware.
- Generate a Simulink Real-Time™ model. The model is an interface subsystem model that contains the blocks to program the FPGA and communicate with the board during real-time execution.

For more information, see “IP Core Generation Workflow for Speedgoat Simulink-Programmable I/O Modules” on page 47-125.

FPGA-in-the-Loop

Test your Simulink model or MATLAB algorithm on a target FPGA. This workflow requires HDL Verifier. You can select from one of these synthesis tools, as listed in “FPGA-in-the-Loop Hardware”.

Use this workflow to:

- Choose boards from the FPGA Board Manager that are **FIL Enabled** or create your own custom boards for verification. See “FPGA Board Customization” on page 42-2.
- Generate HDL code for your fixed-point MATLAB algorithm or your HDL-compatible Simulink model.
- Perform FPGA implementation and connect to the target FPGA board by using Ethernet, JTAG, or PCI Express for FIL simulation.

To learn more, see:

- “FIL Simulation with HDL Workflow Advisor for Simulink” (HDL Verifier)
- “FIL Simulation with HDL Workflow Advisor for MATLAB” (HDL Verifier)

More About

- “Getting Started with the HDL Workflow Advisor” on page 36-6
- “HDL Workflow Advisor Tasks” on page 43-2
- “Run HDL Workflow with a Script” on page 36-49
- “Get Started with HDL Workflow Command-Line Interface” on page 36-59

Getting Started with the HDL Workflow Advisor

In this section...

- “Open the HDL Workflow Advisor” on page 36-6
- “Run Tasks in the HDL Workflow Advisor” on page 36-7
- “Fix HDL Workflow Advisor Warnings or Failures” on page 36-8
- “Save and Restore the HDL Workflow Advisor State” on page 36-8
- “View and Save HDL Workflow Advisor Reports” on page 36-9

The HDL Workflow Advisor guides you through the stages of generating HDL code for a Simulink subsystem and the FPGA design process, such as:

- Checking the model for HDL code generation compatibility and automatically fixing incompatible settings.
- Generation of HDL code, a test bench, and scripts to build and run the code and test bench.
- Generation of cosimulation or SystemVerilog DPI test benches and code coverage (requires HDL Verifier).
- Synthesis and timing analysis through integration with third-party synthesis tools.
- Back-annotation of the model with critical path information and other information obtained during synthesis.
- Complete automated workflows for selected FPGA development target devices, including FPGA-in-the-loop simulation (requires HDL Verifier), and the Simulink Real-Time FPGA I/O workflow.

Open the HDL Workflow Advisor

To start the HDL Workflow Advisor from a Simulink model:

- 1 In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
- 2 Select the DUT Subsystem in your model, and make sure that this Subsystem name appears in the **Code for** option. To remember the selection, you can pin this option. Click **Workflow Advisor**.

To start the HDL Workflow Advisor for a model from the command line, enter `hdladvisor(system)`. *system* is a handle or name of the model or subsystem that you want to check. For more information, see the `hdladvisor` function reference page.

For how to use the HDL Workflow Advisor to generate HDL code from a MATLAB script, see “Basic HDL Code Generation and FPGA Synthesis from MATLAB”.

HDL Workflow Advisor is not available in Simulink Online.

In the HDL Workflow Advisor, the left pane lists the folders in the hierarchy. Each folder represents a group or category of related tasks. Expanding the folders shows available tasks in each folder. From the left pane, you can select a folder or an individual task. The HDL Workflow Advisor displays information about the selected folder or task in the right pane. The contents of the right pane depends on the selected folder or task. For some tasks, the right pane contains simple controls for running the task and a display area for status messages and other task results. For other tasks that involve setting code or test bench generation parameters, the right pane displays several parameter and option settings.

Run Tasks in the HDL Workflow Advisor

In the HDL Workflow Advisor window, you can run individual tasks, a group of tasks, or all the tasks in the workflow. For example, before you generate HDL code, prepare the Simulink model for HDL code generation. In the **Set Target** folder, for each individual task, you can specify the target device settings and the target frequency. Then, select the task that you want to run and click **Run This Task**. To run a task, all tasks before it must have run successfully.

To learn more about each individual task, right-click that task, and select **What's This?**.

To generate HDL code, run the workflow to the **Generate RTL Code and Testbench** task. To run the workflow to a specific task inside a subfolder, expand that folder, and then right-click the task and select **Run To Selected Task**.

To rerun a task that you have already run, click **Reset This Task**. HDL Coder then resets the task and all tasks that follow it. For example, to customize the basic options for generating HDL code after running the **Generate RTL Code and Testbench** task, right-click the **Set Basic Options** task and select **Reset This Task**. You can then set the basic options on the model and click **Run This Task** to rerun the task.

To run all the tasks in the HDL Workflow Advisor with the default settings, in the HDL Workflow Advisor window, select **Run > Run All**. To run a group of tasks in a specific folder, select that folder and click **Run All**.

Fix HDL Workflow Advisor Warnings or Failures

In the HDL Workflow Advisor, if a task terminates due to a warning or failure condition, the right pane shows the warning or failure information in a **Result** subpane. The **Result** subpane displays model settings that you can use to fix the warnings. For some tasks, use the **Action** subpane to apply those recommended actions.

The screenshot shows the HDL Workflow Advisor window for a project named 'vdp/Subsystem'. The left pane displays a tree view of tasks, with '2.1. Check Global Settings' selected and marked as failed. The right pane shows the details for this task, including a 'Result' subpane with a 'Failed' status and a message: 'Failed Incorrect model configuration settings for HDL code generation. To fix the problem, click the Modify All button, or click the hyperlink to launch the Configuration Parameter(s) dialog and manually apply the recommended setting.' Below this is a table titled 'Model Settings for HDL Code Generation'.

Block	Settings	Current	Recommended	Severity
vdp	Algebraic Loop	warning	error	warning
vdp	Default parameter behavior	Tunable	Inlined	warning
vdp	Conditional input branch execution	on	off	warning
vdp	Device type	32-bit Generic	ASIC/FPGA- >ASIC/FPGA	warning

Below the table is an 'Action' subpane with the text 'Configure model for recommended simulation settings' and a 'Modify All' button. At the bottom right of the window are 'Help' and 'Apply' buttons.

For example, to apply the model configuration settings that the code generator reported in the **Result** subpane, click the **Modify All** button. After you click **Modify All**, the **Result** subpane reports the changes that were applied, and resets the task. You can now run this task.

Save and Restore the HDL Workflow Advisor State

By default, the HDL Coder software saves the state of the most recent HDL Workflow Advisor session. The next time that you activate the HDL Workflow Advisor, it returns to that state. You can also save the current settings of the HDL Workflow Advisor to a named restore point. Later, you can restore the same settings by loading the restore point data into the HDL Workflow Advisor.

The save and restore process does not:

- Include operations that you perform outside the HDL Workflow Advisor.
- Save or restore the state of HDL Workflow Advisor tasks involving third-party tools.

To save the Workflow Advisor state, in the HDL Workflow Advisor Window, select **File > Save Restore Point As**. Enter a **Name** and **Description**, and then click **Save**. You can save more than one restore point.

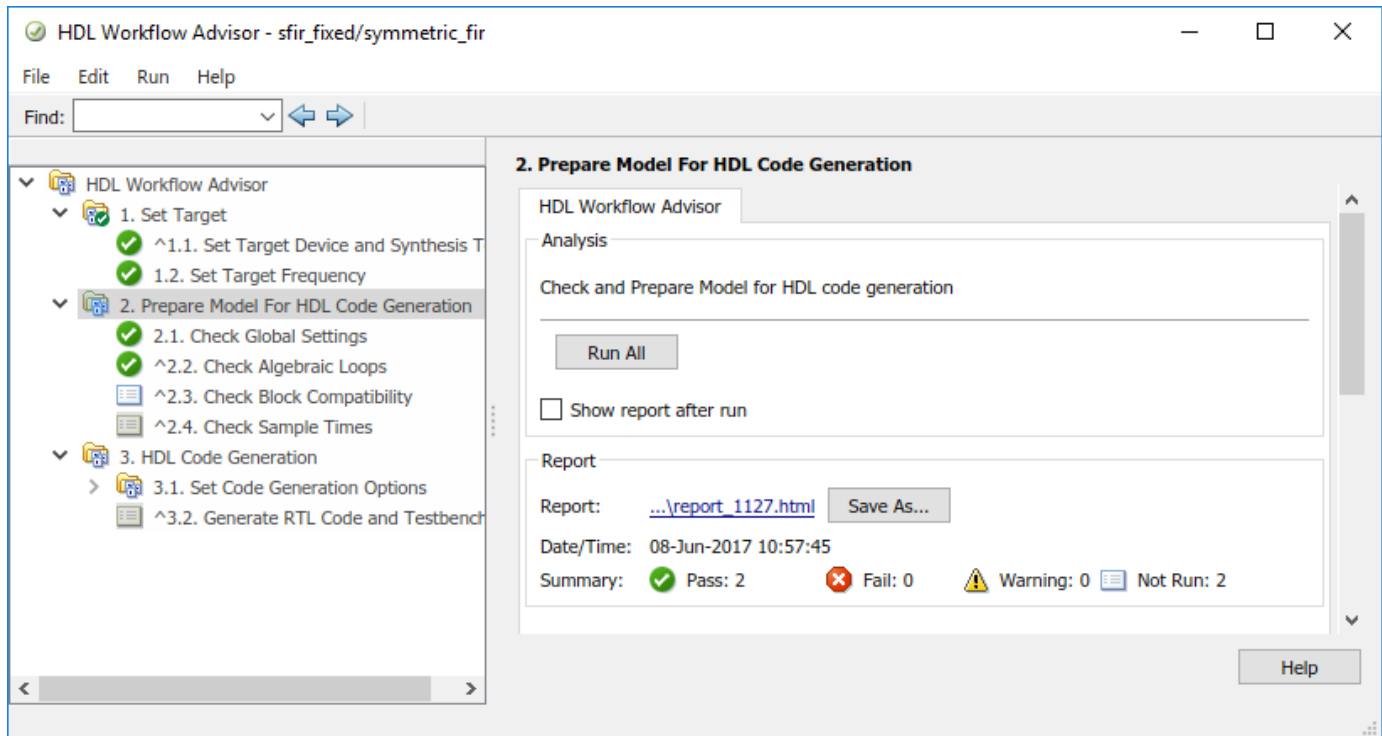

To restore a Workflow Advisor state, in the HDL Workflow Advisor, select **File > Load Restore Point**. Select the restore point that you want to load and click **Load**. When you load a restore point, the HDL Workflow Advisor warns that the restoration overwrites the current settings.

View and Save HDL Workflow Advisor Reports

When you run tasks in the HDL Workflow Advisor, HDL Coder generates an HTML report of the task results. Each folder in the HDL Workflow Advisor contains a report for the checks within that folder and its subfolders. To access reports, select a folder, such as **Prepare Model for HDL Code Generation**, and in the **Report** subpane, click **Save As**. If you rerun the HDL Workflow Advisor, the report is updated in the working folder.

This report shows typical results after running the **Prepare Model For HDL Code Generation** tasks.

Passed Correct Simulation settings for HDL code generation

Input Parameters Selection

Name	Value
Ignore warnings	false

As you run checks, the HDL Workflow Advisor updates the reports with the latest information for each check in the folder. When you run the checks at different times, timestamps appear at the top right of the report to indicate when checks have been run. Checks that occurred during previous runs have a timestamp following the check name. You can filter checks in the report. For example, you can filter out tasks that are **Not Run** from the report, or you can filter the report to show tasks that **Passed**, and so on. To view the report for a folder each time the tasks in a folder are run, select **Show report after run**.

Generate Code and Synthesize on FPGA Using HDL Workflow Advisor

The HDL Workflow Advisor guides you through the stages of generating HDL code for a Simulink subsystem and the FPGA design process, such as:

- Checking the model for HDL code generation compatibility and automatically fixing incompatible settings.
- Generation of HDL code, a test bench, and scripts to build and run the code and test bench.
- Generation of cosimulation or SystemVerilog DPI test benches and code coverage (requires HDL Verifier).
- Synthesis and timing analysis through integration with third-party synthesis tools.
- Back-annotation of the model with critical path information and other information obtained during synthesis.
- Complete automated workflows for selected FPGA development target devices, including FPGA-in-the-loop simulation (requires HDL Verifier), and the Simulink Real-Time FPGA I/O workflow.

FIR Filter Model

This example illustrates how you can generate HDL code for the FIR filter model and synthesize the design on an FPGA device. Before you generate HDL code, the model must be compatible for HDL code generation. To check and update your model for HDL compatibility, see “Check HDL Compatibility of Simulink Model Using HDL Code Advisor” on page 45-2. HDL Workflow Advisor is not available in Simulink Online.

This example uses the Symmetric FIR filter model that is compatible for HDL code generation. To open this model at the command line, enter:

```
sfir_fixed
```

The model uses a division of labor that is suitable for HDL design.

- The `symmetric_fir` subsystem, which implements the filter algorithm, is the device under test (DUT). An HDL entity is generated from this subsystem.
- The top-level model components that drive the subsystem work as a test bench.

The top-level model generates 16-bit fixed-point input signals for the `symmetric_fir` subsystem. The Signal From Workspace block generates a test input (stimulus) signal for the filter. The four Constant blocks provide filter coefficients. The Scope blocks are used for simulation and are not used for HDL code generation.

To navigate to the `symmetric_fir` subsystem, enter:

```
open_system('sfir_fixed/symmetric_fir')
```

Create a Folder and Copy Relevant Files

In MATLAB:

- 1 Create a folder named `sl_hdlcoder_work`, for example:

```
mkdir C:\work\sl_hdlcoder_work
```

sl_hdlcoder_work stores a local copy of the example model and folders and generated HDL code. Use a folder location that is not within the MATLAB folder tree.

- 2 Make the sl_hdlcoder_work folder your working folder, for example:

```
cd C:\work\sl_hdlcoder_work
```

- 3 Save a local copy of the sfir_fixed model to your current working folder. Leave the model open.

Set Up Tool Path

If you do not want to synthesize your design, but want to generate HDL code, you do not have to set the tool path. In the HDL Workflow Advisor, on the **Set Target > Set Target Device and Synthesis Tool** step, leave the **Synthesis tool** setting to the default `No Synthesis Tool Specified`, and then run the workflow.

If you want to synthesize your design on a target platform, before you open the HDL Workflow Advisor and run the workflow, set up the path to your synthesis tool. This example uses Xilinx Vivado, so you must have already installed Xilinx Vivado. To set the tool path, use the `hdlsetuptoolpath` function to point to an installed Xilinx Vivado 2019.2 executable. Optionally, you can use a different synthesis tool of your choice and follow this example. To set the path to that synthesis tool, use `hdlsetuptoolpath`. To learn about the latest supported tools, see “HDL Language Support and Supported Third-Party Tools and Hardware”.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', ...
    'C:\Xilinx\Vivado\2019.1\bin\vivado.bat');
```

Open the HDL Workflow Advisor

To start the HDL Workflow Advisor from a Simulink model,

- 1 In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
- 2 Select the DUT Subsystem in your model, and make sure that this Subsystem name appears in the **Code for** option. To remember the selection, you can pin this option. Click **Workflow Advisor**.

When you open the HDL Workflow Advisor, the code generator might warn that the project folder is incompatible. To open the Advisor, select **Remove slprj and continue**.

In the HDL Workflow Advisor, the left pane lists the folders in the hierarchy. Each folder represents a group or category of related tasks. From the left pane, you can select a folder or an individual task. The HDL Workflow Advisor displays information about the selected folder or task in the right pane.

To learn more about each individual task, right-click that task, and select **What's This?**.

To learn more about the HDL Workflow Advisor window, see “Getting Started with the HDL Workflow Advisor” on page 36-6.

Generate HDL Code and Synthesize on FPGA

- 1 In the **Set Target > Set Target Device and Synthesis Tool** step, for **Synthesis tool**, select **Xilinx Vivado** and select **Run This Task**.
- 2 To generate code, right-click the **Generate RTL Code and Testbench** task, and select **Run to Selected Task**.
- 3 In the **FPGA Synthesis and Analysis > Perform Synthesis and P/R > Run Implementation** task, clear **Skip this task** and click **Apply**.
- 4 Right-click the **Annotate Model with Synthesis Result** and select **Run to Selected Task**.

Run Workflow at Command Line with a Script

To run the HDL workflow at a command line, you can export the Workflow Advisor settings to a script. To export to script, in the HDL Workflow Advisor window, select **File > Export to Script**. In the Export Workflow Configuration dialog box, enter a file name and save the script.

The script is a MATLAB file that you can run from the command line. You can modify the script directly or, import the script into the HDL Workflow Advisor, modify the tasks, and export the updated script. To learn more, see “Run HDL Workflow with a Script” on page 36-49.

More About

- “Generate Test Bench and Enable Code Coverage Using the HDL Workflow Advisor” on page 36-17
- “Generate HDL Code from Simulink Model Using Configuration Parameters” on page 16-11
- “Generate HDL Code from Simulink Model from Command Line” on page 16-15

Generate Test Bench and Enable Code Coverage Using the HDL Workflow Advisor

The HDL Workflow Advisor guides you through the stages of generating HDL code for a Simulink subsystem and the FPGA design process, such as:

- Checking the model for HDL code generation compatibility and automatically fixing incompatible settings.
- Generation of HDL code, a test bench, and scripts to build and run the code and test bench.
- Generation of cosimulation or SystemVerilog DPI test benches and code coverage (requires HDL Verifier).
- Synthesis and timing analysis through integration with third-party synthesis tools.
- Back-annotation of the model with critical path information and other information obtained during synthesis.
- Complete automated workflows for selected FPGA development target devices, including FPGA-in-the-loop simulation (requires HDL Verifier), and the Simulink Real-Time FPGA I/O workflow.

HDL Workflow Advisor is not available in Simulink Online.

To select test bench and code coverage options for generating HDL code from a Simulink model using the HDL Workflow Advisor:

- 1 Perform the setup steps in “HDL Code Generation and FPGA Synthesis from Simulink Model”.
- 2 In Step 3.1.4 of the HDL Workflow Advisor, **Set Testbench Options**, select test bench and code coverage options from the **Test Bench Generation Output** section. The coder generates a build-and-run script for your test bench and the **Simulation tool** you specify. If you select multiple test bench options, the coder generates one test bench and script for each type of test bench selected. If you select **HDL code coverage**, the test bench scripts turn on code coverage for your generated HDL code. For more information about the different kinds of test benches, see “Choose a Test Bench for Generated HDL Code” on page 32-40. After you select your test bench options, click **Apply**.

3 In Step 3.2, **Generate RTL Code and Testbench**, select **Generate test bench**. Click **Apply**, and then click **Run This Task**. The coder generates HDL code for your subsystem, and the test benches and scripts you selected in step 3.1.3.

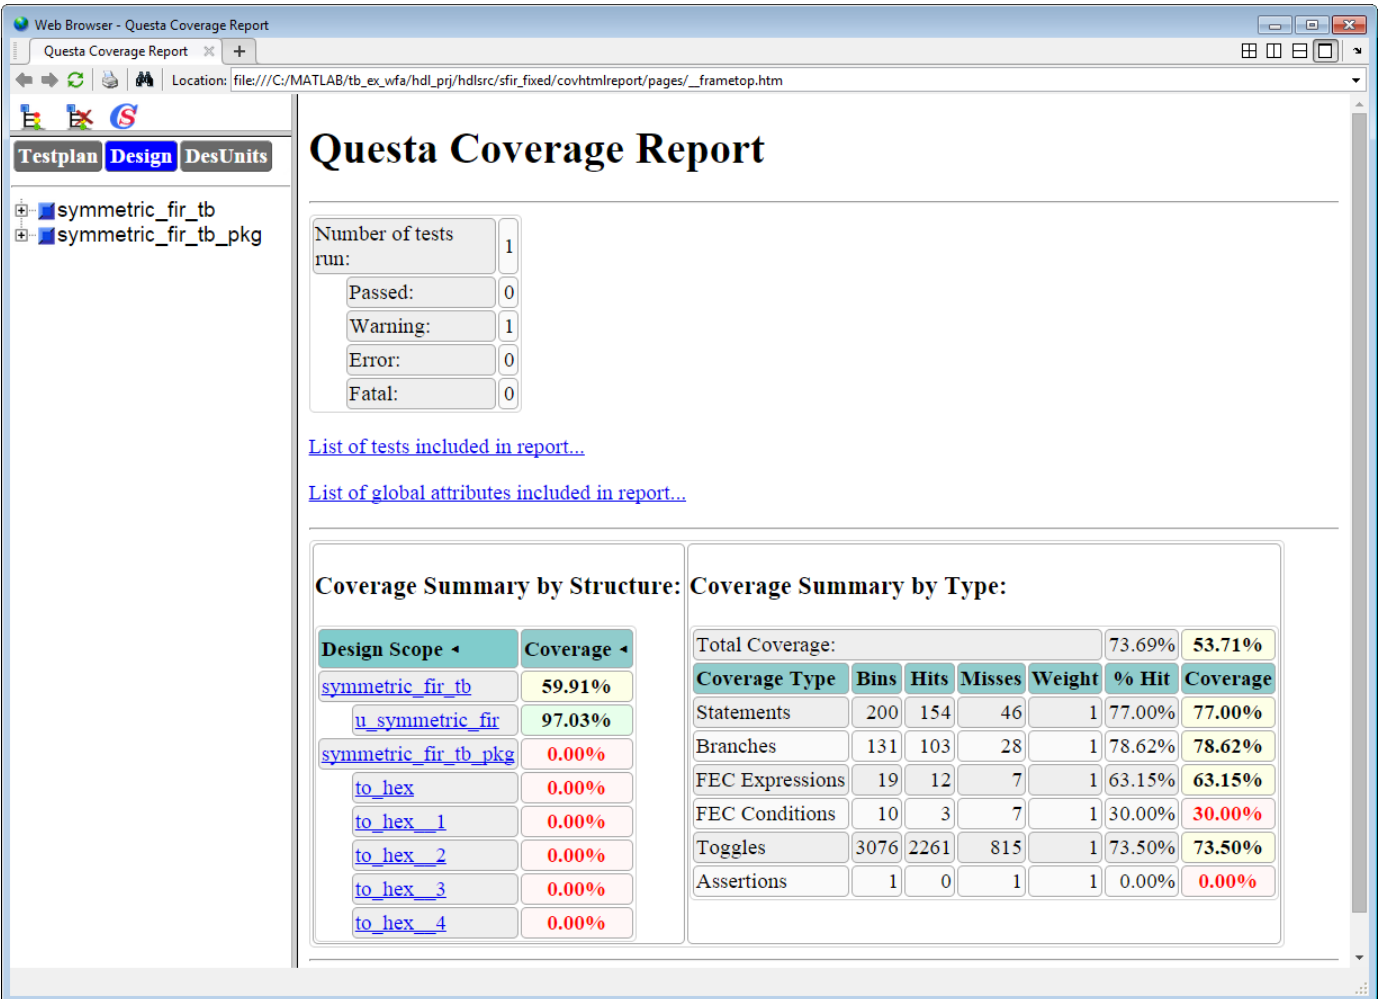

- If you selected **Cosimulation model**, then step 3.3, **Verify with HDL Cosimulation**, appears in the HDL Workflow Advisor. This step automatically runs the generated cosimulation model. The model compares the result of the HDL code running in your HDL simulator with the output of your Simulink subsystem.
- If you selected **HDL test bench**, the coder generates a compile script, *subsystemname_tb_compile*, and a run script, *subsystemname_tb_sim*. The script file extension depends on your selected simulator. For example, at the command line in the Mentor Graphics ModelSim simulator, change to the `hdl_prj/hdlsrc/modelname` folder and run these commands:

```
do symmetric_fir_compile.do
do symmetric_fir_tb_compile.do
do symmetric_fir_tb_sim.do
```

- If you selected **SystemVerilog DPI test bench**, the coder generates a script file, *subsystemname_dpi_tb*, that compiles the HDL code and runs the test bench simulation. The script file extension depends on your selected simulator. For example, at the command line in the Mentor Graphics ModelSim simulator, change to the `hdl_prj/hdlsrc/modelname` folder and run this command:

```
do symmetric_fir_dpi_tb.do
```

- If you selected **HDL code coverage**, the code coverage report from running any test bench, including the cosimulation model, is saved in `hdl_prj\hdlsrc\modelname\covhtmlreport`.

The screenshot shows a web browser window titled "Web Browser - Questa Coverage Report". The address bar shows the file path: `file:///C:/MATLAB/tb_ex_vfa/hdl_prj/hdlsrc/sfir_fixed/covhtmlreport/pages/_frametop.htm`. The page content includes a navigation menu with "Testplan", "Design", and "DesUnits". The left sidebar shows a tree view with "symmetric_fir_tb" and "symmetric_fir_tb_pkg".

The main content area displays the "Questa Coverage Report" with the following statistics:

Number of tests run:	1
Passed:	0
Warning:	1
Error:	0
Fatal:	0

Below the statistics are two links: [List of tests included in report...](#) and [List of global attributes included in report...](#)

The report is divided into two summary sections:

Coverage Summary by Structure:

Design Scope	Coverage
symmetric_fir_tb	59.91%
u_symmetric_fir	97.03%
symmetric_fir_tb_pkg	0.00%
to_hex	0.00%
to_hex_1	0.00%
to_hex_2	0.00%
to_hex_3	0.00%
to_hex_4	0.00%

Coverage Summary by Type:

Total Coverage:							73.69%	53.71%
Coverage Type	Bins	Hits	Misses	Weight	% Hit	Coverage		
Statements	200	154	46	1	77.00%	77.00%		
Branches	131	103	28	1	78.62%	78.62%

Generate HDL Code for Vendor-Specific FPGA Floating-Point Target Libraries

In this section...

“Set Up Design for Mixed-Mode Mapping” on page 36-20

“Map to Native Floating-Point and FPGA Floating-Point Libraries” on page 36-21

“View Code Generation Reports of Floating-Point Library Mapping” on page 36-22

“Analyze Results of Floating-Point Library Mapping” on page 36-23

Mapping to a floating-point library enables you to synthesize your floating-point design without doing floating-point to fixed-point conversion. Eliminating the conversion step reduces the loss of data precision and enables you to model a wider dynamic range.

An FPGA floating-point library is a set of floating-point IP blocks that are optimized for synthesis on specific target hardware. These libraries are also referred to as vendor-specific floating point libraries because they target vendor-specific hardware. Altera Megafunctions and Xilinx LogiCORE IP are examples of these libraries. You can create a design and generate code that consists of HDL Coder native floating point (NFP) and vendor-specific FPGA point IP to more efficiently use resources on the FPGA, such as hardened DSP floating point adder or multiplier primitives, which allows you to fit a bigger design into the FPGA fabric. This mixed design is advantageous for large and complex models. Additionally, you can map blocks that are unsupported by the vendor-specific library to NFP and use the vendor library to map other blocks to vendor-specific floating point resources.

You can map your model to either the:

- Native floating-point library. This option is the default mapping.
- Native floating-point library and a vendor-specific floating point library. This is also called mixed-mode mapping.

When you map to both a native floating-point library and a vendor-specific floating-point library, HDL Coder maps to the vendor library IP wherever possible. The blocks that cannot be mapped to the vendor library then map to native floating-point library IP instead.

To see a list of HDL Coder blocks that support FPGA floating-point library mapping, see “HDL Coder Support for FPGA Floating-Point Library Mapping” on page 36-43.

Set Up Design for Mixed-Mode Mapping

To map your floating-point design to the native floating-point library and an Altera or Xilinx FPGA floating-point library:

- 1 Set up the path to your synthesis tool executable file by using `hdlsetuptoolpath`. For example, to set the path to the Altera Quartus II synthesis tool, enter:

```
hdlsetuptoolpath('ToolName', 'Altera Quartus II', 'ToolPath', ...
  'C:\altera\14.0\quartus\bin\quartus.exe');
```

See “Synthesis Tool Path Setup”.

- 2 Set the target device options for your Altera or Xilinx FPGA synthesis tool using `hdlset_param`. For example, to set the synthesis tool as Altera Quartus II and chip family as Arria10, enter:

```
hdlset_param(model, 'SynthesisToolChipFamily', 'Arria10', ...
                 'SynthesisToolDeviceName', '10AS066H2F34E1SG', ...
                 'SynthesisToolPackageName', '', ...
                 'SynthesisToolSpeedValue', '')
```

- 3 Set up your Altera or Xilinx FPGA floating-point simulation libraries. See “FPGA Simulation Library Setup”.

Map to Native Floating-Point and FPGA Floating-Point Libraries

You can map your Simulink model to floating-point target libraries from the Configuration Parameters dialog box or from the command line.

Map to Floating-Point Target Libraries from the Configuration Parameters Dialog Box

To map to the native floating point library and FPGA floating-point library:

- 1 In the **Apps** tab, select **HDL Coder**. In the **HDL Code** tab, click **Settings**.
- 2 In the **HDL Code Generation > Floating Point** pane, select **Use Floating Point**.
- 3 The **Vendor Specific Floating Point Library** parameter displays options based the synthesis tool you chose for your design. To use the Xilinx LogiCORE IP, set the **Vendor Specific Floating Point Library** to **XILINXLOGICORE**. For Altera megafunction IP, you can set **Vendor Specific Floating Point Library** to **ALTFP** or **ALTERAFPFUNCTIONS**.

Note When mapping to ALTERA FP FUNCTIONS, the target language must be VHDL.

- 4 You can customize the IP settings of the vendor-specific floating-point target library by using the `hdlcoder.FloatingPointTargetConfig` and the `hdlcoder.FloatingPointTargetConfig.IPConfig` objects. For more information, see “Customize Floating-Point IP Configuration” on page 36-38.
- 5 To share floating-point IP resources, in the **HDL Code Generation > Optimizations** pane, in the **Resource Sharing** tab, select **Floating-point IPs**. The number of floating-point IP blocks that get shared depends on the **SharingFactor** that you specify on the subsystem.
- 6 Click **OK**. In the **HDL Code** tab, click **Generate HDL Code**.

Map to Floating-Point Target Libraries from the Command Line

To generate HDL code from the command line, you can use the `hdlcoder.createFloatingPointTargetConfig` function to create a floating-point IP configuration.

- 1 Use the `hdlcoder.createFloatingPointTargetConfig` function to create a `hdlcoder.FloatingPointTargetConfig` object for the native floating-point library and a vendor-specific floating-point library. Then, use `hdlset_param` to save the configuration on the model.

For example, to create a floating-point target configuration for the native floating point and ALTERA FP FUNCTIONS libraries with the default settings and set the configuration to the `sfir_single` model, use these commands:

```
fpconfig = hdlcoder.createFloatingPointTargetConfig("NativeFloatingPoint", ...
          VendorFloatingPointLibrary="ALTERAFPFUNCTIONS");
hdlset_param('sfir_single', 'FloatingPointTargetConfiguration', fpconfig);
```

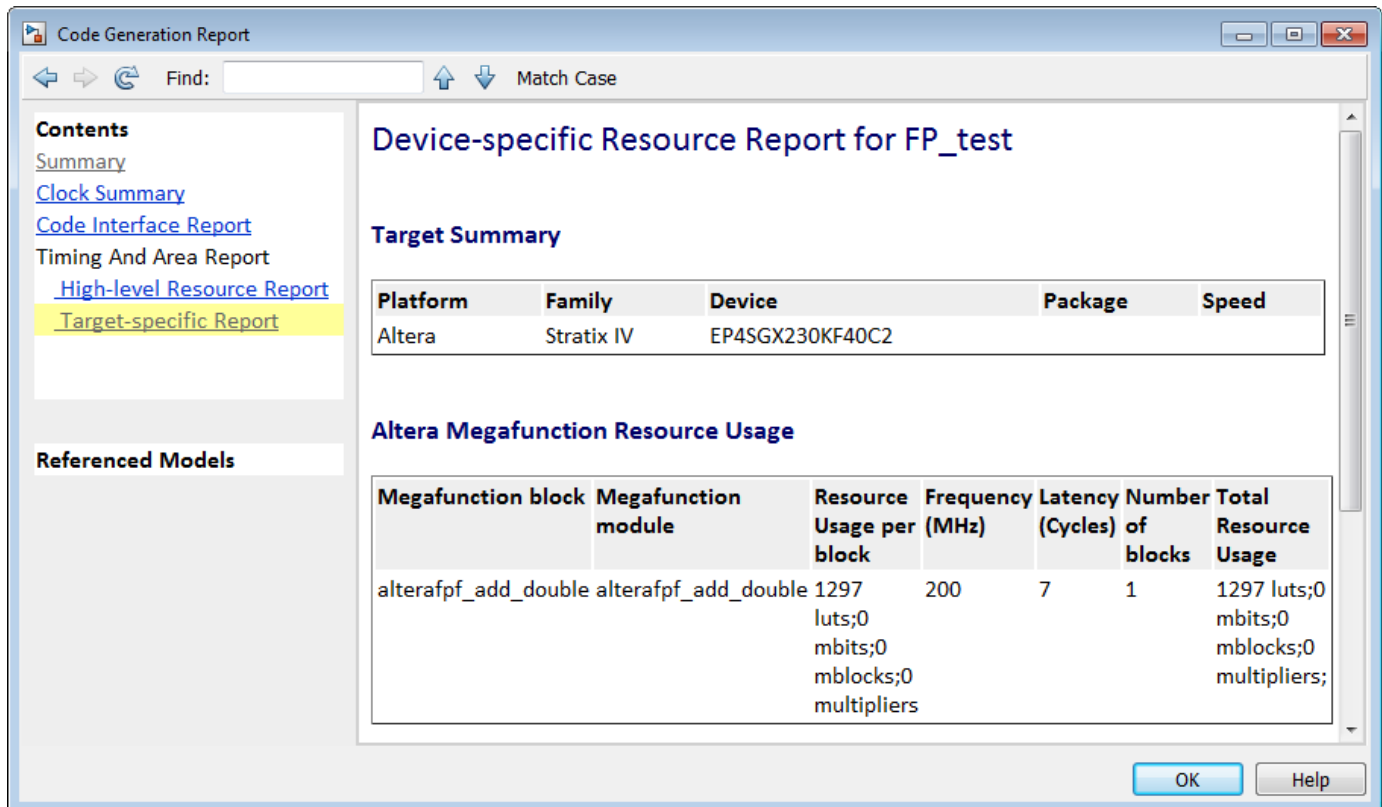

- 2 You can customize the IP settings based on the floating-point library that you specify. For more information, see “Customize Floating-Point IP Configuration” on page 36-38.
- 3 Use the `makehdl` function to generate HDL code from the DUT subsystem.

View Code Generation Reports of Floating-Point Library Mapping

To view information about the floating-point library mapping in the code generation report, before you begin code generation, enable the resource utilization report and optimization report. To learn how to generate these reports, see “Create and Use Code Generation Reports” on page 30-2.

Target-Specific Report

To see the target floating-point block your design mapped to, the latency, and number of target-specific hardware resources, in the code generation report, select **Target-specific Report**.

The screenshot shows the 'Code Generation Report' window. The 'Contents' pane on the left has 'Target-specific Report' selected. The main area displays the 'Device-specific Resource Report for FP_test'.

Target Summary

Platform	Family	Device	Package	Speed
Altera	Stratix IV	EP4SGX230KF40C2		

Altera Megafunction Resource Usage

Megafunction block	Megafunction module	Resource Usage per block	Frequency (MHz)	Latency (Cycles)	Number of blocks	Total Resource Usage
alterafpf_add_double	alterafpf_add_double	1297 luts;0 mbits;0 mblocks;0 multipliers	200	7	1	1297 luts;0 mbits;0 mblocks;0 multipliers;

Buttons for 'OK' and 'Help' are visible at the bottom right of the window.

Target Code Generation Report

In the code generation report, the **Optimization Report > Target Code Generation** section shows the optimization settings applied to the model. This section shows whether HDL Coder successfully generated floating-point target code.

Analyze Results of Floating-Point Library Mapping

You can get the latency information of the floating-point target IP from the generated model after HDL code generation. For example, consider this Add block in Simulink that has inputs of single data type.

- 1 After HDL code generation, the optimization report displays a link to the generated model. To see the floating-point target library that your Simulink block mapped to, open the generated model and double-click the DUT subsystem. The blocks that map to native floating point IP are light blue and include NFP on the block mask. The blocks that map to the vendor-specific floating point IP are cyan and have initials associated with the vendor library on the block mask. In this example, the initials on the blocks that map to the ALTERA FP FUNCTIONS library display the initials ALT.

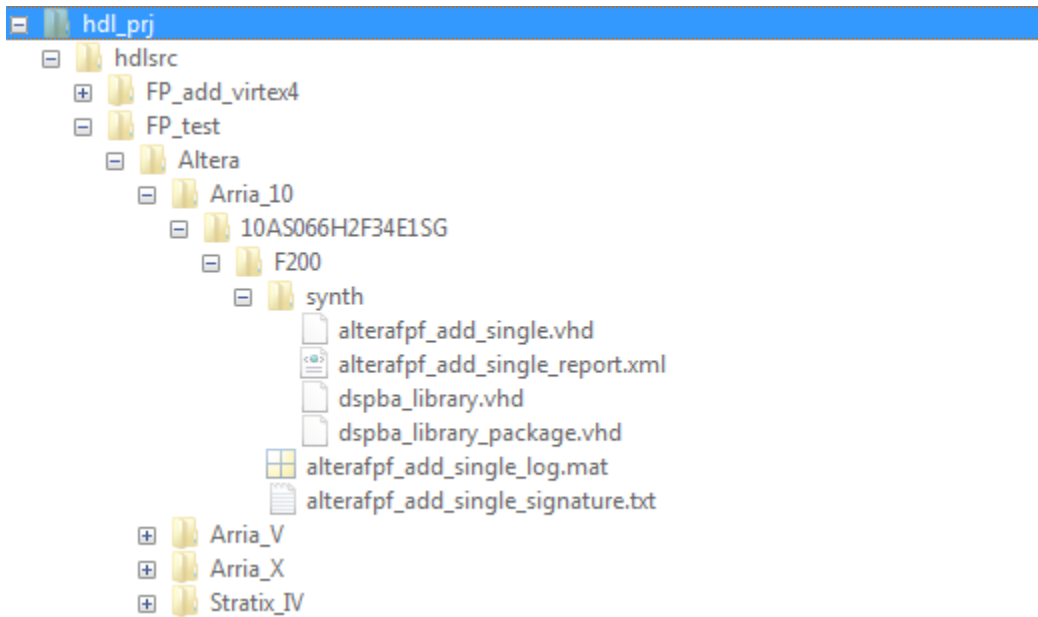

- 2 Double-click the Add block. The length of the delay block is the latency of the floating-point target IP.

To learn more about the generated model, see “Generated Model and Validation Model” on page 28-10.

To see your FPGA floating-point library mapping results, you can view the IP core files generated after HDL code generation.

HDL Coder checks and reuses existing generated IP core files, which takes less time when successively generating code for the same floating-point target IP.

FPGA Floating-Point Library IP Mapping

This example shows how to use vendor-specific floating-point IP libraries, such as Altera® and Xilinx®, to generate target specific HDL code. For more information on how to map designs to floating-point libraries, see “Generate HDL Code for Vendor-Specific FPGA Floating-Point Target Libraries” on page 36-20.

When you implement designs with floating-point arithmetic, you can model with higher precision and a wider dynamic range and you can avoid converting floating-point data to fixed-point data. Floating-point designs particularly beneficial for model-based design, where high-level algorithms are modeled with floating-point data and do not have implementation timing details, such as pipelining and timing constraints. However, timing details are necessary to map operations to floating-point IP modules. HDL Coder™ automatically optimizes and implements your designs with these timing details and provides interfaces for you to adjust them. HDL Coder then implements the floating-point math by integrating it with the floating-point IP modules from vendor libraries.

Open Model

This field-oriented control (FOC) algorithm example demonstrates how to map designs to floating-point libraries. For more information about this algorithm, see “Field-Oriented Control of a Permanent Magnet Synchronous Machine” on page 14-66.

This model uses single-precision data types and contains blocks that perform basic math operators, such as adders, multipliers, comparators, and complex sine and cosine functions.

This model models the signal rates at 20 μ s or 50 KHz. This model only contains the numerical implementation, and does not have FPGA implementation timing details, such as operation latencies. All numerical operations, including the sine and cosine functions, compute in a single sample time-step.

```
load_system('hdlcoderFocCurrentSingleTargetHdl');
open_system('hdlcoderFocCurrentSingleTargetHdl/F0C_Current_Control/Sine_Cosine');
```

Sine Cosine Coefficients

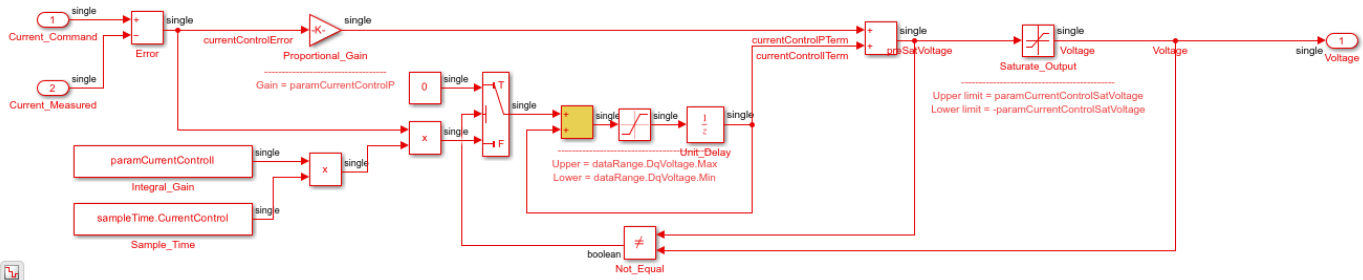

Set Up FPGA for Floating-Point Mapping

To map to a vendor-specific floating-point library, set the FPGA device by choosing a synthesis tool and chip to target. Before setting the synthesis tool, use the `hdlsetuptoolpath` function to set your

The error messages indicate that HDL Coder cannot replace operations in feedback loops with floating-point IP modules because these loops have fewer delays than the latency of the floating-point IP modules that HDL Coder tries to replace them with. HDL Coder implements floating-point IP modules as pipelined blocks. For some modules, there are minimum latency requirements. Because changing the latency of a feedback loop generates an incorrect implementation, HDL Coder prevents the addition of latency inside these feedback loops.

The error indicates that the adder inside the feedback loop requires multiple cycles of latency budget, but the loop has only one delay.

```
hilite_system('hdlcoderFocCurrentSingleTargetHdl/FOC_Current_Control/DQ_Current_Control/D_Current')
```

To address these errors, you can use one of these approaches:

- Reducing the target frequency may lower the pipelining depth requirement. This change may also slow down all other IP modules in the design.
- Configuring the IP modules used in the loop with a smaller latency also slows down the operating frequency of the IP modules, but only for specified IP modules.
- Applying clock rate pipelining. When the data rate is slower than the FPGA clock rate, the FPGA has multiple cycles at clock rate to finish operations and still retain numerical consistency. For more information about clock rate pipelining, see “Clock-Rate Pipelining” on page 28-149.

Because the sample time is $20 \mu\text{s}$ and the FPGA target frequency is 250 MHz, or 4 ns, you can apply clock-rate pipelining to solve the feedback loop problem by defining the oversampling factor as the ratio of the two values. For this example, specify the oversampling factor as 5000, which means that one unit delay with a sample time of $20 \mu\text{s}$ in the model, is equivalent to 5000 clock-rate cycles at a sample time of 4 ns on the FPGA. This value is sufficient for floating-point IP modules in the loops.

Set the oversampling factor to 5000 and enable the generation of the generated and validation model.

```
hdlset_param('hdlcoderFocCurrentSingleTargetHdl', 'Oversampling', 5000);
hdlset_param('hdlcoderFocCurrentSingleTargetHdl', 'GenerateModel', 'on');
hdlset_param('hdlcoderFocCurrentSingleTargetHdl', 'GenerateValidationModel', 'on');
```

Generate HDL code for the DUT subsystem, FOC_Current_Control, by using the makehdl command.

```
makehdl('hdlcoderFocCurrentSingleTargetHdl/FOC_Current_Control');
```

```

The design now maps to floating-point IP modules. The target code generation report summarizes the floating IP module usage. Open and view the generated model. For example, the subsystem `gm_hdlcoderFocCurrentSingleTargetHdl/FOC_Current_Control/DQ_Current_Control/D_Current_Control/Add` that corresponds to the subsystem `hdlcoderFocCurrentSingleTargetHdl/FOC_Current_Control/DQ_Current_Control/D_Current_Control/Add` shows that this operation takes 3 cycles.

```

hilite_system('gm_hdlcoderFocCurrentSingleTargetHdl/FOC_Current_Control/DQ_Current_Control/D_Cur
get_param('gm_hdlcoderFocCurrentSingleTargetHdl/FOC_Current_Control/DQ_Current_Control/D_Current
'DelayLength')

```

```

ans =
     '3'

```

Because floating-point IP modules introduce latencies across the design, HDL Coder adds matching delays to maintain data synchronization. See “Delay Balancing” on page 28-81 for more details.

Share Floating-Point IPs

Floating-point IP modules are suitable to share, because they are usually identical for the same kind. Floating-point IPs are typically expensive operations and it is desirable to share these resources, if possible, to reduce the area footprint. HDL Coder shares resources in the same subsystem. In order to allow more resources to share, flatten the subsystem hierarchy and set resource sharing factor on the top network to 4.

```

hdlset_param('hdlcoderFocCurrentSingleTargetHdl/FOC_Current_Control', 'FlattenHierarchy', 'on');
hdlset_param('hdlcoderFocCurrentSingleTargetHdl/FOC_Current_Control', 'SharingFactor', 4);

```

Generate HDL code for the DUT subsystem, `FOC_Current_Control`, by using the `makehdl` command.

```

makehdl('hdlcoderFocCurrentSingleTargetHdl/FOC_Current_Control');

```

```

```

Create a mixed-mode floating-point target configuration object for the native floating-point and XILINX LOGICORE libraries.

```
fc = hdlcoder.createFloatingPointTargetConfig(VendorFloatingPointLibrary = 'XILINXLOGICORE');
```

In addition to the library name, library settings, and individual IP model settings for the native floating point library stored in the configuration object as `Library`, `LibrarySettings`, and `IPConfig`, respectively, the configuration object also has those properties for the XILINX LOGICORE library, specified as `VendorLibrary`, `VendorLibrarySettings`, and `VendorIPConfig`. View the configuration object, `fc`.

```
fc
```

```
fc =
```

```
  FloatingPointTargetConfig with properties:
```

```
      Library: 'NATIVEFLOATINGPOINT'
      LibrarySettings: [1x1 fpconfig.NFPLatencyDrivenMode]
      IPConfig: [1x1 hdlcoder.FloatingPointTargetConfig.IPConfig]
      VendorLibrary: 'XILINXLOGICORE'
      VendorLibrarySettings: [1x1 fpconfig.LatencyDrivenMode]
      VendorIPConfig: [1x1 hdlcoder.FloatingPointTargetConfig.IPConfig]
```

The `VendorLibrarySettings` property contains library-wide settings for the vendor-specific floating-point library. Check the setting for XILINX LOGICORE library.

```
fc.VendorLibrarySettings
```

```
ans =
```

```
  LatencyDrivenMode with properties:
```

```
      LatencyStrategy: 'MIN'
      Objective: 'SPEED'
```

The `Objective` property specifies the `c_optimization` parameter to XILINX LOGICORE. Set the `Objective` property to `AREA`.

```
fc.VendorLibrarySettings.Objective = 'AREA';
fc.VendorLibrarySettings
```

```
ans =
```

```
  LatencyDrivenMode with properties:
```

```
      LatencyStrategy: 'MIN'
      Objective: 'AREA'
```

Vendor library settings are specific to the library. To see the settings for specific libraries, see `hdlcoder.FloatingPointTargetConfig`.

The `VendorIPConfig` property holds the `IPConfig` object for the vendor-specific library. This object has settings for individual IP modules that you can change by using the `customize` function, such as `Latency` and `ExtraArgs`.

Specify the latency for individual IP modules in the configuration object by using the `customize` function. HDL Coder uses the value of the `Latency` input argument that you set for code generation and optimizations.

```
fc.VendorIPConfig.customize('ADDSUB', 'SINGLE', 'Latency', 11);
fc.VendorIPConfig
```

ans =

Name	DataType	MinLatency	MaxLatency	Latency	ExtraArgs
{'ADDSUB' }	{'DOUBLE' }	12	12	-1	{0x0 char
{'ADDSUB' }	{'SINGLE' }	12	12	11	{0x0 char
{'CONVERT' }	{'DOUBLE_TO_NUMERICTYPE' }	6	6	-1	{0x0 char
{'CONVERT' }	{'NUMERICTYPE_TO_DOUBLE' }	6	6	-1	{0x0 char
{'CONVERT' }	{'NUMERICTYPE_TO_SINGLE' }	6	6	-1	{0x0 char
{'CONVERT' }	{'SINGLE_TO_NUMERICTYPE' }	6	6	-1	{0x0 char
{'DIV' }	{'DOUBLE' }	57	57	-1	{0x0 char
{'DIV' }	{'SINGLE' }	28	28	-1	{0x0 char
{'MUL' }	{'DOUBLE' }	9	9	-1	{0x0 char
{'MUL' }	{'SINGLE' }	8	8	-1	{0x0 char
{'RELOP' }	{'DOUBLE' }	2	2	-1	{0x0 char
{'RELOP' }	{'SINGLE' }	2	2	-1	{0x0 char
{'SQRT' }	{'DOUBLE' }	57	57	-1	{0x0 char
{'SQRT' }	{'SINGLE' }	28	28	-1	{0x0 char

The latency for the `ADDSUB` IP becomes 11 instead of the default value 12.

You can specify other IP-specific settings by setting the `ExtraArgs` property for individual IP modules. For example, HDL Coder calls XILINX LOGICORE to generate floating-point IP modules without using any DSP blocks by default. XILINX LOGICORE uses the `c_mult_usage` parameter to control DSP usage. In order to use DSP blocks, pass a different setting by using the `ExtraArgs` input argument to override the default behavior. Because the `ExtraArgs` string is appended to the default IP module generation parameters, it must comply with library setting syntax. Check the IP library documents for parameter usage and syntax.

```
fc.VendorIPConfig.customize('ADDSUB', 'SINGLE', 'ExtraArgs', 'CSET c_mult_usage=Full_Usage');
fc.VendorIPConfig
```

ans =

Name	DataType	MinLatency	MaxLatency	Latency	ExtraArgs
{'ADDSUB' }	{'DOUBLE' }	12	12	-1	{0x0 char
{'ADDSUB' }	{'SINGLE' }	12	12	11	{'CSET c_r
{'CONVERT' }	{'DOUBLE_TO_NUMERICTYPE' }	6	6	-1	{0x0 char
{'CONVERT' }	{'NUMERICTYPE_TO_DOUBLE' }	6	6	-1	{0x0 char
{'CONVERT' }	{'NUMERICTYPE_TO_SINGLE' }	6	6	-1	{0x0 char

{'CONVERT' }	{'SINGLE_TO_NUMERICTYPE' }	6	6	-1	{0x0 char
{'DIV' }	{'DOUBLE' }	57	57	-1	{0x0 char
{'DIV' }	{'SINGLE' }	28	28	-1	{0x0 char
{'MUL' }	{'DOUBLE' }	9	9	-1	{0x0 char
{'MUL' }	{'SINGLE' }	8	8	-1	{0x0 char
{'RELOP' }	{'DOUBLE' }	2	2	-1	{0x0 char
{'RELOP' }	{'SINGLE' }	2	2	-1	{0x0 char
{'SQRT' }	{'DOUBLE' }	57	57	-1	{0x0 char
{'SQRT' }	{'SINGLE' }	28	28	-1	{0x0 char

Open the model `hdlcoder_targetIP_configuration` and set the floating-point configuration object `fc` to the floating-point target configuration on the model.

```
open_system('hdlcoder_targetIP_configuration');
hdlset_param('hdlcoder_targetIP_configuration', 'FloatingPointTargetConfiguration', fc);
```

Copyright 2016 The MathWorks, Inc.

Run synthesis and mapping by using these commands to confirm the DSP block usage.

```
hWC = hdlcoder.WorkflowConfig('SynthesisTool','Xilinx ISE', ...
    'TargetWorkflow','Generic ASIC/FPGA');
hWC.SkipPreRouteTimingAnalysis = true;
hWC.RunTaskAnnotateModelWithSynthesisResult = false;
hWC.GenerateRTLCode = true;
hWC.validate;
hdlcoder.runWorkflow('hdlcoder_targetIP_configuration/Add_Subsystem', hWC);
```

- “HDL Coder Support for FPGA Floating-Point Library Mapping” on page 36-43

Customize Floating-Point IP Configuration

When mapping your Simulink model to floating-point target libraries, you can create a floating-point target configuration with your own custom IP settings. To customize the IP settings, you can use an IP configuration table to choose from different combinations of IP names and data types. The table contains a list of IP types and additional columns that you can use to specify your own custom latency value and other IP settings.

The IP configuration depends on the library settings. The library settings are specific to the floating-point library that you choose. You can customize the IP latency by using the target frequency or the latency strategy setting.

In this section...

“Customize the IP Latency with Target Frequency” on page 36-39

“Customize the IP Latency with Latency Strategy” on page 36-41

Customize the IP Latency with Target Frequency

To specify the target frequency that you want the IP to achieve, use the Altera Megafunctions (ALTERA FP Functions) library. HDL Coder infers the latency of the IP based on the target frequency value. If you do not specify the target frequency, HDL Coder sets the target frequency to 200 MHz.

You can customize the IP latency by using the **Target Frequency (MHz)** parameter in the Configuration Parameters dialog box or the TargetFrequency property from the command line.

Customize the IP Latency in the Configuration Parameters Window

To customize the IP latency by using the **Target Frequency (MHz)** parameter:

- 1 Specify the vendor-specific floating-point library.
 - a In the **Apps** tab, select **HDL Coder**. In the **HDL Code** tab, click **Settings**.
 - b In the **HDL Code Generation > Target** pane, set **Synthesis Tool** to the synthesis tool of your choice. To use the Altera Megafunctions (ALTERA FP Functions) library, set **Synthesis Tool** to Altera Quartus II or Intel Quartus Pro. For more information on synthesis tools, see “Tool Setup”.
 - c In the **HDL Code Generation > Floating Point** pane, select **Use Floating Point**.
 - d Set **Vendor Specific Floating Point Library** to ALTERAFPFUNCTIONS.
- 2 Specify the target frequency. In the **Target** pane, set **Target Frequency (MHz)** to the target frequency that you want the floating-point IP to achieve. If you do not specify a target frequency, HDL Coder sets the target frequency to 200 MHz. Click **OK**.
- 3 To specify the vendor specific library settings, get the model floating-point target configuration object, `hdlcoder.FloatingPointTargetConfig`, by using this command:

```
fpconfig = hdlget_param(gcs, 'FloatingPointTargetConfiguration')
```

- 4 Specify the vendor-specific floating-point library settings. Use the floating point target configuration object `fpconfig` to set the `InitializeIPipelinesToZero` property which specifies whether to initialize pipeline registers in the IP to zero. To avoid potential numerical mismatches in the HDL simulation, it is recommended to leave the `InitializeIPipelinesToZero` option set to `true`.
- 5 Specify the IP settings. Use the `VendorIPConfig` property of the `fpconfig` object to specify a custom latency and settings specific to the IP. To view the `VendorIPConfig` table, use this command:

```
fpconfig.VendorIPConfig
```

- In the **Latency** column, the default latency value of `-1` means that the IP inherits the latency value from the target frequency. If you specify a latency value, HDL Coder tries to map your Simulink model to the IP at a target frequency corresponding to that latency value.
 - In the **ExtraArgs** column, you can specify additional settings specific to the IP.
- 6 Generate code. In Simulink, in the **HDL Coder** tab, click **Generate HDL Code**.

Customize the IP Latency Programmatically

To customize the IP latency from the command line:

- 1 Specify the library. Create a `hdlcoder.FloatingPointTargetConfig` object for the floating-point library by using the `hdlcoder.createFloatingPointTargetConfig` function. Then, use `hdlset_param` to save the configuration on the model.

For example, to create a floating-point target configuration for the Altera Megafuncions (ALTERA FP FUNCTIONS) library with the default settings for the model `sfir_single`, enter:

```
fpconfig = hdlcoder.createFloatingPointTargetConfig("NativeFloatingPoint",...
    VendorFloatingPointLibrary="ALTERAFPFUNCTIONS");
hdlset_param('sfir_single', 'FloatingPointTargetConfiguration', fpconfig);
```

To see the default settings for the floating-point IP, enter `fpconfig`.

```
fpconfig =
```

```
FloatingPointTargetConfig with properties:
```

```
Library: 'NATIVEFLOATINGPOINT'
LibrarySettings: [1x1 fpconfig.NFPLatencyDrivenMode]
IPConfig: [1x1 hdlcoder.FloatingPointTargetConfig.IPConfig]
VendorLibrary: 'ALTERAFPFUNCTIONS'
VendorLibrarySettings: [1x1 fpconfig.FrequencyDrivenMode]
VendorIPConfig: [1x1 hdlcoder.FloatingPointTargetConfig.IPConfig]
```

- 2 Specify the target frequency. If you choose ALTERA MEGAFUNCTION (ALTERA FP FUNCTIONS) as the vendor-specific floating-point library, you can create a floating-point configuration with a custom target frequency. To specify the target frequency for the IP to achieve, use the `TargetFrequency` property. For example:

```
hdlset_param('sfir_single', 'TargetFrequency', 300);
```

- 3 Specify the vendor-specific floating-point library settings. Specify whether you want to initialize the pipeline registers in the IP to zero. Use the `InitializeIPipelinesToZero` property of the `fpconfig.VendorLibrarySettings` property.

For example, to set the `InitializeIPipelinesToZero` property to false, enter:

```
fpconfig.VendorLibrarySettings.InitializeIPipelinesToZero = false;
```

To see the library settings, enter `fpconfig.VendorLibrarySettings`.

```
ans =
```

```
FrequencyDrivenMode with properties:
```

```
InitializeIPipelinesToZero: 0
```

To avoid potential numerical mismatches in the HDL simulation, it is recommended to set `InitializeIPipelinesToZero` to true.

- 4 Specify the IP settings. Use the `Latency` and `ExtraArgs` input arguments of the `VendorIPConfig.customize` method to customize the latency of the IP and specify additional settings specific to the IP.

For example, when mapping to the `ADDSUB` IP with Xilinx LogiCORE libraries, to specify a custom latency of 8:

```
fpconfig.VendorIPConfig.customize('ADDSUB', 'SINGLE', 'Latency', 8);
```

To see the IP settings, enter `fpconfig.VendorIPConfig`.

```
ans =
```

Name	DataType	Latency	ExtraArgs
'ABS'	'DOUBLE'	-1	''
'ABS'	'SINGLE'	-1	''
'ADDSUB'	'DOUBLE'	-1	''
'ADDSUB'	'SINGLE'	8	''
'CONVERT'	'DOUBLE_TO_NUMERICTYPE'	-1	''
'CONVERT'	'NUMERICTYPE_TO_DOUBLE'	-1	''
'CONVERT'	'NUMERICTYPE_TO_SINGLE'	-1	''
'CONVERT'	'SINGLE_TO_NUMERICTYPE'	-1	''

- 5 Generate HDL code. To generate code from the subsystem, use `makehdl`.

Customize the IP Latency with Latency Strategy

To customize the IP latency with the latency strategy setting, use the ALTERA MEGAFUNCTION (ALTFP) or XILINX LOGICORE libraries. Specify whether to map your Simulink model to maximum or minimum latency. HDL Coder infers the latency of the IP from the latency strategy setting.

To customize the IP latency from the command line:

- 1 Specify the library. Create a `hdlcoder.FloatingPointTargetConfig` object for the floating-point library by using the `hdlcoder.createFloatingPointTargetConfig` function. Then, use `hdlset_param` to save the configuration on the model.

For example, to create a floating-point target configuration for the ALTERA MEGAFUNCTION (ALTFP) library with the default settings for the model `sfir_single`, enter:

```
fpconfig = hdlcoder.createFloatingPointTargetConfig("NativeFloatingPoint",...
    VendorFloatingPointLibrary="ALTFP");
hdlset_param('sfir_single', 'FloatingPointTargetConfiguration', fpconfig);
```

By default, the library uses the minimum latency and speed objective for the floating-point IP.

- 2 Specify the library settings. Customize the library settings by setting the `Objective` and `LatencyStrategy` properties of the `fpconfig.VendorLibrarySettings` object.

For example, to customize the ALTERA MEGAFUNCTION (ALTFP) library to use the maximum latency and objective as area, enter:

```
fpconfig.VendorLibrarySettings.Objective = 'AREA';
fpconfig.VendorLibrarySettings.LatencyStrategy = 'MAX';
```

To see the library settings, enter `fpconfig.VendorLibrarySettings`.

```
ans =
```

```
LatencyDrivenMode with properties:
```

```

    LatencyStrategy: 'MAX'
    Objective: 'AREA'

```

- Specify the IP settings. Use the `Latency` and `ExtraArgs` input arguments of the `VendorIPConfig.customize` method to customize the latency of the IP and specify additional settings specific to the IP.

For example, when mapping to the `ADDSUB` IP with Xilinx LogiCORE libraries, to use a custom latency of 8 and specify the DSP resource usage with the `cmultusage` parameter, enter:

```

fpconfig.VendorIPConfig.customize('ADDSUB', 'SINGLE',...
    'Latency', 8, 'ExtraArgs', 'CSET c_mult_usage=Full_usage');

```

To see the IP settings, enter `fpconfig.VendorIPConfig`.

```
ans =
```

Name	Data Type	MinLatency	MaxLatency	Latency	ExtraArgs
'ADDSUB'	'DOUBLE'	7	14	-1	''
'ADDSUB'	'SINGLE'	7	14	8	'CSET c_mult_usage=Full_usage'
'CONVERT'	'DOUBLE_TO_NUMERICTYPE'	6	6	-1	''
'CONVERT'	'NUMERICTYPE_TO_DOUBLE'	6	6	-1	''
'CONVERT'	'NUMERICTYPE_TO_SINGLE'	6	6	-1	''

- Generate HDL code. To generate code from the subsystem, use `makehdl`.

HDL Coder Support for FPGA Floating-Point Library Mapping

In this section...

“Supported Blocks That Map to FPGA Floating-Point Target IP” on page 36-43

“Supported Blocks That Do Not Need to Map to FPGA Floating-Point Target IP” on page 36-45

“Limitations for FPGA Floating-Point Library Mapping” on page 36-46

In the HDL Coder block library, a subset of Simulink blocks support floating-point library mapping. The subset includes:

- Blocks that perform basic math operations such as addition, multiplication, and complex trigonometric sine and cosine functions. These blocks map to one or more floating-point IP units on the target FPGA device.
- Discrete blocks, blocks that perform signal routing, and blocks that perform math operations such as matrix concatenation. These blocks need not map to a floating-point IP unit on the target FPGA device.

Supported Blocks That Map to FPGA Floating-Point Target IP

The following table summarizes the Simulink blocks that can map to FPGA floating-point IP cores.

When mapping to floating-point IP cores, some blocks have mode restrictions.

Note Some blocks do not map to a floating-point IP core in the third-party hardware. For example, the Abs block maps to an Altera target IP core but not to a Xilinx target IP core.

Block	Altera Megafunction IP (ALTFP and ALTERA FP Functions)	Xilinx LogiCORE IP	Remarks and Limitations
Abs	✓		—
Add	✓	✓	—
Bias	✓	✓	—
Compare To Constant	✓	✓	—
Compare To Zero	✓	✓	—

Block	Altera Megafunction IP (ALTFP and ALTERA FP Functions)	Xilinx LogiCORE IP	Remarks and Limitations
Trigonometric Function	✓		<ul style="list-style-type: none"> Only single data types are supported for floating-point library mapping. In the Block Parameters dialog box, Function must be set to either sin or cos and Approximation method must be set to None. If you are using Altera Quartus 10.1 or 11.0, turn on the AlteraBackward Incompatible SinCosPipeline global property using <code>hdlset_param</code>.
Unary Minus	✓	✓	—

Supported Blocks That Do Not Need to Map to FPGA Floating-Point Target IP

Following are the Simulink blocks that generate HDL code but need not map to an FPGA floating-point IP core.

- Bus Assignment
- Bus Creator
- Bus Selector
- Constant
- Delay
- Demux
- Deserializer1D
- Downsample
- From
- Goto
- Index Vector
- Vector Concatenate, Matrix Concatenate
- Memory
- Model Info
- Multiport Switch
- Mux
- Rate Transition
- Reshape

- Serializer1D
- Subsystem, Atomic Subsystem, CodeReuse Subsystem
- Switch block with control input other than `u2 ~= 0`.
- Unit Delay
- Upsample
- Zero-Order Hold

Limitations for FPGA Floating-Point Library Mapping

- If your synthesis tool is Xilinx Vivado, you cannot use FPGA floating-point library mapping.
- Complex data types are not supported.
- The streaming optimization is not supported with floating-point library mapping.
- The resource sharing optimization is not supported with Unary Minus and Abs blocks.
- For IP Core Generation, FPGA Turnkey, and Simulink Real-Time FPGA I/O workflows, your DUT ports cannot use floating-point data types.

Synthesis Objective to Tcl Command Mapping

In this section...

"Altera Quartus II" on page 36-47

"Xilinx Vivado 2014.4" on page 36-47

"Xilinx ISE 14.7 with PlanAhead" on page 36-48

The HDL Workflow Advisor guides you through the stages of generating HDL code for a Simulink subsystem and the FPGA design process, such as:

- Checking the model for HDL code generation compatibility and automatically fixing incompatible settings.
- Generation of HDL code, a test bench, and scripts to build and run the code and test bench.
- Generation of cosimulation or SystemVerilog DPI test benches and code coverage (requires HDL Verifier).
- Synthesis and timing analysis through integration with third-party synthesis tools.
- Back-annotation of the model with critical path information and other information obtained during synthesis.
- Complete automated workflows for selected FPGA development target devices, including FPGA-in-the-loop simulation (requires HDL Verifier), and the Simulink Real-Time FPGA I/O workflow.

When you specify a synthesis objective in the HDL Workflow Advisor **Synthesis objective** field, or in the HDL Workflow CLI workflow `hdlcoder.Objective`, the HDL Coder software generates Tcl commands that are specific to your synthesis tool.

Altera Quartus II

Synthesis objective	Tcl Commands
Area Optimized	<code>set_global_assignment -name OPTIMIZATION_TECHNIQUE "Area"</code> <code>set_global_assignment -name FITTER_EFFORT "Standard Fit"</code>
Compile Optimized	<code>set_global_assignment -name OPTIMIZATION_TECHNIQUE "Balanced"</code> <code>set_global_assignment -name FITTER_EFFORT "Fast Fit"</code>
Speed Optimized	<code>set_global_assignment -name OPTIMIZATION_TECHNIQUE "Speed"</code> <code>set_global_assignment -name FITTER_EFFORT "Standard Fit"</code>

Xilinx Vivado 2014.4

If your tool version is different, the Tcl commands are slightly different.

Synthesis objective	Tcl Commands
Area Optimized	<code>set_property strategy {Vivado Synthesis Defaults} [get_runs synth_1]</code> <code>set_property strategy "Area_Explore" [get_runs impl_1]</code>

Synthesis objective	Tcl Commands

 “IP Core Generation Workflow Script Example” on page 36-55
 “Simulink Real-Time FPGA I/O Workflow Example” on page 36-57

The HDL Workflow Advisor guides you through the stages of generating HDL code for a Simulink subsystem and the FPGA design process, such as:

- Checking the model for HDL code generation compatibility and automatically fixing incompatible settings.
- Generation of HDL code, a test bench, and scripts to build and run the code and test bench.
- Generation of cosimulation or SystemVerilog DPI test benches and code coverage (requires HDL Verifier).
- Synthesis and timing analysis through integration with third-party synthesis tools.
- Back-annotation of the model with critical path information and other information obtained during synthesis.
- Complete automated workflows for selected FPGA development target devices, including FPGA-in-the-loop simulation (requires HDL Verifier), and the Simulink Real-Time FPGA I/O workflow.

HDL Workflow Advisor is not available in Simulink Online.

To run the HDL workflow as a command-line script, configure and run the HDL Workflow Advisor with your Simulink design, then export a script. The script uses HDL Workflow CLI commands to perform the same tasks as the HDL Workflow Advisor, including FPGA bitstream or synthesis project generation.

You can export an HDL workflow script for these target workflows:

- Generic ASIC/FPGA
- FPGA-in-the-Loop (requires HDL Verifier license)
- FPGA Turnkey
- IP Core Generation
- Simulink Real-Time FPGA I/O (requires Simulink Real-Time)

To update an existing script, import it into the HDL Workflow Advisor, modify the tasks, and export the updated script. Alternatively, you can manually edit the script.

Export an HDL Workflow Script

- 1 In the HDL Workflow Advisor, configure and run all the tasks.
- 2 Select **File > Export to Script**.
- 3 In the Export Workflow Configuration dialog box, enter a file name and save the script.

The script is a MATLAB file that you can run from the command line.

Note When you export to script, default values such as Asynchronous value for **Reset type** are not exported. When you import from the script, if the model is unchanged, you do not see the default settings in the script.

Specify Verbosity of Workflow Script

You can use the `Verbosity` property of the `hdlcoder.runWorkflow` function to specify the level of detail for progress messages generated as code generation and deployment proceeds. To generate verbose messages while running the workflow for a `hdlcoder.WorkflowConfig` workflow configuration object, `hWC` and Simulink design, `model/DUTname`, set `Verbosity` to `on`.

```
hdlcoder.runWorkflow('model/DUTname', hWC, 'Verbosity', 'on');
```

Enable or Disable Tasks in HDL Workflow Script

To disable all workflow tasks, update the workflow configuration object with the `clearAllTasks` method.

To reenable all workflow tasks, update the workflow configuration object with the `setAllTasks` method.

Run a Single Workflow Task

To run a single workflow task without rerunning other workflow tasks:

- 1 Disable all tasks in the workflow configuration object by running the `clearAllTasks` method.
- 2 In the workflow configuration object, enable the task that you want to run.

For example, if you previously ran an HDL workflow script and generated a bitstream, you can program your target hardware without rerunning the other workflow tasks. To run the target device programming task for an `hdlcoder.WorkflowConfig` workflow configuration object, `hWC` and Simulink design, `model/DUTname`:

- 1 Run the `clearAllTasks` method.

```
hWC.clearAllTasks;
```
- 2 Enable the target device programming task.

```
hWC.RunTaskProgramTargetDevice = true;
```
- 3 Run the workflow.

```
hdlcoder.runWorkflow('model/DUTname', hWC);
```

Import an HDL Workflow Script

- 1 In the HDL Workflow Advisor, select **File > Import from Script**.
- 2 In the Import Workflow Configuration dialog box, select the script file and click **Open**.

The HDL Workflow Advisor updates the tasks with the imported script settings.

Note When you import a HDL Workflow Advisor script, make sure you use the same script that was exported from the HDL Workflow Advisor UI.

Generic ASIC/FPGA Workflow Script Example

This example shows how to configure and run an exported HDL workflow script.

This script is a generic ASIC/FPGA workflow script that targets a Xilinx Virtex 7 device. It uses the Xilinx Vivado synthesis tool.

Open and view your exported HDL workflow script.

```
% Export Workflow Configuration Script

hwc.MACAddress = '00-0A-35-02-21-8A';
hwc.SourceFiles = '';
hwc.Connection = 'Ethernet';
hwc.RunExternalBuild = true;

% Validate the Workflow Configuration Object
hwc.validate;

%% Run the workflow
hdlcoder.runWorkflow('sfir_fixed/symmetric_fir', hwc);
hdlcoder.runWorkflow('hdlcoder/UARTServoControllerExample/UART_Servo_on_FPGA', hwc);

```

Optionally, edit the script.

For example, enable or disable tasks in the `hdlcoder.WorkflowConfig` object, `hwc`.

Run the HDL workflow script.

For example, if the script file name is `FIL_workflow_example.m`, at the command line, enter:

```
fil_workflow_example.m
```

FPGA Turnkey Workflow Script Example

This example shows how to configure and run an exported HDL workflow script.

This script is an FPGA Turnkey workflow script that targets a Xilinx Virtex 5 development board. It uses the Xilinx ISE synthesis tool.

Open and view your exported HDL workflow script.

```

%-----

Get Started with HDL Workflow Command-Line Interface

This example shows how to use the HDL Workflow Advisor to run HDL workflows from the command line and the **Export to script** option.

Introduction

This example is a step-by-step guide that helps introduce you to the HDL Workflow Command Line Interface.

Using the HDL Workflow Command Line Interface, you can run the same sequence of steps and control the same configuration settings that are available in the HDL Workflow Advisor for the following workflows:

- 1 Generic ASIC/FPGA
- 2 FPGA Turnkey
- 3 IP Core Generation
- 4 Simulink Real-Time FPGA I/O

Open the Model

In this example we will use the **hdlcoder_sfir_fixed_stream** model, but the HDL Workflow Command Line Interface can be used with any model that works with the workflows listed above.

```
open_system('hdlcoder_sfir_fixed_stream')
```

Copyright 2015 The MathWorks, Inc.

Make sure that the desired third party tools are included on the path. For example, to include Vivado installed locally in its default windows location, use the following command:

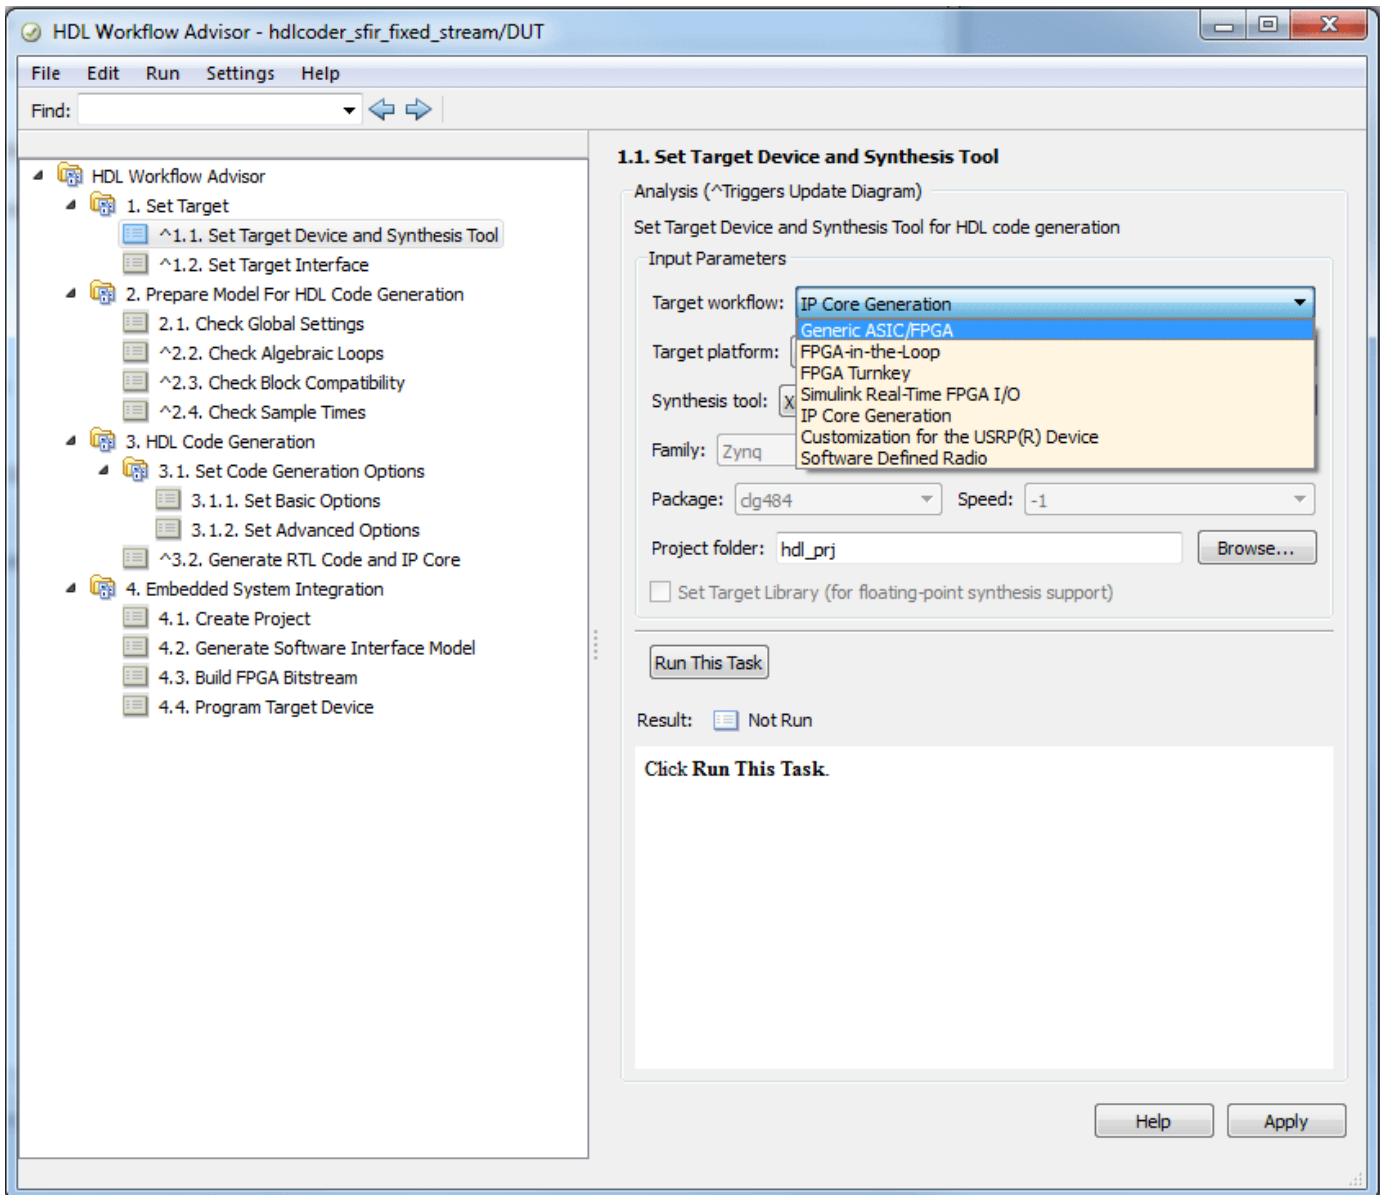

```
>> hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2020.2\bin\vivado.
```

Next, launch the workflow advisor and select the appropriate subsystem as the DUT.

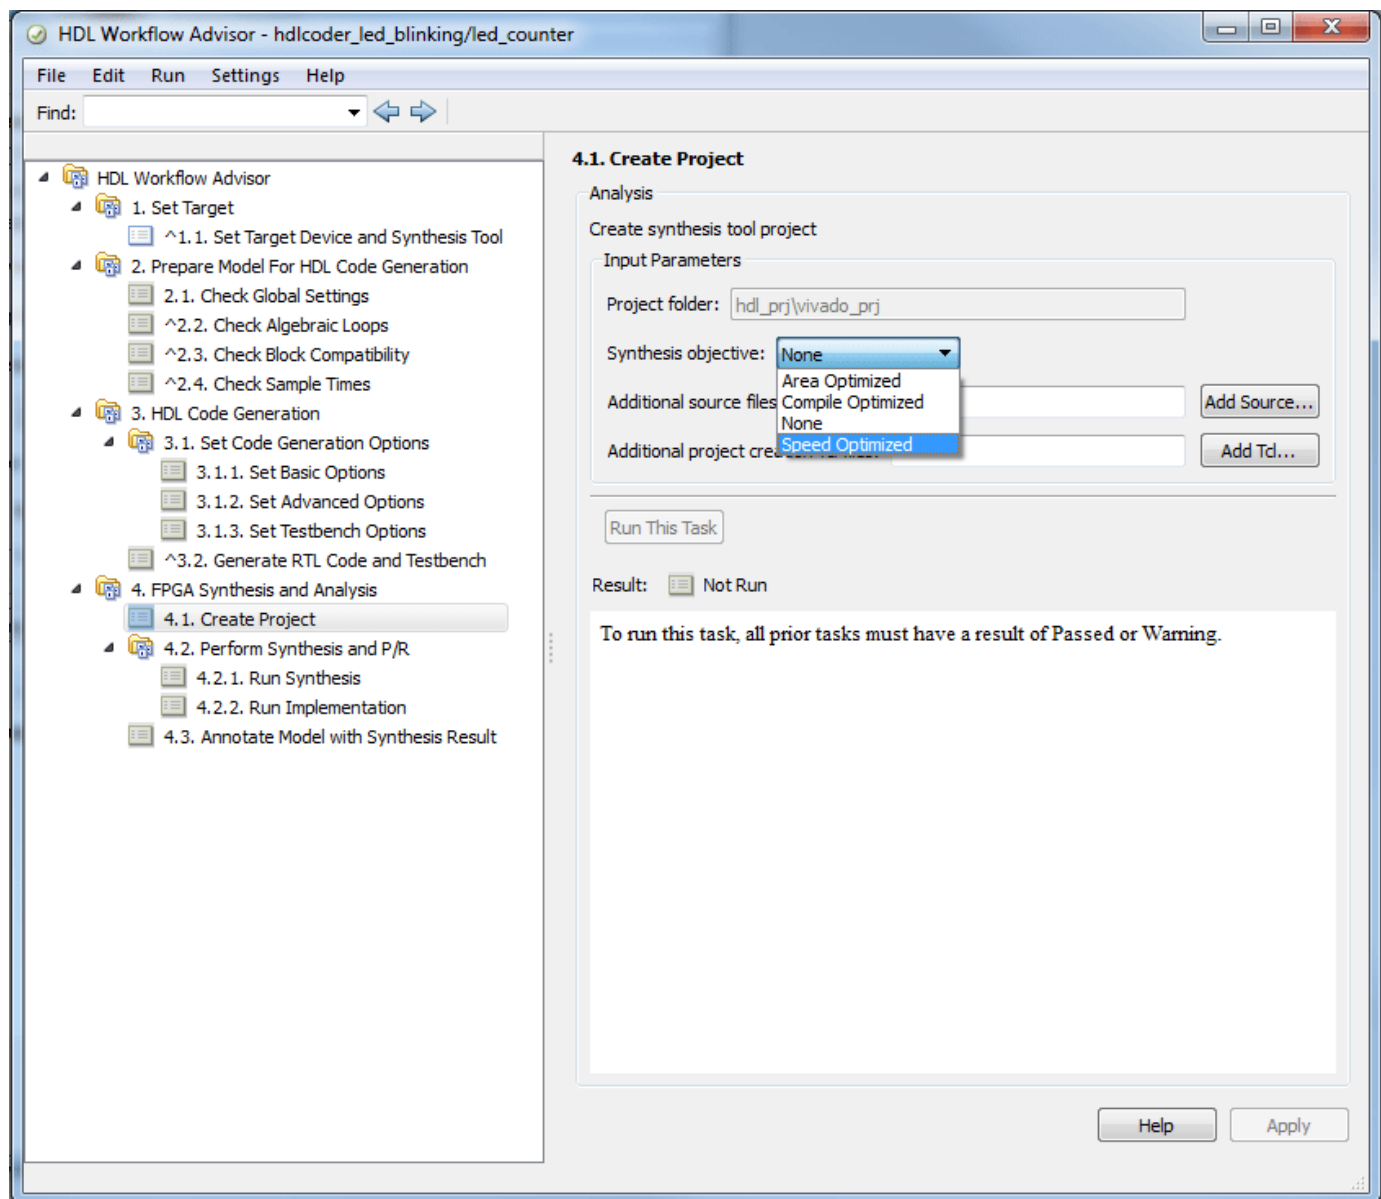

Setup the Workflow

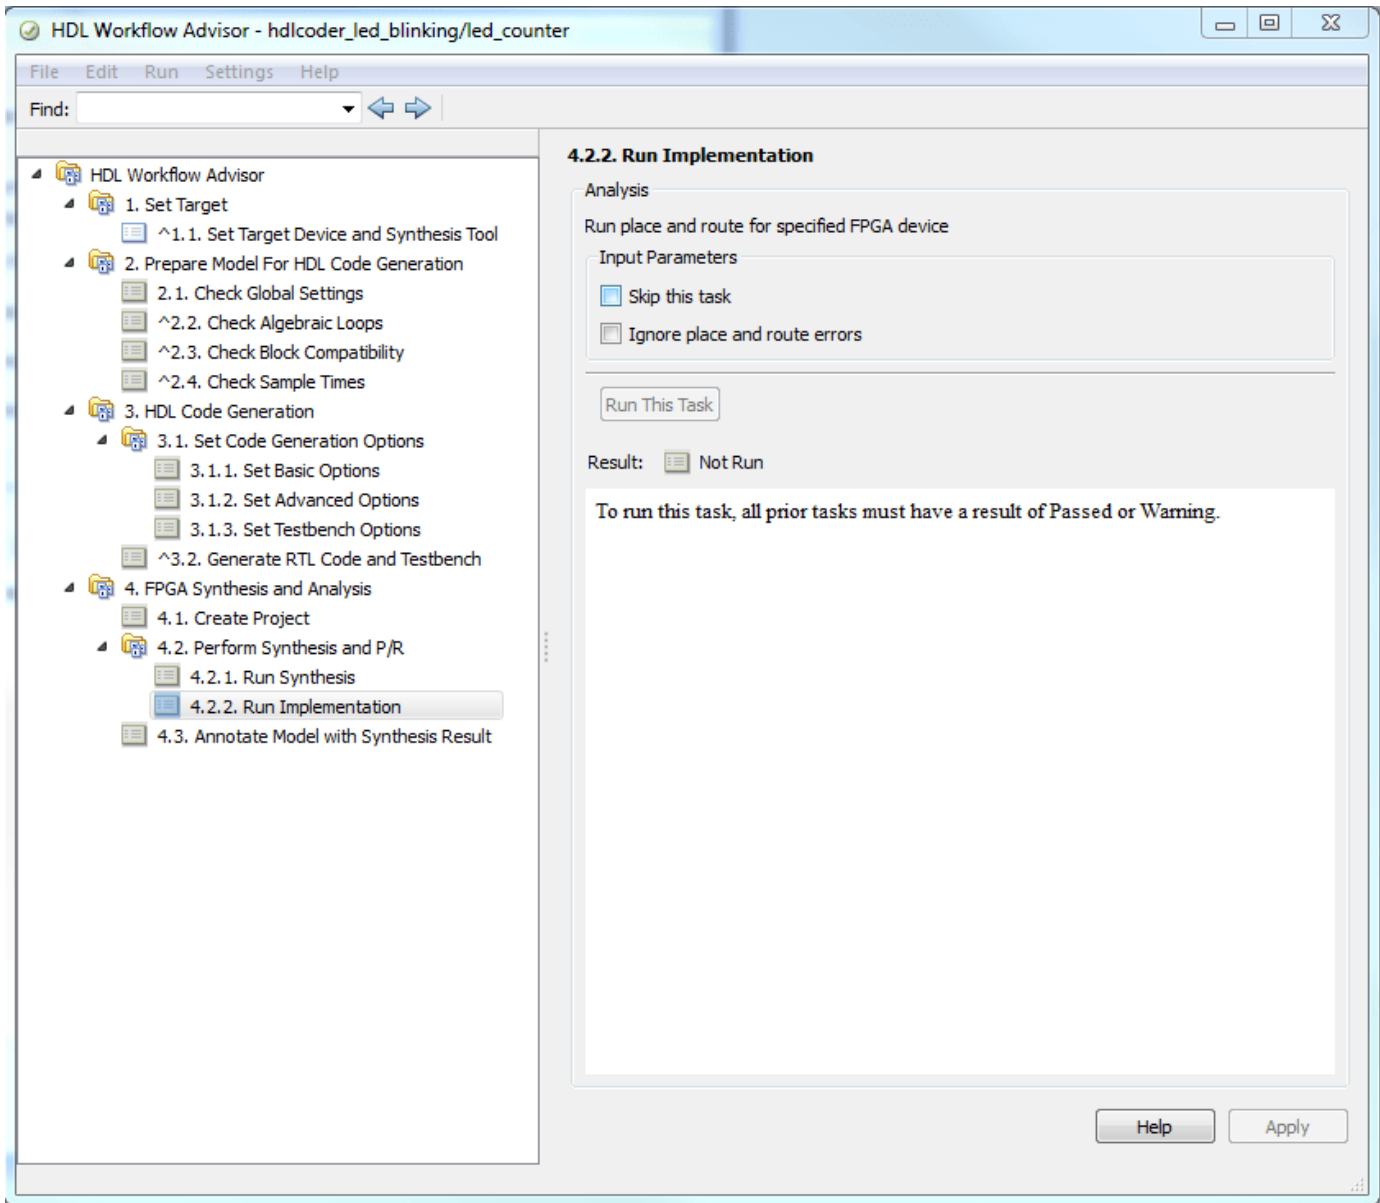

Use the HDL Workflow Advisor to setup your project with your desired settings, such as a Synthesis Tool and Device. Start by changing the workflow to "Generic ASIC/FPGA" so that we can Annotate the model with synthesis results.

You can also specify high level objectives for the synthesis tool. For example, try setting the tool to "Speed Optimized".

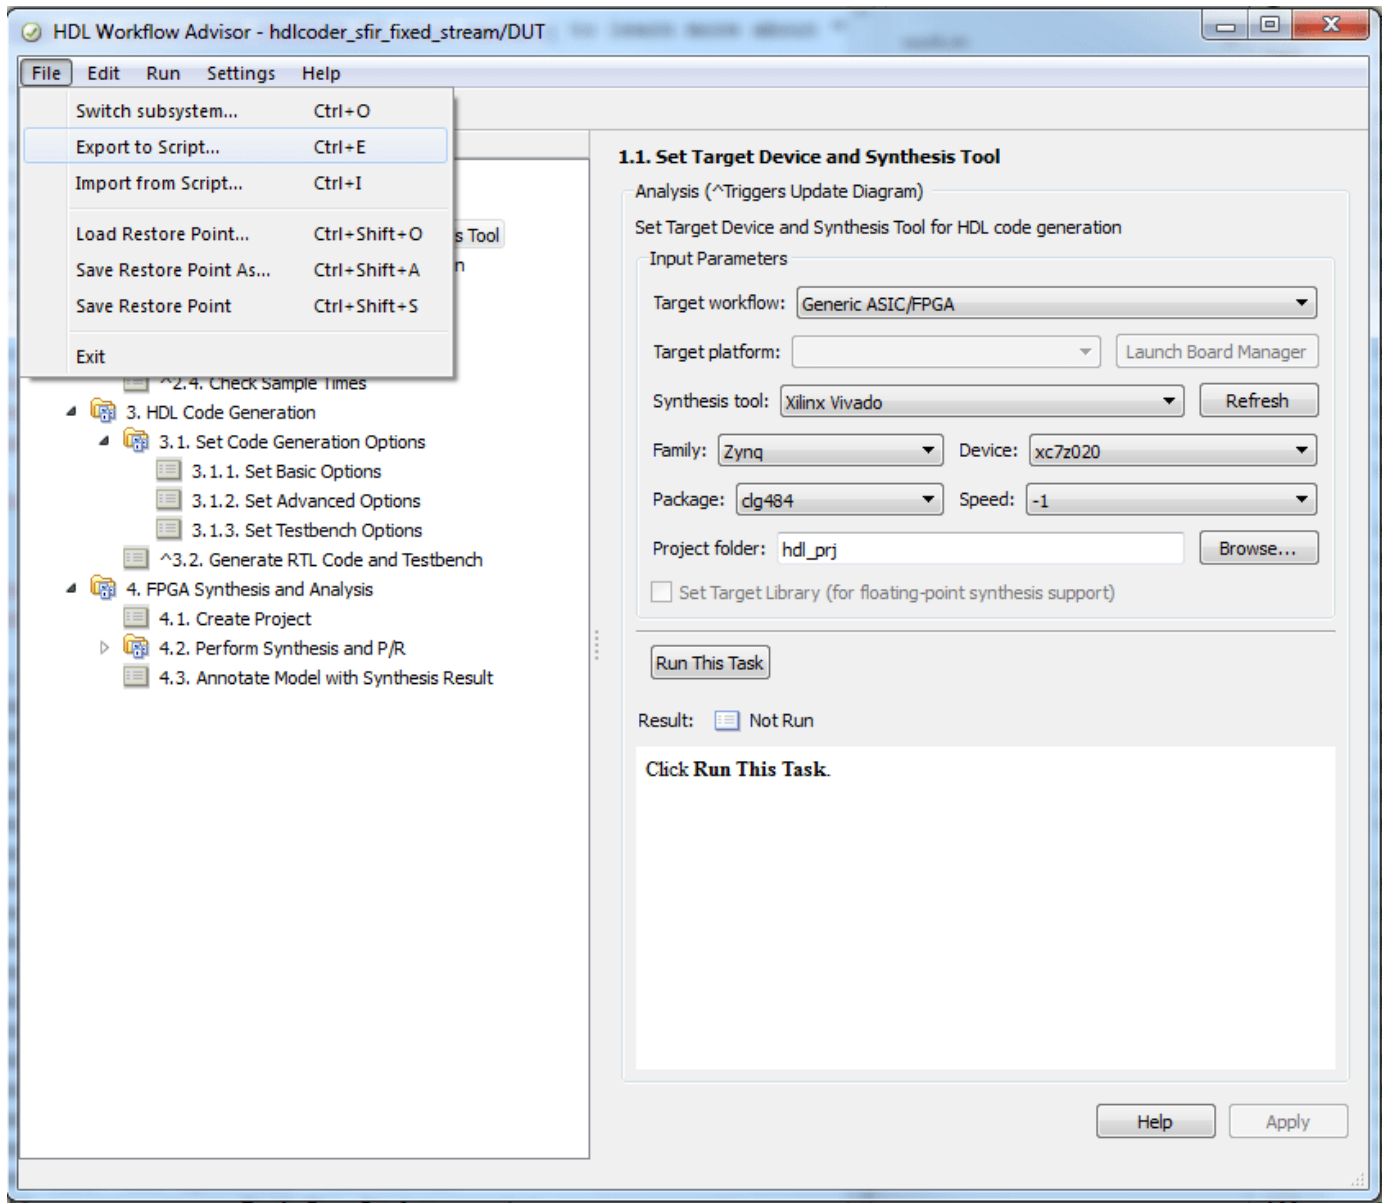

Also, change the "Skip this task" checkbox for Run Implementation so that the exported script runs this step as well

Export to Script

After all the initial settings have been entered, export your workflow to a script which can be run directly from the command-line for faster design iterations.

Save the file as any name you like. The default will be "hdlworkflow.m". The exported script is shown below:

```
%-----
% HDL Workflow Script
% Generated with MATLAB 9.0 (R2016b Prerelease) at 10:40:45 on 31/12/2015
% This script was generated using the following parameter values:
%   Filename   : '/mathworks/dev/sandbox/cherry/work/demo/hdlworkflow.m'
%   Overwrite  : true
%   Comments   : true
%   Headers    : true
%   DUT        : 'hdlcoder_sfir_fixed_stream/DUT'
% To view changes after modifying the workflow, run the following command:
% >> hWC.export('DUT','hdlcoder_sfir_fixed_stream/DUT');
```

```

%-----

% Copyright 2018 The MathWorks, Inc.

%% Load the Model
load_system('hdlcoder_sfir_fixed_stream');

%% Restore the Model to default HDL parameters
%hdlrestoreparams('hdlcoder_sfir_fixed_stream/DUT');

%% Model HDL Parameters
%% Set Model 'hdlcoder_sfir_fixed_stream' HDL parameters
hdlset_param('hdlcoder_sfir_fixed_stream', 'HDLSubsystem', 'hdlcoder_sfir_fixed_stream/DUT');
hdlset_param('hdlcoder_sfir_fixed_stream', 'ReferenceDesign', 'Default system with AXI4-Stream i
hdlset_param('hdlcoder_sfir_fixed_stream', 'ResetType', 'Synchronous');
hdlset_param('hdlcoder_sfir_fixed_stream', 'SynthesisTool', 'Xilinx Vivado');
hdlset_param('hdlcoder_sfir_fixed_stream', 'SynthesisToolChipFamily', 'Zynq');
hdlset_param('hdlcoder_sfir_fixed_stream', 'SynthesisToolDeviceName', 'xc7z020');
hdlset_param('hdlcoder_sfir_fixed_stream', 'SynthesisToolPackageName', 'clg484');
hdlset_param('hdlcoder_sfir_fixed_stream', 'SynthesisToolSpeedValue', '-1');
hdlset_param('hdlcoder_sfir_fixed_stream', 'TargetDirectory', 'hdl_prj/hdlsrc');

%% Workflow Configuration Settings
% Construct the Workflow Configuration Object with default settings
hWC = hdlcoder.WorkflowConfig('SynthesisTool', 'Xilinx Vivado', 'TargetWorkflow', 'Generic ASIC/FPGA

% Specify the top level project directory
hWC.ProjectFolder = 'hdl_prj';

% Set Workflow tasks to run
hWC.RunTaskGenerateRTLCodeAndTestbench = true;
hWC.RunTaskCreateProject = true;
hWC.RunTaskRunSynthesis = true;
hWC.RunTaskRunImplementation = false;
hWC.RunTaskAnnotateModelWithSynthesisResult = true;

% Set properties related to 'RunTaskGenerateRTLCodeAndTestbench' Task
hWC.GenerateRTLCode = true;
hWC.GenerateRTLTestbench = false;
hWC.GenerateCosimulationModel = false;
hWC.CosimulationModelForUseWith = 'Mentor Graphics ModelSim';
hWC.GenerateValidationModel = false;

% Set properties related to 'RunTaskCreateProject' Task
hWC.Objective = hdlcoder.Objective.None;
hWC.AdditionalProjectCreationTclFiles = '';

% Set properties related to 'RunTaskRunSynthesis' Task
hWC.SkipPreRouteTimingAnalysis = false;

% Set properties related to 'RunTaskRunImplementation' Task
hWC.IgnorePlaceAndRouteErrors = false;

% Set properties related to 'RunTaskAnnotateModelWithSynthesisResult' Task
hWC.CriticalPathSource = 'pre-route';
hWC.CriticalPathNumber = 1;
hWC.AnnotateModel = 'original';

```

Run workflow interactively

The HDL Workflow Command-Line interface can also be used interactively. For example, after either running the entire script or just the section "Workflow Configuration Settings", the WorkflowConfig object, hWC, will be populated in the workspace:

```
>> hWC =
```

```
GenericTurnkeyConfig with properties:
```

```
    SynthesisTool: 'Xilinx Vivado'  
    TargetWorkflow: 'Generic ASIC/FPGA'  
    ProjectFolder: 'hdl_prj'
```

```
    RunTaskGenerateRTLCodeAndTestbench: true  
    RunTaskCreateProject: true  
    RunTaskRunSynthesis: true  
    RunTaskRunImplementation: true  
    RunTaskAnnotateModelWithSynthesisResult: true
```

```

TaskGenerateRTLCodeAndTestbench
    GenerateRTLCode: true
    GenerateRTLTestbench: false
    GenerateCosimulationModel: false
    CosimulationModelForUseWith: 'Mentor Graphics ModelSim'
    GenerateValidationModel: false

    TaskCreateProject
        Objective: hdlcoder.Objective.SpeedOptimized
AdditionalProjectCreationTclFiles: ''

    TaskRunSynthesis
SkipPreRouteTimingAnalysis: false

    TaskRunImplementation
IgnorePlaceAndRouteErrors: false

TaskAnnotateModelWithSynthesisResult
    CriticalPathSource: 'pre-route'
    CriticalPathNumber: 1
    AnnotateModel: 'original'
    ShowAllPaths: false
    ShowDelayData: true
    ShowUniquePaths: false
    ShowEndsOnly: false

```

You can edit this configuration object and then run the workflow with the modified settings. For example, since the task "Run Implementation" was enabled in the previous run, we can change the critical path source to "post-route" with and rerun just the Annotate model task:

```

>> hWC.clearAllTasks;
>> hWC.RunTaskAnnotateModelWithSynthesisResult = true;
>> hWC.CriticalPathSource = 'post-route';

```

Then run the modified workflow configurations directly using the `hdlcoder.runWorkflow` command:

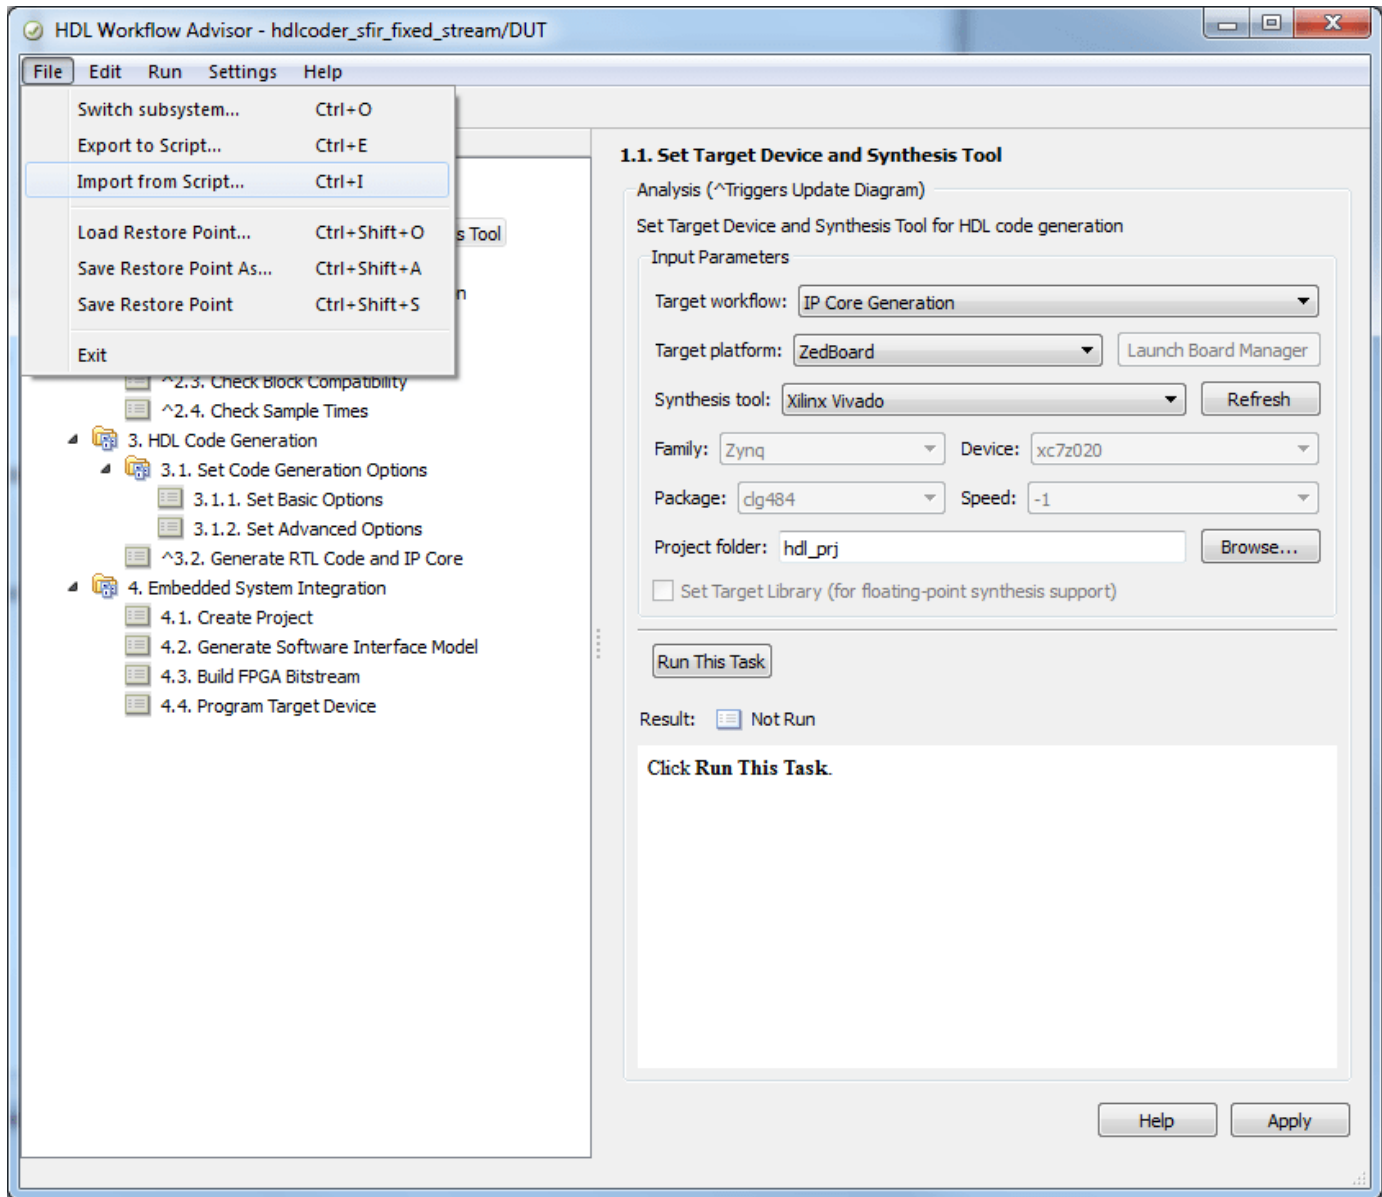

```

>> hdlcoder.runWorkflow('hdlcoder_led_blinking/led_counter', hWC)

```

Import script into HDL Workflow Advisor

Any changes you make to the exported script can also be imported back into the HDL Workflow Advisor at any time. To do this, make sure the model loaded is the same as the model used in the script, and select "Import from script" from the File menu.

After importing, all of the script settings will be populated in the HDL Workflow Advisor.

Save the HDL Workflow Command-Line Interface programming script for later use

In certain cases, you can avoid re-running all the steps in the HDL Workflow Advisor just to perform specific tasks in the Advisor. For example, when running the IP Core Generation Workflow, after you generate the FPGA bitstream in the Build FPGA Bitstream Task, the Advisor provides a link that generates a script to run the Program Target Device Task.

Click on the link for `hdlworkflow_ProgramTargetDevice.m` in Build FPGA Bitstream Task to generate an HDL Workflow Command-Line Interface script which will execute only the Program Target Device Task from an existing `hdl_prj` directory. Therefore, you can avoid running all the steps in the workflow just to re-program the target device.

4.2. Build FPGA Bitstream

Analysis

Synthesis and generate bitstream for embedded system on FPGA

Input Parameters

Run build process externally

Tcl file for synthesis build:

Result:  Passed

Passed Build Embedded System.

Synthesis Tool Log:

```
Task "Build FPGA Bitstream" successful.
Generated logfile: hdl_prj\hdlsrc\hdlcoder_led_vector\workflow_task_BuildFPGABitstream.log

Running embedded system build outside MATLAB.
Please check external shell for system build progress.

The generated bitstream file is located at: hdl_prj\vivado_ip_prj\vivado_prj.runs\impl_1\system_top_wrapper.bit

Generate an HDL Workflow Command-Line Interface script to program the target device: hdlworkflow_ProgramTargetDevice.s.
```

The generated script is a standard HDL Workflow CLI script. When running HDL Workflow in command-line interface, the Program Target Device Task can be run independent of previous tasks, as long as the FPGA bitstream is already generated.

As a related note, if you are using the Download programming method in the Program Target Device Task, the HDL Workflow Advisor copies the generated bitstream file onto the SD card on the Zynq or Intel SoC board, so you do not need to re-run the Program Target Device Task to download the bitstream. The FPGA bitstream will be reloaded from the SD card automatically during the Linux boot up process.

Summary

The HDL Workflow Command-Line Interface provides an easily scripted alternative to the graphical HDL Workflow Advisor. Workflows can be setup initially using the HDL Workflow Advisor and then exported to script for iterative or automated use.

Getting Started with FPGA Turnkey Workflow

This example shows how to program a standalone FPGA with your MATLAB® design, using the FPGA Turnkey workflow.

The target device in this example is a Xilinx® Virtex-5 ML506 development board.

Introduction

In this example, the function `mlhdlc_ip_core_led_blinking` models a counter that blinks the LEDs on an FPGA board.

Two input ports, `Blink_frequency` and `Blink_direction`, are control ports that determine the LED blink frequency and direction.

You can adjust the input values of the hardware via push-buttons on Xilinx Virtex-5 ML506 development board. The output port of the design function, 'LED', connects to the LED hardware.

```
design_name = 'mlhdlc_turnkey_led_blinking';  
testbench_name = 'mlhdlc_turnkey_led_blinking_tb';
```

Take a look at the MATLAB design:

```
type(design_name);  
  
function [LED, Read_back] = mlhdlc_turnkey_led_blinking(Blink_frequency, Blink_direction)  
%  
% Copyright 2013-2015 The MathWorks, Inc.  
  
persistent freqCounter LEDCounter  
  
if isempty(freqCounter)  
    freqCounter = 0;  
    LEDCounter = 255;  
end  
  
if Blink_frequency <= 0  
    Blink_frequency = 0;  
elseif Blink_frequency >= 15  
    Blink_frequency = 15;  
end  
  
blinkFrequencyOut = LookupTable(Blink_frequency);  
if blinkFrequencyOut == freqCounter  
    freqMatch = 1;  
else  
    freqMatch = 0;  
end  
  
freqCounter = freqCounter + 1;  
  
if freqMatch  
    freqCounter = 0;  
end
```

```

if Blink_direction
    LED = 255 - LEDCounter;
else
    LED = LEDCounter;
end

if LEDCounter == 255
    LEDCounter = 0;
elseif freqMatch
    LEDCounter = LEDCounter + 1;
end

Read_back = LED;
end

function y = LookupTable(idx)
s = 2.^(26:-1:11)';

y = s(idx+1);
end

type(testbench_name);

%

% Copyright 2013-2015 The MathWorks, Inc.

for i=1:16
    [yout, ~] = mlhdlc_turnkey_led_blinking(i-1, 0);
    [yout2, ~] = mlhdlc_turnkey_led_blinking(i-1, 1);
end

```

Create a New HDL Coder™ Project

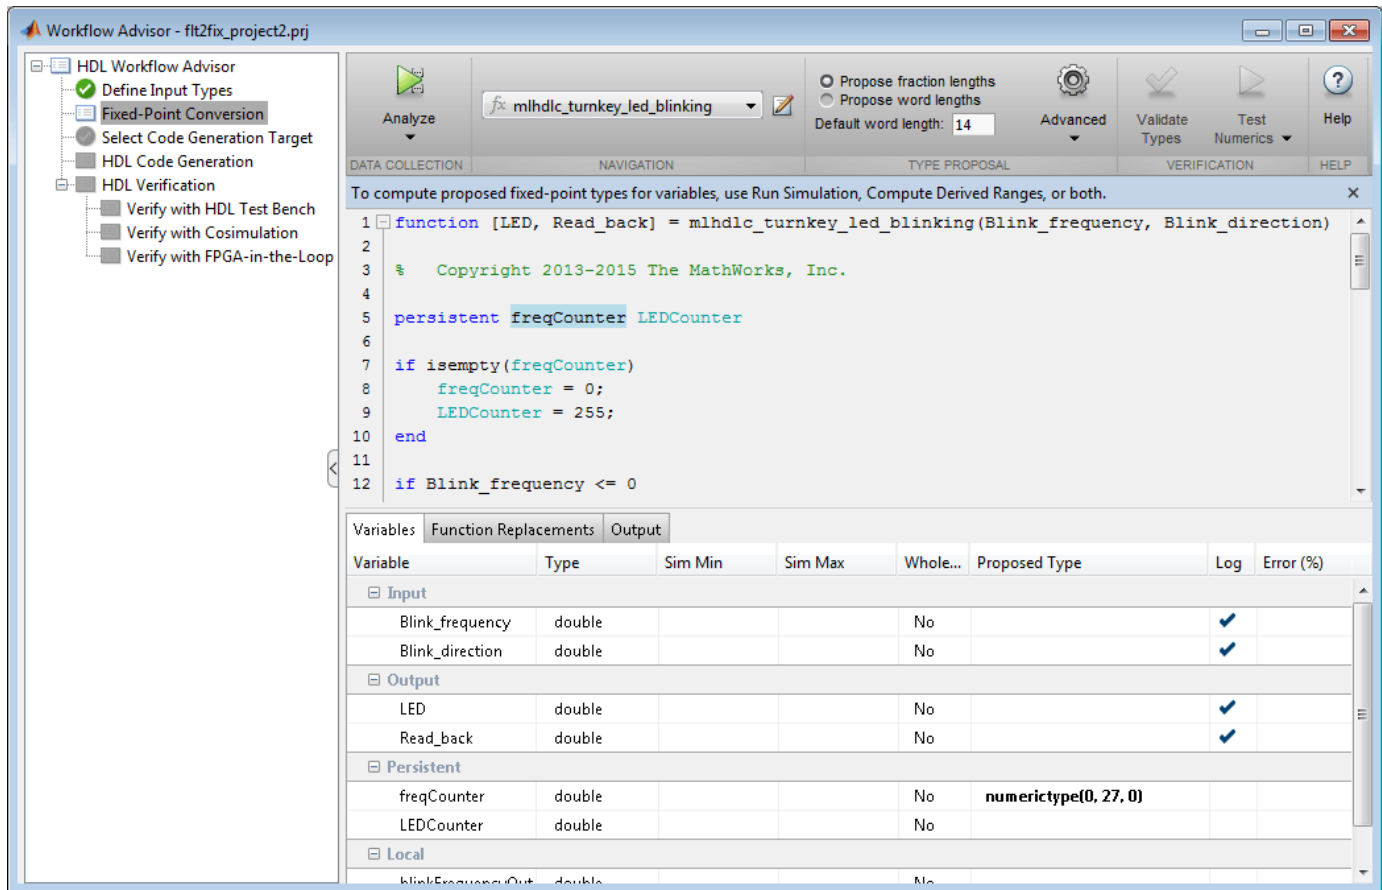

```
coder -hdlcoder -new mlhdlc_turnkey_led_blinking_prj
```

Next, add the file `mlhdlc_turnkey_led_blinking.m` to the project as the MATLAB Function and `mlhdlc_turnkey_led_blinking_tb.m` as the MATLAB Test Bench.

For a more complete tutorial on creating and populating MATLAB HDL Coder projects, see “Get Started with MATLAB to HDL Workflow”.

Convert Design To Fixed-Point

1. Right-click the **Define Input Types** task and select **Run This Task**.
2. In the Fixed-Point Conversion task, click **Advanced** and set the **Safety margin for sim min/max (%)** to 0.
3. Set the proposed type of the `freqCounter` variable to unsigned 27-bit integer by entering `numericType(0, 27, 0)` in its **Proposed Type** column.

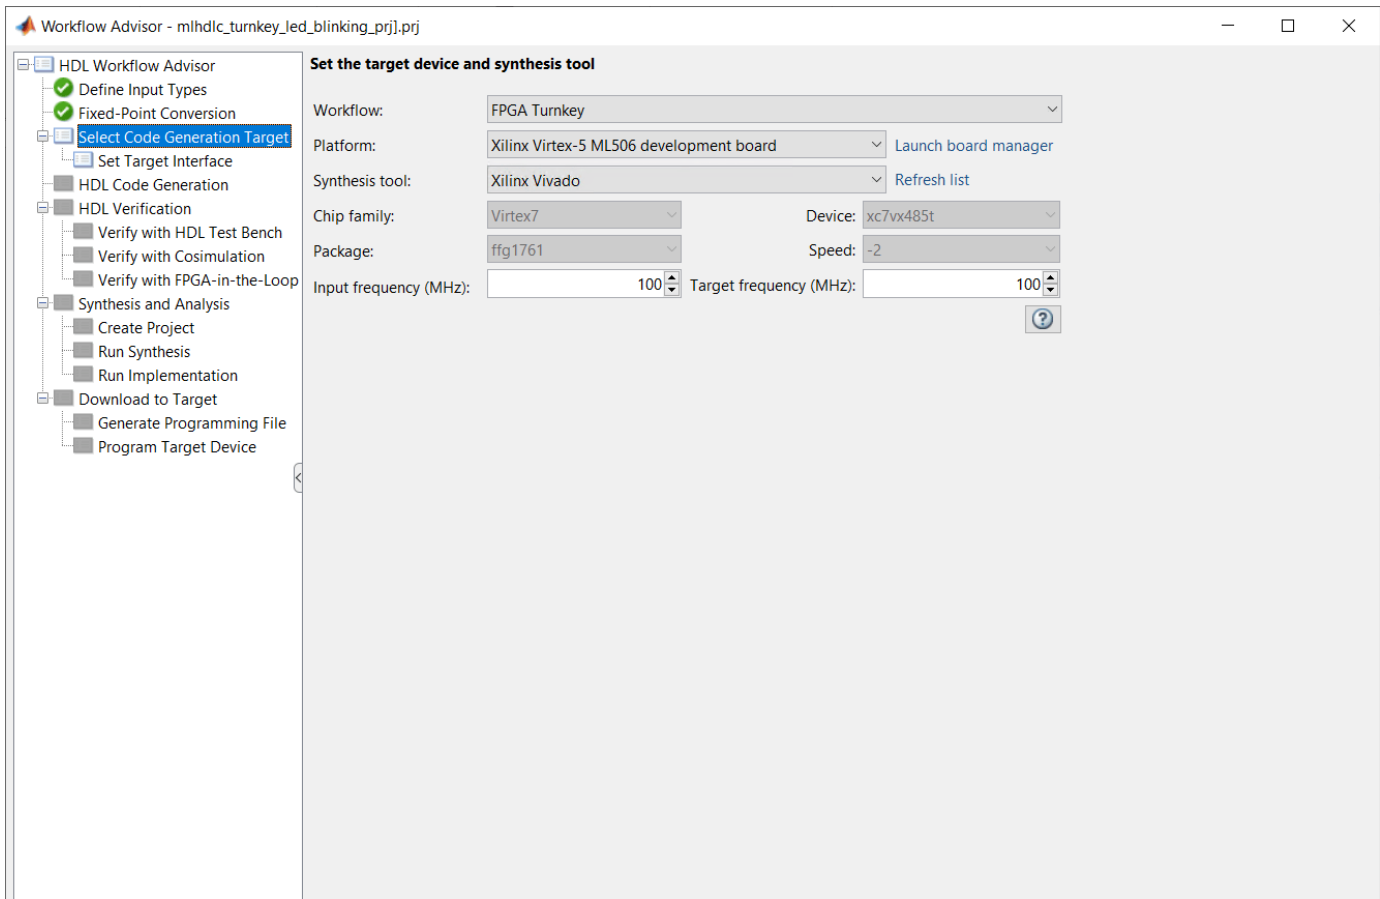

4. On the left, right-click the **Fixed-Point Conversion** task and select **Run This Task**.

Map Design Ports to Target Interface

In the **Select Code Generation Target** task, select the **FPGA Turnkey** workflow and **Xilinx Virtex-5 ML506 development board** as follows:

1. For **Workflow**, select **FPGA Turnkey**.
2. For **Platform**, select **Xilinx Virtex-5 ML506 development board**. If your target device is not in the list, select **Get more** to download the support package. The coder automatically sets **Chip family**, **Device**, **Package**, and **Speed** according to your platform selection.
3. For the FPGA clock frequency, set both **Input frequency (MHz)** and **Target frequency (MHz)** to 100.

4. In the **Set Target Interface** task, map the design input and output ports to interfaces on the target device by setting the fields in the **Target Platform Interfaces** column as follows:

- Blink_frequency_1 to User Push Buttons N-E-S-W-C [0:4]
- Blink_direction to User Push Buttons N-E-S-W-C [0:4]
- LED to LEDs General Purpose [0:7]

You can leave the Read_back port unmapped.

Generate Programming File and Download To Hardware

You can generate code, perform synthesis and analysis, and download the design to the target hardware using the default settings:

1. For the **Synthesis and Analysis** task group, uncheck the **Skip this Step** option.
2. For the **Download to Target** task group, uncheck the **Skip this Step** option.
3. Right-click **Download to Target > Generate Programming File** and select **Run to Selected Task**.
4. If your target hardware is connected and ready to program, select the **Program Target Device** subtask and click **Run**.

Get Started with Simscape Hardware-in-the-Loop Workflow

You can convert a Simscape model to HDL code for field-programmable gate array (FPGA) deployment, which requires HDL Coder. The simulation of physical systems is accelerated, enabling you to rapidly prototype models. The conversion also provides real-time simulation of your HDL implementation model by using hardware-in-the-loop (HIL) simulation.

You can perform HIL simulation with smaller time steps and increased accuracy by deploying the Simscape plant models to the generic FPGAs, system on a chip (SoCs), or Speedgoat FPGA I/O modules. Using this workflow, you can:

- Generate an HDL implementation model by using the Simscape HDL Workflow Advisor. The implementation model is a Simulink model that replaces the Simscape components with HDL-compatible Simulink blocks. For more information, see *Generate HDL Implementation Model by Using the Simscape HDL Workflow Advisor* on page 37-4.
- Generate HDL code for the implementation model, and then deploy the generated code to Speedgoat FPGA I/O modules by using the HDL Workflow Advisor. For more information, see *HDL Code Generation and Deployment* on page 37-7.

You can model and deploy complex physical systems in Simscape while converting your models into HDL code.

This workflow diagram shows the functionalities at various stages of the Simscape hardware-in-the-loop workflow.

Modeling Physical Systems in Simscape for HDL Compatibility

When you design your Simscape model for compatibility with the Simscape HDL Workflow Advisor, follow these guidelines. Before using this workflow, convert Simscape subsystems into state-space algorithms. For more information, see “Modeling Guidelines for Simscape Subsystem Replacement” on page 37-9.

You can create a Simscape model by using linear, switched linear, and nonlinear blocks.

- Linear blocks are blocks that are defined by a linear relationship such as resistors.
- Switched linear blocks are blocks such as diodes and switches. These blocks are also defined by a linear relationship, such as $V = IR$, where R can switch between two or more values depending on the state of the diodes or switches.
- Nonlinear blocks are blocks that are defined by nonlinear equations, such as nonlinear resistor, nonlinear inductor, DC Motor, and PMSM blocks.

You can choose a solver type (Backward Euler or Partitioning) based on the type of blocks in your model. If you have linear and switched linear blocks in your model, choose the Backward Euler solver

type. If you have nonlinear blocks in your model, choose the Partitioning solver type. For more information, see Solver Configuration.

Configure Solver Settings

To configure the solver settings for HDL code generation, open your model, for example:

```
open_system('sschdlexBoostConverterExample/Simscape_system')
```

Double-click the Solver Configuration block.

Select Solver type

To choose a solver type for the block, double-click the Solver Configuration block.

- 1 In the Block Parameters dialog box, select **Use local solver**.
- 2 From the **Solver type** drop-down list, select **Backward Euler** for linear and switched linear blocks. For nonlinear blocks, select **Partitioning**. For boost converter, select **Backward Euler**.

Specify Sample Time

Similarly you can specify a discrete sample time.

- 1 In the Block Parameters dialog box, select **Use local solver**.
- 2 In the **Sample time** text box, specify a discrete sample time T_s .

To verify that the solver settings are specified correctly, run the “Check Solver Configuration” on page 38-3 in the Simscape HDL Workflow Advisor.

Run hdlsetup Function

After creating the model, configure the model for HDL code generation by running the `hdlsetup` function. The function `hdlsetup` sets your model configuration parameters to default values recommended for code generation. Open the model before you invoke the `hdlsetup` function.

To invoke `hdlsetup` function for your `current_model`, at the MATLAB command prompt, enter:

```
hdlsetup('current_model')
```

After running `hdlsetup` function, make sure your model compiles without any errors or warnings.

Simscape Example Models for HDL Code Generation

For HDL code generation, you can design your own Simscape algorithm or choose from a list of example models that are created in Simscape.

Example Models That Use Backward Euler Solver

- Boost converter on page 37-102
- Bridge rectifier on page 37-95
- Buck converter on page 37-9
- Half-wave rectifier on page 37-13

- Solar power inverter model on page 37-64
- Three-phase converter with grid on page 37-49
- Two-level converter ideal on page 37-28
- Variable resistor on page 37-80
- Vienna rectifier on page 37-20

Example Models That Use Partitioning Solver

- Permanent magnet synchronous motor (PMSM) on page 37-106
- DC motor on page 37-113
- Two-speed transmission on page 37-132
- Three-phase PMSM drive on page 37-125

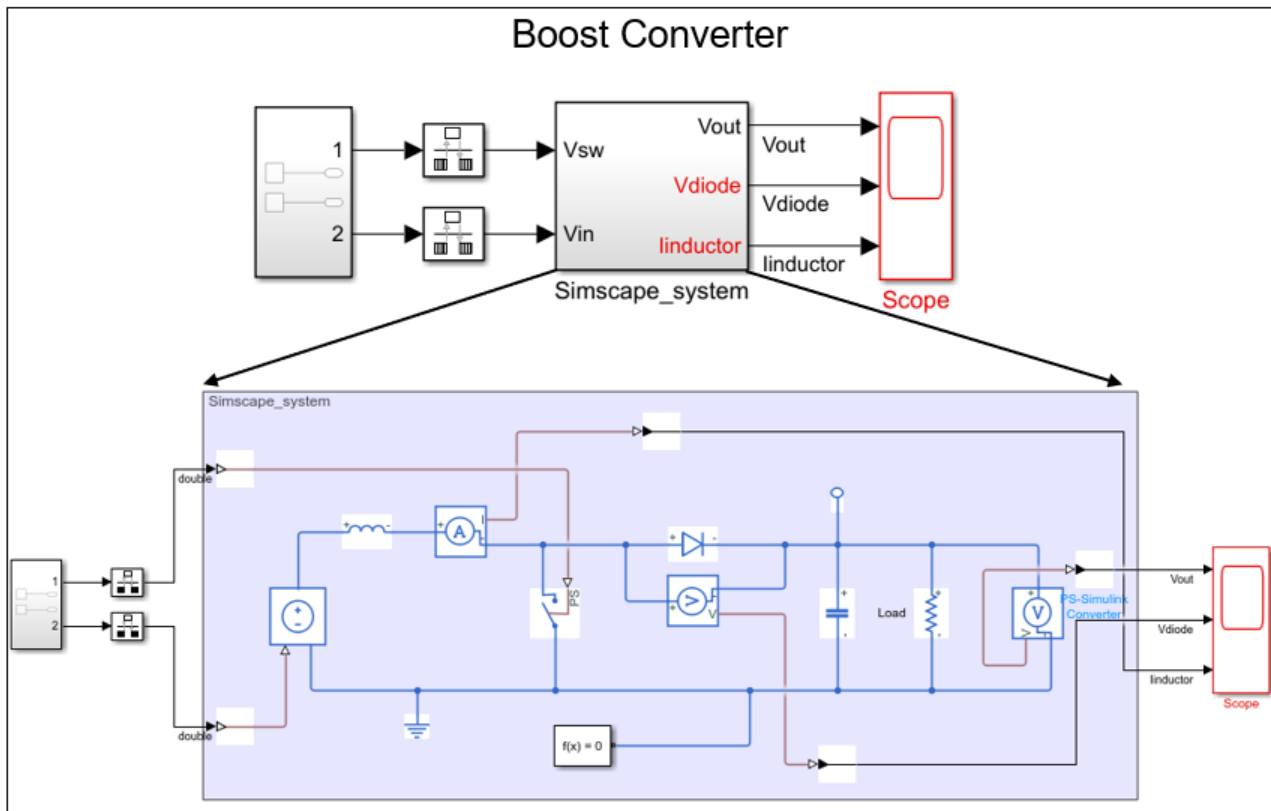

All examples are prefixed with `sschdlex` and postfixed with `Example`. For example, to open the boost converter model, at the MATLAB command prompt, enter:

```
load_system('sschdlexBoostConverterExample')  
open_system('sschdlexBoostConverterExample/Simscape_system')
```

You can also find many other application-specific example models. To get a list of all the Simscape models designed for HDL code generation, type `sschdlex` in the MATLAB Command Window and press the **Tab** key.

Generate HDL Implementation Model by Using the Simscape HDL Workflow Advisor

You first generate an HDL implementation model from the Simscape model by using the Simscape HDL Workflow Advisor.

To generate an HDL implementation model, open the Simscape HDL Workflow Advisor.

At the MATLAB command prompt, run the `sschdladvisor` function:

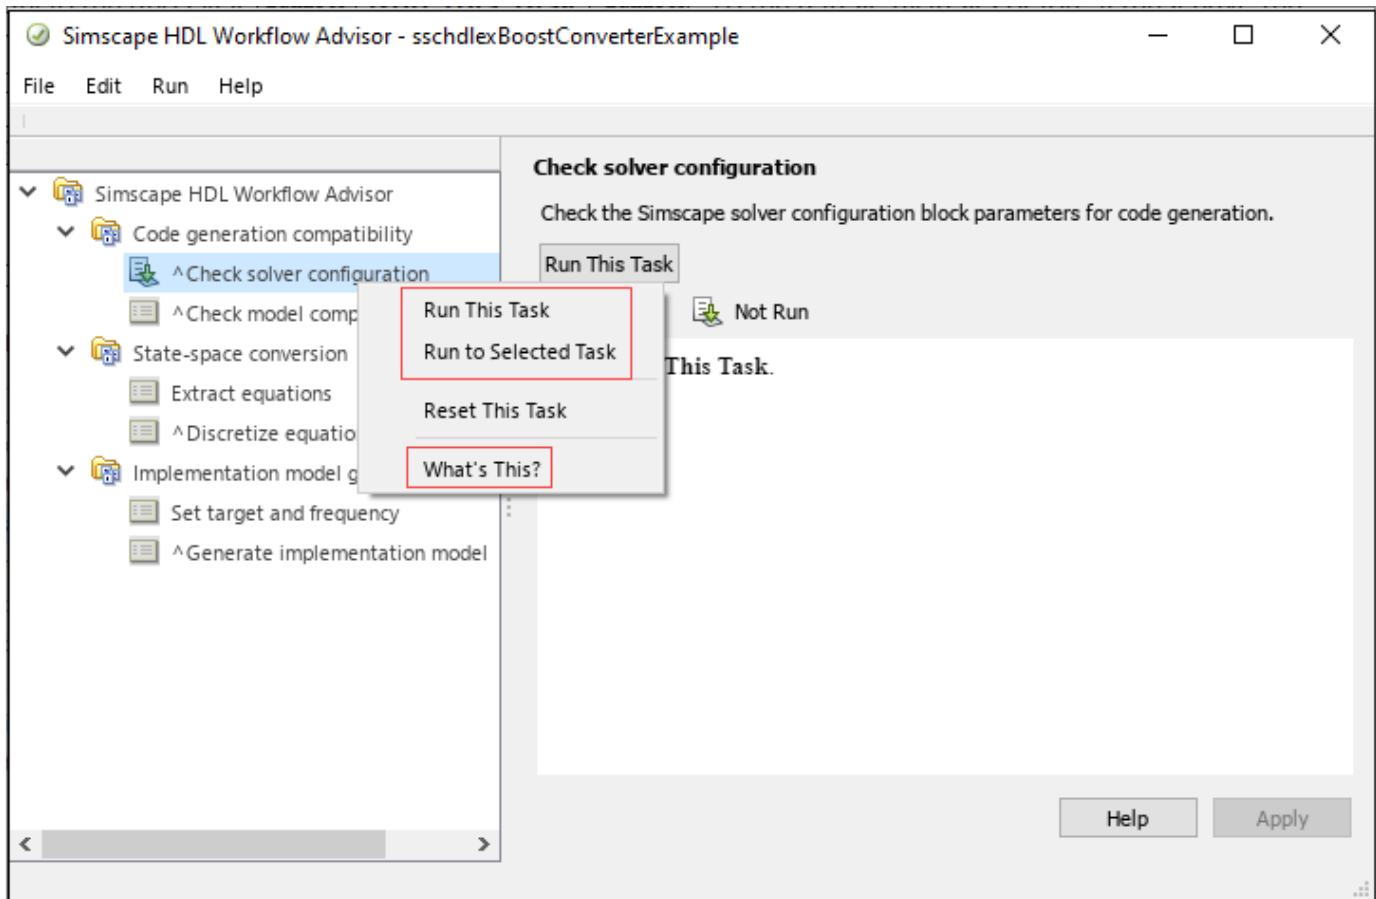

```
sschdladvisor('current_model')
```

This function opens the Simscape HDL Workflow Advisor for the `current_model`.

Run Tasks in the Simscape HDL Workflow Advisor

In the Simscape HDL Workflow Advisor, the left pane lists the folders containing a group or category of related tasks. Expanding the folders shows available tasks in each folder. From the left pane, you can select a folder or an individual task and see the related information in the right pane. For the tasks in the left pane, the right pane contains controls for running the task, a display area for status messages, and other task results. To learn more about each individual task, right-click that task, and select **What's This?** from the list.

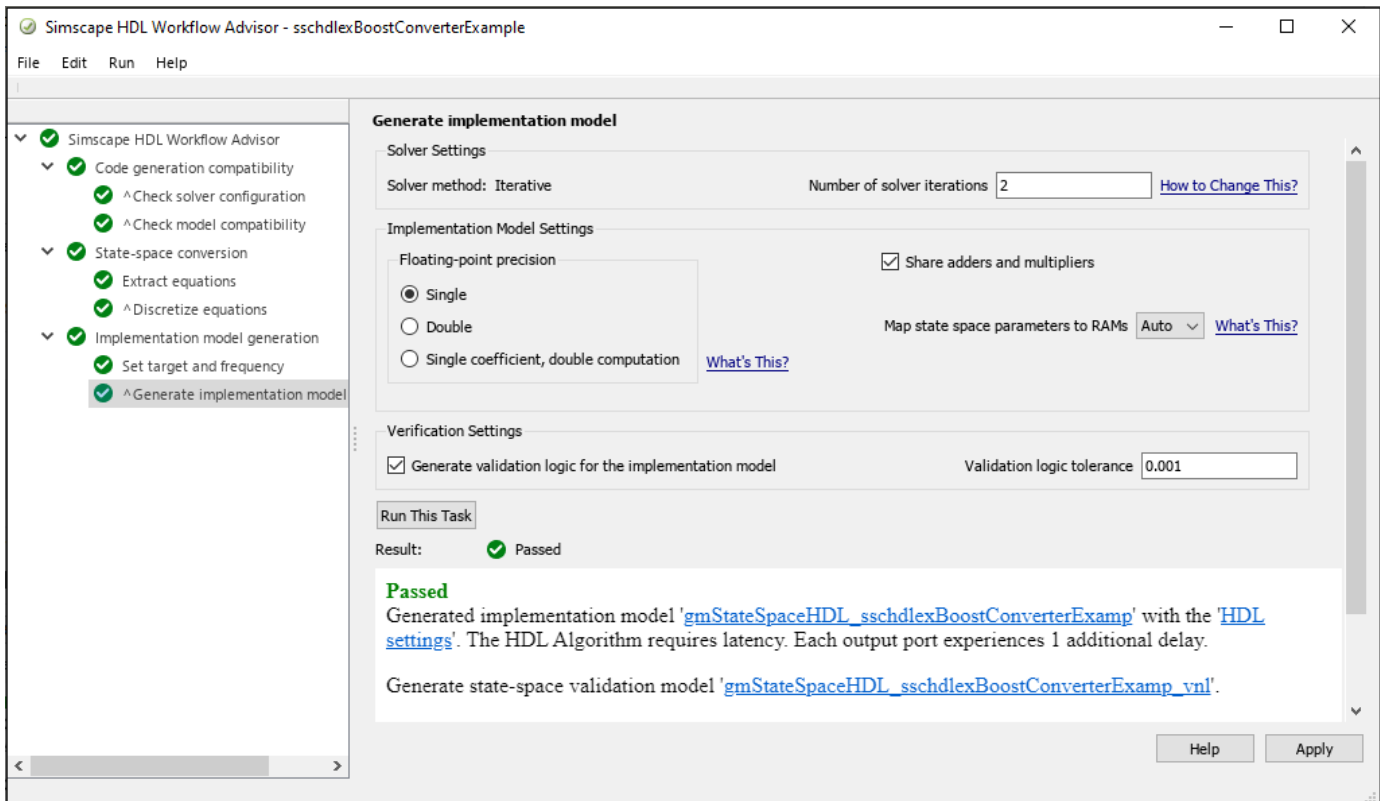

In the Simscape HDL Workflow Advisor window, you can run an individual task or all the tasks in the list. Select the task that you want to run and click **Run This Task**. To run a task, all tasks before it must have run successfully. To run the workflow to a specific task inside a subfolder, expand that folder, and then right-click the task and select **Run to Selected Task**.

To run the workflow and compare functionality of the HDL implementation model with the original Simscape algorithm:

- 1 Select the **Generate implementation model** task.
- 2 Under **Verification Settings**, select the **Generate validation logic for the implementation model** check box. This enables the **Validation logic tolerance** which is set with the default value of 0.001.
- 3 Right-click the **Generate implementation model** task and select **Run to Selected Task** from the list.

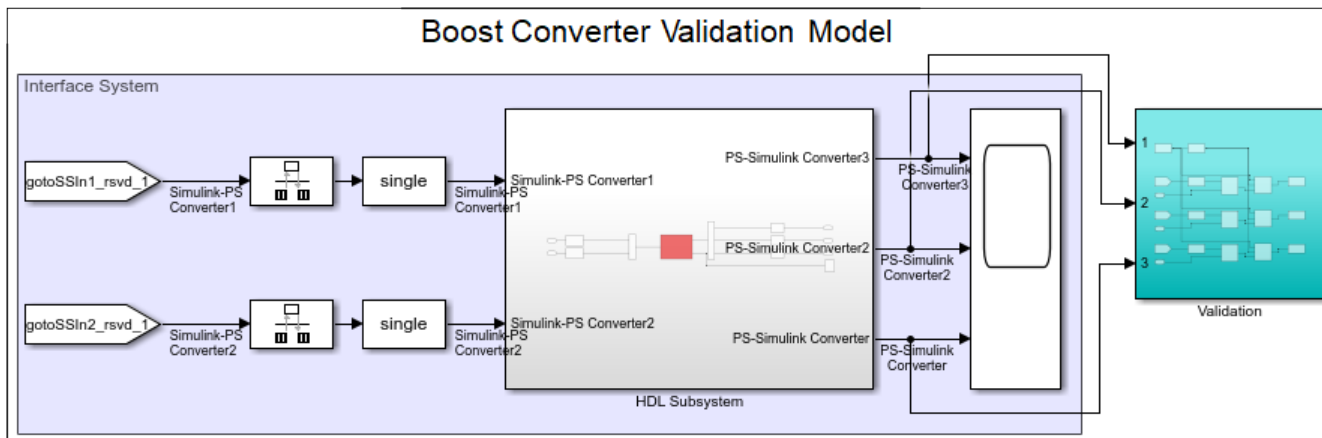

After the task passes, you see a link to the HDL implementation model and a state-space validation model. The implementation model has the same name as the original Simscape model and uses the prefix gmStateSpaceHDL. The state-space validation model has the same name as the implementation model and uses the postfix _vn \downarrow .

For more information on Simscape HDL Workflow Advisor tasks, see “Simscape HDL Workflow Advisor Tasks” on page 38-2.

HDL Code Generation and Deployment

For HDL code generation, you can verify the numeric results of the HDL implementation model and your original Simscape algorithm by using the generated state-space validation model.

Before you generate HDL code, validate the generated HDL implementation model.

Validate HDL Algorithm

You can compare the functionality of the HDL implementation model to the original Simscape algorithm. To validate the HDL implementation model, simulate the state-space validation model. If the simulation does not result in any assertion or warning, then it indicates that the output of the HDL implementation model matches the original Simscape algorithm within the specified tolerance. For more information, see “Validate HDL Implementation Model to Simscape Algorithm” on page 37-95.

Generate Code

Once you validate the HDL algorithm, you can then generate HDL code for the implementation model. At the MATLAB command prompt, enter:

```
makehdl('gmStateSpaceHDL_current_model/HDL Subsystem')
```

For more information, see “Generate HDL Code for Simscape Models” on page 37-13.

After generating the HDL code, you can deploy the real-time model onto your target hardware. For more information on how to deploy the code, see “Deploy Simscape Buck Converter Model to Speedgoat IO Module Using HDL Workflow Script” on page 37-36.

Restrictions for HDL Code Generation from Simscape Models

HDL Coder does not support code generation from Simscape networks that contain:

- events
- delay
- Run-time parameters (Simscape)
- Simscape Multibody™ blocks
- Simscape Electrical™ Specialized Power Systems blocks
- Time-varying Simscape source blocks, such as PS Counter, PS Random Number, PS Repeating Sequence, and PS Uniform Random Number
- Partitions that have nonlinear equation type. For more information, see “Understanding How the Partitioning Solver Works” (Simscape).

More About

- “Generate HDL Code for Simscape Models” on page 37-13
- “Simscape HDL Workflow Advisor Tips and Guidelines” on page 38-7
- “Generate Simulink Real-Time Interface Subsystem for Simscape Two-Level Converter Model” on page 37-28

Modeling Guidelines for Simscape Subsystem Replacement

To generate HDL code for Simscape algorithms, you generate an HDL implementation model by using the Simscape HDL Workflow Advisor. If you follow certain guidelines when modeling the Simscape algorithm, the Simscape HDL Workflow Advisor replaces the Simscape subsystem with a corresponding HDL `Subsystem` block in the HDL implementation model. The HDL `Subsystem` block contains the state-space algorithm that uses HDL-compatible Simulink blocks instead of Simscape blocks. You can generate HDL code for the HDL `Subsystem` block and deploy the code onto FPGA target devices and FPGAs on board Speedgoat FPGA I/O modules. In this case, when you select the **Generate validation logic for the implementation model** check box in the **Generate implementation model** task of the Simscape HDL Workflow Advisor, the Advisor generates a separate state-space validation model. This model compares the outputs from the HDL `Subsystem` and the original Simscape subsystem to verify that they are functionally equivalent.

If you do not follow the guidelines, the Simscape HDL Workflow Advisor might not be able to perform this replacement. In that case, the HDL implementation model contains the state-space algorithm with the original Simscape subsystem beside it. Before generating code, you modify the implementation model and rearrange the blocks such that it replaces the Simscape subsystem with the state-space algorithm. In this case, when you select the **Generate validation logic for the implementation model** check box, the Advisor places a validation logic subsystem inside the implementation model to verify functional equivalence.

In addition to these guidelines, make sure that the Simscape model is configured for compatibility with Simscape HDL Workflow Advisor. See “Modeling Physical Systems in Simscape for HDL Compatibility” on page 37-2.

Enclose Simscape Blocks Inside a Subsystem

- Enclose the Simscape blocks for which you are generating an HDL implementation model inside a Subsystem block and provide the test inputs. Inside the Subsystem block, your model can have multiple hierarchies that use Simscape blocks.
- Do not use masked subsystems. The Simscape HDL Workflow Advisor cannot replace masked subsystems in the HDL implementation model. For automatic subsystem replacement, you can use masked subsystems that have cosmetic masks. Cosmetic masks are masks that only has an icon but doesn't have any parameters or initialization code.
- Inside the Subsystem block that contains Simscape blocks, at the input ports, add Simulink-PS Converter blocks. At the output ports of this subsystem, add PS-Simulink Converter blocks.
 - Use a meaningful name for the Simulink-PS Converter and PS-Simulink Converter blocks.

The Simscape HDL Workflow Advisor uses the names of the Simulink-PS Converter and PS-Simulink Converter blocks for the input and output ports of the HDL `Subsystem` block. Using a meaningful name makes it easier to identify what the input and output ports in the HDL implementation model correspond to.

- In the Block Parameters dialog box of the Simulink-PS Converter and PS-Simulink Converter blocks, on the **Input Handling** tab, leave **Filtering and derivatives** set to Provide signals and **Provided signals** set to Input only.

For example, open the buck converter model. The `Simscape_system` block contains Simscape blocks. Blocks outside this subsystem form the test environment.

```
open_system('sschdlexBuckConverterExample')
sim('sschdlexBuckConverterExample')
```

Inside the Simscape_system subsystem, the model uses Simscape blocks and physical signals. The model has Simulink-PS Converter and PS-Simulink Converter blocks at the interfaces. Provide unique names for these blocks such that they match the corresponding port names.

```
open_system('sschdlexBuckConverterExample/Simscape_system')
```

Multiple Simscape Network Considerations

If your Simscape model contains multiple networks:

- Enclose each network inside a subsystem. Add Simulink-PS Converter and PS-Simulink Converter blocks at the subsystem interface.
- Use a Solver Configuration block for each network. Use the same sample time across Solver Configuration blocks inside the different networks.

For example, this model contains more Simscape networks than Solver Configuration blocks, the Simscape network is not replaced with the HDL subsystem.

The Simscape HDL Workflow Advisor then replaces each Simscape subsystem with the corresponding HDL Subsystem.

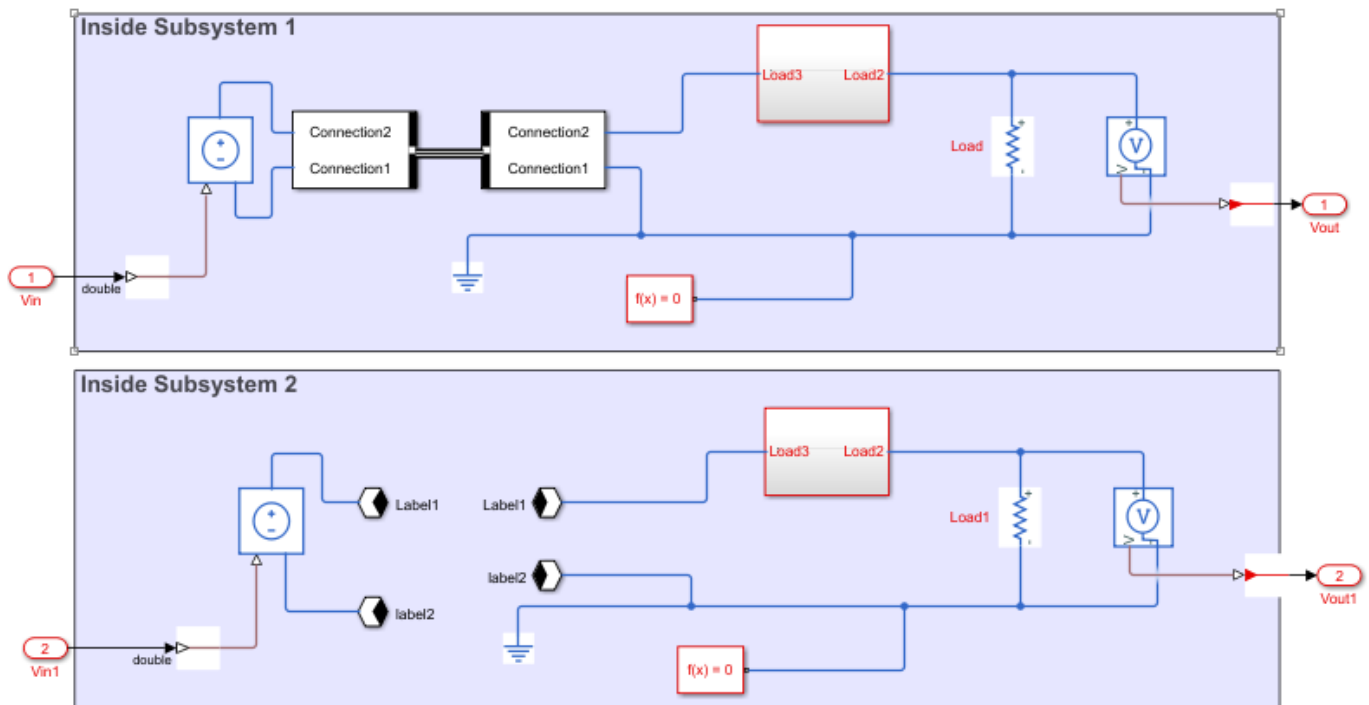

For an example that shows how to generate HDL code for a model that has multiple networks, see “Generate HDL Code for Simscape Models with Multiple Networks” on page 37-71.

Avoid Using Certain Blocks in Simscape Utilities Library

To generate an implementation model that replaces the Simscape subsystem with the state-space algorithm, in your original Simscape model, do not use these blocks from the **Simscape > Utilities** Library:

- Simscape Bus
- Connection Port
- Connection Label

For example, this model contains Connection Label and Simscape Bus blocks inside two different subsystems. The Simscape HDL Workflow Advisor cannot replace these subsystems with the state-space algorithm.

More About

- “Get Started with Simscape Hardware-in-the-Loop Workflow” on page 37-2
- “Generate HDL Code for Simscape Models” on page 37-13
- “Generate Simulink Real-Time Interface Subsystem for Simscape Two-Level Converter Model” on page 37-28

Generate HDL Code for Simscape Models

This example shows how to generate HDL code for a half-wave rectifier model that uses Simscape™ blocks. Use the Simscape HDL Workflow Advisor to generate an HDL implementation model. You can then generate HDL code for the implementation model. See “Get Started with Simscape Hardware-in-the-Loop Workflow” on page 37-2.

The Halfwave Rectifier Model

To open the half-wave rectifier model, at the MATLAB® command prompt, enter:

```
open_system('sschdlexHalfWaveRectifierExample')
```

Save this model locally as `HalfWaveRectifier_HDL` to run the workflow.

```
open_system('HalfWaveRectifier_HDL')
set_param('HalfWaveRectifier_HDL', 'SimulationCommand', 'Update')
```

Copyright 2020 The MathWorks, Inc.

At the top level of the model, a `Simscape_system` block models the half-wave rectifier algorithm. The model accepts a Sine Wave input, uses a Rate Transition block to discretize the continuous time input, and has a Scope block that calculates the output. To see the half-wave rectifier algorithm, double-click the `Simscape_system` subsystem.

```
open_system('HalfWaveRectifier_HDL/Simscape_system')
```

The half-wave rectifier consists of a resistor, which is a linear block, and a diode, which is a switched linear block. The Simscape model is preconfigured for HDL compatibility. At the input and output port interfaces, the model has Simulink-PS Converter and PS-Simulink Converter blocks. The solver settings are configured for compatibility with Simscape HDL Workflow Advisor. If you open the Block Parameters dialog box for the Solver Configuration block, **Use local solver** is selected and **Backward Euler** is specified as the **Solver type**. See “Get Started with Simscape Hardware-in-the-Loop Workflow” on page 37-2.

To see the functionality, simulate the model and then open the Scope block.

```
sim('HalfWaveRectifier_HDL')
open_system('HalfWaveRectifier_HDL/Scope')
```

Run Simscape HDL Workflow Advisor

To generate an HDL implementation model from which you generate code, use the Simscape HDL Workflow Advisor. To open the Advisor, run this command:

```
sschdladvisor('HalfWaveRectifier_HDL')
```

This command updates the model advisor cache and opens the Simscape HDL Workflow Advisor. To learn more about the Simscape HDL Workflow Advisor and the various tasks, right-click that folder or task, and select **What's This?**. See also “Simscape HDL Workflow Advisor Tasks” on page 38-2.

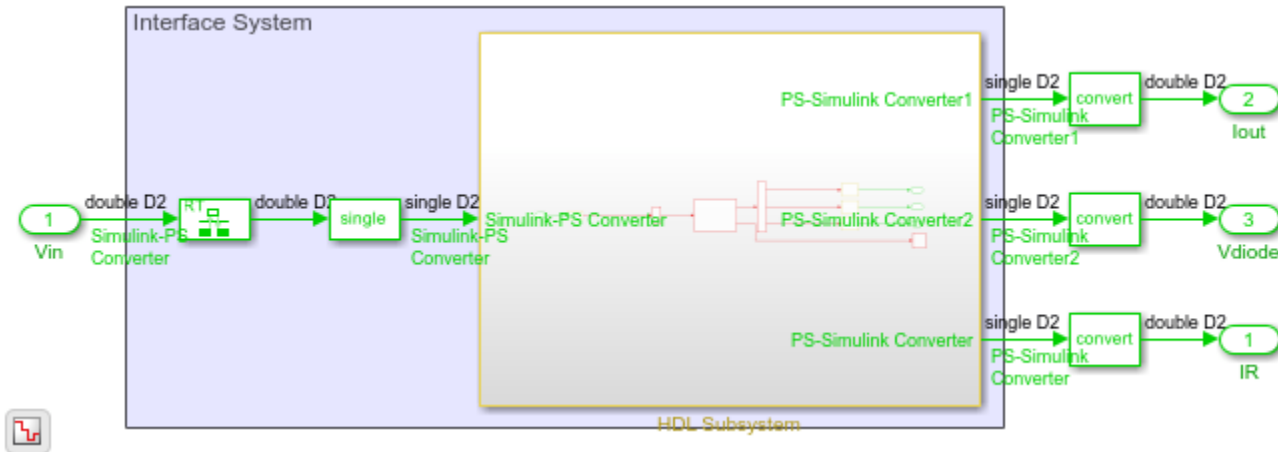

To run the workflow and compare functionality of the HDL implementation model with the original Simscape algorithm, select the **Generate implementation model** step, and then select the **Generate validation logic for the implementation model** check box. Use a **Validation logic tolerance** of 0.001. Right-click the **Generate implementation model** step and select **Run to Selected Task**.

The Advisor generates an HDL implementation model and a state-space validation model. The implementation model has the same name as the original Simscape model and uses the prefix gmStateSpaceHDL_. The state-space validation model has the same name as the implementation model and uses the postfix _vnl.

Open and Examine HDL Implementation Model

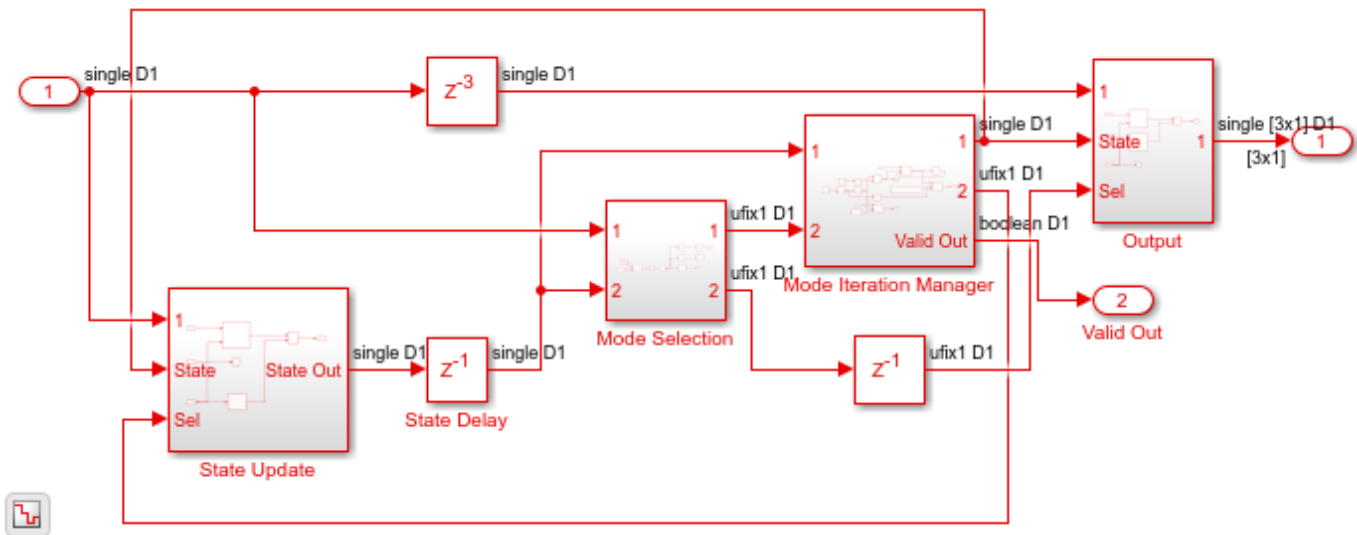

In the **Generate implementation model task**, click the link to open the implementation model. The model contains a `Simscape_system` subsystem that contains a `HDL Subsystem` block. The `HDL Subsystem` models the state-space representation that you generated from the Simscape model.

```
open_system('gmStateSpaceHDL_HalfWaveRectifier_HDL')
open_system('gmStateSpaceHDL_HalfWaveRectifier_HDL/Simscape_system')
set_param('gmStateSpaceHDL_HalfWaveRectifier_HDL','SimulationCommand','Update')
```

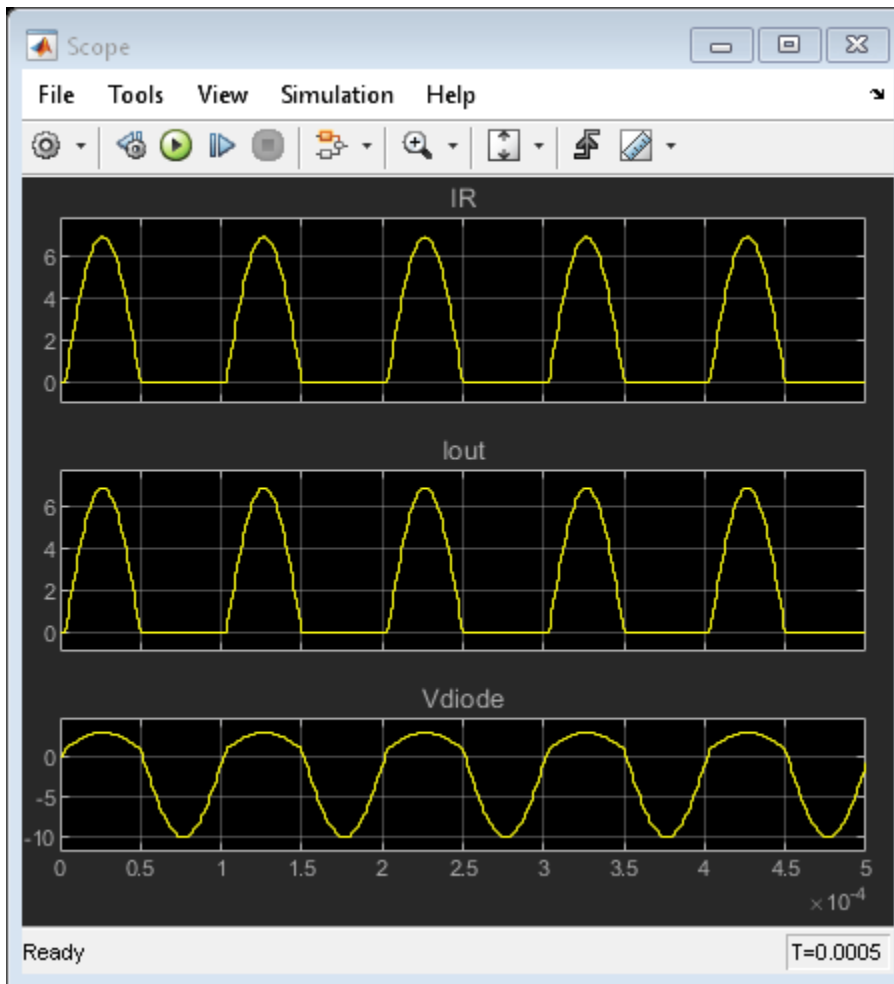

The ports of this subsystem use the same name as the Simulink-PS Converter and PS-Simulink Converter blocks in your original Simscape model. If you navigate inside this subsystem, you see several delays, adders, and Matrix Multiply blocks that model the state-space equations.

```
open_system('gmStateSpaceHDL_HalfWaveRectifier_HDL/Simscape_system/HDL Subsystem/HDL Algorithm')
```

To simulate the HDL Implementation model, enter these commands. Open the Scope block to view results.

```
sim('gmStateSpaceHDL_HalfWaveRectifier_HDL')
open_system('gmStateSpaceHDL_HalfWaveRectifier_HDL/Scope')
```

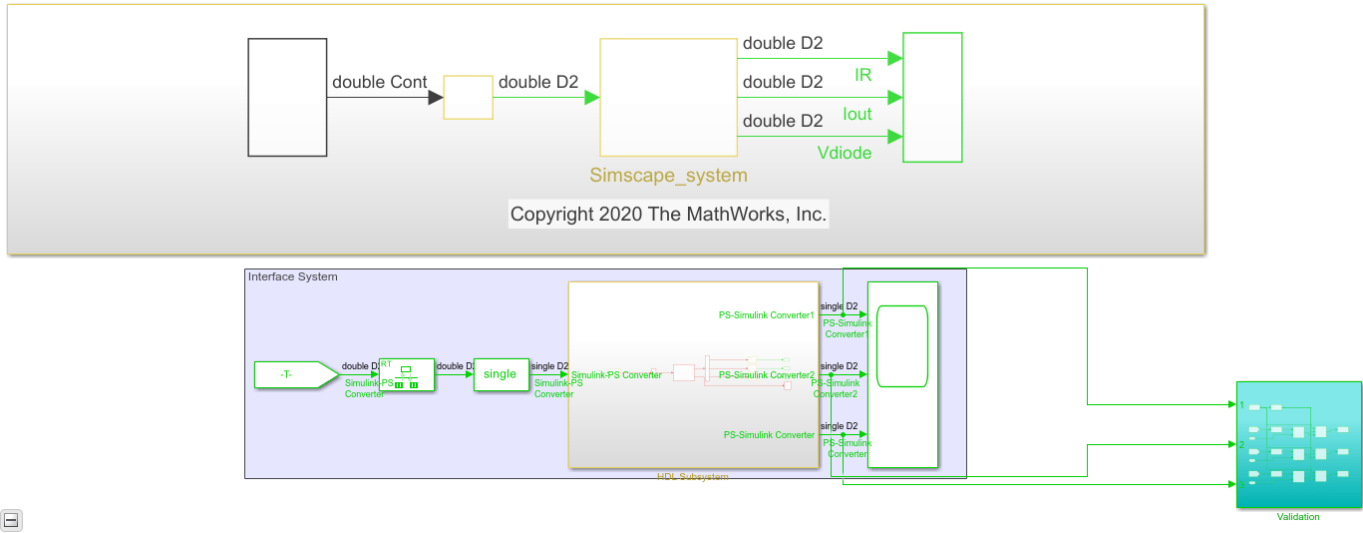

HDL code is generated for the HDL Subsystem block inside this model.

Validate HDL Algorithm

To compare functionality of the HDL implementation model with the original Simscape algorithm, open and simulate the state-space validation model.

```
open_system('gmStateSpaceHDL_HalfWaveRectifier_HDL_vnl')
sim('gmStateSpaceHDL_HalfWaveRectifier_HDL_vnl')
```

The output of this model matches the original Simscape model. The simulation does not generate assertions, which indicates that the outputs match. For a more systemic verification, see “Validate HDL Implementation Model to Simscape Algorithm” on page 37-95.

Generate HDL Code and Validation Model

The HDL model and subsystem parameter settings are saved using this command:

```
hdlsaveparams('gmStateSpaceHDL_HalfWaveRectifier_HDL');
```

```

%% Set Model 'gmStateSpaceHDL_HalfWaveRectifier_HDL' HDL parameters
hdlset_param('gmStateSpaceHDL_HalfWaveRectifier_HDL', 'FPToleranceValue', 1.000000e-03);
fpconfig = hdlcoder.createFloatingPointTargetConfig('NATIVEFLOATINGPOINT' ...
, 'LatencyStrategy', 'Min' ...
);
hdlset_param('gmStateSpaceHDL_HalfWaveRectifier_HDL', 'FloatingPointTargetConfiguration', fpconfi
hdlset_param('gmStateSpaceHDL_HalfWaveRectifier_HDL', 'HDLSubsystem', 'gmStateSpaceHDL_HalfWaveR
hdlset_param('gmStateSpaceHDL_HalfWaveRectifier_HDL', 'MaskParameterAsGeneric', 'on');
hdlset_param('gmStateSpaceHDL_HalfWaveRectifier_HDL', 'Oversampling', 13);
hdlset_param('gmStateSpaceHDL_HalfWaveRectifier_HDL', 'UseFloatingPoint', 'on');

hdlset_param('gmStateSpaceHDL_HalfWaveRectifier_HDL/Simscape_system/HDL Subsystem/HDL Algorithm/

```

The model uses single data types and generates HDL code in **Native Floating Point** mode. Floating-point operators can introduce delays. Because the design contains feedback loops, to allocate sufficient delays for the operators inside the feedback loops, the model uses clock-rate pipelining.

For more information, see:

- “Clock-Rate Pipelining” on page 28-149
- “Oversampling factor” on page 21-15
- “Allocate Sufficient Delays for Floating-Point Operations” on page 14-79

Before you generate HDL code, enable generation of the validation model. The validation model compares the output of the generated model after code generation and the original model. To learn more, see “Generated Model and Validation Model” on page 28-10.

Run these commands to save validation model generation settings on your Simulink model:

```
HDLmodelName = 'gmStateSpaceHDL_HalfWaveRectifier_HDL';  
hdlset_param(HDLmodelName, 'TargetDirectory', 'C:/Temp/hdlsrc');  
hdlset_param(HDLmodelName, 'GenerateValidationModel', 'on');
```

To generate HDL code, run this command:

```
makehdl('gmStateSpaceHDL_HalfWaveRectifier_HDL/Simscape_system/HDL_Subsystem');
```

The generated HDL code and validation model are saved in C:/Temp/hdlsrc directory. The generated code is saved as HDL_Subsystem.vhd. To open the validation model, click the link to gm_gmStateSpaceHDL_HalfWaveRectifier_HDL_vnl.slx in the code generation logs in the Command Window.

Open the Compare block at the output of HDL_Subsystem_vnl subsystem of the validation model. To see the simulation results after HDL code generation, double-click the Double click to turn 'on/off' all scopes block. For each of the scopes (IR, Iout, and Vdiode), the first graph represents the output of the generated model, and the middle graph represents the output of the implementation model. The bottom graph calculates the difference between outputs of both models. As the outputs match, the error is zero.

Generate Optimized HDL Implementation Model from Simscape

This example shows how you can generate an optimized HDL implementation model for a Simscape™ vienna rectifier model by using optimizations such as resource sharing and RAM mapping.

Why Optimize the HDL Implementation Model

For Simscape models that have many switching elements, the state-space representation contains a large number of configurations. The Simscape HDL Workflow Advisor simulates the Simscape model to calculate the number of relevant configurations. Certain Simscape models can have a large number of configurations that are relevant. The generated HDL implementation model for such a large design can consume a significantly large number of resources. Synthesizing the generated code can cause the design to occupy a large amount of resources on the FPGA device. In some cases, the design might not fit on the target FPGA device. To save resources and make the design fit on the FPGA, the Simscape HDL Workflow Advisor uses HDL Coder™ optimizations such as clock-rate pipelining, resource sharing, and RAM mapping.

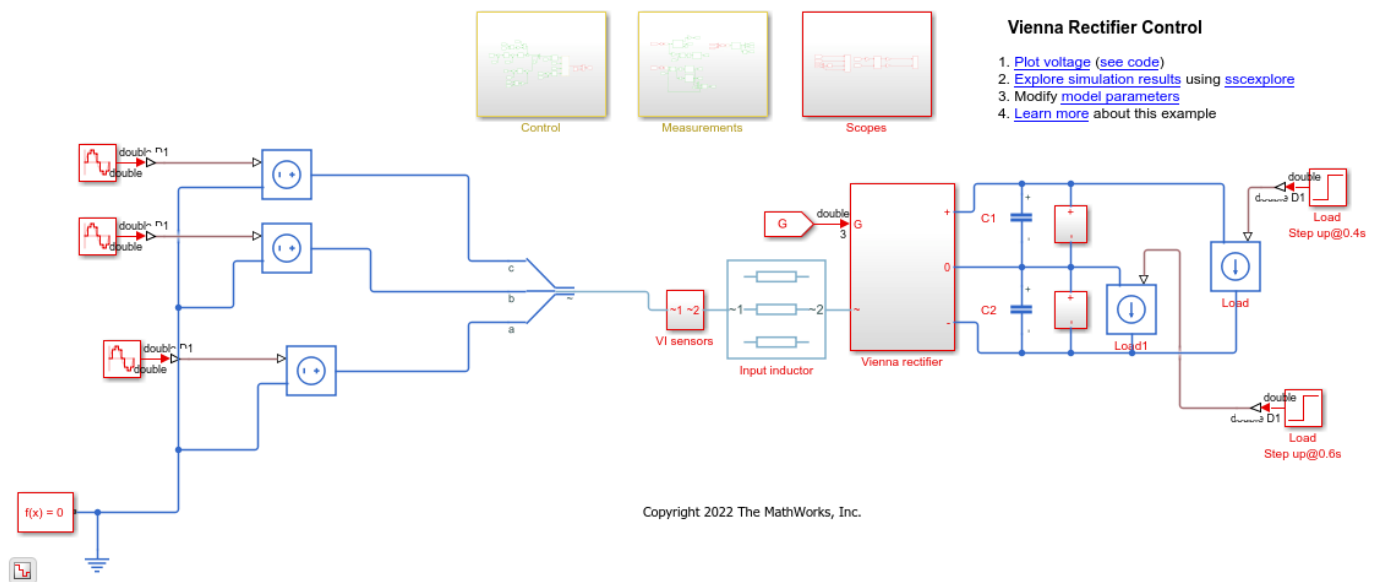

Vienna Rectifier Model

To open the model, at the MATLAB® command prompt, enter:

```
open_system('sschdlexViennaRectifierExample')
```

Save this model as ViennaRectifier_HDL to run the workflow.

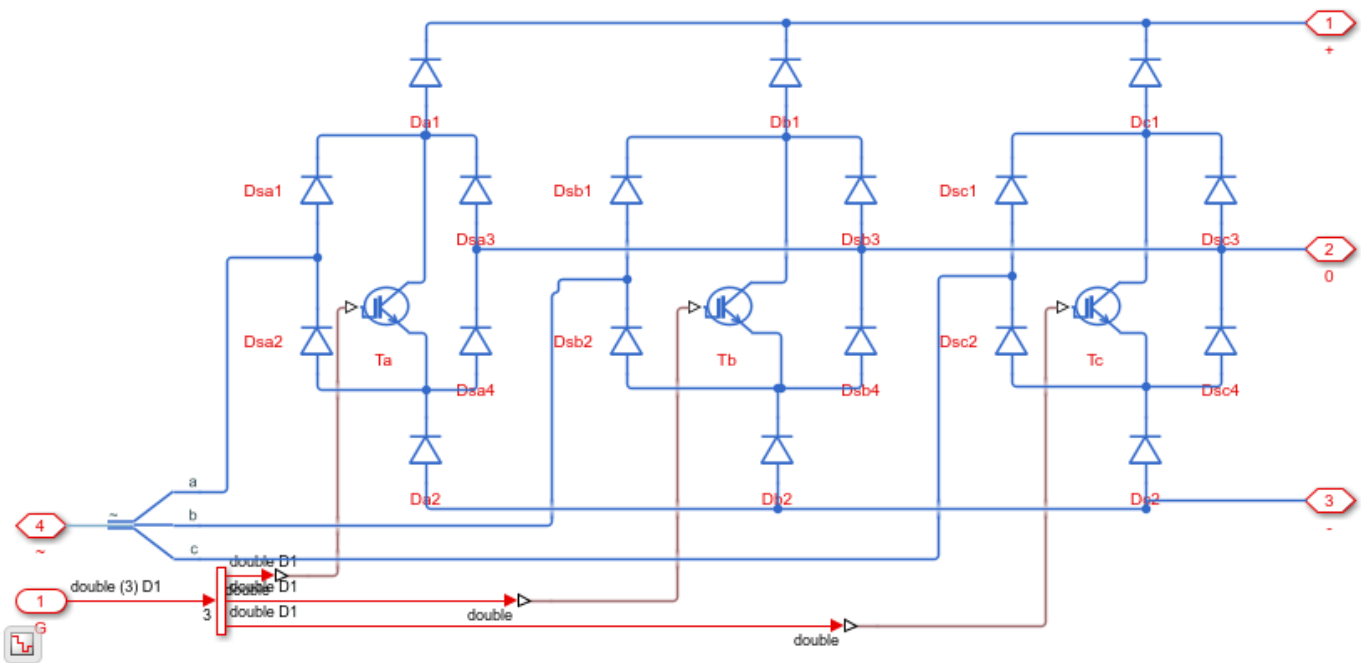

```
open_system('ViennaRectifier_HDL')
set_param('ViennaRectifier_HDL', 'SimulationCommand', 'Update')
```

The Control subsystem implements a closed-loop control strategy for the Vienna rectifier subsystem by using space-vector modulation. At simulation time 0.1s, the vienna rectifier is engaged. At times 0.4s and 0.6s, the load steps up on the DC side.

The Vienna rectifier subsystem consists of three-phase legs. Each leg has one power switch and six power diodes. See “Vienna Rectifier Control” (Simscape Electrical).

```
open_system('ViennaRectifier_HDL/Vienna_rectifier')
```

Simulate the model. View the simulation results by double-clicking the Scope blocks inside the Scopes subsystem.

```
sim('ViennaRectifier_HDL')
open_system('ViennaRectifier_HDL/Scopes/Scope')
```

Generate HDL Implementation Model and Validate HDL Algorithm

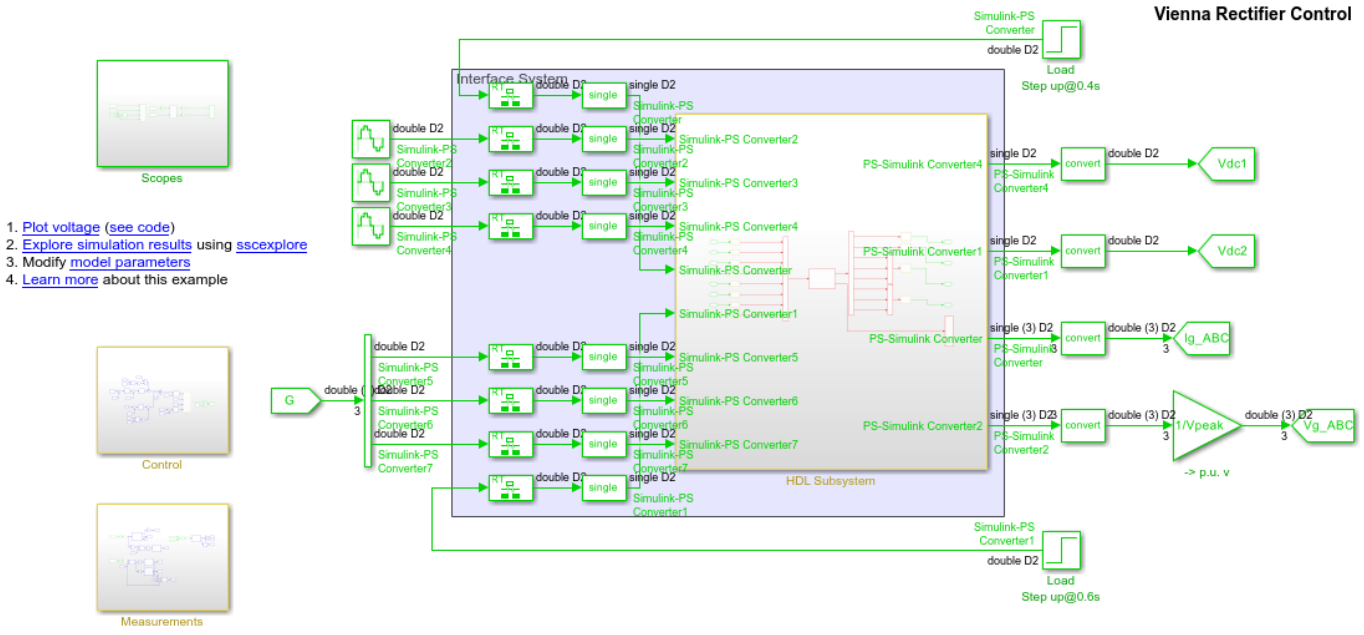

To generate an HDL implementation model, use the Simscape HDL Workflow Advisor. You can generate HDL code for the implementation model. To open the Advisor, run this command:

```
sschldadvisor('ViennaRectifier_HDL')
```

To generate the HDL implementation model, in the **Implementation model generation** subfolder, right-click the **Generate implementation model** task and select **Run to Selected Task**. After the task passes, you see a link to the HDL implementation model. To see the number of configurations, select the **Extract Equations** task under **State-space conversion** subfolder. When you click the task, you see that simulating the model reaches 397 modes. Such a large number of modes can increase resource consumption of the design on the FPGA.

To open the HDL implementation model, enter these commands:

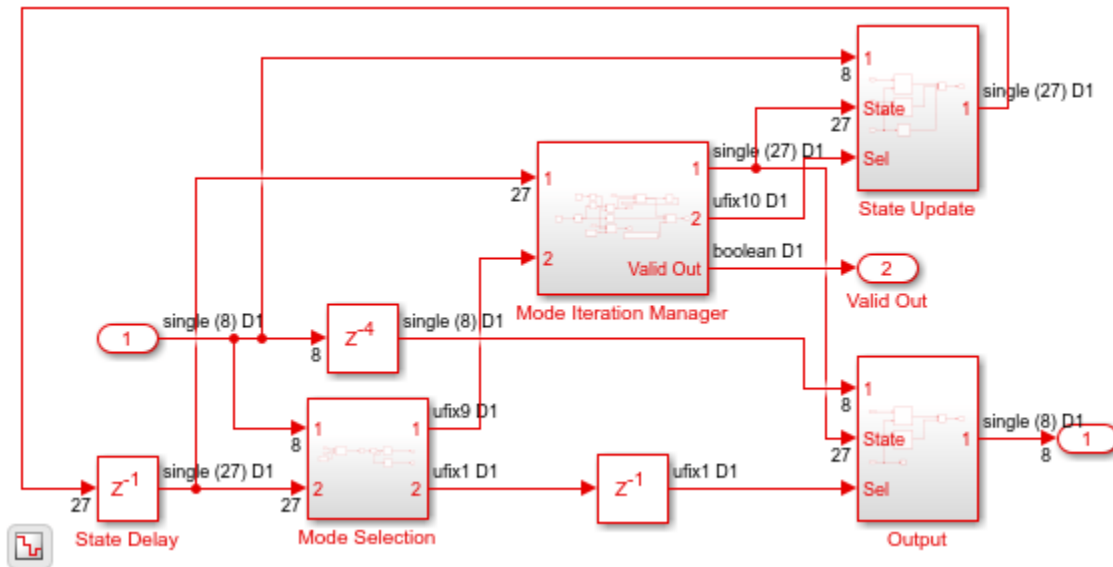

```
open_system('gmStateSpaceHDL_ViennaRectifier_HDL')
set_param('gmStateSpaceHDL_ViennaRectifier_HDL', 'SimulationCommand', 'Update')
```

Copyright 2022 The MathWorks, Inc.

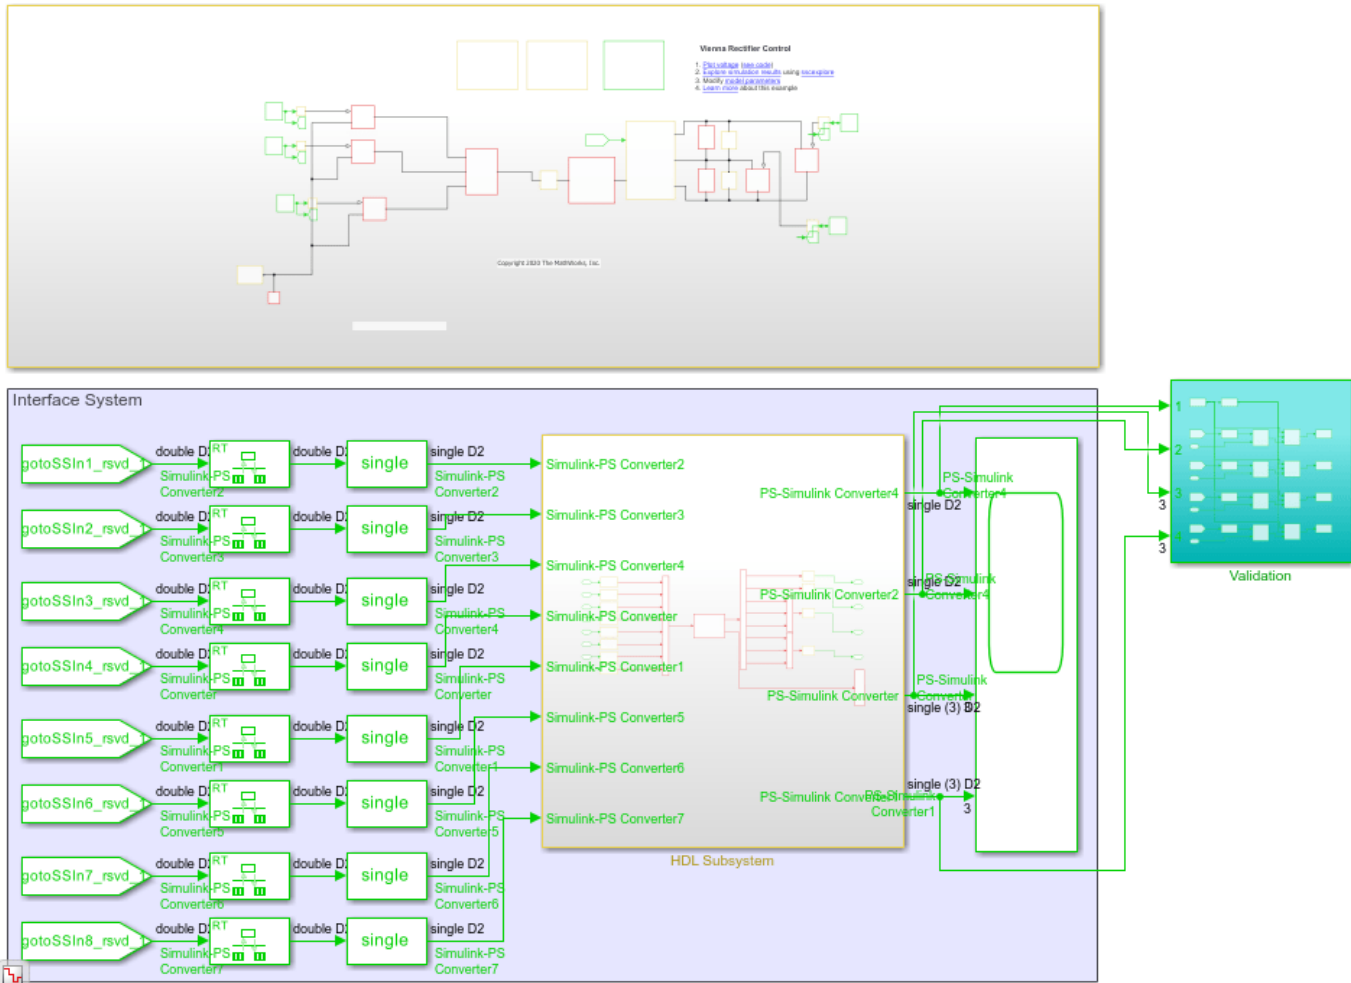

The ports of this subsystem use the same name as the Simulink-PS Converter and PS-Simulink Converter blocks in your original Simscape model. If you navigate inside this subsystem, you see several delays, adders, and Matrix Multiply blocks that model the state-space equations.

```
open_system('gmStateSpaceHDL_ViennaRectifier_HDL/HDL Subsystem/HDL Algorithm')
```

To validate the HDL algorithm, in the **Generate implementation model** task, select the **Generate validation logic for the implementation model** check box in the **Verification Settings**, set the **Validation logic tolerance** to 0.001, and rerun this task. The task generates a state-space validation model that compares the implementation model and the original Simscape model.

```
open_system('gmStateSpaceHDL_ViennaRectifier_HDL_vnl')
set_param('gmStateSpaceHDL_ViennaRectifier_HDL_vnl', 'SimulationCommand', 'Update')
```

Simulating the model does not display assertions, which indicates that the HDL algorithm matches the original model.

```
sim('gmStateSpaceHDL_ViennaRectifier_HDL_vnl')
```

Map State-Space Parameters in Implementation Model to RAM

The HDL implementation model uses `single` data types and contains large Delay blocks that are inside a feedback loop in the HDL Algorithm subsystem. To accommodate the large delays and make the design run at a faster clock rate on the target FPGA, the model uses clock-rate pipelining in conjunction with a large value of **Oversampling factor**.

```
hdlsaveparams('gmStateSpaceHDL_ViennaRectifier_HDL')
```

For more information, see:

- “Clock-Rate Pipelining” on page 28-149
- “Oversampling factor” on page 21-15

- “Allocate Sufficient Delays for Floating-Point Operations” on page 14-79

In the **Generate implementation model** task, the **Map state space parameters to RAMs** setting uses the default value of **Auto**. This setting maps large state-space parameters in the HDL implementation model to RAMs when the number of modes exceed a threshold value of 200. As the vienna rectifier model uses a large number of modes, the state-space parameters are mapped to RAMs. By mapping to RAMs, you save lookup table resources on the FPGA. To enable the RAM mapping, the “UseRAM” on page 26-25 parameter is enabled on the masked subsystem blocks that perform the state update and compute the output.

To map the parameters to RAMs irrespective of the threshold, set **Map state space parameters to RAMs** to **on**.

To see the effect of RAM mapping on the vienna rectifier model:

1. Verify the **UseRAM** parameter setting by running the `hdlget_param` function on the **Multiply Input** and **Multiply State** blocks.

```
Multiplysubsys1 = 'gmStateSpaceHDL_ViennaRectifier_HDL/HDL Subsystem/HDL Algorithm/State Update'
Multiplysubsys2 = 'gmStateSpaceHDL_ViennaRectifier_HDL/HDL Subsystem/HDL Algorithm/Output';
UseRAM1 = hdlget_param([Multiplysubsys1 '/Multiply Input'], 'UseRAM')
UseRAM2 = hdlget_param([Multiplysubsys1 '/Multiply State'], 'UseRAM')
```

```
UseRAM1 =
```

```
    'on'
```

```
UseRAM2 =
```

```
    'on'
```

2. Enable generation of the resource utilization report.

```
hdlset_param('gmStateSpaceHDL_ViennaRectifier_HDL', 'ResourceReport', 'on')
```

3. Generate HDL code for the implementation model.

```
makehdl('gmStateSpaceHDL_ViennaRectifier_HDL/HDL Subsystem');
```

When you generate code, HDL Coder opens a Code Generation report. The **High-level Resource Report** shows 136 RAMs utilized.

Multipliers	294
Adders/Subtractors	4894
Registers	28386
Total 1-Bit Registers	274486
RAMs	136
Multiplexers	44200
I/O Bits	516
Static Shift operators	0
Dynamic Shift operators	632

Resource Sharing of State Update and Output Computation Blocks

Before you generate HDL code for the HDL Subsystem, you can optimize the algorithm by using the resource sharing optimization in HDL Coder. Resource sharing is an area optimization that identifies multiple functionally equivalent resources and replaces them with a single, equivalent resource. The data is time-multiplexed over the shared resource to perform the same operations. See “Resource Sharing” on page 28-45.

In the HDL implementation model, you can share the masked subsystem blocks that perform state updates and compute the output.

To share these subsystems for the vienna rectifier and generate HDL code:

1. Specify a **SharingFactor** of 2 on the Multiply Input and Multiply State subsystems.

```
hdlset_param([Multipliesys1 '/Multiply Input'],'SharingFactor', 2)
hdlset_param([Multipliesys1 '/Multiply State'],'SharingFactor', 2)
hdlset_param([Multipliesys2 '/Multiply Input'],'SharingFactor', 2)
hdlset_param([Multipliesys2 '/Multiply State'],'SharingFactor', 2)
```

2. Enable generation of the optimization report

```
hdlset_param('gmStateSpaceHDL_ViennaRectifier_HDL', 'OptimizationReport', 'on')
```

3. Generate HDL code for the HDL Subsystem block in the implementation model.

```
makehdl('gmStateSpaceHDL_ViennaRectifier_HDL/HDL Subsystem');
```

When you generate code, HDL Coder opens a Code Generation report. To see the status of the resource sharing optimization, click the **Streaming and Sharing** section of the report. This sharing group shows the dot products that the optimization shared. When you click the **High-level Resource Report**, you see that the consumption of adders, multipliers, and registers have decreased.

Subsystem: Multiply Input

SharingFactor: 2

[Highlight shared resources and diagnostics](#)

Group Id	Resource Type	I/O Wordlengths	Group Size	Block Name	Color Legend

- “Speed and Area Optimizations in HDL Coder” on page 28-3
- “Generate HDL Code for Simscape Models” on page 37-13

Generate Simulink Real-Time Interface Subsystem for Simscape Two-Level Converter Model

This example shows how to generate a Simulink® Real-Time Interface subsystem for a Simscape™ two-level converter plant model. You can then deploy the interface model on the Speedgoat FPGA I/O module. This example uses the Speedgoat IO334-325k module.

Real-Time Simulation

Simulating the plant model on the FPGA provides:

- **Real-time Simulation:** Hardware-in-the-loop provides real-time simulation of your Simscape plant model on the target hardware.

- **Hardware Acceleration:** Accelerated simulation of complex physical systems on hardware while reconfigurable FPGAs provide rapid prototyping.

To use the workflow:

- 1 Develop the Simscape model and convert it into an implementation model by using the Simscape HDL Workflow Advisor.
- 2 Generate HDL code and deploy the code to the Speedgoat I/O module by using the HDL Workflow Advisor.

Setup and Configuration

Before deploying your algorithm on the Speedgoat I/O module:

1. Install the latest version of Xilinx® Vivado® as listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.

Then, set the tool path to the installed Xilinx Vivado executable by using the `hdlsetuptoolpath` function.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2019.2\bin\vivado.bat')
```

2. For real-time simulation, set up the development environment and target computer settings. See “Get Started with Simulink Real-Time” (Simulink Real-Time).
3. Install the Speedgoat I/O Blockset and the Speedgoat HDL Coder Integration packages. See Install Speedgoat HDL Coder Integration Packages.

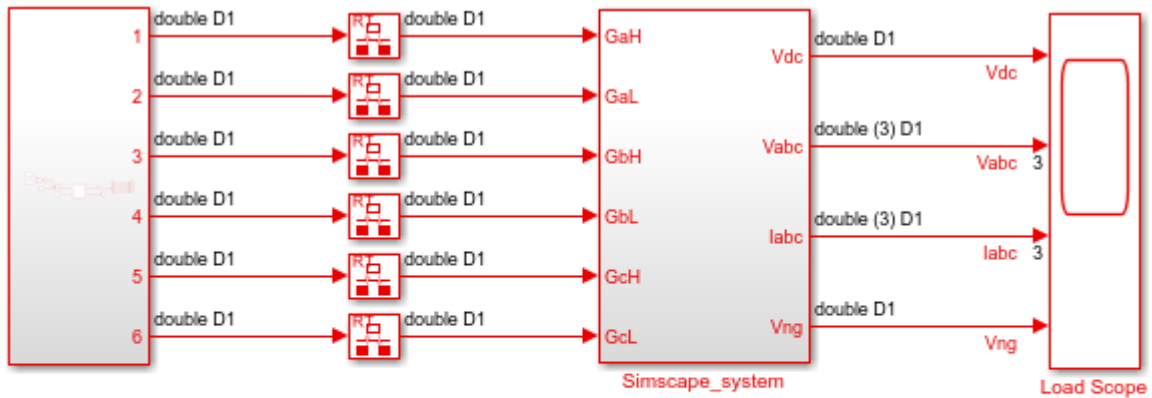

Two-Level Converter Ideal Model

To open this model, enter:

```
open_system('sschdlexTwoLevelConverterIdealExample')
```

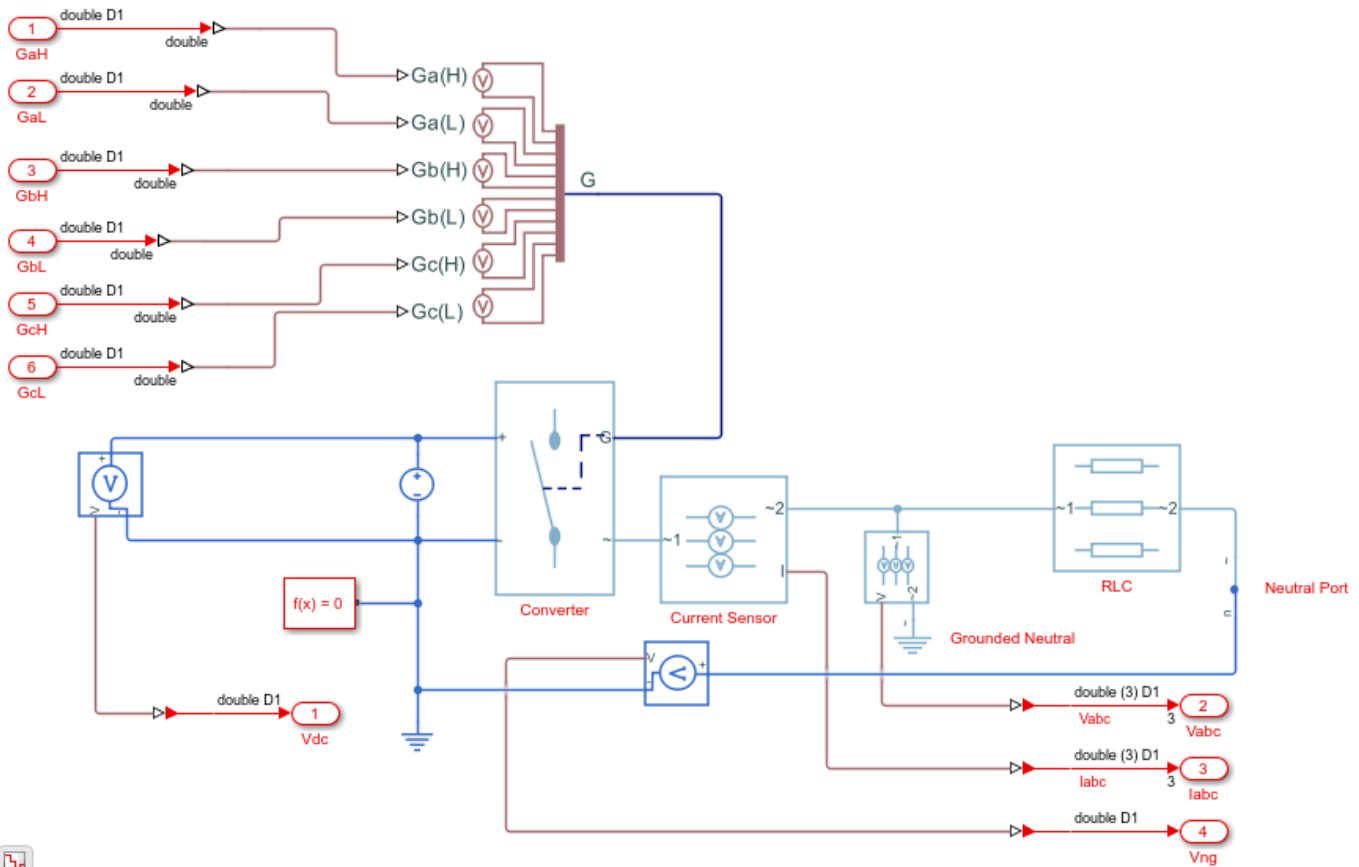

Save this model locally as TwoLevelConverter_HDL.slx to run this workflow.

```
open_system('TwoLevelConverter_HDL')
set_param('TwoLevelConverter_HDL', 'SimulationCommand', 'update')
```

Copyright 2020 The MathWorks, Inc.

```
open_system('TwoLevelConverter_HDL/Simscape_system')
```

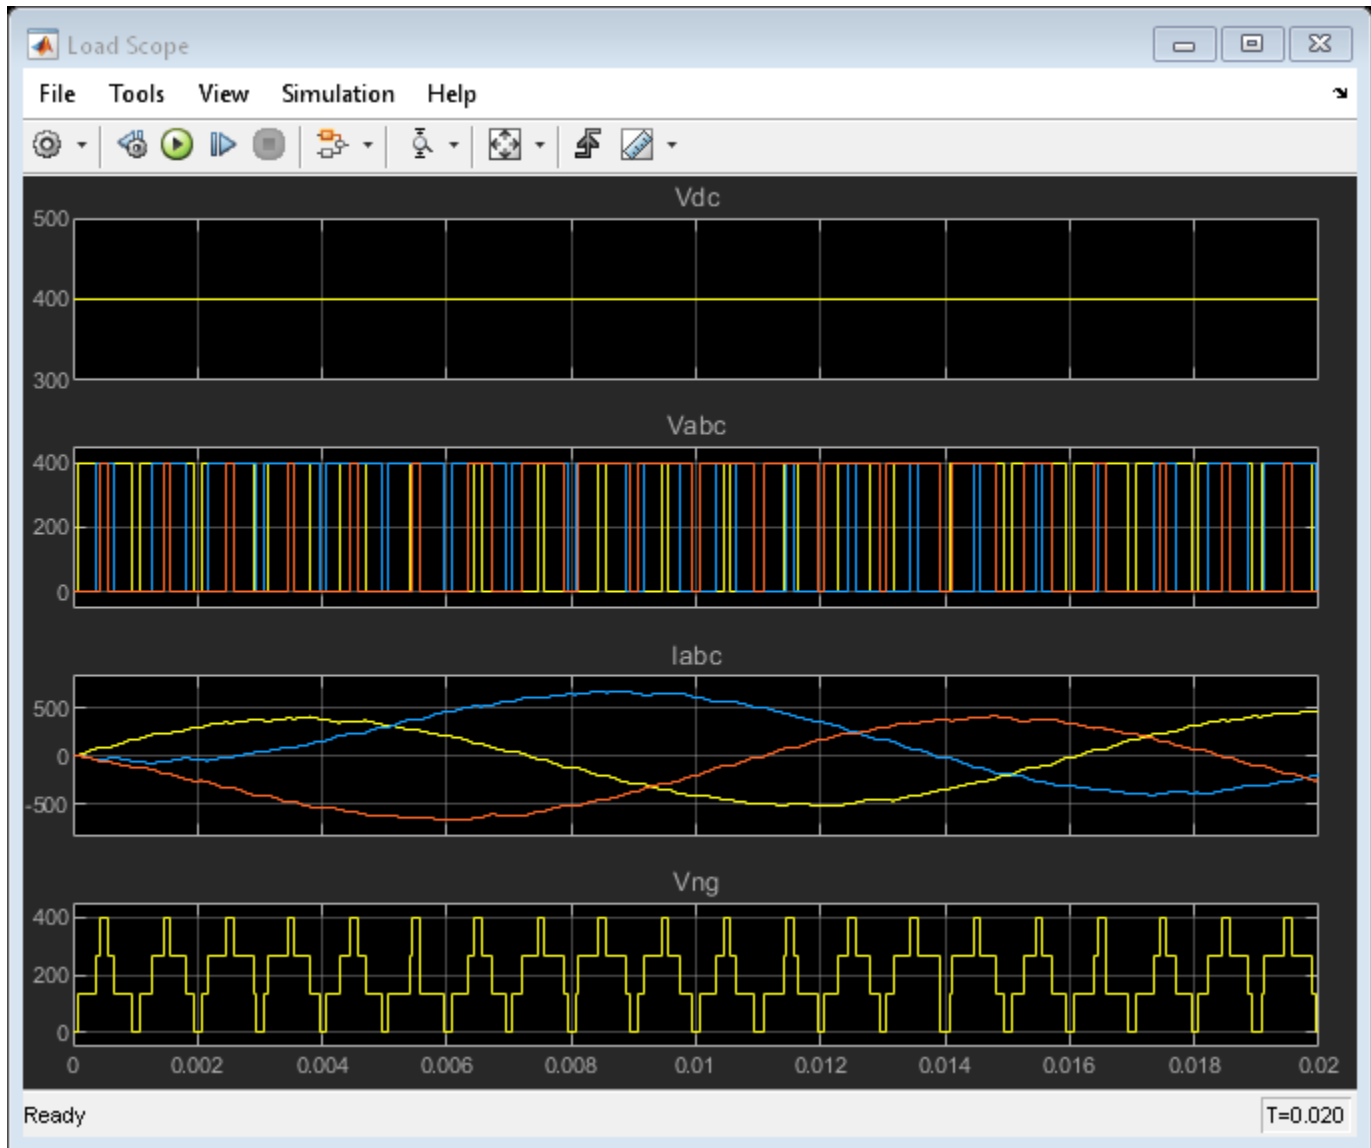

The Simscape subsystem receives six-switch controlling pulses as input. The Simscape subsystem acts as a generator that uses a two-level, carrier-based PWM method to:

- 1 Sample a reference wave.
- 2 Compare the sample to a triangular carrier wave.
- 3 Generate a switch-on pulse if a sample is higher than the carrier signal or a switch-off pulse if a sample is lower than the carrier wave.

Simulate the model.

```
sim('TwoLevelConverter_HDL')
open_system('TwoLevelConverter_HDL/Load Scope')
```

Generate HDL Implementation Model

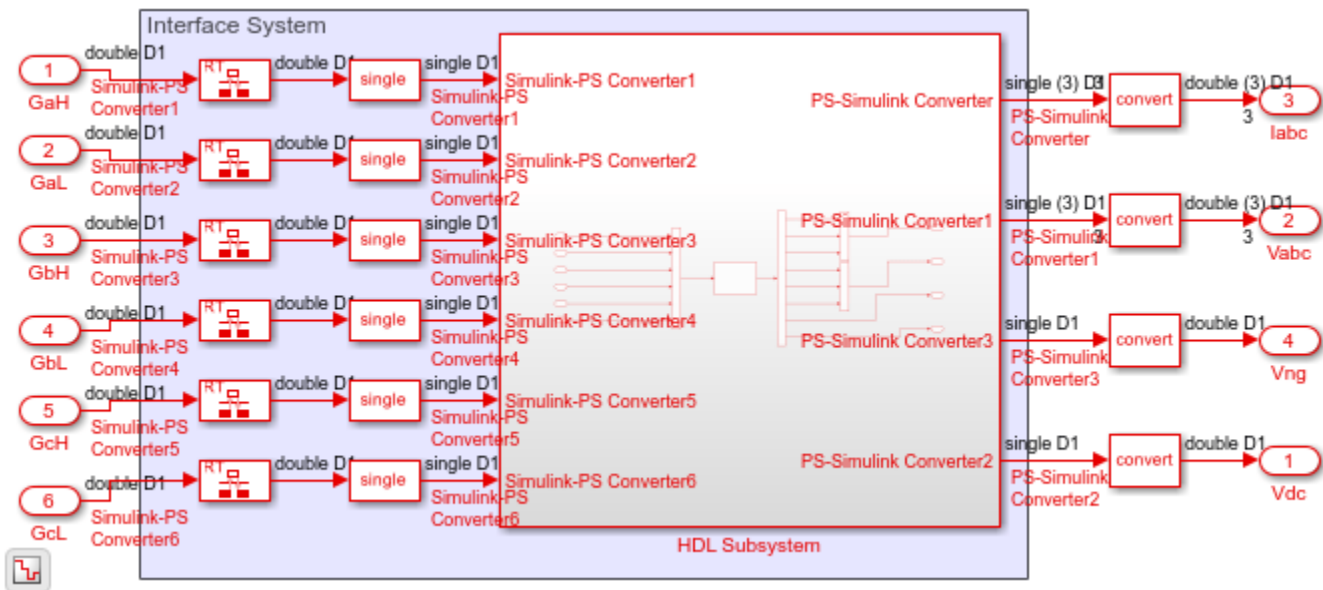

To generate an implementation model, use the Simscape HDL Workflow Advisor. Run the `sschdladvisor` function for your model:

```
sschdladvisor('TwoLevelConverter_HDL')
```

To generate the implementation model, in the Simscape HDL Workflow Advisor, keep the default settings for the tasks, and then run the tasks. You see a link to the model in the **Generate implementation model** task. This model has the same name as the original model prefixed with `gmStateSpaceHDL`.

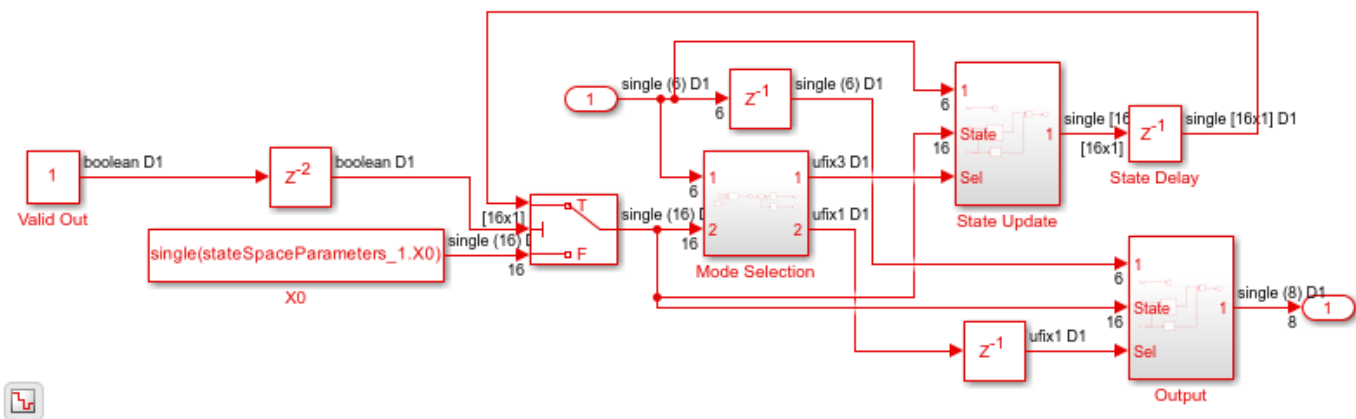

To open the implementation model, enter:

```
load_system('gmStateSpaceHDL_TwoLevelConverter_HDL')
open_system('gmStateSpaceHDL_TwoLevelConverter_HDL/Simscape_system')
set_param('gmStateSpaceHDL_TwoLevelConverter_HDL', 'SimulationCommand', 'update')
```

The implementation model replaces the Simscape subsystem with the HDL algorithm that performs the state-space computations. When you navigate inside this subsystem, you see several delays, adders, and Matrix Multiply blocks that model the state-space equations. From and Goto blocks inside this subsystem provide the same input as that of the original model to the HDL Subsystem.

```
open_system('gmStateSpaceHDL_TwoLevelConverter_HDL/Simscape_system/HDL Subsystem/HDL Algorithm')
```

HDL Workflow Advisor

The HDL Workflow Advisor guides you through HDL code generation and the FPGA design process. Use the Advisor to:

- Check the model for HDL code generation compatibility and fix incompatible settings.
- Generate HDL code, test bench, and scripts to build and run the code and test bench.
- Perform synthesis and timing analysis.
- Deploy the generated code on SoCs, FPGAs, and Speedgoat I/O modules.

To open the HDL Workflow Advisor for a subsystem inside the model, use the `hdladvisor` function.

```
load_system('sschdlexTwoLevelConverterIgbtExample')
hdladvisor('sschdlexTwoLevelConverterIgbtExample/Simscape_system')
```

The left pane contains folders that represent a group of related tasks. Expanding the folders and selecting a task displays information about that task in the right pane. The right pane contains simple controls for running the task to advanced parameters and option settings that control code and test bench generation. To learn more about each task, right-click that task, and select **What's This?**. See “Getting Started with the HDL Workflow Advisor” on page 36-6.

Deploy Two Level Ideal Converter Model to Speedgoat IO334-325K Module

1. Open the HDL Workflow Advisor for the implementation model.

```
hdladvisor('gmStateSpaceHDL_TwoLevelConverter_HDL/Simscape_system/HDL Subsystem')
```

2. In **Set Target Device and Synthesis Tool** task, specify **Target workflow** as Simulink Real-Time FPGA I/O and **Target platform** as Speedgoat IO334-325K

1.1. Set Target Device and Synthesis Tool

Analysis (^Triggers Update Diagram)

Set Target Device and Synthesis Tool for HDL code generation

Input Parameters

Target workflow: Simulink Real-Time FPGA I/O

Target platform: Speedgoat IO334-325k Launch Board Manager

Synthesis tool: Xilinx Vivado Tool version: 2019.2.1 Refresh

Family: Kintex7 Device: xc7k325t

Package: fbg676 Speed: -2

Project folder: hdl_prj Browse...

3. Run the **Set Target Reference Design** task, select a value of x4 for the parameter PCIe lanes, and select **Run This Task**.

4. In **Set Target Interface** task, map the input and output single data type ports to PCIe Interface and select **Run This Task**.

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
Simulink-PS Convert...	Inport	single	PCIe Interface	x"100"	Options...
Simulink-PS Convert...	Inport	single	PCIe Interface	x"104"	Options...
Simulink-PS Convert...	Inport	single	PCIe Interface	x"108"	Options...
Simulink-PS Convert...	Inport	single	PCIe Interface	x"10C"	Options...
Simulink-PS Convert...	Inport	single	PCIe Interface	x"110"	Options...
Simulink-PS Convert...	Inport	single	PCIe Interface	x"114"	Options...
PS-Simulink Converter	Outport	single (3)	PCIe Interface	x"120"	
PS-Simulink Convert...	Outport	single (3)	PCIe Interface	x"140"	
PS-Simulink Convert...	Outport	single	PCIe Interface	x"118"	
PS-Simulink Convert...	Outport	single	PCIe Interface	x"11C"	

5. Right-click **Generate RTL Code and IP Core** task and select **Run to Selected Task**. As the model uses vector data types, the **Generate RTL Code and IP Core** fails because the **ScalarizePorts** property must be set to **outlevel**. Click the link to change this setting and rerun the task.

6. Run the workflow to the **Generate Simulink Real-Time interface** task. In **Create Project** task, you can open the Vivado project and see the implemented design. After the **Generate Simulink Real-Time interface** task passes, click the link to open the Simulink Real-Time Interface Model.

Export HDL Workflow to Script

For rapid prototyping, you can export the HDL Workflow Advisor settings to a script. The script is a MATLAB® file that you can run from the command line. You can then modify and run the script, or import the settings into the HDL Workflow Advisor User Interface.

To export an HDL Workflow script, after you run the tasks in the Advisor, select **File > Export to Script**. For this example, when you export to script, this file shows the settings you saved.

```
edit('hdlworkflow_slrt.m')
```

To import an HDL Workflow script, in the HDL Workflow Advisor, select **File > Import from Script**. Select the script file and click **Open**. The HDL Workflow Advisor updates the tasks with the imported script settings.

For an example that shows how to run the real-time application by deploying the FPGA bitstream, see “Hardware-in-the-Loop Implementation of Simscape Model on Speedgoat FPGA I/O Modules” on page 37-88.

Deploy Simscape Buck Converter Model to Speedgoat IO Module Using HDL Workflow Script

This example shows how to deploy a Simscape™ buck converter model to a Speedgoat IO334 Simulink®-programmable I/O module and then run the model in real-time at a sample step size as small as 1 microsecond. The example uses a DCDC converter topology to show how to prepare your power electronic converter model for hardware in the loop (HIL) simulation on a Speedgoat real-time target machine.

To use this workflow:

- 1 Convert your model into an HDL-compatible implementation model by using the Simscape HDL Workflow Advisor
- 2 Generate HDL code and FPGA bitstream for the IO334 module by using the HDL Workflow Advisor.
- 3 Deploy the real-time model to the Speedgoat real-time target machine by using Simulink Real-Time.

The model runs at a sample time of 1us till HDL code generation and then runs at 50us on the CPU in real time. To generate HDL code and FPGA bitstream, the example shows how to run the HDL workflow script from the command line. For an example that shows how you can use the Workflow Advisor User Interface to run this workflow, see “Hardware-in-the-Loop Implementation of Simscape Model on Speedgoat FPGA I/O Modules” on page 37-88.

Setup and Configuration

Before deploying your algorithm on the Speedgoat IO module:

1. Install the latest version of Xilinx® Vivado® as listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.

Then, set the tool path to the installed Xilinx Vivado executable by using the `hdlsetuptoolpath` function.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2019.2\bin\vivado.bat')
```

2. For real-time simulation, set up the development environment and target computer settings. See “Get Started with Simulink Real-Time” (Simulink Real-Time).
3. Install the Speedgoat Library and the Speedgoat HDL Coder Integration packages. See Install Speedgoat HDL Coder Integration Packages.

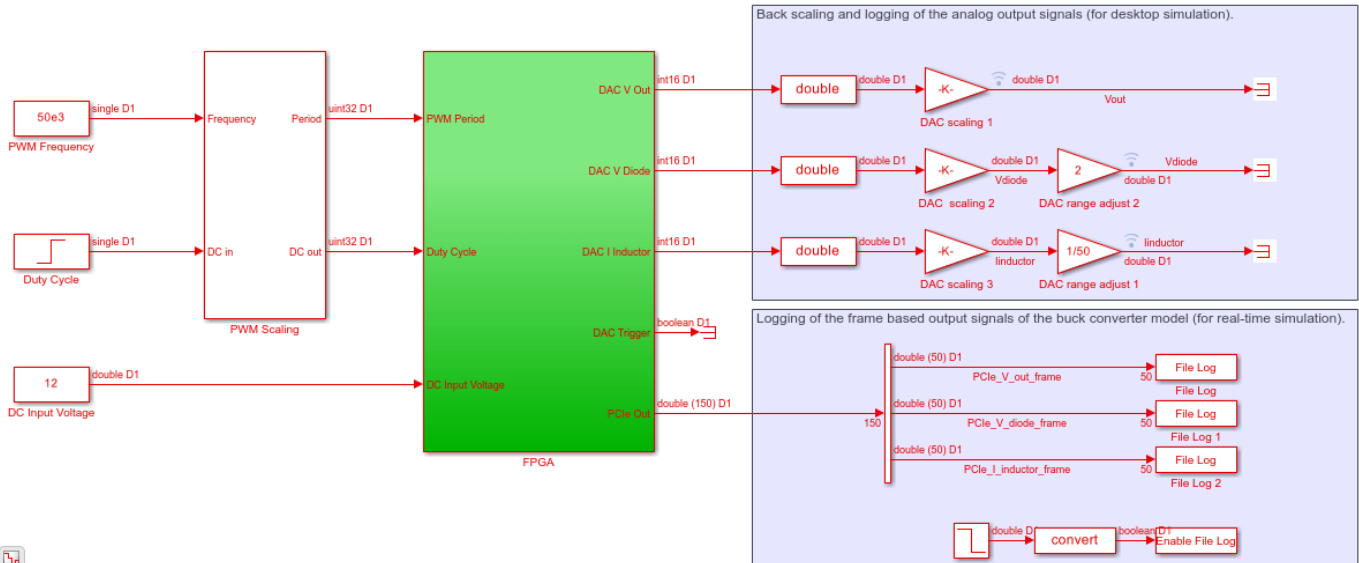

Buck Converter Model

To see the buck converter model, run this command:

```
open_system('sschdlexBuckConverterExample')
```

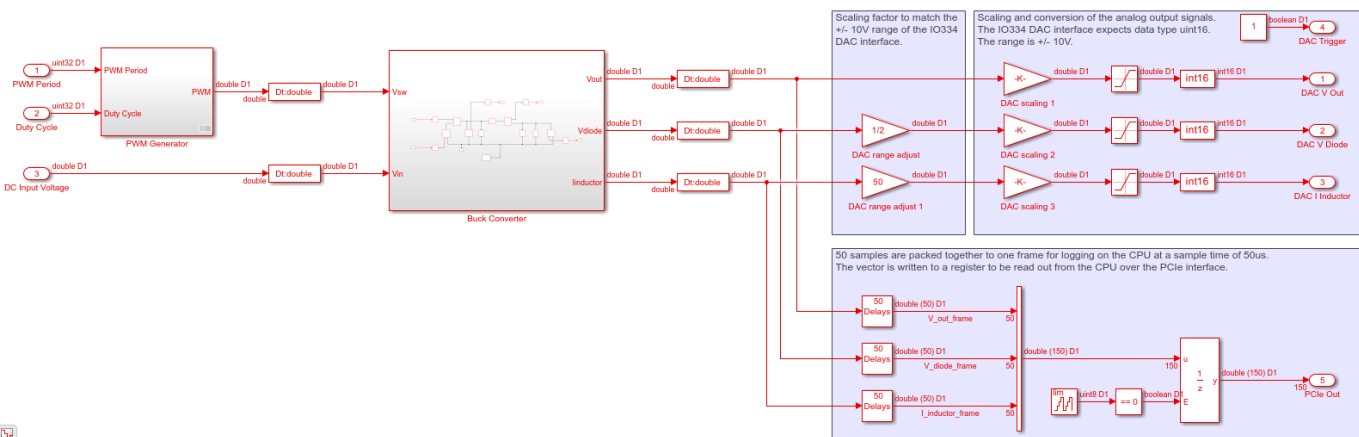

This model is modified for real-time deployment and saved as `sschdlex_I0334_BuckConverter`. The model has been partitioned into parts that run on the FPGA and parts that run on CPU. Parts inside the green FPGA subsystem run on the FPGA. Parts outside this subsystem run on the CPU in real time.

```
open_system('sschdlex_I0334_BuckConverter')
set_param('sschdlex_I0334_BuckConverter', 'SimulationCommand', 'Update')
```

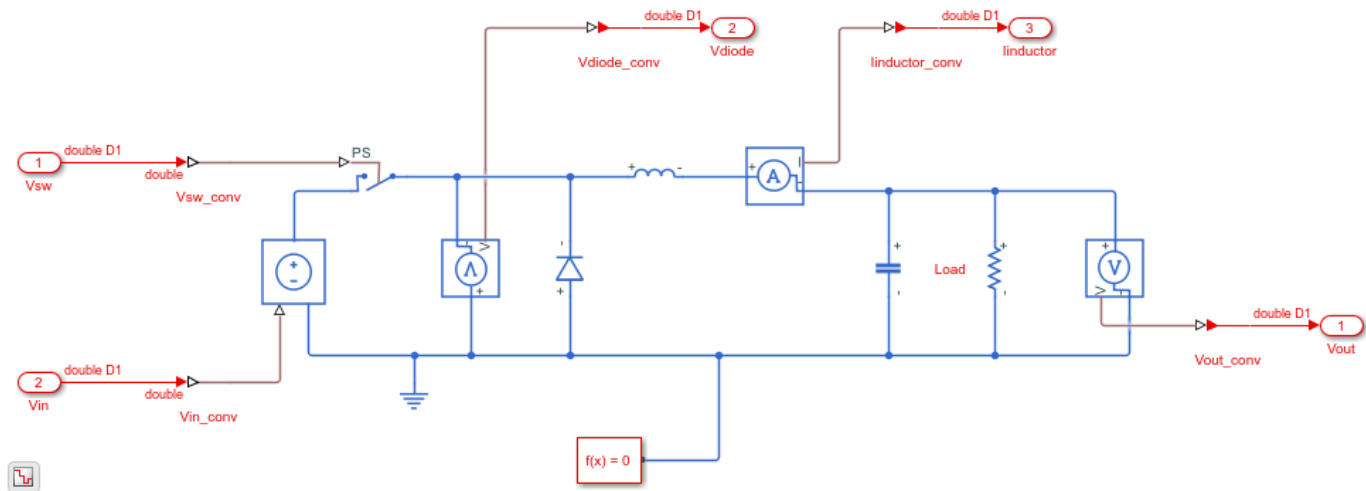

You generate VHDL code for blocks that are inside the green FPGA subsystem that contains the PWM generator and buck converter. The code is then deployed to the FPGA on board the IO334 module. The outputs of the subsystem are mapped to DAC interfaces. The output signals from the Buck Converter subsystem are scaled within a 10V range and converted to use uint16 data types. 50 samples are packed together to one frame to log the output signals on the CPU.

```
open_system('sschdlex_I0334_BuckConverter/FPGA')
```

To see the buck converter model, double-click the Buck Converter subsystem. The buck converter is a power converter model that steps down the input voltage at the output. The voltage at the output is stepped down by the duty cycle, D. The output voltage, V_{out} , is calculated as V_{in}/D

```
open_system('sschdlex_I0334_BuckConverter/FPGA/Buck Converter')
```

Run Desktop Simulation of Simscape model

The Simulation input is a duty cycle step wave from 0.2 to 0.8. The input signals that include the DC input voltage, PWM frequency, and duty cycle are generated on the top level of the model. The sample time for the Simscape model is set to 1 μ s. Signal logging is enabled on the top level of the model.

```
sim('sschdlex_I0334_BuckConverter')

% Display the buck converter output signals in SDI
Simulink.sdi.clearAllSubPlots
Simulink.sdi.setSubPlotLayout(3,1);

allIDs2 = Simulink.sdi.getAllRunIDs;
runID2 = allIDs2(end);
run2 = Simulink.sdi.getRun(runID2);
run2.name = 'Simscape Desktop Simulation';

run2.getAllSignals;
plotOnSubPlot(run2.getSignalsByName('Vout'),1,1,true);
plotOnSubPlot(run2.getSignalsByName('Iinductor'),2,1,true);
plotOnSubPlot(run2.getSignalsByName('Vdiode'),3,1,true);

Simulink.sdi.view;
```

Generate HDL Implementation Model

For HDL code generation compatibility, you run the Simscape HDL Workflow Advisor to generate an HDL implementation model.

The Simscape solver is set to run for two iterations at each sample step. The Simscape HDL Workflow Advisor uses the solver settings in the next step for deterministic real-time behavior.

```
set_param('sschdlex_I0334_BuckConverter/FPGA/Buck Converter/Solver Configuration','DoFixedCost',
set_param('sschdlex_I0334_BuckConverter/FPGA/Buck Converter/Solver Configuration','MaxNonlinIter
```

To open the Advisor, run the `sschdladvisor` function for your model:

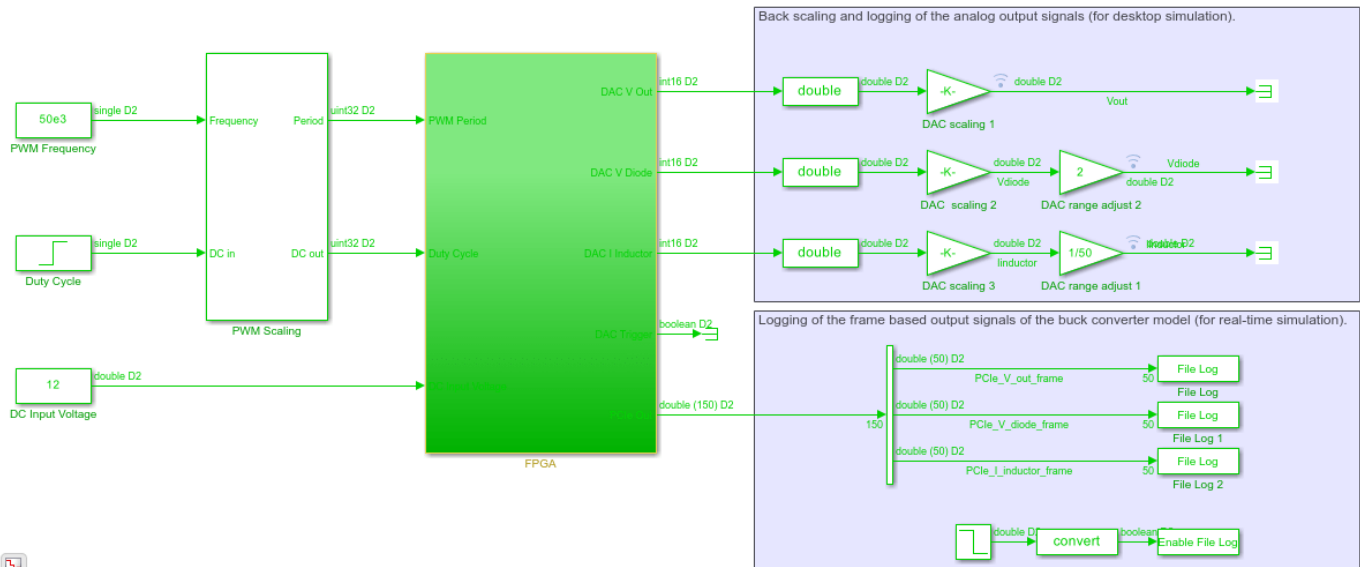

```
sschdladvisor('sschdlex_I0334_BuckConverter')
```

To generate the implementation model, in the Simscape HDL Workflow Advisor, keep the default settings for the tasks, and then run the tasks. Run the tasks in the Advisor by clicking the **Run all** button. You see a link to the model in the **Generate implementation model** task. This model has the same name as your original model with the prefix `gmStateSpaceHDL_`.

Prepare Implementation Model for HDL Code Generation

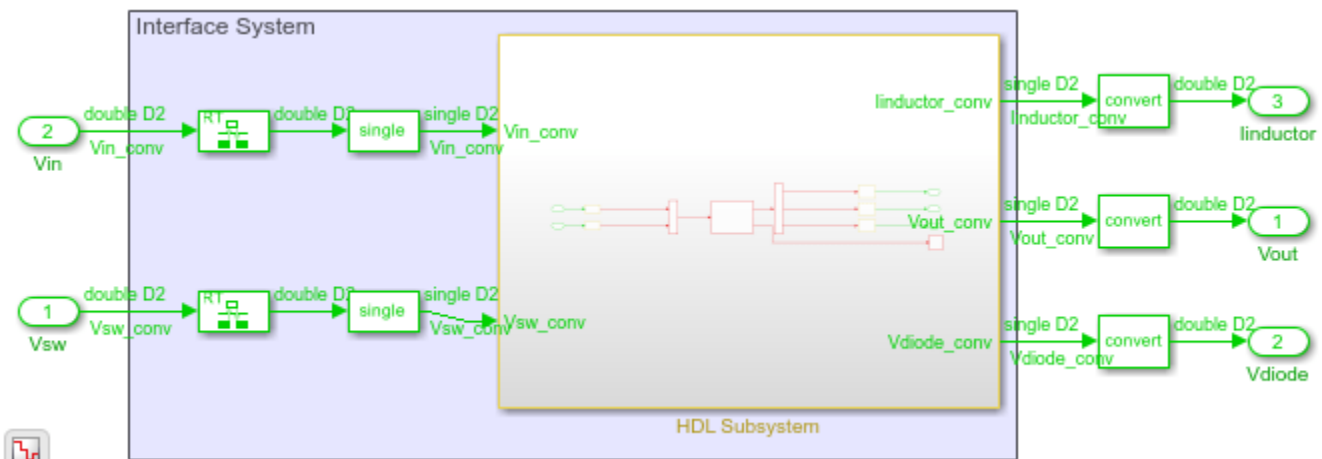

To open the implementation model, click the link in the **Generate implementation model** task.

```
open_system('gmStateSpaceHDL_sschedlex_I0334_BuckConverte');
set_param('gmStateSpaceHDL_sschedlex_I0334_BuckConverte', 'SimulationCommand', 'Update')
```

The model contains a switched linear Simulink replacement of the original buck converter model. You see that the Simscape model was replaced.

```
open_system('gmStateSpaceHDL_sschedlex_I0334_BuckConverte/FPGA/Buck Converter');
```

The implementation model replaces the Simscape subsystem with the HDL-compatible algorithm that performs the state-space computations. When you navigate inside this subsystem, you see several delays, adders, and Matrix Multiply blocks that model the state-space equations. From and Goto blocks inside this subsystem provide the same input as that of the original model to the HDL Subsystem.

```
open_system('gmStateSpaceHDL_sschedlex_I0334_BuckConverte/FPGA/Buck Converter/HDL Subsystem/HDL A
```

The data type of the buck converter output signals is set to single precision floating point for HDL code generation.

```
set_param('gmStateSpaceHDL_sschedlex_I0334_BuckConverte/FPGA/Signal Specification','OutDataTypeSt
set_param('gmStateSpaceHDL_sschedlex_I0334_BuckConverte/FPGA/Signal Specification1','OutDataTypeS
set_param('gmStateSpaceHDL_sschedlex_I0334_BuckConverte/FPGA/Signal Specification2','OutDataTypeS
set_param('gmStateSpaceHDL_sschedlex_I0334_BuckConverte/FPGA/Signal Specification3','OutDataTypeS
set_param('gmStateSpaceHDL_sschedlex_I0334_BuckConverte/FPGA/Signal Specification4','OutDataTypeS
```

Run Desktop Simulation of HDL Implementation Model and Validate HDL Algorithm

You can simulate the switched linear state-space model of the buck converter in Simulink and display the signals in Simulation Data Inspector. The comparison of the runs show that the numeric results match.

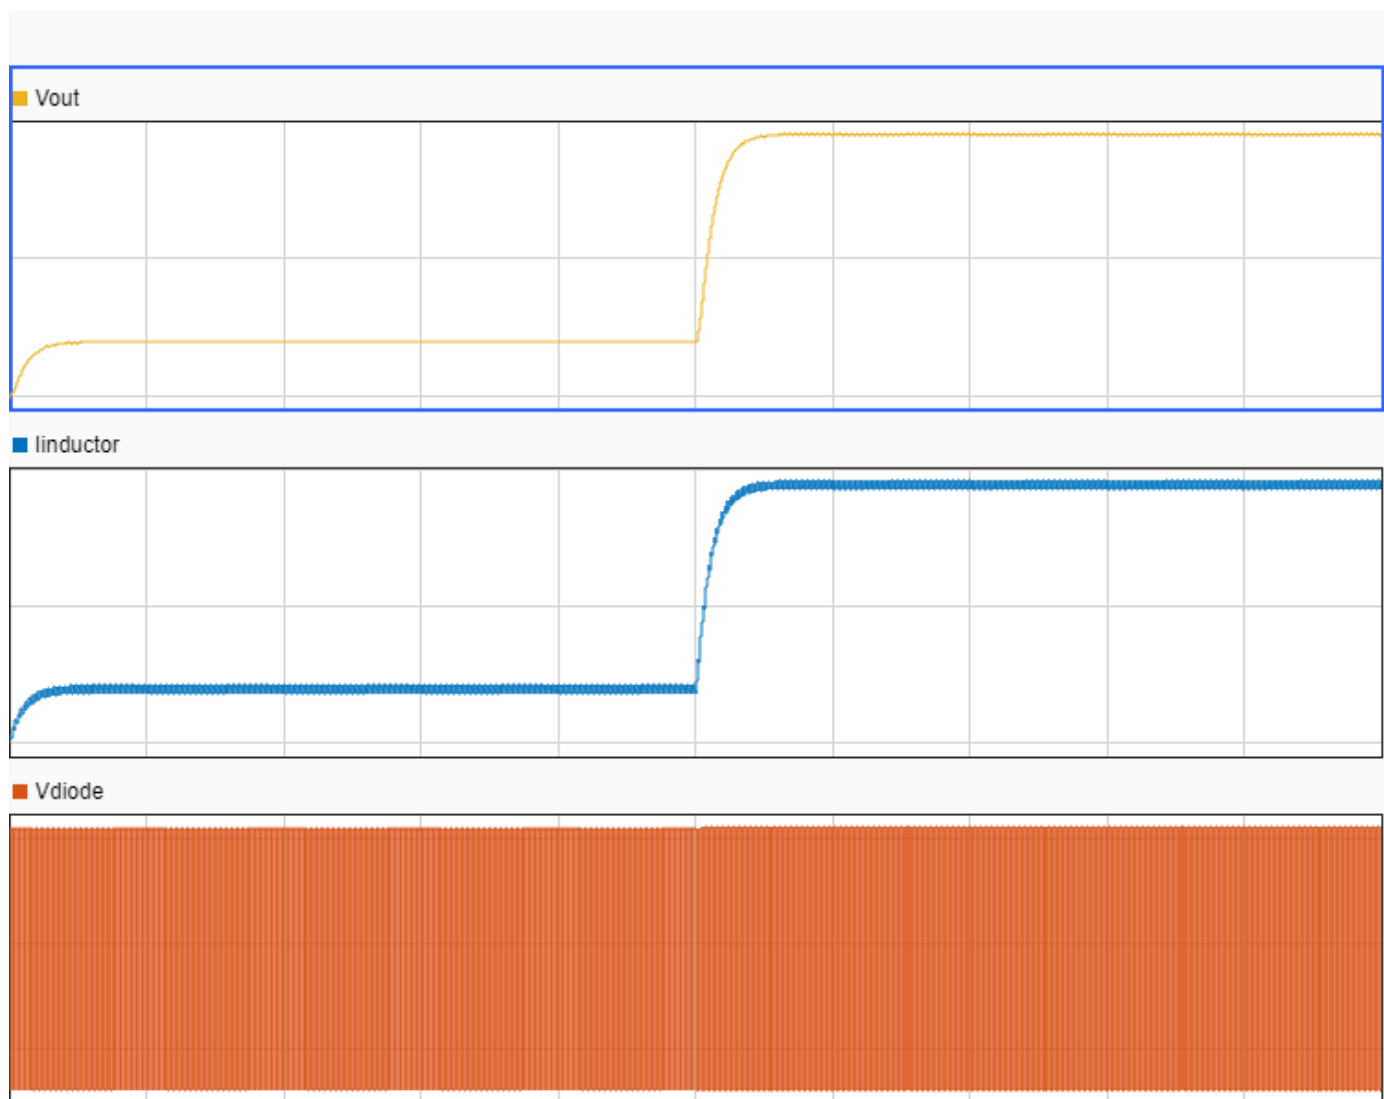

Simulate the HDL implementation model.

```
sim('gmStateSpaceHDL_sschedlex_I0334_BuckConverte')
%
% Display output signals of buck converter Simscape model in Simulation
% Data Inspector.
Simulink.sdi.clearAllSubPlots
Simulink.sdi.setSubPlotLayout(3,1);

allIDs2 = Simulink.sdi.getAllRunIDs;
runID2 = allIDs2(end);
run2 = Simulink.sdi.getRun(runID2);
run2.name = 'HDL Desktop Simulation';

run2.getAllSignals;
plotOnSubPlot(run2.getSignalsByName('Vout'),1,1,true);
plotOnSubPlot(run2.getSignalsByName('Iinductor'),2,1,true);
plotOnSubPlot(run2.getSignalsByName('Vdiode'),3,1,true);

Simulink.sdi.view;
```

To verify that the HDL implementation model matches the original Simscape model, generate a state-space validation model. In the **Generate implementation model** task, select the **Generate validation logic for the implementation model** check box and then run this task. Simulating the model does not display assertions, which indicates that the numeric results match. See “Validate HDL Implementation Model to Simscape Algorithm” on page 37-95.

HDL Workflow Advisor

The HDL Workflow Advisor guides you through HDL code generation and the FPGA design process. Use the Advisor to:

- Check the model for HDL code generation compatibility and fix incompatible settings.
- Generate HDL code, test bench, and scripts to build and run the code and test bench.
- Perform synthesis, timing analysis, and deploy the generated code on SoCs, FPGAs, and Speedgoat I/O modules.

You run the Advisor for the FPGA subsystem in your model. To open the HDL Workflow Advisor for the subsystem inside the model, use the `hdladvisor` function. For example:

```
hdladvisor('gmStateSpaceHDL_sschedlex_I0334_BuckConverte/FPGA')
```

To learn about the tasks in the Advisor, right-click that task, and select **What's This?**. See “Getting Started with the HDL Workflow Advisor” on page 36-6.

Run Workflow Script to Generate Simulink Real-Time Interface Model

For rapid prototyping, export the HDL Workflow Advisor settings to a script. The script is a MATLAB® file that you run from the command line. You can modify and run the script, or import the settings into the HDL Workflow Advisor User Interface. See “Run HDL Workflow with a Script” on page 36-49.

This example shows how to run the HDL Workflow script. To generate a Simulink Real-Time Interface model, open and run this MATLAB script.

```
edit('hdlworkflow_buck_I0334')

%% -----
% This script contains the model, target settings, interface mapping, and
% the Workflow Configuration settings for generating HDL code for the HDL
% implementation model generated for the buck converter model, and for

hWC = hdlcoder.WorkflowConfig('SynthesisTool','Xilinx Vivado','TargetWorkflow','Simulink Real-Time');

% Specify the top level project directory.
hWC.ProjectFolder = 'hdl_prj';
hWC.ReferenceDesignToolVersion = '2019.2';

% Set Workflow tasks to run.
hWC.RunTaskGenerateRTLCodeAndIPCore = true;
hWC.RunTaskCreateProject = true;
hWC.RunTaskBuildFPGABitstream = true;
hWC.RunTaskGenerateSimulinkRealTimeInterface = true;

%% Run the Workflow
hdlcoder.runWorkflow('gmStateSpaceHDL_sschedlex_I0334_BuckConverte/FPGA', hWC);

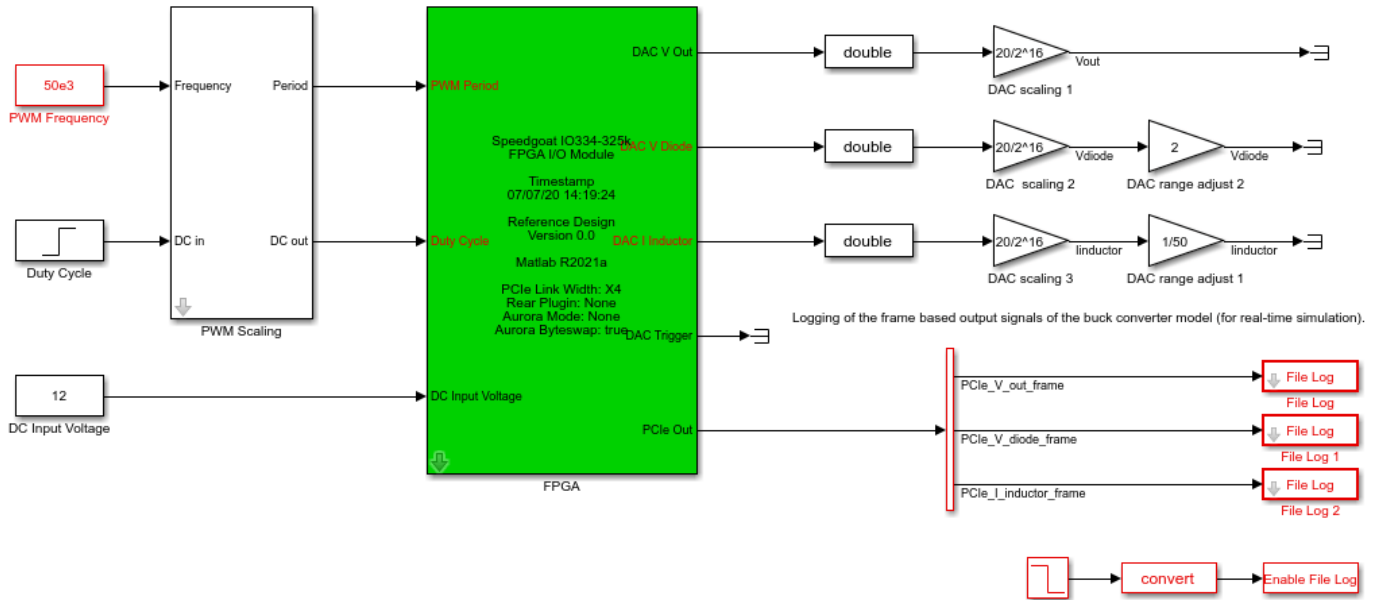

```

Prepare Simulink Real-Time Interface Model for Real-Time Simulation

Running the workflow script generates RTL code and IP core, creates a Vivado project, builds the FPGA bitstream, and then generates the Simulink Real-Time Interface model.

Generated by HDL Workflow Advisor on 07-Jul-2020 14:23:53

Back scaling and logging of the analog output signals (for desktop simulation).

Before deploying the model to the Speedgoat real-time target machine:

1. Set the sample time for all blocks running on the CPU of the Speedgoat real-time target machine to 50us (including driver blocks for the FPGA).

```
generated_model = gcs;
Ts = 50e-6;
set_param([generated_model, '/FPGA'], 'ts', 'Ts');
```

2. Set the Simulation Data Inspector setting **Input processing** to Columns as channels (frame based) for the signals PCIe_V_out_frame, PCIe_V_diode_frame and PCIe_I_inductor_frame. Inside the mask of the File Log blocks, right-click the logging symbol and navigate to the Instrumentation Properties dialog box. To make the logging signal appear, you might have to update the model.

```
set_param(generated_model, 'SimulationCommand', 'update');
```

Alternatively, you can set signal logging to frame based mode by using these commands.

```
Simulink.sdi.setSignalInputProcessingMode([generated_model, '/File Log/Demux'], 1, 'frame');
Simulink.sdi.setSignalInputProcessingMode([generated_model, '/File Log 1/Demux'], 1, 'frame');
Simulink.sdi.setSignalInputProcessingMode([generated_model, '/File Log 2/Demux'], 1, 'frame');
```

Connect to Target Machine and Run Real-Time Simulation

The model can now be deployed to the Speedgoat real-time target machine. The buck converter model is automatically loaded to the FPGA on the IO334.

Connect to the Speedgoat real-time target machine.

```
tg = slrealtime;
tg.connect;
```

Build and download the model to the target machine.

```
rtwbuild(generated_model);
tg.load(generated_model);
```

Start the model execution.

```
tg.start;  
pause(10);
```

The file logging blocks store the signals on the SSD of the target-machine. The data is automatically uploaded to the host computer once the model is stopped. The data is visualized in Simulation Data Inspector. You can verify that the results of the real-time simulation matches the original Simscape model.

```
Simulink.sdi.setSubPlotLayout(3,1);  
  
allIDs = Simulink.sdi.getAllRunIDs;  
runID = allIDs(end);  
run = Simulink.sdi.getRun(runID);  
run.name = 'Real Time Simulation on I0334';  
  
run.getAllSignals  
plotOnSubPlot(run.getSignalsByName('PCle_V_out_frame'),1,1,true);  
plotOnSubPlot(run.getSignalsByName('PCle_I_inductor_frame'),2,1,true);  
plotOnSubPlot(run.getSignalsByName('PCle_V_diode_frame'),3,1,true);  
  
Simulink.sdi.view
```

Alternatively, you can measure the signals at the analog output of the IO334. This figure shows a plot of the signals in MATLAB.

Deploy Simscape Grid Tied Converter Model to Speedgoat IO Module Using HDL Workflow Script

This example shows how to deploy a three-phase two-level voltage source converter connected to a low voltage grid modeled in Simscape™ to a Speedgoat IO334 Simulink®-programmable I/O module to achieve a simulation time step of 1 microsecond (us).

The PWM signals can be captured with an increased resolution by modeling the converter using the sub-cycle averaging method. A maximum resolution of 4ns is possible, allowing to simulate state of the art power converters with switching frequencies above 100kHz. The switching frequency of this example is 20kHz.

This example demonstrates how to:

- 1 Convert your Simscape model into an HDL-compatible implementation model by using the Simscape HDL Workflow Advisor
- 2 Generate HDL code and FPGA bitstream for the IO334 module by using the HDL Workflow Advisor.
- 3 Deploy the real-time model to the Speedgoat real-time target machine by using Simulink Real-Time.

The plant model runs eventually at a 1us time step on the FPGA and the controller is executed at a 50us time step on the CPU of the real-time system. To generate HDL code and FPGA bitstream, this example shows how to run the HDL workflow script from the command line. You can use the Workflow Advisor User Interface to run this workflow. For more information, see “Hardware-in-the-Loop Implementation of Simscape Model on Speedgoat FPGA I/O Modules” on page 37-88.

Setup and Configuration

Before deploying your algorithm on the Speedgoat IO module:

1. Install the latest version of Xilinx® Vivado® as listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.

Then, set the tool path to the installed Xilinx Vivado executable by using the `hdlsetuptoolpath` function.

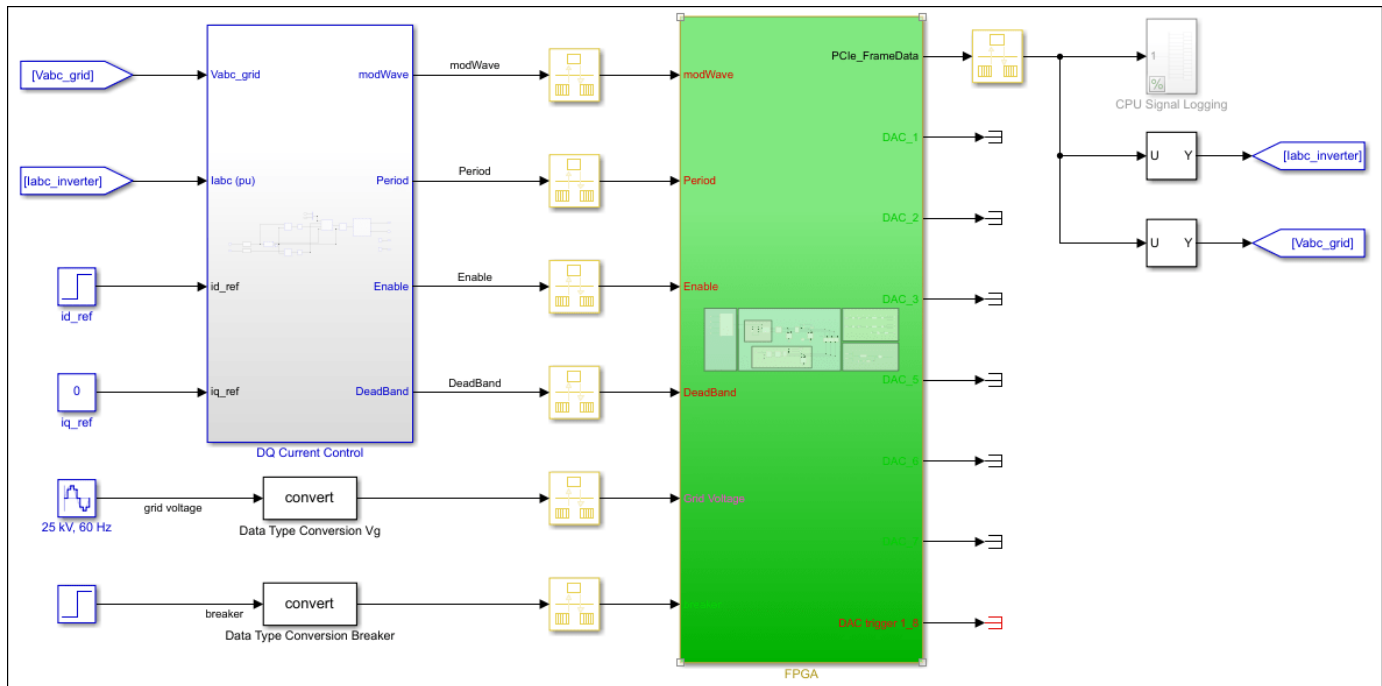

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath','C:\Xilinx\Vivado\2020.1\bin\vivado.l
```

2. For real-time simulation, set up the development environment and target computer settings. See “Get Started with Simulink Real-Time” (Simulink Real-Time).
3. Install the Speedgoat Library and the Speedgoat HDL Coder Integration packages. See Install Speedgoat HDL Coder Integration Packages.

Three-Phase Two-Level Voltage Source Converter Model

To see the three-phase two-level converter model, run this command:

```
open_system('sschdlexThreePhaseConverterWithGridExample')
```

This example model consists of a three-phase two-level voltage source converter connected to a low voltage grid through an LC filter. A circuit breaker allows to disconnect and connect the converter with the grid. There is a low voltage load on the grid side and a transformer connecting to the medium voltage grid.

In the first step, the model is used to validate the closed-loop control by desktop simulation. The controller consists of a phase-locked loop for grid synchronization and PI current control in the synchronous reference frame.

In a second step, the model can be deployed to the real-time platform for HIL testing of the embedded controller.

The model has been partitioned into parts that run on the FPGA and parts that run on the CPU in real time. Parts inside the green FPGA subsystem run on the FPGA. Parts outside this subsystem run on the CPU in real time.

```
open_system('sschdlexThreePhaseConverterWithGridExample/FPGA')
```

Run Desktop Simulation of Simscape model

The base sample rate is set to $1/(180e6)$ to match the clock ticks at the target frequency of 180 MHz on the hardware. To accelerate the desktop simulation, you can consider increasing the value of base sample rate.

```
Tbase = 1/(180e6);
```

Set the simulation and step time to close the circuit breaker

```
set_param('sschdlexThreePhaseConverterWithGridExample','StopTime','0.09');
set_param(['sschdlexThreePhaseConverterWithGridExample','/Step'],'Time','0.03');
```

Desktop simulation of the model

```
sim('sschdlexThreePhaseConverterWithGridExample')
```

Display output signals of three-phase two-level voltage source converter in Simulink Data Inspector

```
Simulink.sdi.clearAllSubPlots
Simulink.sdi.setSubPlotLayout(2,1);

allIDs = Simulink.sdi.getAllRunIDs;
runID1 = allIDs(end);
run1 = Simulink.sdi.getRun(runID1);
run1.name = 'Desktop Simulation';

Vabc_grid = run1.getSignalsByName('Vabc_grid');
Iabc_conv = run1.getSignalsByName('Iabc_conv');
plotOnSubPlot(Vabc_grid.Children(1),1,1,true);
plotOnSubPlot(Vabc_grid.Children(2),1,1,true);
plotOnSubPlot(Vabc_grid.Children(3),1,1,true);
plotOnSubPlot(Iabc_conv.Children(1),2,1,true);
plotOnSubPlot(Iabc_conv.Children(2),2,1,true);
plotOnSubPlot(Iabc_conv.Children(3),2,1,true);

Simulink.sdi.view;
```

Generate HDL Implementation Model

For HDL code generation compatibility, you run the Simscape HDL Workflow Advisor to generate an HDL implementation model.

The Simscape solver is set to run for one iteration at each sample step. The Simscape HDL Workflow Advisor uses the solver settings in the next step for deterministic real-time behaviour.

The averaged switch model allows us to set the solver iterations to 1

```
set_param(['sschdlexThreePhaseConverterWithGridExample','/FPGA/Solver Configuration'],'DoFi
set_param(['sschdlexThreePhaseConverterWithGridExample','/FPGA/Solver Configuration'],'MaxN
```

To accelerate the `sschdlexThreePhaseConverterWithGridExample` we reduce the sample time of the model. The time at which the circuit breaker closes is adapted to make sure that the workflow advisor captures all switching modes during simulation.

```
set_param('sschdlexThreePhaseConverterWithGridExample','StopTime','0.002');
set_param(['sschdlexThreePhaseConverterWithGridExample','/Step'],'Time','0.001');
```

To open the Advisor, run the `sschdlexThreePhaseConverterWithGridExample` function for your model:

```
sschdlexThreePhaseConverterWithGridExample
```

To generate the implementation model, in the Simscape HDL Workflow Advisor, keep the default settings for the tasks, and then run the tasks. Run the tasks in the Advisor by clicking the **Run all** button. You see a link to the generated model in the **Generate implementation model** task. This model has the same name as your original model with the prefix `gmStateSpaceHDL_`.

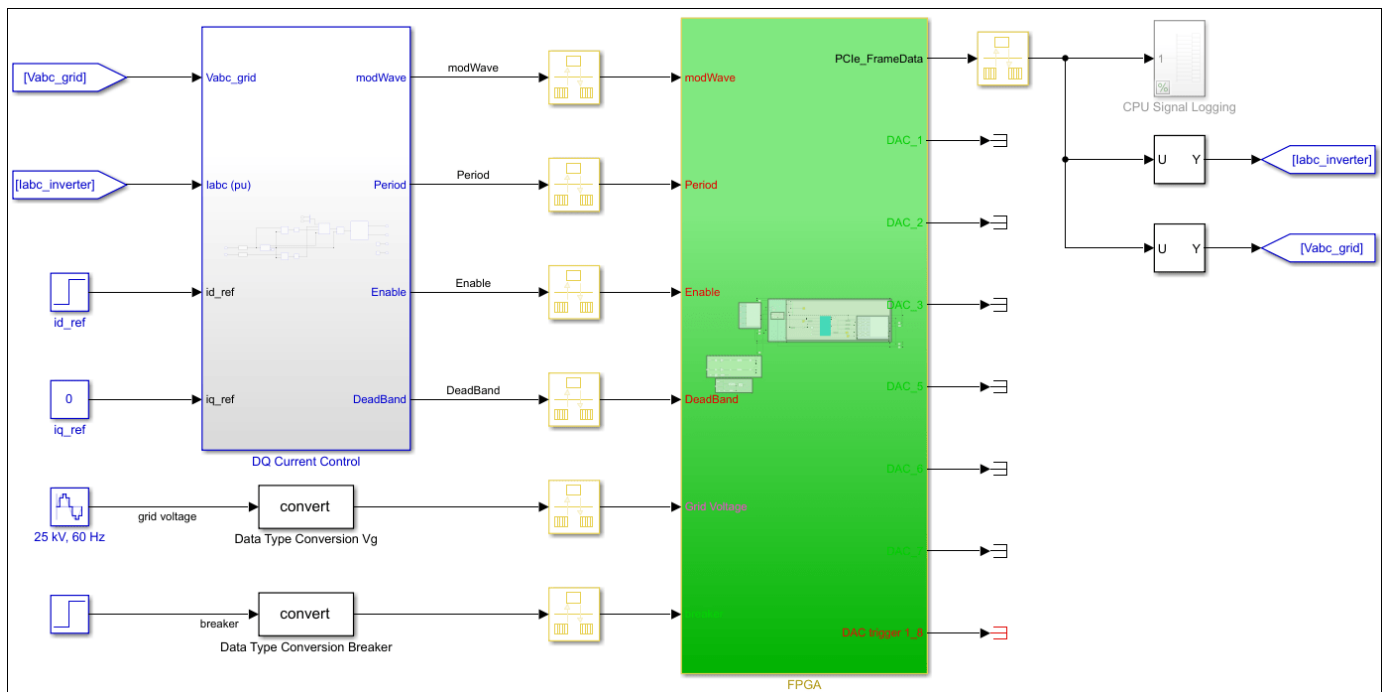

We set the simulation and step time to the original values

```
set_param('sschdlexThreePhaseConverterWithGridExample','StopTime','0.09');
set_param(['sschdlexThreePhaseConverterWithGridExample','/Step'],'Time','0.03');
```

Prepare Implementation Model for HDL Code Generation

To open the implementation model, click the link in the **Generate implementation model** task.

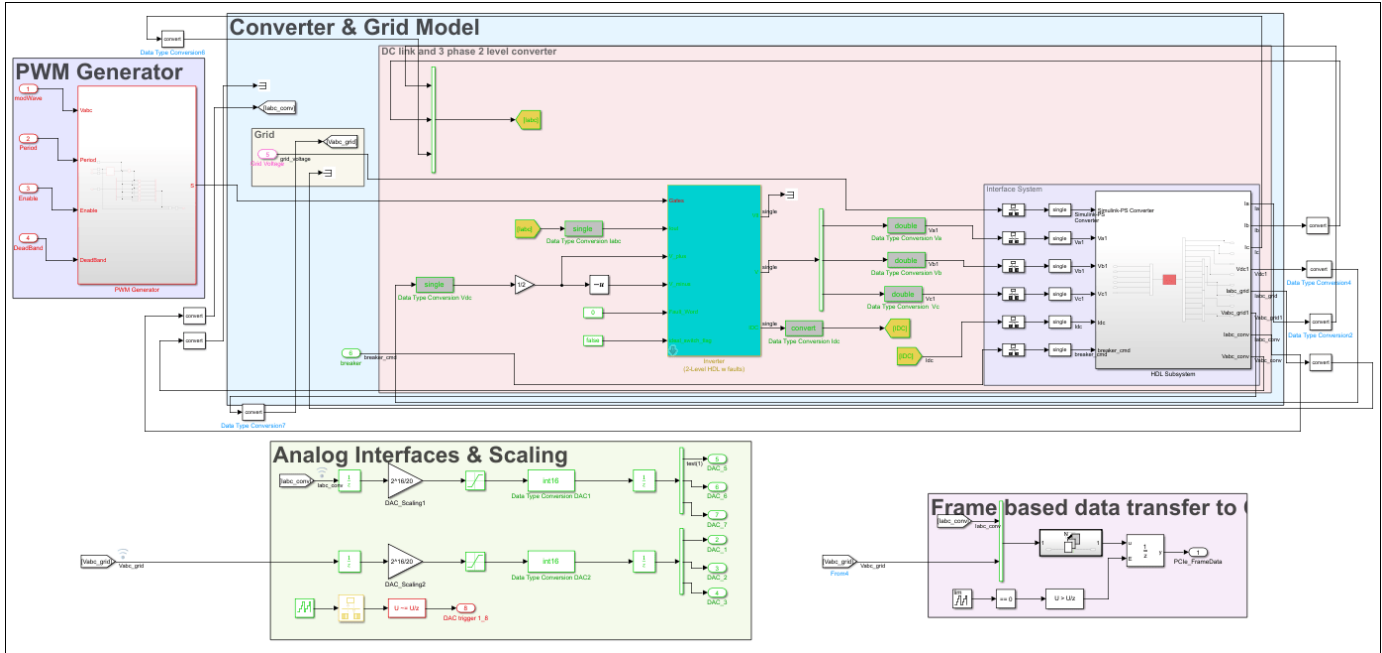

```
open_system('gmStateSpaceHDL_sschdlexThreePhaseConverter')
```

```
set_param('gmStateSpaceHDL_sschdlexThreePhaseConverter','StopTime','0.09');
set_param(['gmStateSpaceHDL_sschdlexThreePhaseConverter','/Step'],'Time','0.03');
```

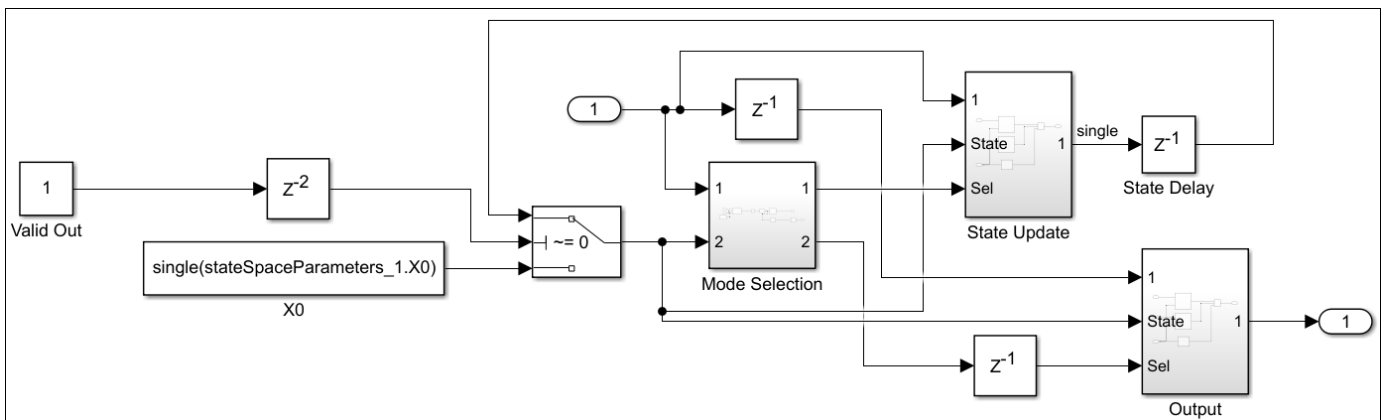

The model contains a switched linear Simulink replacement of the original three-phase two-level voltage source converter model. You see that the Simscape model was replaced.

```
open_system('gmStateSpaceHDL_sschdlexThreePhaseConverter/FPGA')
```

The implementation model replaces the Simscape subsystem with the HDL-compatible algorithm that performs the state-space computations. When you navigate inside this subsystem, you see several delays, adders, and Matrix Multiply blocks that model the state-space equations. From and Goto blocks inside this subsystem provide the same input as that of the original model to the HDL Subsystem.

```
open_system('gmStateSpaceHDL_sschdlexThreePhaseConverter/FPGA/HDL Subsystem/HDL Algorithm')
```

Run Desktop Simulation of HDL Implementation Model and Validate HDL Algorithm

You can simulate the switched linear state-space model of the three-phase two-level voltage source converter in Simulink and display the signals in Simulation Data Inspector. The comparison of the runs show that the numeric results match with the original Simscape model.

Simulate the HDL implementation model.

```
sim('gmStateSpaceHDL_sschedlexThreePhaseConverter')
```

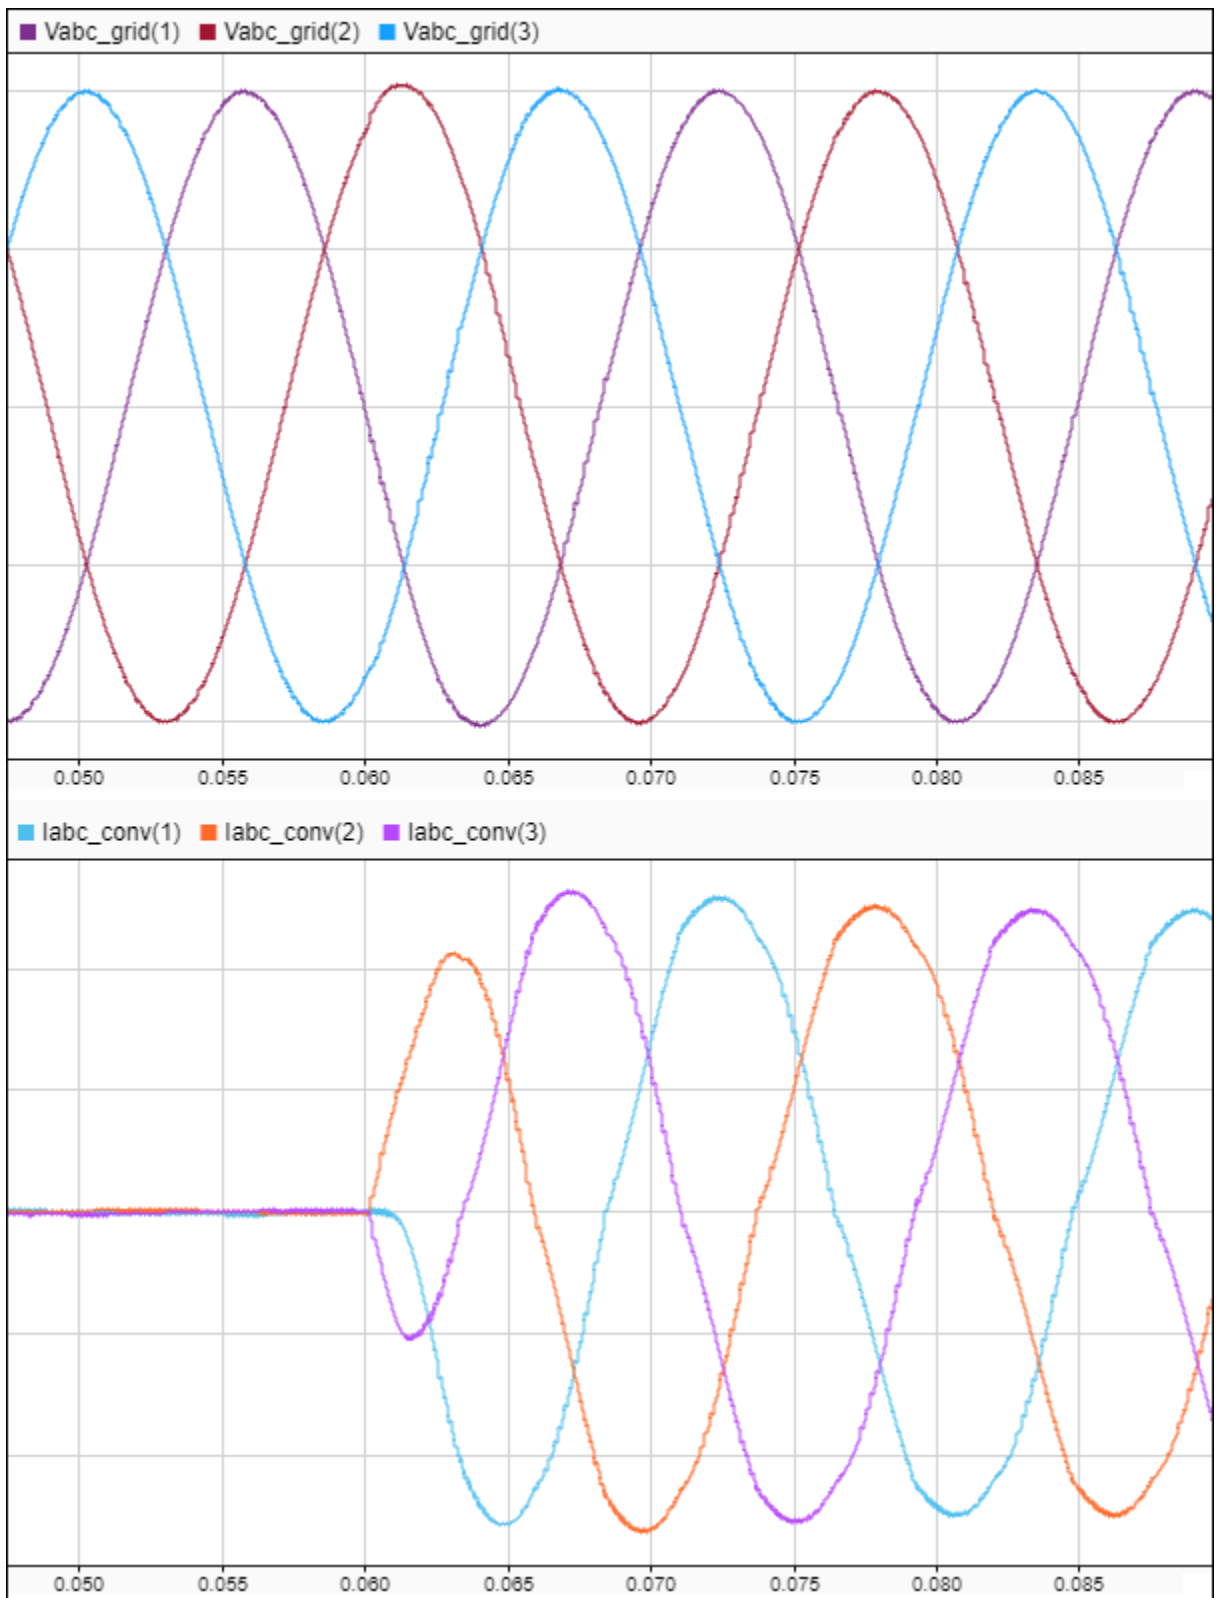

Display output signals of three-phase two-level voltage source converter Simscape model in Simulink Data Inspector

```
Simulink.sdi.clearAllSubPlots
Simulink.sdi.setSubPlotLayout(2,1);

allIDs = Simulink.sdi.getAllRunIDs;
runID1 = allIDs(end);
run2 = Simulink.sdi.getRun(runID1);
run2.name = 'HDL Model Simulation';

Vabc_grid = run2.getSignalsByName('Vabc_grid');
Iabc_conv = run2.getSignalsByName('Iabc_conv');
plotOnSubPlot(Vabc_grid.Children(1),1,1,true);
plotOnSubPlot(Vabc_grid.Children(2),1,1,true);
plotOnSubPlot(Vabc_grid.Children(3),1,1,true);
plotOnSubPlot(Iabc_conv.Children(1),2,1,true);
plotOnSubPlot(Iabc_conv.Children(2),2,1,true);
plotOnSubPlot(Iabc_conv.Children(3),2,1,true);

Simulink.sdi.view;
```

To verify that the HDL implementation model matches the original Simscape model, generate a state-space validation model. In the **Generate implementation model** task, select the **Generate validation logic for the implementation model** check box and then run this task. Simulating the model does not display assertions, which indicates that the numeric results match. See “Validate HDL Implementation Model to Simscape Algorithm” on page 37-95.

HDL Workflow Advisor

The HDL Workflow Advisor guides you through HDL code generation and the FPGA design process. Use the Advisor to:

- Check the model for HDL code generation compatibility and fix incompatible settings.
- Generate HDL code, test bench, and scripts to build and run the code and test bench.
- Perform synthesis, timing analysis, and deploy the generated code on SoCs, FPGAs, and Speedgoat I/O modules.

You run the Advisor for the FPGA subsystem in your model. To open the HDL Workflow Advisor for the subsystem inside the model, use the `hdladvisor` function. For example:

```
hdladvisor('gmStateSpaceHDL_sschedlexThreePhaseConverter/FPGA')
```

To learn about the tasks in the Advisor, right-click that task, and select **What's This?**. See “Getting Started with the HDL Workflow Advisor” on page 36-6.

Run Workflow Script to Generate Simulink Real-Time Interface Model

You can export the HDL Workflow Advisor settings to a script to expedite and automate your workflow. The script is a MATLAB® file that you run from the command line. You can modify and run the script, or import the settings into the HDL Workflow Advisor User Interface. See “Run HDL Workflow with a Script” on page 36-49.

This example shows how to run the HDL Workflow script. To generate a Simulink Real-Time Interface model, open and run this MATLAB script.

```
edit('hdlworkflow_I0334')

%% -----
% This script contains the model, target settings, interface mapping, and

Prepare Simulink Real-Time Interface Model for Real-Time Simulation

Running the workflow script generates RTL code and IP core, creates a Vivado project, builds the FPGA bitstream, and then generates the Simulink Real-Time Interface model.

Before deploying the model to the Speedgoat real-time target machine, getting model ready for real time testing:

```

generated_model = get_param(gcs, 'Name');

% comment through all rate transition blocks
RateTransitionBlocks = Simulink.findBlocksOfType(generated_model, 'RateTransition', Simulink.
for i = 1:length(RateTransitionBlocks)
    BlockName = get_param(RateTransitionBlocks(i), 'Name');
    if ~any(strcmp(BlockName, {'Data Type Conversion DAC1', 'Data Type Conversion DAC2'}))
        set_param([generated_model, '/', BlockName], 'Commented', 'through');
    end
end
end

```

```
% uncomment the subsystem for logging
set_param([generated_model,'/CPU Signal Logging'],'Commented','off');
```

Connect to Target Machine and Run Real-Time Simulation

The model can now be deployed to the Speedgoat real-time target machine. The three-phase two-level voltage source converter model is automatically loaded to the FPGA on the IO334.

Connect to the Speedgoat real-time target machine.

```
tg = slrealtime;
tg.connect;
```

Build and download the model to the target machine.

```
rtwbuild(generated_model);
tg.load(generated_model);
```

Start the model execution.

```
tg.start;

while strcmp(tg.status,'running')
    pause(10);
end
```

The file logging blocks store the signals on the SSD of the target-machine. The data is automatically uploaded to the host computer once the model is stopped. The data is visualized in Simulation Data Inspector. You can verify that the results of the real-time simulation matches the original Simscape model.

```
% Display grid voltage and converter current in SDI
Simulink.sdi.clearAllSubPlots
Simulink.sdi.setSubPlotLayout(2,1);

allIDs = Simulink.sdi.getAllRunIDs;
runID1 = allIDs(end);
run3 = Simulink.sdi.getRun(runID1);
run3.name = 'Real-Time Simulation';

Vabc_grid = run3.getSignalsByName('Vabc_grid');
Iabc_conv = run3.getSignalsByName('Iabc_conv');
plotOnSubPlot(Vabc_grid.Children(1),1,1,true);
plotOnSubPlot(Vabc_grid.Children(2),1,1,true);
plotOnSubPlot(Vabc_grid.Children(3),1,1,true);
plotOnSubPlot(Iabc_conv.Children(1),2,1,true);
plotOnSubPlot(Iabc_conv.Children(2),2,1,true);
plotOnSubPlot(Iabc_conv.Children(3),2,1,true);

Simulink.sdi.view;
```

Alternatively, you can measure the signals at the analog output of the IO334.

Partition Simscape Models Containing a Large Network into Multiple Smaller Networks

This example shows how to partition a solar power inverter model that contains a single, large Simscape™ network into multiple networks. After you partition the network, you can run the Simscape HDL Workflow Advisor to generate the HDL implementation model. To learn how you run the Advisor for the model, see “Generate HDL Code for Simscape Models with Multiple Networks” on page 37-71.

Why Partition a Simscape Network

When your Simscape model contains many switching elements, the state-space representation can contain a large number of modes. The Simscape HDL Workflow Advisor simulates the Simscape model to calculate the number of modes that are relevant. Certain Simscape models can have a large number of modes that are relevant. The generated HDL implementation model for such a large design can consume a significantly large number of resources, and the generated HDL implementation md may even fail to synthesize on the target FPGA device. To reduce the number of modes, you can partition the Simscape network in your model into multiple networks, and then run the Simscape HDL Workflow Advisor.

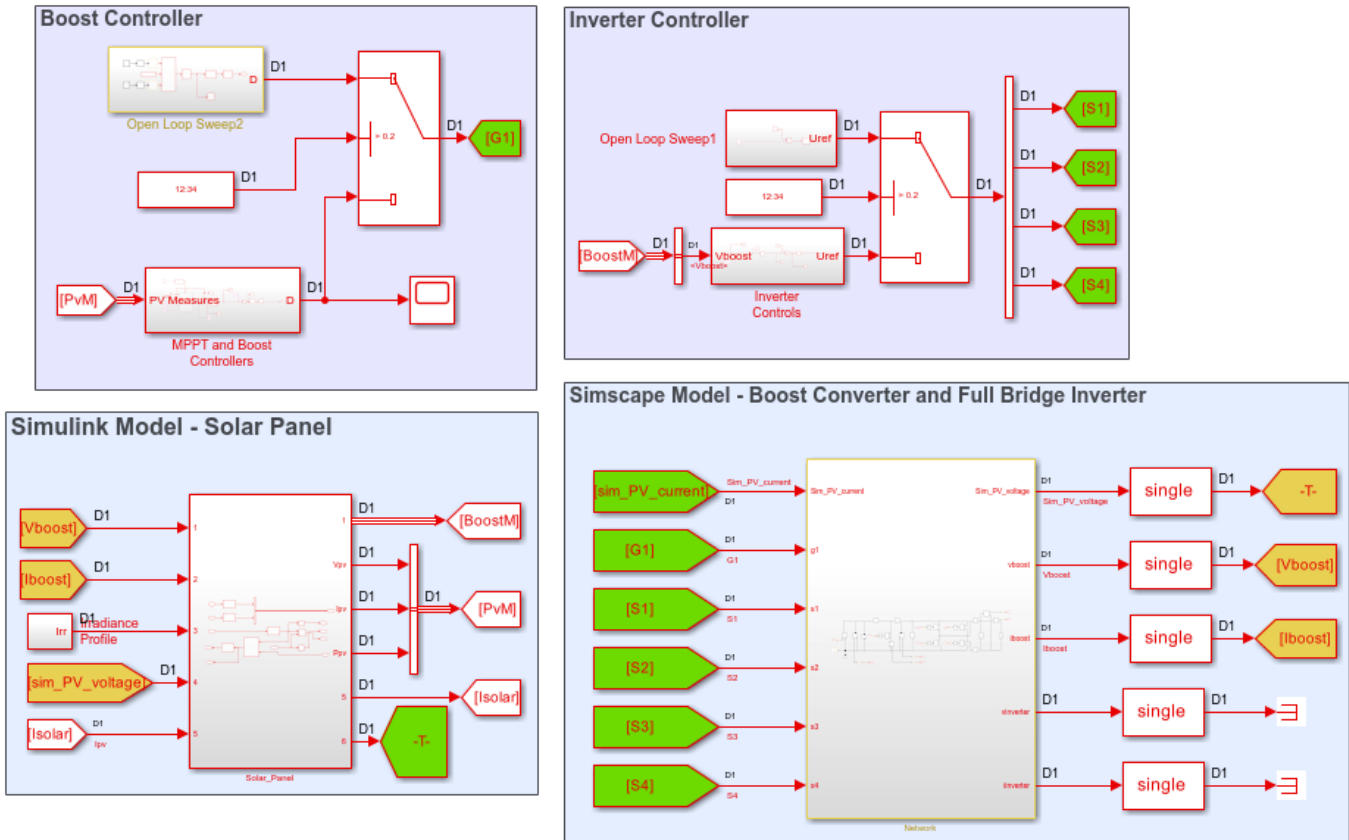

Solar Power Inverter Model with Single Network

To open the solar power inverter example model, run:

```
open_system('sschdlexSolarInverterSingleNetworkExample')
```

For this example, the model is saved as `Solar_Power_Inverter_Single_Network_HDL`. This model is the same as `sschdlexSolarInverterSingleNetworkExample` but has the subsystems rearranged and the logic for the solar panel placed inside a `Solar_Panel` subsystem.

```
open_system('Solar_Power_Inverter_Single_Network_HDL')
set_param('Solar_Power_Inverter_Single_Network_HDL', 'SimulationCommand', 'Update')
```

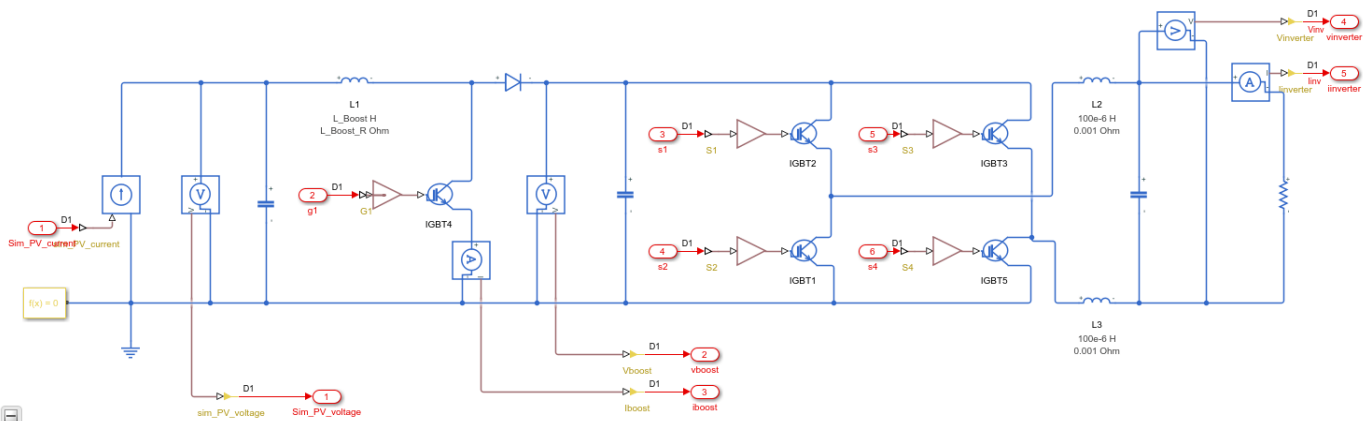

Copyright 2019 The MathWorks, Inc

The model consists of four parts: solar panel, boost controller, inverter controller, and a boost converter and full bridge inverter. The solar panel is modeled in Simulink® by using lookup tables. The boost controller and inverter controller provide the control signals for the boost converter and the full bridge inverter which is an H-bridge.

To see the boost converter and inverter, open the Network subsystem.

`open_system('Solar_Power_Inverter_Single_Network_HDL/Network')`

Run Simscape HDL Workflow Advisor

1. To open the Simscape HDL Workflow Advisor for the model, enter:

```
sschdladvisor('Solar_Power_Inverter_Single_Network_HDL')
```

```
### Running Simscape HDL Workflow Advisor for <a href="matlab:(Solar_Power_Inverter_Single_Netwo
```

2. Run the workflow to the **Discretize Equations** task. You see that the state-space representation uses around 173 modes, which is a large number of modes.

Summary of the state-space representation:

Details related to the Simscape network [Solar_Power_Inverter_Single_Network_HDL/Network/Solver Configuration](#)

Parameter	Parameter size
A	18 x 18 x 173
B	18 x 6 x 173
F0	18 x 1 x 173
C	5 x 18 x 173
D	5 x 6 x 173
Y0	5 x 1 x 173

Such a large number of modes can consume a significantly large number of hardware resources, and may even cause the DUT subsystem in the HDL implementation model to fail to synthesize on the target FPGA device.

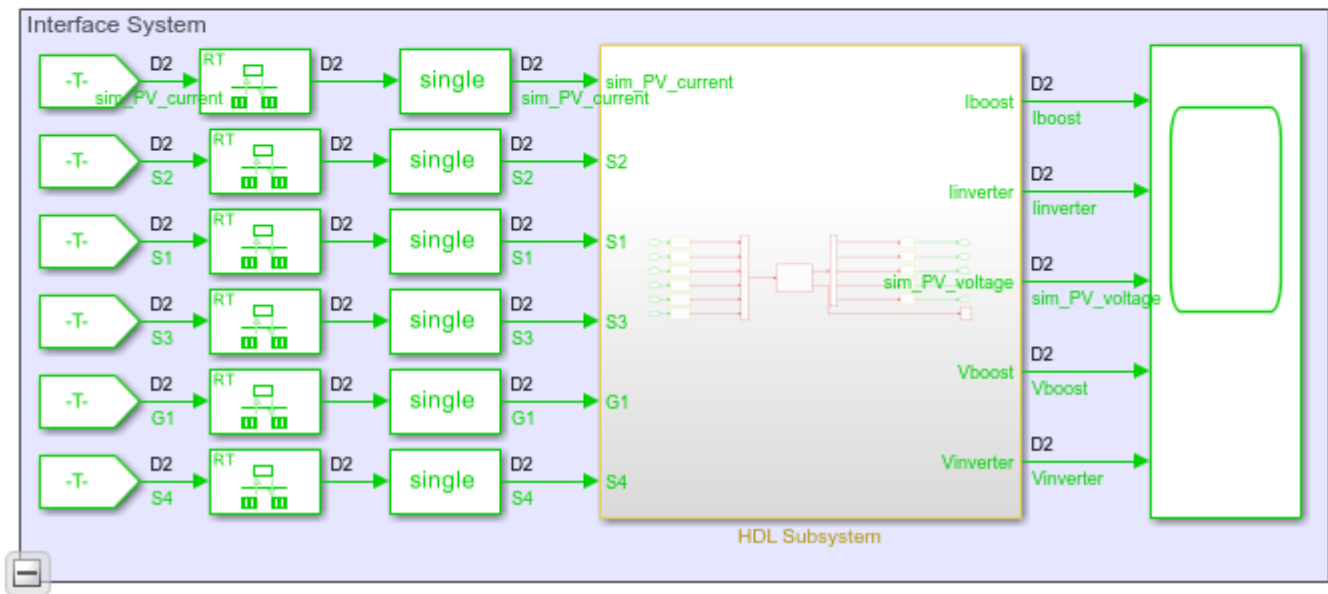

Generate HDL Implementation Model and View Resource Consumption

To see the resource consumption:

1. Run the **Generate implementation model** task. Click the link to open the HDL implementation model.

The model contains a HDL Subsystem block that models the state-space equations for the Simscape network. Save the model as `Solar_Power_Inverter_Single_Network_StateSpace.slx`.

```
open_system('Solar_Power_Inverter_Single_Network_StateSpace')
set_param('Solar_Power_Inverter_Single_Network_StateSpace', 'SimulationCommand', 'Update')
```

2. Enable generation of the resource utilization report.

```
hdlset_param('Solar_Power_Inverter_Single_Network_StateSpace', 'ResourceReport', 'on')
```

3. Run the makehdl function to generate code for the HDL Subsystem block.

```
makehdl('Solar_Power_Inverter_Single_Network_StateSpace/HDL Subsystem')
```

If HDL Coder™ generates an error that it is unable to allocate delays, increase the **Oversampling factor**. Start by increasing the **Oversampling factor** to 100, and then generate HDL code. If HDL Coder is still unable to allocate delays, then further increase the **Oversampling factor**.

```
hdlset_param('Solar_Power_Inverter_Single_Network_StateSpace', 'Oversampling', 100)
```

4. As you generate HDL code, open the Code Generation Report. The resource utilization report indicates a large amount of multipliers, adders, and registers that might be consumed on the target FPGA device.

Summary

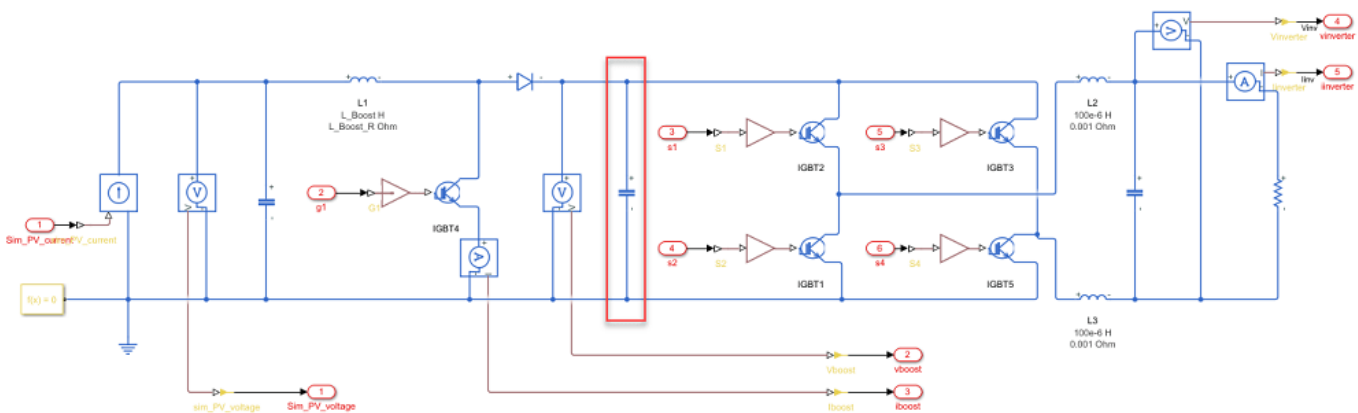

Multipliers	173
Adders/Subtractors	2959
Registers	16218
Total 1-Bit Registers	161776
RAMs	0
Multiplexers	25511
I/O Bits	356
Static Shift operators	0
Dynamic Shift operators	352

Partition Solar Inverter Network into Multiple Simscape Networks

To reduce the number of modes, you can partition the Simscape network inside the Network subsystem into two Simscape networks. To partition the network into multiple networks:

1. Identify the boundary for partitioning the network into multiple networks. An energy storage element such as a capacitor or an inductor makes a good candidate for partitioning the network. To produce a Simscape model that contains multiple networks and effectively reduces the number of modes in the state-space representation, choose a boundary that produces identical or near identical partitions. That is, the number of switching elements on either side of the boundary are identical or nearly identical.

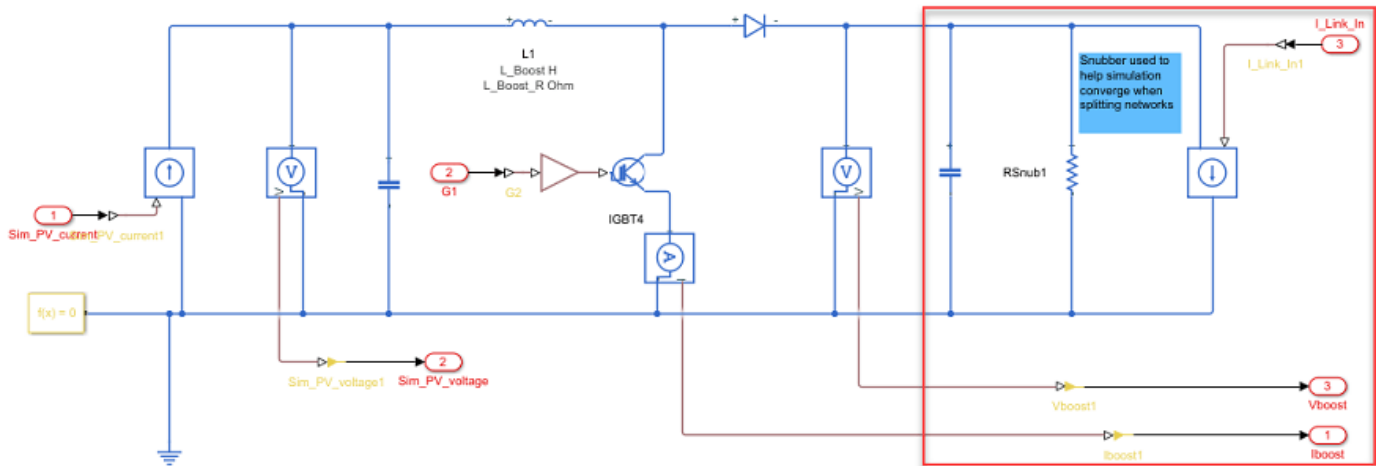

For the solar power inverter, you can choose the DC link capacitor between the H-bridge inverter and the boost converter as the boundary for partitioning the network.

2. After you partition the network, prepare the modified Simscape model for compatibility with the Simscape HDL Workflow Advisor. Place each partitioned network inside a subsystem and use a Solver Configuration block for each network.

The Simscape HDL Workflow Advisor uses the Solver Configuration block to identify each unique network in your Simscape model.

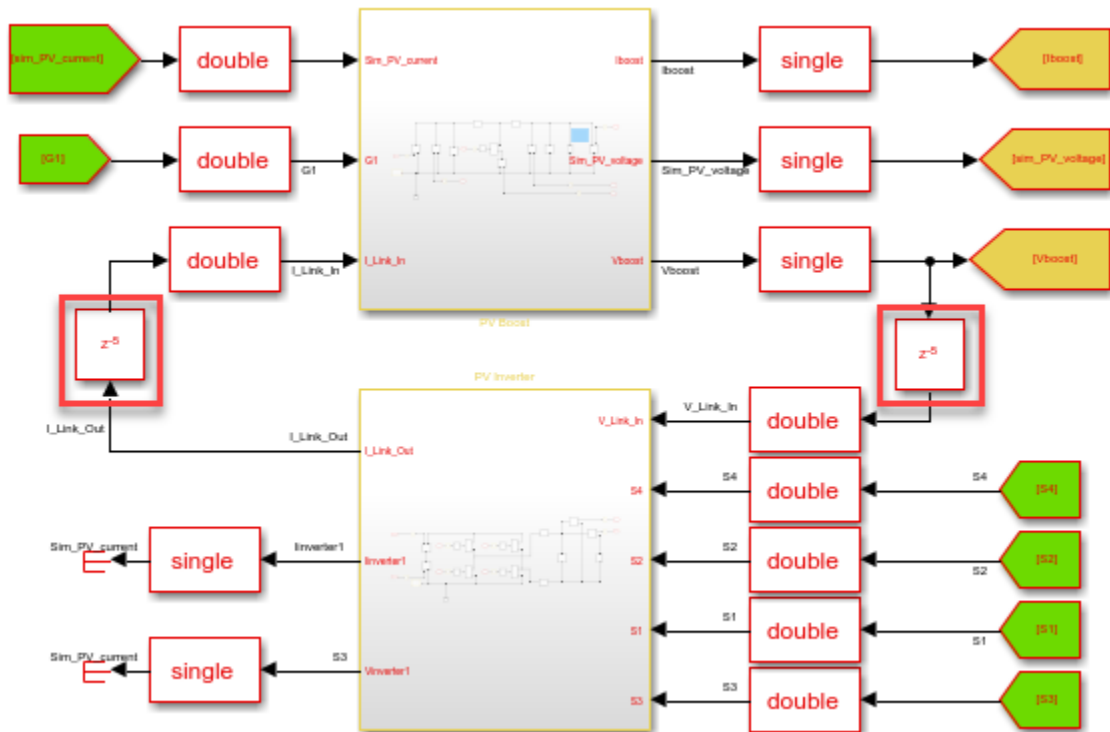

3. For the simulation to converge when using multiple networks, in the network containing the boost converter, add a snubber resistance and a controlled current source in parallel to the capacitor for the current output to the inverter network.

4. In the inverter network, add a controlled voltage source to the voltage input to the network.

5. To break the algebraic loops in the system, add Delay blocks between the signal lines that connect the output of one subsystem to the input of the other subsystem. For higher accuracy, add Data Type Conversion blocks to provide double data types as inputs to the networks.

Solar Power Inverter Model with Multiple Networks

The single network model is now partitioned into multiple networks. To open the model containing multiple networks, enter:

```
open_system('sschdlexSolarInverterPartitionedNetworkExample')
```

To learn how you run the Simscape HDL Workflow Advisor and generate HDL code for this model, see “Generate HDL Code for Simscape Models with Multiple Networks” on page 37-71.

Generate HDL Code for Simscape Models with Multiple Networks

This example shows how you can run the Simscape HDL Workflow Advisor to generate the HDL implementation model for a Simscape™ model that contains multiple networks. You can also generate a validation logic that numerically compares each Simscape network with the corresponding state-space implementation in the HDL implementation model. The Simscape model in this example is a solar power inverter partitioned into two networks. To learn how this network is partitioned, see “Partition Simscape Models Containing a Large Network into Multiple Smaller Networks” on page 37-64.

Why Use a Simscape Model with Multiple Networks

When your Simscape model contains many switching elements, the state-space representation can contain a large number of modes. The generated HDL implementation model for such a large design can consume a significantly large number of resources, and may even fail to synthesize on the target FPGA device. To reduce the number of modes, you can partition the Simscape network in your model into multiple networks, and then run the Simscape HDL Workflow Advisor.

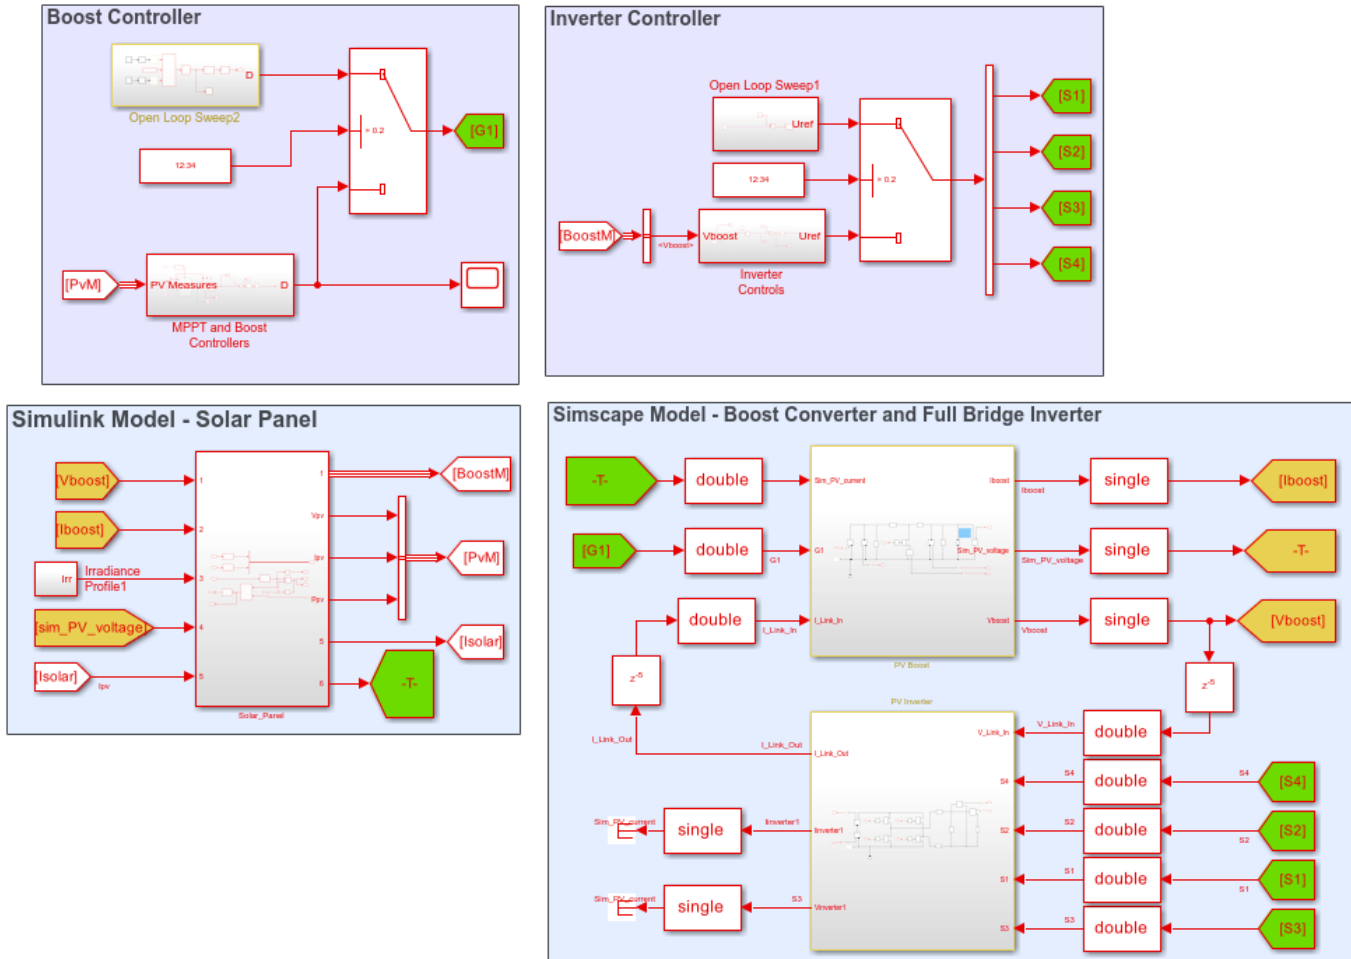

Solar Power Inverter Model with Multiple Networks

To open the model that contains multiple networks, run:

```
open_system('sschdlexSolarInverterPartitionedNetworkExample')
```

For this example, the model is saved as `Solar_Power_Inverter_Multiple_Network_HDL`. This model is the same as `sschdlexSolarInverterPartitionedNetworkExample` but has the subsystems rearranged and the logic for the solar panel placed inside a `Solar_Panel` subsystem.

```
open_system('Solar_Power_Inverter_Multiple_Network_HDL')
set_param('Solar_Power_Inverter_Multiple_Network_HDL', 'SimulationCommand', 'Update')
```

Copyright 2019 The MathWorks, Inc

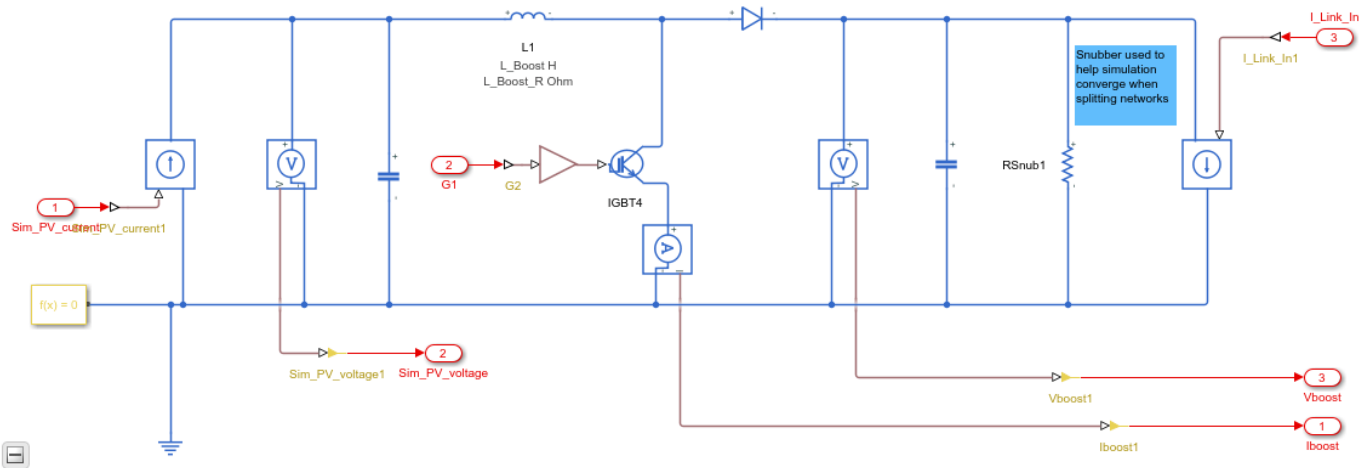

The model consists of four parts: solar panel, boost controller, inverter controller, and a boost converter and full bridge inverter. The solar panel is modeled in Simulink® by using lookup tables. The boost controller and inverter controller provide the control signals for the boost converter and the full bridge inverter which is an H-bridge.

The original model contains the boost converter and full bridge inverter as a single network inside one subsystem. To see this model, enter:

```
open_system('sschdlexSolarInverterSingleNetworkExample')
```

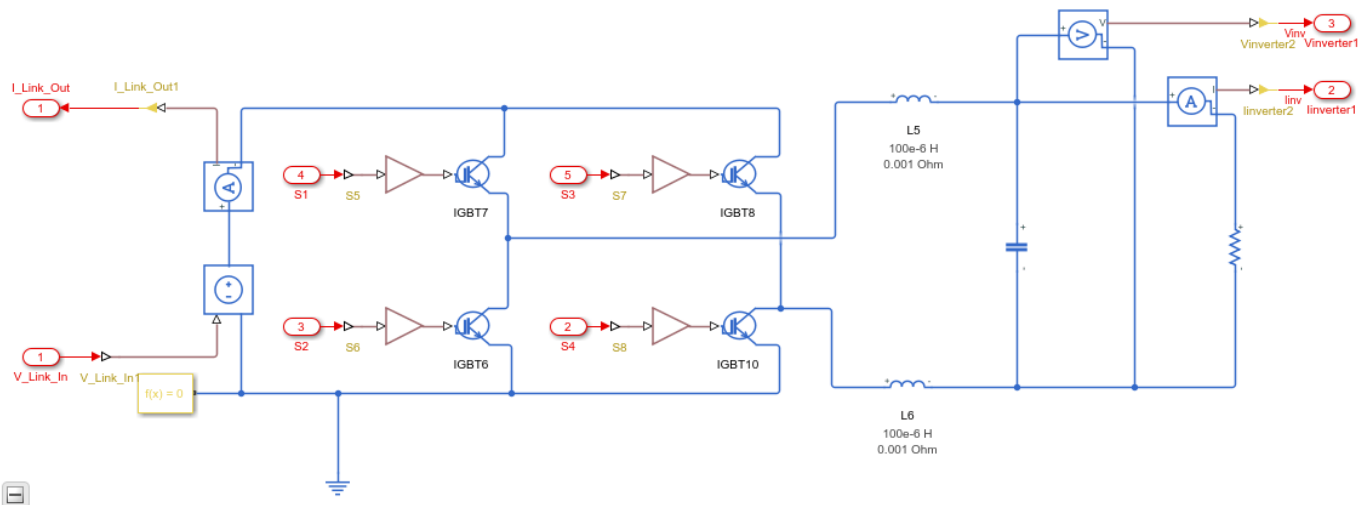

The partitioned model contains the two networks inside separate subsystems. To see the boost converter, open the PV Boost subsystem.

```
open_system('Solar_Power_Inverter_Multiple_Network_HDL/PV Boost')
```

To see the full bridge inverter, open the PV Inverter subsystem.

```
open_system('Solar_Power_Inverter_Multiple_Network_HDL/PV Inverter')
```

Run Simscape HDL Workflow Advisor for Model with Multiple Networks

1. To open the Simscape HDL Workflow Advisor for the model, enter:

```
sschdladvisor('Solar_Power_Inverter_Multiple_Network_HDL')
```

```
### Running Simscape HDL Workflow Advisor for <a href="matlab:(Solar_Power_Inverter_Multiple_Net
Updating Model Advisor cache...
Model Advisor cache updated. For new customizations, to update the cache, use the Advisor.Manage
```

2. Run the workflow to the **Check switched linear** task.

The Simscape HDL Workflow Advisor lists the number of networks present in the model and the number of algebraic and differential variables for each network. The Advisor uses the Solver Configuration block to identify each unique network in your model.

Number of Simscape networks present in the model: 2

Open HDL Implementation Model and Validate HDL Algorithm

To open the implementation model, click the link in the **Generate implementation model** task log. Rename the model as Solar_Power_Inverter_Multiple_Network_StateSpace.

```
open_system('Solar_Power_Inverter_Multiple_Network_StateSpace')
set_param('Solar_Power_Inverter_Multiple_Network_StateSpace', 'SimulationCommand', 'Update')
```

The model contains two HDL Subsystems. The HDL Subsystem block models the state-space equations for the boost converter. The HDL Subsystem1 block models the state-space equations for the full bridge inverter. The Validation and Validation1 subsystems compare functional equivalence of the state space representation of the boost converter and full bridge inverter with the corresponding Simscape network in the original model.

The state-space parameters are saved in a MAT file `Solar_multiple_network_stateSpaceParameters.mat`. The file contains a cell array of two structures. One structure contains the parameters for the boost converter. The other structure contains the parameters for the full bridge inverter.

To compare the functional equivalence, simulate the model. If simulating the model produces assertions, you can resolve the validation mismatch by modifying a combination of various settings in the **Generate implementation model** task until the HDL implementation model matches the Simscape algorithm. The settings include increasing the validation logic tolerance, increasing the number of solver iterations, and changing the floating-point precision. For more information, see “Validate HDL Implementation Model to Simscape Algorithm” on page 37-95.

Generate HDL Code and Validation Model

1. Enable generation of the resource utilization report.

```
hdlset_param('Solar_Power_Inverter_Multiple_Network_StateSpace', 'ResourceReport', 'on')
```

2. Before you generate HDL code, it is recommended that you enable generation of the validation model. The validation model compares the output of the generated model after code generation to the output of the original model. To learn more, see “Generated Model and Validation Model” on page 28-10.

```
HDLmodelName = 'Solar_Power_Inverter_Multiple_Network_StateSpace';
hdlset_param(HDLmodelName, 'TargetDirectory', 'C:/Temp/hdlsrc');
hdlset_param(HDLmodelName, 'GenerateValidationModel', 'on');
```

3. Run the `makehdl` function to generate code. To generate HDL code for both HDL Subsystem blocks, you can place the blocks inside another top level subsystem and then generate HDL code. Name this subsystem as `HDL_DUT`.

```
makehdl('Solar_Power_Inverter_Single_Network_StateSpace/HDL_DUT')
```

The generated HDL code and validation model are saved in `C:/Temp/hdlsrc` directory. The generated code is saved as `HDL_DUT_tc.vhd`. To open the validation model, click the link to `gm_Solar_Power_Inverter_Multiple_Network_StateSpace_vnl.slx` in the code generation logs in the Command Window.

4. As you generate HDL code, open the Code Generation Report. The resource utilization report indicates a large amount of adders, multipliers, and registers that might be consumed on the target FPGA device.

Summary

Multipliers	103
Adders/Subtractors	1751
Registers	9957
Total 1-Bit Registers	100465
RAMs	0
Multiplexers	15562
I/O Bits	452
Static Shift operators	0
Dynamic Shift operators	214

The overall resource consumption of the two networks is significantly less than the resource consumption of a single, large network. To learn about the resource consumption of the single solar power inverter network, see “Partition Simscape Models Containing a Large Network into Multiple Smaller Networks” on page 37-64.

Replace Piecewise-Constant Resistor with Switched Linear Components

This example shows how to convert a Simscape™ model that has a Piecewise-Constant Resistor (nonlinear component) into a switched linear model, making it compatible with Simscape Hardware-in-the-Loop (HIL) workflow.

Introduction

Simscape HIL workflow supports conversion of Simscape models to functionally equivalent Simulink® models that are compatible for HDL code generation. In this example, the model uses a Piecewise-Constant Resistor that is event based. Events are not supported by the Simscape HIL workflow. You can convert such Simscape models to a switched linear model and make it compatible for HDL code generation. For more information, see “Generate HDL Code for Simscape Models” on page 37-13.

Open the Simscape model from the MATLAB® command prompt.

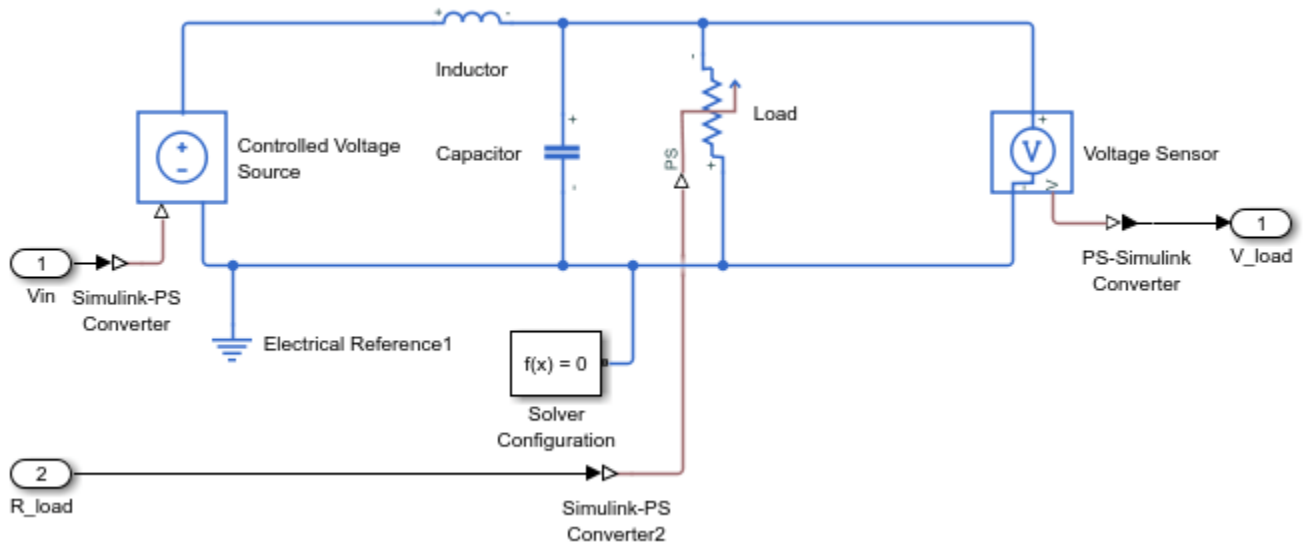

```
NonlinearModel = 'sschdlexVariableResistorExample';  
open_system(NonlinearModel)  
set_param(NonlinearModel, 'SimulationCommand', 'update');
```

Copyright 2019-2022 The MathWorks, Inc.

Open the Simscape subsystem.

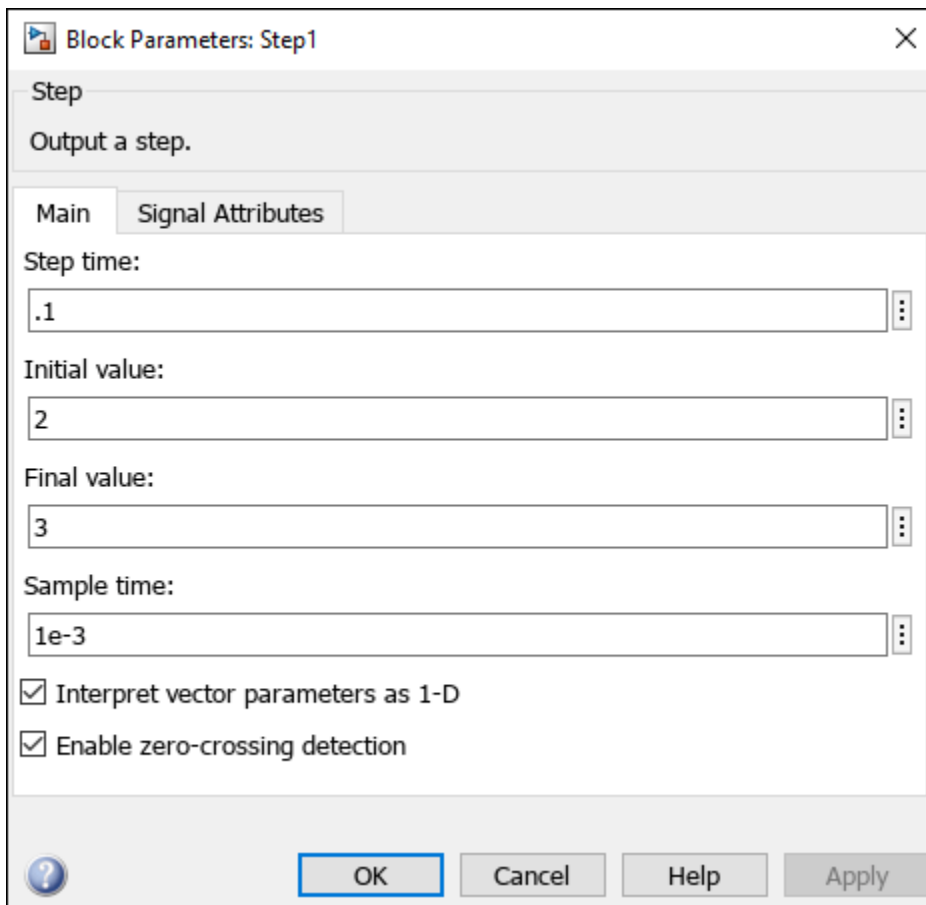

```
open_system([NonlinearModel, '/Simscape Subsystem'])
```

This model is an RLC circuit with a Piecewise-Constant Resistor acting as a "Load" resistance. For the Piecewise-Constant Resistor, the relationship between voltage V and current I is $V = I * R$, where R is the numerical value presented at the physical signal port R .

To ensure a positive value for the resistance, any value below $1e-6$ is replaced by $1e-6$. This resistor is piecewise-constant because the resistance only changes when the input value differs from the current resistance value by more than the set tolerance. Thus, a continuously changing input is converted to a discrete set of resistances.

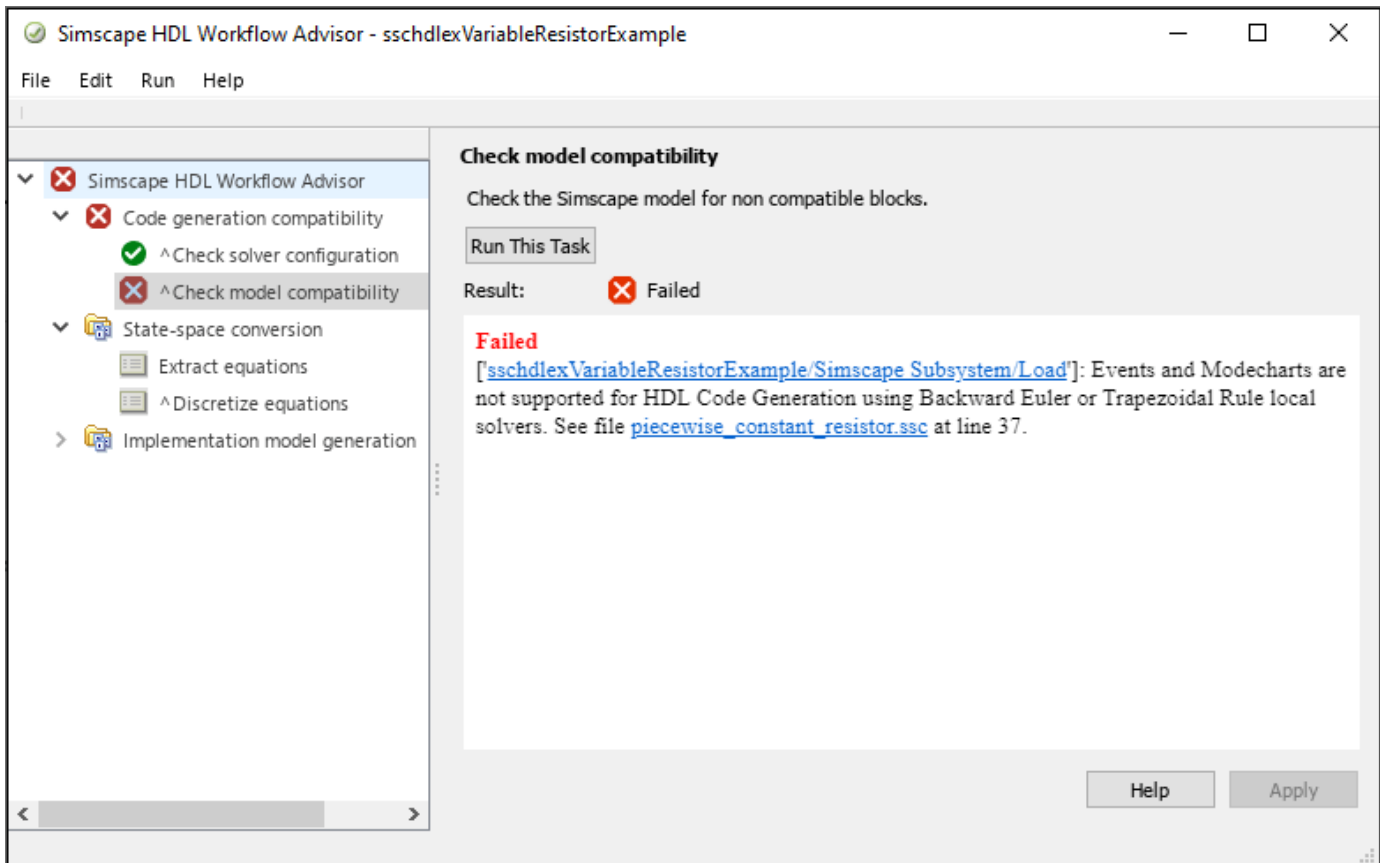

In this model, the signal going into the Piecewise-Constant Resistor is a step function that changes from 2 to 3 at $t = 0.1$ thus changing the load resistance from 2Ω to 3Ω .

Open the Simscape HDL Workflow Advisor using `sschdladvisor` function.

```
sschdladvisor(NonlinearModel)
```

In the Simscape HDL Workflow Advisor, right-click the **Code generation compatibility > Check model compatibility** task and select **Run to Selected Task**. This task fails because of the presence of the Piecewise-Constant Resistor.

Replace Piecewise-Constant Resistor with Switches and Constant Resistors

To convert this model to an equivalent switched linear model, replace the Piecewise-Constant Resistor with a set of switches and resistors for each desired value. Open the switched linear version of the model.

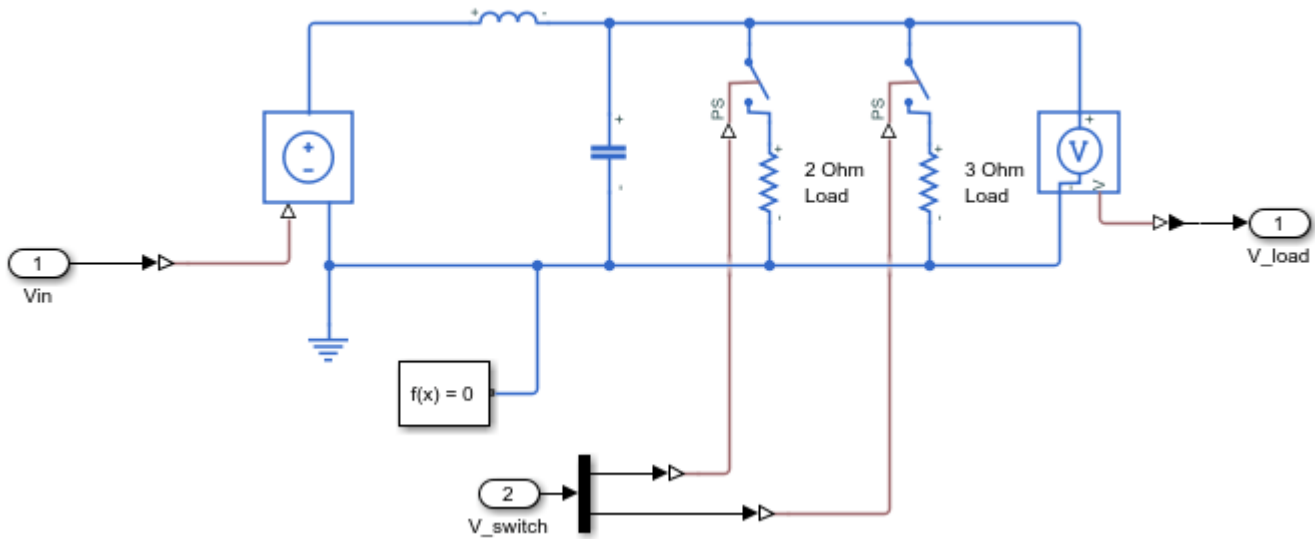

```
SwitchedLinearModel = 'sschdlexVariableResistorSwitchedLinearExample';
open_system(SwitchedLinearModel)
set_param(SwitchedLinearModel, 'SimulationCommand', 'update');
```

Copyright 2019-2022 The MathWorks, Inc.

Instead of a Piecewise-Constant Resistor, the model uses a resistor and a switch for each desired resistance. In particular, it uses a resistance of $2\ \Omega$ and the other with a resistance of $3\ \Omega$. By closing and opening the switches at $t = 0.1$, the model changes the load resistance from $2\ \Omega$ to $3\ \Omega$.

```
open_system([SwitchedLinearModel, '/Simscape Subsystem'])
```

Controlling the Switches

Open the control signals for the switches.

```
open_system([SwitchedLinearModel, '/Input'])
```

The input signal V_switch contains two step functions, one that opens the switch in series with the $2\ \Omega$ resistor at $t = 0.1$ and one that closes the switch in series with the $3\ \Omega$ resistor at the same time.

Generate HDL Implementation Model

Use the default **Solver Configuration** settings for the switched linear model:

- Solver type: Backward Euler
- Sample time: $1e-3$

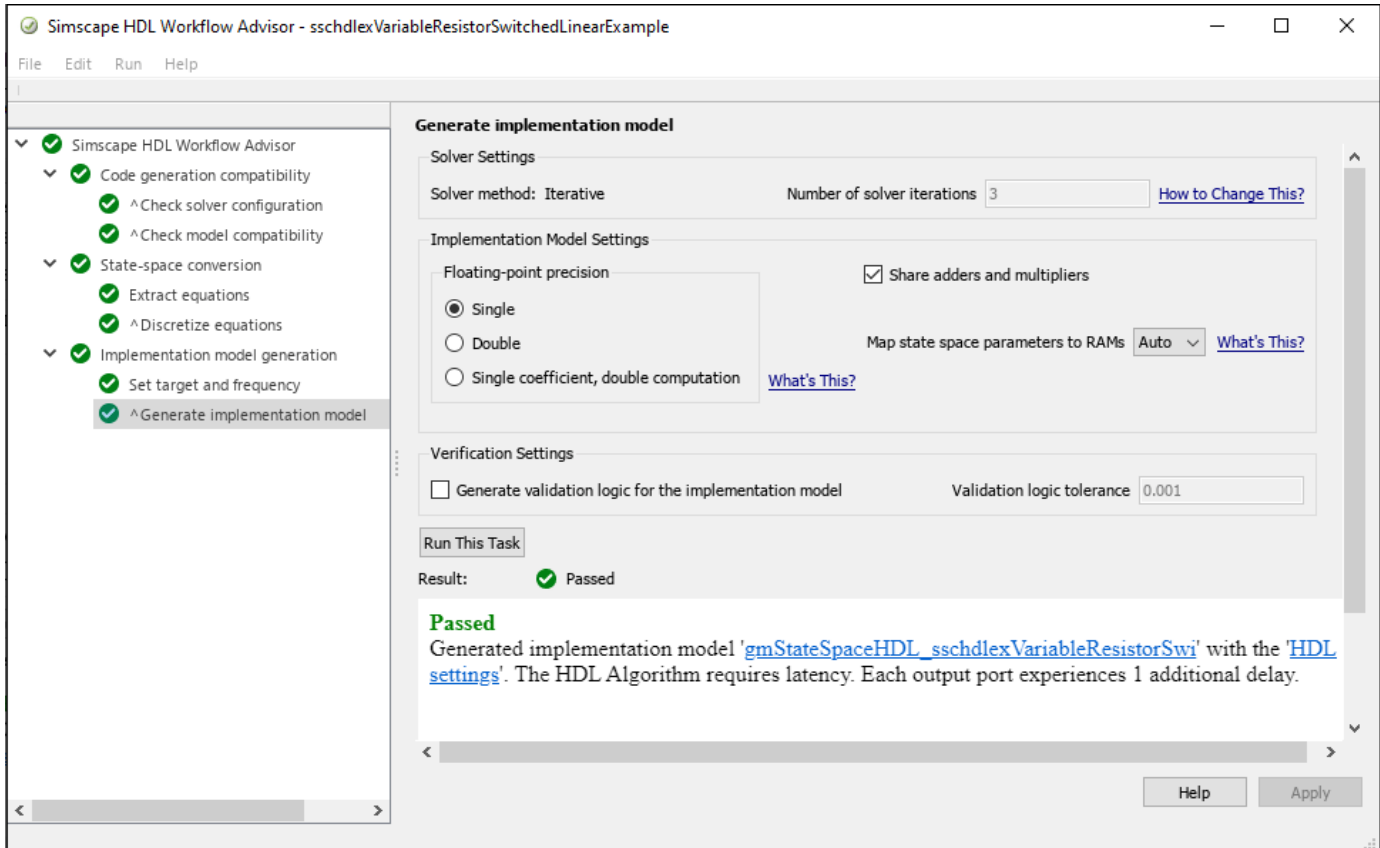

In the model window, you can view the model statistics. Select the **Debug** tab and click **Simscape > Statistics Viewer**. This opens the Simscape Statistics window for `sschdlexVariableResistorExample` model.

Open the Simscape HDL Workflow Advisor for the switched linear model.

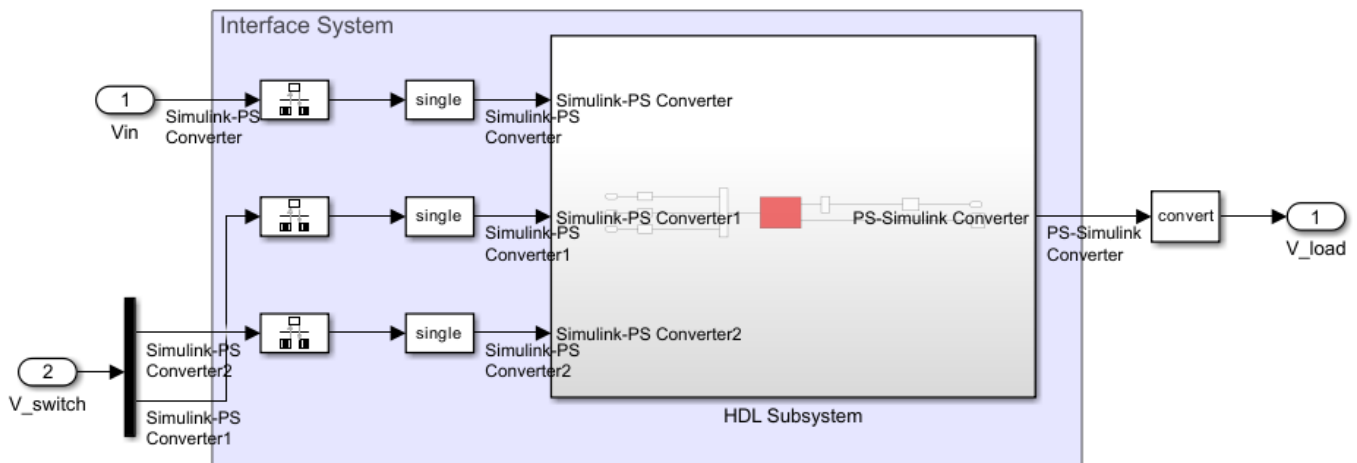

```
sschdladvisor(SwitchedLinearModel)
```

To generate the HDL implementation model, right-click the **Implementation model generation > Generate implementation model** task, and then select **Run to Selected Task**.

After the last task passes, it creates a link to the HDL implementation model `gmStateSpaceHDL_sschdlexVariableResistorSwi`.

Click on this link to open the generated implementation model.

The **Extract equations** task output displays the number of states, inputs, outputs, modes, and differential variables for the Simscape network.

Details related to the Simscape network [sschdlexVariableResistorSwitchedLinearExample/Simscape Subsystem/Solver Configuration](#)

- Number of states: 5
- Number of inputs: 3
- Number of outputs: 1
- Number of modes: 2
- Number of differential variables: 2

The **Discretize equations** task output displays the state-space representation in the right pane.

Details related to the Simscape network [sschdlexVariableResistorSwitchedLinearExample/Simscape Subsystem/Solver Configuration](#)

Parameter	Parameter size
A	5 x 5 x 2
B	5 x 3 x 2
F0	5 x 1 x 2
C	1 x 5 x 1
D	1 x 3 x 1
Y0	1 x 1 x 1

Generate HDL Code

To set up model parameters for HDL code generation, run the `hdlsetup` function.

```
hdlsetup('gmStateSpaceHDL_sschdlexVariableResistorSwi')
```

Save the parameters for the HDL implementation model.

```
hdlsaveparams('gmStateSpaceHDL_sschdlexVariableResistorSwi')
```

Enable generation of the resource utilization report.

```
hdlset_param('gmStateSpaceHDL_sschdlexVariableResistorSwi', 'ResourceReport', 'on')
hdlset_param('gmStateSpaceHDL_sschdlexVariableResistorSwi', 'MaskParameterAsGeneric', 'off');
```

Generate HDL code for the implementation model.

```
makehdl('gmStateSpaceHDL_sschdlexVariableResistorSwi/Simscape Subsystem/HDL Subsystem');
```

When you generate code, HDL Coder creates a code generation report. The resource utilization report in the **High-level Resource Report** indicates the number of adders, multipliers, and registers that might be consumed on the target FPGA device.

Summary

Multipliers	17
Adders/Subtractors	227
Registers	1250
Total 1-Bit Registers	11316
RAMs	0
Multiplexers	1789
I/O Bits	132
Static Shift operators	0
Dynamic Shift operators	22

By changing the Piecewise-Constant Resistor to resistors that switch on and off, you change the model to a form that is compatible with the Simscape to HDL workflow.

Hardware-in-the-Loop Implementation of Simscape Model on Speedgoat FPGA I/O Modules

This example shows how to synthesize and generate FPGA bitstream from a Simscape™ half-wave rectifier model and download the bitstream to a Speedgoat® FPGA I/O 334-325K target for Hardware-in-the-Loop (HIL) implementation.

Hardware-in-the-Loop Workflow

- 1 Generate a HDL implementation model from the Simscape model by using the Simscape HDL Workflow Advisor. The HDL implementation model is a Simulink® model that replaces the Simscape algorithm with HDL-compatible blocks
- 2 Generate FPGA bitstream for the HDL implementation model by using the HDL Workflow Advisor
- 3 Download the bitstream to the Speedgoat FPGA I/O module by using the Simulink Real-Time Explorer for Hardware-in-the-Loop Simulation.

Half Wave Rectifier Model

Open the Simscape half wave rectifier model. In the MATLAB® command prompt, enter:

```
ModelName = 'sschdlexHalfWaveRectifierExample';
open_system(ModelName)
set_param(ModelName, 'SimulationCommand', 'update');
```

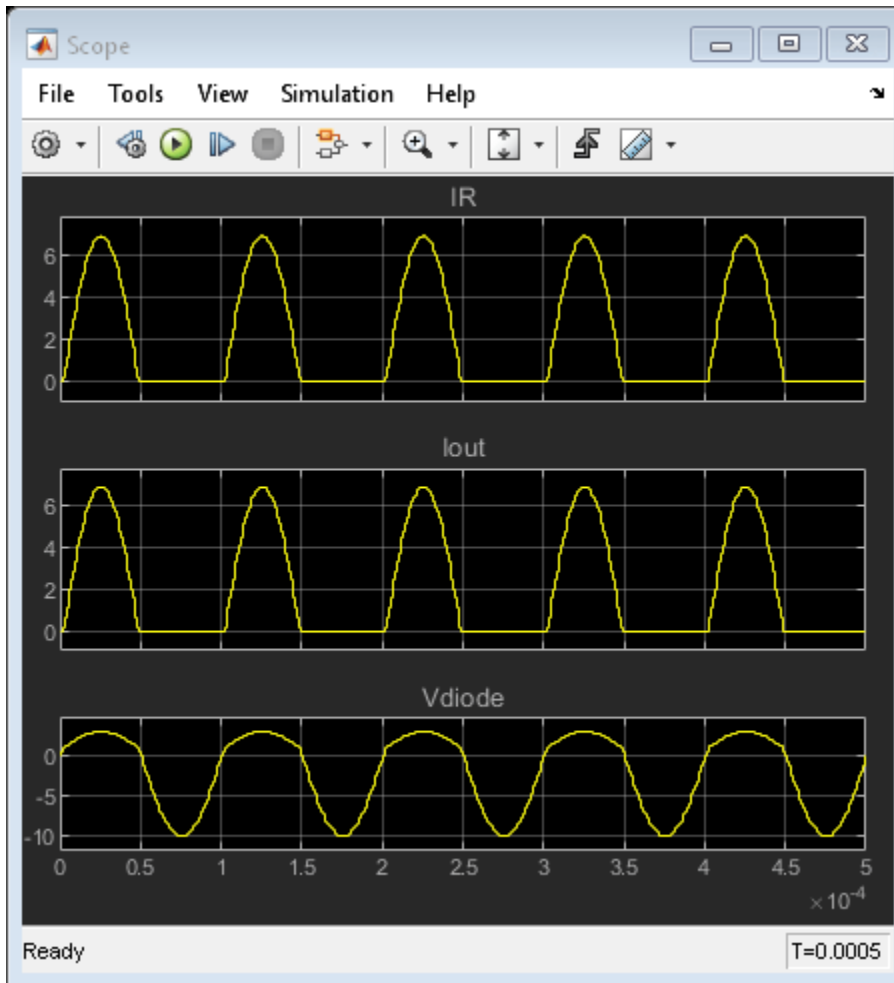

```
open_system([ModelName, '/Simscape_system'])
```

The half-wave rectifier consists of a Resistor, which is a linear block, and a Diode, which is a switched linear block. At the input and output port interfaces, the model has Simulink-PS Converter and PS-Simulink Converter blocks. The solver settings are configured for compatibility with Simscape HDL Workflow Advisor. If you open the Block Parameters dialog box for the Solver Configuration block, **Use local solver** is selected and **Backward Euler** is specified as the **Solver type**. See “Get Started with Simscape Hardware-in-the-Loop Workflow” on page 37-2.

To see the algorithm functionality, simulate the model.

```
sim(ModelName)
open_system([ModelName, '/Scope'])
```

2. Configure the Simscape Model for HDL compatibility by using the `hdlsetup` function:

```
hdlsetup('sschdlexHalfWaveRectifierExample')
```

Generate HDL Implementation Model

To generate the HDL implementation model:

1. Open the Simscape HDL Workflow Advisor:

```
sschdladvisor('sschdlexHalfWaveRectifierExample')
```

2. To compare functionality of the HDL implementation model with the original Simscape algorithm, select the **Generate implementation model** step, and then select the **Generate validation logic for the implementation model** check box. Use a **Validation logic tolerance** of 0.001. Right-click the **Generate implementation model** step and select **Run to Selected Task**.

The Advisor generates an HDL implementation model and a state-space validation model. To compare functionality of the HDL implementation model with the original Simscape algorithm, open and simulate the state-space validation model. The output of this model matches the original Simscape model. For a more systemic verification, see “Validate HDL Implementation Model to Simscape Algorithm” on page 37-95.

See also “Simscape HDL Workflow Advisor Tasks” on page 38-2.

Setup and Configuration

The Speedgoat IO334-325K FPGA module uses Xilinx® Vivado® and *IP Core Generation* workflow infrastructure. Before you deploy the HDL implementation model on the Speedgoat I/O module:

1. Install Xilinx Vivado and Setup Tool Path

Install the latest version of Xilinx® Vivado® as listed in “HDL Language Support and Supported Third-Party Tools and Hardware”. Then, set the tool path to the installed Xilinx Vivado executable by using the `hdlsetuptoolpath` function.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2020.1\bin\vivado.bat')
```

2. Install Speedgoat I/O Blockset and Speedgoat - HDL Coder Integration Packages

Install the Speedgoat I/O Blockset and the Speedgoat - HDL Coder Integration packages. See Install Speedgoat HCIP.

3. Setup I/O Module

For real-time simulation, set up the I/O module. See Xilinx HDL Software for Speedgoat I/O Modules.

HDL Workflow Advisor

The HDL Workflow Advisor guides you through HDL code generation and the FPGA design process. Use the Advisor to:

- Check the model for HDL code generation compatibility and fix incompatible settings.
- Generate HDL code, test bench, and scripts to build and run the code and test bench.
- Perform synthesis and timing analysis.
- Deploy the generated code on SoCs, FPGAs, and Speedgoat I/O modules.

To open the HDL Workflow Advisor, use the `hdladvisor` function.

```
hdladvisor('gmStateSpaceHDL_sschedlexHalfWaveRectifierEx/Simscape_system/HDL Subsystem')
```

The left pane contains folders that represent a group of related tasks. Expanding the folders and selecting a task displays information about that task in the right pane. The right pane can contain simple controls for running the task to advanced parameters and option settings that control code and test bench generation. To learn more about each task, right-click that task, and select **What's This?**. See “Getting Started with the HDL Workflow Advisor” on page 36-6.

Generate FPGA Bitstream for Speedgoat Target Computer

1. Open the HDL implementation model, and then open the HDL Workflow Advisor for the implementation model.

```
open_system('gmStateSpaceHDL_sschedlexHalfWaveRectifierEx')
hdladvisor('gmStateSpaceHDL_sschedlexHalfWaveRectifierEx/HDL Subsystem')
```

2. In **Set Target Device and Synthesis Tool** task, specify **Target workflow** as Simulink Real-Time FPGA I/O and **Target platform** as Speedgoat IO334-325K.

1.1. Set Target Device and Synthesis Tool

Analysis (^Triggers Update Diagram)

Set Target Device and Synthesis Tool for HDL code generation

Input Parameters

Target workflow: Simulink Real-Time FPGA I/O

Target platform: Speedgoat IO334-325k Launch Board Manager

Synthesis tool: Xilinx Vivado Tool version: 2019.2.1 Refresh

Family: Kintex7 Device: xc7k325t

Package: fbg676 Speed: -2

Project folder: hdl_prj Browse...

3. In the **Set Target Reference Design** task, select a value of x4 for the parameter PCIe lanes, and select **Run This Task**.

4. In **Set Target Interface** task, map the input and output single data type ports to PCIe Interface and select **Run This Task**.

1.3. Set Target Interface

Analysis (^Triggers Update Diagram)

Set target interface for HDL code generation

Input Parameters

Processor/FPGA synchronization: Free running

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
Simulink-PS Converter	Inport	single	PCIe Interface	x"100"	Options...
PS-Simulink Converte...	Outport	single	PCIe Interface	x"104"	
PS-Simulink Converter	Outport	single	PCIe Interface	x"108"	
PS-Simulink Converte...	Outport	single	PCIe Interface	x"10C"	

5. In the **Set Target Frequency** task, set the **Target Frequency (MHz)** as 100.

6. Right-click the **Generate Simulink Real-Time Interface** task and select **Run to Selected Task** to generate the HDL IP core, FPGA bitstream, and download the bitstream to the IO334 I/O module in the Speedgoat target computer.

A Simulink Real-Time Interface model is generated, and named as **gm_gmStateSpaceHDL_sschdexHalfWaveRectifierEx_slrt**.

For rapid prototyping, you can export the Workflow Advisor settings to a script. The script is a MATLAB file that you run from the command line. You can modify and run the script, or import the settings into the HDL Workflow Advisor User Interface. To save the workflow, in the HDL Workflow Advisor User Interface, select **File > Export to Script**. Save the file as `hdlworkflow_slrt_IO334.m`.

To import this file, in the HDL Workflow Advisor User Interface, select **File > Import from Script**. In the Import Workflow Configuration dialog box, select the `hdlworkflow_slrt_IO334.m` file. The HDL Workflow Advisor updates the tasks according to the imported script. See “Run HDL Workflow with a Script” on page 36-49.

Deploy Bitstream to Speedgoat IO334-325k Target

1. Connect Development Computer to Target

Connect the development computer to the target by using a cross-over network cable. The default IP address for the Speedgoat target computer is `192.168.7.5`. Set the IP address of the communication link between the development computer and target computer to a value `192.168.7.2` because the communication link must be in the same network.

2. Setup and Configure Simulink Real-Time Explorer

You download the bitstream by using the Simulink Real-Time Explorer. To open the Simulink Real-Time Explorer, enter the command `slrtExplorer`. Alternatively, you can open the Explorer from the **Real-Time** tab of the Simulink Toolstrip.

```
slrtExplorer
```

The Simulink Editor displays the **Real-Time** tab for models that are configured for the `slrealtime.tlc` code generation target.

a. In Simulink Real-Time Explorer, on the Target Configuration tab, configure settings on the development computer:

- Set **IP Address** as `192.168.7.5`, or set as needed for a custom target computer IP address.

- Set **Name** as TargetPC1, or set as needed for a custom target computer name.

b. If you change the settings on the development computer, click the Change IP Address button to apply corresponding changes on the target computer.

3. Create Real-Time Application

Open the Simulink Real-Time Interface model. Add a Scope block to the model and connect it to the outputs. Log the output signals to view the simulation results on the Simulation Data Inspector.

4. Build and Run Real-Time Application

Click the **Run on Target** button on the **Real-Time** tab to compile and download the model onto Speedgoat IO334-325k target.

Observe the output simulation results on the Simulation Data Inspector. The simulation results of the downloaded model match the original Simscape model simulation.

Validate HDL Implementation Model to Simscape Algorithm

If you design your algorithm by using Simscape switched linear blocks, you can run the Simscape HDL Workflow Advisor to generate an HDL implementation model. The HDL implementation model represents the Simscape algorithm by using Simulink blocks that are compatible for HDL code generation.

Before you prototype the implementation model on an FPGA or target Speedgoat FPGA I/O modules, you can verify the functionality of your design in the Simulink modeling environment. To verify the functionality, specify insertion of validation logic in the HDL implementation model when you run the Simscape HDL Workflow Advisor. This logic verifies whether the numeric results of the HDL implementation model match the original Simscape algorithm.

In some cases, there can be a mismatch in simulation results between the Simscape algorithm and the corresponding HDL implementation. Such mismatches generate warnings or assertions when you simulate the implementation model. To resolve the warnings, use a combination of various settings in the **Generate implementation model** task as illustrated below.

Bridge Rectifier Model

This example uses the bridge rectifier model to illustrate how to generate an implementation model with validation logic inserted in the model, and how you can resolve any assertions that may be generated when you simulate the implementation model.

- 1 Open the bridge rectifier model. In the MATLAB Command Window, enter:

```
open_system('sschdlexBridgeRectifierExample')
open_system('sschdlexBridgeRectifierExample/Simscape_system')
```

Inside the `Simscape_system`, you see four diodes arranged in a bridge configuration. For both positive and negative input values, this configuration provides a positive, rectified output.

- 2 Open the Simscape HDL Workflow Advisor for your model:

```
sschdladvisor('sschdlexBridgeRectifierExample')
```

- 3 Right-click the **Get state-space parameters** task and select **Run to Selected Task** to run all tasks in the Advisor except for the **Generate implementation model** task.
- 4 In the **Generate implementation model** task, select the **Generate validation logic for the implementation model** check box. Leave the other options with their default values and select **Run This Task**.

Generate validation logic for the implementation model Validation logic tolerance: 1e-12

[Run This Task](#)

Result: ✔ Passed

After running this task, keep the UI window for this task open. If simulating the HDL implementation model generates warnings, you modify the settings in the **Generate implementation model** task and then rerun this task. You do not have to modify or rerun other tasks.

- 5 Click the link to open the HDL implementation model. You see a **Validation Subsystem** that compares the simulation results of the Simscape model to the HDL implementation model. Simulate the implementation model.

You see that simulating the model generates multiple assertions indicating a mismatch in the simulation results. If you open the Diagnostic Viewer, you see this message:

```
Assertion detected in 'gmStateSpaceHDL_BridgeRectifier_HDL_SimMismatch/
Validation/Check Static Range1' at time 0.04186 [4982 similar]
```

The message indicates that the Simscape algorithm does not match the equivalent HDL implementation. To resolve the validation mismatch, you can modify various settings in the **Generate implementation model** task until the HDL implementation model matches the Simscape algorithm. In most cases, to resolve the numeric mismatch, you may want to use a combination of these settings.

Increase Validation Logic Tolerance

Conversion of a Simscape algorithm to an equivalent HDL implementation leads to rounding errors. The default tolerance value is relatively small and can be difficult to achieve especially with single-precision data types in the HDL implementation model. To resolve the mismatch:

- 1 Start by increasing the **Validation logic tolerance** to an initial value such as $1e-4$.
- 2 Select **Generate validation logic for the implementation model** and run the task to generate the HDL implementation model that includes validation logic.
- 3 Simulate the model and check whether the simulation displays assertions in the Diagnostic Viewer. If the simulation results produce warnings, proceed to the next step to increase the number of solver iterations.

Increase Number of Solver Iterations

For each mode in the physical system, the switched linear workflow arrives at a state-space representation. The solver method is iterative and performs multiple computations to determine the correct mode for the next time step. After a certain number of iterations, the output value from the next time step becomes the same as the value from the previous time step. This consistency in the output value indicates the correct number of solver iterations.

The Advisor by default chooses an optimal value for the number of solver iterations. See “Using Number of Solver Iterations” on page 38-10. If increasing the tolerance value does not improve accuracy of the HDL implementation model, you can resolve the numeric mismatch by increasing the number of solver iterations.

When you increase the number of solver iterations, the code generator changes the sample time of the generated HDL implementation model. A large number of iterations can increase the simulation time significantly. See “Reducing Number of Solver Iterations” on page 37-104. This flowchart illustrates how to change the **Number of solver iterations**.

Use Larger Floating-Point Precision

You can use the **Floating-point precision** setting in the **Generate implementation model** task to specify the floating-point data type you want to use for the algorithm inside the HDL Subsystem. Specify whether you want to store the matrix coefficients in **single** or **double** data types and whether to use **single** or **double** when performing the computations.

Floating-Point Precision	Description
Double	Using double floating-point precision increases the numerical accuracy of the generated model and the maximum achievable target frequency. However, the area consumption and pipeline latency are also increased.
Single	This is the default setting for floating-point precision.
Single coefficient, double computation	This mode offers a tradeoff between Single and Double modes of floating-point precision. To save memory usage, the coefficients that are stored in single . The matrix computations are then performed in double for improved accuracy.

This flowchart illustrates how to change the **Floating Point Precision** and improve the numeric accuracy of the generated HDL implementation model.

Note Double-precision operations have large latencies and require a large **Oversampling factor** to allocate sufficient delays for the floating-point operations, which reduces the sampling frequency. For a tradeoff between accuracy and precision, use **Single coefficient, double computation** as the **Floating Point Precision**.

After specifying double data types, if the simulation results still produce warnings:

- 1 Proceed to the first step to further increase the validation logic tolerance. Use a tolerance value of $1e-03$ and then simulate the model to see if the numeric accuracy requirements are met.
- 2 Increase the number of solver iterations if you still see warnings in the Diagnostic Viewer. Continue iterating between these steps till the HDL implementation model numerically matches the Simscape algorithm.

For the bridge rectifier model, to resolve the warnings, set the **Validation logic tolerance** to $1e-4$ and specify the **Floating Point Precision** as **double**. After you generate the implementation model with the validation logic, you see that simulating the model does not display warnings in the Diagnostic Viewer.

Improve Sampling Rate of HDL Implementation Model Generated from Simscape Algorithm

If you design your algorithm by using Simscape switched linear blocks, you can run the Simscape HDL Workflow Advisor to generate an HDL implementation model. When you open the HDL implementation model, you see the HDL algorithm that models the state-space representation by using Simulink blocks that are compatible for HDL code generation. To learn more about the Simscape HDL Workflow Advisor, see “Simscape HDL Workflow Advisor Tasks” on page 38-2.

Sampling Frequency

When you generate HDL code and deploy the plant model onto an FPGA, you may want to improve the sampling frequency. The sampling frequency depends on these parameters:

- FPGA clock frequency
- Oversampling factor
- Number of solver iterations

$$\text{Sampling Frequency} = \text{FPGA clock frequency} / (\text{Oversampling factor} * \text{Number of solver iterations})$$

To improve the sampling rate, you want to maximize the FPGA clock frequency, and minimize the oversampling factor and number of solver iterations. As you improve the sampling rate, make sure that the updated sampling frequency is equivalent to the fixed sample time that you specify for your original Simscape model by using the Solver Configuration block. To learn more about how this block is used in your model before running the Simscape HDL Workflow Advisor, see “Generate HDL Code for Simscape Models” on page 37-13.

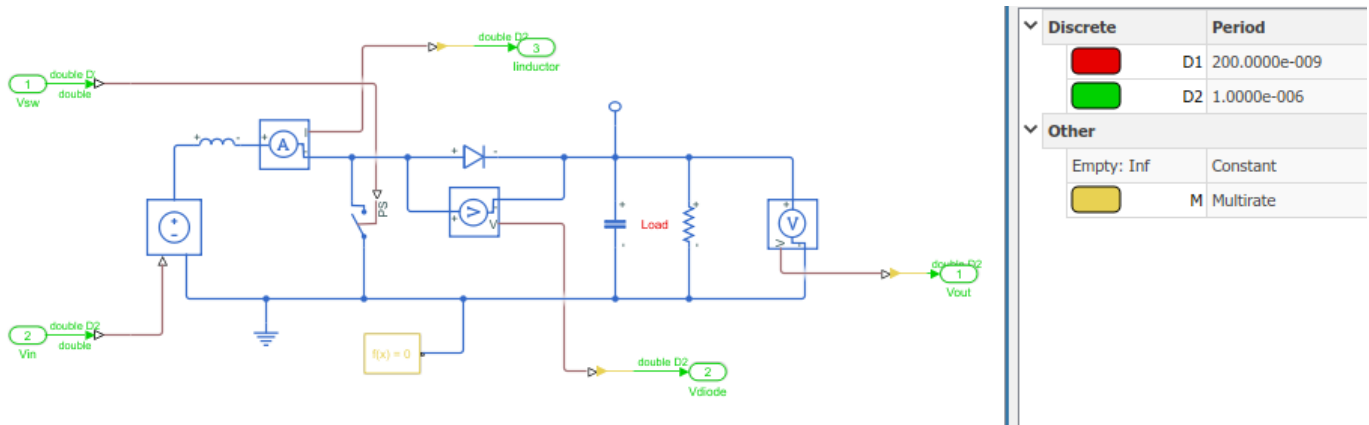

The preceding section uses the boost converter model as an example to illustrate how you can modify the oversampling factor and the number of solver iterations to improve the sampling rate.

Boost Converter Model

This example uses the boost converter model to illustrate the change in sample time in the generated HDL implementation model and the oversampling factor that is saved on the model.

- 1 Open the boost converter model. To learn how the boost converter is implemented, open the `Simscape_system` Subsystem. To open the boost converter model, in the MATLAB Command Window, enter:

```
open_system('sschdlexBoostConverterExample')  
open_system('sschdlexBoostConverterExample/Simscape_system')
```

You see that the model runs at a sample time $1e-6$. The sample time of $200e-9$ corresponds to the sample time of the sources that drive the Simscape algorithm.

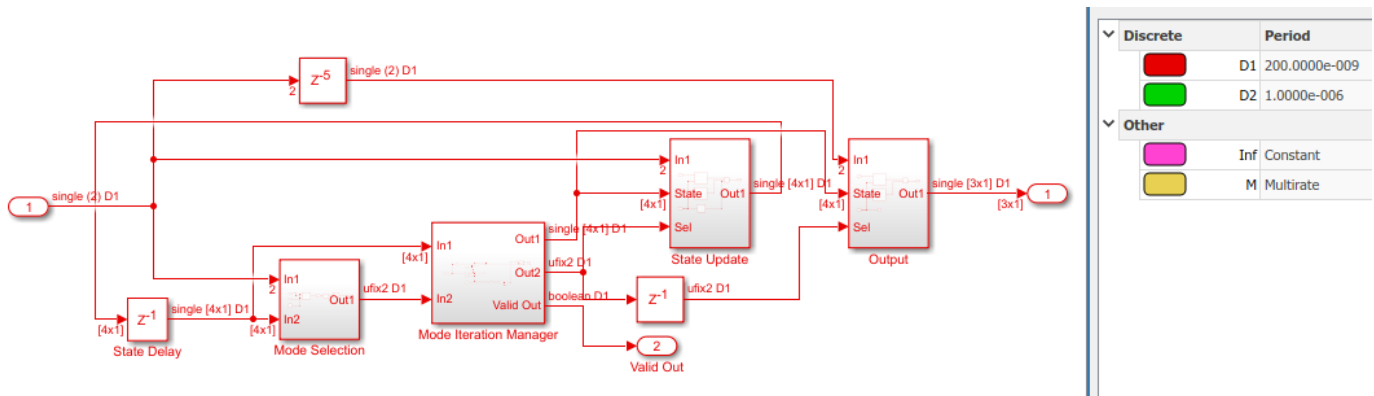

- 2 Open the Simscape HDL Workflow Advisor for your model:

```
sschdladvisor('sschdlexBoostConverterExample')
```

- 3 Run the workflow to the **Generate implementation model** task.

After running this task, you see a link to the generated HDL implementation model. Click the link to open the HDL implementation model.

- 4 Simulate the HDL implementation model. When you navigate the model to the HDL Algorithm Subsystem, you see that the model uses `single` data types and runs at a sample time $200e-9$, which is 5 times faster than the original Simscape model.

- 5 Run this command to see the HDL parameter settings that are saved on the model:

```
hdlsaveparams('gmStateSpaceHDL_sschdlexBoostConverterExamp')
```

```
% Set Model 'gmStateSpaceHDL_BoostConverter_HDL' HDL parameters
hdlset_param('gmStateSpaceHDL_BoostConverter_HDL', 'FloatingPointTargetConfiguration', ...
    hdlcoder.createFloatingPointTargetConfig('NativeFloatingPoint' ...
    , 'LatencyStrategy', 'MIN') ...
);
hdlset_param('gmStateSpaceHDL_BoostConverter_HDL', 'HDLSubsystem', ...
    'gmStateSpaceHDL_BoostConverter_HDL');
hdlset_param('gmStateSpaceHDL_BoostConverter_HDL', 'MaskParameterAsGeneric', 'on');
hdlset_param('gmStateSpaceHDL_BoostConverter_HDL', 'Oversampling', 60);

% Set SubSystem HDL parameters
hdlset_param('gmStateSpaceHDL_BoostConverter_HDL/HDL Subsystem', 'FlattenHierarchy', 'on');
```

```
% Set SubSystem HDL parameters
hdlset_param('gmStateSpaceHDL_BoostConverter_HDL/HDL Subsystem/HDL Algorithm/State Update/Multiply State', ...
'SharingFactor', 1);
```

The HDL parameters that are saved indicate that the model has the native floating-point mode enabled and uses an **Oversampling factor** of 60 and has **Latency Strategy** set to MIN. This default values chosen for number of solver iterations and combination of HDL parameters offers an optimal trade-off between oversampling factor and the target FPGA clock frequency and improves the sampling frequency. To further improve the sampling frequency, reduce the number of iterations and the oversampling factor.

Reducing Number of Solver Iterations

For each mode in the physical system, the switched linear workflow arrives at a state-space representation. The solver method is iterative and performs multiple computations to determine the correct mode for the next time step. After a certain number of iterations, the output value from the next time step becomes the same as the value from the previous time step. This consistency in the output value indicates the correct number of solver iterations.

The Advisor by default chooses an optimal value for the number of solver iterations. See “Using Number of Solver Iterations” on page 38-10. To improve the sampling rate, reduce the number of solver iterations. The number of solver iterations depends on various factors such as the complexity of your design, the number of modes in the design that the workflow calculates, and so on.

In the **Generate implementation model** task of the Simscape HDL Workflow Advisor:

- 1 Start by reducing the **Number of solver iterations** to a value such as 3
- 2 Select **Generate validation logic for the implementation model**, and then generate the HDL implementation model.
- 3 Simulate the HDL implementation model and open the Diagnostic Viewer to verify that the model does not display warnings or assertions.

If you see warnings or assertions, it indicates a simulation mismatch because the number of solver iterations that you specified is not adequate to compute the required number of modes in the state-space design. Resolve the mismatch by increasing the validation logic tolerance value or the number of solver iterations. Changing **Floating-point precision** to double is not recommended. Double-precision operations have large latencies and require a large **Oversampling factor** to allocate sufficient delays, which reduces the sampling frequency. See “Validate HDL Implementation Model to Simscape Algorithm” on page 37-95.

Using Oversampling Factor and Latency Strategy

The **Oversampling factor** specifies the factor by which the FPGA clock rate is a multiple of the HDL implementation model base sample rate. The HDL implementation model contains feedback loops and performs multiplication of large matrices that have floating-point data types inside the feedback loops. To accommodate the large latency introduced by these floating-point operations inside the feedback loops, the code generator uses a large value of oversampling factor in conjunction with the clock-rate pipelining optimization on the model. For more information, see “Strategy 1: Global Oversampling” on page 14-80.

You vary the oversampling factor and latency strategy of the floating-point operator in conjunction. The default oversampling factor of 60 and minimum latency strategy gives an optimal sampling

frequency. To achieve the maximum FPGA clock frequency, use the maximum latency strategy. When you specify this latency strategy, the floating-point operations introduce the maximum number of delays. To allocate these delays, increase the oversampling factor. If the increase in FPGA clock frequency outweighs the increase in oversampling factor, you achieve a higher sampling frequency.

To change the latency strategy and oversampling factor in conjunction from the Configuration parameters dialog box:

- 1 On the **HDL Code Generation > Floating Point** pane, change the **Latency Strategy** to Max .
- 2 On the **HDL Code Generation > Global Settings** pane, increase the **Oversampling factor** to a value such as 100 depending on the complexity of your HDL design.

For the boost converter model, the default settings of **Number of solver iterations** set to 5, **Oversampling factor** set to 60, and **Latency Strategy** set to Min provides the optimal sampling frequency.

Generate HDL Code for Nonlinear Simscape Models by Using Partitioning Solver

This example shows how to generate HDL code for a nonlinear Simscape™ model by using the Partitioning solver. You can then deploy the generated HDL code onto a Speedgoat® FPGA I/O module.

Introduction

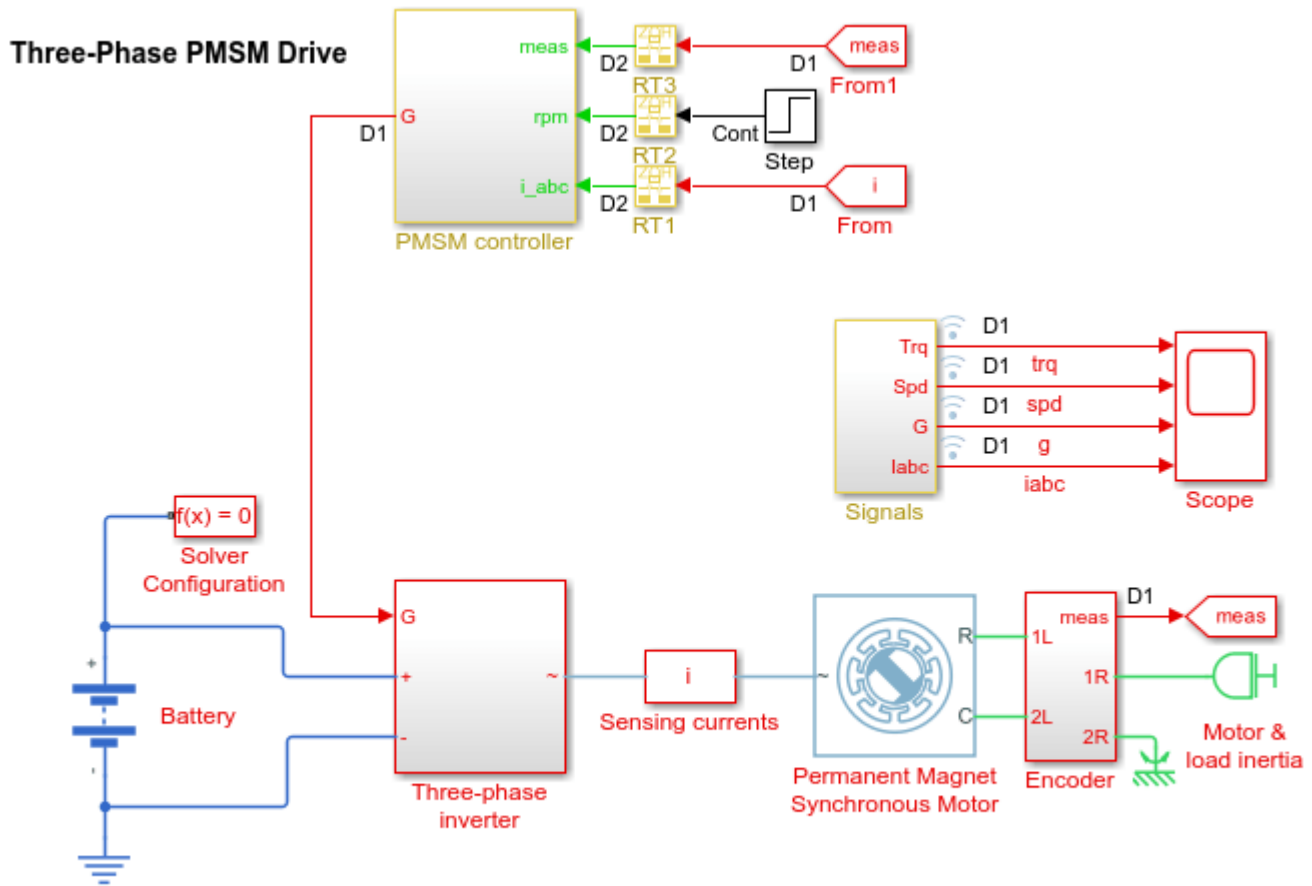

In this example, you learn how you can convert the Simscape™ three-phase permanent magnet synchronous motor (PMSM) model to an HDL implementation model by using the Simscape HDL Workflow Advisor. PMSM is a nonlinear block in the model that uses Partitioning solver. The Partitioning solver converts the entire system of equations for the Simscape network into several smaller sets of switched linear equations that are connected through nonlinear functions. By using this solver, you can run the Simscape HDL Workflow Advisor without having to remove nonlinear blocks in your model or replacing them with the corresponding Simulink blocks. For more information, see “Understanding How the Partitioning Solver Works” (Simscape). You can then generate HDL code and deploy the code to Speedgoat® FPGA I/O modules.

Permanent Magnet Synchronous Motor Model

The PMSM model is a physical system in Simscape™. This model uses field-oriented control (FOC) to control the speed of a three-phase permanent magnet synchronous motor (PMSM). The model contains a PMSM and a three-phase inverter that you can use in a typical hybrid vehicle. The inverter is connected to the battery.

To open the model, in the MATLAB® command prompt, enter:

```
modelName = 'sschdlexPMSMExample';  
open_system(modelName)  
set_param(modelName, 'SimulationCommand', 'update');
```

Copyright 2021 The MathWorks, Inc.

To see how the model works, simulate the model.

```
sim(ModelName)
open_system([ModelName '/Scope'])
```

Configure the Simscape Model for HDL compatibility by using the `hdlsetup` function:

```
hdlsetup('sschdlexPMSMExample')
```

Setup and Configuration

To support the deployment of nonlinear models, choose the **Solver type** as Partitioning and a **Sample time** T_s . You can select a **Partition method** from the drop-down list. Select whether to prioritize speed or robustness when using the Partitioning solver. For more information, see Solver Configuration (Simscape). To show the functionality of the PMSM model, the default **Solver Configuration** settings are:

- Solver type: Partitioning
- Sample time: T_s
- Partitioning method: Robust simulation

In the model window, you can view the model statistics. Select the **Debug** tab and click **Simscape > Statistics Viewer**. This opens the Simscape Statistics window for `sschdlexPMSMExample` model.

Alternatively, you can click the **Model Statistics** link generated when the **Check model compatibility** task passes in the Simscape HDL Workflow Advisor. You can see that the solver divides the system into three partitions. The first partition is solved by using the Forward Euler method. The other two partitions are solved by using the Backward Euler method. Expand the **Number of partitions** node. Click each of the partitions to get a detailed description.

Name	Value
1-D Physical System	
Number of variables	159
Number of zero crossing signals	0
Number of dynamic variable constraints	0
Number of partitions	3
Total memory estimate	97
Partition 1	Forward Euler
Equation Type	Linear time-invariant
Number of variables	2

Partition 3	Backward Euler
Equation Type	Switched linear
Number of variables	10
Number of equations	10
Number of modes	6
Number of configurations	64
Memory estimate	95

Generate HDL Implementation Model

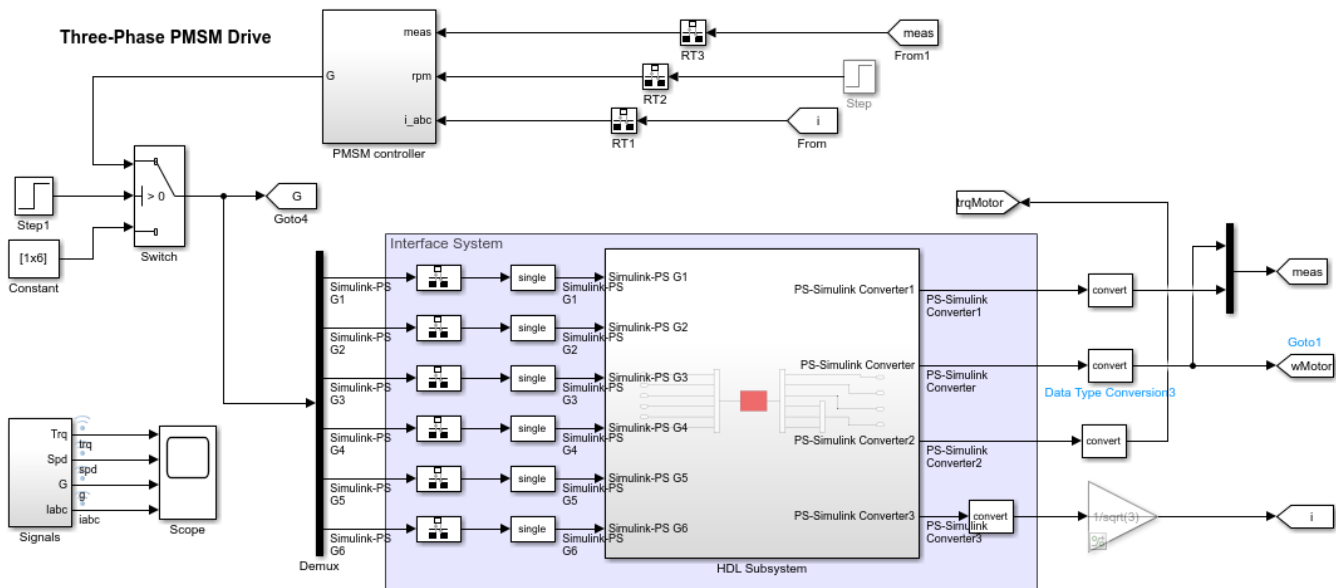

The Simscape HDL Workflow Advisor converts the Simscape plant model to an HDL-compatible implementation model from which you generate HDL code. The PMSM block is a nonlinear block for which you generate HDL-compatible implementation model. To generate the HDL implementation model:

1. Open the Simscape HDL Workflow Advisor:

```
sschdladvisor('sschdlexPMSMExample')
```

2. To generate the HDL implementation model, in the **Implementation model generation** task drop-down list, right-click the **Generate implementation model** task, and then select **Run to Selected Task** from the list.

After the task passes, you see a link to the HDL implementation model `gmStateSpaceHDL_sschdlexPMSMExample`.

Copyright 2021 The MathWorks, Inc.

See also “Simscape HDL Workflow Advisor Tasks” on page 38-2.

When you run the **Extract equations** task, the task displays the number of modes, states, and clumps for the Simscape network.

Details related to the Simscape network [sschdlexPMSMExample/Solver Configuration](#)

- Number of States: 16
- Number of Modes: 6
- Number of Clumps: 3

When you run the **Discretize equations** task, the state-space representation is displayed in the right pane.

Summary of the Partition Solver representation:

Details related to the Simscape network [sschdlexPMSMExample/Solver Configuration](#)

Clump	Parameter size of Ad	Parameter size of Bd
Differential Clump	2 x 2	
Algebraic Clump 1	4 x 4	4 x 4
Algebraic Clump 2	10 x 10 x 8	10 x 10 x 8

Generate HDL Code

Save the parameters for HDL implementation model.

```
hdlsaveparams('gmStateSpaceHDL_sschdlexPMSMExample')
```

Enable generation of the resource utilization report.

```
hdlset_param('gmStateSpaceHDL_sschdlexPMSMExample', 'ResourceReport', 'on')
```

Generate HDL code for the implementation model.

```
makehdl('gmStateSpaceHDL_sschdlexPMSMExample/HDL Subsystem');
```

When you generate code, HDL Coder creates a code generation report. The resource utilization report in the **High-level Resource Report** indicates the amount of adders, multipliers, and registers that might be consumed on the target FPGA device.

Summary

Multipliers	217
Adders/Subtractors	2328
Registers	14345
Total 1-Bit Registers	152947
RAMs	0
Multiplexers	19473
I/O Bits	388
Static Shift operators	82
Dynamic Shift operators	266

For the PMSM model, the default settings of **Number of solver iterations** set to 5, **Oversampling factor** set to 291, and **Latency Strategy** set to Min provides the optimal sampling frequency.

Deploy Permanent Magnet Synchronous Motor to Speedgoat FPGA I/O Modules

In the HDL implementation model, the HDL Subsystem contains blocks you run on the FPGA. You can run the HDL Workflow Advisor on this Subsystem to deploy the HDL algorithm onto FPGA boards in

Speedgoat target computers. For an example, see “Hardware-in-the-Loop Implementation of Simscape Model on Speedgoat FPGA I/O Modules” on page 37-88.

Deploy Simscape DC Motor Model to Speedgoat FPGA IO Module

This example shows how to generate an FPGA bitstream for a nonlinear Simscape™ model, such as a DC motor, and deploy it onto a Speedgoat® FPGA I/O module.

Introduction

In this example, you learn how to generate HDL code for Simscape models (both linear and nonlinear) and deploy the code onto FPGAs. You can generate an HDL implementation model by using the Simscape HDL Workflow Advisor. You then generate the HDL code and FPGA bitstream for the generated implementation model by using the HDL Workflow Advisor. You can simulate and validate your HDL compatible Simulink® model (HDL implementation model) against the Simscape model. Use the Simulink Real-Time™ development environment to generate, deploy, and run the real-time model run onto Speedgoat real-time target computers directly.

In this example, you learn how to:

- 1 Generate HDL code for a linear Simscape model by using the Backward Euler solver.
- 2 Generate HDL code for a nonlinear Simscape model by using the Partitioning solver.
- 3 Generate FPGA bitstream for the I/O 334-325K module by using the HDL Workflow Advisor.
- 4 Deploy the real-time model onto the Speedgoat real-time target machine by using Simulink Real-Time.

Setup and Configuration

1. Install the latest version of Xilinx® Vivado® as listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.

Then, set the tool path to the installed Xilinx Vivado executable by using the `hdlsetuptoolpath` function.

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath','C:\Xilinx\Vivado\2020.2\bin\vivado.bat')
```

2. For real-time simulation, set up the development environment and target computer settings. See “Get Started with Simulink Real-Time” (Simulink Real-Time).
3. Install the Speedgoat Library and the Speedgoat HDL Coder Integration packages. See Install Speedgoat HDL Coder Integration Packages.

Buck Converter

A buck converter is a DC/DC power converter that steps down voltage from its input (source) to its output (load). In continuous conduction mode (current through the inductor never falls to zero), the theoretical transfer function of the buck converter is

$$V_{out}/V_{in} = D,$$

where D is the duty cycle. In this example, the converter feeds a resistor load from a 12 V source and the PWM frequency is set to 200 Hz. This example shows how to control the output voltage of a buck converter. To adjust the duty cycle, the Control subsystem uses a PI-based control algorithm.

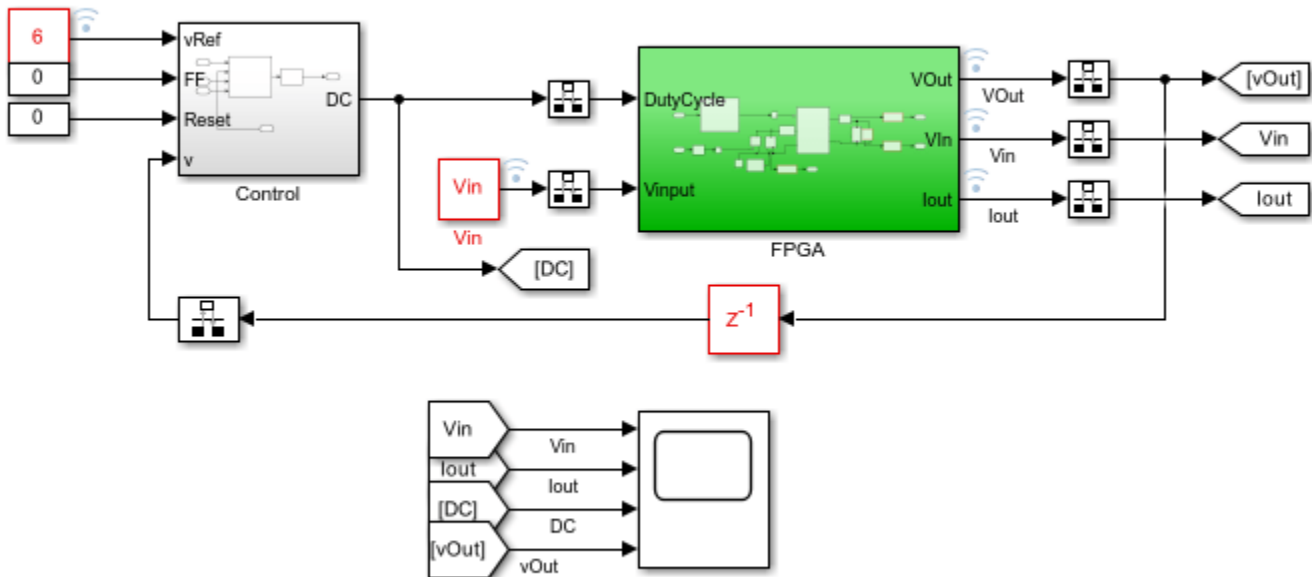

Buck Converter with Fixed Resistor (Linear Simscape Network)

The model `ee_buck_converter_hdl.slx` consists of a buck converter with a fixed resistor as load. The fixed resistor is a linear Simscape element and therefore the model uses a Backward Euler solver.

To see the buck converter model, run this command.

```
open_system('ee_buck_converter_hdl')
```

Buck Converter Voltage Control with fixed resistor load

Copyright 2022 The MathWorks, Inc.

For details on steps of HDL code generation and deployment, see “Deploy Simscape Grid Tied Converter Model to Speedgoat IO Module Using HDL Workflow Script” on page 37-49.

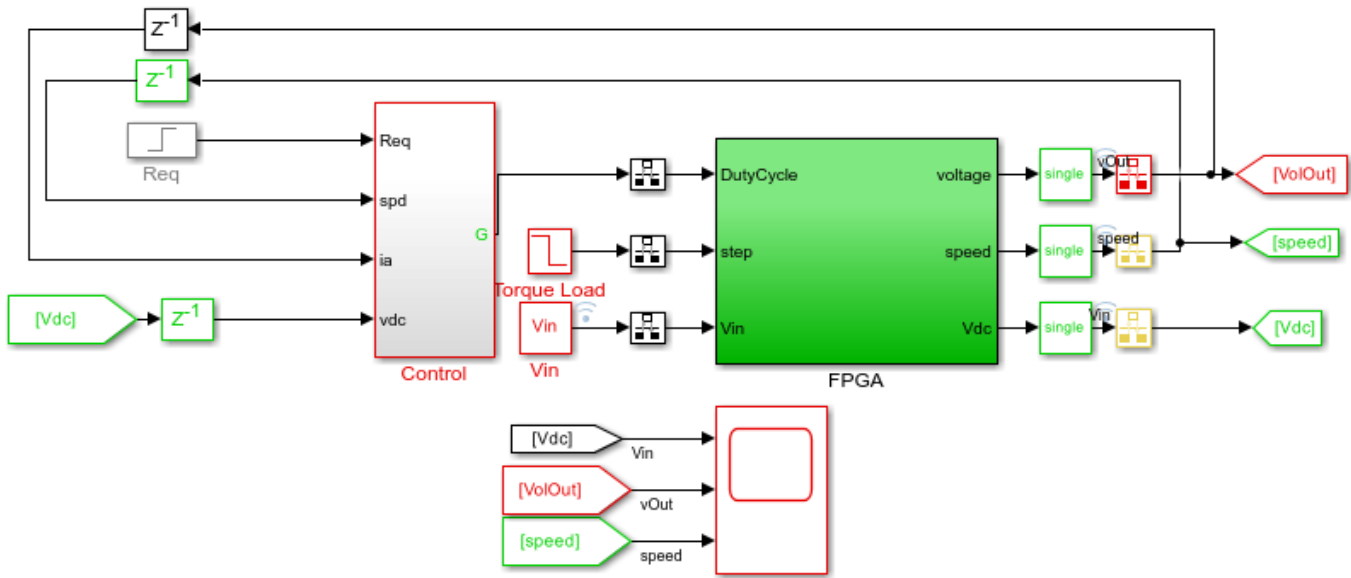

Buck Converter with DC Motor (Nonlinear Simscape Network)

The model `ee_buck_converter_dc_motor_hdl.slx` consists of a buck converter with a DC motor as load. The DC motor is a nonlinear element, and this model therefore uses a Partitioning solver. For more information, see “Understanding How the Partitioning Solver Works” (Simscape).

To see the buck converter model, run this command.

```
open_system('ee_buck_converter_dc_motor_hdl')
```

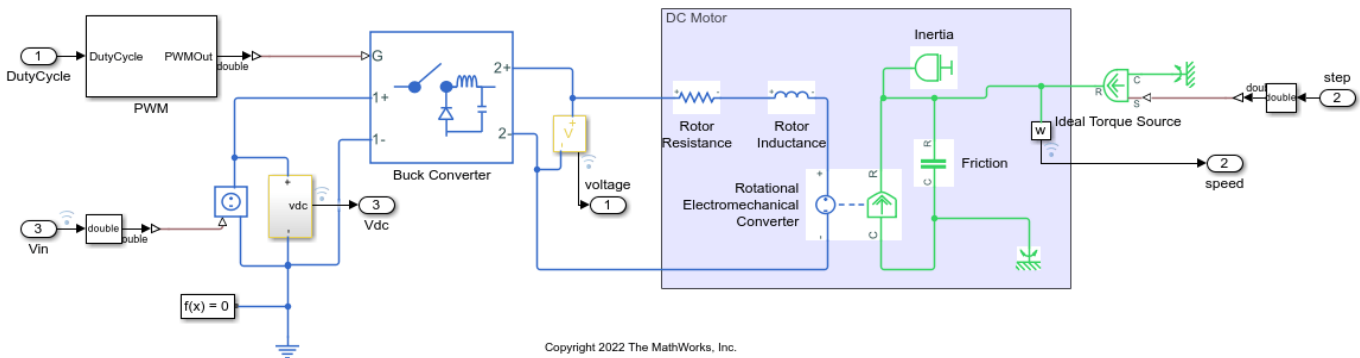

Buck Converter Voltage Control with DC motor load

Copyright 2022 The MathWorks, Inc.

You generate VHDL® or Verilog® code for the blocks that are inside the green FPGA subsystem that contains the PWM generator and buck converter.

```
open_system('ee_buck_converter_dc_motor_hdl/FPGA')
```

Copyright 2022 The MathWorks, Inc.

In the model, the Buck Converter block represents a converter that steps down DC voltage as driven by an attached controller and gate-signal generator. Buck converters are also known as step-down voltage regulators because they decrease voltage magnitude. The Rotational Electromechanical Converter block provides an interface between the electrical and mechanical rotational domains. It converts electrical energy into mechanical energy in the form of rotational motion, and can also convert the rotational motion into electrical energy.

Run Desktop Simulation of Buck Converter Model

The input signals that include the DC input voltage, PWM frequency, and duty cycle are generated on the top level of the model. The sample time for the Simscape model is set to 6 μ s. Signal logging is enabled on the top level of the model.

```
sim('ee_buck_converter_dc_motor_hdl')

% Display the buck converter output signals in SDI
Simulink.sdi.clearAllSubPlots
Simulink.sdi.setSubPlotLayout(3,1);

allIDs2 = Simulink.sdi.getAllRunIDs;
runID2 = allIDs2(end);
run2 = Simulink.sdi.getRun(runID2);
run2.name = 'Simscape Desktop Simulation';

run2.getAllSignals;
plotOnSubPlot(run2.getSignalsByName('Vin'),1,1,true);
plotOnSubPlot(run2.getSignalsByName('speed'),2,1,true);
plotOnSubPlot(run2.getSignalsByName('vOut'),3,1,true);

Simulink.sdi.view;
```

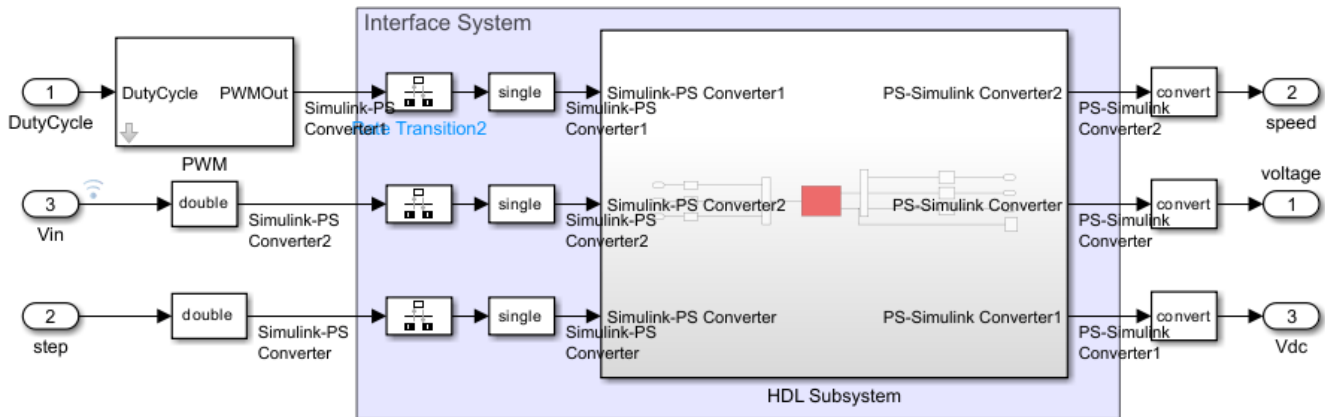

Generate HDL Implementation Model and Validate HDL Algorithm

The Simscape HDL Workflow Advisor converts the Simscape model to an HDL-compatible implementation model from which you generate HDL code. To open the Advisor, run the `sschdladvisor` function for your model.

```
sschdladvisor('ee_buck_converter_dc_motor_hdl')
```

To generate the HDL implementation model, in the **Implementation model generation** task drop-down list, right-click the **Generate implementation model** task, and then select **Run to Selected Task** from the list. After the task passes, you see a link to the HDL implementation model `gmStateSpaceHDL_ee_buck_converter_dc_motor_`.

```
open_system('gmStateSpaceHDL_ee_buck_converter_dc_motor_/FPGA')
```

To verify that the HDL implementation model matches the original Simscape model, generate a state-space validation model. In the **Generate implementation model** task, select the **Generate validation logic** for the implementation model check box and set the **Validation logic tolerance** to 1e-1. Then, run the task. See “Validate HDL Implementation Model to Simscape Algorithm” on page 37-95.

HDL Workflow Advisor

The HDL Workflow Advisor guides you through HDL code generation and the FPGA design process. Use the Advisor to:

- Check the model for HDL code generation compatibility and fix incompatible settings.

```
hdlsetup('gmStateSpaceHDL_ee_buck_converter_dc_motor_')
```

- Generate HDL code, test bench, and scripts to build and run the code and test bench.
- Perform synthesis and timing analysis.
- Deploy the generated code on SoCs, FPGAs, and Speedgoat I/O modules.

Generate FPGA Bitstream for Speedgoat Target Computer

Use HDL Workflow Advisor to Generate Simulink Real-Time Interface Model

1. Open the HDL implementation model, and then open the HDL Workflow Advisor for the implementation model.

```
open_system('gmStateSpaceHDL_ee_buck_converter_dc_motor_')
```

To open the HDL Workflow Advisor for a subsystem inside the model, use the `hdladvisor` function.

```
hdladvisor('gmStateSpaceHDL_ee_buck_converter_dc_motor_/FPGA')
```

2. In the **Set Target Device and Synthesis Tool** task, specify **Target workflow** as Simulink Real-Time FPGA I/O and **Target platform** as Speedgoat I0334-325K.

1.1. Set Target Device and Synthesis Tool

Analysis (^Triggers Update Diagram)

6. Right-click the **Generate Simulink Real-Time Interface** task, and select **Run to Selected Task** to generate the HDL IP core and FPGA bitstream.

Run Workflow Script to Generate Simulink Real-Time Interface Model

You can export the HDL Workflow Advisor settings to a script to expedite and automate your workflow. The script is a MATLAB® file that you run from the command line. You can modify and run the script, or import the settings into the HDL Workflow Advisor User Interface. See “Run HDL Workflow with a Script” on page 36-49.

This example shows how to run the HDL Workflow script. To generate a Simulink Real-Time Interface model, open and run this MATLAB script.

```
edit('hdlworkflow_dcmotor_I0334')
```

```
%-----
```

```

% HDL Workflow Script

Deploy Bitstream to Speedgoat IO334-325k Target

Prepare Simulink Real-Time Interface Model for Real-Time Simulation

Running the workflow script generates RTL code and IP core, creates a Vivado project, builds the FPGA bitstream, and then generates the Simulink Real-Time interface model.

The FPGA subsystem is automatically replaced in the real-time interface model with Speedgoat driver blocks to initialize the hardware and to interface with the FPGA during runtime.

Buck Converter Voltage Control with DC motor load

Copyright 2022 The MathWorks, Inc.

Make sure you comment out any remaining Rate Transition blocks in the model to obtain a single rate model. All the blocks in the generated Simulink Real-Time model are executed on the CPU of the real-time system. The buck converter and DC motor are programmed in the bitstream and run at the faster rate on the FPGA.

Connect to Target Machine and Run Real-Time Simulation

The model can now be deployed onto the Speedgoat real-time target machine. Make sure that the Speedgoat real-time target machine is connected to the host computer and powered on.

You download the bitstream by using the Simulink Real-Time Explorer. To open the Simulink Real-Time Explorer, enter the command `slrtExplorer`. Alternatively, you can open the Explorer from the **Real-Time** tab of the Simulink Toolstrip.

```
slrtExplorer
```

The Simulink Editor displays the **Real-Time** tab for models that are configured for the `slrealtime.tlc` code generation target. Click the **Connect to Target Computer** button in the Simulink **Real-Time** tab to connect to the machine. Once connected, click the **Run on Target** button to deploy the model.

Simulink Real-Time automatically generates C code from your model by using Simulink Coder. The generated code and the bitstream for the FPGA are loaded onto the target machine, and model execution starts automatically.

Generate HDL Code for Simscape Three-Phase PMSM Drive Containing Averaged Switch

This example shows how to generate HDL code and synthesize the results for a three-phase PMSM Simscape™ model that has an averaged switch.

Simscape Models with Averaged Switch

You can generate HDL code for Simscape models with converter blocks that have averaged switches and deploy onto the FPGAs. This example uses a three-phase PMSM model with a six-pulse three-phase controlled converter block consisting of averaged switches. The switching frequency of this model is 50 kHz. For the system to be HDL compatible, the averaged switches use a piecewise constant approximation method for the gate input. Note that this model with the averaged switches might introduce instability during dead time (when all gate inputs are set to 0) with the Partitioning local solver.

Set Up Synthesis Tool Path

If you want to synthesize the generated HDL code, before you use HDL Coder™ to generate code, set up your synthesis tool path. For example, if your synthesis tool is Xilinx® Vivado®, then, install the latest version of Xilinx Vivado as listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.

Then, set the tool path to the installed Xilinx Vivado executable by using the `hdlsetuptoolpath` function:

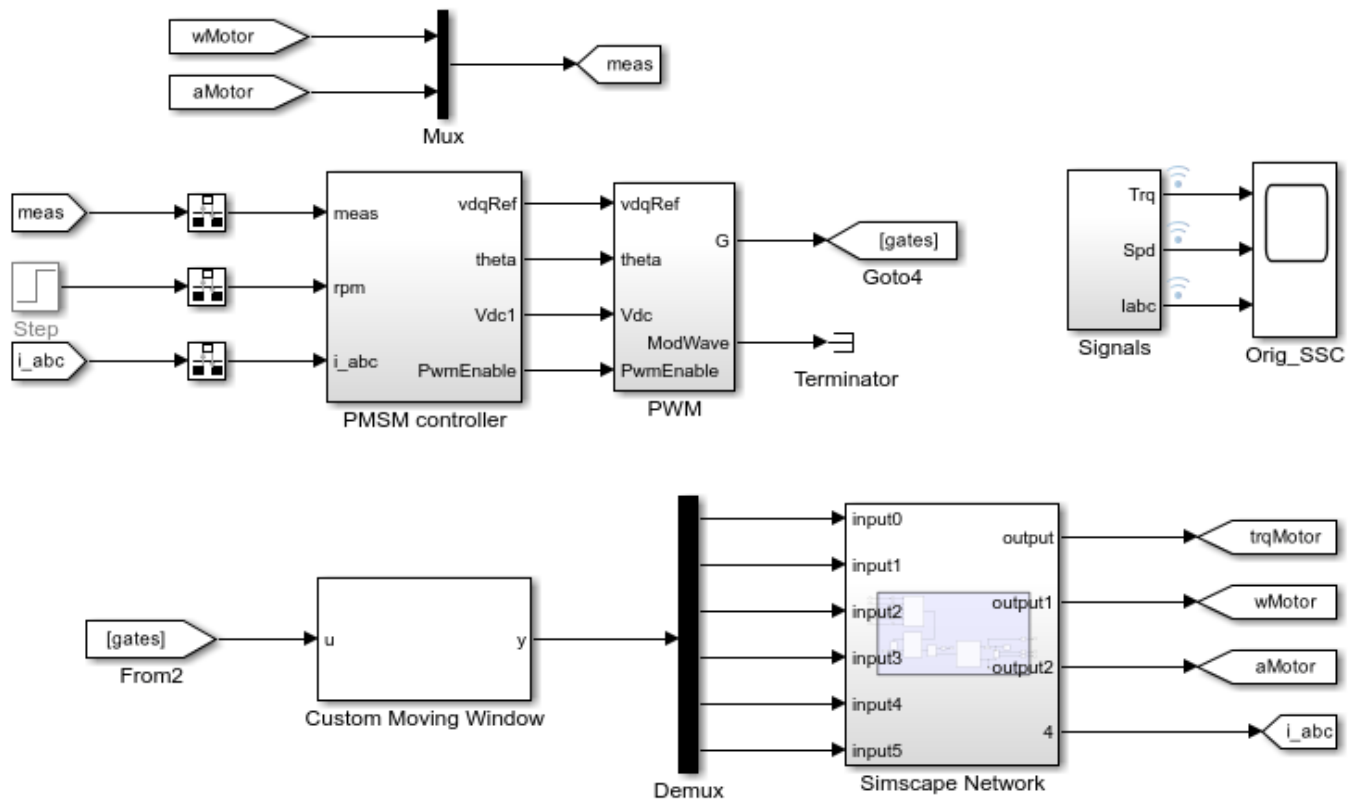

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath','C:\Xilinx\Vivado\2020.2\bin\vivado.bat')
```

Three-Phase PMSM Drive Model

Open the model from the MATLAB® command prompt.

```
modelName = 'ee_pmsm_drive_averaged_switch_hdl';  
open_system(modelName)
```

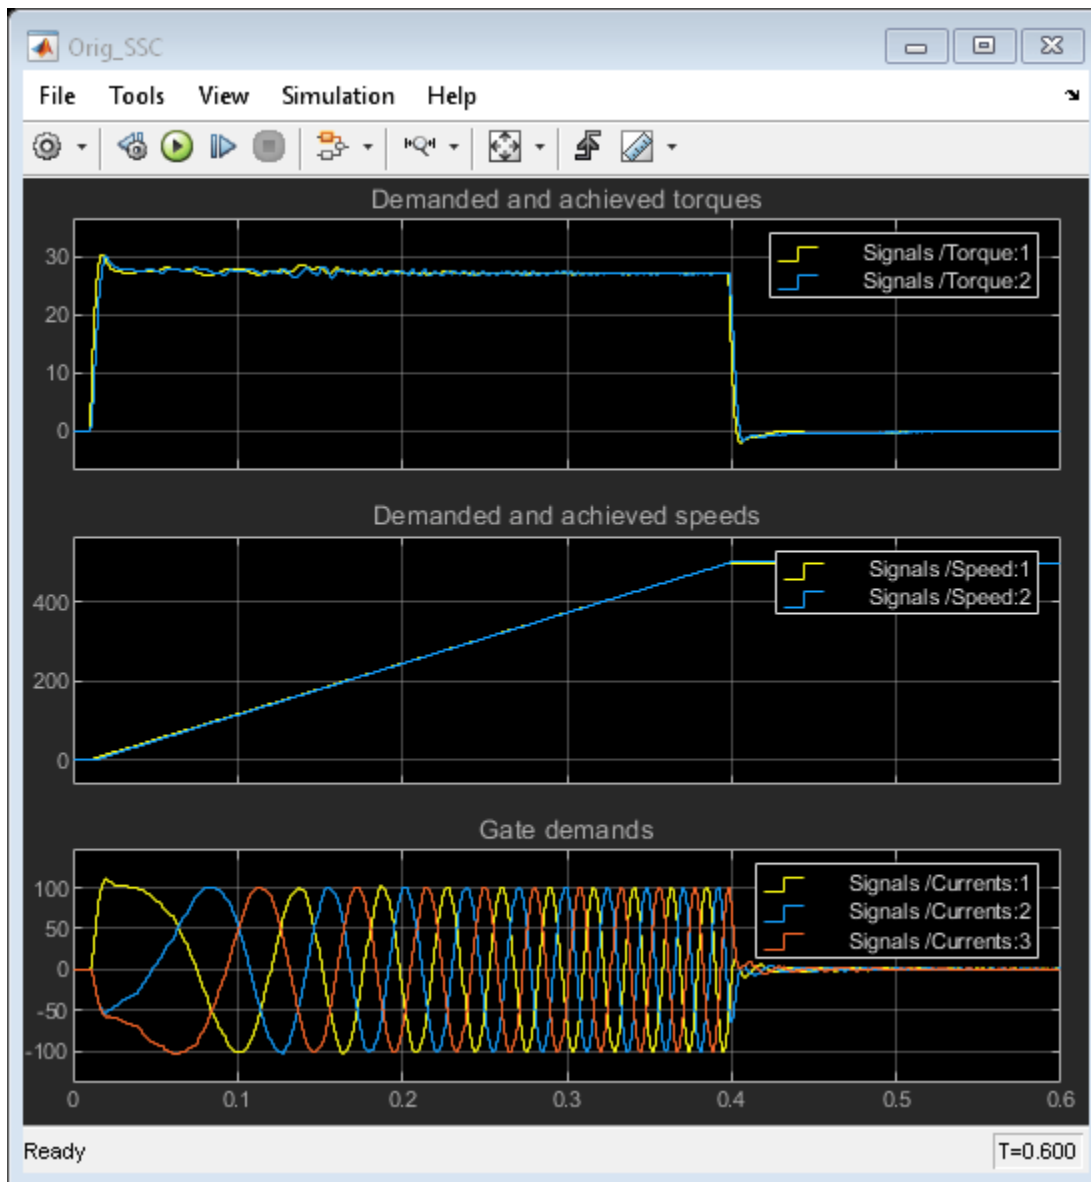

Three-Phase PMSM Drive with Averaged Switch

Copyright 2022 The MathWorks, Inc.

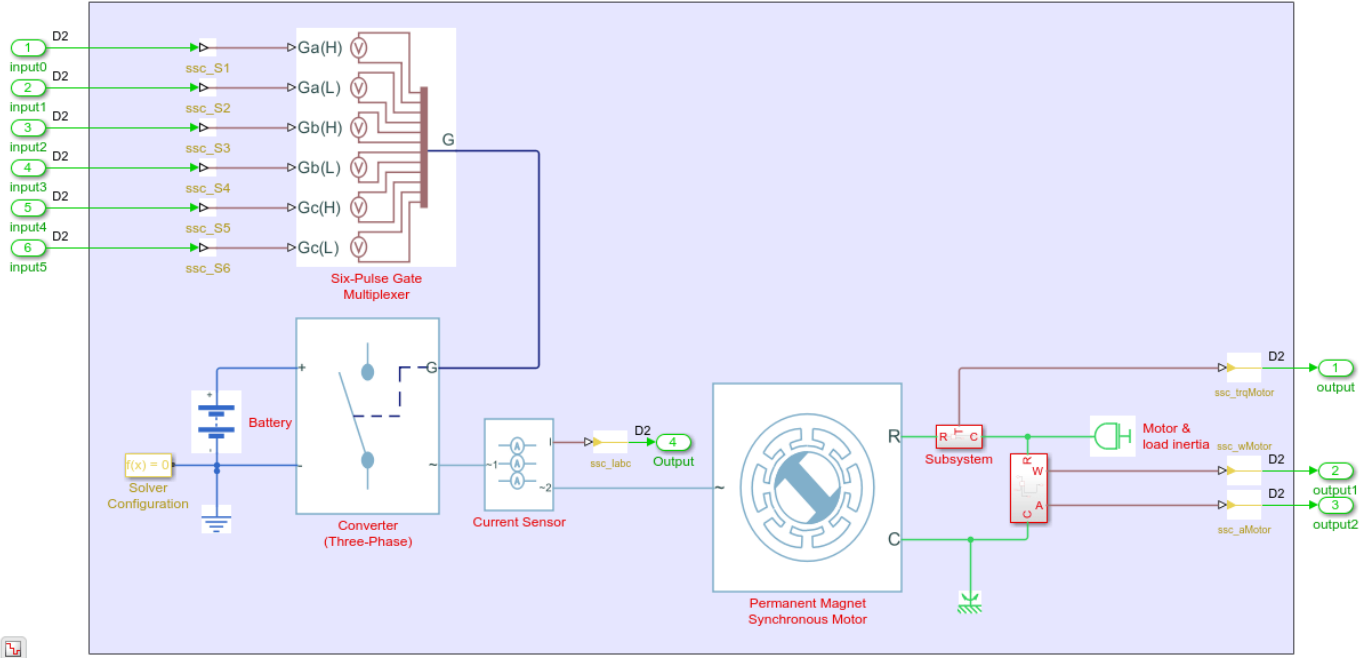

To see how the model works, simulate it.

```
sim(ModelName)
open_system(['ModelName '/Orig_SSC'])
```

To see the components inside the Simscape Network subsystem, enter:

```
open_system('ee_pmsm_drive_averaged_switch_hdl/Simscape Network')
```

For HDL code generation, in the Converter(Three-Phase) block parameter **Settings** tab, the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter value is set to 10. The model is set up to use Partitioning solver by selecting the **Use local solver** check box in the Solver Configuration (Simscape) block.

Generate HDL Implementation Model

The Simscape HDL Workflow Advisor converts the Simscape plant model to an HDL-compatible implementation model from which you generate HDL code. To generate the HDL implementation model:

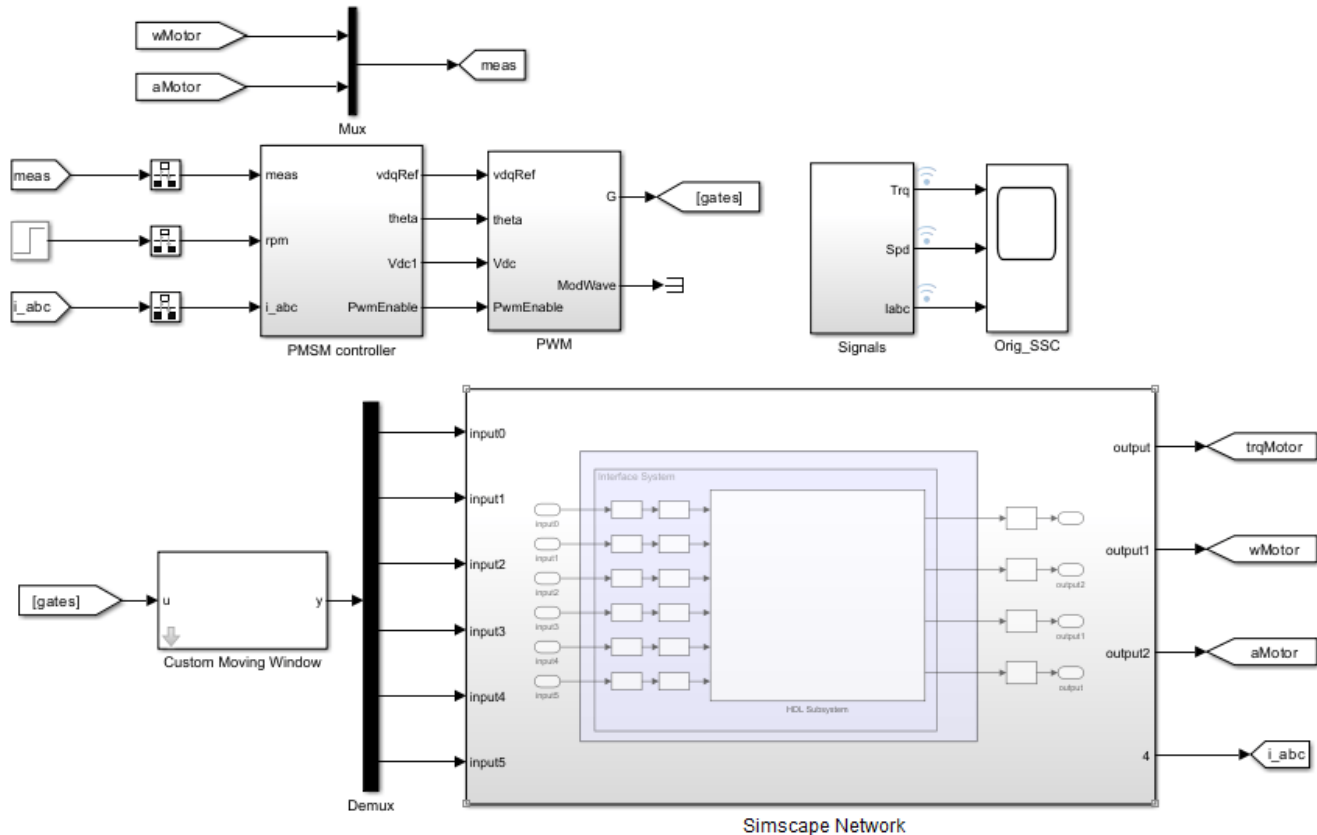

1. Open the Simscape HDL Workflow Advisor.

```
sschdladvisor('ee_pmsm_drive_averaged_switch_hdl')
```

2. In the **Implementation model generation** task drop-down list, right-click the **Generate implementation model** task, then select **Run to Selected Task** from the list. To get better resource utilization, in the **Generate implementation model** task window, set **Map state space parameter to RAM** to **On**.

After the task passes, you see a link to the HDL implementation model `gmStateSpaceHDL_ee_pmsm_drive_averaged_swit`.

Three-Phase PMSM Drive with Averaged Switch

Generate HDL Code

To modify the configuration parameter values for HDL code generation, navigate to `gmStateSpaceHDL_ee_pmsm_drive_averaged_swit/Simscape Network/HDL Subsystem`. Right-click the HDL Algorithm subsystem and select **HDL Block Properties** from the **HDL Code** list. In the HDL Properties dialog box, set the `DistributedPipelining` to `On`. Click **Apply** and then click **OK**. Then navigate to the `gmStateSpaceHDL_ee_pmsm_drive_averaged_swit/Simscape Network/HDL Subsystem/HDL Algorithm/State Update/Algebraic Clump2/Mode Vector To Index` block. Right-click the block and select **HDL Block Properties** from the **HDL Code** list. In the HDL Properties dialog box, set the `InputPipeline` and `OutputPipeline` parameter values to `2`, click **Apply** and then click **OK**. Right-click the `Multiply State` and `Multiply F` blocks, set the `SharingFactor` to `8` for the two blocks. Save the model and proceed to the next step.

Set your model configuration parameters to default values recommended for HDL code generation.

```
hdlsetup('gmStateSpaceHDL_ee_pmsm_drive_averaged_swit')
```

HDL Workflow Advisor

The HDL Workflow Advisor guides you through the necessary tasks required for generating HDL code and an FPGA design process. It provides you with feedback on the results of each task. When you complete the tasks, you have a synthesis result report from one of the supported synthesis tools.

Open the subsystem HDL Subsystem within the HDL implementation model into the HDL Workflow Advisor.

```
hdladvisor('gmStateSpaceHDL_ee_pmsm_drive_averaged_swit/Simscape Network/HDL Subsystem')
```

You can also open the HDL Workflow Advisor from your model window. Right-click the HDL Subsystem and select HDL Workflow Advisor from the list.

Set Target Device and Synthesis Tool

Before you generate HDL code, if you want to deploy the code onto a target platform, specify the synthesis tool.

- 1 Open the HDL Workflow Advisor.
- 2 Under the **Set Target** task folder, in the **Set Target Device and Synthesis Tool** task, specify **Target workflow** as Generic ASIC/FPGA and **Synthesis tool** as Xilinx Vivado. The rest of the fields are auto-populated. Specify the **Family** as Kintex7, **Device** as xc7k325t, **Package** as fbg676, and **Speed** as -1.
- 3 In the **Set Target Frequency** window, specify the **Target Frequency** as 150.
- 4 Select the task that you want to run and click **Run This Task**.

HDL Code Generation

- In the **HDL Code Generation** task folder, click **Set HDL Options** and then click the **HDL Code Generation Settings** button. This opens the Configuration Parameters dialog box. Select Adaptive pipelining under **HDL Code Generation > Optimizations > Pipelining** and click **Apply**.
- Under the **HDL Code Generation > Global Settings > Clock Settings** section, set the Oversampling factor to 300. Click **Apply** then click **OK**. To generate HDL code, run the tasks under the **HDL Code Generation** task folder.

Synthesize Generated HDL Code

HDL Coder synthesizes the HDL code on the target platform and generates area and timing reports for your design based on the target device that you specify. You can run logic synthesis for a specified FPGA device and get the synthesis reports.

In the **FPGA Synthesis and Analysis** task folder:

- Create an FPGA synthesis project for your supported FPGA synthesis tool.
- Start supported FPGA synthesis tools to perform synthesis, mapping, and place/route tasks. To run FPGA synthesis, right-click the **Run Synthesis** task under the **Perform Synthesis and P/R** subtask folder. This starts Xilinx Vivado and executes the Vivado **Synthesis** step. You can annotate your original model with critical path information obtained from the synthesis tools.

Generate HDL Code for Two-Speed Transmission Model Containing Mode Charts

This example shows how to generate HDL code for a Simscape™ model containing mode charts.

Simscape Models with Mode Charts

You can use a mode chart implementation to model a Simscape component with multiple operating modes and transitions. Mode charts provide an intuitive way to model components characterized by a discrete set of distinct operating modes. A car clutch is a good example of such a component. To learn more about mode charts, see `modecharts` (Simscape) and “Mode Chart Modeling” (Simscape).

In this example, a two-speed transmission model with braking is designed for HDL code generation. This model uses the Partitioning solver as a local solver. For more information, see “Understanding How the Partitioning Solver Works” (Simscape). First, you generate an HDL implementation model by using the Simscape HDL Workflow Advisor. For this implementation model, you generate the HDL code and can synthesize the results by using the guided steps in the HDL Workflow Advisor.

Set Up Synthesis Tool Path

If you want to synthesize the generated HDL code, before you use HDL Coder™ to generate code, set up your synthesis tool path. For example, if your synthesis tool is Xilinx® Vivado®, install the latest version of Xilinx Vivado as listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.

Then, set the tool path to the installed Xilinx Vivado executable by using the `hdlsetuptoolpath` function:

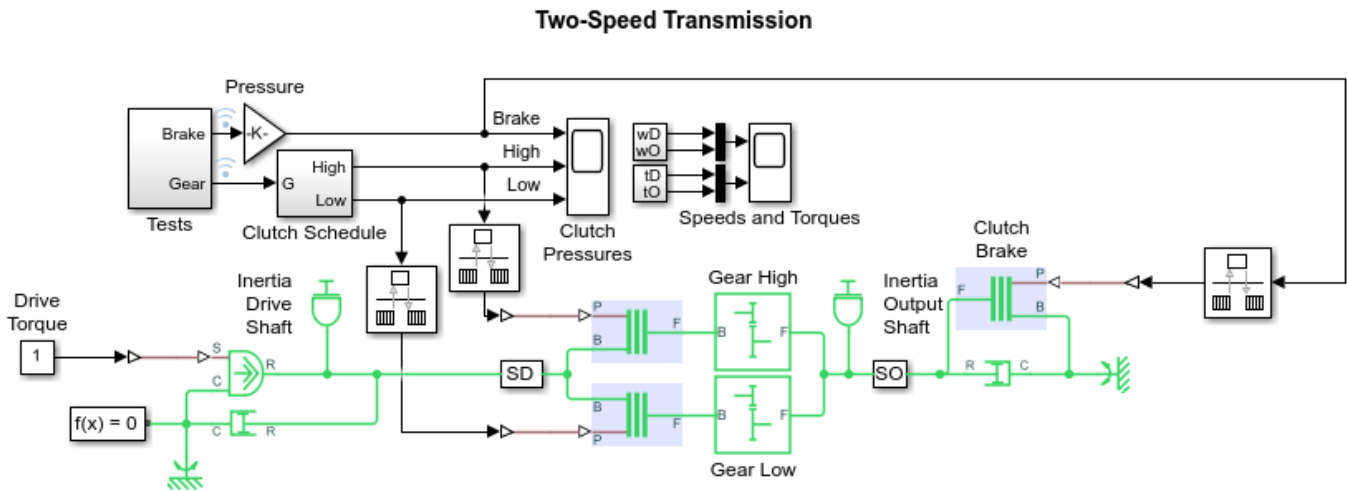

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath','C:\Xilinx\Vivado\2020.2\bin\vivado.bat')
```

Two-Speed Transmission Model with Braking

The two-speed transmission model is a Simscape driveline model. This transmission model couples the gears in a simple way, with each gear and the brake associated with its own clutch. Coupling one gear requires engaging and locking the corresponding clutch, while ensuring that the other two clutches are disengaged. The brake clutch is directly activated by its own switch. Two clutches control which gear is selected. A brake is connected to the output shaft and can be controlled independently. The highlighted blocks in the model contain mode charts.

Open the model from the MATLAB® command prompt.

```
ModelName = 'sdl_transmission_2spd_hdl';  
open_system(ModelName)
```

Copyright 2022 The MathWorks, Inc.

To see how the model works, simulate it

```
sim(ModelName)
open_system(['sdl_transmission_2spd_hdl' '/Speeds and Torques'])
```

Generate HDL Implementation Model

The Simscape HDL Workflow Advisor converts the Simscape plant model to an HDL-compatible implementation model from which you generate HDL code. To generate the HDL implementation model:

1. Open the Simscape HDL Workflow Advisor.

```
sschdladvisor('sdl_transmission_2spd_hdl')
```

2. In the **Implementation model generation** task drop-down list, right-click the **Generate implementation model** task, then select **Run to Selected Task** from the list. To get better resource utilization, in the **Generate implementation model** task window, set **Map state space parameter to RAM** to **On**.

After the task passes, you see a link to the HDL implementation model `gmStateSpaceHDL_sdl_transmission_2spd_hdl`.

Copyright 2022 The MathWorks, Inc.

Generate HDL Code

To modify the configuration parameter values for HDL code generation, run

```
hdlsetup('gmStateSpaceHDL_sdl_transmission_2spd_hdl')
```

HDL Workflow Advisor

The HDL Workflow Advisor guides you through the necessary tasks required for generating HDL code and an FPGA design process. It provides you with feedback on the results of each task. When you complete the tasks, you have a synthesis result report from one of the supported synthesis tools.

To open the subsystem HDL Subsystem within the HDL implementation model into the HDL Workflow Advisor, run

```
hdladvisor('gmStateSpaceHDL_sdl_transmission_2spd_hdl/HDL Subsystem')
```

You can also open the HDL Workflow Advisor from your model window. Right-click the HDL Subsystem and select HDL Workflow Advisor from the list.

Set Target Device and Synthesis Tool

Before you generate HDL code, if you want to deploy the code onto a target platform, specify the synthesis tool.

- 1 Open the HDL Workflow Advisor.
- 2 Under the **Set Target** task folder, in the **Set Target Device and Synthesis Tool** task, specify **Target workflow** as Generic ASIC/FPGA and **Synthesis tool** as Xilinx Vivado. The rest of

the fields are auto-populated. Specify the **Family** as Kintex7, **Device** as xc7k325t, **Package** as fbg676, and **Speed** as -1.

- 3 In the **Set Target Frequency** window, specify the **Target Frequency** as 100.
- 4 Select the task that you want to run and click **Run This Task**.

HDL Code Generation

- In the **HDL Code Generation** task folder, click **Set HDL Options** and then click the **HDL Code Generation Settings** button. This opens the Configuration Parameters dialog box. Select Adaptive pipelining under **HDL Code Generation > Optimizations > Pipelining** and click **Apply**.
- Under the **HDL Code Generation > Global Settings > Clock Settings** section, set the **Oversampling** factor to 500. Click **Apply** then click **OK**. To generate HDL code, run the tasks under the **HDL Code Generation** task folder.

Synthesize Generated HDL Code

HDL Coder synthesizes the HDL code on the target platform and generates area and timing reports for your design based on the target device that you specify. You can run logic synthesis for a specified FPGA device and get the synthesis reports.

In the **FPGA Synthesis and Analysis** task folder:

- Create an FPGA synthesis project for your supported FPGA synthesis tool.
- Start supported FPGA synthesis tools to perform synthesis, mapping, and place/route tasks. To run FPGA synthesis, right-click the **Run Synthesis** task under the **Perform Synthesis and P/R** subtask folder. This starts Xilinx Vivado and executes the Vivado **Synthesis** step. You can annotate your original model with critical path information obtained from the synthesis tools.

Simscape Language Support

In this section...

“Domain and Component Declarations” on page 37-138

“Equations” on page 37-139

“Discrete Events and Mode Charts” on page 37-140

“Composite Components” on page 37-141

The Simscape language extends the Simscape modeling environment by enabling you to create new components that do not exist in the Foundation library or in any of the add-on products. It is a dedicated textual language for modeling physical systems. The Simscape language lets you define custom components as textual files, complete with parameterization, physical connections, and underlying equations. The components you create can reuse the physical domain definitions provided with Simscape to ensure that your components are compatible with the standard Simscape components. You can also add your own physical domains and provide complete component libraries for these domains. You can deploy the textual component files in block diagrams by converting them into custom Simscape blocks. For more information, see “What Is the Simscape Language?” (Simscape).

The tables list the Simscape Hardware-in-the-Loop (HIL) Workflow support for the Simscape language for different solvers.

Domain and Component Declarations

Keyword	Description	Backward Euler/ Trapezoidal Rule Solver	Partitioning Solver
annotations	Control appearance of Simscape block based on the component	✓	✓

Generate HDL Code for Simscape Models by Using Trapezoidal Rule Solver

This example shows how to generate HDL code for a Simscape™ model by using the Trapezoidal Rule solver. You can then deploy the generated HDL code onto a Speedgoat® FPGA I/O module.

Setup and Configuration

1. Install the latest version of Xilinx® Vivado® as listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.

Then, set the tool path to the installed Xilinx Vivado executable by using the `hdlsetuptoolpath` function.

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath','C:\Xilinx\Vivado\2020.2\bin\vivado.bat')
```

2. For real-time simulation, set up the development environment and target computer settings. See “Get Started with Simulink Real-Time” (Simulink Real-Time).

3. Install the Speedgoat Library and the Speedgoat HDL Coder Integration packages. See Install Speedgoat HDL Coder Integration Packages.

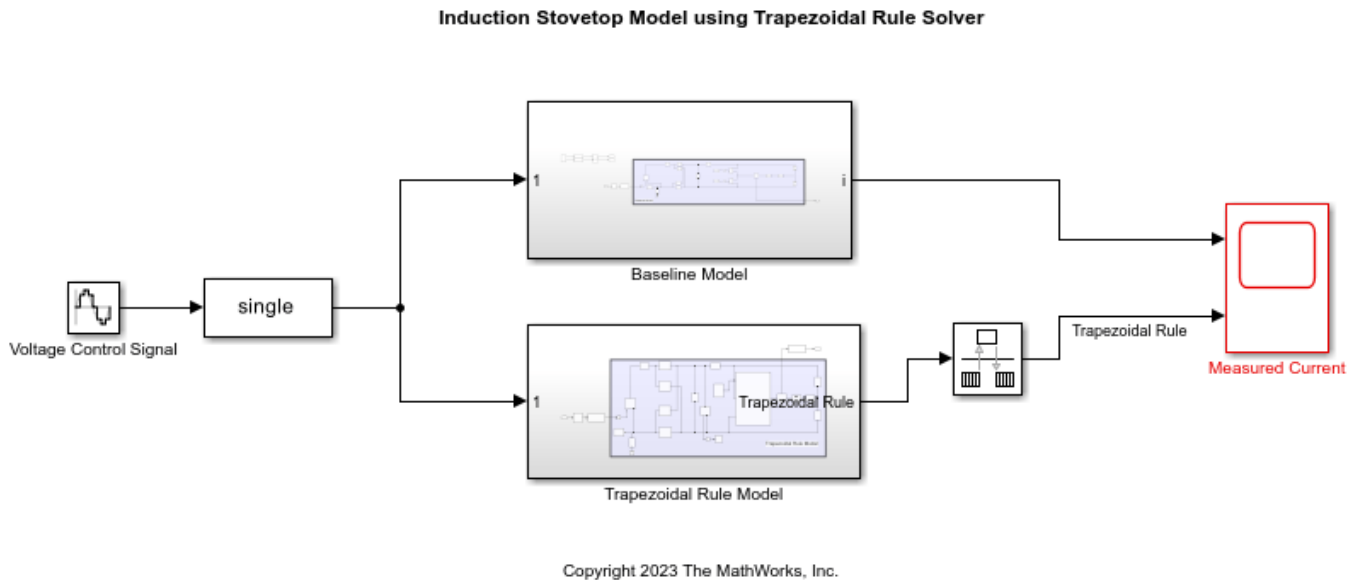

Use Trapezoidal Rule Solver to Simulate Large Time Steps

This example models an induction stovetop. The network model uses a half-bridge with subcycle averaging to generate alternating current to power induction coils. The model contains a network with fast RLC time constants. With the local solver set to Trapezoidal Rule, you can simulate the model with a larger time step and increased accuracy than with a Backward Euler local solver. Some electrical topologies such as wireless power transfer circuits cannot be accurately simulated with a Backward Euler solver with a time step larger than 100 ns. For real-time simulation, the Trapezoidal Rule solver lets you run these models with larger time steps (~1 μs) for specific hardware requirements.

The model in this example generates the necessary current to pass through the induction coils in an induction stovetop. The current is measured at the output.

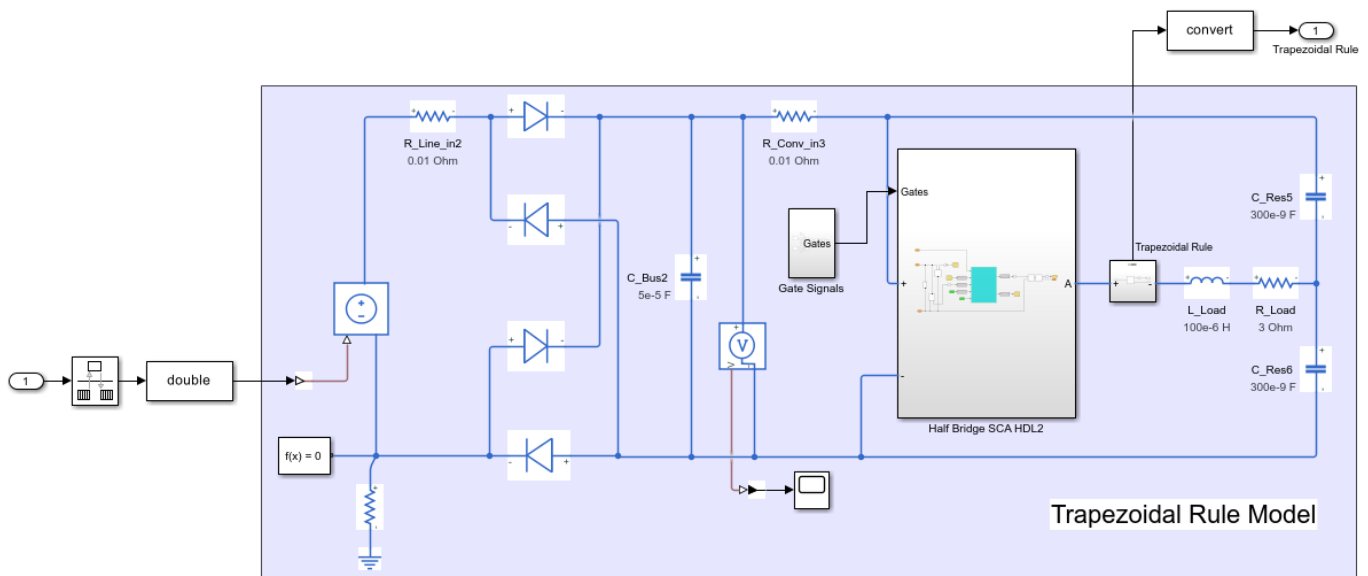

Open the model from the MATLAB® command prompt.

```
modelName = 'sshdl_trapezoidal_example';  
open_system(modelName)
```

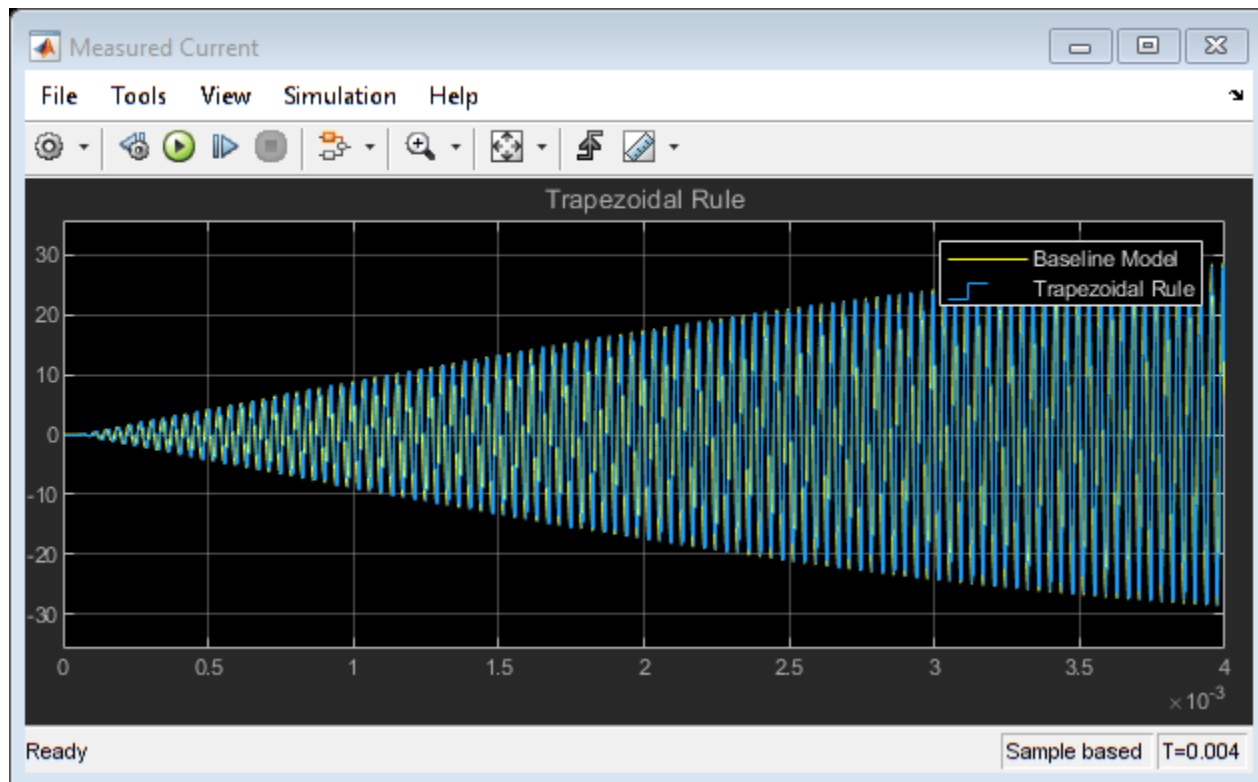

Open the Trapezoidal Rule Model subsystem

```
open_system('sschdl_trapezoidal_example/Trapezoidal Rule Model')
```

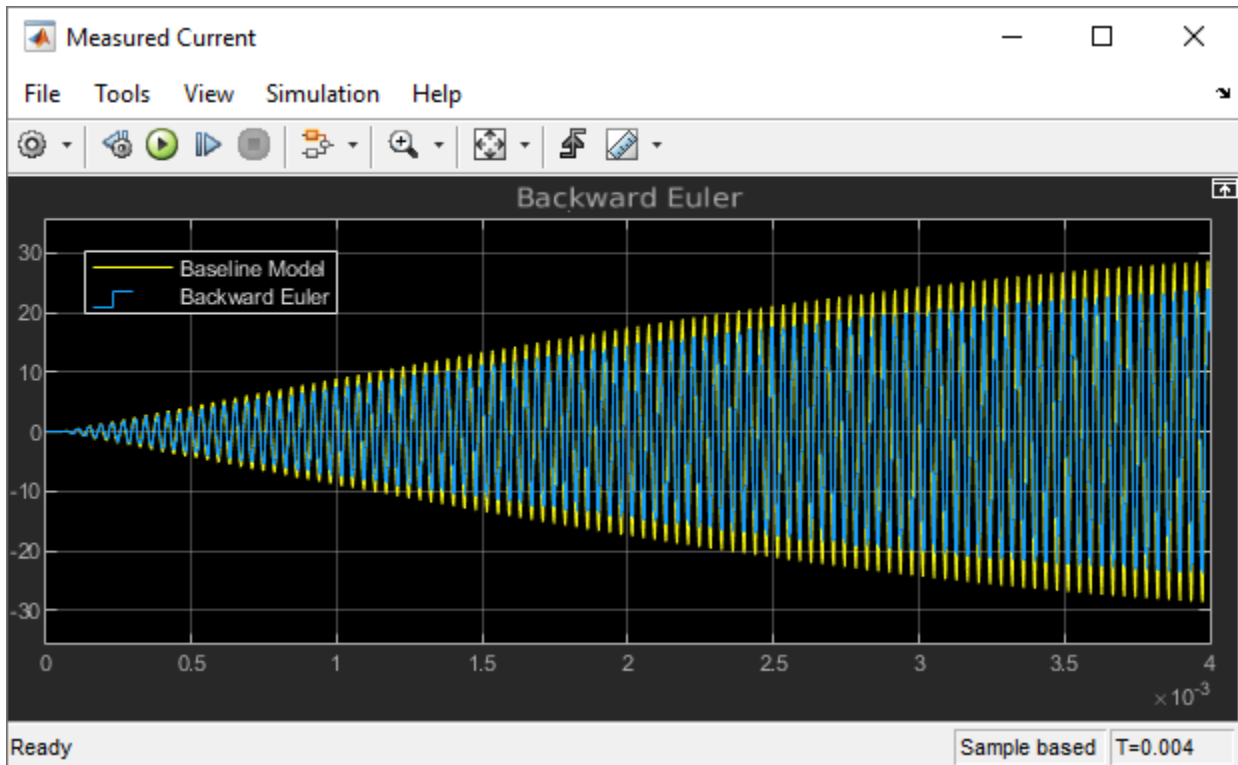

Simulate the model. To compare the results of Trapezoidal Rule local solver with the expected results from Baseline Model (using a variable step solver), open the Measured Current scope and observe the waveforms.

```
sim(ModelName);
open_system(['sschdl_trapezoidal_example' '/Measured Current'])
```

You can see that the two waveforms for the Baseline Model and Trapezoidal Rule Model overlap. There is no difference in the two results.

When you use the Backward Euler local solver with the same time step (1e-6 s) used with the Trapezoidal Rule local solver, the measured current is not correct. The Backward Euler local solver requires a smaller time step to provide accurate results for this model.

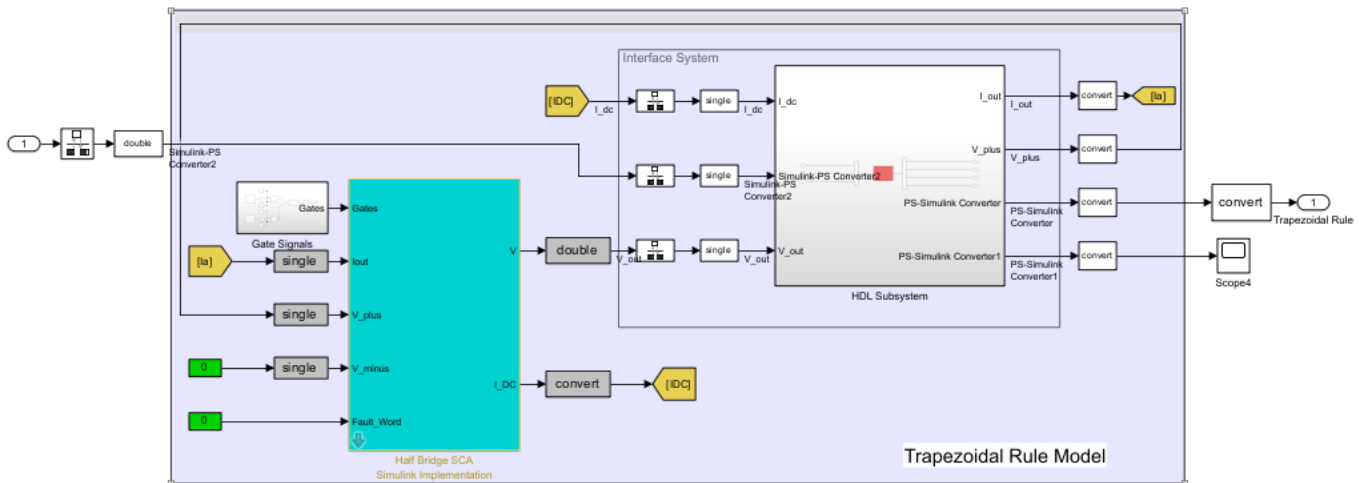

To continue with this example, right-click the Baseline Model, click **Comment Out** and save the model. On the **Modeling** tab, click **Model Settings** and select **Model Settings** from the drop-down menu. In the Solver window, specify the Solver selection options. From the **Type** list, select **Fixed-step**, and from the **Solver** list select **discrete (no continuous states)**. Save the model.

Generate HDL Implementation Model and Validate HDL Algorithm

The Simscape HDL Workflow Advisor converts the Simscape plant model to an HDL-compatible implementation model from which you generate HDL code. To open the Advisor, run the `sschdladvisor` function for your model.

```
sschdladvisor('sschdl_trapezoidal_example')
```

To generate the HDL implementation model, in the **Implementation model generation** task drop-down list, right-click the **Generate implementation model** task, and then select **Run to Selected Task** from the list. After the task passes, you see a link to the HDL implementation model `gmStateSpaceHDL_sschdl_trapezoidal_example`.

To verify that the HDL implementation model matches the original Simscape model, generate a state-space validation model. In the **Generate implementation model** task, select the **Generate validation logic** for the implementation model check box and set the **Validation logic tolerance** to 1e-1. Then, run the task. See “Validate HDL Implementation Model to Simscape Algorithm” on page 37-95.

To modify the configuration parameter values for HDL code generation, navigate to `gmStateSpaceHDL_sschedl_trapezoidal_example/Trapezoidal Rule Model/HDL Subsystem`. Right-click the HDL Algorithm subsystem and select **HDL Block Properties** from the **HDL Code** list. In the HDL Properties dialog box, set the **FlattenHierarchy** to On. Click **Apply** and then click **OK**.

HDL Workflow Advisor

The HDL Workflow Advisor guides you through HDL code generation and the FPGA design process. Use the Advisor to:

- Check the model for HDL code generation compatibility and fix incompatible settings.

```
hdlsetup('gmStateSpaceHDL_sschedl_trapezoidal_example')
```

- Generate HDL code, test bench, and scripts to build and run the code and test bench.
- Perform synthesis and timing analysis.
- Deploy the generated code on SoCs, FPGAs, and Speedgoat I/O modules.

Generate FPGA Bitstream for Speedgoat Target Computer

Use HDL Workflow Advisor to Generate Simulink Real-Time Interface Model

1. Open the HDL implementation model, and then open the HDL Workflow Advisor for the implementation model.

```
open_system('gmStateSpaceHDL_sschedl_trapezoidal_example')
```

To open the HDL Workflow Advisor for a subsystem inside the model, use the `hdladvisor` function.

```
hdladvisor('gmStateSpaceHDL_sschedl_trapezoidal_example/Trapezoidal Rule Model')
```

2. In the **Set Target Device and Synthesis Tool** task, specify **Target workflow** as Simulink Real-Time FPGA I/O and **Target platform** as Speedgoat IO334-325k.

1.1. Set Target Device and Synthesis Tool

Analysis (^Triggers Update Diagram)

Set Target Device and Synthesis Tool for HDL code generation

Input Parameters

Target workflow: Simulink Real-Time FPGA I/O

Target platform: Speedgoat IO334-325k Launch Board Manager

Synthesis tool: Xilinx Vivado Tool version: 2020.2 Allow unsupported version Refresh

Family: Kintex7 Device: xc7k325t

Package: fbg676 Speed: -2

Project folder: hdl_prj Browse...

3. In the **Set Target Reference Design** task, select a value of X4 for the parameter PCIe lanes, and click the **Run This Task** button.

1.2. Set Target Reference Design

Analysis (^Triggers Update Diagram)

Set target reference design options

Input Parameters

Reference design: Speedgoat IO334-325k

Reference design tool version: 2020.2 Ignore tool version mismatch

Reference design parameters

Parameter	Value
PCIe Endpoint: Link Width	X4
Bitstream Timing Closure Severity	error
Rear Plugin	None
Aurora Mode	None
Aurora CRC Enabled	true
Aurora IP Core: Little Endian Support [...]	true

4. In **Set Target Interface** task, map the input and output single data type ports to PCIe Interface and click the **Run This Task** button.

1.3. Set Target Interface

Analysis (^Triggers Update Diagram)

Set target interface for HDL code generation

Input Parameters

Processor/FPGA synchronization:

Enable HDL DUT output port generation for test points

Generate default AXI4 slave interface

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
Input	Inport	single	PCIe Interface	x"100"	Options...
Trapezoidal Rule	Outport	single	PCIe Interface	x"104"	

5. In the **Set Target Frequency** task, the default value of **Target Frequency (MHz)** is set to 100. For this example model, this value is same as default value.

1.4. Set Target Frequency

Analysis

Set Target Frequency

Input Parameters

Target Frequency (MHz):

Default (MHz):

Frequency Range (MHz):

6. In the **HDL Code Generation** task folder, click **Set HDL Options** then click the **HDL Code Generation Settings** button. This opens the Configuration Parameters dialog box. Under **HDL Code Generation > Global Settings > Clock Settings**, set the Oversampling factor to 1.

7. Right-click the **Generate Simulink Real-Time Interface** task, and select **Run to Selected Task** to generate the HDL IP core and FPGA bitstream.

Run Workflow Script to Generate Simulink Real-Time Interface Model

You can export the HDL Workflow Advisor settings to a script to expedite and automate your workflow. The script is a MATLAB® file that you run from the command line. You can modify and run the script, or import the settings into the HDL Workflow Advisor User Interface. See “Run HDL Workflow with a Script” on page 36-49.

This example shows how to run the HDL Workflow script. To generate a Simulink Real-Time Interface model, open and run this MATLAB script.

```
edit('hdlworkflow_trapezoidal_I0334')
```

```
%-----  
% HDL Workflow Script
```

```

% This script contains the model, target settings, interface mapping, and
% the Workflow Configuration settings for generating HDL code for the HDL
% implementation model generated for the Trapezoidal Example Model
% and for deploying the code to the FPGA on board the Speedgoat
% I0334-325K module.
%-----

hWC.RoutedDesignCheckpointFilePath = '';
hWC.MaxNumOfCoresForBuild = '';

% Validate the Workflow Configuration Object
hWC.validate;

%% Run the workflow
hdlcoder.runWorkflow('gmStateSpaceHDL_sschedl_trapezoidal_example/Trapezoidal Rule Model', hWC);

% Set the sample time in the final SLRT model
set_param('gm_gmStateSpaceHDL_sschedl_trapezoidal_example_slrt/Voltage Control Signal', 'SampleTime', 4e-6);
```

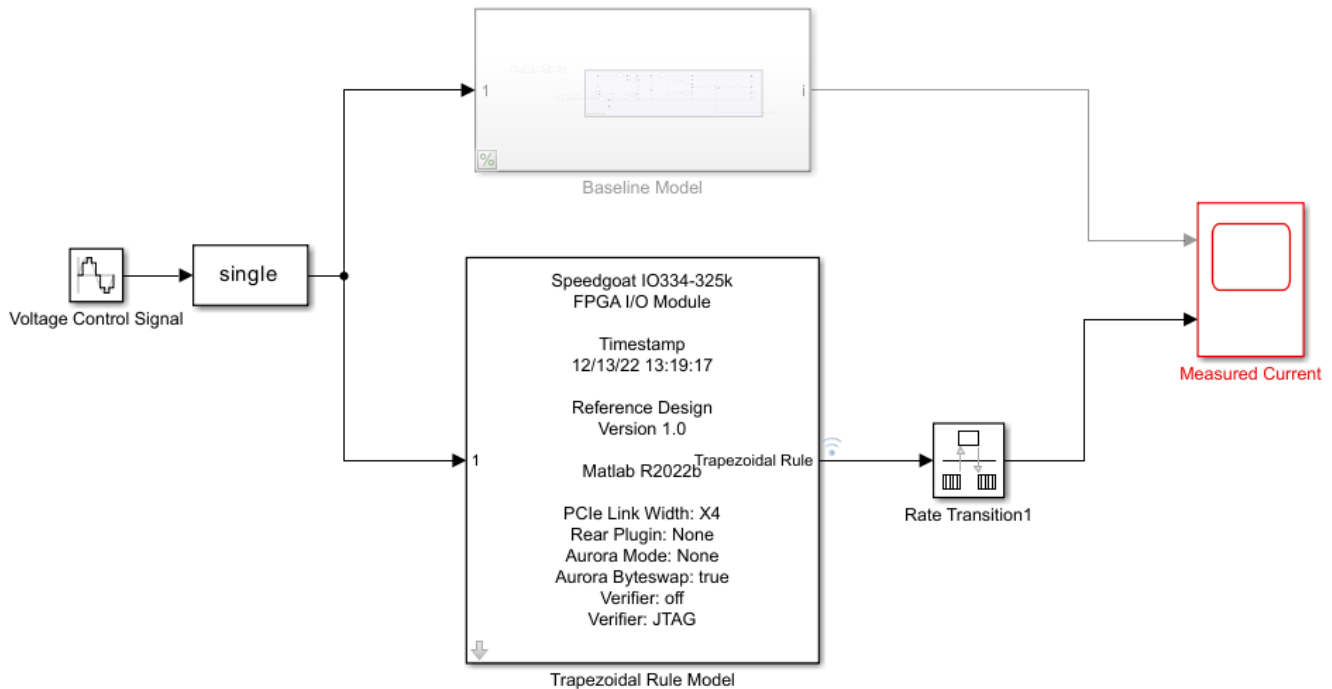

The last line of the script sets the sample time of the Voltage Control Signal block in the generated Simulink Real-Time Interface model to 4e-6.

Deploy Bitstream to Speedgoat IO334-325k Target

Prepare Simulink Real-Time Interface Model for Real-Time Simulation

Running the workflow script generates RTL code and IP core, creates a Vivado project, builds the FPGA bitstream, and then generates the Simulink Real-Time interface model.

The FPGA subsystem is automatically replaced in the real-time interface model with Speedgoat driver blocks to initialize the hardware and to interface with the FPGA during runtime.

Make sure you comment out any remaining Rate Transition blocks in the model to obtain a single rate model. All the blocks in the generated Simulink Real-Time model are executed on the CPU of the real-time system. The induction stovetop model is programmed in the bitstream and run at the faster rate on the FPGA.

Connect to Target Machine and Run Real-Time Simulation

The model can now be deployed onto the Speedgoat real-time target machine. Make sure that the Speedgoat real-time target machine is connected to the host computer and powered on.

You download the bitstream by using the Simulink Real-Time Explorer. To open the Simulink Real-Time Explorer, enter the command `slrtExplorer`. Alternatively, you can open the Explorer from the **Real-Time** tab of the Simulink Toolstrip.

```
slrtExplorer
```

The Simulink Editor displays the **Real-Time** tab for models that are configured for the `slrealtime.tlc` code generation target. Click the **Connect to Target Computer** button in the Simulink **Real-Time** tab to connect to the machine. Once connected, click the **Run on Target** button to deploy the model.

Simulink Real-Time automatically generates C code from your model by using Simulink Coder. The generated code and the bitstream for the FPGA are loaded onto the target machine, and model execution starts automatically.

Simscape HDL Workflow Advisor Tasks

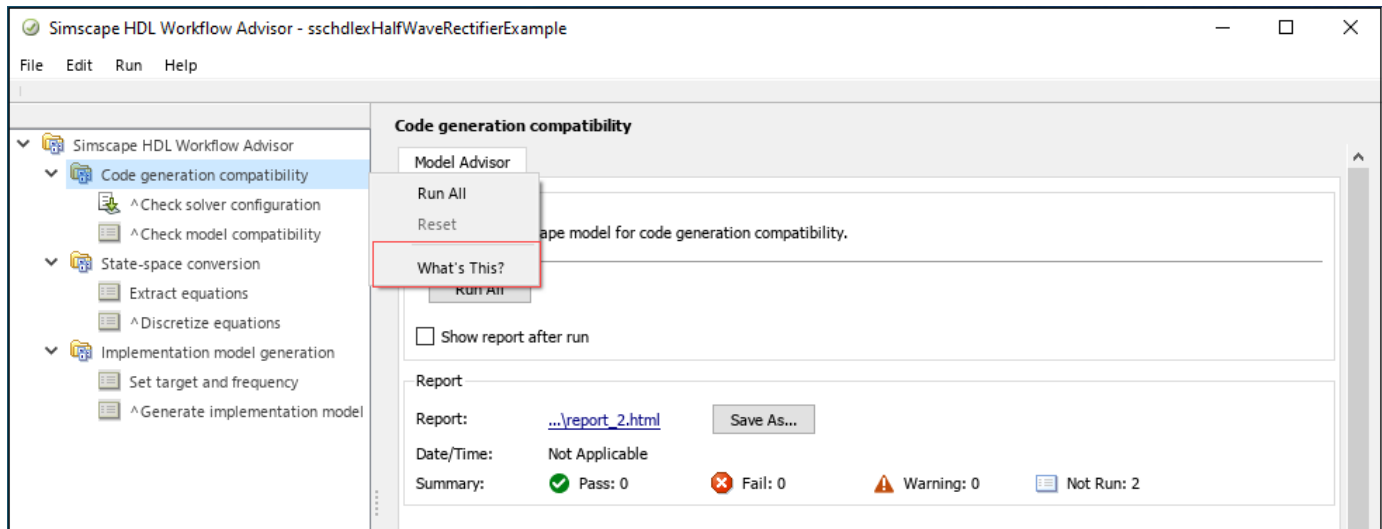

- “Simscape HDL Workflow Advisor Tasks” on page 38-2
- “Simscape HDL Workflow Advisor Tips and Guidelines” on page 38-7

Simscape HDL Workflow Advisor Tasks

By using the Simscape HDL Workflow Advisor, you can generate an HDL implementation model. You can then generate HDL code for the implementation model and deploy the code onto FPGA platforms. To open the Advisor, run the `sschdladvisor` function. For example:

```
sschdladvisor('sschdlexHalfWaveRectifierExample')
```

For summary information on each Simscape HDL Workflow folder or task, right-click the folder or task and select **What's This?**.

Simscape HDL Workflow Advisor

To convert your Simscape model to an HDL implementation model, the Simscape HDL Workflow Advisor contains various tasks that you can use. You can then generate code for the HDL Subsystem in the HDL implementation model. The tasks in the Simscape HDL Workflow Advisor are in these folders:

- The **Code generation compatibility** folder contains tasks that check whether the model uses the correct solver configuration settings and reports blocks that are not compatible for HDL code generation.
- The **State-space conversion** folder contains tasks that get the state-space parameters from your model for generating the implementation model.
- The **Implementation model generation** folder contains tasks that generate the HDL implementation model from the state-space parameters for the specified target hardware settings.

To learn more about each folder or task, right-click the folder or task and select **What's This?**.

Code Generation Compatibility

The tasks in the **Code generation compatibility** folder check whether:

- You have correctly specified the solver configuration settings and the settings are consistent across Solver Configuration blocks inside each network in your Simscape model.
- Your model uses HDL-compatible blocks.

Check Solver Configuration

The **Check solver configuration** task checks whether you have specified the correct settings and the settings are consistent across Solver Configuration blocks inside each network in your Simscape model.

The Simscape HDL Workflow Advisor checks whether you specified these settings for all Solver Configuration blocks:

- **Use local solver** is selected.
- **Solver type** is set to Backward Euler, Partitioning, or Trapezoidal Rule.
- A discrete sample time, T_s , is specified.
- **Use fixed-cost runtime consistency iterations** selection is same (either selected or cleared).
- The **Nonlinear iterations** value is same when **Use fixed-cost runtime consistency iterations** is selected.

If you did not specify these settings, the task provides a link to the Solver Configuration block in your model and the settings to modify.

Check Model Compatibility

The **Check model compatibility** task checks whether you use HDL-compatible blocks in your Simscape model.

If this task passes, it displays :

- A message indicating that the model is switched linear.
- The number of Simscape networks present in the model.
- The number of algebraic and differential variables for each Simscape network with links to the related blocks in your Simscape model.

Differential variables consume a quadratic amount of multiplier resources on the target FPGA device. Algebraic variables consume a linear amount of multiplier resources. You can use this information to determine how many multiplier resources your Simscape design consumes on the FPGA device.

- A message with links to the Simulink-PS Converter and PS-Simulink Converter blocks in your model if you use the default names for these blocks.

The input and output ports of the HDL `Subsystem` in the implementation model use the names that you specify for the Simulink-PS Converter and PS-Simulink Converter blocks. To avoid this message, use a meaningful name for these blocks.

State-Space Conversion

Before you can generate the HDL implementation model, run the tasks in this folder to get the state-space parameters from your model. The tasks in this folder:

- Simulate the Simscape model to extract the differential algebraic equations and mode-switching function.
- Discretize the differential algebraic equations to generate an abstract state-space representation that represents the model in the form of linear modes.

Extract Equations

The **Extract equations** task simulates your Simscape model and extracts the differential algebraic equations and mode switching function. This task gets the **Simulation stop time** value from the original Simscape model.

If this task passes, it displays the number of states, inputs, outputs, modes, and differential variables for each Simscape network present in the model.

The number of modes is limited by the number of switches present in your Simscape model. The maximum number of modes possible are 2^n , where n is the number of switches. All the modes that the Simscape HDL Workflow Advisor generates are executed as per the input parameters by using a switching logic. The Advisor selects a valid number of modes depending on the design of your Simscape model.

Discretize Equations

The **Discretize Equations** task discretizes the differential algebraic equations and generates an abstract, discrete state-space representation of the model in the form of linear modes. Each mode is represented by a set of state-space matrices. This task gets the **Discrete sample time** value from the original Simscape model.

If this task passes, it displays the **Discrete sample time**, number of parameters and parameter size for each Simscape network present in the model.

Passed

Discrete sample time of all Simscape networks: 1e-06

Summary of the state-space representation:

Details related to the Simscape network [sschdlexHalfWaveRectifierExample/Simscape_system/Solver Configuration](#)

Parameter	Parameter size
A	1 x 1 x 2
B	1 x 1 x 2
F0	1 x 1 x 2
C	3 x 1 x 1
D	3 x 1 x 1
Y0	3 x 1 x 1

Implementation Model Generation

The tasks in the **Implementation model generation** folder generate an HDL implementation model from the discrete state-space representation. The implementation model represents the Simscape algorithm by using Simulink blocks that are compatible for HDL code generation for the specified target hardware settings. If the task **Generate implementation model** in this folder passes, it provides a link to the generated HDL implementation model.

Set Target and Frequency

In this task, you can provide the information required for target hardware settings before generating the HDL implementation model. This helps incorporate the HDL optimizations required for hardware deployment. In the right pane, select a **Synthesis Tool** option and update **Family**, **Device**, **Package**, and **Speed** for the target hardware. Then, set the **Target Frequency (MHz)** in the text box.

Generate Implementation Model

To generate an HDL implementation model from the discrete state-space representation, run the **Generate implementation model** task. The HDL implementation model contains an HDL **Subsystem** that models the state-space equations by using the state-space parameters you get by running the tasks in the **State-space conversion** folder. The HDL **Subsystem** block represents the DUT for which you can generate HDL code.

Before you run this task, you can:

- Specify a custom value for the **Number of solver iterations** setting. To learn more, see “Using Number of Solver Iterations” on page 38-10.
- Use the **Floating-point precision** setting to specify whether the HDL **Subsystem** in the generated implementation model stores matrix types in `single` or `double` and computes the results in `single` or `double` data types. To learn more, see “Floating-Point Precision and Numerical Accuracy” on page 38-11.
- Use the **Map state space parameters to RAMs** setting to map the state-space parameters onto the hardware resources such as RAMs or lookup tables (LUTs). To learn more, see “Map State Space Parameters to RAMs” on page 38-11.
- Select the **Generate validation logic for the implementation model** to generate the logic that verifies whether the generated HDL implementation model is functionally equivalent to the original Simscape model. This task generates the logic for each Simscape network present in the model. You can specify a tolerance for the numerical correctness by setting **Validation logic tolerance**. The **Validation logic tolerance** is an absolute value. For example, you can specify a tolerance value of $1e-12$.
- Select the **Share adders and multipliers** option to set an optimal value of the **SharingFactor** for the Matrix Multiply (Product) blocks in your HDL implementation model. The optimal sharing factor value for a model is calculated based on the target details provided in the **Set target and frequency** task in the **Implementation model generation** folder of the Simscape HDL Workflow Advisor. Setting this option reduces synthesis overhead and optimizes resource utilization before generating HDL code for your model.

If the task passes, you see a link to the generated HDL implementation model.

Simscape HDL Workflow Advisor Tips and Guidelines

By using the Simscape HDL Workflow Advisor, you can generate an HDL implementation model. You can generate HDL code for the implementation model and deploy the generated code onto FPGA platforms. To open the Advisor, run the `sschdladvisor` function. For example:

```
sschdladvisor('sschdlexBoostConverterExample')
```

The Simscape HDL Workflow Advisor contains various tasks that convert your Simscape model to the HDL implementation model. When running various tasks in the Simscape HDL Workflow Advisor, you can follow certain tips and guidelines. You see these tips in the UI window of a particular task. For example, in the task that discretizes the equations to state-space parameters, the UI has a tip that suggests how to change the sample time. This section contains more information about each tip in the Simscape HDL Workflow Advisor UI.

Estimating Resource Consumption Using Algebraic and Differential Variables

After you run the **Check model compatibility** task, the task reports the number of differential and algebraic variables for each Simscape network present in the model. For example, this figure illustrates that there are two differential and two algebraic variables in the boost converter example model `sschdlexBoostConverterExample`.

```
sschdladvisor('sschdlexBoostConverterExample')
```

Run the workflow to the **Check model compatibility** task.

Details

Number of Discrete Variables: 4

Number of Differential Variables: 2

Source	Value
Simscape_system.Capacitor.vc	Capacitor voltage
Simscape_system.Inductor.i_L	Inductor current

Number of Algebraic Variables: 2

Source	Value
Simscape_system.Capacitor.i	Current
Simscape_system.Inductor.v	Voltage

By viewing the number of algebraic and differential variables, you can determine how the design consumes resources on the FPGA device. If N_d is the number of differential variables and N_a is the number of algebraic variables, the resource usage on the target hardware varies according to the

relation $N_d * (N_d + N_a)$. Differential variables consume a quadratic amount of multiplier resources on the target FPGA device. Algebraic variables consume a linear amount of multiplier resources. You can use this information to determine how many multiplier resources your Simscape design consumes on the FPGA device and whether your design is ready for conversion to state-space representation.

Setting Simulation Stop Time for Extracting Equations

Change Simulation Stop Time

When you run the **Extract equations** task, the Simscape HDL Workflow Advisor reports the simulation stop time. The simulation stop time corresponds to the amount of time that the Advisor takes to run simulation on your Simscape model. The stop time must not be significantly large such that the Advisor takes a long time to run this task. Use a stop time that is sufficient to reach the required number of modes for your model. To change the stop time, navigate to the Simscape model, and then specify the **Stop Time**.

Simulation Stop Time and Number of Modes

In the **Extract equations** task, when you extract the differential algebraic equations, the Simscape HDL Workflow Advisor simulates the model to cover the nonlinear range of Simscape blocks. This task can take a long time depending on the number of switching elements in the Simscape model.

For a switched linear model, each switching element in the design has two modes. A switched linear model with n switching elements has 2^n possible modes. For Simscape models with large number of switching elements, the number of modes can become significantly large. For example, the Vienna rectifier has 21 switching elements, which translates to 2^{21} possible modes. The Simscape HDL Workflow Advisor can take a long time to simulate such a large model and cover such a large number of modes. In addition, the HDL implementation model that you generate for such a design can consume a large amount of resources or may not even fit on the target FPGA device.

In most cases, while simulating the model, the Advisor does not have to reach the entire 2^n modes. For example, consider this bridge rectifier model. To open this model, enter:

```
open_system('sschdlexBridgeRectifierExample')
```

Inside the `Simscape_system` Subsystem, you see the four diodes arranged in a bridge configuration.

As each diode has two states, the Simscape design can have $2^4 = 16$ possible states. In contrast, the bridge rectifier has only three modes. The modes are:

- Diodes D1 and D2 are ON, D3 and D4 are OFF
- Diodes D1 and D2 are OFF, D3 and D4 are ON
- Diodes D1, D2, D3, and D4 are OFF

This example shows that, based on the Simscape algorithm and the input to the design, you can set the simulation stop time to a minimum value that covers the number of modes to be reached.

Changing Sample Time for Discretizing Equations

Change Sample Time

When you run the **Discretize equations** task, the Simscape HDL Workflow Advisor reports the discrete sample time. The discrete sample time corresponds to the sample time that the Advisor uses to discretize the differential algebraic equations to state-space parameters. To change the sample time, in your Simscape model, open the Block Parameters dialog box for the Solver Configuration block, and then specify the **Sample time**.

Sample Time and Discretizing Equations

In the **Discretize equations** task, the Simscape HDL Workflow Advisor discretizes the differential algebraic equations into state-space parameters. You extract the differential algebraic equations by simulating the Simscape model in the previous task, **Extract equations**. The **Discretize equations** task runs much faster than the **Extract equations** task because the Advisor only has to discretize the differential algebraic equations to state-space parameters.

The **Discretize equations** task obtains the sample time information from the sample time that you specify for the Solver Configuration block in your model. The Advisor then discretizes the equations to state-space parameters based on this sample time information.

Using Number of Solver Iterations

What is Number of Solver Iterations?

In the **Generate implementation model** task, you can specify the **Number of solver iterations**. The number of solver iterations refer to the number of times the state-space model is executed per mode. The Simscape HDL Workflow Advisor generates the number of iterations that are required for executing the state-space model, automatically.

For each mode in the physical system, the switched linear workflow arrives at a state-space representation. The solver method is iterative and performs multiple computations to determine the correct mode for the next time step. After a certain number of iterations, the output value from the next time step becomes the same as the value from the previous time step. This consistency in the output value indicates the correct number of solver iterations.

By default, the **Number of Solver iterations** is 1 for linear models. For switched linear models, the **Number of solver iterations** depends on the number of mode iterations that Simscape uses during model simulation. This chosen value is optimal such that it causes the model to converge and avoids exceeding the threshold value for real-time deployment.

Using Fixed-Cost Runtime Consistency Iterations

On the Solver Configuration block, the **Use fixed-cost runtime consistency iterations** check box is cleared by default. If you select this check box, the **Nonlinear iterations** setting on the Solver Configuration block becomes the same as the **Number of solver iterations** setting in the **Generate implementation model** task.

By default, **Nonlinear iterations** is set to 2. When you run the **Generate implementation model** task, the Advisor sets the **Number of solver iterations** to 2 and this setting cannot be modified. To modify the **Number of solver iterations**, either:

- Change **Nonlinear iterations**.
- Clear **Use fixed-cost runtime consistency iterations** and then change the **Number of solver iterations**.

To learn more about the **Use fixed-cost runtime consistency iterations** setting, see Solver Configuration. See also “Solvers for Real-Time Simulation” (Simscape).

Change Number of Solver Iterations

By default, you can change the number of solver iterations on this task. Increasing the number of solver iterations improves the numerical accuracy of generated HDL implementation model. To achieve higher sampling frequencies, reduce the number of solver iterations. Choose a value for number of solver iterations that trades off numerical accuracy and sampling frequency.

On the Solver Configuration block, if you specify the **Use fixed-cost runtime consistency iterations** setting, you cannot change the **Number of solver iterations** setting on this task. To change the number of solver iterations, on the Solver Configuration block, change the **Nonlinear iterations** parameter and rerun the **Generate implementation model** task.

Trading off Numerical Accuracy and Sampling Frequency

To verify whether the numeric results of the HDL implementation model matches the original Simscape model, select **Generate validation logic for the implementation model**. If the numeric

results from the HDL implementation model do not match, you can increase the number of solver iterations. To learn more, see “Increase Number of Solver Iterations” on page 37-98.

Changing the number of solver iterations trades off numerical accuracy for sampling frequency. Increasing the number of solver iterations increases the sample time of the HDL implementation model which can reduce the sampling frequency. See “Reducing Number of Solver Iterations” on page 37-104.

Floating-Point Precision and Numerical Accuracy

Use the **Floating-point precision** setting to specify whether you want the algorithm inside the HDL Subsystem in the generated implementation model to use `single` or `double` data types when performing the matrix computations.

Floating-Point Precision	Description
Double	Using <code>double</code> floating-point precision increases the numerical accuracy of the generated model and the maximum achievable target frequency. However, the area consumption and pipeline latency are also increased.
Single	This is the default setting for floating-point precision.
Single coefficient, double computation	This mode offers a tradeoff between <code>Single</code> and <code>Double</code> modes of floating-point precision. To save memory usage, the coefficients that are stored in <code>single</code> . The matrix computations are then performed in <code>double</code> for improved accuracy.

To learn more about the floating-point precision settings and tradeoffs, see “Use Larger Floating-Point Precision” on page 37-99.

Map State Space Parameters to RAMs

The **Map state space parameters to RAMs** setting enables you to map the state space parameters onto the hardware resources such as RAMs or lookup tables (LUTs).

Map State Space Parameters to RAMs	Description
Auto (default)	Maps the state space parameters to RAMs when the number of modes exceeds a set threshold value (200). Otherwise, it maps them to LUTs.
On	Maps state space parameters to RAMs.
Off	Maps state space parameters to LUTs.

Troubleshooting

Troubleshooting Real-Time Hardware Deployment Issues in Simscape Hardware-in-the-Loop Workflow

Simscape lets you rapidly create models of physical systems within the Simulink environment. You model and simulate multidomain physical systems such as electric motors, bridge rectifiers, hydraulic actuators, and refrigeration systems by assembling fundamental components into a schematic. For more information, see “How Simscape Models Represent Physical Systems” (Simscape).

You can generate HDL code for the plant model you develop using Simscape blocks and then deploy the generated code to platforms such as standalone FPGA boards, Speedgoat FPGA I/O modules, and system on a chip (SoC) devices. By deploying the plant model to an FPGA board, you can accelerate the simulation of your plant model and simulate the model in real time by using hardware-in-the-loop (HIL) simulations. For more information, see “Get Started with Simscape Hardware-in-the-Loop Workflow” on page 37-2.

This workflow diagram shows the different stages of the Simscape HIL workflow.

In this topic, you will learn how:

- Timing violations occur on hardware.
- To address timing violations on hardware.

Parameter Settings

You can generate HDL code for a wide variety of Simscape networks and simulate it. However, hardware deployment of the same models has certain requirements that need to be addressed early in the design process. For instance, the generated HDL code may consume a lot of hardware resources. Understanding how your design maps to your target device, is key to generating HDL code that will meet your needs when implemented downstream.

When you generate HDL code and deploy the plant model onto an FPGA, you may want to improve the sampling frequency.

- **Sampling Frequency:** The sampling frequency (FPGA sampling frequency) is the frequency at which the models run on the hardware. It is defined as,

$$\text{Sampling Frequency} = \frac{\text{FPGA clock frequency}}{(\text{Oversampling factor} \times \text{Number of solver iterations})}$$

The sampling frequency depends on these parameters:

- FPGA clock frequency
- Oversampling factor
- Number of solver iterations

The real time step on FPGA, T_{s_fpga} , is the sample time at which the models run on the hardware. It is the reciprocal of the sampling frequency.

The value of Simscape sample time is fixed for a Simscape model. Simscape sampling frequency is the reciprocal of the Simscape sample time. For the Simscape model simulation, you can specify the **Sample time** in the Solver Configuration block dialog box under the **Use local solver** parameter. To learn more about how this block is used in your model before running the Simscape HDL Workflow Advisor, see “Generate HDL Code for Simscape Models” on page 37-13.

- **Number of Solver Iterations:** The number of solver iterations refer to the number of times the state-space model is executed per time step. The Simscape HDL Workflow Advisor calculates the number of iterations that is required for executing the state-space model, automatically. You can specify the **Number of solver iterations** in the **Generate implementation model** task of the Simscape HDL Workflow Advisor.
- **Oversampling Factor:** The **Oversampling factor** specifies the factor by which the global clock signal is a multiple of the base rate at which the model operates. Generation of the global oversampling clock affects the generated HDL code. It does not affect the simulation behavior of your model. You can specify the value of oversampling factor in the **Clock Settings** section of the **HDL Code Generation > Global Settings** pane in the Configuration Parameters dialog box. For more information on oversampling factor, see “Oversampling factor” on page 21-15.
- **Target Frequency:** The target frequency refers to the clock rate for the FPGA implementation of your design. When you specify the target frequency, the HDL Coder modifies the clock module setting in the reference design to produce the clock signal with that frequency.

Before setting the target frequency, make sure that you specify the **Synthesis Tool**.

Specify the target frequency in the **Target Frequency (MHz)** text box under the **Set target and frequency** task in the Simscape HDL Workflow Advisor.

You can also set the target frequency by using the **Target Frequency (MHz)** setting in the **Set Target Frequency** task in the HDL Workflow Advisor. For more information, see “HDL Workflow Advisor Tasks” on page 43-2.

The Speedgoat boards that are supported by Xilinx Vivado use the IP Core Generation workflow infrastructure. Enter a target frequency value that is within the **Frequency Range (MHz)**. If you do not specify the target frequency, HDL Coder uses the **Default (MHz)** target frequency.

To get correct results, the Simscape time step and real time step on the FPGA need to match.

Critical Path Estimation

You can use critical path estimation to check if the model meets the timing requirement imposed by the target frequency. A critical path is a combinational path between an input and output that has the maximum timing delay. To make the critical path timing meet the target frequency that you want your design to achieve, break the critical path by adding delays. The additional delays increase the latency and register usage on the target FPGA. Critical path estimation speeds up the design iteration process. Critical path estimation is an alternative to annotating the critical path by performing **FPGA**

Synthesis and Analysis with the HDL Workflow Advisor. For more information, see “Critical Path Estimation Without Running Synthesis” on page 28-192.

How Sample Rate Affects the Timing on the Hardware

Variation of Sample Rate

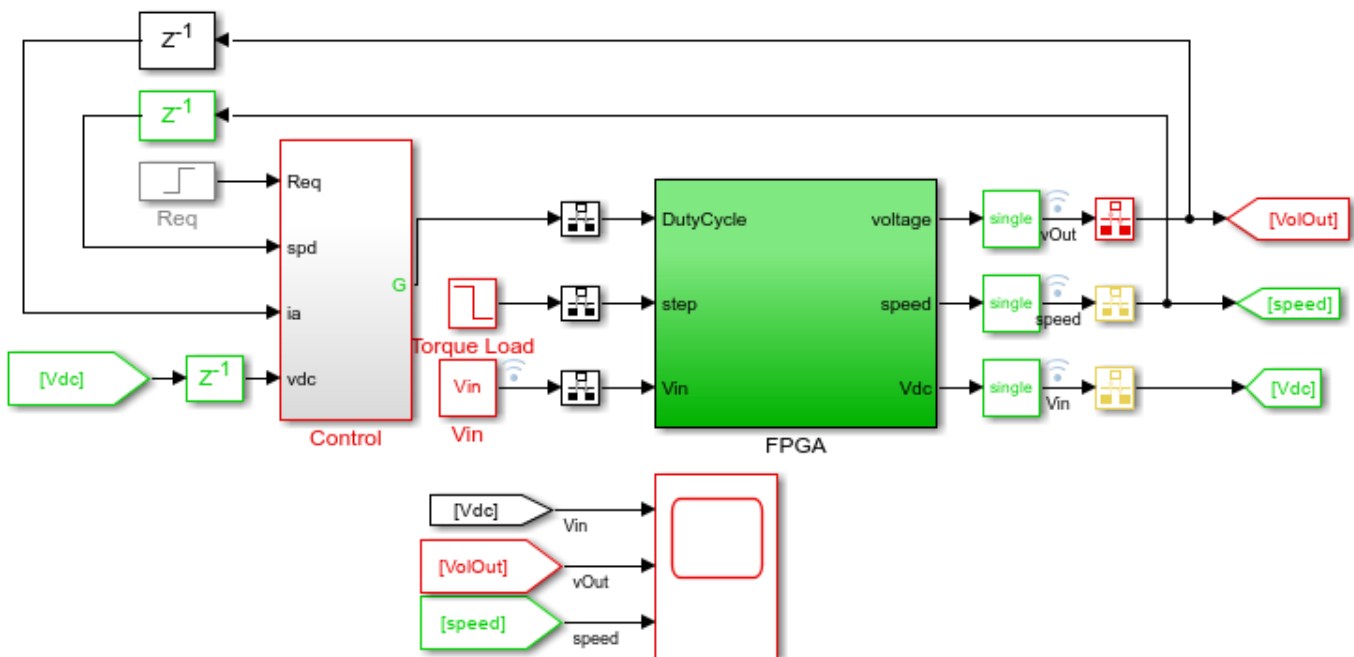

In Simscape HIL workflow, the sample rate varies for the Simscape model, the HDL implementation model, and the Simulink Real-Time (SLRT) Interface model of the same design due to the dependency on other parameters such as oversampling factor and solver iterations.

Buck Converter with DC Motor

To understand the variation of sample rate, consider the model `ee_buck_converter_dc_motor_hdl.slx` that consists of a buck converter with a DC motor as load. To see the buck converter model, run this command.

```
open_system('ee_buck_converter_dc_motor_hdl')
```

Buck Converter Voltage Control with DC motor load

For the Simscape model, the Sample time, T_s is $6e-6$, which means that the sampling frequency of the Simscape model is 1/6 MHz. To understand the effect of different parameters on the hardware deployment, you can change the parameter values and see the effect on the output. For example, change the value of T_s to the default value $1e-6$. On the **Modeling** tab, select **Model Settings** > **Model Properties**. On the **Callbacks** tab, in the **Model callback** pane, select **PreLoadFcn** and change the value of T_s from $6e-6$ to $1e-6$. Save and close the model. Reopen it for further steps.

To simulate the model, click the **Run** button or press **Ctrl + T**. You can view the Timing Legend for the Simscape model. The Timing Legend contains the sample time color, annotation, and value for each sample time in the model. To view the Timing Legend:

- 1 In the Simulink model window, on the **Modeling** tab, click **Update Model**.
- 2 On the **Debug** tab, select **Information Overlays > Timing Legend**, or press **Ctrl + J**.

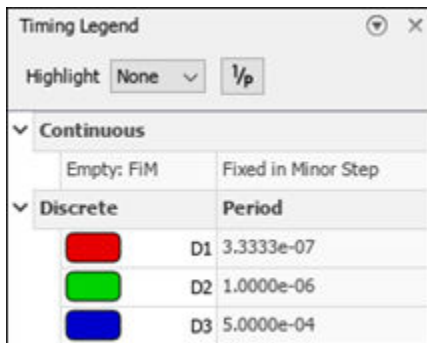

Generate the HDL implementation model by using Simscape HDL Workflow Advisor.

```
sschdladvisor('ee_buck_converter_dc_motor_hdl')
```

When you generate the HDL implementation model, the **Number of solver iterations** is set to an optimal value of 3 by default.

The sampling frequency of the generated HDL implementation model is 1 MHz. Because the HDL Algorithm in the HDL implementation model is iterative and with the value of **Number of solver iterations** (3 times), the HDL Algorithm subsystem runs at an updated sampling frequency of 3 MHz. The generated HDL implementation model uses Rate Transition blocks to handle the data transfer between the two subsystems (and blocks) operating at different rates.

You can now see the updated Timing Legend for the generated HDL implementation model.

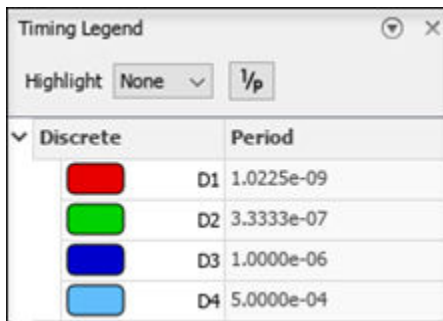

For the generated HDL implementation model, you can generate HDL code. To generate HDL code, use these commands:

```
open_system('gmStateSpaceHDL_ee_buck_converter_dc_motor_')
hdlsetup('gmStateSpaceHDL_ee_buck_converter_dc_motor_')
hdlset_param('gmStateSpaceHDL_ee_buck_converter_dc_motor_', 'ResourceReport', 'on')
hdlset_param('gmStateSpaceHDL_ee_buck_converter_dc_motor_', 'AdaptivePipelining', 'on');
hdlset_param('gmStateSpaceHDL_ee_buck_converter_dc_motor_', 'FloatingPointTargetConfiguration',...
hdlcoder.createFloatingPointTargetConfig('NativeFloatingPoint', 'LatencyStrategy', 'Max'));
makehdl('gmStateSpaceHDL_ee_buck_converter_dc_motor_/FPGA/HDL Subsystem');
```

When you run this code, you may encounter an error message that says to increase the oversampling factor to 326 to provide sufficient latency budget. The adaptive pipelining optimization and maximum latency strategy used for code generation increase the required value of the oversampling factor. Update the value of oversampling factor from 275 to 326 and generate the HDL code.

```
hdlset_param('gmStateSpaceHDL_ee_buck_converter_dc_motor_', 'Oversampling', 326);
makehdl('gmStateSpaceHDL_ee_buck_converter_dc_motor_/FPGA/HDL Subsystem');
```

When you run `makehdl`, it generates the HDL code and the generated model for `gmStateSpaceHDL_ee_buck_converter_dc_motor_` in the `hdlsrc` folder. Run the generated model `gm_gmStateSpaceHDL_ee_buck_converter_dc_motor_`. Observe the Timing Legend for this model.

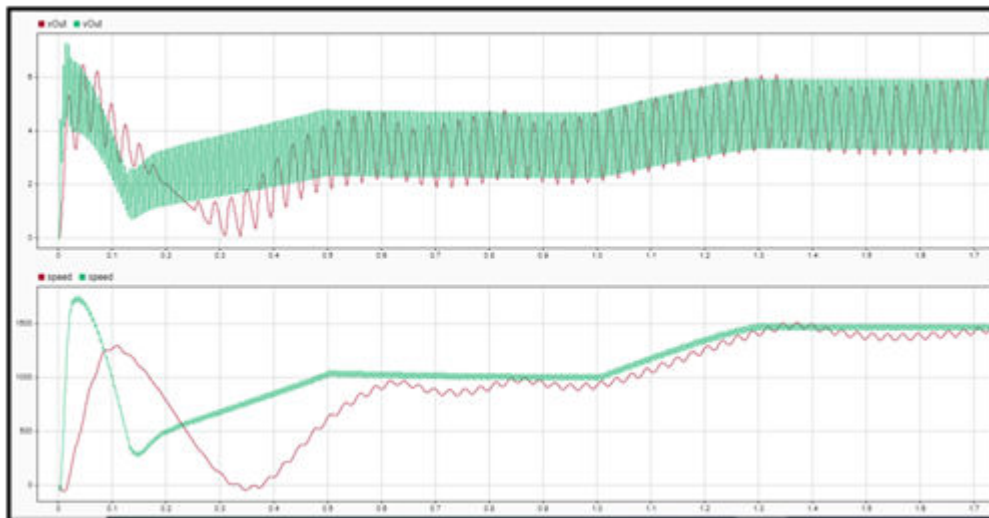

Discrete		Period
■	D1	1.0225e-09
■	D2	3.3333e-07
■	D3	1.0000e-06
■	D4	5.0000e-04

To generate a Simulink Real-Time (SLRT) Interface model, follow the steps from Simulink Real-Time FPGA I/O workflow by using the HDL Workflow Advisor. To learn more about each step, see “Deploy Simscape DC Motor Model to Speedgoat FPGA IO Module” on page 37-113.

With the oversampling factor set to the value 326, the FPGA clock frequency is 3×326 MHz, or 978 MHz. However, the allowable FPGA clock frequency range for the Speedgoat devices (IO334 module) is 50-250 MHz. This creates timing violation on the hardware.

As a result, the desktop simulation and the hardware results have a mismatch due to high FPGA clock frequency. The waveforms show the mismatch in desktop simulation (in green) and hardware results (in red) for the outputs `vOut` and `speed`.

How to Reduce the Sample Rate Variation

The Simscape sampling frequency is the rate at which the Simscape models run.

As mentioned in the previous section, the sampling frequency depends on FPGA clock frequency, the oversampling factor, and the number of solver iterations. To improve the sampling frequency, you can maximize the FPGA clock frequency, and minimize the oversampling factor and number of solver iterations. As you improve the sampling frequency, make sure that the updated sampling frequency is equivalent to the fixed sample time that you specify for your original Simscape model by using the Solver Configuration block.

You can synthesize your implementation model to find out the frequency at which the slack is positive. Then, using the number of solver iterations and the oversampling factor, calculate the correct Simscape time step.

Calculate the real time step on FPGA (T_{s_fpga}) by taking the reciprocal of the FPGA sampling frequency.

$$\text{Real time step on FPGA} = \frac{(\text{Oversampling factor} \times \text{Number of solver iterations})}{\text{FPGA clock frequency}}$$

The target frequency of your current design is 164 MHz for which the design meets the timing constraints. Here, the oversampling factor is 326 and the number of solver iterations is 3. The updated real time step on FPGA is

$$T_{s_fpga} = (326 \times 3) / 164 = 5.963 \approx 6 \mu\text{s}$$

To avoid timing violations on the hardware, use the calculated value of T_{s_fpga} as the Simscape sample time.

Change the sample time from $1\text{e-}6$ to $6\text{e-}6$ in the PreLoadFcn callback. Save the model, close, and reopen it.

Adjusting the parameter values reduces the mismatches in the results obtained from desktop simulation and the hardware results. The desktop simulation results align closely with the hardware results.

Limitations

- To estimate the correct target frequency, you need to perform model synthesis which might take some time (a few hours).
- Changing the sample time affects the discretization step in the Simscape HDL Workflow Advisor. As a result, the state-space parameters (A, B, C, D parameters) change, and you need to rerun the workflow from the beginning.

Model Protection in HDL Coder

- “Create Protected Models to Conceal Contents and Generate HDL Code” on page 40-2
- “Test Protected Models” on page 40-10
- “Package and Share Protected Models” on page 40-12
- “Obfuscate Generated HDL Code from Simulink Models” on page 40-15

Create Protected Models to Conceal Contents and Generate HDL Code

When you want to share a model with a third party without revealing intellectual property, protect the model. When you create a protected model, you conceal the implementation details of the original model by compiling it into a referenced model. The protected model includes derived files to support the optional functionalities that you specify, such as support for C code generation or HDL code generation.

If you have a HDL Coder license, you can create a protected model with simulation and HDL code generation support. The protected model user can then generate HDL code for models that reference the protected model that you created. To enable C code generation support or specify additional options such as code interface, you must have a Simulink Coder or Embedded Coder® license. To learn more about that workflow, see “Protect Models to Conceal Contents”.

How Model Protection Works

When you protect a model, you can allow the user of the protected model to:

- Open a read-only web view of the model, including model contents and block parameters.
- Simulate the model in accelerator (default), rapid accelerator, and normal modes.
- Generate HDL code for a model that includes the protected model.
- Generate C code for a model that includes the protected model, if you have Simulink Coder.
- Generate code for the protected model through the standalone interface, if you have Embedded Coder and specify an ERT-based system target file for the model.

You can optionally password-protect each option. If you choose password protection for one of these options, the software protects the supporting files by using AES-256 encryption.

How to Create a Protected Model

Create a protected model by using one of these options:

- To create a protected model from a referenced model, select the Model block and on the Simulink Toolstrip **Model Block** tab, click the **Protect** button.
- To create a protected model from the current model:
 - On the Simulink Toolstrip **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
 - Select the Model block and on the **HDL Code > Share** tab, select **Generate Protected Model**.
- To programmatically create a protected model, use the `Simulink.ModelReference.protect` function.

When you create a protected model:

- Simulink creates and stores a protected version of the model in a file that has the same name as the source model, with an `.slxp` extension.
- The original model file, with the `.slx` extension, does not change. If you protect the model through a Model block, that Model block does not change.

- Optionally, Simulink creates a project archive (.mlproj) that contains the protected model, a harness model for the protected model, and additional supporting files.

If your protected model requires additional supporting files, such as base workspace definitions or a data dictionary, include these files with the model when you share the protected model. For more information, see “Package and Share Protected Models” on page 40-12.

General Protected Model Requirements and Limitations

When you create a protected model, consider these requirements:

- You must have a HDL Coder or Simulink Coder license to create a protected model.
- The model must be available on the MATLAB path.
- The model cannot have unsaved changes.
- The model uses the configuration that is active during protection. You cannot change the configuration of a protected model.
- If the model contains variants, the protected model includes only the variant that is active during protection.
- The protected model name must not be modified. Renaming the model or changing the suffix makes the model unusable until you restore its original name and suffix.

The model must also meet all requirements listed in “Model Reference Requirements and Limitations”.

Protected Model Restrictions for HDL Code Generation

When you create a protected model that has HDL code generation support, these restrictions apply:

- The protected model must use the same configuration parameters as the top level that it is referenced from.

In R2021b, HDL Coder enables a difference in the values of these parameters between the protected model and the top model so that you can simulate and generate HDL code for top model and protected models while retaining top model synthesis parameters settings.

- Family
- Device Name
- Package Name
- Speed value
- Target frequency
- The solver settings that you specify in the **Solver** pane of the Configuration Parameters dialog box must be **Fixed-step** and **auto**.
- You must not enable these settings in the Configuration Parameters dialog box:
 - **Generate parameterized HDL code from masked subsystem**
 - **Module name prefix**
 - **Use trigger signal as clock**
 - **Minimize clock enables**

- **Scalarize vector ports**
- **Allow clock-rate pipelining at DUT output ports**
- Models with multiple clock signals or the **Clock inputs** set to **multiple** in the Configuration Parameters dialog box are not supported.
- Models that contain model arguments are not supported.
- HDL source code of the protected model cannot be obfuscated.
- Nested protected models are not supported.
- The protected model cannot have callbacks.

To learn more about limitations for C code generation, see “Code Generation Requirements and Limitations”.

Prepare the Parent Model

This example shows how you can protect a model that is referenced by a Model block in the parent model. Open the parent model `hdlcoder_protected_model_parent_harness`.

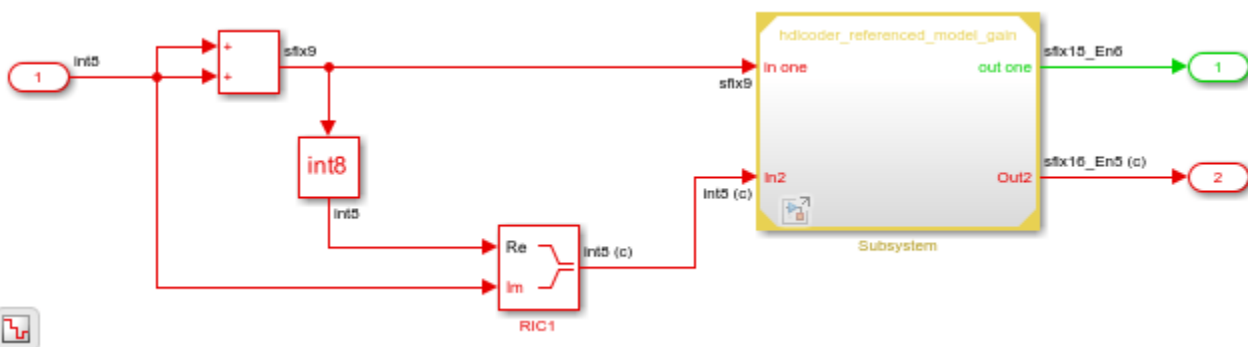

```
open_system('hdlcoder_protected_model_parent_harness')
set_param('hdlcoder_protected_model_parent_harness', 'SimulationCommand', 'Update')
```

Copyright 2015 The MathWorks, Inc.

Navigate to the Model block in your parent model. If you double-click the DUT Subsystem, and then open the `mynested` Subsystem, you see a Model block that references the model `hdlcoder_referenced_model_gain`.

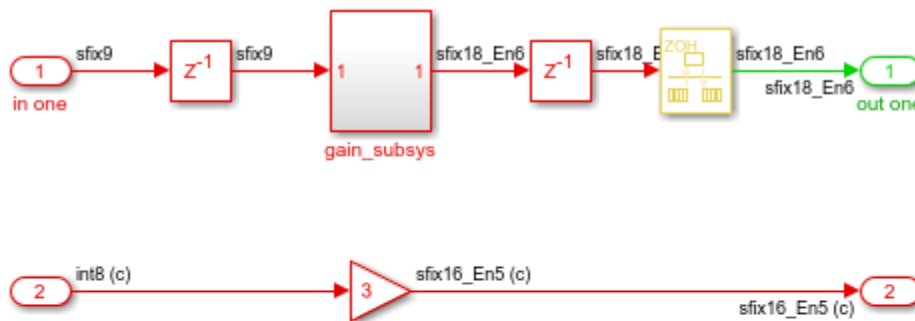

```
open_system('hdlcoder_protected_model_parent_harness/DUT/mynested')
```

Open the Model block and make sure that a *modelname* with the extension *.slx* is specified in the **Model name** field. When both the referenced model and the protected model exist in the same folder, the parent model references the protected model unless the extension is specified.

In this case, the Model block is referencing the model `hdlcoder_referenced_model_gain.slx`, the model that you want to protect. Double-click the Model block or open the model `hdlcoder_referenced_model_gain` in a separate window.

```
open_system('hdlcoder_referenced_model_gain')
set_param('hdlcoder_referenced_model_gain', 'SimulationCommand', 'Update')
```

Copyright 2018-2021 The MathWorks, Inc.

Protect the Referenced Model

- 1 Select the Model block.
- 2 On the Simulink Toolstrip **Model Block** tab, click **Protect**.

- 3 In the Create Protected Model dialog box, select the **Simulate** dialog box. This option allows the protected model user to simulate the model that references the protected model.
- 4 If you have Simulink Coder or Embedded Coder, you can specify additional settings such as enabling code generation support with password protection by using the **Use generated code** check box or specifying a **Code interface**. To learn more about these options, see “Protect Models to Conceal Contents” (Embedded Coder).
- 5 Select the **Use generated HDL code** check box to generate HDL code for a model that references the protected model. If you want to password-protect this functionality of the protected model, you must specify a minimum of eight characters. You can specify a unique password for this option. You cannot obfuscate the HDL source code for a protected model.
- 6 In the **Destination folder** box, specify the folder path for the protected model. The default value is the current working folder.
- 7 To automatically collect, create, and package supporting files with the protected model, set **Contents** to Protected Model (.slxp) and dependencies in a project. In this example, set **Contents** to Protected Model (.slxp) only.

8 To create a harness model for the protected model, select the **Create harness model for protected model** check box. The harness model provides an isolated environment for the Model block that references the protected model. In this example, leave the check box cleared.

9 Click **Create**.

HDL Coder checks compatibility of the model for HDL code generation then generates code for the model. The generated code file contents are in the `hdlsrc` folder. To learn about the files that are generated, see “Package and Share Protected Models” on page 40-12.

10 To use the protected model in a model hierarchy, reference it through a Model block. The **Simulation mode** for Model blocks that reference a protected model is set to **Accelerator**. You cannot change the mode. For more information, see “Reference Protected Models from Third Parties”.

To learn more about the options, see “Create Protected Model”.

To create a protected model when using the `Simulink.ModelReference.protect` function, set the `Mode` to `HDLCodeGeneration`. For example, run this command to protect the referenced model `hdlcoder_referenced_model_gain`:

```
Simulink.ModelReference.protect('hdlcoder_referenced_model_gain', ...
                               'Mode', 'HDLCodeGeneration')
```

Protected Model Report

When you create the protected model from the Simulink Editor, a protected model report is generated and included as part of the protected model. For this example, to view the protected model report, double-click the protected model or right-click the protected-model badge icon on the block in the harness model and select **Display Report**.

The report contains:

- A **Summary**, including the following tables:
 - **Environment**, providing the Simulink version, the Simulink Coder version, the HDL Coder version, and platform used to create the protected model.
 - **Supported functionality**, reporting On, Off, or On with password protection for each possible functionality that the protected model supports. If you configure your protected model for multiple targets, this table includes a list of supported targets.

- **Licenses**, listing licenses required to run the protected model.
- An **Interface Report**, including model interface information such as input and output specifications, interface parameters, and data stores.

To generate a report when using the `Simulink.ModelReference.protect` function, set the 'Report' option to True.

Generate HDL Code for Models Referencing Protected Model

If the protected model has simulation and HDL code generation support, the protected model user can simulate and generate HDL code from a model that references the protected model. You generate HDL code for a model that references a protected model in the same manner as how you would generate code for a regular model.

If the protected model is password-protected, before you generate code, right-click the protected model badge icon and select **Authorize**. You must then enter the password for each option. If the entered password matches the password that you specified when creating the protected model, the model is authorized. You can then generate HDL code for the model.

For example, to generate HDL code for the protected model `hdlcoder_referenced_model_gain.slxp` that is referenced by the `hdlcoder_protected_model_parent_harness` model:

- 1 Authorize the protected model `hdlcoder_referenced_model_gain.slxp` if you specified a password when creating the protected model.
- 2 Generate HDL code for the DUT Subsystem from the context menu or by using the `makehdl` function.

```
makehdl('hdlcoder_protected_model_parent_harness/DUT')
```

More About

- “Test Protected Models” on page 40-10
- “Package and Share Protected Models” on page 40-12

Test Protected Models

To test a protected model that you created, compare the simulation results of the protected model to the output of the original model. As you supply the protected model from the original model, both the original and the protected model might exist on the MATLAB path.

In the parent model, if the Model block **Model name** parameter names the model without providing a suffix, the protected model takes precedence over the unprotected model. To override this default when testing the output, in the Model block **Model name** parameter, specify the file name with the extension of the unprotected model, `.slx`.

To compare the unprotected and protected versions of a Model block, you can use the Simulation Data Inspector. This example uses `hdlcoder_protected_model_parent_harness` and the protected model, `hdlcoder_referenced_model_gain.slxp`, which you created in “Create Protected Models to Conceal Contents and Generate HDL Code” on page 40-2.

- 1 If it is not already open, open the model `hdlcoder_protected_model_parent_harness`.

```
open_system('hdlcoder_protected_model_parent_harness')
```
- 2 Make sure that the Model block in the `hdlcoder_protected_model_parent_harness/DUT/mynested` subsystem is referencing the original model `hdlcoder_referenced_model_gain.slx` and not the protected model.
- 3 Enable logging for the output signals of the Model block. Right-click the output signals and select **Log Selected Signals**.
- 4 Simulate the model and click the **Simulation Data Inspector**. In the Simulation Data Inspector, select the signals that you logged to see the simulation results. Save this simulation run with a name such as `original_model_run`.
- 5 Now, in the Block Parameters dialog box for the Model block, change the **Model name** to `hdlcoder_referenced_model_gain.slxp`.

A badge icon appears on the Model block indicating that you are referencing the protected model. If you haven't already created the protected model, follow the steps mentioned in “Create Protected Models to Conceal Contents and Generate HDL Code” on page 40-2.

- 6 Simulate the model, which now refers to the protected model. When the simulation is complete, a new run appears in the Simulation Data Inspector. Save this run as `protected_model_run`.
- 7 In the Simulation Data Inspector, click the **Compare** tab. From the **Baseline** and **Compare To** lists, select the `original_model_run` and the `protected_model_run`. To compare the runs, click **Compare Runs**.

This figure displays the comparison between the **Baseline** and **Compare To** lists. You see that the simulation results match.

- “Save Signal Data Using Signal Logging”
- “Compare Simulation Data”
- “Package and Share Protected Models” on page 40-12

Package and Share Protected Models

When you protect a model, you can automatically create and package the following contents in a project archive (.mlproj) for easy sharing:

- Protected model file (.slxp)
- Harness model file
- MAT-file with base workspace definitions
- Data dictionary pruned to relevant definitions
- Other supporting files

In the Create Protected Model dialog box, set **Contents** to Protected model (.slxp) and dependencies in a project.

Note Before sharing the project, check whether the project contains the required supporting files. If supporting files are missing, simulating or generating code for the related harness model can help identify them. Add the missing dependencies to the project and update the harness model if required.

Alternatively, you can use one of these options to deliver the protected model package:

- Create a project archive to share a project that contains the protected model file and supporting files. For more information, see “Create a Project from a Model” and “Share Projects”.
- Provide the protected model file and supporting files as separate files.
- Combine the files into a ZIP or other container file.
- Provide the files in some other standard or proprietary format specified by the receiver.

Whichever approach you use to deliver a protected model, include information on how to retrieve the original files.

Harness Model

You can create a harness model when you create your protected model. The harness model contains a Model block that references the protected model. A third party can use the Model block to reference your protected model. The harness model is set up for simulation of the protected model.

MAT-File with Base Workspace Definitions

Referenced models can use object definitions or tunable parameters that are defined in the MATLAB base workspace. These variables are not saved with the model. When you protect a model, you must obtain the definitions of required base workspace entities and ship them with the model.

For example, if the model uses the following base workspace variables, they must be saved to a MAT-file:

- Global tunable parameter
- Global data store
- The following objects used by a signal that connects to a root-level model Inport or Outport:

- `Simulink.Signal`
- `Simulink.Bus`
- `Simulink.Alias`
- `Simulink.NumericType` that is an alias

To determine the required base workspace definitions and save them to a MAT-file, see “Explore Protected Model Capabilities”. Before executing the protected model as a part of a third-party model, the receiver of the protected model must load the MAT-file.

Simulink Data Dictionary

Referenced models can use data definitions from a data dictionary, which are not saved with the model. When you protect a model that uses a data dictionary, package and ship the data dictionary with the protected model.

Protected Model File Contents

A protected model file (`.slxp`) consists of the derived files that support the options that you select when you create the protected model. The derived files are unpacked when you or a third party use the protected model in simulation or code generation.

The derived files that are unpacked depends on the support that you enabled when creating the protected model. The `slprj/sim/model/*` files are deleted after they are used.

This table provides the files that are unpacked depending on the options that you specify. If you specify the **Use generated code** or **Code Interface** options when you create the protected model, additional files are unpacked in the derived folder. To learn about these files, see “Protected Model File Contents”.

Supported Functionality	Derived Files
Simulation only and the referencing model simulates in normal mode	The <code>model.mexext</code> file is placed in the build folder.
Simulation only and the referencing model simulates in accelerator or rapid accelerator mode	<p>These files are unpacked in the <code>slprj/sim/</code> folder:</p> <ul style="list-style-type: none"> • <code>slprj/sim/model/*.h</code> • <code>slprj/sim/model/modellib.a</code> (or <code>modellib.lib</code>) • <code>slprj/sim/model/tmwinternal/*</code> • <code>slprj/sim/_sharedutils/*</code> <p>For the protected model report, these additional files are unpacked (but not in the build folder):</p> <ul style="list-style-type: none"> • <code>slprj/sim/model/html/*</code> • <code>slprj/sim/model/buildinfo.mat</code>

Supported Functionality	Derived Files
HDL code generation	<p>These files are unpacked in the <code>hdlsrc</code> folder: (Additional files depend on whether you enabled support for other options such as code generation).</p> <ul style="list-style-type: none"> • <code>hdlsrc/model/model.vhd</code> (<i>model.v</i> if you specified Verilog as the Target language.) • <code>hdlsrc/model/Subsystem.vhd</code> (<i>Subsystem.v</i> if you specified Verilog as the Target language of the model that you protected. The additional HDL files depend on how hierarchically the referenced model was designed.) • <code>hdlsrc/model/model_pkg.vhd</code> (This file is not generated if you specified Verilog as the Target language of the model that you protected.) • <code>hdlsrc/model/model_report.html</code> • <code>hdlsrc/model/gm_model.slxp</code> (This file is a generated protected model. If you use cosimulation, HDL Coder software instantiates this generated protected model.)

Obfuscate Generated HDL Code from Simulink Models

To share HDL code with a third party without revealing the intellectual property, you can generate obfuscated HDL code from Simulink models. Obfuscation reduces readability of the code. The generated HDL code does not have any comments, newlines, or spaces, and replaces identifier names with random names.

How to Generate Obfuscated HDL Code

By default, the generated HDL code is not obfuscated. The HDL code contains newlines, comments, and is readable.

To generate obfuscated HDL code for the DUT subsystem in your model:

- 1 In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
- 2 Open the **HDL Code Generation** pane of the Configuration Parameters dialog box. In the **HDL Code** tab, select **Settings > HDL Code Generation Settings**.
- 3 Specify generation of obfuscated HDL code. In the Configuration Parameters dialog box, on the **HDL Code Generation > Global Settings > Coding Style > RTL Style** section, select the **Generate obfuscated HDL code** check box.
- 4 Generate HDL code. Select the DUT subsystem as the **Code for** subsystem, and then click the **Generate HDL Code** button.

Tip By default, HDL Coder generates obfuscated VHDL code. To generate obfuscated Verilog code, in the **HDL Code Generation** pane, set **Language** to Verilog and then click the **Generate HDL Code** button.

To generate obfuscated HDL code from the command line, use the `ObfuscateGeneratedHDLCode` property with `hdlset_param` or `makehdl`. For example, to generate obfuscated HDL code for the `symmetric_fir` subsystem in the `sfir_fixed` model:

```
makehdl('sfir_fixed/symmetric_fir', 'ObfuscateGeneratedHDLCode', 'on')

% To generate obfuscated Verilog code, set 'TargetLanguage' to 'Verilog'
makehdl('sfir_fixed/symmetric_fir', 'TargetLanguage', 'Verilog', ...
        'ObfuscateGeneratedHDLCode', 'on')
```

Generated HDL Code with Obfuscation

By default, the generated HDL code is not obfuscated. For example, this code shows the generated VHDL code for the **Complex Multiplier** model template in Simulink. To learn more about this template, see “Use Simulink Templates for HDL Code Generation” on page 14-8.

```
...

Code Obfuscation Report

When you specify generation of obfuscated HDL code, and then generate code, HDL Coder produces a Code Obfuscation report. The Code Obfuscation report displays the status of HDL code obfuscation. It also displays whether the model uses configuration parameters that are incompatible with code obfuscation and provides a link to disable these parameters. These parameters are ignored during the obfuscation process.

HDL Model Parameters Incompatible with Code Obfuscation

HDL code obfuscation is not compatible with certain Configuration Parameters and ignores these parameters if they are enabled on the model. The parameters include:

- These parameters in the **HDL Code Generation > Global Settings > General** pane:
 - “Enable prefix” on page 21-13, “Clocked process postfix” on page 21-6, and “Timing controller postfix” on page 21-7
 - “Split entity and architecture Parameters” on page 21-25
 - “Complex Signals Postfix Parameters” on page 21-28
 - “Pipeline postfix” on page 21-23
 - “Instance prefix” on page 21-34 and “Instance postfix” on page 21-33
 - “Language-Specific Identifiers and Postfix Parameters” on page 21-21
 - “Generate Statement and Vector and Component Instance Label Parameters” on page 21-32
- These parameters in the **HDL Code Generation > Global Settings > Coding Standards** tab:
 - “Choose Coding Standard and Report Option Parameters” on page 21-73
 - “Basic Coding Practices Parameters” on page 21-76
 - “RTL Description Rules for clock enables and resets Parameters” on page 21-81, “RTL Description Rules for Conditional Parameters” on page 21-84, and “Other RTL Description Rule Parameters” on page 21-88
- The “File Comment Customization Parameters” on page 21-69 parameters in the **HDL Code Generation > Global Settings > Coding Style** tab.

- The “Generate traceability report” on page 22-3 parameter in the **HDL Code Generation > Report** pane.

Code Obfuscation Considerations and Restrictions

- Synthesizing the obfuscated HDL code might produce different synthesis results from the synthesis results of the original HDL code. For best results, perform synthesis on the original code instead of the obfuscated code.
- HDL code obfuscation replaces only names corresponding to HDL files, signals, blocks, variable names, or ports with random names. Other identifier names are not replaced, such as names of vectors or enumerations.
- For some interfaces that you use in your Simulink model, the interface information such as the port names and interface names are preserved in the obfuscated HDL code. These names are not obfuscated. The interfaces include:
 - DUT
 - Model reference
 - Black box
 - Xilinx or Intel floating-point target
- You cannot obfuscate the HDL code generated for these blocks:
 - CIC Interpolation
 - FIR Decimation
 - FIR Interpolation

“What is a HDL Test Bench?” on page 41-5

“How to Verify the Generated Code” on page 41-5

“Generate HDL Test Bench” on page 41-5

“View HDL Test Bench Files” on page 41-6

“Run Simulation and Verify Generated HDL Code” on page 41-7

This example shows how to generate a HDL test bench and verify the generated code for your design. The example assumes that you have generated HDL code for your model. If you haven't generated HDL code, you can still open this model and generate the HDL test bench. Before generating the test bench, HDL Coder runs code generation to make sure that there is at least one successful code generation run before generating the testbench.

This example illustrates how to verify the generated code for the FIR filter model. To learn how to generate HDL code for this model, see “Generate HDL Code from Simulink Model Using Configuration Parameters” on page 16-11.

FIR Filter Model

This example uses the Symmetric FIR filter model that is compatible for HDL code generation. To open this model at the command line, enter:

```
sfir_fixed
```

The model uses a division of labor that is suitable for HDL design.

- The `symmetric_fir` subsystem, which implements the filter algorithm, is the device under test (DUT). An HDL entity is generated from this subsystem.
- The top-level model components that drive the subsystem work as a test bench.

The top-level model generates 16-bit fixed-point input signals for the `symmetric_fir` subsystem. The Signal From Workspace block generates a test input (stimulus) signal for the filter. The four Constant blocks provide filter coefficients. The Scope blocks are used for simulation and are not used for HDL code generation.

To navigate to the `symmetric_fir` subsystem, enter:

```
open_system('sfir_fixed/symmetric_fir')
```

Create a Folder and Copy Relevant Files

In MATLAB:

- 1 Create a folder named `sl_hdlcoder_work`, for example:

```
mkdir C:\work\sl_hdlcoder_work
```

`sl_hdlcoder_work` stores a local copy of the example model and folders and generated HDL code. Use a folder location that is not within the MATLAB folder tree.

- 2 Make the `sl_hdlcoder_work` folder your working folder, for example:

```
cd C:\work\sl_hdlcoder_work
```

- 3 Save a local copy of the `sfir_fixed` model to your current working folder. Leave the model open.

What is a HDL Test Bench?

To verify the functionality of the HDL code that you generated for the DUT, generate a HDL test bench. A test bench includes:

- Stimulus data generated by signal sources connected to the entity under test.
- Output data generated by the entity under test. During a test bench run, this data is compared to the outputs of the VHDL code, for verification purposes.
- Clock, reset, and clock enable inputs to drive the entity under test.
- A component instantiation of the entity under test.
- Code to drive the entity under test and compare its outputs to the expected data.

You can simulate the generated test bench and script files with the Mentor Graphics ModelSim simulator.

How to Verify the Generated Code

This example illustrates how to generate a HDL test bench to simulate and verify the generated HDL code for your design. You can also verify the generated HDL code from your model using these methods:

Verification Method	For More Information
Validation Model	“Generated Model and Validation Model” on page 28-10
HDL Cosimulation (requires HDL Verifier)	“Cosimulation”
SystemVerilog DPI Test Bench (requires HDL Verifier)	“SystemVerilog DPI Test Bench”
FPGA-in-the-Loop (requires HDL Verifier)	“FPGA-in-the-Loop”

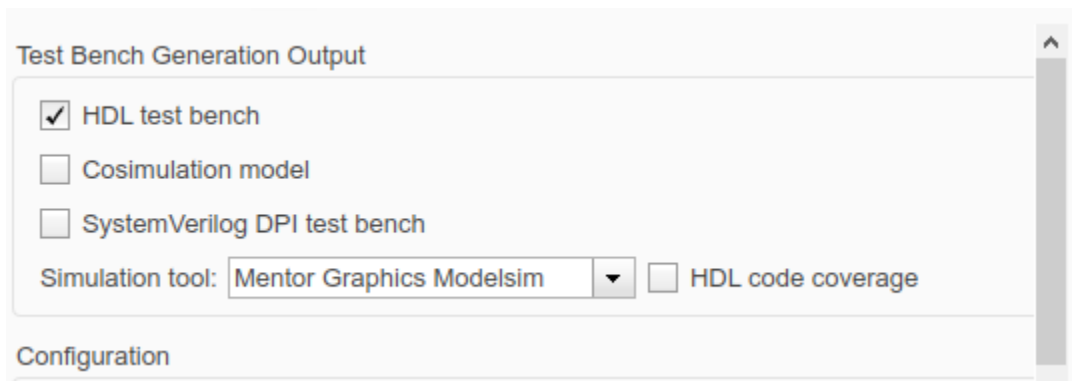

Generate HDL Test Bench

Depending on whether you generated VHDL or Verilog code, generate VHDL or Verilog test bench code. The test bench code drives the HDL code that you generated for the DUT. By default, the HDL code and the test bench code are written to the same target folder `hdlsrc` relative to the current folder.

For the FIR filter, the **symmetric_fir** subsystem is the DUT. To generate the testbench, select this subsystem. You cannot generate a HDL testbench for an entire model.

- 1 In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
- 2 Select the DUT Subsystem in your model, and make sure that this Subsystem name appears in the **Code for** option. To remember the selection, you can pin this option. Click **Generate Testbench**.

By default, HDL Coder generates VHDL testbench code in the target `hdlsrc` folder.

Generate Verilog Test Bench Code

If you want to generate Verilog test bench code, you can specify this setting in the **HDL Code Generation** pane of the Configuration Parameters dialog box.

To generate Verilog testbench code for the counter model:

- 1 In the **HDL Code** tab, click **Settings**.
- 2 In the **HDL Code Generation** pane, for **Language**, select **Verilog**. Leave other settings to the default.
- 3 In the **HDL Code Generation > Test Bench** pane, click **Generate Test Bench**.

If you haven't already generated code for your model, HDL Coder compiles the model and generates HDL code before generating the test bench. Depending on model display options such as port data types, the model can change in appearance after code generation.

As test bench generation proceeds, HDL Coder displays progress messages. The process should complete with the message

```
### HDL TestBench Generation Complete.
```

After generating the test bench, you see the generated files in the `hdlsrc` folder.

View HDL Test Bench Files

- `symmetric_fir_tb.vhd`: VHDL test bench code, with generated test and output data. If you generated Verilog test bench code, the generated file is `symmetric_fir_tb.v`.
- `symmetric_fir_tb_pkg.vhd`: Package file for VHDL test bench code. This file is not generated if you specified Verilog as the target language.
- `symmetric_fir_tb_compile.vhd`: Compilation script (vcom commands). This script compiles and loads the entity to be tested (`symmetric_fir.vhd`) and the test bench code (`symmetric_fir_tb.vhd`).
- `symmetric_fir_tb_sim.do`: Mentor Graphics ModelSim script to initialize the simulator, set up **wave** window signal displays, and run a simulation.

To view the generated test bench code in the MATLAB Editor, double-click the `symmetric_fir_tb.vhd` or `symmetric_fir_tb.v` file in the current folder.

Run Simulation and Verify Generated HDL Code

To verify the simulation results, you can use the Mentor Graphics ModelSim simulator. Make sure that you have already installed Mentor Graphics ModelSim.

To launch the simulator, use the `vsim` (HDL Verifier) function. This command shows how to open the simulator by specifying the path to the executable:

```
vsim('vsimdir','C:\Program Files\ModelSim\questasim\10.6b\win64\vsim.exe')
```

To compile and run a simulation of the generated model and test bench code, use the scripts that are generated by HDL Coder. Following example illustrates the commands that compile and simulate the generated test bench for the `sfir_fixed/symmetric_fir` subsystem.

- 1 Open the Mentor Graphics ModelSim software and navigate to the folder that has the previously generated code files and the scripts.

```
QuestaSim>cd C:/work/sl_hdlcoder_work/hdlsrc
```

- 2 Use the generated compilation script to compile and load the generated model and text bench code. Run this command to compile the generated code.

```
QuestaSim>do symmetric_fir_tb_compile.do
```

- 3 Use the generated simulation script to execute the simulation. The following listing shows the command and responses. You can ignore any warning messages. The test bench termination message indicates that the simulation has run to completion without comparison errors. Run this command to simulate the generated code.

```
QuestaSim>do symmetric_fir_tb_sim.do
```

The simulator optimizes your design and displays the results of simulating your HDL design in a **wave** window. If you don't see the simulation results, open the **wave** window. The simulation script displays inputs and outputs in the model including the clock, reset, and clock enable signals in the **wave** window.

You can now view the signals and verify that the simulation results match the functionality of your original design. After verifying, close the Mentor Graphics ModelSim simulator, and then close the files that you have opened in the MATLAB Editor.

“Run Simulation and Verify Generated HDL Code” on page 41-13

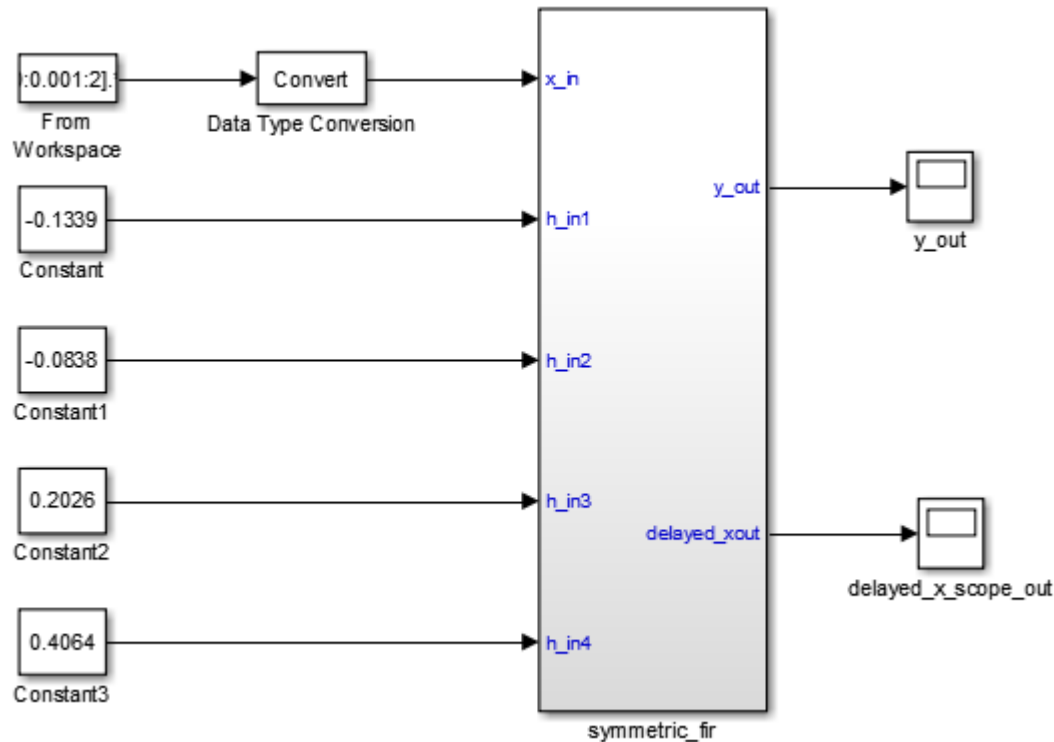

This example shows how to generate a HDL test bench and verify the generated code for your design. The example assumes that you have already generated HDL code for your model. If you haven't already generated HDL code, you can still open this model and generate the HDL test bench. Before generating the test bench, HDL Coder runs code generation to make sure that there is at least one successful code generation run before generating the testbench.

This example illustrates how to verify the generated code for the FIR filter model. To learn how to generate HDL code, see “Generate HDL Code from Simulink Model from Command Line” on page 16-15.

FIR Filter Model

This example uses the Symmetric FIR filter model that is compatible for HDL code generation. To open this model at the command line, enter:

```
sfir_fixed
```

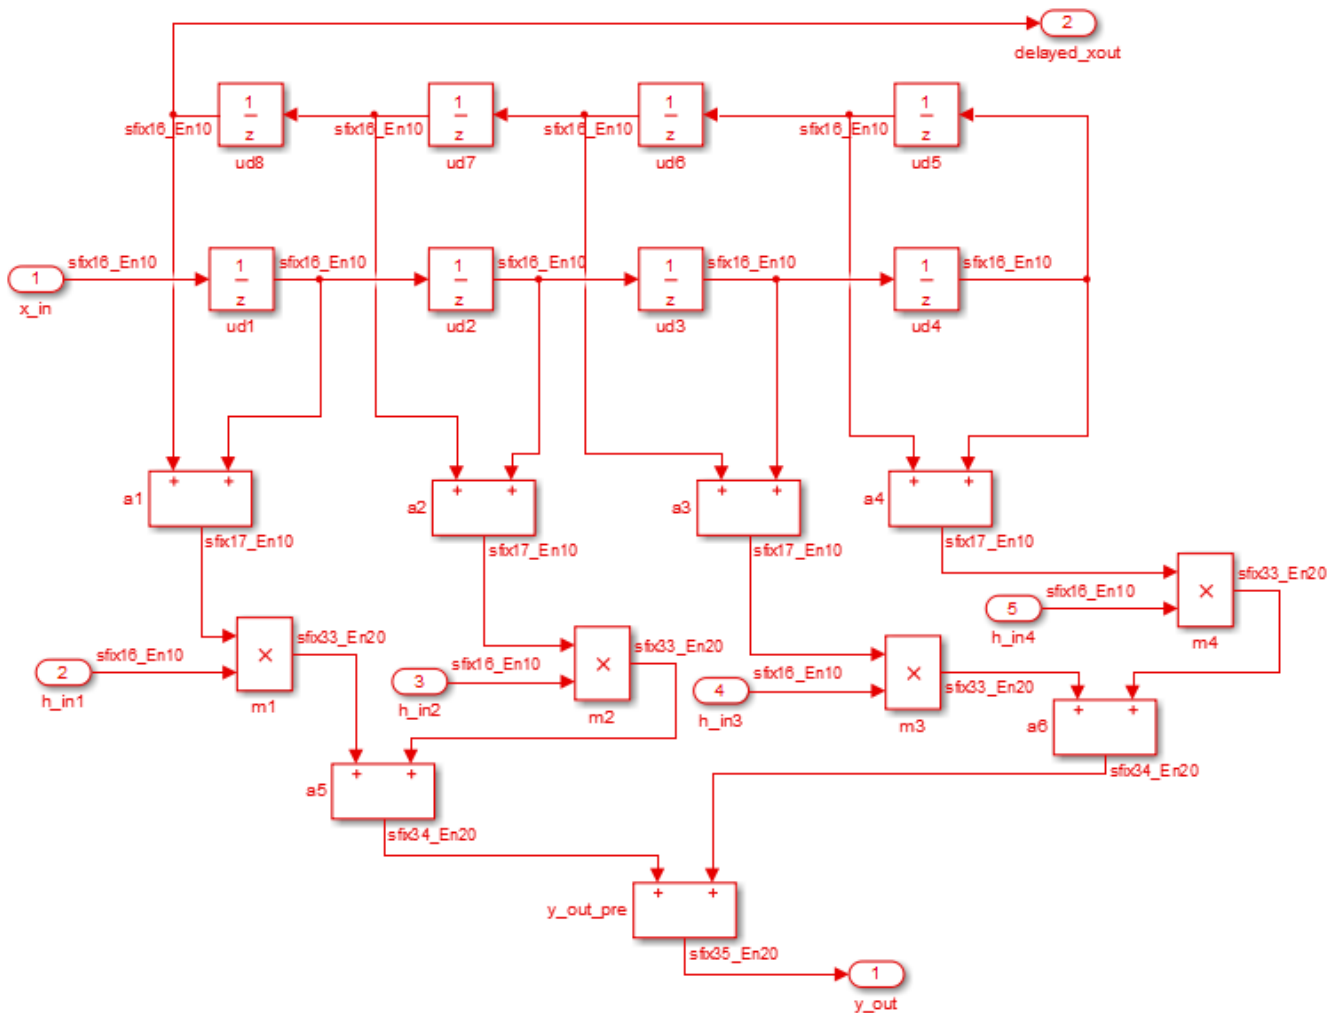

The model uses a division of labor that is suitable for HDL design.

- The `symmetric_fir` subsystem, which implements the filter algorithm, is the device under test (DUT). An HDL entity is generated from this subsystem.
- The top-level model components that drive the subsystem work as a test bench.

The top-level model generates 16-bit fixed-point input signals for the `symmetric_fir` subsystem. The Signal From Workspace block generates a test input (stimulus) signal for the filter. The four Constant blocks provide filter coefficients. The Scope blocks are used for simulation and are not used for HDL code generation.

To navigate to the `symmetric_fir` subsystem, enter:

```
open_system('sfir_fixed/symmetric_fir')
```

Create a Folder and Copy Relevant Files

In MATLAB:

- 1 Create a folder named `sl_hdlcoder_work`, for example:

```
mkdir C:\work\sl_hdlcoder_work
```

`sl_hdlcoder_work` stores a local copy of the example model and folders and generated HDL code. Use a folder location that is not within the MATLAB folder tree.

- 2 Make the `sl_hdlcoder_work` folder your working folder, for example:

```
cd C:\work\sl_hdlcoder_work
```

- 3 Save a local copy of the `sfir_fixed` model to your current working folder. Leave the model open.

What is a HDL Test Bench?

To verify the functionality of the HDL code that you generated for the DUT, generate a HDL test bench. A test bench includes:

- Stimulus data generated by signal sources connected to the entity under test.
- Output data generated by the entity under test. During a test bench run, this data is compared to the outputs of the VHDL code, for verification purposes.
- Clock, reset, and clock enable inputs to drive the entity under test.
- A component instantiation of the entity under test.
- Code to drive the entity under test and compare its outputs to the expected data.

You can simulate the generated test bench and script files with the Mentor Graphics ModelSim simulator.

How to Verify the Generated Code

This example illustrates how to generate a HDL test bench to simulate and verify the generated HDL code for your design. You can also verify the generated HDL code from your model using these methods:

Verification Method	For More Information
Validation Model	“Generated Model and Validation Model” on page 28-10
HDL Cosimulation (requires HDL Verifier)	“Cosimulation”
SystemVerilog DPI Test Bench (requires HDL Verifier)	“SystemVerilog DPI Test Bench”
FPGA-in-the-Loop (requires HDL Verifier)	“FPGA-in-the-Loop”

Generate HDL Test Bench

Depending on whether you generated VHDL or Verilog code, generate VHDL or Verilog test bench code. The test bench code drives the HDL code that you generated for the DUT. By default, the HDL code and the test bench code are written to the same target folder `hdlsrc` relative to the current folder.

To generate test bench code and the scripts for compilation and simulation, use the `makehdltb` function. At the command line, enter:

```
makehdltb('sfir_fixed/symmetric_fir')
```

To specify the customizations before you generate testbench code, use the `hdlset_param` function. You can also specify various name-value pair arguments with the `makehdltb` function to customize HDL code generation options while generating HDL code. For example, to generate Verilog test bench code, use the `TargetLanguage` property.

```
makehdltb('sfir_fixed/symmetric_fir', 'TargetLanguage', 'Verilog')
```

Alternatively, if you are using `hdlset_param`, set this parameter on the model and then run the `makehdltb` function.

```
hdlset_param('sfir_fixed', 'TargetLanguage', 'Verilog')
makehdltb('sfir_fixed/symmetric_fir')
```

If you haven't already generated code for your model, HDL Coder compiles the model and generates HDL code before generating the test bench. Depending on model display options such as port data types, the model can change in appearance after code generation.

As test bench generation proceeds, HDL Coder displays progress messages. The process should complete with the message

```
### HDL TestBench Generation Complete.
```

After generating the test bench, you see the generated files in the `hdlsrc` folder.

View HDL Test Bench Files

- `symmetric_fir_tb.vhd`: VHDL test bench code, with generated test and output data. If you generated Verilog test bench code, the generated file is `symmetric_fir_tb.v`.
- `symmetric_fir_tb_pkg.vhd`: Package file for VHDL test bench code. This file is not generated if you specified Verilog as the target language.
- `symmetric_fir_tb_compile.vhd`: Compilation script (vcom commands). This script compiles and loads the entity to be tested (`symmetric_fir.vhd`) and the test bench code (`symmetric_fir_tb.vhd`).
- `symmetric_fir_tb_sim.do`: Mentor Graphics ModelSim script to initialize the simulator, set up **wave** window signal displays, and run a simulation.

To view the generated test bench code in the MATLAB Editor, double-click the `symmetric_fir_tb.vhd` or `symmetric_fir_tb.v` file in the current folder.

Run Simulation and Verify Generated HDL Code

To verify the simulation results, you can use the Mentor Graphics ModelSim simulator. Make sure that you have already installed Mentor Graphics ModelSim.

To launch the simulator, use the `vsim` (HDL Verifier) function. This command shows how to open the simulator by specifying the path to the executable:

```
vsim('vsimdir','C:\Program Files\ModelSim\questasim\10.6b\win64\vsim.exe')
```

To compile and run a simulation of the generated model and test bench code, use the scripts that are generated by HDL Coder. Following example illustrates the commands that compile and simulate the generated test bench for the `sfir_fixed/symmetric_fir` subsystem.

- 1 Open the Mentor Graphics ModelSim software and navigate to the folder that has the previously generated code files and the scripts.

```
QuestaSim>cd C:/work/sl_hdlcoder_work/hdlsrc
```

- 2 Use the generated compilation script to compile and load the generated model and text bench code. Run this command to compile the generated code.

```
QuestaSim>do symmetric_fir_tb_compile.do
```

- Use the generated simulation script to execute the simulation. The following listing shows the command and responses. You can ignore any warning messages. The test bench termination message indicates that the simulation has run to completion without comparison errors. Run this command to simulate the generated code.

```
QuestaSim>do symmetric_fir_tb_sim.do
```

The simulator optimizes your design and displays the results of simulating your HDL design in a **wave** window. If you don't see the simulation results, open the **wave** window. The simulation script displays inputs and outputs in the model including the clock, reset, and clock enable signals in the **wave** window.

You can now view the signals and verify that the simulation results match the functionality of your original design. After verifying, close the Mentor Graphics ModelSim simulator, and then close the files that you have opened in the MATLAB Editor.

More About

- “Test Bench Generation Output Parameters” on page 23-3
- “HDL Test Bench”
- “HDL Code Generation and FPGA Synthesis from Simulink Model”

Test Bench Generation

You can generate a HDL Testbench for a subsystem or model reference that you specify in your Simulink model. The coder generates an HDL test bench by running a Simulink simulation to capture input vectors and expected output data for your DUT.

In this section...

“How Test Bench Generation Works” on page 41-15

“Test Bench Data Files” on page 41-15

“Test Bench Data Type Limitations” on page 41-15

“Use Constants Instead of File I/O” on page 41-15

How Test Bench Generation Works

HDL Coder writes the DUT stimulus and reference data from your MATLAB or Simulink simulation to data files (.dat).

During HDL simulation, the HDL test bench reads the saved stimulus from the .dat files. The test bench compares the actual DUT output with the expected output, which is also saved in .dat files. After you generate code, the message window displays links to the test bench data files.

Reference data is delayed by one clock cycle in the waveform viewer compared to default test bench generation due to the delay in reading data from files.

Test Bench Data Files

The coder saves stimulus and reference data for each DUT input and output in a separate test bench data file (.dat), with the following exceptions:

- Two files are generated for the real and imaginary parts of complex data.
- Constant DUT input data is written to the test bench as constants.

Vector input or output data is saved as a single file.

Test Bench Data Type Limitations

If you have double, single, or enumeration data types at the DUT inputs and outputs, the simulation data is generated as constants in the test bench code, instead of writing the simulation data to files.

Use Constants Instead of File I/O

You can generate test bench stimulus and reference data as constants in the test bench code instead of using file I/O. Simulating a long running test bench that uses constants requires more memory than a test bench that uses file I/O.

If your DUT inputs or outputs use data types that are not supported for file I/O, test bench generation automatically generates data as constants. For details, see “Test Bench Data Type Limitations” on page 41-15.

Using the HDL Workflow Advisor

To generate a test bench that uses constants:

- 1 In the **HDL Code Generation > Set Code Generation Options > Set Testbench Options** task, clear **Use file I/O to read/write test bench data** and click **Apply**.
- 2 In the **HDL Code Generation > Generate RTL Code and Testbench** task, select **Generate RTL testbench** and click **Apply**.

Using the Command Line

To generate a test bench that uses constants, use the `UseFileIOInTestBench` parameter with `makehdltb`.

For example, to generate a Verilog test bench by using constants for a DUT subsystem, `sfir_fixed/symmetric_fir`, enter:

```
makehdltb('sfir_fixed/symmetric_fir','TargetLanguage','Verilog',...  
         'UseFileIOInTestBench','off');
```

FPGA Board Customization

In this section...

“Feature Description” on page 42-2

“Custom Board Management” on page 42-2

“FPGA Board Requirements” on page 42-2

Feature Description

Both HDL Coder and HDL Verifier software include a set of predefined FPGA boards you can use with the Turnkey or FPGA-in-the-loop (FIL) workflows. You can view the lists of these supported boards in the HDL Workflow Advisor or in the FIL wizard. With the FPGA Board Manager, you can add additional boards to use either of these workflows. To add a board, you need the relevant information from the board specification documentation.

The FPGA Board Manager is the hub for accessing wizards and dialog boxes that take you through the steps necessary to create a custom board configuration. You can also access options for:

- Importing a custom board
- Copying a board definition file for further modification
- Verifying a new board

Custom Board Management

You manage FPGA custom boards through the following user interfaces:

- “FPGA Board Manager” on page 42-18: portal to adding, importing, deleting, and otherwise managing board definition files.
- “New FPGA Board Wizard” on page 42-22: This wizard guides you through creating a custom board definition file with information you obtain from the board specification documentation.
- “FPGA Board Editor” on page 42-33: user interface for viewing or editing board information.

To begin, review the “FPGA Board Requirements” on page 42-2 and then follow the steps described in “Create Custom FPGA Board Definition” on page 42-6.

FPGA Board Requirements

- “FPGA Device” on page 42-2
- “FPGA Design Software” on page 42-3
- “General Hardware Requirements” on page 42-3
- “Ethernet Connection Requirements for FPGA-in-the-Loop” on page 42-3
- “JTAG Connection Requirements for FPGA-in-the-Loop” on page 42-5

FPGA Device

Select one of the following links to view a current list of supported FPGA device families:

- For use with FPGA-in-the-loop (FIL), see “Supported FPGA Device Families for Board Customization” (HDL Verifier).
- For use with FPGA Turnkey, see “Supported FPGA Device Families for Board Customization”.

FPGA Design Software

Altera Quartus II or Xilinx ISE is required. See product documentation for HDL Coder or HDL Verifier for the specific software versions required.

The following MathWorks tools are required to use FIL or FPGA Turnkey.

Workflow	Required Tools
FPGA-in-the-loop	<ul style="list-style-type: none"> • HDL Verifier • Fixed-Point Designer
FPGA Turnkey	<ul style="list-style-type: none"> • HDL Coder • Simulink • Fixed-Point Designer

General Hardware Requirements

To use an FPGA development board, make sure that you have the following FPGA resources:

- **Clock:** An external clock connected to the FPGA is required. The clock can be differential or single-ended. The accepted clock frequency is from 5 MHz to 300 MHz. When used with FIL, there are additional requirements to the clock frequency (see “Ethernet Connection Requirements for FPGA-in-the-Loop” on page 42-3).
- **Reset:** An external reset signal connected to the FPGA is optional. When supplied, this signal functions as the global reset to the FPGA design.
- **JTAG download cable:** A JTAG download cable that connects host computer and FPGA board is required for the FPGA programming. The FPGA must be programmable using Xilinx iMPACT or Altera Quartus II.

Ethernet Connection Requirements for FPGA-in-the-Loop

- “Supported Ethernet PHY Device” on page 42-3
- “Ethernet PHY Interface” on page 42-4
- “Special Timing Considerations for RGMII” on page 42-4
- “Special Clock Frequency Requirement for GMII/RGMII/SGMII Interface” on page 42-4

Supported Ethernet PHY Device

On the FPGA board, the Ethernet MAC is implemented in FPGA. An Ethernet PHY chip is required to be on the FPGA board to connect the physical medium to the Media Access (MAC) layer in the FPGA.

Note When programming the FPGA, HDL Verifier assumes that there is only one download cable connected to the Host computer. It also assumes that the FPGA programming software automatically recognizes the cable. If not, use FPGA programming software to program your FPGA with the correct options.

The FIL feature is tested with the following Ethernet PHY chips and may not work with other Ethernet PHY devices.

Ethernet PHY Chip	Test
Marvell® Alaska 88E1111	For GMII, RGMII, SGMII, and 100 Base-T MII interfaces
National Semiconductor DP83848C	For 100 Base-T MII interface only

Ethernet PHY Interface

The Ethernet PHY chip must be connected to the FPGA using one of the following interfaces:

Interface	Note
Gigabit Media Independent Interface (GMII)	Only 1000 Mb/s speed is supported using this interface.
Reduced Gigabit Media Independent Interface (RGMII)	Only 1000 Mb/s speed is supported using this interface.
Serial Gigabit Media Independent Interface (SGMII)	Only 1000 Mb/s speed is supported using this interface.
Media Independent Interface (MII)	Only 100 Mb/s speed is supported using this interface.

Note For GMII, the TXCLK (clock signal for 10/100 Mb/s signal) signal is not required because only 1000 Mb/s speed is supported.

In addition to the standard GMII/RGMII/SGMII/MII interface signals, FPGA-in-the-loop also requires an Ethernet PHY chip reset signal (ETH_RESET_n). This active-low reset signal performs the PHY hardware reset by FPGA. It is active-low.

Special Timing Considerations for RGMII

When the RGMII interface is used, the MAC on the FPGA assumes that the data are aligned with the edges of reference clock as specified in the original RGMII v1.3 standard. In this case, PC board designs provide additional trace delay for clock signals.

The RGMII v2.0 standard allows the transmitter to integrate this delay so that PC board delay is not required. Marvell Alaska 88E1111 has internal registers to add internal delays to RX and TX clocks. The internal delays are not added by default, which means that you must use the MDIO module to configure Marvell 88E1111 to add internal delays. For more information on the MDIO module, see “FIL I/O” on page 42-26.

Special Clock Frequency Requirement for GMII/RGMII/SGMII Interface

When GMII/RGMII/SGMII interfaces are used, the FPGA requires an exact 125 MHz clock to drive the 1000 Mb/s communication. This clock is derived from the user supplied external clock using the clock module or PLL.

Not all external clock frequencies can derive an exact 125 MHz clock frequency. The acceptable clock frequencies vary depending on the FPGA device family. The recommended clock frequencies are 50, 100, 125, and 200 MHz.

JTAG Connection Requirements for FPGA-in-the-Loop

Vendor	Required Hardware	Required Software
Intel	USB Blaster I or USB Blaster II download cable	<ul style="list-style-type: none"> • USB Blaster I or II driver • For Windows® operating systems: Quartus Prime executable directory must be on system path. • For Linux® operating systems: versions below Quartus II 13.1 are not supported. Quartus II 14.1 is not supported. Only 64-bit Quartus is supported. Quartus library directory must be on LD_LIBRARY_PATH before starting MATLAB. Prepend the Linux distribution library path before the Quartus library on LD_LIBRARY_PATH. For example, /lib/x86_64-linux-gnu:\$QUARTUS_PATH.
Xilinx	Digilent® download cable <ul style="list-style-type: none"> • If your board has an onboard Digilent USB-JTAG module, use a USB cable • If your board has a standard Xilinx 14 pin JTAG connector, use with HS2 or HS3 cable from Digilent 	<ul style="list-style-type: none"> • For Windows operating systems: Xilinx Vivado executable directory must be on system path. • For Linux operating systems: Digilent Adept 2. Microchip	JTAG connection not supported	

Create Custom FPGA Board Definition

- 1 Be ready with the following:
 - a Board specification document. Any format you are comfortable with is fine. However, if you have it in an electronic version, you can search for the information as it is required.
 - b If you plan to validate (test) your board definition file, set up FPGA design software tools:

For validation, you must have Xilinx or Altera on your path. Use the `hdlsetuptoolpath` function to configure the tool for use with MATLAB.
- 2 Open the FPGA Board Manager by typing `fpgaBoardManager` in the MATLAB command window. Alternatively, if you are using the HDL Workflow Advisor, you can click **Launch Board Manager** at Step 1.1.
- 3 Open the New FPGA Board wizard by clicking **Create Custom Board**. For a description of all the tasks you can perform with the FPGA Board Manager, see “FPGA Board Manager” on page 42-18.
- 4 The wizard guides you through entering all board information. At each page, fill in the required fields. For assistance in entering board information, see “New FPGA Board Wizard” on page 42-22.
- 5 Save the board definition file. This step is the last and is automatically instigated when you click **Finish** in the New FPGA Board wizard. See “Save Board Definition File” on page 42-13.

Your custom board definition now appears in the list of available FPGA Boards in the FPGA Board Manager. If you are using HDL Workflow Advisor, it also shows in the **Target platform** list.

Follow the example “Create Xilinx KC705 Evaluation Board Definition File” on page 42-7 for a demonstration of adding a custom FPGA board with the New FPGA Board Manager.

Create Xilinx KC705 Evaluation Board Definition File

In this section...

“Overview” on page 42-7
 “What You Need to Know Before Starting” on page 42-7
 “Start New FPGA Board Wizard” on page 42-7
 “Provide Basic Board Information” on page 42-8
 “Specify FPGA Interface Information” on page 42-9
 “Enter FPGA Pin Numbers” on page 42-10
 “Run Optional Validation Tests” on page 42-12
 “Save Board Definition File” on page 42-13
 “Use New FPGA Board” on page 42-14

Overview

For FPGA-in-the-loop, you can use your own qualified FPGA board, even if it is not in the pre-registered FPGA board list supplied by MathWorks. Using the New FPGA Board wizard, you can create a board definition file that describes your custom FPGA board.

In this example, you can follow the workflow of creating a board definition file for the Xilinx KC705 evaluation board to use with FIL simulation.

What You Need to Know Before Starting

- Check the board specification so that you have the following information ready:
 - FPGA interface to the Ethernet PHY chip
 - Clock pins names and numbers
 - Reset pins names and numbers

In this example, the required information is supplied to you. In general, you can find this type of information in the board specification file. This example uses the KC705 Evaluation Board for the Kintex-7 FPGA User Guide, published by Xilinx.

- For validation, you must have Xilinx or Altera on your path. Use the `hdlsetuptoolpath` function to configure the tool for use with MATLAB.
- To verify programming the FPGA board after you add its definition file, attach the custom board to your computer. However, having the board connected is not necessary for creating the board definition file.

Start New FPGA Board Wizard

- 1 Start the FPGA Board Manager by entering the following command at the MATLAB prompt:

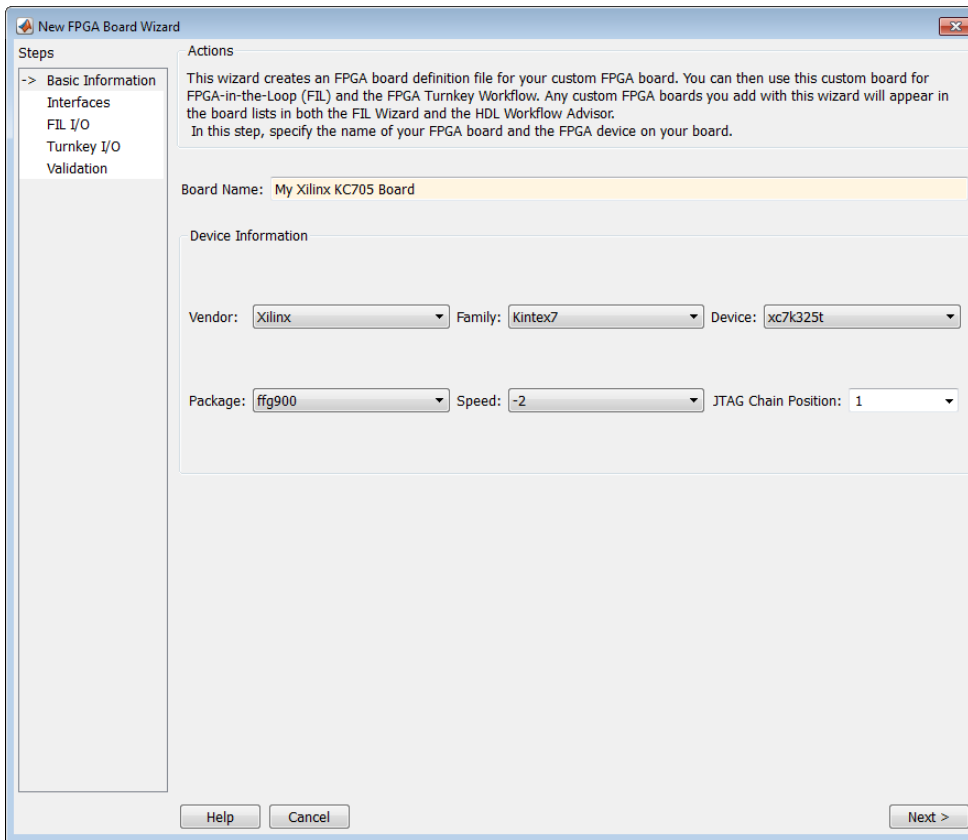

```
>>fpgaBoardManager
```

- 2 Click **Create Custom Board** to open the New FPGA Board wizard.

Provide Basic Board Information

- In the Basic Information pane, enter the following information:
 - **Board Name:** Enter "My Xilinx KC705 Board"
 - **Vendor:** Select Xilinx
 - **Family:** Select Kintex7
 - **Device:** Select xc7k325t
 - **Package:** Select ffg900
 - **Speed:** Select -2
 - **JTAG Chain Position:** Select 1

The information you just entered can be found in the KC705 Evaluation Board for the Kintex-7 FPGA User Guide.

- 2 Click **Next**.

Specify FPGA Interface Information

- 1 In the Interfaces pane, perform the following tasks.
 - a Select **FIL Interface**. This option is required for using your board with FPGA-in-the-loop.
 - b Select **GMII** in the PHY Interface Type. This option indicates that the onboard FPGA is connected to the Ethernet PHY chip via a GMII interface.
 - c Leave the **User-defined I/O** option in the FPGA Turnkey Interface section cleared. FPGA Turnkey workflow is not the focus of this example.
 - d **Clock Frequency**: Enter 200. This Xilinx KC705 board has multiple clock sources. The 200 MHz clock is one of the recommended clock frequencies for use with Ethernet interface (50, 100, 125, and 200 MHz).
 - e **Clock Type**: Select **Differential**.
 - f **Clock_P Pin Number**: Enter AD12.
 - g **Clock_N Pin Number**: Enter AD11.
 - h **Clock IO Standard** — Leave blank.
 - i **Reset Pin Number**: Enter AB7. This value supplies a global reset to the FPGA.

- j **Active Level:** Select Active-High.
- k **Reset IO Standard** — Leave blank.

You can obtain all necessary information from the board design specification.

- 2 Click **Next**.

Enter FPGA Pin Numbers

- 1 In the FIL/I/O pane, enter the numbers for each FPGA pin. This information is required.

Pin numbers for RXD and TXD signals are entered from the least significant digit (LSD) to the most significant digit (MSB), separated by a comma.

For signal name...	Enter FPGA pin number...
ETH_COL	W19
ETH_CRS	R30
ETH_GTXCLK	K30
ETH_MDC	R23
ETH_MDIO	J21
ETH_RESET_n	L20

For signal name...	Enter FPGA pin number...
ETH_RXCLK	U27
ETH_RXD	U30,U25,T25,U28,R19,T27,T26,T28
ETH_RXDV	R28
ETH_RXER	V26
ETH_TXD	N27,N25,M29,L28,J26,K26,L30,J28
ETH_TXEN	M27
ETH_TXER	N29

- 2 Click Advanced Options to expand the section.
- 3 Check the **Generate MDIO module to override PHY settings** option.

This option is selected for the following reasons:

- There are jumpers on the Xilinx KC705 board that configure the Ethernet PHY device to MII, GMII, RGMII, or SGMII mode. Since this example uses the GMII interfaces, the FPGA board does not work if the PHY devices are set to the wrong mode. When the **Generate MDIO module to override PHY settings** option is selected, the FPGA uses the Management Data Input/Output (MDIO) bus to override the jumper settings and configure the PHY chip to the correct GMII mode.
- This option currently only applies to Marvell Alaska PHY device 88E1111 and this KC705 board is using the Marvel device.

- 4 **PHY address (0 - 31):** Enter 7.

5 Click **Next**.

Run Optional Validation Tests

This step provides a validation test for you to verify if the entered information is correct by performing FPGA-in-the-loop cosimulation. You need Xilinx ISE 13.4 or higher versions installed on the same computer. This step is optional and you can skip it, if you prefer.

Note For validation, you must have Xilinx or Altera on your path. Use the `hdlsetuptoolpath` function to configure the tool for use with MATLAB.

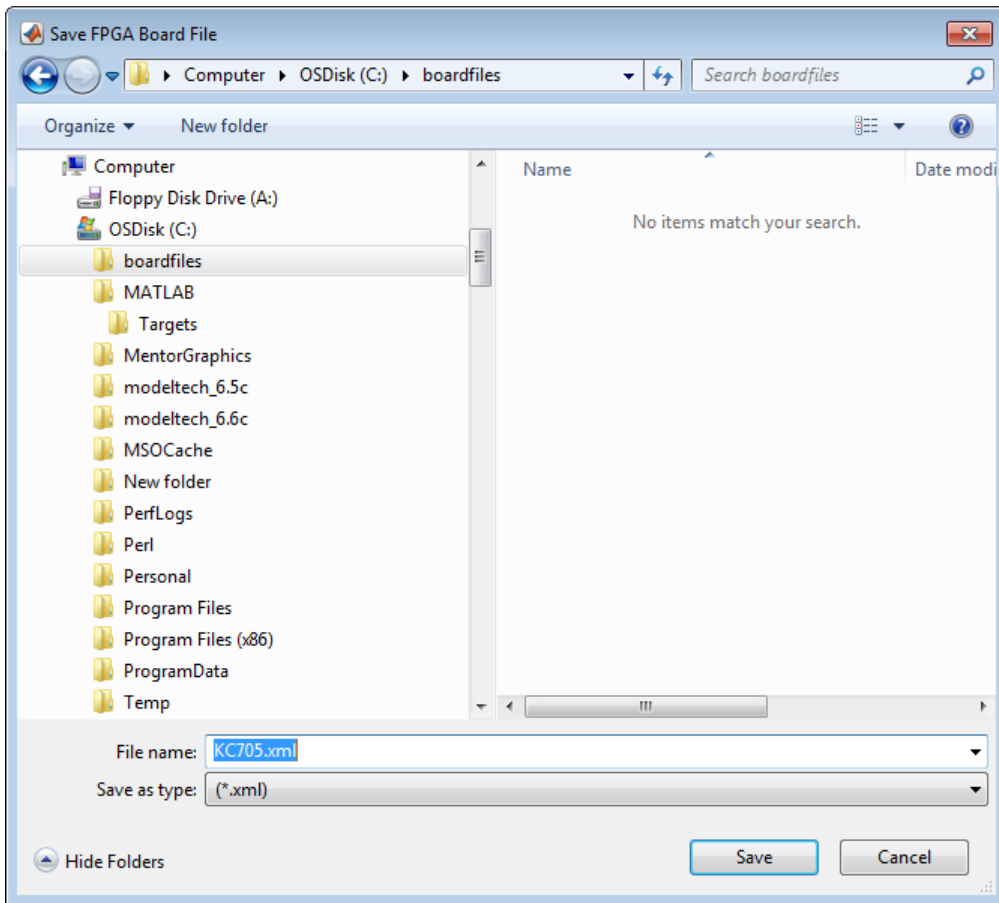

To run this test, perform the following actions.

- 1 Check the **Run FPGA-in-the-Loop test** option.
- 2 If you have the board attached, check the **Include FPGA board in the test** option. You need to supply the IP address of the FPGA Board. This example assumes that the Xilinx KC705 board is attached to your host computer and it has an IP address of 192.168.0.2.
- 3 Click **Run Selected Test(s)**. The tests take about 10 minutes to complete.

Save Board Definition File

- 1 Click **Finish** to exit the New FPGA Board wizard. A **Save As** dialog box pops up and asks for the location of the FPGA board definition file. For this example, save as C:\boardfiles \KC705.xml.

- 2 Click **Save** to save the file and exit.

Use New FPGA Board

- 1 After you save the board definition file, you are returned to the FPGA Board Manager. In the FPGA Board List, you can now see the new board you defined.

Click **OK** to close the FPGA Board Manager.

- 2 You can view the new board in the board list from either the FIL wizard or the HDL Workflow Advisor.

- a Start the FIL wizard from the MATLAB prompt.

```
>>filWizard
```

The Xilinx KC705 board appears in the board list and you can select it for FPGA-in-the-loop simulation.

b Start HDL Workflow Advisor.

In step 1.1, select **FPGA-in-the-Loop** and click **Launch Board Manager**.

The Xilinx KC705 board appears in the board list and you can select it for FPGA-in-the-loop simulation.

FPGA Board Manager

In this section...

“Introduction” on page 42-18

“Filter” on page 42-19

“Search” on page 42-19

“FIL Enabled/Turnkey Enabled” on page 42-20

“Create Custom Board” on page 42-20

“Add Board from File” on page 42-20

“Get More Boards” on page 42-20

“View/Edit” on page 42-20

“Remove” on page 42-20

“Clone” on page 42-20

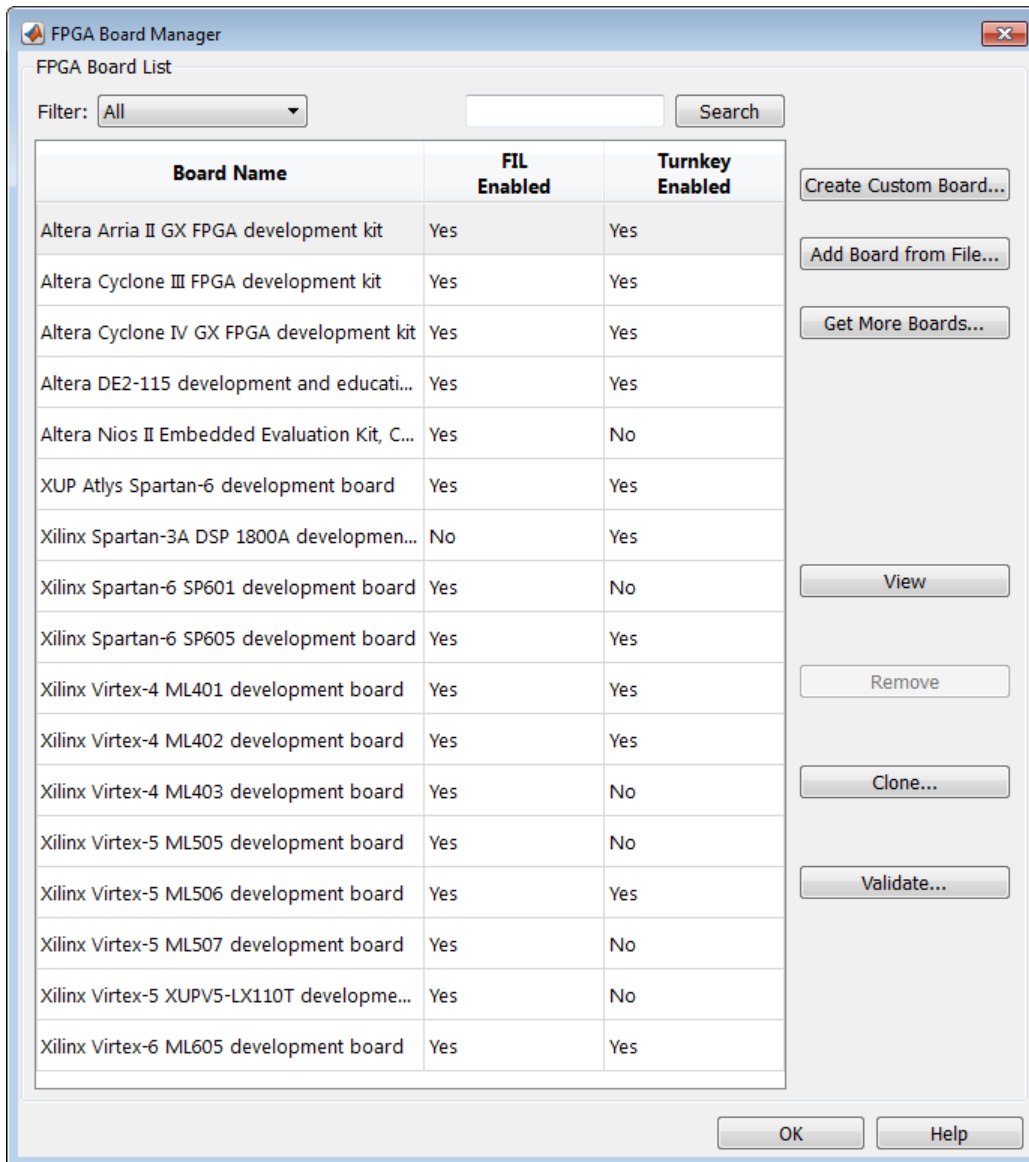

“Validate” on page 42-20

Introduction

The FPGA Board Manager is the portal to managing custom FPGA boards. You can create a board definition file or edit an existing one. You can even import a custom board from an existing board definition file.

You start the FPGA Board Manager by one of the following methods:

- By typing `fpgaBoardManager` in the MATLAB command window
- From the FIL wizard by clicking **Launch Board Manager** on the first page
- From the HDL Workflow Advisor (when using HDL Coder) at Step 1.1

Filter

Choose one of the following views:

- All boards
- Only those boards that were preinstalled with HDL Verifier or HDL Coder
- Only custom boards

Search

Find a specific board in the list or those boards that fully or partially match your search string.

FIL Enabled/Turnkey Enabled

These columns indicate whether the specified board is supported for FIL or Turnkey operations.

Create Custom Board

Start New FPGA Board wizard. See “New FPGA Board Wizard” on page 42-22. You can find the process for creating a board definition file in “Create Custom FPGA Board Definition” on page 42-6.

Add Board from File

Import a board definition file (.xml).

Get More Boards

Download FPGA board support packages for use with FIL

- 1** Click **Get more boards**.
- 2** Follow the prompts in the Support Package Installer to download an FPGA board support package.
- 3** When the download is complete, you can see the new boards in the board list in the FPGA Board Manager.

Offline Support Package Installation You can install an FPGA board support package without an internet connection. See “Install Support Package Offline” (HDL Verifier).

View/Edit

View board configurations and modify the information. You can view a read-only file but not edit it. See “FPGA Board Editor” on page 42-33.

Remove

Remove custom board from the list. This action does not delete the board definition XML file.

Clone

Makes a copy of an existing custom board for further modification.

Validate

Runs the validation tests for FIL See “Run Optional Validation Tests” on page 42-12.

See Also

Related Examples

- “Create Custom FPGA Board Definition” (HDL Verifier)
- “Create Xilinx KC705 Evaluation Board Definition File” (HDL Verifier)

New FPGA Board Wizard

Using the New FPGA Board wizard, you can enter all the required information to add a board to the FPGA board list. This list applies to both FIL and Turnkey workflows. Review “FPGA Board Requirements” on page 42-2 before adding an FPGA board to make sure that it is compatible with the workflow for which you want to use it.

Several buttons in the New FPGA Board wizard help with navigation:

- **Back:** Go to a previous page to review or edit data already entered.
- **Next:** Go to next page when all requirements of current page have been satisfied.
- **Help:** Open Doc Center, and display this topic.
- **Cancel:** Exit New FPGA Board wizard. You can exit with or without saving the information from your session.

Adding Boards Once for Multiple Users To add new boards globally, follow these instructions. To access a board added globally, all users must be using the same MATLAB installation.

- 1 Create the following folder:

matlabroot/toolbox/shared/eda/board/boardfiles

- 2 Copy the board description XML file to the *boardfiles* folder.
- 3 After copying the XML file, restart MATLAB. The new board appears in the FPGA board list for either or both the FIL and Turnkey workflows.

All boards under this folder show-up in the FPGA board list automatically for users with the same MATLAB installation. You do not need to use FPGA Board Manager to add these boards again.

The workflow for adding an FPGA board contains these steps:

In this section...
“Basic Information” on page 42-23
“Interfaces” on page 42-23
“FIL I/O” on page 42-26
“Turnkey I/O” on page 42-28
“Validation” on page 42-31
“Finish” on page 42-32

Basic Information

Board Name: Enter a unique board name.

Device Information:

- **Vendor:** Xilinx or Altera
- **Family:** Family depends on the specified vendor. See the board specification file for applicable settings.
- **Device:** Use the board specification file to select the correct device.
- For Xilinx boards only:
 - **Package:** Use the board specification file to select the correct package.
 - **Speed:** Use the board specification file to select the correct speed.
 - **JTAG Chain Position:** Value indicates the starting position for JTAG chain. Consult the board specification file for this information.

Interfaces

- “FIL Interface for Altera Boards” on page 42-24
- “FIL Interface for Xilinx Boards” on page 42-25
- “FPGA Turnkey Interface” on page 42-25

- “FPGA Input Clock and Reset” on page 42-26

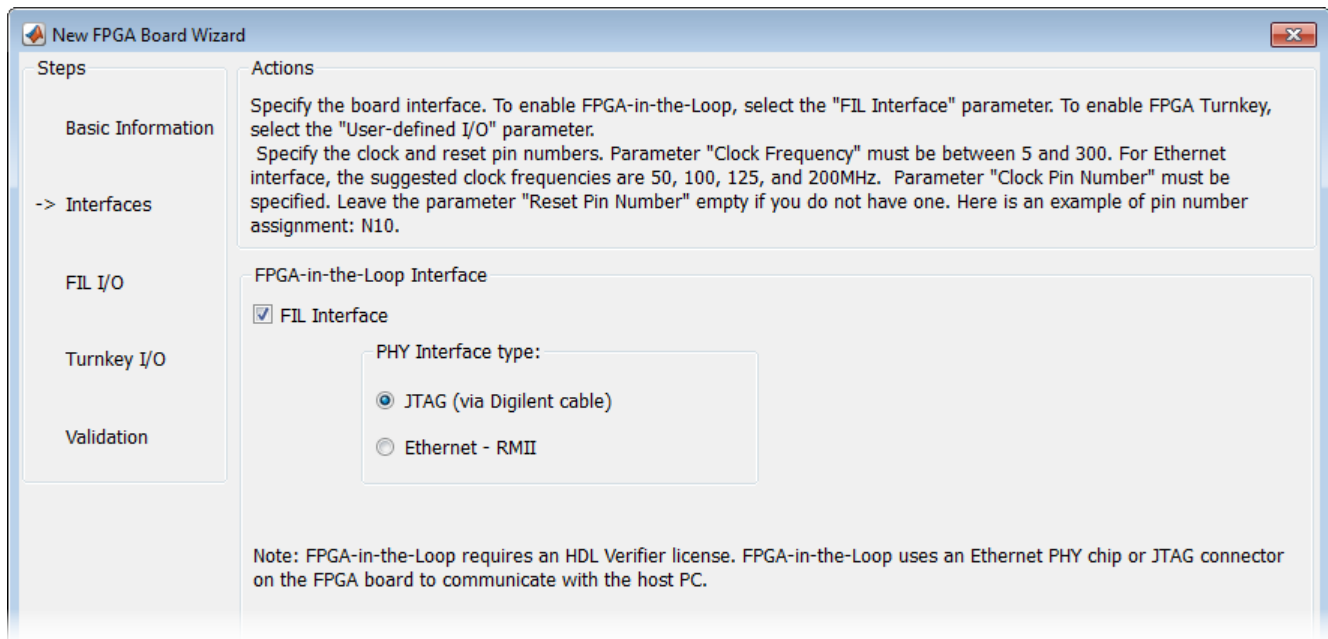

FIL Interface for Altera Boards

- 1 FPGA-in-the-Loop:** To use this board with FIL, select **FIL Interface**.
- Select one of the following **PHY Interface types**:
 - **Gigabit Ethernet – GMII**
 - **Gigabit Ethernet – RGMII**
 - **Gigabit Ethernet – SGMII** (the SGMII option appears if you select a board from the Stratix V or Stratix IV device families)
 - **Ethernet – MII**
 - **Altera JTAG** (Altera boards only)

Note Not all interfaces are available for all boards. Availability depends on the board you selected in Basic Information.

FIL Interface for Xilinx Boards

- 1 **FPGA-in-the-Loop Interface:** To use this board with FIL, select **FIL Interface**.
- 2 Select one of the following **PHY Interface types**:
 - **JTAG (via Digilent cable)** (Xilinx boards only)
 - **Ethernet – RMII**

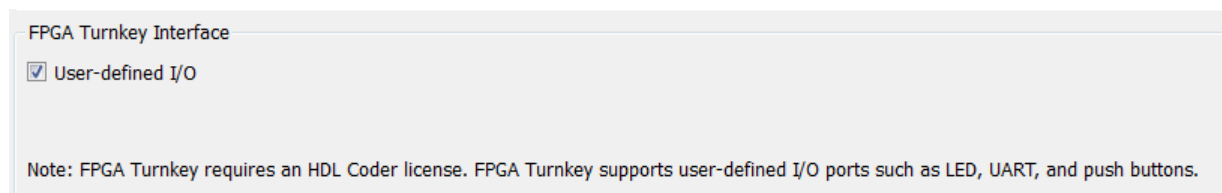

Note Not all interfaces are available for all boards. Availability depends on the board you selected in Basic Information.

For more information on how to set up the JTAG connection for Xilinx boards, see “JTAG with Digilent Cable Setup” on page 42-35.

Limitations

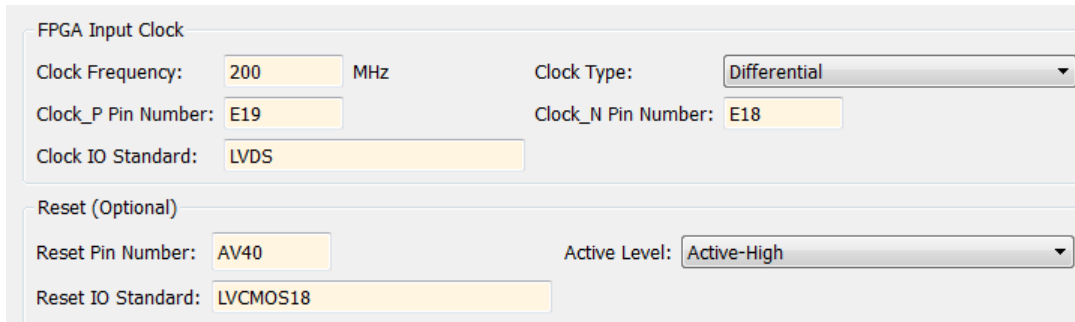

When you simulate your FPGA design through a Digilent JTAG cable, you cannot use any other debugging feature that requires access to the JTAG; for example, the Vivado Logic Analyzer.

FPGA Turnkey Interface

FPGA Turnkey Interface: If you want to use with board with the HDL Coder FPGA Turnkey workflow, select **User-defined I/O**.

FPGA Input Clock and Reset

The screenshot shows a configuration window with two main sections. The top section, titled 'FPGA Input Clock', contains the following fields: 'Clock Frequency' set to 200 MHz, 'Clock Type' set to Differential, 'Clock_P Pin Number' set to E19, 'Clock_N Pin Number' set to E18, and 'Clock IO Standard' set to LVDS. The bottom section, titled 'Reset (Optional)', contains: 'Reset Pin Number' set to AV40, 'Active Level' set to Active-High, and 'Reset IO Standard' set to LVCMOS18.

- 1 **FPGA Input Clock** — Clock details are required for both workflows. You can find all necessary information in the board specification file.
 - **Clock Frequency** — Must be from 5 through 300. For an Ethernet interface, the suggested clock frequencies are 50, 100, 125, and 200 MHz.
 - **Clock Type** — `Single_Ended` or `Differential`.
 - **Clock Pin Number** (`Single_Ended`) — Must be specified. Example: N10.
 - **Clock_P Pin Number** (`Differential`) — Must be specified. Example: E19.
 - **Clock_N Pin Number** (`Differential`) — Must be specified. Example: E18.
 - **Clock IO Standard** — The programmable I/O Standard to use to configure input, output, or bi-directional ports. For example, LVDS.
- 2 **Reset (Optional)** — If you want to indicate a reset, find the pin number and active level in the board specification file, and enter that information.
 - **Reset Pin Number** — Leave empty if you do not have one.
 - **Active Level** — `Active-Low` or `Active-High`.
 - **Reset IO Standard** — The programmable I/O Standard to use to configure input, output, or bi-directional ports. For example, LVCMOS33.

FIL I/O

When you select an Ethernet connection to your board, you must specify pins for the Ethernet signals on the FPGA.

Signal List: Provide all the FPGA pin numbers for the specified signals. You can find this information in the board specification file. For vector signals, list all pin numbers on the same line, separated by commas.

Note If your PHY chip does not have the optional TX_ER pin, tie ETH_TXER to one of the unused pins on the FPGA.

Generate MDIO module to override PHY settings: See the next section on FPGA Board Management Data Input/Output Bus (MDIO) to determine when to use this feature. If you do select this option, enter the PHY address.

What Is the Management Data Input/Output Bus?

Management Data Input/Output (MDIO) is a serial bus, defined in the IEEE 802.3 standard, that connects MAC devices and Ethernet PHY devices. The FPGA MAC uses the MDIO bus to set control registers in the Ethernet PHY device on the board.

Currently only the Marvell 88E1111 PHY chip is supported by this MDIO module implementation. Do not select this check box if you are not using Marvell 88E1111.

The generated MDIO module is used to perform the following operations:

- **GMII mode:** The PHY device can start up using other modes, such as RGMII/SGMII. The generated MDIO module sets the PHY chip in GMII mode.

- **RGMI mode:** The PHY device can start up using other modes, such as GMII/SGMII. The generated MDIO module sets the PHY device in RGMI mode. In addition, the module sets the PHY chip to add internal delay for RX and TX clocks.
- **SGMI mode:** The PHY device can start up using other modes, such as RGMI/GMII. The generated MDIO module sets the PHY chip in SGMI mode.
- **MII mode:** The generated MDIO module sets the PHY device in GMII compatible mode. The module also sets the autonegotiation register to remove the 1000 Base-T capability advertisement. This reset ensures that the autonegotiation process does not select 1000 Mbits/s speed, which is not supported in MII mode.

When To Select MDIO: Select the **Generate MDIO module to override PHY settings** option when both the following conditions are met:

- The onboard Ethernet PHY device is Marvell 88E1111.
- The PHY device startup settings are not compatible with the FPGA MAC. The MDIO modules for different PHY modes must override these settings, as previously described.

Specifying the PHY Address: The PHY address is a 5-bit integer. The value is determined by the CONFIG[0] and CONFIG[1] pin on Marvell 88E1111 PHY device. See the board manual for this value.

Turnkey I/O

Note Provide FIL I/O for an Ethernet connection only. Define at least one output port for the Turnkey I/O interface.

Signal List: Provide all the FPGA pin numbers for the specified signals. You can find this information in the board specification file. For vector signals, list all pin numbers on the same line, separated by commas. The number of pin numbers must match the bit width of the corresponding signal.

Add New: You are prompted to enter all entries in the signal list manually.

Add Using Template: The wizard prepopulates a new signal entry for UART, LED, GPIO, or DIP Switch signals with the following:

- A generic signal name
- Description
- Direction
- Bit width

You can change the values in any of these prepopulated fields.

Delete: Delete the selected signal from list.

The following example demonstrates using the **Add Using Template** feature.

- 1 In the Turnkey I/O dialog box, click **Add Using Template**.
- 2 You can now view the template dialog box.

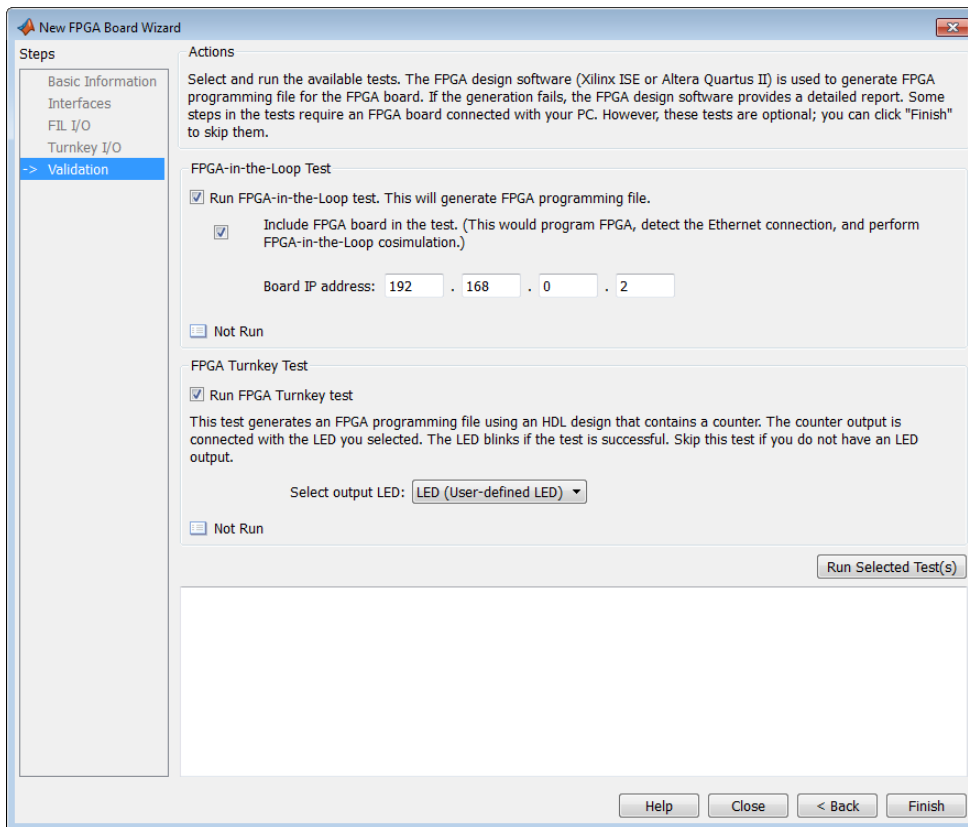

- 3 Pull down the I/O list and select from the following options:

- 4 Click **OK**.
- 5 The wizard adds the specified signal (or signals) to the I/O list.

Validation

FPGA-in-the-Loop Test

- **Run FPGA-in-the-Loop test:** Select to generate an FPGA programming file.
 - **Include FPGA board in the test:** (Optional) This selection program the FPGA with the generated programming file, detects the Ethernet connection (if selected), and performs FPGA-in-the-loop simulation.
 - **Board IP address:** (Ethernet connection only) Use this option for setting the board IP address if it is not the default IP address (192.168.0.2).

If necessary, change the computer IP address to a different subnet from 192.168.0.x when you set up the network adapter. If the default board IP address 192.168.0.2 is in use by another device, change the Board IP address according to the following guidelines:

- The subnet address, typically the first 3 bytes of board IP address, must be the same as the host IP address.
- The last byte of the board IP address must be different from the host IP address.
- The board IP address must not conflict with the IP addresses of other computers.

For example, if the host IP address is 192.168.8.2, then you can use 192.168.8.3, if available.

FPGA Turnkey Test

- **Run FPGA Turnkey test:** Select to generate an FPGA programming file using an HDL design that contains a counter. You must have a board attached.
- **Select output LED:** The counter's output is connected with the LED you select. Skip this test if you do not have an LED output.

Finish

When you have completed validation, click **Finish**. See "Save Board Definition File" on page 42-13.

FPGA Board Editor

In this section...

“General Tab” on page 42-33

“Interface Tab” on page 42-35

To edit a board definition XML file, first make it writeable. If the file is read-only, the FPGA Board Editor only lets you view the board configuration information. You cannot modify that information.

Clock IO Standard: LVDS

Reset (Optional)

Reset Pin Number: AV40 Active Level: Active-High

Reset IO Standard: LVCMOS18

OK Cancel Help Apply

Board Name: Unique board name

Device Information:

- **Vendor:** Xilinx or Altera
- **Family:** Family depends on the specified vendor. See the board specification file for applicable settings.
- **Device:** Device depends on the specified vendor and family. See the board specification file for applicable settings.
- For Xilinx boards only:

- **Package:** Package depends on specified vendor, family, and device. See the board specification file for applicable settings.
- **Speed:** Speed depends on package. See the board specification file for applicable settings.
- **JTAG Chain Position:** Value indicates the starting position for JTAG chain. Consult the board specification file for this information.
- **FPGA Input Clock.** Clock details are required for both the FIL and Turnkey workflows. You can find all necessary information in the board specification file.
 - **Clock Frequency.** Must be from 5 through 300. For an Ethernet interface, the suggested clock frequencies are 50, 100, 125, and 200 MHz.
 - **Clock Type:** Single_Ended or Differential.
 - **Clock Pin Number** (Single_Ended) — Must be specified. Example: N10.
 - **Clock_P Pin Number** (Differential) — Must be specified. Example: E19.
 - **Clock_N Pin Number** (Differential) — Must be specified. Example: E18.
 - **Clock IO Standard** — The programmable I/O Standard to use to configure input, output, or bi-directional ports. For example, LVDS.
- **Reset (Optional).** If you want to indicate a reset, find the pin number and active level in the board specification file, and enter that information.
 - **Reset Pin Number.** Leave empty if you do not have one.
 - **Active Level** : Active-Low or Active-High.
 - **Reset IO Standard** — The programmable I/O Standard to use to configure input, output, or bi-directional ports. For example, LVCMOS33.

Interface Tab

The Interface page describes the supported FPGA I/O Interfaces. Select any listed interface and click **View** to see the **Signal List**. If the board definition file has write permission, you can also **Add New** interface, **Edit** the interface, or **Remove** an interface.

JTAG with Digilent Cable Setup

Note Enter information for the JTAG cable setup carefully. If the settings are incorrect, the simulation errors out and does not work. If you are still unsure about how to setup your JTAG cable after reading these instructions, contact MathWorks technical support with detailed information about your board.

- 1 **Signal/Parameter List** — Provide the sum of the lengths of the instruction registers (IR) for all devices before and after the FPGA in the chain.
 - If the FPGA is the only item in the device chain, use zeros in both **Sum of IR length before** and **Sum of IR length after**.
 - If you are using a Zynq device, and it is the only item in the device chain, enter 4 in **Sum of IR length before** and 0 in **Sum of IR length after**.

If your board does not meet either of those conditions, follow these instructions to obtain the IR lengths:

- a Connect the FPGA board to your computer using the JTAG cable. Turn on the board.
- b Make sure that you installed the cable drivers during Vivado installation.
- c Open Vivado Hardware Manager and select **Open a new hardware target**. In the dialog box is a summary of the IR lengths for all devices for that target.
- d Sum the IR lengths before the FPGA and enter the total in **Sum of IR length before**. Sum the IR lengths after the FPGA and enter the total in **Sum of IR length after**.

Vivado Hardware Manager cannot recognize the IR length of less common devices. For these devices, consult the device manual for instruction register length.

- 2 **Advanced Options** — If the default values are not the same as the most common settings for many devices, set the **User1 Instruction** and **JTAG Clock Frequency (MHz)** parameters. The most common settings are 000010 and 66, respectively.
 - **User1 Instruction** — The JTAG USER1 Instruction defined in the Xilinx Bscane2 primitive. This binary instruction number, defined by Xilinx, varies from device to device. For most of the

7-series devices, this instruction is 000010. If your device has a different value, enter it in this parameter.

To find this value, look at the `bsd` file for your specific device, found in your Vivado installation. For example, for the XA7A32T-CPG236 device, the `bsd` file is located in Vivado \2020.2\data\parts\xilinx\artix7\public\bsdl\xc7a35t_cpg236.bsd.

Open this file. The `USER1` value is 000010. Enter this value at **User1 Instruction**.

```
"USER1      (000010),"
```

- **JTAG Clock Frequency (MHz)** — Clock frequency used by the JTAG circuit. This value varies by device. You can find this value in the same `bsd` file described under **User1 Instruction**. For example, the JTAG clock frequency is 66 MHz for device XA7A32T-CPG236:

```
attribute TAP_SCAN_CLOCK of TCK : signal is (66.0e6, BOTH);
```

HDL Workflow Advisor Tasks Overview

The HDL Workflow Advisor is a tool that supports a suite of tasks covering the stages of the FPGA design process. Some tasks perform model validation or checking. Other tasks run the HDL code generator or third-party tools. Each folder at the top level of the HDL Workflow Advisor contains a group of related tasks that you can select and run.

HDL Workflow Advisor is not available in Simulink Online.

For summary information on each HDL Workflow Advisor folder or task, select the folder or task icon, and then click the HDL Workflow Advisor **Help** button.

- **Set Target:** The tasks in this category enable you to select the target device and map its I/O interface to the inputs and outputs of your model.
- **Prepare Model For HDL Code Generation:** The tasks in this category check your model for HDL code generation compatibility. The tasks also report on model settings, blocks, or other conditions (such as algebraic loops) that impede code generation, and provide advice on how to fix such problems.
- **HDL Code Generation:** This category supports all HDL-related options in the Configuration Parameters dialog box, including setting HDL code and test bench generation parameters, and generating code, test bench, or a cosimulation model.
- **FPGA Synthesis and Analysis:** The tasks in this category support:
 - Synthesis and timing analysis through integration with third-party synthesis tools
 - Back annotation of the model with critical path and other information obtained during synthesis
- **FPGA-in-the-Loop Implementation:** This category implements the phases of FIL, including providing block generation, synthesis, logical mapping, PAR (place-and-route), programming file generation, and a communications channel. These capabilities are designed for a particular board and tailored to your register transfer level (RTL) code. HDL Verifier is required for FIL.
- **Download to Target:** The tasks in this category depend on the selected target device and potentially include:
 - Generation of a target-specific FPGA programming file
 - Programming the target device
 - Generation of a model that contains a Simulink Real-Time interface subsystem

“Getting Started with the HDL Workflow Advisor” on page 36-6

Set Target Overview

In the **Set Target** folder, you can select a target FPGA device and define the interface generated for the device.

- **Set Target Device and Synthesis Tool:** Select a target FPGA device and synthesis tools.
- **Set Target Reference Design:** For IP Core Generation workflow, select a reference design for your target device.
- **Set Target Interface:** For IP Core Generation, FPGA Turnkey, and Simulink Real Time FPGA I/O workflows, use the target platform interface table to assign each port on your DUT to an I/O resource on the target device. Use **Enable HDL DUT port generation for test points** to create DUT output ports for the test point signals in the generated HDL code.
- **Set Target Frequency:** Select the target clock rate for the FPGA implementation of your design.

For more information on each **Set Target** task, select the task icon, and then click the HDL Workflow Advisor **Help** button.

See Also

“Getting Started with the HDL Workflow Advisor” on page 36-6

Set Target Device and Synthesis Tool

The **Set Target Device and Synthesis Tool** task enables you to select an FPGA target device and an associated synthesis tool from a context menu that lists the devices that HDL Workflow Advisor supports.

Description

This task displays these options:

- **Target Workflow:** A context menu that lists the possible workflows that HDL Workflow Advisor supports. Choose from:
 - Generic ASIC/FPGA
 - FPGA-in-the-loop
 - FPGA Turnkey
 - Simulink Real-Time FPGA I/O
 - IP Core Generation
 - Customization for the USRP device
 - Software Defined Radio
- **Target platform:** A context menu that lists the devices the HDL Workflow Advisor supports. Not available for the Generic ASIC/FPGA workflow.
- **Synthesis tool:** Select a synthesis tool, then select the **Family**, **Device**, **Package**, and **Speed** for your synthesis target.

If your synthesis tool is not one of the **Synthesis tool** options, see “Synthesis Tool Path Setup”. After you set up your synthesis tool path, click **Refresh** to make the tool available in the HDL Workflow Advisor.

- **Project folder:** Specify the project folder name.
- **Tool version:** This box displays the current synthesis tool version.
- **Allow unsupported version:** When you are using an unsupported synthesis tool version, selecting this check box. You can continue to create a project with unsupported synthesis tool

version. If you clear this check box, HDL Coder generates an error when you run this task. This option is unavailable when you are using the supported synthesis tool version.

It is not recommended to use the unsupported tool version because it can potentially cause synthesis failure. For more information on the list of supported tools, see “HDL Language Support and Supported Third-Party Tools and Hardware”

Note If you select Intel Quartus Pro or Microchip Libero SoC as the **Synthesis tool**, you can run only the Generic ASIC/FPGA workflow. When you use these tools, the **Annotate Model with Synthesis Result** task is not available. In this case, you can run the workflow for synthesis, and then view the timing reports to see the critical path.

Set Target Reference Design

The **Set Target Reference Design** task displays when **IP Core Generation** is selected as the **Target Workflow** and the **Target Platform** is not generic. This task displays the reference design input parameters and the tool version. A **Reference design parameters** section displays any custom parameters that you specify for the reference design.

Description

The task displays the following options:

- **Reference design:** A context menu that lists the reference designs that HDL Coder supports and any custom reference designs that you specify. To learn more about creating a custom board and reference design, see “Board and Reference Design Registration System” on page 47-68.
- **Reference design tool version:** A text box that displays the current reference design tool version. It is recommended to use a reference design tool version that is compatible with the supported tool version. If there is a tool version mismatch, HDL Coder generates an error when you run this task. The tool version mismatch can potentially cause the **Create Project** task to fail.

If you select the **Ignore tool version mismatch** check box, HDL Coder generates a warning instead of an error. You can attempt to continue with creating the reference design project.

- **Reference design parameters:** A context menu that lists the parameters of the reference design. These parameters can be parameters available with the default reference designs that HDL Coder supports or parameters that you define for your custom reference design. For more information, see “Define Custom Parameters and Callback Functions for Custom Reference Design” on page 47-77.
- **FPGA Data Capture (HDL Verifier required):** Generate and integrate the data capture IP into your reference design. Use FPGA data capture to observe signals from your design while the design is running on the FPGA. This feature captures a window of signal data from the FPGA and returns the data to MATLAB or Simulink over a JTAG or Ethernet connection. To capture data over a JTAG connection, set this parameter to JTAG. To capture data over an Ethernet connection, set this parameter to Ethernet. Then, map each signal that you want to capture to the FPGA Data Capture interface in the **Set Target Interface** task.

Note

- FPGA data capture support for JTAG connections is available for Intel and Xilinx boards. Support for Ethernet connections is available for Xilinx boards only.
 - FPGA data capture in the HDL Workflow Advisor supports programmable logic (PL) Ethernet only. The processing system (PS) Ethernet is not supported.
 - By default, the `Ethernet` option is available for the Artix-7 35T Arty and Kintex-7 KC705 boards. To enable this option for other Xilinx boards that have the Ethernet physical layer (PHY), manually add the Ethernet media access controller (MAC) Hub IP in the `plugin_board` file using the `addEthernetMACInterface` method before you launch the HDL Workflow Advisor.
 - FPGA data capture in the HDL Workflow Advisor does not support SGMII interface.
-

To use this capability, you must have the HDL Verifier hardware support packages installed and downloaded. See “Download FPGA Board Support Package” (HDL Verifier).

- **Board IP Address:** Specify the IP address of the Ethernet port on the target board as a dotted-quad value. The target IP address must be a set of four numbers consisting of integers in the range [0, 255] that are separated by three dots. The default value is `192.168.0.2`.

To enable this parameter, set **FPGA Data Capture (HDL Verifier required)** to `Ethernet`.

- **Insert AXI Manager (HDL Verifier required):**

By default, HDL Coder adds the **Insert AXI Manager (HDL Verifier required)** parameter to all reference designs. When you set this parameter to `JTAG`, the code generator inserts the JTAG AXI Manager IP into your reference design. When you set this parameter to `Ethernet`, the code generator inserts the UDP AXI Manager IP into your reference design.

Note By default, the `Ethernet` option is available for only the Artix-7 35T Arty, Kintex-7 KC705, and Virtex-7 VC707 boards. To enable this option for other Xilinx boards that have the Ethernet physical layer (PHY), manually add the Ethernet media access controller (MAC) Hub IP in the `plugin_board` file using the `addEthernetMACInterface` method before you launch the **HDL Workflow Advisor** tool.

By using the AXI manager IP, you can easily access the AXI registers in the generated DUT IP core on a hardware board from MATLAB or Simulink through the JTAG or Ethernet connection. See also “Set Up AXI Manager” (HDL Verifier).

Set Target Interface

The **Set Target Interface** task, when **FPGA Turnkey** is selected as the **Target Workflow**, displays properties of input and output ports on your DUT and enables you to map these ports to I/O resources on the target device.

Description

Set Target Interface displays the Target Platform Interface Table, which shows:

- The name, port type (inputs and outputs), and data type for each port on your DUT.

- A context menu listing the available I/O resources for the target device.

These resources are device-specific. For detailed information on each resource, see the documentation for your FPGA development board.

Set Target Interface

The **Set Target Interface** task that displays when **Simulink Real-Time FPGA I/O** or **IP Core Generation** is selected as the **Target Workflow**. Select a processor-FPGA synchronization mode and map your DUT input ports, output ports, and test points to I/O resources on the target device.

Description

Coprocessing mode is not supported for the **Simulink Real-Time FPGA I/O** workflow. For **Processor/FPGA synchronization**, select:

- **Free running** if you do not want your processor and FPGA to be automatically synchronized.
- **Coprocessing - blocking** if you want HDL Coder to generate synchronization logic for the FPGA automatically, so that the processor and FPGA run in tandem. Select this mode when FPGA execution time is short relative to the processor sample time and you want the FPGA to complete the synchronization before the processor continues.

This setting is saved with the model as the ProcessorFPGASynchronization HDL block property for the DUT block.

Selecting the **Enable HDL DUT port generation for testpoints**:

- Marks test point signals for code generation. See “Model and Debug Test Point Signals with HDL Coder” on page 14-70.
- Enables the “Enable HDL DUT port generation for test points” on page 21-43 configuration set option.
- Refreshes the target interface table to display the test point output ports in the interface table.

The Target Platform Interface Table displays:

- The name, port type (input, output, and test point), and data type for each port on your DUT.
- A context menu listing the available I/O resources for the target device.

These resources are device-specific. For detailed information on each resource, see the documentation for your FPGA development board.

- “FPGA Programming and Configuration on Speedgoat Simulink-Programmable I/O Modules” on page 47-92
- “Enable HDL DUT port generation for test points” on page 21-43

Set Target Frequency

Specify the target frequency for these workflows:

- **Generic ASIC/FPGA:** Specify the target frequency that you want your design to achieve. HDL Coder generates a timing constraint file for that clock frequency and adds the constraint to the FPGA synthesis tool project that you create in the **Create Project** task. If the target frequency is not achievable, the synthesis tool generates an error.
- **IP Core Generation:** Specify the target frequency for HDL Coder to modify the clock module setting in the reference design to produce the clock signal with that frequency. Enter a target frequency value that is within the **Frequency Range (MHz)**. If you do not specify the target frequency, HDL Coder uses the **Default (MHz)** target frequency.
- **Simulink Real-Time FPGA I/O:** For Speedgoat boards that are supported by Xilinx ISE, specify the target frequency to generate the clock module to produce the clock signal with that frequency.

The Speedgoat boards that are supported by Xilinx Vivado use the **IP Core Generation** workflow infrastructure. Specify the target frequency for HDL Coder to modify the clock module setting in the reference design to produce the clock signal with that frequency. Enter a target frequency value that is within the **Frequency Range (MHz)**. If you do not specify the target frequency, HDL Coder uses the **Default (MHz)** target frequency.

- **FPGA Turnkey:** Generate the clock module to automatically produce the clock signal with that frequency.

See Also

“Target Frequency Parameter” on page 18-8

Prepare Model for HDL Code Generation Overview

The tasks in the **Prepare Model For HDL Code Generation** folder check the model for compatibility with HDL code generation. If a check encounters a condition that raises a code generation warning or error, the right pane of the HDL Workflow Advisor displays information about the condition and how to fix it. The **Prepare Model For HDL Code Generation** folder contains these checks:

- **Check Model Settings** check expedites model checks by removing redundant checks. The check provides you the option to open the **HDL Code Advisor** checks in a separate window and run those checks.
- **Check FPGA-in-the-Loop Compatibility:** Check model compatibility with FPGA-in-the-loop, specifically:
 - Not allowed: sink/source subsystems, single/double data types, zero sample time
 - Must be present: HDL Verifier

This option is available only if you select **FPGA-in-the-Loop** for Target workflow.

- **Check USRP Compatibility:** The model must have two input ports and two output ports of signed 16-bit signals.

This option is available only if you select **Customization for the USRP Device** for Target workflow.

For summary information on each **Prepare Model For HDL Code Generation** task, select the task icon, and then click the HDL Workflow Advisor **Help** button.

See Also

“Getting Started with the HDL Workflow Advisor” on page 36-6

Check Model Settings

Check Model Settings checks model-wide parameter settings for HDL code generation compatibility of the model.

Description

This check examines the model parameters for compatibility with HDL code generation and flags conditions that raise an error or a warning during code generation. The HDL Workflow Advisor displays a table with the following information about each condition detected:

- **Block:** Hyperlink to the model configuration dialog box page that contains the error or warning condition.
- **Settings:** Name of the model parameter that caused the error or warning condition.
- **Current:** Current value of the setting.
- **Recommended:** Recommended value of the setting.
- **Severity:** Severity level of the warning or error condition. Minimally, fix settings that are tagged as **error**.

This check provides a button to open the **HDL Code Advisor** checks in a separate window. Clicking **Run This Task** does not open the **HDL Code Advisor** checks. HDL Code Advisor can run additional HDL code generation compatibility checks not covered in this task. For more info, see “Model configuration checks” on page 45-10.

Tip To set reported settings to their recommended values, click the **Modify All** button. You can then rerun the check again and proceed to the next check.

Check FPGA-in-the-Loop Compatibility

HDL Verifier checks model for compatibility with FPGA-in-the-loop processing.

See Also

“Prepare DUT For FIL Interface Generation” (HDL Verifier).

HDL Code Generation Overview

The tasks in the **HDL Code Generation** folder enable you to:

- Set and validate HDL code and test bench generation parameters. Most parameters on the **HDL Code Generation** pane in the Configuration Parameters dialog box and the Model Explorer are supported.
- Generate any or all of:
 - RTL code
 - RTL test bench
 - Cosimulation model
 - SystemVerilog DPI test bench

To run the tasks in the **HDL Code Generation** folder automatically, select the folder and click **Run All**.

Tip After each task in this folder runs, HDL Coder updates the Configuration Parameters dialog box and the Model Explorer.

Set HDL Options

Optional task to open the HDL Coder Configuration Parameters dialog box.

Description

The **Set HDL Options** is an optional task. This task provides you with the option to open the HDL Coder Configuration Parameters dialog box in a separate window. Changes to the configuration parameters are used in the next HDL Coder Workflow Advisor task.

Note Before doing this task, close the HDL Coder Configuration Parameters dialog box.

Limitations

When the Workflow Advisor window is open for the current design under test (DUT), these configuration parameters are disabled for editing:

- Name of the DUT model or subsystem.
- Name and path of the target code generation folder.
- Name of the synthesis tool.
- Device family selection.
- Device selection.
- Device package selection.
- Device speed selection.
- Target frequency.

If you make any changes to these configuration parameters, rerun all the previous Workflow Advisor tasks.

Generate RTL Code and Testbench

Select and initiate generation of RTL code, RTL test bench, and cosimulation model.

Description

The **Generate RTL Code and Testbench** task enables choosing what type of code or model that you want to generate. You can select any combination of the following:

- **Generate RTL code:** Generate RTL code in the target language.
- **Generate test bench:** Generate the test bench if **HDL Test Bench** is selected in HDL Coder Configuration Parameters > **Test Bench** > **Test Bench Generation Output**.
- **Generate validation model:** Generate a validation model that highlights generated delays and other differences between your original model and the generated cosimulation model. With a validation model, you can observe the effects of streaming, resource sharing, and delay balancing.

The validation model contains the DUT from the original model and the DUT from the generated cosimulation model. Using the validation model, you can verify that the output of the optimized DUT is bit-true to the results produced by the original DUT.

See Also

“Generating a Simulink Model for Cosimulation with an HDL Simulator” (Filter Design HDL Coder).

Verify with HDL Cosimulation

Run this step to verify the generated HDL code using cosimulation between the HDL Simulator and the Simulink test bench. This step shows as a Workflow Advisor Task only if you:

- Select **Generate test bench** in **Generate RTL Code and Testbench**.
- Select **Cosimulation model** and specify a **Simulation Tool** in HDL Coder Configuration Parameters > **Test Bench** > **Test Bench Generation Output**.

Generate RTL Code and IP Core

Select and initiate generation of RTL code and a custom IP core.

Description

In the **Generate RTL Code and IP Core** task, specify characteristics of the generated IP core:

- **IP core name:** Enter the IP core name.

This setting is saved with the model as the `IPCoreName` HDL block property for the DUT block.

- **IP core version:** Enter the IP core version number. HDL Coder appends the version number to the IP core name to generate the output folder name.

This setting is saved with the model as the `IPCoreVersion` HDL block property for the DUT block.

- **IP core folder** (not editable): HDL Coder generates the IP core files in the output folder shown, including the HTML documentation.
- **IP repository:** If you have an IP repository folder, enter its path manually or by using the **Browse** button. The coder copies the generated IP core into the IP repository folder.
- **Additional source files:** If you are using a black box interface in your design to include existing Verilog or VHDL code, enter the file names. Enter each file name manually, separated with a semicolon (;) or by using the **Add** button.

This setting is saved with the model as the `IPCoreAdditionalFiles` HDL block property for the DUT block.

- **FPGA Data Capture buffer size:** Specify the size of the memory in the generated IP core. The width of the memory is the total bit width of the data signals. The buffer size uses values equal to $128 \cdot (2^n)$, where n is an integer. By default, the buffer size is 128 ($n = 0$). The maximum value of n is 13, which means that the maximum value for buffer size is $128 \cdot (2^{13}) = 1048576$.

This setting is saved with the model as the `IPDataCaptureBufferSize` HDL block property for the DUT block.

- **FPGA Data Capture maximum sequence depth:** Specify the maximum sequence depth to capture data from an FPGA in one or more trigger stages. The maximum sequence depth is an integer that ranges from 1 to 10. By default, the maximum sequence depth is 1. To capture the specified data by providing a set of trigger conditions in multiple stages, set the maximum sequence depth to a value greater than 1.

This setting is saved with the model as the `IPDataCaptureSequenceDepth` HDL block property for the DUT block.

- **Include capture condition logic in FPGA Data Capture:** Select this parameter to include capture condition logic in the IP core. Include capture condition logic to use a capture condition to control which data to capture from the FPGA. The IP core evaluates the capture condition at each clock cycle and captures only the data that satisfies the capture condition. For more information on capture conditions, see “Capture Conditions” (HDL Verifier).

Set up a capture condition in the **FPGA Data Capture** tool or the `hdlverifier.FPGADataReader` System object.

This setting is saved with the model as the `IncludeDataCaptureControlLogicEnable` HDL block property for the DUT block.

- When you select **Insert AXI Manager**, AXI4-Slave ID Width value is adjusted for the DUT IP core that HDL Coder generates. When you select **Insert AXI Manager** and add custom IPs, you must specify the new adjusted slave ID width value. For example, when you select **Insert AXI Manager** and add custom IPs, if you get this error message during the **Create Project** task:

```

2020.12.07.16:29:20 Info: system_soc.hps_0: HPS Main PLL counter settings: n = 0 m = 47
2020.12.07.16:29:20 Info: system_soc.hps_0: HPS peripheral PLL counter settings: n = 0 m = 39
2020.12.07.16:29:20 Info: system_soc.pll_0: The legal reference clock frequency is 5.0 MHz..650.0 MHz
2020.12.07.16:29:20 Info: system_soc.pll_0: Able to implement PLL with user settings
2020.12.07.16:29:20 Error: system_soc.i2c_ssm2603_0.s_axi: Width of slave ID signals (12) must be at least 13. Increase slave ID width or reduce ID widths for any connected AXI masters.
2020.12.07.16:29:20 Error: system_soc.i2s_ssm2603_0.s_axi: Width of slave ID signals (12) must be at least 13. Increase slave ID width or reduce ID widths for any connected AXI masters.

```

Regenerate the IP cores by setting the target platform as either Generic Intel or Generic Xilinx. Then map one of the DUT ports to the AXI4 interface, calculate the new width by using **New**

$\text{width} = \text{Base Width} + \log_2(\text{Number of AXI Masters} + 1)$, and enter the calculated width value in **AXI4 Slave ID width**. Add the regenerated IP cores with the new width values to the reference design folder. Right-click **Create Project** and select **Run to Selected Task**. In this example, the two custom IPs are I2C and I2s. The new calculated width is 13.

- **Generate IP core report:** Leave this option selected to generate HTML documentation for the IP core.
- **Enable readback on AXI4 slave write registers:** Select this option if you want to read back the value that is written to the AXI4 slave registers by using the AXI4 slave interface. When you run this task, the code generator adds a mux for each AXI4 register in the address decoder logic. This mux compares the address that the data is written to when reading the values. If you are reading from multiple AXI4 slave registers, the readback logic becomes a long mux chain that can affect synthesis frequency.

This setting is saved with the model as the `AXI4RegisterReadback` HDL block property for the DUT block.

- **Generate default AXI4 slave interface:** Leave this option selected if you want to generate an HDL IP core with the AXI4 slave interface for signals such as clock, reset, ready, timestamp, and so on. If you want to generate a generic HDL IP core without any AXI4 slave interfaces, clear this check box. Make sure that you do not map any of the DUT ports to AXI4 or AXI4-Lite interfaces. You can map the ports to only External or Internal IO interfaces or to AXI4-Stream interface with TLAST mapping.

This setting is saved with the model as the `GenerateDefaultAXI4Slave` HDL block property for the DUT block.

- **Expose DUT clock enable input port:** Select this option if you want to expose the DUT clock enable input port. Trigger the DUT from upstream IPs by using the clock enable input port. If your design has ports mapped to the AXI4 Slave interface, this option is disabled.
- **Expose DUT clock enable output port:** Select this option if you want to expose the clock enable output port to downstream IPs. Drive or synchronize downstream custom IPs by using the clock enable output port.
- **AXI4 slave port to pipeline register ratio:** Specify the number of AXI4 subordinate ports for which you want a pipeline register to be inserted by using the **AXI4 Slave port to pipeline register ratio** setting in the **Generate RTL Code and IP Core** task of the **IP Core Generation** workflow. To learn more, see “Model Design for AXI4 Slave Interface Generation” on page 47-3.

Values: 'off' (default) | 'on' '10' '20' '35' '50'

FPGA Synthesis and Analysis Overview

Create projects for supported FPGA synthesis tools, perform FPGA synthesis, mapping, and place/route tasks, and annotate critical paths in the original model.

Description

The tasks in the **FPGA Synthesis and Analysis** folder enable you to:

- Create FPGA synthesis projects for supported FPGA synthesis tools.
- Start supported FPGA synthesis tools, using the project files to perform synthesis, mapping, and place/route tasks.
- Annotate your original model with critical path information obtained from the synthesis tools.

For a list of supported third-party synthesis tools, see “Third-Party Synthesis Tools and Version Support”.

The tasks in the folder are:

- **Create Project**
- **Perform Synthesis and P/R**
- **Annotate Model with Synthesis Result**

See Also

“HDL Code Generation and FPGA Synthesis from Simulink Model”

Create Project

Create an FPGA synthesis project for a supported FPGA synthesis tool.

Description

This task creates a synthesis project for the selected synthesis tool and loads the project with the HDL code generated for your model.

When the project creation is complete, the HDL Workflow Advisor displays a link to the project in the right pane. Click this link to view the project in the synthesis tool project window.

Synthesis objective

Select a synthesis objective to generate tool-specific optimization Tcl commands for your project. If you specify **None**, no Tcl commands are generated.

See “Synthesis Objective to Tcl Command Mapping” on page 36-47.

Additional source files

Enter additional HDL source files that you want included in your synthesis project. Enter each file name manually, separated with a semicolon (;) or by using the **Add Source** button.

For example, you can include HDL source files (.vhd or .v) or a constraint file (.ucf or .sdc).

Additional project creation Tcl files

Enter additional project creation Tcl files that you want to include in your synthesis project. Enter each file name manually, separated with a semicolon (;) or by using the **Add Tcl** button.

For example, you can include a Tcl script (.tcl) to execute after creating the project.

See Also

- “HDL Code Generation and FPGA Synthesis from Simulink Model”
- “Synthesis Objective to Tcl Command Mapping” on page 36-47

Perform Synthesis and P/R Overview

Start supported FPGA synthesis tools to perform synthesis, mapping, and place/route tasks.

Description

The tasks in the **Perform Synthesis and P/R** folder enable you to start supported FPGA synthesis tool and:

- Synthesize the generated HDL code.
- Perform mapping and timing analysis.
- Perform place and route functions.

For a list of supported third-party synthesis tools, see “Third-Party Synthesis Tools and Version Support”.

See Also

“HDL Code Generation and FPGA Synthesis from Simulink Model”

Perform Logic Synthesis

Start supported FPGA synthesis tool and synthesize the generated HDL code.

Description

The **Perform Logic Synthesis** task:

- Starts the synthesis tool in the background.
- Opens the previously generated synthesis project, compiles HDL code, synthesizes the design, and emits netlists and related files.
- Displays a synthesis log in the **Result** subpane.

See Also

“HDL Code Generation and FPGA Synthesis from Simulink Model”

Perform Mapping

Starts supported FPGA synthesis tool and maps the synthesized logic design to the target FPGA.

Description

The **Perform Mapping** task:

- Starts the synthesis tool in the background.
- Runs a mapping process that maps the synthesized logic design to the target FPGA.
- Emits a circuit description file for use in the place and route phase.
- Emits pre-routing timing information for use in critical path analysis and back annotation of your source model.
- Displays a log in the **Result** subpane.

Enable **Skip pre-route timing analysis** if your tool does not support early timing estimation. When this option is enabled, the **Annotate Model with Synthesis Result** task sets **Critical path source** to **post-route**.

See Also

“HDL Code Generation and FPGA Synthesis from Simulink Model”

Perform Place and Route

Starts the synthesis tool in the background and runs a Place and Route process.

Description

The **Perform Place and Route** task:

- Starts the synthesis tool in the background.
- Runs a Place and Route process that takes the circuit description produced by the previous mapping process, and emits a circuit description suitable for programming an FPGA.
- Starts post-routing timing information for use in critical path analysis and back annotation of your source model.
- Displays a log in the **Result** subpane.

If you select **Skip this task**, the HDL Workflow Advisor executes the workflow, but omits the **Perform Place and Route** task, marking it Passed. If you prefer to do place and route work manually, you might want to select **Skip this task**.

If **Perform Place and Route** fails, but you want to use the post-mapping timing results to find critical paths in your model, you can select **Ignore place and route errors** and continue to the **Annotate Model with Synthesis Result** task.

See Also

“HDL Code Generation and FPGA Synthesis from Simulink Model”

Run Synthesis

Starts Xilinx Vivado and executes the Vivado **Synthesis** step.

If you do not want to do early timing estimation, enable **Skip pre-route timing analysis**.

Run Implementation

Starts Xilinx Vivado and executes the Vivado **Implementation** step.

If you select **Skip this task**, the HDL Workflow Advisor omits the **Run Implementation** task, marking it Passed. If you prefer to do place and route work manually, select **Skip this task**.

If **Run Implementation** fails, you can select **Ignore place and route errors** and continue to the **Annotate Model with Synthesis Result** task.

Check Timing Report

If there are timing failures during this task, the task does not fail. You must check the timing report for timing failures.

Annotate Model with Synthesis Result

Analyzes pre- or post-routing timing information and visually highlights critical paths in your model.

Description

The **Annotate Model with Synthesis Result** task helps you to identify critical paths in your model. Depending on your option selection, the task analyzes pre- or post-routing timing information produced by the **Perform Synthesis and P/R** task group and visually highlights one or more critical paths in your model.

Note If you select Intel Quartus Pro or Microchip Libero SoC as the **Synthesis tool**, the **Annotate Model with Synthesis Result** task is not available. Run the workflow to synthesis, and then view the timing reports to see the critical path.

If you select **Generate FPGA top level wrapper** in the **Generate RTL Code and Testbench** task, **Annotate Model with Synthesis Result** is not available. To perform back-annotation analysis, clear the check box for **Generate FPGA top level wrapper**.

Input Parameters

Critical path source

Select **pre-route** or **post-route**.

The **pre-route** option is unavailable when **Skip pre-route timing analysis** is enabled in the previous task group.

Critical path number

You can annotate up to three critical paths. Select the number of paths that you want to annotate.

Choose Model to Annotate

You can perform the annotation on the original as well as generated model. Select the **original** or **generated** model that you want to annotate. For more information on generated model, see “Generated Model and Validation Model” on page 28-10.

Show all paths

Show critical paths, including duplicate paths.

Show unique paths

Show only the first instance of a path that is duplicated.

Show delay data

Annotate the cumulative timing delay on each path.

Show ends only

Show the endpoints of each path, but omit the connecting signal lines.

Results and Recommended Actions

When the **Annotate Model with Synthesis Result** task runs to completion, HDL Coder displays the DUT with critical path information highlighted.

“HDL Code Generation and FPGA Synthesis from Simulink Model”

Download to Target Overview

The **Download to Target** folder supports the following tasks:

- **Generate Programming File:** Generate an FPGA programming file.
- **Program Target Device:** Download generated programming file to the target development board.
- **Generate Simulink Real-Time Interface** (for Speedgoat target devices only): Generate a model that contains a Simulink Real-Time interface subsystem.

For summary information on each **Download to Target** task, select the task icon, and then click the HDL Workflow Advisor **Help** button.

See Also

“Getting Started with the HDL Workflow Advisor” on page 36-6

Generate Programming File

The **Generate Programming File** task generates an FPGA programming file that is compatible with the selected target device.

Program Target Device

The **Program Target Device** task downloads the generated FPGA programming file to the selected target device.

Before executing the **Program Target Device** task, make sure that your host PC is properly connected to the target development board using the required programming cable.

Generate Simulink Real-Time Interface

The **Generate Simulink Real-Time Interface** task generates a model containing an interface subsystem that you can plug into a Simulink Real-Time model.

The naming convention for the generated model is:

```
gm_fpgamodelname_slrt
```

where `fpgamodelname` is the name of the original model.

Save and Restore HDL Workflow Advisor State

You can save the current settings of the HDL Workflow Advisor to a named restore point. Later, you can restore the same settings by loading the restore point data into the HDL Workflow Advisor.

See Also

“Getting Started with the HDL Workflow Advisor” on page 36-6.

FPGA-in-the-Loop (FIL) Implementation

Set FIL options and run FIL processing.

Set FPGA-in-the-Loop Options

Set connection type, board IP, and MAC addresses and select additional files, if required.

Connection

Select either JTAG (Altera boards only) or Ethernet.

Board IP Address

Set the IP address of the board if it is not the default IP address (192.168.0.2).

Board MAC Address

Under most circumstances, you do not need to change the Board MAC address. If you connect more than one FPGA development board to a single computer (for which you must have a separate NIC for each board), you must change the Board MAC address. You must change the Board MAC address for additional boards so that each address is unique.

Additional Source Files

Select additional source files for the HDL design that is to be verified on the FPGA board, if required. HDL Workflow Advisor attempts to identify the file type. Change the file type in the **File Type** column if it is incorrect.

Build FPGA-in-the-Loop

During the build process:

- FPGA-in-the-loop generates a FIL block named after the top-level module and places it in a new model.
- After new model generation, FIL opens a Command Prompt. In this Command Prompt, the FPGA design software performs synthesis, fit, place-and-route, timing analysis, and FPGA programming file generation. When the process is complete, a message in the Command Prompt prompts you to close the window.
- FPGA-in-the-loop builds a test bench model around the generated FIL block.

Embedded System Integration

Tasks in this folder integrate your generated HDL IP core into the embedded processor.

Create Project

Create project for embedded system tool.

In the message window, after the project is generated, you can click the project link to open the generated embedded system tool project.

Embedded system tool

Embedded design tool.

Project folder

Folder where your generated project files are saved.

Synthesis objective

Select a synthesis objective to generate tool-specific optimization Tcl commands for your project. If you specify **None**, no Tcl commands are generated.

To learn how the synthesis objectives map to Tcl commands, see “Synthesis Objective to Tcl Command Mapping” on page 36-47.

Enable IP caching

Create IP cache to reduce reference design synthesis time. When you enable IP caching, the code generator creates an IP cache. The **IP Core Generation** workflow uses an out-of-context (OOC) workflow. This workflow synthesizes the IP in the reference design out of context from the top-level design. You can reuse this cache in subsequent project runs, which reduces reference design synthesis time. To learn more, see “IP Caching for Faster Reference Design Synthesis” on page 46-37.

Generate Software Interface

To generate the embedded C code, generate a Simulink software interface model with the IP core driver blocks. To verify the IP core functionality and connect to the onboard memory locations, generate a host interface model, host interface script, or both with the AXI Manager.

When you clear the **Generate Simulink software interface model**, **Generate host interface model**, and **Generate host interface script** check boxes, the HDL Workflow Advisor skips this task.

Description

In the **Generate Software Interface** task, specify a software interface that you want to generate for the IP core.

- **Generate Simulink software interface model** — Select this parameter to generate a Simulink software interface model for an SoC device. The software interface model is your original model with the AXI driver blocks replacing the parts you want to run on hardware. This parameter is not available for standalone FPGA boards.

After you generate the Simulink software interface model, you can generate C code from it by using Embedded Coder. If you do not have the Embedded Coder hardware support package for the target board installed, this parameter is not available. For example, if the target hardware board is a Zynq device, you must have the Embedded Coder Support Package for Xilinx Zynq Platform installed.

- **Operating system** — Select your target operating system.
- **Host target interface** — Select an interface that communicates between your host machine and the target hardware. Use one of these options.
 - **JTAG AXI Manager (HDL Verifier)** — Use the JTAG interface to access AXI4 and AXI4-Lite registers on the target hardware. To enable this option, in the **Set Target Reference Design** task, set **Insert AXI Manager (HDL Verifier required)** to JTAG and in the **Set Target Interface** task, map each DUT signal that you want to capture to the AXI4 or AXI4-Lite interface.
 - **Ethernet AXI Manager (HDL Verifier)** — Use the Ethernet interface to access AXI4 and AXI4-Lite registers on the target hardware. To enable this option, in the **Set Target Reference Design** task, set **Insert AXI Manager (HDL Verifier required)** to Ethernet and in the **Set Target Interface** task, map each DUT signal that you want to capture to the AXI4 or AXI4-Lite interface.
 - **Ethernet** — Use the Ethernet interface to access the generated IP core deployed on your target hardware. This option is not available for standalone FPGA boards.
- **Generate host interface model** — Select this parameter to generate a host interface model. The host interface model enables you to write to or read from the memory-mapped locations on the target hardware over a JTAG or Ethernet cable by using the AXI Manager Write and AXI Manager Read blocks.

To enable this parameter, set **Host target interface** to JTAG AXI Manager (HDL Verifier) or Ethernet AXI Manager (HDL Verifier).

- **Generate host interface script** — Select this parameter to generate a host interface script. The host interface script contains commands that enable you to connect to the target hardware and to write to or read from the generated IP core by using the AXI driver blocks or the AXI Manager.

Build FPGA Bitstream

Generate bitstream for embedded system.

Run build process externally

Enable this option to run the build process in parallel with MATLAB. If this option is disabled, you cannot use MATLAB until the build is finished. This option is valid only when you use the IP Core Generation workflow.

Tcl file for synthesis build

To customize your synthesis build, save your custom Tcl commands in a file and select **Custom**. Enter the file path manually or find the path by using the **Browse** button. The contents of your custom Tcl file are inserted between the Tcl commands that open and close the project.

If you select **Custom** and want to generate a bitstream, the bitstream generation Tcl command must refer to the top file wrapper name and location either directly or implicitly. For example, the following Xilinx Vivado Tcl command generates a bitstream and implicitly refers to the top file name and location:

```
launch_runs impl_1 -to_step write_bitstream
```

Enable routed design checkpoint for build

Select this option to expedite bitstream generation time by using the design checkpoint from the previous build. This option is available only when using the Xilinx Vivado synthesis tool.

Routed design checkpoint file for build

To use this option, select **Enable routed design checkpoint for build**. To use the default routed design checkpoint file, select **Default**. The default file location is `hdl_prj\checkpoint\system_routed.dcp`. To use a custom routed design checkpoint file, select **Custom** and provide the file path to your custom file location. This option is available only when using the Xilinx Vivado synthesis tool.

Routed design checkpoint file

To use this option, select **Custom** for **Routed design checkpoint file for build**. Use this option to point to your custom routed design checkpoint file. After bitstream generation is completed the new routed checkpoint design file is written to the location specified in **Routed design checkpoint file**. This option is available only when using the Xilinx Vivado synthesis tool.

Maximum number of cores for build

Reduce bitstream generation times by using multiple logical cores of the PC. Use this option to choose the maximum number of PC cores to use. Selecting `synthesis tool default` selects the maximum number of cores set in the synthesis tool. To manually select the maximum number of cores, select between 2 and 32.

Program Target Device

Program the connected target SoC device. Specify the **Programming method** for the target device:

- **JTAG**: Uses a JTAG cable to program the target SoC device.
- **Download**: This is the default **Programming method**. Copies the generated FPGA bitstream, device tree, and system initialization scripts to the SD card on the Zynq board and keeps the

bitstream on the SD card persistently. To use this programming method, you do not need Embedded Coder. You can create an SSH object by specifying the **IP Address**, **SSH Username**, and **SSH Password**. HDL Coder uses the SSH object to copy the bitstream to the SD card and reprogram the board.

To define your own function to program the target device in your custom reference design, you can use the Custom **Programming method**. To use the custom programming, register the function handle of the custom programming function by using the `CallbackCustomProgrammingMethod` method of the `hdlcoder.ReferenceDesign` class. For example:

```
hRD.CallbackCustomProgrammingMethod = ...  
    @parameter_callback.callback_CustomProgrammingMethod;
```

For more information, see “Program Target FPGA Boards or SoC Devices” on page 46-57.

HDL Coder Checks in Model Advisor / HDL Code Advisor Overview

The **HDL Coder** checks in the Model Advisor or the HDL Code Advisor verify and update your Simulink model or subsystem for compatibility with HDL code generation. Running the checks produces a report that lists suboptimal conditions or settings, and then proposes better model configuration settings.

To learn about:

- HDL Code Advisor UI, see “Check HDL Compatibility of Simulink Model Using HDL Code Advisor” on page 45-2.
- Model Advisor, see “Run Model Advisor Checks for HDL Coder” on page 45-6.

The left pane displays folders that perform various checks:

- **Model configuration checks:** Prepare your model for compatibility with HDL code generation. This folder contains checks that verify whether model parameters are HDL-compatible, whether your design contains algebraic loops, and so on.
- **Checks for ports and subsystems:** Verify whether ports and subsystems in your model have settings that are compatible for HDL code generation. The checks include whether you have a valid top-level DUT Subsystem and whether you have specified an initial condition for Enabled Subsystem and Triggered Subsystem blocks.
- **Checks for blocks and block settings:** Verify whether blocks in your model are supported for HDL code generation, and whether the supported blocks have HDL-compatible settings. The checks include whether source blocks in your model have a continuous sample time and whether Stateflow Charts and MATLAB Function blocks have HDL-compatible settings, and so on.
- **Native Floating Point checks:** Verify whether the block is compatible for HDL code generation in **Native Floating Point** mode. The checks include whether the blocks in your Simulink model are supported for HDL code generation with **Native Floating Point**, and whether the model uses single data types, and so on. Native floating-point support in HDL Coder generates target-independent HDL code from your single-precision floating-point model. For more information, see “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116.
- **industry-standard checks:** Verify whether your Simulink model conforms to the industry-standard rules. Industry-standard rules recommend using certain HDL coding guidelines. When generating code, HDL Coder displays an HDL coding standard report that shows how well the generated code adheres to the industry-standard guidelines. For more information, see “HDL Coding Standards” on page 31-4.

To learn more about each individual check, right-click that check, and select **What's This?**.

See also “HDL Code Advisor Checks” on page 45-9.

Model configuration checks overview

Use the checks in this folder to prepare your model for compatibility with HDL code generation. This folder contains checks that verify whether:

- The model parameters and visualization settings are compatible with HDL code generation.
- Your model uses foreign characters that are incompatible with the current encoding.
- The global reset setting is asynchronous for Altera devices and synchronous for Xilinx devices.
- The `InlineConfigurations` setting is enabled on the model.
- The design contains algebraic loops.

Check for model parameters suited for HDL code generation

Check ID: com.mathworks.HDL.ModelChecker.runModelParamsChecks

Check ID: com.mathworks.HDL.ModelAdvisor.runModelParamsChecks

Check for model parameters set up for HDL code generation.

Description

This check verifies whether the model parameters that you specify are compatible for HDL code generation. This check ensures that you use these settings in the Configuration Parameters dialog box.

Command-Line Parameter Setting	Configuration Parameter Setting
Set Solver to FixedStepDiscrete.	Set Type to Fixed-step and Solver to Discrete (no continuous states).
Set FixedStep to auto.	Set Fixed-step size (fundamental sample time) to auto.
Set EnableMultiTasking to off.	Disable the Treat each discrete rate as a separate task check box.
Set AlgebraicLoopMsg to error	Set Algebraic loop to error.
Set SingleTaskRateTransMsg to error.	Set Single task data transfer to error.
Set MultiTaskRateTransMsg to error.	Set Multitask data transfer to error.
Set BlockReduction to off	Disable the Block Reduction check box.
Set ConditionallyExecuteInputs to off.	Disable Conditional input branch execution .
Set DefaultParameterBehaviour to Inlined. You can set this parameter at the command line by using set_param or hdlsetup.	Set Default parameter behavior to Inlined. If you want to set this parameter in the Configuration Parameters dialog box, you must have Simulink Coder. Note Enabling this parameter is the same as setting the InlineParams property to on. Setting InlineParams to off changes DefaultParameterBehavior value to Tunable.
Set DataTypeOverride to off.	No dialog box prompt.
Set ProdHWDeviceType to ASIC/FPGA->ASIC/FPGA.	Set Device vendor to ASIC/FPGA.
Set ShowLineDimensions and ShowPortDataTypes to on.	In the Debug tab, on the Information Overlays > Ports section, select Base data types .
Set SignalLoggingSaveFormat to Dataset.	No dialog box prompt.
Set UnconnectedInputMsg to error or warning.	Set Unconnected block input ports to error or warning.

Command-Line Parameter Setting	Configuration Parameter Setting
Set UnconnectedOutputMsg to error or warning.	Set Unconnected block output ports to error or warning.
Set UnconnectedLineMsg to error or warning.	Set Unconnected lines to error or warning.

If there are incompatible model parameters, HDL Coder displays a warning and lists the model parameters that have to be fixed.

Results and Recommended Actions

To fix this warning, click **Modify Settings**, and the code generator runs the `hdlsetup` command to set up the model parameters for HDL code generation. You can then rerun the check.

See Also

- `hdlsetup`
- “Create HDL-Compatible Simulink Model”

Check for global reset setting for Xilinx and Altera devices

Check ID: `com.mathworks.HDL.ModelChecker.runGlobalResetChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runGlobalResetChecks`

Check asynchronous reset setting for Altera devices and synchronous reset setting for Xilinx devices.

Description

This check verifies whether you use a global synchronous reset for a Xilinx device or a global asynchronous reset for an Altera device. You can improve the performance of your design by adhering to this recommended global reset setting depending on whether you target a Xilinx device or an Altera device.

Note If you do not specify a target device, this check passes successfully.

Results and Recommended Actions

To fix this warning, click **Modify Settings**, and the code generator updates the **Reset type** setting to Synchronous if you use a Xilinx device and Asynchronous if you use an Altera device. You can then rerun the check.

See Also

“Reset type” on page 21-8

Check inline configurations setting

Check ID: `com.mathworks.HDL.ModelChecker.runInlineConfigurationsChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runInlineConfigurationsChecks`

Check `InlineConfigurations` is enabled.

Description

This check verifies whether you have the `InlineConfigurations` property enabled. By default, this property is enabled, and HDL Coder includes VHDL configurations for the model inline with the rest of the VHDL code. If you disable this property, the code generator displays a warning.

Results and Recommended Actions

To fix this warning, click **Modify Settings**, and the code generator updates the `InlineConfigurations` setting to on.

Check algebraic loops

Check ID: `com.mathworks.HDL.ModelChecker.runAlgebraicLoopChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runAlgebraicLoopChecks`

Check model for algebraic loops.

Description

HDL Coder does not support code generation for models in which algebraic loop conditions exist. This check examines the model and fails the check if it detects an algebraic loop.

Results and Recommended Actions

To fix this warning, eliminate algebraic loops from your model and then run this check again.

See Also

“Algebraic Loop Concepts”

Check for visualization settings

Check ID: `com.mathworks.HDL.ModelChecker.runVisualizationChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runVisualizationChecks`

Check for display settings: port data types and sample time color coding.

Description

This check determines whether you have:

- Enabled the **Port Data Types** setting on the model.
- Set the **Sample Time** to **Colors** on the model.

This check displays a message if your Simulink model doesn't have either or both of these settings.

Results and Recommended Actions

Click **Modify Settings**, and the code generator:

- Enables the **Port Data Types** setting on the model.
- Sets the **Sample Time** to **Colors**.

You can then rerun the check.

See Also

- “Display Port Data Types”
- “View Sample Time Information”

Check delay balancing setting

Check ID: `com.mathworks.HDL.ModelChecker.runBalanceDelaysChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runBalanceDelaysChecks`

Check Balance Delays is enabled.

Description

This check reports a warning if the **Balance delays** setting is disabled on the model. When you generate HDL code, certain optimizations or block implementations can introduce delays along some signal paths in your model. If **Balance delays** is disabled, the code generator does not introduce equivalent delays on other parallel signal paths, which can result in a numerical mismatch between the original model and the generated model.

Results and Recommended Actions

To fix this warning, click **Modify Settings**, and the code generator enables the **Balance delays** setting on the model. You can then rerun the check.

See Also

- “Delay Balancing” on page 28-81
- “Balance delays” on page 19-4

Check for ports and subsystems overview

This folder contains checks that verify whether ports and subsystems in your model have settings that are compatible for HDL code generation. You can verify whether:

- The subsystem in your Simulink model is a valid top level subsystem.
- The initial condition of Enabled Subsystem or Triggered Subsystem blocks in your model is zero.

Check for invalid top level subsystem

Check ID: `com.mathworks.HDL.ModelChecker.runInvalidDUTChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runInvalidDUTChecks`

Check for subsystems that cannot be at the top level for HDL code generation.

Description

This check verifies whether your Subsystem is a valid DUT for generating HDL code. For example, if you use an invalid DUT, such as an Enabled Subsystem, For Each Subsystem or a BlackBox Subsystem, this check displays a warning and provides a link to the Subsystem.

Results and Recommended Actions

To fix this warning, place this Subsystem inside another Subsystem, and then use that Subsystem as the DUT. You can then rerun the check.

Check for blocks and block settings overview

These checks verify whether blocks in your model are supported for HDL code generation, and whether the supported blocks have HDL-compatible settings. You can verify whether:

- There are source blocks with infinite sample time in your model.
- The blocks in your Simulink model are compatible for HDL code generation.
- There are unconnected lines, input ports, or output ports in your model.
- There are unresolved or disabled library links.
- MATLAB Function and Stateflow Chart blocks in your model have HDL-compatible settings.
- There are Delay, Unit Delay, and Zero-Order Hold blocks in the model that perform rate transition and replace them with Rate Transition blocks.

Check for infinite and continuous sample time sources

Check ID: `com.mathworks.HDL.ModelChecker.runSampleTimeChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runSampleTimeChecks`

Check source blocks with infinite or continuous sample time.

Description

By default, the **Sample time** parameter of a Constant block is `inf`. During HDL code generation, HDL Coder does not resolve `inf` sample times of Constant blocks if the sample times propagate to the device under test (DUT) output. For more details, see the “HDL Code Generation” section of the Constant block page.

This check reports a warning if your design contains source blocks that have an infinite or continuous sample time.

Results and Recommended Actions

To fix this warning, click **Modify Settings** to update the **Sample time** of these source blocks to inherit through back propagation. That is, HDL Coder sets **Sample time** of these blocks to `-1`. You can then rerun the check.

See Also

- “What Is Sample Time?”
- “Usage of Rate Change and Constant Blocks” on page 25-93

Check for unsupported blocks

Check ID: `com.mathworks.HDL.ModelChecker.runBlockSupportChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runBlockSupportChecks`

Check for unsupported blocks for HDL code generation.

Description

This check displays a warning if your model uses blocks that are not supported for HDL code generation.

Results and Recommended Actions

To fix this warning, update your design to use blocks that are supported with HDL Coder. You can then rerun the check.

Check for large matrix operations

Check ID: `com.mathworks.HDL.ModelChecker.runMatrixSizesChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runMatrixSizesChecks`

Check for large matrix operations.

Description

This check displays a warning if your design contains:

- Signals with matrix types that have more than two dimensions. HDL code generation supports matrix types that have a maximum of two dimensions.
- Large matrix operations with Add, Sum, or Product blocks that result in a matrix output with more than ten elements. Synthesizing the generated HDL code from such a design can result in the utilization of large number of resources on the target FPGA. For more details, see the "HDL Code Generation" sections of the block reference pages.

Results and Recommended Actions

To fix this warning, update your design so that there are no matrix types with more than two dimensions and the result of a matrix operation does not produce an output with more than ten elements. To verify that the check passes, compile the design and rerun the check.

See Also

- Product
- "Signal and Data Type Support" on page 14-3

Check for MATLAB Function block settings

Check ID: `com.mathworks.HDL.ModelChecker.runMLFcnBlkChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runMLFcnBlkChecks`

Check HDL compatible settings for MATLAB Function blocks.

Description

This check displays a warning if your model uses MATLAB Function blocks that have settings not recommended for HDL code generation. The settings include checking whether the MATLAB Function block has:

- `fimath` settings defined as per `hdlfimath`. The `hdlfimath` function uses `fimath` settings that are compatible for HDL code generation.
- **Saturate on integer overflow** check box cleared.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator updates the MATLAB Function block settings to be compatible with HDL code generation.

See Also

“Design Guidelines for the MATLAB Function Block” on page 34-23

Check for Stateflow chart settings

Check ID: com.mathworks.HDL.ModelChecker.runStateflowChartSettingsChecks

Check ID: com.mathworks.HDL.ModelAdvisor.runStateflowChartSettingsChecks

Check HDL-compatible settings for Stateflow Chart blocks.

Description

This check displays a warning if your model uses Stateflow Chart blocks that have settings incompatible for HDL code generation. The check passes when you select these settings for the Stateflow charts:

- **Execute (enter) chart at initialization** property is selected.
- **Action Language** is set to MATLAB.
- **Support variable-size arrays** property is disabled.

For more information, see “Specify Properties for Stateflow Charts” (Stateflow).

Results and Recommended Actions

To fix this warning, click **Modify Settings**. The code generator updates the Stateflow Chart settings to be compatible with HDL code generation.

See Also

Chart

Check for obsolete Unit Delay Enabled/Resettable Blocks

Check ID: `com.mathworks.HDL.ModelChecker.runObsoleteDelaysChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runObsoleteDelaysChecks`

Check if the DUT contains obsolete Unit Delay Enabled/Resettable blocks

Description

This check displays a warning if the DUT Subsystem contains any of these blocks:

- Unit Delay Enabled
- Unit Delay Resettable
- Unit Delay Enabled Resettable

These blocks have been obsoleted. The code generator does not recommend usage of these blocks in your Simulink model.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator replaces these blocks with the corresponding synchronous counterparts:

- Unit Delay Enabled is replaced by Unit Delay Enabled Synchronous.
- Unit Delay Resettable is replaced by Unit Delay Resettable Synchronous.
- Unit Delay Enabled Resettable is replaced by Unit Delay Enabled Resettable Synchronous.

These blocks are recommended because they use the State Control block for synchronous simulation behavior and generate hardware-friendly HDL code. For more information, see “Synchronous Subsystem Behavior with the State Control Block” on page 32-72.

Check for blocks that have nonzero output latency

Check ID: `com.mathworks.HDL.ModelChecker.runNFPLatencyChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runNFPLatencyChecks`

Check for blocks that introduce latency in the generated code but do not simulate with latency in original model

Description

Native floating-point operators and certain fixed-point blocks introduce latency in the generated HDL code. This check detects blocks in your Simulink model that introduce latency in the generated HDL code when you use fixed point and floating-point types. If your model uses floating-point types, select **Use Floating Point**.

When you run the check, the **Result** subpane displays hyperlinks to the blocks that have a nonzero output latency, and the latency value. When you generate code, HDL Coder figures out this latency.

Results and Recommended Actions

By using the latency information reported in the **Result** subpane, you can add the corresponding number of delays adjacent to those blocks in your original model, and therefore simulate the original model with latency. The code generator absorbs the delays you added to your model, and does not have to introduce additional latency in the generated model.

For blocks with nonzero latency that are reported by this check, consider the effect this latency has in the validation model. In the generated model and validation model, you see the additional delays that the code generator adds to account for the latency.

“Latency Considerations with Native Floating Point” on page 14-109

Check for unsupported storage class for signal objects

Check ID: `com.mathworks.HDL.ModelChecker.runSignalObjectStorageClassChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runSignalObjectStorageClassChecks`

Check whether signal object storage class is 'ExportedGlobal' or 'ImportedExtern' or 'ImportedExternPointer'

Description

This check displays a warning if your model contains signals that have the signal object storage class set to 'ExportedGlobal', 'ImportedExtern', or 'ImportedExternPointer'. The warning message also provides links to those signals that have the signal object storage class set to one of these signal object storage class specifications.

HDL code generation ignores these storage class specifications that you specify in your design, which may sometimes result in conflicting signal names. When you simulate the validation model, HDL Coder may generate errors.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator replaces those signals that have the signal object storage class specified as `ExportedGlobal`, `ImportedExtern`, or `ImportedExternPointer` to `Auto`.

Check for HDL Reciprocal block usage

Check ID: `com.mathworks.HDL.ModelChecker.runHDLRecipChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runHDLRecipChecks`

Check if the model uses HDL Reciprocal blocks

Description

This check displays a warning if your Simulink model contains HDL Reciprocal blocks.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator replaces the HDL Reciprocal blocks with Math Reciprocal blocks.

See Also

HDL Reciprocal

Check for Trigonometric Function block for LUT-based approximation method

Check ID: `com.mathworks.HDL.ModelChecker.runUnsupportedLUTTrigFunChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runUnsupportedLUTTrigFunChecks`

Check Trigonometric Function blocks in a model that use the look up table (LUT) based approximation method

Description

This check displays a warning if your Simulink model contains Trigonometric Function blocks such as `sin`, `cos`, `sincos`, `atan2`, and `cos+jsin` that use the approximation method as `Lookup`.

This check requires Simulink and HDL Coder.

Results and Recommended Actions

To fix this warning for `sin`, `cos`, `sincos`, and `cos+jsin` blocks that have the LUT-based approximation method, use Sine HDL Optimized or Cosine HDL Optimized blocks instead.

Capabilities and Limitations

- Provides the list of the unsupported Trigonometric Function blocks that have the LUT-based approximation method in your Simulink model.
- HDL code generation is not supported for the `atan2` block in the LUT-based approximation method.

See Also

Sine HDL Optimized, Cosine HDL Optimized

Native Floating Point Checks Overview

These checks verify whether the model is compatible for HDL code generation in `Native Floating Point` mode. Native floating-point support in HDL Coder generates target-independent HDL code from your single-precision floating-point model. For more information, see “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116.

Use the checks in this folder to verify whether:

- You use the `Native Floating Point` mode when your design contains single data types.
- Your model uses double data types in `Native Floating Point` mode.
- Blocks in your model are supported for HDL code generation in `Native Floating Point` mode.
- Blocks in your model have a nonzero ulp error and a nonzero output latency.

Check for single datatypes in the model

Check ID: com.mathworks.HDL.ModelChecker.runNFPSuggestionChecks

Check ID: com.mathworks.HDL.ModelAdvisor.runNFPSuggestionChecks

Check for single data types in the model.

Description

This check detects whether your Simulink model uses single data types and displays a warning if **Use Floating Point** is not selected.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator selects **Use Floating Point**. You can then rerun the check.

See Also

“Getting Started with HDL Coder Native Floating-Point Support” on page 14-92

“Check for double data types in the model” on page 44-27

Check for double data types in the model

Check ID: `com.mathworks.HDL.ModelChecker.runDoubleDatatypeChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runDoubleDatatypeChecks`

Check for double data types in the model.

Description

This check detects whether your Simulink model uses double data types and displays a warning if **Use Floating Point** is not selected.

Results and Recommended Actions

To fix this warning, enable **Use Floating Point** configuration setting for your model. You can then rerun the check.

See Also

“Getting Started with HDL Coder Native Floating-Point Support” on page 14-92

“Check for single datatypes in the model” on page 44-26

Check for Data Type Conversion blocks with incompatible settings

Check ID: `com.mathworks.HDL.ModelChecker.runNFPDTCChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runNFPDTCChecks`

Check conversion mode of Data Type Conversion blocks.

Description

This check displays a warning when Data Type Conversion blocks in your model convert from a floating-point data type to a fixed-point data type or vice-versa, and has **Input and output to have equal** parameter set to `Stored Integer (SI)`.

HDL Coder does not support Data Type Conversion blocks that use the `Stored Integer (SI)` conversion mode and convert between floating point and fixed point data types. During this conversion, the `Stored Integer (SI)` mode does not preserve the underlying stored integer bits of the floating point input signal.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator replaces Data Type Conversion blocks in `Stored Integer (SI)` mode with Float Typecast blocks.

Using the Float Typecast block, you can access the stored integer bits of a floating point input signal when converting between floating point and fixed point data types. The block works similar to the `typecast` function.

“Getting Started with HDL Coder Native Floating-Point Support” on page 14-92

Check for HDL Reciprocal block usage

Check ID: `com.mathworks.HDL.ModelChecker.runNFPHDLRecipChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runNFPHDLRecipChecks`

Check HDL Reciprocal blocks are not using floating point types

Description

This check displays a warning if your Simulink model contains HDL Reciprocal blocks that use floating-point data types. HDL Reciprocal blocks with floating point data types can have potential numerical mismatches with the Simulink simulation results, and can use more resources on the target hardware.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator replaces the HDL Reciprocal blocks with Math Reciprocal blocks.

See Also

HDL Reciprocal

Check for Relational Operator block usage

Check ID: `com.mathworks.HDL.ModelChecker.runNFPrelopChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runNFPrelopChecks`

Check Relational Operator blocks which use floating point types have boolean outputs.

Description

This check displays a warning if your Simulink model contains Relational Operator blocks that compare floating-point data types and produce a nonboolean output. By default, the **Output data type** of the block is `boolean`. If you specify a nonboolean output, the block implementation after HDL code generation is not optimal, and can increase the resource usage on the target hardware device.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator changes the **Output data type** of the block to `boolean`.

See Also

Relational Operator

Check for unsupported blocks with Native Floating Point

Check ID: `com.mathworks.HDL.ModelChecker.runNFPSupportedBlocksChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runNFPSupportedBlocksChecks`

Check for unsupported blocks with Native Floating Point.

Description

This check displays a warning if your Simulink model contains blocks that use `single` data types, and are not supported for HDL code generation in the native floating-point mode.

Results and Recommended Actions

To fix this warning, make sure that your design uses blocks that are supported for HDL code generation with `Native Floating Point`.

See Also

“Simulink Blocks Supported by Using Native Floating Point” on page 14-142

Check blocks with nonzero ULP error

Check ID: `com.mathworks.HDL.ModelChecker.runNFPULPErrorChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runNFPULPErrorChecks`

Check for blocks that have nonzero ULP error with Native Floating Point.

Description

This check detects blocks in your Simulink model that have a nonzero ULP error in native floating-point mode. When you run the check, the **Result** subpane displays hyperlinks to the blocks that have nonzero ULP error, and the ULP values.

Results and Recommended Actions

To fix this warning, look for instances of blocks that have nonzero ULP error and specify a **Tolerance Value** by setting **Floating point tolerance check based on** the ULP error. You can then rerun the check.

Note Fixing warnings that are reported by this check does not guarantee that your Simulink model has a zero ULP error. Make sure that you verify the ULP of your design by using multiple methods, such as by generating HDL code and test benches.

Industry standard checks overview

These checks verify whether your Simulink model conforms to the industry-standard rules. Industry-standard rules recommend using certain HDL coding guidelines. When generating code, HDL Coder displays an HDL coding standard report that shows how well the generated code adheres to the industry-standard guidelines. For more information, see “HDL Coding Standards” on page 31-4

Use the checks in this folder to verify whether:

- Names in your design adhere to the standard naming conventions.
- Subsystem names, top-level subsystem and port names, and signal and port names have the recommended number of characters in length.
- The generated VHDL code from your design follows recommended guidelines. The guidelines recommend that the file name extension is `.vhd`, the architecture name is `rtl`, the package file postfix is `_pkg`, and that the generated code does not use generics at the top level.
- Clock settings adhere to the industry-standard guidelines, and whether clock, reset, and enable signals adhere to the naming conventions.

Check file extension

Check ID: com.mathworks.HDL.ModelChecker.runFileExtensionChecks

Check ID: com.mathworks.HDL.ModelAdvisor.runFileExtensionChecks

Check file extensions based on the target language.

Description

This check detects whether the file extension is:

- .vhd when you generate code with VHDL as the target language.
- .v when you generate code with Verilog as the target language.

This check corresponds to rule 1.A.A.1 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator updates the file name extension to .vhd.

See Also

Rule 1.A.A.1 of “Basic Coding Practices” on page 31-7.

Check naming conventions

Check ID: com.mathworks.HDL.ModelChecker.runNameConventionChecks

Check ID: com.mathworks.HDL.ModelAdvisor.runNameConventionChecks

Check standard keywords used by EDA tools.

Description

This check detects whether names in the design are adhering to the standard naming convention and not using names starting with VDD, VSS, and so on. This check corresponds to rule 1.A.A.4 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator updates the names by replacing the reserved keywords with `rsvd` to adhere to the industry-standard rule.

See Also

Rule 1.A.A.4 of “Basic Coding Practices” on page 31-7.

Check top-level subsystem/port names

Check ID: `com.mathworks.HDL.ModelChecker.runToplevelNameChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runToplevelNameChecks`

Check top-level module/entity and port names.

Description

This check verifies whether top-level module/entity and port names are of the same case and less than or equal to 16 characters in length. This check corresponds to rule 1.A.A.9 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator updates the top-level module/entity and port names to be of the same case and less than or equal to 16 characters. Names longer than 16 characters are truncated to fit within 16 characters in length.

See Also

Rule 1.A.A.9 of “Basic Coding Practices” on page 31-7.

Check module/entity names

Check ID: `com.mathworks.HDL.ModelChecker.runSubsystemNameChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runSubsystemNameChecks`

Check module/entity names.

Description

This check verifies whether subsystems in your model have names between 2 and 32 characters in length. This check corresponds to rule 1.A.B.1 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator updates the Subsystem names such that the module/entity and port names are between 2 and 32 characters.

See Also

Rule 1.A.B.1 of “Basic Coding Practices” on page 31-7.

Check signal and port names

Check ID: `com.mathworks.HDL.ModelChecker.runPortSignalNameChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runPortSignalNameChecks`

Check signal and port name lengths.

Description

This check verifies whether ports and signals from the blocks have names between 2 and 40 characters in length. This check corresponds to rule 1.A.C.3 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator updates the signal and port names to be between 2 and 40 characters in length.

See Also

Rule 1.A.C.3 of “Basic Coding Practices” on page 31-7.

Check package file names

Check ID: com.mathworks.HDL.ModelChecker.runPackageNameChecks

Check ID: com.mathworks.HDL.ModelAdvisor.runPackageNameChecks

Check file name containing packages.

Description

This check verifies whether the package file postfix is `_pac` when you generate code with VHDL as the target language. By default, the generated package file postfix is `_pkg`. This check corresponds to rule 1.A.D.1 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator updates the package file name to `_pac`.

See Also

Rule 1.A.D.1 of “Basic Coding Practices” on page 31-7.

Check generics

Check ID: `com.mathworks.HDL.ModelChecker.runGenericChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runGenericChecks`

Check generics at top level subsystem.

Description

This check verifies whether you have generics at the top-level subsystem. If your design uses mask parameters and has the `MaskParameterAsGeneric` setting enabled, then the top-level subsystem can have generics. This check corresponds to rule 1.A.D.9 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator disables the `MaskParameterAsGeneric` setting so that there are no generics at the top-level subsystem.

See Also

Rule 1.A.D.9 of “Basic Coding Practices” on page 31-7.

Check clock, reset, and enable signals

Check ID: `com.mathworks.HDL.ModelChecker.runClockResetEnableChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runClockResetEnableChecks`

Check naming convention for clock, reset, and enable signals.

Description

This check verifies whether clock, reset, and clock enable signals follow the recommended naming convention. Clock signal names must contain `clk` or `ck`, reset signal names must contain `rstx`, `resetx`, `rst_n`, `reset_n`, `rst_x`, or `reset_x`, and clock enable signal names must contain `en`. This check corresponds to rule 1.A.E.2 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator updates the clock, reset, and enable signals to adhere to the naming conventions.

See Also

Rule 1.A.E.2 of “Basic Coding Practices” on page 31-7.

Check architecture name

Check ID: `com.mathworks.HDL.ModelChecker.runArchitectureNameChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runArchitectureNameChecks`

Check VHDL architecture name in the generated HDL code.

Description

This check verifies whether the architecture name is `rtl` when you generate code with VHDL as the target language. This check corresponds to rule 1.A.F.1 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator updates the `VHDLArchitectureName` setting to `rtl` to adhere to the industry-standard rule.

See Also

Rule 1.A.F.1 of “Basic Coding Practices” on page 31-7.

Check entity and architecture

Check ID: com.mathworks.HDL.ModelChecker.runSplitEntityArchitectureChecks

Check ID: com.mathworks.HDL.ModelAdvisor.runSplitEntityArchitectureChecks

Check whether the VHDL entity and architecture are described in the same file.

Description

This check detects when you have the entity and architecture descriptions in separate files when you generate code with VHDL as the target language. The entity and architecture descriptions can be in separate files if you enable the `SplitEntityArch` setting. This check corresponds to rule 1.A.F.4 of the industry-standard rules.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator disables the `SplitEntityArch` setting so that the entity and architecture descriptions are in the same file.

See Also

Rule 1.A.F.4 of “Basic Coding Practices” on page 31-7.

Check clock settings

Check ID: `com.mathworks.HDL.ModelChecker.runClockChecks`

Check ID: `com.mathworks.HDL.ModelAdvisor.runClockChecks`

Check constraints on clock signals.

Description

This check detects multiple constraints on clock signals that correspond to these industry-standard rules:

- Rule 1.B.A.1: Design should have only a single clock and use only one edge of the clock. This rule may be violated if you have the `ClockInputs` property set to `Multiple`.
- Rule 1.D.C.6: Do not use flip-flops with inverted edges.
- Rule 1.D.D.2: One hierarchical level should have a single clock only. This rule can be violated if you set `ClockInputs` to `Multiple`, or your design uses trigger signals and enabling `TriggerAsClock` can result in clock signals at various levels in the hierarchy.

Results and Recommended Actions

To fix this warning, click **Modify Settings** and the code generator:

- Updates the `ClockInputs` property to `Single`.
- Disables the `TriggerAsClock` setting.

See Also

Rules 1.B.A.1, 1.D.C.6, and 1.D.D.2 of “Basic Coding Practices” on page 31-7.

Using the HDL Code Advisor

- “Check HDL Compatibility of Simulink Model Using HDL Code Advisor” on page 45-2
- “Run Model Advisor Checks for HDL Coder” on page 45-6
- “HDL Code Advisor Checks” on page 45-9

Check HDL Compatibility of Simulink Model Using HDL Code Advisor

In this section...

“Open the HDL Code Advisor” on page 45-2

“Run Checks In the HDL Code Advisor” on page 45-3

“Fix HDL Code Advisor Warnings or Failures” on page 45-3

“View and Save HDL Code Advisor Reports” on page 45-4

The HDL Code Advisor verifies and updates your Simulink model or subsystem for compatibility with HDL code generation. The Model Checker checks for model configuration settings, ports and subsystem settings, block settings, support for native floating point, and conformance to the industry-standard rules. The Code Advisor produces a report that lists suboptimal conditions or settings, and then proposes better model configuration settings.

The HDL Code Advisor has these caveats:

- If you reference one model in another by using a Model block, the HDL Code Advisor checks the model configurations or settings of the parent model. To check whether the referenced model is compatible with HDL code generation, open the HDL Code Advisor for the referenced model, and then run the checks.
- If you run the checks on masked library blocks in your Simulink model, the Code Advisor cannot verify whether the blocks inside the library blocks have HDL-compatible settings.
- When you apply Model Advisor checks to your model, it increases the likelihood that your model does not violate certain modeling standards or guidelines. However, it does not guarantee that the design is ready for HDL code generation. Make sure that you verify the design by using multiple methods for HDL code generation readiness.

Open the HDL Code Advisor

To open the HDL Code Advisor:

- From the UI, in the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select the DUT Subsystem and then click **HDL Code Advisor**.
- To run the checks for the Subsystem you want to analyze, right-click that Subsystem, and in the context menu, select **HDL Code > HDL Code Advisor**.
- At the command line, enter `hdlcodeadvisor('system')`. *system* is a handle or name of the model or subsystem that you want to check. For more information, see `hdlcodeadvisor`.

In the HDL Code Advisor, the left pane lists the folders in the hierarchy. Each folder represents a group or category of related checks. Expanding the folders shows available checks in each folder. From the left pane, you can select a folder or an individual check. The HDL Code Advisor displays information about the selected folder or check in the right pane. The content of the right pane depends on the selected folder or check. The right pane has a **Result** subpane that contains a display area for status messages and other task results.

To learn more about each individual check, right-click that check, and select **What's This?**.

Run Checks In the HDL Code Advisor

In the HDL Code Advisor window, you can run individual checks or a group of checks. To run a check, **Select** that check and then click **Run This Check**. For example, to run the **Check for safe model parameters**, select the check box, and then click **Run This Check**.

In the HDL Code Advisor window, you can run a group of checks within a folder.

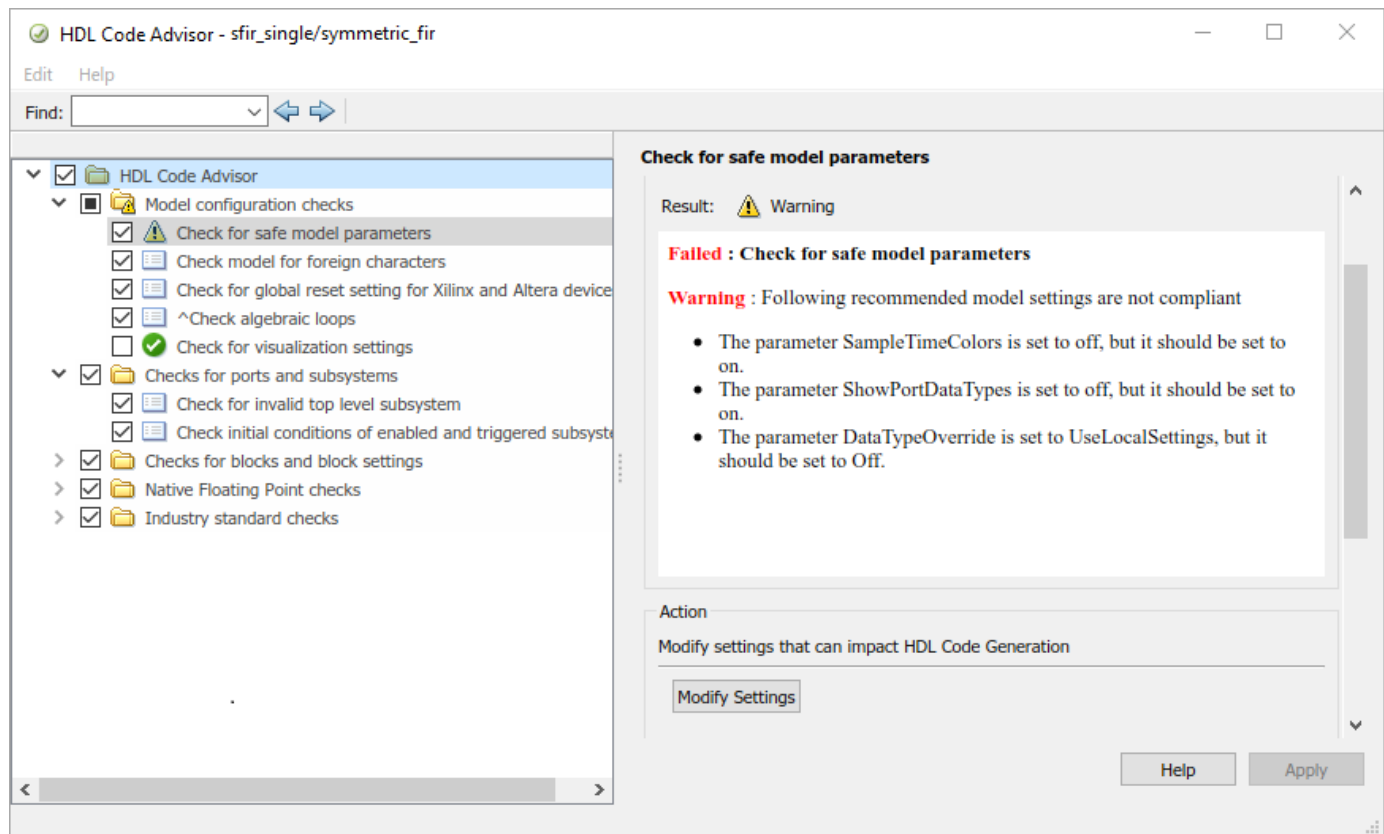

- 1 Select the checks that you want to run.
- 2 Select the folder that contains these checks and then click **Run Selected Checks**.

This example shows how to run selected checks in the **Model configuration checks** folder.

Fix HDL Code Advisor Warnings or Failures

In the HDL Code Advisor, if a check fails, the right pane shows the warning or failure information in a **Result** subpane. The **Result** subpane displays model settings that are not compliant. For some tasks, use the **Action** subpane to apply the Code Advisor recommended settings. This example displays the incorrect model settings that caused the **Check for safe model parameters** to fail.

To apply the corresponding model configuration settings that the code generator reported in the **Result** subpane, click the **Modify Settings** button. After you click **Modify Settings**, the **Result** subpane reports the changes that were applied. You can now run this check.

View and Save HDL Code Advisor Reports

When you run checks in the HDL Code Advisor, HDL Coder generates an HTML report of the check results. Each folder in the HDL Code Advisor contains a report for the checks within that folder and its subfolders. To access reports, select a folder such as **Model configuration checks**, and in the **Report** subpane, click **Save As**. If you rerun the HDL Code Advisor, the report is updated in the working folder, not in the save location.

This report shows typical results for a run of the **Model configuration checks** folder.

Model Advisor Report - **sfir_single.slx**

Simulink version: 9.0 **Model version: 1.82**

System: sfir_single/symmetric_fir **Current run: 08-Jun-2017 17:38:57**

Treat as Referenced Model: off

Run Summary

Pass	Fail	Warning	Not Run	Total
 3	 0	 0	 2	5

Model configuration checks

 **Check for safe model parameters**

Passed : Check for safe model parameters

 **Check model for foreign characters**

Check that the characters in the model can be represented in the current encoding.

Passed
All the characters in the model can be represented in the current encoding.

As you run the checks, the HDL Code Advisor updates the reports with the latest information for each check in the folder. When you run the checks at different times, timestamps appear at the top right of the report to indicate when checks have been run. Checks that occurred during previous runs have a timestamp following the check name. You can filter checks in the report such that tasks that are **Not Run** do not appear or show tasks that **Passed**, and so on. To view the report for a folder each time the tasks for the folder have been run, select **Show report after run**.

More About

- “HDL Code Advisor Checks” on page 45-9

Run Model Advisor Checks for HDL Coder

The Model Advisor checks a model or subsystem for conditions and configuration settings that can result in inaccurate or inefficient simulation. The Model Advisor produces a report that lists the suboptimal conditions or settings that it finds, and proposes better model configuration settings where possible. HDL Coder integrates the checks in the HDL Code Advisor with the Model Advisor.

Open the Model Advisor Checks

You can open the Model Advisor in either of these ways:

- In the **Modeling** tab, select **Model Advisor**. In the System Selector dialog box, select the model or Subsystem that you want to analyze, and click **OK**.
- To run the model advisor checks for the Subsystem that you want to analyze, right-click that Subsystem, and select **Model Advisor > Open Model Advisor**.
- At the command line, enter `modeladvisor('system')`. *system* is the name of the model or Subsystem that you want to analyze. For more information, see `modeladvisor`.

When you open the Model Advisor in Simulink, you see the checks in the **HDL Coder** subfolder of the **By Product** folder. Each subfolder in the **HDL Coder** folder represents a group or category of related checks. Expanding the folders display available checks in each folder. From the left pane, you can select a folder or an individual check. The Model Advisor displays information about the selected folder or check in the right pane. The content of the right pane depends on the selected folder or check. The right pane has a **Result** subpane that contains a display area for status messages and other task results.

To learn more about each individual check, right-click that check, and select **What's This?**.

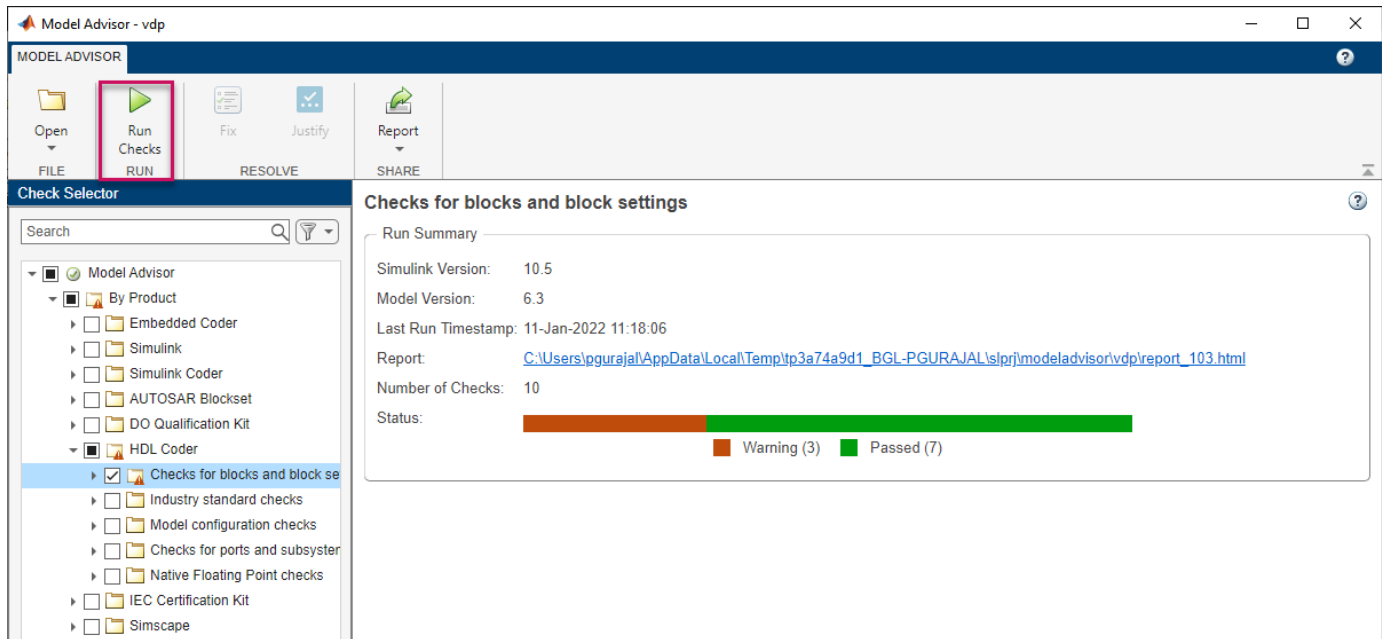

Run Checks in the Model Advisor

In the Model Advisor window, you can run individual checks or a group of checks. To run a check, **Select** that check, and then click **Run This Check**.

To run a group of checks within a folder:

- 1 Select the checks that you want to run.
- 2 Select the folder that contains these checks and then click **Run Checks**

For example, to run the checks in the **Checks for blocks and block settings** folder, select the folder, and then click **Run Checks**.

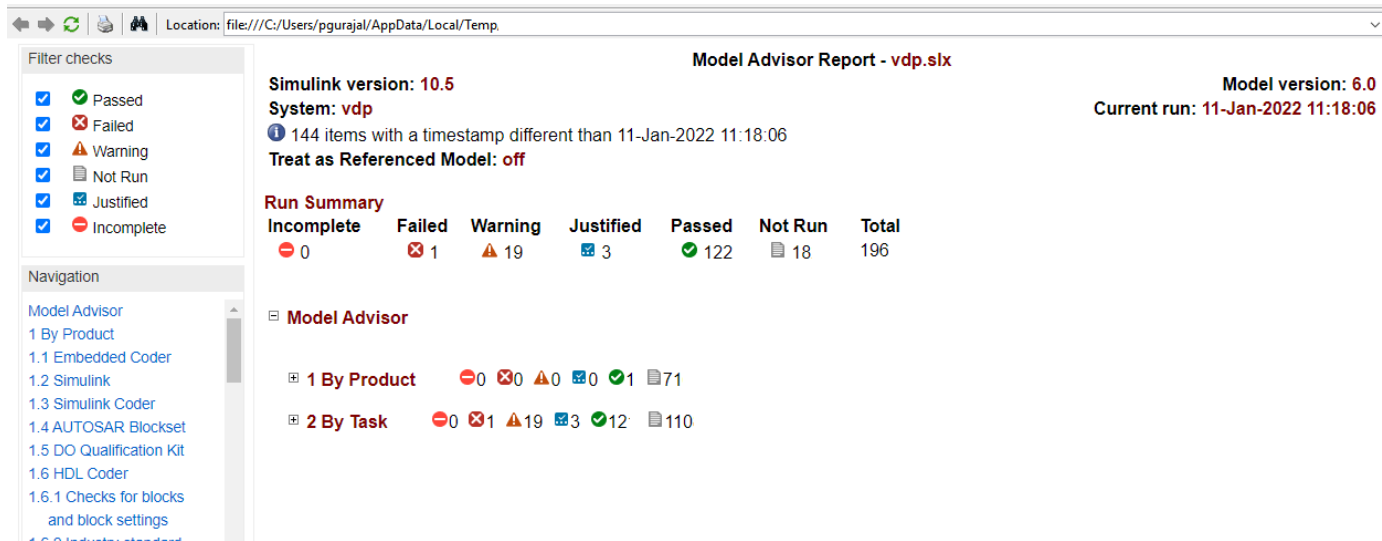

You can also right-click the folder **Checks for blocks and block settings**, and select **Run Selected Checks** in the Model Advisor.

Display Check Results in the Model Advisor Report

To display an HTML report of the check results, click **Report** from the toolbar. You can use the **Report** drop-down to change the report format to **PDF** or **WORD**.

This report shows typical results for a run of the **Checks for blocks and block settings** folder.

The report displays a run summary of the checks in the folder that you generated the report for. As you run the checks, the Model Advisor updates the reports with the latest information for each check in the folder. When you run the checks at different times, timestamps appear at the top right of the

report to indicate when checks have been run. Checks that occurred during previous runs have a timestamp following the check name. You can filter checks in the report to show checks that display a **Warning**, or show checks that **Passed**, and so on.

Fix Warnings or Failures

When a model or referenced model has a suboptimal condition, checks can fail. After you run a Model Advisor analysis,  indicates checks that have warnings. A warning result is informational. You can fix the reported issue or move on to the next task.

To fix warnings or failures, in the **Result** sub-pane, review the recommended actions to make changes to your model. When you fix a warning or failure, to verify that the check passes, re-run the check.

Some checks can use the **Fix** option from the toolstrip. Note that this option is available for selected checks that display violations with input parameters. This example displays the incorrect Reciprocal block settings that caused the check to display a warning.

When you select **Fix**, the **Action Report** window shows the changes that were applied. To verify that the check passes, rerun the check. If you use the Model Advisor dashboard, you see that the analysis is faster when you rerun the check because the Model Advisor does not reload the checks before executing them.

HDL Code Advisor Checks

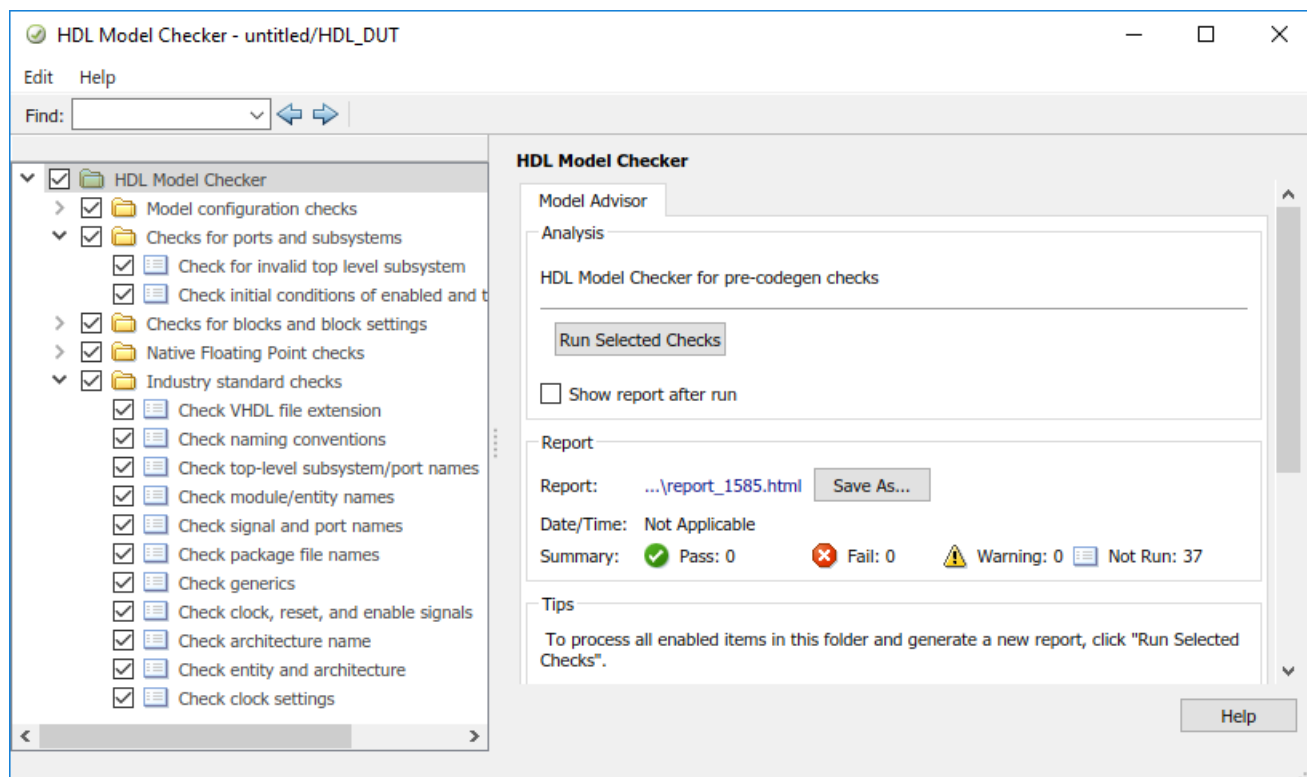

In this section...

- “Model configuration checks” on page 45-10
- “Checks for ports and subsystems” on page 45-10
- “Checks for blocks and block settings” on page 45-10
- “Native Floating Point checks” on page 45-11
- “industry standard checks” on page 45-12

The HDL Code Advisor and the Model Advisor checks in HDL Coder verify and update your Simulink model or subsystem for compatibility with HDL code generation. The Code Advisor has checks for:

- Model configuration settings
- Ports and Subsystem settings
- Blocks and block settings
- Native Floating Point support
- Industry standard guidelines

When you run a check, the Code Advisor displays the result as a pass or a failure. You can fix warnings or failures by using the Model Advisor recommended settings.

Model configuration checks

Use the checks in this folder to prepare your model for compatibility with HDL code generation. This folder contains checks that verify whether model parameters are HDL-compatible, whether your design contains algebraic loops, and so on.

Check Name	Description
"Check for model parameters suited for HDL code generation" on page 44-5	Check for model parameters set up for HDL code generation.
"Check for global reset setting for Xilinx and Altera devices" on page 44-7	Check asynchronous reset setting for Altera devices and synchronous reset setting for Xilinx devices.
"Check inline configurations setting" on page 44-8	Check whether you have <code>InlineConfigurations</code> enabled.
"Check algebraic loops" on page 44-9	Check model for algebraic loops.
"Check for visualization settings" on page 44-10	Check model for display settings: port data types and sample time color coding.
"Check delay balancing setting" on page 44-11	Check Balance Delays is enabled.

Checks for ports and subsystems

This folder contains checks that verify whether ports and subsystems in your model have settings that are compatible for HDL code generation. The checks include whether you have a valid top-level DUT Subsystem and whether you have specified an initial condition for Enabled Subsystem and Triggered Subsystem blocks.

Check Name	Description
"Check for invalid top level subsystem" on page 44-13	Check for subsystems that cannot be at the top level for HDL code generation.

Checks for blocks and block settings

These checks verify whether blocks in your model are supported for HDL code generation, and whether the supported blocks have HDL-compatible settings. The checks include whether source blocks in your model have a continuous sample time and whether Stateflow Charts and MATLAB Function blocks have HDL-compatible settings, and so on.

Check Name	Description
"Check for infinite and continuous sample time sources" on page 44-15	Check source blocks with continuous sample time.
"Check for unsupported blocks" on page 44-16	Check for unsupported blocks for HDL code generation.
"Check for large matrix operations" on page 44-17	Check for large matrix operations.
"Identify unconnected lines, input ports, and output ports"	Check for unconnected lines or ports.

Check Name	Description
"Identify disabled library links"	Search model for disabled library links.
"Identify unresolved library links"	Search the model for unresolved library links, where the specified library block cannot be found.
"Check for MATLAB Function block settings" on page 44-18	Check HDL compatible settings for MATLAB Function blocks.
"Check for Stateflow chart settings" on page 44-19	Check HDL compatible settings for Stateflow Chart blocks.
"Check Delay, Unit Delay and Zero-Order Hold blocks for rate transition"	Identify Delay, Unit Delay, or Zero-Order Hold blocks that are used for rate transition. Replace these blocks with actual Rate Transition blocks.
"Check for blocks that have nonzero output latency" on page 44-21	Check for blocks that have nonzero output latency with fixed point and native floating point.
"Check for unsupported storage class for signal objects" on page 44-22	Check whether signal object storage class is 'ExportedGlobal' or 'ImportedExtern' or 'ImportedExternPointer'.
"Check for Trigonometric Function block for LUT-based approximation method" on page 44-24	Check for Trigonometric Function blocks in a model that use the look up table (LUT) based approximation method.
"Check for HDL Reciprocal block usage" on page 44-23	Check if the model uses HDL Reciprocal blocks.

Note If you use the Model Advisor, you see the "Identify unconnected lines, input ports, and output ports", "Identify disabled library links", "Identify unresolved library links", and "Check Delay, Unit Delay and Zero-Order Hold blocks for rate transition" in the **Simulink** folder.

Native Floating Point checks

These checks verify whether the model is compatible for HDL code generation in **Native Floating Point** mode. The checks include whether the blocks in your Simulink model are supported for HDL code generation with **Native Floating Point**, and whether the model uses single data types, and so on. Native floating-point support in HDL Coder generates target-independent HDL code from your single-precision floating-point model. For more information, see "Generate Target-Independent HDL Code with Native Floating-Point" on page 14-116.

Check Name	Description
"Check for single datatypes in the model" on page 44-26	Check for single data types in the model.
"Check for double data types in the model" on page 44-27	Check for double data types in the model.
"Check for Data Type Conversion blocks with incompatible settings" on page 44-28	Check conversion mode of Data Type Conversion blocks.
"Check for HDL Reciprocal block usage" on page 44-29	Check HDL Reciprocal blocks are not using floating point types.

Check Name	Description
“Check for Relational Operator block usage” on page 44-30	Check Relational Operator blocks which use floating point types have boolean outputs.
“Check for unsupported blocks with Native Floating Point” on page 44-31	Check for unsupported blocks with native floating-point.
“Check blocks with nonzero ULP error” on page 44-32	Check for blocks that have nonzero ulp error with native floating-point.

industry standard checks

These checks verify whether your Simulink model conforms to the industry-standard rules. industry-standard rules recommend using certain HDL coding guidelines. When generating code, HDL Coder displays an HDL coding standard report that shows how well the generated code adheres to the industry-standard guidelines.

Check Name	Description
“Check file extension” on page 44-34	Check file extensions of VHDL files containing entities.
“Check naming conventions” on page 44-35	Check standard keywords used by EDA tools.
“Check top-level subsystem/port names” on page 44-36	Check top-level module/entity and port names.
“Check module/entity names” on page 44-37	Check module/entity names.
“Check signal and port names” on page 44-38	Check signal and port name lengths.
“Check package file names” on page 44-39	Check file name containing packages.
“Check generics” on page 44-40	Check generics at top-level subsystem.
“Check clock, reset, and enable signals” on page 44-41	Check naming convention for clock, reset, and enable signals.
“Check architecture name” on page 44-42	Check VHDL architecture name in the generated HDL code.
“Check entity and architecture” on page 44-43	Check whether the VHDL entity and architecture are described in the same file.
“Check clock settings” on page 44-44	Check constraints on clock signals.

Targeting FPGA & SoC Hardware Overview

Target an FPGA or SoC device by following the steps that design and deploy your algorithm specifically on hardware. You start with a Simulink model or MATLAB function, choose a hardware platform to target, and follow the Hardware-Software Co-Design workflow. Explore the best ways to partition and deploy your design by iterating through these steps.

Choose your target platform. After modeling your design in Simulink or as a MATLAB function, decide what target platform you want to deploy your design to. Consider:

- Which type of device do you want to target: standalone FPGA, SoC device, or a platform that has a separate FPGA and processor?

Device Type	Recommended Workflow
Standalone FPGA	If you are deploying only to an FPGA, use only the first part of the Hardware-Software Co-Design Workflow: Prototype and Deploy HDL Algorithm for FPGA.
SoC Device	To deploy a model to an SoC device, you need to partition the design to contain a hardware portion for the FPGA, and an embedded software portion for the processor, referred to as a hardware-software model. The FPGA requires a bitstream to alter its physical connections, the hardware part of the model, and the processor requires a new set of instructions in the form of an executable, the software part of the model.
Simulink Real-Time FPGA I/O Modules	This type of platform refers to a Speedgoat target machine, which acts as a processor, and an FPGA IO module. You can program both the FPGA and processor using the targeting FPGA & SoC hardware steps. For more information, see "IP Core Generation Workflow for Speedgoat Simulink-Programmable I/O Modules" on page 47-125.

- What stage of development are you in: rapid prototyping or production?
 - For rapid prototyping, save development time by selecting a pre-existing target device that HDL Coder supports. You can then immediately get started using the Hardware-Software Co-Design workflow. See "HDL Coder Supported Hardware".
 - For production, or rapid prototyping with an unsupported device, create a custom hardware platform first, and then follow the Hardware-Software Co-Design workflow. See "Create Custom Hardware Platform" on page 46-6.

Hardware-Software Co-Design

The Hardware-Software Co-Design workflow is broken into two stages:

- Prototype and Deploy HDL Algorithm for an FPGA

Prepare your model for deployment on target hardware. HDL Coder generates an IP core and bitstream containing the generated HDL Code from your design to deploy to the FPGA of your device. You can then run and verify that the IP core is working on your target hardware. This stage can be used to target a standalone FPGA device, an SoC device, or platform that has a separate FPGA and processor.

- Deploy C Algorithm for Processor

Configure the hardware-software interface by configuring the connection between the FPGA and processor generating C code for your processor.

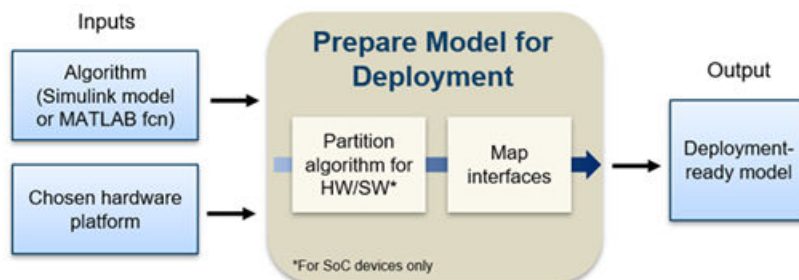

Deploy your design that has been partitioned into hardware and embedded software components to run on a platform containing an FPGA and an embedded processor, such as an SoC device. The design consists of the DUT algorithm for which you generate an IP core and a bitstream containing your HDL code, and software components for which you generate embedded code to run on the processor. You use the generated software interface model and IP core that includes hardware interface components, such as AXI interfaces, to interface between the hardware and software components.

Prototype and Deploy HDL Algorithm for an FPGA

Prepare Model for Deployment

For the model and design of your algorithm to be deployable on your target device, these are the high-level tasks:

- 1 Partition your design for hardware and software components of your target hardware, if you are using a platform containing a processor and an FPGA, such as an SoC device. You can partition your design to generate the hardware that targets the FPGA and the software that runs on the embedded processor.
- 2 Map the inputs and outputs of your model to hardware interfaces, such as AXI4 interfaces, push buttons, and LEDs. The generated design can then communicate with the rest of the hardware system when it is deployed. For more information, see “Target Platform Interfaces” on page 46-16.

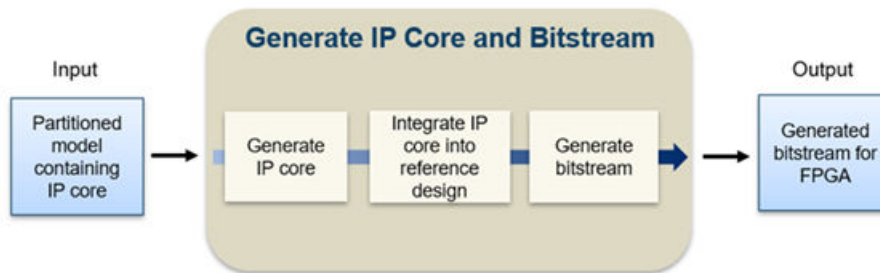

For an example on preparing a model for deployment, see “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

Generate IP Core and Bitstream

Once your design is prepared for deployment, you can use the HDL Workflow Advisor to:

- Generate a generic board-independent Xilinx or Intel HDL IP core. The IP core is a shareable and reusable HDL component that implements a specific function, typically an algorithm. An IP core consists of IP core definition files, HDL code generated for your algorithm, a C header file containing the register address map, and the IP core report. For an example, see “Generate Board-Independent HDL IP Core from Simulink Model” on page 46-26.
- Integrate the IP core into a reference design to target standalone FPGA boards or SoC platforms by using Xilinx Vivado IP integrator or Intel Qsys. The reference design contains elements that the Intel or Xilinx software requires to deploy your design to the SoC platform, except for the custom IP core and embedded software that you generate from the hardware-software model. The reference design acts a platform to build your algorithm on top of and abstracts your hardware platform so you can focus on your algorithm development. Once you have completed your algorithm development, HDL Coder enables you to package the algorithm as an IP core and fit it into the reference design.
- Generate a bitstream that contains your IP core for deployment on your target FPGA.

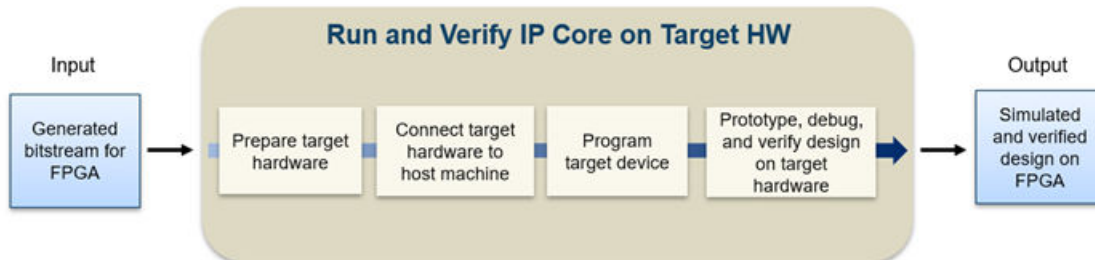

For an example on generating an IP core and bitstream, see “Generate IP Core from MATLAB for Blinking LED on FPGA Board” on page 46-174.

Run and Verify IP Core on Target Hardware

Run and verify the generated bitstream from your IP core design on your target hardware:

- 1 Prepare your target hardware by connecting it to the host machine. If you are using a platform containing an FPGA and processor, such as an SoC device, download a Linux image for the processor. For more information, see “Guided SD Card Setup” (HDL Coder Support Package for Xilinx Zynq Platform) for Xilinx Zynq Platforms or “Guided SD Card Setup” (HDL Coder Support Package for Intel SoC Devices) for Intel SoC Devices.
- 2 Establish a JTAG or Ethernet connection from your host machine to the target hardware.
- 3 Program your target device.
- 4 Prototype, debug, and verify your design on your target hardware by using one of these prototyping approaches:
 - FPGA I/O. You can use the host interface model or host interface script generated by the HDL Workflow Advisor to communicate between your host PC, running MATLAB and Simulink, and the generated IP core deployed on your FPGA.
 - AXI Manager

- FPGA Data Capture
- FPGA-in-the-Loop (FIL)
- Software Interface Model Generation, see “Configure Software Interface to FPGA”.

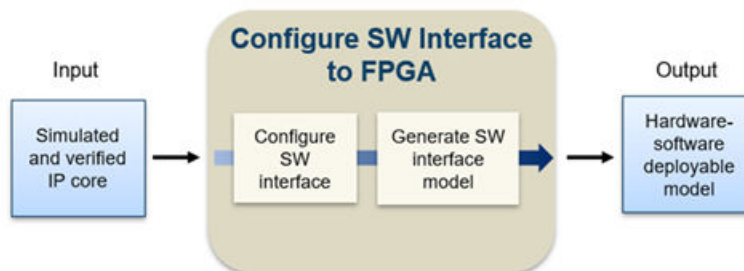

For an example, see “Prototype FPGA Design on Hardware with Live Data by Using MATLAB Commands” on page 46-234.

Deploy C Algorithm for Processor

Configure Software Interface to FPGA

To target a complete hardware-software system, HDL Workflow Advisor generates a software interface model from your original Simulink model. The software interface model can be used for deployment to the on-board processor of your target platform. This model contains properly configured device drivers for the processor on-board your SoC device or target platform. If you are targeting an SoC device, this model is the second model required for the hardware-software design. The first model is the original model with your HDL algorithm to target the on-board FPGA. This software interface model targets your processor and communicates between the software deployed to the processor and the generated IP core deployed to the FPGA.

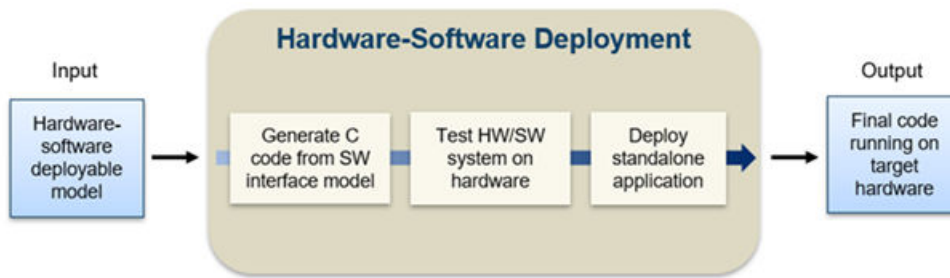

For more information, see “Generate Software Interface Model to Probe and Rapidly Prototype HDL IP Core” on page 46-68.

Hardware-Software Deployment

Generate C code (requires Embedded Coder) from your software interface model and use external mode or processor-in-the-loop (PIL) mode to deploy and run your hardware-software model on target hardware. The deployable design for your SoC device consists of:

- A generated bitstream from your original model containing your HDL IP core.
- A software interface model containing configured device drivers to allow communication between your processor and FPGA and C code generation for embedded processor.

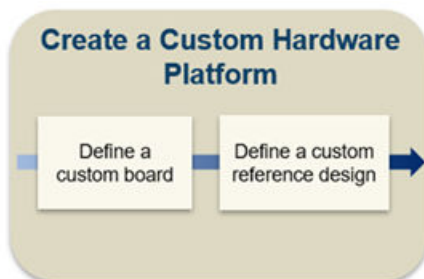

The deployment of your complete partitioned design into generated C code for the processor, from the software interface model, and a bitstream for the on-board FPGA, from your original model containing your IP core, enables you to run your algorithm on board an SoC or a Simulink Real-Time target machine that has FPGA I/O boards.

For an example, see “Debug a Zynq Design Using HDL Coder and Embedded Coder” on page 47-324.

Create Custom Hardware Platform

If there are no platforms already available for your hardware, you can define a custom hardware platform to use with the Hardware-Software Codesign workflow. A custom hardware platform creates flexibility to define your hardware system and deploy your design. For example, you can define a custom platform when deploying to production hardware. Creating a hardware platform consists of creating a new board definition to describe your hardware and creating one or more new reference designs for your board. You can also create new reference designs for an existing board.

A reference design provides a level of abstraction between your algorithmic IP core and the hardware board, making it easier and more efficient to design an algorithm to deploy on hardware. The reference design acts as the layer between your algorithm and the hardware platform, which you can use to leverage resources within your hardware without having to model these specific hardware resources in your design. You can focus on your algorithm design without implementing low-level details of the hardware. You can also retarget your algorithm to different hardware. For example, you can retarget your algorithm design when you transition from an evaluation board used for prototyping to production hardware.

For more information, see “Board and Reference Design Registration System” on page 47-68.

- “HDL Coder Supported Hardware”

Hardware-Software Co-Design Workflow for SoC Platforms

The HDL Coder hardware-software co-design workflow helps automate the deployment of your MATLAB and Simulink design to a Zynq-7000 platform or Intel SoC platform. You can explore the best ways to partition and deploy your design by iterating through the following workflow.

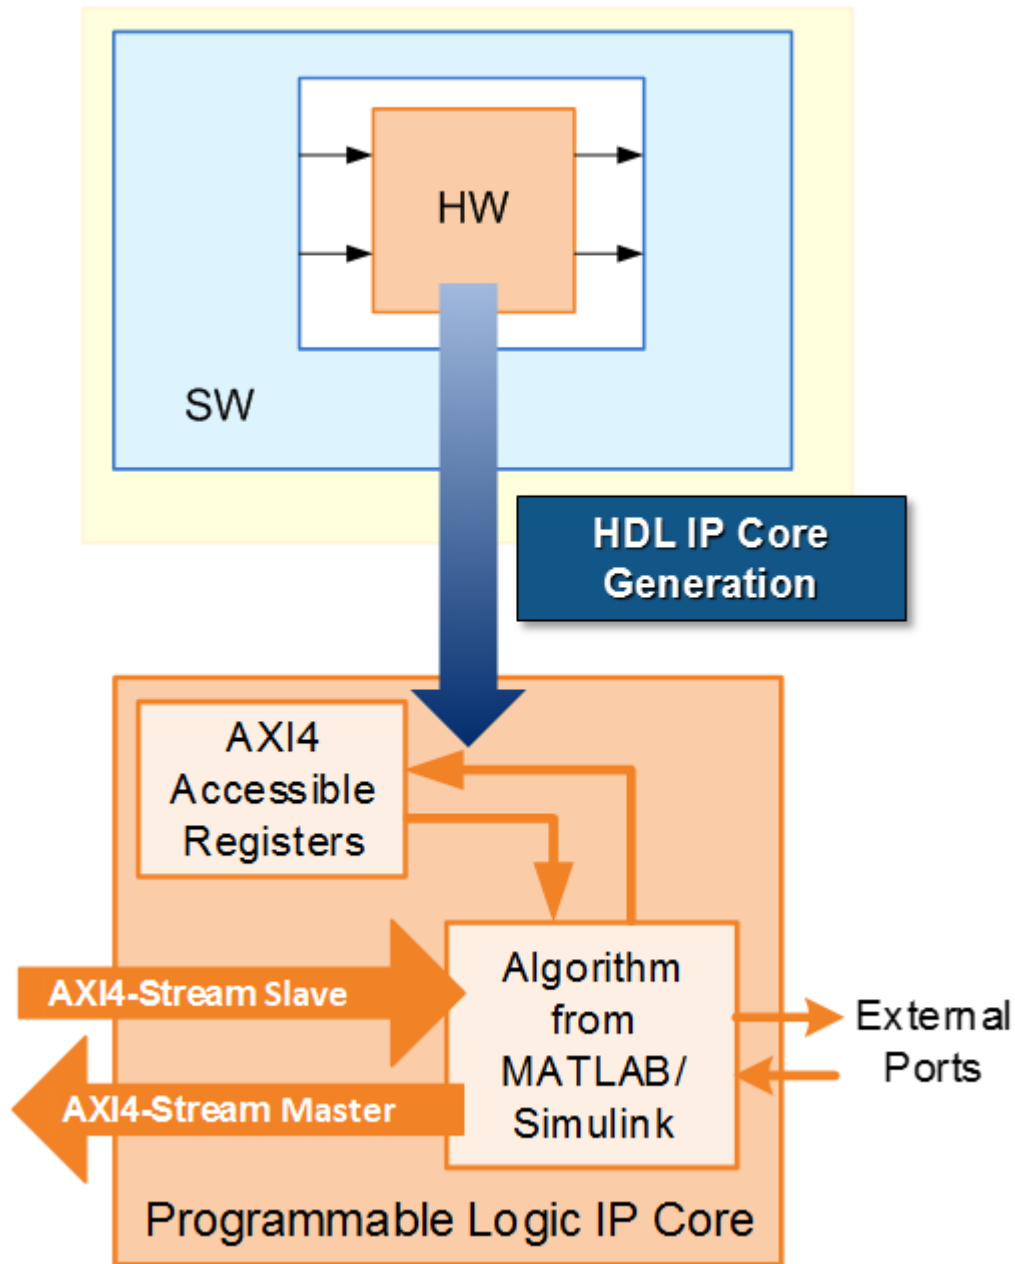

- 1 *MATLAB and Simulink Algorithm and System Design:* You begin by implementing your design in MATLAB or Simulink. When the design behavior meets your requirements, decide how to partition your design: which parts you want to run in hardware, and which parts you want to run in embedded software.

The part of the design that you want to run in hardware must use MATLAB syntax or Simulink blocks that are supported and configured for HDL code generation. See:

- “MATLAB Algorithm Design”
 - “Model and Architecture Design”
- 2** *HDL IP Core Generation*: Enclose the hardware part of your design in an atomic Subsystem block or MATLAB function, and use the HDL Workflow Advisor to define and generate an HDL IP core.

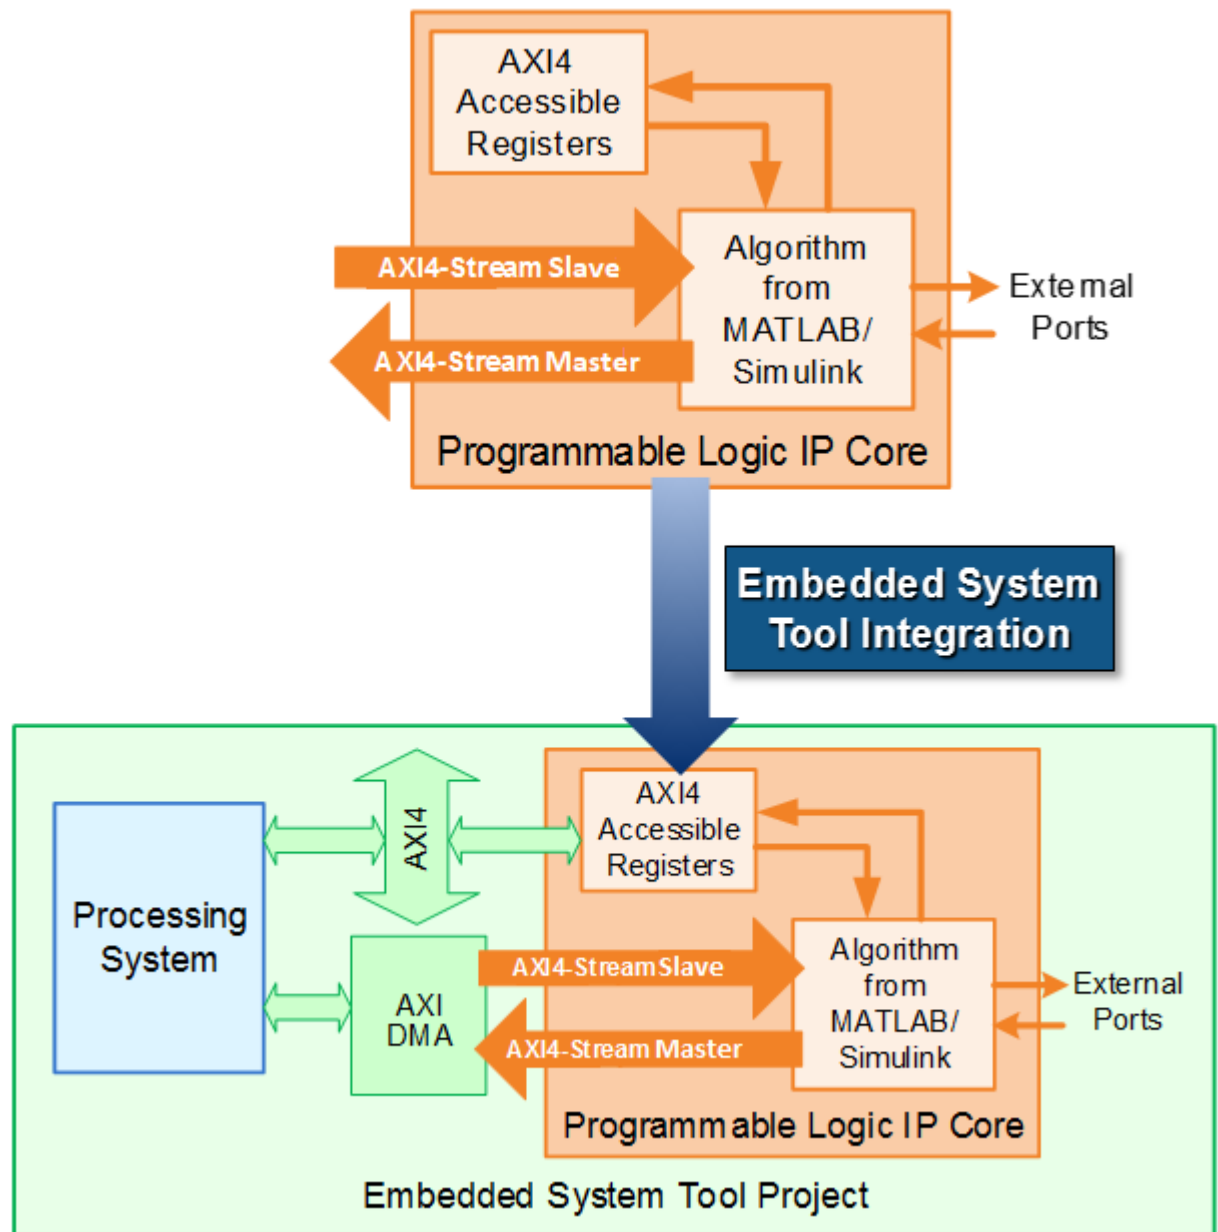

The following diagram shows a design that has been partitioned into a hardware part, in orange, and software part, in blue. HDL IP core generation creates an IP core from the hardware part of the model. The IP core includes hardware interface components such as AXI4 accessible registers, AXI4 or AXI4-Lite interfaces, AXI4-Stream or AXI4-Stream Video interfaces, AXI4 Master interfaces, and external ports.

- 3 *Embedded System Tool Integration:* As part of the HDL Workflow Advisor IP core generation workflow, you insert your generated IP core into a *reference design*, and generate an FPGA bitstream for the SoC hardware.

The *reference design* is a predefined embedded system integration project. It contains all elements the Intel or Xilinx software needs to deploy your design to the SoC platform, except for the custom IP core and embedded software that you generate.

The following diagram illustrates the relationship between the reference design, in green, and the generated IP core, in orange.

- 4 *SW Interface Generation* (requires a Simulink license and Embedded Coder license): In the HDL Workflow Advisor, after you generate the IP core and insert it into the reference design, you can optionally generate a software interface model, host interface model, and host interface script. The software interface model is your original model with AXI driver blocks replacing the hardware part. The host interface model enables you to write to or read from the memory-mapped locations on the target hardware over a JTAG or Ethernet cable by using the AXI Manager Write and AXI Manager Read blocks. The host interface script is a MATLAB file that is generated based on the reference design and Target platform interface table settings. It contains commands that enable you to connect to the target hardware, and to write to or read from the generated IP core by using the AXI driver blocks or the AXI Manager.

If you have an Embedded Coder license, you can automatically generate the software interface model and host interface script, generate embedded code from it, and build and run the executable on the Linux kernel on the ARM® processor. The generated embedded software includes AXI driver code generated from the AXI driver blocks that controls the HDL IP core.

If you do not have an Embedded Coder license or Simulink license, you can write the embedded software and manually build it for the ARM processor. See “Generate Host Interface Script to Probe and Rapidly Prototype HDL IP Core” on page 46-61

The following diagram shows the difference between the original model and the software interface model.

- 5 *SoC Platform and External Mode PIL*: Using the HDL Workflow Advisor, you program your FPGA bitstream to the SoC platform. You can then run the software interface model in external mode, or processor-in-the-loop (PIL) mode, to test your deployed design.

If your deployed design does not meet your design requirements, you can repeat the workflow with a modified model, or a different hardware-software partition.

Speedgoat FPGA Support with HDL Workflow Advisor

Use Simulink Real-Time and HDL Coder to implement Simulink algorithms and configure I/O functionality on Speedgoat Simulink-Programmable I/O modules. For an example that shows the development workflow for FPGA I/O modules, see “FPGA Programming and Configuration on Speedgoat Simulink-Programmable I/O Modules” on page 47-92.

When you open the HDL Workflow Advisor in HDL Coder and run the Simulink Real-Time FPGA I/O workflow, you generate a Simulink Real-Time interface subsystem. The subsystem mask controls the block parameters. Do not edit the parameters directly. The FPGA I/O board block descriptions are for informational purposes only.

Speedgoat Simulink-Programmable I/O Module Support

Speedgoat Simulink-Programmable I/O modules are part of Speedgoat target computer systems. To run the Simulink Real-Time FPGA I/O workflow, install the Speedgoat I/O Blockset and the Speedgoat HDL Coder Integration Packages. You can then choose the **Target platform** and run the workflow to generate a Simulink Real-Time interface subsystem. To see the documentation for the integration packages, enter this command at the MATLAB command prompt.

```
speedgoat.hdlc.doc
```

To learn about	See links
The integration packages and how you can install them.	See Speedgoat - HDL Coder Integration Packages.
Speedgoat I/O modules that are supported with the HDL Workflow Advisor.	See Speedgoat Real-Time FPGA Application Support from HDL Coder.
Applications and use cases	See Common Use Cases and Applications.
Supported interfaces for various types of I/O connectivity and protocols as well as fundamental functionality such as PCIe read/write and DMA.	See Supported Interfaces.
Provided examples for all supported I/O modules and functionality	See Speedgoat I/O Examples.

Prepare for FPGA Workflow

To work with FPGAs in the Simulink Real-Time environment, install:

- HDL Coder and Simulink Real-Time.
- Xilinx design tools with specific tool and version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”. You must also set up the path to the tool by using the `hdlsetuptoolpath` function.
- Speedgoat I/O Blockset and the Speedgoat HDL Coder Integration Packages.
- Speedgoat FPGA I/O module in the Speedgoat target machine.

You can use the workflow in HDL Coder to generate HDL code for your FPGA target device.

Custom IP Core Generation

In this section...

- “Custom IP Core Architectures” on page 46-16
- “Target Platform Interfaces” on page 46-16
- “Processor and FPGA Synchronization” on page 46-17
- “Custom IP Core Generated Files” on page 46-17
- “Restrictions” on page 46-18

Using the HDL Workflow Advisor, you can generate a custom IP core from a model or algorithm. The generated IP core is sharable and reusable. You can integrate it with a larger design by adding it in an embedded system integration environment, such as Intel Qsys, Xilinx EDK, or Xilinx IP Integrator.

To learn how to generate a custom IP core, see:

- “Generate Board-Independent HDL IP Core from Simulink Model” on page 46-26
- “Generate Board-Independent IP Core from MATLAB Algorithm” on page 5-37

Custom IP Core Architectures

You can generate an IP core:

- With an AXI4 or AXI4-Lite interface.

- With an AXI4 or AXI4-Lite interface and AXI4-Stream Video interfaces.

- Without any AXI4 or AXI4-Lite interfaces. To learn more, see “Generate Board-Independent HDL IP Core from Simulink Model” on page 46-26.

The Algorithm from MATLAB and Simulink block represents your DUT. HDL Coder generates the rest of the IP core based on your target platform interface settings and processor or FPGA synchronization mode.

Target Platform Interfaces

You can map each port in your DUT to one of these target platform interfaces in the IP core:

- AXI4-Lite: Use this interface to access control registers or for lightweight data transfer. HDL Coder generates memory-mapped registers and allocates address offsets for the ports.

- **AXI4:** Use this interface to connect to components that support burst data transmission. HDL Coder generates memory-mapped registers and allocates address offsets for the ports. In the generated HDL IP core, you can have either AXI4 or AXI4-Lite interface but not both interfaces.
- **AXI4-Stream Video:** Use this interface to send or receive a 32-bit scalar video data stream.
- **External ports:** Use external ports to connect to FPGA external IO pins or to other IP cores with external ports.
- **FPGA Data Capture:** Use FPGA Data Capture over the JTAG or Ethernet interface to observe test point signals and signals at the DUT output ports while your design runs on the FPGA. For an example of marking internal signals as test points, see “Debug IP Core Using FPGA Data Capture” on page 47-329. For more information on capturing data, see “Data Capture Workflow” (HDL Verifier).

Note To use this interface, you must download a hardware support package for your FPGA board. See “Download FPGA Board Support Package” (HDL Verifier).

To learn more about the AXI4, AXI4-Lite, and AXI4-Stream Video protocols, refer to your target hardware documentation.

Processor and FPGA Synchronization

HDL Coder generates synchronization logic in the IP core based on the processor and FPGA synchronization mode that you choose.

When generating a custom IP core, these processor and FPGA synchronization options are available:

- Free running (default)
- Coprocessing – blocking

To learn more, see “Processor and FPGA Synchronization” on page 46-31.

Custom IP Core Generated Files

After you generate a custom IP core, the IP core files are in the `ipcore` folder within your project folder. In the HDL Workflow Advisor, you can view the IP core folder name in the **IP core folder** field of the **HDL Code Generation > Generate RTL Code and IP Core** task.

The IP core folder contains:

- IP core definition files.
- HDL source files (`.vhd` or `.v`).
- A C header file with the register address map.
- (Optional) An HTML report with instructions for using the core and integrating the IP core in your embedded system project.
- When you use the multicycle path constraints to meet the timing requirements, HDL Coder generates the constraints file of XDC format (`.xdc`) for Xilinx workflow and SDC format (`.sdc`) for Intel workflow.

Restrictions

The IP Core Generation workflow does not support :

- **RAM Architecture** set to Generic RAM without clock enable.
- Using different clocks for the IP core and the AXI interface. The `IPCore_Clk` and `AXILite_ACLK` must be synchronous and connected to the same clock source. The `IPCore_RESETN` and `AXILite_ARESETN` must be connected to the same reset source. See “Synchronization of Global Reset Signal to IP Core Clock Domain” on page 46-33.

Custom IP Core Report

In this section...

“Summary” on page 46-19
 “Target Interface Configuration” on page 46-19
 “Register Address Mapping” on page 46-20
 “Bit Packing Order” on page 46-21
 “IP Core User Guide” on page 46-22
 “IP Core File List” on page 46-25

You generate an HTML custom IP core report by default when you generate a custom IP core. The report describes the behavior and contents of the generated custom IP core.

Summary

The Summary section shows your coder settings when you generated the custom IP core.

The following figure is an example of a Summary section.

Summary

IP core name	DUT_ip
IP core version	1.0
IP core folder	hdl_prj\ipcore\DUT_ip_v1_0
Target platform	Arrow SoCKit development board
Target tool	Altera QUARTUS II
Target language	Verilog
Reference Design	Default system
Model	axi4_vec
Model version	1.91
HDL Coder version	3.10
IP core generated on	10-Dec-2016 21:06:26
IP core generated for	DUT

Target Interface Configuration

The Target Interface Configuration section shows how your DUT ports map to the target hardware interface and the processor/FPGA synchronization mode.

The following figure is an example of a Target Interface Configuration section.

Target Interface Configuration

You chose the following target interface configuration for [axi4_vec](#) :

Processor/FPGA synchronization mode: **Free running**

Target platform interface table:

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
In1	Inport	uint8 (3)	AXI4	x"100"
In2	Inport	uint16 (100)	AXI4	x"200"
In3	Inport	single	AXI4	x"114"
In4	Inport	uint32	AXI4	x"118"
Out1	Outport	uint8 (3)	AXI4	x"160"
Out2	Outport	uint16 (100)	AXI4	x"A00"
Out3	Outport	single	AXI4	x"11C"
Out4	Outport	uint32	AXI4	x"120"

To learn more about processor/FPGA synchronization modes, see “Processor and FPGA Synchronization” on page 46-31.

To learn more about target platform interfaces, see “Custom IP Core Generation” on page 46-16.

Register Address Mapping

The Register Address Mapping section shows the address offsets for AXI4-Lite bus accessible registers in your custom IP core, and the name of the C header file that contains the same address offsets.

The following figure is an example of a Register Address Mapping section.

Register Address Mapping

The following AXI4 bus accessible registers were generated for this IP core:

Register Name	Address Offset	Description
IPCore_Reset	0x0	write 0x1 to bit 0 to reset IP core
IPCore_Enable	0x4	enabled (by default) when bit 0 is 0x1
In1_Data	0x100	data register for Inport In1, vector with 3 elements, address ends at 0x108
In1_Strobe	0x110	strobe register for port In1
In3_Data	0x114	data register for Inport In3
In4_Data	0x118	data register for Inport In4
Out3_Data	0x11C	data register for Outputport Out3
Out4_Data	0x120	data register for Outputport Out4
Out1_Data	0x160	data register for Outputport Out1, vector with 3 elements, address ends at 0x168
Out1_Strobe	0x170	strobe register for port Out1
In2_Data	0x200	data register for Inport In2, vector with 100 elements, address ends at 0x38C
In2_Strobe	0x400	strobe register for port In2
Out2_Data	0xA00	data register for Outputport Out2, vector with 100 elements, address ends at 0xB8C
Out2_Strobe	0xC00	strobe register for port Out2

The register address mapping is also in the following C header file for you to use when programming the processor:

[include\DUT_ip_addr.h](#)

The IP core name is appended to the register names to avoid name conflicts.

Bit Packing Order

The Bit Packing Order section gives a high-level overview of the data packing order for vector inputs and outputs for Internal IO, External IO, and External port interfaces. This section only appears when the port width for Internal IO, External IO, and External ports are set to greater than 128 bits wide.

This image is an example of the Bit packing Order section:

Bit Packing Order

Following is the general representation of data packing order and data unpacking order for Vector Input and output cases for Internal IO, External IO and External port interfaces. If it is assumed that an interface is mapped to one input(or output) port of the model which has a port width of 128 and port dimension of 4, then:

Following is the bit packing order to the DUT IP for Input vector case.

Following is the bit unpacking order from the DUT IP for Vector Output case.

It should be noted that the above instances are just for demonstration purpose and may not represent the actual mapped port width and port dimension.

IP Core User Guide

The IP Core User Guide section gives a high-level overview of the system architecture, describes the processor and FPGA synchronization mode, and gives instructions for integrating the IP core in your embedded system integration environment.

The following figure is an example of an IP Core User Guide system architecture description.

Theory of Operation

This IP core is designed to be connected to an embedded processor with an **AXI4-Lite bus**. The processor acts as bus master, and the IP core acts as slave. By accessing the generated registers via the AXI4-Lite bus, the processor can control the IP core, and read and write data from and to the IP core.

For example, to reset the IP core, write 0x1 to the bit 0 of IPCore_Reset register. To enable or disable the IP core, write 0x1 or 0x0 to the IPCore_Enable register. To access the data ports of the MATLAB/Simulink algorithm, read or write to the associated data registers.

This IP core also support the **External Port** interface. To connect the external ports to the FPGA external IO pins, add FPGA pin assignment constraints in the Xilinx EDK environment.

The following figure is an example of a processor/FPGA synchronization description.

Processor/FPGA Synchronization

The **Free running** mode means there is no explicit synchronization between embedded processor software execution (SW) and the IP core (HW). SW and HW runs independently. The data written from the processor to IP core takes effect immediately, and the data read from the IP core is the latest data available on the IP core output ports.

If you use vector data signals at the DUT interface, the IP core report displays this section that shows how the code generator synchronizes vector data across the AXI4 interface.

Vector Data Read/Write with Strobe Synchronization

All the elements of vector data are treated as synchronous to the IP core algorithm logic. Additional strobe registers added for each vector input and output port maintain this synchronization across multiple sequential AXI4 reads/writes. For input ports, the strobe register controls the enables on a set of shadow registers, allowing the IP core logic to see all the updated vector elements simultaneously. For output ports, the strobe register controls the synchronous capturing of vector data to be read.

To read a vector data port, first write the strobe address with 0x1, then read each desired data element from corresponding address range. To write a vector data port, first write each desired data element, then write 0x1 to the strobe address to complete the transaction.

The following figure is an example of instructions for integrating the IP core into your embedded system integration environment on the Xilinx platform. If you are targeting an Altera platform, the report displays similar instructions for integrating the IP core into the Altera Qsys environment.

EDK Environment Integration

This IP Core is generated for the Xilinx EDK environment. The following steps are an example showing how to add the IP core into the EDK environment:

1. Copy the IP core folder into the "pcores" folder in your Xilinx Platform Studio (XPS) project. This step adds the IP core into the XPS project user library.
2. In the XPS project, find the IP core in the user library and add the IP core to the design.
3. Connect the S_AXI port of the IP core to the embedded processor's AXI master port.
4. Connect the clock and reset ports of the IP core to the global clock and reset signals.
5. Assign a base address for the IP core.
6. Connect external ports and add FPGA pin assignment constraints.
7. Generate FPGA bitstream and download the bitstream to target device.

IP Core File List

The IP Core File List section lists the files and file folders that comprise your custom IP core.

The following figure is an example of an IP core file list.

IP Core File List

The IP core folder is located at:

[hdl_prj\ipcore\hdlcoder_led_blinking_led_counter_pcore_v1_00_a](#)

Following files are generated under this folder:

IP core definition files

[data\hdlcoder_led_blinking_led_counter_pcore_v2_1_0.mpd](#)

[data\hdlcoder_led_blinking_led_counter_pcore_v2_1_0.pao](#)

IP core report

[doc\hdlcoder_led_blinking_ip_core_report.html](#)

IP core HDL source files

[hdl\vhdl\led_counter_pkg.vhd](#)

[hdl\vhdl\led_counter.vhd](#)

[hdl\vhdl\hdlcoder_led_blinking_led_counter_pcore_dut.vhd](#)

[hdl\vhdl\hdlcoder_led_blinking_led_counter_pcore_axi_lite_module.vhd](#)

Generate Board-Independent HDL IP Core from Simulink Model

In this section...

“Generate Board-Independent IP Core” on page 46-26

“Generate Tool-Independent IP Core” on page 46-28

“IP Core Without AXI4 Slave Interfaces” on page 46-29

“Requirements and Limitations for IP Core Generation” on page 46-29

When you open the HDL Workflow Advisor and run the IP Core Generation workflow for your Simulink model, you can specify a generic Xilinx platform, a generic Intel platform, generic Microchip platform or generic platform. The workflow then generates a generic IP core that you can integrate into any target platform of your choice. For IP core integration, define and register a custom reference design for your target board by using the `hdlcoder.ReferenceDesign` class. To learn more, see:

- “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231
- “Define Custom Board and Reference Design for Intel SoC Workflow” on page 47-249
- “Define Custom Board and Reference Design for Microchip Workflow” on page 47-263

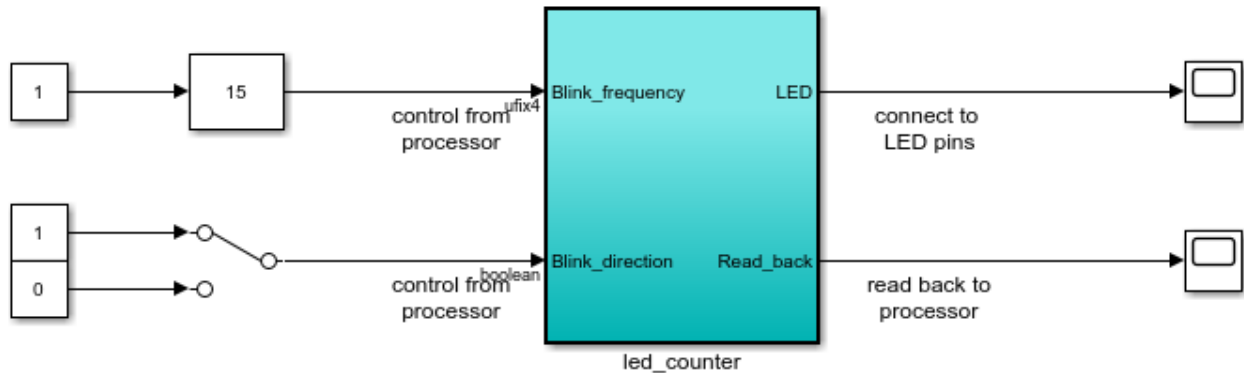

Generate Board-Independent IP Core

To generate a board-independent custom IP core to use in an embedded system integration environment, such as Intel Qsys, Xilinx EDK, or Xilinx IP Integrator:

- 1 Select DUT in Simulink model and open the HDL Workflow Advisor. For example, open the model `hdlcoder_led_blinking`.

```
open_system('hdlcoder_led_blinking')
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2012 The MathWorks, Inc.

- Set the path to the installed synthesis tool for the target device by using the `hdlsetuptoolpath` function. For example, if Xilinx Vivado is the synthesis tool, use the command:

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath',...
    'C:\Xilinx\Vivado\2020.2\bin\vivado.bat');
```

See “HDL Language Support and Supported Third-Party Tools and Hardware” for latest supported version of the synthesis tool.

- Open the HDL Workflow Advisor for the DUT Subsystem. For the LED blinking model, the `led_counter` Subsystem is the DUT. In the **Set Target > Set Target Device and Synthesis Tool** task:
 - For **Target workflow**, select IP Core Generation.
 - For **Target platform**, depending on the synthesis tool and device that you are targeting, select Generic Altera Platform or Generic Xilinx Platform. Click **Run This Task**.
- In the **Set Target > Set Target Interface** task, select a **Target Platform Interface** for each port, and then click **Apply**. You can map each DUT port to one of these interfaces: AXI4-Lite, AXI4, AXI4-Stream, AXI4-Stream Video, External Port, or FPGA Data Capture. For more information about these interfaces, see “Target Platform Interfaces” on page 46-16.

You can also map the ports to multiple target platform interfaces. To learn more, see “Generate HDL IP Core with Multiple AXI4-Stream and AXI4 Master Interfaces” on page 47-30.

If you do not want to map the DUT ports to AXI4 slave interfaces, you can map them to External Port interfaces.

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
Blink_frequency	Inport	ufix4	External Port ▼	
Blink_direction	Inport	boolean	External Port ▼	
LED	Outport	uint8	External Port ▼	
Read_back	Outport	uint8	External Port ▼	

- 5 Expand the **Set Code Generation Options** task. Right-click the **Set Optimization Options** task and select **Run to Selected Task**.
- 6 In the **HDL Code Generation > Generate RTL Code and IP Core** task, you can specify:
 - Whether you want to connect the DUT IP core to multiple AXI Master interfaces. By default, the **AXI4 Slave ID Width** value is 12, which enables you to connect the HDL IP core to one AXI Master interface. To connect the DUT IP core to multiple AXI Master interfaces, you may want to increase the **AXI4 Slave ID Width**. When you run this task, this setting is saved on the DUT as the HDL block property **AXI4SlaveIDWidth**.

To learn more, see “Define Multiple AXI Master Interfaces in Reference Designs to Access DUT AXI4 Slave Interface” on page 46-53.

- Whether you want to generate the default AXI4 slave interface. By default, HDL Coder generates AXI4 slave interfaces for signals such as clock, reset, ready, timestamp, and so on. If you do not want to generate any AXI4 slave interfaces, clear the **Generate default AXI4 slave interface** check box.

Note If you mapped any of the DUT ports to AXI4 slave interfaces in the **Set Target Interface** task, the code generator maps the ports to AXI4 slave interfaces, whether or not the **Generate default AXI4 slave interface** check box is cleared.

Click **Run This Task**. When you clear the check box and run the task, the code generator saves this setting on the DUT Subsystem as the HDL block property **GenerateDefaultAXI4Slave**.

- 7 After running the task, HDL Coder generates the IP core files in the output folder shown the **IP core folder** field, including the HTML documentation. To view the IP core report, click the link in the message window.

Generate Tool-Independent IP Core

Using **Generic Platform**, you can generate IP core and RTL code without setting the third-party synthesis tool. To generate IP core using **Generic Platform**, follow these steps:

- 1 In step **1.1 Set Target Device and Synthesis Tool**, set **Target workflow** to **IP Core Generation**. Then, set the **Target platform** to **Generic Platform**. Synthesis tool and target device information are not required when you set this target platform.
- 2 In step **1.2. Set Target Interface**, set **Target Platform Interfaces** for the input and output ports. You can choose AXI4 as well as external port as the target interface for the ports.
- 3 Perform all the tasks in the HDL Workflow Advisor until step **3.1. Set HDL Options**.

- 4 In step **3.2. Generate RTL Code and IP Core**, run this task to generate RTL code and IP core for your model. The generated code can be integrated on the hardware.

IP Core Without AXI4 Slave Interfaces

When you run the IP Core Generation workflow, you can also generate an HDL IP core without any AXI4 slave interfaces in your reference design.

To run this workflow, open the HDL Workflow Advisor, specify `Generic Xilinx Platform` or `Generic Altera Platform` as the target platform, and map the DUT ports to only External Port, or AXI4-Stream interface with TLAST mapping. In addition, when you generate the HDL IP core, in the **Generate RTL Code and IP Core** task, clear the **Generate default AXI4 slave interface** check box, and then select **Run This Task**.

Use this capability when:

- You do not want to tune the IP core parameters by using the AXI4 slave interfaces.
- You want to create a custom reference design without AXI4 slave interfaces, such as standalone FPGA boards.

In addition, avoiding generation of the AXI4 slave interfaces in such cases reduces hardware resource usage and design complexity.

Note External IO and internal IO interfaces connect your HDL IP core to other existing IPs in your custom reference design. To define these interfaces, you use the `addInternalIOInterface` and `addExternalIOInterface` methods of the `hdlcoder.ReferenceDesign` class.

To integrate the HDL IP core, you can create a custom reference design without AXI4 slave interfaces. In the custom reference design, you can only use External IO, Internal IO or AXI4-Stream interface with TLAST mapping. For examples, see:

- “Access DUT Registers on Xilinx Pure FPGA Board Using IP Core Generation Workflow” on page 46-183
- “Access DUT Registers on Intel Pure FPGA Board Using IP Core Generation Workflow” on page 46-194

When you generate an HDL IP core without AXI4 slave interfaces, certain restrictions apply. See “IP Core Without AXI4 Slave Interface Restrictions” on page 46-30.

Requirements and Limitations for IP Core Generation

Custom IP Core Generation Limitations

- The DUT must be an atomic system.
- The same IP core cannot use both an AXI4 interface and an AXI4-Lite interface.
- The DUT cannot contain Xilinx System Generator blocks or Intel DSP Builder Advanced blocks.
- If your target language is VHDL, and your synthesis tool is Xilinx ISE or Intel Quartus Prime, the DUT cannot contain a model reference.

AXI4-Lite Interface Restrictions

- The input and output ports must have a bit width less than or equal to 32 bits.
- The input and output ports must be scalar.

AXI4-Stream Video Interface Restrictions

- Ports must have a 32-bit width.
- Ports must be scalar.
- You can have a maximum of one input video port and one output video port.
- The AXI4-Stream Video interface is not supported in Coprocessing – blocking mode. **Processor/FPGA synchronization** must be set to Free running mode.

IP Core Without AXI4 Slave Interface Restrictions

- You can only map the ports to External/Internal IO interfaces, or AXI4-Stream interface with TLAST mapping. Other interfaces that require AXI4 slave interfaces such as AXI4 Master, AXI4-Stream, and AXI4-Stream Video are not supported.
- You must use the Free running mode for **Processor/FPGA synchronization**. Coprocessing – blocking mode is not supported.

- “Generate Board-Independent HDL IP Core for Microchip Platforms” on page 46-254

Processor and FPGA Synchronization

In the HDL Workflow Advisor, you can choose a **Processor/FPGA synchronization mode** for your processor and FPGA when you generate a custom IP core to use in an embedded system integration project. The following synchronization modes are available:

- Free running (default)
- Coprocessing – blocking
- Coprocessing – nonblocking with delay

Free Running Mode

In free running mode, the processor and FPGA each run nonsynchronized, continuously, and in parallel.

Select **Free running** as the **Processor/FPGA synchronization mode** when you do not want your processor and FPGA to be automatically synchronized.

The following diagram shows how the processor and FPGA can communicate in free running mode. The shaded areas indicate that the processor and FPGA are running continuously.

Coprocessing - Blocking Mode

In blocking coprocessor mode, HDL Coder automatically generates synchronization logic for the FPGA so that the processor and FPGA run in tandem.

Select **Coprocessing - blocking** as the **Processor/FPGA synchronization mode** when FPGA execution time is short relative to the processor sample time, and you want the FPGA to complete before the processor continues.

The following diagram shows how the processor and FPGA run in blocking coprocessing mode.

The shaded areas indicate when the processor and FPGA are running. During each sample time, the processor writes to the FPGA, then stops and waits for an indication that the FPGA has finished processing before continuing to run. Each time the FPGA runs, it executes the logic generated for one DUT subsystem sample time.

Synchronization of Global Reset Signal to IP Core Clock Domain

The HDL DUT IP core and the Address Decoder logic in the AXI4 Slave interface wrapper of the HDL IP core are driven by a global reset signal. If you generate an HDL IP core without any AXI4 slave interfaces, HDL Coder does not generate the AXI4 slave interface wrapper. The global reset signal becomes the same as the IP core reset signal and drives the HDL IP core for the DUT. To learn how you can generate an IP core without AXI4 slave interfaces, see “Generate Board-Independent HDL IP Core from Simulink Model” on page 46-26.

When you generate the AXI4 slave interfaces in the HDL IP core, the global reset signal is driven by three reset signals: the IP core external reset, the reset signal of the AXI interconnect, and the soft reset for the ARM processor core. The global reset signal in this case drives the HDL IP core for the DUT and the Address Decoder logic in the AXI4 slave wrapper.

The `IPCore_Clk` and `AXILite_ACLK` must be connected to the same clock source. The `IPCore_RESETN` and `AXILite_ARESETN` must be connected to the same reset source.

These reset signals can be either synchronous or asynchronous. Using asynchronous reset signals can be problematic and result in potential metastability issues in flipflops when the reset de-asserts within the latching window of the clock. To avoid generation of possible metastable values when combining the reset signals, HDL Coder automatically inserts a reset synchronization logic, as indicated by the `Reset Sync` block. The reset synchronization logic synchronizes the global reset signal to the IP core clock domain. This logic is inserted when you open the HDL Workflow Advisor and run the **Generate RTL Code and IP Core** task of the IP Core Generation workflow.

The reset synchronization logic contains two back-to-back flipflops that are synchronous to the `IPCore_CLK` signal. The flipflops make sure that de-assertion of the reset signal occurs after two clock cycles of when the `IPCore_CLK` signal becomes high. This synchronous de-assertion avoids generation of a global reset signal that has possible metastable values.

The logic works differently depending on whether you specify the **Reset type** as Synchronous or Asynchronous on the model. If your **Reset type** is Asynchronous, the synchronization logic asserts the reset signal asynchronously and de-asserts the reset signal synchronously. For example, this code illustrates the generated Verilog code for the reset synchronization logic when you generate the IP core with asynchronous reset.

...
...

```
reg_reset_pipe_process : PROCESS (clk, reset_in)
BEGIN
  IF reset_in = '1' THEN
    reset_pipe <= '1';
  ELSIF clk'EVENT AND clk = '1' THEN
    IF enb = '1' THEN
      reset_pipe <= const_0;
    END IF;
  END IF;
END PROCESS reg_reset_pipe_process;

reg_reset_delay_process : PROCESS (clk, reset_in)
BEGIN
  IF reset_in = '1' THEN
    reset_out <= '1';
  ELSIF clk'EVENT AND clk = '1' THEN
    IF enb = '1' THEN
      reset_out <= reset_pipe;
    END IF;
  END IF;
END PROCESS reg_reset_delay_process;
```

```
END rtl;
```

If your **Reset type** is Synchronous, the synchronization logic asserts and de-asserts the reset signal synchronously. For example, this code illustrates the generated Verilog code for the reset synchronization logic when you generate the IP core with synchronous reset.

```
...  
...  
reg_reset_pipe_process : PROCESS (clk)  
  BEGIN  
    IF clk'EVENT AND clk = '1' THEN  
      IF reset_in = '1' THEN  
        reset_pipe <= '1';  
      ELSIF enb = '1' THEN  
        reset_pipe <= const_0;  
      END IF;  
    END IF;  
  END PROCESS reg_reset_pipe_process;  
  
reg_reset_delay_process : PROCESS (clk)  
  BEGIN  
    IF clk'EVENT AND clk = '1' THEN  
      IF reset_in = '1' THEN  
        reset_out <= '1';  
      ELSIF enb = '1' THEN  
        reset_out <= reset_pipe;  
      END IF;  
    END IF;  
  END PROCESS reg_reset_delay_process;  
  
END rtl;
```

IP Caching for Faster Reference Design Synthesis

In this section...

- “Requirements for Using IP Caching” on page 46-37
- “What Is an IP Cache?” on page 46-37
- “How IP Caching Works” on page 46-38
- “Enable IP Caching” on page 46-38
- “IP Caching in HDL Coder Reference Designs” on page 46-39
- “IP Caching in Custom Reference Designs” on page 46-40

For target platforms that support the IP Core Generation workflow with Xilinx Vivado, you can use IP caching. IP caching reduces the synthesis time of reference designs that have many IP modules or that have IP modules with a significant synthesis run time. When you enable IP caching, the Vivado project uses an out-of-context (OOC) workflow. This workflow synthesizes the IP in the reference design out of context from the top-level design. The OOC workflow accelerates project runs because the synthesis tool reuses the IP cache, and does not have to resynthesize the IP when you run the workflow.

If you do not enable IP caching, by default, the Vivado project uses the global synthesis flow. This flow synthesizes the IP modules in the reference design along with the top-level design. In subsequent project runs, this workflow resynthesizes the IP modules in the reference design.

Requirements for Using IP Caching

- **Target workflow:**
 - IP Core Generation
 - Simulink Real-Time FPGA I/O for Speedgoat boards that use Xilinx Vivado
- **Synthesis tool:** Xilinx Vivado

What Is an IP Cache?

An IP cache is a folder that consists of subfolders corresponding to IP modules in the reference design. Each subfolder is organized by a hash index that corresponds to the file name. For each IP module, the subfolder consists of Xilinx Core Instance (XCI) files, Design Checkpoint (DCP) files, and synthesis log files. The DCP is a container file that contains synthesized netlists, black box HDL stub files, and the output clock constraints.

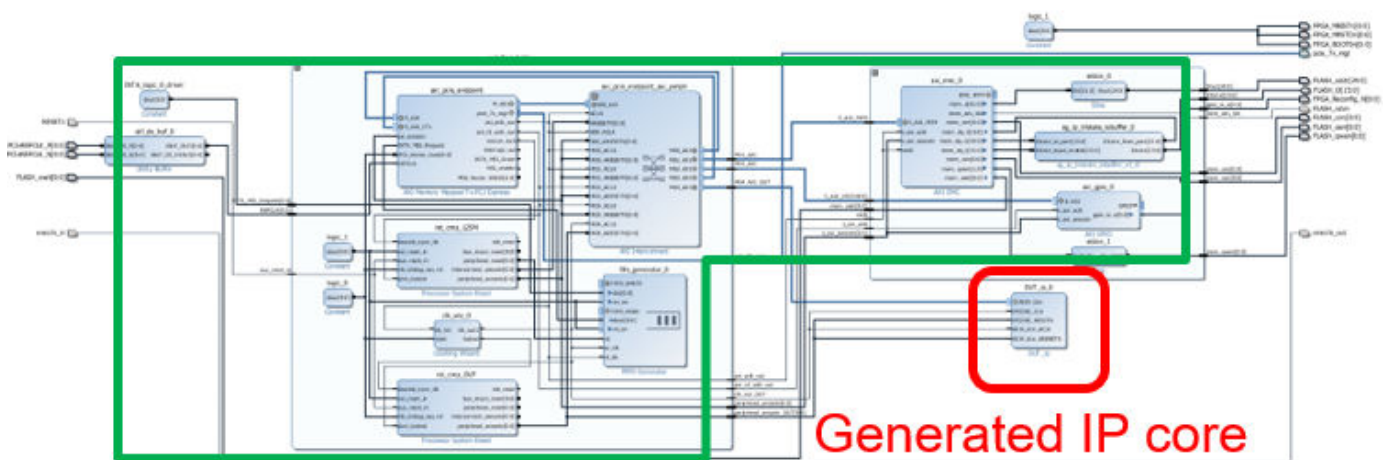

To reuse the IP cache when you run the workflow, the IP synthesis has to match the hash index in the IP cache. The hash index match corresponds to a hit in the IP cache. To hit the IP cache in subsequent runs, use the same:

- Part, language, and target platform settings
- Reference design version
- Target frequency
- `hdl_prj` folder when you created the IP cache

How IP Caching Works

When you enable IP caching, the Xilinx Vivado project uses an out-of-context (OOC) workflow. The OOC design flow is a bottom-up workflow that:

- 1 Synthesizes the IP modules in the reference design separately from the top-level design. The synthesis output is the Design Checkpoint (DCP) file.
- 2 Synthesizes your top-level design while treating the IP in the reference design as a black box by using the HDL stub files provided with the DCP.
- 3 Implements your design on the target device by linking the netlists from the IP design checkpoint files with your top-level netlist.

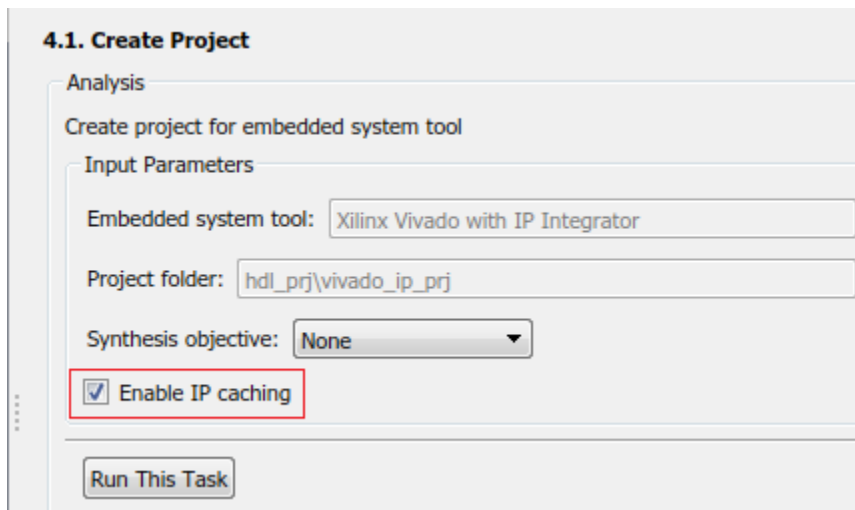

No need to re-synthesize

For large reference designs, the OOC flow improves synthesis run time, because you do not have to resynthesize the IP when you modify your design and run the workflow. To learn more about the OOC workflow and IP synthesis options, refer to the Xilinx documentation.

Enable IP Caching

Before you enable IP caching, specify IP Core Generation as the target workflow, and then specify the target platform settings. To enable IP caching:

- From the HDL Workflow Advisor, in the **Create Project** task, select the **Enable IP caching** check box.

- From the command line, use the `EnableIPCaching` property of the `hdlcoder.WorkflowConfig` class. To use this property, create an object of the `hdlcoder.WorkflowConfig` class, or export the HDL Workflow Advisor settings to a script.

```
hWC = hdlcoder.WorkflowConfig('SynthesisTool','Xilinx Vivado','TargetWorkflow','IP Core Generation');
% ...
% ...
hWC.EnableIPCaching = true;
```

IP Caching in HDL Coder Reference Designs

Use IP caching for large reference designs that have a significant synthesis time. For example, the HDL Coder reference design `Default video system` (requires HDMI FMC module) is a potential candidate for IP caching.

Note The Speedgoat I0333-325K board that you use with the Simulink Real-Time FPGA I/O workflow comes with an IP cache. The first time that you run the workflow, the code generator reuses this IP cache, which improves reference design synthesis time.

To enable IP caching, in the HDL Workflow Advisor, specify `IP Core Generation` as the target workflow, and then specify the target platform settings. Before you run the workflow for the first time:

- 1 In the **Create Project** task, select the **Enable IP caching** check box.

When you run this task, the workflow creates an empty IP cache folder. You can see the `ipcache` folder in the `hdl_prj/vivado_ip_prj` path.

- 2 Run the **Build FPGA Bitstream** task.

This task populates the IP cache folder with synthesis logs and design checkpoint files generated for the HDL IP core and other IP blocks in the reference design. When this task has run successfully, you can see the generated files in the `ipcache` folder.

When you run the `IP Core Generation` workflow a second time, in the **Build FPGA Bitstream** task, you can see an improvement in the task run time. Make sure that you use the same IP settings

and `hdl_prj` folder as the first time that you ran the workflow. When this task has run successfully, to see if your workflow reused the IP cache, open the `workflow_task_buildFPGABitstream.log` file.

This code snippet shows that the Vivado project launches a maximum number of jobs to synthesize the design and reuse the IP modules in the IP cache folder. You can see that the cacheID of the IP modules match the file names of the subfolders in the `ipcache` folder.

```
...
# reset_run impl_1
# reset_run synth_1
# launch_runs -jobs 4 synth_1
...
...
INFO: [IP_Flow 19-4760] Using cached IP synthesis design for IP system_top_RGBtoYCbCr_0_0, cacheID = 3575924730488800
INFO: [IP_Flow 19-4760] Using cached IP synthesis design for IP system_top_YCbCrtoRGB_0_0, cacheID = e71459f41e26e141
INFO: [IP_Flow 19-4760] Using cached IP synthesis design for IP system_top_xbar_0, cacheID = d0f0971cb77bcaed

...
```

IP Caching in Custom Reference Designs

If you are using your own custom reference design, IP caching can accelerate reference design synthesis when you run the workflow for the first time. To reuse the IP cache, create an IP cache zip file, and then make sure that the reference design definition file points to this zip file.

To create an IP cache zip file:

- 1 Open the HDL Workflow Advisor for any Simulink model that has a DUT subsystem, and then run the **IP Core Generation** workflow to the **Generate RTL Code and IP Core** task.

- 2 In the **Create Project** task, select the **Enable IP caching** check box, and then click **Run This Task**. This task creates an empty IP cache folder.
- 3 Run the workflow to the **Build FPGA Bitstream** task. This task populates the IP cache with the HDL IP core and the reference design IP modules.
- 4 In the IP cache folder, delete the IP core files generated for the DUT. Extract the remaining files from this folder into a zip file, name it `ipcache.zip`, and then save the file in the reference design folder.

To reuse the IP cache, in the reference design definition file `plugin_rd.m`, use the `IPCacheZipFile` property of the `hdlcoder.ReferenceDesign` class. By using that property, you add the `ipcache.zip` file to the Xilinx Vivado project.

```
function hRD = plugin_rd()
% Reference design definition

hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');
% ...
% ...
hRD.IPCacheZipFile = 'ipcache.zip';
```

When you use the workflow to target your custom reference design, the code generator selects the **Enable IP caching** check box. To see the improvement in synthesis time, run the **Build FPGA Bitstream** task.

Resolve Timing Failures in IP Core Generation and Simulink Real-Time FPGA I/O Workflows

In this section...

“Step 1: Identify the Timing Failure” on page 46-42

“Step 2: Find the Critical Path” on page 46-45

“Step 3: Resolve Timing Failures” on page 46-49

Synchronous circuits require that data propagates from a source register to a destination register within one clock cycle. For the synthesis tools, the Delay blocks that you add to your Simulink model run at the clock rate. The tools require data to travel between the blocks within one clock cycle. If the tool is unable to propagate the data between the registers for one or more signal paths in your model within one clock cycle, a timing failure occurs.

The tools report a slack information for each signal path, which corresponds to the difference between the required time and the arrival time. Required time is the expected time at which a signal must arrive at the destination register. Arrival time is the time elapsed for a signal to arrive at that point. A positive slack indicates that the signal arrived much faster than the required time, and the path passes the timing requirement. A negative slack indicates that the signal path is slower than the required time, and the path fails the timing requirement. To make sure that your design meets the timing requirements, speed up all signal paths that have a negative slack.

To identify if your design meets the timing requirements and how you can resolve timing failures, perform these steps.

Step 1: Identify the Timing Failure

When you run the IP Core Generation workflow or the Simulink Real-Time FPGA I/O workflow for Vivado-based boards, if your Simulink model does not meet the timing requirements, HDL Coder generates an error in the **Build FPGA Bitstream** step of the workflow. See:

- “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 for information about how to run the IP Core Generation workflow.
- “FPGA Programming and Configuration on Speedgoat Simulink-Programmable I/O Modules” on page 47-92 for information about how to run the Simulink Real-Time FPGA I/O workflow. When you run this workflow, use a Speedgoat board that supports Xilinx Vivado as the synthesis tool.

When you run the **Build FPGA Bitstream** task, if you left the **Run build process externally** check box selected by default, whether or not there is a timing failure, HDL Coder displays the results as **Passed** and provides warning messages. View the build log in the external console to identify if there is a potential timing failure.

4.3. Build FPGA Bitstream

Analysis

Synthesis and generate bitstream for embedded system on FPGA

Input Parameters

Run build process externally

Tcl file for synthesis build: Default ▾ Browse...

Run This Task

Result: ✔ Passed

Warning Run build process externally: The system build has been launched in an external shell, please check the external console to make sure the bitstream generation is completed. The system build may fail if the timing constraints are not met by the synthesis tool. If a timing failure occurs, the bitstream will be renamed to "system_timingfailure.sof". For more details on how to resolve the timing failure, please follow the "[Article on timing failure](#)" and also read the "[timing report](#)" for details. The system build may also fail because of other reasons, please read the log in the external console to identify reason.

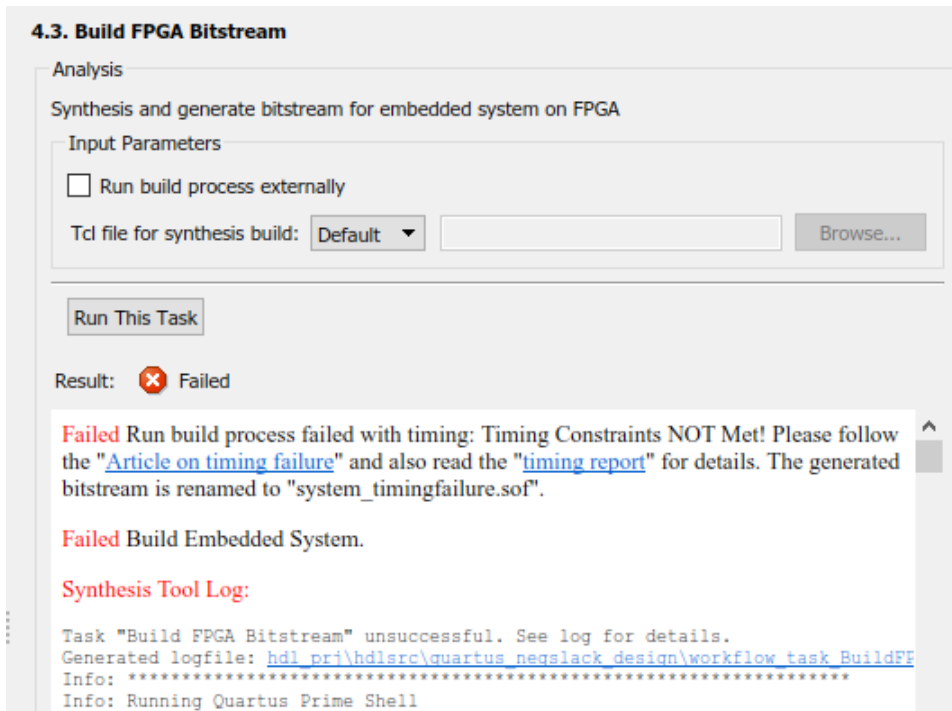

Passed Build Embedded System.

Synthesis Tool Log:

```
Task "Build FPGA Bitstream" successful.
Generated logfile: hdl_pri\hdlsrc\quartus_negslack_design\workflow_task_BuildFPGA
Running embedded system build outside MATLAB.
Please check external shell for system build progress.
```

In the external console, if there is a timing failure, you see the worst slack and this message: Timing constraints NOT met!

When you clear the **Run build process externally** check box, and then run the **Build FPGA Bitstream** task, if a timing failure occurs, the task fails, and you see these messages in the **Result** subpane.

In both cases, when there is a timing failure, the code generator replaces the previous bitstream with a bitstream that has the same name and the postfix `_timingfailure.bit` or `_timingfailure.sof` depending on whether you created a project by using Vivado or Quartus. For example, if the previous generated bitstream was called `system_top_wrapper.bit`, and if there is a timing failure, HDL Coder renames this bitstream to `system_top_wrapper_timingfailure.bit`.

If you run the **Program Target Device** task, the task fails.

Report Timing Failures as Warnings

If you have already implemented the custom logic to resolve the timing failures, you can specify the timing failures to be reported as warnings instead of errors. You can then continue the workflow and generate the FPGA bitstream. Before programming the target SoC device, it is recommended that you have resolved the timing failures.

After you have resolved the timing failures, to verify that the failures have been resolved, you can use the HDL Coder software. Change the timing failures to be reported as errors and then rerun the IP Core Generation workflow to ensure that the **Build FPGA Bitstream** task passes. If the **Build FPGA Bitstream** task still fails, perform the steps in the preceding sections to identify and resolve the timing failures.

To specify timing failures to be reported as warnings:

- After you run the **Build FPGA Bitstream** task, export the HDL Workflow Advisor to a script. In the script, to report timing failures as warnings, use the `ReportTimingFailure` property of the `hdlcoder.WorkflowConfig` class. You can then run the script or import the script to the HDL Workflow Advisor and then run the workflow.

```
hWC.ReportTimingFailure = hdlcoder.ReportTiming.Warning;
```

- If you are targeting a custom reference design that you have already defined for the board, to report timing failures as warnings, use the `ReportTimingFailure` property of the `hdlcoder.ReferenceDesign` class.

```
hRD.ReportTimingFailure = hdlcoder.ReportTiming.Warning;
```

To learn how you can identify the critical path and resolve the timing failures, perform the steps in the preceding sections.

Step 2: Find the Critical Path

Critical path is a combinational path between the input and the output that has the maximum delay. This path corresponds to the signal path that has the worst negative slack. By identifying and optimizing the critical path, you can resolve timing failures and improve the timing of your design. You can identify the critical path in your design by using either of these strategies.

Strategy 1: Check the Timing Report

In the **Result** subpane, to open the timing report that is generated by the synthesis tool, select the **timing_report** link. You can use the report to identify the critical path in your design. In the report, if you search for **Worst Slack**, you can identify the worst setup slack. Then, use the **Source** and **Destination** points to identify the critical path. For example, this report for the LED blinking model `hdlcoder_led_blinking` shows that the critical path is inside the HDL Counter block.

```
-----
From Clock:  clk_out1_system_top_clk_wiz_0_0
To Clock:    clk_out1_system_top_clk_wiz_0_0

Setup : 1193 Failing Endpoints, Worst Slack -2.478ns, Total Violation -1226.784ns
Hold   :    0 Failing Endpoints, Worst Slack  0.034ns, Total Violation  0.000ns
PW    :    2 Failing Endpoints, Worst Slack -0.576ns, Total Violation -0.731ns
-----

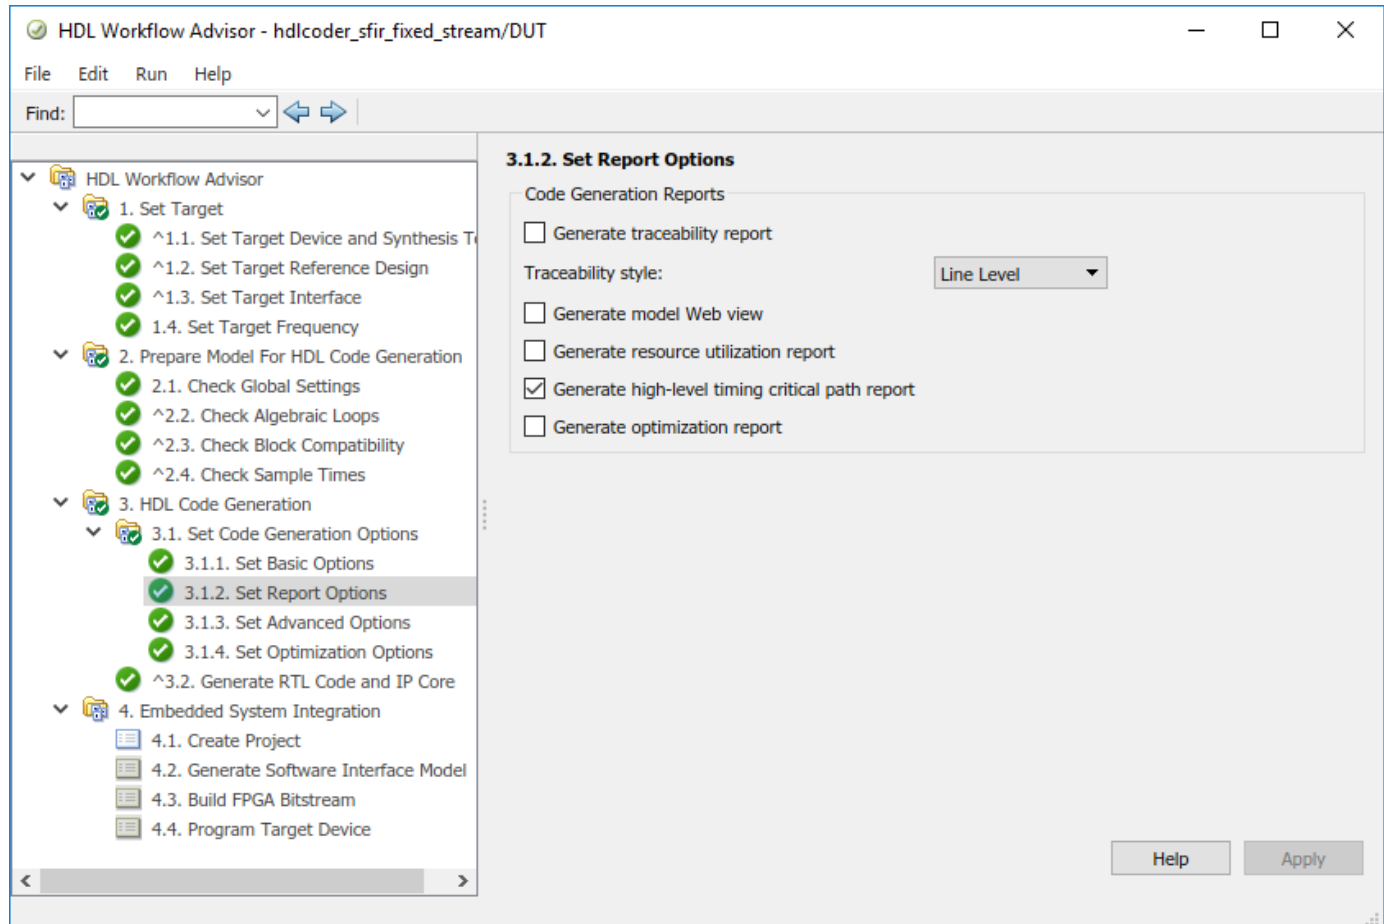

Max Delay Paths
-----
Slack (VIOLATED) : -2.478ns (required time - arrival time)
Source:          system_top_i/led_count_ip_0/U0/u_led_count_ip_dut_inst/
                  u_led_count_ip_src_led_counter/HDL_Counter1_out1_reg[0]/C
                  (rising edge-triggered cell FDRE clocked by clk_out1_system_top_clk_wiz_0_0
                   {rise@0.000ns fall@1.000ns period=2.000ns})
Destination:    system_top_i/led_count_ip_0/U0/u_led_count_ip_dut_inst/
                  u_led_count_ip_src_led_counter/HDL_Counter1_out1_reg[20]/R
                  (rising edge-triggered cell FDRE clocked by clk_out1_system_top_clk_wiz_0_0
                   {rise@0.000ns fall@1.000ns period=2.000ns})

Path Group:     clk_out1_system_top_clk_wiz_0_0
Path Type:      Setup (Max at Slow Process Corner)
Requirement:    2.000ns (clk_out1_system_top_clk_wiz_0_0 rise@2.000ns -
                  clk_out1_system_top_clk_wiz_0_0 rise@0.000ns)
Data Path Delay: 3.899ns (logic 1.412ns (36.211%) route 2.487ns (63.789%))
```

Strategy 2: Estimate Critical Path Without Running Synthesis

Use HDL Coder to estimate and highlight the critical path in your model without synthesizing your design. Critical path estimation identifies the critical path by performing static timing analysis with timing data from target-specific databases. Estimating the critical path without using synthesis tools can lead to inaccurate timing results. Critical path estimation speeds up the process of identifying and optimizing the critical path in your design. It is an alternative to performing **FPGA Synthesis and Analysis** with the HDL Workflow Advisor. To learn more, see “Critical Path Estimation Without Running Synthesis” on page 28-192.

To estimate the critical path, in the **Set Report Options** task, select the **Generate high-level timing critical path report** check box. Run the workflow to the **Generate RTL Code and IP Core** task.

HDL Coder generates a critical path estimation section in the Code Generation Report. On this section, when you select the link to the `criticalpathestimated` script, the code generator highlights the critical path in the generated model. This figure shows a section of the `hdlcoder_sfir_fixed_stream` model with the critical path highlighted.

Strategy 3: Annotate Critical Path By Using Backannotation

For more accurate critical path information and highlighting of critical path in your design, use backannotation. To use backannotation, you have to leave the current Workflow Advisor session, and then run the Generic ASIC/FPGA workflow to annotate the model with the synthesis results.

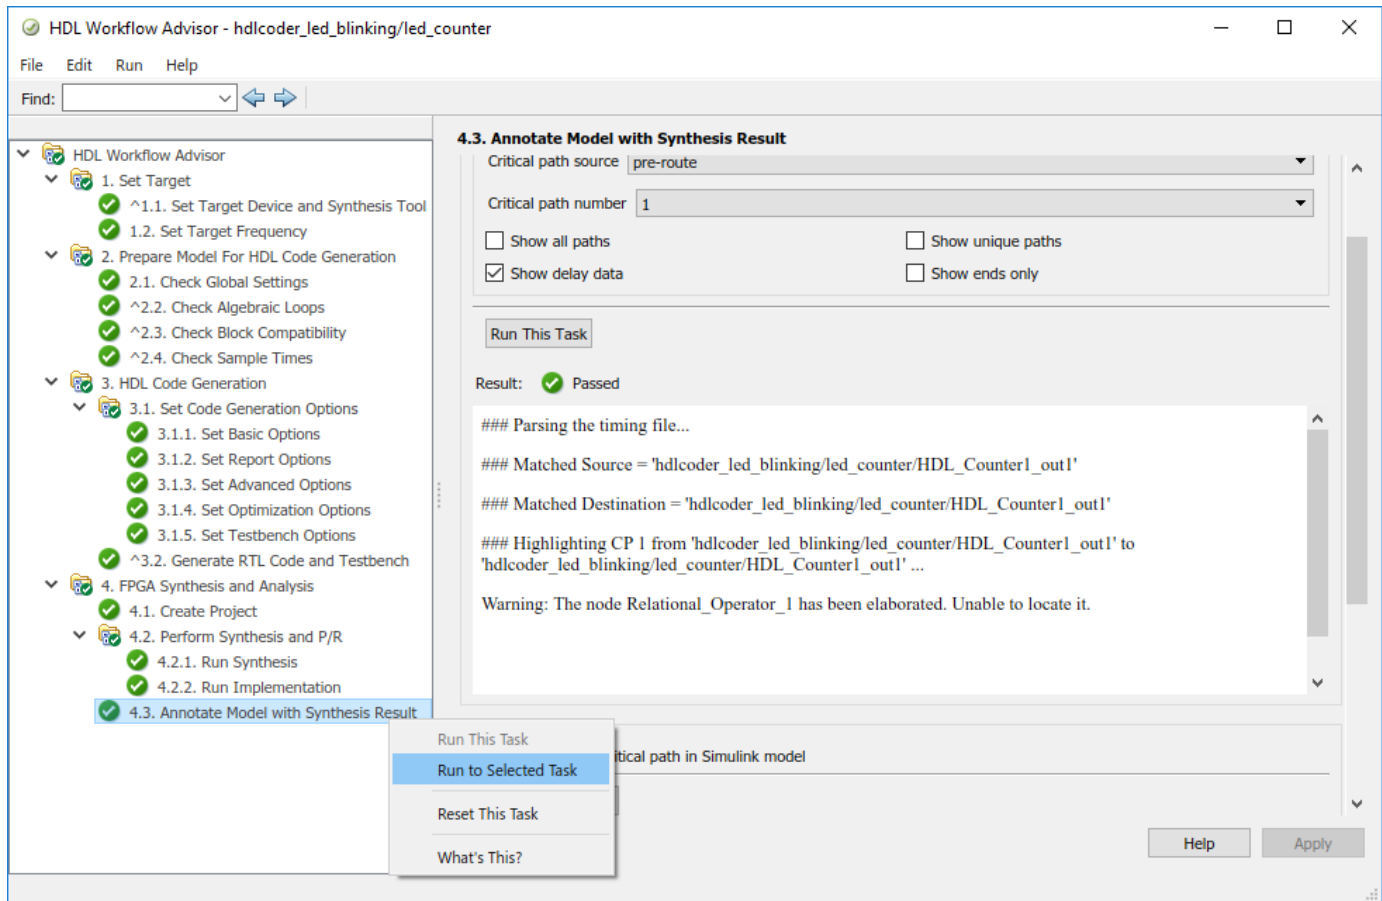

Before you use backannotation, it is recommended that you export the current HDL Workflow Advisor settings to a script. By exporting the settings to a script, you can iterate on the critical path and customize various settings to optimize your design until you meet the timing requirements. You can import the Workflow Advisor script to the HDL Workflow Advisor and then run the workflow. See also “Run HDL Workflow with a Script” on page 36-49.

To use backannotation:

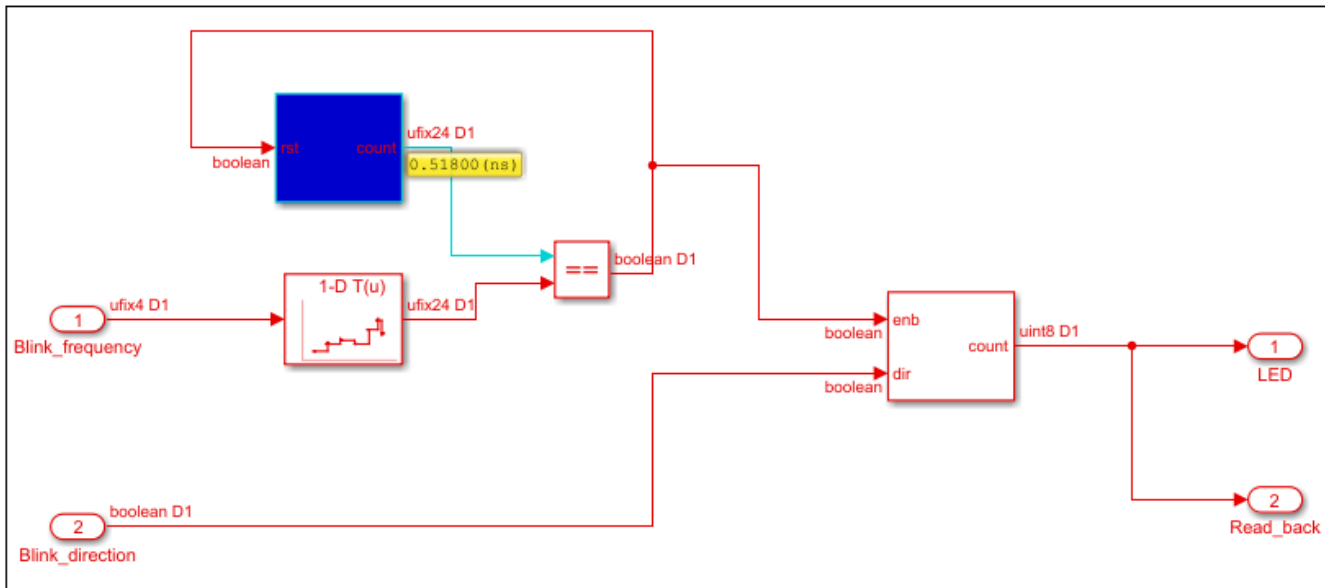

- 1 In the **Set Target Device and Synthesis Tool** task, select Generic ASIC/FPGA as the **Target workflow**. For **Synthesis tool**, specify the same tool that you used to run the IP Core Generation workflow.

When you specify these settings, HDL Coder resets this task and all tasks that follow it.

- 2 Select **Run This Task**.
- 3 In the **Set Target Frequency** task, specify the same target frequency that you used to run the IP Core Generation workflow. Select **Run This Task**.
- 4 Right-click the **Annotate Model with Synthesis Result** task and select **Run to Selected Task**.

When you run the link to the **Annotate Model with Synthesis Result** task, the code generator highlights the critical path in the generated model. This figure shows that the critical path in the `hdlcoder_led_blinking` model is inside the HDL Counter block.

Step 3: Resolve Timing Failures

To resolve timing failures, you can use any of these recommendations or a combination of the recommendations until your design meets the target frequency.

Recommendation 1: Use Speed Optimizations

You can use speed optimizations such as distributed pipelining and clock-rate pipelining to break the critical path by adding pipeline registers while preserving the functional behavior. By reducing the critical path, you can achieve higher clock frequencies and increase the arrival time of the signal until it equals the required time and the slack becomes zero.

Distributed pipelining optimization move the existing delays you have in your design across the subsystem hierarchy. To enable distributed pipelining on a subsystem, set **DistributedPipelining** as on. If your design does not meet the timing requirements, you can add more pipelines by using **InputPipeline** or **OutputPipeline** block properties. You can specify these properties in the HDL Block Properties dialog box of the Subsystem.

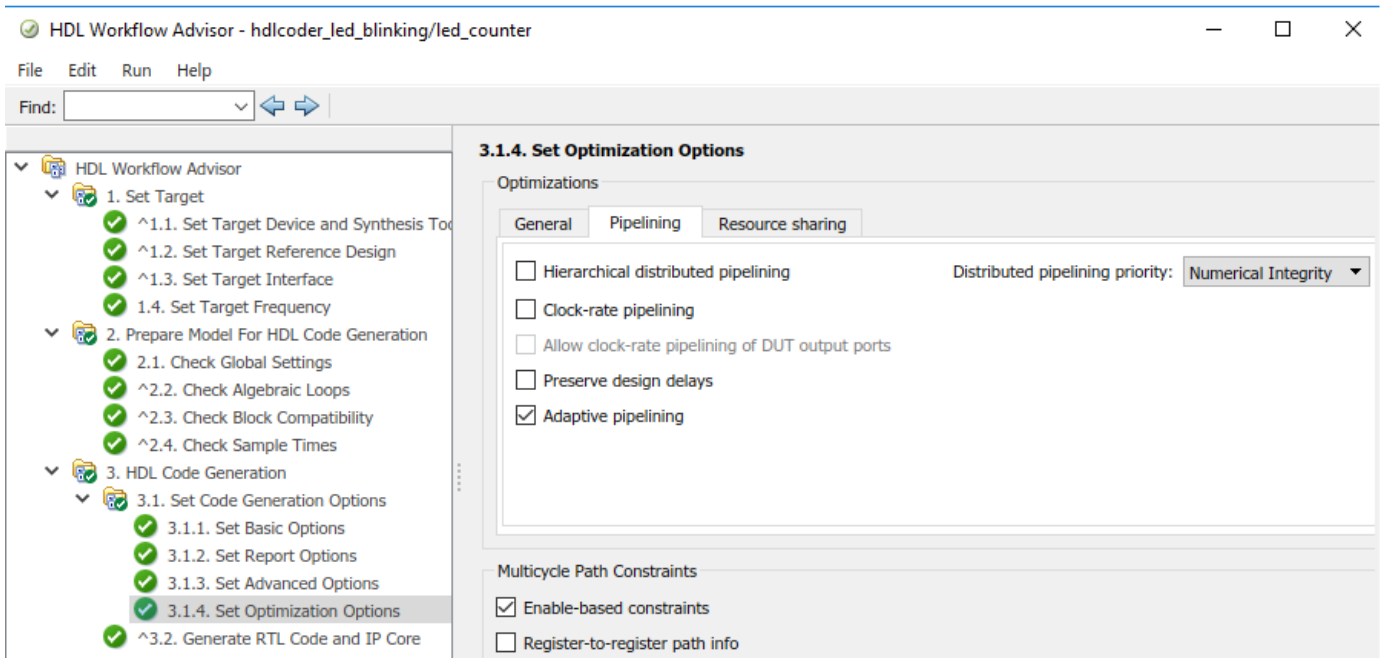

If distributed pipelining is unable to move the registers, you can add Delay blocks to your model, and then enable the **Preserve design delays** setting. Reset the **Check Global Settings** task and run the workflow to the **Build FPGA Bitstream** task. You can iterate on this approach and use other optimizations such as clock-rate pipelining with a large value for the **Oversampling factor** if the design does not meet the timing requirements. To specify these settings, use the **Pipelining** tab of the **Set Optimization Options** task in the HDL Workflow Advisor. For more information, see “Speed Optimization”.

Recommendation 2: Specify Enable-Based Multicycle Path Constraints

If your design contains multiple sample rates or uses certain HDL block implementations or speed optimizations that insert pipeline registers at a faster rate after code generation, your design can have multicycle paths. By default, HDL Coder uses a single clock mode that generates a primary clock at the fastest sample rate and creates a timing controller entity. The timing controller generates a set of clock enables with the required rate and phase information to sample the clock signal for blocks that operate at a slower sample time.

If your critical path is on a slower signal rate, synthesis tools can fail to meet the timing requirements. A timing failure occurs because the tools cannot infer the sample rates from the generated HDL code and assume that these paths have to run at the fastest rate. You can use enable-based multicycle path constraints to generate a constraints file that enables the synthesis tool to ease the clock constraint on the multicycle paths. To specify generation of multicycle path constraints, in the **Set Optimization Options** task, select the **Enable-based constraints** check box. Run the workflow to the **Build FPGA Bitstream** task. For an example, see “Use Multicycle Path Constraints to Meet Timing for Slow Paths” on page 27-43.

Recommendation 3: Reduce the Target Frequency

Use the **Target Frequency (MHz)** setting to specify the target frequency for HDL Coder to modify the clock module setting in the reference design to produce the clock signal with that frequency. See also “Target Frequency Parameter” on page 18-8.

To resolve timing failures, reduce the **Target Frequency (MHz)** setting so that the synthesis tool can meet the timing constraint. To see what target frequency you can specify, use the slack and the critical path information from the synthesis tool timing report. Because slack is equal to the difference between the required time and arrival time, you can add the slack to the required time, and then use this sum as the **New required time**. Use the reciprocal of this **New required time** as the target frequency value to meet the timing requirements because the **New required time** equals the arrival time. To compute the target frequency, in the MATLAB Command Window, run this script.

```
% Specify the required time (ns) and slack (ns) using timing report
required_time = 2;
slack = 2.2;

% Slack is difference between required_time and arrival_time
% By adding slack to required_time you can resolve
New_required_time = required_time + slack;
Target_frequency = 1 / (New_required_time);

% Since we computed the new time in nanoseconds
Target_frequency_MHz = Target_frequency * 10^3;
```

In the **Set Target Frequency** task, specify this value for **Target Frequency (MHz)**, and then run the workflow to the **Build FPGA Bitstream** task. If you see a timing failure, you can use this approach to iterate on the target frequency value until your design meets the timing requirements and the slack becomes zero.

You can also export the HDL Workflow Advisor settings to a script and keep iterating on the target frequency value by specifying `Target_frequency_MHz` as the value for the `TargetFrequency` property. Then, run the script.

```
% Set this frequency as the new target frequency
hdlset_param('hdlcoder_led_blinking', 'TargetFrequency', Target_frequency_MHz);
```

Define Multiple AXI Master Interfaces in Reference Designs to Access DUT AXI4 Slave Interface

In this section...

“Vivado-Based Reference Designs” on page 46-54

“Qsys-Based Reference Designs” on page 46-55

You can define multiple AXI Master interfaces in your custom reference design and access the AXI4 slave interfaces in the generated HDL DUT IP core for the DUT. This capability enables you to simultaneously connect the HDL DUT IP core to two or more AXI Master IP in the reference design, such as the HDL Verifier JTAG AXI Manager IP and the ARM processor in the Zynq processing system.

Vivado-Based Reference Designs

To define multiple AXI Master interfaces, you specify the `BaseAddressSpace` and `MasterAddressSpace` for each AXI Master instance, and also the `IDWidth` property.

`IDWidth` is the width of all ID signals, such as `AWID`, `WID`, `ARID`, and `RID`, specified as a positive integer. By default, the `IDWidth` is 12, which enables you to specify one AXI Master interface connection to the DUT IP core. To connect the DUT IP core to multiple AXI Master interfaces, you may have to increase the `IDWidth`. The `IDWidth` value is tool-specific. To see the value that you must use when specifying more than one AXI Master interface, refer to the documentation for that tool. If you use an incorrect ID width, the synthesis tool generates an error, and reports the correct `IDWidth` that you must use.

This code is the syntax for the `MasterAddressSpace` field when specifying multiple AXI Master interfaces in Vivado-based reference designs:

```
'MasterAddressSpace', ...
  {'AXI Master Instance Name1/Address Space of Instance Name1', ...
   'AXI Master Instance Name2/Address_Space of Instance Name2',...};
```

For example, this code illustrates how you can modify the `plugin_rd` file to define two AXI Master interfaces.

```
% ...

%% Add custom design files
% add custom Vivado design
hRD.addCustomVivadoDesign( ...
  'CustomBlockDesignTcl', 'system_top.tcl', ...
  'VivadoBoardPart',     'xilinx.com:zc706:part0:1.0');

% ...
% ...

% The DUT IP core in this reference design is connected
% to both Zynq Processing System and the AXI Manager IP.
% Because of 2 AXI Master, ID width has to be increased
% from 12 to 13.
hRD.addAXI4SlaveInterface( ...
  'InterfaceConnection', 'axi_interconnect_0/M00_AXI', ...
  'BaseAddress',         {'0x40010000', '0x40010000'}, ...
  'MasterAddressSpace', {'processing_system7_0/Data', 'hdlverifier_axi_manager_0/axi4m'}, ...
  'IDWidth',             13);

% ...
```

In this example, the two AXI Master IP are the HDL Verifier AXI Manager IP and the ARM processor. Based on the syntax of the `MasterAddressSpace`, for the HDL Verifier AXI Manager IP, the AXI Master Instance Name is `hdlverifier_axi_manager_0` and the `Address_Space` of Instance Name is `axi4m`.

The AXI4 slave interfaces in the HDL DUT IP core connect to the Xilinx AXI Interconnect IP that is defined by the `InterfaceConnection` property of the `addAXI4SlaveInterface` method. The AXI4 slave interfaces have a `BaseAddress`. This `BaseAddress` must map to the `MasterAddressSpace` for the two AXI Master IP, which is specified as a cell array of character vectors.

You must make sure that the AXI Master IPs have already been included in the Vivado reference design project. `system_top.tcl` is the TCL file that is defined by the `CustomBlockDesignTcl`

property of the `addCustomVivadoDesign` method. In this TCL file, you must make sure that the two AXI Master IP are connected to the same Xilinx AXI Interconnect IP. The interconnects then connect the AXI Master IPs to the AXI4 slave interfaces in the HDL IP core.

After you run the **IP Core Generation** workflow and create the Vivado project, open the project. In the Vivado project, if you open the block design, you see the two AXI Master IP connected to the HDL DUT IP core. If you select the **Address Editor** tab, you see the AXI Master instance names and the corresponding address spaces.

Cell	Slave Interface	Base Name	Offset Address	Range	High Address
hdlverifier_axi_master_0					
axi4m (32 address bits : 4G)					
led_count_ip_0	AXI4_Lite	reg0	0x4001_0000	64K	0x4001_FFFF
processing_system7_0					
Data (32 address bits : 0x40000000 [1G])					
led_count_ip_0	AXI4_Lite	reg0	0x4001_0000	64K	0x4001_FFFF

Qsys-Based Reference Designs

To define multiple AXI Master interfaces, you specify the `InterfaceConnection` and `BaseAddressSpace` for each AXI Master instance, and also the `IDWidth` property. This code is the syntax for the `InterfaceConnection` field when specifying multiple AXI Master interfaces in Qsys-based reference designs:

```
'InterfaceConnection', ...
  {'AXI Master Instance Name1/Port name of Instance Name1', ...
   'AXI Master Instance Name2/Port name of Instance Name1', ...};
```

For example, this code illustrates how you can modify the `plugin_rd` file to define three AXI Master interfaces.

```
% ...

%% Add custom design files
% add custom Qsys design
hRD.addCustomQsysDesign('CustomQsysPrjFile', 'system_soc.qsys');
hRD.CustomConstraints = {'system_soc.sdc', 'system_setup.tcl'};

% ...

% add AXI4 slave interfaces
hRD.addAXI4SlaveInterface( ...
  'InterfaceConnection', {'hps_0.h2f_axi_master', 'master_0.master', 'AXI_Manager_0.axm_m0'}, ...
  'BaseAddress',         {'0x0000_0000', '0x0000_0000', '0x0000_0000'}, ...
  'InterfaceType',       'AXI4' ...
  'IDWidth',             14);

% ...
```

Based on the syntax of the `InterfaceConnection` option, for the HDL Verifier AXI Manager IP, the AXI Master Instance Name is `AXI_Manager_0` and the Port name is `axm_m0`. For each AXI Master IP, the `BaseAddress` of the HDL IP core and `InterfaceConnection` must be specified as a cell array of character vectors.

You must make sure that the AXI Master IPs have already been included in the Qsys reference design project. `system_soc.qsys` is the file that is defined by the `CustomQsysPrjFile` property of the `addCustomQsysDesign` method. In this file, you must make sure that the two AXI Master IP are connected to the same Qsys AXI Interconnect IP.

The interconnects then connect the AXI Master IPs to the AXI4 slave interfaces in the HDL IP core.

After you run the `IP Core Generation` workflow and create the Quartus project, open the project. In the Quartus project, you see the three AXI Master IP and the AXI Master interfaces connected to the HDL IP core for the DUT. If you select the **Address Map** tab, you see the AXI Master instance names, the port names, and the corresponding address spaces.

System: system_soc		Path: hps_0		
	MATLAB_as_AXI_Master_0.axm_m0	hps_0.h2f_axi_master	hps_0.h2f_lw_axi_master	master_0.master
hps_0.f2h_axi_slave				
led_count_ip_0.s_axi	0x0000_0000 - 0x0000_ffff	0x0000_0000 - 0x0000_ffff		0x0000_0000 - 0x0000_ffff

Program Target FPGA Boards or SoC Devices

In this section...

“How to Program Target Device” on page 46-57

“Programming Methods” on page 46-58

To configure or program the connected target SoC device or FPGA board, use the IP Core Generation workflow in the HDL Workflow Advisor.

How to Program Target Device

Using the Workflow Advisor UI

- 1 Open the HDL Workflow Advisor. Right-click the DUT Subsystem that contains the algorithm to be deployed on the target FPGA, and select **HDL Code > HDL Workflow Advisor**.
- 2 In the **Set Target Device and Synthesis Tool** task, specify IP Core Generation as the **Target workflow**, and specify a **Target platform** other than the Generic Xilinx Platform or Generic Altera Platform.
- 3 Right-click the **Program Target Device** task and select **Run to Selected Task**.
- 4 In the **Program Target Device** task, specify the **Programming method**, and run this task.

To learn more about the HDL Workflow Advisor, see “Getting Started with the HDL Workflow Advisor” on page 36-6.

Using the Workflow Advisor Script

To program the target device at the command line, after you specify the target workflow and target platform in the **Set Target Device and Synthesis Tool** task, export the HDL Workflow Advisor settings to a script. In the HDL Workflow Advisor window, select **File > Export to Script**. The script creates and configures an `hdlcoder.WorkflowConfig` object that is denoted by `hWC`.

Before you run the script, you can specify how to program the target hardware by using the `ProgrammingMethod` property of the `WorkflowConfig` object. This code snippet shows an example script that is exported from the HDL Workflow Advisor when you use the default **Download Programming method**. To run the **Program Target Device** task, customize this script by setting the `RunTaskProgramTargetDevice` attribute of the `WorkflowConfig` object to `true`.

```
% This script was generated using the following parameter values:
% ...

% Set properties related to 'RunTaskProgramTargetDevice' Task
hWC.RunTaskProgramTargetDevice = true;
hWC.ProgrammingMethod = hdlcoder.ProgrammingMethod.Download;

% Validate the Workflow Configuration Object
hWC.validate;

%% Run the workflow
hdlcoder.runWorkflow('hdlcoder_led_blinking/led_counter', hWC);
```

After you run the **Build FPGA Bitstream** task, the Workflow Advisor provides you a link to generate a Workflow script that programs the target device without rerunning the previous tasks in the Workflow Advisor.

Result:  Passed

Passed Build Embedded System.

Synthesis Tool Log:

Task "Build FPGA Bitstream" successful.
Generated logfile: [hdl_prj\hdlsrc\hdlcoder_led_blinking\workflow_task_BuildFPGABitstream.log](#)

Running embedded system build outside MATLAB.
Please check external shell for system build progress.

The generated bitstream file is located at: hdl_prj\vivado_ip_prj\vivado_prj.runs\impl_1\system_top_wrapper.bit

Generate an HDL Workflow Command-Line Interface script to program the target device: [hdlworkflow_ProgramTargetDevice.m](#).

Click the link to open the script in the MATLAB Editor. This code snippet shows an example script that is generated by the HDL Workflow Advisor. If close the HDL Workflow Advisor, you can run the script to program the target hardware without running other workflow tasks.

```
% Load the Model
% ...

% Set Workflow tasks to run
hWC.RunTaskGenerateRTLCodeAndIPCore = false;
hWC.RunTaskCreateProject = false;
hWC.RunTaskGenerateSoftwareInterface = false;
hWC.RunTaskBuildFPGABitstream = false;
hWC.RunTaskProgramTargetDevice = true;

% Set properties related to 'RunTaskProgramTargetDevice' Task
hWC.ProgrammingMethod = hdlcoder.ProgrammingMethod.Download;

% Validate the Workflow Configuration Object
hWC.validate;
```

To learn more about the script-based workflow, see “Run HDL Workflow with a Script” on page 36-49.

Programming Methods

Download

If you use the reference designs for Zynq and Intel SoC hardware platforms, the code generator uses Download as the default **Programming method**.

When you use Download as the **Programming method** and run the **Program Target Device** task, HDL Coder copies the generated FPGA bitstream, Linux devicetree, and system initialization scripts to the SD card on the target board, and then keeps the bitstream on the SD card persistently. To use this programming method, you do not require an Embedded Coder license. You can create an SSH object by specifying the **IP Address**, **SSH Username**, and **SSH Password**. HDL Coder uses the SSH object to copy the bitstream to the SD card and reprogram the board.

It is recommended that you use the `Download` method, because this method programs the FPGA bitstream and loads the corresponding Linux devicetree before booting the Linux system. Therefore, the `Download` method is more robust and does not result in a kernel panic or kernel hang on boot up. During the Linux reboot, the FPGA bitstream is reprogrammed from the SD card automatically. To specify `Download` as the **Programming method** when you run the workflow using the Workflow Advisor script, before you run the script, make sure that the `ProgrammingMethod` property of the `WorkflowConfig` object, `hWC`, is set to `Download`.

```
hWC.ProgrammingMethod = hdlcoder.ProgrammingMethod.Download;
```

JTAG

When you specify JTAG as the **Programming method** and run the **Program Target Device** task, HDL Coder uses a JTAG cable to program the target SoC device. Use this method to program Intel and Xilinx SoC devices and standalone FPGA boards.

For programming SoC devices, it is recommended that you use the `Download` method. The JTAG mode does not involve the ARM processor and programs the onboard FPGA directly. This mode does not update the Linux devicetree, and can crash the Linux system or result in a kernel panic when the bitstream does not match the devicetree. To avoid this situation, use the `Download` method to program the SoC device.

The standalone Intel and Xilinx FPGA boards do not have an embedded ARM processor. JTAG is the default method that you use to program the FPGA boards.

To specify JTAG as the **Programming method** when you run the workflow using the Workflow Advisor script, before you run the script, change the `ProgrammingMethod` property of the `WorkflowConfig` object, `hWC`, to `JTAG`.

```
hWC.ProgrammingMethod = hdlcoder.ProgrammingMethod.JTAG;
```

Custom

To program the target device, you can specify a custom programming method when you create your own custom reference design. Use the `CallbackCustomProgrammingMethod` of the `hdlcoder.ReferenceDesign` class to register a function handle for the callback function that gets executed when running the **Program Target Device** task. To define your callback function, create a file that defines a MATLAB function and add the file to your MATLAB path.

This example code snippet shows a reference design definition file that uses a custom programming method. To learn more, see `CallbackCustomProgrammingMethod`.

```
unction hRD = plugin_rd()
% Reference design definition

% ...

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');

hRD.ReferenceDesignName = 'Parameter Callback Custom';
hRD.BoardName = 'ZedBoard';

Generate Host Interface Script to Probe and Rapidly Prototype HDL IP Core

When you run the hardware-software co-design workflow for SoC platforms, you generate an HDL IP core for the DUT algorithm and then integrate the IP core into the reference design. See “Hardware-Software Co-Design Workflow for SoC Platforms” on page 46-8.

To rapidly prototype and test the HDL IP core on the target hardware, you can generate a host interface script. The script contains the DUT ports and interface mapping information, which HDL Coder uses to create the AXI drivers and access the HDL IP core.

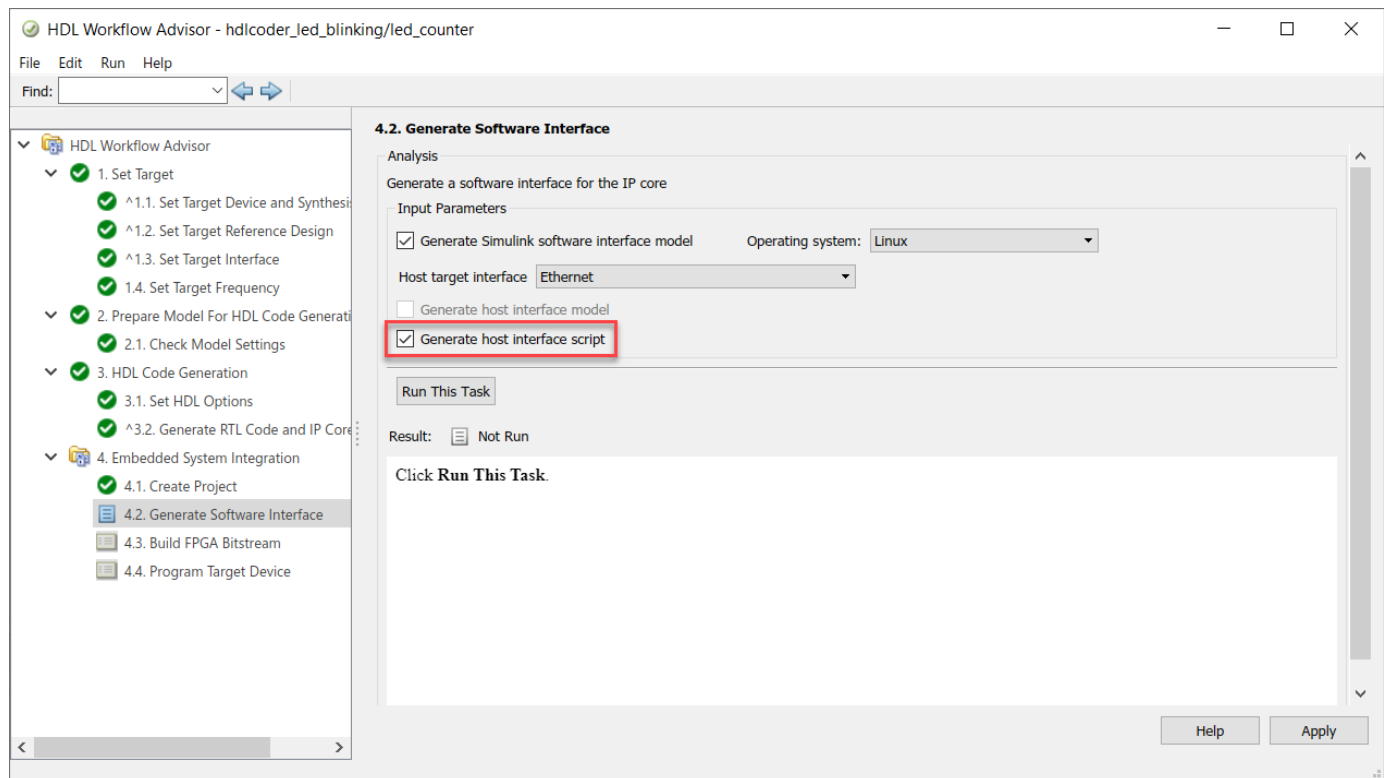

Prerequisites

- A target platform, such as ZedBoard, where you want to deploy your software interface model.
- The latest version of the third-party synthesis tool, such as Xilinx Vivado. See “HDL Language Support and Supported Third-Party Tools and Hardware”. In your MATLAB session, set the path to that installed synthesis tool by using the `hdlsetuptoolpath` function.

Generate Software Interface

When running the IP Core Generation workflow, you can generate a host interface script and software interface model from the HDL Workflow Advisor UI or at the command line.

From the UI, in the **Embedded System Integration > Generate Software Interface** task, select your **Host target interface** and then select the **Generate host interface script** check box.

When you run the IP Core Generation workflow to the **Generate Software Interface** task and select the **Generate host interface script** check box, two MATLAB files are generated:

- `gs_modelName_setup.m`, which is a setup script that adds the AXI4 slave and AXI4-Stream interfaces. The script also contains DUT port objects that have the port name, direction, data type, and interface mapping information. The script then maps the DUT ports to the corresponding interfaces.
- `gs_modelName_interface.m`, which creates a target object, instantiates the setup script `gs_modelName_setup.m`, and then connects to the target hardware. The script then sends read and write commands to the generated HDL IP core.

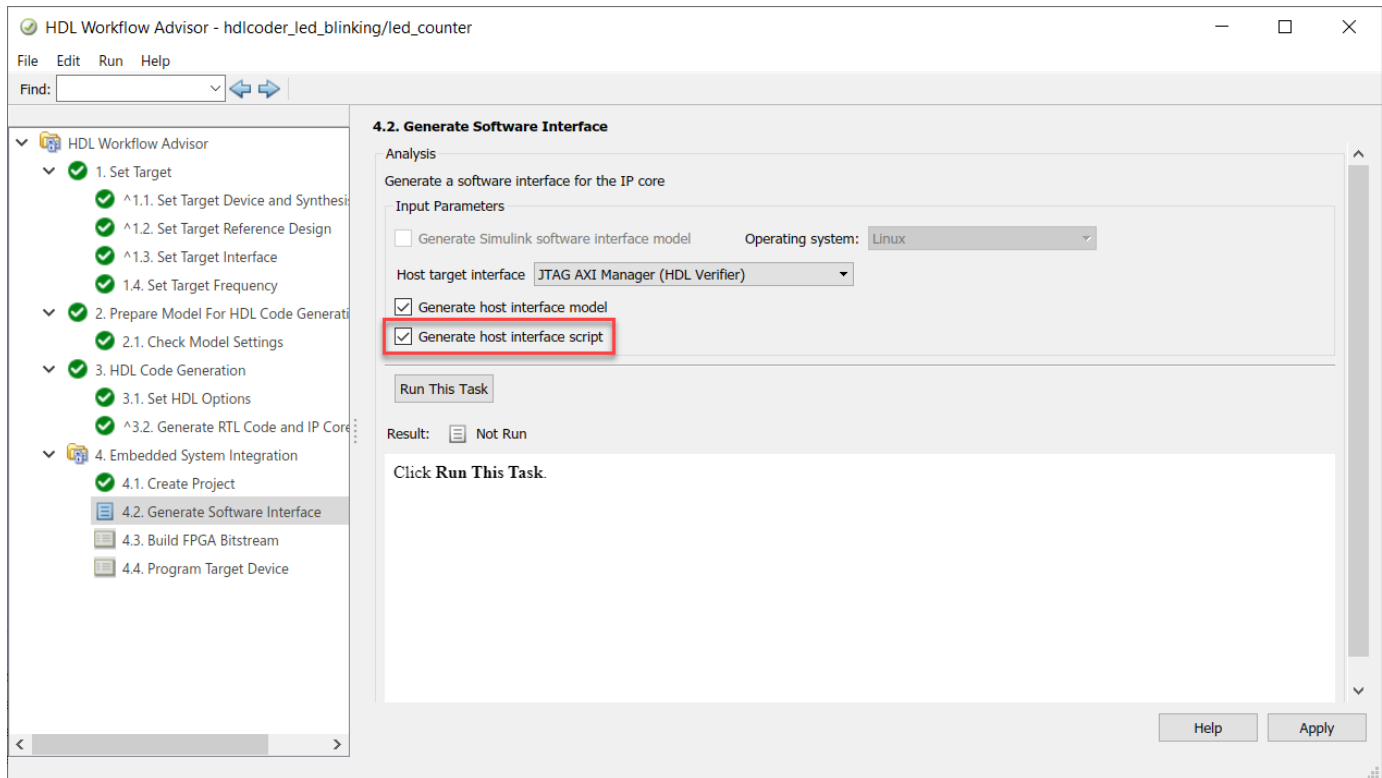

If you are targeting standalone FPGA boards, you cannot generate a software interface model. Instead, you can generate a host interface model, host interface script, or both and test the IP core by using the AXI Manager driver.

- 1 In the **Set Target Reference Design** task, set **Insert AXI Manager (HDL Verifier required)** to JTAG or Ethernet based on the interface that communicates between your host machine and the FPGA board. For Ethernet, specify the IP address of the FPGA board using the **Board IP Address** parameter.

Note By default, the Ethernet option is available for only the Artix-7 35T Arty, Kintex-7 KC705, and Virtex-7 VC707 boards. To enable this option for other Xilinx boards that have the Ethernet physical layer (PHY), manually add the Ethernet media access controller (MAC) Hub IP in the `plugin_board` file using the `addEthernetMACInterface` method before you launch the **HDL Workflow Advisor** tool.

Run the workflow to the **Generate Software Interface** task.

- 2 In the **Generate Software Interface** task, select the **Generate host interface script** check box and run this task.

At the command line, export the HDL Workflow Advisor settings to a script, and then use these properties with the Workflow Configuration object. This script specifies running the software interface task by generating the software interface model and host interface script. If you skip the task by setting the `RunTaskGenerateSoftwareInterface` to false, then the model and script are not generated. See “Configure and Run IP Core Generation Workflow with a Script”.

```
% Export Workflow Configuration Script
```

```
% ...
```

```
%% Load the Model
load_system('hdlcoder_led_blinking');
```

```
%% Model HDL Parameters
% Set Model HDL parameters
```

```
% ...
```

```
hdlset_param('hdlcoder_led_blinking', 'SynthesisTool', 'Xilinx Vivado');
hdlset_param('hdlcoder_led_blinking', 'Workflow', 'IP Core Generation');
```

```
% ...
```

```
% Set Workflow tasks to run
hWC.RunTaskGenerateSoftwareInterface = true;
hWC.GenerateSoftwareInterfaceModel = true;
hWC.GenerateHostInterfaceScript = true;
```

```
% ...
```

```
%% Run the workflow
hdlcoder.runWorkflow('hdlcoder_led_blinking/led_counter', hWC);
```

Host Interface Script

For rapid prototyping and testing the HDL IP core functionality, use the host interface script. The script is a MATLAB file that is generated based on the reference design and target platform interface table settings. It contains commands that enable you to connect to the target hardware, and write to or read from the generated IP core from MATLAB. For standalone FPGA boards, use the generated host interface script to verify the HDL IP core functionality by using the AXI Manager.

The host interface script has the same name as your original model with the prefix `gs_` and the postfix `_interface`. The script instantiates a setup function that is generated when you enable the generation of the host interface script. For example, this code shows the setup function generated for the model `hdlcoder_sfir_fixed_stream.slx`, with the reference design and target platform interface table settings previously specified. The setup function contains commands for the AXI4 slave and AXI4-Stream interfaces that HDL Coder uses to control the DUT ports in the generated HDL IP core that are mapped to the corresponding interfaces.

```
function gs_hdlcoder_sfir_fixed_stream_setup(hFPGA)

```

See “Prototype FPGA Design on Hardware with Live Data by Using MATLAB Commands” on page 46-234

This is an example host interface script to read and write data for models that have bus data types mapped to AXI4 slave interfaces.

To write to a bus port, you can either:

- Write to individual subports by specifying the full subport name, such as `bus1_in.scalar_in1`.

- Write to the entire bus by specifying the top port name, such as `bus1_in`. Pass the data to be written as a struct whose field names match the subport names. Not all subport names need to be part of the struct. The subports without corresponding struct fields are skipped when writing to the port.

To read from a bus port, you can either:

- Read an individual subport by specifying the full subport name such as `bus1_out.scalar.in1`.
- Read the entire bus port by specifying the top port name such as `bus1_out`.

```

More About

- “Model Design for AXI4-Stream Interface Generation” on page 47-13
- “Model Design for AXI4 Slave Interface Generation” on page 47-3
- “Create Host Interface Script to Control and Rapidly Prototype HDL IP Core” on page 46-74

Generate Software Interface Model to Probe and Rapidly Prototype HDL IP Core

When you run the hardware-software co-design workflow for SoC platforms, you generate an HDL IP core for the DUT algorithm, and then integrate the IP core into the reference design. See “Hardware-Software Co-Design Workflow for SoC Platforms” on page 46-8.

To test the HDL IP core on the target hardware, generate a software interface model. The software interface model uses AXI driver blocks to test the HDL IP core functionality in external mode simulation.

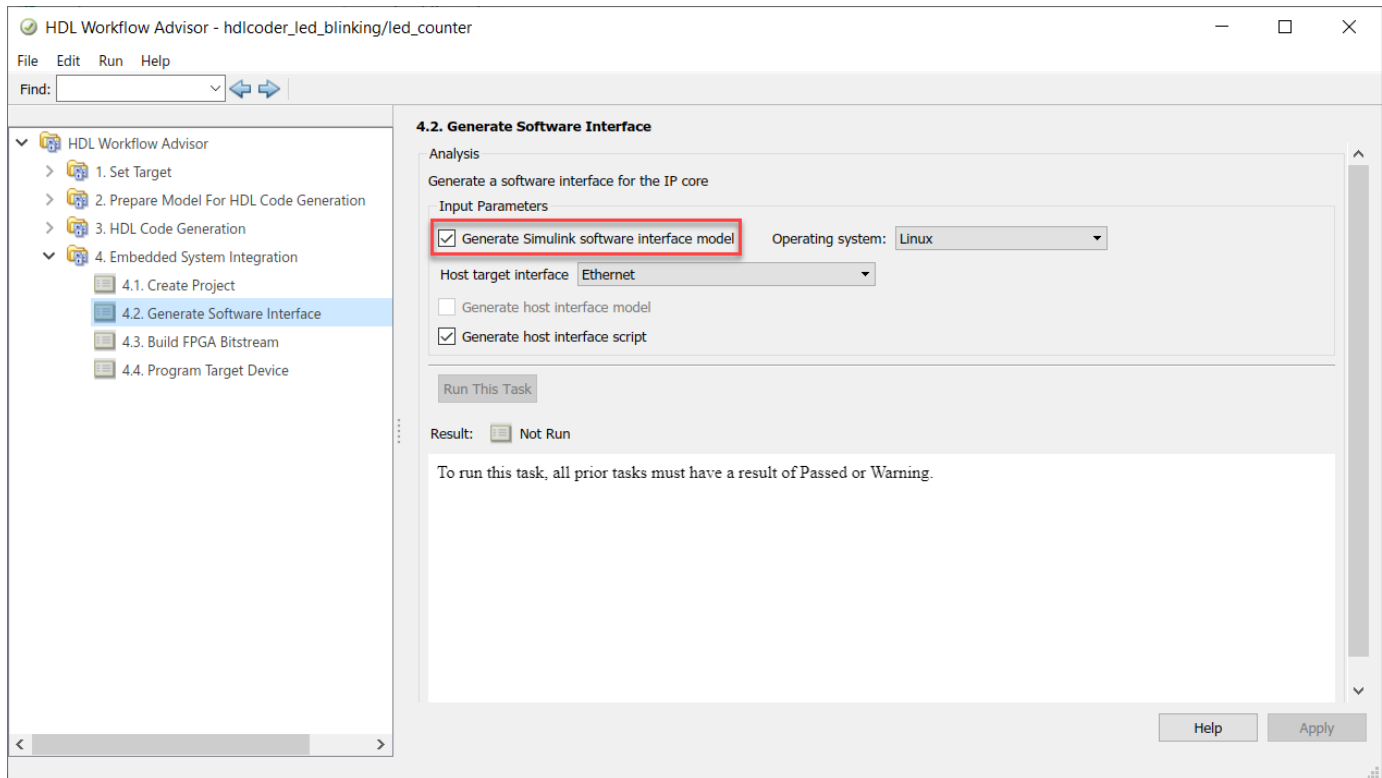

Prerequisites

- A target platform, such as ZedBoard, where you want to deploy your software interface model.
- The latest version of the third-party synthesis tool, such as Xilinx Vivado. See “HDL Language Support and Supported Third-Party Tools and Hardware”. In your MATLAB session, set the path to that installed synthesis tool by using the `hdlsetuptoolpath` function.
- If you are generating the software interface model, install Embedded Coder and Simulink Coder.
- Install the HDL Coder and Embedded Coder support packages for the target platform. On the MATLAB Toolstrip, click **Home** > **Add-Ons** > **Get Add-Ons** button. See “Get and Manage Add-Ons”.

Generate Software Interface

When running the IP core generation workflow, you can generate a host interface script and software interface model from the HDL Workflow Advisor UI or at the command line.

From the UI, in the **Embedded System Integration** > **Generate Software Interface** task, select the **Generate Simulink software interface model** check box.

If you are targeting standalone FPGA boards, you cannot generate a software interface model. Instead, you can generate a host interface script and test the IP core by using the AXI Manager driver.

- 1 In the **Set Target Reference Design** task, set **Insert AXI Manager (HDL Verifier required)** to JTAG or Ethernet based on the interface that communicates between your host machine and the FPGA board. For Ethernet, specify the IP address of the FPGA board using the **Board IP Address** parameter.

Note By default, the Ethernet option is available for only the Artix-7 35T Arty, Kintex-7 KC705, and Virtex-7 VC707 boards. To enable this option for other Xilinx boards that have the Ethernet physical layer (PHY), manually add the Ethernet media access controller (MAC) Hub IP in the `plugin_board` file using the `addEthernetMACInterface` method before you launch the **HDL Workflow Advisor** tool.

Run the workflow to the **Generate Software Interface** task.

- 2 In the **Generate Software Interface** task, select the **Generate host interface script** check box and run this task.

At the command line, export the HDL Workflow Advisor settings to a script, and then use these properties with the Workflow Configuration object. This script specifies running the software interface task by generating the model and script. If you skip the task by setting `RunTaskGenerateSoftwareInterface` to false, then the model and script are not generated. See “Configure and Run IP Core Generation Workflow with a Script”.

```

% Export Workflow Configuration Script

% ...

%% Load the Model
load_system('hdlcoder_led_blinking');

%% Model HDL Parameters
% Set Model HDL parameters

% ...

hdlset_param('hdlcoder_led_blinking', 'SynthesisTool', 'Xilinx Vivado');
hdlset_param('hdlcoder_led_blinking', 'Workflow', 'IP Core Generation');

% ...

% Set Workflow tasks to run
hWC.RunTaskGenerateSoftwareInterface = true;
hWC.GenerateSoftwareInterfaceModel = true;
hWC.GenerateHostInterfaceScript = true;

% ...

%% Run the workflow
hdlcoder.runWorkflow('hdlcoder_led_blinking/led_counter', hWC);

```

Software Interface Model

When you run the workflow for SoC platforms, a software interface model is generated to test the HDL IP core functionality. If you have Embedded Coder and Simulink Coder installed, you can generate embedded code from the model and build and run the executable on the ARM processor. When you target standalone FPGA boards, you cannot generate a software interface model because the boards do not have an embedded ARM processor. Instead, generate a host interface script to test the IP core by using the AXI Manager.

The generated software interface model replaces the DUT algorithm in your original model with AXI driver blocks based on the target platform interface table and reference design settings. To test the HDL IP core functionality, simulate the model in external mode to run on the target hardware. The model has concurrent execution enabled by default, which means that multiple tasks are executed concurrently by the processor on board the SoC platform.

The software interface model has the same name as your original model with the prefix `gm_` and the postfix `_interface`. The generated model from HDL code generation has the prefix `gm_`. To indicate that you are using this model as the software interface model, change the prefix to `sm_`.

Open the model `hdlcoder_sfir_fixed_stream`. This model maps the `sfir_fixed` model to the simplified AXI4-Stream protocol by inserting the `Valid` signal as an input control port.

```
open_system('hdlcoder_sfir_fixed_stream')
```

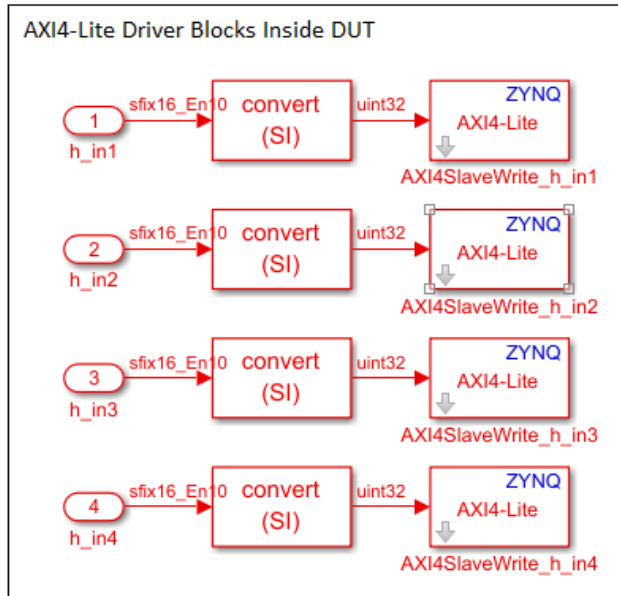

- 1 Open the HDL Workflow Advisor for the DUT subsystem. In the **Set Target Device and Synthesis Tool** task, specify IP Core Generation as **Target workflow** and ZedBoard as **Target platform**. Click **Run this task**.
- 2 In the **Set Target Reference Design** task, specify Default system with AXI4-Stream interface as the **Target Reference Design**. Click **Run this task**.
- 3 In the **Set Target Interface** task, map the DUT ports to target interfaces in the Target platform interface table. Click **Run this task**.

Target platform interface table					
Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
x_in_data	Inport	sfix16_En...	AXI4-Stream Slave ▼	Data ▼	
x_in_valid	Inport	boolean	AXI4-Stream Slave ▼	Valid ▼	
h_in1	Inport	sfix16_En...	AXI4-Lite ▼	x"100"	Options...
h_in2	Inport	sfix16_En...	AXI4-Lite ▼	x"104"	Options...
h_in3	Inport	sfix16_En...	AXI4-Lite ▼	x"108"	Options...
h_in4	Inport	sfix16_En...	AXI4-Lite ▼	x"10C"	Options...
y_out_data	Output	sfix32_En...	AXI4-Stream Master ▼	Data ▼	
y_out_valid	Output	boolean	AXI4-Stream Master ▼	Valid ▼	

- 4 Right-click the **Generate Software Interface** task and select **Run to selected task**. Run the workflow to generate the software interface model.

The generated software interface model has the name `gm_hdlcoder_sfir_fixed_stream_interface.slx`. Because your original model uses scalar ports for the data ports `x_in_data` and `y_out_data`, the **Generate software interface** task displays a warning that AXI4-Stream IIO driver blocks are not automatically generated in the software interface model. You can either insert the driver blocks from the Embedded Coder Support Package Library for the target platform in the Simulink Library Browser or rerun the workflow by mapping the data ports to vector signals. To see a software interface model that has the AXI4-Stream IIO driver blocks inserted in it, open `hdlcoder_sfir_fixed_stream_sw`. The model uses AXI4-Stream IIO Write and AXI4-Stream IIO Read blocks for the data ports. The filter ports are mapped to AXI4-Lite driver blocks.

```
open_system('hdlcoder_sfir_fixed_stream_sw')
```

Configure the model with a stop time of `inf`. On the **Hardware** tab, the hardware settings specified on the model. You can then connect, and build and run the application on the target platform to verify the HDL IP core functionality. See “Deploy Model with AXI-Stream Interface in Zynq Workflow” on page 47-172.

More About

- “Model Design for AXI4-Stream Interface Generation” on page 47-13
- “Model Design for AXI4 Slave Interface Generation” on page 47-3
- “Generate Host Interface Script to Probe and Rapidly Prototype HDL IP Core” on page 46-61
- “Create Host Interface Script to Control and Rapidly Prototype HDL IP Core” on page 46-74

Create Host Interface Script to Control and Rapidly Prototype HDL IP Core

Rapidly prototype the HDL IP core by interfacing with your target board over Ethernet or JTAG. Use an Ethernet connection for boards that have an ARM processor. Use a JTAG connection for boards that do not have an ARM processor.

Prerequisites

- A target platform, such as ZedBoard™, where you deploy your software interface model
- The latest version of the third-party synthesis tool, such as Xilinx Vivado. See “HDL Language Support and Supported Third-Party Tools and Hardware”. In your MATLAB session, set the path to that installed synthesis tool by using the `hdlsetuptoolpath` function.

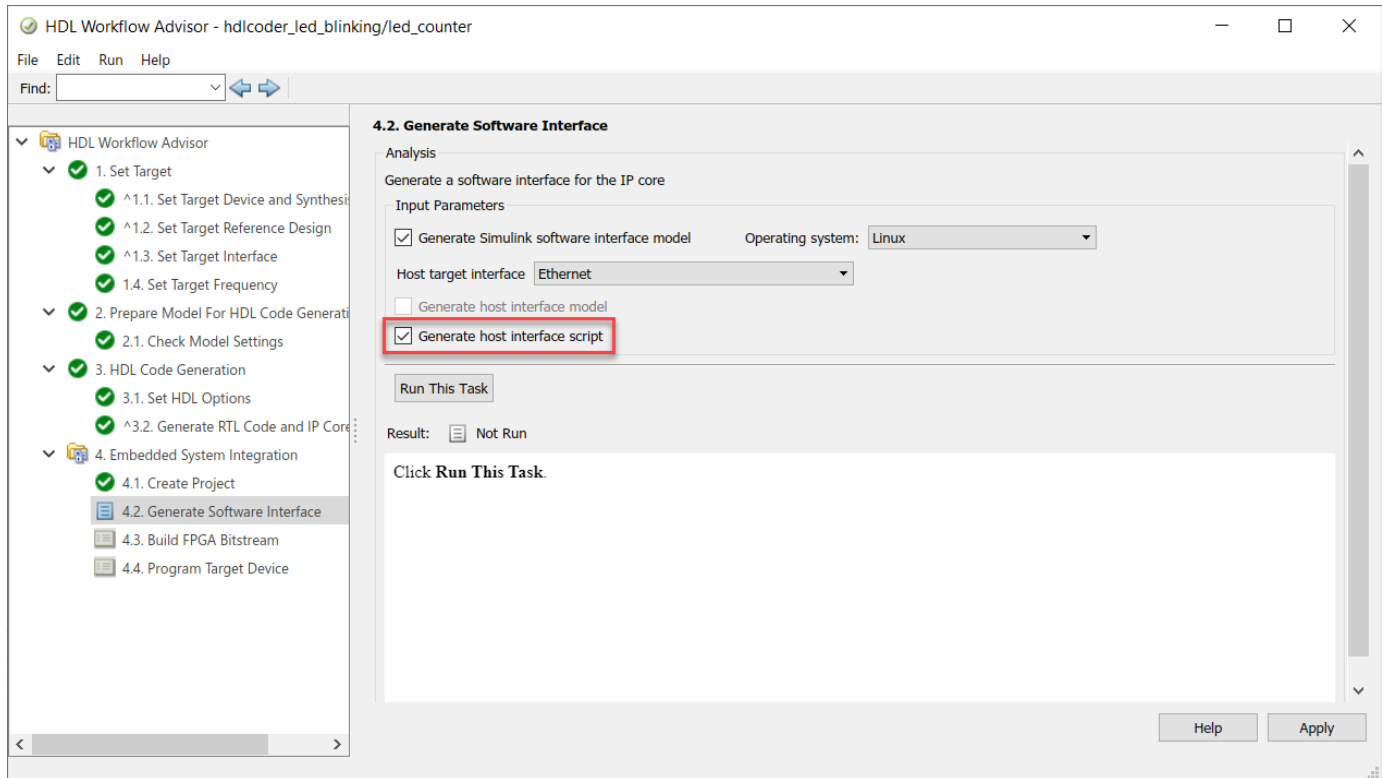

Ethernet-Based Interface

To use an Ethernet-based connection to your target hardware boards that have an embedded ARM processor, you can either generate a host interface script or create a custom software script. Before setting up the Ethernet-based interface, set up the board’s SD card with the MathWorks firmware image. To set up the firmware image for your target board:

- For Intel related boards, see “Guided SD Card Setup” (HDL Coder Support Package for Intel SoC Devices)
- For Xilinx related boards, see “Guided SD Card Setup” (HDL Coder Support Package for Xilinx Zynq Platform).

Host Interface Script

Set the **Host target interface** parameter to Ethernet and select the **Generate host interface script** check box. Then, run the **Generate Software Interface** task.

The generated MATLAB files are:

- `gs_modelName_setup.m`, which is a setup script that adds the AXI4 slave and AXI4-Stream interfaces. The script also contains DUT port objects that have the port name, direction, data type, and interface mapping information. The script then maps the DUT ports to the corresponding interfaces.
- `gs_modelName_interface.m`, which creates a target object, instantiates the setup script `gs_modelName_setup.m`, and then connects to the target hardware. The script then sends read and write commands to the generated HDL IP core.

See “Generate Host Interface Script to Probe and Rapidly Prototype HDL IP Core” on page 46-61.

Customize the Host Interface Script

For rapid prototyping, customize the host interface script or create your own script based on how you modify your original design. Customize the script to specify:

- A target object for a different FPGA vendor.
- Additional interfaces or configure existing interfaces based on modifications to your original design. HDL Coder uses this information to create the IIO drivers to access the HDL IP core.
- Additional DUT port objects or remove existing objects based on how you modify your design, and then change the mapping information accordingly.

- Input data to write to the DUT ports and output data to read from the ports.

Develop Host Interface Script

You can customize the generated host interface script or create your own host interface script. To create a custom host interface script:

- 1 Create an fpga object for the target device and store in hFPGA.

```
hFPGA = fpga("Xilinx")

hFPGA =

    fpga with properties:

        Vendor: "Xilinx"
        Interfaces: [0x0 fpgaio.interface.InterfaceBase]
```

To use an Intel target:

```
hFPGA = fpga("Intel")

hFPGA =

    fpga with properties:

        Vendor: "Intel"
        Interfaces: [0x0 fpgaio.interface.InterfaceBase]
```

- 2 Configure the AXI interfaces to map the DUT ports in the generated HDL IP core. You can add AXI4 slave and AXI4-Stream interfaces. To add AXI4 slave interfaces, use the `addAXI4SlaveInterface` function.

```
addAXI4SlaveInterface(hFPGA, ...
    ... % Interface properties
    "InterfaceID", "AXI4-Lite", ...
    "BaseAddress", 0xA0000000, ...
    "AddressRange", 0x10000, ...
    ... % Driver properties
    "WriteDeviceName", "mwipcore0:mmwr0", ...
    "ReadDeviceName", "mwipcore0:mrd0");
```

To add AXI4-Stream interfaces, use the `addAXI4StreamInterface` function.

```
addAXI4StreamInterface(hFPGA, ...
    ... % Interface properties
    "InterfaceID", "AXI4-Stream", ...
    "WriteEnable", true, ...
    "ReadEnable", true, ...
    "WriteFrameLength", 1024, ...
    "ReadFrameLength", 1024, ...
    ... % Driver properties
    "WriteDeviceName", "mwipcore0:mm2s0", ...
    "ReadDeviceName", "mwipcore0:s2mm0");
```

The interface mapping information that you specified is saved as a property on the `fpga` object, `hFPGA`.

```
hFPGA
```

```
hFPGA =
```

```
    fpga with properties:
```

```
        Vendor: "Xilinx"
        Interfaces: [1x2 fpgaio.interface.InterfaceBase]
```

For standalone FPGA boards that do not have an embedded ARM processor, you can create an object, and then use the `aximanager` object. Then use this object as the driver for the `addAXI4SlaveInterface` function. The `aximanager` object requires the HDL Verifier support package for the Intel or Xilinx FPGA boards.

```
% Create an "aximanager" object
hAXIMDriver = aximanager("Xilinx");

% Pass it into the addInterface command
addAXI4SlaveInterface(hFPGA, ...
    ... % Interface properties
    "InterfaceID", "AXI4-Lite", ...
    "BaseAddress", 0xB0000000, ...
    "AddressRange", 0x10000, ...
    ... % Driver properties
    "WriteDriver", hAXIMDriver, ...
    "ReadDriver", hAXIMDriver, ...
    "DriverAddressMode", "Full");
```

- 3 Specify information about the DUT ports in the generated HDL IP core as a port object array by using the `hdlcoder.DUTPort` object. The object represents the ports of your DUT on the target hardware.

```
hPort_h_in1 = hdlcoder.DUTPort("h_in1", ...
    "Direction", "IN", ...
    "DataType", numerictype(1,16,10), ...
    "Dimension", [1 1], ...
    "IOInterface", "AXI4-Lite", ...
    "IOInterfaceMapping", "0x100")
```

```
hPort_h_in1 =
```

```
    DUTPort with properties:
```

```
        Name: "h_in1"
        Direction: IN
        DataType: [1x1 embedded.numerictype]
        Dimension: [1 1]
        IOInterface: "AXI4-Lite"
        IOInterfaceMapping: "0x100"
```

To write to or read from the DUT ports in the generated HDL IP core, map the ports to the AXI interface by using the `mapPort` function. After you map the ports to the interfaces, this information is saved on the `fpga` object as the `Interfaces` property.

```
mapPort(hFPGA, hPort_h_in1);
hFPGA.Interfaces
```

```
ans =
```

```
AXI4Slave with properties:
```

```
    InterfaceID: "AXI4-Lite"
    BaseAddress: "0xA0000000"
    AddressRange: "0x10000"
    WriteDriver: [1x1 fpgaio.driver.AXIMemoryMappedIIOWrite]
    ReadDriver: [1x1 fpgaio.driver.AXIMemoryMappedIIOWrite]
    InputPorts: "h_in1"
    OutputPorts: [0x0 string]
```

You can also specify this information for ports mapped to AXI4-Stream interfaces.

```
hPort_x_in_data = hdlcoder.DUTPort("x_in_data", ...
    "Direction", "IN", ...
    "DataType", numerictype(1,16,10), ...
    "Dimension", [1 1], ...
    "IOInterface", "AXI4-Stream");

hPort_y_out_data = hdlcoder.DUTPort("y_out_data", ...
    "Direction", "OUT", ...
    "DataType", numerictype(1,32,20), ...
    "Dimension", [1 1], ...
    "IOInterface", "AXI4-Stream");
```

To write to or read from the DUT ports in the generated HDL IP core, map the ports to the AXI interface by using the `mapPort` function.

```
mapPort(hFPGA, [hPort_x_in_data, hPort_y_out_data]);
```

After you map the ports to the interfaces, this information is saved on the `fpga` object as the `Interfaces` property.

```
hFPGA
```

```
hFPGA =
```

```
    fpga with properties:
```

```
        Vendor: "Xilinx"
        Interfaces: [1x2 fpgaio.interface.InterfaceBase]
```

```
hFPGA.Interfaces
```

```
ans =
```

```
AXI4Slave with properties:
```

```
    InterfaceID: "AXI4-Lite"
    BaseAddress: "0xA0000000"
```

```

AddressRange: "0x10000"
WriteDriver: [1x1 fpgaio.driver.AXIMemoryMappedIIOWrite]
ReadDriver: [1x1 fpgaio.driver.AXIMemoryMappedIIOWrite]
InputPorts: "h_in1"
OutputPorts: [0x0 string]

```

AXI4Stream with properties:

```

InterfaceID: "AXI4-Stream"
WriteEnable: 1
ReadEnable: 1
WriteFrameLength: 1024
ReadFrameLength: 1024
WriteDriver: [1x1 fpgaio.driver.AXIStreamIIOWrite]
ReadDriver: [1x1 fpgaio.driver.AXIStreamIIOWrite]
InputPorts: "x_in_data"
OutputPorts: "y_out_data"

```

- 4 To test the HDL IP core functionality, use the `readPort` and `writePort` functions to write data to or read data from these ports.

```

writePort(hFPGA, "h_in1", 5);

writePort(hFPGA, "x_in", sin(linspace(0, 2*pi, 1024)));
data = readPort(hFPGA, "y_out");

```

- 5 After you have tested the HDL IP core, you can release the hardware resource associated with the `fpga` object by using the `release` function.

```
release(hFPGA)
```

- 6 For an example on creating a custom interface script and prototyping your design on a target FPGA board over an Ethernet connection, see “Prototype FPGA Design on Hardware with Live Data by Using MATLAB Commands” on page 46-234.

JTAG-Based Interface

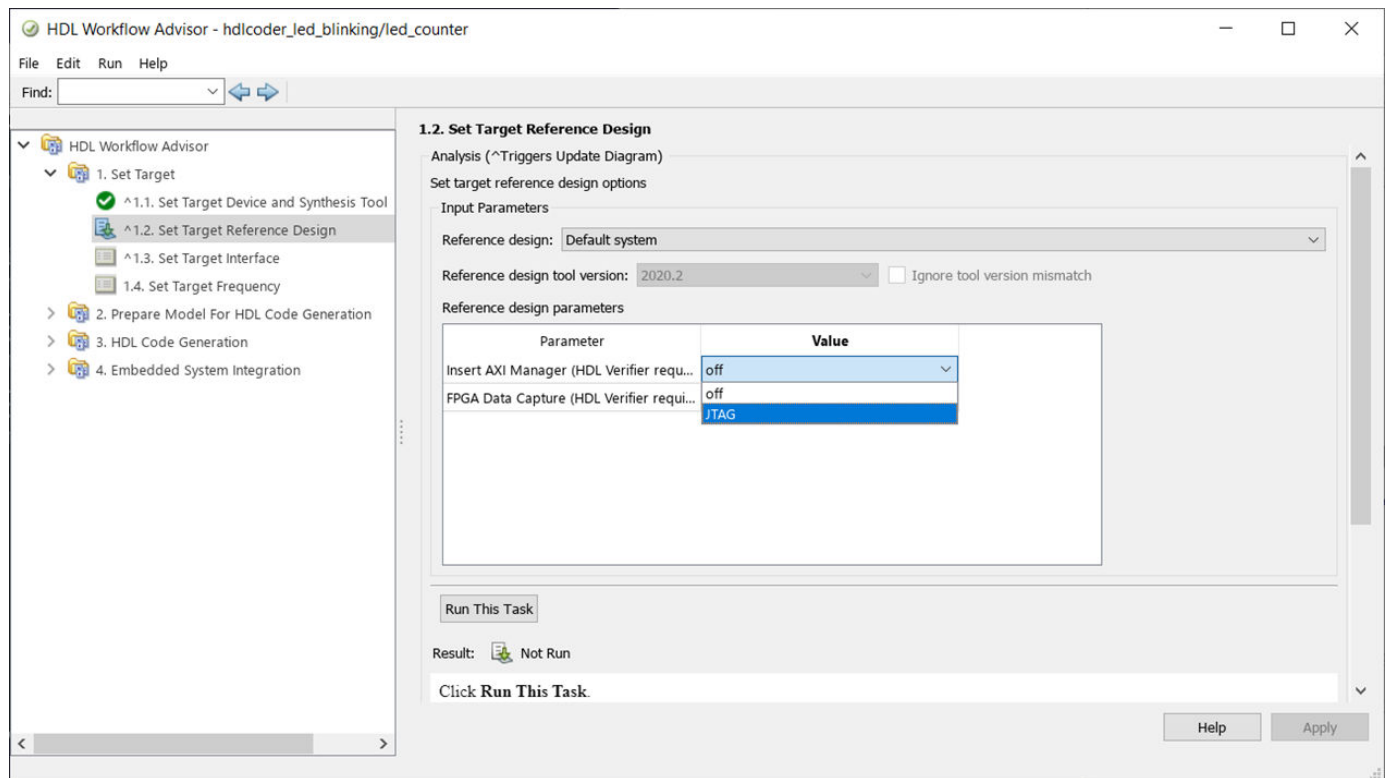

For standalone FPGA boards that do not have an embedded ARM processor, you can insert the JTAG AXI Manager IP into your reference design. Create a script that uses the `aximanager` object that connects to the IP over a physical JTAG cable. This script enables read and write commands to slave memory locations from the MATLAB command line.

To use AXI Manager:

- Install the HDL Verifier hardware support packages.
- Do not target standalone boards that do not have the `hRD.AXI4SlaveInterface` functionality or boards that are based on Xilinx ISE.

Insert JTAG AXI Manager

When you run the IP Core Generation workflow, in the **Set Target > Set Target Reference Design** task, choose `Default` system for **Reference Design** and set **Insert AXI Manager (HDL Verifier required)** to JTAG.

To generate the IP Core and create a project with AXI Manager IP, right-click the **Create Project** task and select **Run to Selected Task**.

Control the HDL Coder IP Core at the MATLAB Command Line

You can now interact with your target FPGA board by using the JTAG AXI Manager feature. Create an object by using the `aximanager` object. Use the created object as the driver for the `addAXI4SlaveInterface` function.

```
% Create an "aximanager" object
hAXIMDriver = aximanager("Xilinx");

% Pass it into the addInterface command
addAXI4SlaveInterface(hFPGA, ...
    ... % Interface properties
    "InterfaceID", "AXI4-Lite", ...
    "BaseAddress", 0xB0000000, ...
    "AddressRange", 0x10000, ...
    ... % Driver properties
    "WriteDriver", hAXIMDriver, ...
    "ReadDriver", hAXIMDriver, ...
    "DriverAddressMode", "Full");
```

For an example on how to interface with a target board over JTAG, see “Use JTAG AXI Manager to Control HDL Coder Generated IP Core” on page 47-311.

Getting Started with Targeting Xilinx Zynq Platform

This example shows how to use the hardware-software co-design workflow to blink LEDs at various frequencies on the Xilinx® Zynq® ZC702 evaluation kit.

Introduction

This example is a step-by-step guide that helps you use HDL Coder™ to generate a custom HDL IP core which blinks LEDs on the Xilinx Zynq ZC702 evaluation kit, and shows how to use Embedded Coder® to generate C code that runs on the ARM® processor to control the LED blink frequency.

You can use MATLAB® and Simulink® to design, simulate, and verify your application, perform what-if scenarios with algorithms, and optimize parameters. You can then prepare your design for hardware and software implementation on the Zynq-7000 AP SoC by deciding which system elements will be performed by the programmable logic, and which system elements will run on the ARM Cortex-A9.

Using the guided workflow shown in this example, you automatically generate HDL code for the programmable logic using HDL Coder, generate C code for the ARM using Embedded Coder, and implement the design on the Xilinx Zynq Platform.

In this workflow, you perform the following steps:

- 1 Set up your Zynq hardware and tools.
- 2 Partition your design for hardware and software implementation.
- 3 Generate an HDL IP core using HDL Workflow Advisor.
- 4 Integrate the IP core into a Xilinx Vivado project and program the Zynq hardware.
- 5 Generate a software interface model.
- 6 Generate C code from the software interface model and run it on the ARM Cortex-A9 processor.
- 7 Tune parameters and capture results from the Zynq hardware using External Mode.

For more information, refer to other more advanced examples, and the HDL Coder and Embedded Coder documentation.

Requirements

- 1 Xilinx Vivado Design Suite, with supported version listed in the “HDL Language Support and Supported Third-Party Tools and Hardware”.
- 2 Xilinx Zynq-7000 SoC ZC702 Evaluation Kit
- 3 HDL Coder Support Package for Xilinx Zynq Platform
- 4 Embedded Coder Support Package for Xilinx Zynq Platform

Set up Zynq hardware and tools

1. Set up the Xilinx Zynq ZC702 evaluation kit as shown in the figure below. To learn more about the ZC702 hardware setup, please refer to documentation.

1.1. Make sure the SW16 switch is set as shown in the figure below, so you can boot Linux from the SD card.

1.2. Make sure the SW10 switch (JTAG chain input select two-position DIP switch) is set as shown in the figure below, so you can use the Digilent USB-to-JTAG interface (U23). Position 1: Off; Position 2: On.

1.3 Connect your computer to the USB UART connector using a Micro-USB cable. Make sure your USB device drivers, such as for the Silicon Labs CP210x USB to UART Bridge, are installed correctly. If not, search for the drivers online and install them.

1.4 Connect your computer and the Zynq board using an Ethernet cable.

2. Install the HDL Coder and Embedded Coder Support Packages for Xilinx Zynq Platform if you haven't already. To start the installer, go to the MATLAB toolstrip and click **Add-Ons > Get Hardware Support Packages**. For more information, see "Install Support for Xilinx Zynq Platform" (Embedded Coder Support Package for Xilinx Zynq Platform).

3. Make sure you are using the SD card image provided by the Embedded Coder Support Package for Xilinx Zynq Platform. If you need to update your SD card image, see the Hardware Setup section of "Install Support for Xilinx Zynq Platform" (Embedded Coder Support Package for Xilinx Zynq Platform).

4. Set up the Zynq hardware connection by entering the following command in the MATLAB command window:

```
h = zynq
```

The `zynq` function logs in to the hardware via COM port and runs the `ifconfig` command to obtain the IP address of the board. This function also tests the Ethernet connection.

5. You can optionally test the serial connection using the following configuration using a program such as PuTTY™. Baud rate: 115200; Data bits: 8; Stop bits: 1; Parity: None; Flow control: None. You should be able to observe Linux booting log on the serial console when you power cycle the Zynq board. You must close this serial connection before using the `zynq` function again.

6. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2020.2\bin\vivado.ba
```

Partition your design for hardware and software implementation

The first step of the Zynq hardware-software co-design workflow is to decide which parts of your design to implement on the programmable logic, and which parts to run on the ARM processor.

Group all the blocks you want to implement on programmable logic into an atomic subsystem. This atomic subsystem is the boundary of your hardware-software partition. All the blocks inside this subsystem will be implemented on programmable logic, and all the blocks outside this subsystem will run on the ARM processor.

In this example, the subsystem **led_counter** is the hardware subsystem. It models a counter that blinks the LEDs on an FPGA board. Two input ports, **Blink_frequency** and **Blink_direction**, are control ports that determine the LED blink frequency and direction. All the blocks outside of the subsystem **led_counter** are for software implementation.

In Simulink, you can use the **Slider Gain** or **Manual Switch** block to adjust the input values of the hardware subsystem. In the embedded software, this means the ARM processor controls the generated IP core by writing to the AXI interface accessible registers. The output port of the hardware subsystem, **LED**, connects to the LED hardware. The output port, **Read_Back**, can be used to read data back to the processor.

```
open_system('hdlcoder_led_blinking');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2014 The MathWorks, Inc.

Generate an HDL IP core using the HDL Workflow Advisor

Using the IP Core Generation workflow in the HDL Workflow Advisor enables you to automatically generate a sharable and reusable IP core module from a Simulink model. The generated IP core is designed to be connected to an embedded processor on an FPGA device. HDL Coder generates HDL code from the Simulink blocks, and also generates HDL code for the AXI interface logic connecting the IP core to the embedded processor. HDL Coder packages all the generated files into an IP core folder. You can then integrate the generated IP core with a larger FPGA embedded design in the Xilinx Vivado environment.

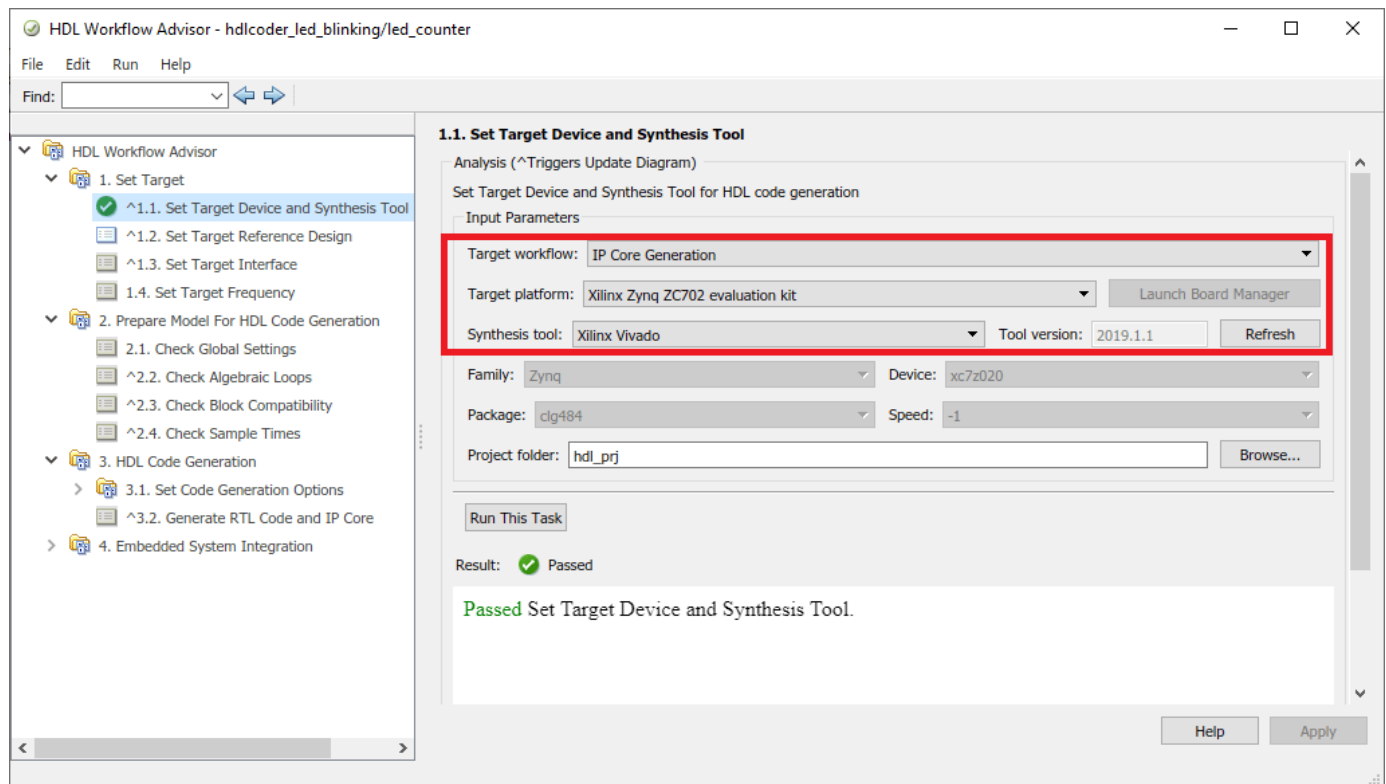

1. Start the IP core generation workflow.

1.1. Open the HDL Workflow Advisor from the `hdlcoder_led_blinking/led_counter` subsystem by right-clicking the `led_counter` subsystem, and choosing **HDL Code > HDL Workflow Advisor**.

1.2. In the **Set Target > Set Target Device and Synthesis Tool** task, for **Target workflow**, select **IP Core Generation**.

1.3. For **Target platform**, select **Xilinx Zynq ZC702 evaluation kit**. If you don't have this option, select **Get more** to open the Support Package Installer. In the Support Package Installer, select Xilinx Zynq Platform and follow the instructions provided by the Support Package Installer to complete the installation.

1.4. Click **Run This Task** to run the **Set Target Device and Synthesis Tool** task.

1.5 In the **Set Target > Set Target Reference Design** task, choose **Default system**.

1.6. Click **Run This Task** to run the **Set Target Reference Design** task.

2. Configure the target interface.

Map each port in your DUT to one of the IP core target interfaces. In this example, input ports **Blink_frequency** and **Blink_direction** are mapped to the AXI4-Lite interface, so HDL Coder generates AXI interface accessible registers for them. The **LED** output port is mapped to an external interface, **LEDs General Purpose [0:7]**, which connects to the LED hardware on the Zynq board.

2.1 In the **Set Target** > **Set Target Interface** task, choose **AXI4-Lite** for **Blink_frequency**, **Blink_direction**, and **Read_back**.

2.2 Choose **LEDs General Purpose [0:7]** for **LED**.

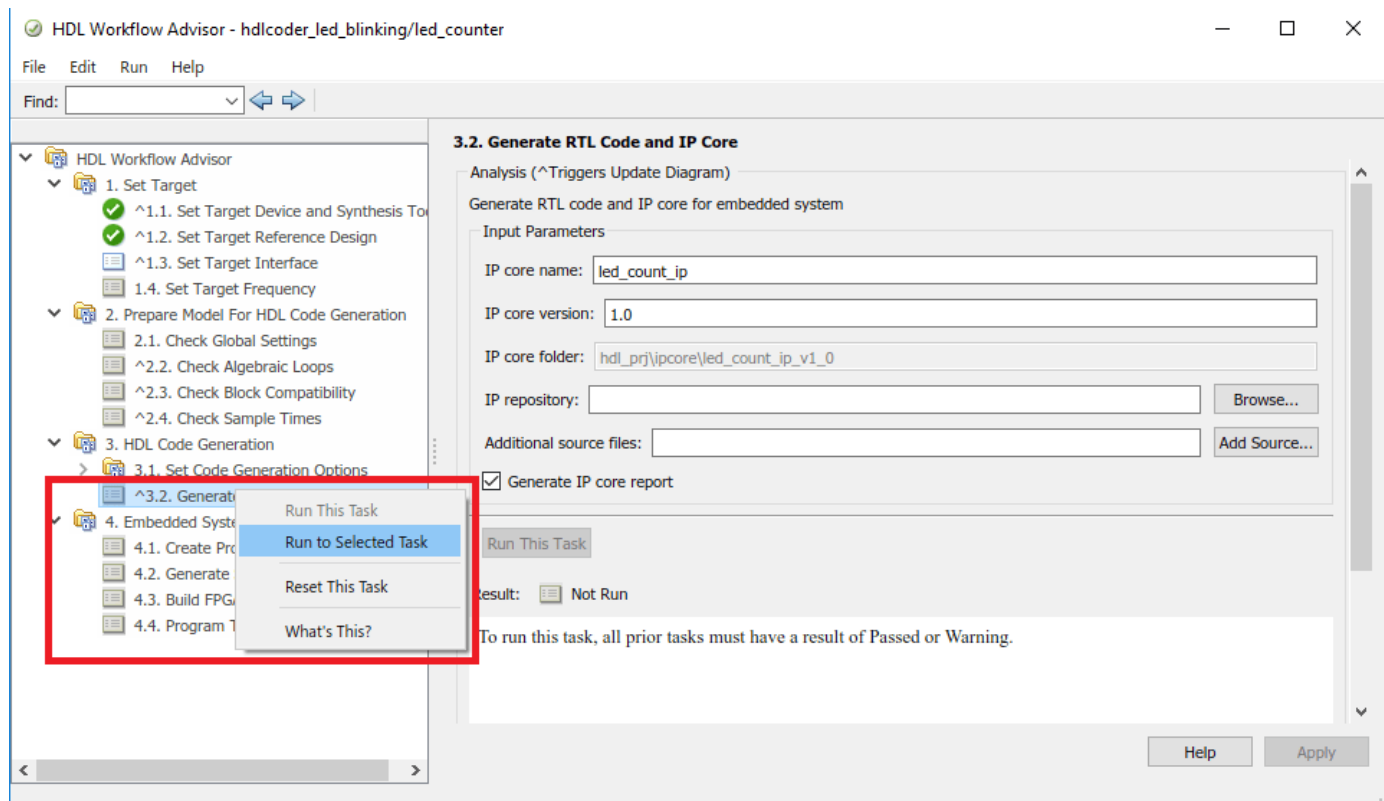

2.3 In the **Set Target** > **Set Target Frequency** task, choose **Target Frequency** as **50 MHz**.

3. Generate the IP Core.

To generate the IP core, right-click the **Generate RTL Code and IP Core** task and select **Run to Selected Task**.

4. Generate and view the IP core report.

After you generate the custom IP core, the IP core files are in the **ipcore** folder within your project folder. An HTML custom IP core report is generated together with the custom IP core. The report describes the behavior and contents of the generated custom IP core.

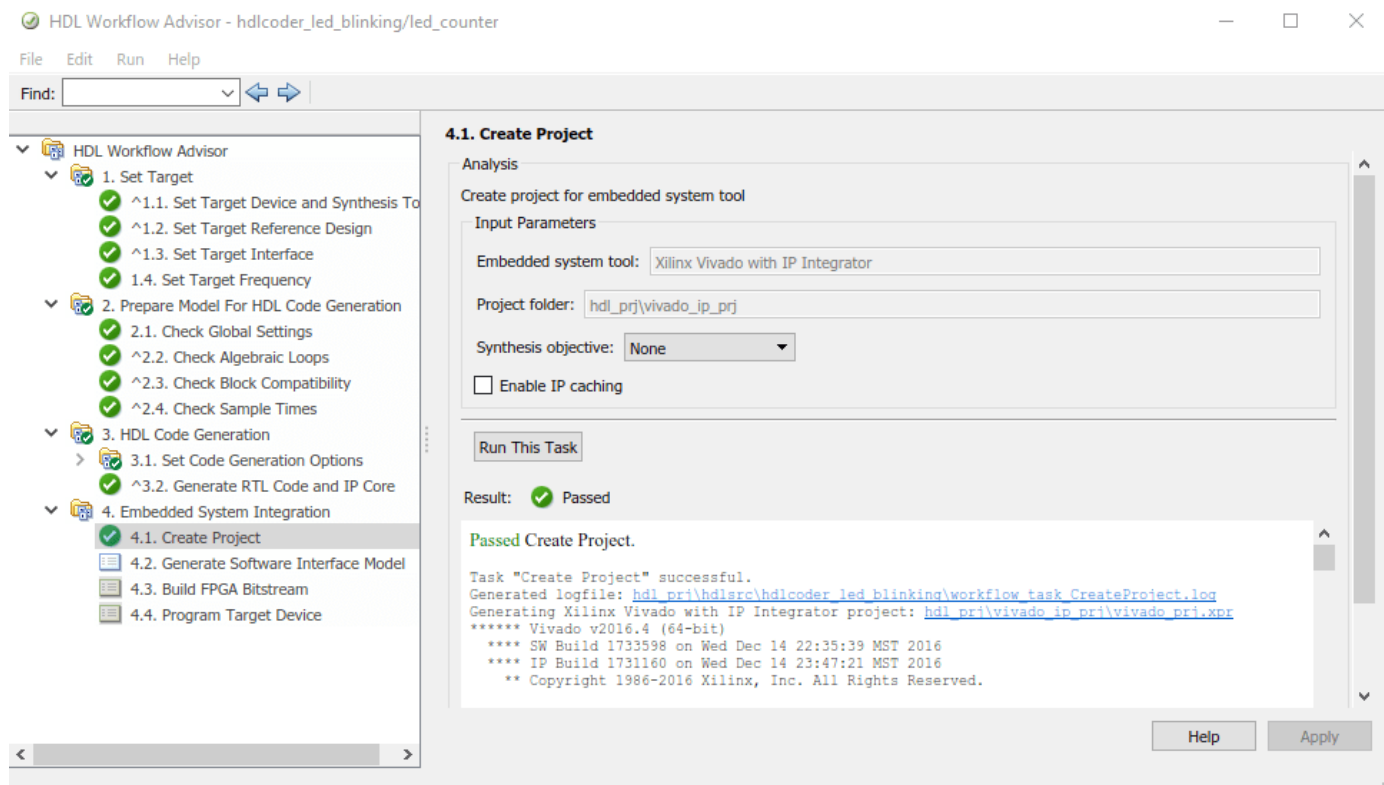

Integrate the IP core with the Xilinx Vivado environment

In this part of the workflow, you insert your generated IP core into an embedded system reference design, generate an FPGA bitstream, and download the bitstream to the Zynq hardware.

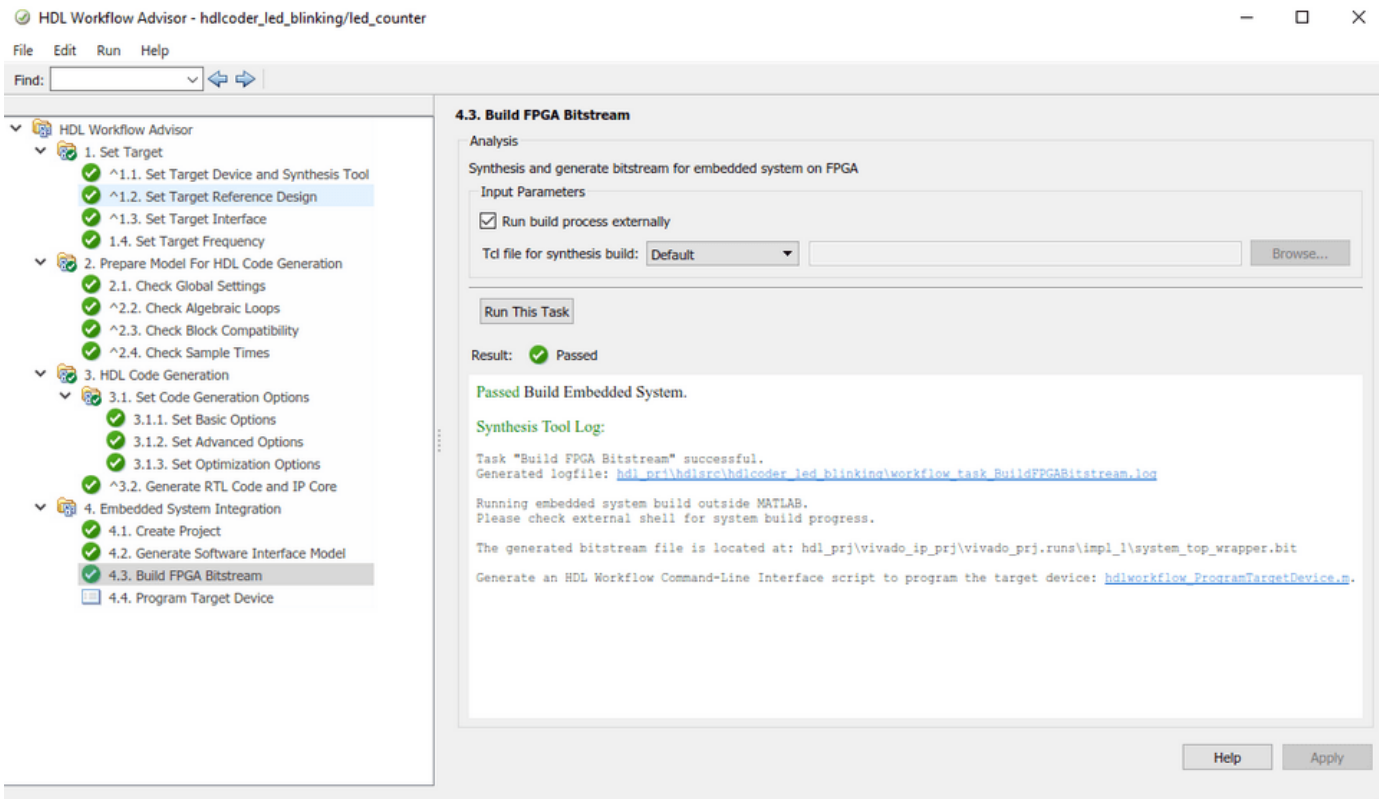

The reference design is a predefined Xilinx Vivado project. It contains all the elements the Xilinx software needs to deploy your design to the Zynq platform, except for the custom IP core and embedded software that you generate.

1. To integrate with the Xilinx Vivado environment, select the **Create Project** task under **Embedded System Integration**, and click **Run This Task**. A Xilinx Vivado project with IP Integrator embedded design is generated, and a link to the project is provided in the dialog window. You can optionally open up the project to take a look.

2. If you have an Embedded Coder license, you can generate a software interface model in the next task, **Generate Software Interface Model**. The details of the software interface model are explained in the next section of this example, "Generate a software interface model".

3. Build the FPGA bitstream in the **Build FPGA Bitstream** task. Make sure the **Run build process externally** option is checked, so the Xilinx synthesis tool will run in a separate process from MATLAB. Wait for the synthesis tool process to finish running in the external command window.

4. After the bitstream is generated, select the **Program Target Device** task. Choose **Download** for **Programming method** to download the FPGA bitstream onto the SD card on the Zynq board, so your design will be automatically reloaded when you power cycle the Zynq board. click **Run This Task** to program the Zynq hardware.

After you program the FPGA hardware, the LED starts blinking on your Zynq board.

Next, you will generate C code to run on the ARM processor to control the LED blink frequency and direction.

Generate a software interface model

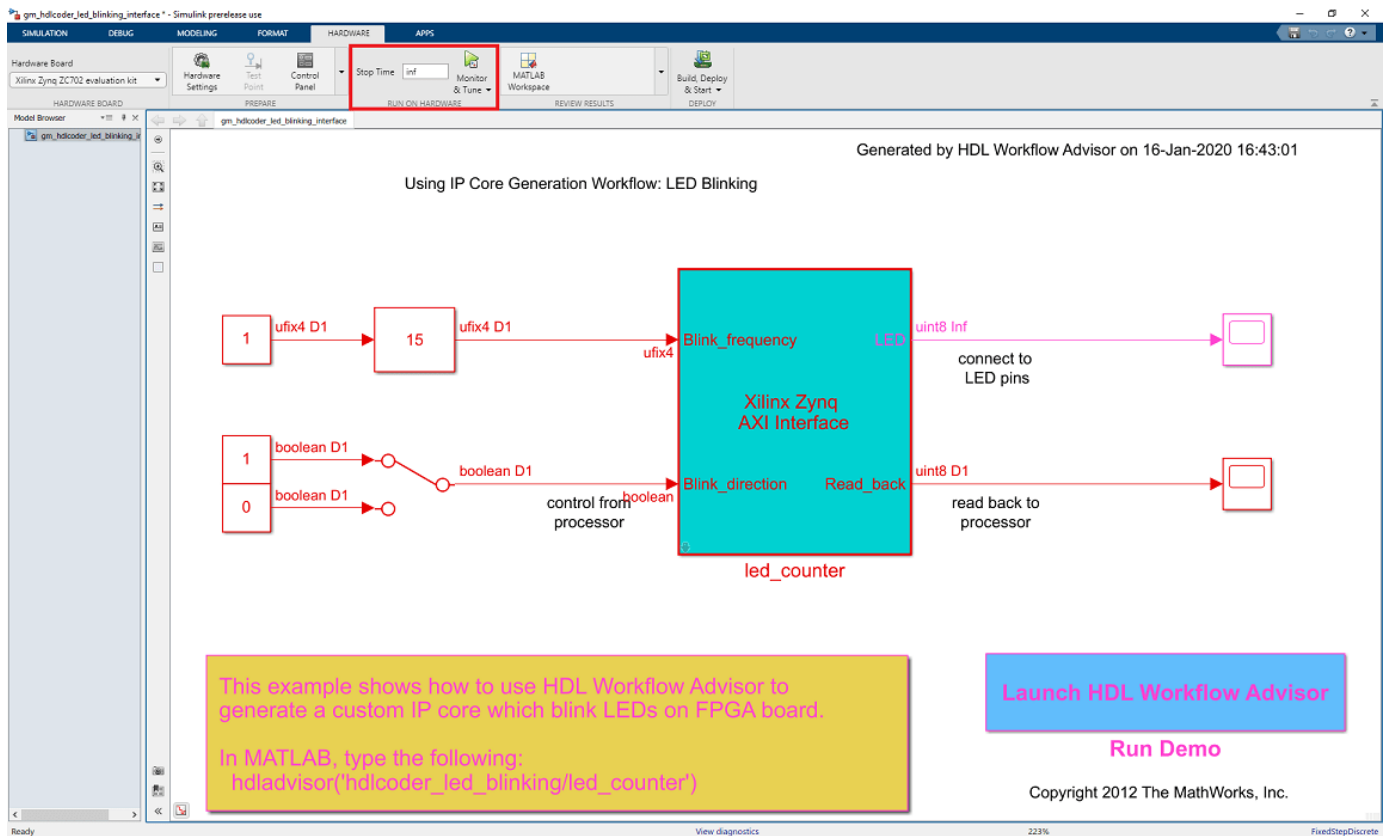

In the HDL Workflow Advisor, after you generate the IP core and insert it into the Vivado reference design, you can optionally generate a software interface model in the **Embedded System Integration > Generate Software Interface Model** task.

The software interface model contains the part of your design that runs in software. It includes all the blocks outside of the HDL subsystem, and replaces the HDL subsystem with AXI driver blocks. If you have an Embedded Coder license, you can automatically generate embedded code from the software interface model, build it, and run the executable on Linux on the ARM processor. The generated embedded software includes AXI driver code, generated from the AXI driver blocks, that controls the HDL IP core.

Run the **Generate Software Interface Model** task and see that a new model is generated. The task dialog shows a link to the model.

In the generated software interface model, the "led_counter" subsystem is replaced with the AXI driver blocks which generate the interface logic between the ARM processor and FPGA.

Run the software interface model on Zynq ZC702 hardware

In this part of the workflow, you configure the generated software interface model, automatically generate embedded C code, and run your model on the ARM processor in the Zynq hardware in External mode.

When you are prototyping and developing an algorithm, it is useful to monitor and tune the algorithm while it runs on hardware. The External mode feature in Simulink enables this capability. In this mode, your algorithm is first deployed to the ARM processor in the Zynq hardware, and then linked with the Simulink model on the host computer through an Ethernet connection.

The main role of the Simulink model is to tune and monitor the algorithm running on the hardware. Because the ARM processor is connected to the HDL IP core through the AXI interface, you can use External mode to tune parameters, and capture data from the FPGA.

- 1 In the generated model, click on Hardware pane and go to **Hardware settings** to open **Configuration Parameter** dialog box.
- 2 Select **Solver** and set "Stop Time" to "inf".
- 3 From the **HARDWARE** pane, click the **Monitor & Tune** button on the model toolstrip to run your model on the ARM processor in the Zynq ZC702 hardware in External mode. Embedded Coder builds the model, downloads the ARM executable to the Zynq ZC702 hardware, executes it, and connects the model to the executable running on the Zynq ZC702 hardware.
- 4 Double-click the **Slider Gain** block. Change the Slider Gain value and observe the change in frequency of the LED array blinking on the Zynq ZC702 hardware. Double-click the **Manual Switch** block to switch the direction of the blinking LEDs.
- 5 Double-click the scope connected to the **Read_back** output port and observe that the output data of the FPGA IP core is captured and sent back to the Simulink scope.
- 6 When you are done changing model parameters, click the **Stop** button on the model. Observe that the system command window opened in the previous step indicates that the model has been stopped. At this point, you can close the system command window.

Summary

This example shows how the hardware and software co-design workflow helps automate the deployment of your MATLAB and Simulink design to a Zynq-7000 All Programmable SoC. You can explore the best ways to partition and deploy your design by iterating through the workflow.

The following diagram shows the high-level picture of the workflow you went through in this example. To learn more about the hardware and software co-design workflow, see “Hardware-Software Co-Design Workflow for SoC Platforms” on page 46-8.

Getting Started with Targeting Zynq UltraScale+ MPSoC Platform

This example shows how to use the hardware-software co-design workflow to blink LEDs at various frequencies on the Xilinx® Zynq® UltraScale+ MPSoC.

Introduction

This example is a step-by-step guide that helps you use the HDL Coder™ software to generate a custom HDL IP core which blinks LEDs on the Xilinx Zynq UltraScale+ MPSoC ZCU102 evaluation kit, and shows how to use Embedded Coder® to generate C code that runs on the ARM® processor to control the LED blink frequency.

You can use MATLAB® and Simulink® to design, simulate, and verify your application, perform what-if scenarios with algorithms, and optimize parameters. You can then prepare your design for hardware and software implementation on the Xilinx Zynq UltraScale+ MPSoC by deciding which system elements will be performed by the programmable logic, and which system elements will run on the ARM Cortex-A53.

Using the guided workflow shown in this example, you automatically generate HDL code for the programmable logic using HDL Coder, generate C code for the ARM processor using Embedded Coder, and implement the design on the Xilinx Zynq UltraScale+ MPSoC Platform.

In this workflow, you perform the following steps:

- 1 Set up your Xilinx Zynq UltraScale+ MPSoC ZCU102 hardware and tools.
- 2 Partition your design for hardware and software implementation.
- 3 Generate an HDL IP core using HDL Workflow Advisor.
- 4 Integrate the IP core into a Xilinx Vivado project and program the Xilinx Zynq UltraScale+ MPSoC hardware.
- 5 Generate a software interface model.
- 6 Generate C code from the software interface model and run it on the ARM Cortex-A53 processor.
- 7 Tune parameters and capture results from the Zynq hardware using External Mode.

Requirements

- 1 Xilinx Vivado Design Suite, with supported version listed in the “HDL Language Support and Supported Third-Party Tools and Hardware”.
- 2 Xilinx Zynq UltraScale+ MPSoC ZCU102 Evaluation Kit
- 3 HDL Coder Support Package for Xilinx Zynq Platform
- 4 Embedded Coder Support Package for Xilinx Zynq Platform

Set up your Xilinx Zynq UltraScale+ MPSoC hardware and tools

1. Set up the Xilinx Zynq UltraScale+ MPSoC ZCU102 evaluation kit as shown in the figure below. To learn more about the ZCU102 hardware setup, please refer to Xilinx documentation.

Ethernet Connector

USB to UART Connector

General Purpose LED's & DIP Switches

Power ON/OFF Switch

Power Supply

4. Set up the Zynq hardware connection by entering the following command in the MATLAB command window:

```
h = zynq
```

The `zynq` function logs in to the hardware via COM port and runs the `ifconfig` command to obtain the IP address of the board. This function also tests the Ethernet connection.

5. You can optionally test the serial connection using the following configuration using a program such as PuTTY™. Baud rate: 115200; Data bits: 8; Stop bits: 1; Parity: None; Flow control: None. You should be able to observe Linux booting log on the serial console when you power cycle the MPSoC board. You must close this serial connection before using the `zynq` function again.

6. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2019.1\bin\vivado.ba
```

Partition your design for hardware and software implementation

The first step of the Zynq hardware-software co-design workflow is to decide which parts of your design to implement on the programmable logic, and which parts to run on the ARM processor.

Group all the blocks you want to implement on programmable logic into an Atomic Subsystem. This Atomic Subsystem is the boundary of your hardware-software partition. All the blocks inside this subsystem will be implemented on programmable logic, and all the blocks outside this subsystem will run on the ARM processor.

In this example, the subsystem **led_counter** is the hardware subsystem. It models a counter that blinks the LEDs on an FPGA board. Two input ports, **Blink_frequency** and **Blink_direction**, are control ports that determine the LED blink frequency and direction. All the blocks outside of the subsystem **led_counter** are used for software implementation.

In Simulink, you can use the **Slider Gain** or **Manual Switch** block to adjust the input values of the hardware subsystem. In the embedded software, this means the ARM processor controls the generated IP core by writing to the AXI interface accessible registers. The output port of the hardware subsystem, **LED**, connects to the LED hardware. The output port, **Read_Back**, can be used to read data back to the processor.

```
open_system('hdlcoder_led_blinking');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2014 The MathWorks, Inc.

Generate an HDL IP core using the HDL Workflow Advisor

Using the IP Core Generation workflow in the HDL Workflow Advisor enables you to automatically generate a sharable and reusable IP core module from a Simulink model. The generated IP core is designed to be connected to an embedded processor on an FPGA device. HDL Coder generates HDL code from the Simulink blocks, and also generates HDL code for the AXI interface logic connecting the IP core to the embedded processor. HDL Coder packages all the generated files into an IP core folder. You can then integrate the generated IP core with a larger FPGA embedded design in the Xilinx Vivado environment.

1. Start the IP core generation workflow.

1.1. Open the HDL Workflow Advisor from the `hdlcoder_led_blinking/led_counter` subsystem by right-clicking the `led_counter` subsystem, and choosing **HDL Code > HDL Workflow Advisor**.

1.2. In the **Set Target > Set Target Device and Synthesis Tool** task, for **Target workflow**, select **IP Core Generation**.

1.3. For **Target platform**, select **Xilinx Zynq UltraScale+ MPSoC ZCU102 Evaluation Kit**. If you don't have this option, select **Get more** to open the Support Package Installer. In the Support Package Installer, select Xilinx Zynq Platform and follow the instructions provided by the Support Package Installer to complete the installation.

1.4. Click **Run This Task** to run the **Set Target Device and Synthesis Tool** task.

1.5 In the **Set Target > Set Target Reference Design** task, choose **Default system**.

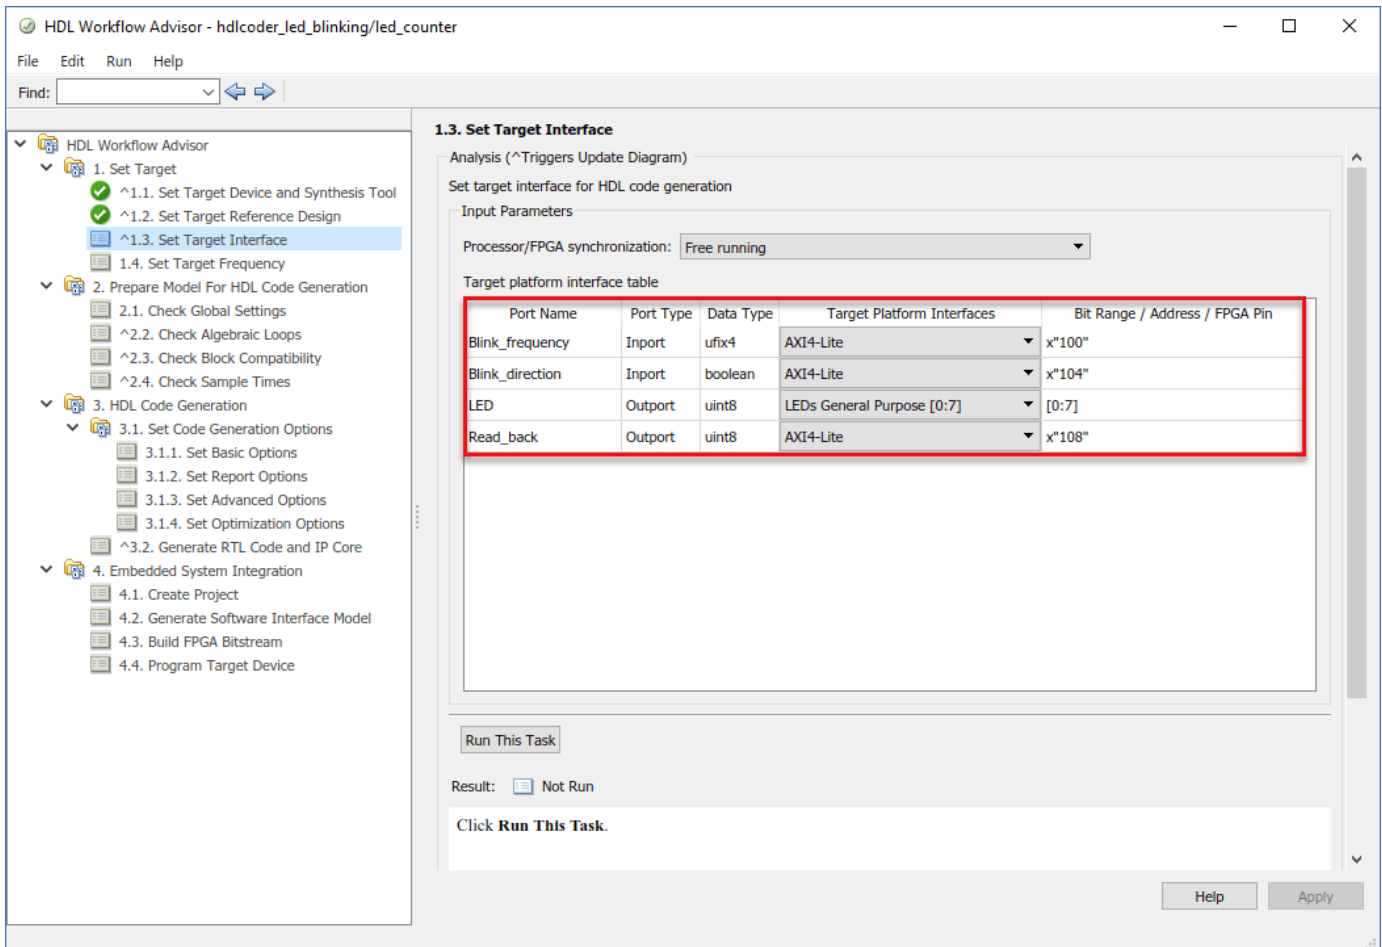

1.6. Click **Run This Task** to run the **Set Target Reference Design** task.

2. Configure the target interface.

Map each port in your DUT to one of the IP core target interfaces. In this example, input ports **Blink_frequency** and **Blink_direction** are mapped to the AXI4-Lite interface, so HDL Coder generates AXI interface accessible registers for them. The **LED** output port is mapped to an external interface, **LEDs General Purpose [0:7]**, which connects to the LED hardware on the Zynq board.

2.1 In the **Set Target** > **Set Target Interface** task, choose **AXI4-Lite** for **Blink_frequency**, **Blink_direction**, and **Read_back**.

2.2 Choose **LEDs General Purpose [0:7]** for **LED**.

2.3 In the **Set Target > Set Target Frequency** task, choose **Target Frequency as 50 MHz**.

3. Generate the IP Core.

To generate the IP core, right-click the **Generate RTL Code and IP Core** task and select **Run to Selected Task**.

4. Generate and view the IP core report.

After you generate the custom IP core, the IP core files are in the **ipcore** folder within your project folder. An HTML custom IP core report is generated together with the custom IP core. The report describes the behavior and contents of the generated custom IP core.

Referenced Models

IP Core User Guide

Theory of Operation

This IP core is designed to be connected to an embedded processor with an **AXI4-Lite interface**. The processor acts as master, and the IP core acts as slave. By accessing the generated registers via the AXI4-Lite interface, the processor can control the IP core, and read and write data from and to the IP core.

For example, to reset the IP core, write 0x1 to the bit 0 of IPCore_Reset register. To enable or disable the IP core, write 0x1 or 0x0 to the IPCore_Enable register. To access the data ports of the MATLAB/Simulink algorithm, read or write to the associated data registers.

Diagram: A Processing System (blue box) is connected to a Programmable Logic IP Core (orange box) via an AXI4-Lite interface (green double-headed arrow). Inside the IP Core, there are AXI4-Lite Accessible Registers and an Algorithm from MATLAB/Simulink. The IP Core also has External Ports (orange arrows).

This IP core also support the **External Port** interface. To connect the external ports to the FPGA external IO pins, add FPGA pin assignment constraints in the Xilinx Vivado environment.

Processor/FPGA Synchronization

The **Free running** mode means there is no explicit synchronization between embedded processor software execution (SW) and the IP core (HW). SW and HW runs independently. The data written from the processor to IP core takes effect immediately, and the data read from the IP core is the latest

OK Help

Integrate the IP core with the Xilinx Vivado environment

In this part of the workflow, you insert your generated IP core into an embedded system reference design, generate an FPGA bitstream, and download the bitstream to the Zynq hardware.

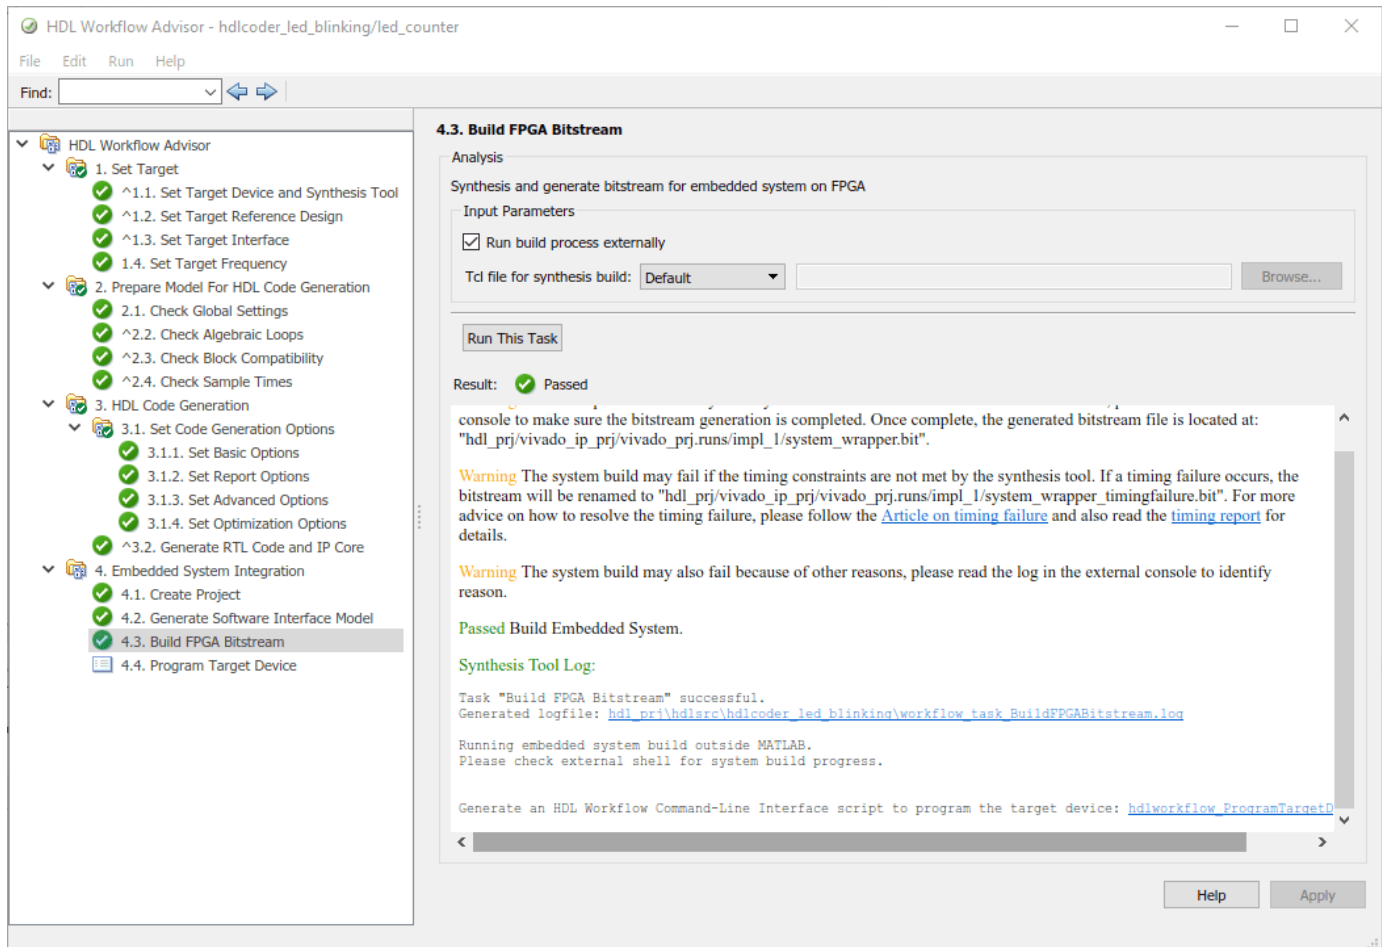

The reference design is a predefined Xilinx Vivado project. It contains all the elements the Xilinx software needs to deploy your design to the Zynq platform, except for the custom IP core and embedded software that you generate.

1. To integrate with the Xilinx Vivado environment, select the **Create Project** task under **Embedded System Integration**, and click **Run This Task**. A Xilinx Vivado project with IP Integrator embedded design is generated, and a link to the project is provided in the dialog window. You can optionally open up the project to take a look.

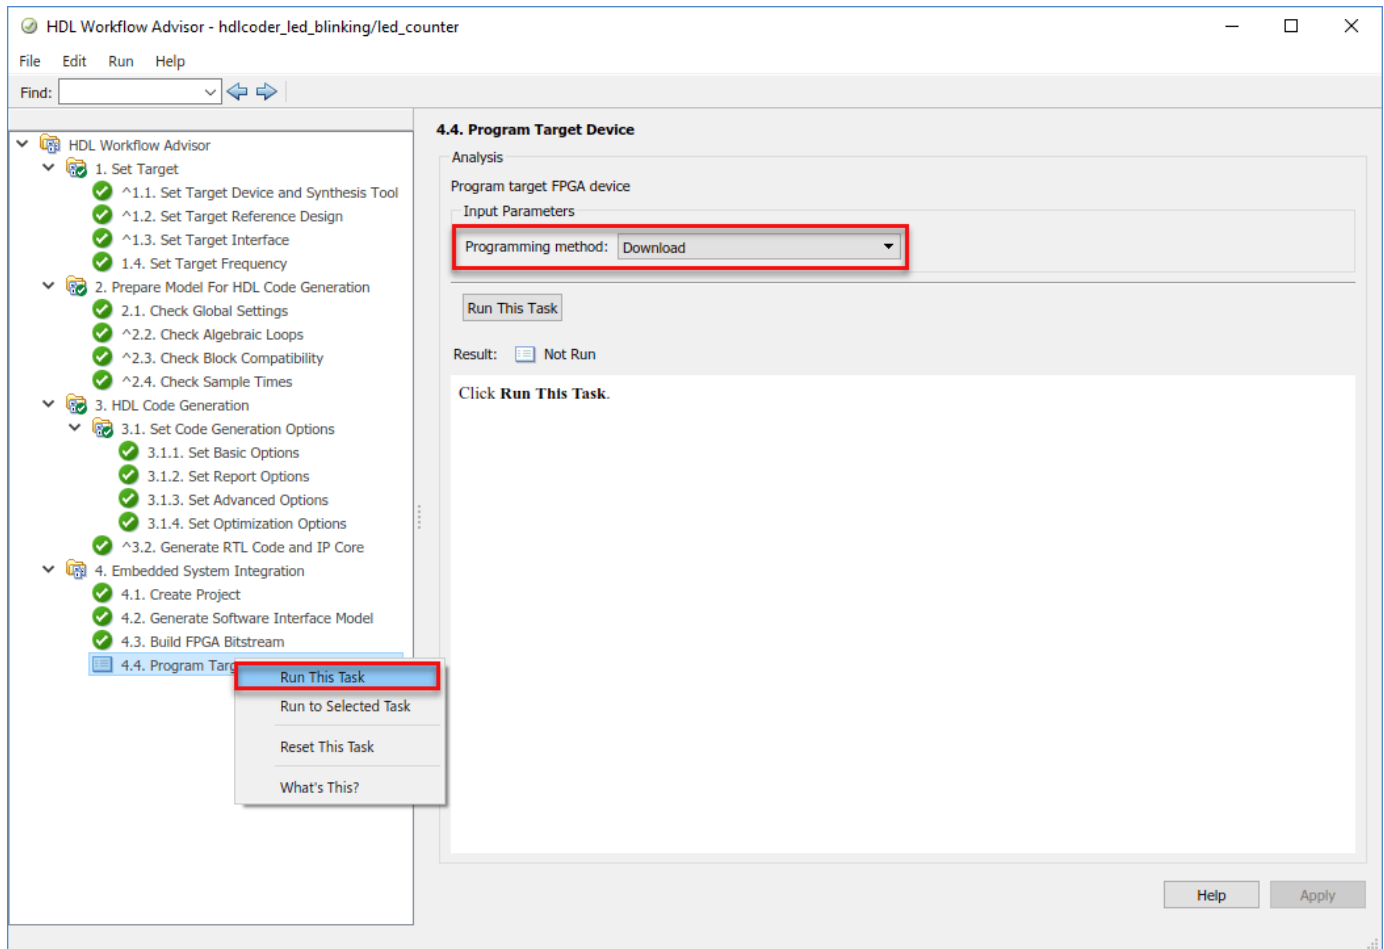

2. If you have an Embedded Coder license, you can generate a software interface model in the next task, **Generate Software Interface Model**. The details of the software interface model are explained in the next section of this example, "Generate a software interface model".

3. Build the FPGA bitstream in the **Build FPGA Bitstream** task. Make sure the **Run build process externally** option is checked, so the Xilinx synthesis tool will run in a separate process from MATLAB. Wait for the synthesis tool process to finish running in the external command window.

4. After the bitstream is generated, select the **Program Target Device** task. Choose **Download for Programming method** to download the FPGA bitstream onto the SD card on the Xilinx Zynq UltraScale+ MPSoC board, so your design will be automatically reloaded when you power cycle the Zynq board. click **Run This Task** to program the Zynq hardware.

After you program the FPGA hardware, the LED starts blinking on your Xilinx Zynq UltraScale+ MPSoC ZCU102 board.

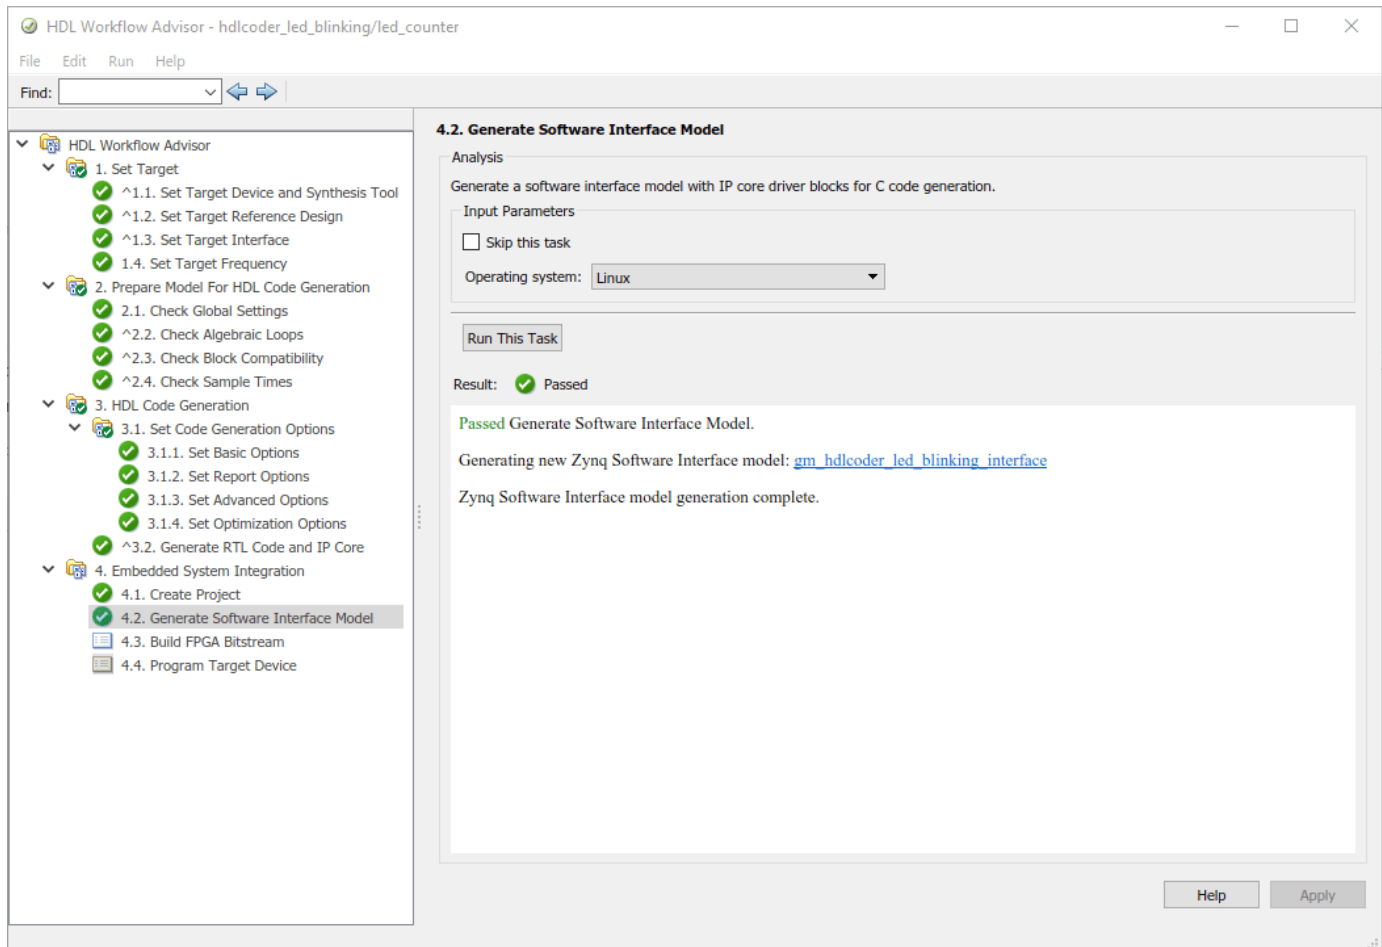

Next, you will generate C code to run on the ARM processor to control the LED blink frequency and direction.

Generate a software interface model

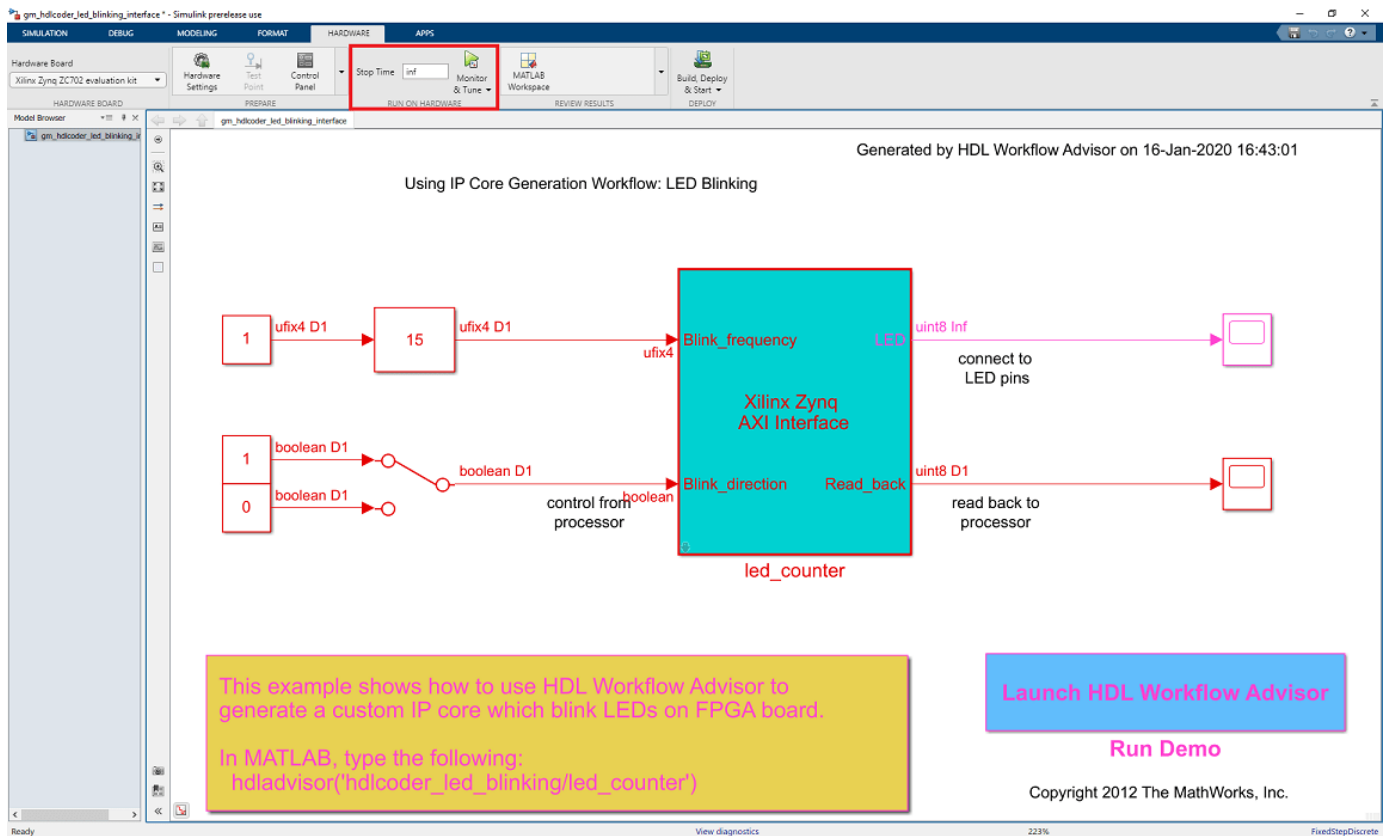

In the HDL Workflow Advisor, after you generate the IP core, you can create a Vivado project in step 4.1, you can optionally generate a software interface model in the **Embedded System Integration > Generate Software Interface Model** task.

The software interface model contains the part of your design that runs in software. It includes all the blocks outside of the HDL subsystem, and replaces the HDL subsystem with AXI driver blocks. If you have an Embedded Coder license, you can automatically generate embedded C code from the software interface model, build it, and run the executable on Linux on the ARM processor. The generated embedded software includes AXI driver code, generated from the AXI driver blocks, that controls the HDL IP core.

Run the **Generate Software Interface Model** task and see that a new model is generated. The task dialog shows a link to the model.

In the generated software interface model, the `led_counter` subsystem is replaced with the AXI driver blocks which generates the interface logic between the ARM processor and FPGA.

Run the software interface model on Zynq ZCU102 hardware

In this part of the workflow, you configure the generated software interface model, automatically generate embedded C code, and run your model on the ARM processor in the Zynq hardware in External mode.

When you are prototyping and developing an algorithm, it is useful to monitor and tune the algorithm while it runs on hardware. The External mode feature in Simulink enables this capability. In this mode, your algorithm is first deployed to the ARM processor in the Zynq hardware, and then linked with the Simulink model on the host computer through an Ethernet connection.

The main role of the Simulink model is to tune and monitor the algorithm running on the hardware. Because the ARM processor is connected to the HDL IP core through the AXI interface, you can use External mode to tune parameters, and capture data from the FPGA.

- 1 In the generated model, click on Hardware pane and go to **Hardware settings** to open **Configuration Parameter** dialog box.
- 2 Select **Solver** and set **Stop Time** to **inf**.
- 3 Select **Hardware Implementation** and set **Feature set for selected hardware board** to **Embedded Coder Hardware Support Package**.
- 4 From the **HARDWARE** menu, click the **Monitor & Tune** button on the model toolstrip to run your model on the ARM processor in the Zynq UltraScale+ MPSoC ZCU102 hardware in External mode. Embedded Coder builds the model, downloads the ARM executable to the Xilinx Zynq UltraScale+ MPSoC ZCU102 hardware, executes it, and connects the model to the executable running on the Zynq hardware.
- 5 Double-click the **Slider Gain** block. Change the Slider Gain value and observe the change in frequency of the LED array blinking on the Zynq hardware. Double-click the **Manual Switch** block to switch the direction of the blinking LEDs.
- 6 Double-click the scope connected to the **Read_back** output port and observe that the output data of the FPGA IP core is captured and sent back to the Simulink scope.
- 7 When you are done changing model parameters, click the **Stop** button on the model.

Summary

This example shows how the hardware-software co-design workflow helps automate the deployment of your MATLAB and Simulink design to a Xilinx Zynq UltraScale+ MPSoC. You can explore the best ways to partition and deploy your design by iterating through the workflow.

The following diagram shows the high-level picture of the workflow you went through in this example. To learn more about the hardware and software co-design workflow, see “Hardware-Software Co-Design Workflow for SoC Platforms” on page 46-8.

Getting Started with Targeting Intel SoC Devices

This example shows how to use the hardware-software co-design workflow to blink LEDs at various frequencies on the Arrow® SoCKit® evaluation kit.

Introduction

This example is a step-by-step guide that helps you use the HDL Coder™ software to generate a custom HDL IP core which blinks LEDs on the Arrow SoCKit evaluation kit, and shows how to use Embedded Coder® to generate C code that runs on the ARM® processor to control the LED blink frequency.

You can use MATLAB® and Simulink® to design, simulate, and verify your application, perform what-if scenarios with algorithms, and optimize parameters. You can then prepare your design for hardware and software implementation on the Altera Cyclone V SoC by deciding which system elements will be performed by the programmable logic, and which system elements will run on the ARM Cortex-A9.

Using the guided workflow shown in this example, you automatically generate HDL code for the programmable logic using HDL Coder, generate C code for the ARM using Embedded Coder, and implement the design on the Intel SoC devices.

In this workflow, you perform the following steps:

- 1 Set up your Intel SoC hardware and tools.
- 2 Partition your design for hardware and software implementation.
- 3 Generate an HDL IP core using HDL Workflow Advisor.
- 4 Integrate the IP core into a Intel Qsys project and program the Intel SoC hardware.
- 5 Generate a software interface model.
- 6 Generate C code from the software interface model and run it on the ARM Cortex-A9 processor.
- 7 Tune parameters and capture results from the Intel SoC hardware using External Mode.

For more information, refer to other more advanced examples, and the HDL Coder and Embedded Coder documentation.

Requirements

- 1 Intel Quartus Prime, with supported version listed in the “HDL Language Support and Supported Third-Party Tools and Hardware”.
- 2 Intel SoC Embedded Design Suite
- 3 Arrow SoCKit Cyclone V SoC evaluation kit
- 4 HDL Coder Support Package for Intel SoC Devices
- 5 Embedded Coder Support Package for Intel SoC Devices

Set up Intel SoC hardware and tools

1. Set up the Arrow SoCKit evaluation kit as shown in the figure below. To learn more about the Arrow SoCKit hardware setup, please refer to the board documentation.

1.1 Set up SW4 switch (JTAG chain select) as shown in the figure below. Position 1 : OFF; Position 2 : ON. This configuration includes HPS in JTAG chain, and bypasses HSMC.

1.2 Set up JP2 as shown in the figure below to adjust the I/O Standard of the FPGA/HSMC pins. Short Pin 5 and 6 to set the I/O voltage to 2.5V.

1.3 Set up J17 - J19 as shown in the figure above to boot HPS from SD card. J17: Short Pin 1 and 2; J18: Short Pin 1 and 2; J19: Short Pin 2 and 3.

1.4 Set up J15 - J16 as shown in the figure above for HPS clock setting. J15: Short Pin 2 and 3; J16: Short Pin 2 and 3.

1.5 Set up SW6 on the back side of the board as shown in the figure below. This switch set the FPGA configuration mode. Set all 6 positions to ON.

1.6 Connect your computer to the USB UART connector using a Micro-USB cable. Make sure your USB device drivers, such as for the FTDI USB to UART, are installed correctly. If not, search for the drivers online and install them.

1.7 Connect your computer and the Arrow SoCKit board using an Ethernet cable.

2. Install the HDL Coder and Embedded Coder Support Packages for Intel SoC Devices if you haven't already. To start the installer, go to the MATLAB toolstrip and click **Add-Ons > Get Hardware Support Packages**.

3. Make sure you are using the SD card image provided by the Embedded Coder Support Package for Intel SoC Devices. If you need to update your SD card image, refer to the "Add Support for Intel SoC Platform" (Embedded Coder Support Package for Intel SoC Devices) of this document.

4. Set up the Arrow SoCKit hardware connection by entering the following command in the MATLAB command window:

```
h = alterasoc
```

The `alterasoc` function logs in to the hardware via COM port and runs the `ifconfig` command to obtain the IP address of the board. This function also tests the Ethernet connection.

5. You can optionally test the serial connection using the following configuration using a program such as PuTTY™. Baud rate: 115200; Data bits: 8; Stop bits: 1; Parity: None; Flow control: None. You

should be able to observe Linux booting log on the serial console when you power cycle the Arrow SoCKit board. You must close this serial connection before using the `alterasoc` function again.

6. Set up the Intel Quartus synthesis tool path using the following command in the MATLAB command window. Use your own Quartus installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Altera Quartus II', 'ToolPath', 'C:\intelFPGA\18.0\quartus\bin64\q
```

Partition your design for hardware and software implementation

The first step of the Intel SoC hardware-software co-design workflow is to decide which parts of your design to implement on the programmable logic, and which parts to run on the ARM processor.

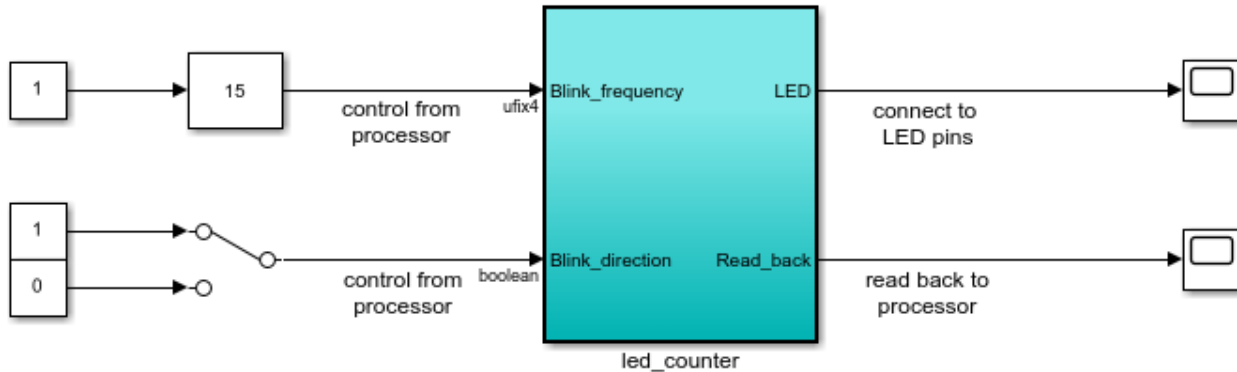

Group all the blocks you want to implement on programmable logic into an atomic subsystem. This atomic subsystem is the boundary of your hardware-software partition. All the blocks inside this subsystem will be implemented on programmable logic, and all the blocks outside this subsystem will run on the ARM processor.

In this example, the subsystem **led_counter** is the hardware subsystem. It models a counter that blinks the LEDs on an FPGA board. Two input ports, **Blink_frequency** and **Blink_direction**, are control ports that determine the LED blink frequency and direction. All the blocks outside of the subsystem **led_counter** are for software implementation.

In Simulink, you can use the **Slider Gain** or **Manual Switch** block to adjust the input values of the hardware subsystem. In the embedded software, this means the ARM processor controls the generated IP core by writing to the AXI interface accessible registers. The output port of the hardware subsystem, **LED**, connects to the LED hardware. The output port, **Read_Back**, can be used to read data back to the processor.

```
open_system('hdlcoder_led_blinking_4bit');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking_4bit/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Generate an HDL IP core using the HDL Workflow Advisor

Using the IP Core Generation workflow in the HDL Workflow Advisor enables you to automatically generate a sharable and reusable IP core module from a Simulink model. The generated IP core is designed to be connected to an embedded processor on an FPGA device. HDL Coder generates HDL code from the Simulink blocks, and also generates HDL code for the AXI interface logic connecting the IP core to the embedded processor. HDL Coder packages all the generated files into an IP core folder. You can then integrate the generated IP core with a larger FPGA embedded design in the Intel Qsys environment.

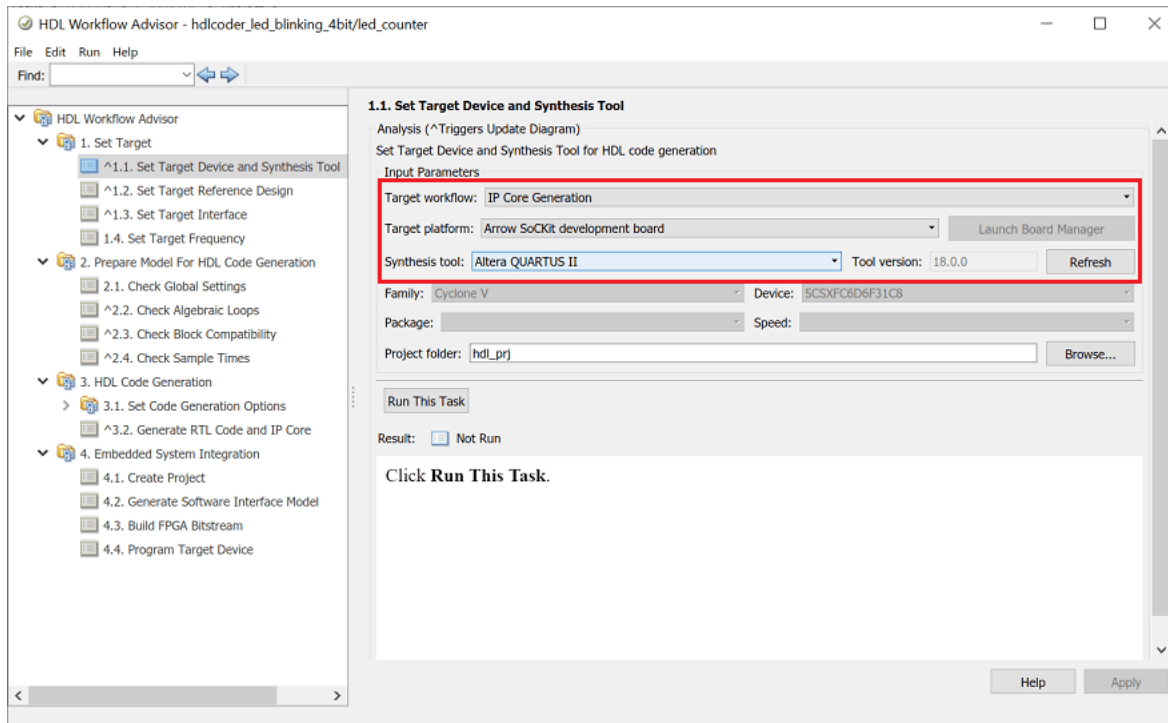

1. Start the IP core generation workflow.

1.1. Open the HDL Workflow Advisor from the `hdlcoder_led_blinking_4bit/led_counter` subsystem by right-clicking the `led_counter` subsystem, and choosing **HDL Code > HDL Workflow Advisor**.

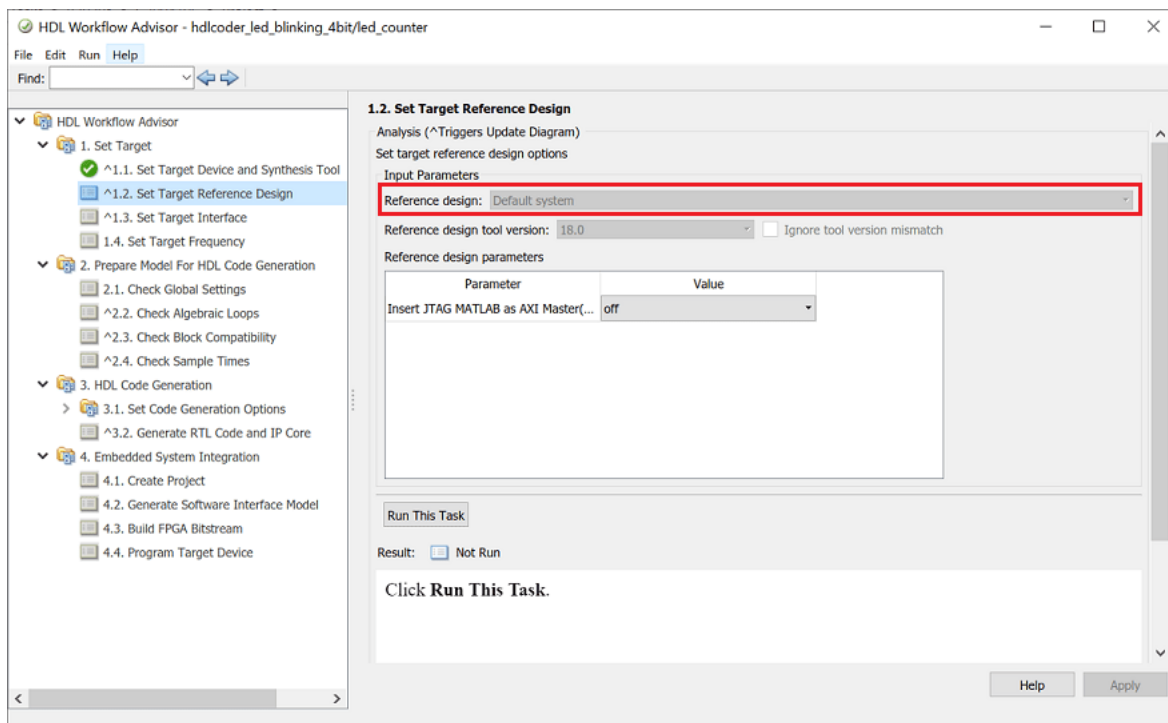

1.2. In the **Set Target > Set Target Device and Synthesis Tool** task, for **Target workflow**, select **IP Core Generation**.

1.3. For **Target platform**, select **Arrow SoCKit development board**. If you don't have this option, select **Get more** to open the Support Package Installer. In the Support Package Installer, select Intel SoC Devices and follow the instructions provided by the Support Package Installer to complete the installation.

1.4. Click **Run This Task** to run the **Set Target Device and Synthesis Tool** task.

1.5 In the **Set Target > Set Target Reference Design** task, choose **Default system**. For this example, it is selected by default

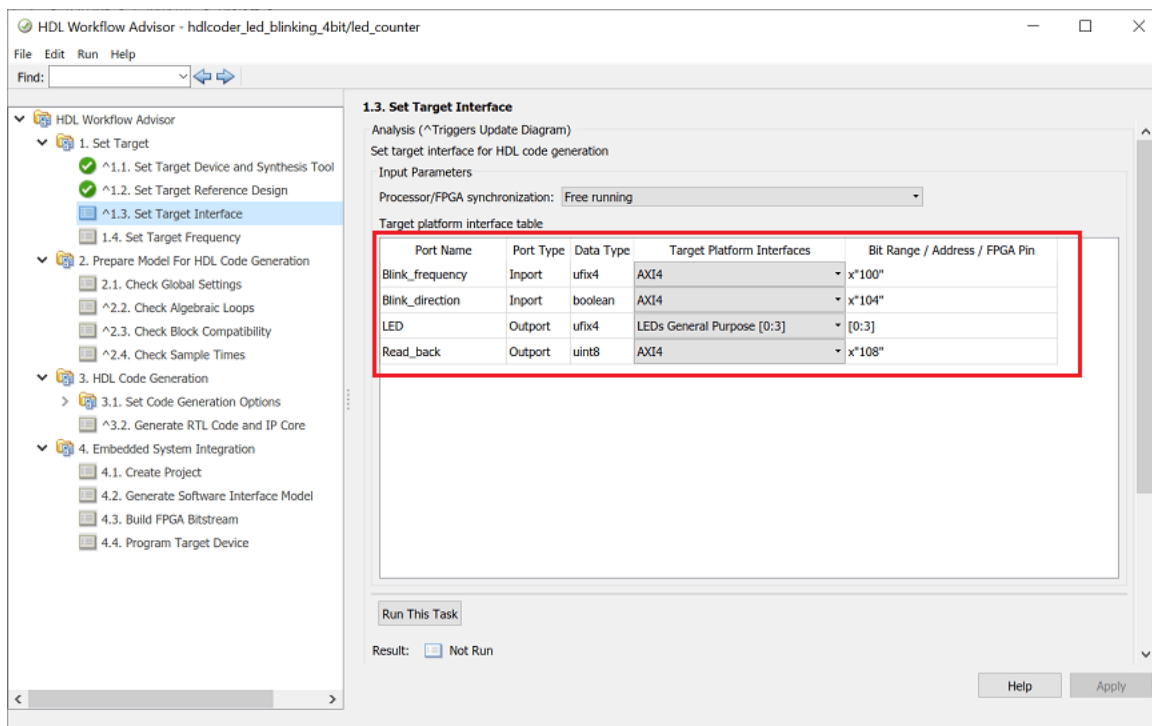

1.6. Click **Run This Task** to run the **Set Target Reference Design** task.

2. Configure the target interface.

Map each port in your DUT to one of the IP core target interfaces. In this example, input ports **Blink_frequency** and **Blink_direction** are mapped to the AXI4 interface, so HDL Coder generates AXI interface accessible registers for them. The **LED** output port is mapped to an external interface, **LEDs General Purpose [0:3]**, which connects to the LED hardware on the Intel SoC board.

2.1 In the **Set Target > Set Target Interface** task, choose **AXI4** for **Blink_frequency**, **Blink_direction**, and **Read_back**.

2.2 Choose **LEDs General Purpose [0:3]** for **LED**.

2.3 In the **Set Target > Set Target Frequency** task, choose **Target Frequency** as **50 MHz**.

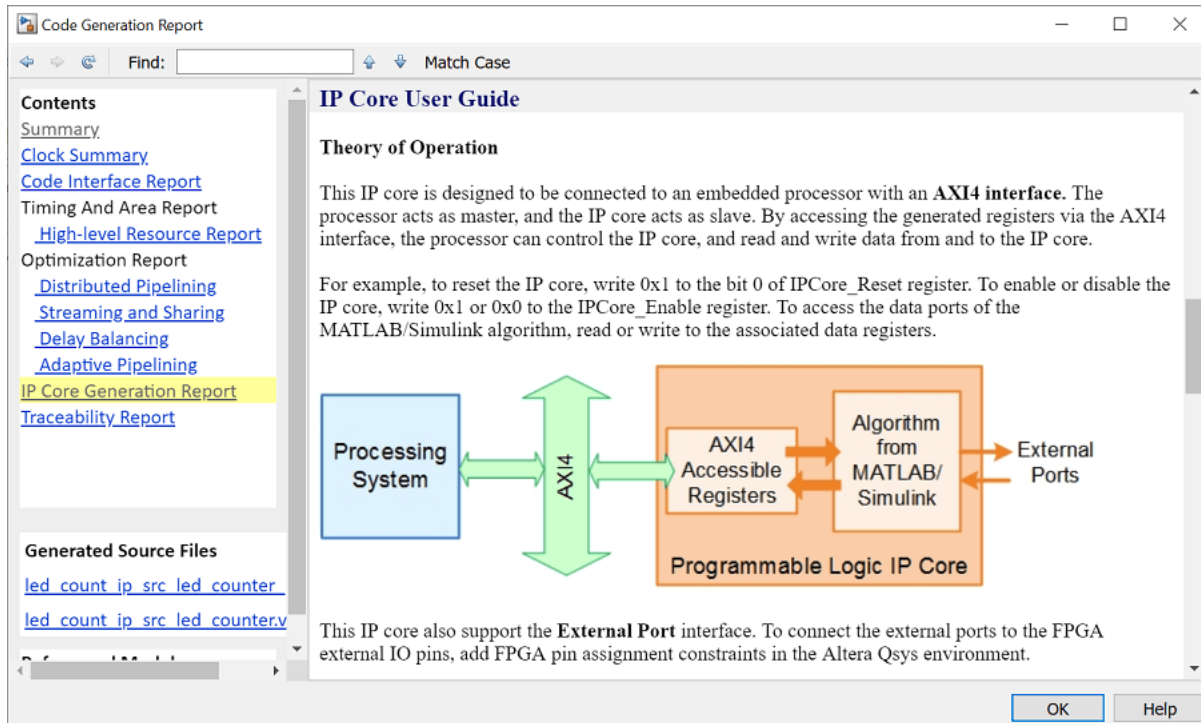

3. Generate the IP Core.

To generate the IP core, right-click the **Generate RTL Code and IP Core** task and select **Run to Selected Task**.

4. Generate and view the IP core report.

After you generate the custom IP core, the IP core files are in the **ipcore** folder within your project folder. An HTML custom IP core report is generated together with the custom IP core. The report describes the behavior and contents of the generated custom IP core.

Integrate the IP core with the Intel Qsys environment

In this part of the workflow, you insert your generated IP core into an embedded system reference design, generate an FPGA bitstream, and download the bitstream to the Intel SoC hardware.

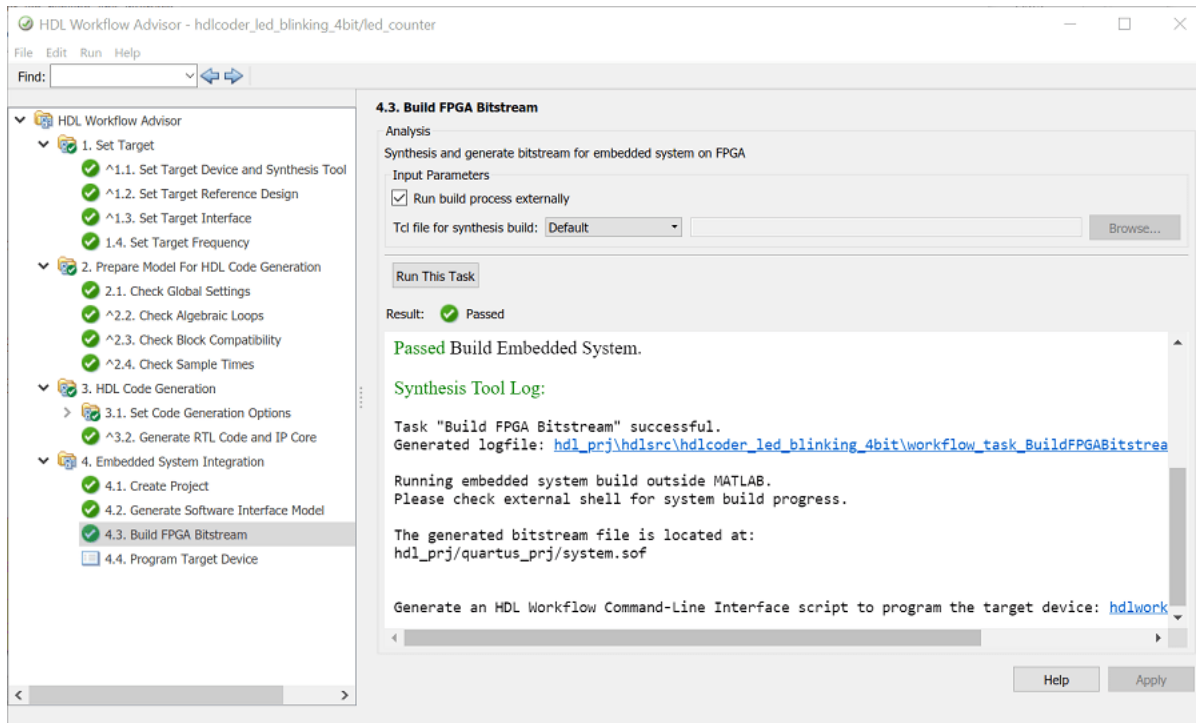

The reference design is a predefined Intel Qsys project. It contains all the elements the Intel software needs to deploy your design to the Intel SoC devices, except for the custom IP core and embedded software that you generate.

1. To integrate with the Intel Qsys environment, select the **Create Project** task under **Embedded System Integration**, and click **Run This Task**. Both an Intel Qsys project and an Intel Quartus project are generated, with links to the projects provided in the dialog window. You can optionally open up the projects to take a look.

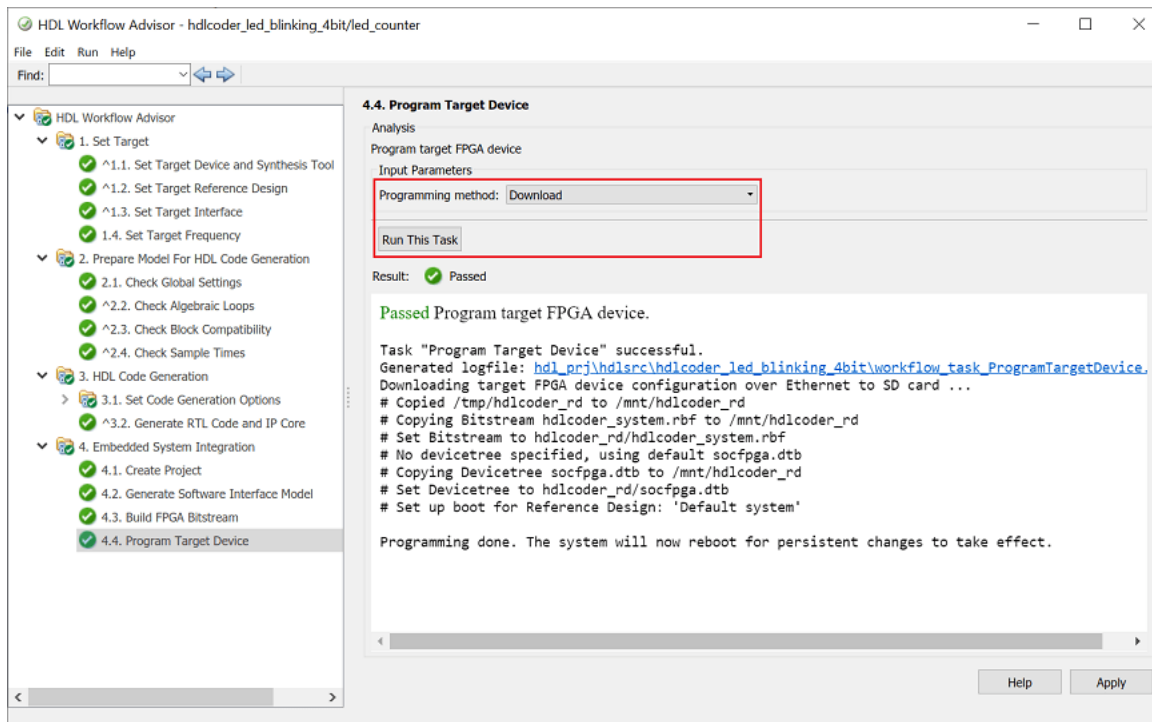

2. If you have an Embedded Coder license, you can generate a software interface model in the next task, **Generate Software Interface Model**. The details of the software interface model are explained in the next section of this example, "Generate a software interface model".

3. Build the FPGA bitstream in the **Build FPGA Bitstream** task. Make sure the **Run build process externally** option is checked, so the Intel synthesis tool will run in a separate process from MATLAB. Wait for the synthesis tool process to finish running in the external command window.

4. After the bitstream is generated, select the **Program Target Device** task. Choose **Download** for **Programming method** to download the FPGA bitstream onto the SD card on the Intel SoC board, so your design will be automatically reloaded when you power cycle the Intel SoC board. click **Run This Task** to program the Intel SoC hardware.

After you program the FPGA hardware, the LED starts blinking on your Intel SoC board.

Next, you will generate C code to run on the ARM processor to control the LED blink frequency and direction.

Generate a software interface model

In the HDL Workflow Advisor, after you generate the IP core and insert it into the Qsys reference design, you can optionally generate a software interface model in the **Embedded System Integration > Generate Software Interface Model** task.

The software interface model contains the part of your design that runs in software. It includes all the blocks outside of the HDL subsystem, and replaces the HDL subsystem with AXI driver blocks. If you have an Embedded Coder license, you can automatically generate embedded code from the software interface model, build it, and run the executable on Linux on the ARM processor. The generated embedded software includes AXI driver code, generated from the AXI driver blocks, that controls the HDL IP core.

Run the **Generate Software Interface Model** task and see that a new model is generated. The task dialog shows a link to the model.

In the generated software interface model, the "led_counter" subsystem is replaced with the AXI driver blocks which generate the interface logic between the ARM processor and FPGA.

Run the software interface model on Intel SoC hardware

In this part of the workflow, you configure the generated software interface model, automatically generate embedded C code, and run your model on the ARM processor in the Intel SoC hardware in External mode.

When you are prototyping and developing an algorithm, it is useful to monitor and tune the algorithm while it runs on hardware. The External mode feature in Simulink enables this capability. In this mode, your algorithm is first deployed to the ARM processor in the Intel SoC hardware, and then linked with the Simulink model on the host computer through an Ethernet connection.

The main role of the Simulink model is to tune and monitor the algorithm running on the hardware. Because the ARM processor is connected to the HDL IP core through the AXI interface, you can use External mode to tune parameters, and capture data from the FPGA.

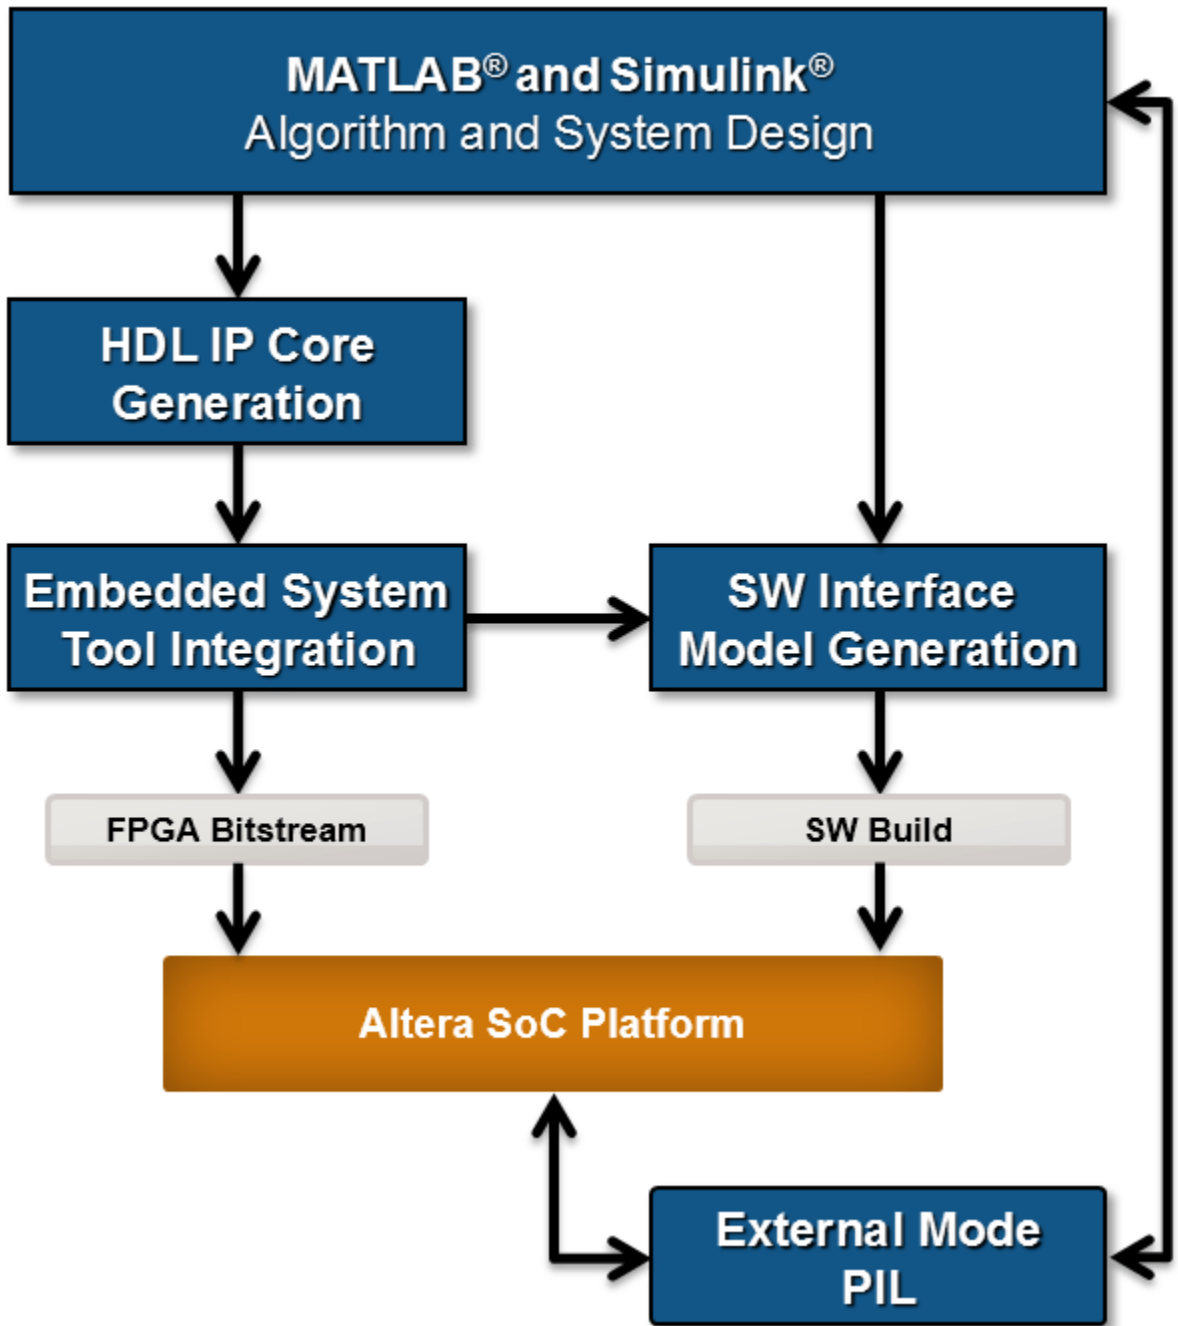

- 1 In the generated model, open the **Configuration Parameters** dialog box.
- 2 Select **Solver** and set "Stop Time" to "inf".
- 3 From the **HARDWARE** menu, click the **Monitor & Tune** button on the model toolstrip to run your model on the ARM processor in the Intel SoC hardware in External mode. Embedded Coder builds the model, downloads the ARM executable to the Intel SoC hardware, executes it, and connects the model to the executable running on the Intel SoC hardware.
- 4 Double-click the **Slider Gain** block. Change the Slider Gain value and observe the change in frequency of the LED array blinking on the Intel SoC hardware. Double-click the **Manual Switch** block to switch the direction of the blinking LEDs.
- 5 Double-click the scope connected to the **Read_back** output port and observe that the output data of the FPGA IP core is captured and sent back to the Simulink scope.
- 6 When you are done changing model parameters, click the **Stop** button on the model. Observe that the system command window opened in the previous step indicates that the model has been stopped. At this point, you can close the system command window.

Summary

This example shows how the hardware and software co-design workflow helps automate the deployment of your MATLAB and Simulink design to the Intel SoC devices. You can explore the best ways to partition and deploy your design by iterating through the workflow.

The following diagram shows the high-level picture of the workflow you went through in this example. To learn more about the hardware and software co-design workflow, please refer to the "Hardware-Software Co-Design Workflow for SoC Platforms" on page 46-8.

Getting Started with Targeting Intel Quartus Pro Based Devices

This example shows how to define and register the board and reference design for the Intel® Arria10 SoC development kit. In this example, you use a partitioned hardware-software co-design implementation to blink LEDs at various frequencies. In this example, you register the Arria 10 SoC development kit and the reference design in the HDL Workflow Advisor. The reference design also shows the *Early I/O (Split bitstream)* feature supported by Intel Arria 10 SoC in HDL Workflow Advisor. This example uses Embedded Coder(R) to generate C code that runs on the ARM(R) processor to control the LED blink frequency. You can prepare your design for hardware and software implementation on the Intel Arria 10 SoC by deciding which system elements are performed by the programmable logic, and which system elements will run on the ARM Cortex-A9.

Requirements

This example requires:

- 1 Supported version of Intel Quartus® Pro (or Intel QUARTUS II). For more information, see “HDL Language Support and Supported Third-Party Tools and Hardware”.
- 2 Intel SoC Embedded Design Suite
- 3 Intel Arria 10 SoC development kit
- 4 HDL Coder Support Package for Intel SoC Devices
- 5 Embedded Coder Support Package for Intel SoC Devices

Set Up Intel SoC Hardware and Tools

1. Set up the Arria 10 SoC as shown in the figure below. To learn more about the Arria 10 SoC hardware setup, refer to the board documentation.

1.1 Set up the DIP switches and jumper settings as shown in the figure below.

1.2 Connect the USB UART using a Micro-USB cable to your computer. Ensure your USB device drivers, such as for the FTDI USB to UART, are installed correctly.

1.3 Connect the Arria10 SoC kit to your computer using an Ethernet cable.

2. Install the HDL Coder and Embedded Coder Support Packages for Intel SoC Devices. To start the installer, open MATLAB and , in the **Home** tab click **Add-Ons > Get Hardware Support Packages**.

3. Ensure you are using the SD card image provided by the Embedded Coder Support Package for Intel SoC Devices. If you need to update your SD card image, refer to the Hardware Setup section of "Add Support for Intel SoC Platform" (Embedded Coder Support Package for Intel SoC Devices).

4. Set up the Arria10 SoC hardware connection by entering:

```
h = alterasoc
```

The `alterasoc` function logs in to the hardware via the COM port and runs the `ifconfig` command to obtain the IP address of the board. This function also tests the Ethernet connection.

5. You can optionally test the serial connection by using the following configuration and a program such as PuTTY™.

*Baud rate: 115200 *Data bits: 8 *Stop bits: 1 *Parity: None *Flow control: None. You should be able to observe Linux booting log on the serial console when you power cycle the Arria10 SoCKit board. You must close this serial connection before using the `alterasoc` function again.

6. Set up the Intel Quartus Pro synthesis tool path by entering this command. Use your own Quartus installation path when you run the command.

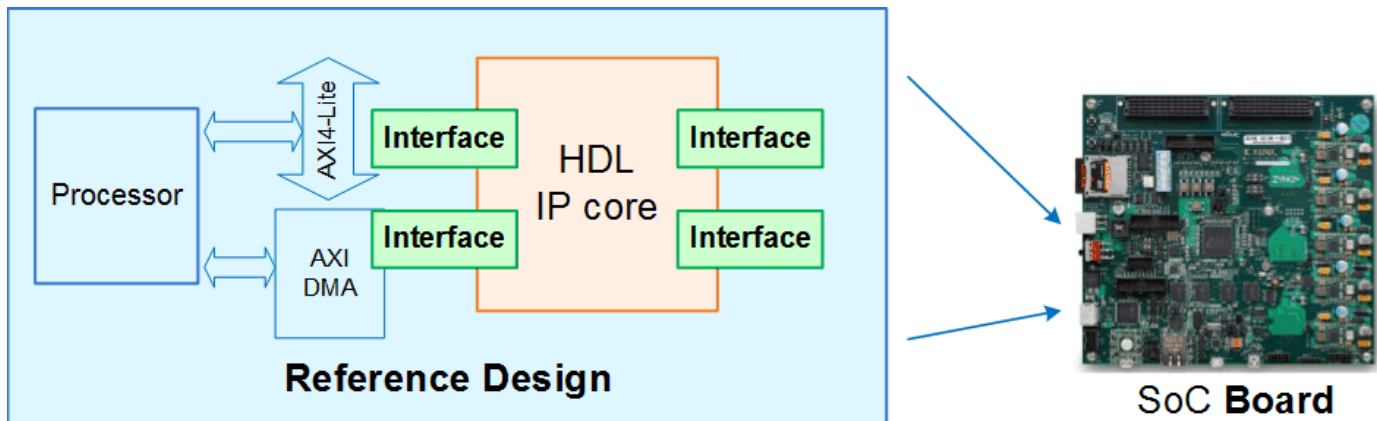

```
hdlsetuptoolpath('ToolName', 'Intel Quartus Pro', 'ToolPath', 'C:\intelFPGA\19.4\quartus\bin64\qu
```

If you are using an Intel QUARTUS II, use the follow command:

```
hdlsetuptoolpath('ToolName', 'Intel QUARTUS II', 'ToolPath', 'C:\intelFPGA\18.1\quartus\bin64\qu
```

Create a Reference Design Using Intel Quartus Pro

A reference design captures the complete structure of an SoC design and defines the different components and their interconnections. HDL Coder generates an IP core that integrates with the reference design, and is then used to program an SoC board. The following figure describes the relationship between a reference design, an HDL IP core, and an SoC board.

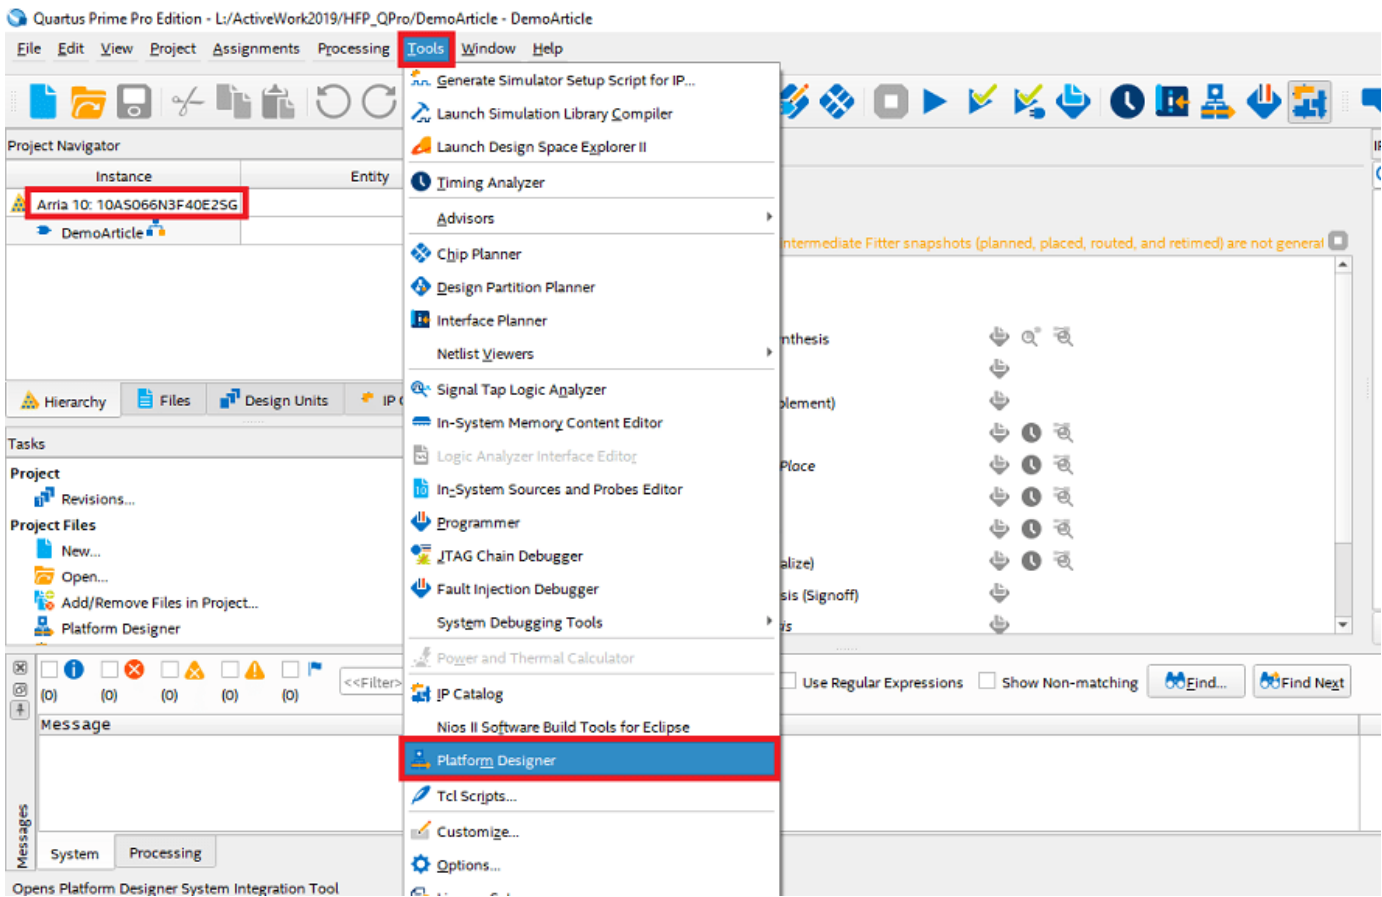

Follow these steps to create and export a simple reference design using the Intel Quartus Pro and Platform Designer (Qsys) environment. For more information about the QSys system integration tool, refer to Intel documentation.

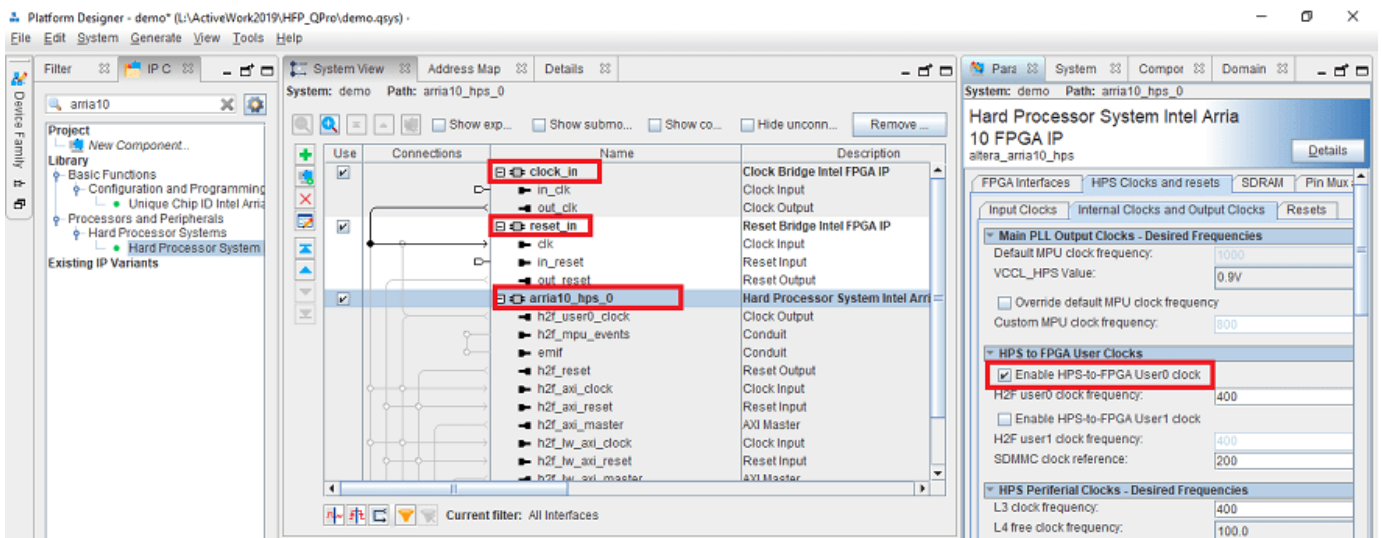

1. Create an empty Quartus project using the New Project wizard. Enter the device part number as shown in this figure:

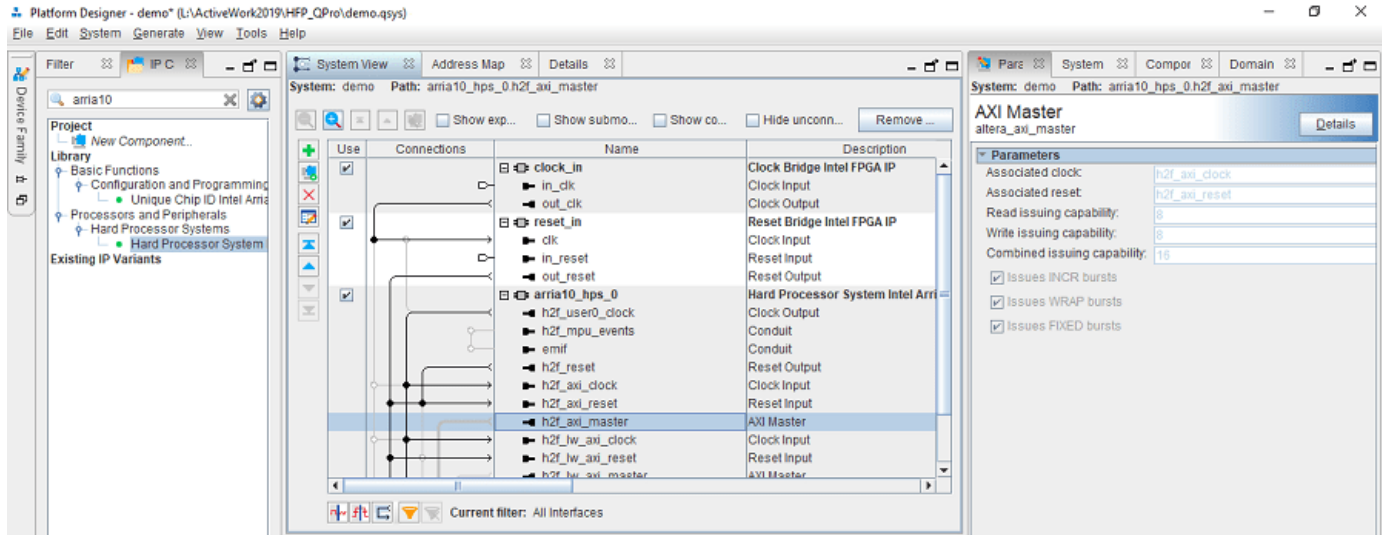

2. Initialize the Platform Designer(Qsys) in Quartus Pro by navigating to **Tools --> Platform Designer** as shown in the following figure.

3. Select Hard Processor System Intel Arria 10 FPGA IP(HPS), clock and reset IPs from IP catalog to the created Platform Designer project. Connect the required clocks and resets to the Arria 10 HPS IP as shown in the following figure. complete the other settings required for Arria 10 Hard Processor System such as Peripheral pin set and mode settings.

- Keep h2f_axi_master port connection open in order to connect to DUT IP during the process of workflow IP integration. Complete the rest of the connections between Altera PLL IP and HPS IP as shown in the following figure.

- Save the Qsys file. This file is used when you create reference design plugin.

Register the Intel Arria 10 SoC development kit.

In this section, You register the Intel Arria 10 SoC development kit in HDL Workflow Advisor.

- Create a board registration file with the name `hdlcoder_board_customization.m` and add it to the MATLAB path.

For more details on creating a board registration file, refer to “Define Custom Board and Reference Design for Intel SoC Workflow” on page 47-249.

- Create the board definition file.

A board definition file contains information about the SoC board.

For more details on creating the board definition file, refer to “Define Custom Board and Reference Design for Intel SoC Workflow” on page 47-249.

Register the custom reference design in HDL Workflow Advisor

In this section, You register the custom reference design in HDL Workflow Advisor.

- Create a reference design registration file named `hdlcoder_ref_design_customization.m` containing a list of reference design plugins associated with an SoC board.

For more details on creating a custom reference design, refer to “Define Custom Board and Reference Design for Intel SoC Workflow” on page 47-249.

- Create the reference design definition file.

A reference design definition file defines the interfaces between the custom reference design and the HDL IP core that is generated by the HDL Coder SoC workflow. For more details on creating the

reference design definition file, refer to “Define Custom Board and Reference Design for Intel SoC Workflow” on page 47-249.

Early I/O for Arria 10: The Intel Arria 10 SoC FPGA device supports Early I/O Release.

Early IO release allows you to enable DDR functioning prior programming the core raw binary file (RBF) for speeding up the boot time. In this flow, the shared I/O and hard memory controller I/O are configured and released allowing HPS immediate access to them.

This feature splits the FPGA configuration sequence into two parts. The first part configures the FPGA I/O, the Shared I/O and also enables the HPS External Memory Interface (EMIF) if present. The second part of the sequence configures the core FPGA fabric. By splitting the configuration sequence, the Arria10 Hard Processing System now has access to Shared I/O and EMIF before the FPGA fabric is configured. This allows more flexibility for designs that need faster boot times or alternate boot sources. In this Early I/O, two Raw Binary Format (.rbf) files are generated: (1) **peripheral.rbf** file. (2) **core.rbf** file. Together, these configuration files contain the same data as a combined configuration .rbf file that is generated when the Early I/O Release feature is not used. The **peripheral.rbf** file is loaded first and configures the FPGA I/O, Shared I/O and HPS EMIF. The **core.rbf** is loaded next and completes the FPGA configuration sequence by configuring the FPGA fabric. After the **peripheral.rbf** is successfully loaded, the Intel Arria 10 SoC FPGA HPS EMIF pins are released and the interface begins calibration.

To use this feature, you need to enable a reference design parameter `hRD.GenerateSplitBitstream = true`; as shown in the below `plugin_rd` file. Accordingly if this reference design parameter is made true, it generates two .rbf files for configuring the FPGA as mentioned above.

The contents of this reference design definition file `plugin_rd.m` is similar to the Intel Quartus standard version, the differences for the Intel Quartus Pro are listed below.

```
function hRD = plugin_rd()
% Reference design definition

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Intel Quartus Pro');

%% Add custom design files
% add custom Qsys design
hRD.addCustomQsysDesign( ...
    'CustomQsysPrjFile', 'system_soc.qsys');

% split the full rbf file into core and peripheral rbf files for Early I/O feature
hRD.GenerateSplitBitstream = true;
```

Partition your design for hardware and software implementation

The first step of the Intel SoC hardware-software co-design workflow is to decide which parts of your design to implement on the programmable logic, and which parts to run on the ARM processor.

Group all the blocks you want to implement on programmable logic into an atomic subsystem. This atomic subsystem is the boundary of your hardware-software partition. All the blocks inside this subsystem are implemented on programmable logic, and all the blocks outside this subsystem will run on the ARM processor.

In this example, the subsystem **led_counter** is the hardware subsystem. It models a counter that blinks the LEDs on an FPGA board. Two input ports, **Blink_frequency** and **Blink_direction**, are

control ports that determine the LED blink frequency and direction. All the blocks outside of the subsystem **led_counter** are for software implementation.

In Simulink, you can use the **Slider Gain** or **Manual Switch** block to adjust the input values of the hardware subsystem. In the embedded software, this means the ARM processor controls the generated IP core by writing to the AXI interface accessible registers. The output port of the hardware subsystem, **LED**, connects to the LED hardware. The output port, **Read_Back**, can be used to read data back to the processor.

```
open_system('hdlcoder_led_blinking_4bit');
```

Generate an HDL IP core using the HDL Workflow Advisor

Using the IP Core Generation workflow in the HDL Workflow Advisor enables you to automatically generate a sharable and reusable IP core module from a Simulink model. The generated IP core is designed to be connected to an embedded processor on an FPGA device. HDL Coder generates HDL code from the Simulink blocks, and also generates HDL code for the AXI interface logic connecting the IP core to the embedded processor. HDL Coder packages all the generated files into an IP core folder. You can then integrate the generated IP core with a larger FPGA embedded design in the Intel Qsys environment.

1. Start the IP core generation workflow.

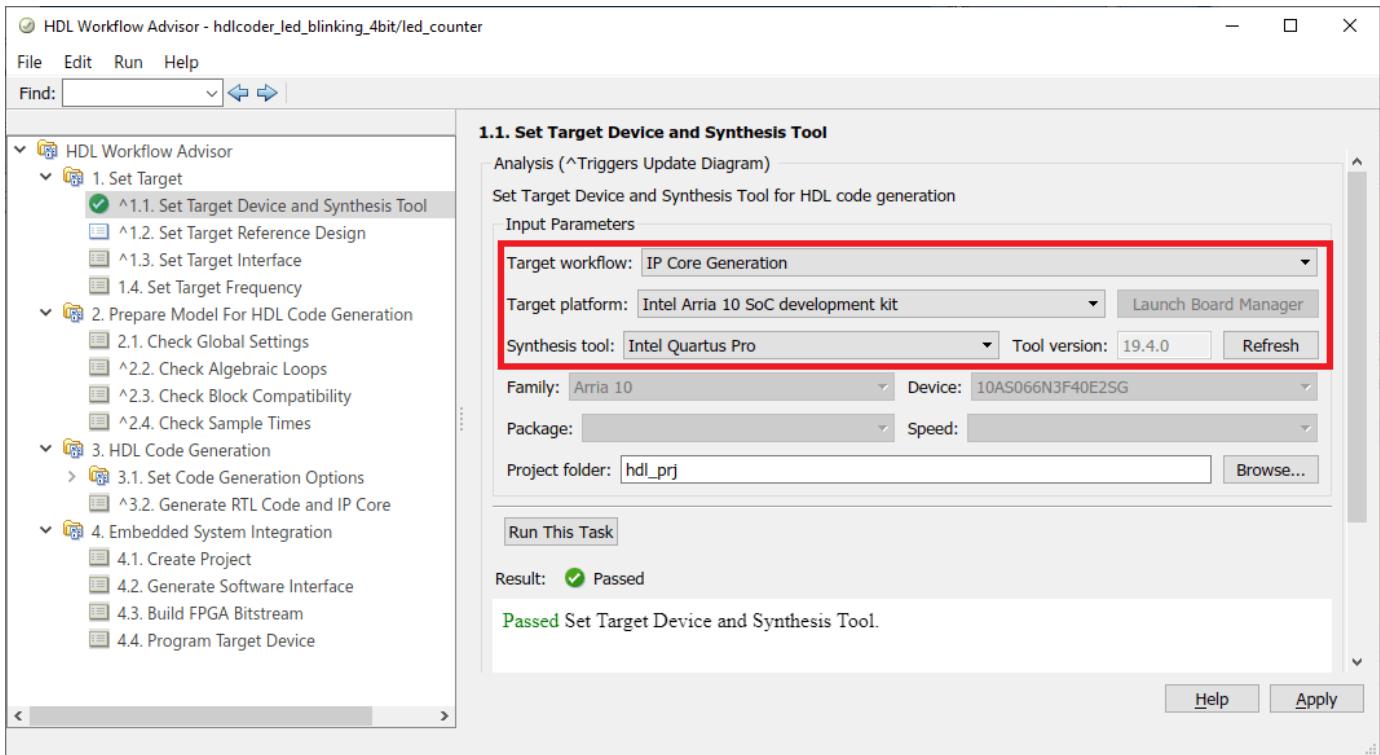

1.1. Open the HDL Workflow Advisor from the `hdlcoder_led_blinking_4bit/led_counter` subsystem by right-clicking the `led_counter` subsystem, and choosing **HDL Code > HDL Workflow Advisor**.

1.2. In the **Set Target > Set Target Device and Synthesis Tool** task, for **Target workflow**, select **IP Core Generation**.

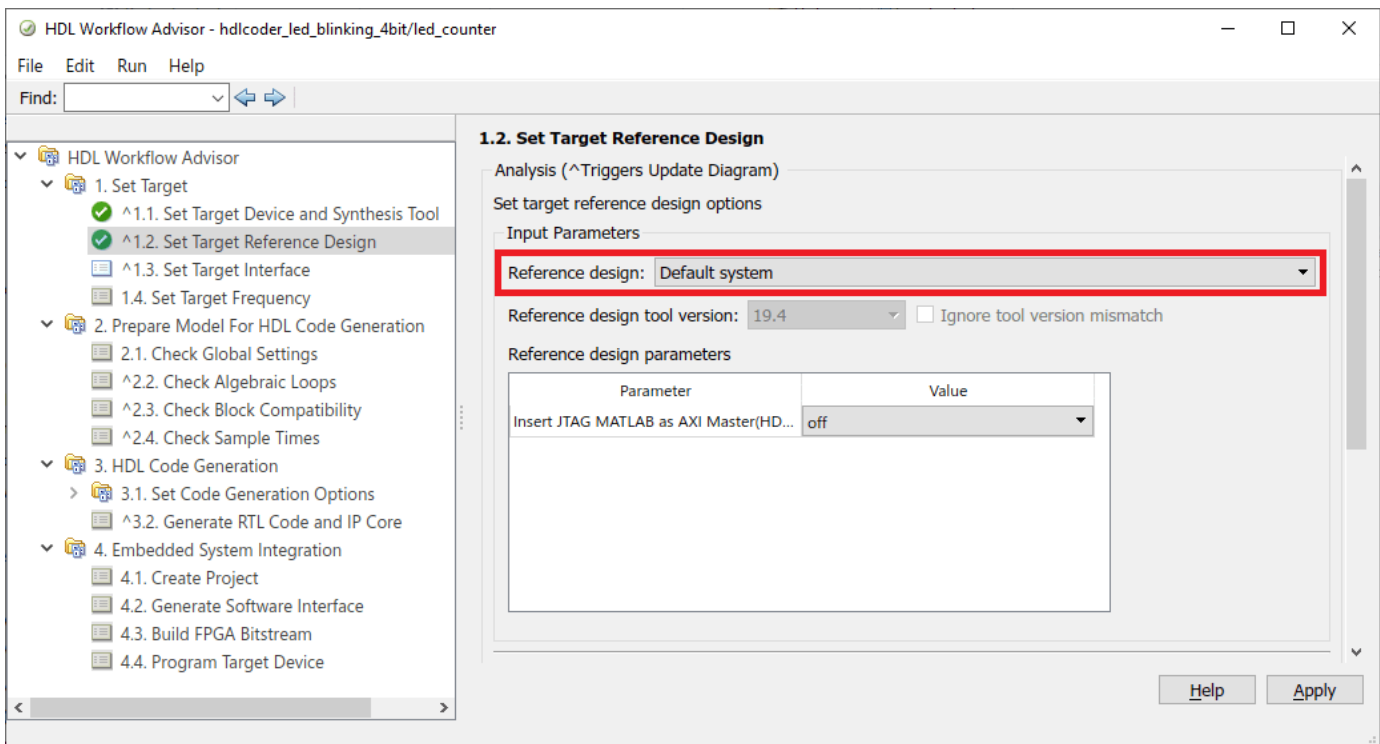

1.3. For **Target platform**, select **Intel Arria 10 SoC development kit**. If you don't have this option, select **Get more** to open the Support Package Installer. In the Support Package Installer, select Intel SoC Devices and follow the instructions provided by the Support Package Installer to complete the installation.

1.4. Select the **Synthesis tool** as **Intel Quartus Pro** (or **Altera QUARTUS II**)

1.5. Click **Run This Task** to run the **Set Target Device and Synthesis Tool** task.

1.6. In the **Set Target > Set Target Reference Design** task, choose **Default system**. For this example, it is selected by default.

1.7. Click **Run This Task** to run the **Set Target Reference Design** task.

2. Configure the target interface.

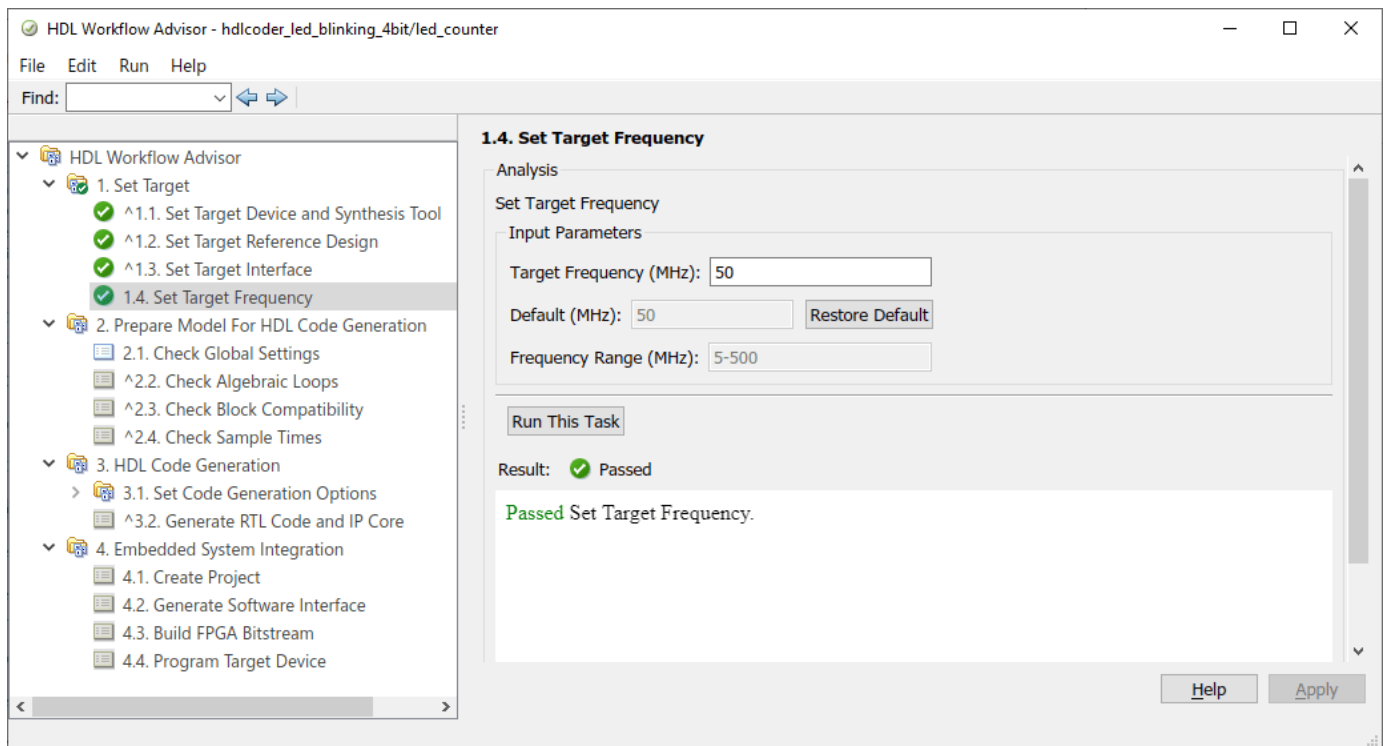

Map each port in your DUT to one of the IP core target interfaces. In this example, input ports **Blink_frequency** and **Blink_direction** are mapped to the AXI4 interface, so HDL Coder generates AXI interface accessible registers for them. The **LED** output port is mapped to an external interface, **LEDs General Purpose [0:3]**, which connects to the LED hardware on the Intel SoC board.

2.1 In the **Set Target > Set Target Interface** task, choose **AXI4** for **Blink_frequency**, **Blink_direction**, and **Read_back**.

2.2 Choose **LEDs General Purpose [0:3]** for **LED**.

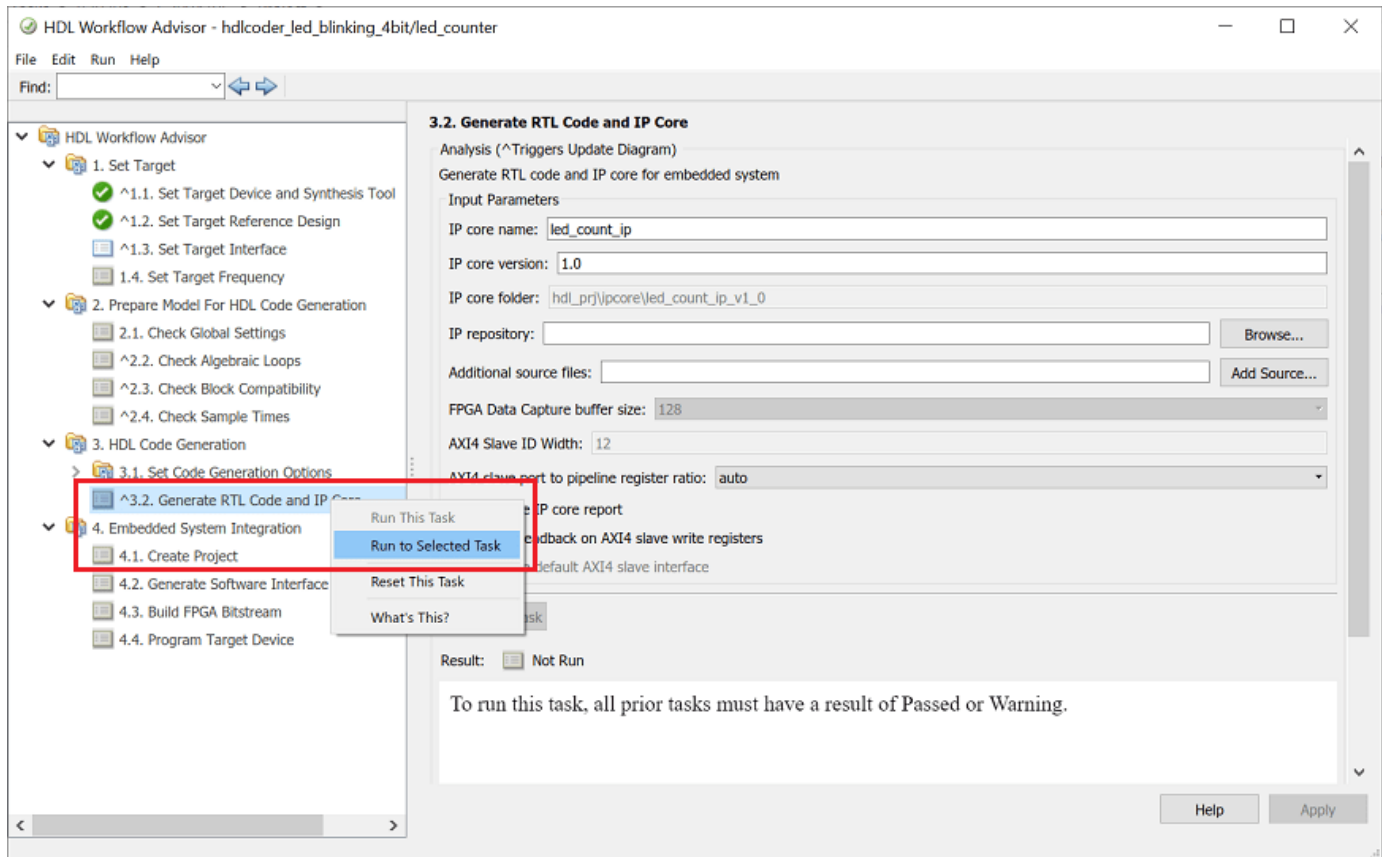

2.3 In the **Set Target > Set Target Frequency** task, choose **Target Frequency** as **50 MHz**.

3. Generate the IP Core.

To generate the IP core, right-click the **Generate RTL Code and IP Core** task and select **Run to Selected Task**.

4. Generate and view the IP core report.

After you generate the custom IP core, the IP core files are in the **ipcore** folder within your project folder. An HTML custom IP core report is generated together with the custom IP core. The report describes the behavior and contents of the generated custom IP core.

IP Core User Guide

Theory of Operation

This IP core is designed to be connected to an embedded processor with an **AXI4 interface**. The processor acts as master, and the IP core acts as slave. By accessing the generated registers via the AXI4 interface, the processor can control the IP core, and read and write data from and to the IP core.

For example, to reset the IP core, write 0x1 to the bit 0 of IPCore_Reset register. To enable or disable the IP core, write 0x1 or 0x0 to the IPCore_Enable register. To access the data ports of the MATLAB/Simulink algorithm, read or write to the associated data registers.

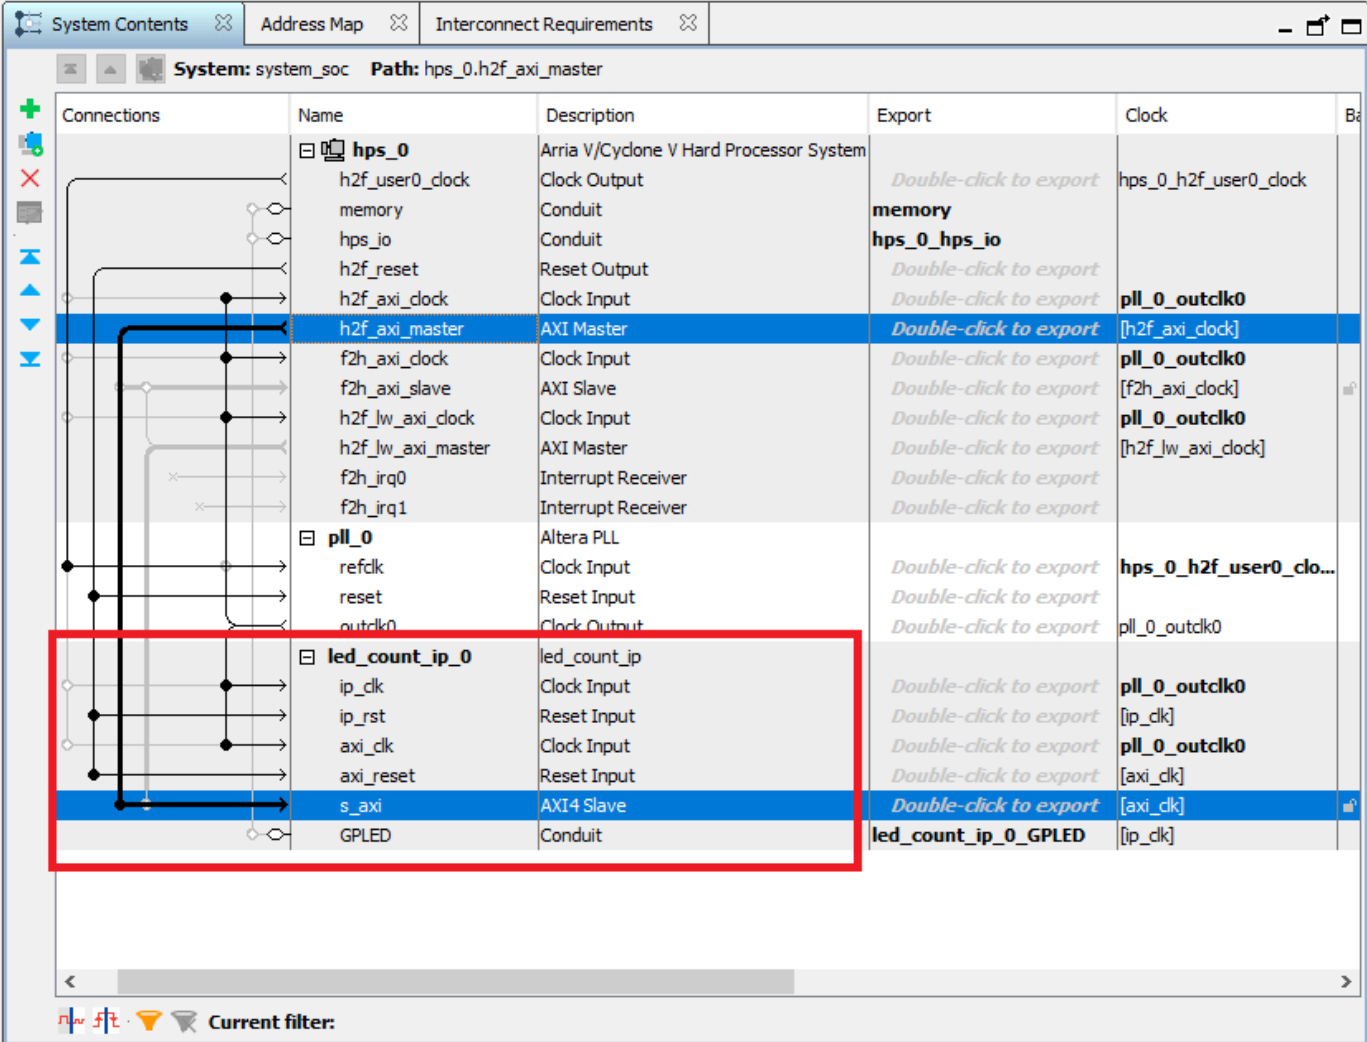

Diagram: A blue box labeled 'Processing System' is connected via a green double-headed arrow labeled 'AXI4' to an orange box labeled 'Programmable Logic IP Core'. Inside the IP core, there is a sub-box containing 'AXI4 Accessible Registers' and 'Algorithm from MATLAB/Simulink'. The IP core also has 'External Ports' connected to it.

This IP core also support the **External Port** interface. To connect the external ports to the FPGA external IO pins, add FPGA pin assignment constraints in the Altera Qsys environment.

OK Help

5. Follow step 1 of **Integrate the IP core with the Intel Qsys environment** section of “Getting Started with Targeting Intel SoC Devices” on page 46-122 example to integrate the IP core in the reference design and create the Qsys project.

6. Now let us examine the Intel Qsys project created by the SoC workflow after completing the Create Project task under Embedded System Integration. The following figure shows the SoC project where we have highlighted the HDL IP Core. It is instructive to compare this project with the previous project used in the custom reference design plugin for a deeper understanding of the relationship between a custom reference design and an HDL IP Core.

Connections	Name	Description	Export	Clock	Base
	hps_0	Arria V/Cyclone V Hard Processor System			
	h2f_user0_clock	Clock Output	Double-click to export	hps_0_h2f_user0_clock

7. Follow the steps 2, 3 and 4 of **Integrate the IP core with the Intel Qsys environment** section of “Getting Started with Targeting Intel SoC Devices” on page 46-122 example to generate software interface model, generate FPGA bitstream and program target device respectively.

8. The LEDs on the Arria 10 SoC will start blinking after loading the bitstream. In addition, you can control the LED blink frequency and direction by executing the software interface model. Refer to the example “Getting Started with Targeting Intel SoC Devices” on page 46-122 example to control the LED blink frequency and direction from the generated software interface model.

Integrate HDL IP Core with Microchip PolarFire SoC Icicle Kit Reference Design

This example shows how to use the hardware-software co-design workflow to blink LEDs at various frequencies on the Microchip PolarFire SoC Icicle kit.

Introduction

This example is a step-by-step guide that helps you use HDL Coder™ to generate a custom HDL IP core that blinks LEDs on the Microchip PolarFire SoC Icicle kit.

You can use MATLAB® and Simulink® to design, simulate, and verify your application, perform what-if scenarios with algorithms, and optimize parameters. You can then prepare your design for hardware and software implementation on the PolarFire SoC Icicle Kit by deciding which system elements are performed by the programmable logic, and which system elements are run on the ARM Cortex-A9.

Using the guided workflow shown in this example, you automatically generate HDL code for the programmable logic by using HDL Coder and implement the design on the Microchip PolarFire SoC Icicle Kit.

In this workflow, you perform these tasks:

- 1 Set up your PolarFire SoC hardware and tools.
- 2 Partition your design for hardware and software implementation.
- 3 Generate an HDL IP core by using HDL Workflow Advisor.
- 4 Integrate the IP core into a Microchip Libero project and program the PolarFireSoC hardware.

Requirements

- 1 Microchip Libero Design Suite, with supported version listed in the “HDL Language Support and Supported Third-Party Tools and Hardware”.
- 2 Microchip PolarFire SoC Icicle Kit
- 3 HDL Coder Support Package for Microchip FPGA and SoC Devices

Set Up PolarFire SoC Hardware and Tools

1. Set up the Microchip PolarFire SoC Icicle Kit as shown in the figure. To learn more about the PolarFire SoC hardware setup, see PolarFire SoC Icicle Kit Quickstart Card.

Connect your computer to the USB UART connector by using a Micro-USB cable. Make sure that your USB device drivers, such as for the Silicon Labs CP210x USB to UART Bridge, are installed correctly. If not, search for the drivers online and install them.

2. Connect your computer and the PolarFire SoC board using an Ethernet cable.

3. Install the HDL Coder Support Packages for Microchip FPGA and SoC Devices if you have not already done so. To start the installer, on the MATLAB toolstrip, click **Add-Ons > Get Hardware Support Packages**. Search for **HDL Coder Support Packages for Microchip FPGA and SoC Devices** and install them.

4. Make sure that you are using the SD card image provided by Microchip from Github Link.

5. Set up the PolarFire SoC hardware connection in this MATLAB Command Window.

6. You can optionally test the serial connection by using the configuration that uses a program such as PuTTY™. Baud rate: 115200; Data bits: 8; Stop bits: 1; Parity: None; Flow control: None. You can see Linux booting log on the serial console when you Power Cycle the PolarFire SoC board.

7. Set up the Microchip Libero SoC synthesis tool path in the MATLAB Command Window. When you run the command, use own Microchip Libero installation path.

```
hdlsetuptoolpath('ToolName', 'Microchip Libero SoC', 'ToolPath', 'C:\Microsemi\Libero_SoC_v12.6\');
```

Partition your Design for Hardware and Software Implementation

For the PolarFire SoC hardware-software co-design workflow, decide which parts of your design to implement on the programmable logic and which parts to run on the ARM processor.

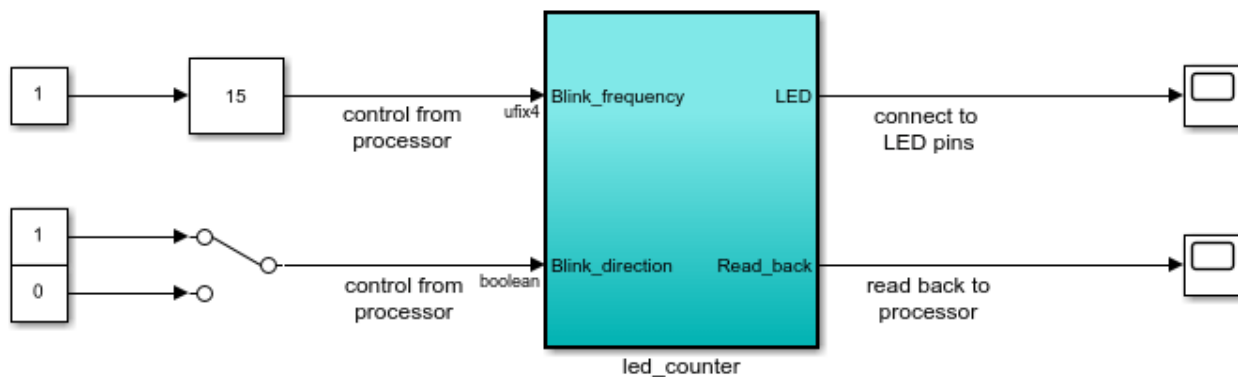

Group all the blocks that you want to implement on programmable logic into an atomic subsystem. This atomic subsystem is the boundary of your hardware-software partition. The blocks inside this subsystem are implemented on programmable logic and the blocks outside this subsystem run on the ARM processor.

In this example, the subsystem **led_counter** is the hardware subsystem. It models a counter that blinks the LEDs on an FPGA board. Two input ports, **Blink_frequency** and **Blink_direction**, are control ports that determine the LED blink frequency and direction. The blocks outside of the subsystem **led_counter** are for software implementation.

In Simulink, you can use the **Slider Gain** or **Manual Switch** block to adjust the input values of the hardware subsystem. In the embedded software, this means the ARM processor controls the generated IP core by writing to the AXI interface accessible registers. The output port of the hardware subsystem, **LED**, connects to the LED hardware. You can use the output port, **Read_Back**, to read data back to the processor.

```
open_system('hdlcoder_led_blinking_4bit');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking_4bit/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2014-2017 The MathWorks, Inc.

Generate HDL IP Core by using the HDL Workflow Advisor

You can generate a sharable and reusable IP core module from a Simulink model. The generated IP core connects to an embedded processor on an FPGA device. HDL Coder generates HDL code from

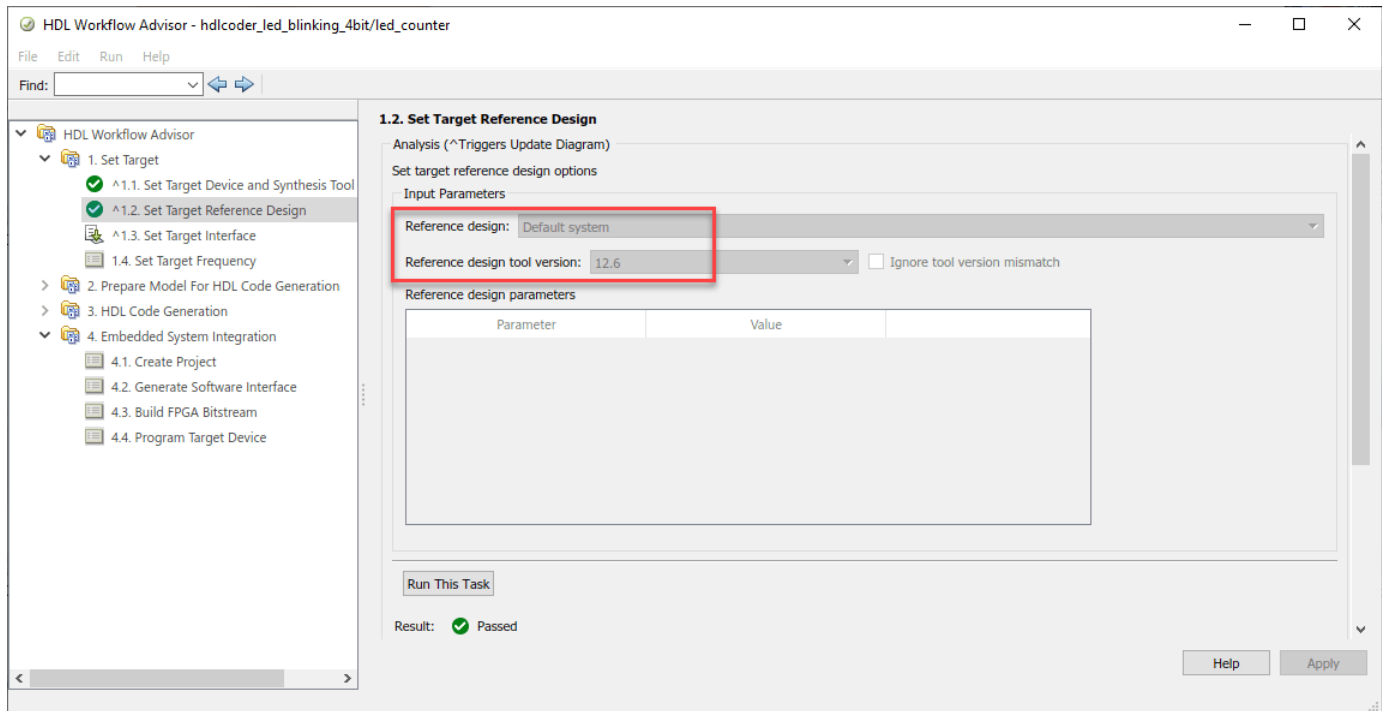

the Simulink blocks and generates HDL code for the AXI interface logic connecting the IP core to the embedded processor. HDL Coder packages the generated files into an IP core folder. You can then integrate the generated IP core with a larger FPGA embedded design in the Microchip Libero environment.

Start IP Core Generation Workflow.

1. Open the HDL Workflow Advisor from the `hdlcoder_led_blinking/led_counter` subsystem by right-clicking the `led_counter` subsystem, and choosing **HDL Code > HDL Workflow Advisor**.
2. In the **Set Target > Set Target Device and Synthesis Tool** task, for **Target workflow**, select **IP Core Generation**.
3. For **Target platform**, select **Microchip PolarFire SoC Icicle kit**. If you don't have this option, select **Get more** to open the Support Package Installer.
4. Click **Run This Task** to run the **Set Target Device and Synthesis Tool** task.

5. In the **Set Target > Set Target Reference Design** task, Reference Design **Default system** is selected by default.

6. Click **Run This Task** to run the **Set Target Reference Design** task.

Configure Target Interface.

Map each port in your DUT to one of the IP core target interfaces. In this example, input ports **Blink_frequency** and **Blink_direction** are mapped to the AXI4 interface. HDL Coder generates AXI interface accessible registers for them. The **LED** output port is mapped to an external interface, **LEDs General Purpose [0:3]**, which connects to the LED hardware on the PolarFire SoC board.

1. In the **Set Target > Set Target Interface** task, choose **AXI4** for **Blink_frequency**, **Blink_direction**, and **Read_back**.

2. Choose **LEDs General Purpose [0:3]** for **LED**.

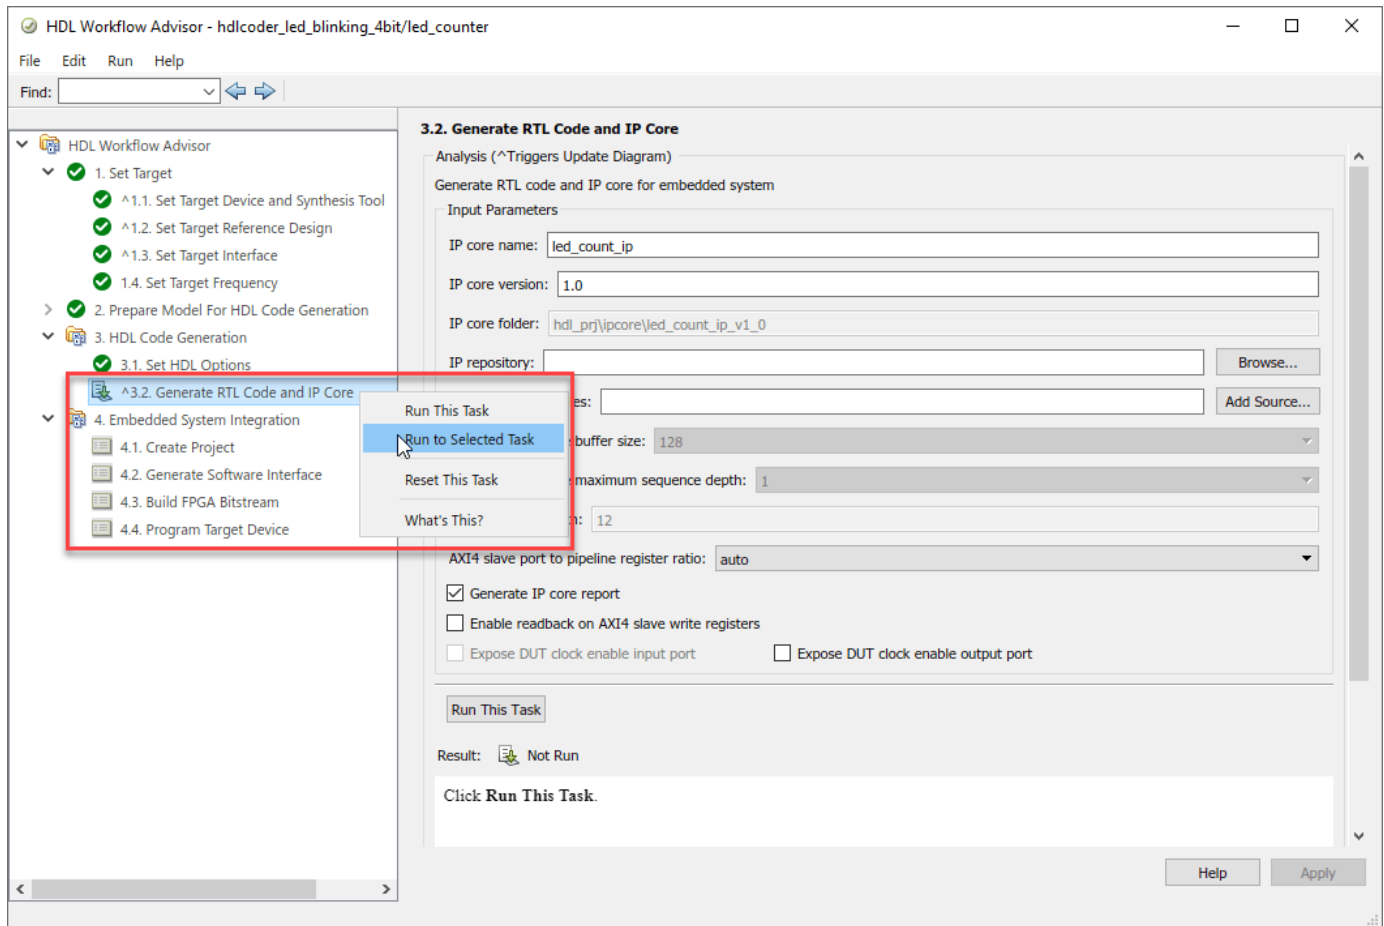

3. In the Set Target > Set Target Frequency task, choose Target Frequency as 50 MHz.

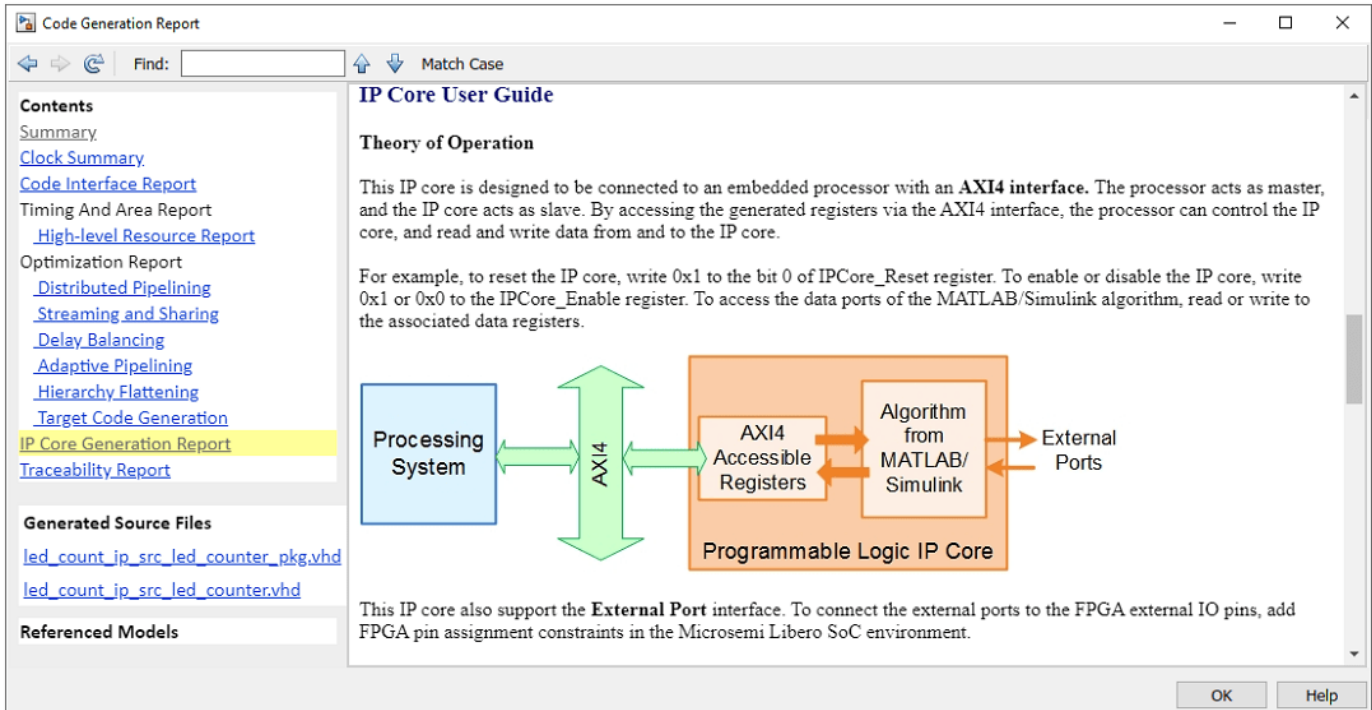

Generate IP Core

1. Right-click the **Generate RTL Code and IP Core** task and select **Run to Selected Task**.

2. Generate and view the IP core report.

After you generate the custom IP core, the IP core files are in the **ipcore** folder within your project folder. An HTML custom IP core report is generated with the custom IP core. The report describes the behavior and contents of the generated custom IP core.

3. Register Address Mapping.

IP Core Generation Report also contains the details about Target Platform Interface of your model. The figure shows the AXI4 interface mapped to the hdlcoder_led_blinking_4bit model ports. The table in IP Core Generation Report shows the interface mapping address of each AXI4 slave register. These addresses are used to read the AXI4 slave input registers.

Code Generation Report

Processor/FPGA synchronization mode: **Free running**

Target platform interface table:

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
Blink_frequency	Inport	ufix4	AXI4	x"100"	
Blink_direction	Inport	boolean	AXI4	x"104"	
LED	Output	ufix4	LEDs General Purpose [0:3]	[0:3]	
Read_back	Output	uint8	AXI4	x"108"	

Register Address Mapping

The following AXI4 bus accessible registers were generated for this IP core:

Register Name	Address Offset	Description
IPCore_Reset	0x0	write 0x1 to bit 0 to reset IP core
IPCore_Enable	0x4	enabled (by default) when bit 0 is 0x1
IPCore_Timestamp	0x8	contains unique IP timestamp (yyymmddHHMM): 2202251538
Blink_frequency_Data	0x100	data register for Inport Blink_frequency
Blink_direction_Data	0x104	data register for Inport Blink_direction
Read_back_Data	0x108	data register for Output Read_back

Following are the AXI4 slave Base address and Master address space specified in the reference design:
Default system.
 AXI4 Slave Base Address: **0x60000000**

AXI4 Slave Master connection:
 Use the AXI4 Slave Base Address plus Address offset to access the IP Core registers shown in Register Address Mapping table

The AXI4 slave write register readback is OFF for the IP core.
 The register address mapping is also in the following C header file for you to use when programming the processor:
[include\led_count_ip_addr.h](#)

The IP core name is appended to the register names to avoid name conflicts.

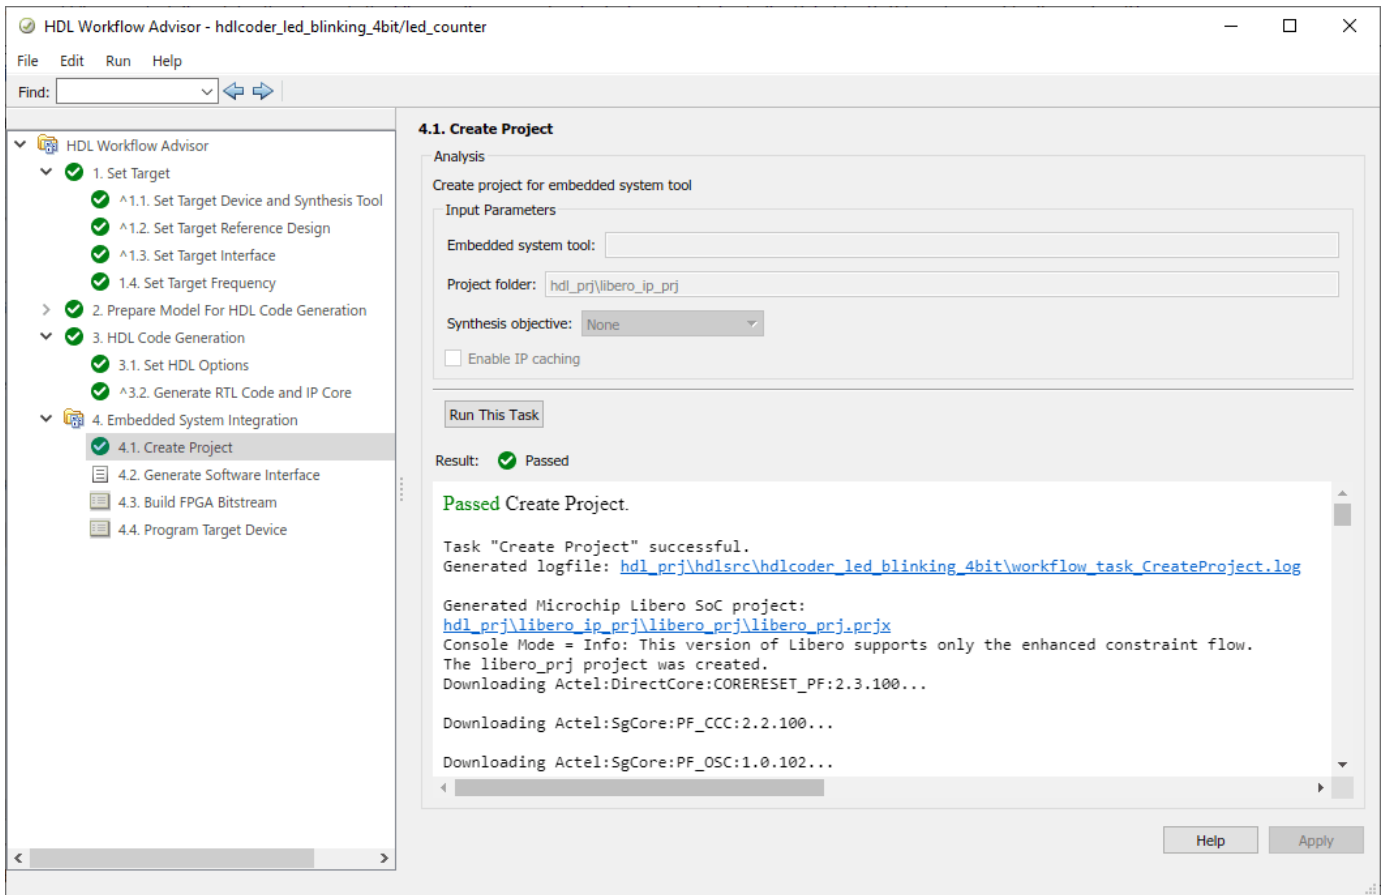

OK Help

Integrate IP Core with Microchip Libero SoC Environment

Insert your generated IP core into an embedded system reference design, generate an FPGA bitstream, and download the bitstream to the PolarFire SoC hardware.

The reference design is a predefined Microchip Libero project. It contains the elements the Libero software requires to deploy your design to the PolarFire SoC board, except for the custom IP core.

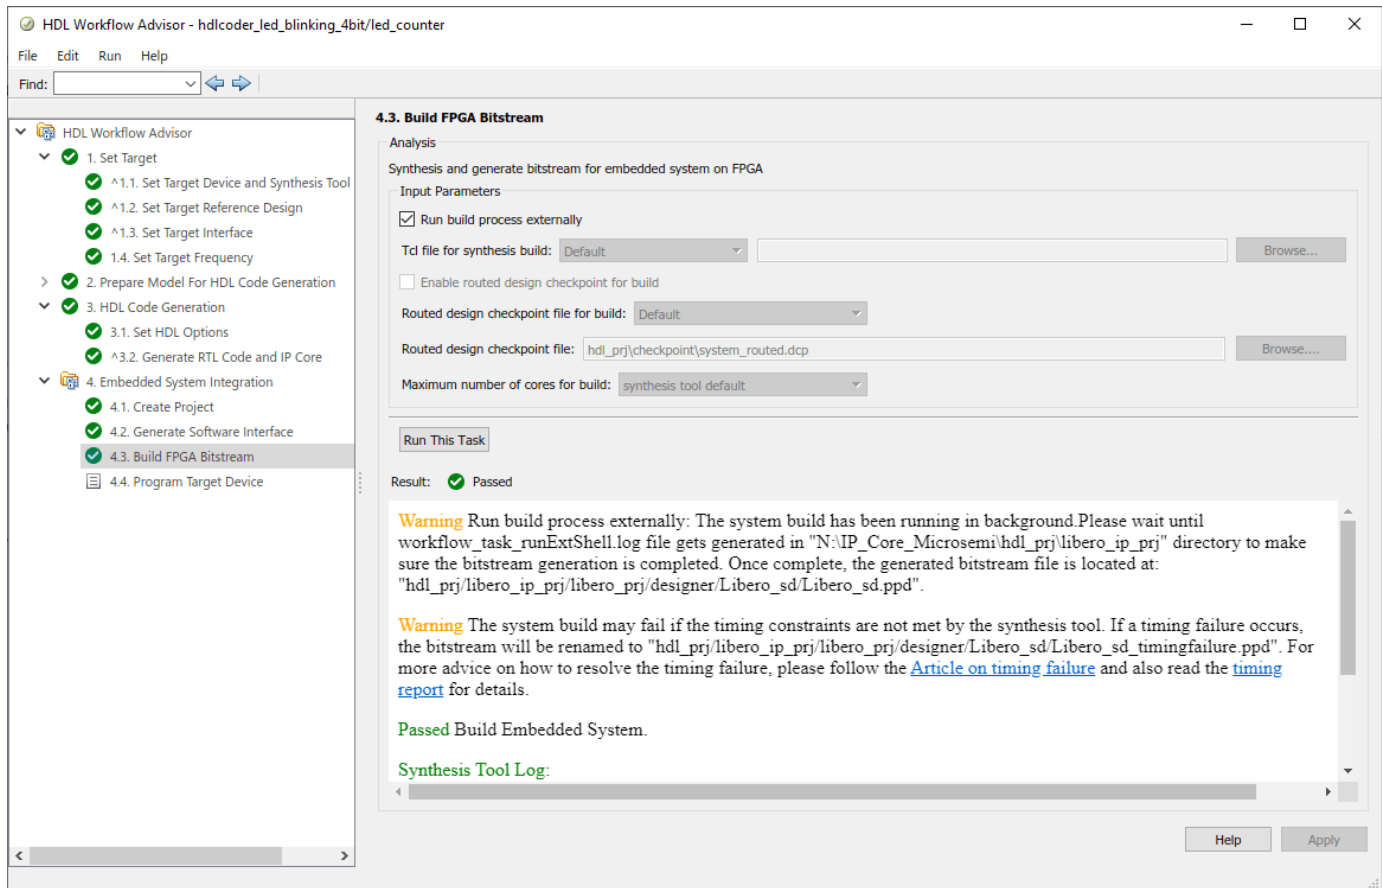

1. To integrate with the Microchip Libero environment, select the **Create Project** task under **Embedded System Integration**. Click **Run This Task**. A Microchip Libero project with the IP Integrator embedded design is generated.

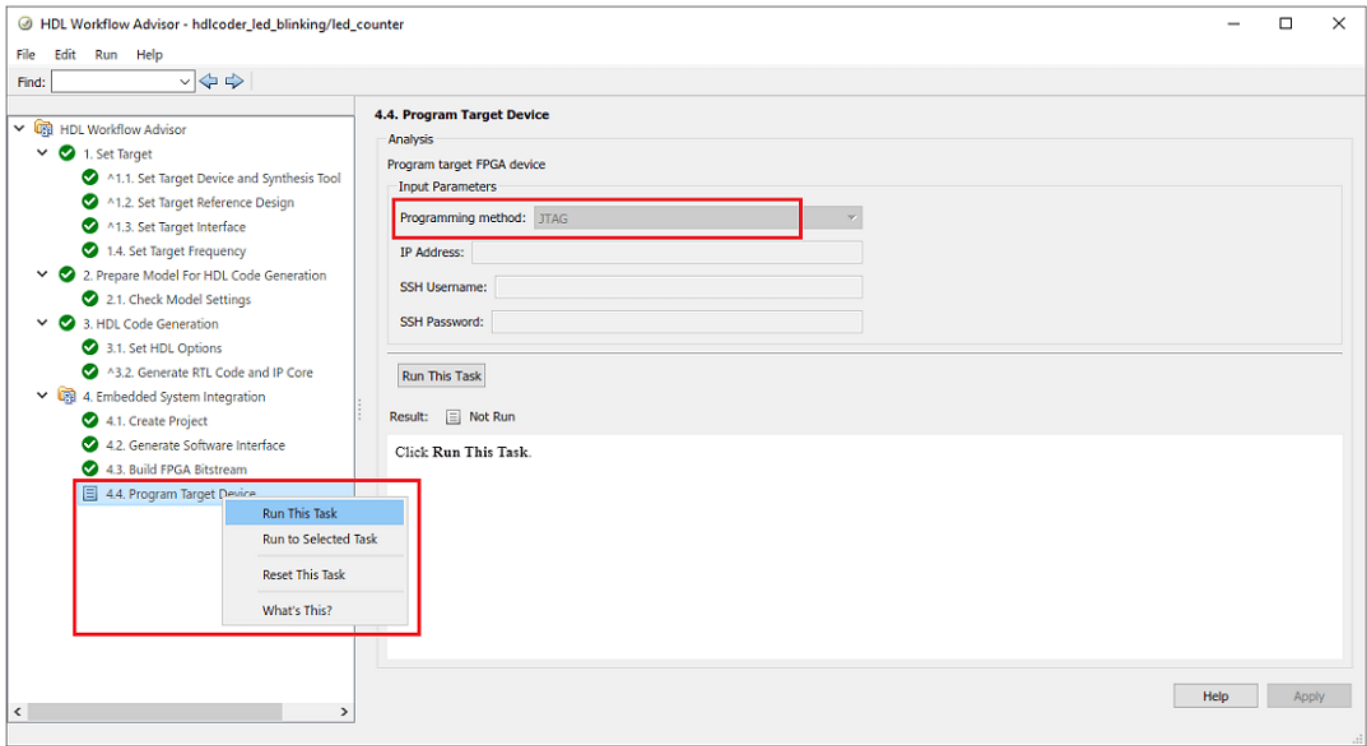

A link to the project is provided in the dialog box. You can optionally open up the project to take a look. From the block diagram in Libero tool, you can see the HDL Coder generated IP core led_count_ip_0 is connected to the Microprocessor Subsystem through the AXI interface.

2. Build the FPGA bitstream in the **Build FPGA Bitstream** task. Make sure that you select **Run build process externally** option so that Libero synthesis tool will runs in a separate process from MATLAB. Wait until workflow_task_runExtShell.log file gets generated in libero_ip_prj folder.

3. After the bitstream is generated, select the **Program Target Device** task. **JTAG** option for **Programming method** will be selected automatically to download the FPGA bitstream onto the PolarFire SoC board. Your design will be automatically reloaded when you power cycle the PolarFire SoC board. click **Run This Task** to program the PolarFire SoC hardware.

After you program the FPGA hardware, the LED starts blinking on your PolarFire SoC board.

Read Values of the AXI4 Slave input registers

The AXI4 slave base address is used together with interface mapping address (from IP Core Generation report) to read the value of AXI4 slave input registers. These address mapping details are used to read the AXI4 slave registers. You can perform the readback of input registers in these ways:

- Using the Devmem command
- Using the MATLAB FPGA Prototyping API Script

Readback of AXI4 Slave Input Registers Using Devmem Command

Devmem command can be used in Putty or Hyper Terminal. Once the bitstream is programmed into the target device, open Putty or hyper terminal using serial interface. From **Register Address Mapping**, AXI4 Slave Base Address is 0x60000000. You can perform read and write operation on AXI4 Slave registers using Base Address and Address Offset. To use devmem command for writing and reading value of **Blink_frequency_Data** register, use these steps.

1. Read the data from address '60000100':

```
devmem2 0x60000100
```

You get the value as 0x00000000.

2. Write some value in address '60000100':

```
devmem2 0x60000100 w 0x1
```

3. Reread the address '60000100':

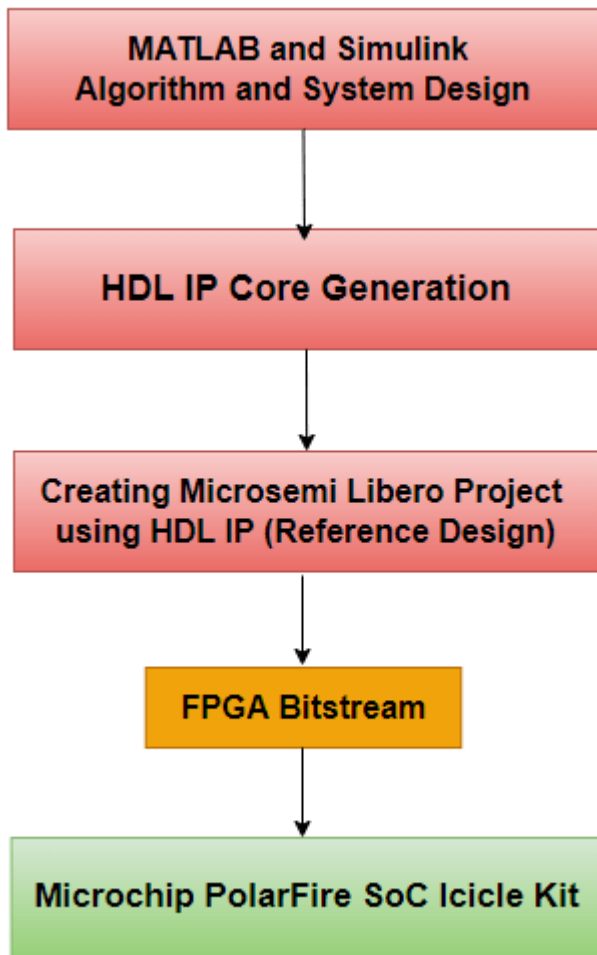

```
devmem2 0x60000100
```

You get the value as 0x00000001.

Summary

This example shows how the hardware and software co-design workflow helps automate the deployment of your MATLAB and Simulink design to a Microchip PolarFire SoC Icicle Kit. You can explore the best ways to partition and deploy your design by iterating through the workflow.

The following diagram shows high-level picture of the workflow you went through in this example. To learn more about the hardware and software co-design workflow, see “Hardware-Software Co-Design Workflow for SoC Platforms” on page 46-8.

Save Target Hardware Settings in Model

This example shows how to save your target hardware settings in a Simulink® model.

This example also shows different ways that you can export, modify, and import target hardware settings. This example uses the Xilinx Zynq platform, but in the same way, you can save target hardware settings in models that target the Intel SoC devices, FPGA Turnkey, and Simulink Real-Time FPGA I/O boards.

Open the Model

```
open_system('hdlcoder_led_blinking');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2014 The MathWorks, Inc.

Configure the Target Hardware Settings

When you configure the target hardware settings, you modify the model. If you save the model, the target hardware settings are saved as part of the model.

You can configure the target hardware settings in three ways:

- HDL Workflow Advisor
- HDL Block Properties dialog box for Inport or Outport
- `hdlset_param`

Since the HDL Workflow Advisor provides a dropdown menu for each target hardware option, it is best to use the HDL Workflow Advisor when you configure the target hardware settings for the first

time. After you save the model with a valid configuration, you can view, modify, and apply settings from the command line.

Use HDL Workflow Advisor to configure model or port hardware settings

Open the HDL Workflow Advisor to generate an IP core from the subsystem `hdlcoder_led_blinking/led_counter` by using the **Launch HDL Workflow Advisor** button in `hdlcoder_led_blinking`. Specify your target hardware settings in task 1 **Set Target**.

In the **Set Target > Set Target Device and Synthesis Tool** task:

- For **Target workflow**, select IP Core Generation.
- For **Target platform**, select Xilinx Zynq ZC702 evaluation kit.

Right-click task 1.2 **Set Target Reference Design** and select **Run to Selected Task**.

In the **Set Target > Set Target Interface** task, map the ports to interfaces as follows:

- For **Blink_frequency** and **Blink_direction** input ports, select the AXI4-Lite interface.
- For the **LED** output port, select External Port.
- For the **Read_back** output port, select the AXI4-Lite interface.

Specify the HDL IP core name and version in task 3.2 **Generate RTL Code and IP Core**. For details, see “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

Use HDL Block Properties dialog box to map DUT ports to target interface

You can specify target interface settings for the DUT interface by using the HDL Block Properties dialog box for any Inport or Outport. You can also specify the HDL IP core settings by using the HDL Block Properties dialog box for the DUT subsystem. However, you can use the HDL Block Properties dialog box to configure only the DUT target interface and HDL IP core settings. Set other target hardware settings from the HDL Workflow Advisor, or by using `hdlset_param` at the command line.

For example, you can change the bit range of the **Blink_frequency** Inport to `x"120"` and remap the **LED** Outport to LEDs General Purpose [0:7]:

- 1 From the subsystem `hdlcoder_led_blinking/led_counter`, right-click the **Blink_frequency** Inport, and select **HDL Code > HDL Block Properties** to open the HDL block properties dialog box. Click the **Target Specification** tab. For **IOInterfaceMapping**, enter `x"120"`.
- 2 Open the HDL block properties dialog for the **LED** Outport. Click the **Target Specification** tab. For **IOInterface**, enter LEDs General Purpose [0:7].

Navigate to the model level `hdlcoder_led_blinking` and right-click the subsystem `hdlcoder_led_blinking/led_counter`. Select **HDL Code > HDL Block Properties**. In the **Target Specification** tab, you can change IP core name and version by using the **IPCoreName** and **IPCoreVersion** parameters respectively.

The target interface and HDL IP core settings you specify using the HDL Block Properties dialog box are validated when you open the HDL Workflow Advisor.

Use hdlset_param to configure model or DUT port hardware settings

To configure target hardware settings for your model or DUT ports, you can use `hdlset_param`.

For example, to change the **TargetPlatform** to Xilinx Zynq ZC706 evaluation kit, enter:

```
hdlset_param('hdlcoder_led_blinking', 'TargetPlatform', 'Xilinx Zynq ZC706 evaluation kit');
```

To set the Bit Range of **Blink_frequency** Inport to x"120"; and set the **LED** Output to LEDs General Purpose [0:7], enter:

```
hdlset_param('hdlcoder_led_blinking/led_counter/Blink_frequency', 'IOInterfaceMapping', 'x"120"');
hdlset_param('hdlcoder_led_blinking/led_counter/LED', 'IOInterface', 'LEDs General Purpose [0:7]');
```

To set the IP core name and version, enter:

```
hdlset_param('hdlcoder_led_blinking/led_counter', 'IPCoreName', 'my_ipcore');
hdlset_param('hdlcoder_led_blinking/led_counter', 'IPCoreVersion', '2.0');
```

Export and Import Target Hardware Settings

To export all non-default HDL code generation options in your model, including the target hardware settings, you can use **hdlsaveparams** and **hdlrestoreparams**. You can modify the model settings in the saved MATLAB file, and apply the settings to the same model or to a different model.

For example, to export the settings from the `hdlcoder_led_blinking` model to a MATLAB file, `targetSetting.m`, enter:

```
hdlsaveparams('hdlcoder_led_blinking/led_counter', 'targetSetting.m')
```

You can modify the settings in `targetSetting.m` as desired, then enter the following command to apply the settings to the model:

```
hdlrestoreparams('hdlcoder_led_blinking/led_counter', 'targetSetting.m')
```

Save and Reopen the Model

- 1 Save the model `hdlcoder_led_blinking` as `hdlcoder_led_blinking_saved`.
- 2 Open the saved model, `hdlcoder_led_blinking_saved`.
- 3 Open the HDL Workflow Advisor by using the **Launch HDL Workflow Advisor** button in `hdlcoder_led_blinking_saved`.

Notice that the modified settings are automatically loaded to task 1 **Set Target** in the HDL Workflow Advisor.

Generate IP Core from MATLAB for Blinking LED on FPGA Board

This example shows how to use the MATLAB® HDL Workflow Advisor to generate a custom HDL IP core that blinks LEDs on an FPGA board. You can use the generated IP on the Xilinx® Zynq® platform or on any Xilinx FPGA with the MicroBlaze processor.

Introduction

You can use MATLAB to design, simulate, and verify your application, perform what-if scenarios with algorithms, and optimize parameters. You can then prepare your application design for hardware and software implementation on the Zynq-7000 AP SoC by deciding which system elements are performed by the programmable logic and which system elements run on the ARM® Cortex-A9.

Using the guided workflow shown in this example, you can:

- * Automatically generate VHDL® code for the programmable logic using HDL Coder™.
- * Export hardware information from the automatically generated EDK project to an SDK project for integration of handwritten C code for the ARM processor.
- * Implement the design on the Xilinx Zynq Platform.

This example is a step-by-step guide that introduces you to the hardware and software co-design workflow. In this workflow, you perform these tasks:

- 1 Set up your Zynq hardware and tools.
- 2 Partition your design for hardware and software implementation.
- 3 Generate an HDL IP core by using the MATLAB HDL Workflow Advisor.
- 4 Integrate the IP core into a Xilinx EDK project and program the Zynq hardware.

Requirements

- Xilinx ISE 14.4
- Xilinx Zynq-7000 SoC ZC702 Evaluation Kit running the Linux® image in the Base Targeted Reference Design 14.4
- HDL Coder Support Package for Xilinx Zynq Platform

Set Up Zynq Hardware and Tools

1. Set up the Xilinx Zynq ZC702 evaluation kit. Follow the hardware setup steps in HDL Coder example "Getting Started with HW/SW Co-Design Workflow for Xilinx Zynq Platform".
2. Set up the Xilinx ISE synthesis tool path. In the MATLAB Command Window use this command. Use your own ISE installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx ISE', 'ToolPath', 'C:\Xilinx\14.4\ISE_DS\ISE\bin\nt64\ise.exe')
```

Partition Design for Hardware and Software Implementation

You must decide which parts of your design to implement on the programmable logic and which parts to run on the ARM processor.

Group the parts of your algorithm that you want to implement on programmable logic into a MATLAB function. This function is the boundary of your hardware/software partition. All the MATLAB code within this function is implemented on programmable logic. You must provide C code that implements the MATLAB code outside this function to run on the ARM processor.

In this example, the function **mlhdlc_ip_core_led_blinking** is implemented on hardware. It models a counter that blinks the LEDs on an FPGA board. Two input ports, **Blink_frequency** and **Blink_direction**, are control ports that determine the LED blink frequency and direction. You can adjust the input values of the hardware subsystem through prompt options in the included embedded software, `mlhdlc_ip_core_led_blinking_driver.c` and `mlhdlc_ip_core_led_blinking_driver.h`. The embedded software, which runs on the ARM processor, controls the generated IP core by writing to the AXI interface accessible registers. The output port of the hardware subsystem, **LED**, connects to the LED hardware. You can use the output port, **Read_Back**, to read data back to the processor.

```
design_name = 'mlhdlc_ip_core_led_blinking';
testbench_name = 'mlhdlc_ip_core_led_blinking_tb';
sw_driver_name = 'mlhdlc_ip_core_led_blinking_driver.c';
sw_driver_header_name = 'mlhdlc_ip_core_led_blinking_driver.h';
```

Review the MATLAB design.

```
type(design_name);

function [LED, Read_back] = mlhdlc_ip_core_led_blinking(Blink_frequency, Blink_direction)
%

```

Create HDL Coder Project

```
coder -hdlcoder -new mlhdlc_ip_core_led_blinking_prj
```

Add the file `mlhdlc_ip_core_led_blinking.m` to the project as the MATLAB Function and `mlhdlc_ip_core_led_blinking_tb.m` as the MATLAB Test Bench.

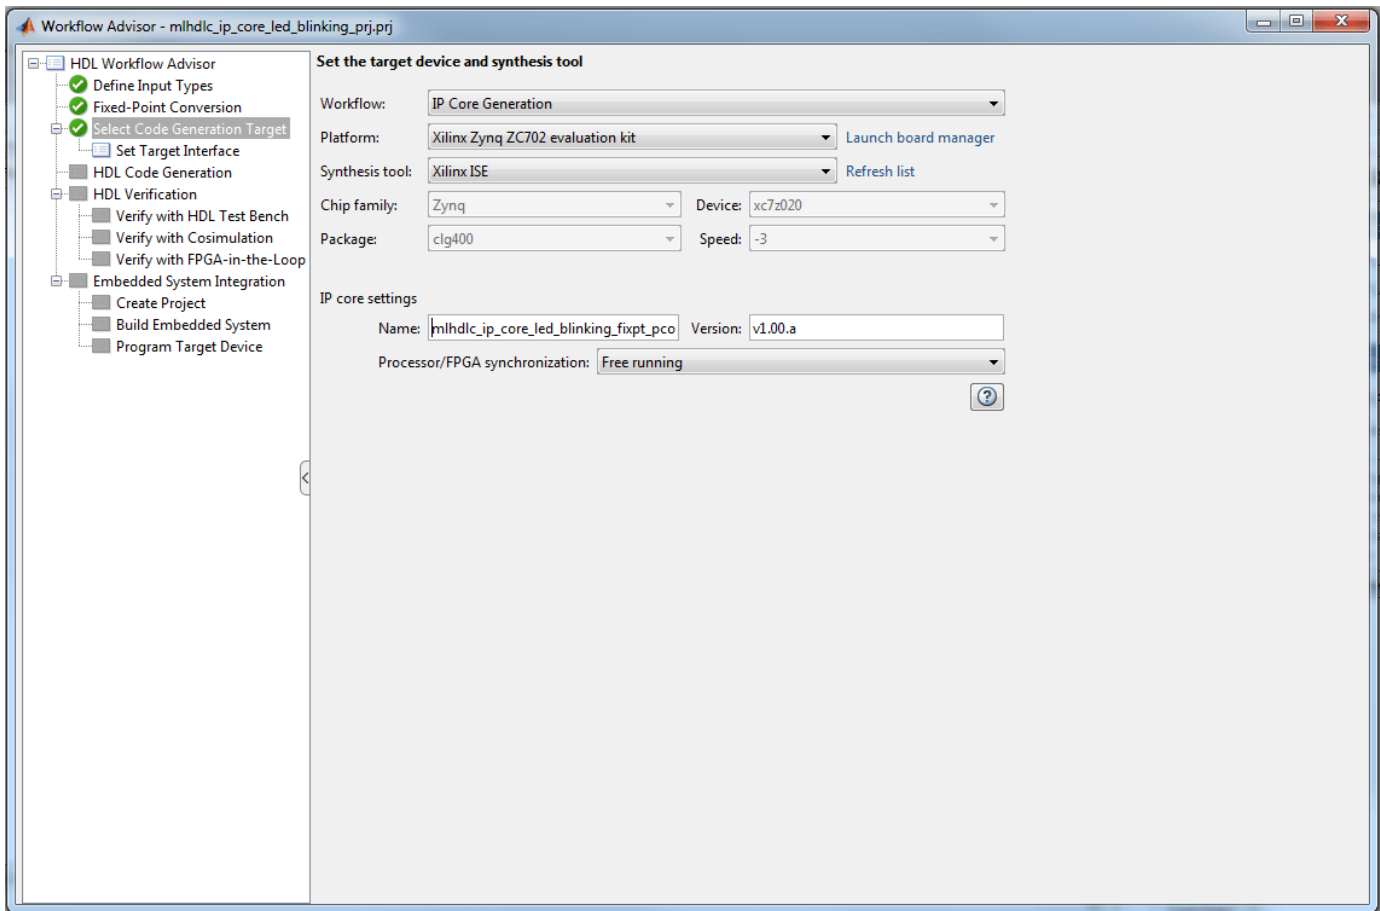

For a more complete tutorial on creating and populating MATLAB HDL Coder projects, see “Get Started with MATLAB to HDL Workflow”.

Select Code Generation Target

Using the IP Core Generation workflow in the HDL Workflow Advisor enables you to automatically generate a sharable and reusable IP core module from a MATLAB function. The generated IP core is designed to be connected to an embedded processor on an FPGA device. HDL Coder generates HDL code from the MATLAB design function and generates HDL code for the AXI interface logic connecting the IP core to the embedded processor. HDL Coder packages call the generated files into an IP core folder. You can then integrate the generated IP core with a larger FPGA embedded design in the Xilinx EDK environment.

To choose the IP Core Generation workflow:

1. Open the HDL Workflow Advisor and right-click **Select Code Generation Target**.
2. For **Workflow**, select **IP Core Generation**.

Select Platform

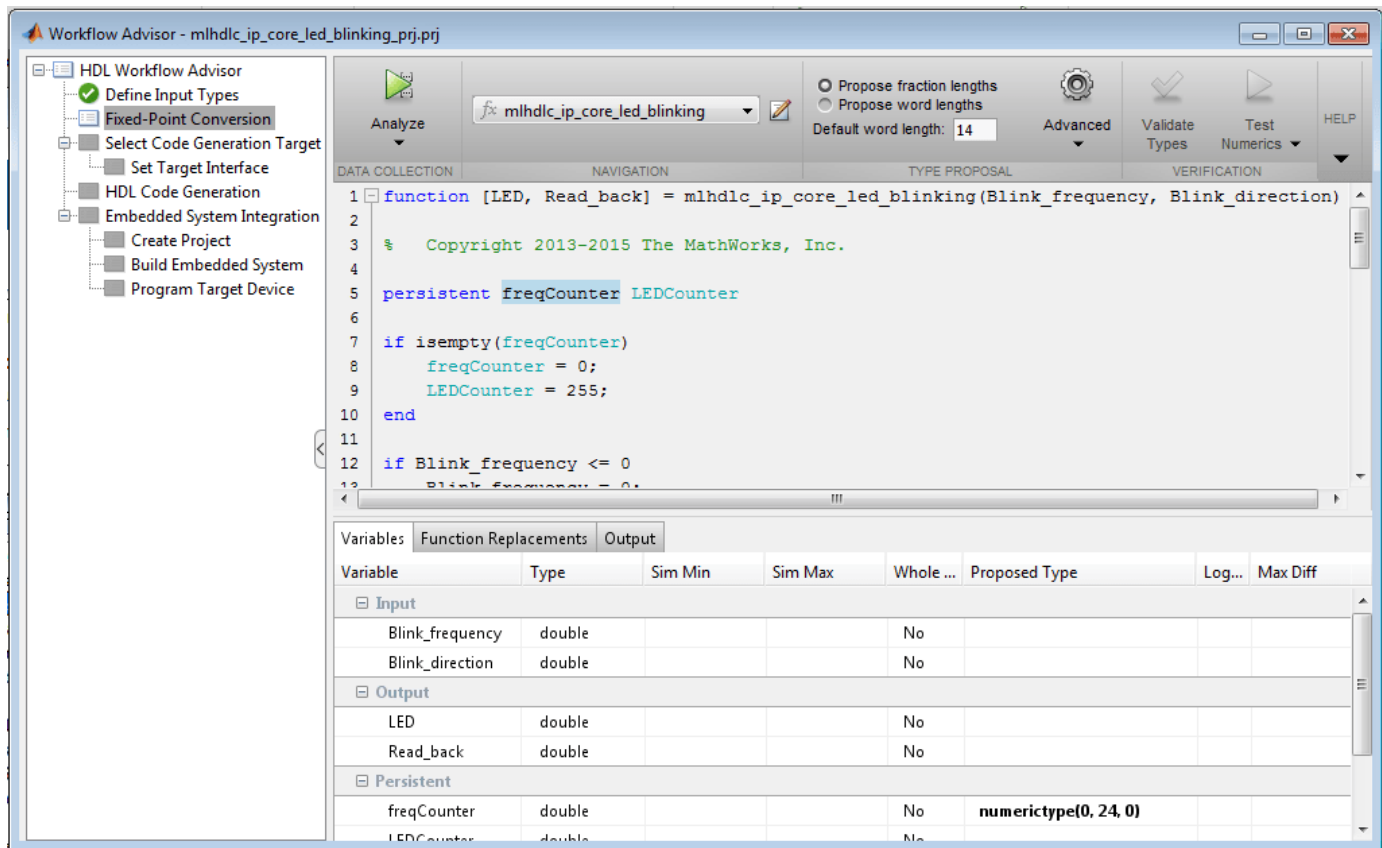

There is a generic option called **Generic Xilinx Platform** in the platform selection. This option is board-independent and generates a generic Xilinx IP core, which has to be manually integrated into your EDK environment.

The remaining options are board-specific and provide the additional capability of integrating the generated IP core into a Xilinx PlanAhead project, synthesize the project, and download the bitstream to FPGA within the HDL Workflow Advisor.

For **Platform**, select **Xilinx Zynq ZC702 evaluation kit**. If you do not have this option, select **Get more** to open the Support Package Installer. In the Support Package Installer, select Xilinx Zynq Platform and follow the instructions to complete the installation.

Convert Design to Fixed-Point Design

1. Right-click the **Define Input Types** task and select **Run This Task**.
2. In the **Fixed-Point Conversion** task, click **Advanced** and set the **Safety margin for sim min/max (%)** to 0.
3. In the Proposed Type column in the Variables tab, set the proposed type of the **freqCounter** variable to unsigned 24-bit integer by entering **numeric_type(0, 24, 0)**.

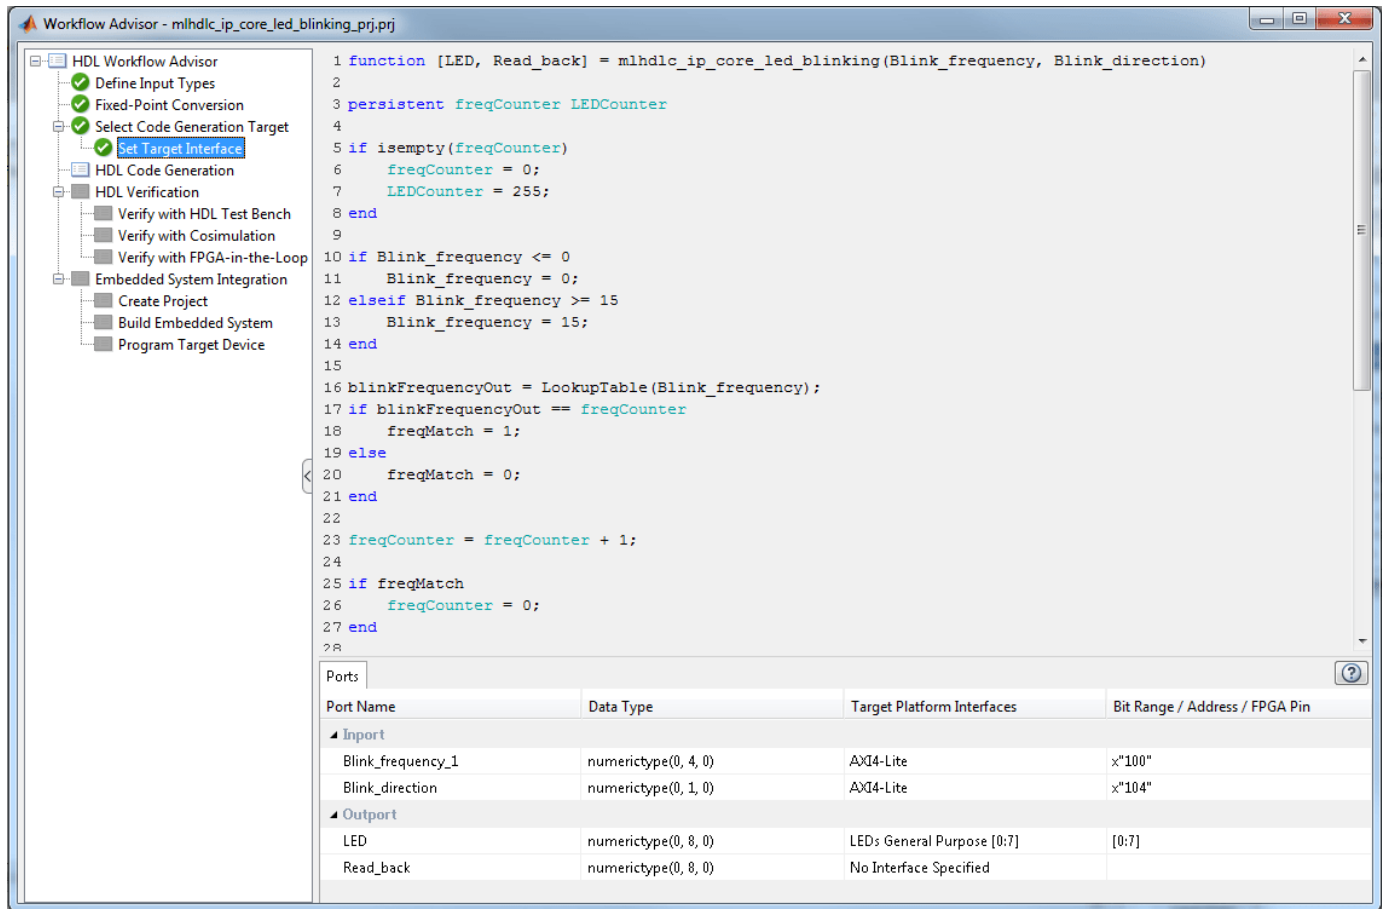

4. Right-click the **Fixed-Point Conversion** task and select **Run This Task**.

Configure Target Interface

Map each port in your MATLAB design function to one of the IP core target interfaces in the **Set Target Interface** subtask.

In this example, input ports **Blink_frequency** and **Blink_direction** are mapped to the AXI4-Lite interface and HDL Coder™ generates AXI interface accessible registers for them. The **LED** output port is mapped to an external interface, **LEDs General Purpose [0:7]**, which connects to the LED hardware on the Zynq board.

```

1 function [LED, Read_back] = mldhc_ip_core_led_blinking(Blink_frequency, Blink_direction)
2
3 persistent freqCounter LEDCounter
4
5 if isempty(freqCounter)
6     freqCounter = 0;
7     LEDCounter = 255;
8 end
9
10 if Blink_frequency <= 0
11     Blink_frequency = 0;
12 elseif Blink_frequency >= 15
13     Blink_frequency = 15;
14 end
15
16 blinkFrequencyOut = LookupTable(Blink_frequency);
17 if blinkFrequencyOut == freqCounter
18     freqMatch = 1;
19 else
20     freqMatch = 0;
21 end
22
23 freqCounter = freqCounter + 1;
24
25 if freqMatch
26     freqCounter = 0;
27 end
28

```

Port Name	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
Input			
Blink_frequency_1	numerictype(0, 4, 0)	Ax14-Lite	x"100"
Blink_direction	numerictype(0, 1, 0)	Ax14-Lite	x"104"
Output			
LED	numerictype(0, 8, 0)	LEDs: General Purpose [0:7]	[0:7]
Read_back	numerictype(0, 8, 0)	No Interface Specified	

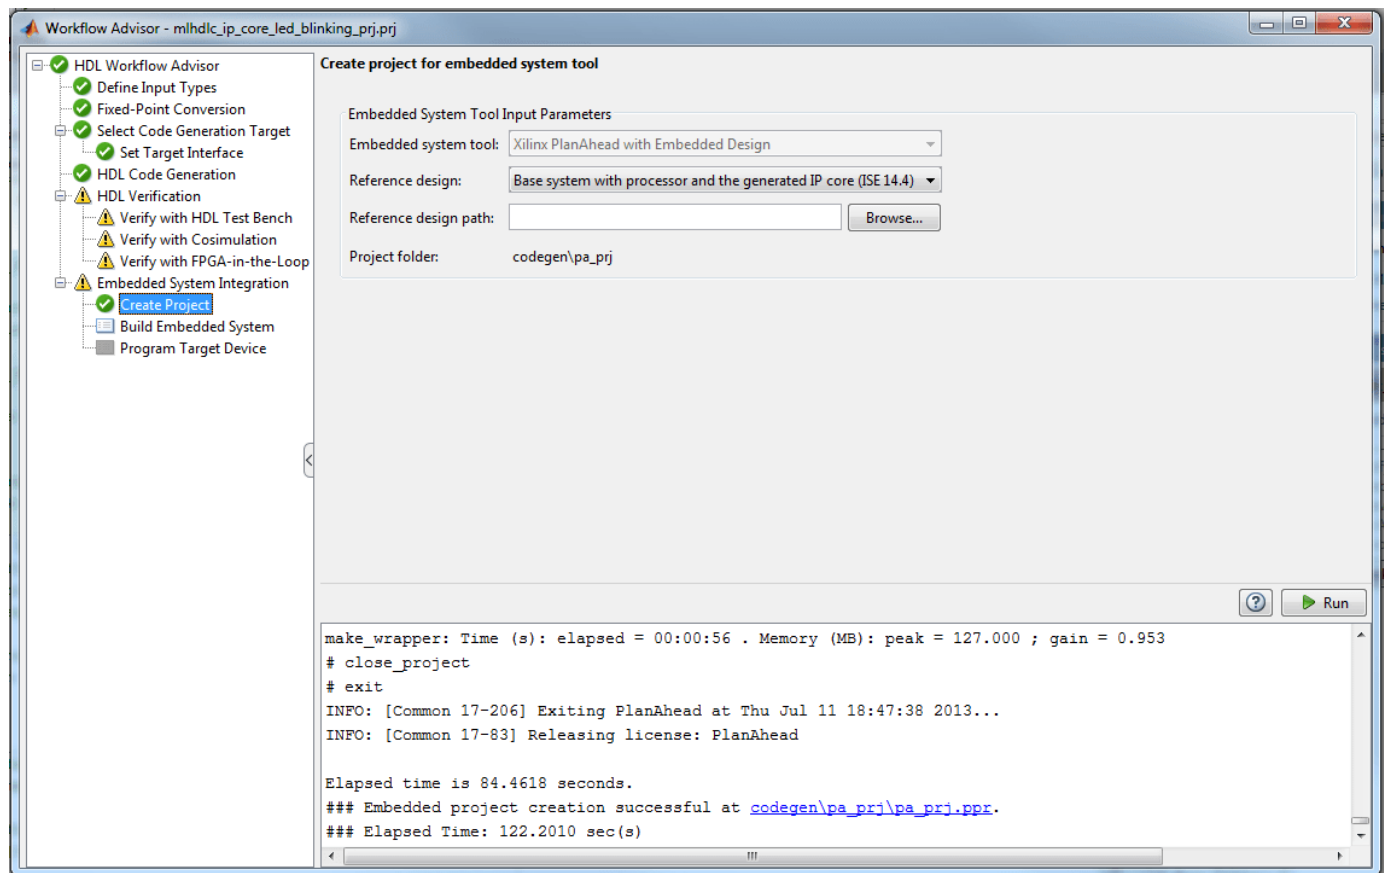

To generate the IP Core and IP Core report, right-click the **HDL Code Generation** step and select **Run this task**.

Integrate IP Core into with the Xilinx EDK Environment

Insert your generated IP core into an embedded system reference design, generate an FPGA bitstream, and download the bitstream to the Zynq hardware.

The reference design is a predefined Xilinx EDK project. It contains the elements the Xilinx software needs to deploy your design to the Zynq platform, except for the custom IP core and embedded software.

1. Under **Embedded System Integration**, right-click the **Create Project** step, and choose **Run This Task**. A Xilinx PlanAhead project with an EDK embedded design is generated. A link to the project is in the dialog box.

2. Build the FPGA bitstream in the **Build Embedded System** step. Make sure the **Run build process externally** option is selected. The Xilinx synthesis tool runs in a separate process from MATLAB. Wait for the synthesis tool process to finish running in the external command window.
3. After the bitstream is generated, right-click the **Program Target Device** step and choose the option **Run This Task** to program the Zynq hardware.

After you program the FPGA hardware, the LED starts blinking on your Zynq board.

Next, you integrate the included handwritten C code to run on the ARM processor to control the LED blink frequency and direction.

Run Software on Zynq ZC702 Hardware

The included C code files, `mlhdlc_ip_core_led_blinking_driver.c` and `mlhdlc_ip_core_led_blinking_driver.h`, implement a simple menu that enables you to set the LED blink frequency and direction. You can use them for your Linux-based SDK project.

```
----- MLHDLC LED Blinking IP: -----  
  
1 -> Change blinking frequency  
2 -> Change blinking direction  
0 -> Exit  
  
Enter your choice :1  
Please enter the frequency index [0:15]  
2  
  
Possible choices: 0, 1, 2  
  
----- MLHDLC LED Blinking IP: -----  
  
1 -> Change blinking frequency  
2 -> Change blinking direction  
0 -> Exit  
  
Enter your choice :2  
Please specify the blinking direction? (1 - up, 0 - down)  
0
```

For instructions on how to integrate the included C code into an SDK project and run it on Zynq ZC702 hardware, refer to the Xilinx documentation.

Access DUT Registers on Xilinx Pure FPGA Board Using IP Core Generation Workflow

This example shows how to use the HDL Coder™ IP core generation workflow to develop reference designs for Xilinx® parts that do not use an embedded ARM® processor present but that still utilize the HDL Coder generated AXI interface to control the design under test (DUT). This example uses the HDL Verifier™ AXI Manager IP to access the HDL Coder generated DUT registers from MATLAB®. Alternatively, you can use the Xilinx JTAG AXI Master to access the DUT registers using Vivado® Tcl console by writing Tcl commands. For the Xilinx JTAG AXI Master, you must create a custom reference design. The FPGA design is implemented on the Xilinx Kintex®-7 KC705 board.

Requirements

- Xilinx Vivado Design Suite, with a supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Xilinx Kintex-7 KC705 development board
- HDL Coder Support Package for Xilinx FPGA Boards
- HDL Verifier Support Package for Xilinx FPGA Boards

Xilinx Kintex-7 KC705 Development Board

This figure shows the Xilinx Kintex-7 KC705 development board.

Example Reference Designs

Designs that can benefit from using the HDL Coder IP core generation workflow without using either an embedded ARM processor or an Embedded Coder™ support package but still leverage the HDL Coder generated AXI4-Lite registers can include one of these IP sets.

- HDL Verifier AXI Manager + HDL Coder IP Core
- Xilinx JTAG Master + HDL Coder IP Core
- MicroBlaze™ + HDL Coder IP Core

- PCIe Endpoint + HDL Coder IP Core

This example includes two reference designs.

- The Default System reference design uses MathWorks® IP and a MATLAB command line interface for issuing read and write commands. To use this design, you must have the HDL Verifier product.
- The Xilinx JTAG to AXI Master reference design uses Vivado IP for the JTAG to AXI Master and requires using the Vivado Tcl console to issue read and write commands.

The two reference designs differ by only the JTAG manager IP that they use, as this figure shows.

HDL Verifier AXI Manager Reference Design

In the IP core generation workflow of the HDL Workflow Advisor, in the **Set Target Reference Design** step, set the **Insert AXI Manager (HDL Verifier required)** parameter to an interface that communicates between your host machine and the target hardware. This option adds AXI manager IP for your interface automatically into the reference design and connects the added IP to the DUT IP using the AXI4-slave interface. The next section details the steps to auto-insert the JTAG AXI Manager IP in the reference design.

Execute IP Core Workflow

Follow these steps to execute the IP core workflow for the Default System reference design, which uses JTAG AXI Manager IP. Using this reference design, you can generate an HDL IP core that blinks LEDs on the KC705 board. To generate an HDL IP core, follow these steps.

1. Set up the Xilinx Vivado tool path by executing this command in MATLAB. Use your own Xilinx Vivado installation path when executing the command.

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath', ...
    'C:\Xilinx\Vivado\2020.2\bin\vivado.bat');
```

2. Open the Simulink model that implements LED blinking by executing this command in MATLAB.

```
open_system('hdlcoder_led_blinking')
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

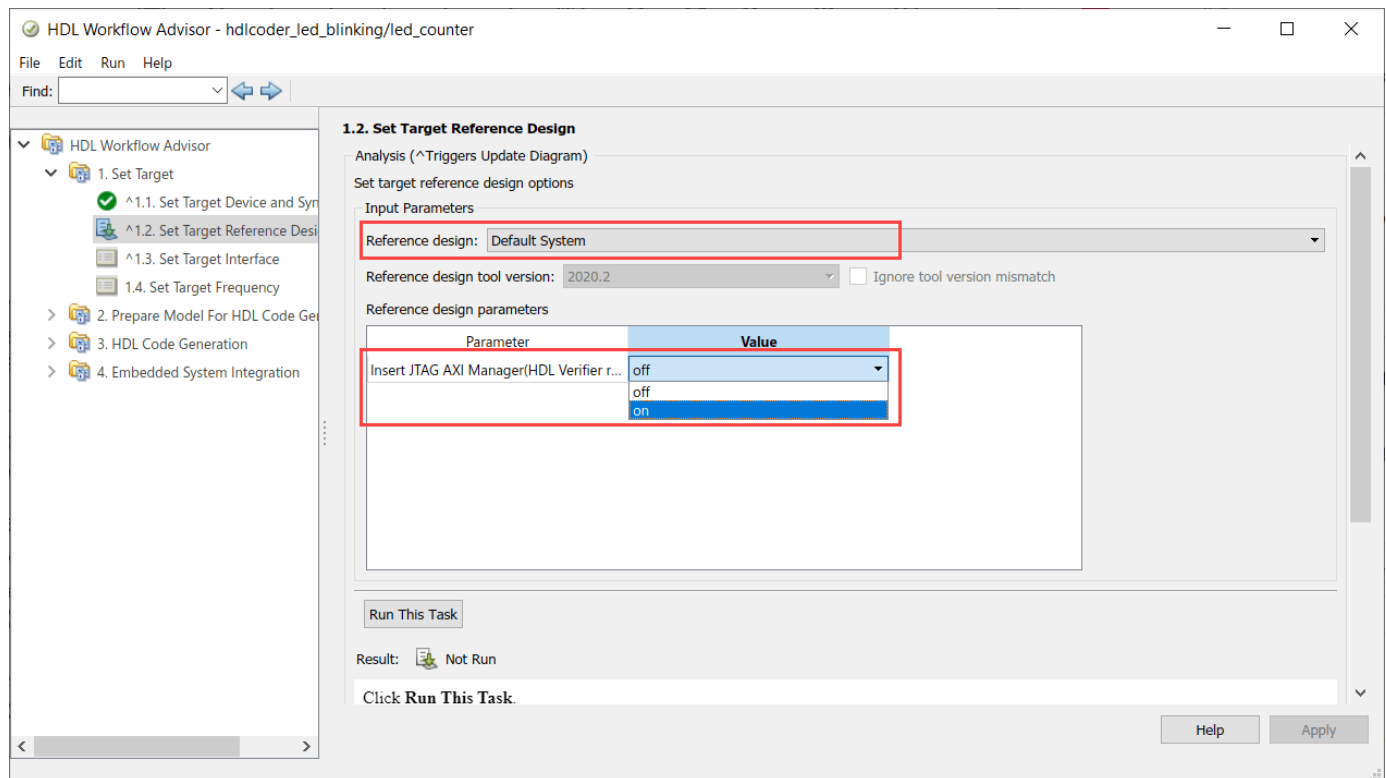

Run Demo

Copyright 2012 The MathWorks, Inc.

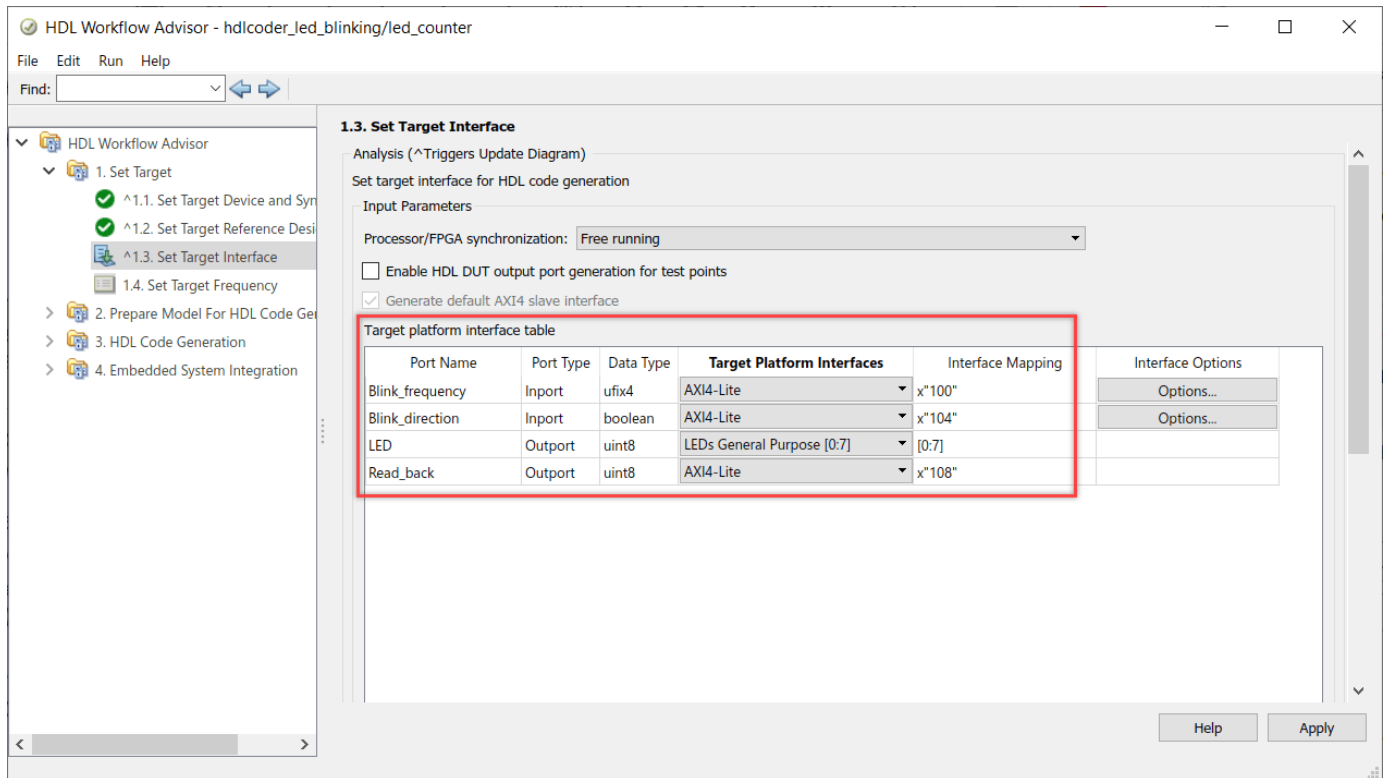

3. Launch HDL Workflow Advisor from the `hdlcoder_led_blinking/led_counter` subsystem by right-clicking the `led_counter` subsystem and selecting **HDL Code** followed by **HDL Workflow Advisor**.

4. In step 1.1, set **Target workflow** to IP Core Generation and **Target platform** to Xilinx Kintex-7 KC705 development board. Click **Run This Task**.

5. In step 1.2, set **Reference design** to Default System. Under **Reference design parameters**, set **Insert AXI Manager (HDL Verifier required)** to JTAG. Click **Run This Task**.

6. In step 1.3, set the interface of the **Blink_frequency**, **Blink_direction**, and **Read_back** ports to AXI4-Lite. Set the interface of the **LED** port to LEDs General Purpose [0:7].

7. Run the remaining steps in the workflow to generate a bitstream and program the target device.

Unlike the Zynq-based reference design, a **Generate Software Interface Model** task does not exist, as this figure shows.

Determine Addresses from IP Core Report

The base address for an HDL Coder IP core is defined as $0x40000000$ for the Default System reference design, which uses the AXI Manager IP. You can see address setting in the generated IP core report as shown in this figure.

Use JTAG AXI Master to control the IP core from MATLAB

In 1.2 Step "Set Target Reference design", "Insert JTAG AXI Manager" is turned "on". This adds Matlab as an "AXI Manager" to control the DUT IP core using AXI4 interface as shown.

JTAG Interface **AXI4 Interface**

The diagram illustrates the hardware flow and the control interface. At the top, a timeline shows the flow from MATLAB to HW (Hardware) and finally to the FPGA. Below this, a detailed diagram shows the interaction between MATLAB, the Reference Design (MATLAB JTAG AXI Master IP), and the DUT IP Core. MATLAB is connected to the Reference Design via a JTAG interface. The Reference Design is connected to the DUT IP Core via an AXI4 interface. The DUT IP Core is connected to the LE (Logic Element) block.

Requires a HDL Verifier license to use this feature. After that use MATLAB® Command line interface to access the DUT IP core registers. **The Base Address of AXI4 Slave is 0x40000000.**

OK Help

The IP core report register address mapping table shows the offsets.

The screenshot shows a window titled "Code Generation Report" with a search bar and "Match Case" option. The left sidebar contains a "Contents" list with "IP Core Generation Report" highlighted. The main content area is titled "Register Address Mapping" and contains the following text:

The following AXI4-Lite bus accessible registers were generated for this IP core:

Register Name	Address Offset	Description
IPCore_Reset	0x0	write 0x1 to bit 0 to reset IP core
IPCore_Enable	0x4	enabled (by default) when bit 0 is 0x1
IPCore_Timestamp	0x8	contains unique IP timestamp (yymmddHHMM): 2201201659
Blink_frequency_Data	0x100	data register for Inport Blink_frequency
Blink_direction_Data	0x104	data register for Inport Blink_direction
Read_back_Data	0x108	data register for Output Read_back

Following are the AXI4 slave Base address and Master address space specified in the reference design:

Default System.
 AXI4 Slave Base Address: **0x40000000**
 AXI4 Slave Master connection: **hdlverifier_axi_mana/axi4m**
 Use the AXI4 Slave Base Address plus Address offset to access the IP Core registers shown in Register Address Mapping table

The AXI4 slave write register readback is OFF for the IP core.
 The register address mapping is also in the following C header file for you to use when programming the processor:
[include\led_count_ip_addr.h](#)
 The IP core name is appended to the register names to avoid name conflicts.

IP Core User Guide

Theory of Operation

At the bottom of the window are "OK" and "Help" buttons.

HDL Verifier Command Line Interface

If you have the HDL Verifier support package for Xilinx FPGA boards, select the AXI Manager reference design, then you can use MATLAB command line interface to access the IP core that is generated by the HDL Coder product.

To write and read from the DDR memory, follow these steps.

1. Create an AXI manager object.

```
h = aximanager('Xilinx')
```

2. Issue a write command. For example, disable the DUT.

```
h.writememory('40000004',0)
```

3. Re-enable the DUT.

```
h.writememory('40000004',1)
```

4. Issue a read command. For example, read the current counter value.

```
h.readmemory('40000108',1)
```

5. Delete the object to free up the JTAG resource. If you do not delete the object, other JTAG operations, such as programming the FPGA, fail.

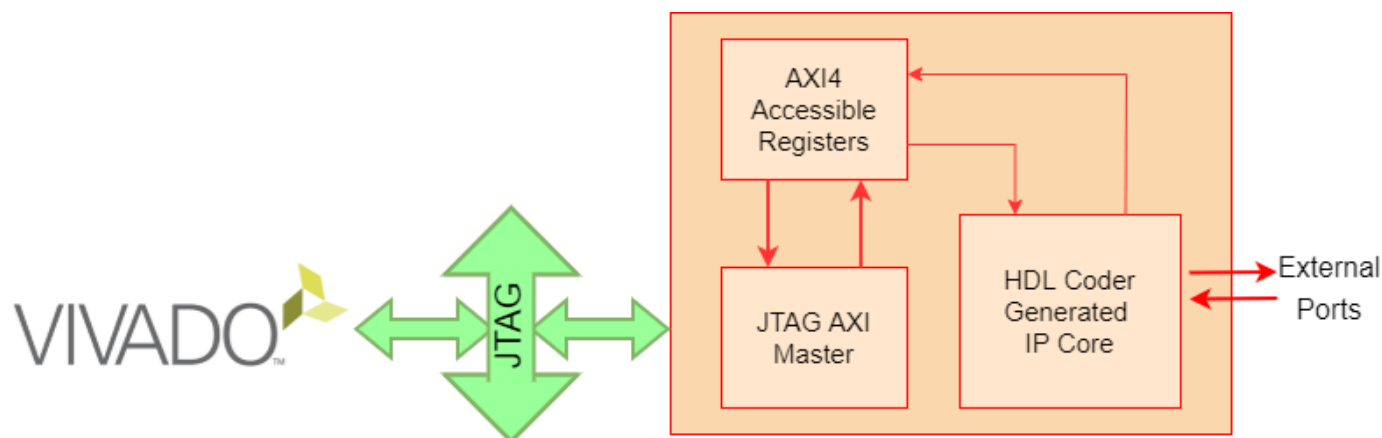

```
delete(h)
```

Xilinx JTAG to AXI Master Reference Design

Create a custom reference design to use the Xilinx JTAG to AXI Master IP in the reference design, and then add the reference design files to the MATLAB path using the `addpath` command.

Access the HDL Coder IP core registers using the Xilinx JTAG to AXI Master IP by using the base address that is defined in reference design plugin file.

Vivado Tcl Commands for AXI Read and Write

This example uses the standalone Vivado Tcl console for basic commands to issue reads and writes. You can use these commands to open the JTAG device and set up an "enable" and "disable" write to the DUT. You can enter these commands directly into the Vivado Tcl console or save them in a Tcl file and source them later. For simplicity, copy these Tcl commands into a file `open_jtag.tcl`.

```
# Open connection to the JTAG Master
open_hw
connect_hw_server
open_hw_target
refresh_hw_device [lindex [get_hw_devices] 0]

# Create some reads/writes
create_hw_axi_txn wr_enable [get_hw_axis hw_axi_1] ...
  -address 44a0_0004 -data 0000_0001 -type write
create_hw_axi_txn wr_disable [get_hw_axis hw_axi_1] ...
  -address 44a0_0004 -data 0000_0000 -type write
```

Launch the Vivado Tcl console, sourcing the file you just created.

```
system('vivado -mode tcl -source open_jtag.tcl&')
```

```
C:\windows\system32\cmd.exe - vivado -mode tcl
WARNING: Default location for XILINX_VIVADO_HLS not found:

```

When you are done using the JTAG Master, close the connection by using these Tcl commands.

```
# Close and disconnect from the JTAG Master
close_hw_target;
disconnect_hw_server;
```

Summary

You can use the JTAG AXI Manager IP to interface with HDL Coder IP core registers in systems that do not have an embedded ARM processor, such as the Kintex-7. You can use this IP as a first step to debug standalone HDL Coder IP cores, prior to hand coding software for soft processors, (such as MicroBlaze), or as a way to tune parameters on a running system.

Access DUT Registers on Intel Pure FPGA Board Using IP Core Generation Workflow

This example shows how to use the HDL Coder™ IP core generation workflow to develop reference designs for Intel® parts that do not use an embedded ARM® processor present but that still utilize the HDL Coder generated AXI interface to control the design under test (DUT). This example uses the HDL Verifier™ AXI Manager IP to access the HDL Coder generated DUT registers from MATLAB®. Alternatively, you can use the Intel Qsys JTAG to Avalon® Master Bridge IP to access the FPGA registers using Tcl commands in the Qsys system console. For the Intel JTAG AXI Master, you must create a custom reference design. The FPGA design is implemented on the Arrow® DECA MAX® 10 FPGA evaluation kit.

Requirements

- Intel Quartus® Prime Standard, with a supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Arrow DECA MAX 10 FPGA evaluation kit
- HDL Coder Support Package for Intel FPGA Boards
- HDL Verifier Support Package for Intel FPGA Boards
- HDL Coder Support Package for Intel SoC Devices (required only when you want to integrate the IP core into your own custom reference design)

Arrow DECA MAX 10 FPGA Evaluation Kit

This figure shows the Arrow DECA MAX 10 FPGA evaluation kit.

Example Reference Designs

Designs that can benefit from using the HDL Coder IP core generation workflow without using either an embedded ARM processor or an Embedded Coder™ support package but still leverage the HDL Coder generated AXI4 registers can include one of these IP sets.

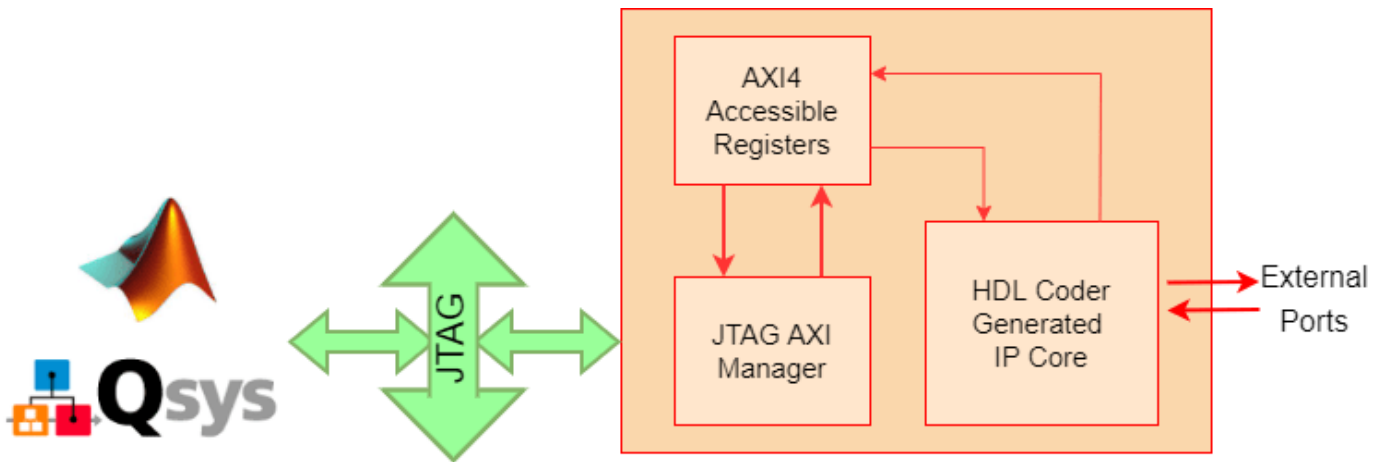

- HDL Verifier AXI Manager + HDL Coder IP Core
- JTAG Master + HDL Coder IP Core
- Nios® II + HDL Coder IP Core
- PCIe® Endpoint + HDL Coder IP Core

This example includes two reference designs.

- The Default System reference design uses MathWorks® IP and a MATLAB command line interface for issuing read and write commands. To use this design, you must have the HDL Verifier product.
- The Intel JTAG to AXI Master reference design uses Quartus IP for the JTAG to AXI Master and requires using the Quartus Tcl console to issue read and write commands.

The two reference designs differ by only the JTAG manager IP that they use.

HDL Verifier AXI Manager Reference Design

In the IP core generation workflow of the HDL Workflow Advisor, in the **Set Target Reference Design** step, enable the **Insert AXI Manager (HDL Verifier required)** parameter. This option adds AXI Manager IP automatically into the reference design and connects the added IP to the DUT IP using the AXI4-slave interface. The next section details the steps to auto-insert the JTAG AXI Manager IP in the reference design.

Execute IP Core Workflow

Follow these steps to execute the IP core workflow for the Default System reference design, which uses JTAG AXI Manager IP. Using this reference design, you can generate an HDL IP core that blinks LEDs on the DECA board. To generate the HDL IP core, follow these steps.

1. Set up the Intel Quartus® tool path. Use your own Intel Quartus installation path by executing this command in MATLAB.

```
hdlsetuptoolpath('ToolName','Altera QUARTUS II', ...
    'ToolPath','C:\intelFPGA\20.1\quartus\bin64\quartus.exe');
```

2. Open the Simulink model that implements LED blinking by executing this command in MATLAB.

```
open_system('hdlcoder_led_blinking')
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

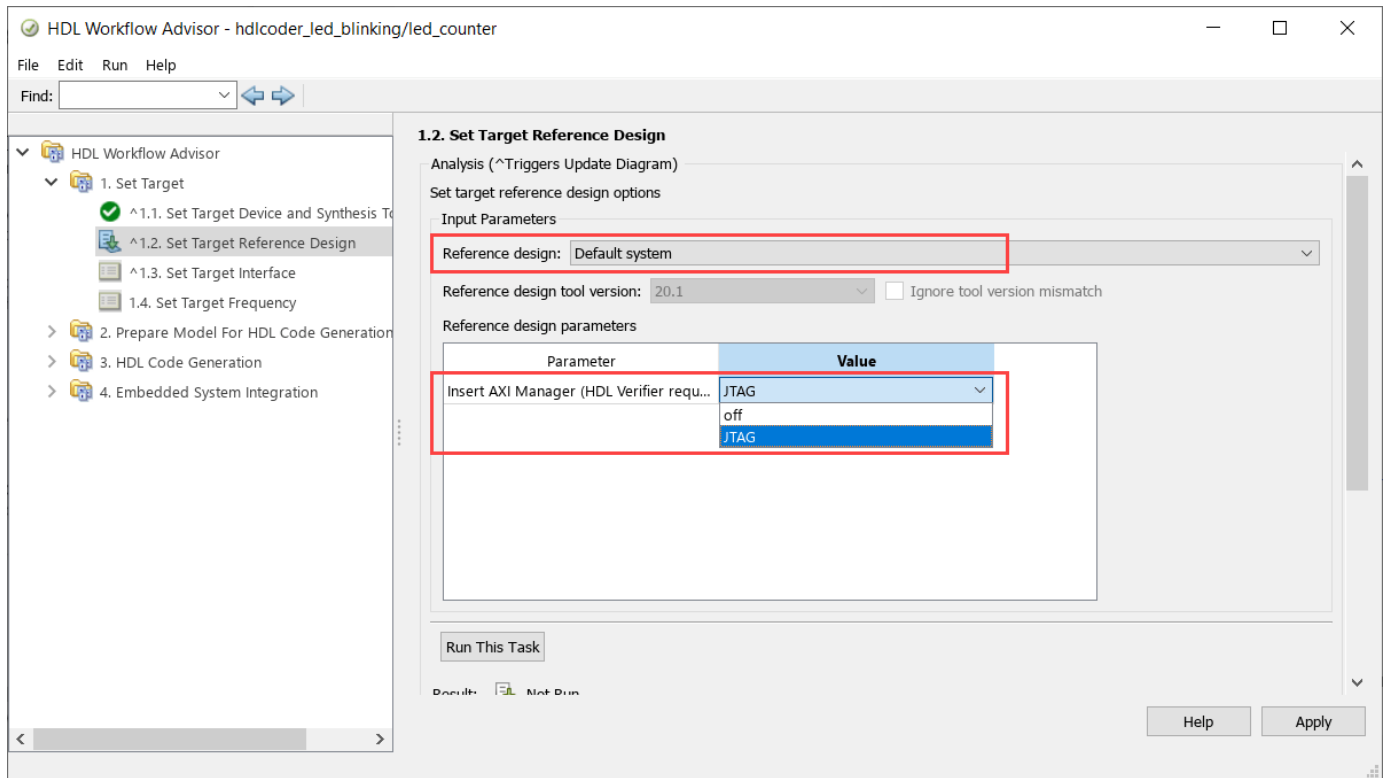

Run Demo

Copyright 2012 The MathWorks, Inc.

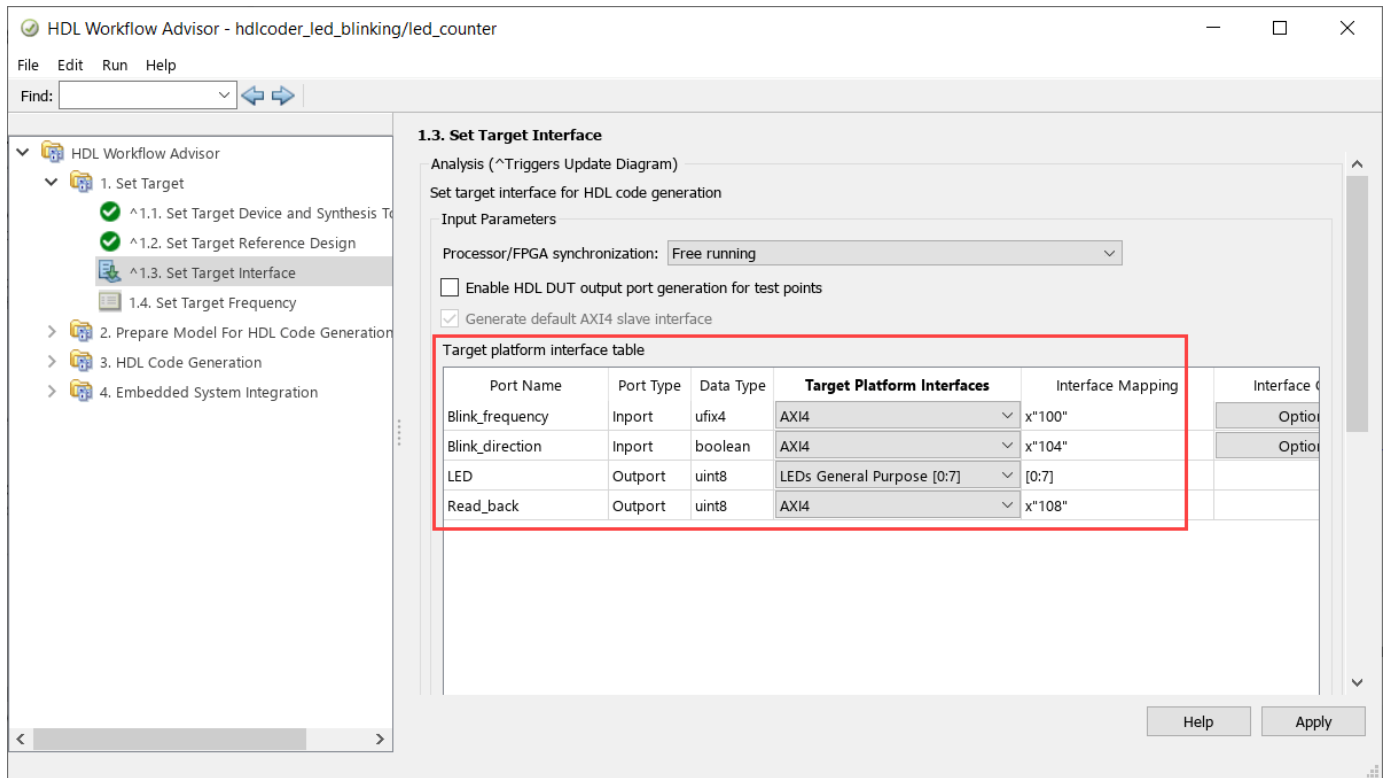

3. Launch HDL Workflow Advisor from the `hdlcoder_led_blinking/led_counter` subsystem by right-clicking the `led_counter` subsystem and selecting **HDL Code** followed by **HDL Workflow Advisor**.

4. In step 1.1, set **Target workflow** to IP Core Generation and **Target platform** to Arrow DECA MAX 10 FPGA evaluation kit. Click **Run This Task**.

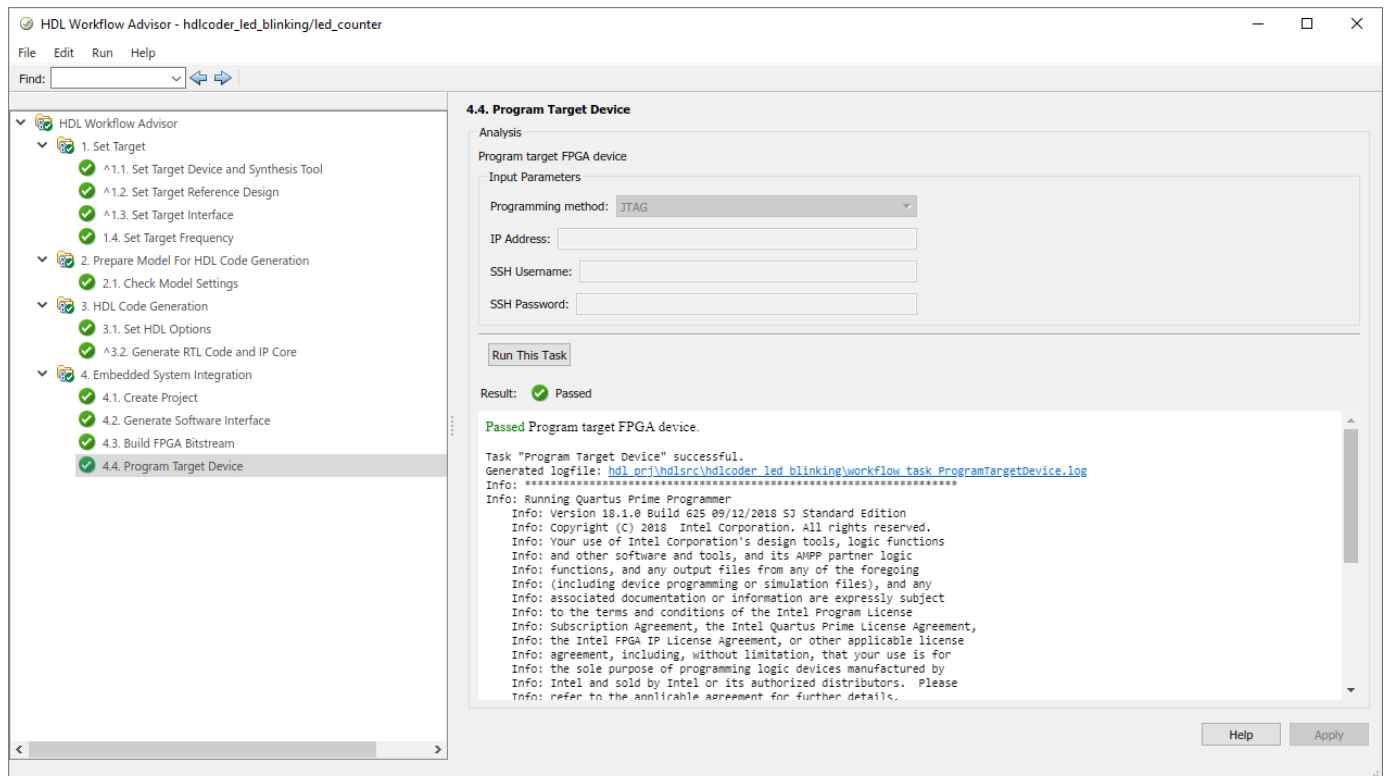

5. In step 1.2, set **Reference design** to Default system. Under **Reference design parameters**, set **Insert AXI Manager (HDL Verifier required)** to JTAG.

6. In step 1.3, set the interface of the **Blink_frequency**, **Blink_direction**, and **Read_back** ports to AXI4. Set the interface of the **LED** port to LEDs General Purpose [0:7].

7. Run the remaining steps in the workflow to generate a bitstream and program the target device.

Determine Addresses from IP Core Report

The base address for an HDL Coder IP core is defined as $0x00000000$ for the Default System reference design, which uses the AXI Manager IP. You can see address setting in the generated IP core report as shown this figure.

Use JTAG AXI Master to control the IP core from MATLAB

In 1.2 Step "Set Target Reference design", "Insert JTAG AXI Manager" is turned "on". This adds Matlab as an "AXI Manager" to control the DUT IP core using AXI4 interface as shown.

JTAG Interface **AXI4 Interface**

MATLAB Reference Design DUT IP Core LED

Requires a HDL Verifier license to use this feature. After that use MATLAB® Command line interface to access the DUT IP core registers. **The Base Address of AXI4 Slave is $0x0000\ 0000$.**

An example JTAG AXI Master commands to access the DUT IP register is :

1. Create the AXI master object
`h = aximanager('ToolName') Here ToolName = xilinx/altera`
2. Command to write into IP Core registers:
`h.writememory('BaseAddress+AddressOffset', WriteValue)`

OK Help

The IP core report register address mapping table shows the offsets.

The screenshot shows a window titled "Code Generation Report" with a search bar and "Match Case" option. The left sidebar contains a "Contents" list with "IP Core Generation Report" highlighted. The main content area is titled "Register Address Mapping" and contains the following text:

The following AXI4 bus accessible registers were generated for this IP core:

Register Name	Address Offset	Description
IPCore_Reset	0x0	write 0x1 to bit 0 to reset IP core
IPCore_Enable	0x4	enabled (by default) when bit 0 is 0x1
IPCore_Timestamp	0x8	contains unique IP timestamp (yymmddHHMM): 2201202309
Blink_frequency_Data	0x100	data register for Inport Blink_frequency
Blink_direction_Data	0x104	data register for Inport Blink_direction
Read_back_Data	0x108	data register for Output Read_back

Following are the AXI4 slave Base address and Master address space specified in the reference design:

Default system.
 AXI4 Slave Base Address: **0x0000 0000**
 AXI4 Slave Master connection: **AXI_Manager_0.axm_m0**
 Use the AXI4 Slave Base Address plus Address offset to access the IP Core registers shown in Register Address Mapping table

The AXI4 slave write register readback is OFF for the IP core.
 The register address mapping is also in the following C header file for you to use when programming the processor:
[include/led_count_ip_addr.h](#)
 The IP core name is appended to the register names to avoid name conflicts.

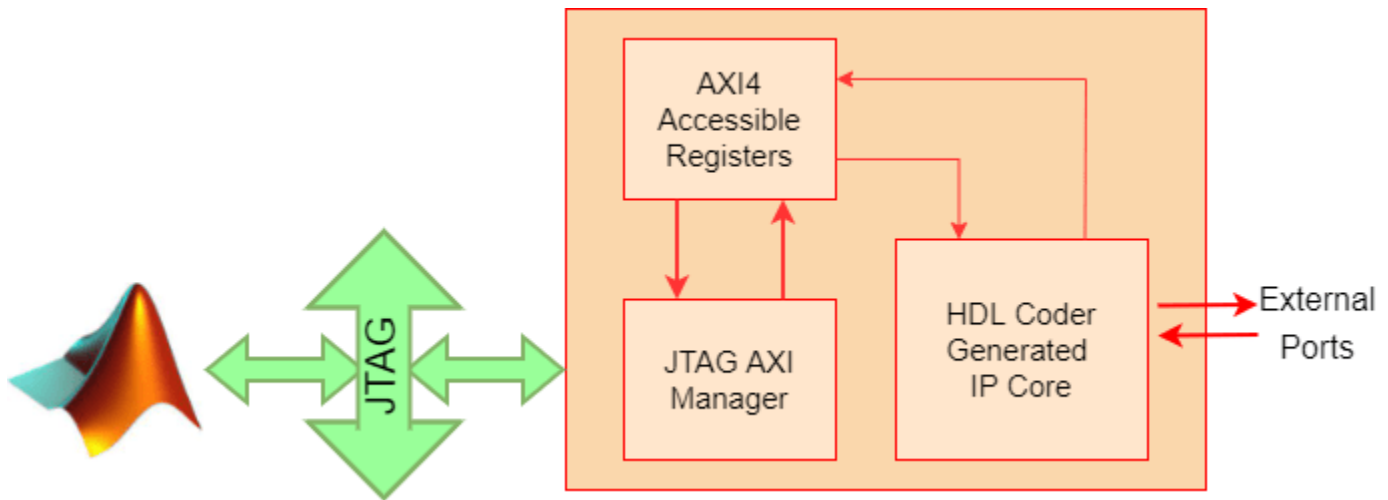

IP Core User Guide

Theory of Operation

At the bottom of the window are "OK" and "Help" buttons.

HDL Verifier Command Line Interface

If you have the HDL Verifier support package for Intel FPGA boards and select the AXI Manager reference design, then you can use the MATLAB command line interface to access the IP core that is generated by the HDL Coder product.

To write and read from the DDR memory, follow these steps.

1. Create an AXI manager object.

```
h = aximanager('Altera')
```

2. Issue a write commands. For example, disable the DUT.

```
h.writememory('4',0)
```

3. Re-enable the DUT.

```
h.writememory('4',1)
```

4. Read the current counter value.

```
h.readmemory('108',1)
```

5. Delete the object to free up the JTAG resource. If you do not delete the object, other JTAG operations, such as programming the FPGA, fail.

```
delete(h)
```

Intel JTAG to AXI Master Reference Design

Create a custom reference design to use the Intel JTAG to AXI Master IP in the reference design, and then add reference design files to the MATLAB path using the `addpath` command.

Access the HDL Coder IP core registers using the Intel JTAG to AXI Master IP by using the base address that is defined in reference design plugin file.

Qsys System Console Tcl Commands for AXI Read and Write

Before opening a system console, choose the appropriate Qsys read and write commands. For this example, because all of the HDL Coder generated IP core registers are currently 32 bits, use these read and write commands.

```
% master_write_32 <service-path> <start-address> <list-of-32-bit-values>
% master_read_32 <service-path> <start-address> <size-in-multiples-of-32-bits>
```

For example, write the 32 bit hex value 0x12345678 to the IP core register defined by offset 0x100 using a previously defined service path stored in the variable `$jtag`.

```
% master_write_32 $jtag 0x100 0x12345678
```

Before you can generate reads and writes, you must first launch a system console and open a connection to the JTAG Master that issues the register reads and writes.

To open a connection to the JTAG Master, first set a variable that stores the service path (in this case, only one master exists).

```
% set jtag [lindex [get_service_paths master] 0]
```

Use the variable to open the JTAG Master in master mode.

```
% open_service master $jtag
```

Launch the Altera® system console and enter the commands to open the JTAG Master.

```
system('C:\intel\FPGA\17.1\quartus\sopc_builder\bin\system-console&')
```

```
Tcl Console
%

When you are done using the JTAG Master, close the connection by using this Tcl command.

```
close_service master $jtag
```

Summary

You can use the JTAG AXI Manager IP to interface with HDL Coder IP core registers in systems that do not have an embedded ARM processor, such as the MAX 10. You can use this IP as a first step to debug standalone HDL Coder IP cores, prior to hand coding software for soft processors, (such as Nios II), or as a way to tune parameters on a running system.

IP Core Generation Workflow with a MicroBlaze processor: Xilinx Kintex-7 KC705

This example shows how to use the HDL Coder™ IP Core Generation Workflow to develop reference designs for Xilinx® parts without an embedded ARM® processor present, but which still utilize the HDL Coder generated AXI interface to control the DUT. Specifically, this example will use the Xilinx Kintex-7 KC705 board and a MicroBlaze™ soft processor running a LightWeightIP (lwIP) based TCP/IP firmware server in the reference design to access the HDL Coder generated DUT registers from anywhere on the connected network. Further, this example will also highlight the difference between accessing data from a collection of registers implemented as multiple scalar ports and a collection of registers implemented as a single vector port.

Requirements

- Xilinx Vivado Design Suite, with the supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.
- Xilinx Kintex-7 KC705 development board
- HDL Coder support package for Xilinx FPGA Boards
- Ethernet connection

Xilinx Kintex-7 KC705 development board

Example Reference Designs

MicroBlaze is a simple, versatile soft-core processor that can be used in Xilinx FPGA only platforms, such as the Kintex-7, to perform the functionality a full-fledged processor, or as a flexible, programmable IP. When programs are small, the ELF can sit in BRAM and the design becomes

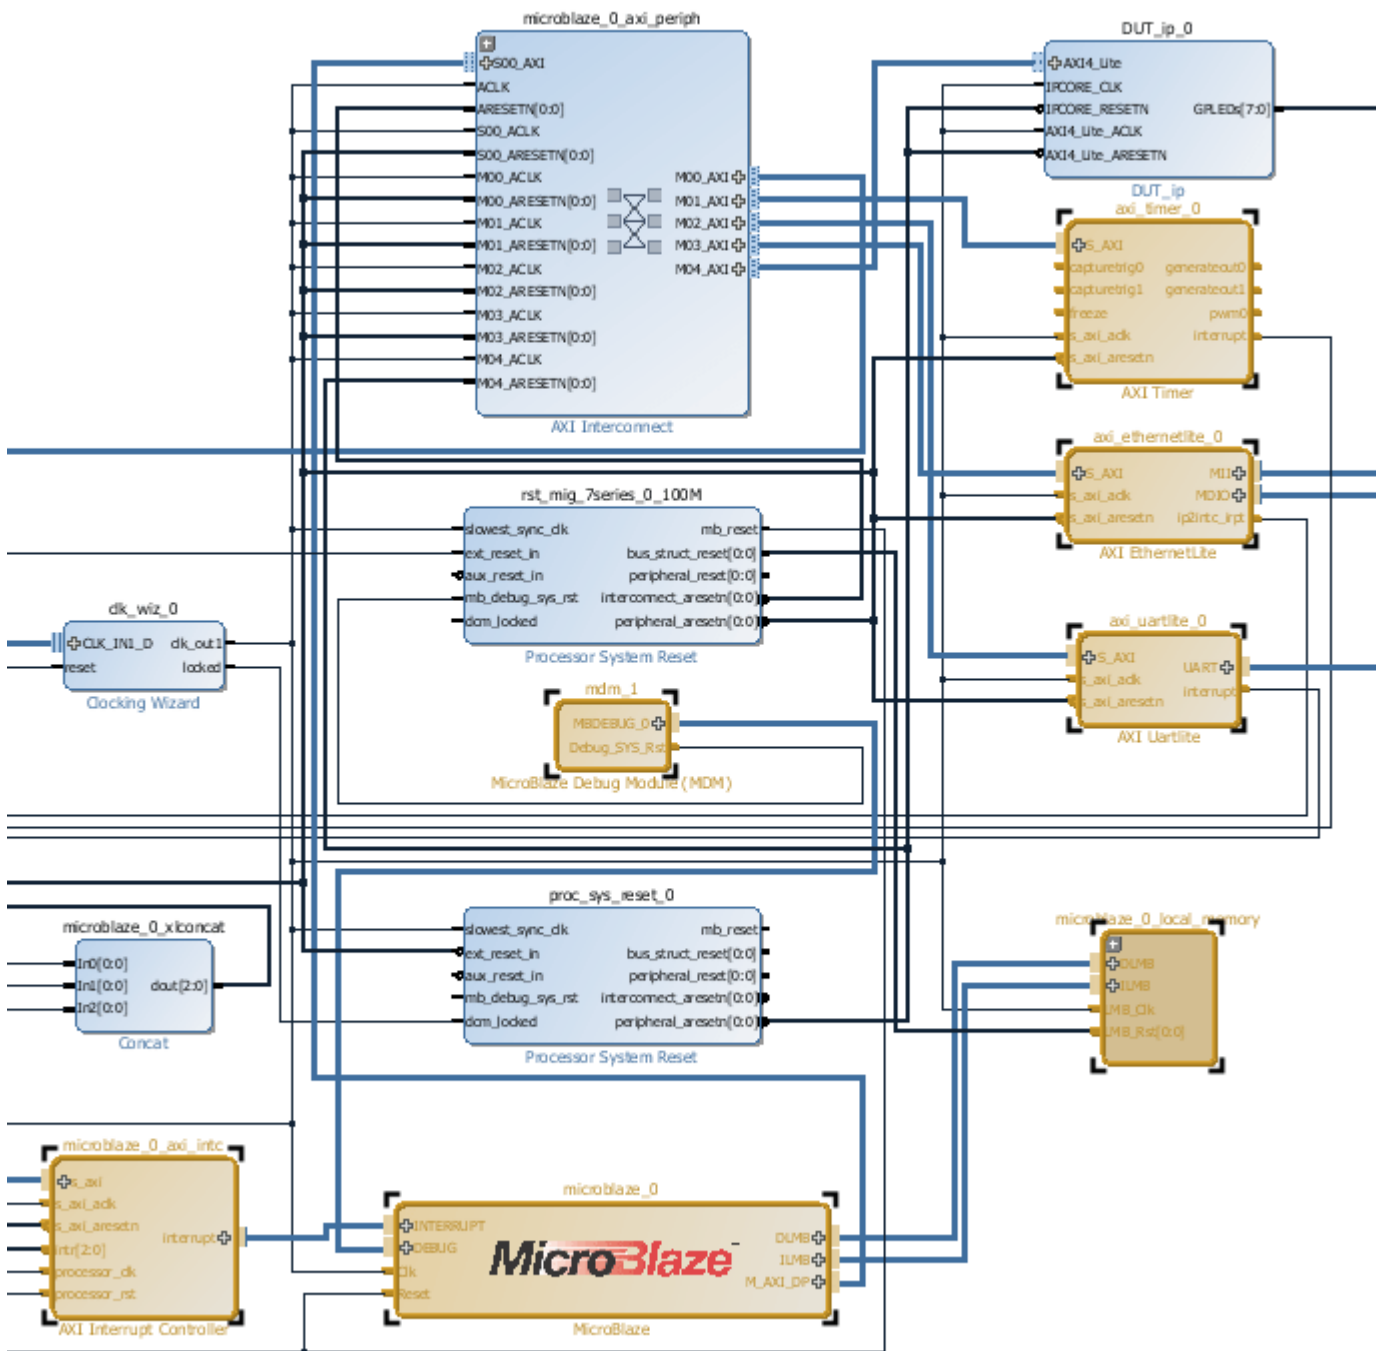

completely self contained in the FPGA. There are many applications well suited to being implemented on a MicroBlaze. Here we list just a few:

- 1 Remote networked control of a deployed IP Core algorithm
- 2 Embedded web server for control and data display
- 3 Integration of existing software algorithms to hardware-only platforms

The following is a system level diagram for this MicroBlaze system:

The reference design, "Xilinx MicroBlaze TCP/IP to AXI4-Lite Master", uses Vivado™ MicroBlaze IP to translate TCP/IP packets into AXI4-Lite reads and writes. Below is a block diagram of the complete system, including all the peripherals required to operate the TCP/IP server and debug via the UART serial console.

MicroBlaze Setup

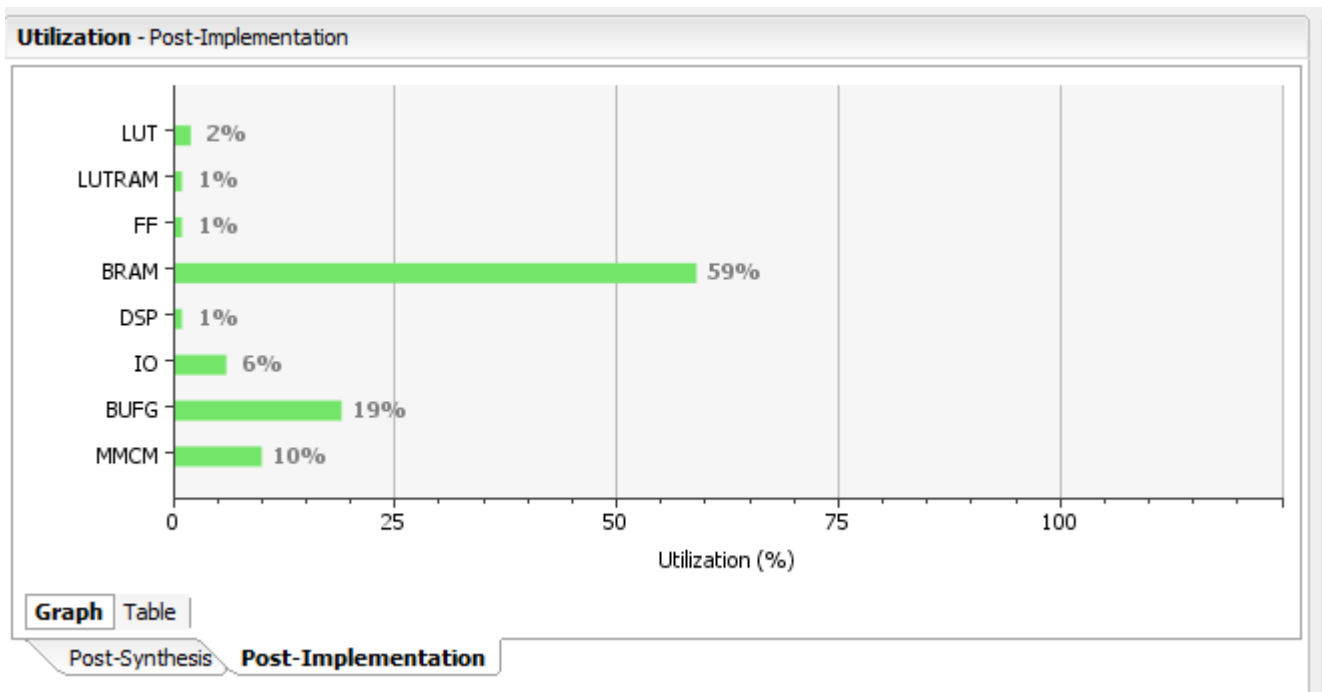

In order to operate the TCP/IP server, the MicroBlaze IP needs a few basic peripherals:

- local memory (BRAM) for data/instructions
- Ethernet core for transmitting and receiving frames
- UART core for sending debug messages
- Timer core for generating timeout interrupts
- Interrupt controller for handling interrupts from all these peripherals.

As can be seen in the address editor below, all these peripherals are connected to the MicroBlaze via AXI4 interfaces.

Cell	Slave Interface	Base Name	Offset Address	Range	High Address
microblaze_0					
Data (32 address bits : 4G)					
axi_ethernetlite_0	S_AXI	Reg	0x40E0_0000	64K	0x40E0_FFFF
axi_timer_0	S_AXI	Reg	0x41C0_0000	64K	0x41C0_FFFF
axi_uartlite_0	S_AXI	Reg	0x4060_0000	64K	0x4060_FFFF
microblaze_0_local_memory/dlmb_bram_if_cntrl	SLMB	Mem	0x0000_0000	1M	0x000F_FFFF
microblaze_0_axi_intc	s_axi	Reg	0x4120_0000	64K	0x4120_FFFF
led_count_ip_0	AXI4_Lite	reg0	0x44A0_0000	64K	0x44A0_FFFF
Instruction (32 address bits : 4G)					
microblaze_0_local_memory/ilmb_bram_if_cntrl	SLMB	Mem	0x0000_0000	1M	0x000F_FFFF

The amount of local memory allocated using BRAM is 1MB. This amount is needed to run the lwIP stack. The benefit of specifying BRAM for local memory is that the executable ELF can be included in the bitstream, which simplifies programming and enables targeting existing FPGA boards which may not have external DRAM memory. However, this convenience comes at a cost of increased utilization:

If BRAM utilization is a concern and DRAM resources are available, you may opt to replace local BRAM memory with external DRAM memory. See Xilinx app note "xapp1026" for more details on alternate configurations and application information.

Example Reference Design plugin_rd.m

The plugin_rd.m for this reference design is shown below:

```
function hRD = plugin_rd()
% Reference design definition

% Copyright 2014-2018 The MathWorks, Inc.

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');

hRD.ReferenceDesignName = 'Xilinx MicroBlaze TCP/IP to AXI4-Lite Master';
hRD.BoardName = 'Xilinx Kintex-7 KC705 development board';

% Tool information
hRD.SupportedToolVersion = {'2017.2', '2017.4'};

%% Add custom design files
% add custom Vivado design
hRD.addCustomVivadoDesign( ...
    'CustomBlockDesignTcl', 'system_top.tcl', ...
    'VivadoBoardPart', 'xilinx.com:kc705:part0:1.1');

% add custom files, use relative path
hRD.CustomFiles = {'mw_lwip_tcpip_axi4.elf'};

%% Add interfaces
% add clock interface
hRD.addClockInterface( ...
    'ClockConnection', 'clk_wiz_0/clk_out1', ...
    'ResetConnection', 'proc_sys_reset_0/peripheral_aresetn', ...
    'DefaultFrequencyMHz', 100, ...
    'MinFrequencyMHz', 100, ...
    'MaxFrequencyMHz', 100, ...
    'ClockNumber', 1, ...
    'ClockModuleInstance', 'clk_wiz_0');

% add AXI4 and AXI4-Lite slave interfaces
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'microblaze_0_axi_periph/M04_AXI', ...
    'BaseAddress', '0x44A00000', ...
    'MasterAddressSpace', 'microblaze_0/Data', ...
    'InterfaceType', 'AXI4-Lite', ...
    'InterfaceID', 'MicroBlaze AXI4-Lite Interface');

hRD.HasProcessingSystem = false; % No hard processing system
```

Note that the reference design includes the MicroBlaze executable `mw_lwip_tcpip_axi4.elf` in the reference design property `CustomFiles`. This will copy the executable from the reference design to the Vivado project so that it can be associated with the MicroBlaze IP.

Additional code in 'system_top.tcl' to attach ELF to uBlaze

The 'system_top.tcl' file included in most reference designs is used to create the top level Vivado IP Integrator block diagram containing most of the reference design IP. Here we are adding some

additional Tcl code to this file after the block diagram has been created to associate the standalone MicroBlaze ELF executable with the MicroBlaze IP.

```
import_files -norecurse mw_lwip_tcpip_axi4.elf
generate_target all [get_files system_top.bd]
set_property SCOPED_TO_REF system_top [get_files -all -of_objects [get_fileset sources_1] {mw_
set_property SCOPED_TO_CELLS { microblaze_0 } [get_files -all -of_objects [get_fileset sources
```

Doing this allows the ELF to be packaged with the bitstream and programmed into the MicroBlaze BRAM memory at the same time as the FPGA.

Execute the IP Core Workflow

Using the above reference design you will generate an HDL IP Core that blinks LEDs on the KC705 board. You will then use `tcpclient` to send/receive formatted packets to the MicroBlaze to issue reads/writes over the AXI4-Lite interface to the generated HDL IP Core. The files used in the following demonstration are located at:

- `matlab/toolbox/hdlcoder/hdlcoderdemos/customboards/KC705`

1. Add the MicroBlaze reference design files to the MATLAB path using the command:

```
unzip('KC705.zip');
addpath(genpath('KC705'));
```

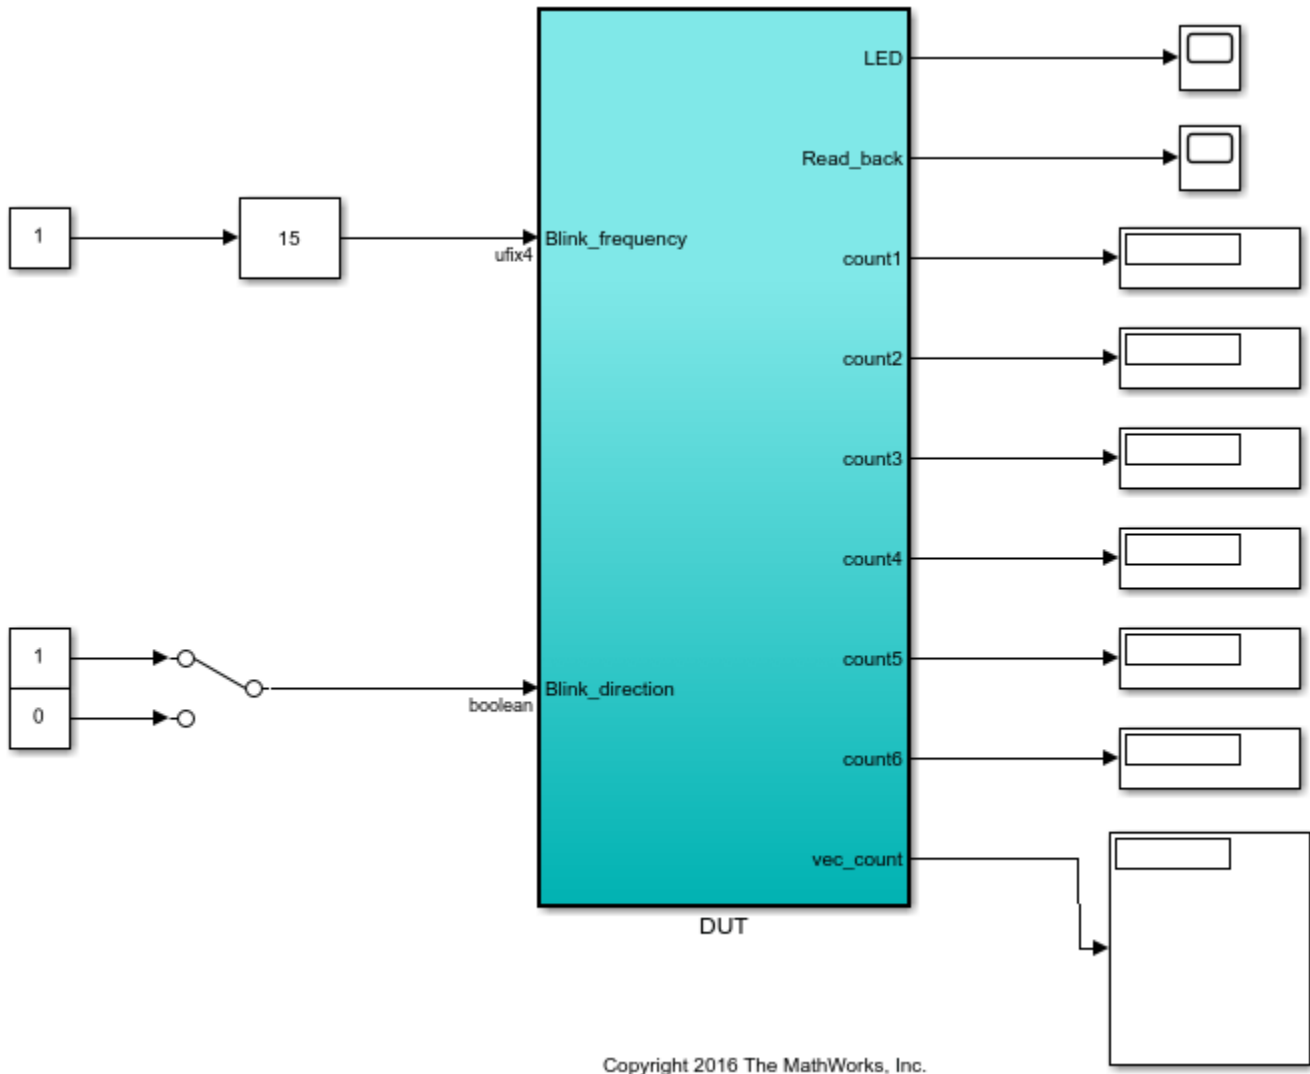

2. Set up the Xilinx Vivado tool path by using the following command:

```
>> hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2020.2\bin\vivado
```

Use your own Xilinx Vivado installation path when executing the command.

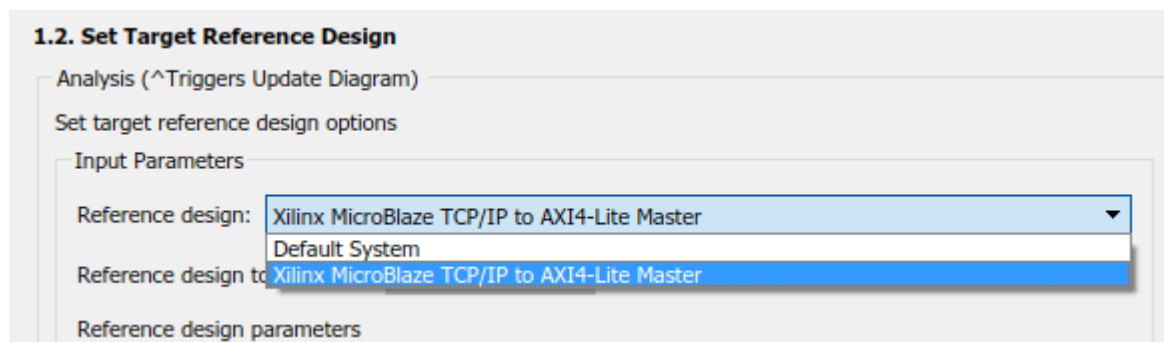

3. Open the Simulink model that implements LED blinking, as well as vector output ports for comparison to scalar ports, using the command:

```
open_system('hdlcoder_led_vector')
```

4. Launch HDL Workflow Advisor from the `hdlcoder_led_vector/DUT` subsystem by right-clicking the DUT subsystem, and selecting **HDL Code > HDL Workflow Advisor**.

5. Select reference design from the drop down in step 1.2

6. Assign register ports to the "MicroBlaze AXI4-Lite Interface". These will then be accessible at the hex offset shown in the table.

1.3. Set Target Interface

Analysis (^Triggers Update Diagram)

Set target interface for HDL code generation

Input Parameters

Processor/FPGA synchronization:

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
Blink_frequency	Inport	ufix4	MicroBlaze AXI4-Lite Interface	x"100"
Blink_direction	Inport	boolean	MicroBlaze AXI4-Lite Interface	x"104"
LED	Output	uint8	LEDs General Purpose [0:7]	[0:7]
Read_back	Output	uint8	MicroBlaze AXI4-Lite Interface	x"108"
count1	Output	uint32	MicroBlaze AXI4-Lite Interface	x"10C"
count2	Output	uint32	MicroBlaze AXI4-Lite Interface	x"110"
count3	Output	uint32	MicroBlaze AXI4-Lite Interface	x"114"
count4	Output	uint32	MicroBlaze AXI4-Lite Interface	x"118"
count5	Output	uint32	MicroBlaze AXI4-Lite Interface	x"11C"
count6	Output	uint32	MicroBlaze AXI4-Lite Interface	x"120"
vec_count	Output	uint32 (6)	MicroBlaze AXI4-Lite Interface	x"140"

7. Run the remaining steps in the workflow to generate a bitstream and program the target device.

Determining Addresses from the IP Core Report

The Base Address for an HDL Coder IP Core is defined in the reference design plugin_rd.m with the following command:

```
% add AXI4 and AXI4-Lite slave interfaces
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'microblaze_0_axi_periph/M04_AXI', ...
    'BaseAddress',        '0x44A00000', ...
    'MasterAddressSpace', 'microblaze_0/Data', ...
    'InterfaceType',      'AXI4-Lite', ...
    'InterfaceID',        'MicroBlaze AXI4-Lite Interface');
```

For this design, the base address is 0x44A0_0000. The offsets can be found in the IP Core Report Register Address Mapping table:

Register Address Mapping

The following AXI4-Lite bus accessible registers were generated for this IP core:

Register Name	Address Offset	Description
IPCore_Reset	0x0	write 0x1 to bit 0 to reset IP core
IPCore_Enable	0x4	enabled (by default) when bit 0 is 0x1
Blink_frequency_Data	0x100	data register for Inport Blink_frequency
Blink_direction_Data	0x104	data register for Inport Blink_direction
Read_back_Data	0x108	data register for Outport Read_back
count1_Data	0x10C	data register for Outport count1
count2_Data	0x110	data register for Outport count2
count3_Data	0x114	data register for Outport count3
count4_Data	0x118	data register for Outport count4
count5_Data	0x11C	data register for Outport count5
count6_Data	0x120	data register for Outport count6
vec_count_Data	0x140	data register for Outport vec_count, vector with 6 elements, address ends at 0x154
vec_count_Strobe	0x160	strobe register for port vec_count

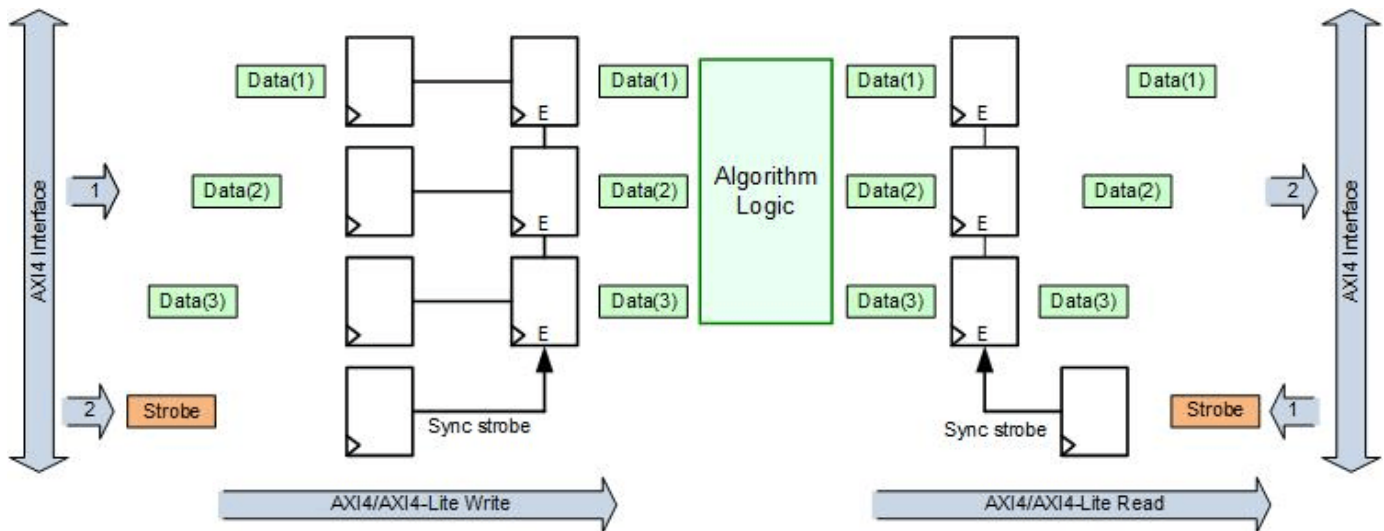

The register address mapping is also in the following C header file for you to use when programming the processor:
[include\DUT_ip_addr.h](#)

The IP core name is appended to the register names to avoid name conflicts.

Vector Data Read/Write with Strobe Synchronization

Vector data is supported on the AXI4/AXI4-Lite interfaces as of R2017a. Unlike a collection of scalar ports, all the elements of vector data are treated as synchronous to the IP Core algorithm logic. Additional strobe registers added for each vector input and output port maintain this synchronization across multiple sequential AXI4 reads/writes.

For input ports, the strobe register controls the enables on a set of shadow registers, allowing the IP core logic to see all the updated vector elements simultaneously. For output ports, the strobe register controls the synchronous capturing of vector data to be read. Below is a diagram of the synchronization logic generated with vector data:

Connect to the TCP/IP server

To start interacting with the TCP/IP server running on the MicroBlaze, first connect the UART serial console to view debug messages, which will help ensure things are working as expected. First find the serial port that is connected to the UART on the board:

- ▼
🖨️ Ports (COM & LPT)
 - 🖨️ Communications Port (COM1)
 - 🖨️ Intel(R) Active Management Technology - SOL (COM3)
 - 🖨️ Silicon Labs CP210x USB to UART Bridge (COM4)

Then use this port to connect using a program such as PuTTY™:

Once connected to the UART serial console, run the `hdlworkflow_ProgramTargetDevice.m` script to reprogram the board.

```
>>hdlworkflow_ProgramTargetDevice
### Workflow begin.
### Loading settings from model.
### ++++++ Task Program Target Device ++++++
### Generated logfile: hdl_prj\hdlsrc\hdlcoder_led_vector\workflow_task_ProgramTargetDevice.l
### Task "Program Target Device" successful.
### Workflow complete.
```

In the console window, you should see the following header, displaying the IP address and port number the server is connected to.

```

COM4 - PuTTY
-----MathWorks HDL Coder AXI4-Lite IP Core Read/Write Server -----
TCP packets sent to port 7 will be issued as AXI4-Lite Read/Writes

[ 32-bit address ] (Base Address = 0x44a0_0000)
[ 32-bit  cmd    ] (read = 0x00, write =0x01, debug = 0x03)
[ 32-bit  len    ] ( N<255)
[ 32-bit  data   ] (N 32-bit data values for write cmd)
-----

auto-negotiated link speed: 100
DHCP Timeout
Configuring default IP of 192.168.1.10
Board IP: 192.168.1.10
Netmask : 255.255.255.0
Gateway : 192.168.1.1
TCP AXI4-Lite server started @ port 7

```

NOTE: If the board is connected to a network with a DHCP server enabled, the IP information will be different than shown above. In this case, you will need to modify line 43 of the `read_write_test.m` script to connect to the correct IP address of the board:

```
t = tcpclient('192.168.1.10',7);
```

Sending AX4-Lite transactions to the MicroBlaze from MATLAB using `tcpipclient`

In order to issue reads and writes to the IP Core via TCP/IP and AXI4-Lite, the address,data and command to be performed must be encoded in the packet sent to the TCP/IP server. For this example, we use the following packet format:

```

[--Address--] 32-bits
[----Cmd----] lower byte of 32-bit word (READ = 0, WRITE = 1, DEBUG = 2)
[---Length---] lower byte of 32-bit work (N<255)
[----Data---] 32-bits, used only for WRITE cmd

```

For example, a packet issuing a read of 3 consecutive values starting at address 0x44a0010c:

```

[44 a0 01 0c]
[00 00 00 00]
[00 00 00 03]

```

This will return data at offsets 0x10c,0x110,0x114.

For example, a packet issuing a write of 0x0 to offset 0x04, would be:

```

[44 a0 00 04]
[00 00 00 01]
[00 00 00 01]
[00 00 00 00]

```

To change the debug level used to print to the console, send a debug cmd packet:

```

[xx xx xx xx]
[00 00 00 03]
[00 00 00 01] %0 = no msg, 1 = READ|WRITE, 2 = full pkt

```

Run the read_write_test.m script

This example includes a script which will setup a connection to the TCP/IP server running on the MicroBlaze, create commands to enable/disable the DUT, read 6 scalar ports and the same data as a vector port and compare the results.

1. To run this script, first copy it to your local directory

```
>> copyfile(fullfile('ublaze_lwip_read_write_vector_test.m'), 'ublaze_test.m');
```

and open the script in the editor:

```
>> edit('ublaze_test.m');
```

The script has three sections. The first section, connects to the board and sets up the commands that will be used. If required, update the IP address of the board on line 41.

2. Execute section 1. You will have generated the following commands as arrays of uint32 types:

```

read6_cmd      = uint32([hex2dec('44a0010c') 0 6]); %read 6 32-bit regs
read_vec_cmd   = uint32([hex2dec('44a00140') 0 6]); %read 6 elements of vec
strobe_vec_cmd = uint32([hex2dec('44a00160') 1 1 1]); %write strobe for vec
enable_cmd     = uint32([hex2dec('44a00004') 1 1 1]); %enable ip core
disable_cmd    = uint32([hex2dec('44a00004') 1 1 0]); %disable ip core
debug0_cmd     = uint32([hex2dec('00000000') 3 0]); %disable all debug printf
debug1_cmd     = uint32([hex2dec('00000000') 3 1]); %enable READ|WRITE printf
debug2_cmd     = uint32([hex2dec('00000000') 3 2]); %enable pkt printf

```

NOTE: these arrays store data in the endian format used by the local machine, which for many x86 systems is the little endian format. However, the TCP/IP server expects values in the big endian format (network byte order). As a result, if the system you are on is little endian, the bytes in each element must be swapped using `swapbytes`.

3. Execute section 2 to disable the DUT logic and read a single counter value connected to the 6 scalar ports as well as all 6 elements in the vector port. Notice that all the counter values match. This is because the same data is driven to all the ports and the DUT is disabled, so the asynchronous access across the AXI4 interface is not apparent.

```

Scalar port (top) vs vector port (bottom) access with DUT disabled:
 7e8aec14  7e8aec14  7e8aec14  7e8aec14  7e8aec14  7e8aec14
 7e8aec14  7e8aec14  7e8aec14  7e8aec14  7e8aec14  7e8aec14

```

4. Execute section 3 to re-enable the DUT logic and read the same counter values back. Notice that the 6 scalar ports all show different values, while the 6 elements of the vector port are all the same. This is due to the sequential access that must occur across the AXI4 interface and the lack of synchronization register in the scalar port case and the presence of an explicit synchronization register in the vector port case.

```

Scalar port (top) vs vector port (bottom) access with DUT enabled:
 7f7796dc  7fc70e4b  8016860a  8065fdce  80b5758d  8104ed4d
 815964dd  815964dd  815964dd  815964dd  815964dd  815964dd

```

The corresponding debug output on the serial console will be:

```

```

Summary

This demo highlighted the use of a MicroBlaze soft-core processor in FPGA only designs. The MicroBlaze is well suited to function as a full-fledged processor or as a flexible IP running legacy C code as a firmware application. This demo also showed the difference between a collection of scalar ports and a vector port in regards to data synchronization across the AXI4 interface.

Appendix A: Creating and editing a Xilinx SDK application

This section will show how to create a new Xilinx SDK project and incorporate the code from this example to then modify or extend.

1. Open the Xilinx Vivado project by clicking the link in HDL Workflow Advisor step 4.1 "Create Project" :

The screenshot shows the HDL Workflow Advisor window for the project 'hdlcoder_led_vector/DUT'. The left sidebar displays a tree view of tasks, with '4.1. Create Project' selected and highlighted. The main panel shows the configuration for this task, including input parameters and a log window.

4.1. Create Project

Analysis

Create project for embedded system tool

Input Parameters

Embedded system tool: Xilinx Vivado with IP Integrator

Project folder: hdl_prj\vivado_ip_prj

Synthesis objective: None

Enable IP caching

Run This Task

Result: **Passed**

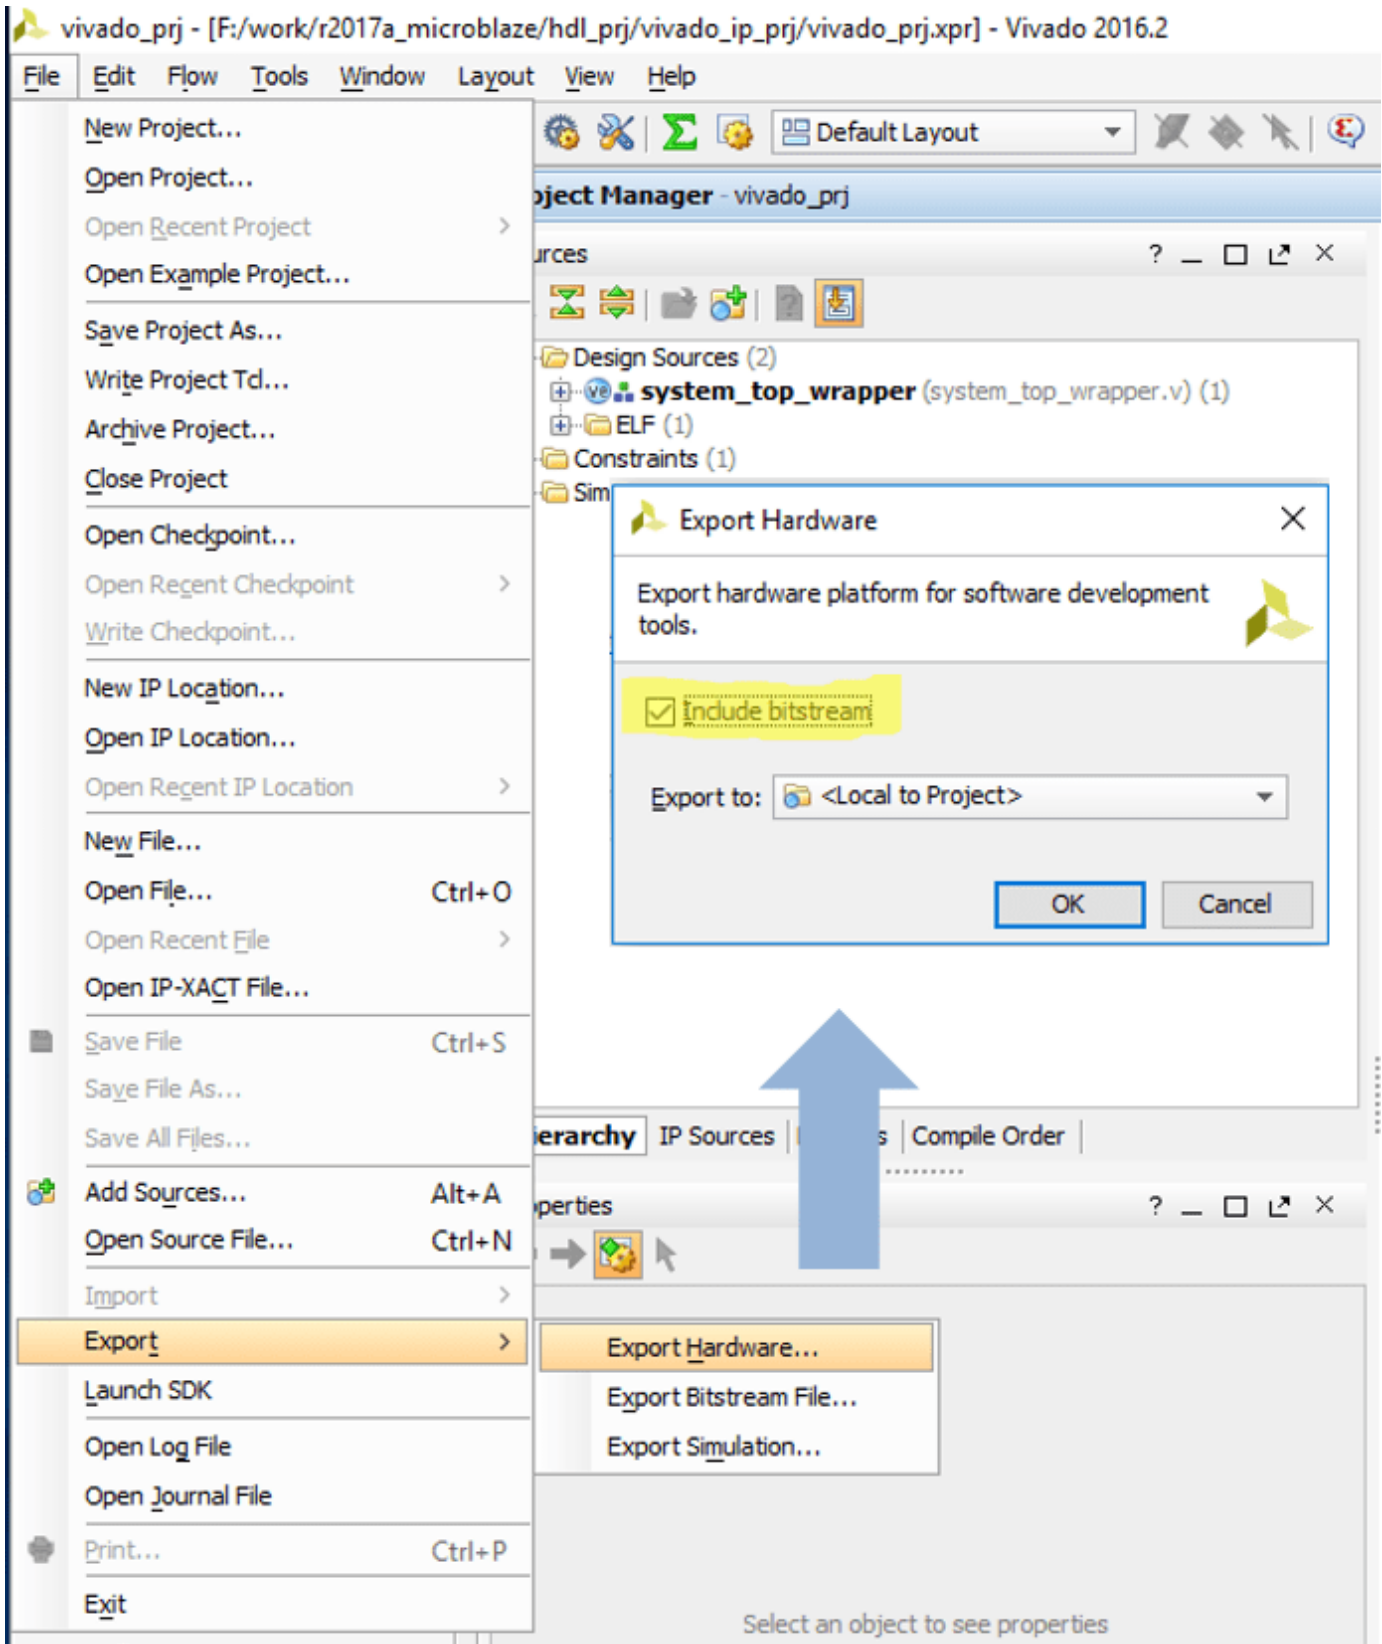

Passed Create Project.

Task "Create Project" successful.
 Generated logfile: [hdl_prj\hdlsrc\hdlcoder_led_vector\workflow_task_CreateProject.log](#)
 Generating Xilinx Vivado with IP Integrator project: [hdl_prj\vivado_ip_prj\vivado_prj.xpr](#)

```
***** Vivado v2016.2 (64-bit)
**** SW Build 1577090 on Thu Jun  2 16:32:40 MDT 2016
**** IP Build 1577682 on Fri Jun  3 12:00:54 MDT 2016

#   set folderList [glob -nocomplain -directory $defaultRepoPath -type d *]
#   if ([lsearch -exact $folderList [file rootname $ipCore]] == -1) {
#     catch {update_ip_catalog -add_ip $ipCore -repo_path $defaultRepoPath}
#   }
}
```

2. Export the existing design, including the generated bitstream, to a local folder. Once this is done, go ahead and "Launch SDK" as well.

3. From within the SDK, create a new application project

4. You will then have the option of naming the project and creating a new bsp

SDK New Project

Application Project
Create a managed make application project.

Project name:

Use default location

Location:

Choose file system:

Compiler:

Board Support Package: Create New
 Use existing

Next you can choose from a few pre-configured example/template projects to get started. This example is built off of the "lwIP Echo Server" project, so select that now.

5. Using the echo server as a template, you can replace the following 3 methods with the code snippet below to modify the behavior of the server

Appendix B: Copy C file contents to project

```
/* Copyright 2016-2020 The MathWorks, Inc. */
#define IPCOREBASE 0x44a00000
#define WRITE 0x01
#define READ 0x00
#define DEBUG 0x03

int transfer_data() {
    return 0;
}
```

```

}

void print_app_header()
{
    xil_printf("\n\r\n\r-----MathWorks HDL Coder AXI4-Lite IP Core Read/Write Server -----\n\r");
    xil_printf("  TCP packets sent to port 7 will be issued as AXI4-Lite Read/Writes\n\r");
    xil_printf("\n\r");
    xil_printf("  [ 32-bit address ] (Base Address = 0x44a0_0000)\n\r");
    xil_printf("  [ 32-bit  cmd   ] (read = 0x00, write =0x01, debug = 0x03)\n\r");

    else
        xil_printf("no space in tcp_sndbuf\n\r");
    break;
case DEBUG:
    debug = pktPtr[3]; // only need the low byte
    pktPtr += 4;
    xil_printf("Debug level set to : 0x%02x\r\n",debug);
    break;
default :
    xil_printf("INVALID | cmd: 0x%08x\r\n",cmd);
}
}
/* free the received pbuf */
pbuf_free(p);

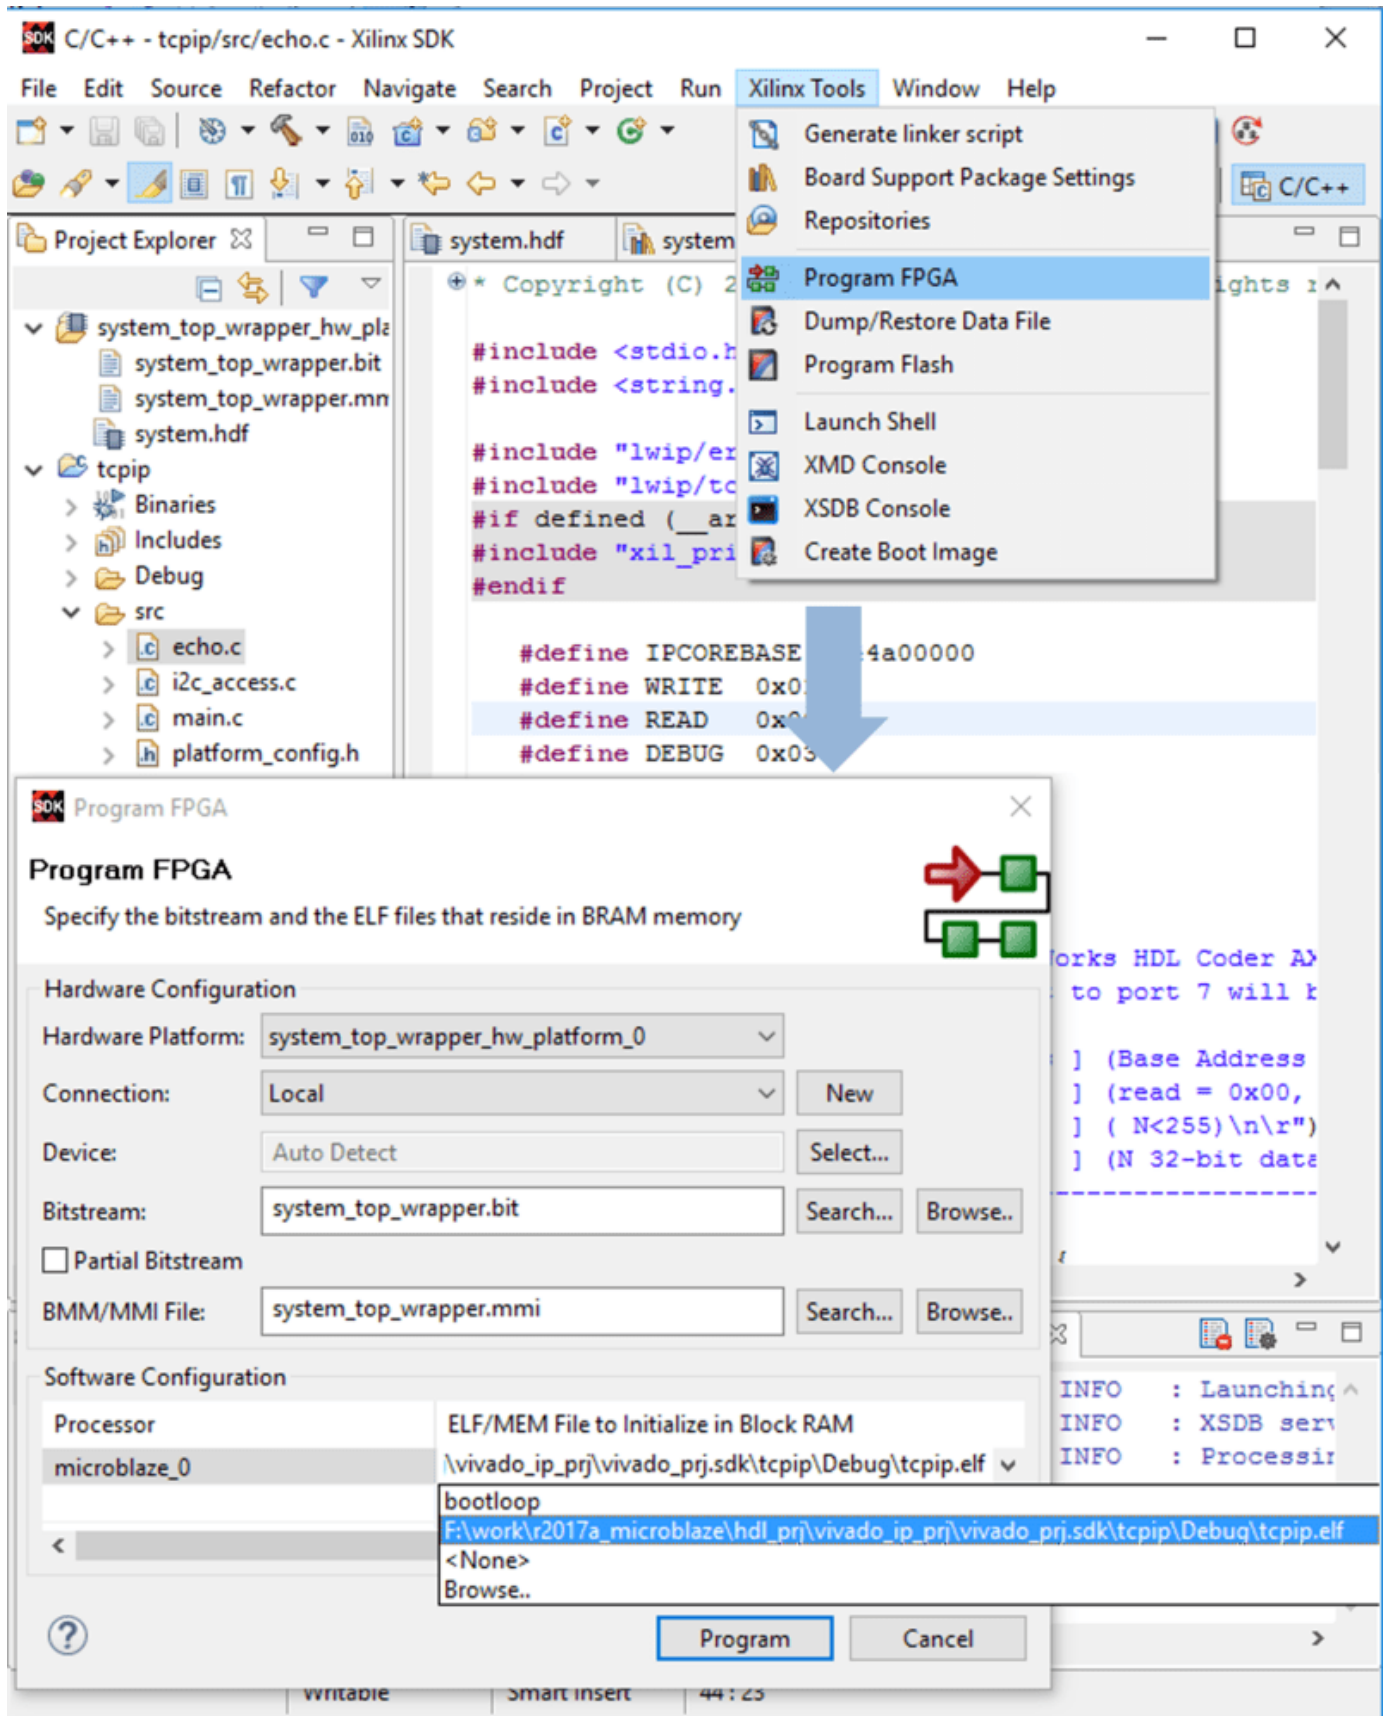

return ERR_OK;
}

```

6. Save the modified echo.c file and the application will be rebuilt.

Appendix C: Program the FPGA with ELF and bitstream

Now, you can program the FPGA using the exported bitstream and the newly created ELF file.

Map Bus Data types to AXI4 Slave Interfaces

This example shows how to map bus data types to an AXI4 slave interface, generate an HDL IP core with a AXI4 Master interface, perform matrix multiplication in HDL IP core, and write the output result to DDR memory.

Before You Begin

For this example, you must have the following software and hardware installed and set up:

- Xilinx Vivado Design Suite, with the supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Xilinx Zynq Ultrascale+ MPSoC ZCU102 Evaluation Kit
- HDL Coder Support Package for Xilinx Zynq Platform
- HDL Verifier Support Package for Xilinx FPGA Boards

Introduction

In this example, you:

- 1 Create a bus element by using bus creator blocks and map the bus element to an AXI4 slave interface.
- 2 Generate an HDL IP core with AXI4 Master interface.
- 3 Access large matrices from the external DDR4 memory on the Xilinx Zynq Ultrascale+ MPSoC ZCU102 Evaluation Kit board using the AXI4 Master interface.
- 4 Perform matrix vector multiplication in the HDL IP core and write the output result back to the DDR memory using the AXI4 Master interface.

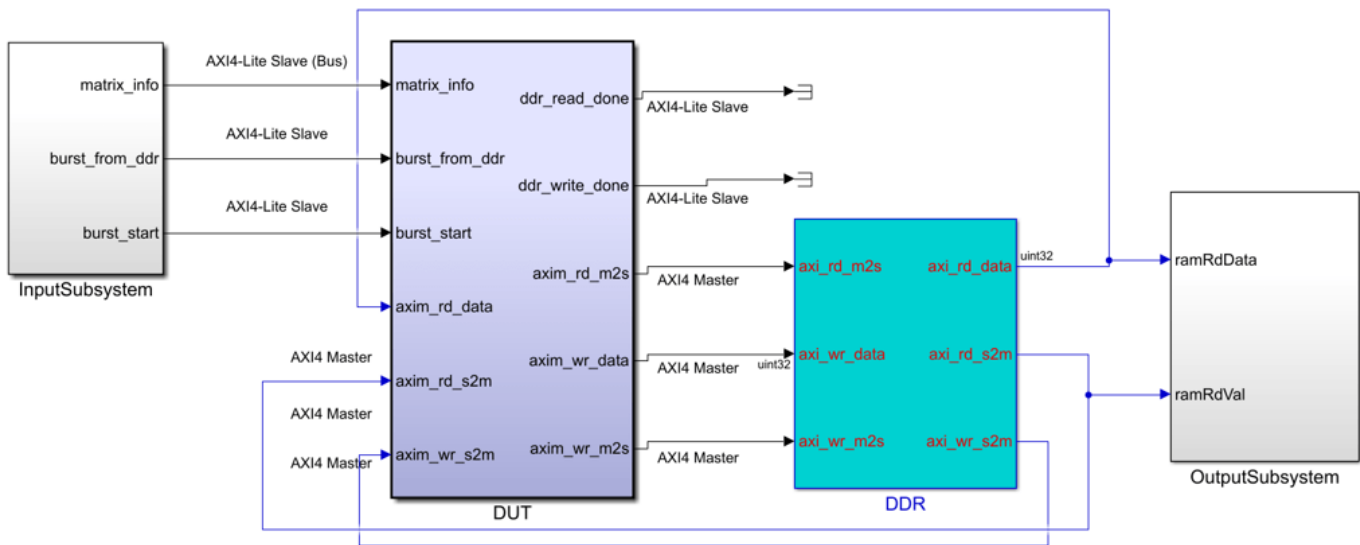

This example models a matrix vector multiplication algorithm and implements the algorithm on the Xilinx Zynq FPGA board. Large matrices might not map efficiently to Block RAMs on the FPGA fabric. Instead, store the matrices in the external DDR memory on the FPGA board. The AXI4 Master interface can access the data by communicating with vendor-provided memory interface IP cores that interface with the DDR memory. This capability enables you to model algorithms that involve large data processing and requires high-throughput DDR access, such as matrix operations, computer vision algorithms, and so on.

The matrix vector multiplication module supports fixed-point matrix vector multiplication, with a configurable matrix size of 2 to 4000. The size of the matrix is run-time configurable through the AXI4 accessible register.

```
modelName = 'hdlcoder_axi_slave_bus_data_type';
open_system(modelName);

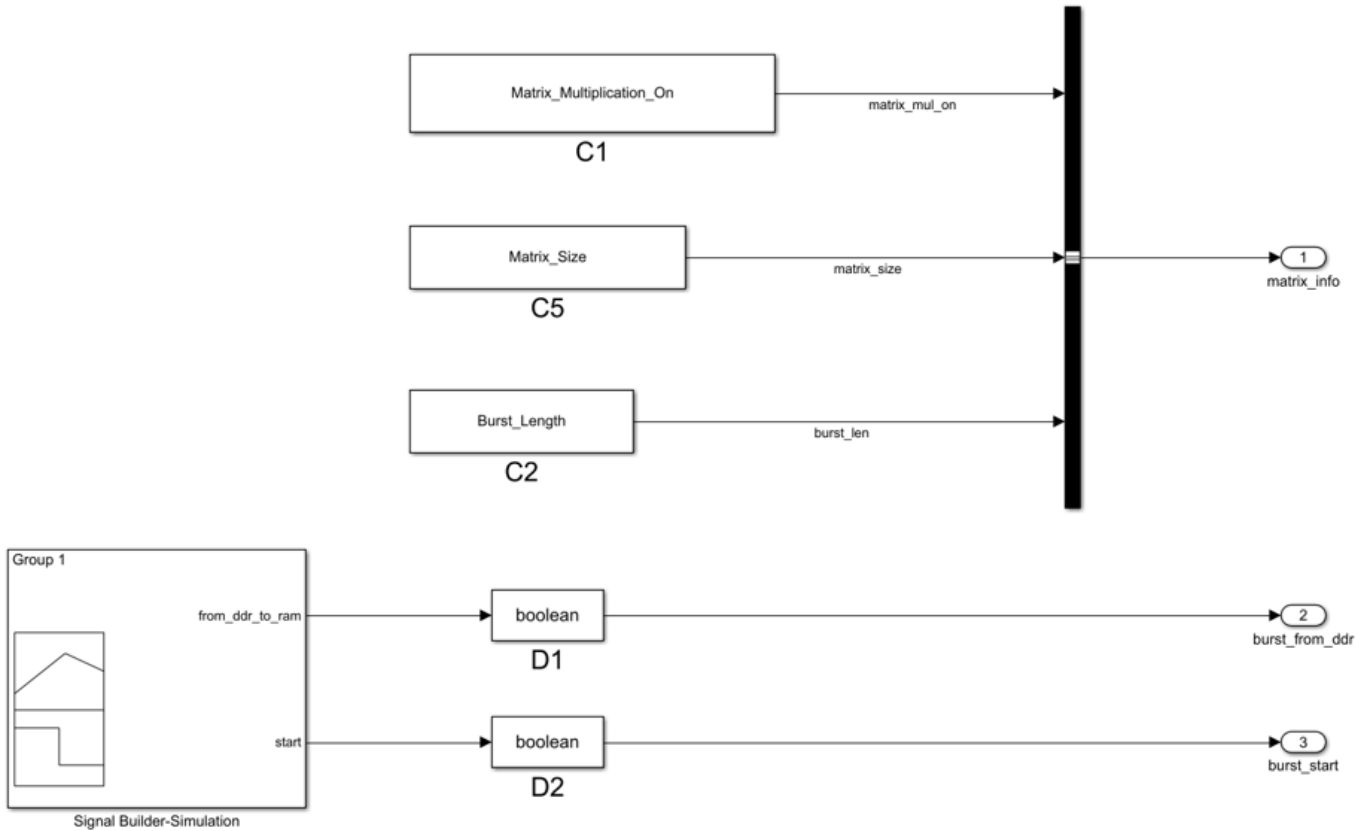

%
% Use HDL Coder to generate a custom IP core that performs large matrix
% operations on FPGAs by using external memory. In MATLAB, type:
%   hdladvisor('hdlcoder_axi_slave_bus_data_type/DUT')
```

IP Core Generation Workflow: External Memory Access

**Create Bus Element**

Use a bus creator block to combine `Matrix_Multiplication_On`, `Matrix_Size`, and `Burst_Length` into a bus data type element. For more information on the bus creator block, see Bus Creator

```
open_system('hdlcoder_axi_slave_bus_data_type/InputSubsystem')
%
```

Functional Simulation in Simulink

You can simulate this example model and verify the simulation result by running this script in MATLAB:

```
hdlcoder_axi_slave_bus_data_type_simulation;
```

This script first initializes the parameters like `Matrix_Size`. By default, the `Matrix_Size` is 64, which means a 64-by-64 matrix. The default `Matrix_Size` is kept small for a faster simulation. After the DUT is implemented onto the FPGA board, the larger `Matrix_Size` is used as the FPGA calculation is much faster. You can also adjust these parameters in the script.

The script then simulates the model and verifies the result by comparing the logged simulation result to the expected value.

```
>> hdlcoder_axi_slave_bus_data_type_simulation
PASSED: DDR initialization data matches.
PASSED: Matrix vector multiplication output matches with the expected data
>>
```

By default, the `Matrix_Multiplication_On` is true. The script verifies the matrix vector multiplication result.

When the `Matrix_Multiplication_On` is false, the script verifies the loop back mode, which means that the DUT read `Burst_Length` amount of data from DDR, and then wrote the data back to DDR.

Generate HDL IP Core with AXI4 Master Interface

Next, we start the HDL Workflow Advisor and use the IP Core Generation workflow to deploy the DUT on the Zynq hardware. For a more detailed step-by-step guide, refer to the “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 example.

1. Set up the Xilinx Vivado synthesis tool path. Use your own Vivado installation path when you run the command. In the MATLAB command window type: `hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2020.1\bin\vivado.bat')`
2. Start the HDL Workflow Advisor from the DUT subsystem `hdlcoder_axi_slave_bus_data_type/DUT`. The target interface settings are saved on the model. The **Target workflow** is IP Core Generation, and the **Target platform** is Xilinx Zynq Ultrascale+ MPSoC ZCU102 Evaluation Kit. The **Reference Design** is Default System with External DDR4 memory access and **Target platform interface table** settings are as shown

The screenshot shows the HDL Workflow Advisor interface for the task "1.3. Set Target Interface". The main configuration area includes a table for "Target platform interface table" with the following data:

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
matrix_info	Inport	bus	AXI4	x"100"	Options...
burst_from_ddr	Inport	boolean	AXI4	x"10C"	Options...
burst_start	Inport	boolean	AXI4	x"110"	Options...
axim_rd_data	Inport	uint32	AXI4 Master Read	Data	
axim_rd_s2m	Inport	bus	AXI4 Master Read	Read Slave to Master Bi	
axim_wr_s2m	Inport	bus	AXI4 Master Write	Write Slave to Master Bi	
ddr_read_done	Output	boolean	AXI4	x"114"	
ddr_write_done	Output	boolean	AXI4	x"118"	
axim_rd_m2s	Output	bus	AXI4 Master Read	Read Master to Slave Bi	
axim_wr_data	Output	uint32	AXI4 Master Write	Data	
axim_wr_m2s	Output	bus	AXI4 Master Write	Write Master to Slave Bi	

The interface also shows a "Run This Task" button, a "Result: Passed" status, and a "Passed Set Target Interface Table" message. The task list on the left includes: 1. Set Target (with sub-tasks 1.1, 1.2, 1.3, 1.4), 2. Prepare Model For HDL Code Generation, 3. HDL Code Generation, and 4. Embedded System Integration.

In this example, the bus datatype ports like `matrix_info` and input parameter ports like `burst_from_ddr` and `burst_start` are mapped to the AXI4 interface. HDL Coder generates the AXI4 interface accessible registers for these ports. Later, you can use MATLAB to tune these parameters at run time when the design is running on FPGA board.

You can specify the bus data type initial values in the **Target platform interface table** by specifying either the initial values directly or by creating a variable to store the initial values in a struct data

type and then using the variable name in the **Interface Options** window. To specify the initial value, click Options under the **Interface Options** column in the **Target platform interface table**.

Specify the initial values directly in the **Interface Options** window.

To store the bus data type initial values in a variable called businit, run this code:

```
businit = struct('matrix_mul_on', Matrix_Multiplication_On, 'matrix_size', Matrix_Size, 'burst_len', Burst_Length);
```

To specify the businit variable in the **Interface Options** window.

The AXI4 Master interface has separate read and write channels. The read channel ports like axim_rd_data, axim_rd_s2m, axim_rd_m2s are mapped to the AXI4 Master Read interface. The write channel ports like axim_wr_data, axim_wr_s2m, axim_wr_m2s are mapped to the AXI4 Master Write interface.

3. Right-click Generate RTL Code and IP Core, and then select **Run to Selected Task** to generate the IP core. You can find the register address mapping and other documentation for the IP core in the generated IP Core Report.

The report shows the individual bus elements and their address mappings:

Target Interface Configuration

You chose the following target interface configuration for [hdlcoder_axi_slave_bus_data_type](#):

Processor/FPGA synchronization mode: **Free running**

Target platform interface table:

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
matrix_info	Inport	bus	AXI4		RegisterInitialValue 0
> matrix_info.matrix_mul_on	Bus element	boolean	AXI4	x"100"	
> matrix_info.matrix_size	Bus element	uint32	AXI4	x"104"	
> matrix_info.burst_len	Bus element	uint32	AXI4	x"108"	
burst_from_ddr	Inport	boolean	AXI4	x"10C"	RegisterInitialValue 0
burst_start	Inport	boolean	AXI4	x"110"	
axim_rd_data	Inport	uint32	AXI4 Master Read	Data	
axim_rd_s2m	Inport	bus	AXI4 Master Read	Read Slave to Master Bus	
axim_wr_s2m	Inport	bus	AXI4 Master Write	Write Slave to Master Bus	
ddr_read_done	Outport	boolean	AXI4	x"114"	
ddr_write_done	Outport	boolean	AXI4	x"118"	
axim_rd_m2s	Outport	bus	AXI4 Master Read	Read Master to Slave Bus	
axim_wr_data	Outport	uint32	AXI4 Master Write	Data	
axim_wr_m2s	Outport	bus	AXI4 Master Write	Write Master to Slave Bus	

If you specified the initial value for the bus element using the `businit` variable, the generated IP core report shows the bus element initial values.

Target Interface Configuration

You chose the following target interface configuration for [hdlcoder_axi_slave_bus_data_type](#) :

Processor/FPGA synchronization mode: **Free running**

Target platform interface table:

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
matrix_info	Inport	bus	AXI4		RegisterInitialValue businit
> matrix_info.matrix_mul_on	Bus element	boolean	AXI4	x"100"	RegisterInitialValue 1
> matrix_info.matrix_size	Bus element	uint32	AXI4	x"104"	RegisterInitialValue 64
> matrix_info.burst_len	Bus element	uint32	AXI4	x"108"	RegisterInitialValue 4160
burst_from_ddr	Inport	boolean	AXI4	x"10C"	
burst_start	Inport	boolean	AXI4	x"110"	
axim_rd_data	Inport	uint32	AXI4 Master Read	Data	
axim_rd_s2m	Inport	bus	AXI4 Master Read	Read Slave to Master Bus	
axim_wr_s2m	Inport	bus	AXI4 Master Write	Write Slave to Master Bus	
ddr_read_done	Output	boolean	AXI4	x"114"	
ddr_write_done	Output	boolean	AXI4	x"118"	
axim_rd_m2s	Output	bus	AXI4 Master Read	Read Master to Slave Bus	
axim_wr_data	Output	uint32	AXI4 Master Write	Data	
axim_wr_m2s	Output	bus	AXI4 Master Write	Write Master to Slave Bus	

4. Right-click **Build FPGA Bitstream**, and then select **Run to Selected Task** to generate the Vivado project. Build the FPGA bitstream.

During the project creation, the generated DUT IP core is integrated into the **Default System with External DDR4 Memory Access** reference design. This reference design is comprised of a Xilinx Memory Interface Generator IP to communicate with the onboard external DDR4 memory on the ZCU102 platform. The MATLAB as AXI Master IP is also added to enable MATLAB to control the DUT IP and to initialize and verify the DDR memory content.

Run FPGA Implementation on Xilinx Zynq Ultrascale+ MPSoC ZCU102 Evaluation Kit

After the FPGA bitstream is generated, run **Program Target Device** to program the FPGA board through the JTAG cable.

You can then run the FPGA implementation and verify the hardware result by running this script in MATLAB:

```
hdlcoder_axi_slave_bus_data_type_hw_run_ZCU102.m
```

This script first initializes the `Matrix_Size` to 2000, which means a 2000-by-2000 matrix. You can adjust the `Matrix_Size` up to 4000.

The AXI4 Master read and write channel base addresses are then configured. These addresses define the base address that DUT reads from the external DDR memory, and writes to external DDR memory. In this script, the DUT reads from base address '80000000', and write to the base address '90000000'.

The MATLAB as AXI Master initializes the external DDR4 memory with input vector and matrix data and clears the output DDR memory location.

The DUT calculation is started by controlling the AXI4 accessible registers. The DUT IP core first reads input data from the DDR memory, performs the matrix vector multiplication, and then writes the result back to the DDR memory.

The output result is read back to MATLAB and compared to the expected value. The hardware results are verified in MATLAB.

```
>> hdlcoder_axi_slave_bus_data_type_hw_run_ZCU102
Initializing external DDR4 memory (data size 4002000) ...
Starting DUT IP core processing ...
Verifying result ...
PASSED: Matrix vector multiplication output matches with the expected data.
```

Prototype FPGA Design on Hardware with Live Data by Using MATLAB Commands

This example shows how to use MATLAB® to prototype an algorithm running on FPGA hardware from your host computer.

Introduction

At many stages in the design process it can be useful to interact with an FPGA design that is running directly on hardware. Working with hardware enables you to rapidly prototype designs, verify functionality, tune key parameters, connect to real-world signals, collect data for analysis, and much more.

This example shows you how to connect MATLAB on your host computer to your FPGA hardware. Use MATLAB to:

- Write input signals to your FPGA algorithm.
- Capture output signals from your FPGA for analysis.
- Read from and write to registers in your FPGA design.

As part of this example, you:

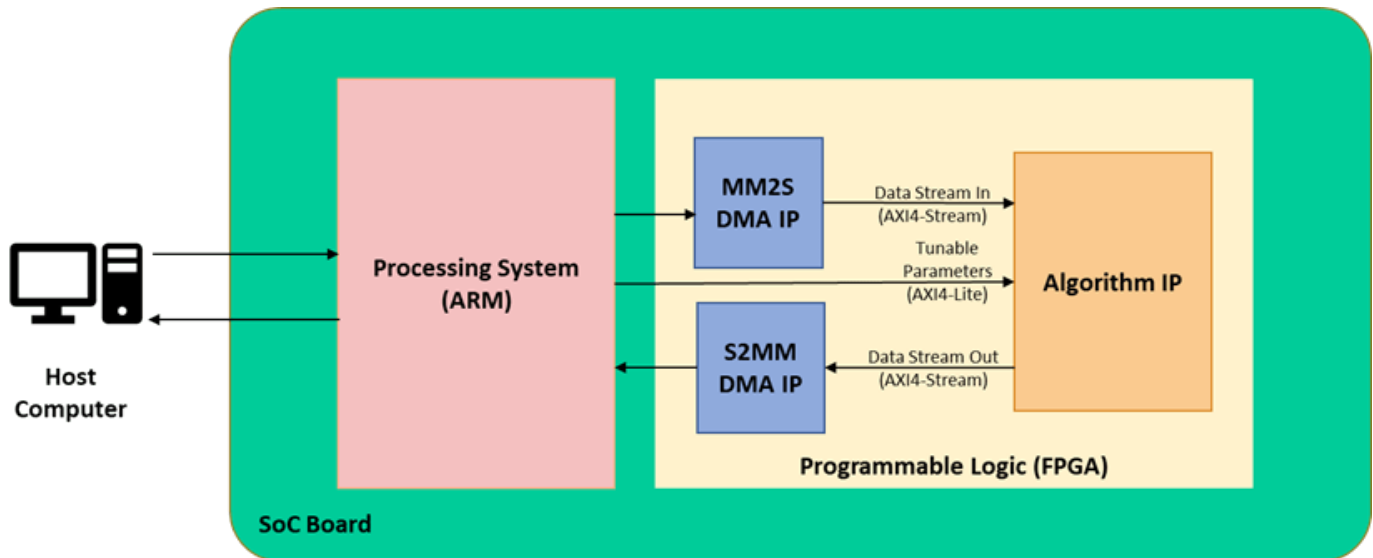

- 1 Generate and deploy a simple algorithm on hardware.
- 2 Create a hardware object to establish a connection to your FPGA.
- 3 Use a simple script to prototype the design running on hardware with live data.

Before You Begin

To run this example, install and set up:

- HDL Coder™ Support Package for Xilinx® Zynq® Platform
- Xilinx Vivado® (version indicated in “HDL Language Support and Supported Third-Party Tools and Hardware”)
- Xilinx SoC board. This example uses the ZedBoard.
- MathWorks® firmware image on the board’s SD card. For help with SD card setup, see “Guided SD Card Setup” (HDL Coder Support Package for Xilinx Zynq Platform) (HDL Coder Support Package for Xilinx Zynq Platform).

System Architecture

The preceding image shows the high-level architecture of the system. The host computer communicates to the FPGA through the processing system on the System on Chip (SoC) board. The host computer can send and receive frames of data, which are translated to and from streaming data by the Direct Memory Access (DMA) IPs. The host computer can also tune parameters by writing to AXI4-Lite registers within the algorithm IP core.

FPGA Algorithm

The algorithm deployed to the FPGA is a simple streaming algorithm that scales the amplitude of the input signal by a constant. The streaming data is modeled with data and valid signals. The amplitude signal is modeled as a constant.

Open the model. The model consists of the design under test (DUT) and the testbench. The DUT contains the algorithm that is deployed to the FPGA. The testbench exercises the DUT during simulation by providing inputs and capturing outputs for display.

```
% open_system hdlcoder_scale_amplitude.slx
```

Generate HDL IP Core

To generate an IP core from the DUT by using the HDL Workflow Advisor:

1. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB Command Window. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2020.2\bin\vivado.bat')
```

2. Open the HDL Coder toolstrip app from **Apps > HDL Coder**. Click the toolstrip icon to open the Workflow Advisor.

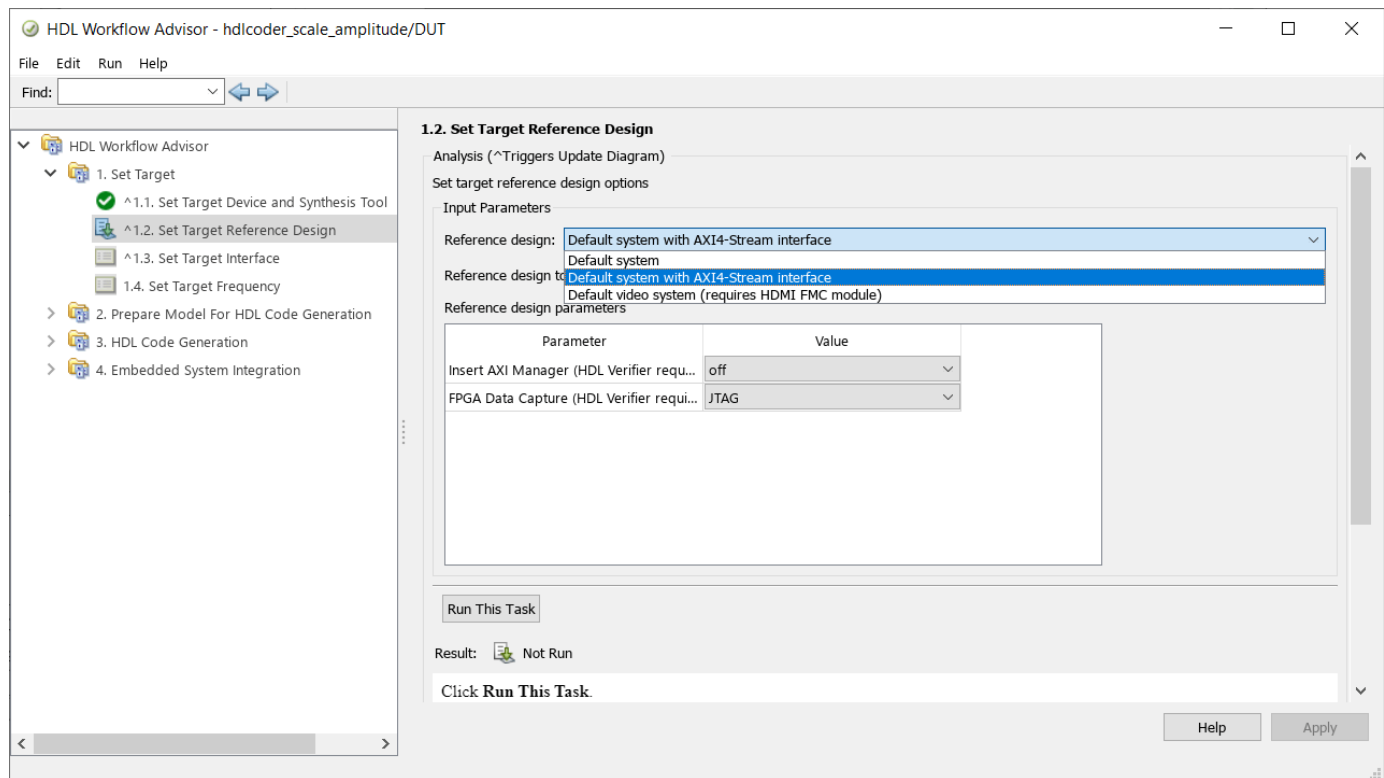

3. In the **Set Target Device and Synthesis Tool** task, select **IP Core Generation** for **Target workflow** and **ZedBoard** for **Target platform**. If you are targeting a different Xilinx SoC, choose your board from the Target platform context menu.

Click **Run This Task**.

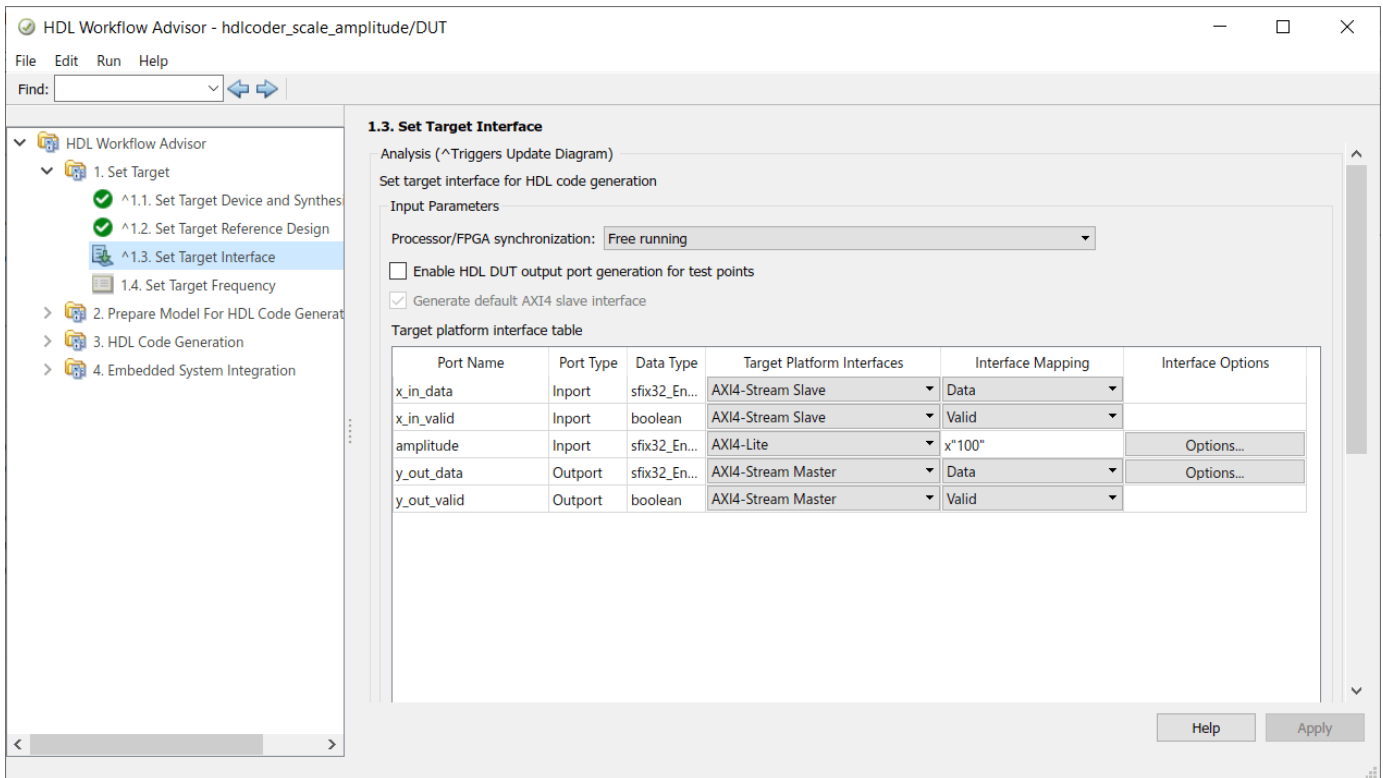

4. In the **Set Target Reference Design** task, select **Default system with AXI4-Stream interface** for **Reference design**.

Click **Run This Task**.

5. In **Set Target Interface** task, the ports of the **DUT** subsystem are mapped to IP Core interfaces. The input data and valid ports are mapped to **AXI4-Stream Slave**. The output data and valid ports are mapped to **AXI4-Stream Master**. The amplitude signal is mapped to **AXI4-Lite**.

Click **Run This Task**.

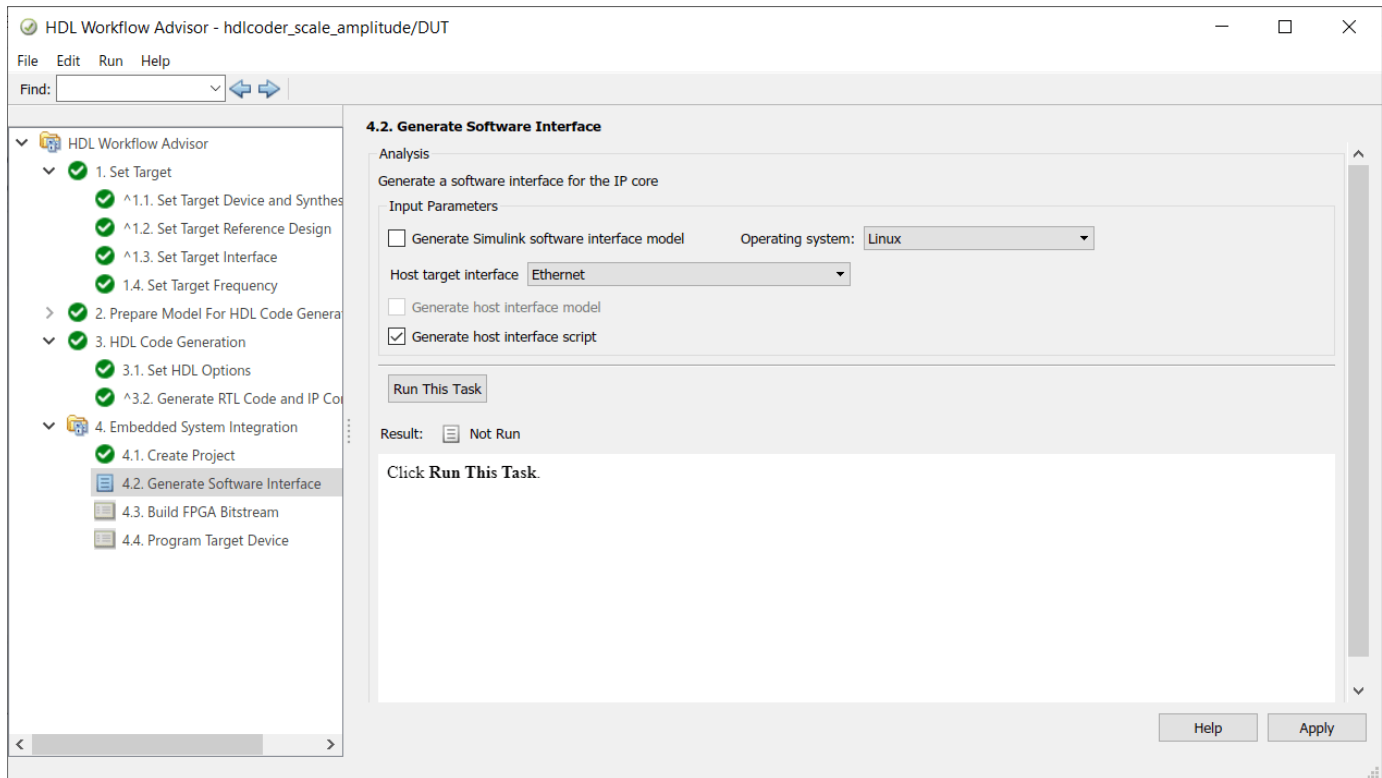

6) Right-click the **Generate RTL Code and IP Core** task, and select **Run to Selected Task** to generate the IP core.

Generate Interface Between Host Computer and IP Core

To generate a host computer interface to the IP core and deploy the design to the target hardware board:

1. Run the **Create Project** task. This task inserts the generated IP core for the FPGA algorithm into the reference design to create the system shown in the System Architecture diagram.
2. In the **Generate Software Interface** task, select the box for **Generate host interface script** then run this task.

3. Two MATLAB files are generated in your current folder that enable you to prototype your generated IP core directly from MATLAB.

4. Inspect these generated files in Interact with FPGA Design from Host Computer. on page 46-242 First, complete the remaining Workflow Advisor tasks. Run the **Build FPGA Bitstream** task, which might take some time to finish.

5. Run the **Program Target Device** task to program the FPGA algorithm onto the board. Choose the **Download** programming method, which downloads the FPGA bitstream onto the SD card and configures the ARM processing system to start up properly.

Interact with FPGA Design from Host Computer

Interact with the FPGA design by reading and writing data from MATLAB on the host computer.

Open the generated script file:

open `gs_hdlcoder_scale_amplitude_interface.m`

This file creates a connection to your FPGA hardware for reading and writing data.

- 1 Creates an “fpga” hardware object, which represents a connection to the FPGA on your hardware board.
- 2 Configures the “fpga” object with the desired hardware interfaces and ports from your DUT algorithm.
- 3 Reads and writes data to DUT ports to exercise your algorithm running on hardware.
- 4 Releases any hardware resources used by the fpga object to clean up the connection.

```

14 %% Create fpga object
15 hFPGA = fpga("Xilinx");
16
17 %% Setup fpga object
18 % This function configures the "fpga" object with the same interfaces as the generated IP core
19 gs_hdlcoder_scale_amplitude_setup(hFPGA);
20
21 %% Write/read DUT ports
22 % Uncomment the following lines to write/read DUT ports in the generated IP Core.
23 % Update the example data in the write commands with meaningful data to write to the DUT.
24 %% AXI4-Lite
25 % writePort(hFPGA, "amplitude", zeros([1 1]));
26
27 %% AXI4-Stream
28 % writePort(hFPGA, "x_in_data", zeros([1 1024]));
29 % data_y_out_data = readPort(hFPGA, "y_out_data");
30
31 %% Release hardware resources
32 release(hFPGA);
    
```

Open the generated setup function:

open `gs_hdlcoder_scale_amplitude_setup.m`

This function configures the fpga hardware object with the same ports and interfaces that were mapped in the **Set Target Interface** task. You can reuse this function can be reused in your own scripts to recreate this configuration.

```

1 function gs_hdlcoder_scale_amplitude_setup(hFPGA)
2 %-----

54
55 mapPort(hFPGA, [DUTPort_x_in_data, DUTPort_y_out_data]);
56
57 end
58

```

DUT input port "amplitude" is mapped to an AXI register

DUT input and output streaming ports

You can modify the generated script file to exercise the algorithm running on hardware. A live script has been prepared, which you can open by running this command:

```
open hdlcoder_scale_amplitude_script.mlx
```

Change the slider value and observe how the output data (orange) changes in the graph below it. As the slider moves, the code below it is executed. Each execution of the code:

- Writes the new amplitude value from the slider to an AXI register in the IP core.
- Writes one frame of the input signal.
- Reads one frame of output signal.
- Plots the input and output signals on the same graph to show the difference in amplitude.

Prepare input signal frame

Create a frame of data for the input signal. This frame is written to the AXI4-Stream interface on the IP core. The DMA on the hardware will take care of translating the frame-based data to sample-based (streaming) data.

A sine wave is being used as the input signal. Try using other MATLAB functions to generate different input signals and observe the output. The input signal must be a vector of length 1024.

```
t = linspace(0, 1, 1024);
w = 2*pi*10;
data_in = sin(w*t);
```

AXI4-Lite

```
ampl = 3  ;  Change the slider value
writePort(hFPGA, "amplitude", ampl);
```

AXI4-Stream

```
writePort(hFPGA, "x_in_data", data_in);
data_y_out_data = readPort(hFPGA, "y_out_data");
```

Plot data

```
plot(t, data_in, t, data_y_out_data);
ylim([-10 10])
```

 Observe changes in the output signal

When finished, run the last line of the script to release any hardware resources used by the fpga object for clean up:

```
release(hFPGA);
```

Next Steps

Experiment further with the generated script:

- Change the MATLAB function used to produce the input signal data on the line 7 of the live script. Some other functions to try are `cos`, `square` (Signal Processing Toolbox), and `sawtooth` (Signal Processing Toolbox).

- Use “Develop Apps Using App Designer” to create a custom app with the commands from this script. Add User Interface (UI) components for interacting with the algorithm as it runs on the hardware.
- Follow the steps from this example with your own model. Use the generated script to prototype your algorithm on hardware.

Author a Xilinx Zynq Linux Image for a Custom Zynq Board by Using MathWorks Buildroot

This example shows how to create a Zynq Linux image for starting a Zynq custom board with the Linux operating system in a Zynq workflow by using MathWorks buildroot system.

Introduction

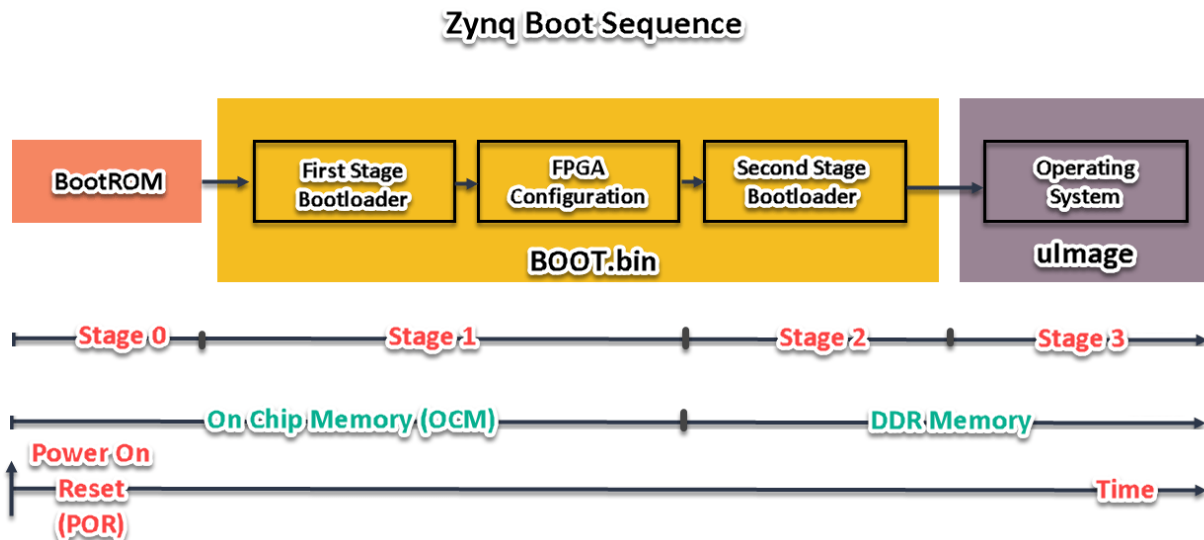

You create a Zynq Linux Image for a Digilent Zybo Z7-10 Zynq development board for the custom reference design in the HDL workflow advisor. This example uses a Zybo Z7-10 board. You can build a Linux image for other Zynq platforms by using the MathWorks build system.

Requirements

- Mathworks build system - Buildroot
- Linux operating system
- Xilinx Vivado Design Suite, the supported version listed in the HDL Coder documentation
- Digilent® Zybo Z7-10 Zynq™ development board with the accessory kit

Zynq Configuration

The Zynq boot process involves the processor system (PS), loading and executing Zynq boot image which consists of a First stage bootloader (FSBL), a bitstream to configure the programmable logic (PL), and user applications.

Boot Process

Stage 0

After the board is switched ON or the Zynq processor is reset. BootROM, a read-only code executes from (CPU0) one of the processor from processing system (PS). Based on the boot mode pin settings

(JP5) in Zybo Z7-10 from available boot mode options, such as QSPI Flash, NAND Flash, SD Card, it copies the BootROM to on-chip memory (OCM). It executes the BootROM. Post-execution, the BootROM transfers execution to FSBL in the OCM.

Stage 1

The FSBL enables by configuring PS components, such as DDR memory controller and I/O components and looks for the bitstream file in the boot device. The FSBL loads application binaries and data files into memory until the complete image has been read from the boot device then FSBL initializes the external RAM and loads the second stage bootloader or stand alone application.

Stage 2

The user application loaded in the previous stage will be executed like U-Boot. It runs in CPU0 to initialize and setup the environment in which OS will boot. Initialization includes configuring the memory management unit.

Stage 3

The bootloader then fetches the kernel image and boots the embedded Linux operating system. In case of Linux, the OS detects and enables the second processor core CPU1, configures and activates the MMU and data caches and performs other actions to make a complete system available to applications.

Mathworks Build System

Mathworks Buildroot is a tool you use to generate embedded Linux systems through cross-compilation. The MathWorks build system wraps Buildroot in pre and post-processing scripts to automate the generation of system images for various platforms. The build system is based on scripts that take as input the target board, platform or image description file and output a complete system image, including bootloaders, kernel, and user space. This repository hosts the buildroot framework that creates the Altera SoC and Xilinx Zynq platform SD Card images for use with MathWorks tools.

Build a Zynq Linux image by Using the Mathworks Build System

1. Setup Cross compiler

Set up the cross compiler by Installing the Linaro ARM toolchain on your Linux machine using the following command. Below command works in Debian® 10 Linux Machines.

```
>> sudo apt-get install gcc-arm-linux-gnueabi
```

2. Sync MathWorks Buildroot from Git Hub

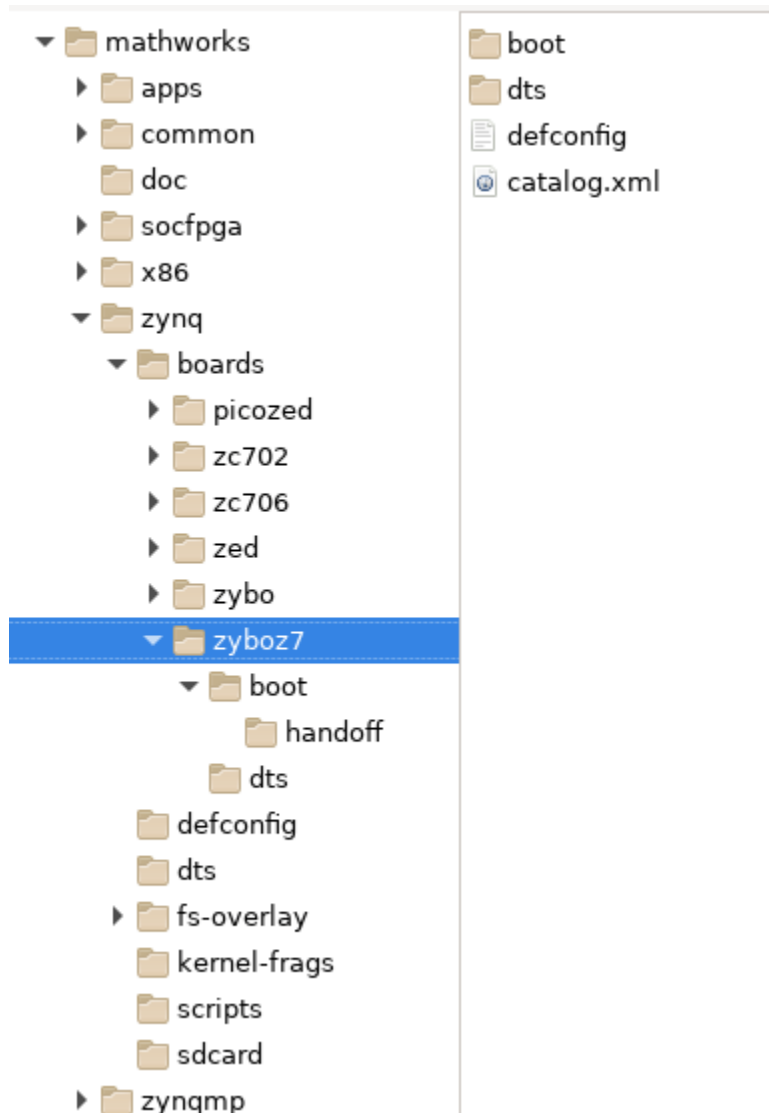

Get the buildroot from the git clone GitHub - MathWorks Buildroot by using the latest release tag.

```
>> git checkout mathworks_zynq_R22.1.0
```

The release tags are labeled as mathworks_zynq_R2x.y.z, where the "R2x" denotes the year of the MATLAB release and "y" denotes the 'a' or 'b' release. The "z" is used for updates to the image within a particular MATLAB release. For example, the tag "R22.1.0" is interpreted as MATLAB R2022a where "R22" represents R2022 and "1.0" is for release 'a'. If there will be any updates to the image within the R2022a release, the versions would be "R22.1.1", "R22.1.2", etc.

After syncing the Mathworks buildroot, build the image by using the following files. Navigate to the file folder and place the required files in it. This image shows the folder hierarchy and contents inside it that you use for building the Linux image for a specific board (ZyboZ7).

/buildroot/board/mathworks/zynq/boards/zyboz7/

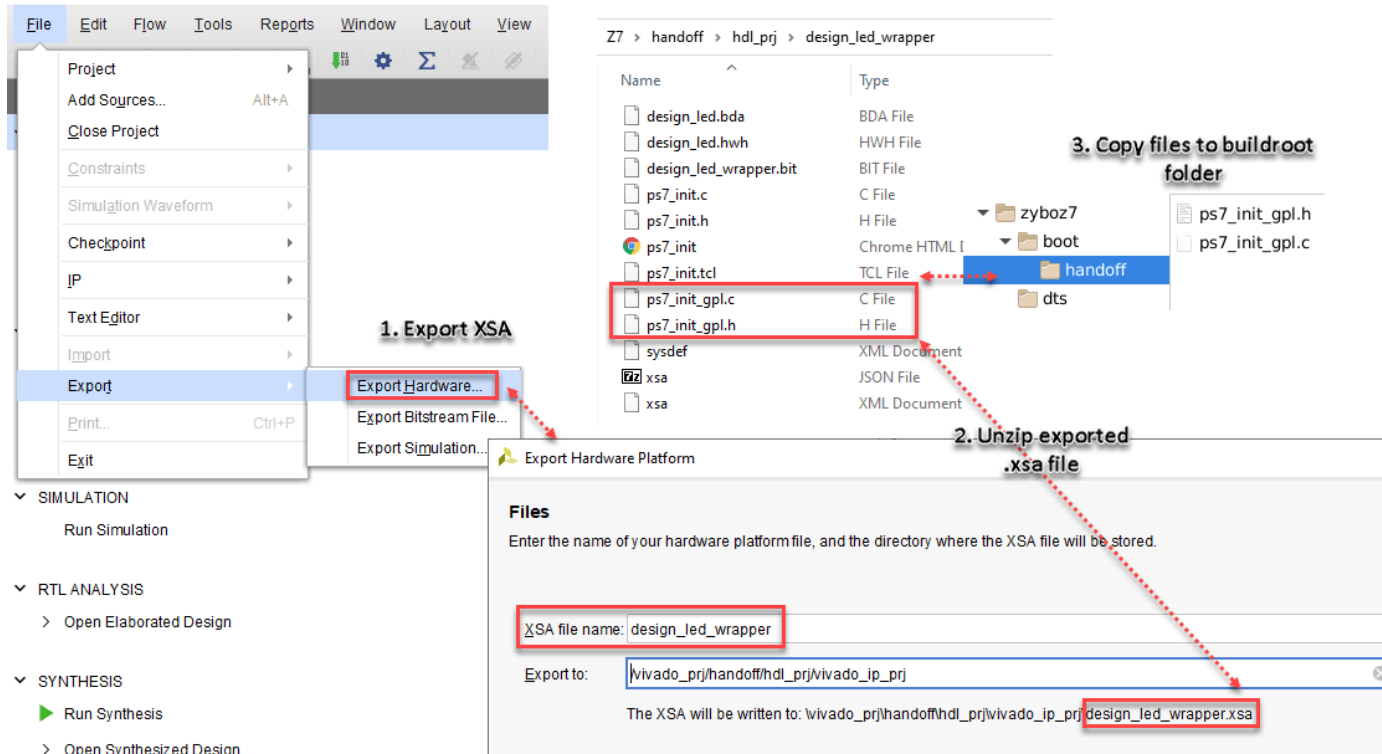

Required files for Building Zynq Linux Image

- Exported Handoff files
- Device Tree Source file
- Zynq Defconfig file

Handoff Files

The settings applied in Zynq processing system IP such as address mapping of memory and peripherals, are exported from the Xilinx Vivado project. Bitstream file, system hardware project file (.hdf) are exported after custom reference design creation. For more information, see the Create and

Export a Custom Reference Design by Using Xilinx Vivado section in “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231. Export the hardware platform from the vivado block design project and unzip the .xsa file to get ps7_init_gpl.c, ps7_init_gpl.h and place these files into handoff folder in the zyboz7 buildroot directory as shown in the below image.

Device Tree Source

Device tree is a data structure that describes the hardware which is readable by an operating system like Linux so that it doesn't need to hard code any details of the machine. A device tree source (DTS) file contains plain text data that describes a list of nodes, properties and child nodes for platform identification, run-time configuration like bootargs. DTS files are compiled using device tree compiler into device tree blob (DTB) which is a binary file that the hardware uses during the boot process.

This code is the sample code of the Zybo Z7-10 Device tree source file.

```

#include "zynq-7000.dtsi"
#include <dt-bindings/gpio/gpio.h>

/ {
    model = "Digilent Zybo Z7 board";
    compatible = "digilent,zynq-zybo-z7", "xlnx,zynq-7000";

    aliases {
        ethernet0 = &gem0;
        serial0 = &uart1;
    };

    memory@0 {
        device_type = "memory";
        reg = <0x0 0x40000000>;
    };

    chosen {
        bootargs = "";
        stdout-path = "serial0:115200n8";
    };

    gpio-leds {
        compatible = "gpio-leds";

        ld4 {
            label = "zynq-zybo-z7:green:ld4";
            gpios = <&gpio0 7 GPIO_ACTIVE_HIGH>;
        };
    };

    usb_phy0: phy0 {
        #phy-cells = <0>;
        compatible = "usb-nop-xceiv";
        reset-gpios = <&gpio0 46 GPIO_ACTIVE_LOW>;
    };
};

&clkc {
    ps-clk-frequency = <33333333>;
};

&gem0 {
    status = "okay";
    phy-mode = "rgmii-id";
    phy-handle = <&ethernet_phy>;

    ethernet_phy: ethernet-phy@0 {
        reg = <0>;
        device_type = "ethernet-phy";
    };
};

&sdhci0 {
    status = "okay";
};

&uart1 {
    status = "okay";
};

&usb0 {

```

3. Zynq Defconfig

The platform defconfig contains the Linux kconfig settings required to properly configure the kernel build. This file is the zynq_zybo_z7_defconfig file used for building the Z7-10 Image.

```
#####
```

```
# Zybo Options
```

```
#####
```

```
BR2_TARGET_UBOOT_BOARD_DEFCONFIG="zynq_zyboz7"
```

```
BR2_PACKAGE_XILINX_BOOTLOADER_UBOOT_TARGET_DIR="board/xilinx/zynq/zynq-zyboz7"
```

Build Script

Using the following build script we can initiate the linux SD image build for the specific board.

```
>> build.py -c board/mathworks/zynq/boards/zyboz7/catalog.xml
```

Otherwise use this command to provide the different toolchain path manually to build.

```
>> ./build.py -p zynq -b zyboz7 --brconfig BR2_TOOLCHAIN_EXTERNAL_PATH='/opt/ARM_CortexA/LinaroToolchain/6.3.1-2017.02/Linux/aarch32'
```

List of files after build

After a build, these files are in the output folder **/buildroot/output/zybo_linux_linaro/images/** as a zip file. Unzip the files into the SD card and insert the SD card on Zybo Z7-10 board. To learn more about board connections, see “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231.

Summary

This example shows step by step process of building a Linux image by using the Mathworks Buildroot system. You can build a Linux image for other Zynq platforms by using the MathWorks build system. Using this example you can create Xilinx Zynq Linux image for the custom Zynq boards by including the required files in the Mathworks buildroot folder and setting up the linaro cross-compiler.

Generate Board-Independent HDL IP Core for Microchip Platforms

This example shows how to generate an HDL IP core for a generic Microchip platform. You generate an HDL IP core for an LED blinking model, then integrate this HDL IP core into a target Microchip platform of your choice. You can generate a board-independent custom IP core to use in an embedded system integration environment, such as Microchip Libero SoC tool.

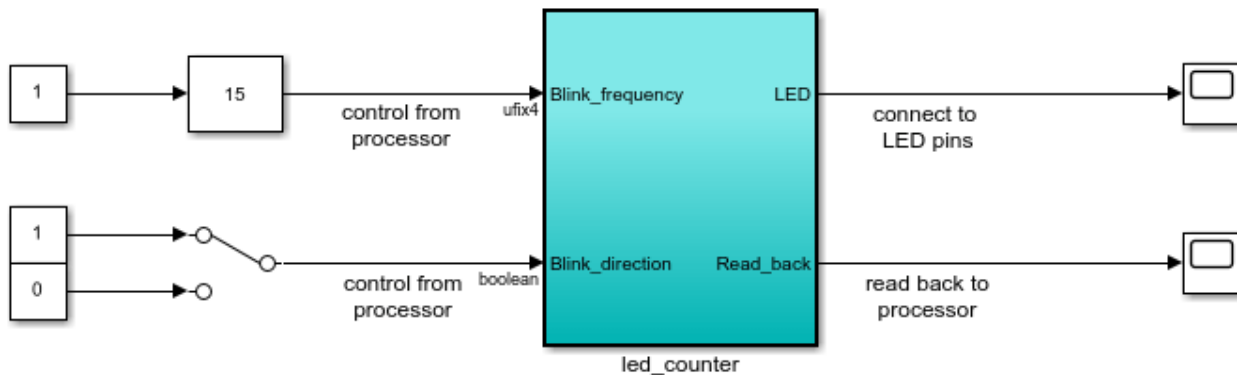

Generate Board-Independent IP Core

To generate a board-independent custom IP core for an LED blinking model, follow these steps:

1. Open the `hdlcoder_led_blinking_4bit` model and click the `led_counter` subsystem.

```
open_system('hdlcoder_led_blinking_4bit');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking_4bit/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2014-2017 The MathWorks, Inc.

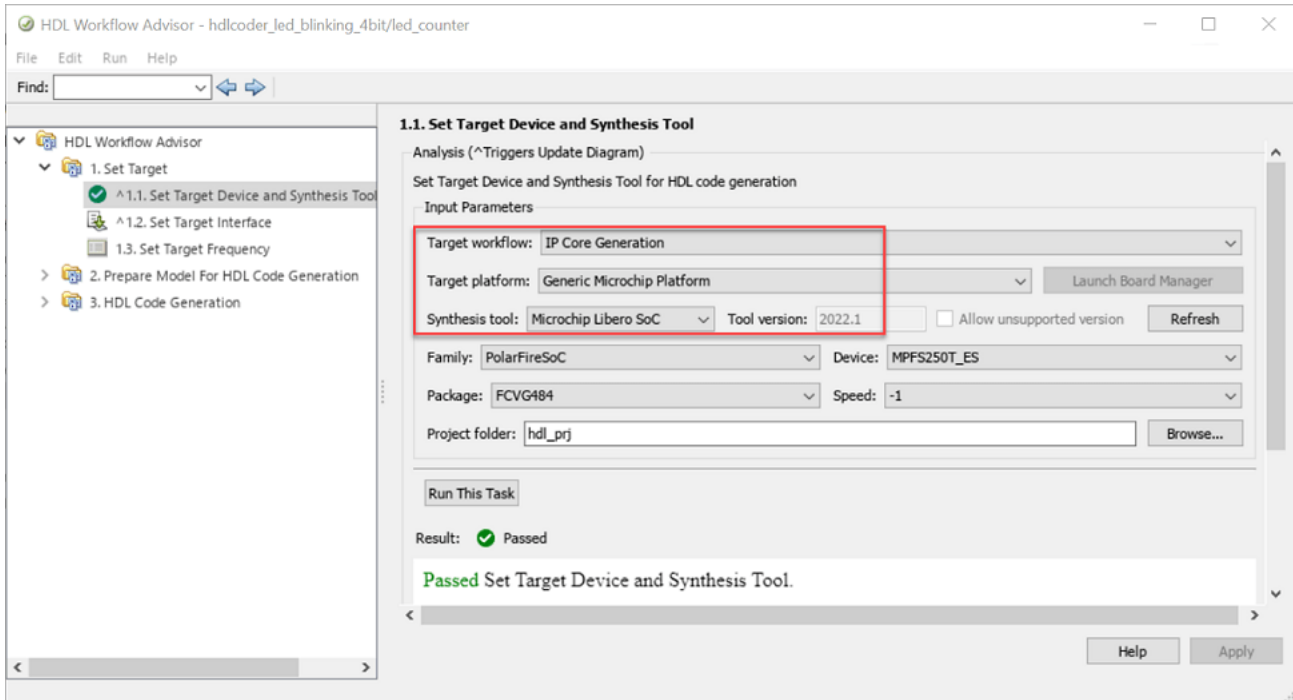

2. Set the path to the Microchip Libero SoC synthesis tool by using the `hdlsetuptoolpath` function,

```
hdlsetuptoolpath('ToolName','Microchip Libero SoC', ...
    'ToolPath','C:\Microsemi\Libero_SoC_v2022.1\Designer\bin\libero.exe')
```

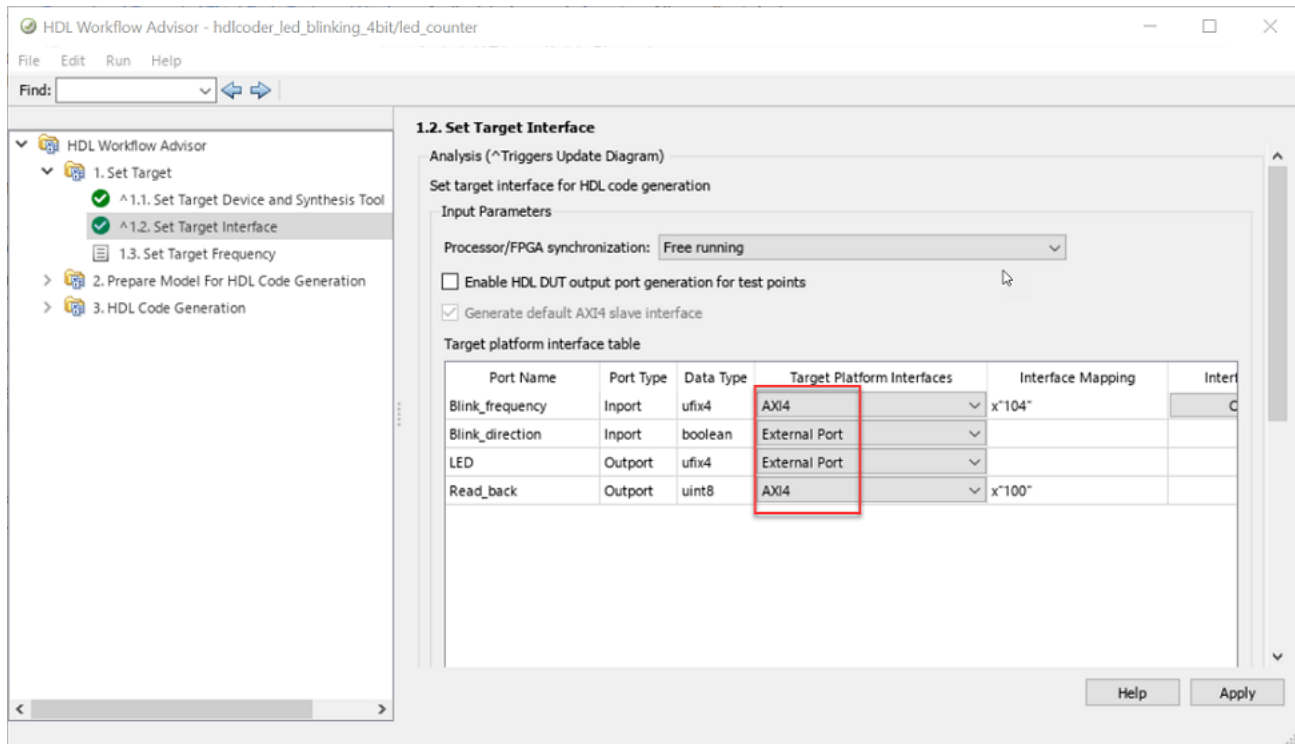

See “HDL Language Support and Supported Third-Party Tools and Hardware” for the latest supported version of the synthesis tool.

3. Open the HDL Workflow Advisor for the subsystem representing the device under test (DUT). For the LED blinking model, the `led_counter` subsystem represents the DUT. In the **Set Target > Set Target Device and Synthesis Tool** task:

- Set **Target workflow** to IP Core Generation.
- Set **Target platform** to Generic Microchip Platform.
- Click **Run This Task**.

4. In the **Set Target > Set Target Interface** task, select a **Target Platform Interface** value for each port, and then click **Apply**. You can map each DUT port to the AXI4-Lite or AXI4 interface. For more information about these interfaces, see “Target Platform Interfaces” on page 46-16.

If you do not want to map the DUT ports to AXI4 slave interfaces, map them to external Port interfaces.

Target platform interface table						
Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options	
Blink_frequency	Inport	ufix4	External Port			
Blink_direction	Inport	boolean	External Port			
LED	Output	ufix4	External Port			
Read_back	Output	uint8	External Port			

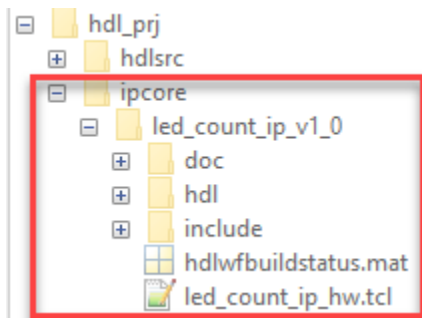

5. Expand the **Set Code Generation Options** task. Right-click the **Set Optimization Options** task and then click **Run to Selected Task**.

6. In the **HDL Code Generation > Generate RTL Code and IP Core** task, you can specify these options:

- Option to connect the DUT IP core to multiple AXI Master interfaces. By default, the **AXI4 Slave ID Width** value is 12, which indicates that you can connect the HDL IP core to one AXI Master interface. To connect the DUT IP core to multiple AXI Master interfaces, to increase the **AXI4 Slave ID Width** parameter value. When you run this task, this setting is saved on the DUT as the HDL block property **AXI4SlaveIDWidth**.
- Option to generate the default AXI4 slave interface. By default, HDL Coder™ generates AXI4 slave interfaces for signals such as the clock, reset, ready, and timestamp. If you do not want to

generate AXI4 slave interfaces, clear the **Generate default AXI4 slave interface** check box. Click **Run This Task**. When you clear the check box and run the task, the code generator saves this setting in the DUT subsystem as the HDL block property **GenerateDefaultAXI4Slave**.

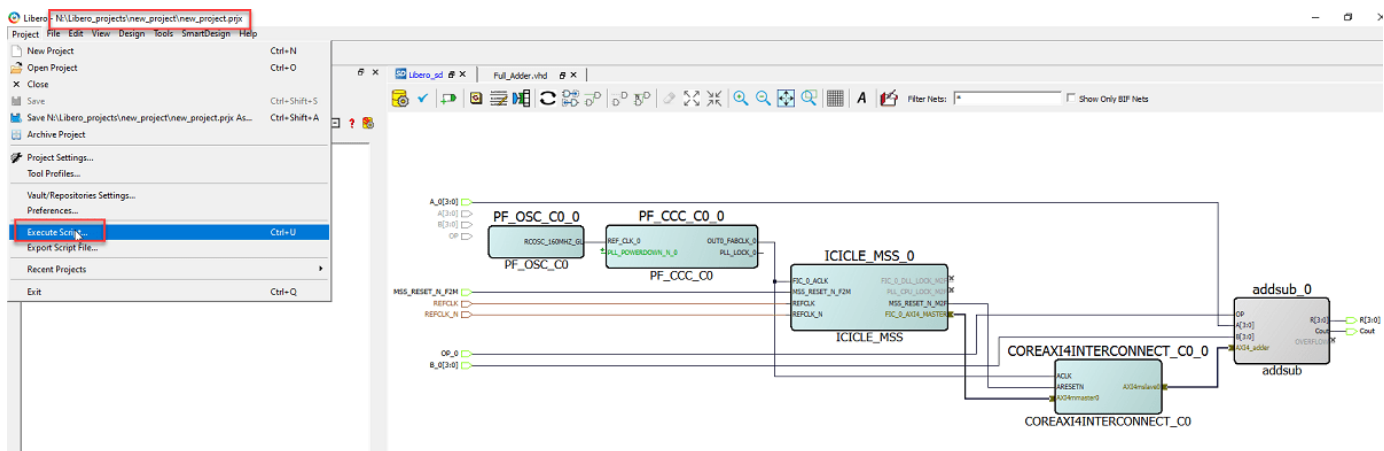

After running the task, HDL Coder generates the IP core files in the output folder in the **IP core folder** field, including the HTML documentation. To view the IP core report, click the link in the message window.

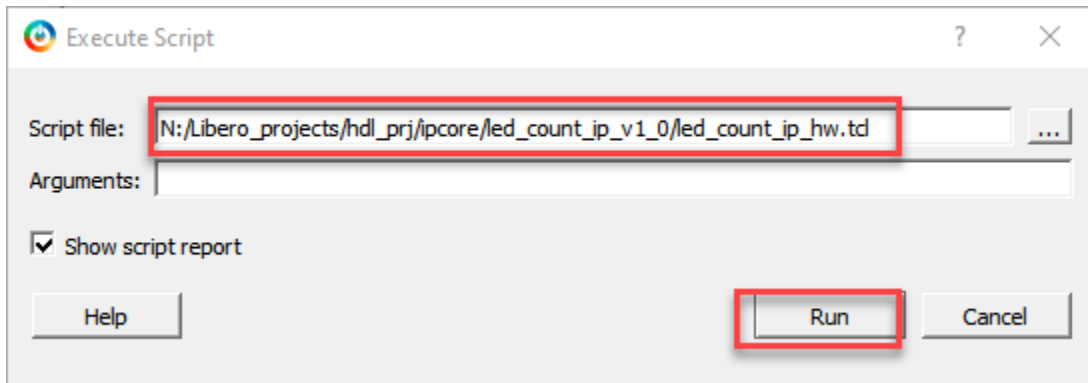

Insert HDL IP Core in Microchip Libero SoC SmartDesign Project

To import generated HDL IP Core into Libero SmartDesign Project, follow the below process.

1. Open Microchip Libero Project in which HDL Coder IP needs to be imported. In the **Project** pane, click **Execute Script**.

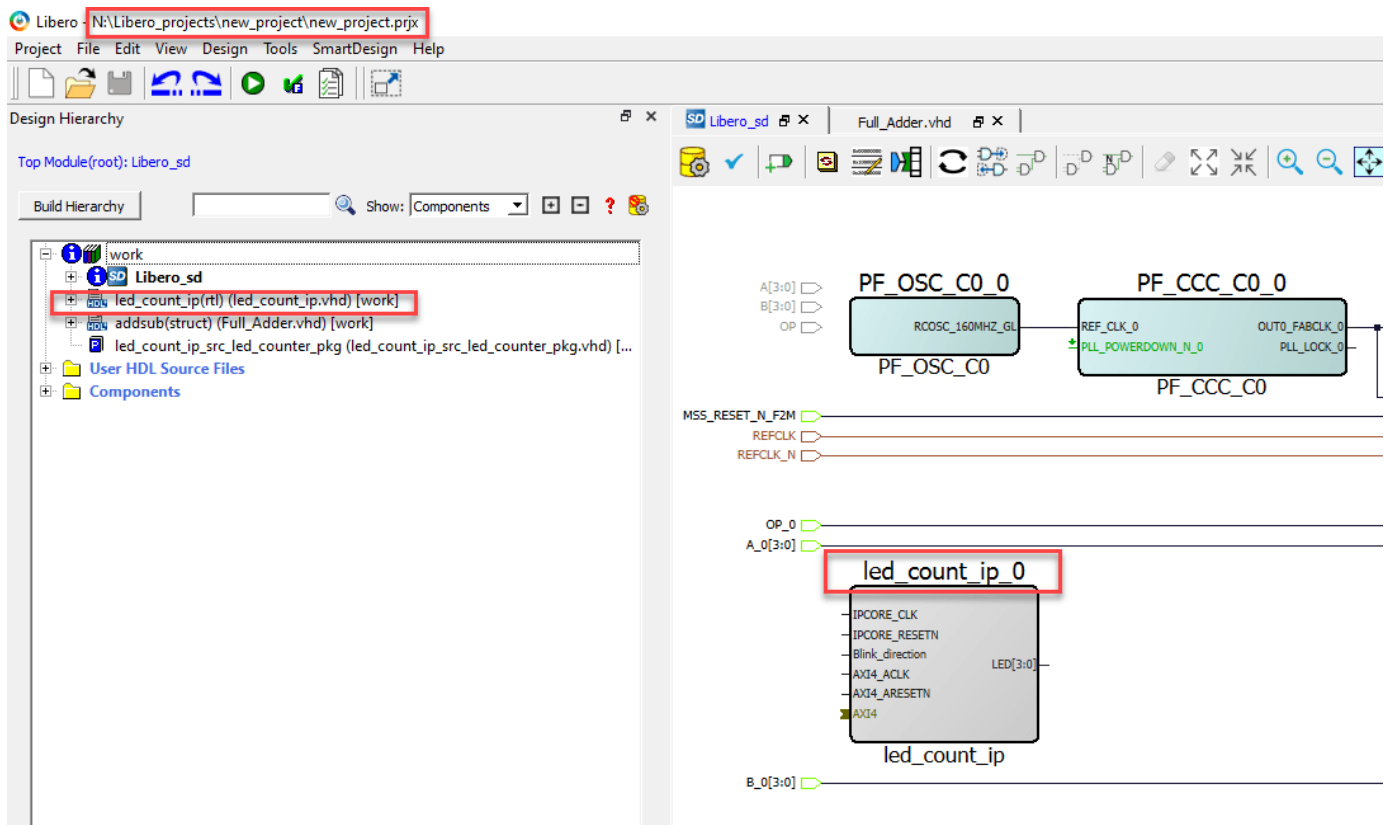

2. In Script file, choose the `led_count_hw_ip.tcl` file from `N:/Libero_Projects/hdl_prj/ipcore/led_count_ip_v1_0` folder. Click **Run**.

3. After running `led_count_hw_ip.tcl` script, HDL Coder IP gets imported into Microchip Libero Project.

4. Instantiate HDL Coder IP by drag and drop of `led_count_ip` module into SmartDesign.

5. Connect `led_count_ip` Clock, Reset ports and Interfaces to other IP's Ports and interface as per requirement. This will form a complete Reference Design.

6. Now, You can follow next steps of implementation in Microchip Libero Tool.

Conclusion and Further Exploration

This example shows how to generate an HDL IP core using a generic microchip platform and integrate the generated IP core into Libero SmartDesign. You can integrate other IP cores into Libero SmartDesign and use these cores to create a complete reference design.

Getting Started with Targeting Xilinx Versal ACAP Platform

This example shows how to use HDL Coder™ and the hardware-software codesign workflow to blink LEDs at various frequencies on the Xilinx® Versal® ACAP platform.

Introduction

This example is a step-by-step guide that helps you use HDL Coder to generate a custom HDL IP core that blinks LEDs on the Xilinx Versal AI Core Series VCK190 Evaluation Kit. It also shows you how to build a bitstream and program the Versal device using the hardware-software codesign workflow.

You can use the hardware-software codesign workflow to help automate the deployment of your MATLAB® and Simulink® design to a Xilinx Versal ACAP device. You can explore the best ways to partition and deploy your design by iterating through this workflow. The following diagram shows a high-level picture of generating an IP core and bitstream, a step in the hardware-software codesign workflow. For more information, see “Targeting FPGA & SoC Hardware Overview” on page 46-2.

You can use MATLAB and Simulink to design, simulate, and verify your application, perform what-if scenarios with algorithms, and optimize parameters. Using the guided workflow shown in this example, you can then automatically generate HDL code for the programmable logic using HDL Coder, and implement the design on the Xilinx Versal ACAP Platform.

In this workflow, you perform the following steps:

- 1 Set up your Xilinx Versal VCK190 hardware and tools.
- 2 Generate an HDL IP core using HDL Workflow Advisor.
- 3 Integrate the IP core into a Xilinx Vivado project and program the Xilinx Versal hardware.
- 4 Tune parameters and capture results using the Xilinx Vivado JTAG tool.

Requirements

- 1 Xilinx Vivado Design Suite, with the supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- 2 Xilinx Versal AI Core Series VCK190 Evaluation Kit
- 3 HDL Coder Support Package for Xilinx Zynq Platform

Set Up Xilinx Versal ACAP Hardware and Tools

1. Set up the Xilinx Versal AI Core Series VCK190 Evaluation Kit as shown in the following figure. To learn more about the VCK190 hardware setup, please refer to the Xilinx VCK190 Board User Guide.

2. Connect your computer to the USB JTAG/UART connector of VCK190 using a Micro USB cable.
3. Install the HDL Coder Support Packages for Xilinx Zynq Platform if you have not already.
4. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2020.2\bin\vivado.ba
```

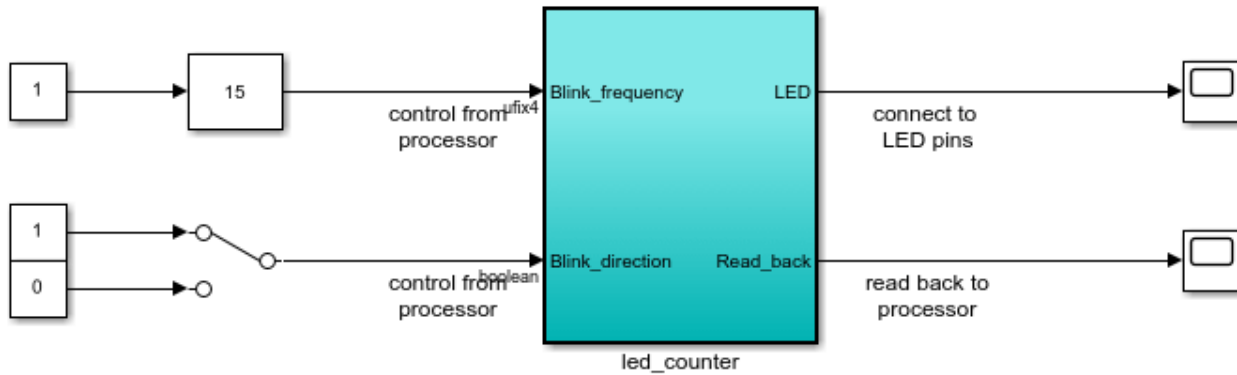

Generate HDL IP Core Using HDL Workflow Advisor

Generating an IP core using the HDL Workflow Advisor enables you to automatically generate a sharable and reusable IP core module from a Simulink model. The generated IP core is designed to be connected to an embedded processor on an FPGA device. HDL Coder generates HDL code from the Simulink blocks, and also generates HDL code for the AXI interface logic connecting the IP core to the embedded processor. HDL Coder packages all the generated files into an IP core folder. You can then integrate the generated IP core with a larger FPGA embedded design in the Xilinx Vivado environment.

In this example, the subsystem `led_counter` is the hardware subsystem. It models a counter that blinks the LEDs on an FPGA board. Two input ports, `Blink_frequency` and `Blink_direction`, are control ports that determine the LED blink frequency and direction.

```
open_system('hdlcoder_led_blinking');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2022 The MathWorks, Inc.

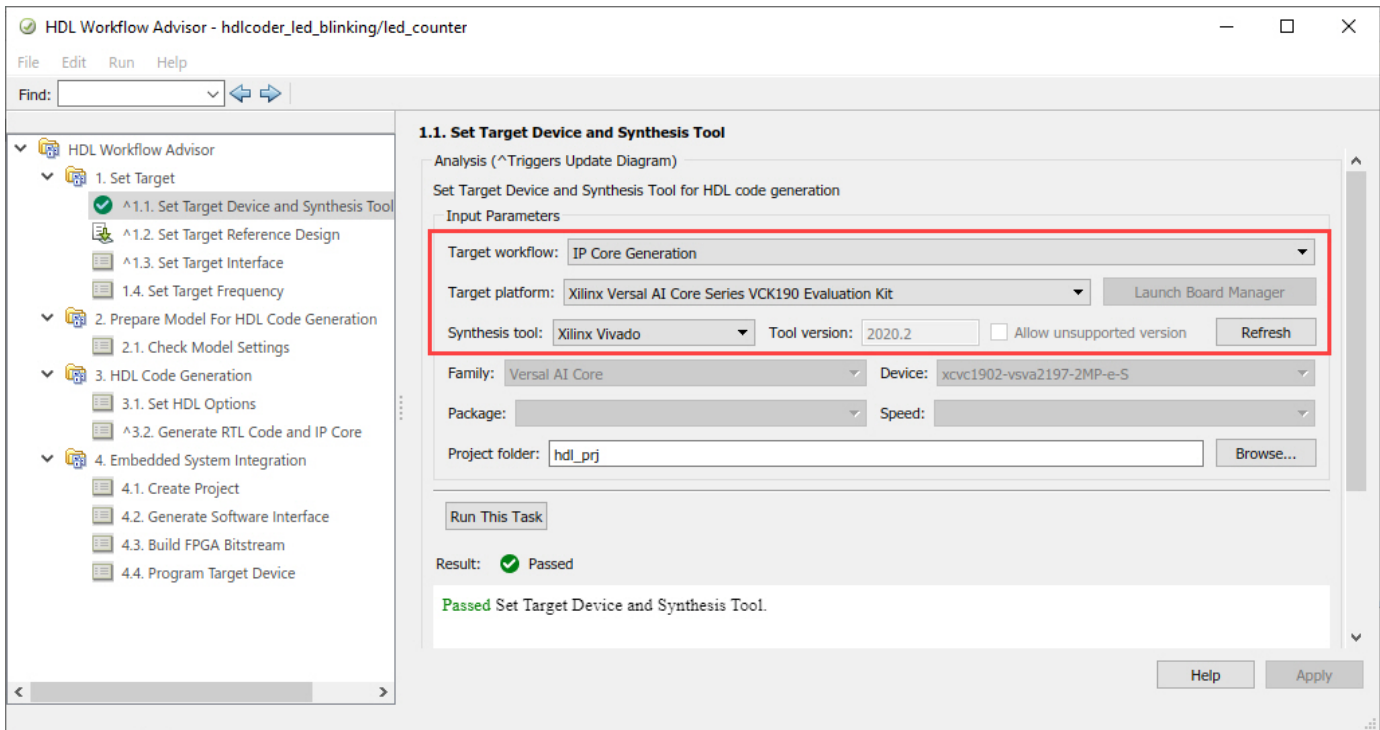

1. Start the IP core generation workflow.

1.1. Open the HDL Workflow Advisor from the `led_counter` subsystem by right-clicking the `led_counter` subsystem and choosing **HDL Code** > **HDL Workflow Advisor**.

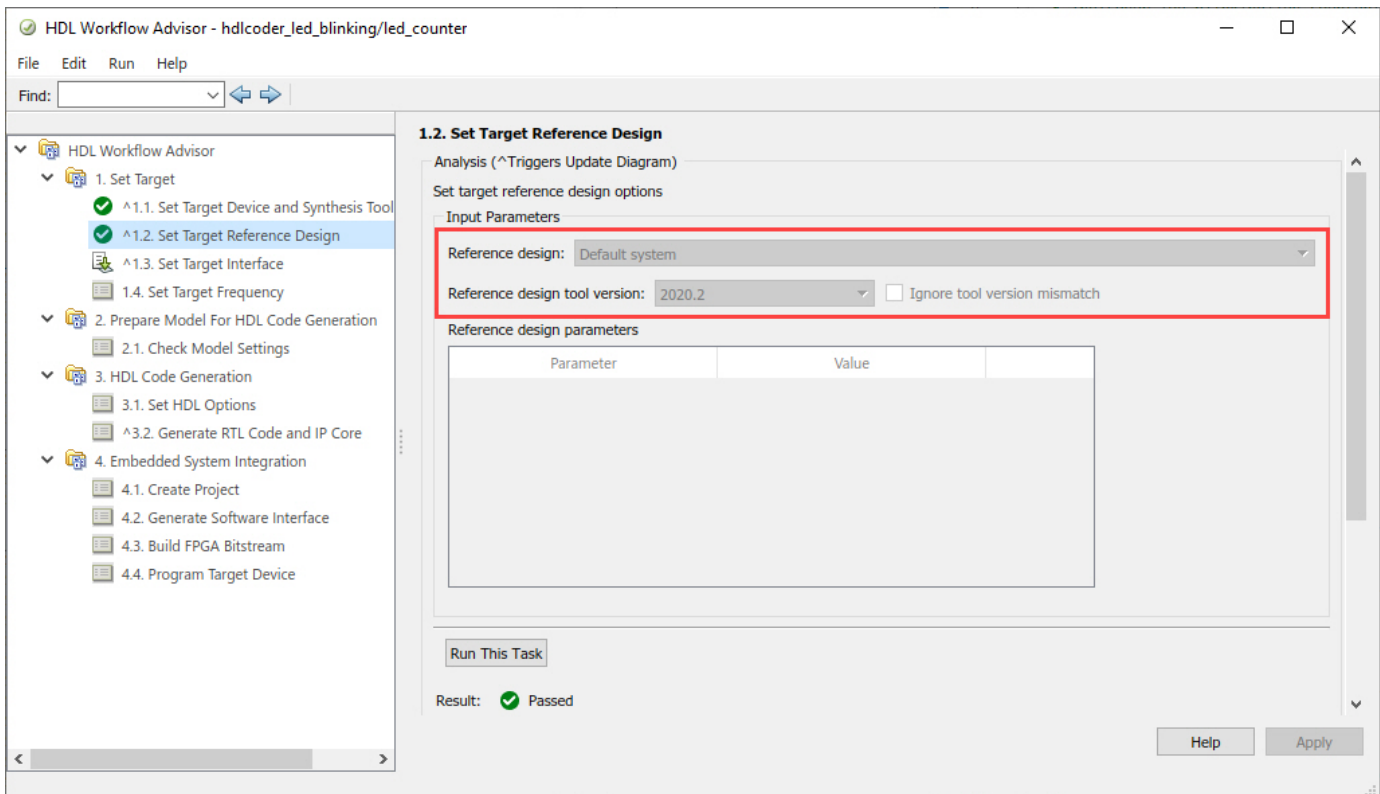

1.2. In the **Set Target** > **Set Target Device and Synthesis Tool** task, for **Target workflow**, select IP Core Generation.

1.3. For **Target platform**, select Xilinx Versal AI Core Series VCK190 Evaluation Kit. If you do not have this option, select **Get more** to open the Support Package Installer. In the Support Package Installer, select Xilinx Zynq Platform and follow the instructions provided by the Support Package Installer to complete the installation.

1.4. Click **Run This Task** to run the **Set Target Device and Synthesis Tool** task.

1.5 In the **Set Target > Set Target Reference Design** task, choose **Default** system.

1.6. Click **Run This Task** to run the **Set Target Reference Design** task.

2. Configure the target interface.

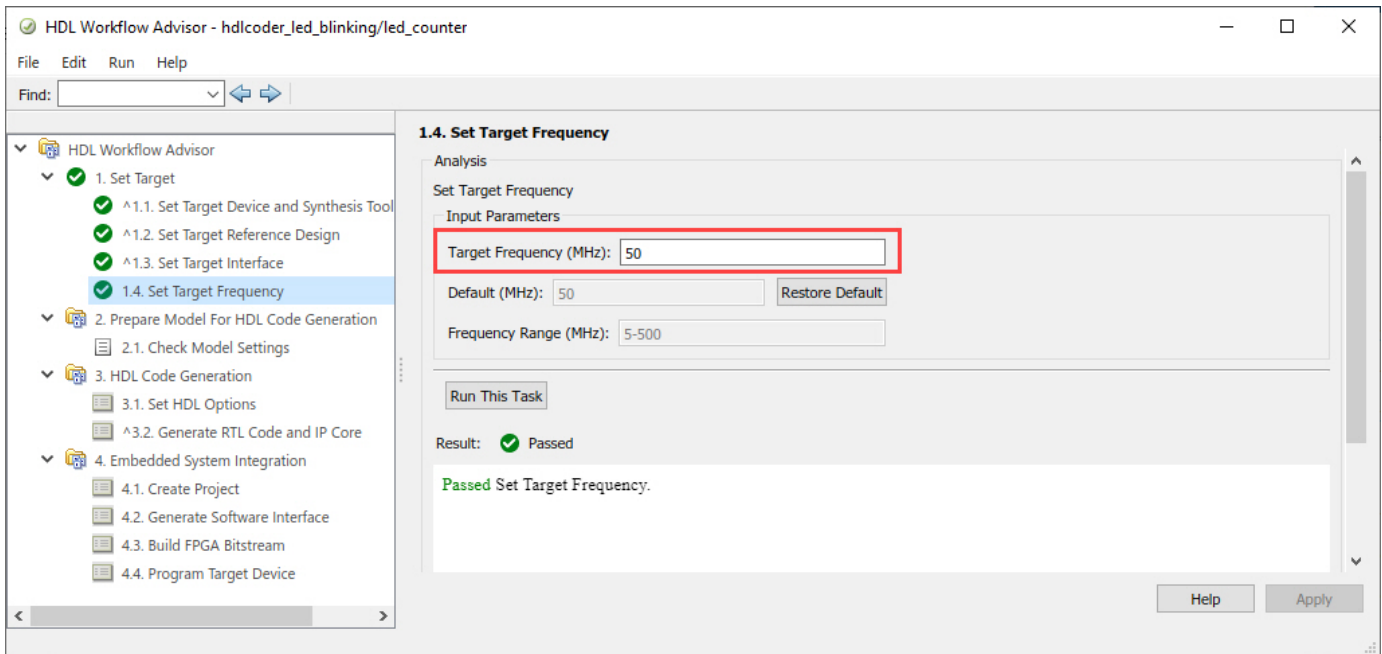

Map each port in your DUT to one of the IP core target interfaces. In this example, input ports **Blink_frequency** and **Blink_direction** are mapped to the AXI4-Lite interface, so HDL Coder generates AXI interface accessible registers for them. The **LED** output port is mapped to an external interface, **LEDs General Purpose [0:3]**, which connects to the LED hardware on the Zynq board.

2.1 In the **Set Target > Set Target Interface** task, choose AXI4-Lite for **Blink_frequency**, **Blink_direction**, and **Read_back**.

2.2 Choose LEDs General Purpose [0:3] for **LED**.

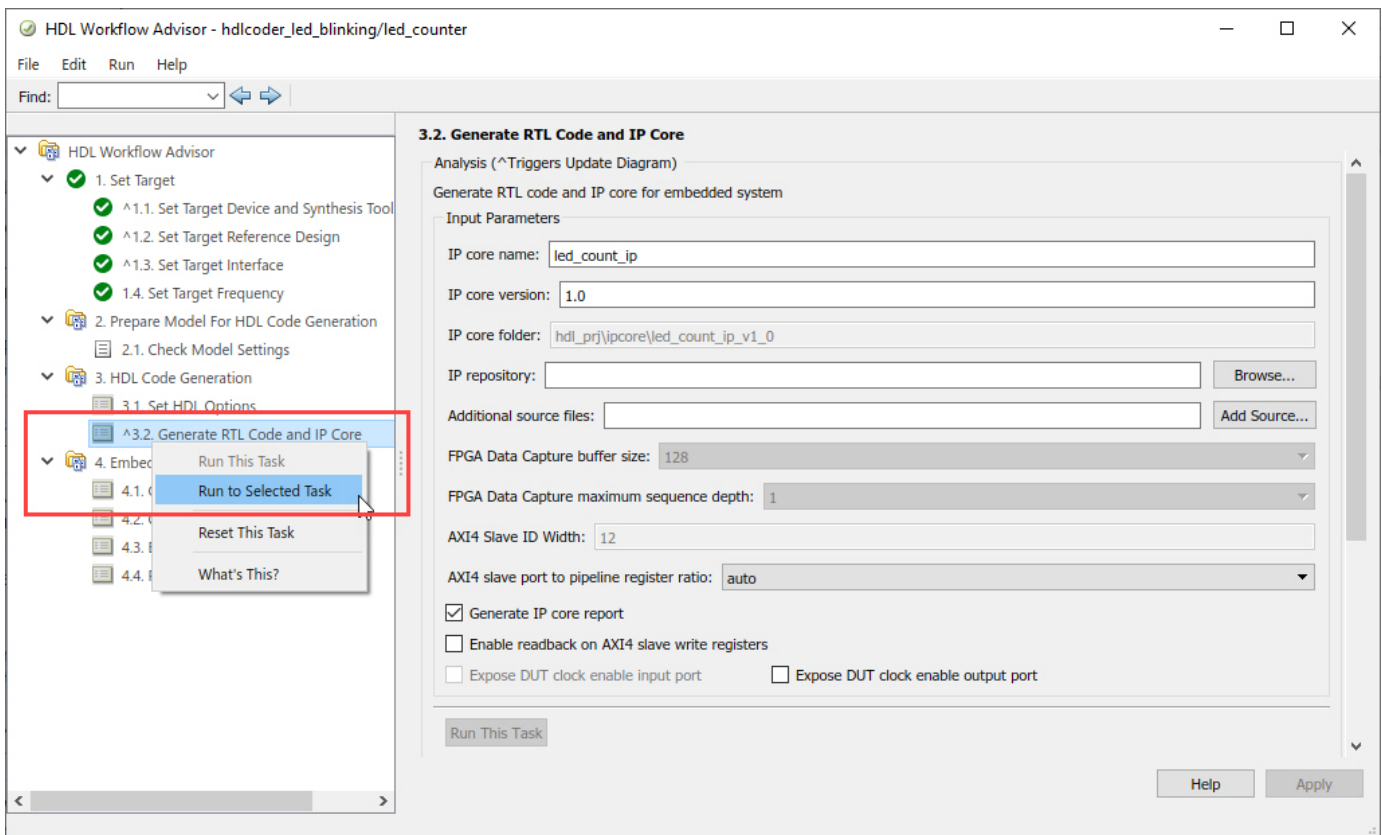

2.3 In the **Set Target > Set Target Frequency** task, set **Target Frequency** to 50 MHz.

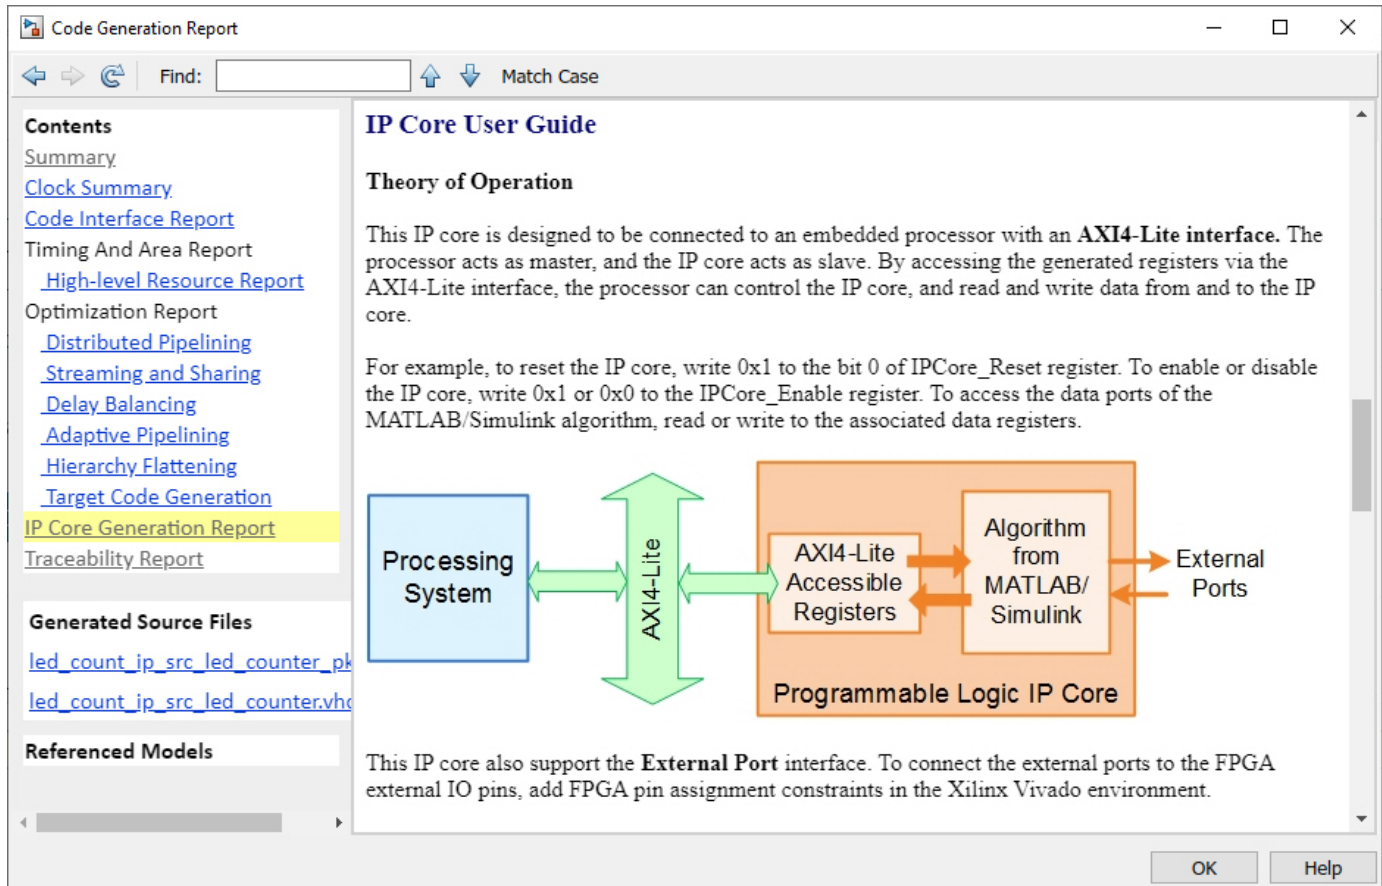

3. Generate the IP core.

To generate the IP core, right-click the **Generate RTL Code and IP Core** task and select **Run to Selected Task**.

4. Generate and view the IP core report.

After you generate the custom IP core, the IP core files are in the `ipcore` folder within your project folder. An HTML custom IP core report is generated together with the custom IP core. The report describes the behavior and contents of the generated custom IP core.

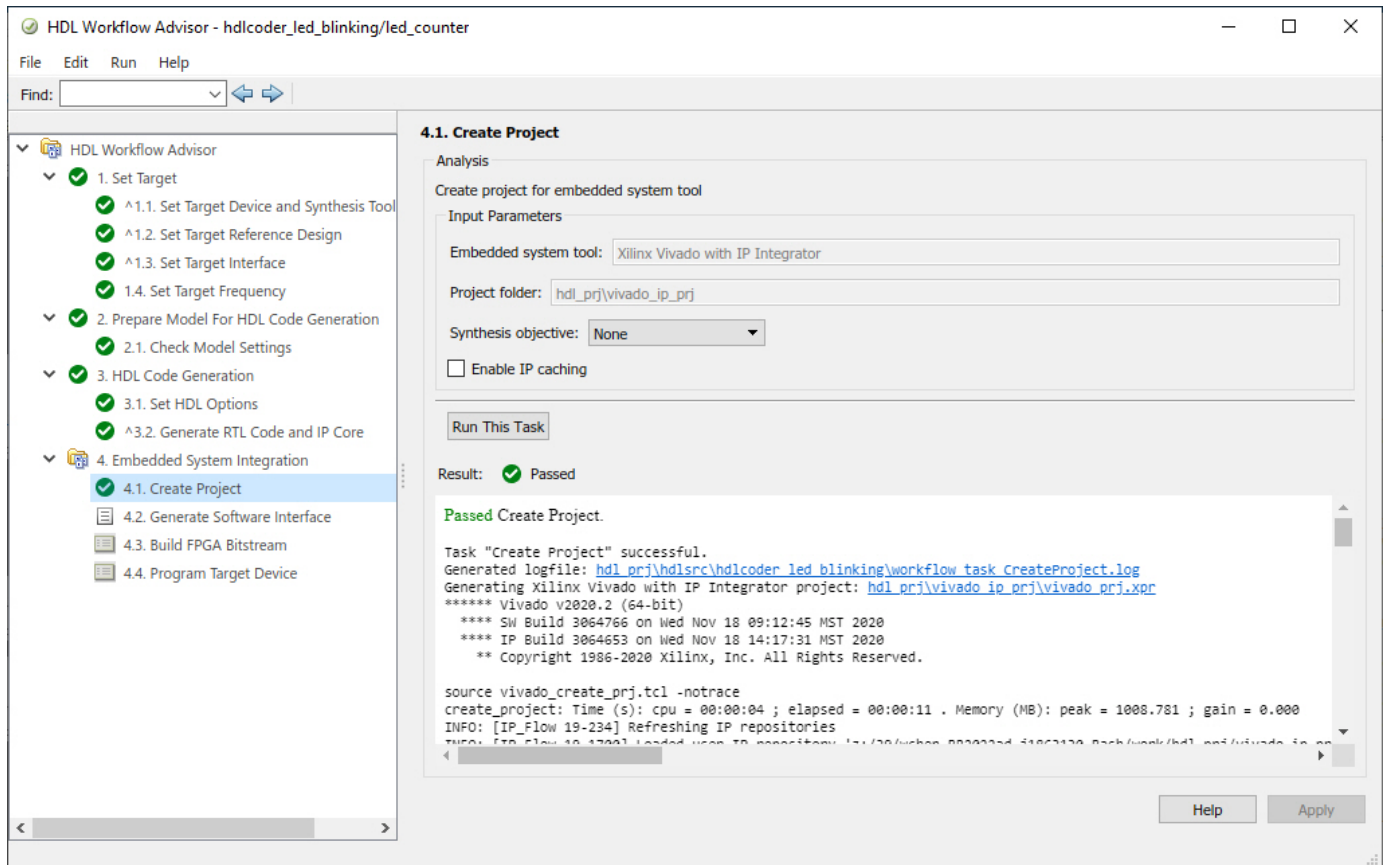

Integrate IP Core with Xilinx Vivado Environment

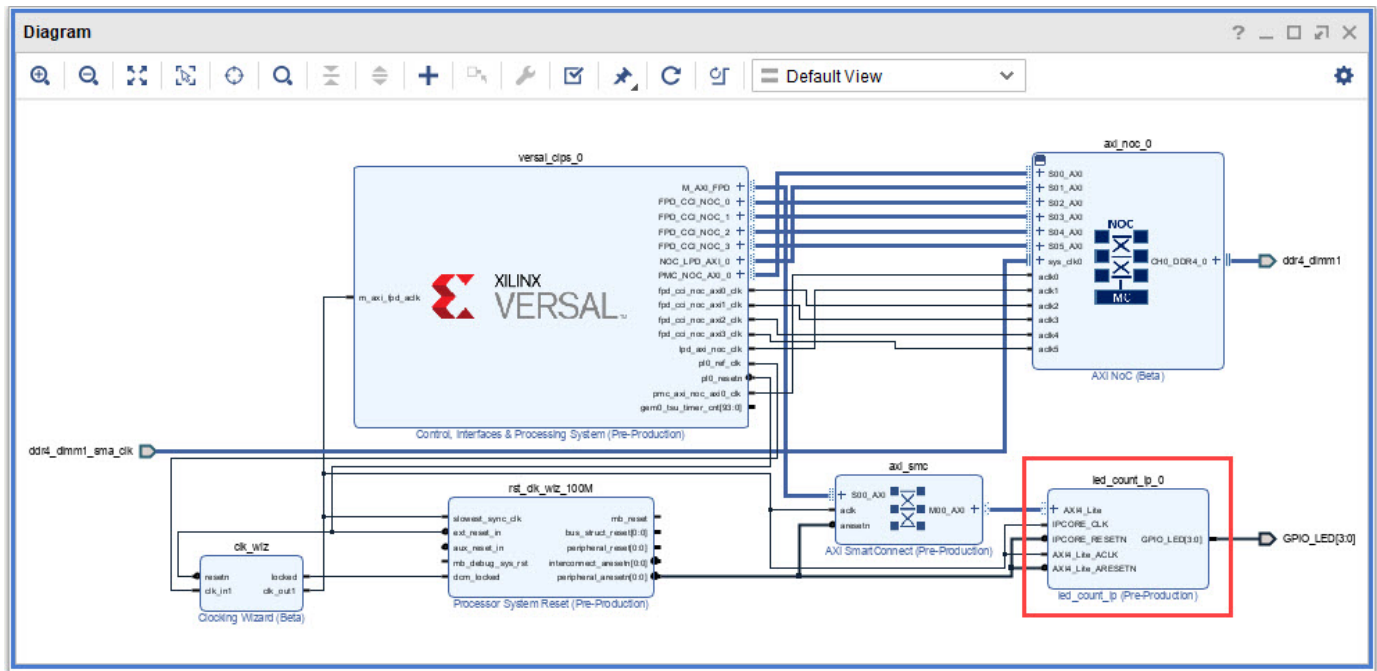

In this part of the workflow, you insert your generated IP core into an embedded system reference design, generate an FPGA bitstream, and download the bitstream to the Zynq hardware.

The reference design is a predefined Xilinx Vivado project. It contains all the elements the Xilinx software needs to deploy your design to the Versal platform, except for the custom IP core and embedded software that you generate.

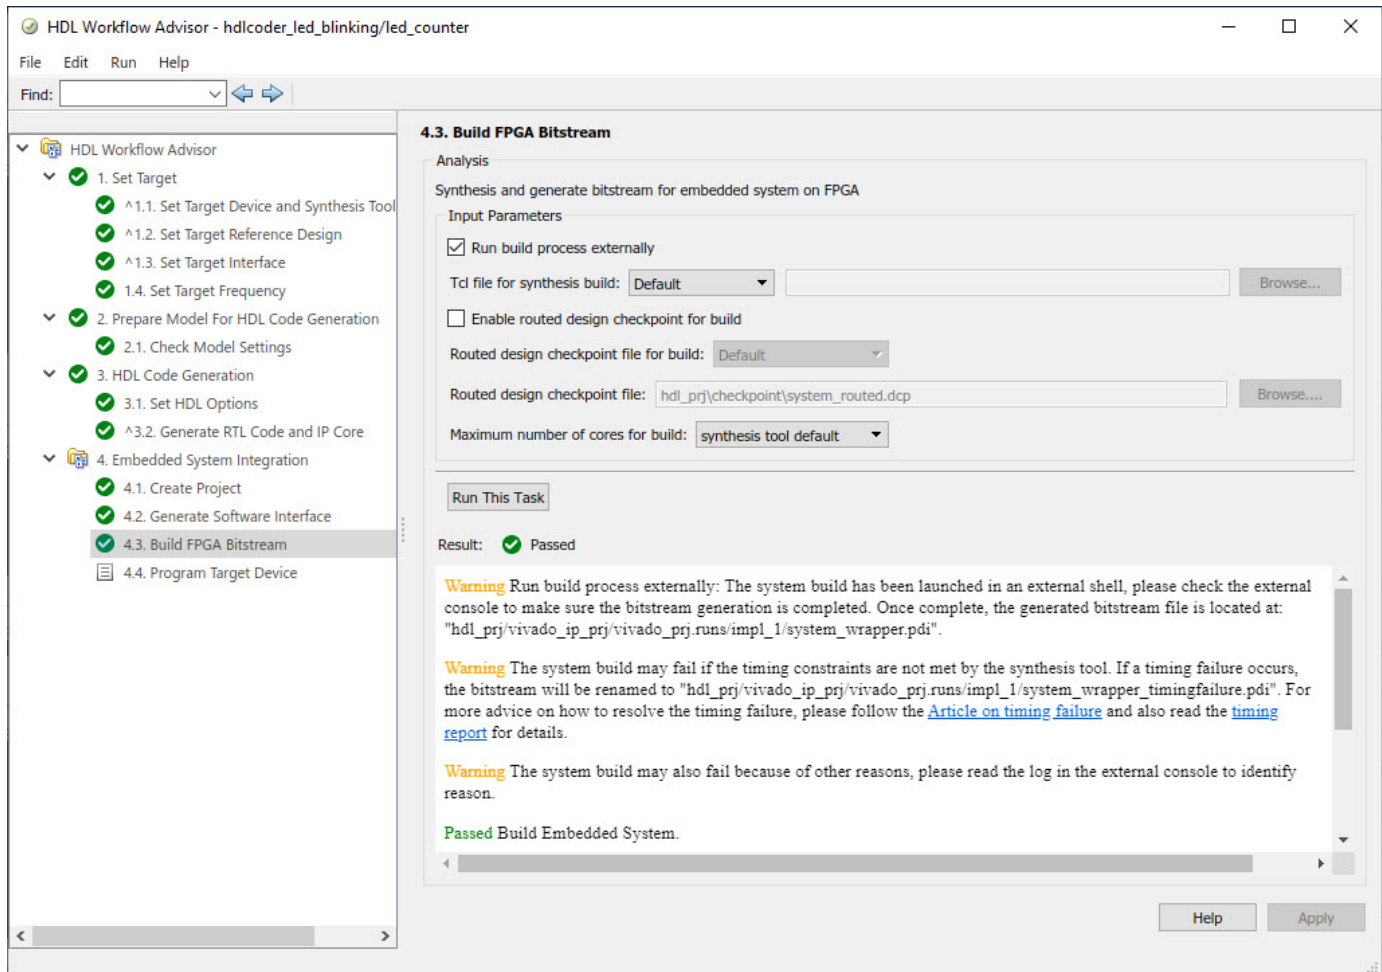

1. To integrate with the Xilinx Vivado environment, select the **Create Project** task under **Embedded System Integration** and click **Run This Task**. A Xilinx Vivado project with IP Integrator embedded design is generated.

A link to the project is provided in the dialog window. You can optionally open up the project to take a look. From the block diagram in Vivado tool, you can see the HDL Coder generated IP core `led_count_ip_0` is connected to the Processing System through the AXI interface.

2. Build the FPGA bitstream in the **Build FPGA Bitstream** task. Make sure the **Run build process externally** option is checked, so the Xilinx synthesis tool runs in a separate process from MATLAB. Wait for the synthesis tool process to finish running in the external command window.

3. After the bitstream is generated, select the **Program Target Device** task. Choose **JTAG** for **Programming method** to program the FPGA bitstream through JTAG to the Xilinx Versal VCK190 board. Click **Run This Task** to program the Versal hardware.

After you program the FPGA hardware, the LED starts blinking on your Xilinx Versal VCK190 board.

Tune Parameters and Capture Results on Versal VCK190 Hardware

When you are prototyping and developing an algorithm, you can monitor and tune the algorithm while it runs on hardware. In this example, you can tune parameters and capture results through JTAG using the Xilinx System Debugger (XSDB) tool.

1. Start the XSDB console by running the following command in MATLAB:

```
!xsdb &
```

2. In the XSDB console, run the following command:

```
connect
```

The XSDB connects to `hw_server`, and is ready to be used.

```
C:\WINDOWS\SYSTEM32\cmd.exe - xsdb

***** Xilinx System Debugger (XSDB) v2020.2
**** Build date : Nov 18 2020-10:01:48
** Copyright 1986-2020 Xilinx, Inc. All Rights Reserved.

xsdb% connect
attempting to launch hw_server

***** Xilinx hw_server v2020.2
**** Build date : Nov 18 2020 at 10:01:48
** Copyright 1986-2020 Xilinx, Inc. All Rights Reserved.

INFO: hw_server application started
INFO: Use Ctrl-C to exit hw_server application

***** Xilinx hw_server v2020.2

11 MicroBlaze PSM (Sleeping)
12 PMC
13 PL
14* DPC
```

4. Now you can read and write to AXI registers on the HDL Coder generated FPGA IP core. For example, you can use the `mrd` command to read out register values such as the IP core version register on address `0xA4000008`.

```
mrd 0xA4000008
```

You can use the `mwr` command to write to an AXI register such as the blink frequency register on address `0xA4000100` or the blink direction register on address `0xA4000104`.

```
mwr 0xA4000100 5
```

```
mwr 0xA4000104 1
```

You can observe the change in frequency and direction of the LED array blinking on the Versal hardware when you change the AXI register values.

```
xbdb% mrd 0xA4000008
A4000008: 83346E68

xbdb% mwr 0xA4000100 5
xbdb%

xbdb% mwr 0xA4000104 1
xbdb% disconnect
xbdb% Info: tcfchan#0 closed

“Read Back Value of AXI4 Slave Interfaces” on page 47-10

“Optimize AXI4 Slave Read Logic” on page 47-12

To perform lightweight data transfer or to access control registers, use AXI4 slave interfaces. The AXI4 slave interfaces include the AXI4 and AXI4-Lite interfaces. With the HDL Coder software, you don't have to implement AXI4 or AXI4-Lite protocol in your model. The software generates AXI4 or AXI4-Lite interfaces in the HDL IP core.

When you model your design, specify the data ports, you want to map to the AXI4 slave interfaces. HDL Coder then maps the data ports to memory-mapped registers and allocates address offsets for the ports.

Considerations

When you map your DUT ports to AXI4 or AXI4-Lite interfaces:

- You can map all scalar, vector, or bus ports in your design to either AXI4 or AXI4-Lite interfaces.
- You cannot map some DUT ports to AXI4 interfaces and other DUT ports to AXI4-Lite interfaces for the same design.

Map Scalar Ports to AXI4 Slave Interface

When you use scalar data types at the DUT interface ports, you can directly map the interface ports to AXI4 or AXI4-Lite interfaces. The code generator assigns a unique address to each data port that you want to map to the AXI4 interface.

For an example that shows how to map scalar ports to AXI4-Lite interfaces, open the model `hdlcoder_led_blinking`.

```
open_system('hdlcoder_led_blinking')
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2012 The MathWorks, Inc.

In this model, the subsystem `led_counter` is the hardware subsystem. It models a counter that blinks the LEDs on an FPGA board. Two input ports, `Blink_frequency` and `Blink_direction`, are control ports that determine the LED blink frequency and direction. All the blocks outside of the subsystem `led_counter` are for software implementation.

In Simulink, you can use the Slider Gain block or the Manual Switch block to adjust the hardware subsystem's input values. The ARM processor controls the generated IP core by writing to the AXI interface accessible registers in the embedded software. The output port of the hardware subsystem connects to the LED hardware. You can use the output port `Read_back` to read data back to the processor.

When you run the IP Core Generation workflow, in the **Set Target Interface** task, you see that the ports `Blink_frequency`, `Blink_direction`, and `Read_back` map to AXI4-Lite interfaces.

To learn more about this example, see:

- “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83
- “Getting Started with Targeting Intel SoC Devices” on page 46-122

Map Vector Ports to AXI4 Slave Interface

When you use vector data types at the DUT interface ports, you can directly map the interface ports to AXI4 or AXI4-Lite interfaces. The code generator assigns a unique address for each data port that you want to map to the AXI4 interface.

When you map vector ports, HDL Coder uses additional strobe registers for each port to maintain the synchronization with the IP core algorithm logic. For input ports, the strobe registers control the

enable signals for a set of shadow registers, making the IP core algorithm logic see the updated vector elements simultaneously. For output ports, the strobe registers make sure that the vector data to be read is captured synchronously.

For an example that shows how to map vector ports to AXI4-Lite interfaces, open the model `hdlcoder_led_vector`.

```
open_system('hdlcoder_led_vector')
```

In this model, the subsystem DUT implements the LED blinking algorithm and has vector output ports. When you run the IP Core Generation workflow, you see that the input ports and output ports map to AXI4-Lite interfaces in the **Set Target Interface** task.

To learn more, see “IP Core Generation Workflow with a MicroBlaze processor: Xilinx Kintex-7 KC705” on page 46-204.

Map Double Data Types and Data Larger than 32 bits to AXI4-Slave Interfaces

When your DUT port has double data types or data types with width greater than 32 bits, HDL Coder:

- Splits the data into individual 32 bit words to match the register width of the AXI4 or AXI4-Lite interface.
- Assigns each 32 bit word to an individual address. You can find the resulting start and end addresses in the IP Core Generation report under the Register Address Mapping section.
- Creates an additional strobe register to synchronize the data at the DUT boundary. The strobe logic behaves the same as the strobe register for vector ports. For more information on how vector ports are handled, see “Map Vector Ports to AXI4 Slave Interface” on page 47-4.

Learn how HDL Coder splits and maps data with bit widths greater than 32 bits to individual addresses. In this example model there are three input ports and three output ports:

- Input and output port one: Scalar with `uint64` datatype.
- Input and output port two: Scalar with `ufix45_En10` datatype.
- Input and output port three: Vector of three elements with 64 bit datatype.

This image shows the example DUT with the corresponding datatypes on the input and output ports. Each port is mapped to the AXI4 interface.

When HDL Coder processes the DUT it converts the data into 32 bit words and maps each 32 bit word to a specific address. This image shows the target interface configuration and register address mapping sections of the generated IP core report. The register address mapping section mentions the start address, number of 32 bit words and the final register address for data with bit widths greater than 32 bits.

Target platform interface table:

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
In1	Inport	uint64	AXI4	x"100"	
In2	Inport	ufix45_En10	AXI4	x"110"	
In3	Inport	double (3)	AXI4	x"120"	
Out1	Outport	uint64	AXI4	x"148"	
Out2	Outport	ufix45_En10	AXI4	x"158"	
Out3	Outport	double (3)	AXI4	x"180"	

Register Address Mapping

The following AXI4 bus accessible registers were generated for this IP core:

Register Name	Address Offset	Description
IPCore_Reset	0x0	write 0x1 to bit 0 to reset IP core
IPCore_Enable	0x4	enabled (by default) when bit 0 is 0x1
IPCore_Timestamp	0x8	contains unique IP timestamp (yymmddHHMM): 2301051005
In1_Data	0x100	data register for Inport In1. Data width is wider than the register width, so data is split into 2 32-bit sections. Register is split across a total of 2 addresses, last address is 0x104.
In1_Strobe	0x108	strobe register for port In1
In2_Data	0x110	data register for Inport In2. Data width is wider than the register width, so data is split into 2 32-bit sections. Register is split across a total of 2 addresses, last address is 0x114.
In2_Strobe	0x118	strobe register for port In2
In3_Data	0x120	data register for Inport In3. Vector with 3 elements. Data width is wider than the register width, so data is split into 2 32-bit sections. Register is split across a total of 6 addresses, last address is 0x134.
In3_Strobe	0x140	strobe register for port In3
Out1_Data	0x148	data register for Outport Out1. Data width is wider than the register width, so data is split into 2 32-bit sections. Register is split across a total of 2 addresses, last address is 0x14C.
Out1_Strobe	0x150	strobe register for port Out1
Out2_Data	0x158	data register for Outport Out2. Data width is wider than the register width, so data is split into 2 32-bit sections. Register is split across a total of 2 addresses, last address is 0x15C.
Out2_Strobe	0x160	strobe register for port Out2
Out3_Data	0x180	data register for Outport Out3. Vector with 3 elements. Data width is wider than the register width, so data is split into 2 32-bit sections. Register is split across a total of 6 addresses, last address is 0x194.
Out3_Strobe	0x1A0	strobe register for port Out3

For input port one the 64 bit data is split into two 32 bit words. The two words are mapped to addresses 0x100 and 0x104 . Bits zero through 31 are mapped to 0x100 and bits 32 through 63 are mapped to 0x104. Output port one is split across addresses 0x148 and 0x14C.

For input port two the 45 bit data is split into two 32 bit words. The two words are mapped to addresses 0x110 and 0x114 . Bits zero through 31 are mapped to 0x110 and bits 32 through 63 are mapped to 0x114. Output port two is split across addresses 0x158 and 0x15C.

For input port three, each vector element is split into two 32 bit words. This results in a total of six 32 bit words for the entire vector. The six words are mapped to the addresses 0x120, 0x124, 0x128, 0x12C, 0x130, and 0x134.

- Bits zero through 31 of the first vector element are mapped to 0x120.
- Bits 32 through 63 of the first vector element are mapped to 0x124.
- Bits zero through 31 of the second vector element are mapped to 0x128.
- Bits 32 through 63 of the second vector element are mapped to 0x12C.
- Bits zero through 31 of the third vector element are mapped to 0x130.
- Bits 32 through 63 of the third vector element are mapped to 0x134.

Output port three is split into 6 32 bit words. The six words are mapped to addresses 0x180, 0x184, 0x188, 0x18C, 0x190, 0x194.

Limitations

HDL Coder does not support mapping::

- Bit widths greater than 128 bits to AXI4-Slave ports
- Complex number data to AXI4-Slave ports
- Shift register data to AXI4-Slave ports

Map Bus Data Types to AXI4 Slave Interface

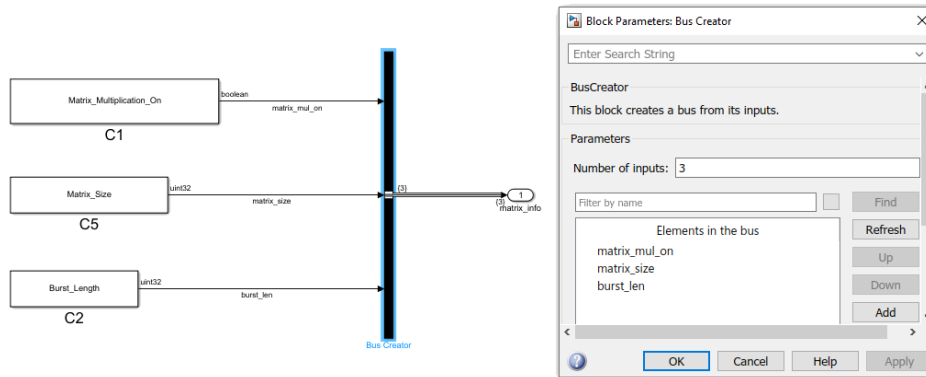

When you use bus data types at the DUT interface ports, you can directly map the interface ports to AXI4 or AXI4-Lite interfaces.

When you map bus data types, HDL Coder assigns a unique address for each data port that you want to map to the AXI4 interface. The top-level and sub-level buses do not have a register offset address. The address mapping for separate scalar or vector bus elements is not contiguous.

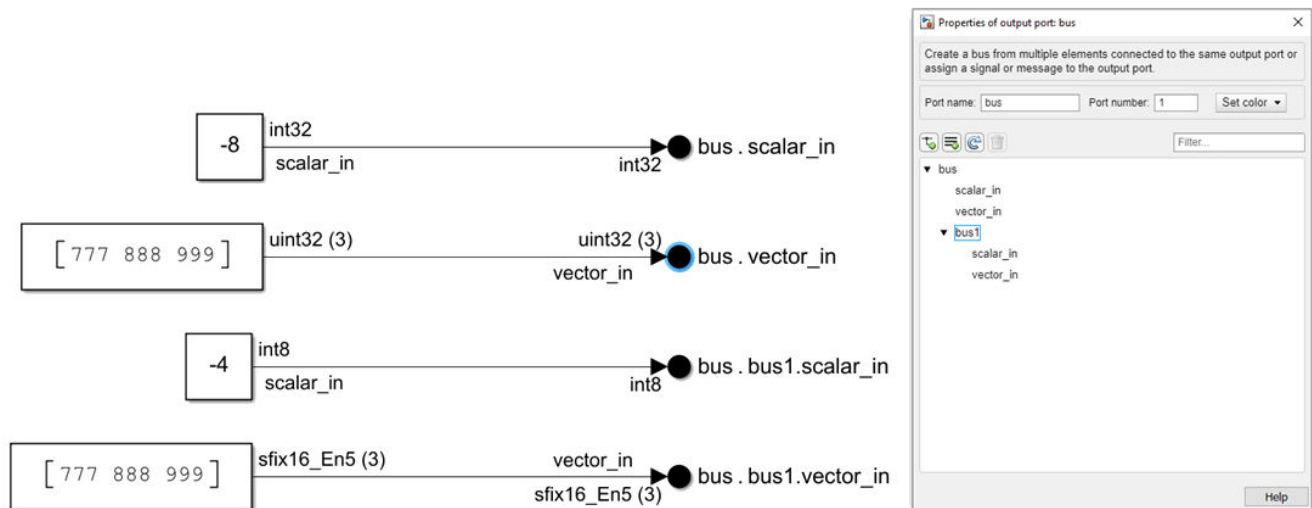

Model Bus Element

Model a bus element by using a bus creator block or bus element block to create a bus port.

Model a bus element by using a bus creator block.

Model a bus element by using bus element blocks:

For more information, see “Map Bus Data types to AXI4 Slave Interfaces” on page 46-227.

Specify Initial Value of AXI4 Slave Registers

When you run the IP Core Generation workflow or the Simulink Real-Time FPGA I/O workflow, you can specify an initial value for input ports mapped to the AXI4 slave registers. You can specify an initial value when mapping to these target interfaces:

- AXI4
- AXI4-Lite
- PCIe

By default, the initial value is zero. To specify a nonzero value:

- 1 In the target platform interface table, when you map an input DUT port to an AXI4 slave interface, an **Options** button appears in the **Interface Options** column.
- 2 Click the **Options** button, and then specify the **RegisterInitialValue**.

The specified value is saved on the DUT Inport blocks as the HDL block property **IOInterfaceOptions** in the **Target Specification** tab. For example, if you map a DUT input port to AXI4-Lite interface, set **RegisterInitialValue** to 5, and then run the **Set Target Interface** task, the **IOInterfaceOptions** property of that input port is saved with the value `{'RegisterInitialValue','5'}`.

To view the `IOInterfaceOptions` value, if the full path to your DUT port is `hdlcoder_led_blinking/led_counter/LED`, enter:

```
hdlget_param('hdlcoder_led_blinking/led_counter/LED',...
             'IOInterfaceOptions')
```

Specify the initial value for scalar ports.

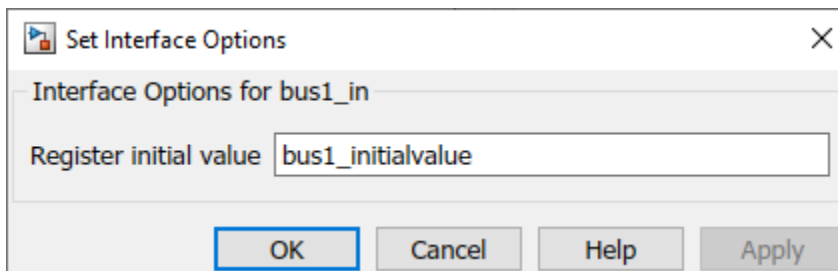

```
hdlset_param('hdlcoder_led_blinking/led_counter/LED', ...
             'IOInterfaceOptions', {'RegisterInitialValue','5'});
```

To set the initial value for a bus, specify a struct whose field names match the bus element names. For example,

You can also specify the initial value by using a variable defined in the MATLAB workspace. For example:

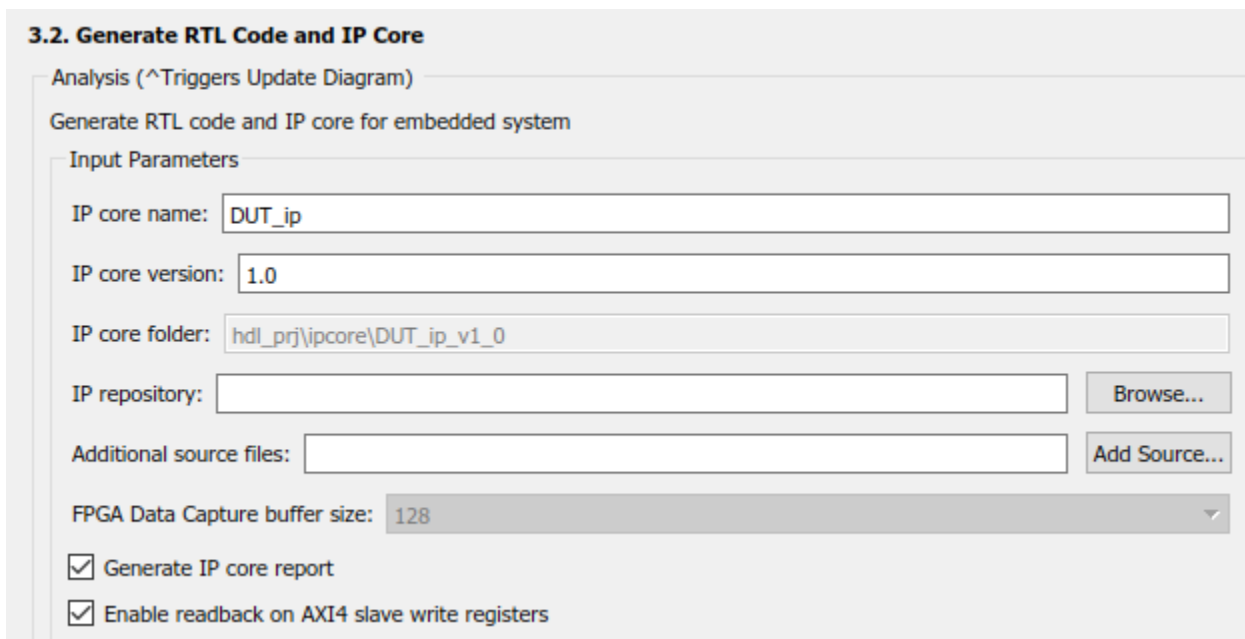

```
bus1_initialvalue = struct('scalar_in1',1,'scalar_in2',2,'scalar_in3',3,'scalar_in4',4,'vector_in',[1 3])
```

Read Back Value of AXI4 Slave Interfaces

When you run the IP Core Generation workflow, you can read back the value that is written to the AXI4 slave registers by using the AXI4 slave interface. For example, you can read back the values that are written to the AXI4 slave registers by using the `devmem` command in the Linux console of the ARM processor. If you have HDL Verifier installed, you can use the MATLAB as AXI Master IP to read back the values.

To use this capability, in the **Generate RTL Code and IP Core** task of the IP Core Generation workflow, select the **Enable read back on AXI4 slave write registers** check box, and then run the **Generate RTL Code and IP Core** task

When you run this task, HDL Coder saves the read back setting that you enabled on the model. In the HDL Block Properties of the DUT Subsystem, on the **IP Core Parameter** section of the **Target Specification** tab, you see a parameter **AXI4RegisterReadback** set to `on`. If you export the HDL Workflow Advisor run to a script, you see this setting saved on the model by using `hdlset_param`.

```
hdlset_param('hdlcoder_led_vector/DUT', 'AXI4RegisterReadback', 'on');
```

These examples show how you can read back values by using the `devmem` command in the Linux console with a program such as PuTTY.

To read back values when mapping scalar ports to AXI4 interfaces, you first write values to the AXI4 registers, and then read back the values. You can see the memory address of the AXI4 registers in the IP Core Generation report.

```
COM7 - PuTTY
zynq>
zynq>
zynq>
zynq> devmem 0x400d0100
0x00000000
zynq> devmem 0x400d0100 w 0x1
zynq> devmem 0x400d0100
0x00000001
zynq> devmem 0x400d0100 w 0x2
zynq> devmem 0x400d0100
0x00000002
zynq>
```

To read back values when mapping vector ports to AXI4 interfaces, you first write to the AXI4 registers, then write the strobe register address with 0x1, and then read back the values. You can see the memory address of the AXI4 registers and the strobe register in the IP Core Generation report.

```
COM7 - PuTTY
zynq>
zynq>
zynq>
zynq> devmem 0x400d0100
0x00000000
zynq> devmem 0x400d0104
0x00000000
zynq> devmem 0x400d0100 w 0x2
zynq> devmem 0x400d0110 w 0x1
zynq> devmem 0x400d0100
0x00000002
zynq> devmem 0x400d0104 w 0x3
zynq> devmem 0x400d0110 w 0x1
zynq> devmem 0x400d0104
0x00000003
zynq>
```

Optimize AXI4 Slave Read Logic

When your model contains several output registers and you want to read back data from multiple AXI4 slave registers, the read back logic becomes a long mux chain that can reduce the synthesis frequency. If you select the **Enable readback on AXI4 slave write registers** setting in the **Generate RTL Code and IP Core** task, HDL Coder adds a mux for each AXI4 register in the Address Decoder logic. As the number of AXI4 slave registers increases, the mux chain becomes longer, which further reduces the synthesis frequency.

You can optimize the readback logic and achieve the target frequency that you want. When you run the **IP Core Generation** workflow, in the **Generate RTL Code and IP Core** task, you see a setting **AX4 slave port to pipeline register ratio**. The default value of this setting is `auto`. This setting indicates how many AXI4 slave registers a pipeline register is inserted for. For example, an **AX4 slave port to pipeline register ratio** of 20 means that one pipeline register is inserted for every 20 AXI slave registers. The `auto` setting means that the code generator inserts a certain number of pipelines for the AXI4 slave ports depending on the number of ports and the synthesis tool that you specify. You can disable this setting or specify one of these valid values, `'off'`, `'10'`, `'20'`, `'35'`, `'50'`.

When you run this task, HDL Coder saves the value that you specified for the setting on the model. In the HDL Block Properties of the DUT Subsystem, on the **IP Core Parameter** section of the **Target Specification** tab, you see a parameter **AX4SlavePortToPipelineRegisterRatio** set to the value that you specified. If you export the HDL Workflow Advisor run to a script, you see this setting saved on the model by using `hdlset_param`.

```
hdlset_param('hdlcoder_led_vector/DUT', ...  
            'AXI4SlavePortToPipelineRegisterRatio', '20');
```

Model Design for AXI4-Stream Interface Generation

In this section...

“Sample-Based Modeling” on page 47-13
 “Frame-Based Modeling” on page 47-20
 “Legacy Frame-Based Modeling” on page 47-20
 “Model Designs with Multiple Streaming Channels” on page 47-21
 “Model Designs That Have Multiple Sample Rates” on page 47-21
 “Interface Options for AXI4-Stream Data” on page 47-22
 “Restrictions” on page 47-24

For designs that require high speed data transfers use AXI4-Stream interfaces. You can implement a simplified, streaming protocol in your model by using HDL Coder. The software generates AXI4-Stream interfaces in the IP core.

Choose from these three modeling styles based on how your algorithm operates:

- **Sample-Based Modeling** — Use these guidelines when your algorithm operates on a stream of samples.
- **Frame-Based Modeling** — Use these guidelines when your algorithm operates on a complete frame of data. The data signals at the design under test (DUT) boundary can be vectors or matrices. Do not use this mode if you want to model the Valid and Ready signals.
- **Legacy Frame-Based Modeling** — Use these guidelines when your algorithm operates on a stream of samples and you want to simulate the data signal as a frame on the boundary of the design under test (DUT).

Note The **Legacy Frame-Based Modeling** style will be deprecated in a future release. If you want to model the Valid and Ready signals, use the sample-based modeling style.

Sample-Based Modeling

When you want to simulate the data signal as a stream of samples on the DUT boundary, model in sample-based mode. You can model the data signal as either a scalar or a vector. If you model the data signal as a vector, in the HDL Coder Workflow Advisor **Task 1.2.Set Target Interface > Interface Options** set the **Sample Packing Dimension** to All. HDL Coder packs the vector elements together and treats the vector as a single sample. You can specify how HDL Coder packs the data by using the “Packing Mode” on page 47-23. See “Sample Packing Dimension” on page 47-22.

Simplified Streaming Protocol

To map the design under test (DUT) ports to AXI4-Stream interfaces, use the simplified AXI4-Stream protocol. You do not have to model the actual AXI4-Stream protocol and instead can use the simplified protocol. When you run the IP Core Generation workflow, the generated HDL code contains wrapper logic that translates between the simplified protocol and the actual AXI4-Stream protocol. The simplified protocol requires fewer protocol signals, eases the handshaking mechanism between valid and ready signals, and supports bursts of arbitrary lengths.

Use the simplified AXI4-Stream protocol for write and read transactions. When you want to generate an AXI4-Stream interface in your IP core, in your DUT interface, implement these signals:

- Data
- Valid

Optionally, when you map scalar DUT ports to an AXI4-Stream interface, you can model these signals:

- Ready
- Other protocol signals, such as:
 - TSRTB
 - TKEEP
 - TLAST
 - TID
 - TDEST
 - TUSER

Data and Valid Signals

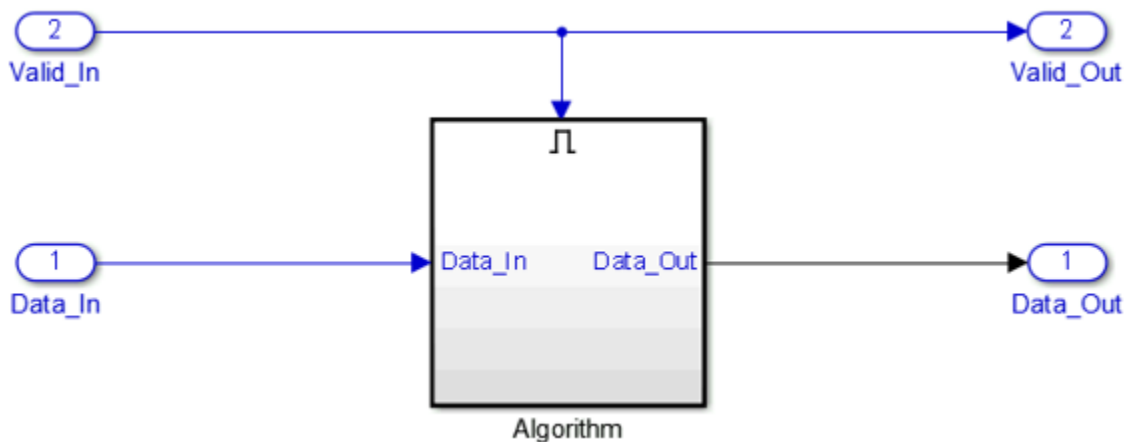

When the Data signal is valid, the Valid signal is asserted. This diagram illustrates the Data and Valid signal relationship according to the simplified streaming protocol. When you run the IP core generation workflow, HDL Coder adds a streaming interface module in the HDL IP core that translates the simplified protocol to the full AXI4-stream protocol. In this image, the clock signal is `clk`.

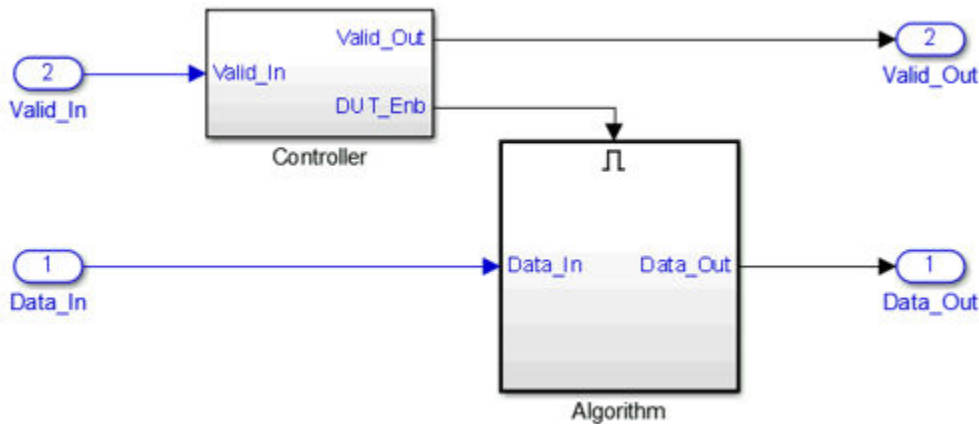

Model Data and Valid Signals in Simulink

- 1 Enclose the algorithm that processes the Data signal by using an enabled subsystem.
- 2 Control the enable port of the enabled subsystem by using the Valid signal.

For example, you can directly connect the Valid signal to the enable port.

You can also use a controller in your DUT that generates an enable signal for the enabled subsystem.

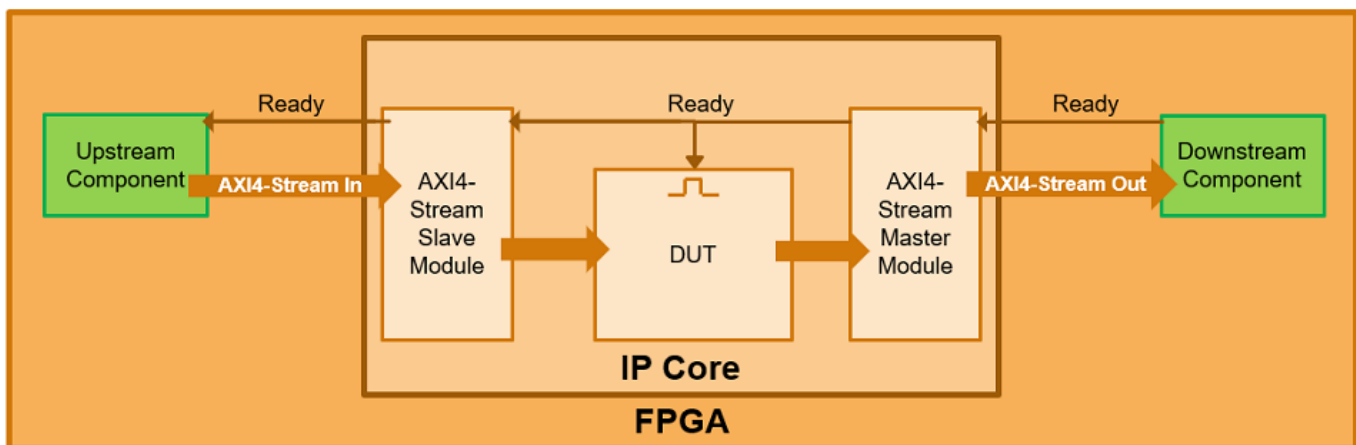

Ready Signal (Optional)

Downstream components use back pressure to tell upstream components they are not ready to receive data. The AXI4-Stream interfaces in your DUT can optionally include a Ready signal. Use the Ready signal to:

- Apply back pressure in an AXI4-Stream slave interface. For example, drop the Ready signal when the downstream component is not ready to receive data.
- Respond to back pressure in an AXI4-Stream master interface. For example, stop sending data when the downstream component Ready signal is low.

When you use a single streaming channel, by default, HDL Coder generates the Ready signal and the logic to handle the back pressure. The back pressure logic ties the Ready signal to the DUT Enable signal. When the input master Ready signal is low, the DUT is disabled, and the output slave Ready signal is driven low. Because HDL Coder generates the back pressure logic and Ready signal, when you use a single streaming channel, the Ready signal is optional and you do not have to model this signal at the DUT port.

When you use multiple streaming channels, HDL Coder generates a ready signal and does not generate the back pressure logic. In a DUT that has multiple streaming channels:

- The master channel ignores the Ready signal from downstream components.
- The slave channel Ready signal is high, which causes upstream components to continue sending data.

The absence of a back pressure logic might result in data being dropped. To avoid data loss and to apply back pressure on the slave interface or respond to back pressure from the master interface in your design:

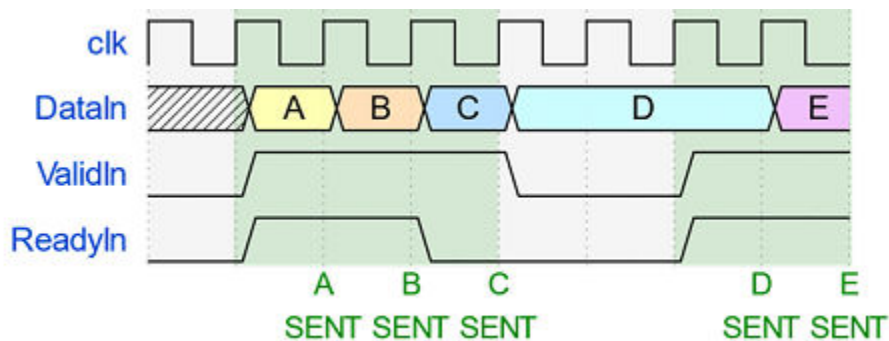

- Model the Ready signal for each additional stream interface.
- Map the modeled Ready signal to a DUT port for the additional interface.

When you do not model the Ready signal, the **Set Target Interface** task displays a warning that provides names of interfaces that require a Ready port. If your design does not require applying or responding to back pressure, ignore this warning.

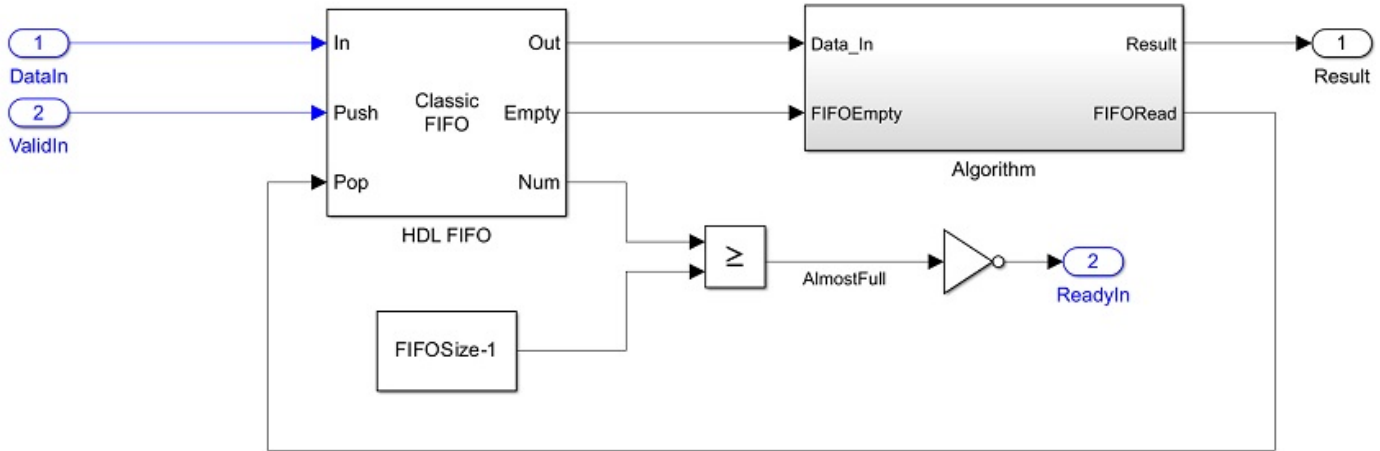

AXI4-Stream Input

This image illustrates the timing relationship between the Data, Valid, and Ready signals according to the simplified streaming protocol. In this image clock is `clk`. The AXI4-Stream Slave module sends the DataIn and ValidIn signals after asserting the ReadyIn signal from the DUT. This is represented by data packets A, B, D, and E in the image. When you drop the ReadyIn signal, the module always sends one more DataIn and ValidIn signal. This is represented by data packet C in the image. When you model the ReadyIn signal, the DUT must be able to accept one more value after de-asserting the ready signal.

For example, if you have a first in first out (FIFO) in your DUT to store a frame of data, to apply backpressure to the upstream component, model the Ready signal based on the FIFO almost full signal.

AXI4-Stream Output

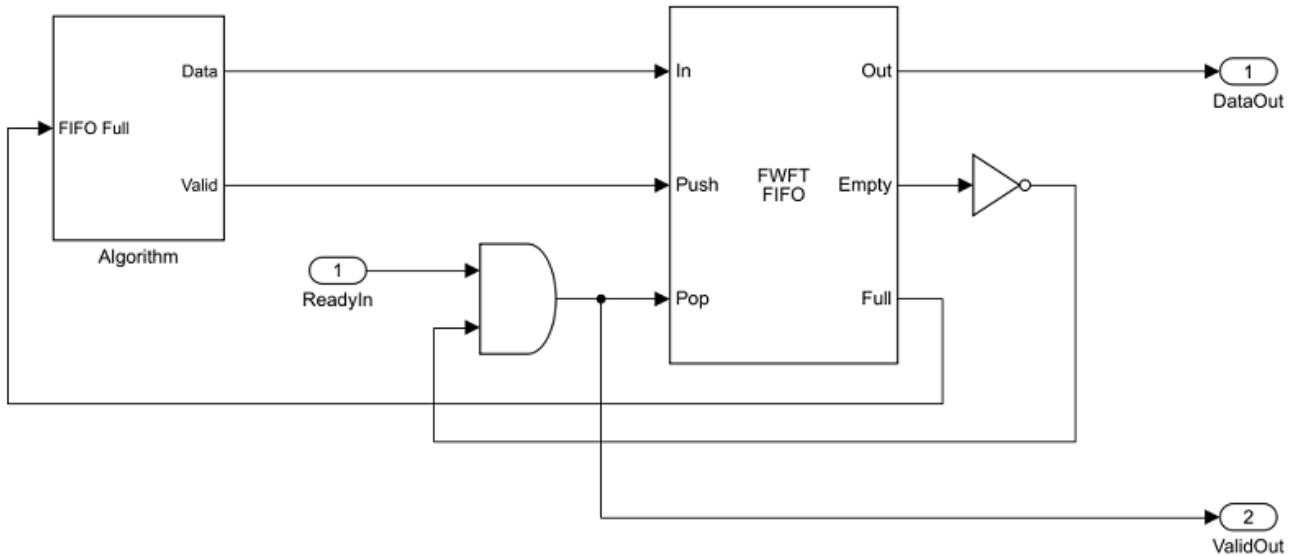

This image illustrates the timing relationship between the Data, Valid, and Ready signals according to the simplified streaming protocol. In this image clock is `clk`. You can send `DataOut` and `ValidOut` signals to the AXI4-Stream Master module after you assert the `ReadyOut` signal. This is represented by data packets A,B,E,F, and G in the image. You can optionally send one more `DataOut` and `ValidOut` signal after the `ReadyOut` signal drops. This is represented by data packet C in the image. You can only send one additional packet after the `ReadyOut` signal drops, subsequent data packets will be dropped until the `Ready` signal is asserted again. This is represented by data packet D in the image.

The optional one cycle latency between the `Valid` and `Ready` signals of the simplified streaming protocol allows you to use a classic or first word fall through (FWFT) FIFO to handle the backpressure from downstream components.

Downstream backpressure handling with FWFT FIFO

You can use a FWFT FIFO to store a frame of data and handle back pressure from downstream components by modeling the `ValidOut` signal as `ReadyOut` and FIFO not empty.

For a DUT using an FWFT FIFO there is zero latency for the Ready signal between upstream and downstream components. This image shows the timing relationship between the Data, Valid, and Ready signals. The clock signal is `clk`.

Downstream backpressure handling with Classic FIFO

If your DUT uses a classic FIFO to store a frame of data, model the ValidOut signal as ReadyOut and FIFO not empty.

This image shows the timing relationship between the Data, Valid, and Ready signals. The clock signal is `clk`.

If you do not model the Ready signal, HDL Coder generates the signal and the associated back pressure logic. When you generate the IP core, HDL Coder adds a streaming interface module in the HDL IP core that translates the simplified protocol to the full AXI4-Stream protocol.

Note If you enable delay balancing, the coder inserts one or more delays on the Ready signal. Disable delay balancing for the Ready signal path.

TLAST Signal (optional)

The AXI4-Stream interface on your DUT can optionally model a TLAST signal, which is used to indicate the end of a frame of data. If you do not model this signal, HDL Coder generates it for you. On the AXI4-Stream Slave interface, the incoming TLAST signal is ignored. On the AXI4-Stream Master interface, the autogenerated TLAST signal is asserted when the number of valid samples counts up to the default frame length value. The default frame length value can be set by using the AXI4-Stream interface options in the Target Interface Table. See “Interface Options for AXI4-Stream Data” on page 47-22.

When the IP core has an AXI4 Slave interface, the default frame length value is stored in a programmable register in the IP core. You can change the default frame length during run time.

When the default frame length register is changed in the middle of a frame, the TLAST counter state is reset to zero and the TLAST signal is asserted early. You can find the address for the programmable TLAST register in the IP core generation report.

Frame-Based Modeling

You can design your DUT to operate on frames of data and map the data ports to a streaming interface. To map frame ports (vectors, matrices, and complex matrices) to an AXI4-Stream interface use the frame-to-sample optimization. For more information, see “Model Design for Frame-Based IP Core Generation” on page 47-26.

Legacy Frame-Based Modeling

Design your algorithm to operate on a stream of samples and model the data signal as a vector. To operate in this mode in the HDL Coder Workflow Advisor **Task 1.2.Set Target Interface > Interface Options** set the **Sample Packing Dimension** to None.

Note This modeling style will be deprecated in a future release.

Data and Valid Signal Modeling Requirements

When you map vector ports to AXI4-Stream interfaces:

- Connect each DUT input vector data port to a Serializer1D block.

The Serializer1D block must have a ValidOut port and the Ratio set to the vector bit width.

- Connect each DUT output vector data port to a Deserializer1D block.

The Deserializer1D block must have a ValidIn port and the Ratio set to the vector bit width.

- Connect each scalar port that maps to an AXI4-Lite interface to a Rate Transition block.

The ratio in the Rate Transition block must match the ratio in the Serializer1D and Deserializer1D blocks.

- Each scalar port that maps to an external port must have the same sample time as the streaming algorithm subsystem.

The streaming algorithm subsystem follows the same Data and Valid signal modeling pattern as the pattern for mapping scalar ports to an AXI4-Stream interfaces. See “Model Data and Valid Signals in Simulink” on page 47-14. When you use frame-based modeling, you cannot use protocol signals other than Data and Valid. For example, Ready and TLAST are not supported.

Example

To map vector ports to AXI4-Stream interfaces, open the `hdlcoder_sfir_fixed_vector.slx` model. In the `hdlcoder_sfir_fixed_vector.slx` model, the `symmetric_fir` block is the streaming algorithm subsystem.

- Setting the AXI4-Stream master channel valid signal to high at the first cycle every N clock cycles. For example, if the design rate is eight times faster than the slow rate DUT ports, the valid signal is high for the first clock cycle every eight clock cycles.
- Asserting back pressure on the AXI4-Stream slave interface to make sure that the incoming data is streamed at the rate of one data frame every N clock cycles. For example, if the design rate is eight times faster than the slow rate DUT ports, the first frame is streamed at clock cycle one, the second frame at clock cycle nine, and so on.

When you map the AXI4-Stream Interface DUT port to the fastest rate in the design, the valid signal is high, making sure there is no back pressure on the AXI4-Stream slave interface.

When designing models that have multiple sample rates, for each AXI4-Stream interface, AXI4-Stream interface signals, such as data signals, valid signals and all the optional signals, need to be mapped at same rate.

To learn more, see “Multirate IP Core Generation” on page 47-64.

Interface Options for AXI4-Stream Data

When you run the IP Core Generation workflow on a model that has vector data, you can specify how the vector data is treated as a sample or as a frame by using the **Sample Packing Dimension**. When the vector data is treated as a sample, you can specify how the vector elements are packed together by using the **Packing mode** option.

When you run the IP Core Generation workflow on a model that has an AXI4-Stream interface with none of the signals mapped to TLAST, you can specify the TLAST register value by using the **DefaultFrameLength** option.

Default Frame Length

When you do not model the TLAST signal, specify the default frame length (TLAST) value for the AXI4 Stream Master interface. The TLAST signal is created for you in the generated IP core and the signal is asserted when the number of valid samples counts up to the value in the default frame length counter. When the generated IP core has an AXI4 Slave interface, HDL Coder generates the default frame length as a programmable register. When the default frame length register is changed in the middle of a frame, the TLAST counter state is reset to zero and the TLAST signal is asserted early. For more information, see “TLAST Signal (optional)” on page 47-19. When you do not select the **Generate default AXI4 slave interface** the default frame length is generated as a constant value and not as a programmable register.

Sample Packing Dimension

Specify if the vector data is treated as a sample or as a frame:

- None. This value is the default value. When you specify None, vectors are treated as frames and vector elements are streamed one after the other. For example, when the input is a six-by-one vector in the first clock cycle, the first vector element is streamed, the second vector element, in the second clock cycle, and so on. To use this mode, the model must contain a Serializer block for inputs and a Deserializer block for the outputs. The **Packing mode** is not available when the **Sample Packing Dimension** is set to None.
- All. When you specify All, the vectors are packed together and streamed in a single clock cycle. For example, when the input is a six-by-one vector, all vector elements are packed together and

streamed in a single clock cycle. In this case, you can specify how the vector elements are packed by using the **Packing mode** option.

Packing Mode

When you set **Sample Packing Dimension** to All, you can specify how HDL Coder packs vector elements, complex data, and complex vectors by specifying the **Packing Mode** parameter to either **Bit Aligned** or **Power of 2 Aligned**. This setting applies to the AXI4-Stream master and slave channels.

Non-Complex Vector Data Packing

- **Bit Aligned.** When you set the **Packing Mode** to this setting, HDL Coder packs the vector elements directly next to each other. If the packed bit width is less than the AXI4-Stream channel width, then pad the packed data with zeros to match the channel width.

For example, if the AXI4-Stream channel width is 256 bits, there are four vector elements, and the vector elements are 30 bits long, the total data width is 120 bits. When the packing mode is set to **Bit Aligned**, HDL Coder packs the AXI4-Stream data as shown in this diagram.

- **Power of 2 Aligned.** In this mode, the vector elements are first padded with zeros to the closest power of two boundary. Then, the padded elements are packed together. If the packed vector bit width is less than the AXI4-Stream channel width, then the packed data is padded with zeros to match the channel width.

For example, if the AXI4-Stream channel width is 256 bits, there are four vector elements, and the vector elements are 30 bits long, the total data width is 120 bits. When the packing mode is set to **Bit Aligned**, HDL Coder packs the AXI4-Stream data as shown in this diagram. When the packing mode is set to **Power of 2 Aligned**, HDL Coder packs the AXI4-Stream data as shown in this diagram.

Each vector element of bit width 30 is padded with zeroes of bit width two to extend the vector element width to 32, the nearest power of two boundary.

Complex Data Packing

When the input data is a complex number, HDL Coder pads the real and imaginary parts with zeroes to the closest power of two boundary. HDL Coder then packs the data together and pads the data with zeroes to match the channel width. For example, if the AXI4-Stream channel width is 64-bits and the complex data type is `ufix7`, HDL Coder packs the stream data as shown in this image:

HDL Coder pads the complex data with zeroes of bit width one to extend the real and imaginary data packets to a size eight, and then pads the data with zeroes of width 48 to extend the complex data frame size to 64, the AXI4-Stream channel width.

When you use the generated software interface model to stream complex data to the target board, you must pack the complex data as shown in the example images.

Complex Vector Data Packing

To model complex data signals as frames on the DUT boundary follow the frame-based modeling requirements. In this case, HDL Coder packs the complex data elements of the frame as described in the Complex Data Packing section.

Alternatively, if you want to treat the entire complex vector as a sample, follow the guidelines in the Sample Based Modeling section. HDL Coder sets the **Sample Packing Dimension** parameter to All and the **Packing Mode** parameter to Power of 2 Aligned.

For example, if the AXI4-Stream channel width is 64-bits, the complex data type is `fix7`, and the complex vector has three elements, HDL Coder packs the data as shown in this image:

HDL Coder pads the complex data with:

- Zeroes of bit width one after every real and imaginary vector element to extend the data size to eight, the nearest power of two boundary.
- Zeroes of bit width 16 at the end to extend the frame size to 64, the width of the AXI4-Stream channel.

When you use the generated software interface model to stream complex data to the target board, you must pack the complex data in the data packing format as shown in the example images.

Restrictions

When you map scalar or vector DUT ports to AXI4-Stream interfaces:

- Xilinx Zynq-7000 or Intel Quartus Prime must be your target platform.
- Xilinx Vivado or Intel Quartus Prime must be your synthesis tool.
- **Processor/FPGA synchronization** must be Free Running.

Model Design for Frame-Based IP Core Generation

In this section...

“Frame-Based Modeling for AXI4-Stream Interfaces” on page 47-26

“Frame-Based Modeling for AXI4-Stream Video Interfaces” on page 47-27

“Enable the Optimization” on page 47-28

“Modeling Requirements” on page 47-29

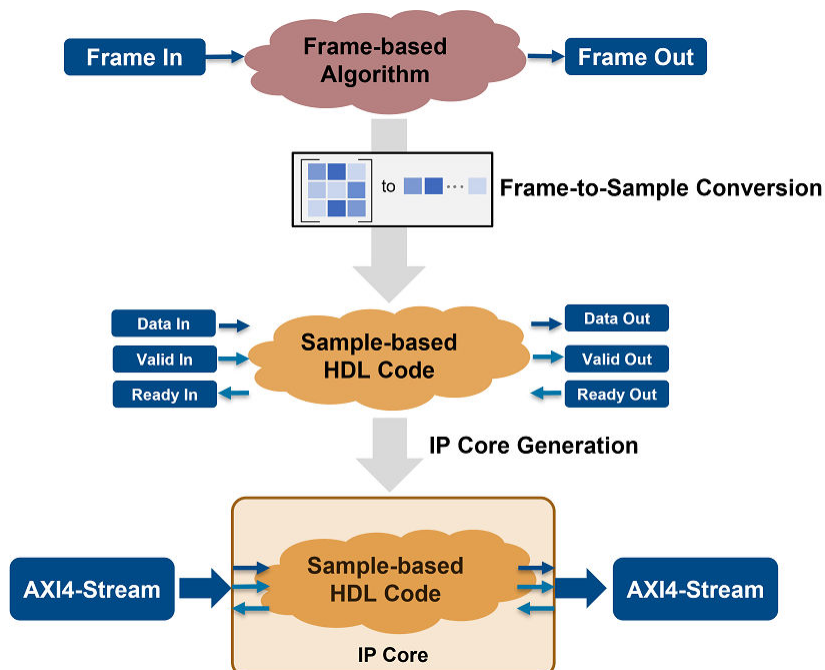

You can use the frame-to-sample optimization to generate IP cores for frame-based models. The frame-to-sample optimization maps matrices and vectors to the AXI4-Stream ports and matrices to AXI4-Stream Video interfaces, and then creates the necessary logic to handle the streamed data in the frame-based design.

Frame-Based Modeling for AXI4-Stream Interfaces

If your model includes streamed data, but does not process videos, you can use the frame-to-sample optimization to generate an IP core that operates on frames of data, then map the data ports to the streaming interface. You can then translate and implement your frame-based models on pixel-based hardware. See “HDL Code Generation from Frame-Based Algorithms” on page 29-2.

When you generate the IP core, you map the frame data ports at the DUT boundary to AXI4-Stream interfaces. HDL Coder generates the Valid and Ready signals for each port. This image shows a top-level overview of the frame-to-sample optimization and IP core generation.

Map vectors, complex vectors, matrices, and complex matrix data to AXI4-Stream interfaces by using frame-to-sample conversion optimization. The TLAST signal is created in the generated IP core and the signal is asserted when the number of valid samples counts to the frame size of the data port.

For an example on modeling a frame-based model with AXI4-Stream interfaces, see “Deploy a Frame-Based Model with AXI4-Stream Interfaces” on page 47-356.

To model your algorithm using a simplified streaming protocol and a sample-based DUT, see “Model Design for AXI4-Stream Interface Generation” on page 47-13.

Frame-Based Modeling for AXI4-Stream Video Interfaces

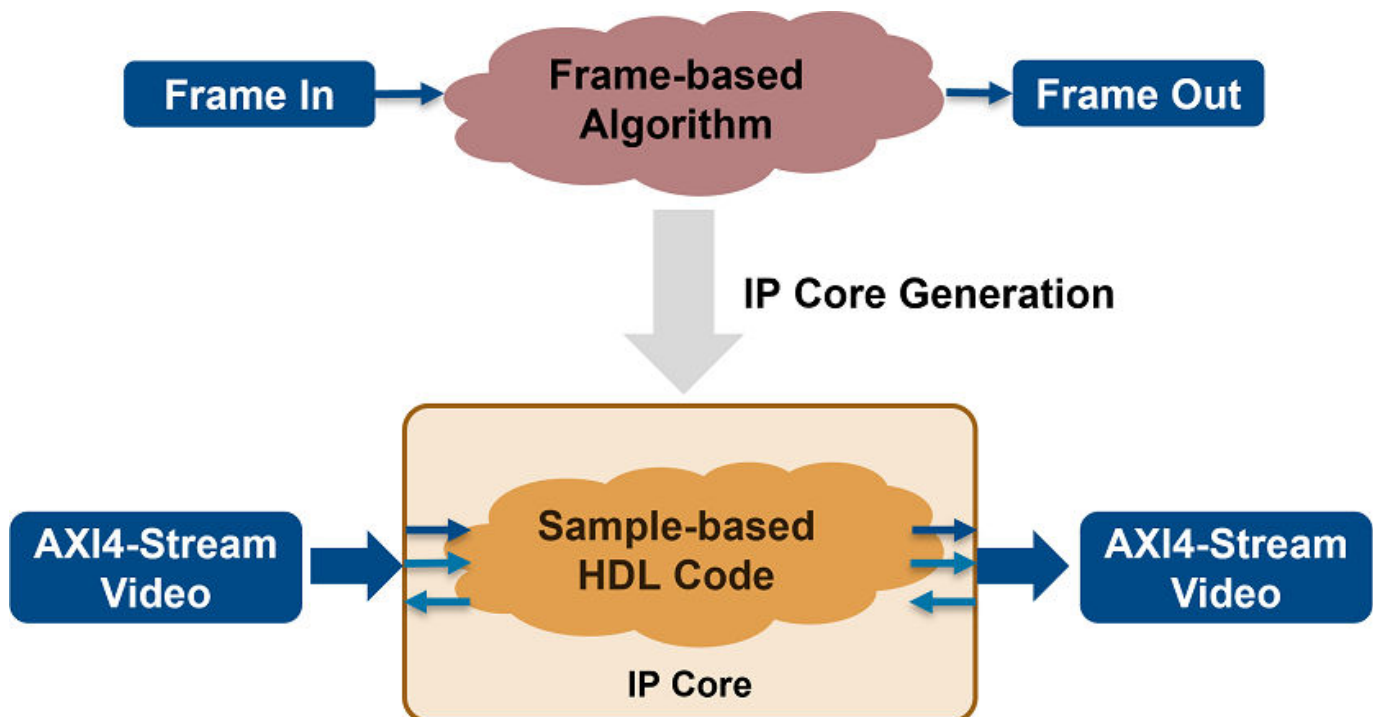

If your model includes streamed video ports, you can use the frame-to-sample optimization to map the two-dimensional matrix ports of your DUT to an AXI4-Stream Video interface. You can then prototype your algorithm in Simulink using frame-based modeling and test the functionality on live video inputs and outputs.

When you use the frame-to-sample optimization, HDL Coder:

- Converts the interface and generates the Data, Valid, and Ready signals for each port.
- Inserts the video porch and handles the start of frame (SOF) signal.

This image shows a top-level overview of the frame-to-sample optimization and IP core generation.

Map matrix ports to an AXI4-Stream Video interface by using the frame-to-sample optimization. The TUSER and TLAST signals are created during IP core generation. TUSER is asserted at the start of every frame and TLAST is asserted at the end of each line.

Video Porch Insertion Logic

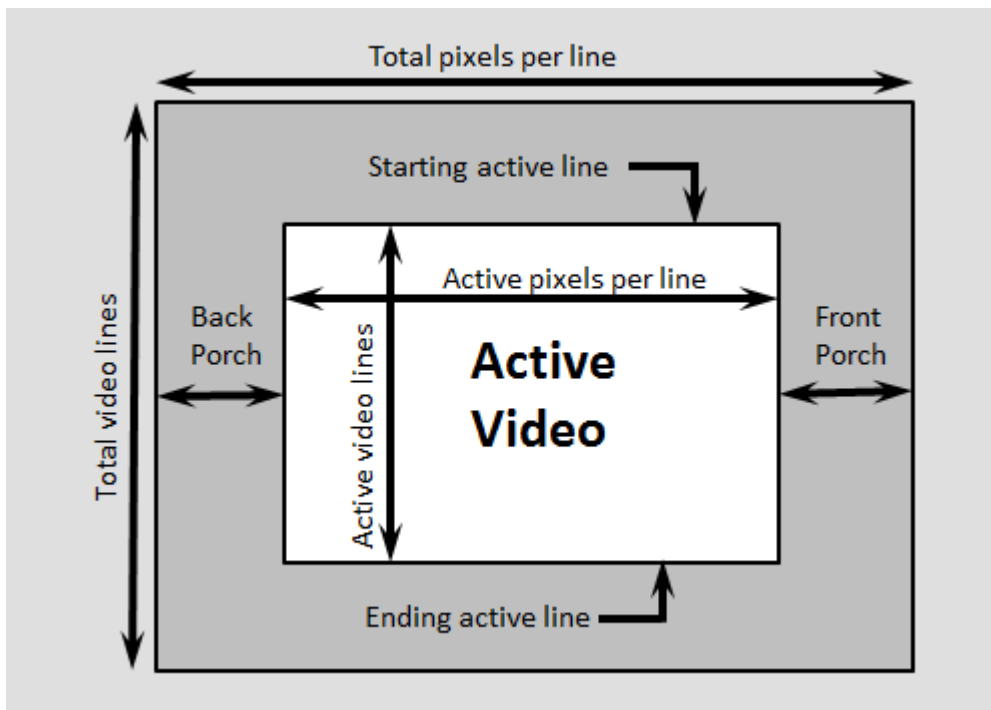

Video capture systems scan video signals from left to right and from top to bottom. As these systems scan, they generate inactive intervals between lines and frames of active video. This inactive interval is called a video porch. When you generate an IP core using frame-to-sample conversion, the active

pixels per line and the active lines in each frame are defined by the frame size of the frame-based model and they are not configurable at runtime. However, you can configure the horizontal and vertical porch. HDL Coder inserts vertical and horizontal porch to the pixel stream based on the AXI4-Lite registers in the generated IP core. You can customize these porch parameters for each video frame:

- Horizontal porch length (Default: 280)
- Vertical porch length (Default: 45)

The default values correspond to the porch values of a 1080p video frame.

This figure shows a video frame with the horizontal porch split into a front and a back porch.

To model your algorithm using a sample-based DUT and the streaming pixel protocol, see “Model Design for AXI4-Stream Video Interface Generation” on page 47-97.

For an example on modeling a frame-based model with AXI4-Stream Video interfaces, see “Deploy Frame-Based Models with AXI4-Stream Video Interfaces in Zynq-Based Hardware” on page 47-364.

Enable the Optimization

To use the frame-to-sample optimization:

- Enable the frame-to-sample optimization. See, “Enable frame to sample conversion” on page 19-34.
- Enable frame-to-sample optimization on the input data signal on the DUT that maps to the AXI4-Stream or AXI4-Stream Video interfaces. See, “Frame to Sample Conversion Parameters” on page 19-34.

Modeling Requirements

- Model only the Data signals. The frame-to-sample conversion optimization generates the Ready and Valid signals.
- Set the `SamplesPerCycle` parameter of the frame-to-sample optimization to 1. See “Frame to Sample Conversion Parameters” on page 19-34.

Generate HDL IP Core with Multiple AXI4-Stream and AXI4 Master Interfaces

When you run the generic IP Core Generation workflow for your Simulink model or target your own custom reference design that you authored, you can generate an HDL IP core with multiple AXI4-Stream interfaces, AXI4-Stream Video interfaces, or AXI4 Master interfaces. To learn about these interfaces, see “Target Platform Interfaces” on page 46-16.

Why Use Multiple AXI4 Interfaces

You can use multiple streaming interfaces to facilitate high-speed data transfer in various applications such as:

- Transferring data between A/D and D/A converters
- Software-defined radio algorithms that process multiple transceiver channels
- Vision algorithms that perform image annotation or object detection

Specify Multiple AXI4 Interfaces in Generic IP Core Generation Workflow

To specify more than one AXI4-Stream, AXI4-Stream Video, or AXI4 Master channel:

- 1 In the **Set Target Device and Synthesis Tool** task, select IP Core Generation as the **Target workflow** and Generic Xilinx Platform or Generic Altera Platform as the **Target platform**. Run this task.
- 2 To add multiple target interfaces, in the **Set Target Interface** task, on the **Target Platform Interfaces** section of the Target platform interface table, select **Add more ...**.

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
x_in_data	Inport	sfix16_E...	AXI4-Stream Slave	Data
x_in_valid	Inport	boolean	No Interface Specified	Valid
x_in_ready	Inport	boolean	AXI4	Ready (optional)
x_in_data1	Inport	sfix16_E...	AXI4-Stream Master	Data
x_in_valid1	Inport	boolean	AXI4-Stream Slave	Valid
x_in_ready1	Inport	boolean	External Port	
y_out_data	Output	sfix32_E...	AXI4 Master Read	
y_out_valid	Output	boolean	AXI4 Master Write	Valid
y_out_ready	Output	boolean	AXI4-Stream1 Master	Ready (optional)
y_out_data1	Output	sfix32_E...	AXI4-Stream1 Master	Data
y_out_valid1	Output	boolean	AXI4-Stream1 Slave	Valid
y_out_ready1	Output	boolean	Add more...	
			AXI4-Stream master	Data
			AXI4-Stream Master	Valid
			AXI4-Stream Slave	Ready (optional)
			AXI4-Stream1 Master	Data
			AXI4-Stream1 Master	Valid
			No Interface Specified	

- 3 You can then add more interfaces in the Add New Target Interfaces dialog box. Specify the type of interface you want to add, the number of interfaces, and a custom name for each additional interface.

After you apply the settings, the interfaces you created appear in the Target platform interface table. After you run this task, the additional interfaces specified are saved on the DUT subsystem as the HDL block property **AdditionalTargetInterfaces**.

If you modify the additional interfaces that were already mapped to DUT ports such as deleting or renaming an interface that was already mapped, the previous interface mapping information might be lost. The ports then become unmapped to interfaces and the **Target platform interfaces** section displays `No interface specified`. Therefore, if you make changes to the additional target interfaces, verify that the DUT ports are mapped to the correct target interfaces.

Specify Multiple AXI4 Interfaces in Custom Reference Designs

When you create your own custom reference design, you can add multiple AXI4-Stream, AXI4-Stream Video, and AXI4 Master interfaces. Depending on the interface type you want to add, specify additional interfaces by using the `addAXI4StreamInterface`, `addAXI4StreamVideoInterface`, or `addAXI4MasterInterface` methods of the `hdlcoder.ReferenceDesign` class.

To add more interfaces, in the `plugin_rd` file, call the interface method each time you want to add more interfaces. This example shows how to add two AXI4-Stream interfaces.

```
function hRD = plugin_rd()
% Reference design definition

% Copyright 2017-2019 The MathWorks, Inc.

% Construct reference design object
hRD = hldcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');

hRD.ReferenceDesignName = 'Multiple Interface Reference Design';
hRD.BoardName = 'ZedBoard';
```

```

% Tool information
hRD.SupportedToolVersion = {'2019.1'};

% ...
% ...

% Add AXI4-Stream interface 1
hRD.addAXI4StreamInterface (...
    'MasterChannelEnable', true, ...
    'SlaveChannelEnable', true, ...
    'MasterChannelConnection', 'axi_dma_s2mm/S_AXIS_S2MM', ...
    'SlaveChannelConnection', 'axi_dma_mm2s/M_AXIS_MM2S', ...
    'MasterChannelDataWidth', 32, ...
    'SlaveChannelDataWidth', 32, ...
    'InterfaceID', 'AXI4-Stream1');

% Add AXI4-Stream interface 2
hRD.addAXI4StreamInterface (...
    'MasterChannelEnable', true, ...
    'SlaveChannelEnable', true, ...
    'MasterChannelConnection', 'ADC/S_AXIS_S2MM', ...
    'SlaveChannelConnection', 'DAC/M_AXIS_MM2S', ...
    'MasterChannelDataWidth', 32, ...
    'SlaveChannelDataWidth', 32, ...
    'InterfaceID', 'AXI4-Stream2');

% ...
% ...

```

When you run the IP Core Generation workflow and target the custom reference design Multiple Interface Reference Design, in the **Set Target Interface** task, you can map the DUT ports to AXI4-Stream1 Master and Slave channels and AXI4-Stream2 Master and Slave channels.

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
x_in_data	Inport	sfix16_E...	AXI4-Stream1 Slave	Data
x_in_valid	Inport	boolean	AXI4-Stream1 Slave	Valid
x_in_ready	Inport	boolean	AXI4-Stream1 Master	Ready (optional)
h_in1	Inport	sfix16_E...	AXI4-Lite	x"100"
h_in2	Inport	sfix16_E...	AXI4-Lite	x"104"
h_in3	Inport	sfix16_E...	AXI4-Lite	x"108"
h_in4	Inport	sfix16_E...	AXI4-Lite	x"10C"
x_in_data1	Inport	sfix16_E...	AXI4-Stream2 Slave	Data
x_in_valid1	Inport	boolean	AXI4-Stream2 Slave	Valid
x_in_ready1	Inport	boolean	AXI4-Stream2 Master	Ready (optional)
h_in5	Inport	sfix16_E...	AXI4-Lite	x"110"
h_in6	Inport	sfix16_E...	AXI4-Lite	x"114"

Note When you target your own custom reference design and map the additional interfaces to DUT ports in the **Set Target Interfaces** task, the additional interfaces are not saved on the model as the **AdditionalTargetInterfaces** HDL block property. Instead, the additional interfaces are saved on the custom reference design in the `plugin_rd.m` file.

You can also dynamically customize the reference design to specify the number of interfaces you want to add and the interface properties.

- 1 In the `plugin_rd` file, create a reference design parameter for the number of additional interfaces you want to add.
- 2 Create a callback function that has different choices for the number of interfaces you want to add and then reference the function in the `plugin_rd` file by using the `CustomizeReferenceDesignFcn` method of the `hdlcoder.ReferenceDesign` class.

To learn more, see “Customize Reference Design Dynamically Based on Reference Design Parameters” on page 47-83.

Ready Signal Mapping for Multiple Streaming Interfaces

When you use a single streaming channel, HDL Coder automatically generates the Ready signal and the associated back pressure logic.

If you use multiple streaming channels, HDL Coder does not automatically generate the back pressure logic. In this case, the Ready signal is generated but the master Ready signal at the input is ignored and the slave Ready signal at the output is tied to high value. The absence of a back pressure logic can result in samples being dropped. If you want your design to apply back pressure on the Slave interface or respond to back pressure from the Master interface, you must model the Ready signal for each additional interface and then map the port to the Ready signal for that interface. When you do not model, the **Set Target Interface** task displays a warning that provides names of interfaces that require a Ready port. If your design does not need to apply or respond to back pressure, you can ignore this warning and you do not have to model the Ready signal.

When using multiple AXI4-Stream interfaces, if you want your design to apply back pressure on the Slave interface or respond to back pressure from the Master interface, you must model the Ready signal for each additional interface and then map the port to the Ready signal for that interface. To learn how the back pressure logic is generated for a single streaming channel and how to model the Ready signal, see “Ready Signal (Optional)” on page 47-15.

Restrictions

- When you run the generic IP Core Generation workflow, you can specify the interface type and a custom interface ID for each additional interface. Other interface properties such as the data width cannot be customized and use default values. When you create your own custom reference design, you can customize the interface name and interface properties.
- When mapping your DUT ports to multiple AXI4-Stream interface channels, you can only use scalar ports. Vector ports can have at most one AXI4-Stream Master channel and one AXI4-Stream Slave channel.
- Xilinx Zynq-7000 or Intel Quartus Prime must be your target platform.
- **Processor/FPGA synchronization** must be Free running.

- Xilinx Vivado or Intel Quartus Prime must be your synthesis tool.

Running Audio Filter with Multiple AXI4-Stream Channels on ZedBoard

This example shows how to model an audio system with multiple AXI4-Stream channels and deploy it on a ZedBoard™ by using an audio reference design.

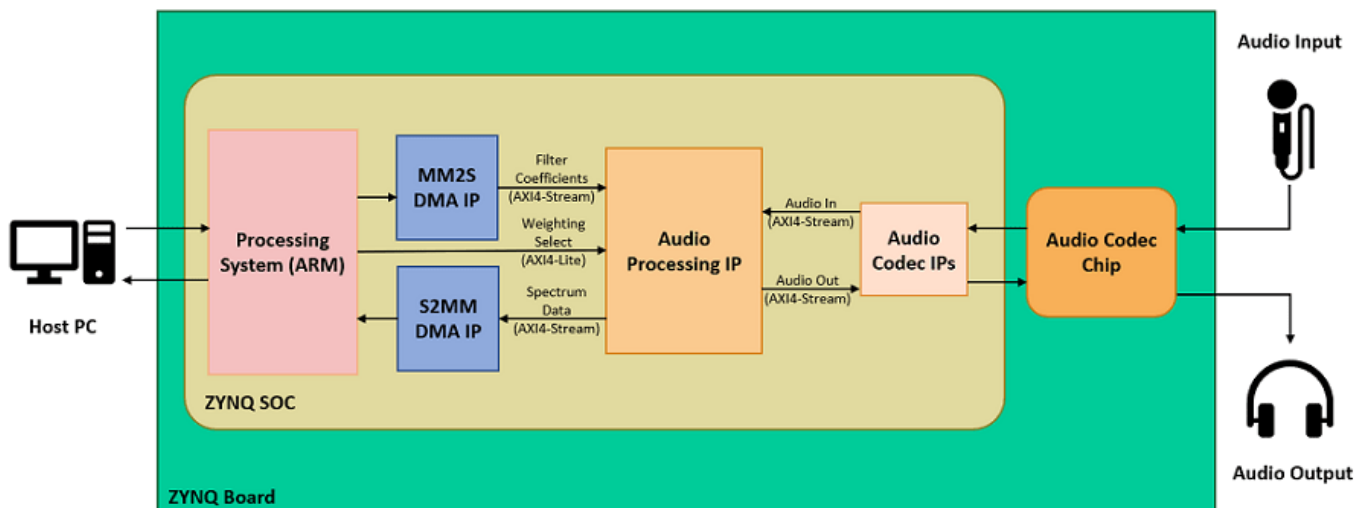

Introduction

In this example, you model a programmable audio filter with spectrogram using multiple AXI4-Stream channels and advanced AXI4-Stream signals Ready and TLAST. One AXI4-Stream channel transfers data between the filter and the audio codec. The other AXI4-Stream channel interfaces with the Processing System to program filter coefficients and transmit spectrogram data to the host computer for analysis.

You can then run the IP Core Generation workflow to generate an HDL IP core and deploy the algorithm on a ZedBoard by using an audio reference design.

System Architecture

This figure shows the high-level architecture of the system.

The **Audio Codec IPs** configure the audio codec and transfer audio data between the ZedBoard and audio codec. The Audio Processing IP generated by HDL Coder™ performs filtering and spectrum analysis. The DMA IPs transfer AXI4-Stream data between the Processing System and the FPGA. The stream data transmitted from the Processing System through the **MM2S DMA IP** programs the filter coefficients on the FPGA. The stream data received by the Processing System through the **S2MM DMA IP** contains the spectrogram data computed on the FPGA. The Processing System also configures the weighting curve for spectrum analysis using an AXI4-Lite interface.

Prerequisites

This example extends the audio filter on live input example to use multiple streaming channels. To learn about the example that uses a single streaming channel, see “Running an Audio Filter on Live Audio Input Using a Zynq Board” on page 47-161.

To run this example, you must have the following software and hardware installed and set up:

- HDL Coder Support Package for Xilinx® Zynq® Platform
- Embedded Coder® Support Package for Xilinx Zynq Platform
- Xilinx Vivado® Design Suite latest version, as mentioned in “HDL Language Support and Supported Third-Party Tools and Hardware”
- ZedBoard

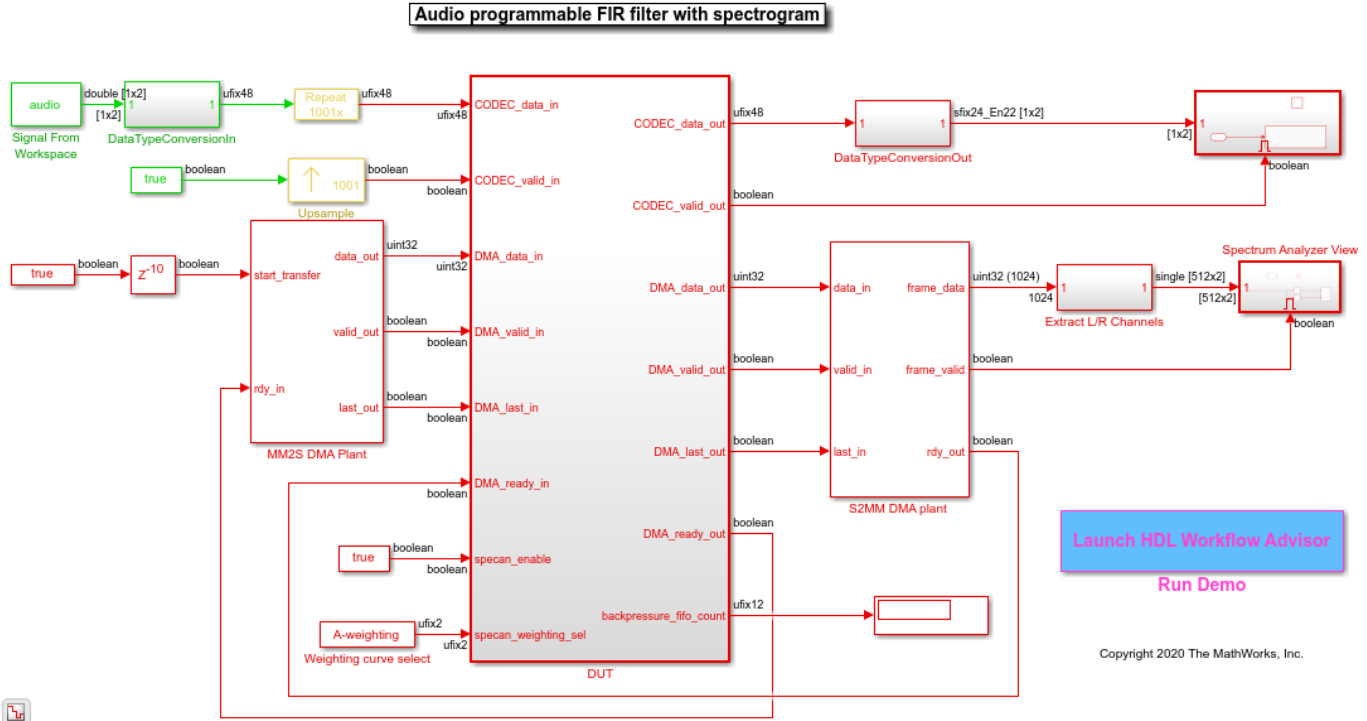

To setup the ZedBoard, refer to the *Set up Zynq hardware and tools* section in the “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 example. Connect an audio input from a mobile or an MP3 player to the **LINE IN** jack and either earphones or speakers to the **HPH OUT** jack on the ZedBoard as shown below.

Model Audio Processing Algorithm

Open the model `hdlcoder_audio_filter_multistream`.

```
open_system('hdlcoder_audio_filter_multistream')
set_param('hdlcoder_audio_filter_multistream', 'SimulationCommand', 'Update')
```

The model contains the DUT subsystem for audio processing, source and sink blocks for simulating the audio, and plant models for DMAs that transfer stream data between the Processing System and FPGA.

Rate Considerations

For audio applications running on the FPGA, the FPGA clock rate is several times faster than the audio sample rate. The ratio of the FPGA clock rate to the audio data sample rate is the **Oversampling factor**. In this example, the **Oversampling factor** is modeled by using Repeat and Upsample blocks.

Modeling your design at the FPGA clock rate allows you to optimize resource usage on the target hardware platform by leveraging idle clock cycles and reusing various components. The audio application illustrated in this example uses an audio sample rate of 48kHz and an FPGA clock rate of 96MHz. The **Oversampling factor** in this case is 2000. Such a large value of **Oversampling factor** slows down the Simulink® simulation significantly.

To reduce the simulation time, instead of using the **Oversampling factor** setting, you can model your design at the minimum **Oversampling factor** that is required by the design. The minimum required **Oversampling factor** for the design can be determined by the length of the audio filter, which is 1001. This value reduces the simulation time by half and provides sufficient idle cycles between the data samples for the serial filter logic.

Audio Filter

Inside the DUT subsystem, the FIR filter processes data from the audio codec AXI4-Stream channel. The filter coefficients are generated in MATLAB® and programmed by using the second AXI4-Stream interface that interfaces with the Processing System. The filtered audio output is streamed back to the audio codec.

The audio filter is a fully serial implementation of an FIR filter. This filter structure is best suited for audio applications that require large **Oversampling factor** because the filter uses a multiply accumulate (MAC) operation for each channel. The filter also uses RAM blocks to implement the data delay line and the coefficient source. This implementation saves area by avoiding the high slice logic usage of high-order filters.

Spectrum Analyzer

The audio signal is fed into a spectrum analyzer after passing through the FIR filter. The spectrum analyzer computes the FFT of the filtered signal, applies a weighting function, and converts the result to dBm. You can program the type of weighting to be performed by using the AXI4-Lite interface as either No-weighting, A-weighting, C-weighting, or K-weighting. The actual weighting functions are implemented using lookup tables that have been generated by using Audio Toolbox™ function `weightingFilter`.

Model AXI4-Stream Interfaces

The model contains two AXI4-Stream interfaces. One AXI4-Stream interface communicates with the audio codec. The other AXI4-Stream interface communicates with the Processing System through the DMAs. The audio codec interface only requires the `Data` and `Valid` signals. The DMA interface, on the other hand, additionally uses the `Ready` and `TLAST` signals of the AXI4-Stream protocol.

To learn more about the signals used in AXI4-Stream modeling, see “Model Design for AXI4-Stream Interface Generation” on page 47-13.

Ready Signal

In an AXI4-Stream interface, you use the `Ready` signal to apply or respond to back pressure. The model uses the `Ready` signal on the AXI4-Stream Master channel from the FPGA to the Processing System to respond to back pressure from the DMA. When the downstream DMA cannot receive more spectrogram samples, it de-asserts the input `Ready` signal on the AXI4-Stream Master channel. To ensure that the spectrogram samples are not dropped, the model buffers the data in a FIFO until the `Ready` signal is asserted, indicating that the DMA is ready to receive samples again.

The AXI4-Stream Slave channel from the Processing System to the FPGA does not have to apply back pressure, and hence its `Ready` signal is always asserted. The audio codec does not process back pressure and does not use its `Ready` signal on either channel. To learn more about the `Ready` signal in AXI4-Stream modeling, see “Ready Signal (Optional)” on page 47-15.

TLAST Signal

The `TLAST` signal is used to indicate the last sample of a frame. The model uses the `TLAST` signal on the AXI4-Stream Slave channel as an indicator that it has received a full set of filter coefficients. On the AXI4-Stream Master channel, the `TLAST` signal is used to indicate the end of a spectrum analyzer frame. To learn more about the `TLAST` signal in AXI4-Stream modeling, see “TLAST Signal (optional)” on page 47-19.

Customize the Model for ZedBoard

To implement this model on the ZedBoard, you must first have a reference design in Vivado that receives audio input on the ZedBoard and transmits the processed audio data out of the ZedBoard. For details on how to create a reference design which interfaces with the audio codec on the ZedBoard, see “Authoring a Reference Design for Audio System on a Zynq Board” on page 47-205. This example extends the reference design in that example by adding DMA IPs for communication with the Processing System.

In the reference design, left and right channel audio data are combined to form a single channel such that the lower 24 bits form the left channel and upper 24 bits form the right channel. In the Simulink model shown above, CODEC_data_in is split into left and right channels. Filtering is done on each channel individually. The channels are then concatenated to form a single channel for CODEC_data_out.

Generate HDL IP Core with AXI4-Stream Interfaces

Next, you can start the HDL Workflow Advisor and use the Zynq hardware-software co-design workflow to deploy this design on the Zynq hardware. For a more detailed step-by-step guide, you can refer to the Getting Started with HW/SW Co-design Workflow for Xilinx Zynq Platform example.

1. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', ...  
                'ToolPath', 'C:\Xilinx\Vivado\2019.1\bin\vivado.bat');
```

2. Add both the IP repository folder and the ZedBoard registration file to the MATLAB path using following commands:

```
unzip('ipcore.zip');  
unzip('ZedBoard.zip');  
addpath(genpath('ipcore'));  
addpath(genpath('ZedBoard'));
```

3. Open the HDL Workflow Advisor from the DUT subsystem, hdlcoder_audio_filter_multistream/DUT or double-click the **Launch HDL Workflow Advisor** box in the model.

The target interface settings are already saved for ZedBoard in this example model, so the settings in tasks **1.1** to **1.3** are automatically loaded. To learn more about saving target interface settings in the model, you can refer to the Save Target Hardware Settings in Model example.

4. Run the **Set Target Device and Synthesis Tool** task.

In this task, IP Core Generation is selected for **Target workflow**, and ZedBoard is selected for **Target platform**.

1.1. Set Target Device and Synthesis Tool

Analysis (^Triggers Update Diagram)

Set Target Device and Synthesis Tool for HDL code generation

Target workflow: IP Core Generation

Target platform: ZedBoard Launch Board Manager

Synthesis tool: Xilinx Vivado Tool version: 2019.1.1 Refresh

Family: Zynq Device: xc7z020

Package: clg484 Speed: -1

Project folder: hdl_prj Browse...

Run This Task

Result: ✔ Passed

Passed Set Target Device and Synthesis Tool.

5. Run the **Set Target Reference Design** task. Audio system with DMA Interface is selected as the **Reference Design**.

1.2. Set Target Reference Design

Analysis (^Triggers Update Diagram)

Set target reference design options

Input Parameters

Reference design: Audio System with AXI DMA interface

Reference design tool version: 2019.1 Ignore tool version mismatch

Reference design parameters

Parameter	Value
Insert JTAG MATLAB as AXI Master(H...	off

Run This Task

Result: ✔ Passed

Passed Set Target Reference Design.

6. Run the **Set Target Interface** task.

In this task, the ports of the DUT subsystem are mapped to the IP Core interfaces. The audio codec ports are mapped to the Audio Interface and the DMA ports are mapped to the AXI DMA interface. These are both AXI4-Stream interfaces. The AXI4-Stream interface communicates in master/slave

mode, where the master device sends data to the slave device. Therefore, if a data port is an input port, it is assigned to an AXI4-Stream Slave interface, and if a data port is output port, it is assigned to an AXI4-Stream Master interface. The exception to this is the **Ready** signal. The AXI4-Stream Master Ready signal is an input to the model, and the AXI4-Stream Slave Ready signal is an output of the model. The spectrum analyzer control ports are mapped to AXI4-Lite.

1.3. Set Target Interface

Analysis (^Triggers Update Diagram)

Set target interface for HDL code generation

Input Parameters

Processor/FPGA synchronization:

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
CODEC_data_in	Inport	ufix48	Audio Interface Slave	Data
CODEC_valid_in	Inport	boolean	Audio Interface Slave	Valid
DMA_data_in	Inport	uint32	AXI DMA Slave	Data
DMA_valid_in	Inport	boolean	AXI DMA Slave	Valid
DMA_last_in	Inport	boolean	AXI DMA Slave	TLAST (optional)
DMA_ready_in	Inport	boolean	AXI DMA Master	Ready (optional)
specan_enable	Inport	boolean	AXI4-Lite	x"100"
specan_weighting_sel	Inport	ufix2	AXI4-Lite	x"104"
CODEC_data_out	Output	ufix48	Audio Interface Master	Data
CODEC_valid_out	Output	boolean	Audio Interface Master	Valid
DMA_data_out	Output	uint32	AXI DMA Master	Data
DMA_valid_out	Output	boolean	AXI DMA Master	Valid

Run This Task

Result:  Passed

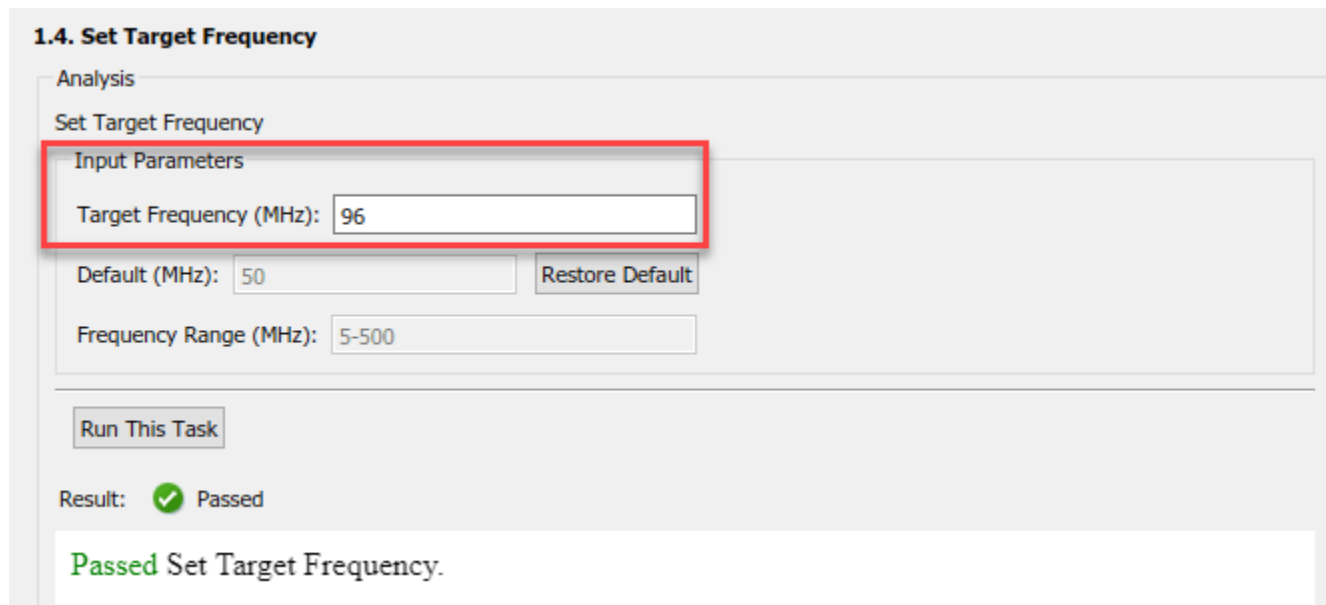

Warning Auto-generation of the Ready signal on AXI4-Stream interfaces has been disabled because multiple AXI4-Stream interfaces are in use. When multiple AXI4-Stream interfaces are in use and not all interfaces assign a port to the Ready signal, HDL Coder generates the signal, but does not generate back pressure logic, which can result in samples being dropped. Interfaces without their Ready port assigned are: Audio Interface Master, Audio Interface Slave. It is recommended that you model the Ready port on these interfaces if your design needs to apply back pressure on the Slave interface or respond to back pressure on the Master interface.

Passed Set Target Interface Table.

Running this task issues a warning that auto-generation of the **Ready** signal is disabled, and that the **Audio Interface** does not assign a **Ready** port. You can ignore the warning for this design, because back pressure has already been accounted for. Namely, the design addressed back pressure on the DMA interface by using a FIFO. On the audio codec interface, back pressure cannot be applied, so no **Ready** signal logic is needed.

7. In the **Set Target Frequency** task, set the **Target Frequency (MHz)** to 96. Run this task.

This target frequency value makes the **Oversampling factor** an even integer relative to the audio sample rate of 48kHz.

1.4. Set Target Frequency

Analysis

Set Target Frequency

Input Parameters

Target Frequency (MHz): 96

Default (MHz): 50 [Restore Default](#)

Frequency Range (MHz): 5-500

[Run This Task](#)

Result: ✔ Passed

Passed Set Target Frequency.

8. Right-click the **Generate RTL Code and IP Core** task and select **Run to Selected Task**.

You can find the register address mapping and other documentation for the IP core in the generated IP Core Report.

Integrate IP into AXI4-Stream Audio-Compatible Reference Design

Next, in the HDL Workflow Advisor, you run the **Embedded System Integration** tasks to deploy the generated HDL IP core on Zynq hardware.

1. Run the **Create Project** task.

This task inserts the generated IP core into the Audio System with AXI DMA Interface reference design. As shown in the first diagram, this reference design contains the IPs to handle streaming audio data in and out of ZedBoard, and for streaming data in and out of the Processing System. The generated project is a complete ZedBoard design. It includes the algorithm part, which is the generated DUT algorithm IP, and the platform part, which is the reference design.

2. Click the link in the **Result** pane to open the generated Vivado project. In the Vivado tool, click **Open Block Design** to view the Zynq design diagram, which includes the generated HDL IP core, other audio processing IPs and the Zynq processor.

3. In the HDL Workflow Advisor, run the remaining tasks to generate the software interface model, and build and download the FPGA bitstream. Choose Download programming method in the task **Program Target Device** to download the FPGA bitstream onto the SD card on the Zynq board. Your design is then automatically reloaded when you power cycle the Zynq board.

Generate ARM Executable to Tune Parameters on FPGA Fabric

In task **Generate Software Interface Model**, a software interface model is generated.

Audio programmable FIR filter with spectrogram

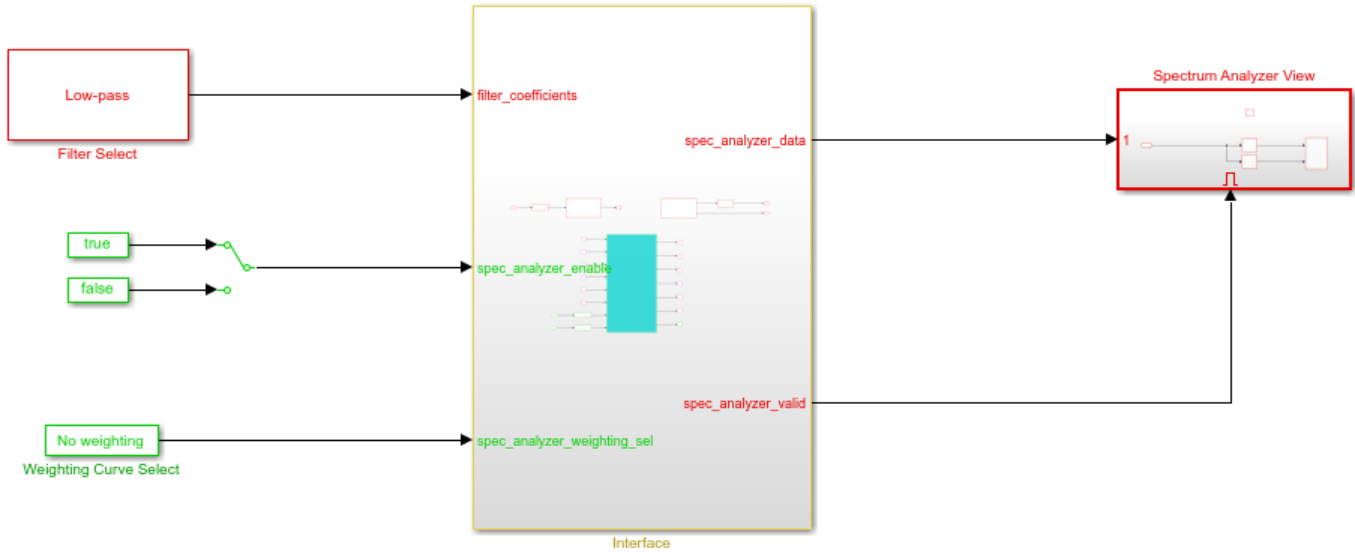

Generated by HDL Workflow Advisor on 03-Jan-2020 16:59:15

In the generated model, AXI4-Lite driver blocks have been automatically added. However, AXI4-Stream driver blocks cannot be automatically generated, because the driver blocks expect vector inputs on the software side, but the DMA DUT ports are scalar ports. For details on how to update the software interface model with the correct driver blocks, refer to “Deploy Model with AXI-Stream Interface in Zynq Workflow” on page 47-172.

For this example, you use an updated software interface model. To open this model, run:

```
open_system('hdlcoder_audio_filter_multistream_sw');
```

Copyright 2020 The MathWorks, Inc.

To tune the parameters:

1. Click the **Monitor & Tune** button on the **Hardware** tab of model toolstrip. Embedded Coder builds the model, downloads the ARM® executable to the ZedBoard hardware, executes it, and connects the model to the running executable. While the model is running, different parameters can be tuned.
2. You can select the type of filter by using the **Filter Type** block parameter of the Filter Select block. The filter coefficients are calculated in this block using the `fir1` function from Signal Processing Toolbox™. The coefficients are sent from the Processing System to the FPGA by using the AXI4-Stream IIO Write block, which communicates through the **MM2S DMA IP**.

3. The weighting curve used by the spectrum analyzer can be selected using the **Curve** block parameter of the Weighting Curve Select block. The selection is sent from the Processing System to the FPGA using the AXI4-Lite interface.

4. The spectrum analyzer output can be viewed in the Array Plot. Select a different filter type or modify the weighting curve and observe how the spectrum data changes.

The filtered audio output can be heard by plugging earphones or speakers to **HPH OUT** jack on the ZedBoard.

Inspect the Written Values of AXI4 Slave Registers by Using the Readback Methods

This example describes the different techniques to read the AXI4 slave input registers in your design. It shows the process of how to enable readback on AXI4 slave input registers and read the values of AXI4 slave input registers for your design.

Introduction

You can select the AXI4 or AXI4-Lite interface in the IP core generation or the Simulink Real-Time FPGA I/O workflow in HDL Workflow Advisor. By default, your IP is generated without the readback capability of the AXI4 or AXI4-Lite input registers. When the readback feature is enabled from HDL Workflow Advisor or from command-line interface, you can read the values of input registers. This technique is useful for debugging the input values, which are written into AXI4 or AXI4-Lite interface. The figure shows the AXI4 slave interface and its registers.

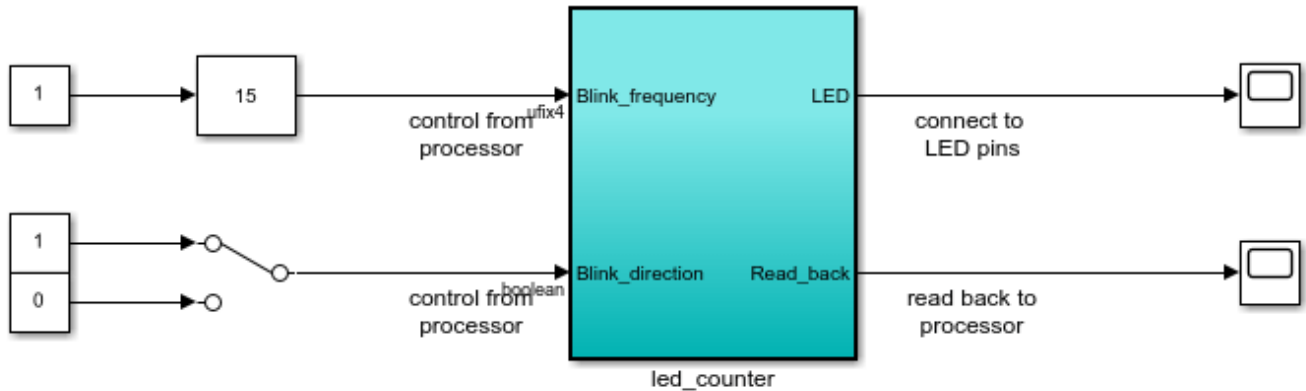

Enabling AXI4 Slave Input Register Readback

1. When your design contains the AXI4 or AXI4 Lite interface, you can perform the readback of AXI4 registers. You can use any model which has these interfaces. Use **hdlcoder_led_blinking** or **hdlcoder_led_blinking_4bit** model. Open the Simulink model that implements LED blinking by entering this command:

```
open_system('hdlcoder_led_blinking');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

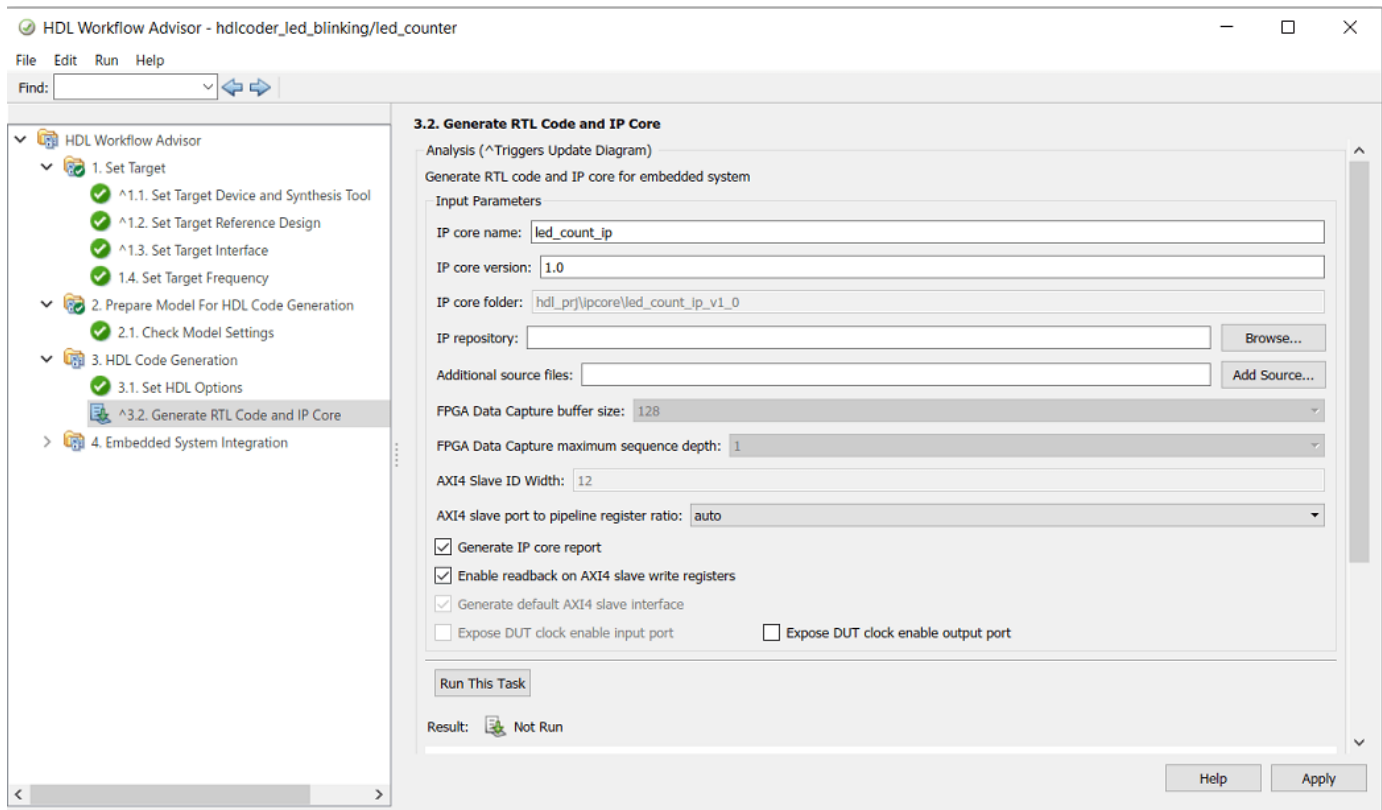

[Launch HDL Workflow Advisor](#)

Run Demo

Copyright 2012 The MathWorks, Inc.

2. Run all the tasks up until **Set HDL Options**.

3. You can turn on the readback on AXI4 slave input registers by using the HDL workflow Advisor or by using the command-line interface. Generate RTL code and IP Core, by default, the readback on AXI4 slave input register is turned off. To enable this option, select **Enable readback on AXI4 slave write registers** under the **Generate RTL Code and IP Core** task of HDL Workflow Advisor.

You can also enable the readback option at the MATLAB command line by using the `hdlset_param` function.

% Set SubSystem HDL parameters

```
hdlset_param('hdlcoder_led_blinking/led_counter', 'AXI4RegisterReadback', 'on');
hdlset_param('hdlcoder_led_blinking/led_counter', 'AXI4SlaveIDWidth', '12');
hdlset_param('hdlcoder_led_blinking/led_counter', 'ProcessorFPGASynchronization',
```

Read Values of the AXI4 input registers

After setting the readback option for your model, generate the RTL code and the IP Core in the HDL Workflow Advisor or through the command-line interface (CLI). Once the IP core is generated, the IP Core Generation Report is generated in the code generation report. The IP Core Generation Report contains the details about the Target Platform Interface of your model. The figure shows the AXI-Lite interface mapped to the `hdlcoder_led_blinking` model ports. The table in the IP Core Generation Report shows the interface mapping address of each AXI4 slave register. These addresses are used to read the AXI4 slave input registers.

The screenshot shows the 'Code Generation Report' window. The left sidebar contains a 'Contents' list with 'IP Core Generation Report' highlighted. The main content area is divided into two sections:

Target platform interface table:

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
Blink_frequency	Inport	ufix4	AXI4-Lite	x"100"	
Blink_direction	Inport	boolean	AXI4-Lite	x"104"	
LED	Output	uint8	LEDs General Purpose	[0:7]	
Read_back	Output	uint8	AXI4-Lite	x"108"	

Register Address Mapping

The following AXI4-Lite bus accessible registers were generated for this IP core:

Register Name	Address Offset	Description
IPCore_Reset	0x0	write 0x1 to bit 0 to reset IP core
IPCore_Enable	0x4	enabled (by default) when bit 0 is 0x1
IPCore_Timestamp	0x8	contains unique IP timestamp (yyymmddHHMM): 2106141555
Blink_frequency_Data	0x100	data register for Inport Blink_frequency
Blink_direction_Data	0x104	data register for Inport Blink_direction
Read_back_Data	0x108	data register for Output Read_back

Following are the AXI4 slave Base address and Master address space specified in the reference design:
Default system.
 AXI4 Slave Base Address: **0x400D0000**
 AXI4 Slave Master connection: **sys_cpu/Data**
 Use the AXI4 Slave Base Address plus Address offset to access the IP Core registers shown in Register Address Mapping table

The AXI4 slave write register readback is ON for the IP core.
 The register address mapping is also in the following C header file for you to use when programming

Buttons: OK, Help

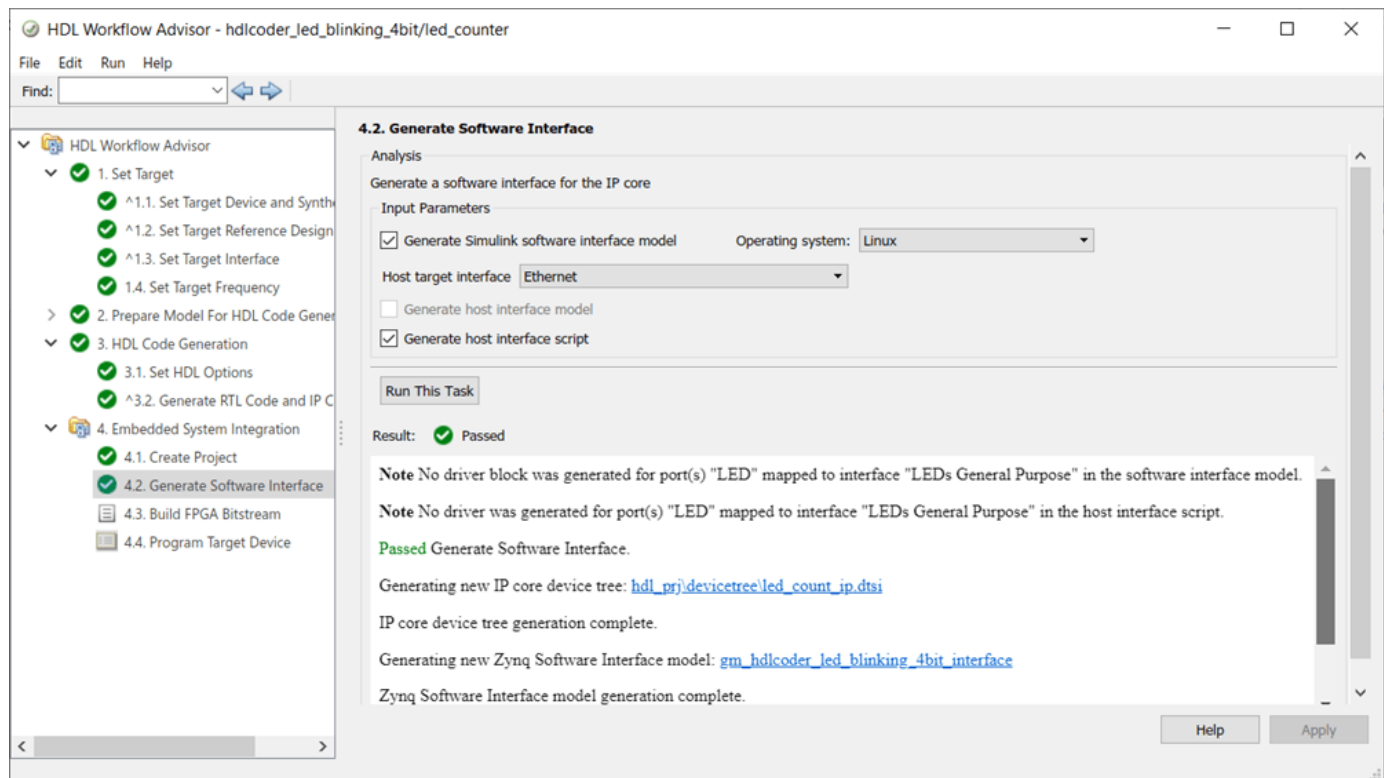

The AXI4 slave base address is used together with interface mapping address to read the value of AXI4 slave input registers. These address mapping details are used to read the AXI4 slave registers. You can perform the readback of input registers in these ways:

- Using the MATLAB FPGA Prototyping API Script
- Using the JTAG AXI Manager
- Using the Devmem command

To read the value, you can use any of the preceding techniques. Then you must complete all the steps in HDL Workflow Advisor. Once the bitstream is generated and programmed into the target device, perform readback of input registers.

Readback of AXI4 Slave Input Registers by Using MATLAB FPGA Prototyping API Script

You can read AXI4 Slave input registers by using MATLAB FPGA prototyping API scripts. Once the RTL code and IP core are generated, host interface scripts can be generated by using the **Generate Software Interface** task from the HDL Workflow Advisor. The option **Generate host interface script** generates the MATLAB prototyping API scripts.

This option generates two scripts that are interface and setup scripts, shown here for the `hdlcoder_led_blinking_4bit` model.

`gs_hdlcoder_led_blinking_4bit_interface.m`
`gs_hdlcoder_led_blinking_4bit_setup.m`

The setup function contains commands for the AXI4 slave interfaces that HDL Coder uses to control the DUT ports in the generated HDL IP core, which are mapped to their corresponding interfaces.

```

1 function gs_hdlcoder_led_blinking_4bit_setup(hFPGA)
2 %-----
3 % Host Interface Script Setup
4 %
5 % Generated with MATLAB 9.12 (R2022a) at 16:26:53 on 10/01/2022.
6 % This function was created for the IP Core generated from design 'hdlcoder_led_blinking_4bit'.
7 %
8 % Run this function on an "fpga" object to configure it with the same interfaces as the generated IP core.
9 %-----
10
11 %% AXI4-Lite
12 addAXI4SlaveInterface(hFPGA, ...
13     "InterfaceID", "AXI4-Lite", ...
14     "BaseAddress", 0x400D0000, ...
15     "AddressRange", 0x10000, ...
16     "WriteDeviceName", "mwipcore0:mmwr0", ...
17     "ReadDeviceName", "mwipcore0:mrrd0");
18
19 DUTPort_Blink_frequency = hdlcoder.DUTPort("Blink_frequency", ...
20     "Direction", "IN", ...
21     "DataType", numerictype(0,4,0), ...
22     "IsComplex", false, ...
23     "Dimension", [1 1], ...
24     "IOInterface", "AXI4-Lite", ...
25     "IOInterfaceMapping", "0x100");
26
27 DUTPort_Blink_direction = hdlcoder.DUTPort("Blink_direction", ...
28     "Direction", "IN", ...
29     "DataType", "logical", ...
30     "IsComplex", false, ...
31     "Dimension", [1 1], ...
32     "IOInterface", "AXI4-Lite", ...
33     "IOInterfaceMapping", "0x104");
34
35 DUTPort_Read_back = hdlcoder.DUTPort("Read_back", ...
36     "Direction", "OUT", ...
37     "DataType", "uint8", ...
38     "IsComplex", false, ...
39     "Dimension", [1 1], ...
40     "IOInterface", "AXI4-Lite", ...
41     "IOInterfaceMapping", "0x108");
42
43 mapPort(hFPGA, [DUTPort_Blink_frequency, DUTPort_Blink_direction, DUTPort_Read_back]);
44
45 end

```

The host interface script instantiates this setup function to connect to the target and send read or write commands. You can uncomment and send meaningful data by using the inputs to the DUT in your original model. After interfacing with the hardware, the script disconnects from the hardware resource associated with the FPGA object.

```

% Use this script to access DUT ports in the design that were mapped to compatible IP core interfaces.
% You can write to input ports in the design and read from output ports directly from MATLAB.
% To write to input ports, use the "writePort" command and specify the port name and input data. The input data will be cast to the DUT port's data type before writing.
% To read from output ports, use the "readPort" command and specify the port name. The output data will be returned with the same data type as the DUT port.
% Use the "release" command to release MATLAB's control of the hardware resources.
%-----

%% Create fpga object
hFPGA = fpga("Xilinx");

%% Setup fpga object
% This function configures the "fpga" object with the same interfaces as the generated IP core
gs_hdlcoder_led_blinking_4bit_setup(hFPGA);

%% Write/read DUT ports
% Uncomment the following lines to write/read DUT ports in the generated IP Core.
% Update the example data in the write commands with meaningful data to write to the DUT.
%% AXI4-Lite
% writePort(hFPGA, "Blink_frequency", zeros([1 1]));
% writePort(hFPGA, "Blink_direction", zeros([1 1]));
% data_Read_back = readPort(hFPGA, "Read_back");

%% Release hardware resources
release(hFPGA);

```

Generate the bitstream and program the target device. To write and read the data for `blink_frequency`, modify the interface script and run the script. The value 10 is written to the `blink_frequency` and `axi4read` shows the readback of `blink_frequency`.

```

18 % This function configures the "fpga" object with the same interfaces as the generated IP core
19 gs_hdlcoder_led_blinking_4bit_setup(hFPGA);
20
21 %% Write/read DUT ports
22 % Uncomment the following lines to write/read DUT ports in the generated IP Core.
23 % Update the example data in the write commands with meaningful data to write to the DUT.
24 %% AXI4-Lite
25 writePort(hFPGA, "Blink_frequency", 10);
26 axi4read = readPort(hFPGA, "Blink_frequency");
27 % writePort(hFPGA, "Blink_direction", zeros([1 1]));
28 % data_Read_back = readPort(hFPGA, "Read_back");
29
30 %% Release hardware resources
31 release(hFPGA);
32

```

Command Window

```

axi4read =
    10

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Unsigned
    WordLength: 4
    FractionLength: 0

```

MATLAB prototyping API uses JTAG AXI Manager for readback of AXI4 slave input registers. For more information, see “Generate Host Interface Script to Probe and Rapidly Prototype HDL IP Core” on page 46-61.

Readback of AXI4 Slave Input Registers by Using JTAG AXI Manager

You can also use separately the JTAG AXI Manager for readback of AXI4 slave input registers. To use JTAG AXI Manager, you must insert the JTAG AXI Manager IP into reference design.

Set the necessary options for enabling readback as mentioned in earlier section and follow the example “Use JTAG AXI Manager to Control HDL Coder Generated IP Core” on page 47-311 for more details.

Readback of AXI4 Slave Input Registers by Using Devmem Command (Probe Registers from Target)

You can use the devmem command in Putty or a hyper terminal. Once you program the bitstream into the target device, open Putty or hyper terminal by using the serial interface. To use devmem command for the hdlcoder_led_blinking model:

1. Read the data from address '400D0100':

```
devmem 0x400D0100
```

You get the value as 0x00000000.

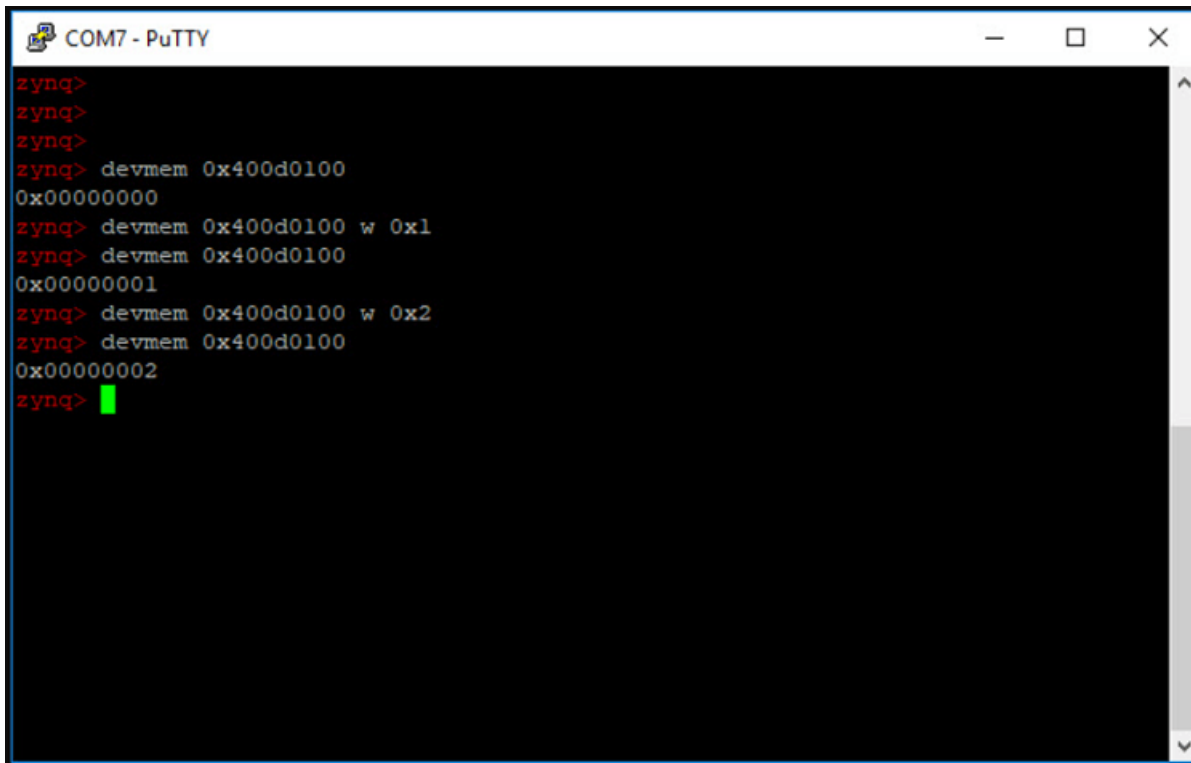

2. Write some value in address '400D0100':

```
devmem 0x400D0100 w 0x1
```

3. Reread the address '400D0100':

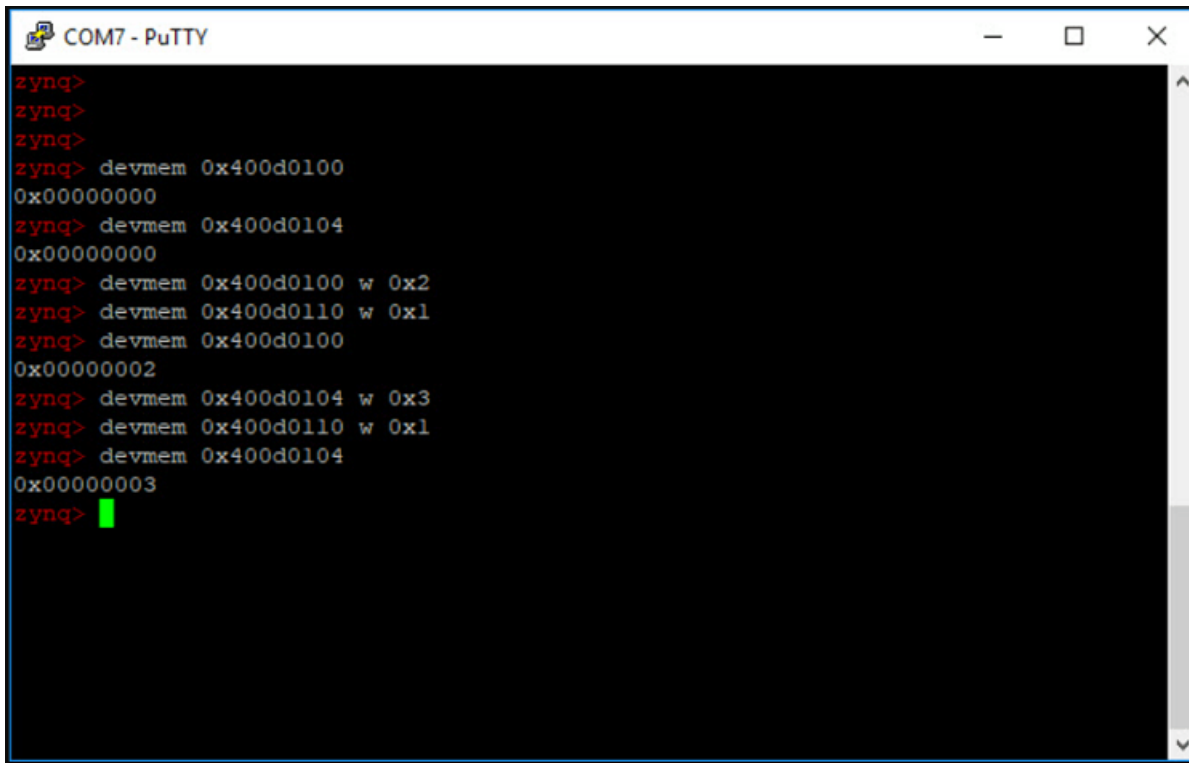

```
devmem 0x400D0100
```

You get the value as 0x00000001.

```
COM7 - PuTTY
zynq>
zynq>
zynq>
zynq> devmem 0x400d0100
0x00000000
zynq> devmem 0x400d0100 w 0x1
zynq> devmem 0x400d0100
0x00000001
zynq> devmem 0x400d0100 w 0x2
zynq> devmem 0x400d0100
0x00000002
zynq> █
```

In this way scalars can be read. In the vector data type, you first need to write the data on the register, and then write 0x1 to the strobe address as in vector mode strobe synchronization done for writing. After writing on strobe address, the customer reads the data on the register by using same address. The figure shows the writing and reading of the values in the vector data type by using devmem.

```
COM7 - PuTTY
zynq>
zynq>
zynq>
zynq> devmem 0x400d0100
0x00000000
zynq> devmem 0x400d0104
0x00000000
zynq> devmem 0x400d0100 w 0x2
zynq> devmem 0x400d0110 w 0x1
zynq> devmem 0x400d0100
0x00000002
zynq> devmem 0x400d0104 w 0x3
zynq> devmem 0x400d0110 w 0x1
zynq> devmem 0x400d0104
0x00000003
zynq>
```

1. Try to read the address 0x400D0100 and 0x400D0104, which shows as 0.
2. Try writing 0x2 on address 0x400D0100, and then write 0x1 on strobe address 0x400D0110.
3. Read the data on address 0x400D0100. It shows as 0x00000002.
4. Write 0x3 on address 0x400D0104, and then write 0x1 on strobe address 0x400D0110.
5. Read the data on address 0x400D0104. It shows 0x00000003.

AXI4 Slave Port to Pipeline Register Ratio

This option is an additional option to optimize your design to meet frequency that you might require. When you have a considerable number of AXI4 slave input ports in the design and AXI4 slave readback of input register is turned on, the design becomes complex and you might not get timing requirements. To optimize the readback capability of the AXI4 slave input registers, you can insert pipelined registers for a number of AXI4 slave ports. You can set the **AXI4 slave port to pipeline register ratio** option from HDL Workflow Advisor, the CLI, or from the HDL Block properties of the DUT subsystem. The figure shows the HDL Workflow Advisor to set the **AXI4 slave port to pipeline register ratio** option.

The table shows the drop-down options available in **AXI4 slave port to pipeline ratio**.

Sr. No	Dropdown Item	Description
1	Off	Pipelining Register insertion is set to off and no register will be inserted in the mux chain of port
2	Auto	One pipelining register will be inserted per 35 AXI4 ports. It is default option
3	10	One pipelining register will be inserted per 10 AXI4 ports
4	20	One pipelining register will be inserted per 20 AXI4 ports
5	35	One pipelining register will be inserted per 35 AXI4 ports
6	50	One pipelining register will be inserted per 50 AXI4 ports

You can also set this option at the MATLAB command line by using the `hdlset_param` function.

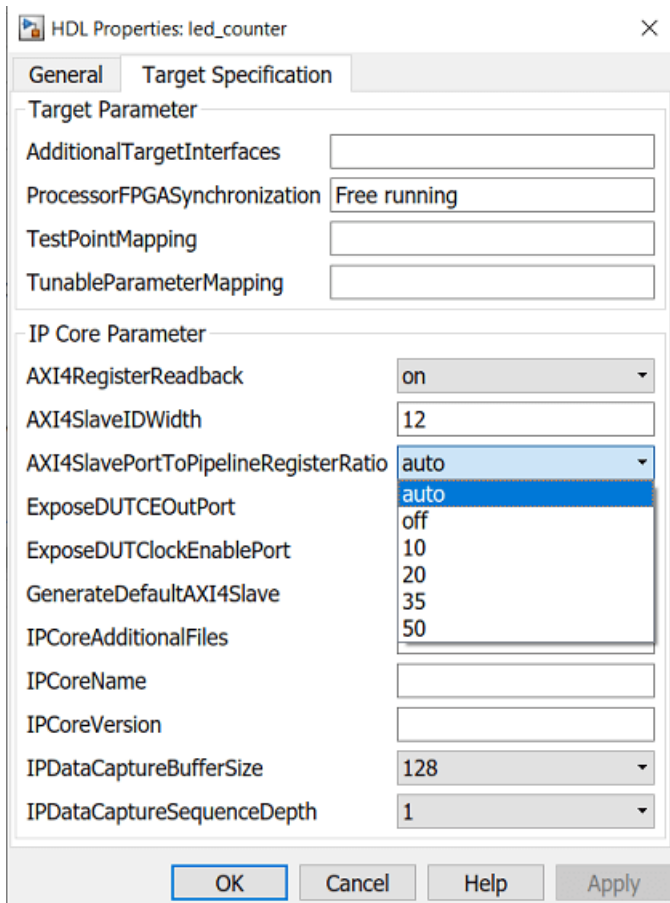

```
% Set SubSystem HDL parameters
hdlset_param('hdlcoder_led_blinking/led_counter', 'AXI4RegisterReadback', 'on');
hdlset_param('hdlcoder_led_blinking/led_counter', 'AXI4SlaveIDWidth', '12');
hdlset_param('hdlcoder_led_blinking/led_counter', 'AXI4SlavePortToPipelineRegisterRatio', '10');
hdlset_param('hdlcoder_led_blinking/led_counter', 'ProcessorFPGASynchronization', 'Free running');
```

To select this option by using HDL Block properties, right-click DUT subsystem and select **HDL Code > HDL Block Properties**.

The screenshot displays a block diagram on the left and a context menu on the right. The block diagram shows a central cyan block with two inputs: 'Blink_frequency' (labeled 'ufix4 D1') and 'Blink_direction' (labeled 'boolean D1'). The 'Blink_frequency' input is connected to a value of 15, and the 'Blink_direction' input is connected to a value of 0. Both inputs are labeled 'control from processor'. A red box highlights the 'Blink_frequency' input. The context menu is open over the cyan block, showing options like Copy, Paste, Comment Through, etc. The 'HDL Code' option is highlighted in blue. A secondary menu is open over 'HDL Code', showing options like 'HDL Code Advisor ...', 'Check Subsystem Compatibility', 'Generate HDL for Subsystem', 'HDL Coder Properties ...', and 'HDL Block Properties ...', with the last option highlighted in blue.

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board. In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking_led_counter')`

In HDL Block Properties, on the **Target Specification** tab and set **AXI4SlavePortToPipelineRegisterRatio** in the **IP Core Parameter** section.

Once you set the **AXI4 slave port to pipeline register ratio** by using one of the receding options, follow the steps for the readback as described in the section **Read Values of the AXI4 Slave input registers**.

Enabling AXI4 Slave Input Register Readback for individual ports

If your design contains a large number of input ports and you enable readback on all of the input ports, your design can consume lot of resources and can have timing violations.

Instead of enabling the global readback on all the input ports, You can enable the readback for individual ports based on your requirement.

1. Below is the example Simulink model which contains large number of input ports.

```
open_system('hdlcoder_portlevel_readback');
```

2. Run all the tasks up until **Set Target Interface** under **Set Target** of the HDL Workflow Advisor

You can turn on the readback for any of the individual ports by clicking the Options under Interface Options.

In the **Set Interface Options** window, you can set the **Enable write register readback** option to on, off or inherit. By default, the **Enable write register readback** option is set to inherit, where the readback on that port will inherit from the global readback option.

You can also turn on the readback for any individual port at the MATLAB command line by using `hdlset_param` function in the exported script.

```
hdlset_param('portlevel_readback/DUT/In1','IOInterfaceOptions',
{'RegisterInitialValue','0','EnableReadback','on'});
```

Utilization Summary for port level readback and global readback

The table below shows the resource utilization for different cases of port level readback and global readback for the above Simulink model `portlevel_readback`.

SNO.	Resource	Available	Case:1	Case:2	Case:3
			Global=OFF, Portlevel=INHERIT	Global=OFF, Portlevel=ON (20 ports)	Global=ON, Portlevel=INHERIT
1	LUT	218600	6458	9124	14538
2	LUTRAM	70400	2554	3869	7191
3	FF	437200	16152	18227	22582

The above table shows the utilization summary for three different cases of portlevel and global readback as described below:

Case1: When global readback is off and portlevel readback is also off. In this case, the global and portlevel readback is set to off for all the ports for the above simulink model.

Case2: When global readback is off and portlevel readback is on. In this case, the portlevel readback is enabled for 20 ports for the above simulink model.

Case3: When global readback is on and portlevel readback is off. In this case, the readback is enabled for all the input ports for the above simulink model.

The below chart shows the utilization summary for different cases of port level readback enabled

Multirate IP Core Generation

This example shows HDL Coder™ supports designs with multiple sample rates when you run the IP Core Generation workflow.

If you are only using AXI4 slave interfaces such as AXI4 or AXI4-Lite, and when you use Free running for **Processor/FPGA Synchronization**, you can use multiple sample rates in your design without restrictions.

When you map the interface ports to AXI4-Stream, AXI4-Stream Video, or AXI4 Master interfaces, to use multiple sample rates, make sure that the DUT ports that map to the AXI4 interfaces run at the fastest rate of the design after HDL code generation.

These examples illustrate how you can model your design with multiple sample rates when using AXI4-Stream, AXI4-Stream Video, or AXI4-Master Master interfaces.

Run Part of Design at Slower Rate

You can run part of the design at a slower rate while making sure that the DUT ports that map to the interface run at the fastest rate. This example illustrates mapping to AXI4-Stream Video interfaces but you can map to AXI4-Stream or AXI4 Master interfaces by using this approach.

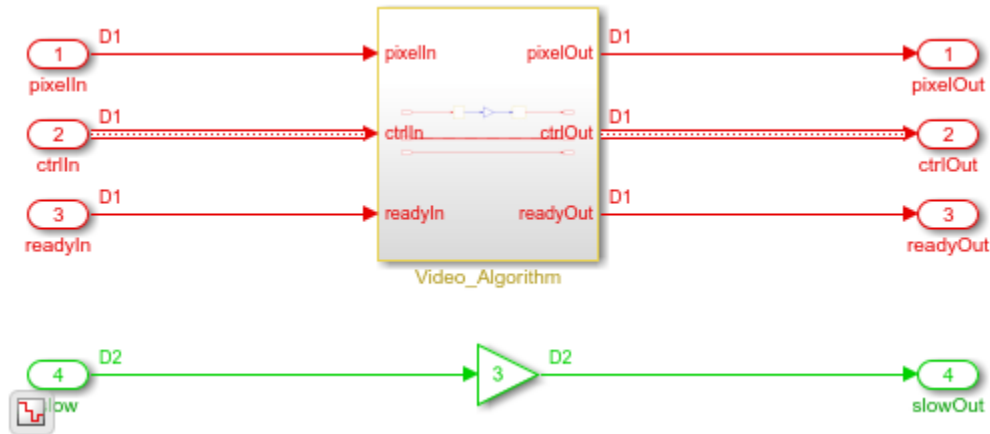

For an example, open the model `hdlcoder_axi_video_multirate`.

```
load_system('hdlcoder_axi_video_multirate')
set_param('hdlcoder_axi_video_multirate', 'SimulationCommand', 'update')
open_system('hdlcoder_axi_video_multirate')
```

In this model, the DUT ports corresponding to inputs and outputs of the Video_Algorithm run at the fastest rate.

```
open_system('hdlcoder_axi_video_multirate/Multirate_DUT')
```

These ports can therefore map to AXI4-Stream Video interfaces. Part of the design running outside this algorithm corresponding to input `slow` and output `slowOut` running at a slower rate can map to AXI4 or AXI4-Lite interfaces. This figure shows an example of the target platform interface mapping for this model.

Target platform interface table				
Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
pixelIn	Inport	uint16	AXI4-Stream Video Slave	Pixel Data
ctrlIn	Inport	bus	AXI4-Stream Video Slave	Pixel Control Bus
readyIn	Inport	boolean	AXI4-Stream Video Master	Ready (optional)
slow	Inport	uint16	AXI4-Lite	x"100"
pixelOut	Outport	uint16	AXI4-Stream Video Master	Pixel Data
ctrlOut	Outport	bus	AXI4-Stream Video Master	Pixel Control Bus
readyOut	Outport	boolean	AXI4-Stream Video Slave	Ready (optional)
slowOut	Outport	uint16	AXI4-Lite	x"104"

Note: To use the Pixel Control Bus Creator and Pixel Control Bus Selector blocks, you must have Vision HDL Toolbox™ installed. If you do not have Vision HDL Toolbox, use Bus Creator and Bus Selector blocks instead.

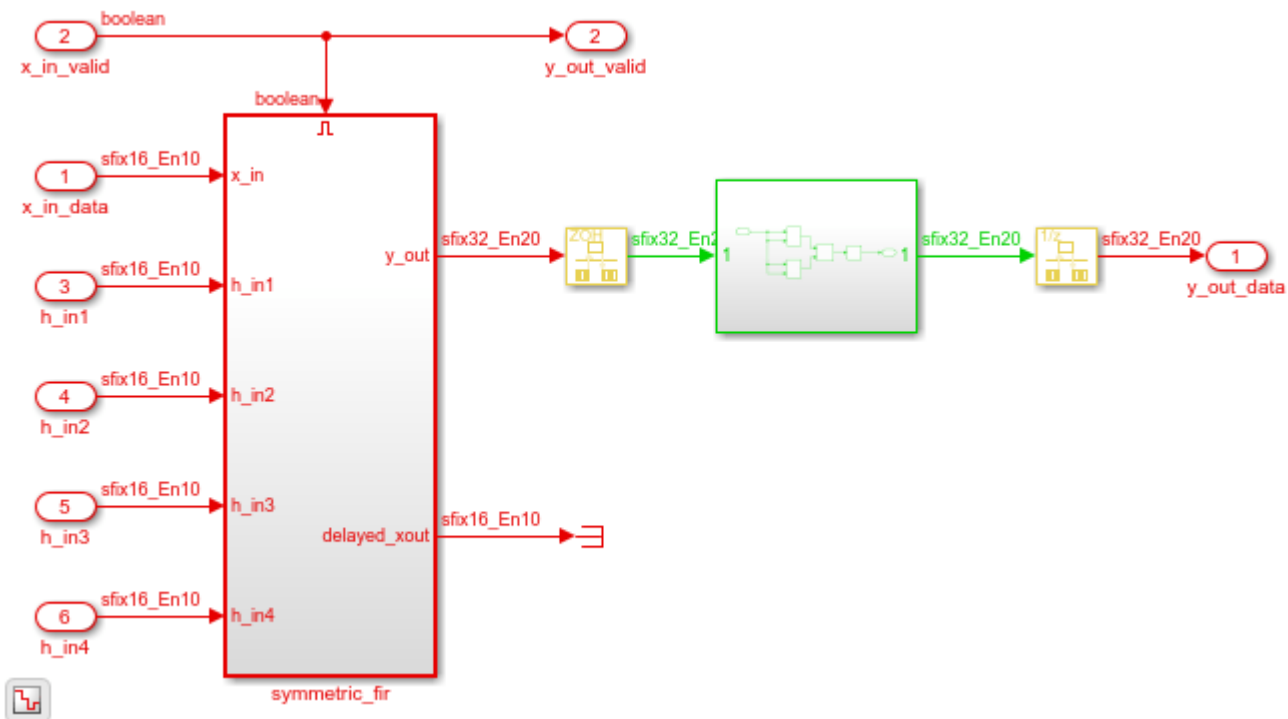

See also "Model Design for AXI4-Stream Video Interface Generation" on page 47-97.

Apply Optimizations to Part of Design Running at Slow Rate

With multirate support, you can apply optimizations such as resource sharing to a part of the design running at a slower rate. Make sure that the optimizations do not introduce a faster rate in your Simulink™ model. This example illustrates mapping to AXI4-Stream interfaces but you can map to AXI4-Stream Video or AXI4 Master interfaces by using this approach.

For an example, open the model `hdlcoder_axi_multirate_sharing`

```
load_system('hdlcoder_axi_multirate_sharing')
set_param('hdlcoder_axi_multirate_sharing','SimulationCommand','update')
open_system('hdlcoder_axi_multirate_sharing/DUT')
```

In this model, the Subsystem contains a simple multiply-add algorithm running at a slower rate.

```
open_system('hdlcoder_axi_multirate_sharing/DUT/Subsystem')
```

Resource sharing can be applied to this part of the design. To see the parameters saved on this Subsystem, run `hdlsaveparams`.

```
hdlsaveparams('hdlcoder_axi_multirate_sharing/DUT/Subsystem')
```

```
% Set Model 'hdlcoder_axi_multirate_sharing' HDL parameters
hdlset_param('hdlcoder_axi_multirate_sharing', 'HDLSubsystem', 'hdlcoder_axi_multirate_sharing/DUT/Subsystem');
hdlset_param('hdlcoder_axi_multirate_sharing', 'ReferenceDesign', 'Default system with AXI4-Stream');
hdlset_param('hdlcoder_axi_multirate_sharing', 'ResetType', 'Synchronous');
hdlset_param('hdlcoder_axi_multirate_sharing', 'SynthesisTool', 'Xilinx Vivado');
hdlset_param('hdlcoder_axi_multirate_sharing', 'SynthesisToolChipFamily', 'Zynq');
hdlset_param('hdlcoder_axi_multirate_sharing', 'SynthesisToolDeviceName', 'xc7z020');
hdlset_param('hdlcoder_axi_multirate_sharing', 'SynthesisToolPackageName', 'clg484');
hdlset_param('hdlcoder_axi_multirate_sharing', 'SynthesisToolSpeedValue', '-1');
hdlset_param('hdlcoder_axi_multirate_sharing', 'TargetDirectory', 'hdl_prj\hdlsrc');
hdlset_param('hdlcoder_axi_multirate_sharing', 'TargetFrequency', 50);
hdlset_param('hdlcoder_axi_multirate_sharing', 'TargetPlatform', 'ZedBoard');
hdlset_param('hdlcoder_axi_multirate_sharing', 'Workflow', 'IP Core Generation');

% Set SubSystem HDL parameters
hdlset_param('hdlcoder_axi_multirate_sharing/DUT/Subsystem', 'SharingFactor', 3);
```

You can map the DUT interface ports to AXI4-Stream Master or AXI4-Stream Slave interfaces. This figure shows an example of the target platform interface mapping for this model.

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
x_in_data	Inport	sfix16_E...	AXI4-Stream Slave	Data
x_in_valid	Inport	boolean	AXI4-Stream Slave	Valid
h_in1	Inport	sfix16_E...	AXI4-Lite	x"100"
h_in2	Inport	sfix16_E...	AXI4-Lite	x"104"
h_in3	Inport	sfix16_E...	AXI4-Lite	x"108"
h_in4	Inport	sfix16_E...	AXI4-Lite	x"10C"
y_out_data	Outport	sfix32_E...	AXI4-Stream Master	Data
y_out_valid	Outport	boolean	AXI4-Stream Master	Valid

Board and Reference Design Registration System

In this section...

“Board, IP Core, and Reference Design Definitions” on page 47-68

“Board Registration Files” on page 47-68

“Reference Design Registration Files” on page 47-69

“Predefined Board and Reference Design Examples” on page 47-70

You can define custom boards and custom reference designs so that they are available as target hardware options in the SoC workflow. Custom boards and custom reference designs use the same system that HDL Coder uses for predefined board and reference design targets.

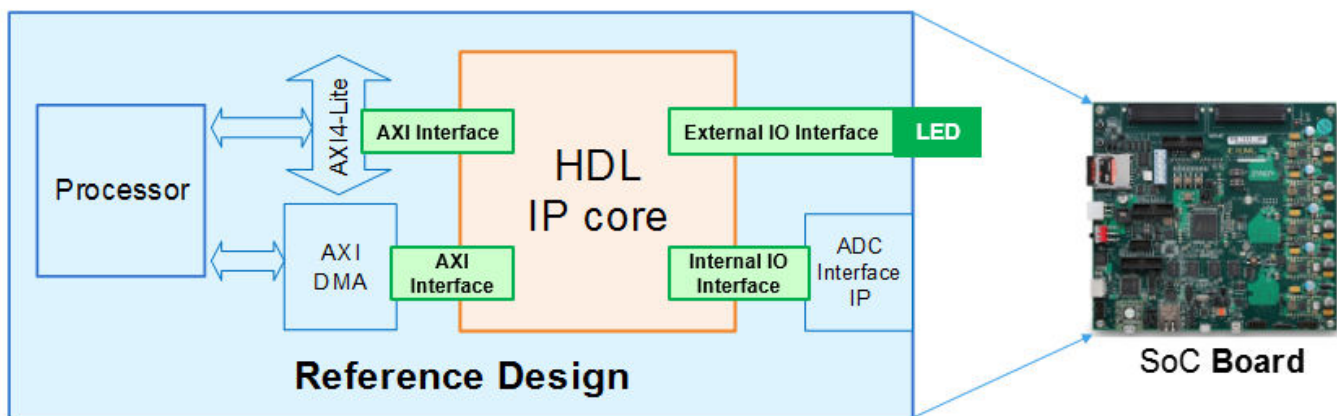

Board, IP Core, and Reference Design Definitions

A reference design is the embedded system design that your generated IP core integrates with. The board is the SoC platform.

For a custom board or custom reference design, you can define different kinds of interfaces:

- *AXI interface*: an interface between your generated IP core and an AXI4 or AXI4-Lite interface.
- *External IO interface*: an interface between your generated IP core and an external interface.
- *Internal IO interface*: an interface between your generated IP core and another IP core in the reference design.

After you integrate your reference design and IP core in an embedded system design project, you can program the board with the embedded system design.

Board Registration Files

To define and register a board, you must have a board definition, a board plugin, and a board registration file.

Board Definition

A board definition is a file that defines the characteristics of a board. You can define more than one custom board.

Board Plugin

A board plugin is a package folder that contains:

- The board definition.
- All reference design plugins that are associated with the board.

A board plugin has one board definition, but can have multiple reference designs.

Board Registration File

A board registration file is always named `hdlcoder_board_customization.m`, and contains a list of board plugins. There can be multiple board registration files on your MATLAB path, but a board plugin cannot be listed in more than one board registration file.

When the HDL Workflow Advisor opens, it searches the MATLAB path for files named `hdlcoder_board_customization.m`, and uses the information to populate the target board options. Interfaces you add and define for the board appear as options in the **Target Platform Interface** drop-down list.

Reference Design Registration Files

To define and register a reference design, you must have a reference design definition, a reference design plugin, and a reference design registration file.

Reference Design Definition

A reference design definition is a file that defines the characteristics of a reference design, including its associated board and interfaces. You can define multiple custom reference designs per board.

Reference Design Plugin

A reference design plugin is a package folder that contains:

- The reference design definition.
- Files that are part of the embedded system design project, and are specific to your third-party synthesis tool, including Tcl, project, and design files.

A reference design plugin has one reference design definition and is associated with one board.

Reference Design Registration File

A reference design registration file is always named `hdlcoder_ref_design_customization.m`, and contains a list of reference design plugins for a specific board. There can be multiple reference design registration files for a specific board on your MATLAB path, but a reference design plugin cannot be listed in more than one reference design plugin registration file.

When the HDL Workflow Advisor opens, it searches the MATLAB path for files named `hdlcoder_ref_design_customization.m`, and uses the information to populate the reference

design options for each board. Interfaces you add and define for the reference design appear as options in the **Target Platform Interface** drop-down list.

Predefined Board and Reference Design Examples

For examples of working board and reference design definitions, refer to the predefined Altera SoC, Xilinx Zynq and Microchip SoC board plug-ins that include predefined reference design plug-ins:

- `support_package_installation_folder/toolbox/hdlcoder/supportpackages/zynq7000/+VCK190/`
- `support_package_installation_folder/toolbox/hdlcoder/supportpackages/zynq7000/+ZCU102/`
- `support_package_installation_folder/toolbox/hdlcoder/supportpackages/zynq7000/+ZedBoard/`
- `support_package_installation_folder/toolbox/hdlcoder/supportpackages/zynq7000/+ZynqZC702/`
- `support_package_installation_folder/toolbox/hdlcoder/supportpackages/zynq7000/+ZynqZC706/`
- `support_package_installation_folder/toolbox/hdlcoder/supportpackages/alterasoc/+AlteraCycloneV/`
- `support_package_installation_folder/toolbox/hdlcoder/supportpackages/alterasoc/+ArrowSoCKit/`
- `support_package_installation_folder/toolbox/hdlcoder/supportpackages/alterasoc/+IntelArria10SoC/`
- `support_package_installation_folder/toolbox/hdlcoder/supportpackages/microchip/+PolarFireSoC/`

To get to the root folder of support packages, use the `matlabshared.supportpkg.getSupportPackageRoot` function.

Register a Custom Board

In this section...

“Define a Board” on page 47-71

“Create a Board Plugin” on page 47-72

“Define a Board Registration Function” on page 47-72

To register a custom board, you must:

- 1 Define a board.
- 2 Create a board plugin.
- 3 Define a board registration function, or add the new board plugin to an existing board registration function.

Define a Board

Before you begin, have the board documentation at hand so you can refer to the details of the board.

Requirements

A board definition must be:

- A MATLAB function that returns an `hdlcoder.Board` object.
The board definition function can have any name.
- In its board plugin folder.

How To Define A Board

- 1 Create a new file that defines a MATLAB function with any name.
- 2 In the MATLAB function, create an `hdlcoder.Board` object and specify its properties and interfaces according the characteristics of your custom board.
- 3 Optionally, to check that the definition is complete, run the `validateBoard` method.

For example, the following code defines a board:

```
function hB = plugin_board()
% Board definition

% Construct board object
hB = hdlcoder.Board;

hB.BoardName    = 'Digilent Zynq ZyBo';

% FPGA device information
hB.FPGAVendor   = 'Xilinx';
hB.FPGAFamily   = 'Zynq';
hB.FPGADevice   = 'xc7z010';
hB.FGAPackage   = 'clg400';
hB.FPGASpeed    = '-2';

% Tool information
```

```
hB.SupportedTool = {'Xilinx Vivado'};

% FPGA JTAG chain position
hB.JTAGChainPosition = 2;

%% Add interfaces
% Standard "External Port" interface
hB.addExternalPortInterface( ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});
```

Create a Board Plugin

Requirements

A board plugin:

- Must be a package folder that contains the board definition file.

A package folder has a + prefix before the folder name. For example, the board plugin can be a folder named +ZedBoard.

- Must be on the MATLAB path.
- Can contain one or more reference design plugins.

How To Create a Board Plugin

- 1 Create a folder that has a name with a + prefix.
- 2 Save your board definition file to the folder.
- 3 Add the folder to your MATLAB path.

Define a Board Registration Function

Requirements

A board registration function:

- Must be named `hdlcoder_board_customization.m`.
- Returns a list of board plugins, specified as a cell array of character vectors.
- Must be on the MATLAB path.

How To Define a Board Registration Function

- 1 Create a file named `hdlcoder_board_customization.m` and save it anywhere on the MATLAB path.
- 2 In `hdlcoder_board_customization.m`, define a function that returns a list of board plugins as a cell array of character vectors.

For example, the following code defines a board registration function.

```
function r = hdlcoder_board_customization
% Board plugin registration files
% Format: % board_folder.board_definition_function
```

```
r = {'ZyboRegistration.plugin_board'};  
end
```

Register a Custom Reference Design

In this section...

“Define a Reference Design” on page 47-74

“Create a Reference Design Plugin” on page 47-75

“Define a Reference Design Registration Function” on page 47-75

To register a custom reference design:

- 1 Define a reference design.
- 2 Create a reference design plugin.
- 3 Define a reference design registration function, or add the new reference design plugin to an existing reference design registration function.

Define a Reference Design

A reference design definition must be a MATLAB function that returns an `hdlcoder.ReferenceDesign` object. Create the reference design definition function in the reference design plugin folder. You can use any name for the reference design definition function.

To create a reference design definition:

- 1 Create a new file that defines a MATLAB function with any name.
- 2 In the MATLAB function, create an `hdlcoder.ReferenceDesign` object and specify its properties and interfaces according to the characteristics of your embedded system design.
- 3 If you want to check that the definition is complete, run the `validateReferenceDesign` method.

This MATLAB function defines a custom reference design:

```
function hRD = plugin_rd()
% Reference design definition

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');

hRD.ReferenceDesignName = 'Demo system';
hRD.BoardName = 'Digilent Zynq ZyBo';

% Tool information
% It is recommended to use a tool version that is compatible with the supported tool
% version. If you choose a different tool version, it is possible that HDL Coder is
% unable to create the reference design project for IP core integration.
hRD.SupportedToolVersion = {'2020.2'};

%% Add custom design files
% add custom Vivado design
hRD.addCustomVivadoDesign( ...
    'CustomBlockDesignTcl', 'design_led.tcl');

hRD.CustomFiles = {'ZYBO_zynq_def.xml'};
%% Add interfaces
% add clock interface
hRD.addClockInterface( ...
    'ClockConnection', 'clk_wiz_0/clk_out1', ...
    'ResetConnection', 'proc_sys_reset_0/peripheral_aresetn');

% add AXI4 and AXI4-Lite slave interfaces
```

```
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'axi_interconnect_0/M00_AXI', ...
    'BaseAddress', '0x40010000', ...
    'MasterAddressSpace', 'processing_system7_0/Data');
```

By default, HDL Coder generates an IP core with the default settings and integrates it into the reference design project. To customize these default settings, use the properties in the `hdlcoder.ReferenceDesign` object to define custom parameters and to register the function handle of the custom callback functions. For more information, see “Define Custom Parameters and Callback Functions for Custom Reference Design” on page 47-77.

Create a Reference Design Plugin

A reference design plugin is a package folder that you define on the MATLAB path. The folder contains the board definition file and any custom callback functions.

To create a reference design plugin:

- 1 In the board plugin folder for the associated board, create a new folder that has a name with a + prefix.
For example, the reference design plugin can be a folder named `+vivado_base_ref_design`.
- 2 In the new folder, save your reference design definition file and any custom callback functions that you create.
- 3 In the new folder, save any files that are required by the embedded system design project, and are specific to your third-party synthesis tool, including Tcl, project, and design files.
- 4 Add the folder to your MATLAB path.

Define a Reference Design Registration Function

A reference design registration function contains a list of reference design functions and the associated board name. You must name the function `hdlcoder_ref_design_customization.m`. When the HDL Workflow Advisor opens, it searches the MATLAB path for files named `hdlcoder_ref_design_customization.m`, and uses the information to populate the reference design options for each board.

To define a reference design registration function:

- 1 Create a file named `hdlcoder_ref_design_customization.m` and save it anywhere on the MATLAB path.
- 2 In `hdlcoder_board_customization.m`, define a function that returns the associated board name, specified as a character vector, and a list of reference design plugins, specified as a cell array of character vectors.

For example, the following code defines a reference design registration function.

```
function [rd, boardName] = hdlcoder_ref_design_customization
% Reference design plugin registration file

rd = {'ZyBoRegistration.Vivado2018_2.plugin_rd', ...
     };

boardName = 'Digilent Zynq ZyBo';
```

end

The reference design registration function returns the associated board name, specified as a character vector, and a list of reference design plugins, specified as a cell array of character vectors.

Define Custom Parameters and Callback Functions for Custom Reference Design

In this section...

“Define Custom Parameters and Register Callback Function Handle” on page 47-77

“Define Custom Callback Functions” on page 47-81

When you define your custom reference design, you can optionally use the properties in the `hdlcoder.ReferenceDesign` object to define custom parameters and callback functions.

Define Custom Parameters and Register Callback Function Handle

This MATLAB code shows how to define custom parameters and register the function handle of the custom callback functions in the reference design definition function.

```
function hRD = plugin_rd()
% Reference design definition

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');
hRD.ReferenceDesignName = 'My Reference Design';
hRD.BoardName = 'ZedBoard';

% Tool information
hRD.SupportedToolVersion = {'2020.2'};

%% Add custom design files
% ...
% ...

%% Add optional custom parameters by using addParameter property.
% Specify custom 'DUT path' and 'Channel Mapping' parameters.
% The parameters get populated in the 'Set Target Reference Design'
% task of the HDL Workflow Advisor.
hRD.addParameter( ...
    'ParameterID', 'DutPath', ...
    'DisplayName', 'Dut Path', ...
    'DefaultValue', 'Rx', ...
    'ParameterType', hdlcoder.ParameterType.DropDown, ...
    'Choice', {'Rx', 'Tx'});
hRD.addParameter( ...
    'ParameterID', 'ChannelMapping', ...
    'DisplayName', 'Channel Mapping', ...
    'DefaultValue', '1');

%% Enable AXI manager IP insertion for the JTAG connection. The IP
% insertion setting is visible in the 'Set Target Reference Design'
% task of the HDL Workflow Advisor. By default, the
% AddMATLABAXIManagerParameter property is set to 'true'.
hRD.AddMATLABAXIManagerParameter = 'true';
hRD.MATLABAXIManagerDefaultValue = 'JTAG';

%% Enable AXI manager IP insertion for the Ethernet connection. The IP
% insertion setting is visible in the 'Set Target Reference Design'
% task of the HDL Workflow Advisor. By default, the Ethernet option
% for the AXI manager IP insertion setting is available for the
% Artix-7 35T Arty, Kintex-7 KC705, and Virtex-7 VC707 boards.
% Enable this option for other Xilinx boards that have the Ethernet
% physical layer (PHY) by adding the Ethernet media access
% controller (MAC) Hub IP in the plugin_board file before launching
% the HDL Workflow Advisor. To add the Ethernet MAC Hub IP, use
% the addEthernetMACInterface method.
hRD.AddMATLABAXIManagerParameter = 'true';
hRD.MATLABAXIManagerDefaultValue = 'Ethernet';
```

```
%% Add custom callback functions. These are optional.
% With the callback functions, you can enable custom
% validations, customize the project creation, software
% interface model generation, and the bistream build.
% Register the function handle of these callback functions.

% Specify an optional callback for 'Set Target Reference Design'
% task in Workflow Advisor. Use property name
% 'PostTargetReferenceDesignFcn'.
hRD.PostTargetReferenceDesignFcn = ...
    @my_reference_design.callback_PostTargetReferenceDesign;

% Specify an optional callback for 'Set Target Interface' task in Workflow Advisor.
% Use the property name 'PostTargetInterfaceFcn'.
hRD.PostTargetInterfaceFcn = ...
    @my_reference_design.callback_PostTargetInterface;

% Specify an optional callback for 'Create Project' task
% Use the property name 'PostCreateProjectFcn' for the ref design object.
hRD.PostCreateProjectFcn = ...
    @my_reference_design.callback_PostCreateProject;

% Specify an optional callback for 'Generate Software Interface Model' task
% Use the property name 'PostSWInterfaceFcn' for the ref design object.
hRD.PostSWInterfaceFcn = ...
    @my_reference_design.callback_PostSWInterface;

% Specify an optional callback for 'Build FPGA Bitstream' task
% Use the property name 'PostBuildBitstreamFcn' for the ref design object.
hRD.PostBuildBitstreamFcn = ...
    @my_reference_design.callback_PostBuildBitstream;

% Specify an optional callback for 'Program Target Device'
% task to use a custom programming method.
hRD.CallbackCustomProgrammingMethod = ...
    @my_reference_design.callback_CustomProgrammingMethod;

%% Add interfaces
% ...
% ...
```

Define Custom Parameters

With the `addParameter` method of the `hdlcoder.ReferenceDesign` class, you can define custom parameters. In the preceding example code, the reference design defines two custom parameters, DUT Path and Channel Mapping. To learn more about the `addParameter` method, see `addParameter`.

Specify Insertion of AXI Manager IP

By default, HDL Coder adds the **Insert AXI Manager (HDL Verifier required)** parameter to all reference designs. When you set this parameter to JTAG, the code generator inserts the JTAG AXI Manager IP into your reference design. When you set this parameter to Ethernet, the code generator inserts the UDP AXI Manager IP into your reference design.

Note By default, the Ethernet option is available for only the Artix-7 35T Arty, Kintex-7 KC705, and Virtex-7 VC707 boards. To enable this option for other Xilinx boards that have the Ethernet physical layer (PHY), manually add the Ethernet media access controller (MAC) Hub IP in the `plugin_board` file using the `addEthernetMACInterface` method before you launch the **HDL Workflow Advisor** tool.

By using the AXI manager IP, you can easily access the AXI registers in the generated DUT IP core on a hardware board from MATLAB or Simulink through the JTAG or Ethernet connection. See also “Set Up AXI Manager” (HDL Verifier).

To use this capability, you must have the HDL Verifier hardware support packages installed and downloaded. See “Download FPGA Board Support Package” (HDL Verifier).

The code generator adjusts the **AXI4 Slave ID Width** to accommodate the AXI manager IP connection. After you generate the HDL IP core and create the reference design project, you can open the Vivado block design to see the AXI manager IP inserted in the reference design.

In the previous example code, the reference design defines the `AddMATLABAXIManagerParameter` and `MATLABAXIManagerDefaultValue` properties of the `hdlcoder.ReferenceDesign` class. These properties control the default behavior of the **Insert AXI Manager (HDL Verifier required)** setting in the **Set Target Reference Design** task of the HDL Workflow Advisor. If you do not specify any of these properties in the `hdlcoder.ReferenceDesign` class, the **Insert AXI Manager (HDL Verifier required)** parameter is visible in the **Set Target Reference Design** task and the value is set to `off`. This example code illustrates the default behavior.

This property controls visibility of the **Insert AXI Manager (HDL Verifier required)** parameter in the **Set Target Reference Design** task of the HDL Workflow Advisor. By default, the property value is `true`, which means that the parameter is visible in the task. To disable the parameter, set this value to `false`.

```
hRD.AddMATLABAXIManagerParameter = 'true';
```

This property controls the value of the **Insert AXI Manager (HDL Verifier required)** parameter in the **Set Target Reference Design** task. By default, the property value is `off`, which means that the parameter is visible in the task and the value is `off`. To enable automatic insertion of AXI manager IP in the reference design, set this value to `JTAG` or `Ethernet`. In that case, you must set the `AddMATLABAXIManagerParameter` to `true`.

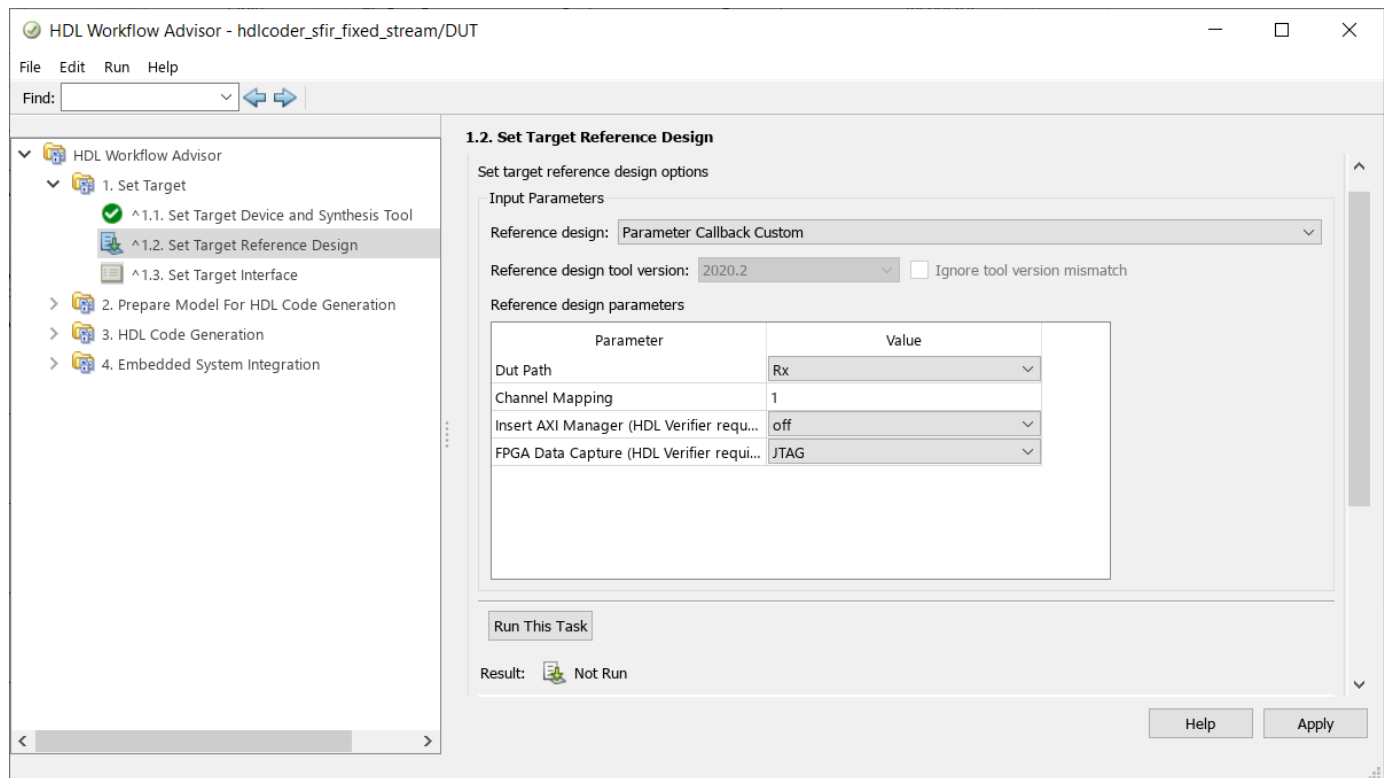

```
hRD.MATLABAXIManagerDefaultValue = 'off';
```

For examples, see:

- Using JTAG MATLAB as AXI Master to control the HDL Coder IP Core on page 47-311
- “Access DUT Registers on Xilinx Pure FPGA Board Using IP Core Generation Workflow” on page 46-183

Run IP Core Generation Workflow

When you open the HDL Workflow Advisor, HDL Coder populates the **Set Target Reference Design** task with the reference design name, tool version, custom parameters that you specified, and the **Insert AXI Manager (HDL Verifier required)** option set to JTAG.

HDL Coder then passes these parameter values to the callback functions in the input structure.

If your synthesis tool is Xilinx Vivado, HDL Coder sets the reference design parameter values to variables. The variables are then input to the block design Tcl file. This code snippet is an example from the reference design project creation Tcl file.

```
update_ip_catalog
set DutPath {Rx}
set ChannelMapping {1}
source vivado_custom_block_design.tcl
```

The code shows how HDL Coder sets the reference design parameters before sourcing the custom block design Tcl file.

Register Callback Function Handles

In the reference design definition, you can register the function handle to reference the custom callback functions. You then can:

- Enable custom validations.
- Customize the reference design dynamically.
- Customize the reference design project creation settings.
- Change the generated software interface model.
- Customize the FPGA bitstream build process.
- Specify custom FPGA programming method.

With the `hdlcoder.ReferenceDesign` class, you can define callback property names. The callback properties have a naming convention. The callback functions can have any name. In the HDL Workflow Advisor, you can define callback functions to customize these tasks.

Workflow Advisor Task	Callback Property Name	Functionality
Set Target Reference Design	<ul style="list-style-type: none"> CustomizeReferenceDesignFcn PostTargetReferenceDesignFcn 	<ul style="list-style-type: none"> CustomizeReferenceDesignFcn enables customization of the reference design dynamically. By using this callback function, you can customize the block design Tcl file, reference design interfaces, reference design interface properties, and IP repositories in your reference design. See “Customize Reference Design Dynamically Based on Reference Design Parameters” on page 47-83. PostTargetReferenceDesignFcn enables custom validations. For an example that shows how you can validate that the Reset type is Synchronous, see <code>PostTargetReferenceDesignFcn</code>.
Set Target Interface	PostTargetInterfaceFcn	Enable custom validations. For an example that shows how you can validate not choosing a certain interface for a certain custom parameter setting, see <code>PostTargetInterfaceFcn</code> .
Create Project	PostCreateProjectFcn	Specify custom settings when HDL Coder creates the project. For an example, see <code>PostCreateProjectFcn</code> .
Generate Software Interface	PostSWInterfaceFcn	Change the generated software interface model. For an example, see <code>PostSWInterfaceFcn</code> .
Build FPGA Bitstream	PostBuildBitstreamFcn	Specify custom settings when you build the FPGA bitstream. When you use this function, the build process cannot be run externally. You must run the build process within the HDL Workflow Advisor by clearing the Run build process externally check box in the Build FPGA Bitstream task. For an example, see <code>PostBuildBitstreamFcn</code> .
Program Target Device	CallbackCustomProgrammingMethod	Specify a custom FPGA programming method. For an example, see <code>CallbackCustomProgrammingMethod</code> .

Define Custom Callback Functions

- 1 For each of the callback function that you want HDL Coder to execute after running a task, create a file that defines a MATLAB function with any name.
- 2 Make sure that the callback function has the documented input and output arguments.
- 3 Verify that the functions are accessible from the MATLAB path.
- 4 Register the function handle of the callback functions in the reference design definition function.
- 5 Follow the naming conventions for the callback property names.

To learn more about these callback functions, see `hdlcoder.ReferenceDesign`.

Customize Reference Design Dynamically Based on Reference Design Parameters

In this section...

“Why Customize the Reference Design” on page 47-83

“How Reference Design Customization Works” on page 47-83

“Customizable Reference Design Parameters” on page 47-84

“Example: Create Master Only or Slave Only or Both Slave and Master Reference Designs” on page 47-85

When you define your own custom reference design, you can dynamically customize the reference design by using the `CustomizeReferenceDesignFcn` method of the `hdlcoder.ReferenceDesign` class.

Why Customize the Reference Design

By customizing the reference design parameters, instead of maintaining separate reference designs that have different interface choices, data widths, or I/O plugins, create one reference design that has different interface choices or data widths as parameters. You can then use the `CustomizeReferenceDesignFcn` method to reference the callback function that has different choices for interfaces or data widths.

For example, instead of creating separate reference designs that have different data widths for the interfaces, you can parameterize the data width and then create a reference design parameter. When you run the IP Core Generation workflow, you can use the parameter to select the data width that you want to use. Similarly, instead of using multiple reference designs, you can create one reference design that has only AXI4-Stream Master or only AXI4-Stream Slave or both AXI4-Stream Master and AXI4-Stream Slave interfaces.

How Reference Design Customization Works

To define the callback function:

- 1 In the `plugin_rd` file, define the reference design parameters you want to customize by using the `addParameter` method.
- 2 Create a MATLAB file that defines the callback function. You can use any arbitrary name for the callback function.
- 3 Save the callback function in the same folder as the `plugin_rd.m` file.
- 4 Register the function handle of the callback function in the reference design definition `plugin_rd` file by using the `CustomizeReferenceDesignFcn` method.

To use the different reference design customizations:

- 1 Open the HDL Workflow Advisor. In the **Set Target Device and Synthesis Tool** task, select IP Core Generation as the **Target workflow** and then select the target board for which you created your own custom reference design as the **Target platform**.
- 2 In the **Set Target Reference Design** task, when you select the custom reference design that you want to customize for the target board, HDL Coder populates the reference design

parameters. Depending on the parameter choices such as the interface types you specify, the callback function is evaluated. Run this task.

- 3 Select the **Set Target Interface** task. Depending on the parameter you selected in the previous step, the target interface selection is populated in the Target platform interface table.

Customizable Reference Design Parameters

In the callback function, you can customize these reference design parameters. Do not specify these parameters in the `plugin_rd` file.

- Block design Tcl file

```
% ...
% if ~isempty(ParamValue)
    hRD.addCustomVivadoDesign( ...
        'CustomBlockDesignTcl', 'system_top.tcl', ...
        'VivadoBoardPart',     'xilinx.com:zc706:part0:1.0');
% ...
```

- Reference design interfaces and reference design interface properties

For example, you can parameterize the data width of the AXI4-Stream Master Channel. In this case, use the `addAXI4StreamInterface` method in the callback function instead of the `plugin_rd` file.

```
% ...
% Add AXI4-Stream interface by parameterizing data width
DataWidth = hRD.getParamValue(paramValue)

if ~isempty(DataWidth)
    hRD.addAXI4StreamInterface(
        'MasterChannelEnable', 'true', ...
        'SlaveChannelEnable',  'true', ...
        'MasterChannelConnection', 'ByPass_0.AXI4_Stream_Slave', ...
        'SlaveChannelConnection', 'ByPass_0.AXI4_Stream_Master', ...
        'MasterChannelDataWidth', DataWidth, ...
        'SlaveChannelDataWidth',  DataWidth);
end
% ...
```

- IP repositories

In the callback function, you must specify the block design Tcl file when you add IP repositories.

```
% ...
%% Add IP Repository
hRD.addIPRepository(...
    'IPListFunction', 'mathworks.hdlcoder.vivado.hdlcoder_video_ip_list',
    'NotExistMessage', 'IP repository not found');

%% Add custom design files
hRD.addCustomVivadoDesign( ...
    'CustomBlockDesignTcl', 'system_top.tcl', ...
    'VivadoBoardPart',     'em.avnet.com:zed:part0:1.0');

% ...
```

Note You cannot modify the reference design name, board name, and supported tool versions in the callback function. These parameters are used in the **Set Target Device and Synthesis Tool** task

before the callback function is evaluated when the target reference design is selected in the **Set Target Reference Design** task.

Example: Create Master Only or Slave Only or Both Slave and Master Reference Designs

Instead of using multiple reference designs, you can create one reference design that has only AXI4-Stream Master or only AXI4-Stream Slave or both AXI4-Stream Master and AXI4-Stream Slave interfaces. This example shows how you can customize the AXI4-Stream interface channels you want to use when targeting your own reference design for the Xilinx Zynq ZC706 evaluation kit.

This code shows the reference design parameter and interface choices for the reference design `my_reference_design` specified by using the `addParameter` method in the `plugin_rd` file. The `CustomizeReferenceDesignFcn` method references a callback function that has the name `customcallback_axistreamchannel`.

```
function hRD = plugin_rd()
% Reference design definition

% Copyright 2017-2019 The MathWorks, Inc.

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');

hRD.ReferenceDesignName = 'Vivado Custom Reference Design';
hRD.BoardName = 'Xilinx Zynq ZC706 evaluation kit';

% Tool information
hRD.SupportedToolVersion = {'2019.1'};

% ...
% ...

% Parameter For calling AXI4 Master
interface from Callback function
hRD.addParameter ...
('ParameterID' , 'stream_channel', ...
 'DisplayName' , 'Stream Channel', ...
 'DefaultValue' , 'Both Master and Slave',...
 'ParameterType' , hdlcoder.ParameterType.DropDown, ...
 'Choice' , {'Both Master and Slave','Master Only','Slave Only'});

% Reference the callback function.
hRD.CustomizeReferenceDesignFcn = @my_reference_design.customcallback_axistreamchannel;

% ...
```

When you create the callback function, pass the `infoStruct` argument to the function. The argument contains the reference design and board information in a structure format. This code shows the callback function `customcallback_axistreamchannel` that has the AXI4-Stream Master or Slave Channels or both channels specified by using the `addAXI4StreamInterface` method.

```
% Control AXI Master or Slave channel selection by using callback function

function customcallback_axistreamchannel(infoStruct)
%% Reference design callback run at the end of the task Set Target Reference Design
%
% infoStruct: information in structure format
% infoStruct.ReferenceDesignObject: current reference design registration object
% infoStruct.BoardObject: current board registration object
% infoStruct.ParameterStruct: custom parameters of the current reference design, in struct format
% infoStruct.HDLModelDutPath: the block path to the HDL DUT subsystem
```

```

% infoStruct.ReferenceDesignToolVersion: Reference design Tool Version set in 1.2 Task

paramStruct = infoStruct.ParameterStruct;

if ~isempty(paramStruct)
    paramIDCell = fieldnames(paramStruct);
    paramValue = '';
    for ii = 1:length(paramIDCell)
        paramID = paramIDCell(ii);
        if strcmp(paramID,'Both Master and Slave')
            paramValue = paramStruct.paramID;
            break;
        elseif strcmp(paramID,'Master Only')
            paramValue = paramStruct.paramID;
            break;
        elseif strcmp(paramID,'Slave Only')
            paramValue = paramStruct.paramID;
            break;
        end
    end
end
interface_type = str2double(paramValue);

if ~isempty(interface_type)

    if strcmp(interface_type, 'Both Master and Slave')

        % add custom vivado design
        hRD.addCustomVivadoDesign( ...
            'CustomBlockDesignTcl', 'system_top.tcl', ...
            'VivadoBoardPart', 'xilinx.com:zc706:part0:1.0');

        hRD.addAXI4StreamInterface( ...
            'MasterChannelEnable', 'true', ...
            'SlaveChannelEnable', 'true', ...
            'MasterChannelConnection', 'axi_dma_s2mm/S_AXIS_S2MM', ...
            'SlaveChannelConnection', 'axi_dma_mm2s/M_AXIS_MM2S', ...
            'MasterChannelDataWidth', 32, ...
            'SlaveChannelDataWidth', 32);

    elseif strcmp(interface_type, 'Master Only')

        % add custom vivado design
        hRD.addCustomVivadoDesign( ...
            'CustomBlockDesignTcl', 'system_top.tcl', ...
            'VivadoBoardPart', 'xilinx.com:zc706:part0:1.0');

        hRD.addAXI4StreamInterface( ...
            'MasterChannelEnable', true, ...
            'MasterChannelConnection', 'axi_dma_s2mm/S_AXIS_S2MM', ...
            'MasterChannelDataWidth', 32);

    % ...

```

Save the callback function in the same folder as the plugin_rd file.

When you run the IP Core Generation workflow with Xilinx Zynq ZC706 evaluation kit as the **Target platform**, you see the parameter **Stream Channel** displayed in the **Set Target Reference Design** task.

You can specify the reference design type you want to use and then run the workflow to specify the target platform interfaces and then generate the HDL IP core and then integrate the IP core into the reference design.

Define and Add IP Repository to Custom Reference Design

In this section...

“Create an IP Repository Folder Structure” on page 47-88

“Define IP List Function” on page 47-89

“Add IP List Function to Reference Design Project” on page 47-90

When you create your custom reference design, you might require custom IP modules that do not come with Altera Qsys or Xilinx Vivado. To use custom IP modules, create your own IP repository folder that contains IP module subfolders. The IP Core Generation workflow then uses these custom IP modules when creating the reference design project. You can create multiple IP repositories and add all or some of the IP modules in each repository to your custom reference design project. You can also reuse and share IP repositories across multiple reference designs.

Create an IP Repository Folder Structure

Create an IP repository folder anywhere on the MATLAB path. This figure shows a typical IP repository folder structure.

When you create the folder structure, use the naming convention +(company)/+(product)/+(tool). In this example, the folder structure is +(mathworks)/+(hdlcoder)/+(vivado). The folder +vivado acts as the IP repository. This folder contains subfolders corresponding to IP modules such as AXI4StoHDMI and HDMItoAXIS. The folder also contains a hdlcoder_video_ipolist MATLAB function. Using this function, specify the IP modules to add to the reference design.

The same repository folder can have multiple MATLAB functions. This figure shows two MATLAB functions, hdlcoder_video1_ipolist and hdlcoder_video2_list, in the +vivado folder. The functions can share the same IP modules or point to different IP modules in the repository.

Note If your synthesis tool is Xilinx Vivado, the IP modules in the repository folder can be in zip file format.

Define IP List Function

Create a MATLAB function that specifies the IP modules to add to the reference design. Save this function in the IP repository folder. For the function name, use the naming convention `hdlcoder_<specific_use>_iplist`. This example uses `hdlcoder_video_ipList` as the function name because it targets video applications. Using this function, specify whether you want to add all or some of the IP modules in the repository to the reference design project. To add all IP modules, use an empty cell array for `ipList`. This MATLAB code shows how to add all IP modules in the repository to the reference design.

```
function [ipList] = hdlcoder_video_ipList( )
% All IP modules in the repository folder.

ipList = {};
```

You can specify the root directory as an optional second output argument to the IP list function. In this case, the IP modules do not have to be located in a path relative to the IP list function. The IP repository can also be located outside the MATLAB path.

If you do not specify the root directory, the function searches for IP modules relative to its location.

```
function [ipList, rootDir] = hdlcoder_video_ipList( )
% All IP modules with a root directory.

ipList = {};
```

To add some of the IP modules that are in the folder, specify the IP modules as a cell array of character vectors. This MATLAB code specifies the AXI4StoHDMI IP and the HDMItoAXIS IP as the IP modules to add to your custom reference design.

```
function [ipList] = hdlcoder_video_ipList( )
% AXI4StoHDMI and HDMItoAXIS IP in the repository folder.

ipList = {'AXI4StoHDMI','HDMItoAXIS'};
```

Add IP List Function to Reference Design Project

Using the `addIPRepository` method of the `hdlcoder.ReferenceDesign` class, add the IP list function to your custom reference design. This example reference design adds `hdlcoder_video_ipList` to the custom reference design `My Reference Design`.

```
function hRD = plugin_rd()
% Reference design definition

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');
hRD.ReferenceDesignName = 'My Reference Design';
hRD.BoardName = 'ZedBoard'

% Tool information
hRD.SupportedToolVersion = {'2020.2'};

%% Add custom design files
hRD.addCustomVivadoDesign( ...
    'CustomBlockDesignTcl', 'system_top.tcl', ...
    'VivadoBoardPart',      'em.avnet.com:zed:part0:1.0');

% Add IP Repository
hRD.addIPRepository(...
    'IPListFunction', 'mathworks.hdlcoder.vivado.hdlcoder_video_ipList',
    'NotExistMessage', 'IP repository not found');

% ...
% ...
```

To use the IP modules when the code generator creates the project, open the HDL Workflow Advisor, and run the IP Core Generation workflow to the **Create Project** task. After running this task, you can see the IP module subfolders in the repository copied over to the `ipcore` folder of the project. The `CustomBlockDesignTcl` can then use these IP modules.

FPGA Programming and Configuration on Speedgoat Simulink-Programmable I/O Modules

This example shows how to implement a Simulink® algorithm on a Speedgoat® Simulink-programmable I/O module by using the HDL Workflow Advisor. You run the Simulink Real-Time FPGA I/O workflow to:

- 1 Specify an FPGA I/O module and its interfaces.
- 2 Synthesize the Simulink algorithm for FPGA programming.
- 3 Generate a Simulink® Real-Time™ interface subsystem model.

The interface subsystem model contains blocks to program the FPGA and communicate with the FPGA module through the PCIe bus during real-time application execution. You add the generated subsystem to your Simulink Real-Time domain model.

This example uses the Speedgoat IO397-50k module. See “Speedgoat FPGA Support with HDL Workflow Advisor” on page 46-14.

Setup and Configuration

Before deploying your algorithm on the Speedgoat IO module:

1. Install the latest version of Xilinx® Vivado® as listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.

Then, set the tool path to the installed Xilinx Vivado executable by using the `hdlsetuptoolpath` function.

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath','C:\Xilinx\Vivado\2019.2\bin\vivado.bat')
```

2. For real-time simulation, set up the development environment and target computer settings. See “Get Started with Simulink Real-Time” (Simulink Real-Time).

3. Install the Speedgoat Library and the Speedgoat HDL Coder Integration packages. See Install Speedgoat HDL Coder Integration Packages.

HDL Workflow Advisor

The HDL Workflow Advisor guides you through HDL code generation and the FPGA design process. Use the Advisor to:

- Check the model for HDL code generation compatibility and fix incompatible settings.
- Generate HDL code, test bench, and scripts to build and run the code and test bench.
- Perform synthesis and timing analysis.
- Deploy the generated code on SoCs, FPGAs, and Speedgoat I/O modules.

To open the HDL Workflow Advisor for a subsystem inside the model, use the `hdladvisor` function.

```
load_system('sschdlexTwoLevelConverterIgbtExample')
hdladvisor('sschdlexTwoLevelConverterIgbtExample/Simscape_system')
```

The left pane of the Advisor contains folders that represent a group of related tasks. Expanding the folders and selecting a task displays information about that task in the right pane. The right pane

contains simple controls for running the task to advanced parameters and option settings that control HDL code and test bench generation. To learn more about each task, right-click that task, and select **What's This?**. See “Getting Started with the HDL Workflow Advisor” on page 36-6.

Simulink Loopback Domain Model

This model is your FPGA domain model. It represents the simulation sample rate of the clock on your FPGA board. The loopback subsystem contains the algorithm to load on the FPGA. The data type and the number of input and output lines of the model are configured to fit the Speedgoat I0397-50k platform.

```
open_system('hdlcoder_slrt_loopback')
set_param('hdlcoder_slrt_loopback', 'SimulationCommand', 'Update')
```

Copyright 2010-2021 The MathWorks, Inc.

Generate Simulink Real-Time Interface Model for Speedgoat IO397 Platform

1. Open the HDL Workflow Advisor for the loopback subsystem. This subsystem is loaded on the FPGA.

```
hdladvisor('hdlcoder_slrt_loopback/loopback')
```

2. Expand the **Set Target** folder. In the **Set Target Device and Synthesis Tool** task, specify **Target workflow** as Simulink Real-Time FPGA I/O and **Target platform** as Speedgoat I0397-50k. Right-click the **Set Target Reference Design** task and select **Run to Selected Task**.

1.1. Set Target Device and Synthesis Tool

Analysis (^Triggers Update Diagram)

Set Target Device and Synthesis Tool for HDL code generation

Input Parameters

Target workflow: Simulink Real-Time FPGA I/O

Target platform: Speedgoat IO397-50k Launch Board ManagerSynthesis tool: Xilinx Vivado Tool version: 2019.2.1 RefreshFamily: Artix7 Device: xc7a50tPackage: csg325 Speed: -2Project folder: hdl_prj Browse...Run This TaskResult: ✓ PassedPassed Set Target Device and Synthesis Tool.

3. In the **Set Target Interface** task, map ports hwIn and hwOut to IO397_TTL [0:13] and pciRead C0-C4 and pciWrite C0-C4 to PCIe interface. Click **Run This Task**.

1.3. Set Target Interface

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping	Interface Options
hwIn C0-C4	Inport	ufix4	IO397 TTL [0:13]	[0:3]	
pciWrite C0-C4	Inport	bus	PCIe Interface	x"100"	Options...
pciRead C0-C4	Output	ufix4	PCIe Interface	x"104"	
hwOut C0-C4	Output	ufix4	IO397 TTL [0:13]	[8:11]	

Run This TaskResult: ✓ PassedPassed Set Target Interface Table.

4. Run the **Set Target Frequency** task with the default value set for **Target Frequency (MHz)**. The target frequency must be in the range **Frequency Range (MHz)**.

5. Expand the **Download to Target** task. Right-click the **Generate Simulink Real-Time interface** task and select **Run to Selected Task**.

This task generates RTL code and IP core, FPGA bitstream, and the Simulink Real-Time Interface model. In the **Create Project** task, open the Vivado project to see the implemented block design.

Real-Time Subsystem Integration and Execution

After the **Generate Simulink Real-Time interface** task passes, click the link to open the Simulink Real-Time interface model.

The Simulink-Real Time Interface model contains a masked subsystem that has the same name as the subsystem in the Simulink FPGA domain model. This subsystem is the Simulink Real-Time Interface subsystem that contains the algorithm which is loaded onto the FPGA. Use the generated Simulink Real-Time Interface model or create a Simulink Real-Time Domain model and copy the Simulink Real-Time Interface subsystem into that model to simulate your FPGA algorithm on the Speedgoat target machine.

In the Simulink Real-Time interface subsystem mask, set three parameters:

- Device index
- PCI slot
- Sample time

When the target has a single FPGA I/O board, leave the device index to the default value. For multiple FPGA I/O boards, specify a unique device index. If two or more boards are of the same type, specify the PCI slot for each board.

For real-time testing, you can log the signals and view the simulation results on the Simulation Data Inspector.

- 1 On the **REAL-TIME** tab, open the Simulink Real-Time Explorer and specify the target interface connection settings. For an example, see “Hardware-in-the-Loop Implementation of Simscape Model on Speedgoat FPGA I/O Modules” on page 37-88.
- 2 On the **REAL-TIME** tab, click **Run on Target** to build and download the Simulink Real-Time application. The real-time application loads onto the Speedgoat target machine and the FPGA algorithm bitstream loads onto the FPGA.

You can then view the simulation results on the Simulation Data Inspector.

Model Design for AXI4-Stream Video Interface Generation

In this section...

“Sample Based Modeling” on page 47-97
 “Protocol Signals and Timing Diagrams” on page 47-98
 “Model Data and Control Bus Signals” on page 47-99
 “Map DUT Ports to Multiple Channels” on page 47-103
 “Model Designs with Multiple Sample Rates” on page 47-103
 “Video Porch Insertion Logic” on page 47-103
 “Default Video System Reference Design” on page 47-104
 “Restrictions” on page 47-105
 “Frame-Based Modeling” on page 47-105

For designs that require high speed video streaming use AXI4-Stream Video interfaces. Choose from these two modeling styles based on how your algorithm operates:

- **Sample-Based Modeling** — Use these guidelines when your algorithm operates on a stream of samples.
- **Frame-Based Modeling** — Use these guidelines when your algorithm operates on a complete frame of data. The data signals at the design under test (DUT) boundary must be matrices. Do not use this mode if you want to model the streaming pixel protocol.

With the HDL Coder software, you can implement a simplified, streaming pixel protocol in your model. The software generates an HDL IP core with AXI4-Stream Video interfaces.

Sample Based Modeling

With the HDL Coder software, you can implement a simplified, streaming pixel protocol in your model. The software generates an HDL IP core with AXI4-Stream Video interfaces. You can use the streaming pixel protocol for AXI4-Stream Video interface mapping. Video algorithms process data serially and generate video data as a serial stream of pixel data and control signals. To learn about the streaming pixel protocol, see “Streaming Pixel Interface” (Vision HDL Toolbox).

To generate an IP core with AXI4-Stream Video interfaces, in your DUT interface, implement these signals:

- Pixel Data
- Pixel Control Bus

The **Pixel Control Bus** is a bus that has these signals:

- hStart
- hEnd
- vStart
- vEnd
- valid

The signals **hStart** and **hEnd** represent the start of an active line and the end of an active line respectively. The signals **vStart** and **vEnd** represent the start of a frame and the end of a frame.

You can optionally model the backpressure signal, **Ready**, and map it to the AXI4-Stream Video interface.

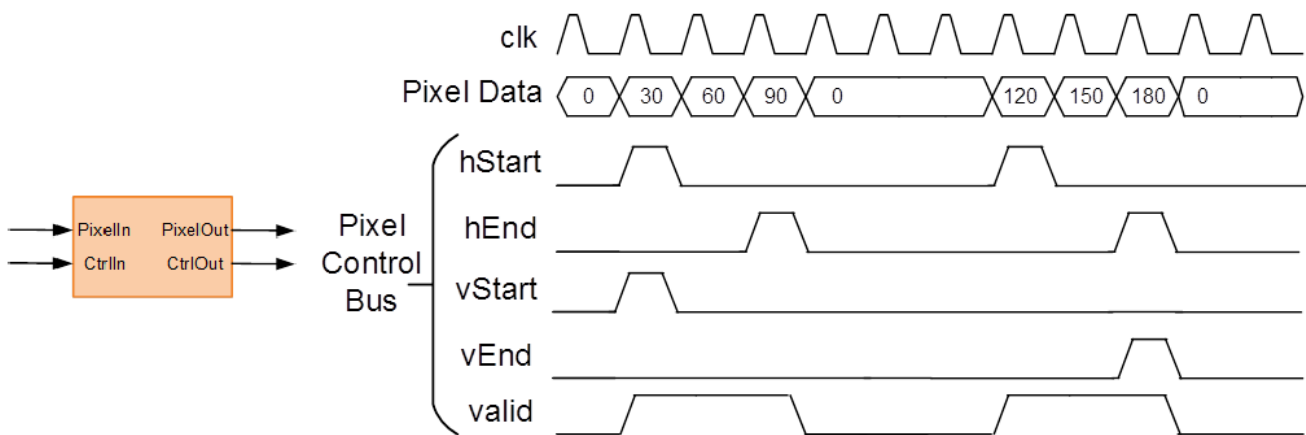

Protocol Signals and Timing Diagrams

This figure is a 2-by-3 pixel image. The active image area is the rectangle with a dashed line around it and the inactive pixels that surround it. The pixels are labeled with their grayscale values.

Pixel Data and Pixel Control Bus

This figure shows the timing diagram for the **Pixel Data** and **Pixel Control Bus** signals that you model at the DUT interface.

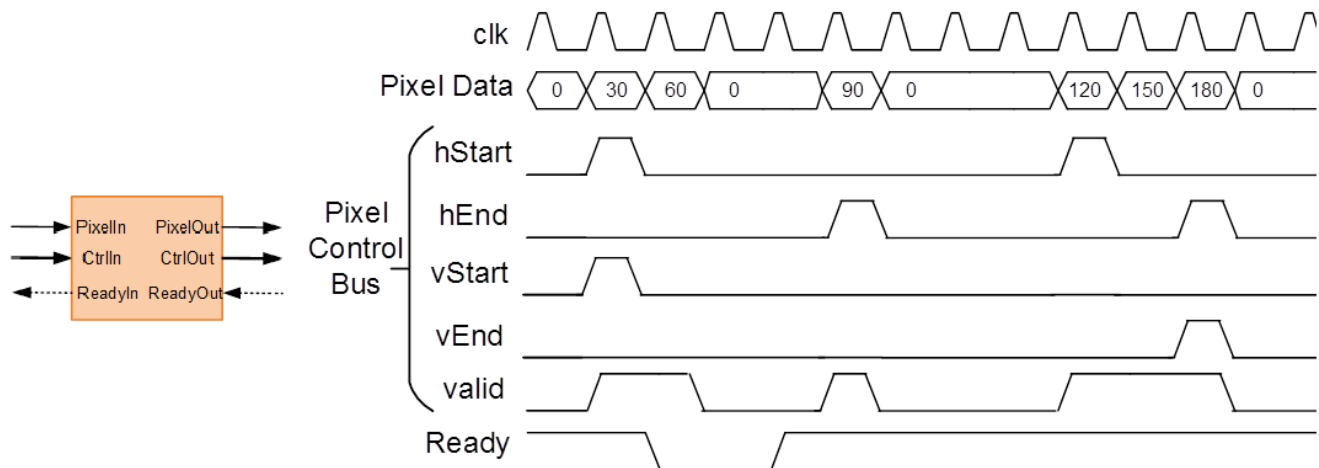

The **Pixel Data** signal is the primary video signal that is transferred across the AXI4-Stream Video interface. When the **Pixel Data** signal is valid, the **valid** signal is asserted.

The **hStart** signal becomes high at the start of the active lines. The **hEnd** signal becomes high at the end of the active lines.

The **vStart** signal becomes high at the start of the active frame in the second line. The **vEnd** signal becomes high at the end of the active frame in the third line.

Optional Ready Signal

This figure shows the timing diagram for the **Pixel Data**, the **Pixel Control Bus**, and the **Ready** signal that you model at the DUT interface.

When you map the DUT ports to an AXI4-Stream Video interface, you can optionally model the backpressure signal, **Ready**, and map it to the AXI4-Stream Video interface.

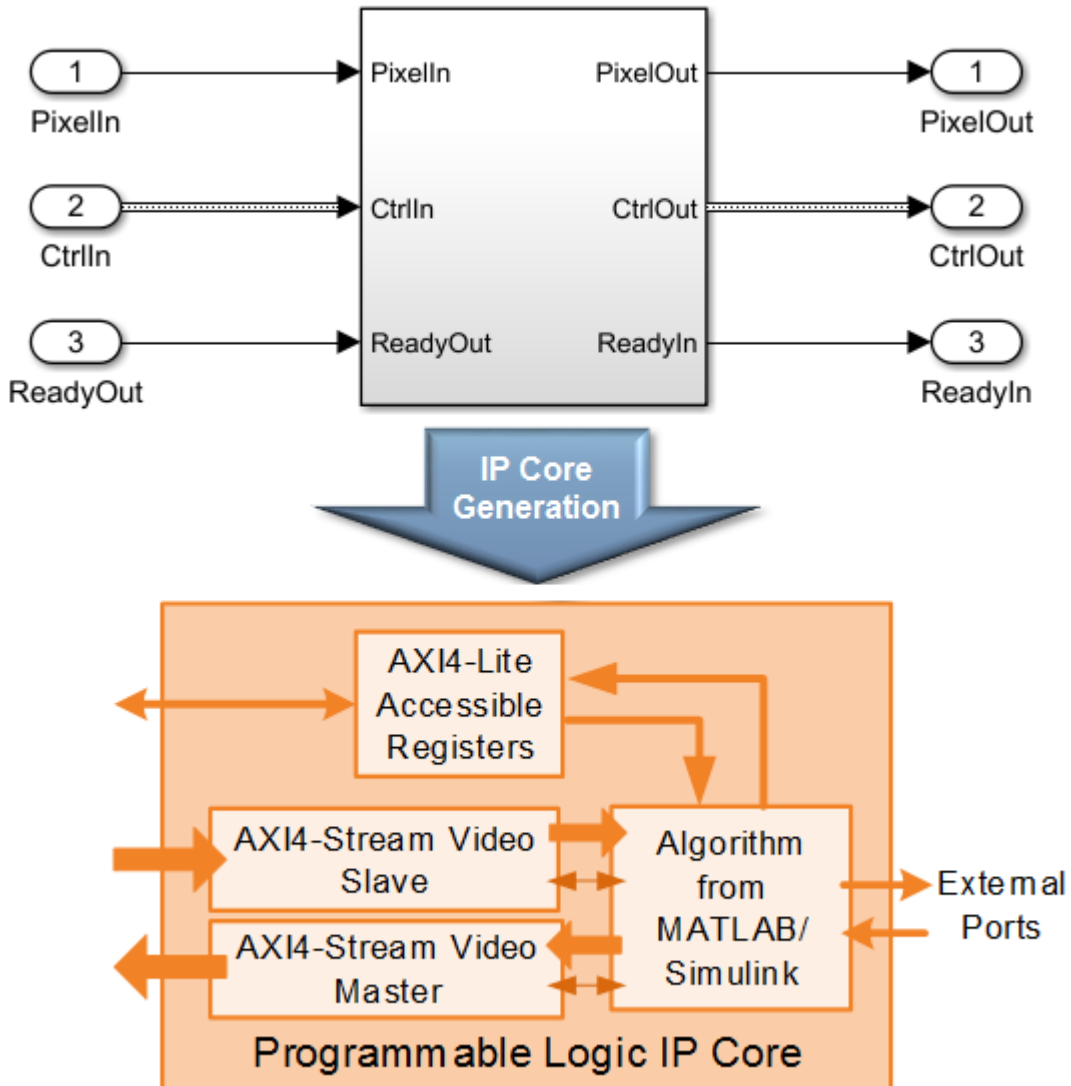

In a Slave interface, with the **Ready** signal, you can apply back pressure. In a Master interface, with the **Ready** signal, you can respond to back pressure.

If you model the **Ready** signal in your AXI4-Stream Video interfaces, your Master interface must deassert its **valid** signal one cycle after the **Ready** signal is deasserted.

If you do not model the **Ready** signal, HDL Coder generates the associated backpressure logic.

Model Data and Control Bus Signals

You can model your video algorithm with **Pixel Data** and **Pixel Control Bus** signals at the DUT ports and map the signals to AXI4-Stream Video interfaces. You can optionally model the backpressure signal, **Ready**, and map it to the AXI4-Stream Video interface.

This figure shows an example of a top-level Simulink model with a Video Source input.

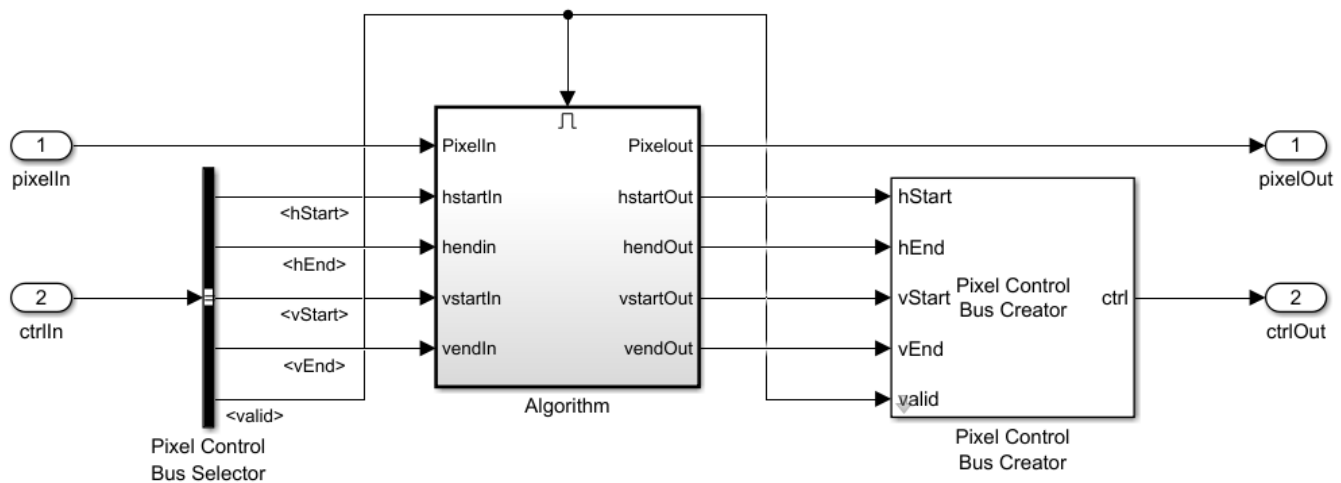

The Frame To Pixels and Pixels To Frame blocks perform the conversion between the video frames and the **Pixel Data** and **Pixel Control Bus** at the DUT interface. To use these blocks, you must have the Vision HDL Toolbox installed.

See also Frame To Pixels and Pixels To Frame.

Pixel Data and Pixel Control Bus Modeling

This figure shows how to model the **Pixel Data** and **Pixel Control Bus** signals inside the **DUT** subsystem.

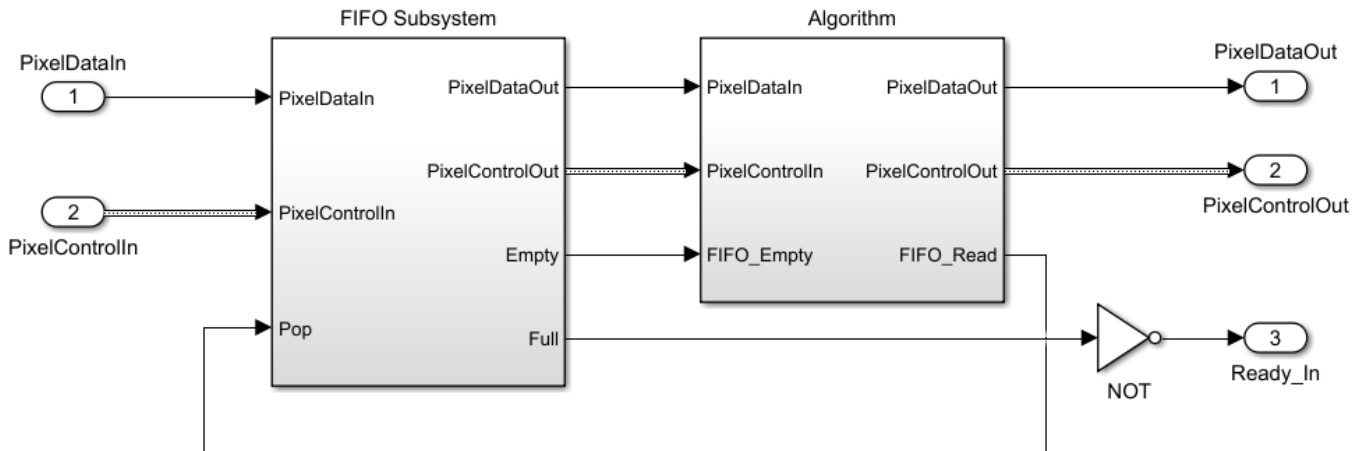

You can directly connect the **valid** signal from the **Pixel Control Bus** to the Enable port. If you do not have the Vision HDL Toolbox software, replace the Pixel Control Bus Selector and Pixel Control Bus Creator blocks with the Bus Selector and Bus Creator blocks respectively.

Ready Signal Modeling

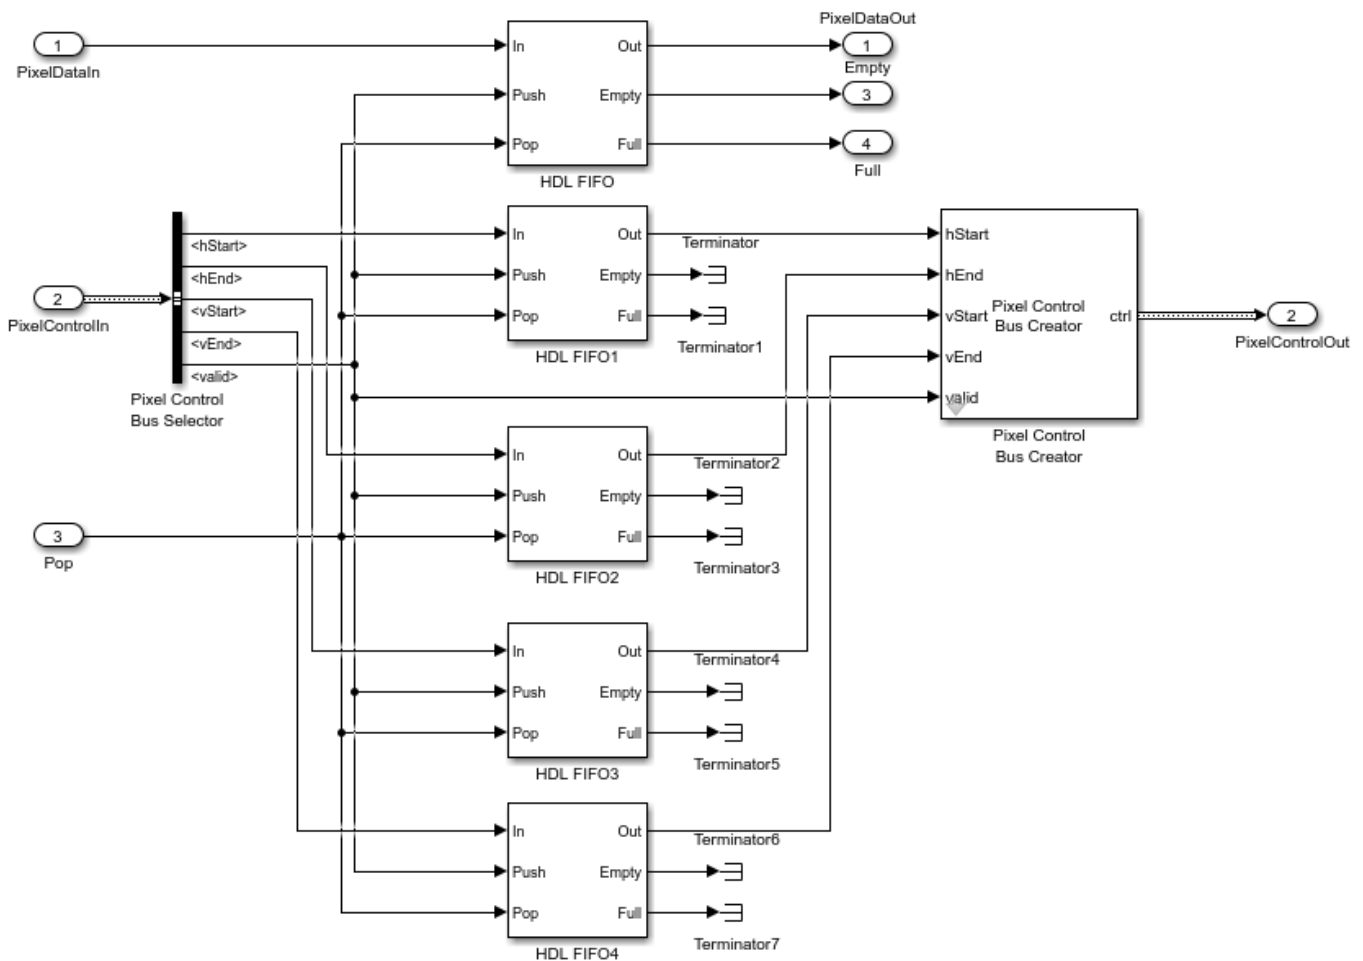

The AXI4-Stream Video interfaces in your DUT can optionally include a **Ready** signal.

For example, you can have a FIFO in your DUT to store some video data before processing the signals. Use a **FIFO Subsystem** that contains HDL FIFO blocks to store the **Pixel Data** and the **Pixel Control Bus** signals. To apply the backpressure to the upstream component, model the **Ready** signal based on the FIFO Full signal.

This figure shows how to model the **Ready** signal inside the **DUT** subsystem.

The **FIFO Subsystem** block uses HDL FIFO blocks for the **Pixel Data** and for the **Pixel Control Bus** signals.

Disable delay balancing for the **Ready** signal path. If you enable delay balancing, the coder can insert one or more delays on the **Ready** signal.

Map DUT Ports to Multiple Channels

When you run the IP Core Generation workflow, you can map multiple DUT ports to AXI4-Stream Video Master and AXI4-Stream Video Slave channels. The DUT ports mapped to multiple interface channels must use scalar data type. When you use vector ports, you can map the ports to at most one AXI4-Stream Video Master channel and one AXI4-Stream Video Slave channel.

To learn more, see “Generate HDL IP Core with Multiple AXI4-Stream and AXI4 Master Interfaces” on page 47-30.

Model Designs with Multiple Sample Rates

The HDL Coder software supports designs with multiple sample rates when you run the IP Core Generation workflow. When you map the interface ports to AXI4-Stream Video Master or AXI4-Stream Video Slave interfaces, to use multiple sample rates, ensure that the DUT ports that map to these AXI4 interfaces run at the fastest rate of the design after HDL code generation.

To learn more, see “Multirate IP Core Generation” on page 47-64.

Video Porch Insertion Logic

Video capture systems scan video signals from left to right and from top to bottom. As these systems scan, they generate inactive intervals between lines and frames of active video. This inactive interval is called a video porch. The horizontal porch consists of inactive cycles between the end of one line and the beginning of next line. The vertical porch consists of inactive cycles between the ending active line of one frame and the starting active line of next frame.

This figure shows a video frame with the horizontal porch split into a front and a back porch.

The AXI4-Stream Video interface does not require a video porch, but Vision HDL Toolbox algorithms require a porch for processing video streams. If the incoming pixel stream does not have a sufficient porch, HDL Coder inserts the required amount of porch to the pixel stream. By using the AXI4-Lite registers in the generated IP core, you can customize these porch parameters for each video frame:

- Active pixels per line (Default: 1920)
- Active video lines: (Default: 1080)
- Horizontal porch length (Default: 280)
- Vertical porch length (Default: 45)

Default Video System Reference Design

You can integrate the generated HDL IP core with AXI4-Stream Video interfaces into the `Default video` system reference design.

This figure is a block diagram of the `Default video` system reference design architecture.

You can use this Default video system reference design architecture with these target platforms:

- Xilinx Zynq ZC702 evaluation kit
- Xilinx Zynq ZC706 evaluation kit
- ZedBoard

To use the Default video system reference design, you must install the Support Package for Vision HDL Toolbox Support Package for Xilinx Zynq-Based Hardware.

Restrictions

When you map the DUT ports to AXI4-Stream Video interfaces:

- The DUT port mapped to the **Pixel Data** signal must use a scalar data type.
- Xilinx Zynq-7000 must be your target platform.
- You must use Xilinx Vivado as your synthesis tool.
- **Processor/FPGA synchronization** must be Free running.

Frame-Based Modeling

Model your DUT algorithm to operate on frames of data and map your matrix port to an AXI4-Stream Video interface by using the frame-to-sample optimization. For more information, see “Model Design for Frame-Based IP Core Generation” on page 47-26.

“Restrictions” on page 47-119

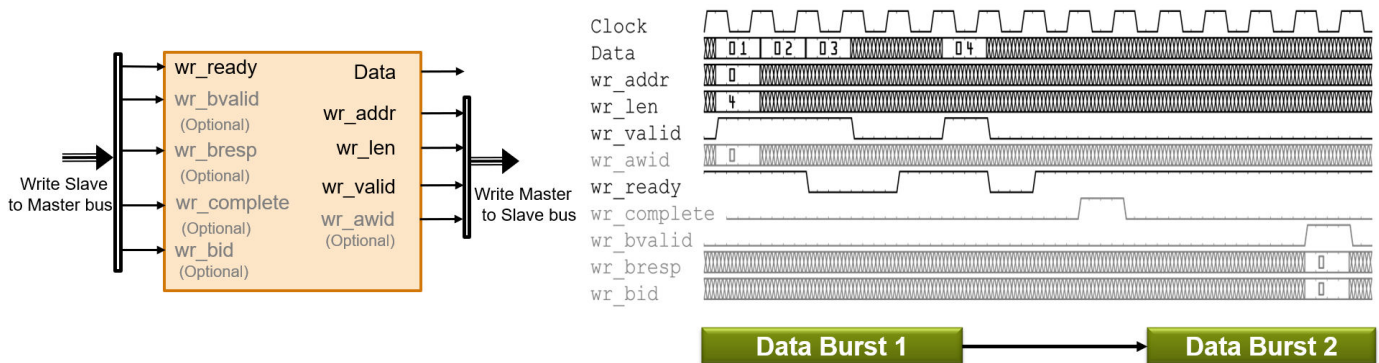

For designs that require accessing large data sets from an external memory, model your algorithm with a simplified AXI4 Master protocol. When you run the `IP Core Generation` workflow, HDL Coder generates an IP core with AXI4 Master interfaces. The AXI4 Master interface can communicate between your design and the external memory controller IP by using the AXI4 Master protocol. Use the AXI4 Master interface when your:

- Design targets multi-frame video processing applications. You can store the image data in external memory, such as a DDR3 memory on board, and then read or write the images to your design in a burst fashion for high-speed processing.
- Algorithm must access memory data in a non-streaming arbitrary pattern.
- DUT IP core must control other IPs with the AXI4 slave interface in the system. This capability is especially useful in standalone FPGA devices.

Simplified AXI4 Master Protocol - Write Channel

To map the DUT ports to AXI4 Master interfaces, use the simplified AXI4 Master protocol. You do not have to model the actual AXI4 Master protocol. Instead, you can use the simplified protocol. When you run the `IP Core Generation` workflow, the generated HDL code contains wrapper logic that translates between the simplified protocol and the actual AXI4 Master protocol. The simplified protocol requires fewer protocol signals, eases the handshaking mechanism between valid and ready signals, and supports bursts of arbitrary lengths.

For a write transaction, use the simplified AXI4 Master write protocol. For a read transaction, use the simplified AXI4 Master read protocol. This figure shows the timing diagram for the signals that you model at the DUT input and output interfaces for an AXI4 Master write transaction.

The DUT waits for `wr_ready` to become high to initiate a write request. When `wr_ready` becomes high, the DUT can send the write request. The write request consists of the `Data` and `Write Master to Slave bus` signals. This bus consists of `wr_len`, `wr_addr`, and `wr_valid`. The `wr_addr` signal specifies the starting address that the DUT writes to. The `wr_len` signal corresponds to the number of data elements in this write transaction. `Data` can be sent when `wr_valid` is high. When `wr_ready` becomes low, the DUT must stop sending data within one clock cycle, and the `Data` signal becomes invalid. If the DUT continues to send data after one clock cycle, the data is ignored.

The simplified AXI4 Master Protocol supports pipelined requests. The protocol is not required to wait for the `wr_complete` signal to be high before issuing a subsequent write request. The interface supports up to 16 transactions (or 16 data words) before the pipeline stalls and the `wr_ready` signal goes low.

Output Signals

Model the `Data` and `Write Master to Slave bus` signals at the DUT output interface.

- `Data`: The data that you want to transfer, valid each cycle of the transaction.
- `Write Master to Slave bus` that consists of:
 - `wr_addr`: Starting address of the write transaction that is sampled at the first cycle of the transaction. The address is specified in bytes.
 - `wr_len`: The number of data values that you want to transfer, sampled at the first cycle of the transaction. The `wr_len` signal is specified in words, meaning that each unit of `wr_len` is a complete data element. For example, when `wr_len` is 2, and the bit width of data is 128 bit, two 128-bit data elements are written.
 - `wr_valid`: When this control signal becomes high, it indicates that the `Data` signal sampled at the output is valid.
 - `wr_awid` (optional signal): This signal is the address ID that identifies multiple streams over a single channel. When you do not map `wr_awid`, the generated IP core sets `wr_awid` to a constant 0.

Input Signals

Model the `Write Slave to Master bus` that consists of:

- `wr_complete` (optional signal): Control signal that when high for one clock cycle, indicates that the write transaction has completed. The next burst of data can be sent after `wr_complete` asserts. The early assertion of `wr_complete` makes the average latency nearly 3 clock cycles

between two bursts, which makes the write operation pipelined and improves the write throughput.

- **wr_ready:** This signal corresponds to the back pressure from the slave IP core or external memory. When this control signal goes high, it indicates that data can be sent. When wr_ready is low, the DUT must stop sending data within one clock cycle. You can also use the wr_ready signal to determine whether the DUT can send a second burst signal immediately after the first burst signal has been sent. Multiple burst signals are supported, which means that the wr_ready signal remains high to accept the second burst immediately after the last element of the first burst has been accepted. Using wr_ready to determine when to start the next burst can reduce the average latency between two bursts to less than 3 clock cycles.
- **wr_bvalid (optional signal):** Response signal from the slave IP core that you can use for diagnosis purposes. The wr_bvalid signal becomes high after the AXI4 interconnect accepts each burst transaction. If wr_len is greater than 256, the AXI4 Master write module splits the large burst signal into 256-sized bursts. The wr_bvalid signal becomes high for each 256-sized burst.
- **wr_bresp (optional signal):** Response signal from the slave IP core that you can use for diagnosis purposes. Use this signal with the wr_bvalid signal.
- **wr_bid (optional signal):** This signal is the write response ID that identifies multiple streams over a single channel. When you do not map wr_bid, the generated IP core terminates wr_bid.

The AXI4 Master protocol supports a maximum burst size of 256. When you have a large burst size of greater than 256, the AXI4 Master interface in the generated HDL IP core divides the large burst into multiple smaller bursts with size 256. Even for large bursts of data, you see an improved write throughput.

Simplified AXI4 Master Protocol - Read Channel

This figure shows the timing diagram for the signals that you model at the DUT input and output interfaces for an AXI4 Master read transaction. These signals include the Data, Read Master to Slave Bus, and Read Slave to Master Bus.

The DUT waits for rd_arsp to become high to initiate a read request. When rd_arsp is high, the DUT can send out the read request. The read request consists of the rd_addr, rd_len, and rd_avalid signals of the Read Master to Slave bus. The slave IP or the external memory responds to the read request by sending the Data at each clock cycle. The rd_len signal

corresponds to the number of data values to read. The DUT can receive Data as long as `rd_dvalid` is high.

Read Request

To model a read request, at the DUT output interface, model the `Read Master to Slave bus` that consists of:

- `rd_addr`: Starting address for the read transaction that is sampled at the first cycle of the transaction. The address is specified in bytes.
- `rd_len`: The number of data values that you want to read, sampled at the first cycle of the transaction. The `rd_len` signal is specified in words, meaning each unit of `rd_len` is a complete data element. For example, when `rd_len` is 2, and the bit width of data is 128 bit, two 128-bit data elements are read.
- `rd_avalid`: Control signal that specifies whether the read request is valid.
- `rd_arid` (optional signal): This signal is the address ID that identifies multiple streams over a single channel. When you do not map `rd_arid`, the generated IP core sets `rd_arid` to a constant 0.

At the DUT input interface, you can model the ready signal `rd_aready` to indicate when to send a new read request. The `rd_aready` signal indicates whether the DUT can send consecutive multiple burst requests. The DUT can send a new request one clock cycle after the ready signal is asserted. After the ready signal is de-asserted, the DUT can send one more read request. The DUT cannot send a new read request and the request is ignored one clock cycle after the ready signal is de-asserted.

The simplified AXI4 Master Protocol supports pipelined requests, so it is not required to wait for the read response to complete before issuing a subsequent read request. The interface supports up to four read transactions before the pipeline stalls and the `rd_aready` signal goes low.

Read Response

At the DUT input interface, model the `Data and Read Slave to Master bus` signals.

- `Data`: The data that is returned from the read request.
- `Read Slave to Master bus` that consists of:
 - `rd_dvalid`: Control signal, which indicates that the Data returned from the read request is valid.
 - `rd_rvalid` (optional signal): Response signal from the slave IP core that you can use for diagnosis purposes.
 - `rd_rresp` (optional signal): Response signal from the slave IP core that indicates the status of the read transaction.
 - `rd_rid` (optional signal): This signal is the data ID that identifies multiple streams over a single channel. When you do not map `rd_rid`, the generated IP core terminates `rd_rid`.

At the DUT output interface, you can optionally implement the `rd_dready` signal. This signal is part of the `Read Master to Slave bus` and indicates when the DUT can start accepting data. By default, if you do not map this signal to the AXI4 Master read interface, the generated HDL IP core ties the `rd_dready` signal to logic high.

Base Address Register Calculation

For IP cores that you generate, HDL Coder includes a base address register to support driver authoring for both the AXI4 Master read and write channels. The base address register is added to the address that is specified by the DUT ADDR port to form the AXI4 Master address. This capability enables the driver to use an addressing mode that programs a fixed register address with the base address of a buffer. The programmed address together with the DUT ADDR port is used to index the buffer. By default, the registers take a value of zero, if you do not use them.

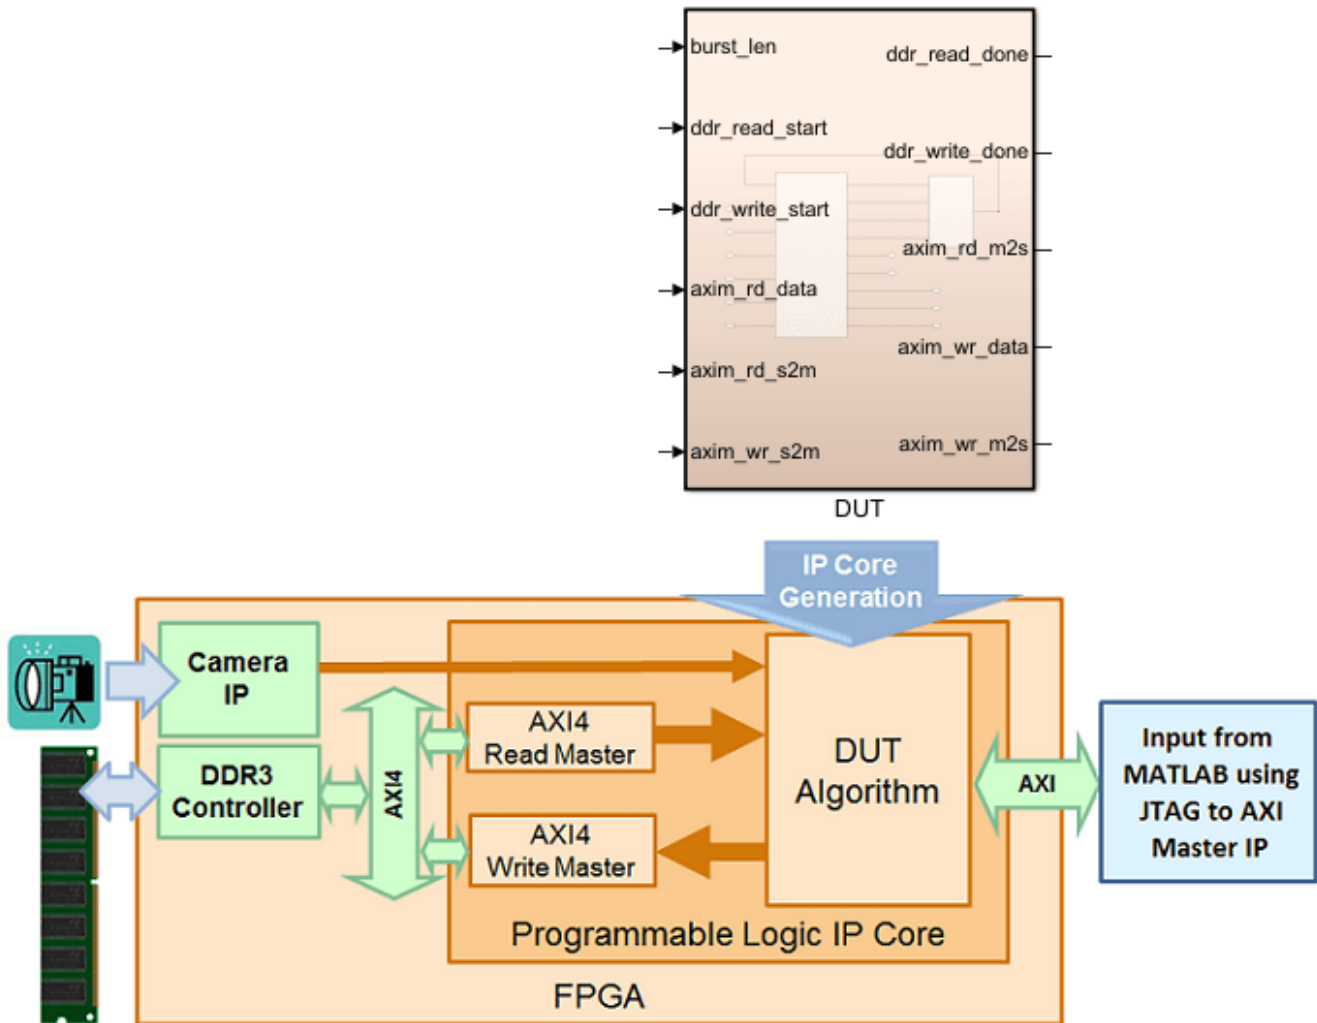

Specify Initial Value of AXI4 Master Read and Write Base Address

When you run the IP Core Generation workflow or the Simulink Real-Time FPGA I/O workflow, you can specify an initial value for the AXI4 master data read and write base address registers. By default, the initial value is zero. To specify a nonzero value:

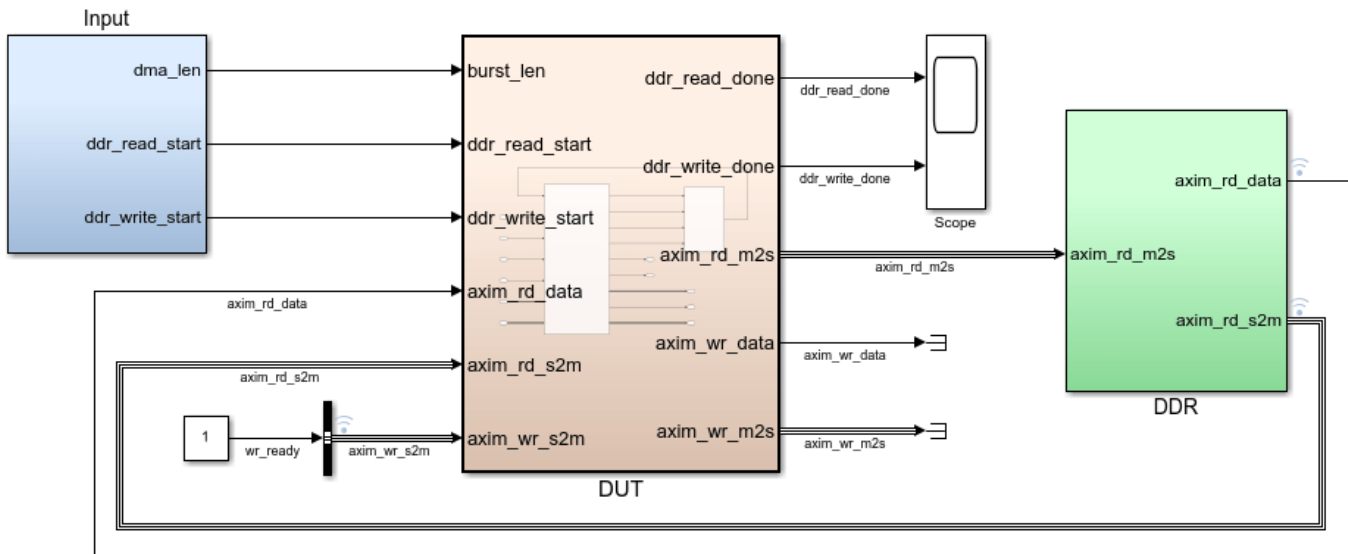

- 1 In the target platform interface table, when you map an input DUT port to an AXI4 Master Read data port, or an output DUT port to an AXI4 Master Write data port interface, an **Options** button appears in the **Interface Options** column.
- 2 Click the **Options** button, and then specify the **DefaultReadBaseAddress** or **DefaultWriteBaseAddress**.

Modeling for AXI4 Master Interfaces

You can model your algorithm with Data and AXI4 Master protocol signals at the DUT ports and then map the signals to AXI4 Master interfaces.

To learn how to model your DUT algorithm for AXI4 Master interface mapping, open this Simulink® model. The DUT Subsystem contains a simple algorithm that reads data from the DDR and writes the data back to a different address in the DDR memory.

Copyright 2017-2021 The MathWorks, Inc.

Double-click the DUT Subsystem. The DDR_Access_Controller Subsystem models the AXI Master read and write channels and has a Simple Dual Port RAM that calculates the `wr_data` signal. If you double-click the DDR_Access_Controller Subsystem, you see two Edge Detection Subsystem blocks that generate the two start pulses as input to each MATLAB Function block. One Edge Detection Subsystem and DDR Read Controller MATLAB Function models the read transaction. The other Edge Detection Subsystem and DDR Write Controller MATLAB Function models the write transaction. You can modify this design to model only the write transaction or the read transaction by using one Edge Detection Subsystem and the corresponding MATLAB Function block.

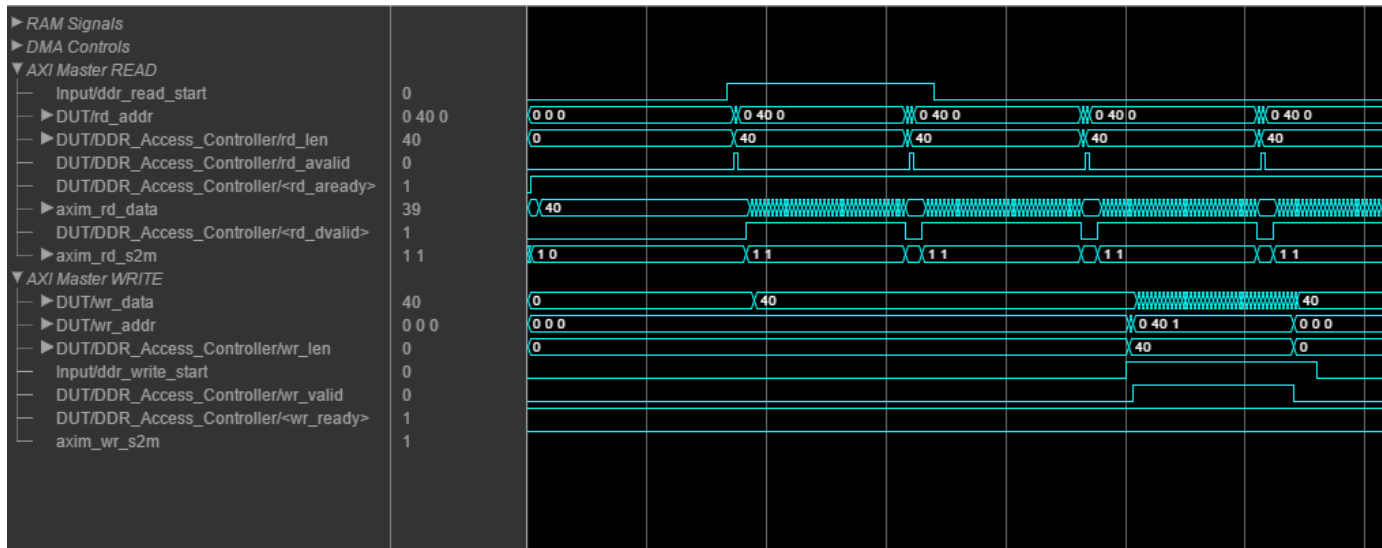

Read Channel

The DDR Read Controller is modeled as a state machine with four states: INIT, IDLE, READ_BURST_START, and DATA_COUNT. The INIT state initializes the read signals and the RAM input signals. When the start signal goes high, the state machine switches to the IDLE state, and then waits for the `rd_ready` signal to become high. When `rd_ready` becomes high, the state machine transitions to the READ_BURST_START state and the DUT starts reading data. The state machine then unconditionally switches to the DATA_COUNT state and continues to read data till `rd_avalid` goes low.

Write Channel

The DDR Write Controller is modeled similar to the Read channel as a state machine with four states: IDLE, WRITE_BURST_START, DATA_COUNT, and ACK_WAIT. The DUT is in the IDLE state and then switches to the WRITE_BURST_START state where it waits for the `wr_ready` signal. When `wr_ready` becomes high, the state machine switches to the DATA_COUNT state and starts writing data. The data is valid when `wr_valid` is high. The DUT continues to write data when `wr_ready` is high. As `wr_ready` becomes low, the state machine switches to the ACK_WAIT state and then waits for the ready signal to initiate the next write transaction.

To see the simplified AXI4 Master protocol in effect, simulate the model. If you have DSP System Toolbox™ installed, you can view and analyze the results in the Logic Analyzer.

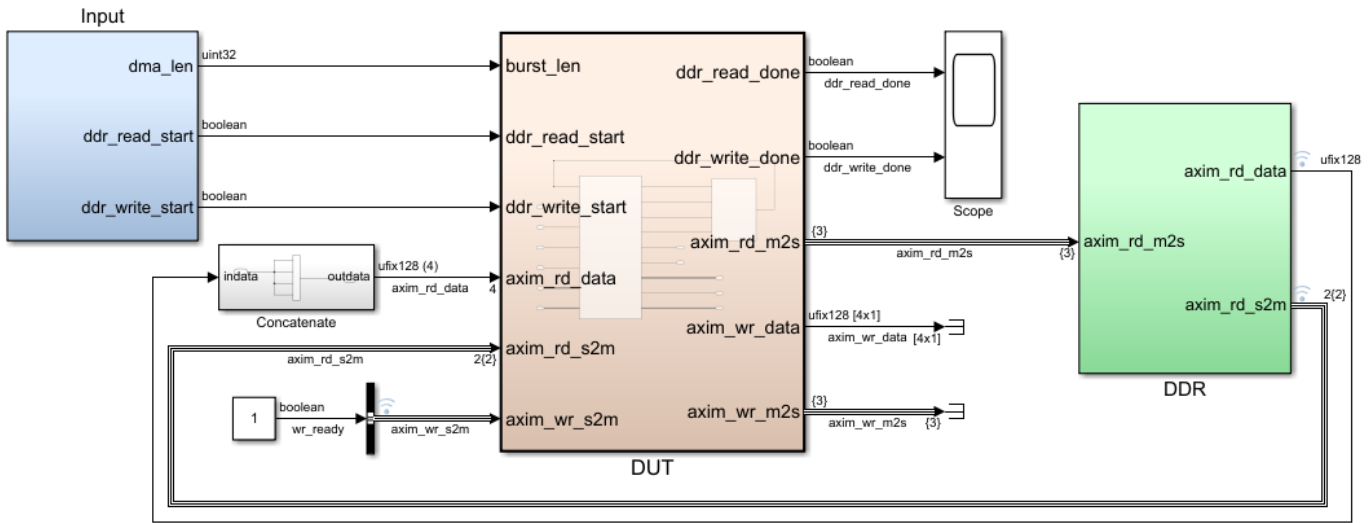

You can use the IP Core Generation workflow to generate an HDL IP core with the AXI4 Master interface. If you have HDL Verifier™ installed, and you use the Xilinx® Zynq® ZC706 board, then you can integrate the IP core into the Default System with External DDR3 memory access reference design.

Map Vector Ports to AXI4 Master Interfaces

To integrate your HDL IP core into larger reference designs, and to achieve higher throughput when you use the AXI4 Master port to access external DDR memory, you may want to use larger bit widths on the **Data** port. The AXI4 Master interface bus supports a maximum bit width of 1024 bits.

Simulink supports fixed-point data types that have word length of up to 128 bits. To model your DUT ports with word lengths greater than 128 bits, use vector data types. If you use a vector port such that the combined bit width of all the elements in the vector is greater than 1024 bits, the **Set Target Interface** task displays an error.

For example, in the `hdlcoder_axi_master` model, to expand the bit width of the `axim_rd_data` port to 512 bits, change the `ddr_data` parameter inside the `DDR` to `fi([40:-1:1],0,128,0)` and then concatenate the 128-bit input four times to generate an output of 512 bits. You can use a Vector Concatenate block to output a combined bit width of 512 bits. To simulate the model, replace the Simple Dual Port RAM block inside the DUT subsystem with a Simple Dual port RAM System.

You can then map these DUT Data ports to AXI4 Master Read or AXI Master Write ports in the Target platform interface table, generate the HDL IP core, and integrate the IP core into your Vivado or Qsys reference designs. In the generated HDL code for the DUT IP core, the Data ports are mapped to 512-bit interfaces. Multiple FIFO blocks are generated corresponding to each element of the vector input.

```

ENTITY DUT_ip IS
  PORT( IPCORE_CLK           : IN    std_logic; -- ufix1
        IPCORE_RESETN       : IN    std_logic; -- ufix1
        AXI4_Master_Rd_RDATA : IN    std_logic_vector(511 DOWNTO 0); -- ufix256
        ...
        AXI4_Master_Wr_WDATA : OUT   std_logic_vector(511 DOWNTO 0); -- ufix256
        ...
  );
END DUT_ip;

```

This figure illustrates the order in which the vector data is written to and read form.

In the HDL code for the DUT IP core, you can see how the AXI4_Master_Rd_RDATA and AXI4_master_Wr_WDATA interfaces are mapped to the DUT ports and the order in which data is written to the AXI4 Master interface and then read back.

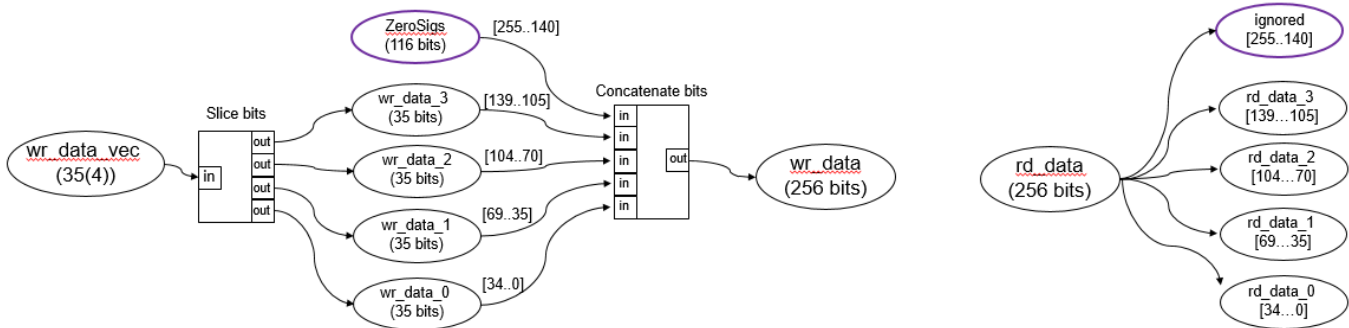

```

...
...
-----
AXI4 Master Read Sequence
-----
AXI4_Master_Rd_RDATA_0 <= AXI4_Master_Rd_RDATA_unsigned(127 DOWNTO 0);
AXI4_Master_Rd_RDATA_1 <= AXI4_Master_Rd_RDATA_unsigned_1(255 DOWNTO 128);
AXI4_Master_Rd_RDATA_2 <= AXI4_Master_Rd_RDATA_unsigned_7(383 DOWNTO 256);
AXI4_Master_Rd_RDATA_3 <= AXI4_Master_Rd_RDATA_unsigned_7(511 DOWNTO 384);
-----
AXI4 Master Write Sequence
-----
AXI4_Master_Wr_WDATA_tmp <= unsigned(AXI4_Master_Wr_WDATA_Vec_3) &
                               unsigned(AXI4_Master_Wr_WDATA_Vec_2) &
                               unsigned(AXI4_Master_Wr_WDATA_Vec_1) &
                               unsigned(AXI4_Master_Wr_WDATA_Vec_0);

AXI4_Master_Wr_WDATA <= std_logic_vector(AXI4_Master_Wr_WDATA_tmp);
...
...

```

If you use a nonstandard bit width for the AXI4 Master Data port, the Data port is upgraded to a standard bit width container that has a bigger size. Standard bit widths include 32, 64, 128, 256, 512, and 1024 bits. For example, if you use a vector that has four 35-bit elements, the resulting bit width of 140 bits (35×4) is mapped to a 256-bit AXI4 Master interface. At the Write channel Data port, bits 255 to 141 are padded with zeroes. At the Read channel Data port, bits 255 to 141 are ignored.

Using nonstandard bit widths can have a performance impact because the entire bandwidth of the AXI4 Master interface is not used. To avoid performance hits, use standard AXI bit widths.

Model ID Signals to Reduce the Number of AXI-4 Master Interfaces

You can model ID signals for the Simplified AXI4 Master Protocol in the IP core generation workflow. Use ID signals to:

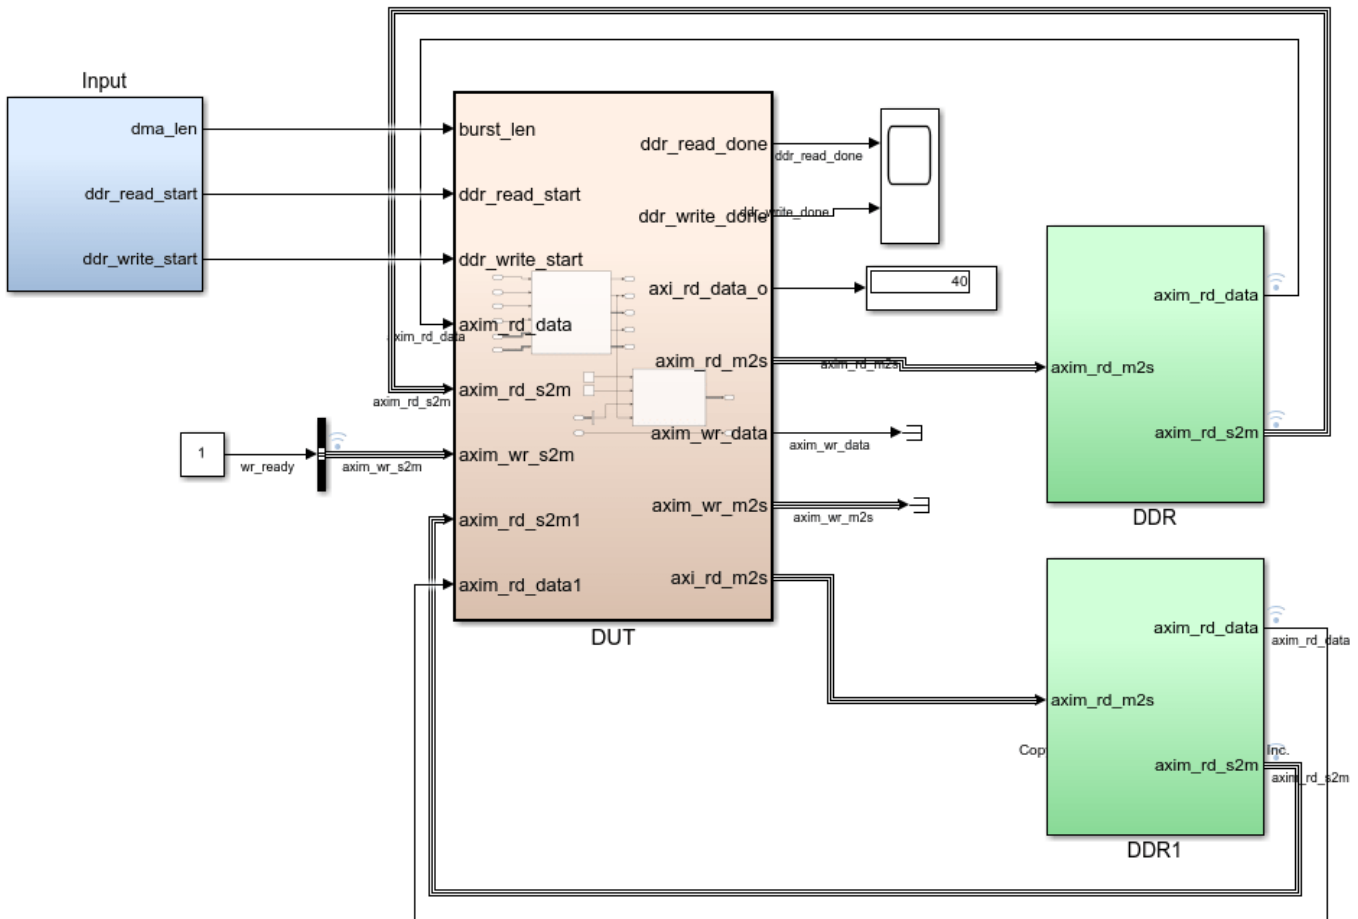

- Allow multiple modules to share the same AXI Master Interface.
- Enable out-of-order requests for data. ID signals allow an AXI Master to issue requests without waiting for a prior request to finish.

- Reduce the amount of AXI4 Master Interfaces needed for a Simulink model.

You can model ID signals in a write channel by using the optional signals `wr_awid` and `wr_bid`. You can model ID signals in a read channel by using the optional signals `rd_arid` and `rd_rid`. ID signal widths have these limitations:

- The ID widths must be an unsigned integer having a maximum of 32 bits.
- The ID widths for the read and write channel of the same AXI4 Master interface must match. Different AXI Master interfaces can have different ID widths.

When there are multiple kernels in the DUT that want to access external memory, during IP core generation, you can generate the read and write AXI masters for each kernel interface inside the DUT. These AXI masters consume hardware resources and add critical delays to the entire IP core when the number of AXI masters increase.

To allow multiple modules to share the same AXI Master Interface to reduce hardware consumption and critical delays, you can use ID signals. Besides modeling the physical ID signals, model an arbitrator inside the DUT. Based on your design needs, the arbitrator can be extendable as the number of processing kernels increases.

To see the simple read arbitrator modeled in this design, open the `multi_masters_with_ID.slx` model and double-click the DUT subsystem.

Model Designs with Multiple Sample Rates

The HDL Coder software supports designs with multiple sample rates when you run the IP Core Generation workflow. When you map the interface ports to AXI4 Master interfaces, to use multiple sample rates, ensure that the DUT ports that map to these AXI4 interfaces run at the fastest rate of the design after HDL code generation.

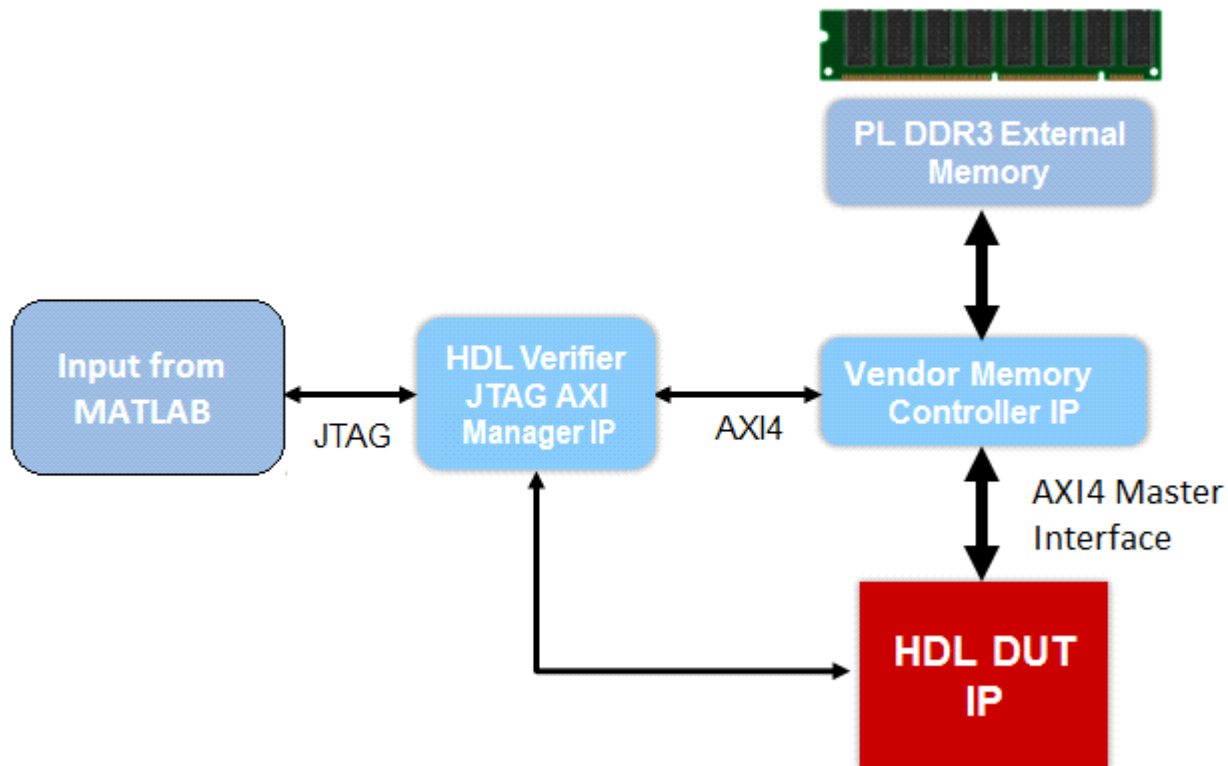

To learn more, see “Multirate IP Core Generation” on page 47-64.

Reference Designs for IP Core Integration

You can integrate the generated HDL IP core with AXI4 Master interfaces into these HDL Coder reference designs:

- Default System with External DDR3 Memory Access: When your target platform is Xilinx Zynq ZC706 evaluation kit.
- Default System with External DDR4 Memory Access: When your target platform is Intel Arria10 SoC development kit.

To use these reference designs, you must have HDL Verifier installed. This figure shows a high level block diagram of the reference design architecture.

In this architecture, the HDL DUT IP block corresponds to the IP core that is generated from the IP Core Generation workflow. Other blocks in the architecture represent the predefined reference design, that consists of a MATLAB based JTAG AXI Manager IP that is provided by HDL Verifier. After you run the FPGA design on the board, using the JTAG AXI Manager IP, you can use the input data in MATLAB to initialize the onboard DDR3 external memory. The HDL DUT IP core reads the input data from the external memory via the AXI4 Master interface. The IP core then performs the algorithm computation and writes the result to DDR3 memory via the AXI4 Master interface. The JTAG AXI Manager IP can read the result from DDR3 memory and then verify the result in MATLAB.

Using the `addAXI4MasterInterface` method of the `hdlcoder.ReferenceDesign` class, you can integrate the IP core with AXI4 Master Interface into your own custom reference design.

Restrictions

- **Synthesis tool:** Must be Xilinx Vivado or Altera QUARTUS II. Xilinx ISE is not supported.
- **Target workflow:** Use the IP Core Generation workflow. To run the workflow, open the HDL Workflow Advisor from your DUT algorithm in Simulink. MATLAB to HDL workflow is not supported.
- **Processor/FPGA synchronization:** Must be Free running mode.

IP Core Generation Workflow for Standalone FPGA Devices

In this section...

“Targeting FPGA Reference Designs with AXI4 Interface” on page 47-122

“Targeting FPGA Reference Designs Without AXI4 Interface” on page 47-124

“Board Support” on page 47-124

“Restrictions” on page 47-124

You can generate a reusable HDL IP core for any supported Xilinx or Altera FPGA device. The workflow produces an IP core report that displays the target interface configuration and the coder settings that you specify. See “Custom IP Core Generation” on page 46-16.

You can optionally build your own custom reference designs and integrate the generated IP core into the reference design. The workflow does not require the Embedded Coder software, because you need not generate the embedded code that is run on the processor. This means that the workflow has a **Generate Software Interface** task, but you cannot generate a software interface model.

If you have HDL Verifier installed, on the **Set Target Reference Design** task, set **Insert AXI Manager (HDL Verifier required)** to JTAG or Ethernet based on the interface that communicates between your host machine and the target board. For Ethernet, specify the IP address of the target board using the **Board IP Address** parameter.

Note By default, the Ethernet option is available for only the Artix-7 35T Arty, Kintex-7 KC705, and Virtex-7 VC707 boards. To enable this option for other Xilinx boards that have the Ethernet physical layer (PHY), manually add the Ethernet media access controller (MAC) Hub IP in the `plugin_board` file using the `addEthernetMACInterface` method before you launch the **HDL Workflow Advisor** tool.

You can then generate a host interface model, host interface script, or both in the **Generate Software Interface** task to rapidly prototype and test the HDL IP core functionality by using the AXI Manager. See “Generate Host Interface Script to Probe and Rapidly Prototype HDL IP Core” on page 46-61.

Note To generate a host interface model, you must map each DUT signal that you want to capture to the AXI4 or AXI4-Lite interfaces in the **Set Target Interface** task.

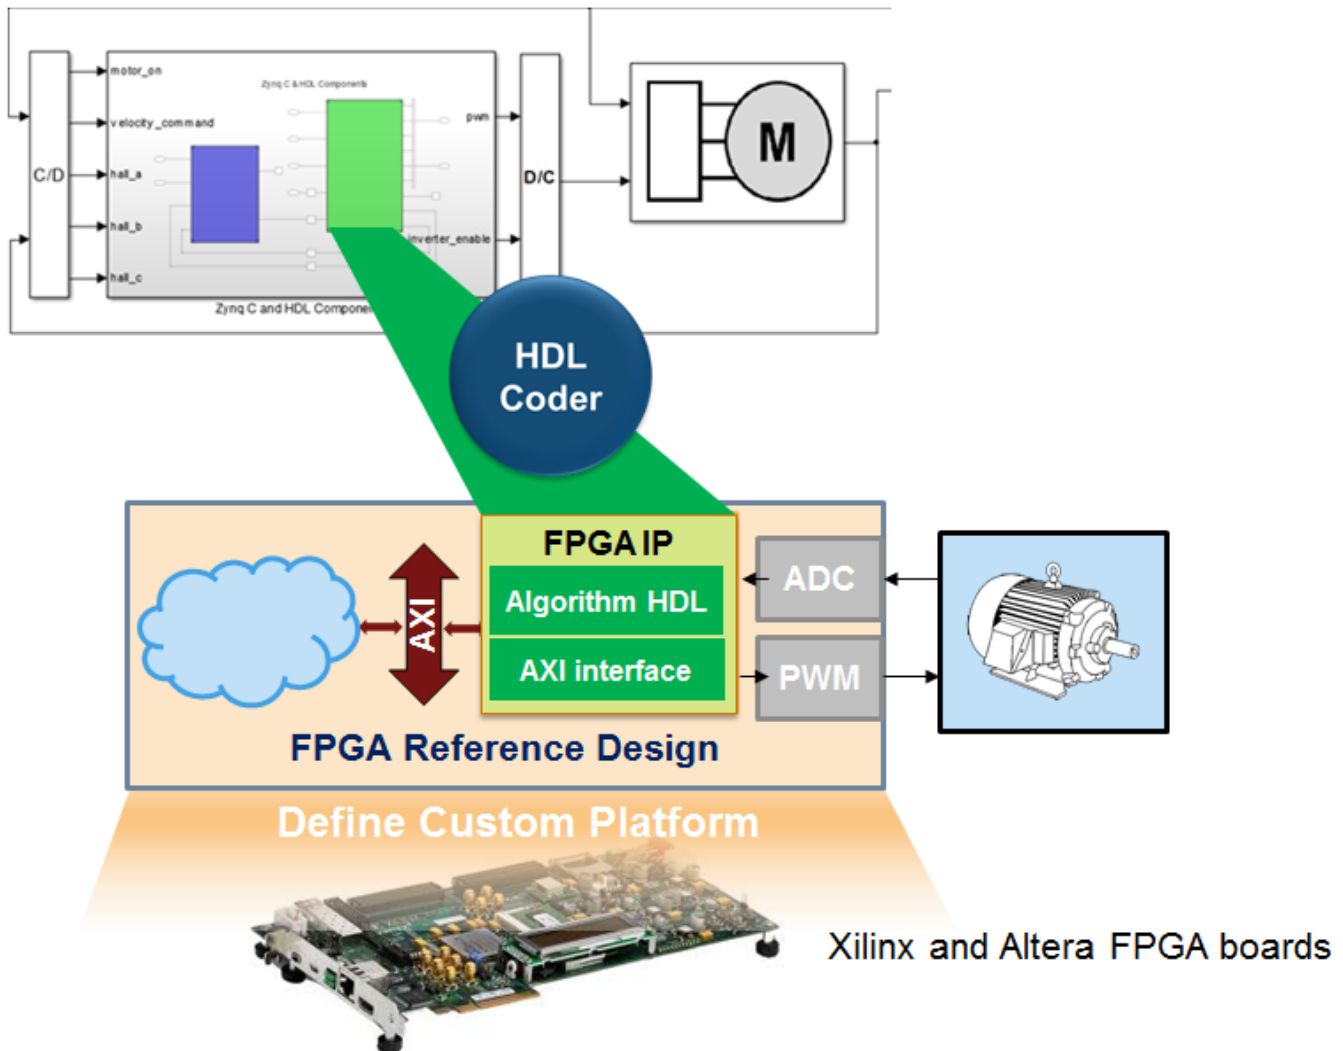

The workflow for the FPGA boards has these features:

- **Set Target Reference Design** task. Populates the reference design, its tool version, and the parameters that you specify.
- **Set Target Interface** task. Map your DUT ports to the interfaces on the target platform.
- **Set Target Frequency** task. Specifies the **Target Frequency (MHz)** to modify the clock module in the reference design to produce a clock signal with that frequency.
- **Generate RTL Code and IP Core** task. Generates a reusable and sharable IP core. The IP core packages the RTL code, a C header file, and the IP core definition files.
- **Create Project** task. Creates a project for integrating the IP core into the predefined reference designs.

You can generate an IP core with an optional AXI4 or an AXI4-Lite interface.

Targeting FPGA Reference Designs with AXI4 Interface

This figure shows how HDL Coder generates an IP core with an AXI4 interface and integrates the IP core into the FPGA reference design. See “Board and Reference Design Registration System” on page 47-68.

Use the HDL Coder generated AXI4-Lite interface to connect the IP core with an AXI4 or AXI4-Lite Master device such as:

- MicroBlaze processor.
- Nios II processor.
- PCIe Endpoint that connects to an external processor.
- JTAG Master.

When you connect the HDL IP core to a processor such as the MicroBlaze, you must integrate the handwritten C code to run on the processor. The generated IP core report displays the register address mapping information. To find the register offsets in the IP core register space, use this mapping information. To get the memory address of each register, add the register offset to the base address that you specify in your reference design. You can also find the register offsets in the C header file in the generated IP core folder.

Targeting FPGA Reference Designs Without AXI4 Interface

In the reference design definition function, you can create your own custom reference designs without the AXI4 slave interface. See also `addAXI4SlaveInterface`.

When creating a custom reference design, to target a standalone FPGA board, use the `EmbeddedCoderSupportPackage` method of the `hdlcoder.ReferenceDesign` class:

```
hRD.EmbeddedCoderSupportPackage = ...  
hdlcoder.EmbeddedCoderSupportPackage.None;
```

See `EmbeddedCoderSupportPackage`.

Board Support

HDL Coder supports these FPGA boards with the IP Core Generation workflow:

- Xilinx Kintex-7 KC705 development board
- Arrow DECA MAX 10 FPGA evaluation kit

Using these boards, you can integrate the generated IP core into the default system reference design. By default, this reference design does not have an AXI4 slave interface. Optionally, you can add the interface in the reference design definition function.

Restrictions

IP Core Generation workflow does not support :

- **RAM Architecture** set to Generic RAM without clock enable.
- Using different clocks for the IP core and the AXI interface. The `IPCore_Clk` and `AXILite_ACLK` must be synchronous and connected to the same clock source. The `IPCore_RESETN` and `AXILite_ARESETN` must be connected to the same reset source. See “Synchronization of Global Reset Signal to IP Core Clock Domain” on page 46-33.

IP Core Generation Workflow for Speedgoat Simulink-Programmable I/O Modules

HDL Coder uses the IP Core Generation workflow infrastructure to generate a reusable HDL IP core for the Speedgoat Simulink-Programmable I/O modules that support Xilinx Vivado. The workflow produces an IP core report that displays the target interface configuration and the code generator settings that you specify. You can integrate the IP core into a larger design by adding it in an embedded system integration environment. See “Custom IP Core Generation” on page 46-16.

This figure shows how the software generates an IP core with an AXI interface and integrates the IP core into the FPGA reference design.

Supported I/O Modules

To learn about I/O modules that HDL Coder supports with the Simulink Real-Time FPGA I/O workflow, see “Speedgoat FPGA Support with HDL Workflow Advisor” on page 46-14.

IP Core Generation Workflow

This workflow has these key features:

- Uses Xilinx Vivado as the synthesis tool.
- Generates a reusable and sharable IP core. The IP core packages the RTL code, a C header file, and the IP core definition files.
- Creates a project for integrating the IP core into the Speedgoat reference design.
- Generates an FPGA bitstream and downloads the bitstream to the target hardware.

Map Bus Data Types to PCIe Interface

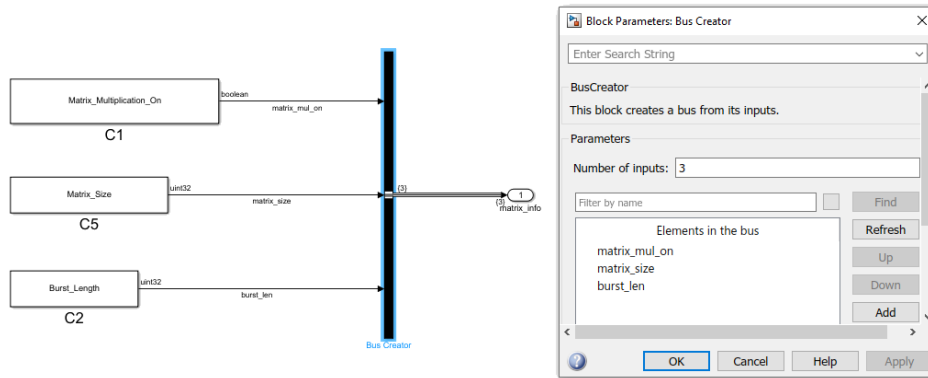

When you use bus data types at the DUT interface ports, you can directly map the interface ports to PCIe interfaces.

When you map bus data types, HDL Coder assigns a unique address for each data port that you want to map to the PCIe interface. The top-level and sub-level buses do not have a register offset address. The address mapping for separate scalar or vector bus elements is not contiguous.

Model Bus Element

Model a bus element by using a bus creator block or bus element block to create a bus port.

Model a bus element by using a bus creator block.

Model a bus element by using bus element blocks:

For an example that maps bus data type to PCIe Interface, see “FPGA Programming and Configuration on Speedgoat Simulink-Programmable I/O Modules” on page 47-92.

IP Core Generation of an I2C Controller IP to Configure the Audio Codec Chip

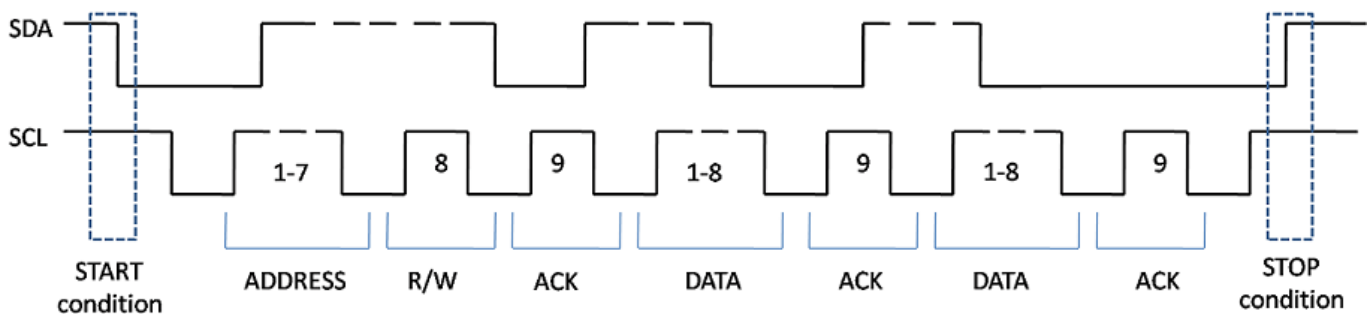

This example illustrates how to model an I2C controller using an I2C Master controller modeled using Stateflow® blocks for configuring the audio codec chip.

In this example, you:

- 1 Model the I2C Master Controller using Stateflow® blocks in Simulink®
- 2 Model the I2C Controller using the I2C Master Controller block for configuring the Audio Codec Chip
- 3 Use the blackbox subsystem and bidirectional port features to handle tri-state logic in I2C IP core
- 4 Use the IP Core Generation workflow to generate an IP core for the I2C Controller

1. Overview of I2C protocol

I2C bus, also called Inter-IC bus, is a simple, multi-master, multi-slave, bidirectional two-wire bus, that consists of serial data (SDA) and serial clock (SCL) lines. Each device connected to the bus is software addressable by a unique 7-bit or 10-bit address, and maintains a simple master-slave relationship. Serial, 8-bit oriented, bi-directional data transfers can be made at up to 100 kbit/s in the Standard mode, up to 400 kbit/s in the Fast-mode, or up to 3.4 Mbit/s in the High-speed mode. I2C bus has two nodes: master node and slave node. The master node generates clock and initiates communication with the slave. The slave node which is addressed by the master receives clock and responds to the master during acknowledgment. There are four modes of operation which are master transmit, master receive, slave transmit and slave receive. The master starts the communication by sending start bit followed by 7 or 10 bit address of the slave followed by read(1) or write(0) bit. If the slave corresponding to that address is present, then it responds with ACK bit. The master continues communication in transmit or receive mode based on the read or write bit. Similarly, the slave continues its operation based on the read or write instruction from the master. The figure below shows the timing diagram of I2C protocol.

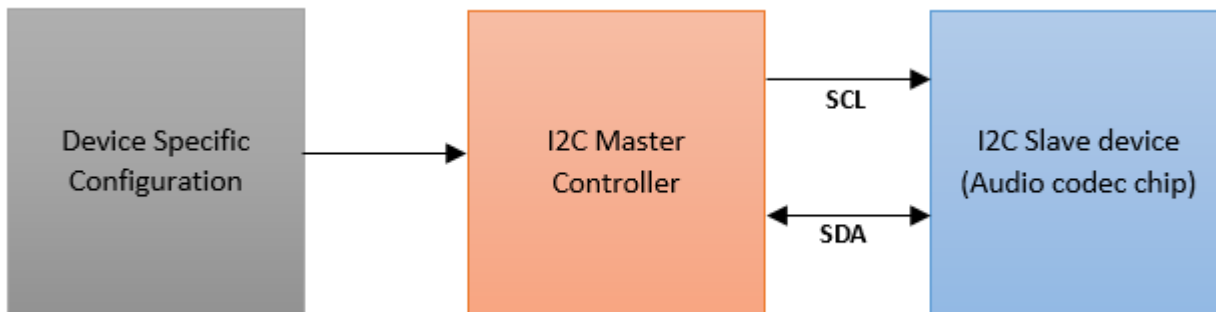

2. Modeling Generalized I2C Master Controller in Simulink Using Stateflow Blocks

Configuring multiple peripherals in the design can be a cumbersome and tedious process. Instead, create a generic I2C Master Controller that you can directly use to configure the audio codec chips. The figure below shows the architecture of the Generalized I2C Master Controller which is implemented using Stateflow blocks in Simulink.

The above part shows the I2C Master Controller block. To configure the peripheral, you must provide device-specific configuration to the I2C Master Controller block. The block diagram to configure the audio codec chip using I2C Master Controller is as shown below.

The below model shows the I2C Master Controller which is modeled in Simulink using Stateflow blocks.

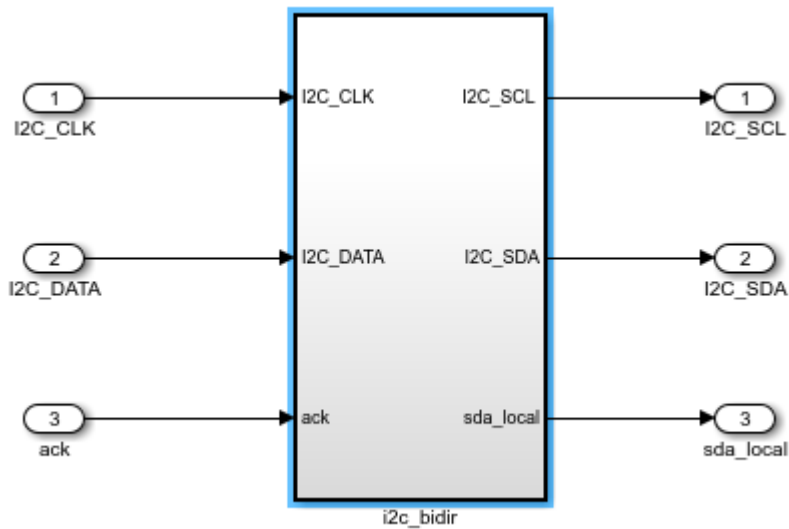

```
modelName = 'hdlcoder_I2C_master_controller';
open_system(modelname);
open_system('hdlcoder_I2C_master_controller/I2C_MasterController');
```

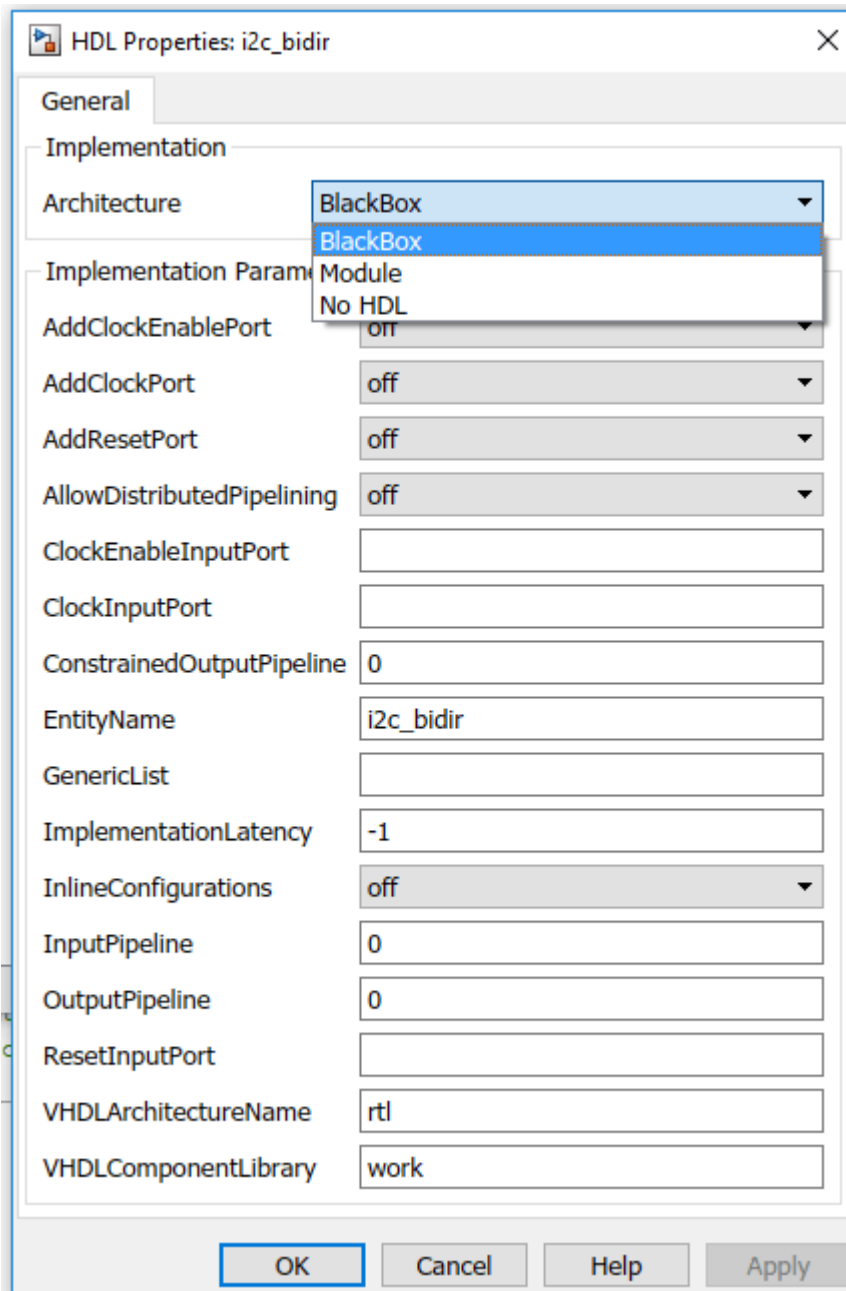

The I2C Master Controller only supports I2C write and doesn't support I2C readback currently. I2C Master Controller consists of two parts, I2C Master Controller chart and tristate buffer blackbox. I2C Master Controller chart provides serial data, SDA and serial clock, SCL to slave device through the tristate buffer blackbox. Tristate buffer blackbox uses the handwritten VHDL code and used for the bidirectional functionality of the SDA port. Tristate buffer blackbox is added in the model as Simulink doesn't support bidirectional port modeling.

To create a blackbox use the following steps.

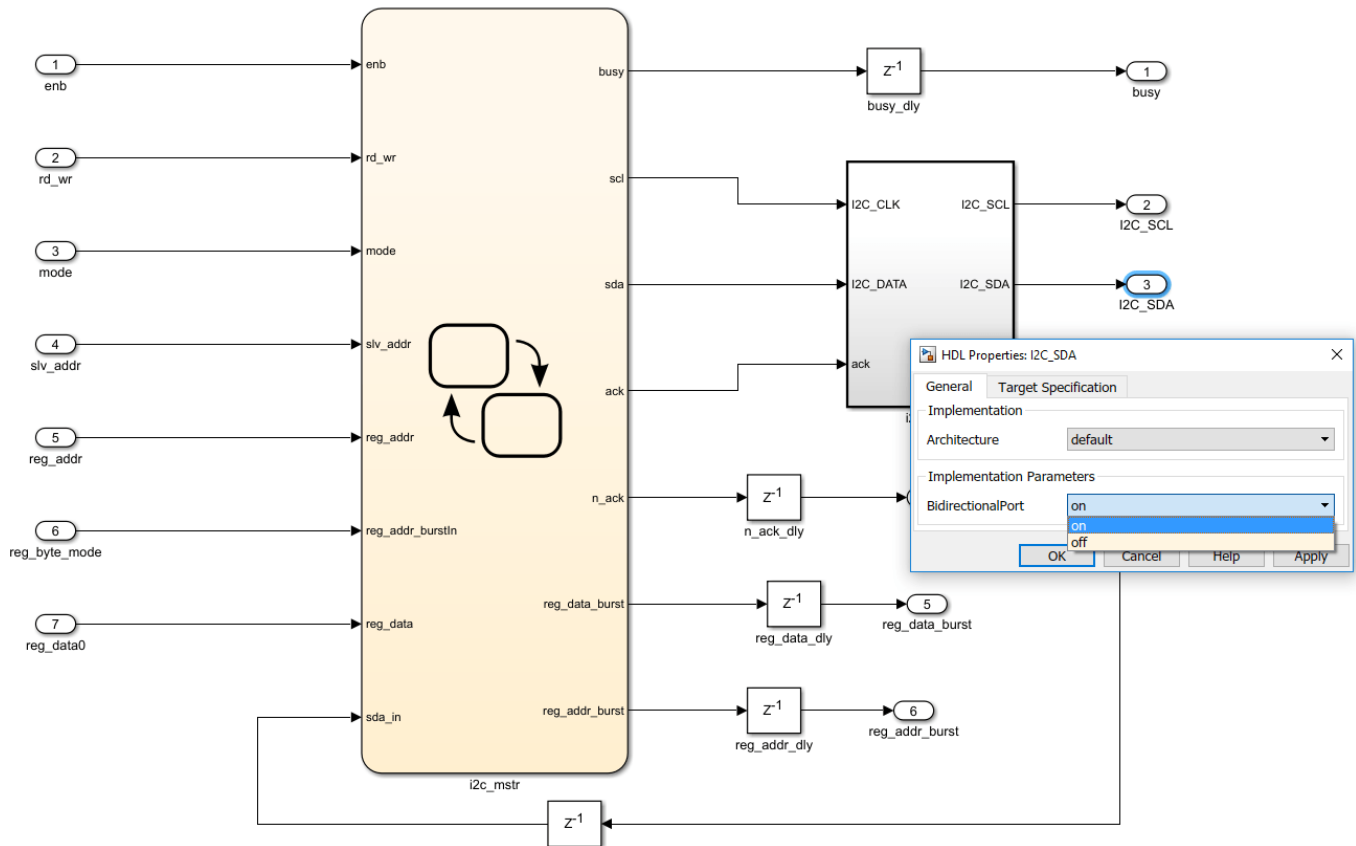

1. Make a subsystem which contains input and output ports of the HDL source code which you want to import for the blackbox creation. The I2C tristate buffer blackbox is as shown below.

2. To specify your subsystem as a black box interface, right click on the subsystem and select **HDL Code > HDL Block Properties** and set the Architecture to Blackbox as shown in the following figure.

3. The data port **I2C_SDA** of I2C Master Controller is bidirectional. To set the port as bidirectional, right click on the **I2C_SDA** port and click on HDL block properties and set the BidirectionalPort on as shown below.

4. During simulation, the actual content inside of the blackbox subsystem will be used for simulation.

During code generation, HDL Coder will not generate the code under the blackbox subsystem. Instead, the code generator integrates your hand-written HDL code into the IP core. Inputs to the I2C Master Controller block can be provided by adding a device specific configuration chart at the input. This chart contains details about the registers that need to be configured for your slave device. More about device configuration is covered in the section of Zedboard, Zybo board and Arrow SoC Development Kit Audio Codec configuration using I2C Master Controller.

2.1 I/O Description of I2C Master Controller block

The following figure gives the details about input and output ports of the I2C Master Controller block.

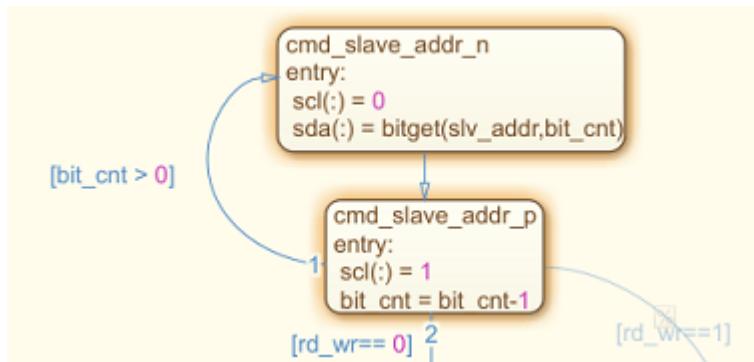

Name	Type	Width (in bits)	Description
enb	Input	1	I2C master controller enable
rd_wr	Input	1	Read/Write cycle
mode	Input	1	Mode of operation Normal = 0 Burst = 1
slv_addr	Input	8	Device address
reg_addr	Input	8	Device register address
reg_byte_mode	Input	1	Register address mode Byte = 0 Burst = 1
reg_data0	Input	8	Device register data
busy	Output	1	Status signal of the master controller chart
I2C_SCL	Output	1	Serial clock to slave device
I2C_SDA	Output	1	Serial data to slave device
n_ack	Output	1	No acknowledgment
reg_data_burst	Output	1	Burst data enable signal
Reg_addr_burst	Output	1	Burst address enable signal

2.2 Description of I2C Master Controller Stateflow chart

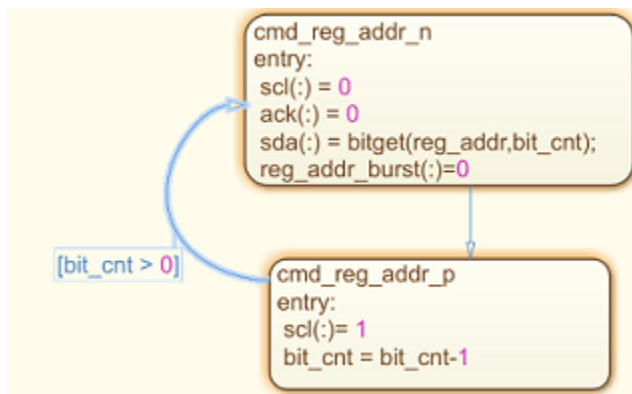

I2C Master Controller chart is made in such a way that in all the states required clock (SCL) is generated and data is provided as per the I2C protocol through serial data (SDA) port. Following states shows the generation of the clock and start bit.

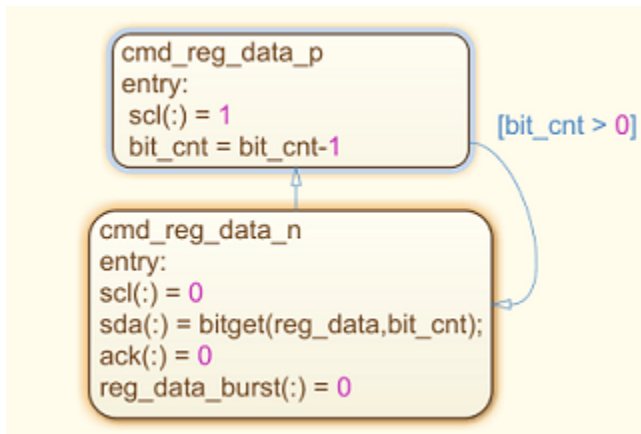

The following states are used to send 7-bit address of the slave device.

The function **bitget** is used to send bits serially to SDA port. It allows user to get bit value at specified position of the integer mentioned in its argument list. The transition from one state to other state depends on execution order specified for the transition conditions. As shown in the above figure the transition from **cmd_slave_addr_p** to the **cmd_slave_addr_n** state occurs based on the transition condition ($\text{bit_cnt} > 0$). The value of bit_cnt keeps decrementing until the transition condition satisfies. The value of bit_cnt is initialized to '7' and its value decrements till it becomes '1' which is used to send 7-bit address of slave device on SDA port. For HDL code generation, supported data types must be used. Colon(:) operator as shown in the states which is a typecasting operator used in cmd_slave_addr_n state ($\text{scl}(:) = 0$) converts a value of type 'double' to a type 'logical' (SCL is the logical datatype in the states shown). The states shown below are used to send register address to the slave device.

The states shown below are used to send register data to the slave device.

Following states shows the stop bit generation.

3. Configuring audio codec ADAU1761 on Zedboard using I2C Master Controller library block

This section shows how to:

- 1 Model audio codec ADAU1761 device configuration chart using Stateflow blocks in Simulink.
- 2 Use I2C Master controller library block to configure audio codec ADAU1761.
- 3 Perform simulation of created model.

As mentioned earlier to configure the audio codec ADAU1761 on Zedboard, device configuration chart for ADAU1761 need to be created. This chart should be connected to the I2C Master controller library block created earlier.

Note: You have to create device configuration chart for your own device. This example is to show how the I2C Master Controller library block can be used to configure audio codec devices. The device configuration chart used for ADAU1761 is specific to this device and can't be used to configure other devices.

The configuration model created for ADAU1761 is as shown below.

```

modelName = 'hdlcoder_I2C_adau1761';
open_system(modelname);
  
```

3.1 Simulating audio codec ADAU1761 configuration model

For Audio codec chip ADAU1761, 20 registers need to be configured. Few of them have to be written by I2C Master Controller in burst mode and few in byte mode. The first register is written in byte mode, second in burst mode of length 6-bytes. Remaining 18 registers are written in byte mode.

Simulation waveform for configuration of audio codec ADAU1761 is as shown below.

Byte mode transfer between I2C Master Controller and audio codec chip ADAU1761 is shown in the following figure.

Below simulation shows sending of start bit, followed by 7-bit address of the slave device(0x3B), followed by write(0) bit, followed by 16-bit register address(0x4000), followed by 8-bit register data(0x0E) and acknowledgements from the slave device.

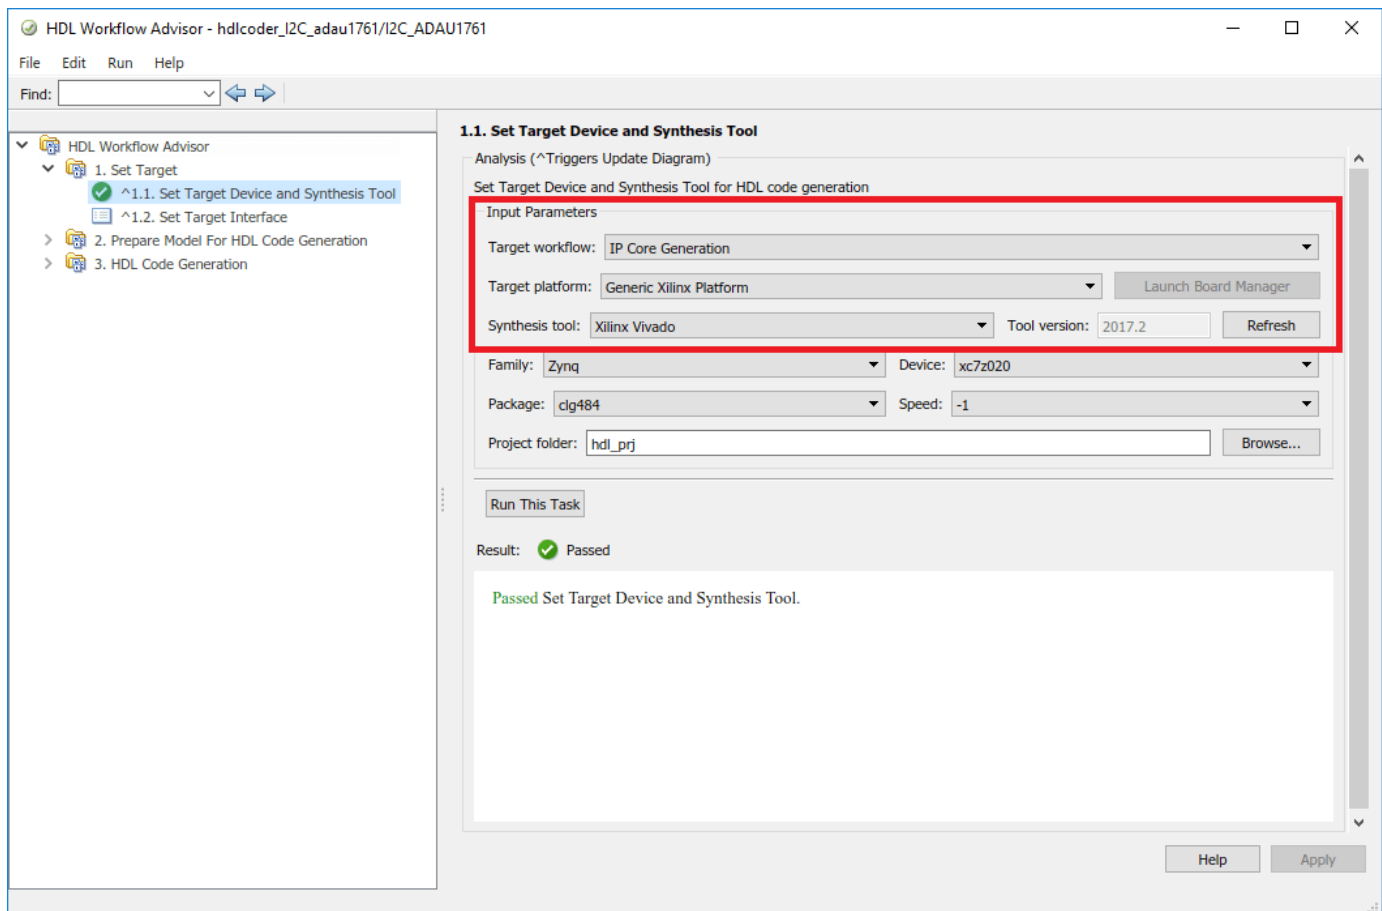

3.2 IP Core generation workflow

To generate the audio codec ADAU1761 configuration HDL IP core, follow the steps given below.

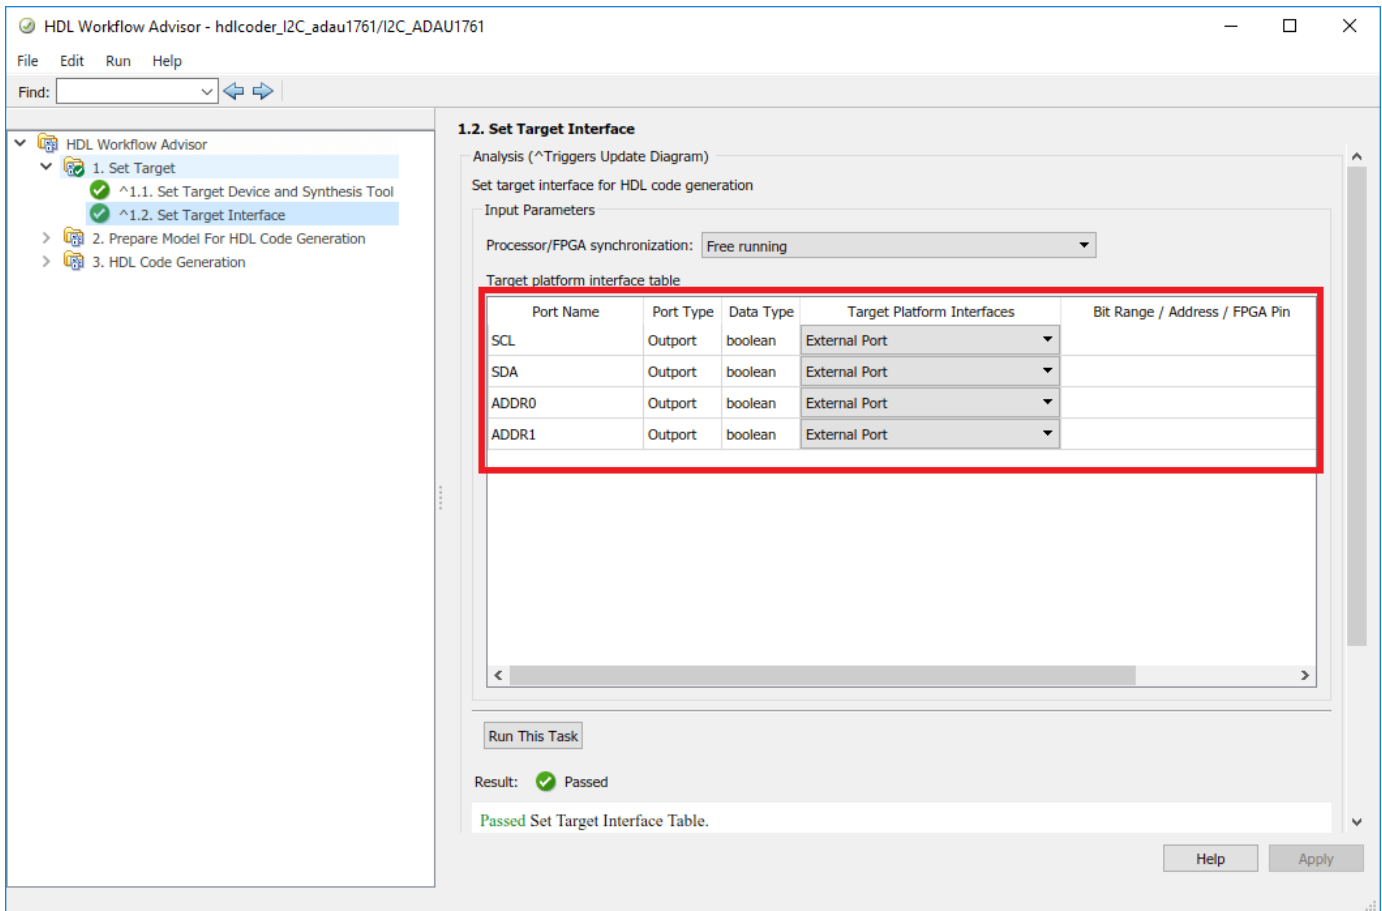

1. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2017.4\bin\vivado.ba
```

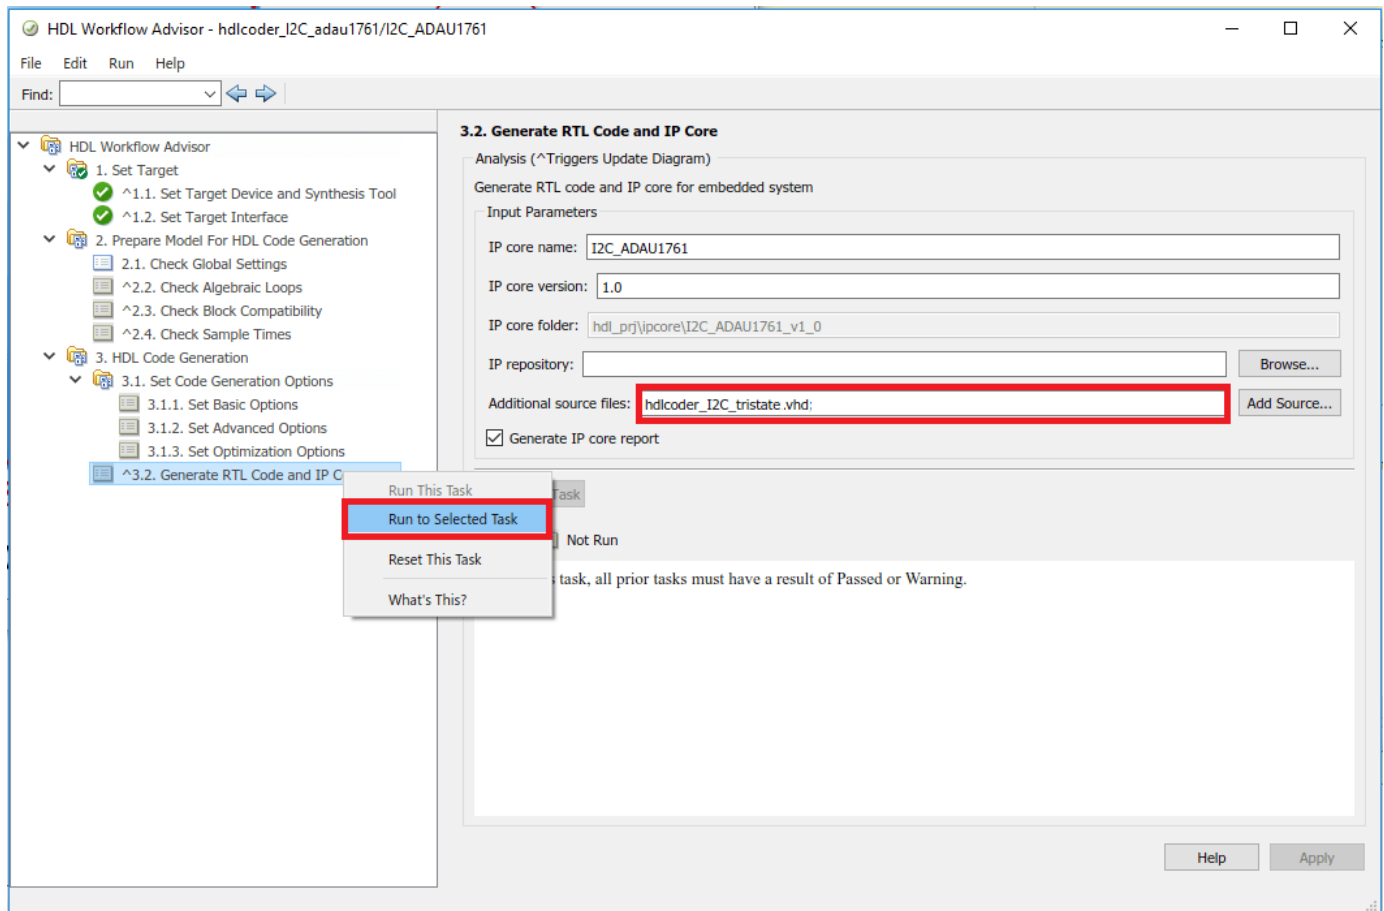

2. In the ADAU1761 configuration model, select I2C IP subsystem and by right clicking open HDL workflow advisor. In Task 1.1, Select **IP Core Generation** for Target workflow, **Generic Xilinx Platform** for Target platform and **Xilinx Vivado** for Synthesis Tool. Also select family, device, package and speed as shown in the figure below.

3. In Task 1.2, set the Target Platform Interfaces to "External Port" for all the ports.

4. In Task 3.2, add the tristate buffer VHDL file in the additional source files. Then right click on Generate RTL code and IP Core and click on Run to Selected Task.

I2C IP Core for configuration of ADAU1761 will be generated. Below figure shows the IP Core generation report.

IP Core Generation Report for hdlcoder_I2C_adau1761

Summary

IP core name	I2C_ADAU1761
IP core version	1.0
IP core folder	hdl_prj\ipcore\I2C_ADAU1761_v1_0
IP core zip file name	I2C_ADAU1761_v1_0.zip
Target platform	Generic Xilinx Platform
Target tool	Xilinx Vivado
Target language	VHDL
Model	hdlcoder_I2C_adau1761
Model version	1.455
HDL Coder version	3.11
IP core generated on	13-Oct-2017 12:07:53
IP core generated for	I2C_ADAU1761

Target Interface Configuration

You chose the following target interface configuration for [hdlcoder_I2C_adau1761](#) :

Processor/FPGA synchronization mode: **Free running**

Target platform interface table:

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
SCL	Output	boolean	External Port	
SDA	Output	boolean	External Port	
ADDR0	Output	boolean	External Port	
ADDR1	Output	boolean	External Port	

Register Address Mapping

The following AXI4-Lite bus accessible registers were generated for this IP core:

Register Name	Address Offset	Description
IPCore_Reset	0x0	write 0x1 to bit 0 to reset IP core
IPCore_Enable	0x4	enabled (by default) when bit 0 is 0x1
IPCore_Timestamp	0x8	contains unique IP timestamp (yyymmddHHMM): 1710131207

OK Help

Generated IP core can be used in user reference designs. For creating the reference design, refer to “Authoring a Reference Design for Audio System on a Zynq Board” on page 47-205.

4. Configuring audio codec SSM2603 on Zybo board using I2C Master Controller library block

This section shows how to:

- 1 Model audio codec SSM2603 device configuration chart using Stateflow blocks in Simulink.
- 2 Use I2C Master controller library block to configure audio codec SSM2603.
- 3 Perform simulation of created model.

To configure the audio codec SSM2603 on Zybo board, device configuration chart for SSM2603 need to be created. This chart should be connected to the I2C Master controller library block created earlier.

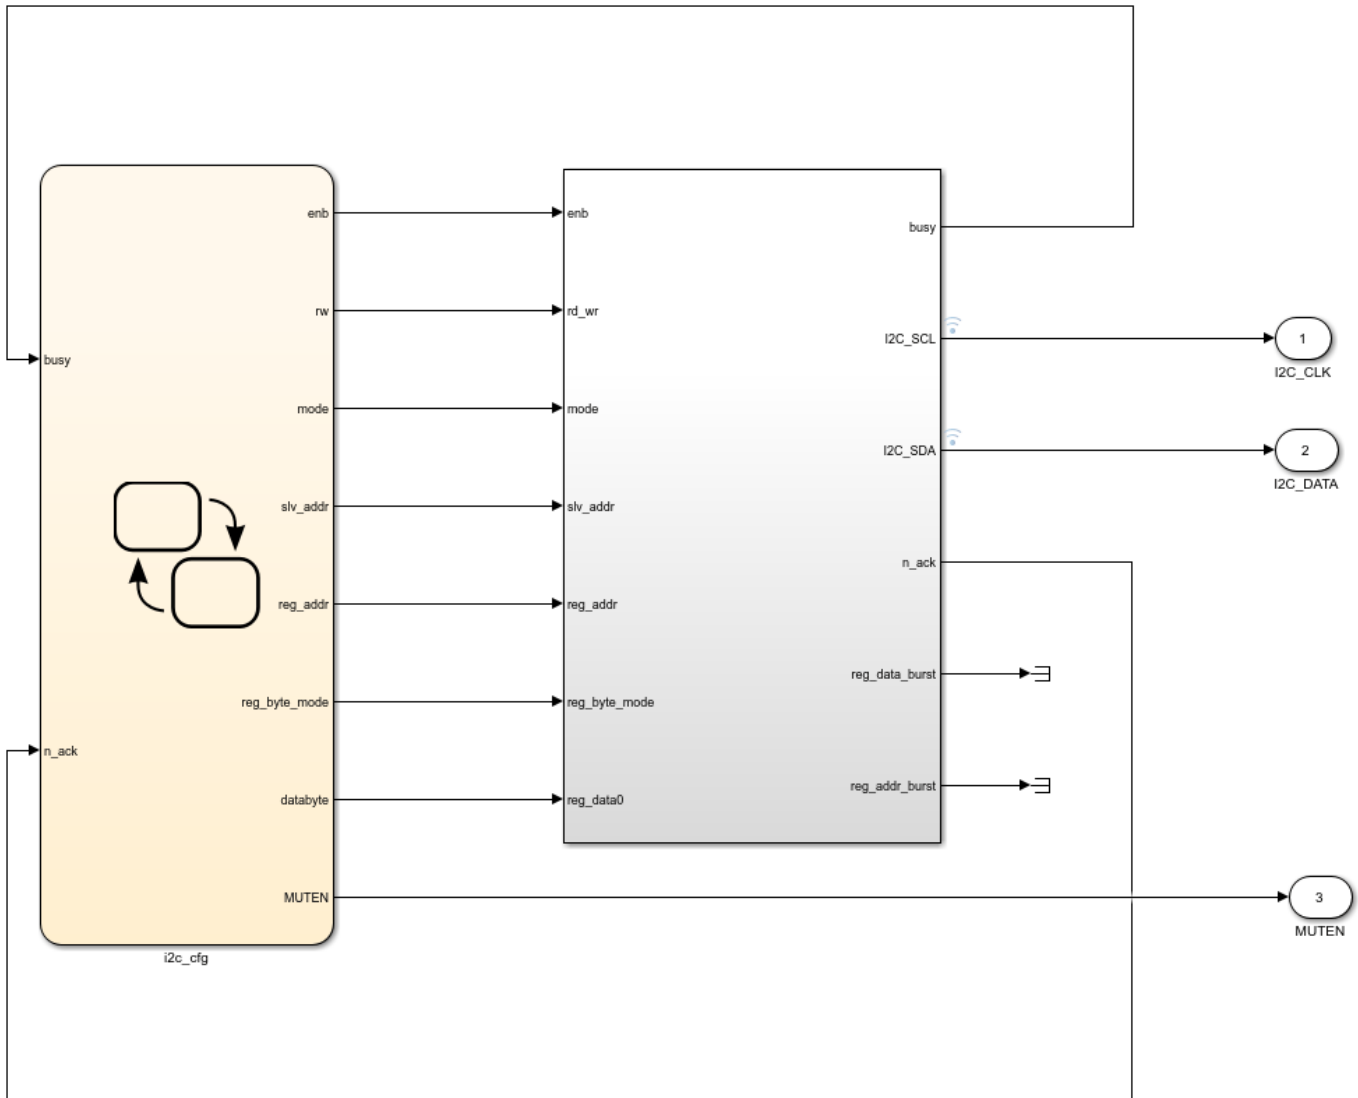

Note: The device configuration chart used for SSM2603 is specific to this device and can't be used to configure other devices.

The configuration model created for SSM2603 is as shown below.

```

modelname = 'hdlcoder_I2C_ssm2603';
open_system(modelname);

```

4.1 Simulating audio codec SSM2603 configuration model

For Audio codec chip SSM2603, 11 registers need to be configured. All the to be written in byte mode.

Simulation waveform for configuration of audio codec SSM2603 is as shown below.

Below simulation shows sending of start bit, followed by 7-bit address of the slave device(0x1A), followed by write(0) bit, followed by 8-bit register address(0x0C), followed by 8-bit register data(0x10) and acknowledgments from the slave device.

4.2 IP Core generation workflow

IP Core generation steps for SSM2603 configuration model are same as the steps mentioned above in section 3.2, IP Core generation workflow. Generated IP core can be used in user reference designs. For creating the reference design, refer to “Authoring a Reference Design for Audio System on a ZYBO Board” on page 47-215.

5 Configuring audio codec SSM2603 on Arrow SoC Development Kit using I2C Master Controller library block

This section shows how to:

- 1 Model audio codec SSM2603 device configuration chart using Stateflow blocks in simulink.
- 2 Use I2C Master controller library block to configure audio codec SSM2603.
- 3 Perform simulation of created model.

To configure the audio codec SSM2603 on Arrow SoC Development Kit, device configuration chart for SSM2603 need to be created. This chart should be connected to the I2C Master controller library block created earlier.

Note: The device configuration chart used for SSM2603 is specific to this device and can't be used to configure other devices.

The configuration model for SSM2603 on Arrow SoC Development Kit is same as configuration model for SSM2603 on Zybo board. Please refer to section 4 of this article for SSM2603 configuration model.

5.1 Simulating audio codec SSM2603 configuration model

The audio codec chip SSM2603 configuration on Arrow SoC Development Kit is same as audio codec chip SSM2603 configuration on Zybo board. Please refer to section 4.1 of this article for simulation.

5.2 IP Core generation workflow

To generate the audio codec SSM2603 configuration HDL IP core, follow the steps given below.

1. Set up the Intel Quartus tool path using the following command in the MATLAB command window. Use your own Quartus installation path when you run the command

```
hdlsetuptoolpath('ToolName', 'Altera Quartus II', 'ToolPath', 'C:\intelFPGA\18.1\quartus\bin64\q
```

2. In the SSM2603 configuration model, select I2C_SSM2603 subsystem and by right clicking open HDL workflow advisor. In Task 1.1, Select **IP Core Generation** for Target workflow, **Generic Altera Platform** for Target platform and **Altera QUARTUS II** for Synthesis Tool. Also select family, device, package and speed as shown in the figure below.

3. In Task 1.2, set the Target Platform Interfaces to "External Port" for all the ports.

4. In Task 3.2, add the tristate buffer Verilog file in the additional source files. Then right click on Generate RTL code and IP Core and click on Run to Selected Task.

I2C IP Core for configuration of SSM2603 will be generated. Below figure shows the IP Core generation report.

IP Core Generation Report for hdlcoder_I2C_ssm2603

Summary

IP core name	I2C_SSM26_ip
IP core version	1.0
IP core folder	hdl_prj\ipcore\I2C_SSM26_ip_v1_0
Target platform	Generic Altera Platform
Target tool	Altera QUARTUS II
Target language	VHDL
Model	hdlcoder_I2C_ssm2603
Model version	1.477
HDL Coder version	3.16
IP core generated on	14-Jan-2020 11:40:49
IP core generated for	I2C_SSM2603

Target Interface Configuration

You chose the following target interface configuration for [hdlcoder_I2C_ssm2603](#) :

Processor/FPGA synchronization mode: **Free running**

Target platform interface table:

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
I2C_CLK	Output	boolean	External Port	
I2C_DATA	Output	boolean	External Port	
MUTEN	Output	boolean	External Port	

Register Address Mapping

The following AXI4 bus accessible registers were generated for this IP core:

Register Name	Address Offset	Description
IPCore_Reset	0x0	write 0x1 to bit 0 to reset IP core
IPCore_Enable	0x4	enabled (by default) when bit 0 is 0x1
IPCore_Timestamp	0x8	contains unique IP timestamp (yyymmddHHMM): 2001141140

OK Help

Generated IP core can be used in user reference designs. For creating the reference design, refer to “Authoring a Reference Design for Audio System on Intel Board” on page 47-221.

Running an Audio Filter on Live Audio Input Using Intel Board

In this example, we illustrate how to:

- 1 Model an audio system with Low pass and Band pass filters
- 2 Implement it on a Intel® board using an audio reference design

The objective of this example is to receive audio input through Arrow SoC Development Kit's line input, process it on the FPGA and transmit the processed audio to a speaker. The above figure shows the high-level architecture of such a system. It uses an audio codec to interface to the peripherals and to convert analog to digital signals and vice-versa. The Audio Codec IPs are used to configure the audio codec and for transferring audio data between Intel SoC and audio codec. The Filter IP is used for audio processing. ARM processor is used to control the type of filter to be used i.e. low pass or band pass.

Before You Begin

To run this example, you must have the following software and hardware installed and set up:

- HDL Coder™ Support Package for Intel SoC Devices
- Embedded Coder® Support Package for Intel SoC Devices
- Intel Quartus® Prime Standard, with supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Intel SoC Embedded Design Suite
- Arrow SoC Development Kit

To setup the Arrow SoC Development Kit, refer to the Set up Intel SoC hardware and tools section in the “Getting Started with Targeting Intel SoC Devices” on page 46-122 example. Connect an audio input from a mobile or an MP3 player to **LINE IN** jack and either earphones or speakers to **LINE OUT** jack on the Arrow SoC as shown below.

Introduction

In the following model, an audio file is used as input to the DUT subsystem, **Audio_filter**. On simulating this model in Simulink, the processed audio effect can be heard through the **Audio Device Writer** block and **Spectrum Analyzer** block displays the spectrogram of the filtered audio output.

```
modelName = 'hdlcoder_audio_filter_biquad';  
open_system(modelname);
```

Using IP Core Generation Workflow: Audio Filtering

Model a System with Low pass and Band pass Filters

Filter coefficients may be generated using a MATLAB function or in Simulink. In this model, `filterDesigner` (DSP System Toolbox) (DSP System Toolbox) tool is used to generate the filter coefficients for each type of filter. Then these filter coefficients are exported and stored as a matlab file. These coefficients will be used to design the filters in Simulink. In this model, discrete IIR filter blocks from Simulink® are used as Biquad low pass or band pass filters depending on the corresponding filter coefficients.

You can test this model by simulating the model in Simulink. The range of frequencies seen on the Spectrum Analyzer and the audio effect heard through the Audio Device Writer block should vary depending on the type of filter selected. **Filter Select** block is used to select the type of filtering to be done on the audio input.

Customize the Model for Arrow SoC Development Kit

In order to implement this model on Arrow SoC, you must first create a reference design in Qsys which receives audio input on Arrow SoC and transmits the processed audio data out of Arrow SoC. For details on how to create a reference design which integrates the audio filter model, refer to “Authoring a Reference Design for Audio System on Intel Board” on page 47-221 example.

In the reference design, left and right channel audio data are combined to form a single channel. They are concatenated such that lower 24 bits is the left channel and upper 24 bits is the right channel. In the Simulink model shown above, `Data_in` is split into 2 channels i.e. left and right accordingly. Their magnitude is divided by 2 and the 2 channels are added together to form a single channel. Filtering is done on this channel.

Data_in and **Valid_in** are the AXI4-Stream signals. **Data_in** contains the audio data to be processed and **Valid_in** acts as the enable signal. Each filter is mapped to an LED on Arrow SoC to visually indicate whether the filter is on or off.

FilterSelect input is controlled via AXI4 interface.

Generate HDL IP core with AXI4-Stream Interface

Next, you can start the HDL Workflow Advisor and use the Intel® hardware-software co-design workflow to deploy this design on the Intel hardware. For a more detailed step-by-step guide, you can refer to the “Getting Started with Targeting Intel SoC Devices” on page 46-122 example.

1. Set up the Intel Quartus synthesis tool path using the following command in the MATLAB command window. Use your own Intel Quartus installation path when you run the command. For example:

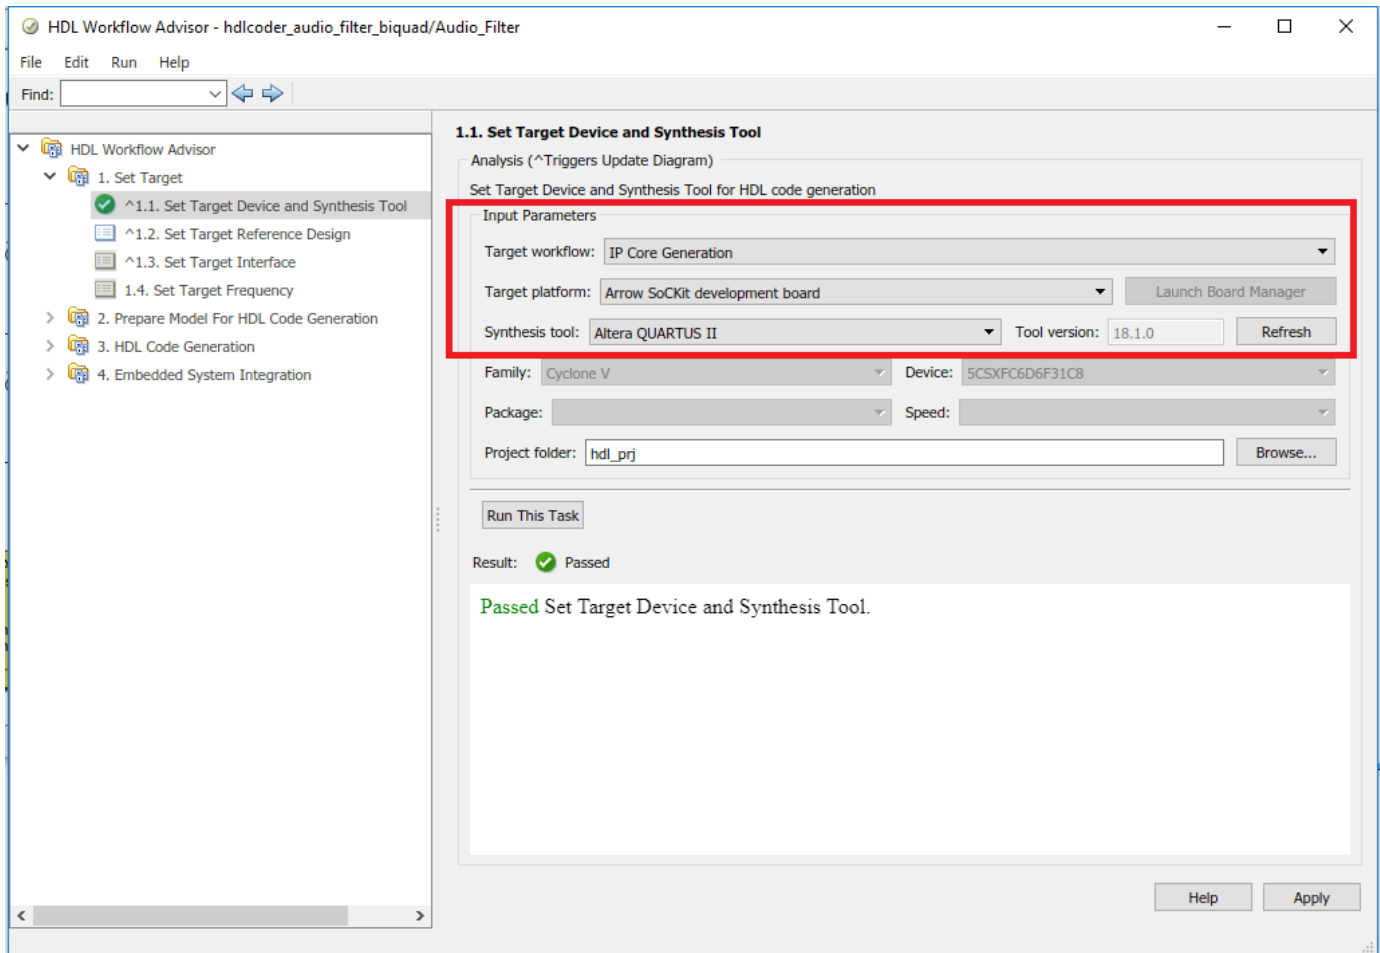

```
hdlsetuptoolpath('ToolName', 'Altera Quartus II', 'ToolPath', 'C:\intelFPGA\18.1\quartus\bin64\q
```

2. Add both the IP repository folder and the Arrow SoC Development Kit registration file to the MATLAB path using following commands:

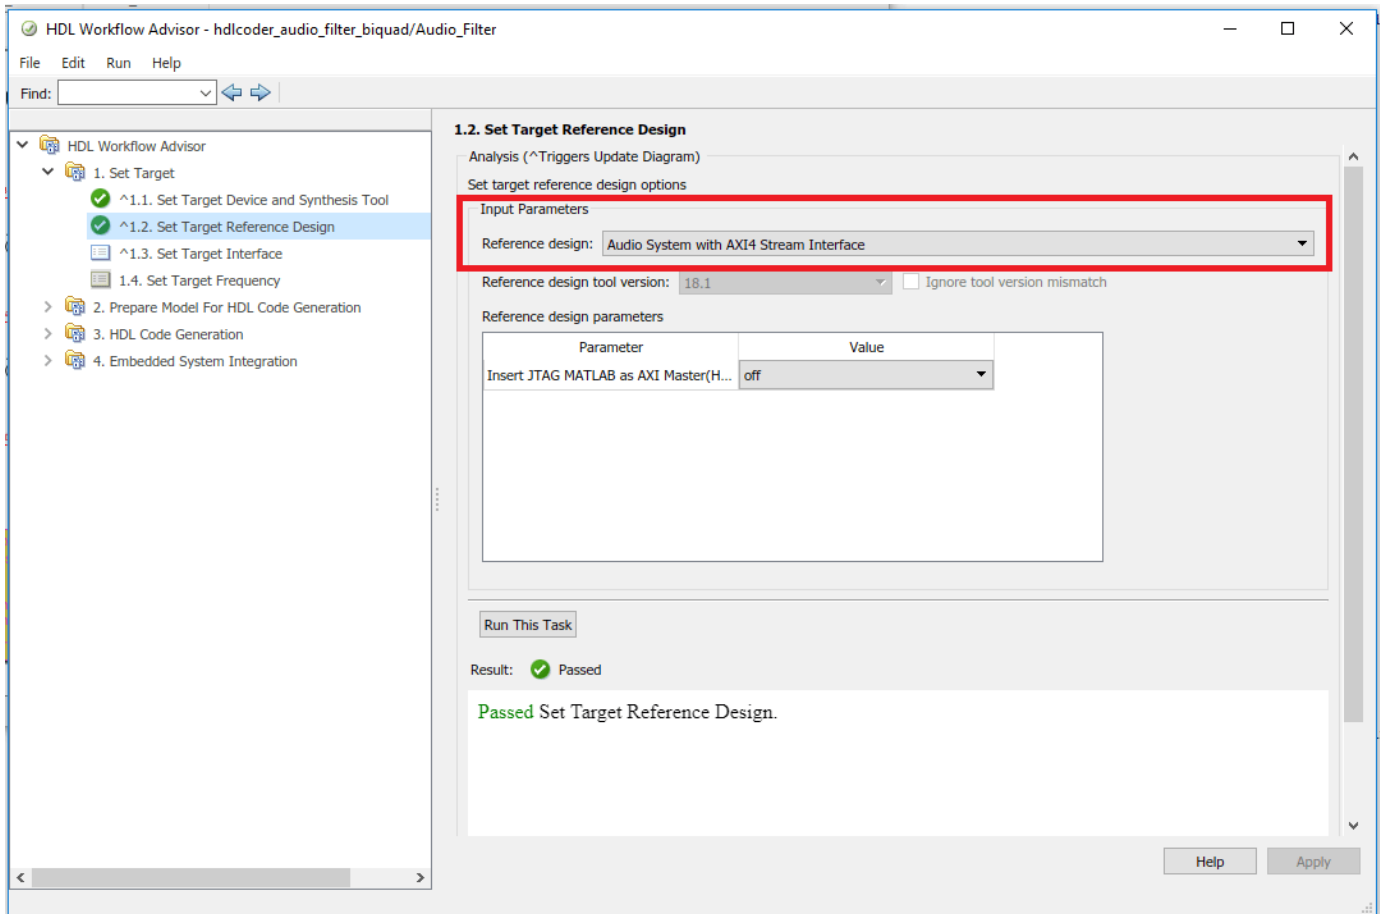

```
unzip('ipcore.zip');  
unzip('ArrowSoC.zip');  
addpath(genpath('ipcore'));  
addpath(genpath('ArrowSoC'));
```

3. Start the HDL Workflow Advisor from the DUT subsystem, `hdlcoder_audio_filter_biquad/Audio_filter` or by double-clicking the Launch HDL Workflow Advisor box in the model.

In Task 1.1, select **IP Core Generation** for **Target workflow**, and select Arrow SoC Development Kit for **Target platform**.

In Task 1.2, Audio System with AXI4 Stream Interface is selected for **Reference Design**.

The AXI4-Stream interface is used for transferring audio data between the reference design and the filtering algorithm IP. The AXI4-Stream interface contains data (**Data**) and control signals such as data valid (**Valid**), back pressure (**Ready**), and data boundary (**TLAST**). At least **Data** and **Valid** signals are required for AXI4-Stream IP core generation. In Task 1.3, the **Target platform interface table** is loaded as shown in the following picture. The audio data stream ports, **Valid_in**, **Data_in**, **Valid_out** and **Data_out**, are mapped to the AXI4-Stream interfaces, **Pass_through_LED**, **BiQuad_LPF_LED**, **BiQuad_BPF_LED** are mapped to the LEDs on Arrow SoC and the control parameter port **Filter_select** is mapped to the AXI4 interface.

The AXI4-Stream interface communicates in master/slave mode, where the master device sends data to the slave device. Therefore, if a data port is an input port, assign it to an **AXI4-Stream Slave** interface, and if a data port is output port, assign it to an **AXI4-Stream Master** interface.

3. Right-click Task 3.2, **Generate RTL Code and IP Core**, and select **Run to Selected Task** to generate the IP core. You can find the register address mapping and other documentation for the IP core in the generated IP Core Report.

Integrate IP Into AXI4-Stream Audio Compatible Reference Design

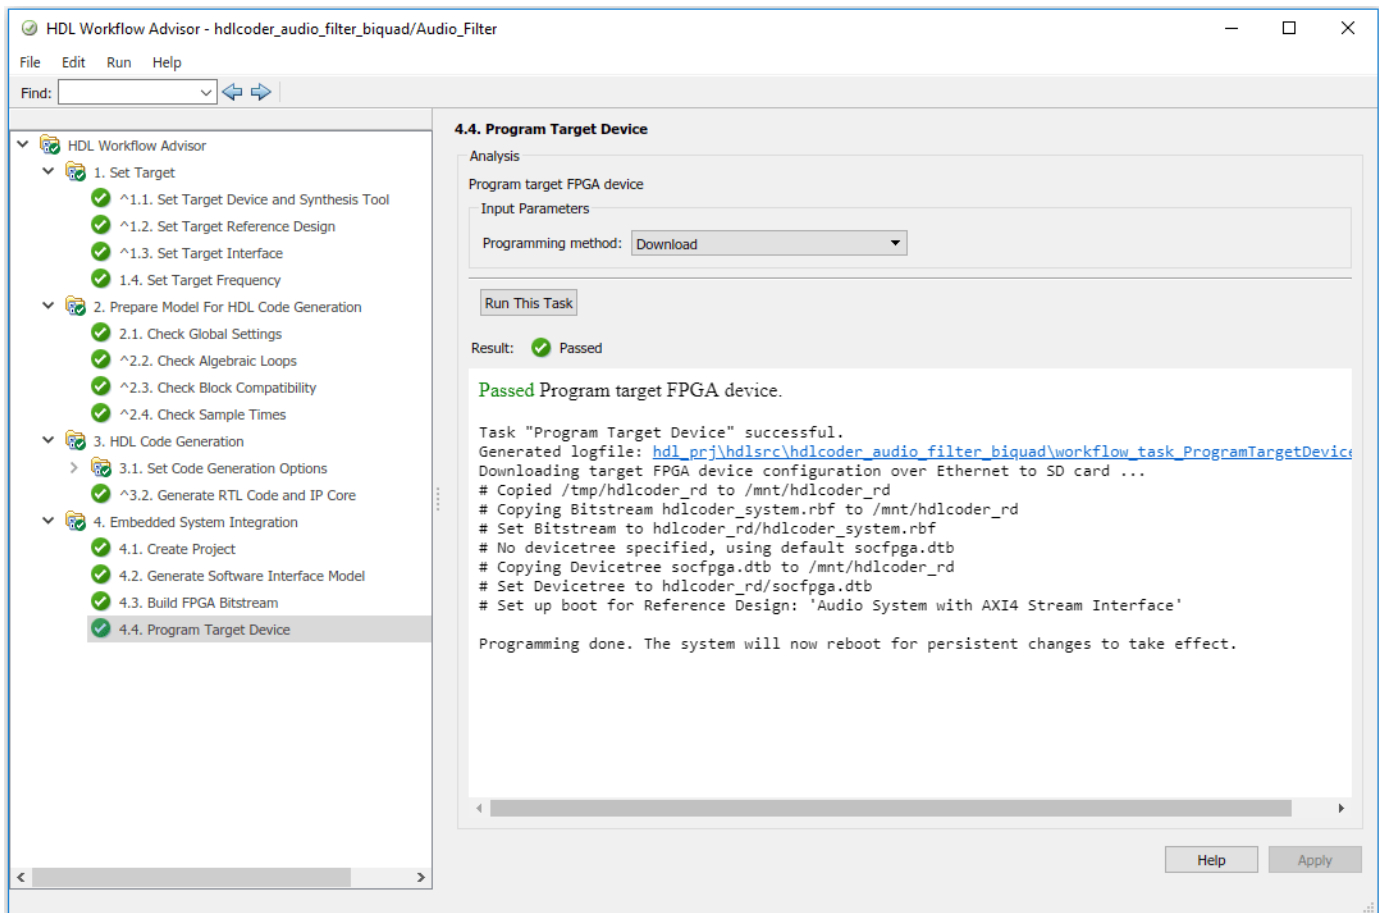

Next, in the HDL Workflow Advisor, you run the **Embedded System Integration** tasks to deploy the generated HDL IP core on Intel SoC.

1. Run Task 4.1, **Create Project**. This task inserts the generated IP core into the **Audio System with AXI4 Stream Interface** reference design. As shown in the first diagram, this reference design contains the IPs to handle audio data in and out of Arrow SOC. The generated project is a complete design, including the algorithm part (the generated DUT algorithm IP), and the platform part (the reference design). For details on how to create a reference design which integrates the audio filter model, refer to “Authoring a Reference Design for Audio System on Intel Board” on page 47-221 example.

2. Click on the **Generated Altera Qsys project** link in the Result pane to open the generated platform designer Qsys project.

3. In the HDL Workflow Advisor, run the rest of the tasks to generate the software interface model, and build and download the FPGA bitstream. Choose **Download** programming method in the task **Program Target Device** to download the FPGA bitstream onto the SD card on the Intel board, so your design will be automatically reloaded when you power cycle the Intel board.

Generate ARM executable to Tune Parameters on the FPGA Fabric

A software interface model is generated in Task 4.2, **Generate Software Interface Model**.

1. Before you generate code from the software interface model, comment out the audio input source and audio output sink i.e. From Multimedia File, Data Type Conversion, Buffer, Audio Device Writer and Spectrum Analyzer Blocks. These blocks do not need to be run on the ARM processor. The Audio_filter IP is running as Filtering_Algorithm on FPGA fabric. The ARM processor is using AXI4 interface for selecting the filter type i.e. Biquad Low pass, Band pass or Pass Through.

- 1 In the generated model, go to **Hardware** pane and then open the Configuration Parameters dialog box by clicking on **Hardware Settings**.
- 1 Select **Solver** and set **Stop Time** to **inf**.
- 2 Then in the **Hardware Pane**, Click on **Monitor & Tune** button. Embedded Coder builds the model, downloads the ARM executable to the Intel board hardware, executes it, and connects the model to the executable running on the Intel board hardware. Then you can tune model parameters.

The type of filter to be used can be selected using the drop down options in **Filter Select** block

The filtered audio output can be heard by plugging earphones or speakers to **LINE OUT** jack on the Arrow SoC. Depending on the filter selected, the corresponding LED on the Arrow SoC turns on. In this example, LD0 turns on when Pass through (No filter used) option is selected, LD1 turns on when Biquad Low pass filter is selected, LD2 turns on when Biquad Band pass filter is selected.

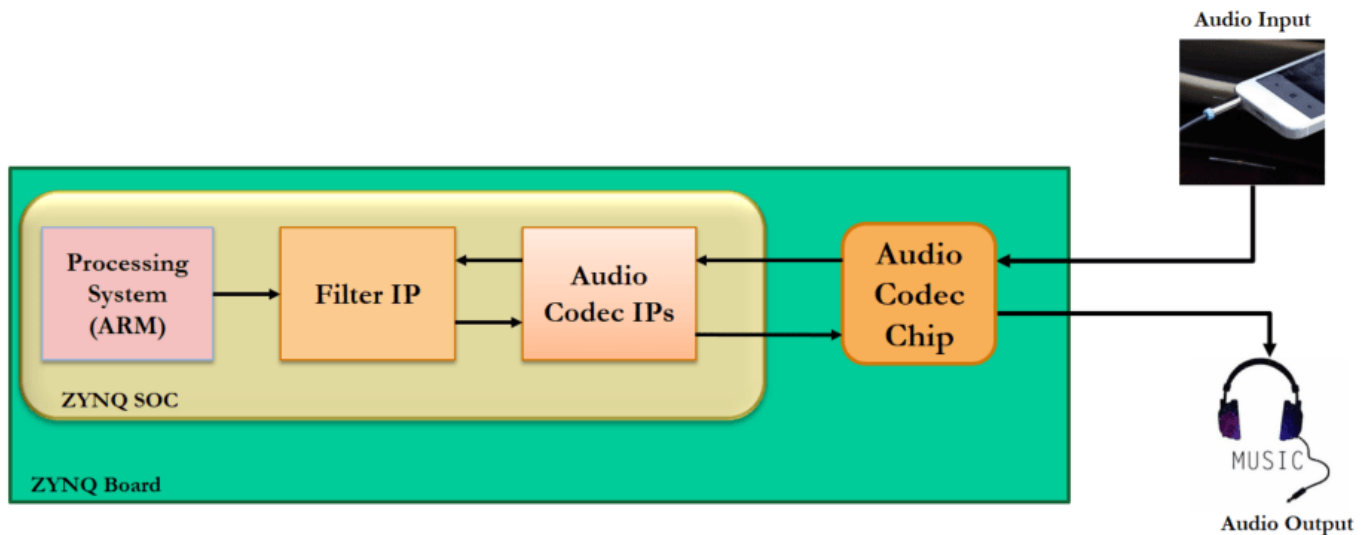

Running an Audio Filter on Live Audio Input Using a Zynq Board

This example shows how to model an audio system and implement it on a Zynq® board using an audio reference design.

Introduction

In this example, you:

- 1 Model an audio system with Low pass, Band pass and High pass filters
- 2 Implement it on a Zynq board using an audio reference design

The objective of this example is to receive audio input through Zedboard or Zybo board's line input, process it on the FPGA and transmit the processed audio to a speaker. The above figure shows the high-level architecture of such a system. It uses an audio codec to interface to the peripherals and to convert analog to digital signals and vice-versa. The Audio Codec IPs are used to configure the audio codec and for transferring audio data between Zynq Soc and audio codec. The Filter IP is used for audio processing. ARM processor is used to control the type of filter to be used i.e. low pass, band pass or high pass.

Before You Begin

To run this example, you must have the following software and hardware installed and set up:

- HDL Coder Support Package for Xilinx Zynq Platform
- Embedded Coder Support Package for Xilinx Zynq Platform
- Xilinx Vivado version 2019.1
- ZedBoard or Zybo Board

To setup the Zedboard board, refer to the *Set up Zynq hardware and tools* section in the "Getting Started with Targeting Xilinx Zynq Platform" on page 46-83 example. Connect an audio input from a

mobile or an MP3 player to **LINE IN** jack and either earphones or speakers to **HPH OUT** jack on the Zedboard as shown below. Similar setup can be done on Zybo board. For Zybo board setup, refer to *Set up the Zybo board* section in the “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231 example.

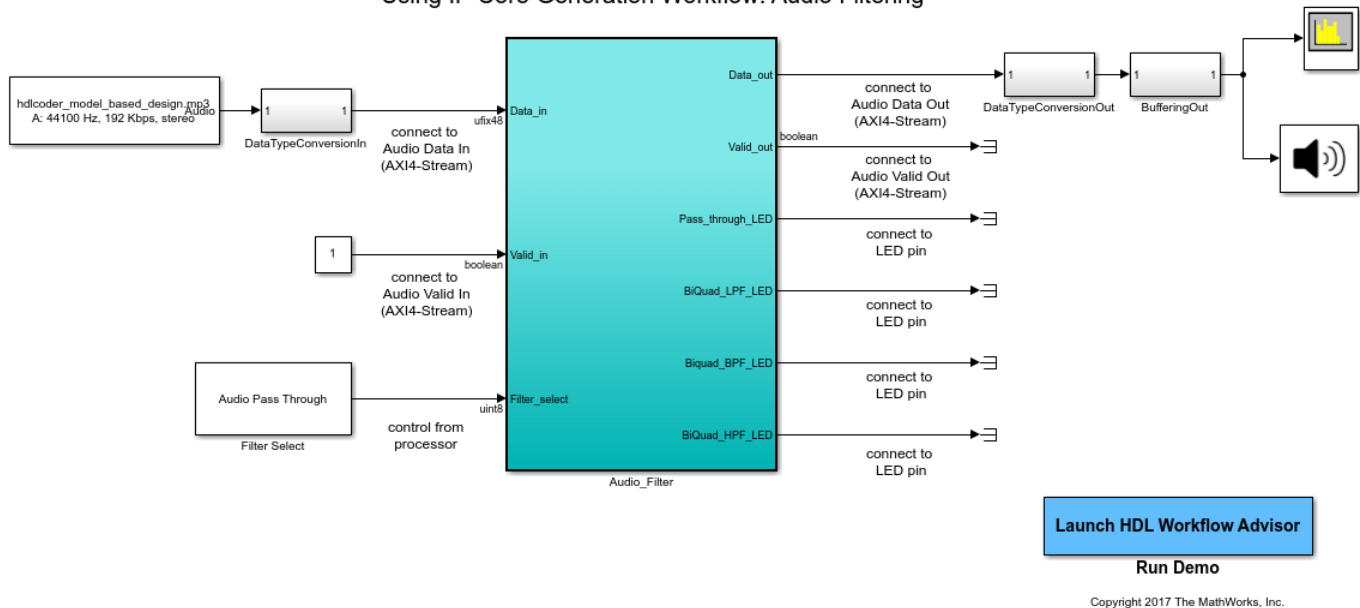

Introduction

In the following model, an audio file is used as input to the DUT subsystem, **Audio_filter**. On simulating this model in Simulink, the processed audio effect can be heard through the **Audio Device Writer** block and **Spectrum Analyzer** block displays the spectrogram of the filtered audio output.

```
modelName = 'hdlcoder_audio_filter_biquad';  
open_system(modelname);
```

Using IP Core Generation Workflow: Audio Filtering

Model a system with Low pass, Band pass and High pass filters

Filter coefficients may be generated using a MATLAB® function or in Simulink®. In this model, filterDesigner tool is used to generate the filter coefficients for each type of filter. Then these filter coefficients are exported and stored as a MATLAB file. These coefficients will be used to design the filters in Simulink. In this model, discrete IIR filter blocks from Simulink are used as Biquad low pass, band pass or high pass filters depending on the corresponding filter coefficients.

You can test this model by simulating the model in Simulink. The range of frequencies seen on the Spectrum Analyzer and the audio effect heard through the Audio Device Writer block should vary depending on the type of filter selected. **Filter Select** block is used to select the type of filtering to be done on the audio input.

Customize the model for Zynq board

In order to implement this model on Zedboard, you must first create a reference design in Vivado which receives audio input on Zedboard and transmits the processed audio data out of Zedboard. For details on how to create a reference design which integrates the audio filter model, refer to “Authoring a Reference Design for Audio System on a Zynq Board” on page 47-205 example.

For Zybo board, refer to “Authoring a Reference Design for Audio System on a ZYBO Board” on page 47-215.

In the reference design, left and right channel audio data are combined together to form a single channel. They are concatenated such that lower 24 bits is the left channel and upper 24 bits is the right channel. In the Simulink model shown above, **Data_in** is split into 2 channels i.e. left and right accordingly. Their magnitude is divided by 2 and the 2 channels are added together to form a single channel. Filtering is done on this channel.

Data_in and **Valid_in** are the AXI4-Stream signals. To understand how AXI4-stream interface is used, refer to *Model Streaming Algorithm with Simplified Streaming Protocol* section in “Deploy Model with AXI-Stream Interface in Zynq Workflow” on page 47-172 example. **Data_in** contains the audio

data to be processed and **Valid_in** acts as the enable signal. Each filter is mapped to an LED on Zedboard or Zybo board to visually indicate whether the filter is on or off.

FilterSelect input is controlled via AXI4 LITE interface.

Generate HDL IP core with AXI4-Stream Interface

Next, you can start the HDL Workflow Advisor and use the Zynq hardware-software co-design workflow to deploy this design on the Zynq hardware. For a more detailed step-by-step guide, you can refer to the “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 example.

1. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2019.1\bin\vivado.ba
```

2. Add both the IP repository folder and the Zedboard registration file to the MATLAB path using following commands:

```
unzip('ipcore.zip');  
unzip('ZedBoard.zip');  
addpath(genpath('ipcore'));  
addpath(genpath('ZedBoard'));
```

For Zybo board use the following commands.

```
unzip('ipcore.zip');  
unzip('ZYBO.zip');  
addpath(genpath('ipcore'));  
addpath(genpath('ZYBO'));
```

3. Start the HDL Workflow Advisor from the DUT subsystem, `hdlcoder_audio_filter_biquad/Audio_filter` or by double clicking on the Launch HDL Workflow Advisor box in the model.

The target interface settings are already saved for Zedboard in this example model, so the settings in Task 1.1 to 1.3 are automatically loaded. To learn more about saving target interface settings in the model, you can refer to the “Save Target Hardware Settings in Model” on page 46-171 example.

In Task 1.1, **IP Core Generation** is selected for **Target workflow**, and **ZedBoard** is selected for **Target platform**. If you are using Zybo board then select **ZYBO** as **Target Platform** instead of Zedboard.

In Task 1.2, **Audio System with AXI4 Stream Interface** is selected for **Reference Design**.

The AXI4-Stream interface is used for transferring audio data between the reference design and the filtering algorithm IP. The AXI4-Stream interface contains data (**Data**) and control signals such as data valid (**Valid**), back pressure (**Ready**), and data boundary (**TLAST**). At least **Data** and **Valid** signals are required for AXI4-Stream IP core generation. In Task 1.3, the **Target platform interface table** is loaded as shown in the following picture. The audio data stream ports, **Valid_in**, **Data_in**, **Valid_out** and **Data_out**, are mapped to the AXI4-Stream interfaces, **Pass_through_LED**, **BiQuad_LPF_LED**, **BiQuad_BPF_LED**, **BiQuad_HPF_LED** are mapped to the LEDs on Zedboard and the control parameter port **Filter_select** is mapped to the AXI4-Lite interface. If you are using Zybo board then map the LEDs to the filter manually by selecting **LEDs General Purpose[0:4]**.

The AXI4-Stream interface communicates in master/slave mode, where the master device sends data to the slave device. Therefore, if a data port is an input port, assign it to an **AXI4-Stream Slave** interface, and if a data port is output port, assign it to an **AXI4-Stream Master** interface.

3. Right-click Task 3.2, Generate RTL Code and IP Core, and select Run to Selected Task to generate the IP core. You can find the register address mapping and other documentation for the IP core in the generated IP Core Report.

Integrate IP Into AXI4-Stream Audio Compatible Reference Design

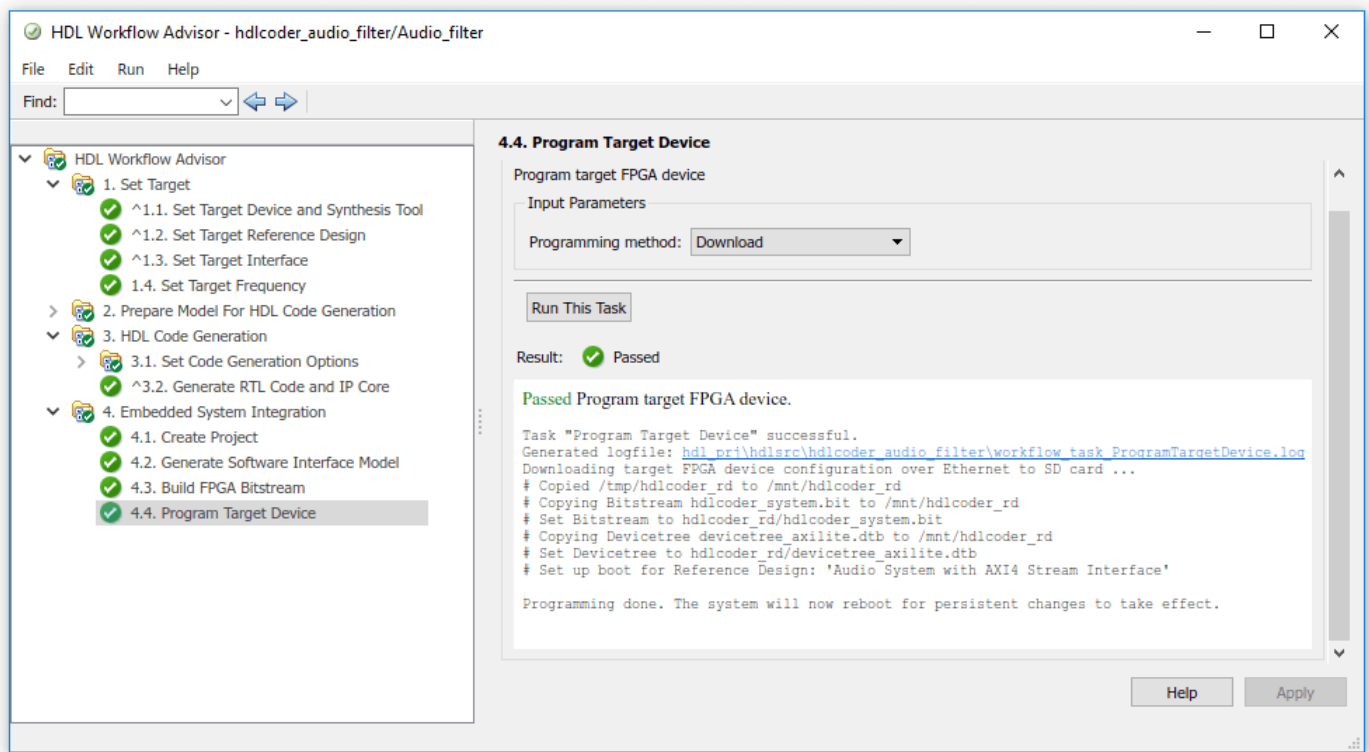

Next, in the HDL Workflow Advisor, you run the **Embedded System Integration** tasks to deploy the generated HDL IP core on Zynq hardware.

1. Run Task 4.1, Create Project. This task inserts the generated IP core into the **Audio System with AXI4 Stream Interface** reference design. As shown in the first diagram, this reference design contains the IPs to handle audio data in and out of Zedboard. The generated project is a complete Zynq design, including the algorithm part (the generated DUT algorithm IP), and the platform part (the reference design). For details on how to create a reference design which integrates the audio filter model, refer to "Authoring a Reference Design for Audio System on a Zynq Board" on page 47-205 or "Authoring a Reference Design for Audio System on a ZYBO Board" on page 47-215 example.

2. Click the link in the Result pane to open the generated Vivado project. In the Vivado tool, click **Open Block Design** to view the Zynq design diagram, which includes the generated HDL IP core, other audio processing IPs and the Zynq processor.

3. In the HDL Workflow Advisor, run the rest of the tasks to generate the software interface model, and build and download the FPGA bitstream. Choose **Download** programming method in the task **Program Target Device** to download the FPGA bitstream onto the SD card on the Zynq board, so your design will be automatically reloaded when you power cycle the Zynq board.

Generate ARM executable to Tune Parameters on the FPGA Fabric

A software interface model is generated in Task 4.2, **Generate Software Interface Model**.

1. Before you generate code from the software interface model, comment out the audio input source and audio output sink i.e. From Multimedia File, Data Type Conversion, Buffer, Audio Device Writer and Spectrum Analyzer Blocks. These blocks do not need to be run on the ARM processor. The Audio_filter IP is running as "Filtering_Algorithm" on FPGA fabric. The ARM processor is using AXI4-Lite interface for selecting the filter type i.e. Biquad Low pass, band pass, High pass or Pass Through.

- 1 In the generated model, click on Hardware pane and go to **Hardware settings** to open **Configuration Parameter** dialog box.
- 2 Select **Solver** and set "Stop Time" to "inf" and click **ok**.
- 3 From the Hardware pane, click the **Monitor and Tune** button.
- 4 Click the **Run** button on the model toolstrip. Embedded Coder builds the model, downloads the ARM executable to the Zynq board hardware, executes it, and connects the model to the executable running on the Zynq board hardware.

The type of filter to be used can be selected using the drop down options in **Filter Select** block

The filtered audio output can be heard by plugging earphones or speakers to **HPH OUT** jack on the Zynq board. Depending on the filter selected, the corresponding LED on the Zynq board turns on. In this example, LD0 turns on when Pass through (No filter used) option is selected, LD1 turns on when Biquad Low pass filter is selected, LD2 turns on when Biquad Band pass filter is selected and LD3 turns on when Biquad High pass filter is selected.

Deploy Model with AXI-Stream Interface in Zynq Workflow

This example shows how to use the AXI4-Stream interface to enable high speed data transfer between the processor and FPGA on Zynq® hardware.

Before You Begin

To run this example, you must have the following software and hardware installed and set up:

- HDL Coder™ Support Package for Xilinx® Zynq Platform
- Embedded Coder® Support Package for Xilinx Zynq Platform
- Xilinx Vivado® Design Suite, with supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Zedboard

To setup the Zedboard, refer to the *Set up Zynq hardware and tools* section in the example “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

Introduction

This example shows how to:

- 1 Model a streaming algorithm using a simplified streaming protocol.
- 2 Generate an HDL IP core with AXI4-Stream interface.
- 3 Integrate the generated IP core into a Zedboard reference design with DMA controller.
- 4 Use the AXI4-Stream driver block to generate C code that runs on an ARM processor.

The picture above is a high level architecture diagram that shows a streaming data transfer between the processor and FPGA fabric on Zynq platform. Typically, the AXI4-Stream interface is used together with a DMA controller to transfer a large chunk of data from the processor to FPGA. The data is usually represented as vector data on the software side. The DMA controller reads the vector data from memory, and "streams" it to the FPGA IP through the AXI4-Stream interface. The "streaming" process sends one data element per sample, which means the data path of the streaming algorithm in the FPGA IP is using a scalar data type.

The FPGA IP can also include an AXI4-Lite interface for control signals or parameter tuning. Compared to the AXI4-Lite interface, the AXI4-Stream interface transfers data much faster, making it more suitable for the data path of an algorithm.

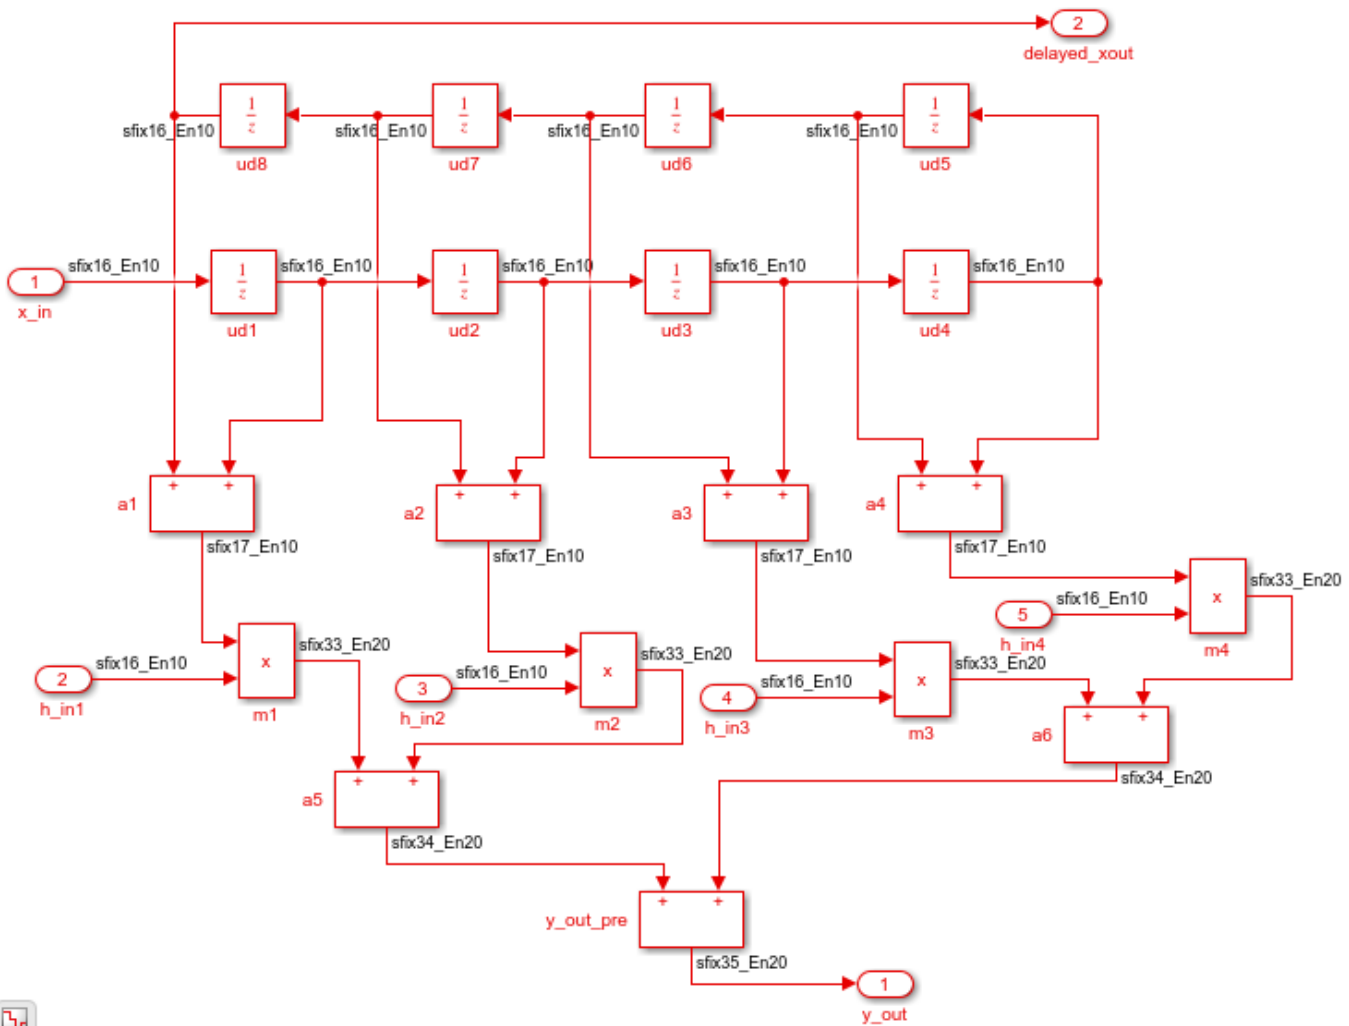

Other than connecting to processor, the FPGA IP with AXI4-Stream interface can also be connected with other IPs with AXI4-Stream interface to transfer data inside of FPGA.

Model Streaming Algorithm with Simplified Streaming Protocol

Suppose we want to deploy a simple symmetric FIR filter on Zynq. We want to implement the filter on FPGA. And the ARM processor generates the source data to stream it to FPGA through the AXI4-Stream interface.

Let's start with the `sfir_fixed` model.

```
open_system('sfir_fixed')
set_param('sfir_fixed', 'SimulationCommand', 'Update')
```

Note that the data path of this model (from $\mathbf{x_in}$ to $\mathbf{y_out}$) is processing scalar input data, which is suitable for a streaming interface.

In order to enable data transfer from the software to the filter algorithm, we need to map the data path ports to the AXI4-Stream interface. The AXI4-Stream interface contains data (**Data**) and control signals such as data valid (**Valid**), back pressure (**Ready**), and data boundary (**TLAST**).

The AXI4-Stream IP core generation feature requires at least the **Data** and **Valid** signals to be modeled in the DUT. The **Data** signal is the primary payload to send across the interface. The **Valid** signal indicates when the **Data** signal is valid. Other control signals are optional.

Note: For IP core generation, Data and Valid follow a simplified streaming protocol. You don't need to model the full AXI4-Stream protocol, which is more complicated. HDL Coder automatically generates a streaming interface module in the HDL IP core to translate the simplified streaming protocol into the full AXI4-Stream protocol. As shown in the picture below, the protocol is simple: whenever the Data signal is valid, the Valid signal must also be asserted.

So, in order to map `sfir_fixed` algorithm to the simplified streaming protocol, a **Valid** signal needs to be added. To add the **Valid** signal to your model, we recommend following modeling pattern:

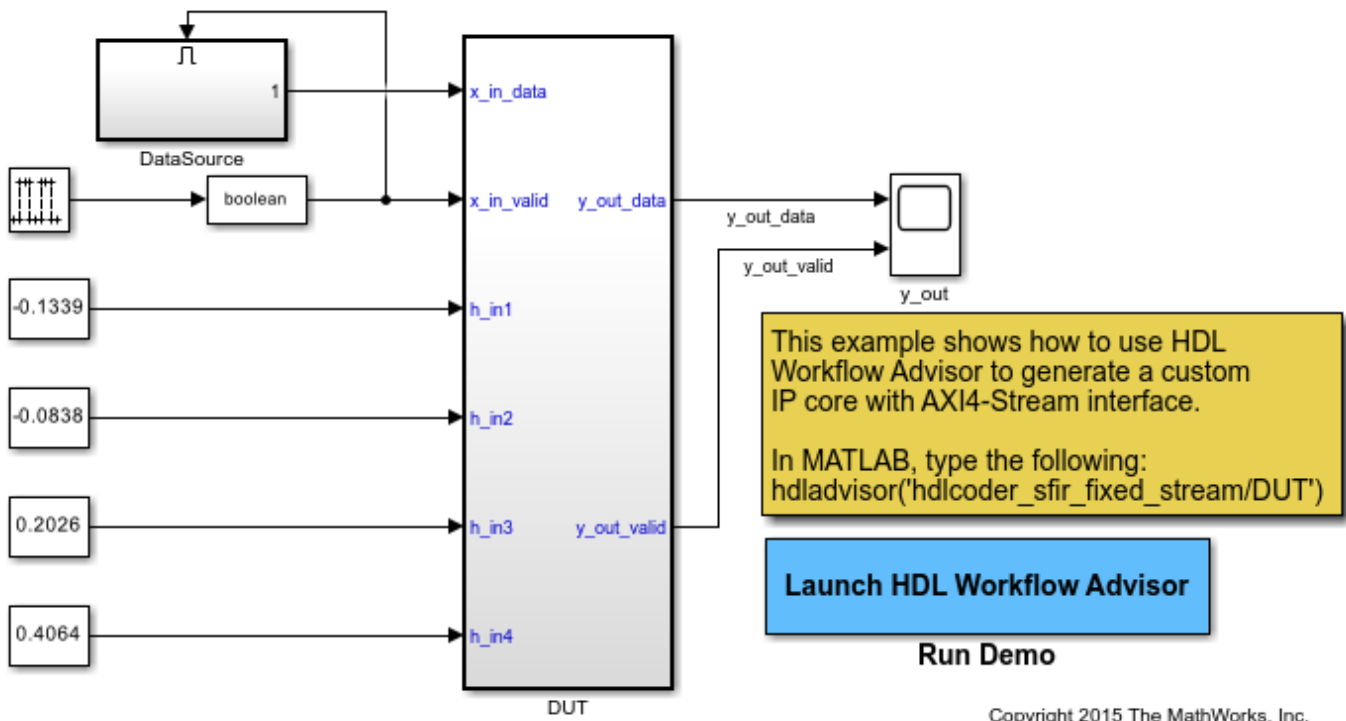

- 1 Convert the algorithm subsystem into an enabled subsystem.
- 2 Add an input control port, `Valid_In`, and output control port, `Valid_Out`.
- 3 Use `Valid_In` to drive both the algorithm subsystem's enable port and `Valid_Out`.

In this pattern, both the input streaming channel and output streaming channel follow the simplified streaming protocol.

Now, let's look at the example model.

```
open_system('hdlcoder_sfir_fixed_stream');
```

The subsystem **DUT** is the hardware subsystem targeting the FPGA fabric. Inside this subsystem, the **symmetric_fir** subsystem represents the filter algorithm. The input ports, **x_in_data** and **x_in_valid**, and output ports, **y_out_data** and **y_out_valid**, are the data path ports of the filter. The other input ports, such as **h_in1**, are control ports that tune the filter parameters.

The model follows the modeling pattern for simplified streaming protocol. The **symmetric_fir** subsystem is an enabled subsystem. The input control signal, **x_in_valid**, controls the **symmetric_fir** subsystem's enable port and also drives the output control signal, **y_out_valid**.

With AXI4-Stream IP core generation, you can optionally model other streaming control signals. For example, you can model the back pressure signal, **Ready**. The AXI4-Stream interface communicates in master/slave mode, where the master device sends data to the slave device. The **Ready** signal is a back pressure signal from the slave device to master device that indicates whether the slave device can accept new data. As shown in following diagram, the **Ready** signal is asserted when the slave device can accept new data. When the slave device can no longer accept new data, it needs to deassert the **Ready** signal. When the master device sees that the **Ready** signal is deasserted, it stops the data transfer at most one sample later. This one sample allowance is built into the protocol.

Note: This diagram illustrates the relationship between the Data, Valid, and Ready signals according to the simplified streaming protocol. When you run the IP Core Generation workflow, the code generator adds a streaming interface module in the HDL IP core that translates the simplified protocol to the full streaming protocol.

For example, you can use the **Ready** signal when you use a FIFO block to collect a frame of incoming streaming data, which is then processed with your algorithm. During data processing, you deassert the **Ready** signal to prevent further incoming data.

Generate HDL IP core with AXI4-Stream Interface

Next, we start the HDL Workflow Advisor and use the Zynq hardware-software co-design workflow to deploy this design on the Zynq hardware. For a more detailed step-by-step guide, you can refer to the “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 example.

1. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2019.1\bin\vivado.l
```

2. Start the HDL Workflow Advisor from the DUT subsystem, `hdlcoder_sfir_fixed_stream/DUT`. The target interface settings are already saved in this example model, so the settings in Task 1.1 and 1.2 are automatically loaded. To learn more about saving target interface settings in the model, you can refer to the “Save Target Hardware Settings in Model” on page 46-171 example.

In Task 1.1, **IP Core Generation** is selected for **Target workflow**, and **Zedboard** is selected for **Target platform**. In Task 1.2, **Default system with AXI4-Stream interface** is selected for **Reference Design**, and the **Target platform interface table** is loaded as shown in the following picture. The data path ports, **x_in_data**, **x_in_valid**, **y_out_data**, and **y_out_valid**, are mapped to the AXI4-Stream interfaces, and the control parameter ports, such as **h_in1**, are mapped to the AXI4-Lite interface.

The AXI4-Stream interface communicates in master/slave mode, where the master device sends data to the slave device. Therefore, if a data port is an input port, assign it to an **AXI4-Stream Slave** interface, and if a data port is output port, assign it to an **AXI4-Stream Master** interface.

3. Right-click Task 3.2, **Generate RTL Code and IP Core**, and select **Run to Selected Task** to generate the IP core. You can find the register address mapping and other documentation for the IP core in the generated IP Core Report.

Integrate IP Into AXI4-Stream Compatible Reference Design

Next, in the HDL Workflow Advisor, we run the **Embedded System Integration** tasks to deploy the generated HDL IP core on Zynq hardware.

1. Run Task 4.1, **Create Project**. This task inserts the generated IP core into the **Default system with AXI4-Stream interface** reference design. This reference design contains Xilinx AXI DMA IP to handle the processor to FPGA fabric data streaming. As shown in the first diagram, or in the IP core report, the data is sent from the ARM processing system, through the DMA controller and AXI4-Stream interface, to the generated HDL FIR filter IP core. The output of the filter IP core is then sent back to the processing system.

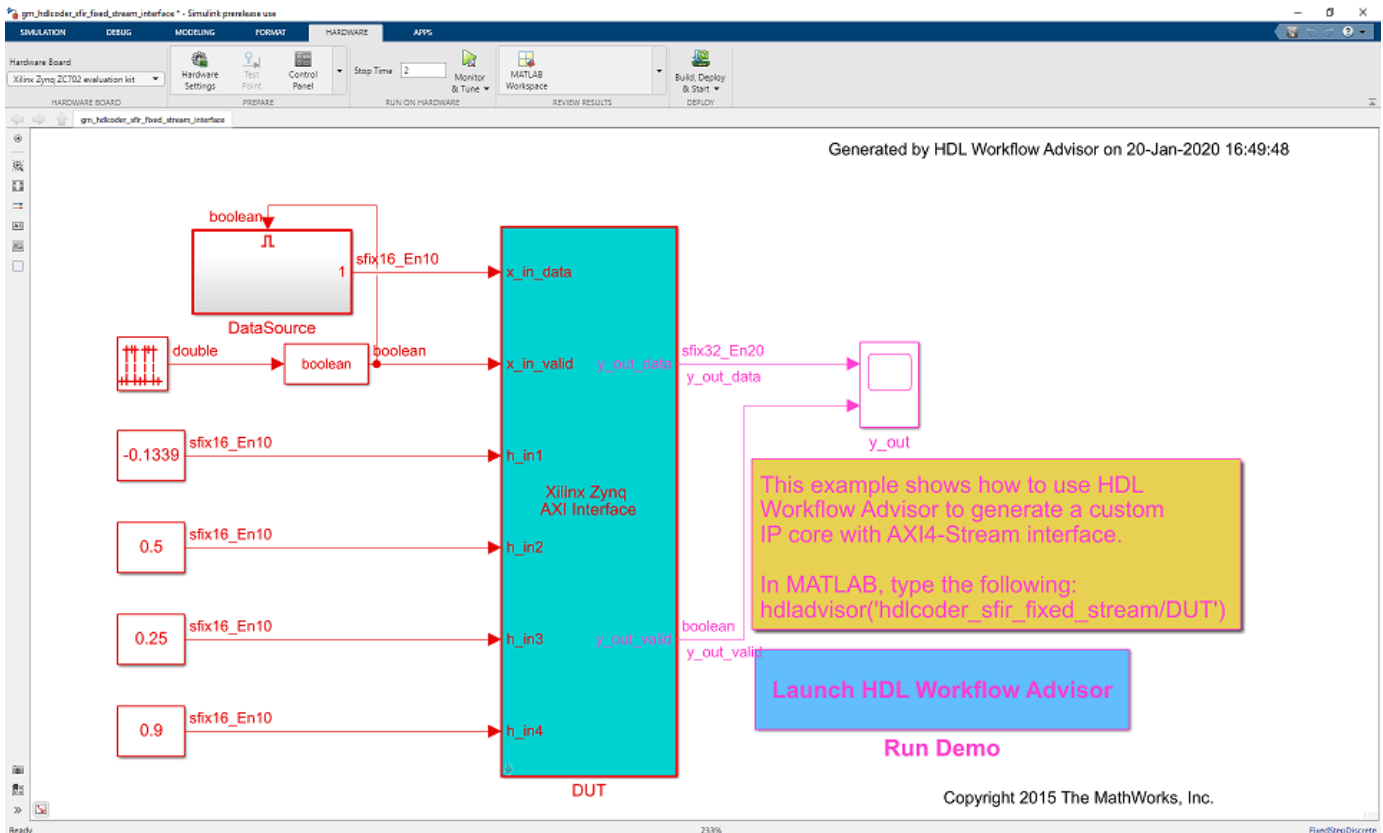

2. Optionally click the link in the Result pane to open the generated Vivado project. In the Vivado tool, click **Open Block Design** to view the Zynq design diagram, which includes the generated HDL IP core, AXI DMA controller and the processor.

3. In the HDL Workflow Advisor, run the rest of the tasks to generate the software interface model, and build and download the FPGA bitstream.

Generate ARM executable Using AXI4-Stream Driver Block

A software interface model is generated in Task 4.2, **Generate Software Interface Model**, as shown in the following picture.

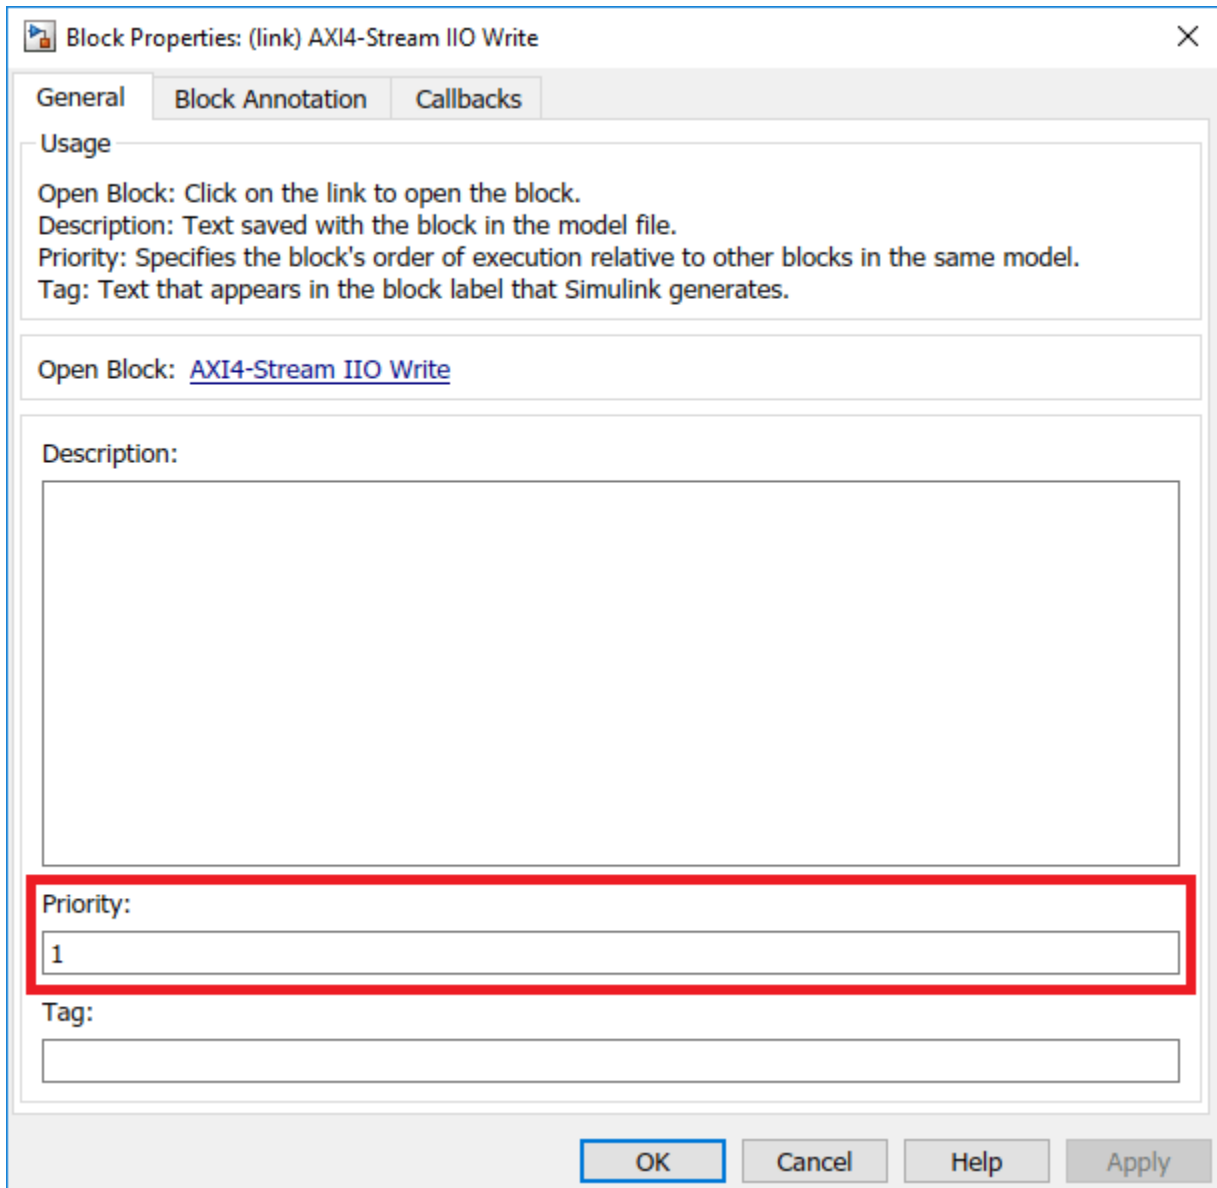

Although the AXI4-Lite driver is automatically generated in the software interface model, the AXI4-Stream driver block cannot be automatically generated. The reason is that the AXI4-Stream driver block expects to be connected to a vector port on the software side, but the **x_in_data** DUT port is a scalar port.

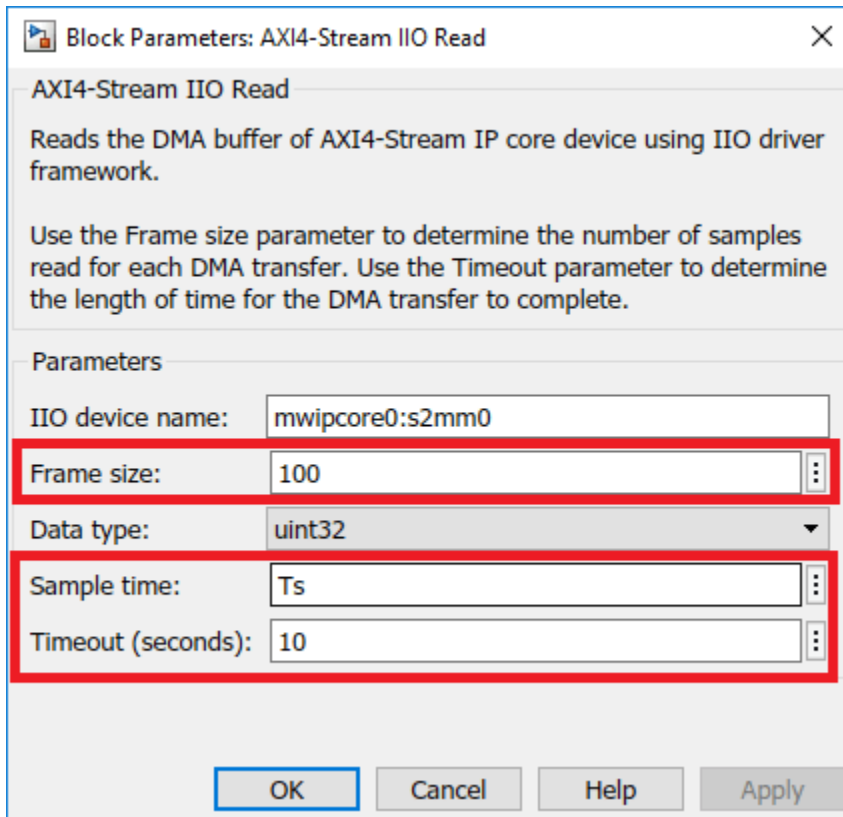

1. Before you generate code from the software interface model:
 - 1 Add the **AXI4-Stream IIO Read** and **AXI4-Stream IIO Write** driver blocks from **Simulink Library Browser -> Embedded Coder Support Package for Xilinx Zynq Platform** library.
 - 2 Use a vector data source to drive the **x_in_data** port.
 - 3 Connect the **x_in_data** port to the driver block.
 - 4 Double click on the **AXI4-Stream IIO Write** block and set the Timeout to 0 instead of inf. This is as shown below.

5. Set the priority of the **AXI4-Stream IIO Write** block to 1 to make sure that write happens before read. To set the priority, right click on the block and open properties, set the priority to 1. This is as shown below.

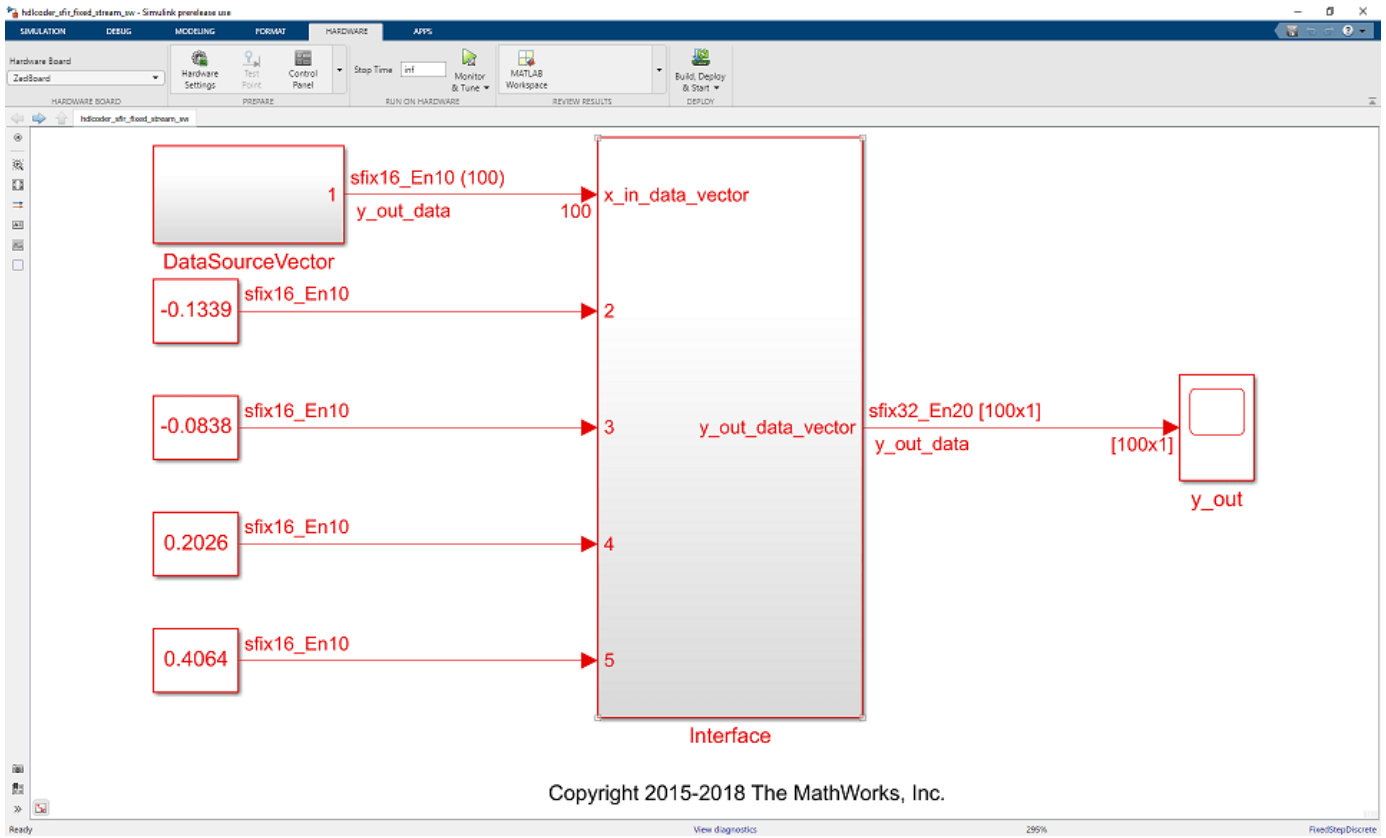

6. Now double click on the **AXI4-Stream IIO Read** block and set the frame size to 100, Sample time to Ts and Timeout to 10. This is as shown below.

7. The priority of the **AXI4-Stream IIO Read** block need not to be set. Setting the priority for write block to 1 alone already ensure that write happens before read.

For this example, the updated software interface model is provided: `hdlcoder_sfir_fixed_stream_sw.slx`. A vector data source with 100 data elements is used in this model, and is connected to the AXI4-Stream DMA driver block. This means that for each processor sample time, the DMA controller will stream 100 32-bit data samples to the HDL IP core via the AXI4-Stream interface, and receive 100 32-bit streaming data samples.

2. Configure and build the software interface model for external mode:

- 1 In the generated model, click on Hardware pane and go to **Hardware settings** to open **Configuration Parameter** dialog box.
- 2 Select **Solver** and set "Stop Time" to "inf".
- 3 From the Hardware pane, click the **Monitor and Tune** button.
- 4 Click the **Run** button on the model toolstrip. Embedded Coder builds the model, downloads the ARM executable to the Zedboard hardware, executes it, and connects the model to the executable running on the Zedboard hardware.

3. Now, both the hardware and software parts of the design are running on Zynq hardware. The ARM processor sends the source data to the FPGA IP, through the DMA controller and the AXI4-Stream interface. The ARM processor receives the filter result data from the FPGA IP, and sends the result data to Simulink via external mode. Observe the output of the FIR filter IP core from the Zynq hardware on the Time Scope **y_out**.

4. Tune the FIR filter parameters in the software interface model and observe how the output of the FIR filter changes as you tune the parameters. The parameter values are sent to the Zynq hardware via external mode and the AXI4-Lite interface.

Deploy Model with AXI4-Stream Video Interface in Zynq Workflow

This example shows how to use the AXI4-Stream Video interface to enable high speed video streaming on the generated HDL IP core.

Before You Begin

To run this example, you must have the following software and hardware installed and set up:

- HDL Coder™ Support Package for Xilinx® Zynq® Platform
- Embedded Coder® Support Package for Xilinx Zynq Platform
- Vision HDL Toolbox™ Support Package for Xilinx Zynq-Based Hardware
- Vision HDL Toolbox
- Xilinx Vivado® Design Suite, with supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- ZedBoard
- FMC HDMI I/O card (FMC-HDMI-CAM or FMC-IMAGEON)

To setup the Zedboard, refer to the *Set up Zynq hardware and tools* section in the example “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

Introduction

This example shows how to:

- 1 Model a video streaming algorithm using the streaming pixel protocol.
- 2 Generate an HDL IP core with AXI4-Stream Video interface.
- 3 Integrate the generated IP core into a ZedBoard video reference design with access to HDMI interfaces.
- 4 Use the ARM® processor to tune the parameters on the FPGA fabric to change the live video output.
- 5 Create your own custom video reference design.

The picture above is a high level architecture diagram that shows how the generated HDL DUT IP core works in a pre-defined video reference design. In this diagram, the **HDL DUT IP** block is the IP

core that is generated from the IP core generation workflow. The rest of the diagram represents the pre-defined video reference design, which contains other IPs to handle the HDMI input and output interfaces.

The **HDL DUT IP** processes a video stream coming from the HDMI input IP, generates an output video stream, and sends it to the HDMI output IP. All of these video streams are transferred in AXI4-Stream Video interface.

The **HDL DUT IP** can also include an AXI4-Lite interface for parameter tuning. Compared to the AXI4-Lite interface, the AXI4-Stream Video interface transfers data much faster, making it more suitable for the data path of the video algorithm.

Set up Zynq hardware and tools

1. Set up the ZedBoard and the FMC HDMI I/O card as shown in the figure below. To learn more about the ZedBoard hardware setup, please refer to the board documentation.

1.1. Connect the USB UART cable, the Ethernet cable and the power cable as shown in the figure above (marker 1 to 3).

1.2. Make sure the JP7 to JP11 jumpers are set as shown in the figure above (marker 4), so you can boot Linux from the SD card. JP7: down; JP8: down; JP9: up; JP10: up; JP11: down.

1.3. Make sure the J18 jumper are set on 2V5 as shown in the figure above (marker 5).

1.4. Connect HDMI video source to the FMC HDMI I/O card as shown in the figure above (marker 6). The video source must be able to provide 1080p video output, for example, it could be a video camera, smart phone, tablet, or your computer's HDMI output.

1.5. Connect a monitor to the FMC HDMI I/O card as shown in the figure above (marker 7). The monitor must be able to support 1080p display.

2. If you haven't already, install the HDL Coder and Embedded Coder Support Packages for Xilinx Zynq Platform, and Vision HDL Toolbox Support Package for Xilinx Zynq-Based Hardware. To install the support package, go to the MATLAB® toolstrip and click **Add-Ons > Get Hardware Support Packages**.

3. Make sure you are using the SD card image provided by the Embedded Coder Support Package for Xilinx Zynq Platform. If you need to update your SD card image, see the Hardware Setup section of “Install Support for Xilinx Zynq Platform” (Embedded Coder Support Package for Xilinx Zynq Platform).

4. Set up the Zynq hardware connection by entering the following command in the MATLAB command window:

```
h = zynq
```

The `zynq` function logs in to the hardware via COM port and runs the `ifconfig` command to obtain the IP address of the board. This function also tests the Ethernet connection.

5. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2020.2\bin\vivado.l
```

Model Video Streaming Algorithm using the Streaming Pixel Protocol

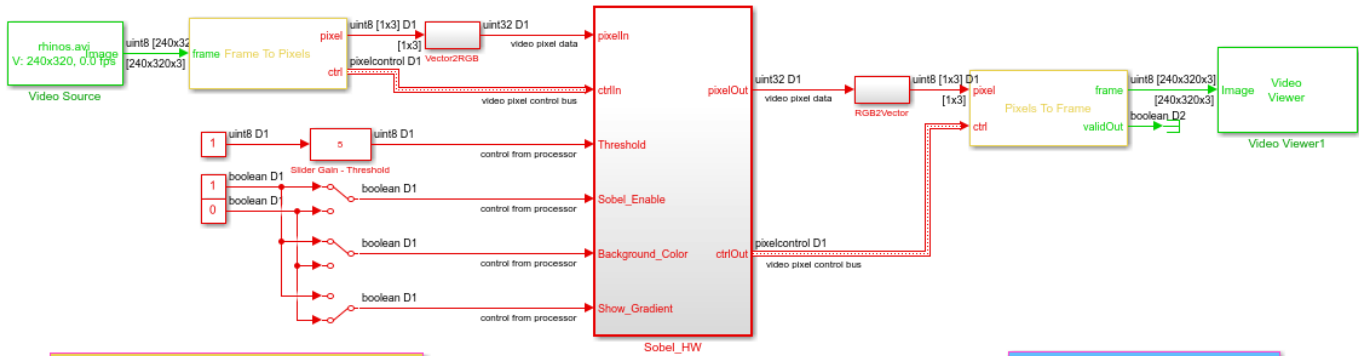

To deploy a simple Sobel edge detection algorithm on Zynq, the first step is to determine which part of the design to be run on FPGA, and which part of the design to be run on the ARM processor. In this example, we want to implement the edge detector on FPGA to process the incoming video stream in AXI4-Stream Video protocol. And we want to use the ARM processor to tune the parameters on FPGA to change the live video output.

In the example model, the DUT subsystem, **Sobel_HW**, uses a edge detector block to implement the Sobel edge detection algorithm. The video data and control signals are modeled in the video streaming pixel protocol, which is used by all the blocks in Vision HDL Toolbox. **pixelIn** and **pixelOut** are data ports for video streams. **ctrlIn** and **ctrlOut** are control ports for video streams. They are modeled using a bus data type (**Pixel Control Bus**) which contains following signals: **hStart**, **hEnd**, **vStart**, **vEnd**, **valid**.

Four input ports, **Threshold**, **Sobel_Enable**, **Background_Color** and **Show_Gradient**, are control ports to adjust the parameters the Sobel edge detection algorithms. You can use the **Slider Gain** or **Manual Switch** block to adjust the input values of these ports. After mapping these ports to AXI4-Lite interface, the ARM processor can control the generated IP core by writing to the generated AXI interface accessible registers.

```
modelName = 'hdlcoder_sobel_video_stream';
open_system(modelname);
sim(modelname);
```

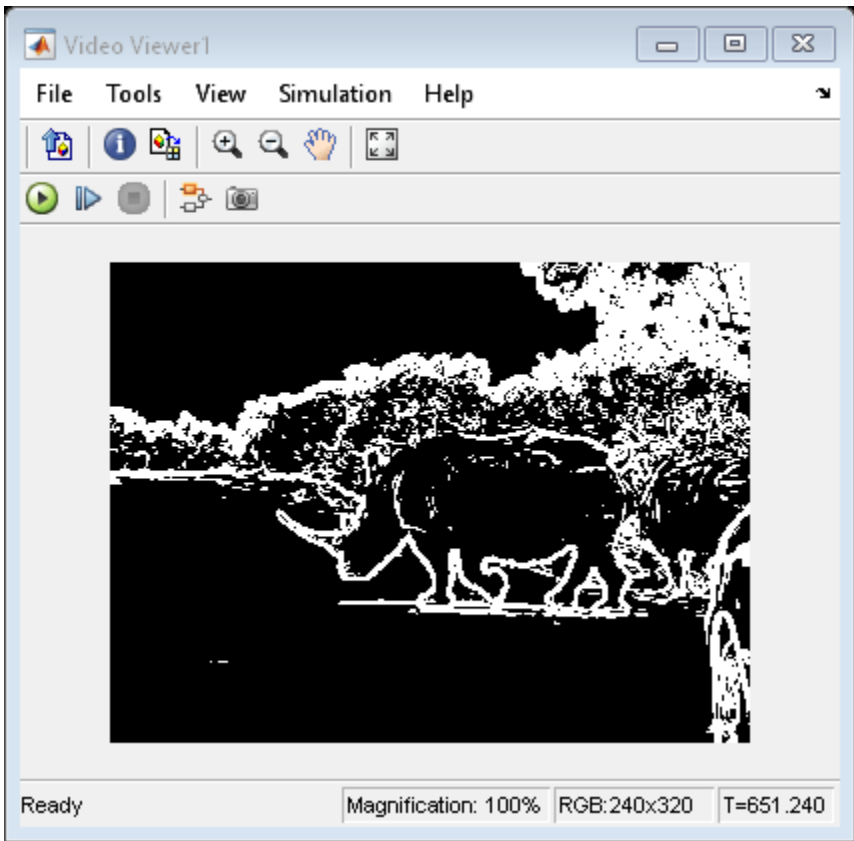

Using IP Core Generation Workflow: Sobel Edge Detection

This example shows how to use HDL Coder to generate a custom IP core which perform Sobel edge detection processing on streaming video.
 In MATLAB, type the following:
`hdlhwiser('hdlcoder_sobel_video_stream/Sobel_HW')`

Launch HDL Workflow Advisor
 Run Demo

Copyright 2016 The MathWorks, Inc.

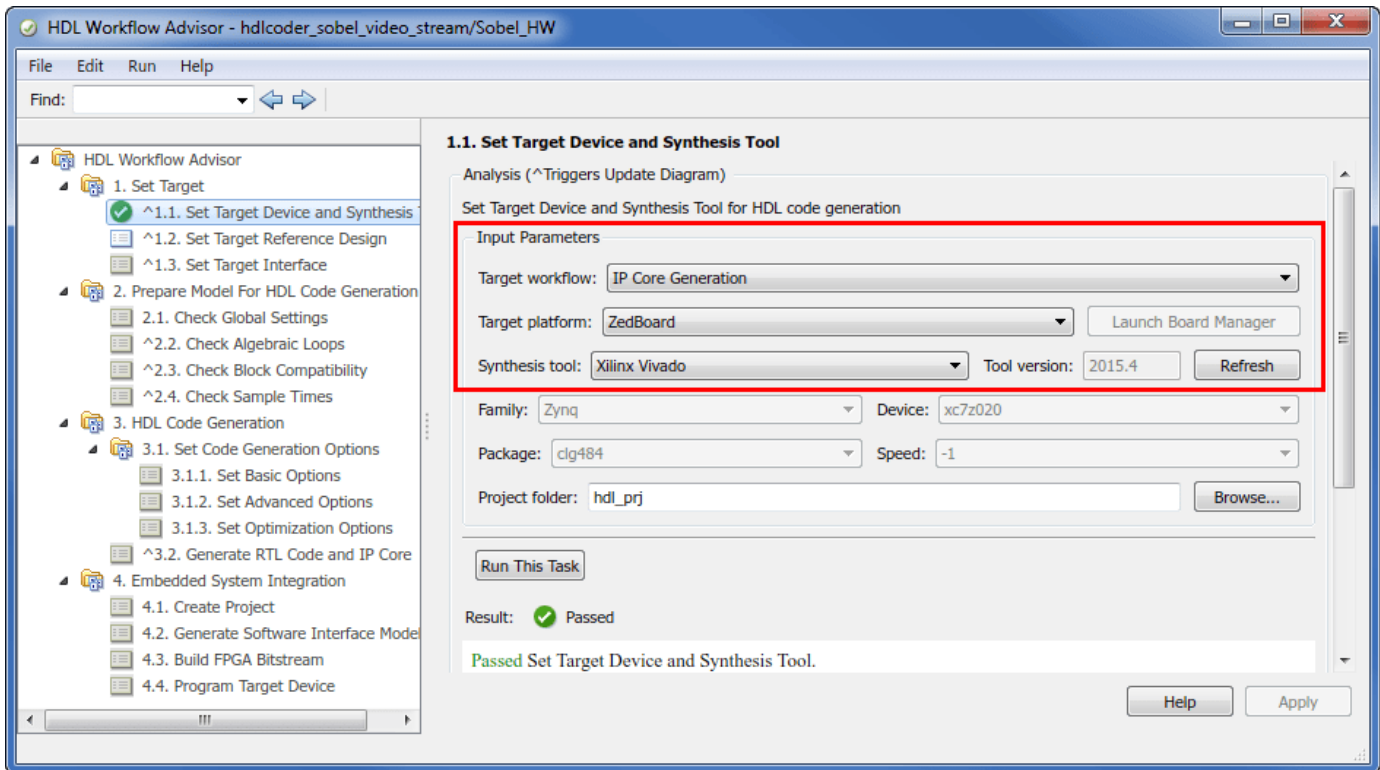

Generate HDL IP core with AXI4-Stream Video Interface

Next, we start the HDL Workflow Advisor and use the Zynq hardware-software co-design workflow to deploy this design on the Zynq hardware. For a more detailed step-by-step guide, you can refer to the “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 example.

1. Start the HDL Workflow Advisor from the DUT subsystem, `hdlcoder_sobel_video_stream/Sobel_HW`. The target interface settings are already saved in this example model, so the settings in Task 1.1 to 1.3 are automatically loaded. To learn more about saving target interface settings in the model, you can refer to the “Save Target Hardware Settings in Model” on page 46-171 example.

In Task 1.1, **IP Core Generation** is selected for **Target workflow**, and **ZedBoard** is selected for **Target platform**.

In Task 1.2, **Default video system (requires HDMI FMC module)** is selected for **Reference Design**.

In Task 1.3, the **Target platform interface table** is loaded as shown in the following picture. The video data stream ports, **pixelIn**, **ctrlIn**, **pixelOut**, and **ctrlOut**, are mapped to the AXI4-Stream Video interfaces, and the control parameter ports, such as **Threshold**, are mapped to the AXI4-Lite interface.

The AXI4-Stream Video interface communicates in master/slave mode, where the master device sends data to the slave device. Therefore, if a data port is an input port, assign it to an **AXI4-Stream Video Slave** interface, and if a data port is output port, assign it to an **AXI4-Stream Video Master** interface.

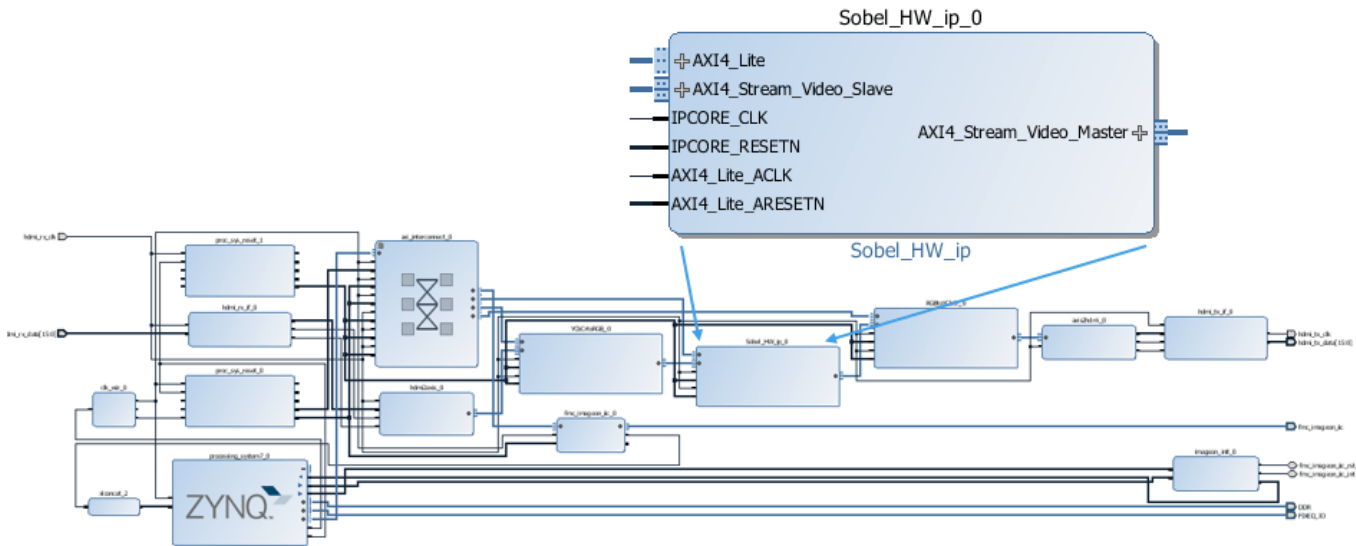

2. Right-click Task 3.2, **Generate RTL Code and IP Core**, and select **Run to Selected Task** to generate the IP core. You can find the register address mapping and other documentation for the IP core in the generated IP Core Report.

Integrate IP Into AXI4-Stream Video Compatible Reference Design

Next, in the HDL Workflow Advisor, we run the **Embedded System Integration** tasks to deploy the generated HDL IP core on Zynq hardware.

1. Run Task 4.1, **Create Project**. This task inserts the generated IP core into the **Default video system** reference design. As shown in the first diagram, this reference design contains the IPs to handle HDMI input and output interfaces. It also contains the IPs to do color space conversion from YCbCr to RGB. The generated project is a complete Zynq design, including the algorithm part (the generated DUT algorithm IP), and the platform part (the reference design).

2. Click the link in the Result pane to open the generated Vivado project. In the Vivado tool, click **Open Block Design** to view the Zynq design diagram, which includes the generated HDL IP core, other video pipelining IPs and the Zynq processor.

3. In the HDL Workflow Advisor, run the rest of the tasks to generate the software interface model, and build and download the FPGA bitstream. Choose **Download** programming method in the task **Program Target Device** to download the FPGA bitstream onto the SD card on the ZedBoard, so your design will be automatically reloaded when you power cycle the ZedBoard.

Generate ARM executable to Tune Parameters on the FPGA Fabric

A software interface model is generated in Task 4.2, **Generate Software Interface Model**.

1. Before you generate code from the software interface model, comment out the **Video Source** and **Video Viewer** in the generated model, as shown in the following picture. These blocks do not need to be run on the ARM processor. The ARM processor is using AXI4-Lite interface to control the FPGA fabric. The actual video source and display interface are all running on the FPGA fabric. The video source comes from the HDMI input, and the video output will be sent to the monitor connected to the HDMI output.

2. Configure and build the software interface model for external mode:

- 1 In the generated model, open the **Configuration Parameters** dialog box.
- 2 Select **Solver** and set "Stop Time" to "inf".
- 3 From the model menu, select **Simulation > Mode > External**.
- 4 Click the **Run** button on the model toolstrip. Embedded Coder builds the model, downloads the ARM executable to the ZedBoard hardware, executes it, and connects the model to the executable running on the ZedBoard hardware.

3. Now, both the hardware and software parts of the design are running on Zynq hardware. Use the **Sobel_Enable** switch to observe that the live video output switches between the edge detector output and the original video. Use the **Threshold** or **Background_Color** switch to see the different edge detection effects on the live video output. These parameter values are sent to the Zynq hardware via external mode and the AXI4-Lite interface.

Customize your video reference design

You may want to extend the existing **Default video system** reference design to add additional pre-processing or post-processing camera pipelining IPs, or you may want to use a different SoC hardware or video camera interface. The **Default video system** reference design is an example or a starting point to create your own custom reference design.

For example, the **Default video system** reference design contains two IP cores to do color space conversion from YCbCr to RGB, as shown in following picture. These two IP cores are generated by HDL Coder as well using the IP Core Generation workflow. You can optionally generate other pre-processing or post-processing camera pipelining IP cores, and add them into a custom reference design to extend your video platform.

For more details on creating your own custom reference design, you can refer to the “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231 example.

Perform Matrix Operation Using External Memory

This example shows how to generate an HDL IP core with AXI4 Master interface, perform matrix multiplication in HDL IP core, and write output result to DDR memory.

Before You Begin

To run this example, you must have the following software and hardware installed and set up:

- Xilinx® Vivado® Design Suite, with supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”.
- Xilinx Zynq® ZC706 Evaluation Kit
- HDL Coder™ Support Package for Xilinx Zynq Platform
- HDL Verifier™ Support Package for Xilinx FPGA Boards
- This example can also be run on a Xilinx Zynq Ultrascale+ MPSoC ZCU102 Evaluation Kit

Introduction

In this example, you:

- 1 Generate an HDL IP core with AXI4 Master interface.
- 2 Access large matrices from the external DDR3 memory on the Xilinx Zynq ZC706 board using the AXI4 Master interface.
- 3 Perform matrix vector multiplication in the HDL IP core and write the output result back to the DDR memory using the AXI4 Master interface.

This example can also be run on a Xilinx Zynq Ultrascale+ MPSoC ZCU102 Evaluation Kit, to access the external DDR4 memory.

This example models a matrix vector multiplication algorithm and implements the algorithm on the Xilinx Zynq FPGA board. Large matrices may not map efficiently to Block RAMs on the FPGA fabric. Instead, we can store the matrices in the external DDR memory on the FPGA board. The AXI4 Master interface can access the data by communicating with vendor-provided memory interface IP cores that interface with the DDR memory. This capability enables you to model algorithms that involve large data processing and requires high-throughput DDR access, such as matrix operations, computer vision algorithms, and so on.

The matrix vector multiplication module supports fixed point matrix vector multiplication, with a configurable matrix size ranging from 2 to 4000. The size of the matrix is run-time configurable through AXI4 accessible register.

```
modelName = 'hdlcoder_external_memory';  
open_system(modelName);
```

Using IP Core Generation Workflow: External Memory Access

This example shows how to use HDL Code to generate a custom IP core which perform large matrix operations on FPGAs using external memory.

In MATLAB, type the following:
`hdladvisor('hdlcoder_external_memory/DUT')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2017 The MathWorks, Inc.

Model Algorithm Using AXI4 Master Protocol

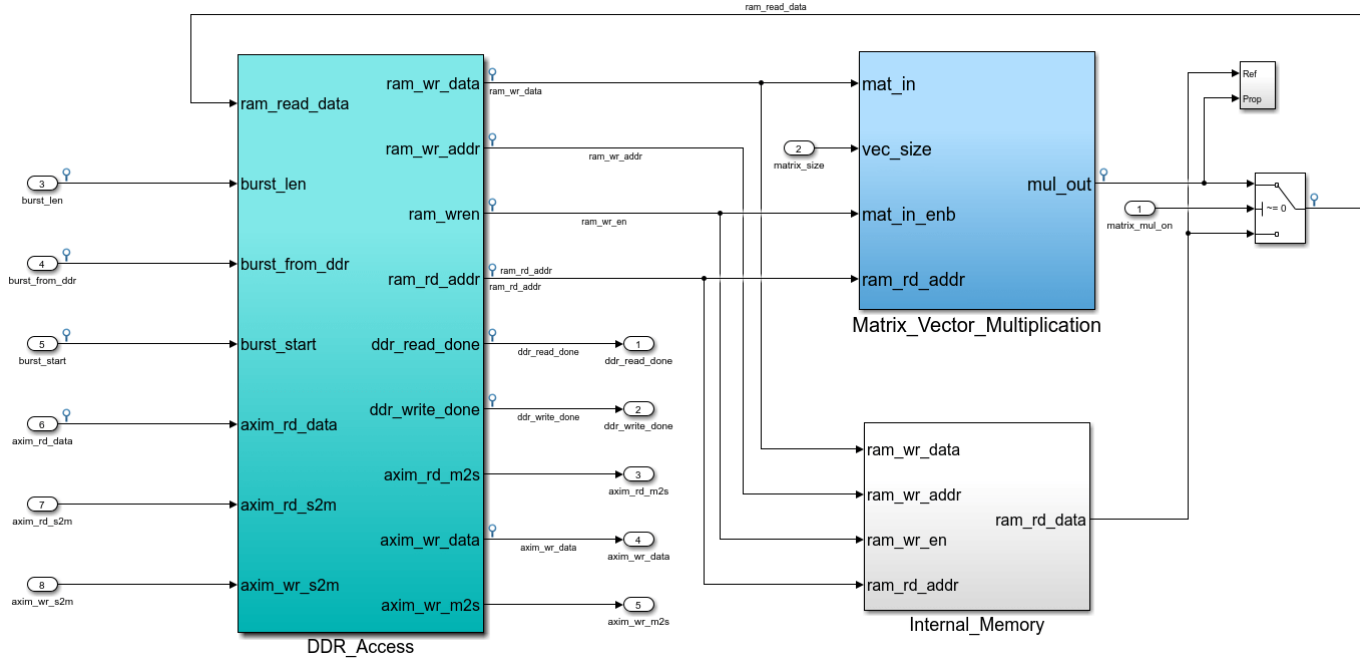

This example model includes the FPGA implementable DUT (Design under test) block, the DDR functional behavior block and the test environment to drive inputs and verify the expected outputs.

The DUT subsystem contains the AXI4 Master read/write controller along with the matrix vector multiplication module. Using the AXI4 Master interface, the DUT subsystem reads data from the external DDR memory, feed the data into the `Matrix_Vector_Multiplication` module, and then write the output data to the external DDR memory using AXI4 Master interface. The DUT module also has several parameter ports. These ports will be mapped to AXI4-Lite accessible registers, so you can adjust these parameters from MATLAB®, even after you implement the design onto the FPGA.

The DDR module represents the external DDR memory in simulation environment. The interface between the DUT and DDR modules are the simplified AXI4 Master protocol.

One of the parameter port `matrix_mul_on` controls whether to run the `Matrix_Vector_Multiplication` module. When the input to `matrix_mul_on` is true, the DUT subsystem performs matrix vector multiplication as describe above. When the input to `matrix_mul_on` is false, the DUT subsystem perform a data loop back mode. In this mode, the DUT subsystem read data from the external DDR memory, write it into the `Internal_Memory` module, and then write the same data back to the external DDR memory. The data loop back mode is a simple way to verify the functionality of the AXI4 Master external DDR memory access.

```
open_system('hdlcoder_external_memory/DUT');
```

Inside the DUT subsystem, the `DDR_Access` module models the simplified AXI4 Master protocol, and use it to read and writes data on DDR. During the IP Core Generation workflow, HDL Coder will then generate the translator between the simplified AXI4 Master protocol and the actual AXI4 Master protocol in the generated HDL IP core. For more information on the simplified AXI4 Master protocol, see “Model Design for AXI4 Master Interface Generation” on page 47-107.

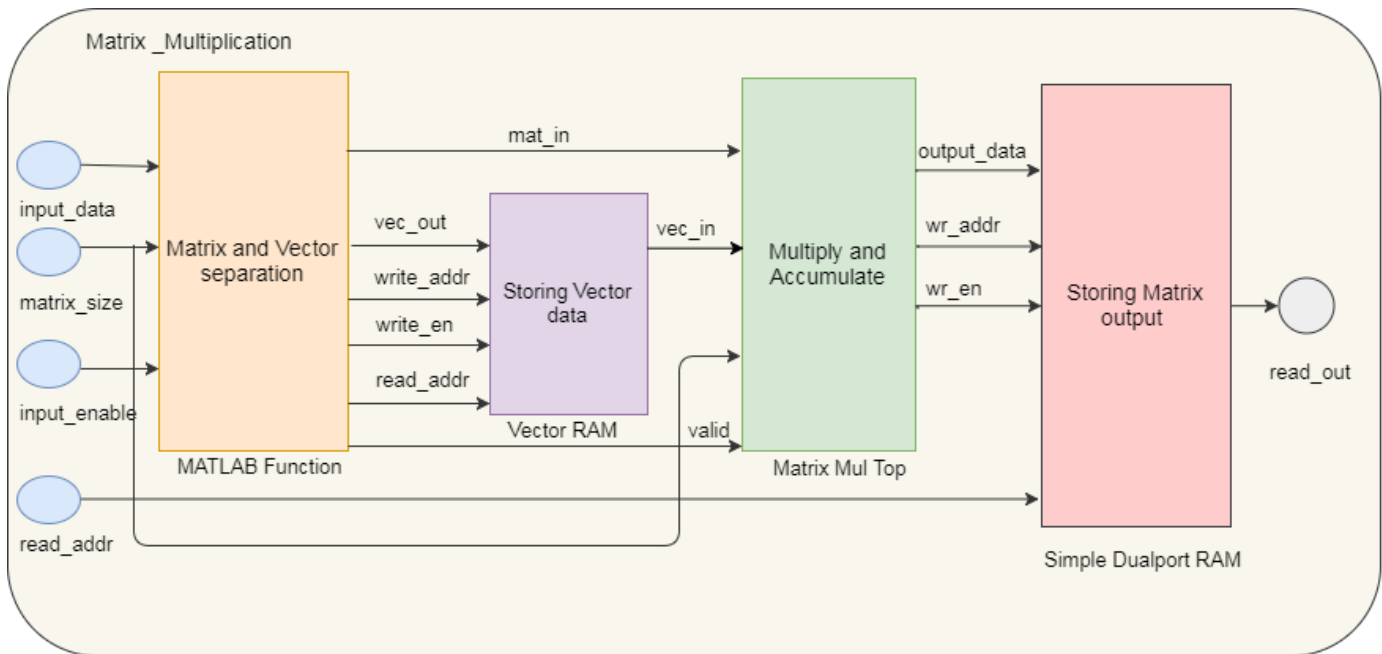

Also inside the DUT subsystem, the `Matrix_Vector_Multiplication` module uses a multiply-add block to implement a streaming dot-product computation for the inner-product of the matrix vector multiplication.

Lets say, A be a matrix of size $N \times N$ and B is a vector of size $N \times 1$

Then, matrix vector multiplication output will be: $Z = A * B$, of size $N \times 1$

The first N values from the DDR are treated as the $N \times 1$ size vector, followed by $N \times N$ size matrix data. First N values (vector data) are stored into a RAM. From $N+1$ values onwards, data is directly streamed as matrix data. Vector data will be read from the `Vector_RAM` in parallel. Both matrix and vector inputs are fed into the `Matrix_mul_top` subsystem. The first matrix output is available after N clock cycles and will be stored into output RAM. Again, vector RAM read address is reinitialized to 0 and starts reading same vector data corresponding to new matrix stream. This operation is repeated for all the rows of the matrix.

The follow diagram shows the architecture of the `Matrix_Vector_Multiplication` module.

Functional Simulation in Simulink

You can simulate this example model, and verify the simulation result by running following script in MATLAB:

```
hdlcoder_external_memory_simulation;
```

```
PASSED: DDR initialization data matches.
```

```
PASSED: Matrix vector multiplication output matches with the expected data
```

This script first initializes the parameters like `Matrix_Size`. By default the `Matrix_Size` is 64, which means a 64x64 matrix. The default `Matrix_Size` is kept small so the simulation is faster. After the DUT is implemented onto the FPGA board, larger `Matrix_Size` then can be used as the FPGA calculation is much faster. You can also adjust these parameters in the script.

The script then simulates the model, and verifies the result by comparing the logged simulation result with the expected value.

By default, the `Matrix_Multiplication_On` is true, the script verifies the matrix vector multiplication result.

When the `Matrix_Multiplication_On` is false, the script verifies the loop back mode, which means the DUT read `Burst_Length` amount of data from DDR, and write the data back to DDR.

If you have a DSP System Toolbox license, you can view the model signals over time using the Logic Analyzer.

Generate HDL IP core with AXI4 Master Interface

Next, we start the HDL Workflow Advisor and use the IP Core Generation workflow to deploy this design on the Zynq hardware. For a more detailed step-by-step guide, see “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

1. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2018.2\bin\vivado.l
```

2. Start the HDL Workflow Advisor from the DUT subsystem, `hdlcoder_external_memory/DUT`. The target interface settings are saved on the model. Notice that **Target workflow** is IP Core Generation, **Target platform** is Xilinx Zynq ZC706 evaluation kit, **Reference Design** is Default System with External DDR3 memory access, and **Target platform interface table** settings are as shown below.

In this example, the input parameter ports like `matrix_mul_on`, `matrix_size`, `burst_len`, `burst_from_ddr` and `burst_start` are mapped to the AXI4-Lite interface. HDL Coder will generate AXI4 interface accessible registers for these ports. Later, you can use MATLAB to tune these parameters at run-time when the design is running on FPGA board.

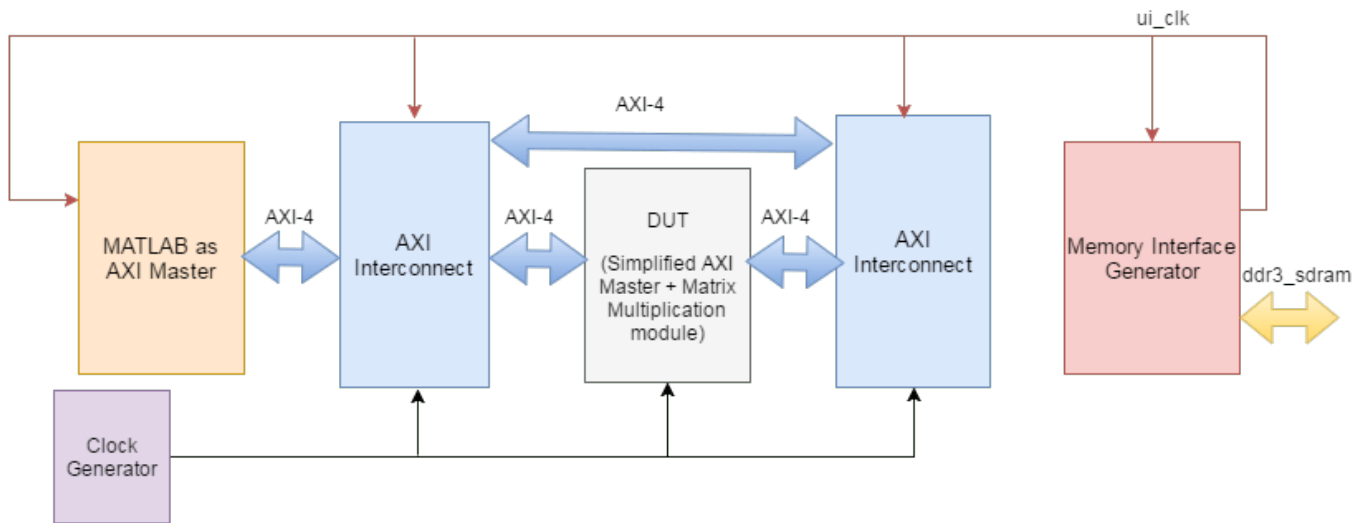

The AXI4 Master interface has separate Read and Write channels. The read channel ports like `axim_rd_data`, `axim_rd_s2m`, `axim_rd_m2s` are mapped to AXI4 Master Read interface. The write channel ports like `axim_wr_data`, `axim_wr_s2m`, `axim_wr_m2s` are mapped to AXI4 Master Write interface.

3. Right-click Task 3.2, **Generate RTL Code and IP Core**, and select **Run to Selected Task** to generate the IP core. You can find the register address mapping and other documentation for the IP core in the generated IP Core Report.

4. Now Right-click Task 4.2 **Build FPGA Bitstream**, and select **Run to Selected Task** to generate the Vivado project, and then build the FPGA bitstream.

During the project creation, the generated DUT IP core is integrated into the **Default System with External DDR3 Memory Access** reference design. This reference design comprises of a Xilinx Memory Interface Generator IP to communicate with the on-board external DDR3 memory on ZC706 platform. The MATLAB as AXI Master IP is also added to enable MATLAB to control the DUT IP, and to initialize and verify the DDR memory content.

You can click the link in the result window in Task 4.1 "Create Project" to view the generate Vivado project. If you open the Vivado block design, the generated reference design project looks similar to this architecture diagram.

Run FPGA Implementation on Xilinx Zynq ZC706 Evaluation Kit

After the FPGA bitstream is generated, you can run Task 4.3 **Program Target Device** to program the FPGA board through JTAG cable.

You can then run the FPGA implementation, and verify the hardware result by running following script in MATLAB

```
hdlcoder_external_memory_hw_run
```

This script first initializes the `Matrix_Size` to 500, which means a 500x500 matrix. You can adjust the `Matrix_Size` up to 4000.

The AXI4 Master Read and Write channel base addresses are then configured. These addresses defines the base address that DUT reads from, and writes to external DDR memory. In this script, the DUT is reading from base address '80000000', and write to base address '81000000'.

Then the MATLAB as AXI Master feature is used to initialize the external DDR3 memory with input vector and matrix data, and also clear the output DDR memory location.

Then the DUT calculation is started by controlling the AXI4-Lite accessible registers. The DUT IP core first read input data from the DDR memory, perform the matrix vector multiplication, and then write the result back to the DDR memory.

Finally, the output result is read back to MATLAB, and compared with the expected value. In this way, the hardware results are verified in MATLAB.

```
>> hdlcoder_external_memory_hw_run
Initializing external DDR3 memory (data size 250500) ...
Starting DUT IP core processing ...
Verifying result ...
PASSED: Matrix vector multiplication output matches with the expected data.
```

Accessing External DDR4 memory on Xilinx Zynq Ultrascale+ MPSoC ZCU102 Evaluation Kit

1. Use the same model `hdlcoder_external_memory` to access external DDR4 memory on ZCU102 using HDL Coder IP core generation workflow.
2. Start the HDL Workflow Advisor from the DUT subsystem, `hdlcoder_external_memory/DUT`. In Task 1.1 Set **Target platform** as Xilinx Zynq Ultrascale+ MPSoC ZCU102 Evaluation Kit and in Task 1.2 set **Reference Design** as Default System with External DDR4 Memory Access
3. Now Right-click Task 4.2 **Build FPGA Bitstream**, and select **Run to Selected Task** to generate the Vivado project, and then build the FPGA bitstream.
4. You can run Task 4.3 **Program Target Device** to program the device and verify the hardware result by running following script in MATLAB:

```
hdlcoder_external_memory_hw_run_ZCU102
```

This script first initializes the `Matrix_Size` to 2000, which means a 2000x2000 matrix. In this script, the DUT is reading from base address '80000000', and write to base address '90000000'.

Finally, the output result is read back to MATLAB, and compared with the expected value. In this way, the hardware results are verified in MATLAB.

```
>> hdlcoder_external_memory_hw_run_ZCU102
Initializing external DDR4 memory (data size 4002000) ...
Starting DUT IP core processing ...
Verifying result ...
PASSED: Matrix vector multiplication output matches with the expected data.
```

Authoring a Reference Design for Audio System on a Zynq Board

This example shows how to build a reference design to run an audio algorithm and access audio input and output on a Zynq® board.

Introduction

In this example you will create a reference design which receives audio input from Zedboard, performs some processing on it and transmits the processed audio data out of Zedboard. You also generate IP cores for peripheral interfaces using **HDL Workflow Advisor**.

To perform audio processing on Zedboard, you need the following 2 protocols:

- 1 I2C to configure the ADAU1761 audio codec chip on Zedboard.
- 2 I2S to stream the digitized audio data between the codec chip and Zynq fabric.

The above figure is a high level architecture diagram that shows how the reference design is used by the Filtering Algorithm IP. I2S IP operates at 50MHz frequency whereas one may want to run the Filtering Algorithm IP at a higher frequency. This frequency is controlled in Step **1.4** in **HDL Workflow Advisor**. In this example, assume that the filter operates at 80MHz. Since I2S and Filtering Algorithm IPs operate at different frequencies, we need FIFOs to handle clock domain crossing. Depending on the type of filter selected, Filtering Algorithm IP filters a range of frequencies from the incoming audio data and passes the filtered audio data out. In the above figure, the Filtering Algorithm IP is our main algorithm that we are modeling in Simulink. While FIFO IP is provided in Vivado, the I2C and I2S IPs need to be created. Here, the user has 3 choices: (a) use pre-packaged IP, e.g., if one exists, (b) model it in Simulink and generate an IP core using IP core generation workflow or (c) use legacy HDL code. To create an IP out of legacy HDL code, use a Simulink model to black box the HDL code and generate IP core from it. FIFO IPs handle the clock domain crossing between incoming audio data at 50MHz and the filter IP running at 80MHz. I2C, I2S, PLL, FIFO IPs and Processing System form a part of the reference design.

The following steps are used to create the reference design described above:

- 1 Generate IP Cores for peripheral interfaces
- 2 Create a custom audio codec reference design in Vivado
- 3 Create the reference design definition file

4 Verify the reference design

1. Generate IP Cores for peripheral interfaces using HDL Workflow Advisor

In this example,

- 1 I2C IP is developed by modeling it using Stateflow blocks, and also using legacy VHDL code for tristate buffer.
- 2 I2S IP is developed by modeling it in Simulink.

1.1 Creation of I2C IP

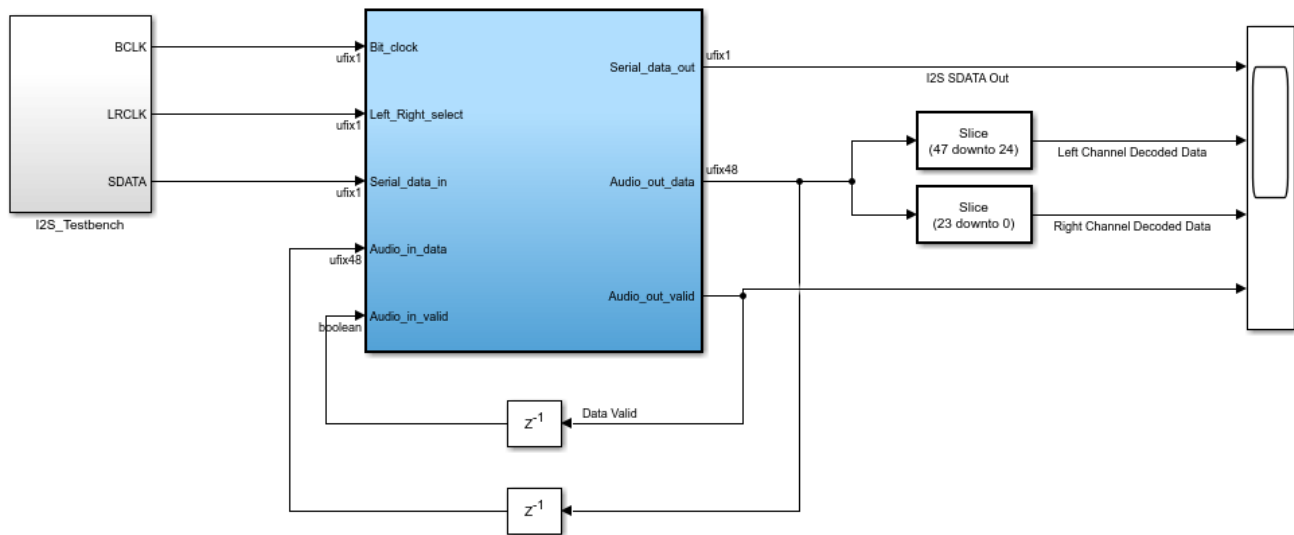

For creation of I2C IP to configure Audio Codec ADAU1761, refer to “IP Core Generation of an I2C Controller IP to Configure the Audio Codec Chip” on page 47-130 article.

1.2 Creation of I2S IP

Design a model in Simulink with a MATLAB function which implements the I2S protocol.

```
modelName = 'hdlcoder_I2S_adau1761';
open_system(modelname);
```

Using IP Core Generation Workflow: I2S IP generation

This example shows how to use HDL Workflow Advisor to generate a custom IP core for implementing I2S protocol

In MATLAB, type the following:
hdladvisor('hdlcoder_I2S_adau1761/Subsystem')

Launch HDL Workflow Advisor

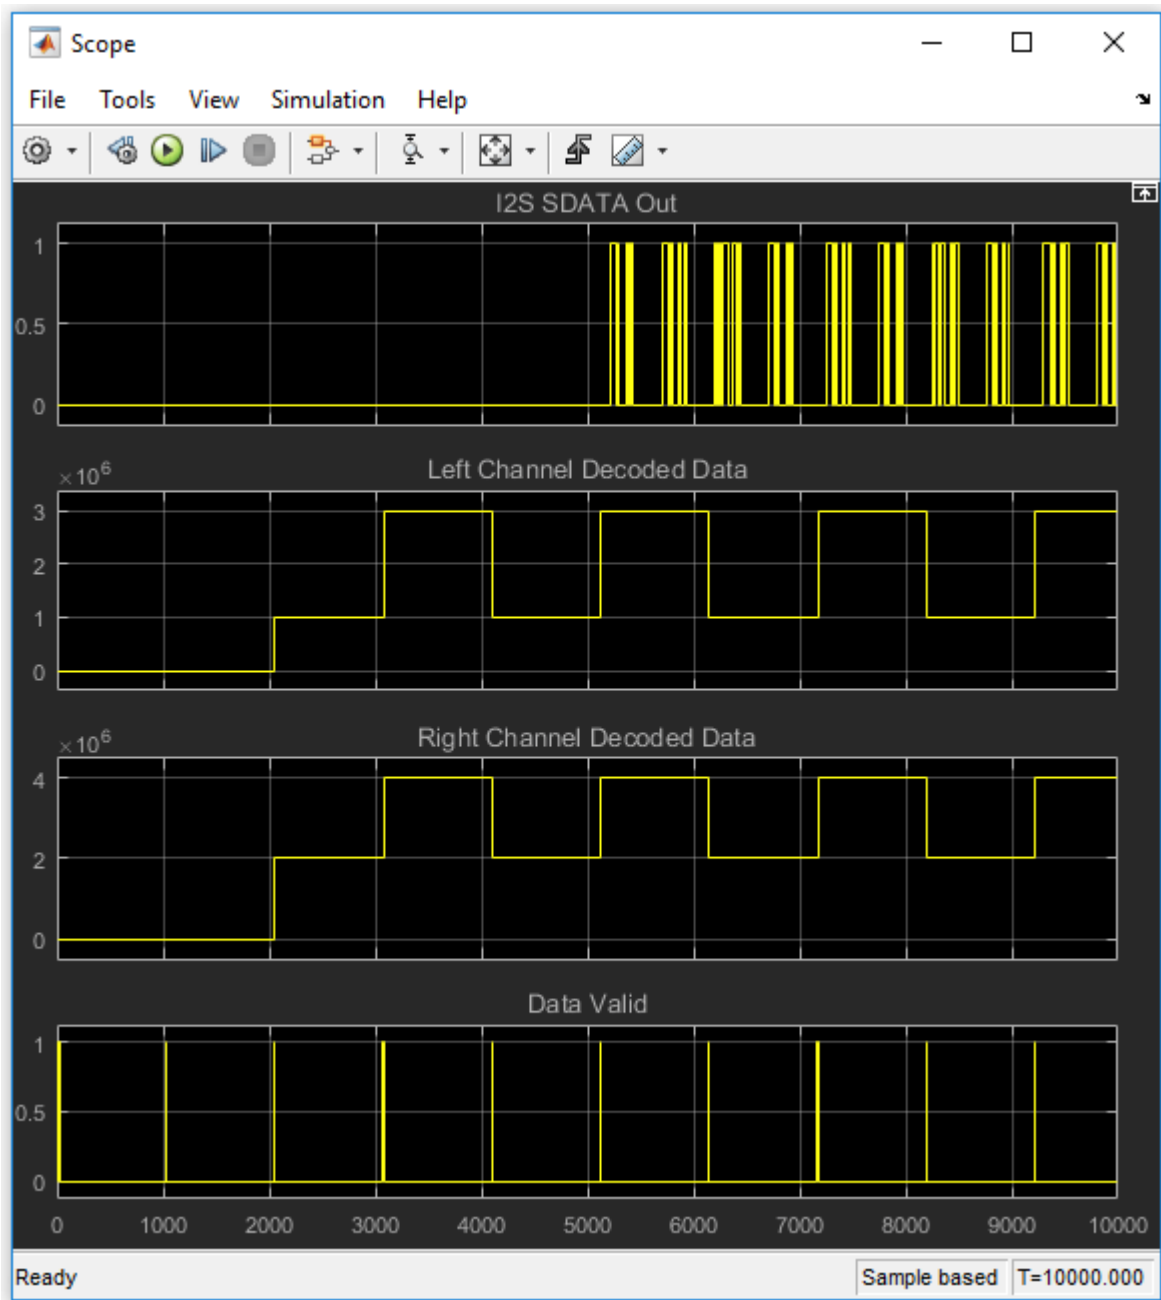

Run Demo

Copyright 2016 The MathWorks, Inc.

Create a test bench in the model to mimic the incoming audio data from the codec.

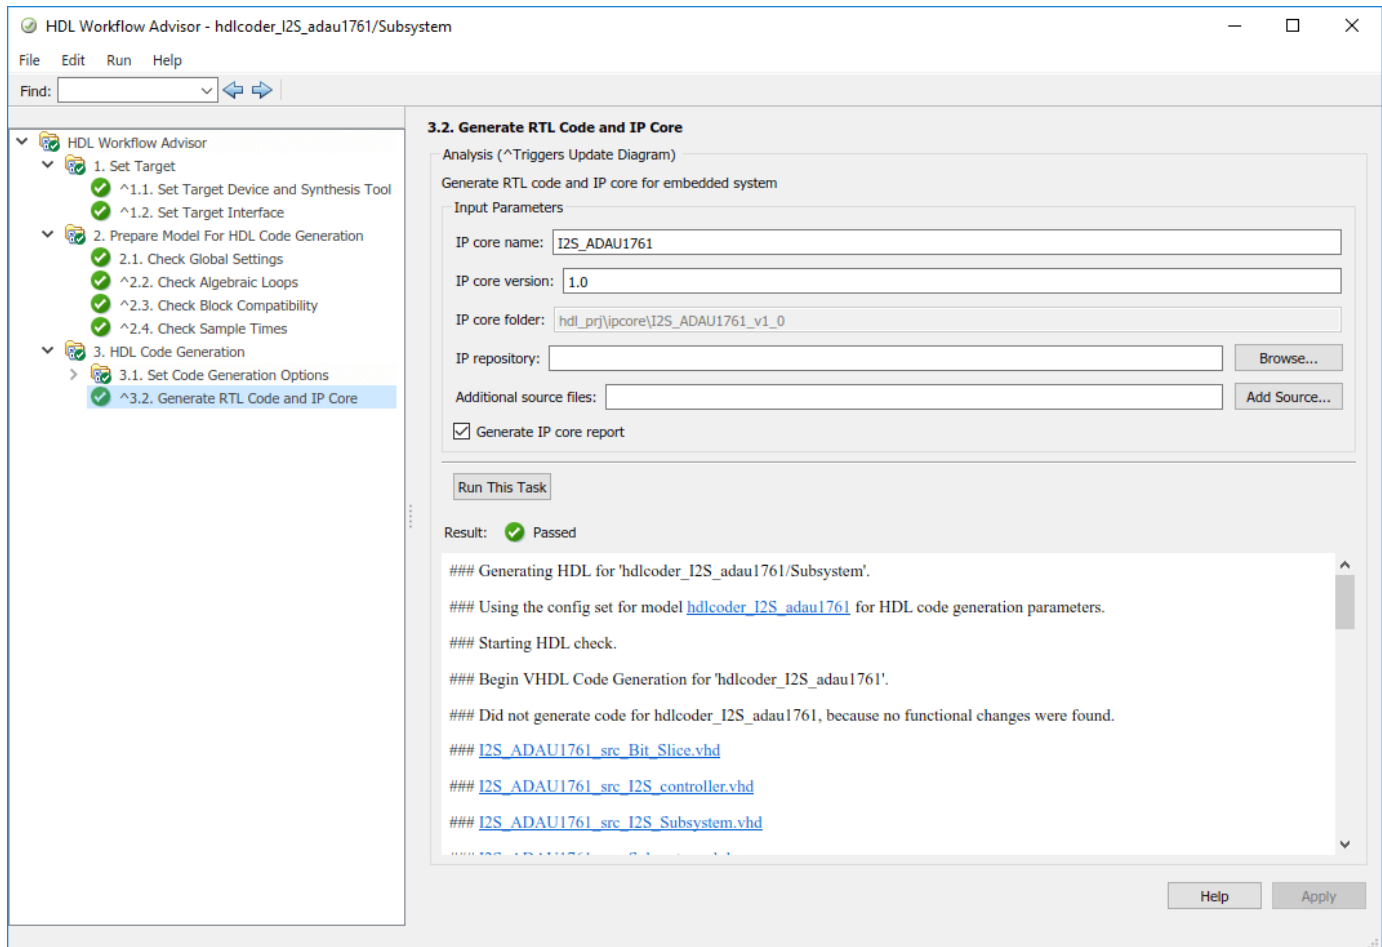

Feed this data to the Subsystem block which does the I2S operation. Verify the output of the Subsystem on a Scope.

Start the HDL Workflow Advisor from the DUT subsystem. In Task 1.1, keep the same settings as those of I2C IP generated earlier. In Task 1.2, set the Target Platform Interfaces as shown below:

Run Task 3.2 and generate the ip core.

2. Create a custom audio codec reference design in Vivado

I2C, I2S and FIFO IPs are incorporated in the custom reference design. To create a custom reference design, refer to the "Create and export a custom reference design using Xilinx Vivado" section in "Define Custom Board and Reference Design for Zynq Workflow" on page 47-231.

Key points to be noted while creating this custom reference design:

- 1 We must understand the theory of operation of the audio codec chip on the Zedboard.
- 2 The FIFOs are set to default values for their configuration.
- 3 For the IP cores generated using HDL Workflow Advisor, **IPCORE_CLK** and **AXI4_Lite_ACLK** should be connected to the same clock source.
- 4 On validating the block design in Vivado, there should be no critical warnings except for the unconnected ports.
- 5 In this reference design, the audio codec is configured to operate in the Master mode.

The following signals run between the reference design on Zynq Soc and the audio codec on Zedboard:

- 1 **Bit_clock** is the product of the sampling frequency, the number of bits per channel and the number of channels. It is driven by the audio codec in master mode. In this example, Sampling frequency is 48KHz, No of channels is 2, Number of bits per channel is 24.

- 2 **Left_right_select** is to distinguish between left audio channel data and right audio channel data. It is in sync with the Bit clock.
- 3 **Serial_data_in** is the analog to digital converted audio data from the codec.
- 4 **Serial_data_out** is the digital audio data going to codec to be converted into analog form.
- 5 **I2C_CLK** and **I2C_DATA** are standard I2C signals
- 6 **ADDR0** and **ADDR1** are the I2C Address Bits.
- 7 **Clk_24MHz** is the 24MHz clock signal required by the codec.

The custom audio codec reference design created for this example is shown below:

3. Create the reference design definition file

The following code describes the contents of the Zedboard reference design definition file **plugin_rd.m** for the above reference design. For more details on how to define and register custom board, refer to “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231 example.

```

function hRD = plugin_rd()
% Reference design definition

% Copyright 2016-2018 The MathWorks, Inc.

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');

hRD.ReferenceDesignName = 'Audio System with AXI4 Stream Interface';
hRD.BoardName = 'ZedBoard';

%% Tool information
hRD.SupportedToolVersion = {'2017.2', '2017.4'};

%% Add custom design files
% add custom Vivado design
hRD.addCustomVivadoDesign( ...
    'CustomBlockDesignTcl', 'system_top.tcl', ...
    'VivadoBoardPart',      'em.avnet.com:zed:part0:1.0');

hRD.addIPRepository(...
    'IPListFunction', 'mathworks.hdlcoderdemo.vivado.hdlcoderdemo_adaul761_iplist');

% Add constraint files
hRD.CustomConstraints = {'Audio_Filter_Demo.xdc'};

%% Add interfaces
% add clock interface
hRD.addClockInterface( ...
    'ClockConnection',      'clk_wiz_0/clk_out3', ...
    'ResetConnection',      'reset_100MHz/peripheral_aresetn',...
    'DefaultFrequencyMHz',  80,...
    'MinFrequencyMHz',      5,...
    'MaxFrequencyMHz',      500,...
    'ClockModuleInstance',  'clk_wiz_0',...
    'ClockNumber',          3);

% add AXI4 and AXI4-Lite slave interfaces
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection',  'Interconnect_IP/M02_AXI', ...
    'BaseAddress',          '0x400D0000', ...
    'MasterAddressSpace',   'processing_system/Data');

% add AXI4-Stream interface
hRD.addAXI4StreamInterface( ...
    'MasterChannelNumber',  1, ...
    'SlaveChannelNumber',   1, ...
    'MasterChannelConnection', 'DUT_to_I2S/S_AXIS', ...
    'SlaveChannelConnection', 'I2S_to_DUT/M_AXIS', ...
    'MasterChannelDataWidth', 48, ...
    'SlaveChannelDataWidth', 48 ...

```

Go to **Zedboard** folder using the following command:

```
unzip('ZedBoard.zip');
addpath(genpath('ZedBoard'));
```

All files that are required for the reference design such as IP core files, XDC files, plugin_rd file etc should be added to the MATLAB path, inside **Zedboard** folder using the hierarchy shown below. The user generated IP core files should be in **+vivado** folder. plugin_rd.m, tcl files and xdc files should be in the reference design plugin folder, for example, **+vivado_audio_filter_2017_2** folder.

4. Verify the reference design

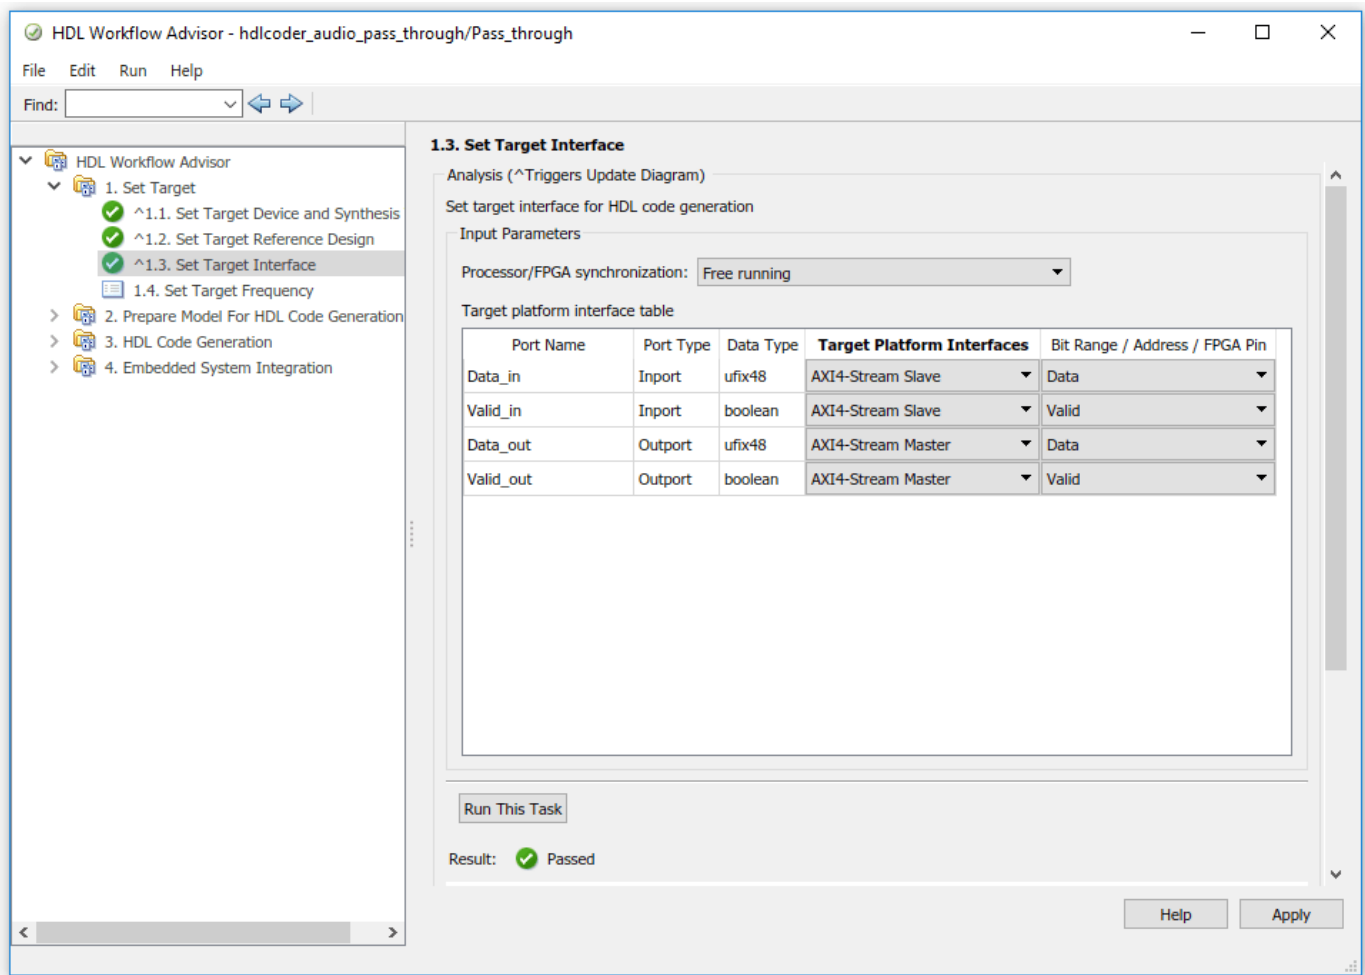

In order to ensure that the reference design and the interfaces in the reference design work as expected, design a Simulink model which just sends the audio through the Algorithm IP, integrate it with the reference design and test it on Zedboard. The user should be able to hear the audio loop back.

```
modelName = 'hdlcoder_audio_pass_through';
open_system(modelName);
```

Copyright 2016 The MathWorks, Inc.

The interfaces in the model should be selected as shown below:

To generate IP core from a model and integrate it with the audio codec reference design, refer to “Running an Audio Filter on Live Audio Input Using a Zynq Board” on page 47-161 example.

Authoring a Reference Design for Audio System on a ZYBO Board

This example shows how to build a reference design to run an audio algorithm and access audio input and output on ZYBO™ Z7-10 board.

Before You Begin

To run this example, you must have the following software and hardware installed and set up:

- HDL Coder™ Support Package for Xilinx® Zynq® Platform
- Embedded Coder® Support Package for Xilinx Zynq Platform
- Xilinx Vivado®, with latest version mentioned in the documentation
- Digilent® Zybo Z7-10 Zynq development board with the accessory kit

This example can be used as reference for creating custom reference design for Digilent® ZYBO Z7-20 board.

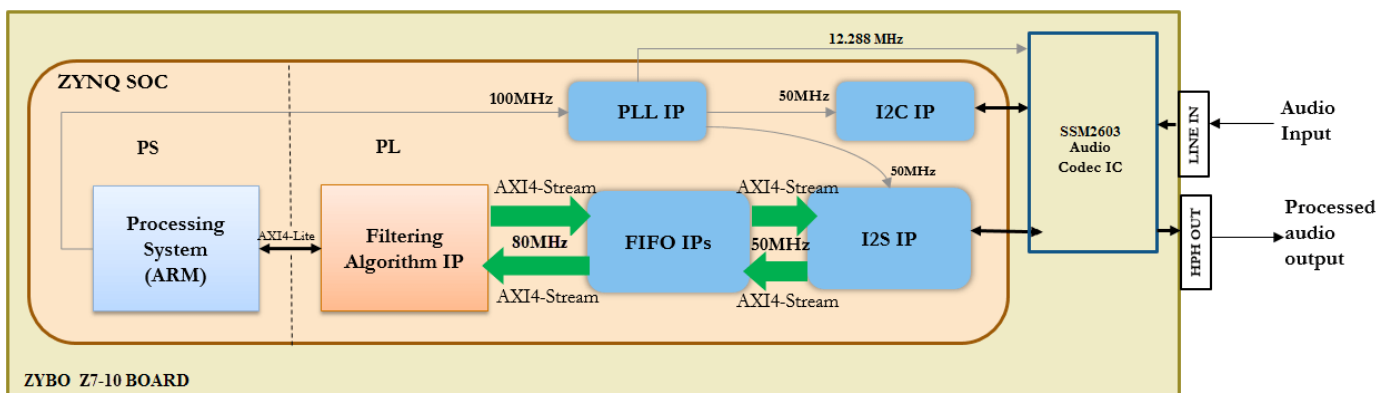

To setup the ZYBO Z7-10 board, refer to the *Set up the Zybo board* section in the “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231 article.

Introduction

In this example you will create a reference design which receives audio input from ZYBO Z7-10 board, performs some processing on it and transmits the processed audio data out of ZYBO Z7-10 board. You also generate IP cores for peripheral interfaces using **HDL Workflow Advisor**.

To perform audio processing on ZYBO Z7-10 board, following 2 protocols are needed:

- 1 I2C to configure the SSM2603 audio codec chip on ZYBO Z7-10 board.
- 2 I2S to stream the digitized audio data between the codec chip and zynq fabric.

The above figure is a high level architecture diagram that shows how the reference design is used by the Filtering Algorithm IP on ZYBO Z7-10 board. This example is similar to the audio system reference design for Zedboard except that the ZYBO Z7-10 board uses a SSM2603 audio codec chip where as the Zedboard uses ADAU1761 audio codec chip. Rest of the operating parameters are same as the Audio System reference design for Zedboard. For more details, please refer to “Authoring a Reference Design for Audio System on a Zynq Board” on page 47-205 example.

The following steps are used to create the reference design described above:

- 1 Generate IP Cores for peripheral interfaces
- 2 Create a custom audio codec reference design in Vivado
- 3 Create the reference design definition file
- 4 Verify the reference design

1. Generate IP Cores for peripheral interfaces using HDL Workflow Advisor

In this example,

- 1 I2C IP is developed using Stateflow® blocks & legacy VHDL code for tristate buffer.
- 2 I2S IP is developed by modelling it in Simulink.

1.1 Creation of I2C IP

For creation of I2C IP to configure Audio Codec SSM2603, refer to “IP Core Generation of an I2C Controller IP to Configure the Audio Codec Chip” on page 47-130 article.

1.2 Creation of I2S IP

Design a model in Simulink® with a MATLAB® function which implements the I2S protocol.

```
modelName = 'hdlcoder_I2S_ssm2603';
open_system(modelname);
```

Using IP Core Generation Workflow: I2S IP generation for Zybo / ArrowSocKit

This example shows how to use HDL Workflow Advisor to generate a custom IP core for implementing I2S protocol

In MATLAB, type the following:
hdladvisor('hdlcoder_I2S_ssm2603/Subsystem')

Launch HDL Workflow Advisor

Run Demo

Copyright 2016-2017 The MathWorks, Inc.

Testing and IP core generation steps are same as Zedboard I2S model. For generation of I2S IP, see "Authoring a Reference Design for Audio System on a Zynq Board" on page 47-205 example.

2. Create a custom audio codec reference design in Vivado

I2C, I2S and FIFO IPs are incorporated in the custom reference design. To create a custom reference design, refer to the "Create and export a custom reference design using Xilinx Vivado" section in "Define Custom Board and Reference Design for Zynq Workflow" on page 47-231.

Key points to be noted while creating this custom reference design:

- 1 We must understand the theory of operation of the audio codec chip on the ZYBO board.
- 2 The FIFOs are set to default values for their configuration.
- 3 For the IP cores generated using HDL Workflow Advisor, **IPCORE_CLK** and **AXI4_Lite_ACLK** should be connected to the same clock source.
- 4 On validating the block design in Vivado, there should be no critical warnings except for the unconnected ports.
- 5 In this reference design, the audio codec is configured to operate in the Master mode.

The following signals run between the reference design on Zynq Soc and the audio codec on ZYBO board:

- 1 **Bit_clock** is the product of the sampling frequency, the number of bits per channel and the number of channels. It is driven by the audio codec in master mode. In this example, Sampling frequency is 48KHz, No of channels is 2, Number of bits per channel is 24.
- 2 **Serial_data_in** is the analog to digital converted audio data from the codec.
- 3 **Serial_data_out** is the digital audio data going to codec to be converted into analog form.
- 4 **I2C_CLK** and **I2C_DATA** are standard I2C signals
- 5 **MUTEN** is the Hardware mute pin connected to audio codec SSM2603.
- 6 **MCLK** is the 12.288MHz clock signal required by the codec.

The custom audio codec reference design created for this example is shown below:

3. Create the reference design definition file

The following code describes the contents of the ZYBO board reference design definition file **plugin_rd.m** for the above reference design. For more details on how to define and register custom board, refer to “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231 example.

```

function hRD = plugin_rd()
% Reference design definition

% Copyright 2021 The MathWorks, Inc.

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');

hRD.ReferenceDesignName = 'Audio System with AXI4 Stream Interface';
hRD.BoardName = 'ZYBO Z7-10';

% Tool information
hRD.SupportedToolVersion = {'2020.2'};

%% Add custom design files
% add custom Vivado design
hRD.addCustomVivadoDesign( ...
    'CustomBlockDesignTcl', 'system_top.tcl', ...
    'VivadoBoardPart',      'digilentinc.com:zybo-z7-10:part0:1.0');

hRD.addIPRepository(...
    'IPListFunction', 'mathworks.hdlcoderdemo.vivado.hdlcoderdemo_ssm2603_iplist');

% Add constraint files
hRD.CustomConstraints = {'ZYBOZ7_audio_filter_demo.xdc'};

%% Add interfaces
% add clock interface
hRD.addClockInterface( ...
    'ClockConnection',    'clk_wiz_0/clk_out1', ...
    'ResetConnection',    'reset_100MHz/peripheral_aresetn',...
    'DefaultFrequencyMHz', 80,...
    'MinFrequencyMHz',    5,...
    'MaxFrequencyMHz',    500,...
    'ClockModuleInstance', 'clk_wiz_0',...
    'ClockNumber',        1);

% add AXI4 and AXI4-Lite slave interfaces
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'Interconnect_IP/M02_AXI', ...
    'BaseAddress',          '0x40010000', ...
    'MasterAddressSpace',   'processing_system/Data');

% add AXI4-Stream interface
hRD.addAXI4StreamInterface( ...
    'MasterChannelEnable', true, ...
    'SlaveChannelEnable',  true, ...
    'MasterChannelConnection', 'DUT_to_I2S/S_AXIS', ...
    'SlaveChannelConnection', 'I2S_to_DUT/M_AXIS', ...
    'MasterChannelDataWidth', 48, ...
    'SlaveChannelDataWidth', 48 ...
);

hRD.DeviceTreeName = 'devicetree_axilite_dth':

```

Unzip and add the **ZYBO** folder to the MATLAB path using the following command:

```
unzip('ZYBO.zip');  
addpath(genpath('ZYBO'));
```

All files that are required for the reference design such as IP core files, XDC files, plugin_rd file etc should be added to the MATLAB path, inside **ZYBO** folder using the hierarchy shown below. The user generated IP core files should be in **+vivado** folder. plugin_rd.m, tcl files and xdc files should be in **+vivado_audio_filter_2020_2** folder.

4. Verify the reference design

To verify the reference design, to generate Audio Filter IP core from a model and integrate it with the audio codec reference design, refer to “Running an Audio Filter on Live Audio Input Using a Zynq Board” on page 47-161 example.

Authoring a Reference Design for Audio System on Intel Board

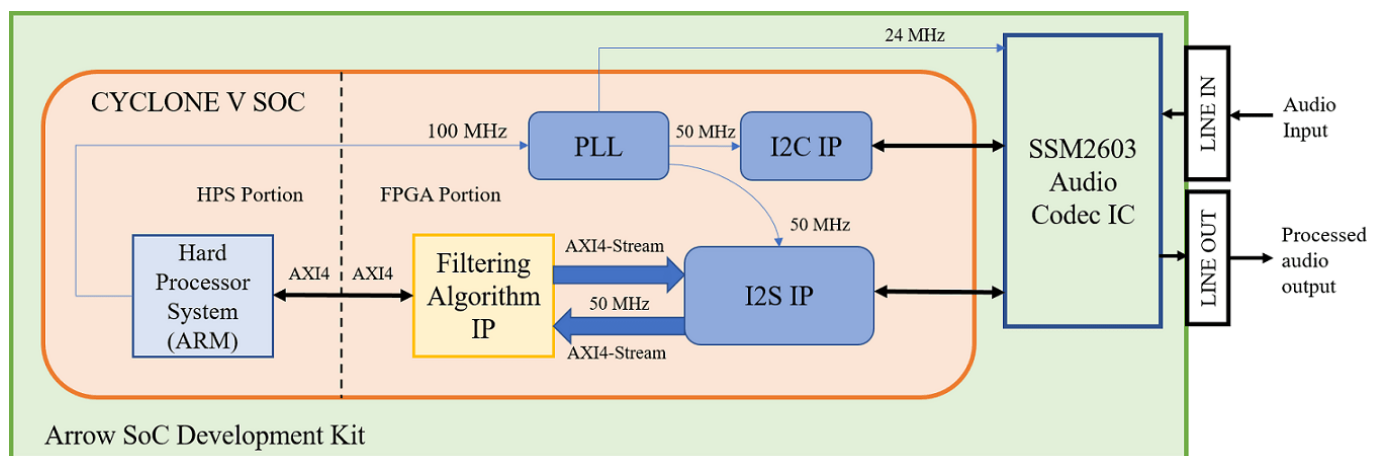

This example shows how to:

- 1 Generate IP cores for peripheral interfaces using **HDL Workflow Advisor**
- 2 Build a reference design to run an audio algorithm and access audio input and output

Introduction

In this example, you create a reference design which receives audio input from Intel Arrow SoC Development Kit, performs some processing on it and transmits the processed audio data out of Arrow SoC Development Kit. To perform audio processing on Arrow SoC, you need the following 2 protocols:

- 1 I2C to configure the SSM2603 audio codec chip on Arrow SoC.
- 2 I2S to stream the digitized audio data between the codec chip and Cyclone V FPGA.

The above figure is a high level architecture diagram that shows how the reference design is used by the Filtering Algorithm IP. I2S IP operates at 50MHz frequency whereas one may want to run the Filtering Algorithm IP at a higher frequency. This frequency is controlled in Step **1.4** in **HDL Workflow Advisor**. In this example, assume that the filter operates at 50MHz. Depending on the type of filter selected, Filtering Algorithm IP filters a range of frequencies from the incoming audio data and passes the filtered audio data out. In the above figure, the Filtering Algorithm IP is our main algorithm that we are modeling in Simulink. While the I2C and I2S IPs need to be created. Here, you have 3 choices:

- Use pre-packaged IP, e.g., if one exists
- Model it in Simulink and generate an IP core using IP core generation workflow or
- Use legacy HDL code. To create an IP out of legacy HDL code, use a Simulink model to black box the HDL code and generate IP core from it. I2C, I2S, PLL IPs and Cyclone V Hard Processor System(HPS) form a part of the reference design.

The following steps are used to create the reference design described above:

- 1 Generate IP Cores for peripheral interfaces

- 2 Create a custom audio codec reference design in Qsys
- 3 Create the reference design definition file
- 4 Verify the reference design

1. Generate IP Cores for peripheral interfaces using HDL Workflow Advisor

In this example,

- 1 I2C IP is developed by modeling it using Stateflow blocks, and also using legacy VHDL code for tristate buffer.
- 2 I2S IP is developed by modeling it in Simulink.

1.1 Creation of I2C IP

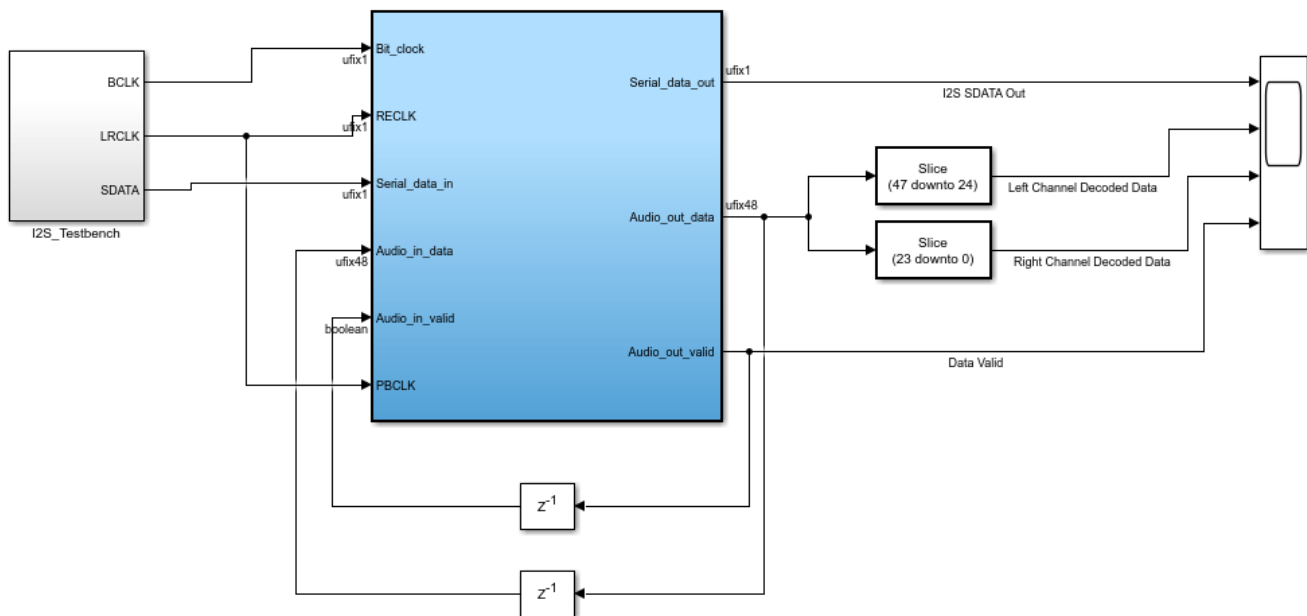

For creation of I2C IP to configure Audio Codec SSM2603, refer to “IP Core Generation of an I2C Controller IP to Configure the Audio Codec Chip” on page 47-130.

1.2 Creation of I2S IP

Design a model in Simulink with a MATLAB function which implements the I2S protocol.

```
modelName = 'hdlcoder_I2S_ssm2603';
open_system(modelname);
```

Using IP Core Generation Workflow: I2S IP generation for Zybo / ArrowSocKit

This example shows how to use HDL Workflow Advisor to generate a custom IP core for implementing I2S protocol

In MATLAB, type the following:
hdladvisor('hdlcoder_I2S_ssm2603/Subsystem')

Launch HDL Workflow Advisor

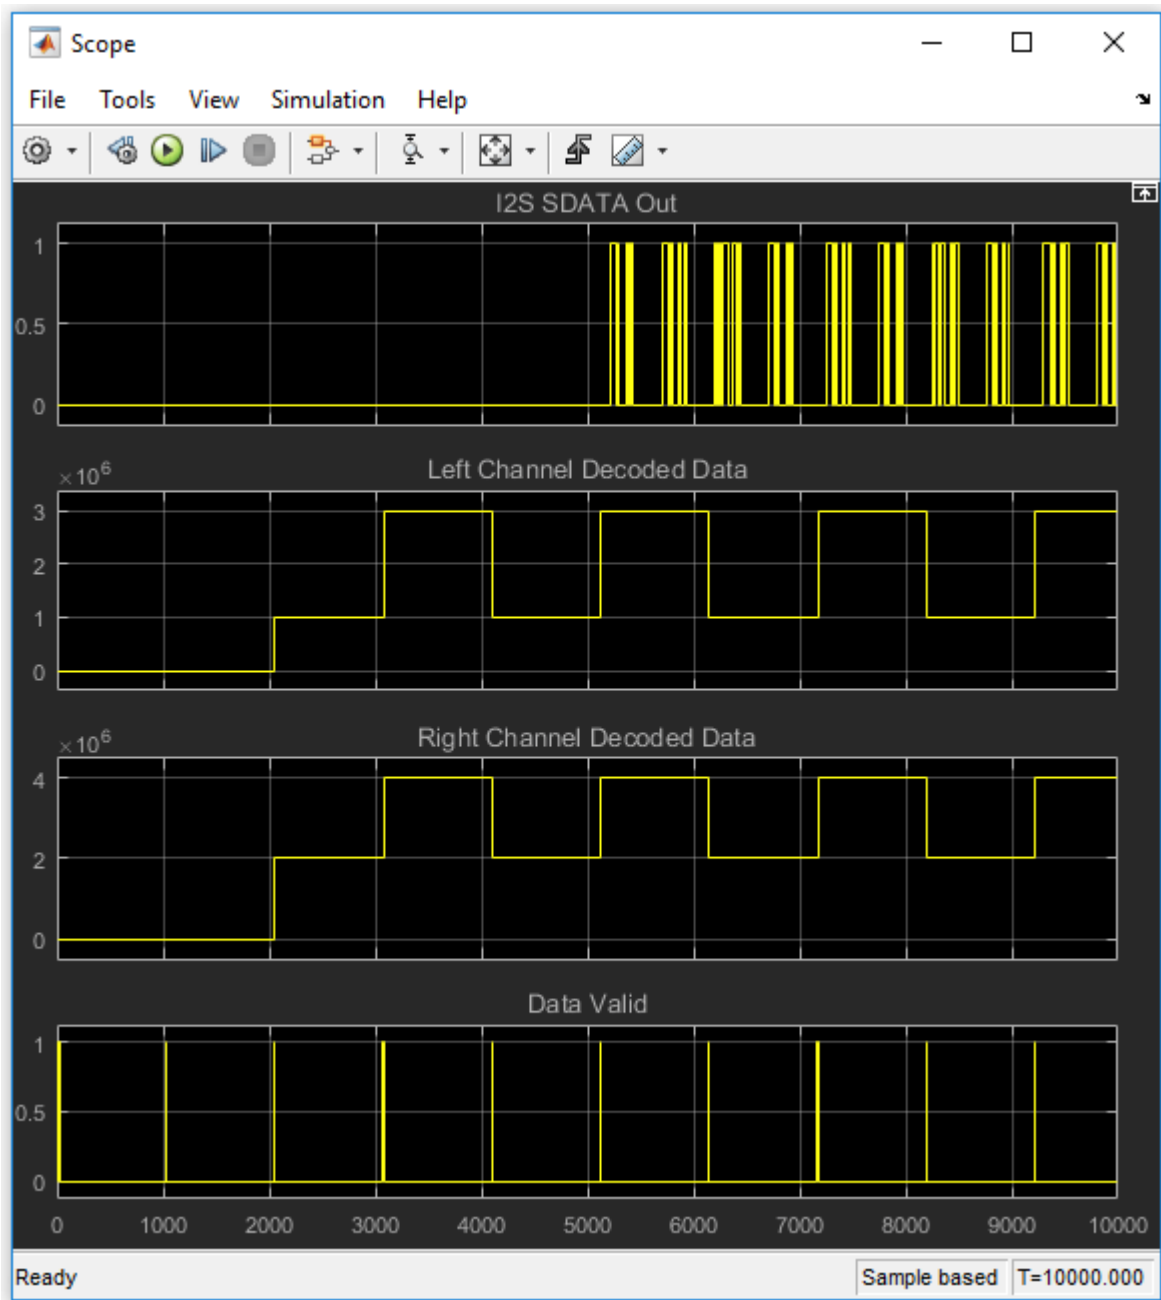

Run Demo

Copyright 2016-2017 The MathWorks, Inc.

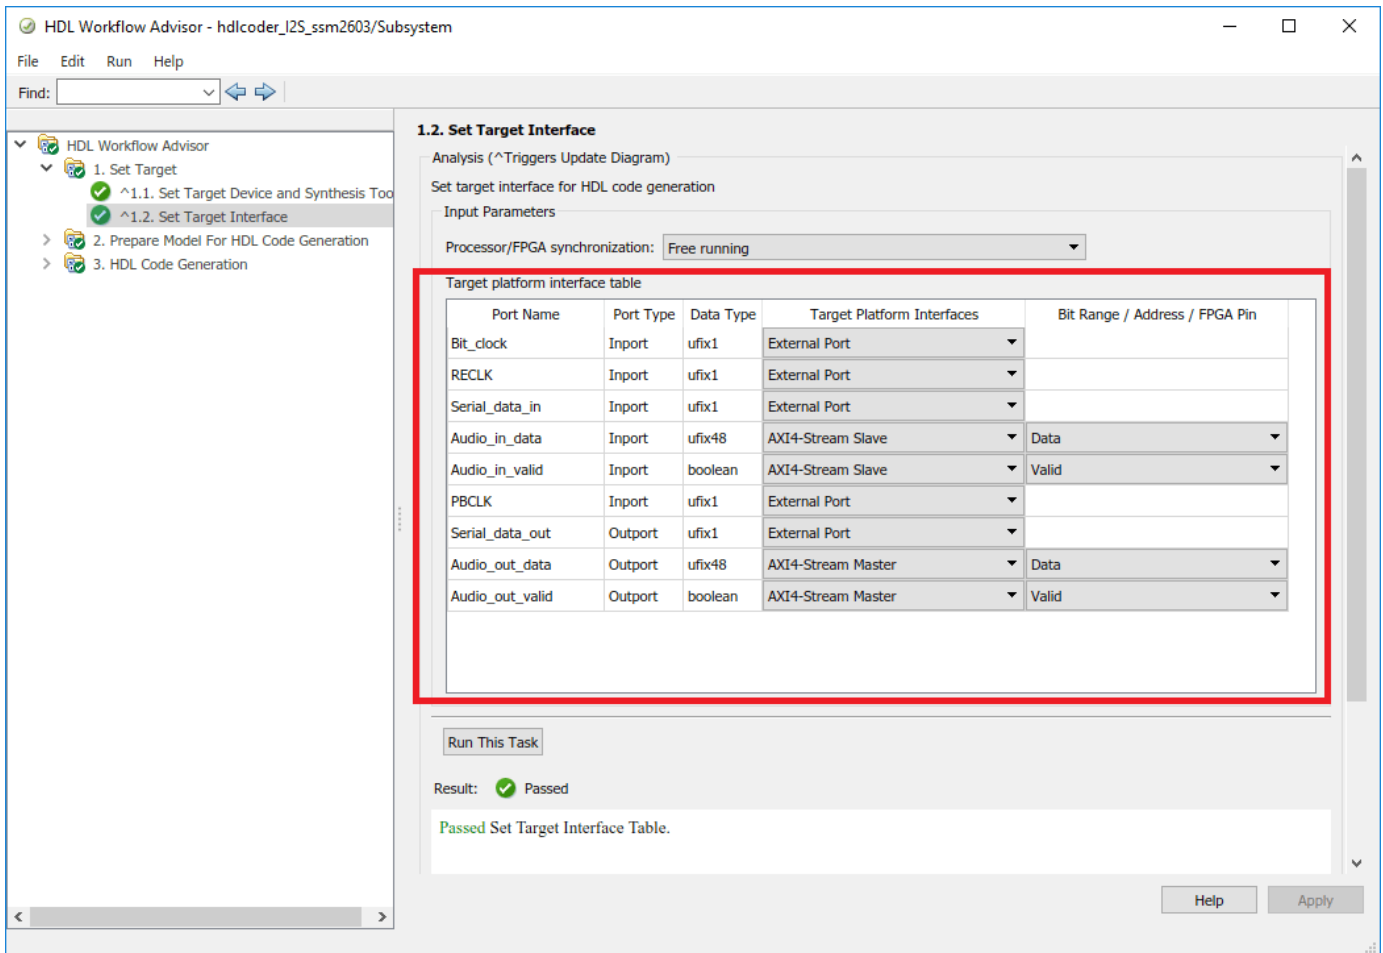

Create a test bench in the model to mimic the incoming audio data from the codec.

Feed this data to the Subsystem block which does the I2S operation. Verify the output of the Subsystem on a Scope.

Start the HDL Workflow Advisor from the DUT subsystem. In Task 1.1, keep the same settings as those of I2C IP generated earlier. In Task 1.2, set the Target Platform Interfaces as shown below:

Run Task 3.2 and generate the ip core.

2. Create a custom audio codec reference design in Qsys

I2C and I2S IPs are incorporated in the custom reference design. To create a custom reference design, refer to the **Reference Design creation using Intel Quartus Prime** section in “Define Custom Board and Reference Design for Intel SoC Workflow” on page 47-249.

Key points to be noted while creating this custom reference design:

- 1 We must understand the theory of operation of the audio codec chip on the Arrow SoC.
- 2 For the IP cores generated using HDL Workflow Advisor, **IPCORE_CLK** and **AXI4_ACLK** should be connected to the same clock source.
- 3 In this reference design, the audio codec is configured to operate in the Master mode.

The following signals run between the reference design on Intel SoC and the audio codec on Arrow SoC:

- 1 **Bit_clock** is the product of the sampling frequency, the number of bits per channel and the number of channels. It is driven by the audio codec in master mode. In this example, Sampling frequency is 48KHz, No of channels is 2, Number of bits per channel is 24.
- 2 **Left_right_select** is to distinguish between left audio channel data and right audio channel data. It is in sync with the Bit clock.

- 3 **Serial_data_in** is the analog to digital converted audio data from the codec.
- 4 **Serial_data_out** is the digital audio data going to codec to be converted into analog form.
- 5 **I2C_CLK** and **I2C_DATA** are standard I2C signals
- 6 **ADDR0** and **ADDR1** are the I2C Address Bits.
- 7 **Clk_24MHz** is the 24MHz clock signal required by the codec.

The custom audio codec reference design created for this example is shown below:

Use	Connections	Name	Description	Export	Clock	Base	End	IRQ	Tags	Opcode Name

3. Create the reference design definition file

The following code describes the contents of the Arrow SoC Development Kit reference design definition file **plugin_rd.m** for the above reference design. For more details on how to define and register custom board, refer to “Define Custom Board and Reference Design for Intel SoC Workflow” on page 47-249.

```

function hRD = plugin_rd()
% Reference design definition

% Copyright 2012-2019 The MathWorks, Inc.

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Altera QUARTUS II');

hRD.ReferenceDesignName = 'Audio System with AXI4 Stream Interface';

hRD.BoardName = 'Arrow SoCKit development board';

% Tool information
hRD.SupportedToolVersion = {'18.1'};

%% Add custom design files
% add custom Qsys design
hRD.addCustomQsysDesign( ...
    'CustomQsysPrjFile', 'system_soc.qsys');

hRD.addIPRepository(...
    'IPListFunction', 'mathworks.hdlcoderdemo.quartus.hdlcoderdemo_ssm2603_quartus_iplist');

% Add constraint files
hRD.CustomConstraints = {'system_soc.tcl'};

%% Add interfaces
% add clock interface
hRD.addClockInterface( ...
    'ClockConnection',    'pll_0.outclk0', ...
    'ResetConnection',    'hps_0.h2f_reset',...
    'DefaultFrequencyMHz', 50,...
    'MinFrequencyMHz',    5,...
    'MaxFrequencyMHz',    500,...
    'ClockModuleInstance', 'pll_0',...
    'ClockNumber',        0);

% add AXI4 slave interfaces
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'hps_0.h2f_axi_master', ...
    'BaseAddress',         '0x0000');

% add AXI4-Stream interface
hRD.addAXI4StreamInterface( ...
    'MasterChannelEnable',    true, ...
    'SlaveChannelEnable',    true, ...
    'MasterChannelConnection', 'I2S_SSM2603_0.AXI4_Stream_Slave', ...
    'SlaveChannelConnection', 'I2S_SSM2603_0.AXI4_Stream_Master', ...
    'MasterChannelDataWidth', 48, ...
    'SlaveChannelDataWidth',  48 ...
);

```

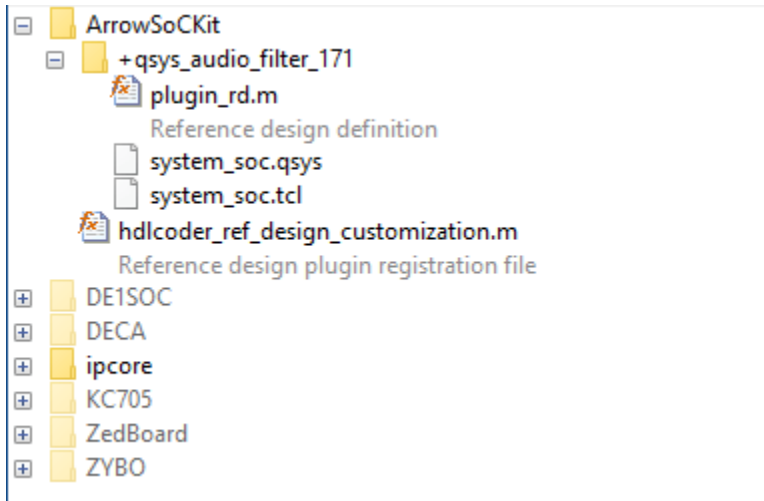

Unzip and add to MATLAB path the **ArrowSoC** folder using the following commands:

```

unzip('ArrowSoC.zip');
addpath(genpath('ArrowSoC'));

```

All files that are required for the reference design such as IP core files, qsys file, tcl file, plugin_rd file etc should be added to the MATLAB path, inside **ArrowSoC** folder using the hierarchy shown below. The user generated IP core files should be in **+quartus** folder. plugin_rd.m, tcl files and qsys files should be in the reference design plugin folder, for example, **+qsys_audio_filter_18_1** folder.

4. Verify the reference design

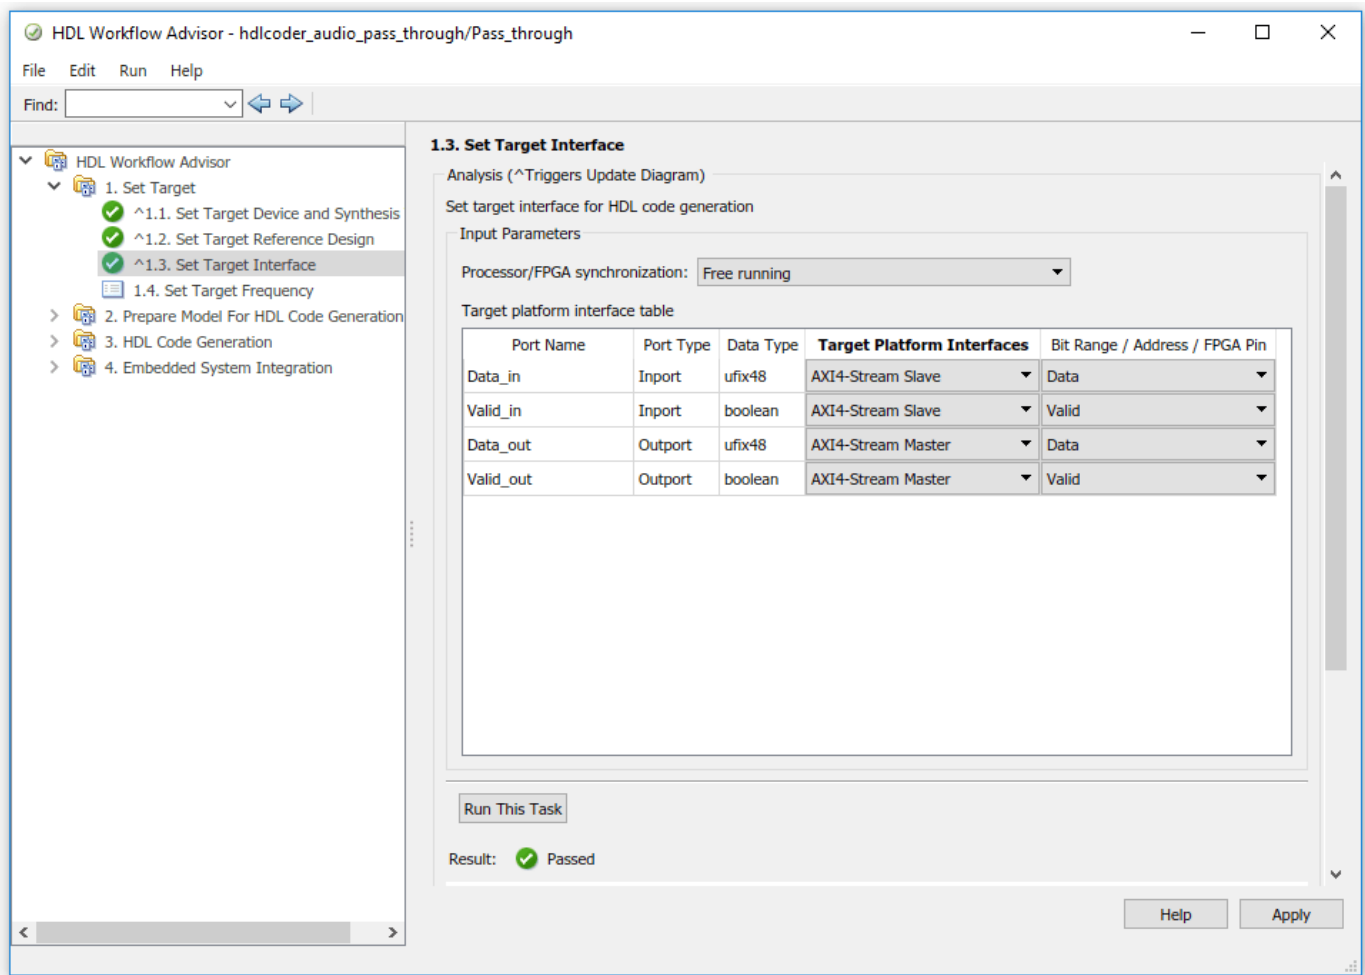

In order to ensure that the reference design and the interfaces in the reference design work as expected, design a Simulink model which just sends the audio through the Algorithm IP, integrate it with the reference design and test it on Arrow SoC. You should be able to hear the audio loop back.

```
modelname = 'hdlcoder_audio_pass_through';
open_system(modelname);
```

Copyright 2016 The MathWorks, Inc.

The interfaces in the model should be selected as shown below:

To generate IP core from a model and integrate it with the audio codec reference design, refer to “Running an Audio Filter on Live Audio Input Using Intel Board” on page 47-150.

Define Custom Board and Reference Design for Zynq Workflow

This example shows how to define and register a custom board and reference design in the Zynq® workflow.

Introduction

You can register the Digilent® Zybo Z7-10 Zynq development board and a custom reference design in the HDL Workflow Advisor for the Zynq workflow.

This example uses a Zybo Z7-10 Zynq board, but you can define and register a custom board or a custom reference design for other Zynq platforms.

Requirements

- Xilinx Vivado Design Suite, with the supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Digilent® Zybo Z7-10 Zynq™ development board with the accessory kit
- HDL Coder Support Package for Xilinx Zynq Platform
- Embedded Coder Support Package for Xilinx Zynq Platform

Note: This example uses Digilent® Zybo Z7-10 Zynq-7000 ARM/FPGA SoC trainer board. This example can be used as reference to create Zybo Z7-20 Custom Board and Reference Design.

Set Up the Zybo board

To become familiar with the features of the Zybo board, see the Zybo Z7-10 Board Reference Manual.

1. Set up the Zybo Z7-10 board.

2. Ensure that you have properly installed the USB COM port device drivers on your computer.

3. Configure the JP5 boot mode jumper to enable the loading of a Zynq Linux image from a microSD card connected to connector J4.

4. Configure the JP7 power source select jumper to use USB as the power source.

5. Connect the shared UART/JTAG USB port on the Zybo board to your computer.

6. Connect the Zybo Z7-10 board to your computer by using an Ethernet cable. The default Zybo IP address is 192.168.1.110.

7. Download the Zybo Zynq Linux image, extract the Zip archive, and copy the contents to the microSD card. Insert the microSD card in connector J4. You can also build the Linux image, by following “Author a Xilinx Zynq Linux Image for a Custom Zynq Board by Using MathWorks Buildroot” on page 46-247.

8. Set up the Xilinx Vivado tool path by using this command:

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2020.2\bin\vivado.ba
```

Use your own Xilinx Vivado installation path when executing the command.

9. Set up the Zynq hardware connection by using this command:

```
h = zynq();
```

Register the Zybo Board in Xilinx Vivado tool

By default, Vivado 2020.2 tool does not have the Zybo board files pre-installed. Download these board files from the Xilinx Board Store GitHub. Unzip the content and navigate to the installation folder of Vivado. Copy the updated Zybo board files to Xilinx Vivado tools.

```
C:\Xilinx\Vivado\2020.2\data\boards\board_files
```

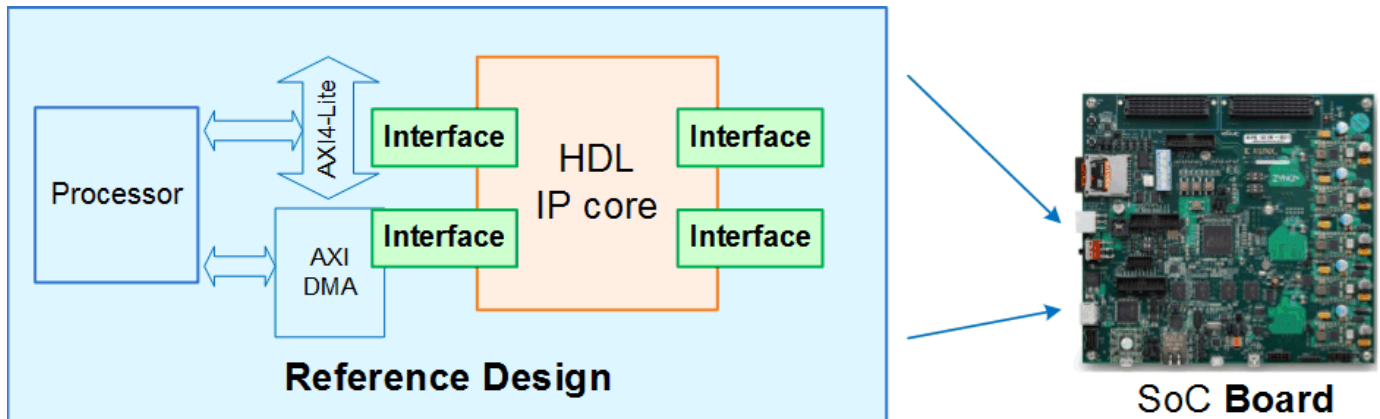

Name	Date modified	Type	Size
zybo-z7-20	04-Jan-21 20:51	File folder	
zybo-z7-10	04-Jan-21 20:51	File folder	
zybo	04-Jan-21 20:51	File folder	
zed	04-Jan-21 19:27	File folder	

The Zybo board part is added to list of development boards while creating Vivado project specific to board.

Note: If the preceding link is unavailable, get the Zybo board files from the Digilent website.

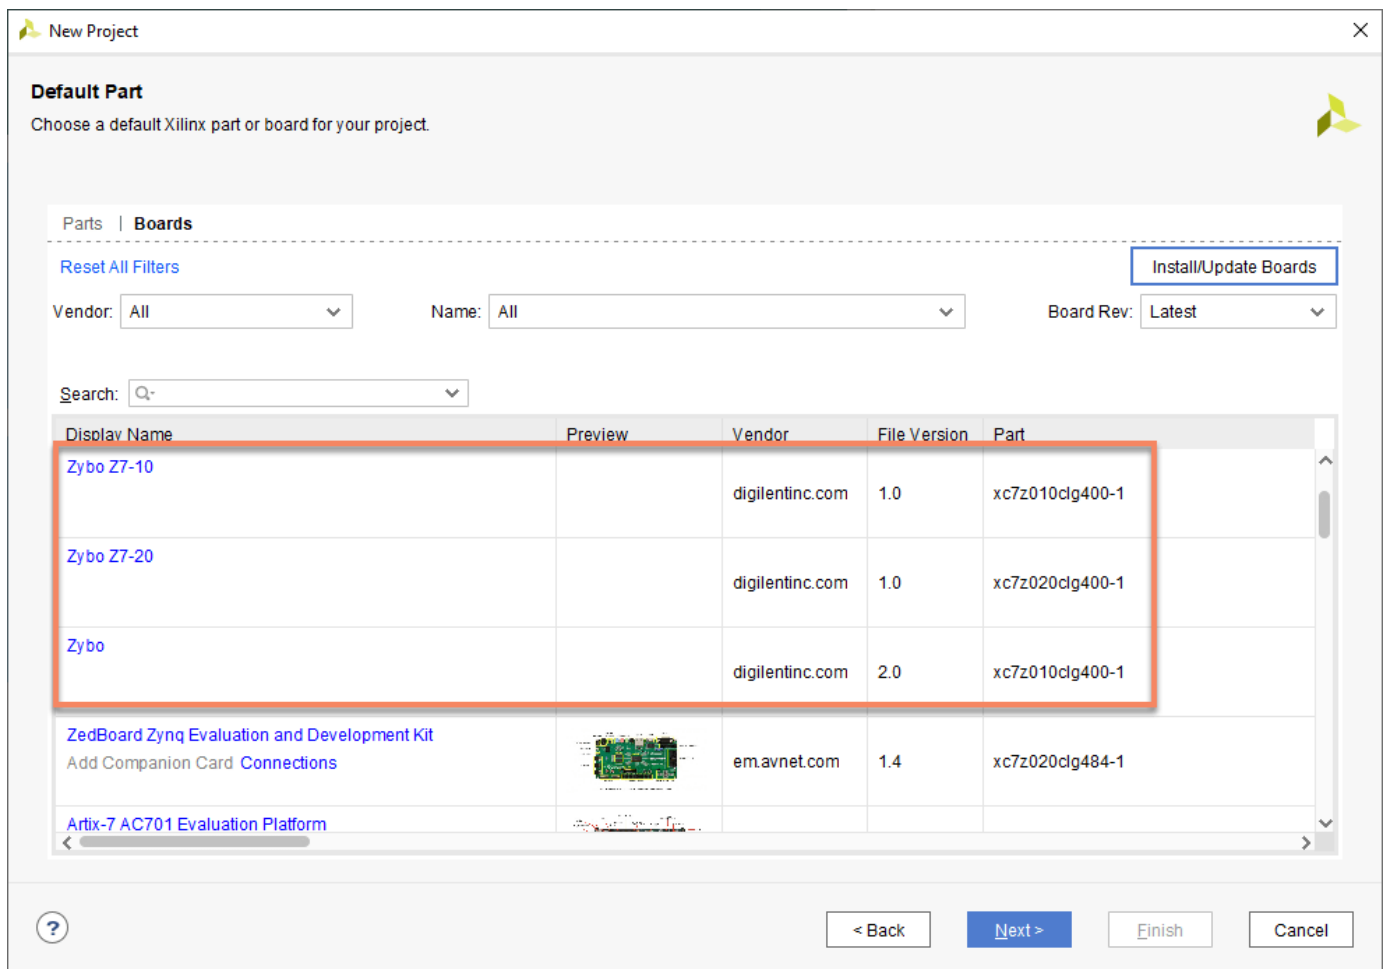

Create and Export a Custom Reference Design by Using Xilinx Vivado

A reference design captures the complete structure of an SoC design, defining the different components and their interconnections. The HDL Coder SoC workflow generates an IP core that integrates with the reference design, and is then used to program an SoC board. This figure shows the relationship between a reference design, an HDL IP core, and an SoC board.

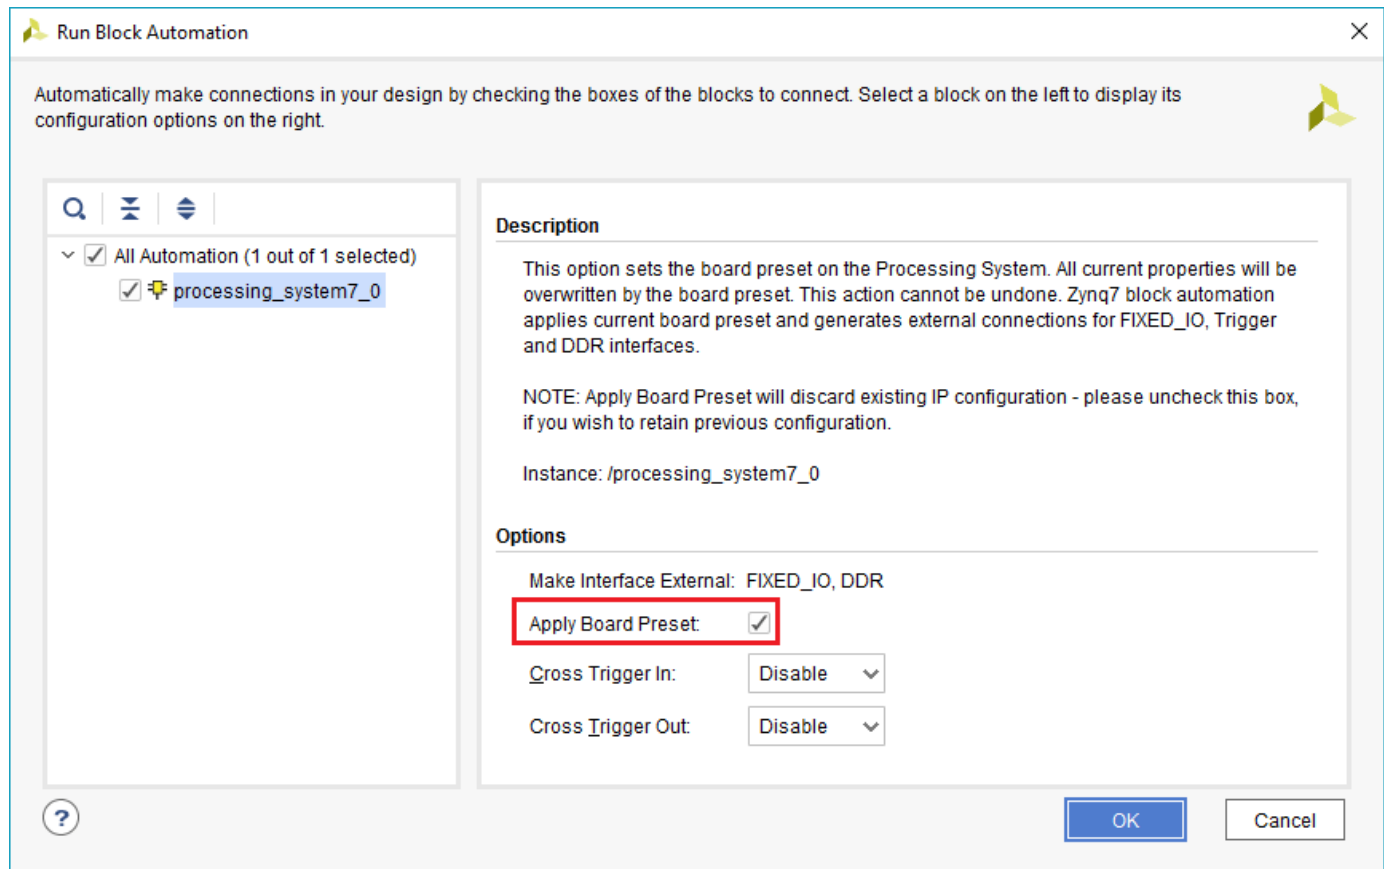

To create and export a simple reference design by using the Xilinx Vivado IP Integrator environment, follow these steps. For more information about the IP Integrator tool, refer to Xilinx documentation.

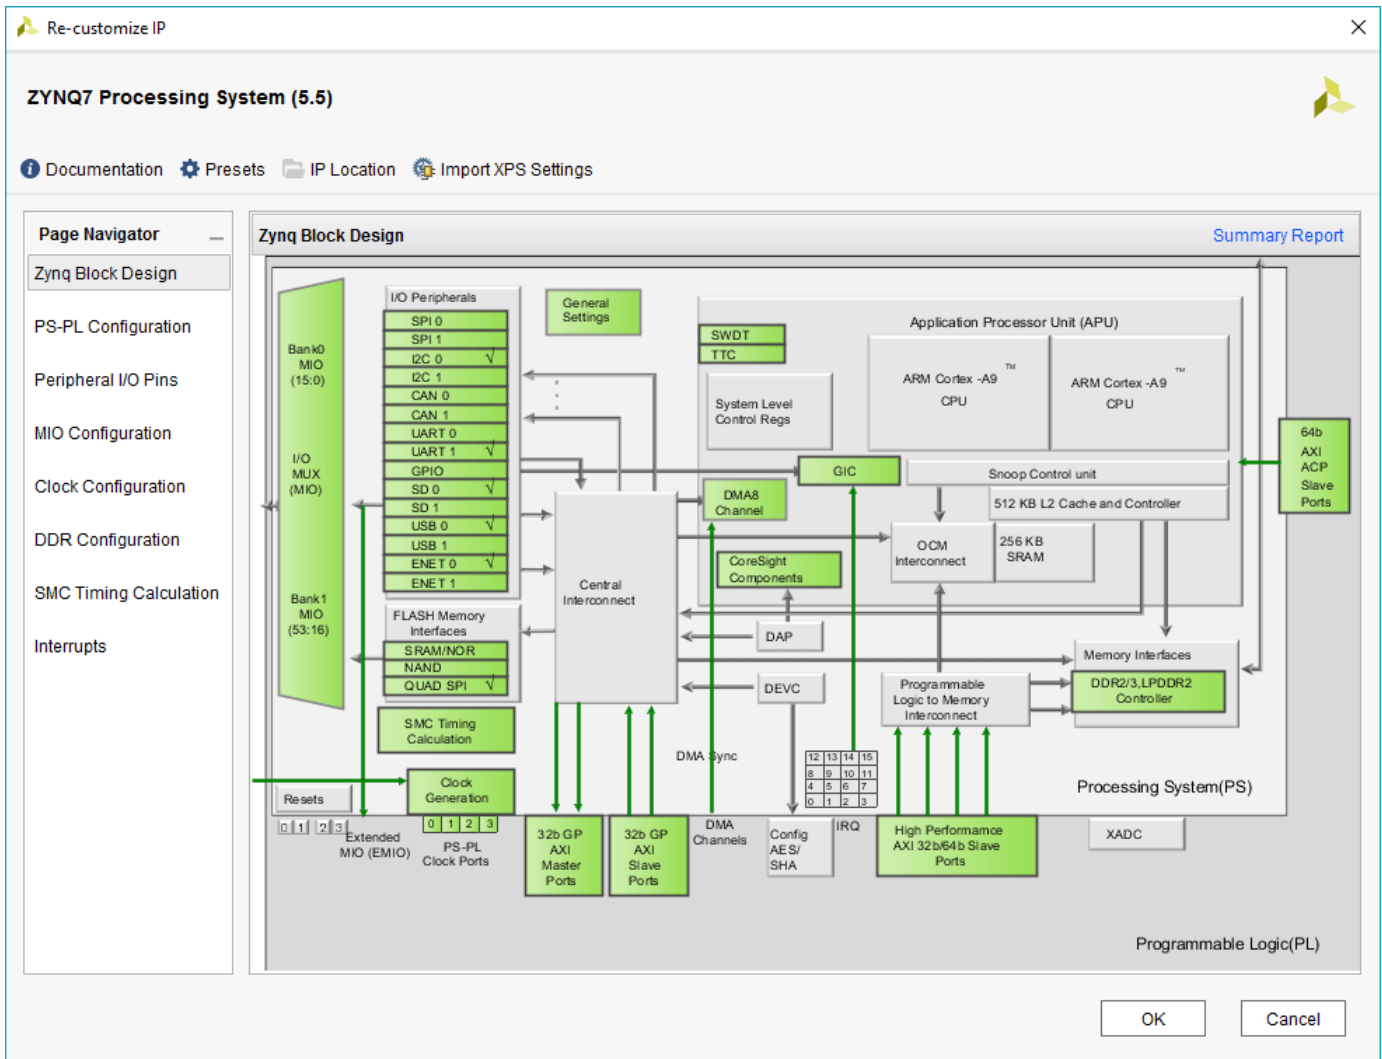

1. Create an empty Xilinx Vivado RTL project by using board part **Zybo Z7-10** as the default board.

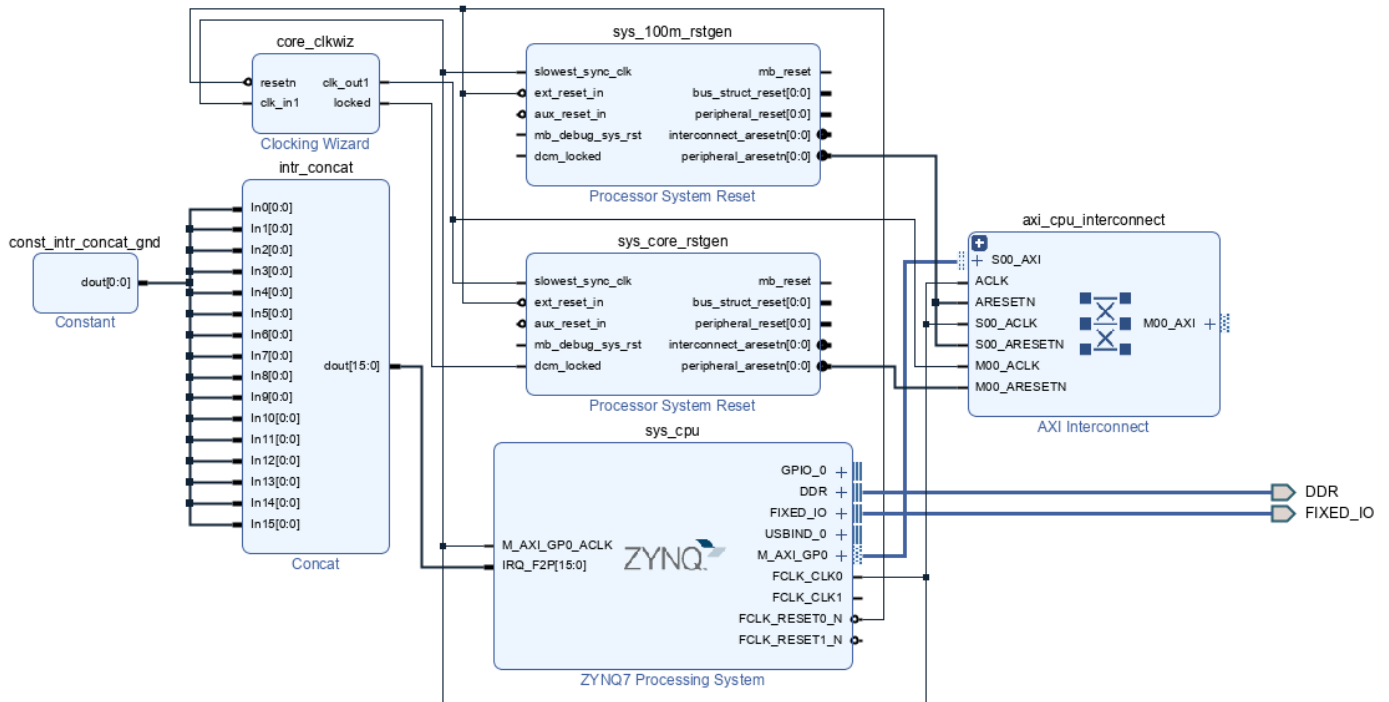

2. Create an empty block design and add the **ZYNQ7 Processing System** IP block. Run block automation to set a board preset for Zybo Z7-10, which contains the parameters for ZYNQ7 Processing system IP related to MIO Configuration, Clock configuration, and DDR Configuration.

The MIO peripherals are been marked in accordance with the Zybo board definition as the result of applying a board preset.

3. Complete the block design.

Notice that the block design does not contain any information about the HDL IP core.

4. Export the completed block design as a Tcl script `design_led.tcl` as shown in the following figure:

The exported Tcl script (`design_led.tcl`) constitutes the custom reference design. The Tcl script is used in the HDL Coder SoC workflow to recreate the block design and integrate the generated HDL IP core with the block design in a Xilinx Vivado project.

Register the Zybo Z7-10 Board in HDL Workflow Advisor

Register the Zybo Z7-10 board in HDL Workflow Advisor.

1. Create a board registration file with the name `hdlcoder_board_customization.m` and add it to the MATLAB path.

A board registration file contains a list of board plugins. A board plugin is a MATLAB package folder containing a board definition file and all reference design plugins associated with the board.

This code describes the contents of a board registration file that contains the board plugin `ZyboZ710Registration` to register the Zybo board in HDL Workflow Advisor.

```
function r = hdlcoder_board_customization
% Board plugin registration file
% 1. Any registration file with this name on MATLAB path will be picked up
% 2. Registration file returns a cell array pointing to the location of
%    the board plugins
% 3. Board plugin must be a package folder accessible from MATLAB path,
%    and contains a board definition file

r = { ...
    'ZyboZ710Registration.plugin_board', ...
    };
end
```

2. Create the board definition file.

A board definition file contains information about the SoC board.

This code describes the contents of the Zybo board definition file `plugin_board.m` that resides inside the board plugin `ZyboZ710Registration`.

Information about the FPGA I/O pin locations ('`FPGAPin`') and standards ('`IOSTANDARD`') is obtained from the Zybo master constraints file from the Digilent website.

The property `BoardName` defines the name of the Zybo Z7-10 board as `ZYBO Z7-10` in HDL Workflow Advisor.

```
function hB = plugin_board()
% Board definition

% Construct board object
hB = hdlcoder.Board;

hB.BoardName    = 'ZYBO Z7-10';

% FPGA device information
hB.FPGAVendor   = 'Xilinx';
hB.FPGAFamily   = 'Zynq';
hB.FPGADevice   = 'xc7z010';
hB.FPGAPackage  = 'clg400';
hB.FPGASpeed    = '-1';
```

```

% Tool information
hB.SupportedTool = {'Xilinx Vivado'};

% FPGA JTAG chain position
hB.JTAGChainPosition = 2;

%% Add interfaces
% Standard "External Port" interface
hB.addExternalPortInterface( ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});

% Custom board external I/O interface
hB.addExternalIOInterface( ...
    'InterfaceID',    'LEDs General Purpose', ...
    'InterfaceType', 'OUT', ...
    'PortName',      'LEDs', ...
    'PortWidth',     4, ...
    'FPGAPin',       {'M14', 'M15', 'G14', 'D18'}, ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});

hB.addExternalIOInterface( ...
    'InterfaceID',    'Push Buttons', ...
    'InterfaceType',  'IN', ...
    'PortName',      'PushButtons', ...
    'PortWidth',     4, ...
    'FPGAPin',       {'K18', 'P16', 'K19', 'Y16'}, ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});

hB.addExternalIOInterface( ...
    'InterfaceID',    'Slide switches ', ...
    'InterfaceType',  'IN', ...
    'PortName',      'SlideSwitches', ...
    'PortWidth',     4, ...
    'FPGAPin',       {'G15', 'P15', 'W13', 'T16'}, ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});

```

Register the Custom Reference Design in HDL Workflow Advisor

Register the custom reference design in HDL Workflow Advisor.

1. Create a reference design registration file named `hdlcoder_ref_design_customization.m` containing a list of reference design plugins associated with an SoC board.

A reference design plugin is a MATLAB package folder containing the reference design definition file and all files associated with the SoC design project. A reference design registration file must also contain the name of the associated board.

This code describes the contents of a Zybo reference design registration file containing the reference design plugin `ZyboZ710Registration.Vivado2020_2` associated with the board `ZYBO Z7-10`.

```

function [rd, boardName] = hdlcoder_ref_design_customization
% Reference design plugin registration file
% 1. The registration file with this name inside of a board plugin folder
%    will be picked up
% 2. Any registration file with this name on MATLAB path will also be picked up
% 3. The registration file returns a cell array pointing to the location of
%    the reference design plugins
% 4. The registration file also returns its associated board name

```

```

% 5. Reference design plugin must be a package folder accessible from
%   MATLAB path, and contains a reference design definition file

rd = {'ZyboZ710Registration.Vivado2020_2.plugin_rd', ...
     };

boardName = 'ZYBO Z7-10';
end

```

2. Create the reference design definition file.

A reference design definition file defines the interfaces between the custom reference design and the HDL IP core that is generated by the HDL Coder SoC workflow.

This code describes the contents of the Zybo Z7-10 reference design definition file `plugin_rd.m` associated with the board `ZYBO Z7-10` that resides inside the reference design plugin `ZyboZ710Registration.Vivado2020_2`. The property `ReferenceDesignName` defines the name of the reference design as `Demo system` in HDL Workflow Advisor.

```

function hRD = plugin_rd()
% Reference design definition

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');

hRD.ReferenceDesignName = 'Demo system';
hRD.BoardName = 'ZYBO Z7-10';

% Tool information
hRD.SupportedToolVersion = {'2020.2'};

% add custom Vivado design
hRD.addCustomVivadoDesign( ...
    'CustomBlockDesignTcl', 'design_led.tcl', ...
    'VivadoBoardPart', 'digilentinc.com:zybo-z7-10:part0:1.0');

%% Add interfaces
% add clock interface
hRD.addClockInterface( ...
    'ClockConnection', 'core_clkwiz/clk_out1', ...
    'ResetConnection', 'sys_core_rstgen/peripheral_aresetn');

% add AXI4 and AXI4-Lite slave interfaces
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'axi_cpu_interconnect/M00_AXI', ...
    'BaseAddress', '0x40010000', ...
    'MasterAddressSpace', 'sys_cpu/Data');

hRD.DeviceTreeName = 'devicetree_axilite.dtb';

```

A reference design plugin must also contain the SoC design project files.

The Zybo reference design plugin folder `ZyboZ710Registration.Vivado2020_2` must contain the Tcl script `design_led.tcl` exported previously from the Xilinx Vivado project. The Zybo reference design definition file `plugin_rd.m` identifies the SoC design project file through this statement:

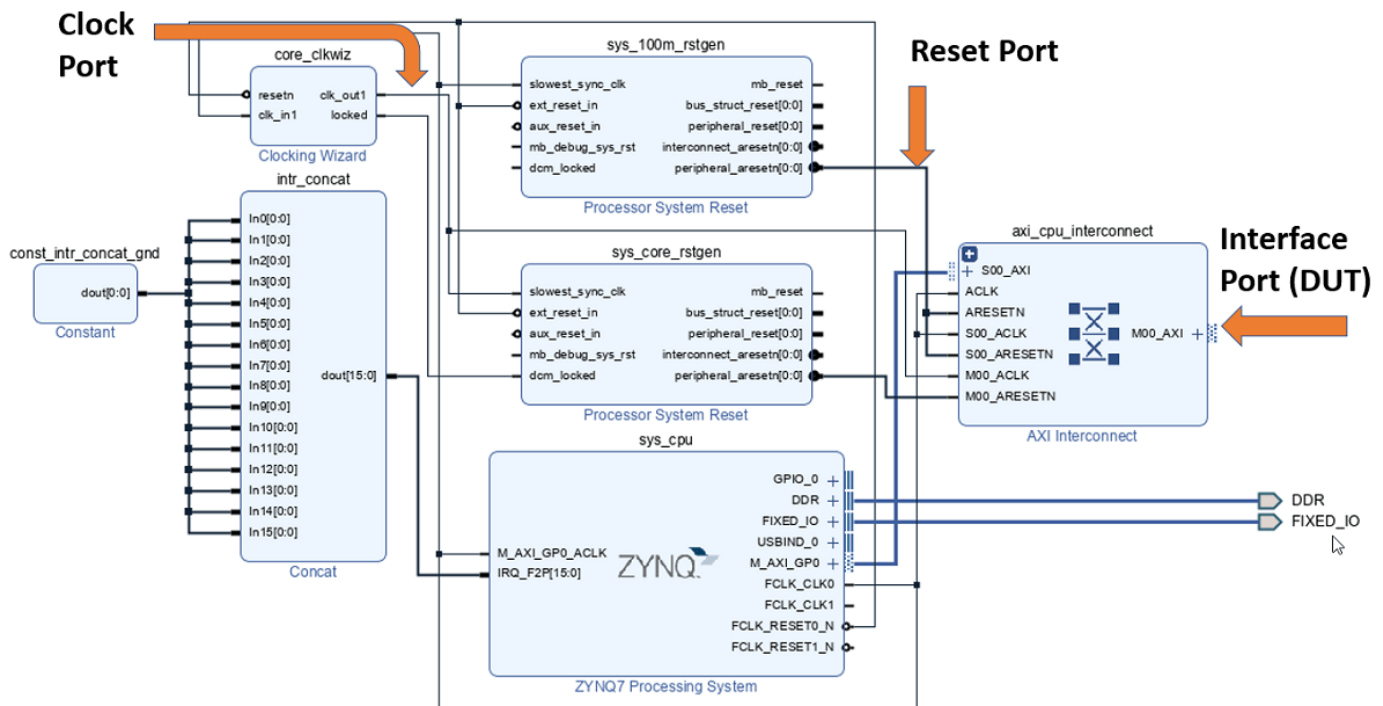

```

hRD.addCustomVivadoDesign('CustomBlockDesignTcl', 'design_led.tcl');

```

plugin_rd.m also defines the interface connections between the custom reference design and the HDL IP core indicated by these statements:

```
hRD.addClockInterface( ...
    'ClockConnection', 'core_clkwiz/clk_out1', ...
    'ResetConnection', 'sys_core_rstgen/peripheral_aresetn');
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'axi_cpu_interconnect/M00_AXI', ...
    'BaseAddress', '0x40010000', ...
    'MasterAddressSpace', 'sys_cpu/Data');
```

Note The 'BaseAddress' of the AXI4 interface must be a valid address in the 'MasterAddressSpace'. The address must not create any address conflict with other address-based peripherals in the custom reference design.

Execute the SoC Workflow for the Zybo Board

Use the custom board and reference design registration system to generate an HDL IP core that blinks LEDs on the Zybo Z7-10 board. The required files used are located in the ZYBO folder.

1. Unzip the Zybo folder.

```
unzip('ZYBO')
```

2. Add the Zybo board registration file to the MATLAB path.

```
addpath(genpath('ZYBO'));
```

3. Open the Simulink model that implements LED blinking.

```
open_system('hdlcoder_led_blinking_4bit');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking_4bit/led_counter')`

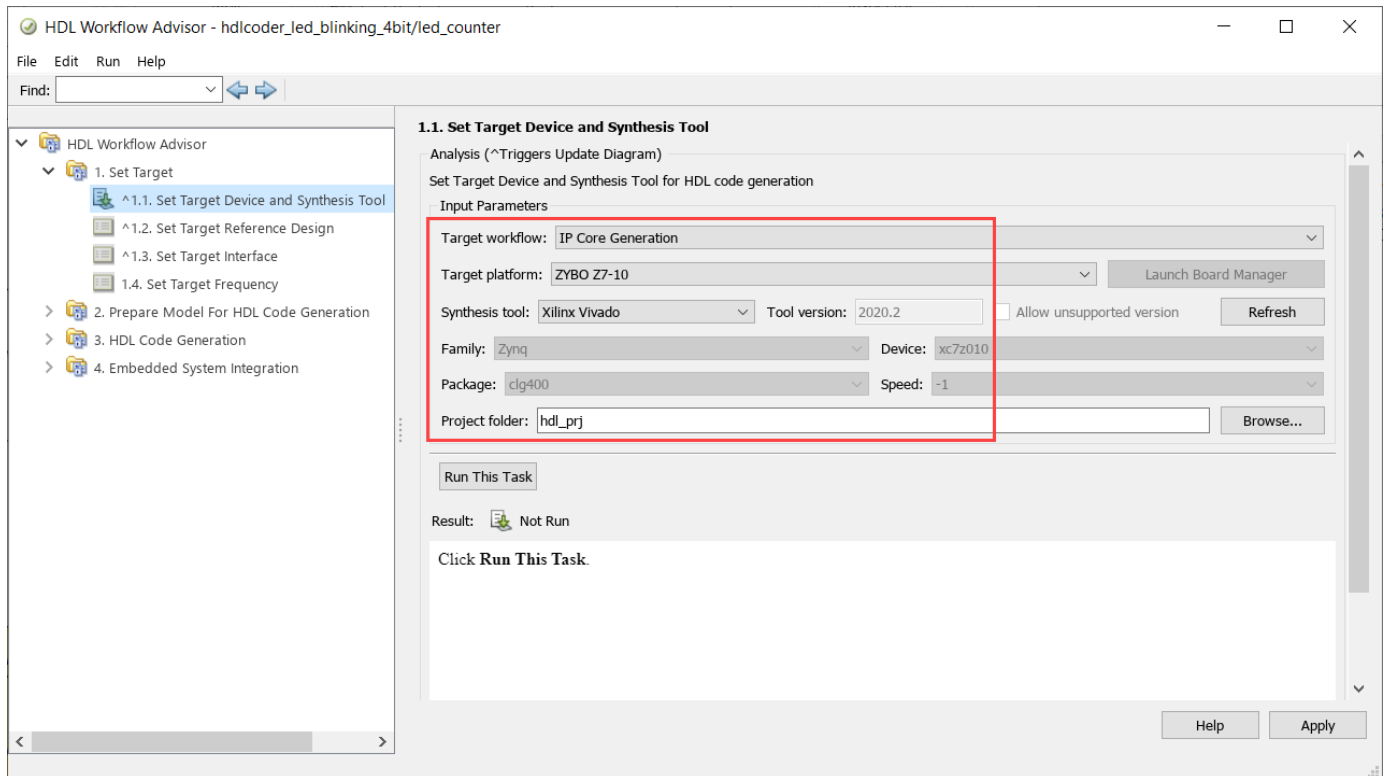

Launch HDL Workflow Advisor

Run Demo

Copyright 2014-2017 The MathWorks, Inc.

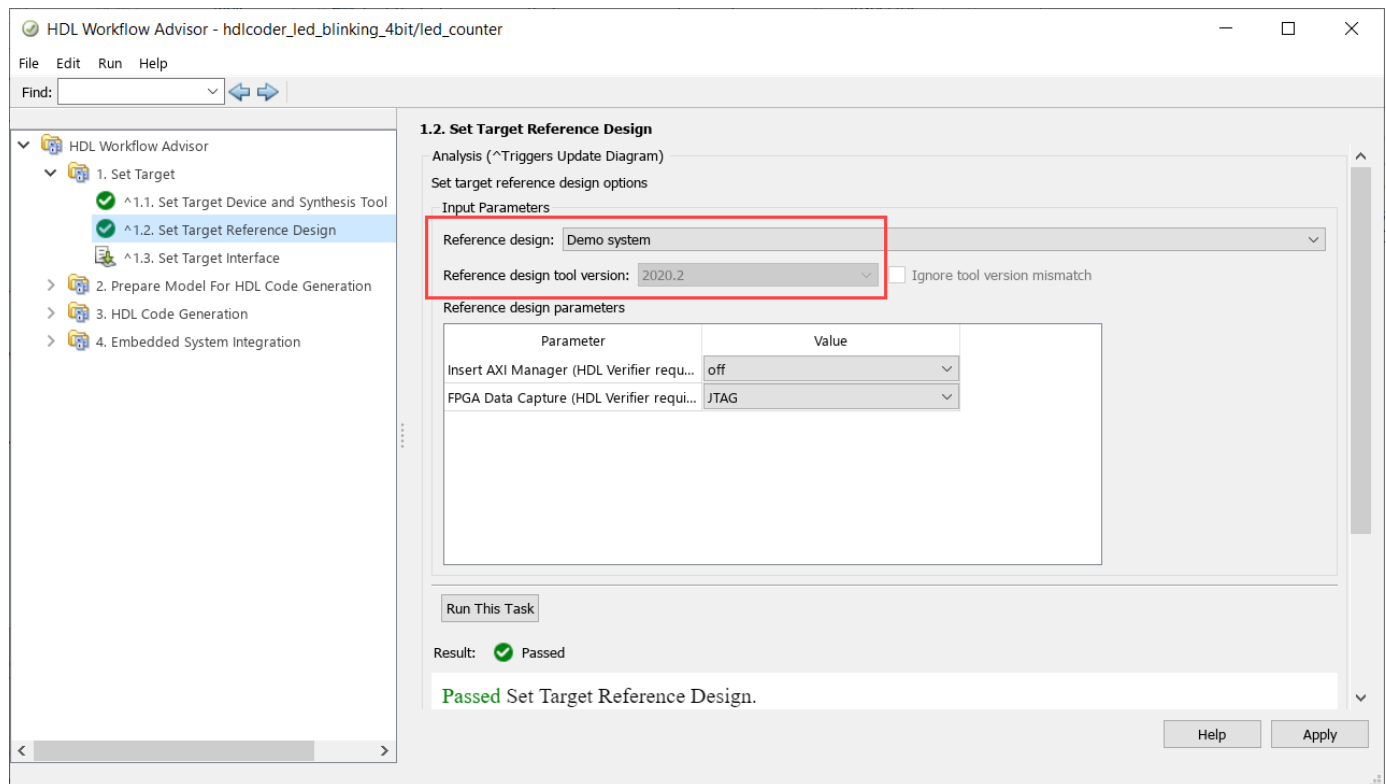

4. Launch HDL Workflow Advisor from the `hdlcoder_led_blinking_4bit/led_counter` subsystem by right-clicking the `led_counter` subsystem, and selecting **HDL Code > HDL Workflow Advisor**. Or, you can click the **Launch HDL Workflow Advisor** box in the model.

In the **Set Target > Set Target Device and Synthesis Tool** task, select **IP Core Generation** for the **Target workflow**. `ZYBO Z7-10` now appears in the drop-down list **Target Platform**. Select `ZYBO Z7-10` as a **Target Platform**.

5. Click **Run This Task** to complete the **Set Target Device and Synthesis Tool** task.

6. In the **Set Target > Set Target Reference Design** task, the custom reference design Demo system now appears in the **Reference design** field. Select Demo system and click **Run This Task**.

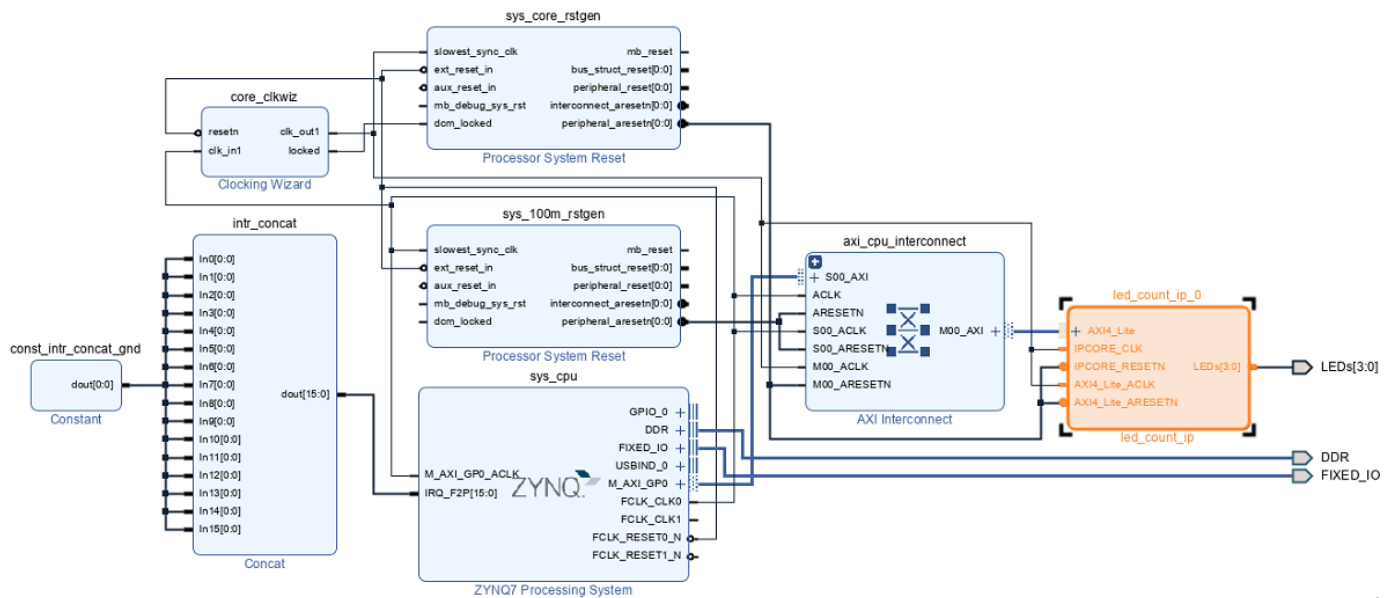

7. In Task 1.3 **Set Target Interface**, select the connections, and then click on **Run This Task**.

8. To generate IP core and view the IP core generation report, follow step 3 and step 4 of **Generate an HDL IP core using the HDL Workflow Advisor** section of “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

9. To integrate the IP core in the reference design and create the vivado project, follow step 1 of **Integrate the IP core with the Xilinx Vivado environment** section of “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

10. After completing the **Create Project** task under **Embedded System Integration**, examine the Xilinx Vivado project created by the SoC workflow . This figure shows the block design of the SoC project where you have highlighted the HDL IP Core. Compare this block design with the previous block design used to export the custom reference design for a deeper understanding of the relationship between a custom reference design and an HDL IP Core.

11. Follow the steps 2, 3 and 4 of **Integrate the IP core with the Xilinx Vivado environment** section of “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 example to generate the software interface model, generate the FPGA bitstream, and program the target device respectively.

12. After loading the bitstream, the LEDs on the Zybo Z7-10 board now start blinking. You can control the LED blink frequency and direction by executing the software interface model on the Zynq ARM processor. Refer to **Generate a software interface model** section of “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 example to control the LED blink frequency and direction from the generated software interface model.

Define Custom Board and Reference Design for Intel SoC Workflow

This example shows how to define and register a custom board and reference design in the HDL Coder™ Intel® SoC workflow.

Introduction

Using this example, you will be able to register the Terasic DE1-SoC development kit and a custom reference design in the HDL Workflow Advisor for the Intel SoC workflow.

This example uses Terasic DE-1 SoC, but in the same way, you can define and register a custom board or a custom reference design for other Intel SoC devices.

Requirements

- 1 Intel Quartus® Prime, with supported version listed in the “HDL Language Support and Supported Third-Party Tools and Hardware”
- 2 Intel SoC Embedded Design Suite
- 3 Terasic DE1-SoC development Kit
- 4 HDL Coder Support Package for Intel SoC Devices
- 5 Embedded Coder® Support Package for Intel SoC Devices

Set up Intel SoC hardware and tools

1. Understand the features available on the Terasic DE1-SoC by reading the board reference manual.
2. Set up the Terasic DE1-SoC as shown in the following figure:

3. Ensure that you have properly installed the USB COM port device drivers on your computer.
4. Connect the UART and USB blaster port on the Terasic DE1-SoC to your computer.
5. Connect the Terasic DE1-SoC to your computer using an Ethernet cable. The default Terasic DE1-SoC IP address is 192.168.1.101.
6. Download the Terasic DE1-SoC Linux image file, extract the GZ archive, and then write the raw disc image file to the microSD card. Insert the microSD card in connector J11.
7. Set up the Intel Quartus tool path by using the following command:

```
hdlsetuptoolpath('ToolName', 'Altera Quartus II', 'ToolPath', 'C:\intelFPGA\20.1.1\quartus\b
```

Use your own Intel Quartus installation path when executing the command.

8. Set up the Terasic DE1-SoC hardware connection by using the following command:

```
h = alterasoc('192.168.1.101', 'root', 'cyclonevsoc');
```

Reference Design creation using Intel Quartus Prime

A reference design captures the complete structure of an SoC design, defining the different components and their interconnections. The HDL Coder SoC workflow generates an IP core that integrates with the reference design, and is then used to program an SoC board. The following figure describes the relationship between a reference design, an HDL IP core and an SoC board

In this section, we outline the basic steps necessary to create and export a simple reference design using the Intel Quartus and QSys environment. For more information about the QSys system integration tool, refer to Altera®/Intel documentation.

1. Create an empty Quartus project using the New project wizard with device part number as shown in the following figure

New Project Wizard

Family, Device & Board Settings

Device Board

Select the family and device you want to target for compilation.
You can install additional device support with the Install Devices command on the Tools menu.

To determine the version of the Quartus Prime software in which your target device is supported, refer to the [Device Support List](#) webpage.

Device family

Family: Cyclone V (E/GX/GT/SX/SE/ST)

Device: All

Target device

Auto device selected by the Fitter

Specific device selected in 'Available devices' list

Other: n/a

Show in 'Available devices' list

Package: Any

Pin count: Any

Core speed grade: Any

Name filter: 5CSEMA5F31C6

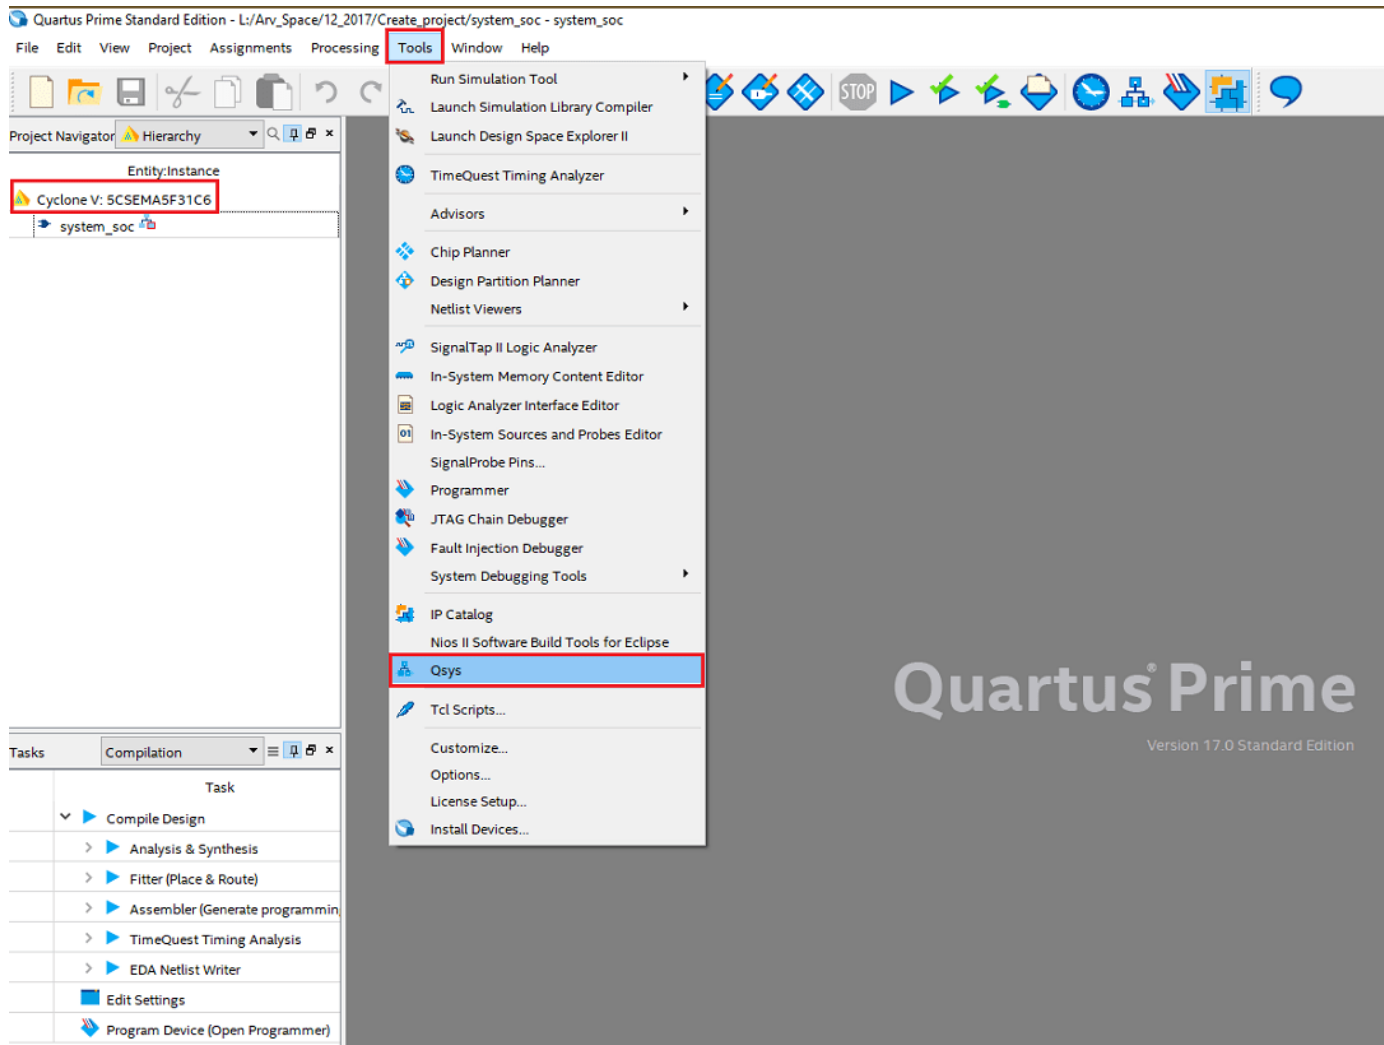

Show advanced devices

Available devices:

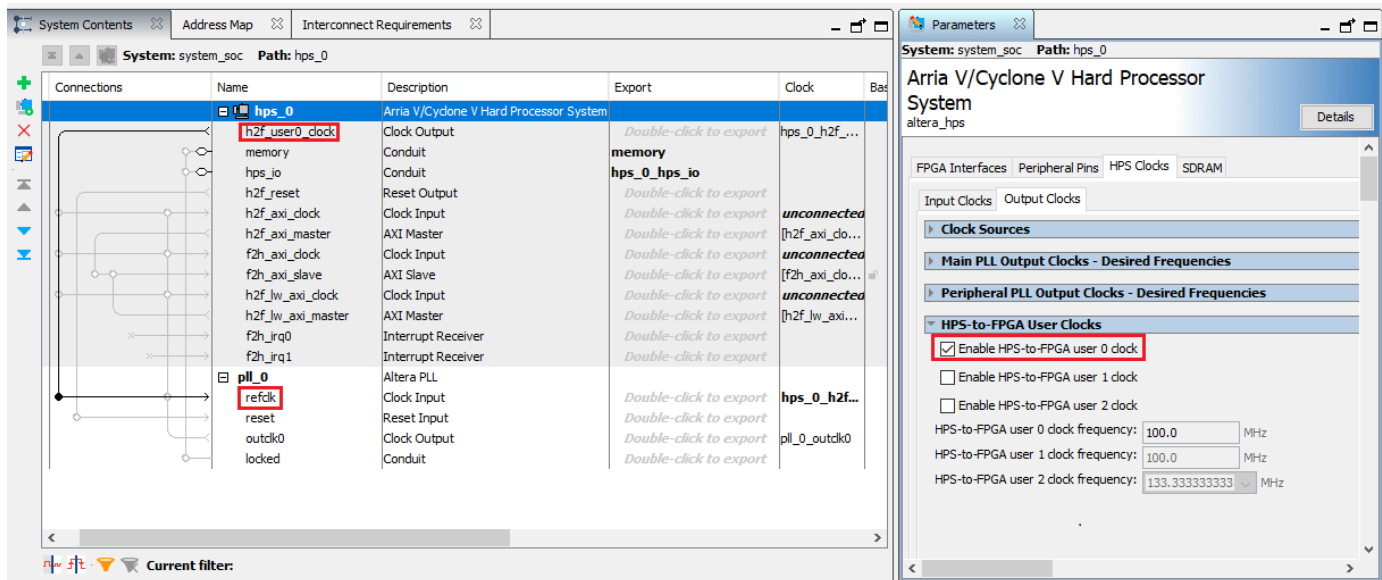

Name	Core Voltage	ALMs	Total I/Os	GPIOs	GXB Channel PMA	GXB Channel PCS
5CSEMA5F31C6	1.1V	32070	457	457	0	0

< Back Next > Finish Cancel Help

2. Initialize the Qsys in Quartus by navigating **Tools --> Qsys** as shown in the following figure

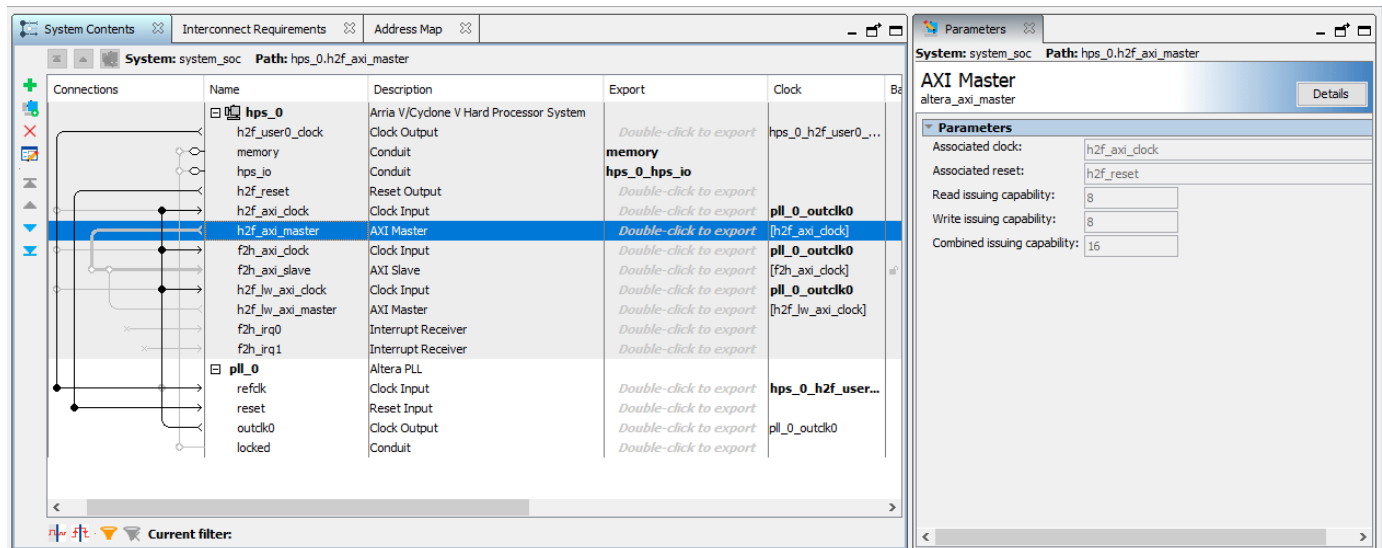

3. Select Cyclone-V Hard Processor System(HPS) & Altera PLL IP's from IP catalog to the created Qsys project. Enable HPS-to-FPGA user 0 clock (h2f_user0_clock) and connect that to refclk of Altera PLL as shown in the following figure

complete the other settings required for Hard Processor System such as Peripheral pin set and mode settings.

4. keep h2f_axi_master port connection open in order to connect to DUT IP during the process of workflow IP integration. Complete the rest of the connections between Altera PLL IP and HPS IP as shown in the following figure

5. Save the Qsys file. This file will be used while you create reference design plugin.

Register the DE1-SoC board in HDL Workflow Advisor

In this section, we outline the steps necessary to register the Terasic DE1-SoC development kit in HDL Workflow Advisor.

1. Create a board registration file with the name `hdlcoder_board_customization.m` and add it to the MATLAB® path.

A board registration file contains a list of board plug-ins. A board plugin is a MATLAB package folder containing a board definition file and all reference design plug-ins associated with the board.

The following code describes the contents of a board registration file that contains the board plugin `DE1SoCRegistration` to register the Terasic DE1-SoC development kit in HDL Workflow Advisor.

```
function r = hdlcoder_board_customization
% Board plugin registration file
% 1. Any registration file with this name on MATLAB path will be picked up
% 2. Registration file returns a cell array pointing to the location of
%    the board plugin
% 3. Board plugin must be a package folder accessible from MATLAB path,
%    and contains a board definition file

r = { ...
    'DE1SoCRegistration.plugin_board', ...
    };
end
```

2. Create the board definition file.

A board definition file contains information about the SoC board.

The following code describes the contents of the DE1-SoC board definition file `plugin_board.m` that resides inside the board plugin `DE1SoCRegistration`.

Information about the FPGA I/O pin locations ('FPGAPin') and standards ('IOSTANDARD') is obtained from the Pin Planner of Intel Quartus-II.

The property `BoardName` defines the name of the DE-1 SoC board as Terasic DE1-SoC development Kit in HDL Workflow Advisor.

```
function hB = plugin_board()
% Board definition

% Construct board object
hB = hdlcoder.Board;

hB.BoardName = 'Terasic DE1-SoC development Kit';

% FPGA device information
hB.FPGAVendor = 'Altera';
hB.FPGAFamily = 'Cyclone V';
hB.FPGADevice = '5CSEMA5F31C6';
hB.FGAPackage = '';
hB.FGASpeed = '';

% Tool information
hB.SupportedTool = {'Altera QUARTUS II'};

% FPGA JTAG chain position
hB.JTAGChainPosition = 2;

%% Add interfaces
% Standard "External Port" interface
hB.addExternalPortInterface( ...
    'IOPadConstraint', {'IO_STANDARD "2.5V"});

% Custom board external I/O interface
hB.addExternalIOInterface( ...
```

```

'InterfaceID',    'LEDs General Purpose', ...
'InterfaceType', 'OUT', ...
'PortName',      'GPLED', ...
'PortWidth',     10, ...
'FPGAPin',       {'V16', 'W16', 'V17', 'V18', 'W17', 'W19', 'Y19', 'W20', 'W21', 'Y21'}, ...
'IOPadConstraint', {'IO_STANDARD "3.3-V LVTTL"});

hB.addExternalIOInterface( ...
'InterfaceID',    'Switches', ...
'InterfaceType', 'IN', ...
'PortName',      'SW', ...
'PortWidth',     10, ...
'FPGAPin',       {'AB12', 'AC12', 'AF9', 'AF10', 'AD11', 'AD12', 'AE11', 'AC9', 'AD10', 'AE12'}, ...
'IOPadConstraint', {'IO_STANDARD "3.3-V LVTTL"});

hB.addExternalIOInterface( ...
'InterfaceID',    'Push Buttons', ...
'InterfaceType', 'IN', ...
'PortName',      'KEY', ...
'PortWidth',     4, ...
'FPGAPin',       {'AA14', 'AA15', 'W15', 'Y16'}, ...
'IOPadConstraint', {'IO_STANDARD "3.3-V LVTTL"});

```

Register the custom reference design in HDL Workflow Advisor

In this section, we outline the steps necessary to register the custom reference design in HDL Workflow Advisor.

1. Create a reference design registration file named `hdlcoder_ref_design_customization.m` containing a list of reference design plugins associated with an SoC board.

A reference design plugin is a MATLAB package folder containing the reference design definition file and all files associated with the SoC design project. A reference design registration file must also contain the name of the associated board.

The following code describes the contents of a DE1-SoC reference design registration file containing the reference design plugin `DE1SoCRegistration.qsys_base_170` associated with the board Terasic DE1-SoC development Kit.

```

function [rd, boardName] = hdlcoder_ref_design_customization
% Reference design plugin registration file
% 1. The registration file with this name inside of a board plugin folder
%    will be picked up
% 2. Any registration file with this name on MATLAB path will also be picked up
% 3. The registration file returns a cell array pointing to the location of
%    the reference design plugins
% 4. The registration file also returns its associated board name
% 5. Reference design plugin must be a package folder accessible from
%    MATLAB path, and contains a reference design definition file

rd = {'DE1SoCRegistration.qsys_base_170.plugin_rd', ...
      };

boardName = 'Terasic DE1-SoC development Kit';
end

```

2. Create the reference design definition file.

A reference design definition file defines the interfaces between the custom reference design and the HDL IP core that will be generated by the HDL Coder SoC workflow.

The following code describes the contents of the DE1-SoC reference design definition file `plugin_rd.m` associated with the board Terasic DE1-SoC development Kit that resides inside the reference design plugin `DE1SoCRegistration.qsys_base_170`. The property `ReferenceDesignName` defines the name of the reference design as `Demo system` in HDL Workflow Advisor.

```
function hRD = plugin_rd()
% Reference design definition

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Altera QUARTUS II');

hRD.ReferenceDesignName = 'Demo system);
hRD.BoardName = 'Terasic DE1-SoC development Kit';

% Tool information
hRD.SupportedToolVersion = {'17.0','17.1'};

%% Add custom design files
% add custom Qsys design
hRD.addCustomQsysDesign( ...
    'CustomQsysPrjFile', 'system_soc.qsys');

%% Add interfaces
% add clock interface
hRD.addClockInterface( ...
    'ClockConnection',    'pll_0.outclk0', ...
    'ResetConnection',   'hps_0.h2f_reset',...
    'DefaultFrequencyMHz', 50,...
    'MinFrequencyMHz',    5,...
    'MaxFrequencyMHz',    500,...
    'ClockModuleInstance', 'pll_0',...
    'ClockNumber',        0);

% add AXI4 and AXI4-Lite slave interfaces
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'hps_0.h2f_axi_master', ...
    'BaseAddress',         '0x0000');
```

The DE1-SoC reference design plugin folder `DE1SoCRegistration.qsys_base_170` must contain the Qsys file `system_soc.qsys` saved previously from the Intel Quartus Prime project . The DE1-SoC reference design definition file `plugin_rd.m` identifies the SoC design project file via the following statement:

```
hRD.addCustomQsysDesign('CustomQsysPrjFile', 'system_soc.qsys');
```

In addition to the SoC design project files, `plugin_rd.m` also defines the interface connections between the custom reference design and the HDL IP core indicated in the following figure via the statements:

```
hRD.addClockInterface( ...
    'ClockConnection',    'pll_0.outclk0', ...
    'ResetConnection',   'hps_0.h2f_reset',...
    'DefaultFrequencyMHz', 50,...
    'MinFrequencyMHz',    5,...
```

```

    'MaxFrequencyMHz',    500,...
    'ClockModuleInstance', 'pll_0',...
    'ClockNumber',       0);
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'hps_0.h2f_axi_master', ...
    'BaseAddress',         '0x0000');

```

Execute the SoC workflow for the Terasic DE1-SoC

The preceding sections discussed the steps to define and register the Terasic DE1-SoC and a custom reference design in the HDL Workflow Advisor for the SoC workflow. In this section, we use the custom board and reference design registration system to generate an HDL IP core that blinks LEDs on the Terasic DE1-SoC.

1. Add the Terasic DE1-SoC registration file to the MATLAB path.

```

unzip('DE1SOC.zip')
addpath(genpath('DE1SOC'));

```

2. Open the Simulink model that implements LED blinking using the command,

```
open_system('hdlcoder_led_blinking');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2014 The MathWorks, Inc.

Generate an HDL IP core using the HDL Workflow Advisor

1. Using the IP Core Generation workflow in the HDL Workflow Advisor enables you to automatically generate a sharable and reusable IP core module from a Simulink model. HDL Coder generates HDL code from the Simulink blocks, and also generates HDL code for the AXI interface logic connecting the IP core to the embedded processor. HDL Coder packages all the generated files into an IP core

folder. You can then integrate the generated IP core with a larger FPGA embedded design in the Intel Qsys environment.

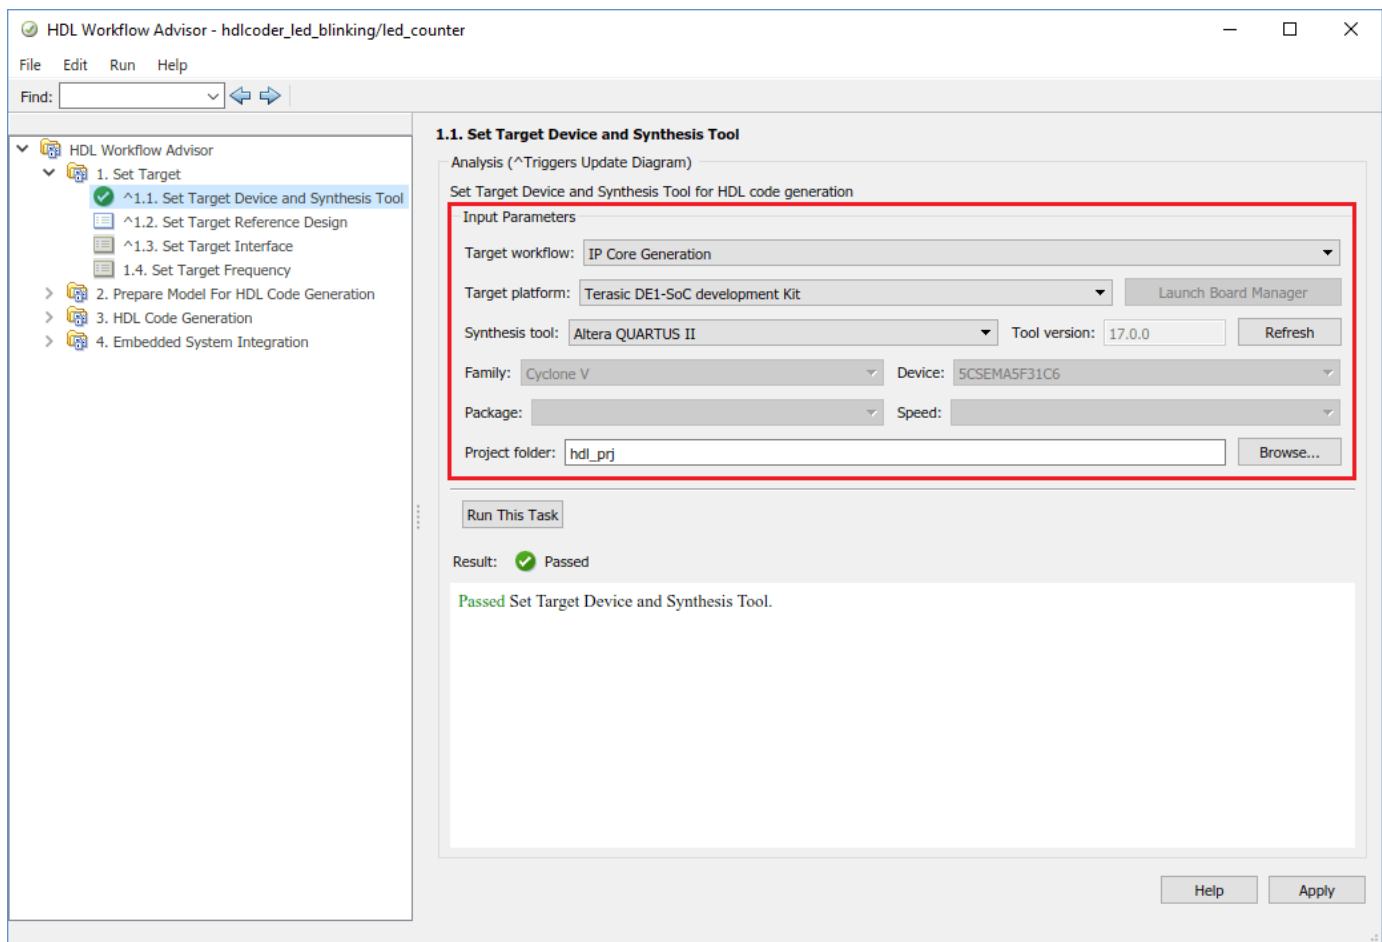

2. Start the IP core generation workflow.

2.1. Open the HDL Workflow Advisor from the `hdlcoder_led_blinking/led_counter` subsystem by right-clicking the `led_counter` subsystem, and choosing **HDL Code > HDL Workflow Advisor**.

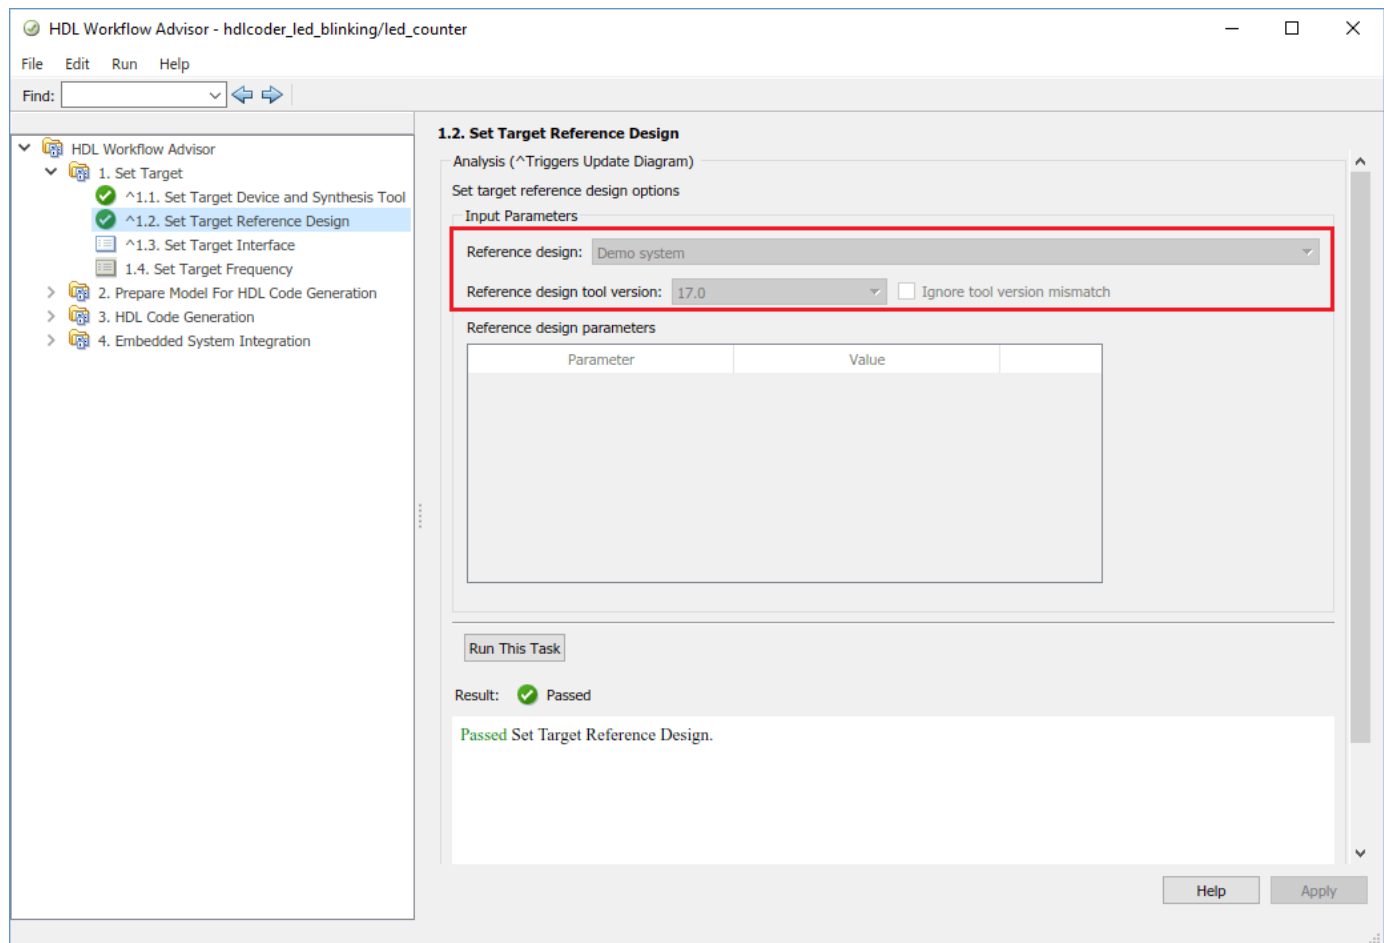

2.2. In the **Set Target > Set Target Device and Synthesis Tool** task, for **Target workflow**, select **IP Core Generation**.

2.3. For **Target platform**, select **Terasic DE1-SoC development Kit**.

2.4. Click **Run This Task** to run the **Set Target Device and Synthesis Tool** task.

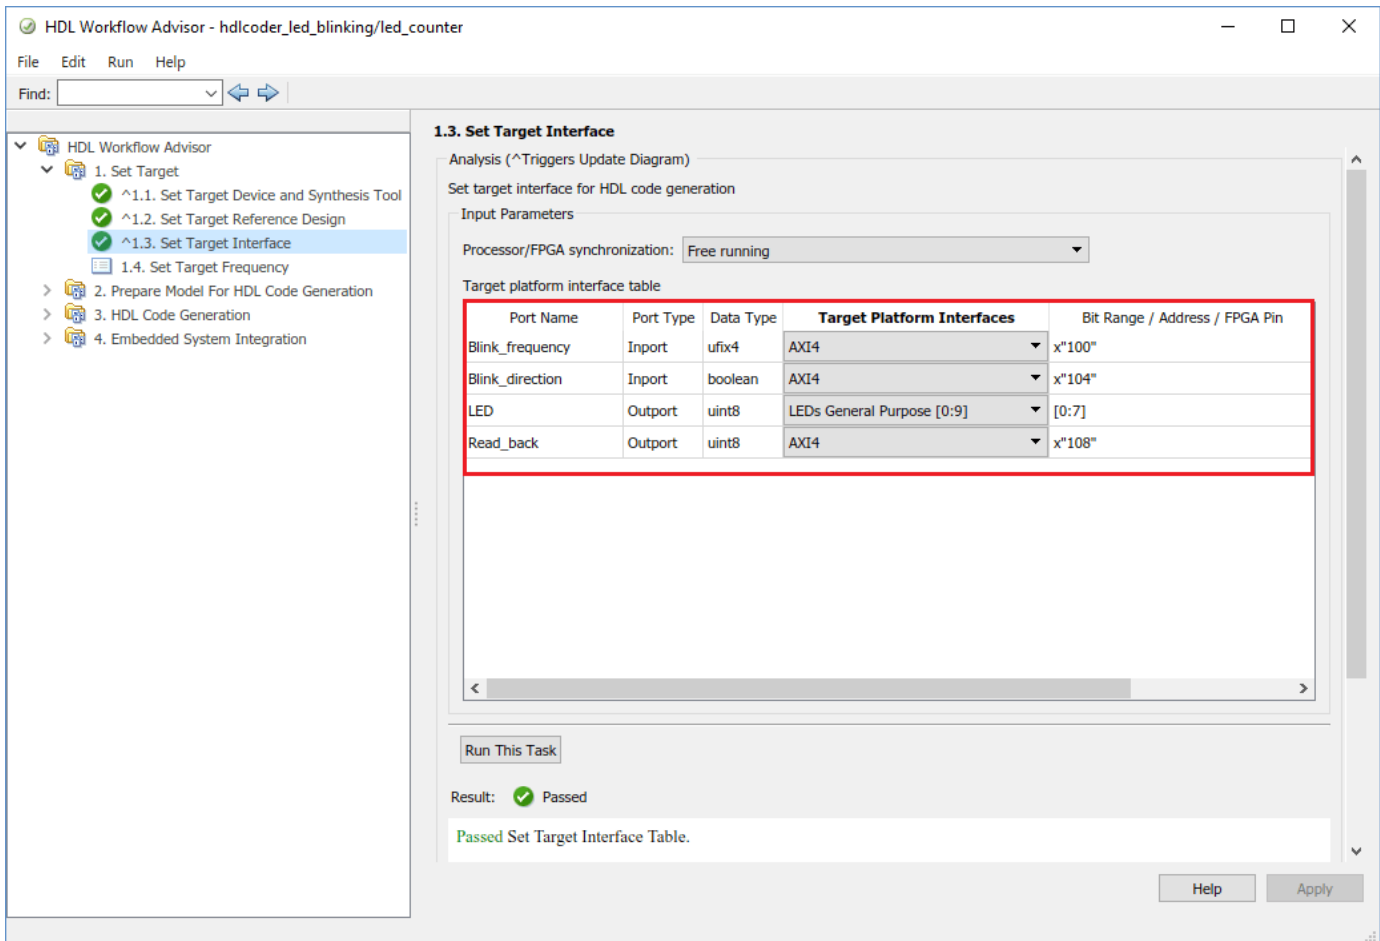

3. In the task 1.2, set target reference design default system is selected. click on **Run This Task**.

4. Configure the Target Interface.

Map each port in your DUT to one of the IP core target interfaces. In this example, input ports **Blink_frequency** and **Blink_direction** are mapped to **AXI4**. The **LED** output port is mapped to an external interface, **LEDs General Purpose [0:9]**, which connects to the LED hardware on the Terasic DE1-SoC development Kit.

5. Follow step 3 and step 4 of **Generate an HDL IP core using the HDL Workflow Advisor** section of “Getting Started with Targeting Intel SoC Devices” on page 46-122 example to generate IP core and view the IP core generation report.

6. Follow step 1 of **Integrate the IP core with the Intel Qsys environment** section of “Getting Started with Targeting Intel SoC Devices” on page 46-122 example to integrate the IP core in the reference design and create the Qsys project.

7. Now let us examine the Intel Qsys project created by the SoC workflow after completing the **Create Project** task under **Embedded System Integration**. The following figure shows the SoC project where we have highlighted the HDL IP Core. It is instructive to compare this project with the previous project used in the custom reference design plugin for a deeper understanding of the relationship between a custom reference design and an HDL IP Core.

The screenshot shows the 'System Contents' window in Intel Quartus II. The system is named 'system_soc' and the path is 'hps_0.h2f_axi_master'. The window displays a tree view of components and their connections. A red box highlights the 'led_count_ip_0' component and its associated signals.

Connections	Name	Description	Export	Clock	Base
	hps_0	Arria V/Cyclone V Hard Processor System			
	h2f_user0_clock	Clock Output	Double-click to export	hps_0_h2f_user0_clock

	axi_reset	Reset Input	Double-click to export	[axi_clk]	
	s_axi	AXI4 Slave	Double-click to export	[axi_clk]	mf
	GPLED	Conduit	led_count_ip_0_GPLED	[ip_clk]	

8. Follow the steps 2, 3 and 4 of **Integrate the IP core with the Intel Qsys environment** section of “Getting Started with Targeting Intel SoC Devices” on page 46-122 example to generate software interface model, generate FPGA bitstream and program target device respectively.

9. The LEDs on the Terasic DE1-SoC will start blinking after loading the bitstream. In addition, you will be able to control the LED blink frequency and direction by executing the software interface model. Refer to **Generate a software interface model** section of “Getting Started with Targeting Intel SoC Devices” on page 46-122 example to control the LED blink frequency and direction from the generated software interface model.

Define Custom Board and Reference Design for Microchip Workflow

This example shows how to define and register a custom board and reference design for a blinking LED model in the Microchip workflow of the HDL Workflow Advisor. You use a SmartFusion2® board, but you can define and register a custom board or a custom reference design for other Microchip platforms.

Requirements

To run this example, you need access to:

- A Microchip Libero SoC Design Suite. For a list of supported versions, see “HDL Language Support and Supported Third-Party Tools and Hardware”.
- A Microchip SmartFusion2 development board with the accessory kit.
- HDL Coder™ Support Package for Microchip FPGA and SoC Devices.

Set Up SmartFusion2 Board

To familiarize yourself with the features of the SmartFusion2 board, see the SmartFusion2 Board Reference Manual. To set up your SmartFusion2 board, follow these steps.

1. Install the USB COM port device drivers on your computer.
2. Connect the shared UART/JTAG USB port on the SmartFusion2 board to your computer.
3. Download and install **HDL Coder Support Package for Microchip FPGA and SoC Devices**. To access the hardware support package, in the **Home** tab of your MATLAB session, click **Add-Ons** and then click **Get Hardware Support Packages**.
4. Set up the Microchip Libero tool path by using the `hdlsetuptoolpath` function. For example, to set up the Microchip Libero SoC tool, specify `ToolName` as `Microchip Libero SoC` and `ToolPath` as your installed Libero executable path.

```
hdlsetuptoolpath('ToolName', 'Microchip Libero SoC', ...  
                'ToolPath', 'C:\Microsemi\Libero_SoC_v2022.1\Designer\bin\libero.exe');
```

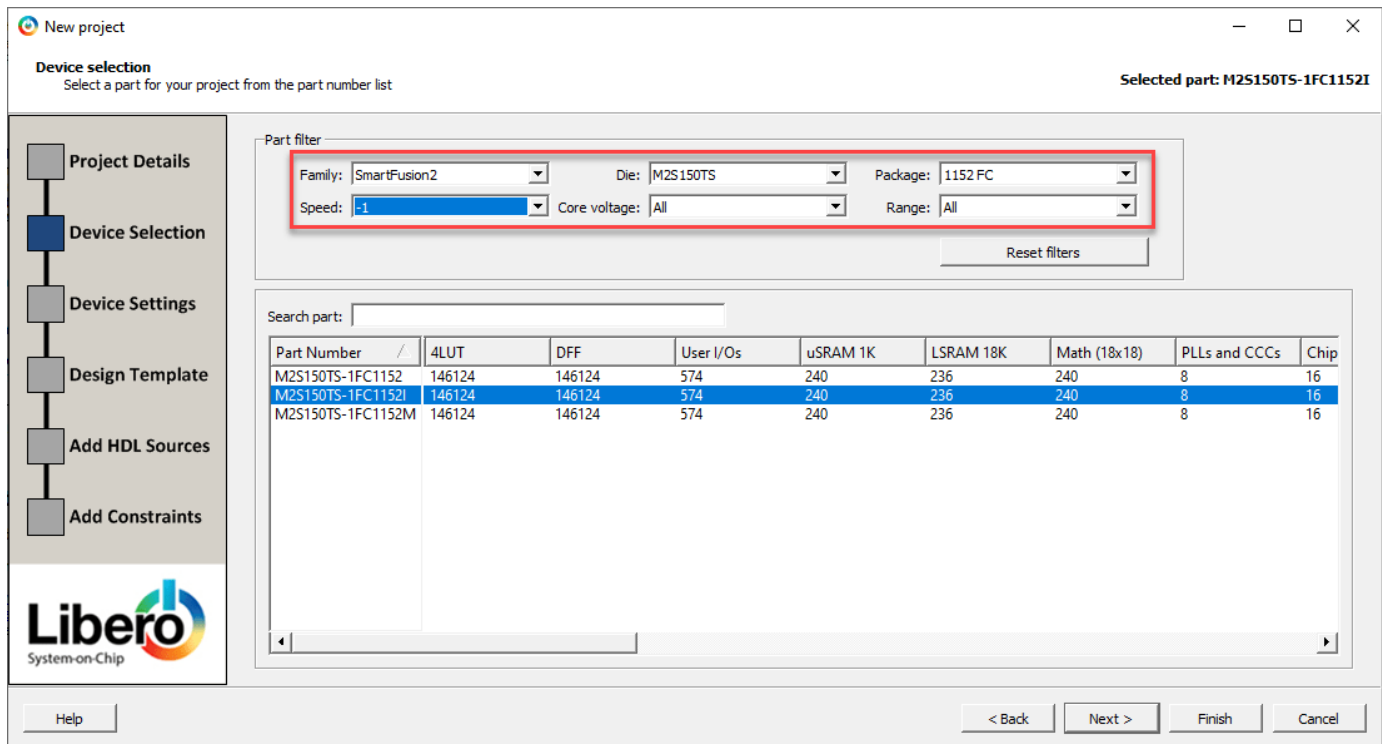

Create and Export Custom Reference Design by Using Microchip Libero SoC

A reference design captures the complete structure of an SoC design, defining the different components and their interconnections. Use the HDL Coder SoC workflow in the HDL Workflow Advisor to generate an IP core that integrates with the reference design and program an SoC board. This figure shows the relationship between a reference design, an HDL IP core, and an SoC board.

To create and export a reference design by using the Microchip Libero Tool environment, follow these steps.

1. Create a microcontroller subsystem (MSS) based Microchip Libero SoC RTL project by using the SmartFusion2 board settings as specified in this figure and then click **Next**. This Libero project is required only to generate SmartFusion2 configuration files.

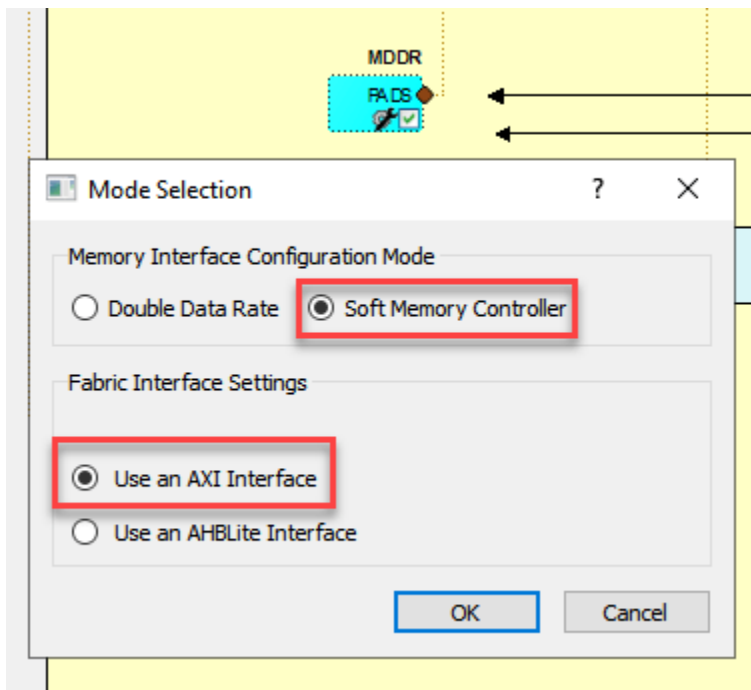

2. In the Design Template window, select **Create a microcontroller (MSS) based design** and then click **Next**.

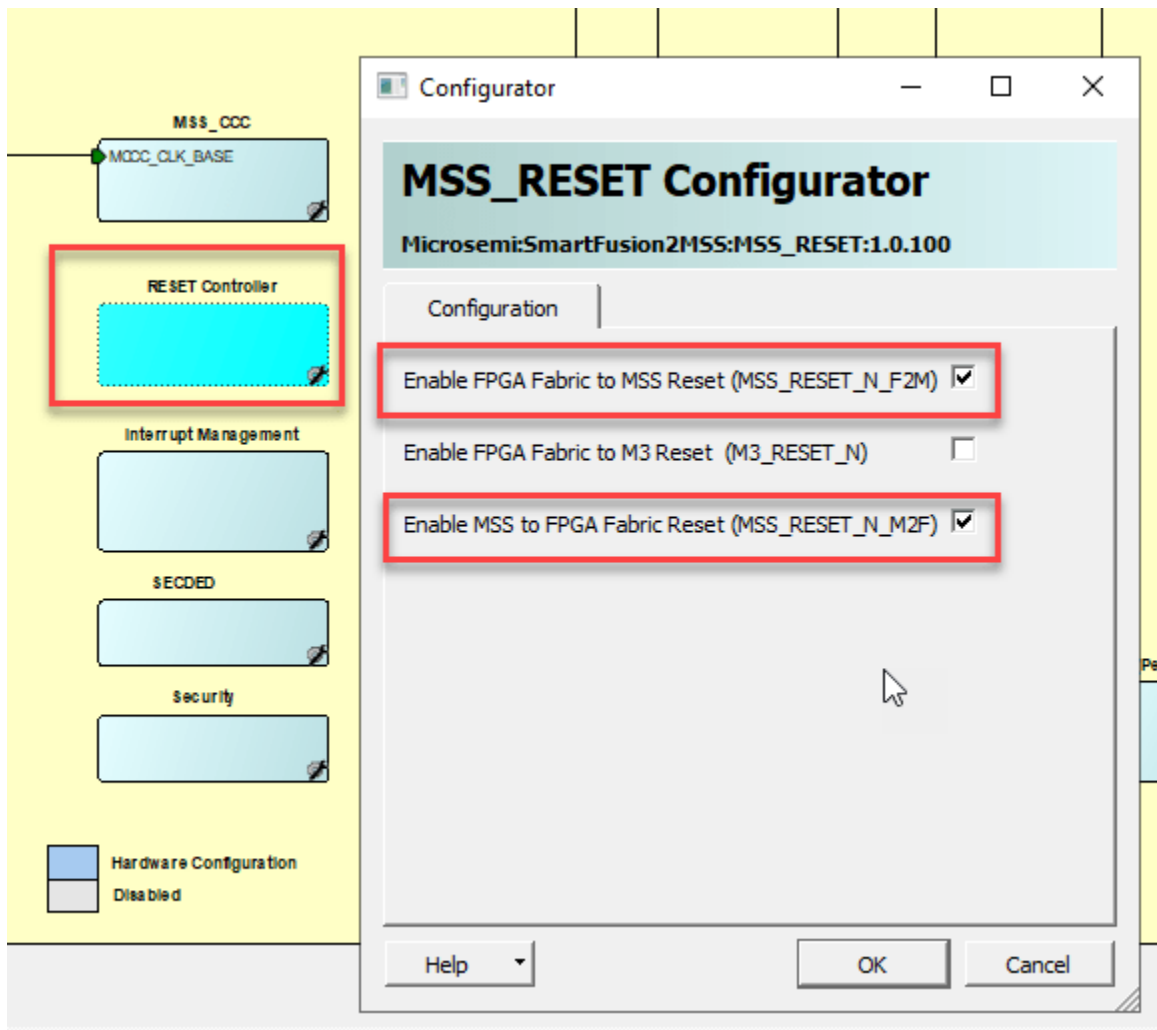

3. Click **Finish** to create a smart design containing the SmartFusion2 MSS component. To configure the MSS, double-click **SmartFusion2_MSS_MSS** IP.

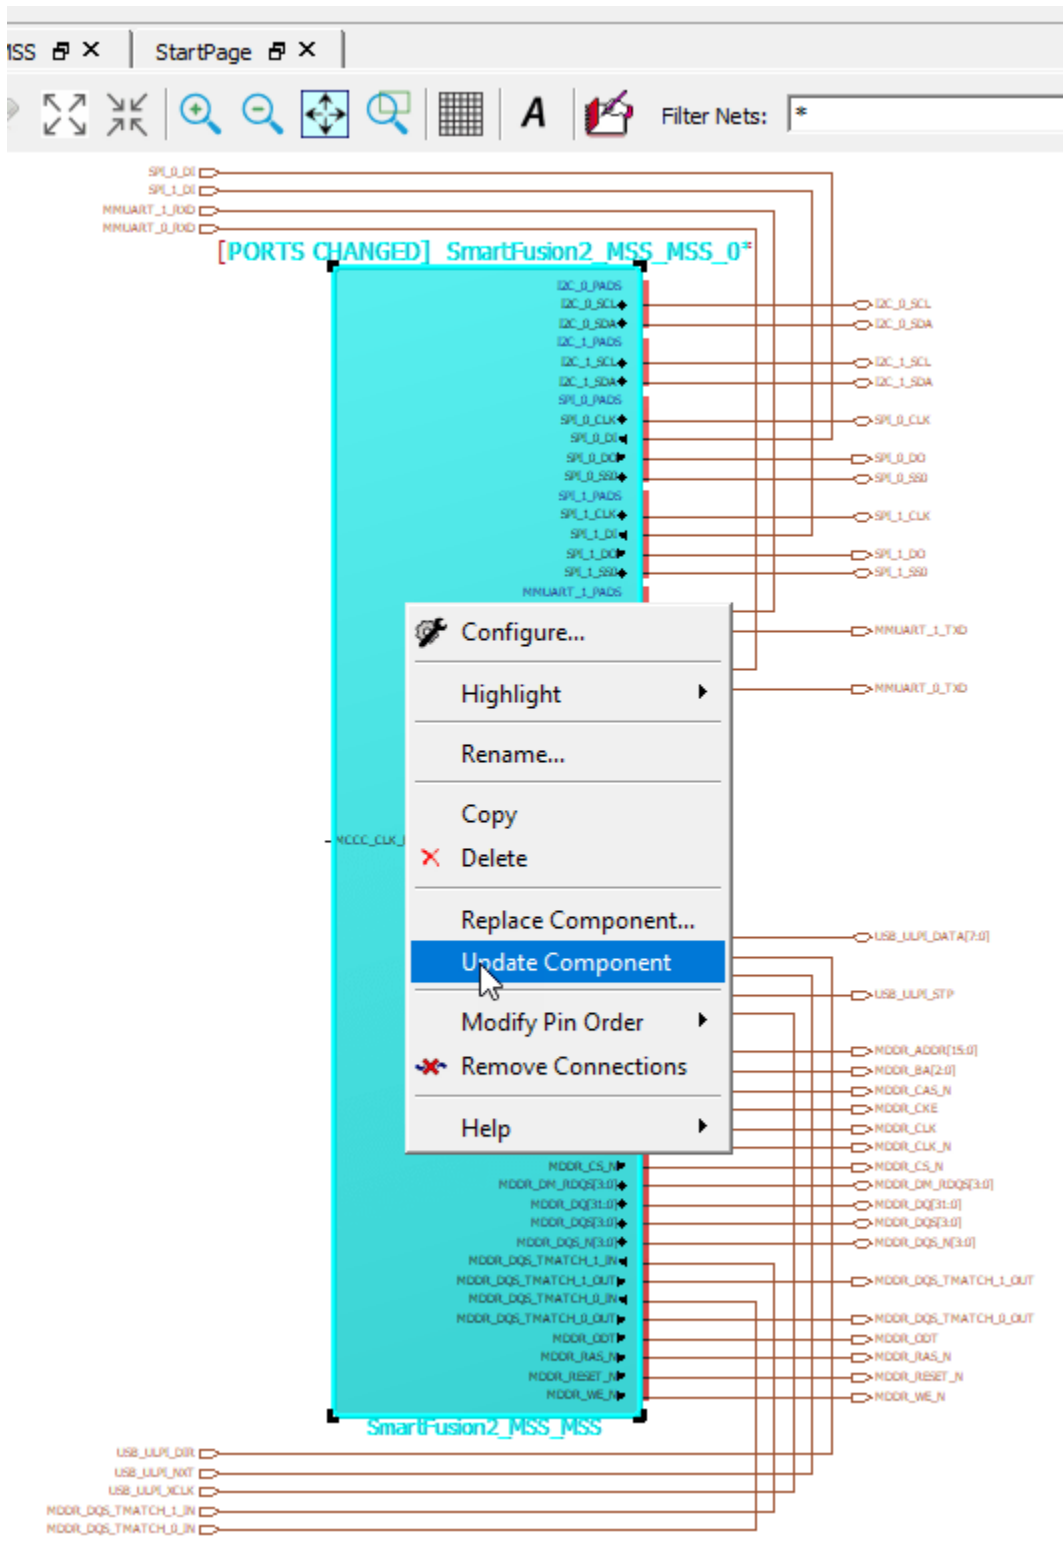

4. Clear the check boxes from the peripherals that you do not want to use. Double-click **MDDR** and select this configuration for the AXI Master interface.

5. Double-click **Reset Controller** to configure the reset controller, which enables the **MSS_RESET_N_M2F** and **MSS_RESET_N_M2F** parameters.

6. Save the **SmartFusion2_MSS_MSS** smart design. Right-click the **SmartFusion2_MSS_MSS** IP and select **Update Component**.

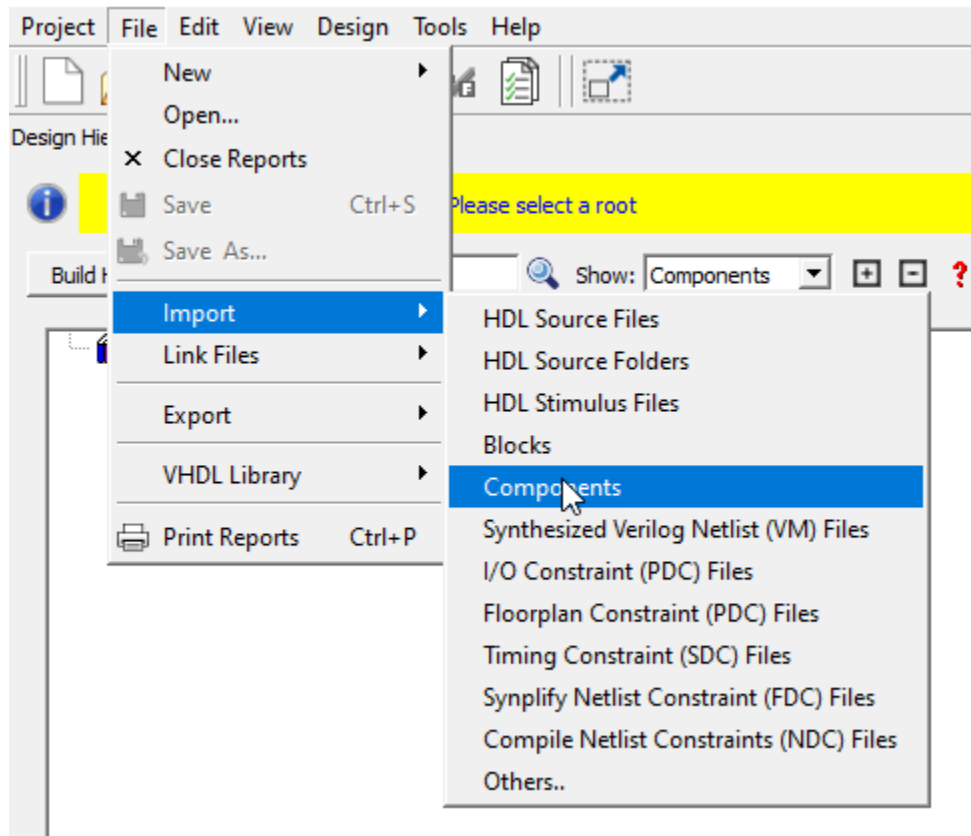

7. MSS IP is configured with AXI Master interface and reset connections. Promote all pins to the top level of your design and click **Generate Component**.

8. Generate the **SmartFusion2_MSS_MSS** component files in the Libero project folder `SmartFusion2_MSS\component\work\SmartFusion2_MSS_MSS`. Save the generated `SmartFusion2_MSS_MSS.cxf` and `SmartFusion2_MSS_MSS.sdb` files in the same folder as the Simulink® blinking LED model is saved.

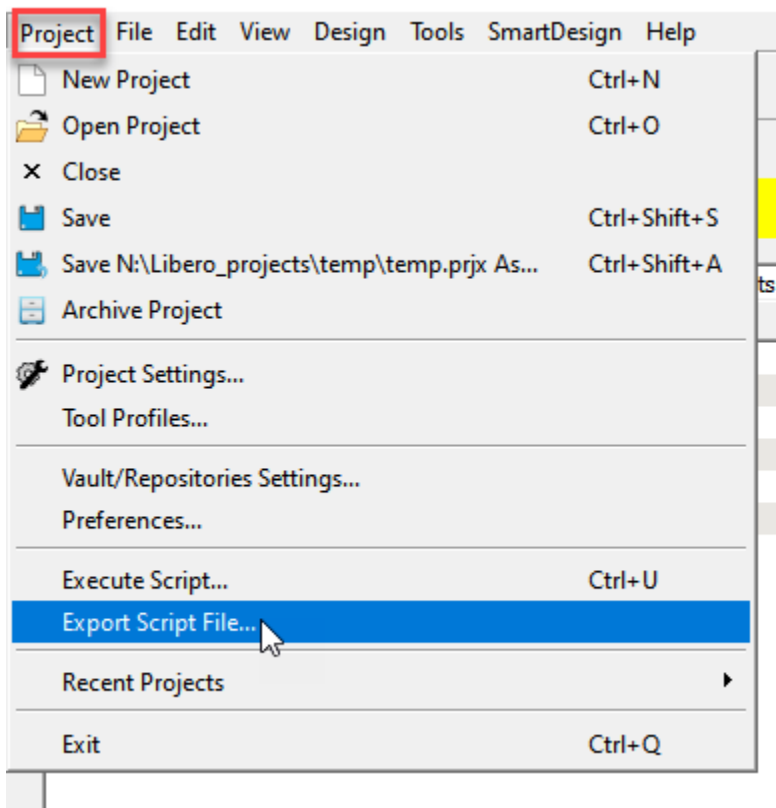

9. Create a new empty Libero project with the same SmartFusion2 device settings and import Microcontroller SubSystem (MSS) processor. Click **File**, hover on **Import**, then click **Components**. Specify the path of the `SmartFusion2_MSS_MSS.cxf` file that you generate in step 8. Create a new smart design with the name `Libero_sd` and instantiate `SmartFusion2_MSS_MSS` IP in `Libero_sd`. Generate a component for the `SmartFusion2_MSS_MSS` IP by promoting all the pins to the top level.

10. Add OSC_C0, FCCC_C0 and COREAXI4INTERCONNECT_C0 IPs to the smart design. Connect the on-chip oscillator clock to clock conditioning circuitry (CCC) and use the output of the CCC to drive whole circuit clock (GL0).

11. Export the completed block design as a Tcl script with the name `design1_led.tcl`.

The exported Tcl script (`design1_led.tcl`) constitutes the custom reference design. You use this reference design in the HDL Coder SoC workflow of the HDL Workflow Advisor to recreate the block design and integrate the generated HDL IP core with the block design in a Microchip Libero project.

Register SmartFusion2 Board in HDL Workflow Advisor

To register the SmartFusion2 board in the HDL Workflow Advisor, follow these steps,

1. Create a board registration file with the name `hdlcoder_board_customization` and add it to the MATLAB path.

A board registration file contains a list of board plugins. A board plugin is a MATLAB package folder containing a board definition file and all the reference design plugins associated with the board.

This code describes the contents of a board registration file that contains SmartFusion2Registration board plugin to register the SmartFusion2 board in HDL Workflow Advisor. The function finds any registration file with the specified name on the MATLAB path and returns a cell array with the locations of the board plugins. The board plugin must be a package folder that is accessible from your MATLAB path containing a board definition file.

```
function r = hdlcoder_board_customization
% Board plugin registration file

r = { ...
    'SmartFusion2Registration.plugin_board', ...
    };
end
```

2. Create the board definition file.

A board definition file contains information about the SoC board.

Create a SmartFusion2 board definition file named `plugin_board.m` that resides inside the board plugin SmartFusion2Registration.

For information about the FPGA I/O pin locations ('FPGAPin') and standards ('IOSTANDARD'), see the SmartFusion2 constraints file from the Microchip website.

The property BoardName defines the name of the SmartFusion2 board in the HDL Workflow Advisor.

```
function hB = plugin_board()
% Board definition

% Construct board object
hB = hdlcoder.Board;

hB.BoardName = 'Microsemi SmartFusion2 SoC FPGA Advanced Development Kit';

% FPGA device information
hB.FPGAVendor = 'Microchip';
hB.FPGAFamily = 'SmartFusion2';
hB.FPGADevice = 'M2S150TS';
hB.FGPAPackage = '1152 FC';
hB.FPGASpeed = '-1';

% Tool information
hB.SupportedTool = {'Microchip Libero SoC'};

% FPGA JTAG chain position
hB.JTAGChainPosition = 2;

%% Add interfaces
% Standard "External Port" interface
hB.addExternalPortInterface( ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});

% Custom board external I/O interface
hB.addExternalIOInterface( ...
    'InterfaceID', 'LEDs General Purpose', ...
    'InterfaceType', 'OUT', ...
```

```

    'PortName', 'LEDs', ...
    'PortWidth', 8, ...
    'FPGAPin', {'D26', 'F26', 'A27', 'C26', 'C28', 'B27', 'C27', 'E26'}, ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});

hB.addExternalIOInterface( ...
    'InterfaceID', 'Push Buttons', ...
    'InterfaceType', 'IN', ...
    'PortName', 'PushButtons', ...
    'PortWidth', 4, ...
    'FPGAPin', {'J25', 'H25', 'J24', 'H23'}, ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS25'});

hB.addExternalIOInterface( ...
    'InterfaceID', 'Slide switches ', ...
    'InterfaceType', 'IN', ...
    'PortName', 'SlideSwitches', ...
    'PortWidth', 8, ...
    'FPGAPin', {'F25', 'G25', 'J23', 'J22', 'G27', 'H27', 'F23', 'G23'}, ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS25'});

```

Register Custom Reference Design in HDL Workflow Advisor

To register the custom reference design in HDL Workflow Advisor, follow these steps

1. Create a reference design registration file named `hdlcoder_ref_design_customization.m` containing a list of reference design plugins associated with an SoC board.

A reference design plugin is a MATLAB package folder containing the reference design definition file and all the files associated with the SoC design project. A reference design registration file must also contain the name of the associated board.

This code describes the contents of a SmartFusion2 reference design registration file containing the reference design plugin `SmartFusion2Registration.Libero_12_6` associated with the Microsemi SmartFusion2 SoC FPGA Advanced Development Kit board. The registration file finds files with the specified name inside a board plugin folder or on the MATLAB path. The function returns a cell array containing the locations of the reference design plugins and a character vector containing the associated board name. The reference design plugin must be a package folder that is accessible from the MATLAB path and must contain a reference design definition file.

```

function [rd,boardName] = hdlcoder_ref_design_customization
% Reference design plugin registration file

rd = {'SmartFusion2Registration.Libero_12_6.plugin_rd', ...
    };

boardName = 'Microsemi SmartFusion2 SoC FPGA Advanced Development Kit';
end

```

2. Create the reference design definition file.

A reference design definition file defines the interfaces between the custom reference design and the HDL IP core that you generate.

Create a SmartFusion2 reference design definition file `plugin_rd.m` to associate with the Microsemi SmartFusion2 SoC FPGA Advanced Development Kit board that resides inside the reference design plugin `SmartFusion2Registration.Libero_12_6`. The

ReferenceDesignName property defines the name of the reference design as Default system in HDL Workflow Advisor.

```
function hRD = plugin_rd()
% Reference design definition

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Microchip Libero SoC');

hRD.ReferenceDesignName = 'Default system';
hRD.BoardName = 'Microsemi SmartFusion2 SoC FPGA Advanced Development Kit';

% Tool information
hRD.SupportedToolVersion = {'12.0', '12.6', '2022.1'};

%% Add custom design files
% Add custom Libero design
hRD.addCustomLiberoDesign( ...
    'CustomBlockDesignTcl', 'design1_led.tcl');

% Add custom MSS Config
hRD.addCustomComponentFiles(...
    'CustomMSSCxfFile', 'SF2_MSS_MSS.cxf', ...
    'CustomMSSSdbFile', 'SF2_MSS_MSS.sdb');

%% Add interfaces
% Add clock interface
hRD.addClockInterface( ...
    'ClockConnection', 'FCCC_C0_0/GL0', ...
    'ResetConnection', 'SF2_MSS_MSS_0/MSS_RESET_N_M2F', ...
    'DefaultFrequencyMHz', 50, ...
    'MinFrequencyMHz', 5, ...
    'MaxFrequencyMHz', 500, ...
    'ClockModuleInstance', 'FCCC_C0_0', ...
    'ClockNumber', 1);

% Add AXI4 and AXI4-Lite slave interfaces
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'COREAXI4INTERCONNECT_C0_0/AXI4mslave0', ...
    'BaseAddress', '0xA0000000');

% Disable 'Generate Software Interface Model' task
hRD.HasProcessingSystem = false;
```

A reference design plugin must also contain the SoC design project files.

The SmartFusion2 reference design plugin folder SmartFusion2Registration.Libero_12_6 must contain the Tcl script design1_led.tcl exported from the Microchip Libero project. The SmartFusion2 reference design definition file plugin_rd.m identifies the SoC design project file by using the addCustomLiberoDesign function.

```
hRD.addCustomLiberoDesign('CustomBlockDesignTcl', 'design1_led.tcl');
```

The reference design definition file plugin_rd.m also defines the interface connections between the custom reference design and the HDL IP core by using the addClockInterface and addAXI4SlaveInterface functions:

```
hRD.addClockInterface( ...
    'ClockConnection', 'FCCC_C0_0/GL0', ...
```

```
'ResetConnection', 'SF2_MSS_MSS_0/MSS_RESET_N_M2F', ...
hRD.addAXI4SlaveInterface( ...
'InterfaceConnection', 'COREAXI4INTERCONNECT_C0_0/AXI4mslave0', ...
'BaseAddress', '0xA0000000');
```

Generate HDL IP core for SmartFusion2 Board

Use the custom board and reference design registration system to generate an HDL IP core that blinks LEDs on the SmartFusion2 board. The required files are in the `matlab/toolbox/hdlcoder/hdlcoderdemos/customboards/SmartFusion2` folder.

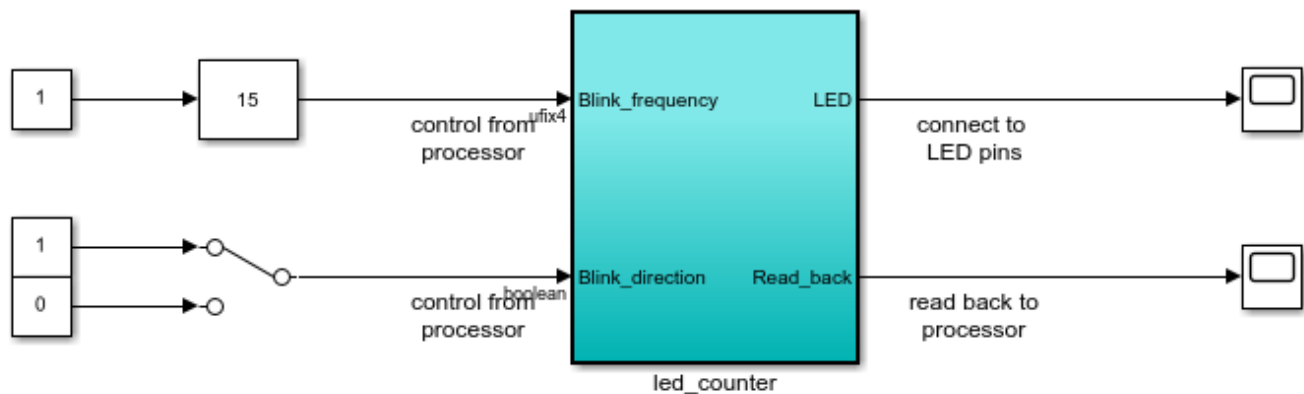

1. Add the SmartFusion2 board registration file to the MATLAB path.

```
addpath(fullfile(matlabroot,'toolbox','hdlcoder','hdlcoderdemos', ...
'customboards','SmartFusion2'));
```

2. Open the Simulink LED blinking model.

```
open_system('hdlcoder_led_blinking');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

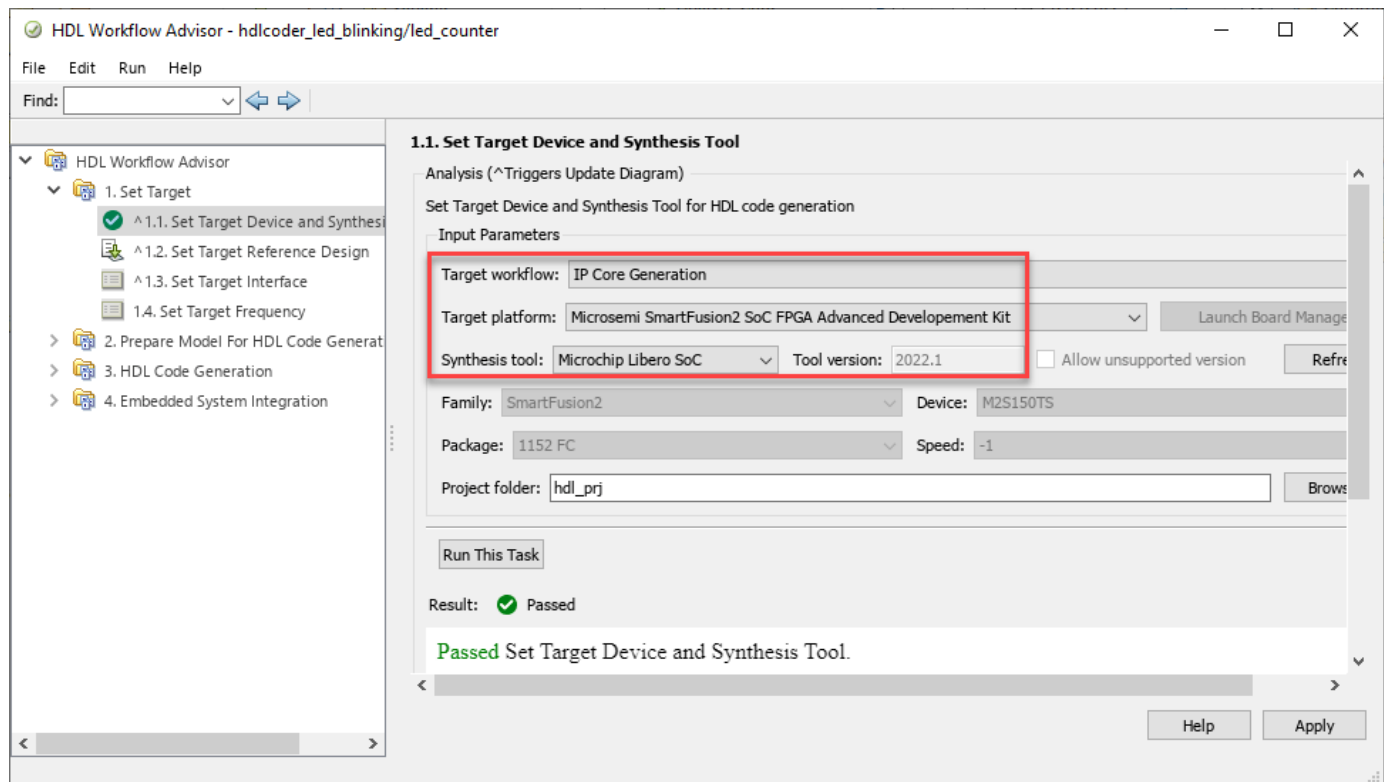

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor
Run Demo

Copyright 2012 The MathWorks, Inc.

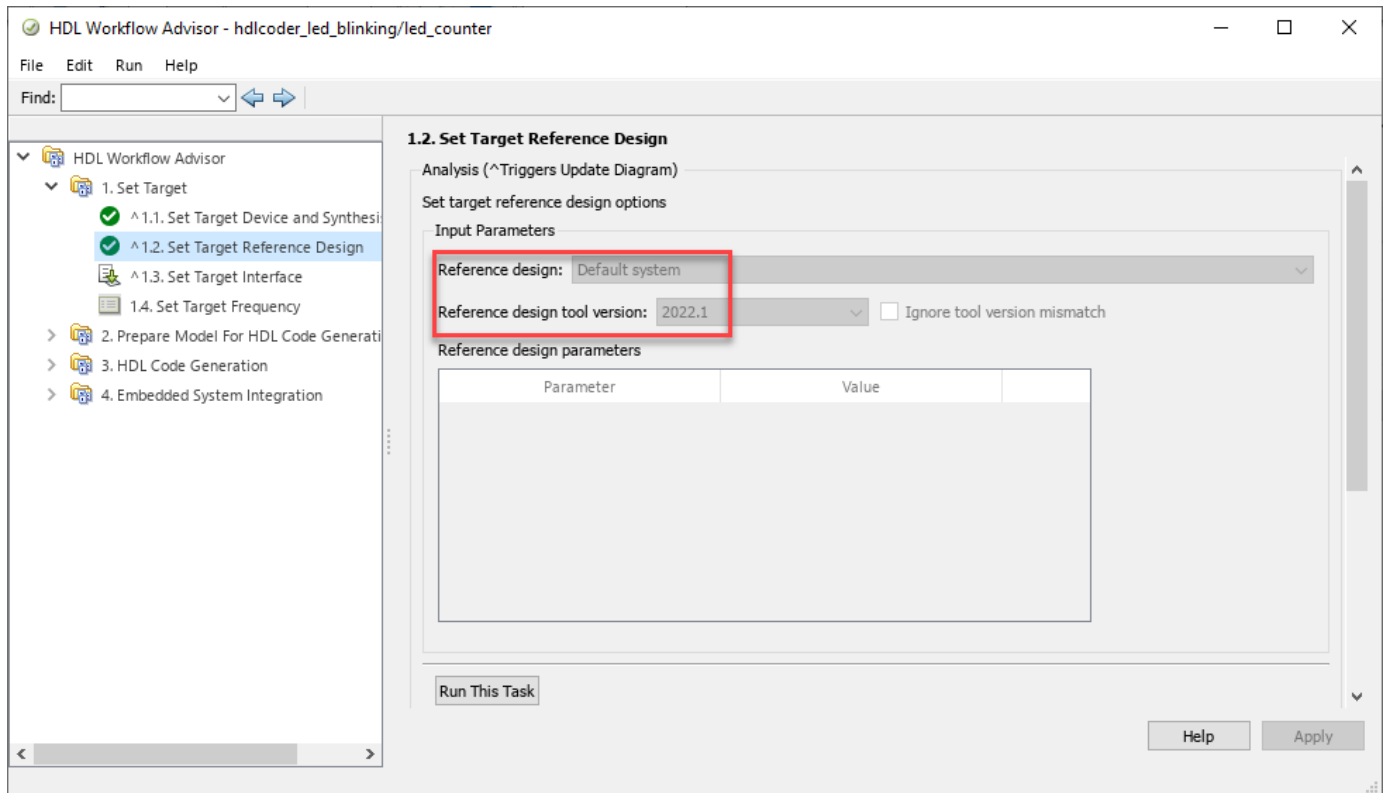

3. Launch the HDL Workflow Advisor from the `hdlcoder_led_blinking_4bit/led_counter` subsystem by right-clicking the `led_counter` subsystem, and hovering over **HDL Code**, and then clicking **HDL Workflow Advisor**. Alternatively, click the **Launch HDL Workflow Advisor** box in the model.

In the **Set Target > Set Target Device and Synthesis Tool** task, set **Target workflow** to IP Core Generation. In the **Target Platform** dropdown menu, select Microsemi SmartFusion2 SoC FPGA Advanced Development Kit.

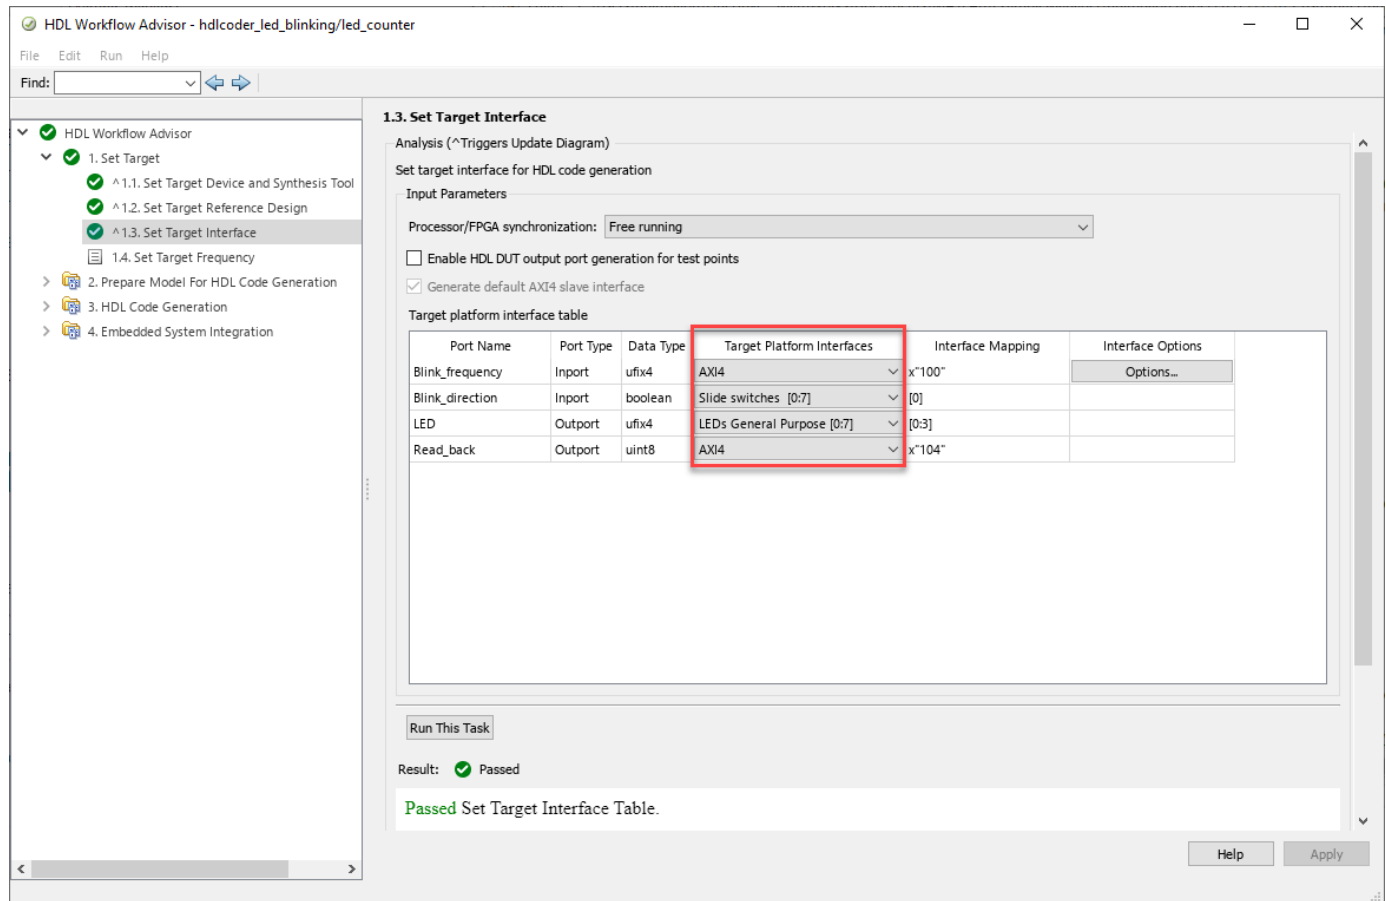

5. Click **Run This Task** to complete the **Set Target Device and Synthesis Tool** task.

6. In the **Set Target > Set Target Reference Design** task, set the **Reference design** field to **Default** system and click **Run This Task**.

7. In the **Set Target Interface** task, set the Target Platform Interface options and click **Run This Task**.

8. In the **Set Target Frequency** task, set **Target Frequency** to 50 MHz.

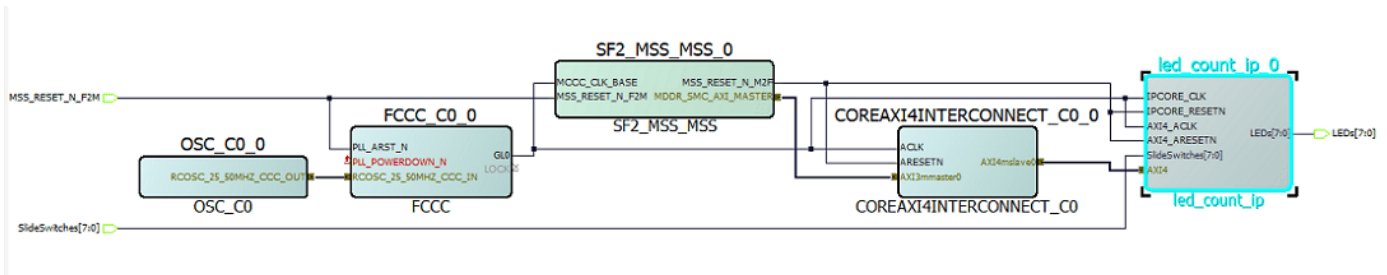

9. To generate the IP core and view the IP core generation report, right-click **Generate RTL Code and IP Core** and select **Run to Selected Task**. After you generate the custom IP core, the IP core files are in the `ipcore` folder within your project folder. An HTML custom IP core report is generated with the custom IP core. The report describes the behavior and contents of the generated custom IP core.

10. To integrate the IP core into the reference design and create the Libero project, follow step 1 of the **Integrate IP Core with Microsemi Libero SoC Environment** section in “Integrate HDL IP Core with Microchip PolarFire SoC Icicle Kit Reference Design” on page 46-155.

11. After completing the **Create Project** task under **Embedded System Integration**, examine the Microchip Libero SoC project. This figure shows the block design of the SoC project when you highlight the HDL IP Core. Compare this block design with the previous block design used to export the custom reference design for a deeper understanding of the relationship between a custom reference design and an HDL IP Core.

12. Follow steps 2 and 3 of the **Integrate IP Core with Microsemi Libero SoC Environment** section of “Integrate HDL IP Core with Microchip PolarFire SoC Icicle Kit Reference Design” on page 46-155 to generate the FPGA bitstream and program the target device, respectively.

13. After you load the bitstream, the LEDs on the SmartFusion2 board start blinking. You can change the direction of LED blinking by pressing **Slide Switch[0]**.

Define Custom Board and Reference Design for Microchip Pure FPGA Platforms

This example shows how to define and register a Pure FPGA boards and reference design for a LED blinking model in the IP Core Generation workflow of the HDL Workflow Advisor. You use a Microchip PolarFire® board, but you can define and register a custom board or a custom reference design for other Microchip platforms.

Requirements

To run this example, you need access to:

- A Microchip Libero SoC Design Suite. For a list of supported versions, see “HDL Language Support and Supported Third-Party Tools and Hardware”.
- A Microchip PolarFire Splash Kit.
- HDL Coder Support Packages for Microchip FPGA and SoC Devices

Set Up PolarFire Splash board

To familiarize yourself with the features of the PolarFire Splash kit, see the PolarFire Splash Kit Reference Manual. To set up your PolarFire Splash kit, follow these steps.

1. Install the USB COM port device drivers on your computer.
2. Connect the shared UART/JTAG USB port on the PolarFire Splash kit to your computer.
3. Download and install **HDL Coder Support Package for Microchip and SoC devices**. To access the hardware support package, in the **Home** tab of your MATLAB session, click **Add-Ons** and then click **Get Hardware Support Packages**.
4. Set up the Microchip Libero tool path by using the `hdlsetuptoolpath` function. For example, to set up the Microchip Libero SoC tool, specify `ToolName` as `Microchip Libero SoC` and `ToolPath` as your installed Libero executable path.

```
hdlsetuptoolpath('ToolName', 'Microchip Libero SoC', ...  
                'ToolPath', 'C:\Microsemi\Libero_SoC_v2022.1\Designer\bin\libero.exe');
```

Create and Export Custom Reference Design by Using Microchip Libero SoC

A reference design captures the complete structure of an SoC design, defining the different components and their interconnections. Use the HDL Coder Reference Design workflow in the HDL Workflow Advisor to generate an IP core that integrates with the reference design and program FPGA board. This figure shows the relationship between a reference design, an HDL IP core, and FPGA board.

To create and export a reference design by using the Microchip Libero Tool environment, follow these steps.

1. Create an empty Microchip Libero project by using below settings for PolarFire family and Click **Next**. Click **Finish** to create a new Libero project.

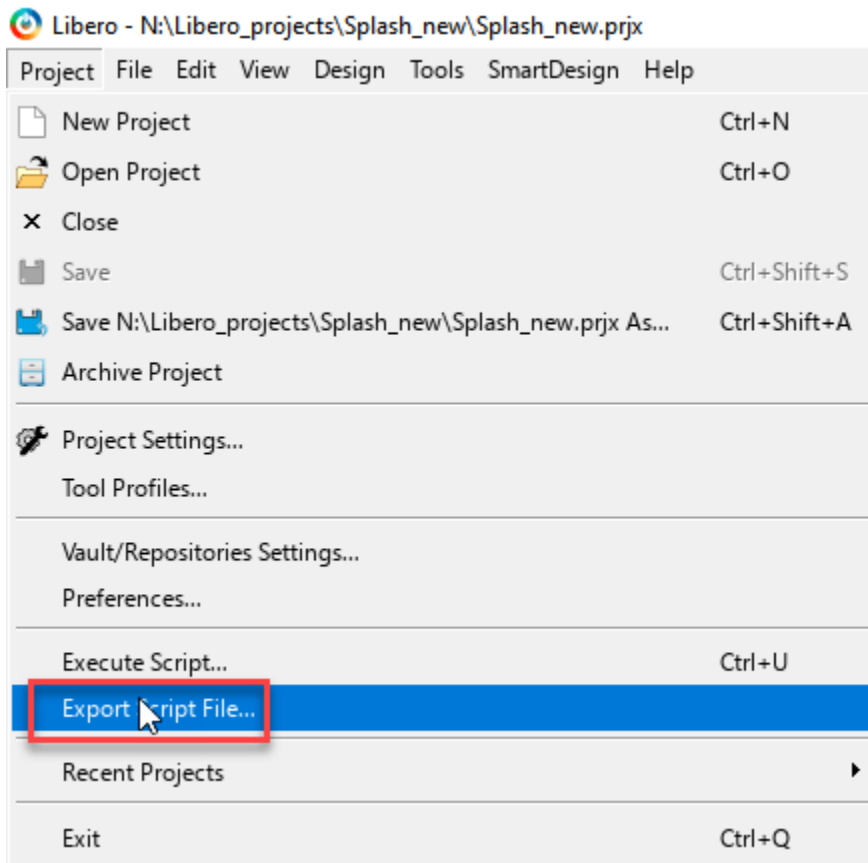

2. Create new Smartdesign from **Design Flow** tab.

3. Add **PF_OSC_C0**, **PF_CCC_C0**, **CORERESET_PF_C0** and **PF_INIT_MONITOR_C0** IP's from IP Catalog to **Libero_sd** and make connections as shown below.

4. Export the completed block design as a Tcl script with the name `design1_led.tcl`.

The exported Tcl script (`design1_led.tcl`) constitutes the custom reference design. You use this reference design in the HDL Coder Reference Design workflow of the HDL Workflow Advisor to recreate the block design and integrate the generated HDL IP core with the block design in a Microchip Libero project.

Register PolarFire Splash Board in HDL Workflow Advisor

To register the PolarFire Splash Kit in the HDL Workflow Advisor, follow these steps,

1. Create a board registration file with the name `hdlcoder_board_customization` and add it to the MATLAB path.

A board registration file contains a list of board plugins. A board plugin is a MATLAB package folder containing a board definition file and all the reference design plugins associated with the board.

This code describes the contents of a board registration file that contains `PolarFireRegistration` board plugin to register the PolarFire Splash Kit in HDL Workflow Advisor. The function finds any registration file with the specified name on the MATLAB path and returns a cell array with the locations of the board plugins. The board plugin must be a package folder that is accessible from your MATLAB path containing a board definition file.

```
function r = hdlcoder_board_customization
% Board plugin registration file

r = { ...
    'PolarFireRegistration.plugin_board', ...
```

```
    };
end
```

2. Create the board definition file.

A board definition file contains information about the FPGA board.

Create a PolarFire Splash board definition file named `plugin_board.m` that resides inside the board plugin `PolarFireRegistration`.

For information about the FPGA I/O pin locations ('FPGAPin') and standards ('IOSTANDARD'), see the PolarFire Splash Kit constraints file from the Microchip website.

The property `BoardName` defines the name of the PolarFire board which will appear in the HDL Workflow Advisor.

```
function hB = plugin_board()
% Board definition

% Construct board object
hB = hdlcoder.Board;

hB.BoardName    = 'Microchip PolarFire Splash Kit (ES)';

% FPGA device information
hB.FPGAVendor   = 'Microchip';
hB.FPGAFamily   = 'PolarFire';
hB.FPGADevice   = 'MPF300TS_ES';
hB.FGAPackage   = 'FCG484';
hB.FGASpeed     = '-1';

% Tool information
hB.SupportedTool = {'Microchip Libero SoC'};

% FPGA JTAG chain position
hB.JTAGChainPosition = 2;

% Add interfaces
% Standard "External Port" interface
hB.addExternalPortInterface( ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});

% Custom board external I/O interface
hB.addExternalIOInterface( ...
    'InterfaceID',    'LEDs General Purpose', ...
    'InterfaceType', 'OUT', ...
    'PortName',      'LEDs', ...
    'PortWidth',     8, ...
    'FPGAPin',       {'P7', 'P8', 'N7', 'N8', 'N6', 'N5', 'M8', 'M9'}, ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});

hB.addExternalIOInterface( ...
    'InterfaceID',    'Push Buttons', ...
    'InterfaceType', 'IN', ...
    'PortName',      'PushButtons', ...
    'PortWidth',     4, ...
    'FPGAPin',       {'L6', 'M7', 'K5', 'K4'}, ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS33'});
```

```
hB.addExternalIIOInterface( ...
    'InterfaceID', 'Slide switches ', ...
    'InterfaceType', 'IN', ...
    'PortName', 'SlideSwitches', ...
    'PortWidth', 4, ...
    'FPGAPin', {'L3', 'M4', 'J6', 'K6'}, ...
    'IOPadConstraint', {'IOSTANDARD = LVCMOS25'});
```

Register Custom Reference Design in HDL Workflow Advisor

To register the custom reference design in HDL Workflow Advisor, follow these steps

1. Create a reference design registration file named `hdlcoder_ref_design_customization.m` containing a list of reference design plugins associated with an SoC board.

A reference design plugin is a MATLAB package folder containing the reference design definition file and all the files associated with the FPGA design project. A reference design registration file must also contain the name of the associated board.

This code describes the contents of a PolarFire Splash reference design registration file containing the reference design plugin `PolarFireRegistration.Libero_12_6` associated with the Microchip PolarFire Splash Kit (ES) board. The registration file finds files with the specified name inside a board plugin folder or on the MATLAB path. The function returns a cell array containing the locations of the reference design plugins and a character vector containing the associated board name. The reference design plugin must be a package folder that is accessible from the MATLAB path and must contain a reference design definition file.

```
function [rd,boardName] = hdlcoder_ref_design_customization
% Reference design plugin registration file

rd = {'PolarFireRegistration.Libero_12_6.plugin_rd', ...
    };

boardName = 'Microchip PolarFire Splash Kit (ES)';
end
```

2. Create the reference design definition file.

A reference design definition file defines the interfaces between the custom reference design and the HDL IP core that you generate.

Create a PolarFire reference design definition file `plugin_rd.m` to associate with the Microchip PolarFire Splash Kit (ES) board that resides inside the reference design plugin `PolarFireRegistration.Libero_12_6`. The `ReferenceDesignName` property defines the name of the reference design as `Default system` in HDL Workflow Advisor.

```
function hRD = plugin_rd()
% Reference design definition

% Construct reference design object
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Microchip Libero SoC');

hRD.ReferenceDesignName = 'Default system';
hRD.BoardName = 'Microchip PolarFire Splash Kit (ES)';

% Tool information
hRD.SupportedToolVersion = {'12.0', '12.6', '2022.1'};
```

```

% Add custom design files
% add custom Libero design
hRD.addCustomLiberoDesign( ...
    'CustomBlockDesignTcl', 'design1_led.tcl');

% Add interfaces
% add clock interface
hRD.addClockInterface( ...
    'ClockConnection',    'PF_CCC_C0_0/OUT0_FABCLK_0', ...
    'ResetConnection',   'CORERESET_PF_C0_0/FABRIC_RESET_N',...
    'DefaultFrequencyMHz', 50,...
    'MinFrequencyMHz',    5,...
    'MaxFrequencyMHz',    500,...
    'ClockModuleInstance', 'PF_CCC_C0_0',...
    'ClockModuleComponent', 'PF_CCC_C0_0',...
    'ClockNumber',        1);

% disable 'Generate Software Interface Model' task
hRD.HasProcessingSystem = false;

```

A reference design plugin must also contain the FPGA design project files.

The PolarFire reference design plugin folder `PolarFireRegistration.Libero_12_6` must contain the Tcl script `design1_led.tcl` exported from the Microchip Libero project. The PolarFire reference design definition file `plugin_rd.m` identifies the FPGA design project file by using the `addCustomLiberoDesign` function.

```
hRD.addCustomLiberoDesign('CustomBlockDesignTcl', 'design1_led.tcl');
```

The reference design definition file `plugin_rd.m` also defines the interface connections between the custom reference design and the HDL IP core by using the `addClockInterface` function:

```
hRD.addClockInterface( ...
    'ClockConnection',    'PF_CCC_C0_0/OUT0_FABCLK_0', ...
    'ResetConnection',   'CORERESET_PF_C0_0/FABRIC_RESET_N',...

```

Generate HDL IP core for PolarFire Splash Kit

Use the custom board and reference design registration system to generate an HDL IP core that blinks LEDs on the PolarFire Splash Kit. The required files are in the `matlab/toolbox/hdlcoder/hdlcoderdemos/customboards/PolarFire` folder.

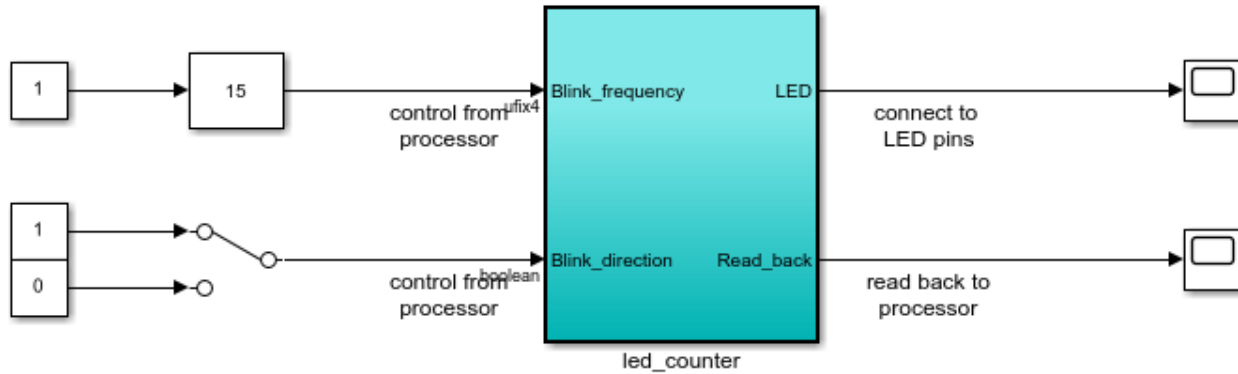

1. Add the PolarFire board registration file to the MATLAB path.

```
addpath(fullfile(matlabroot,'toolbox','hdlcoder','hdlcoderdemos', ...
    'customboards','PolarFire'));
```

2. Open the Simulink LED blinking model.

```
open_system('hdlcoder_led_blinking');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2014 The MathWorks, Inc.

3. Launch the HDL Workflow Advisor from the `hdlcoder_led_blinking/led_counter` subsystem by right-clicking the `led_counter` subsystem, and hovering over **HDL Code**, and then clicking **HDL Workflow Advisor**. Alternatively, click the **Launch HDL Workflow Advisor** box in the model.

In the **Set Target > Set Target Device and Synthesis Tool** task, set **Target workflow** to IP Core Generation. In the **Target Platform** dropdown menu, select Microchip PolarFire Splash Kit (ES).

5. Click **Run This Task** to complete the **Set Target Device and Synthesis Tool** task.

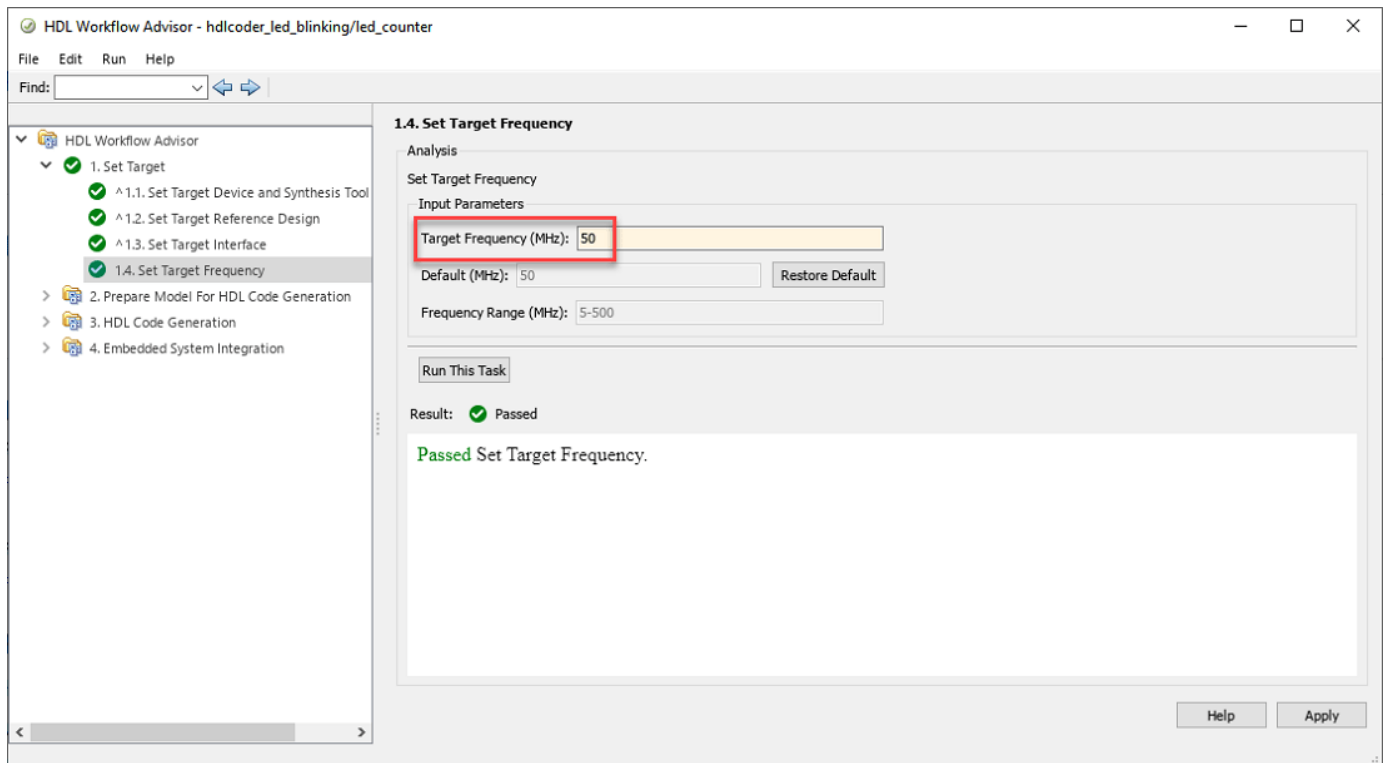

6. In the **Set Target > Set Target Reference Design** task, set the **Reference design** field to **Default** system and click **Run This Task**.

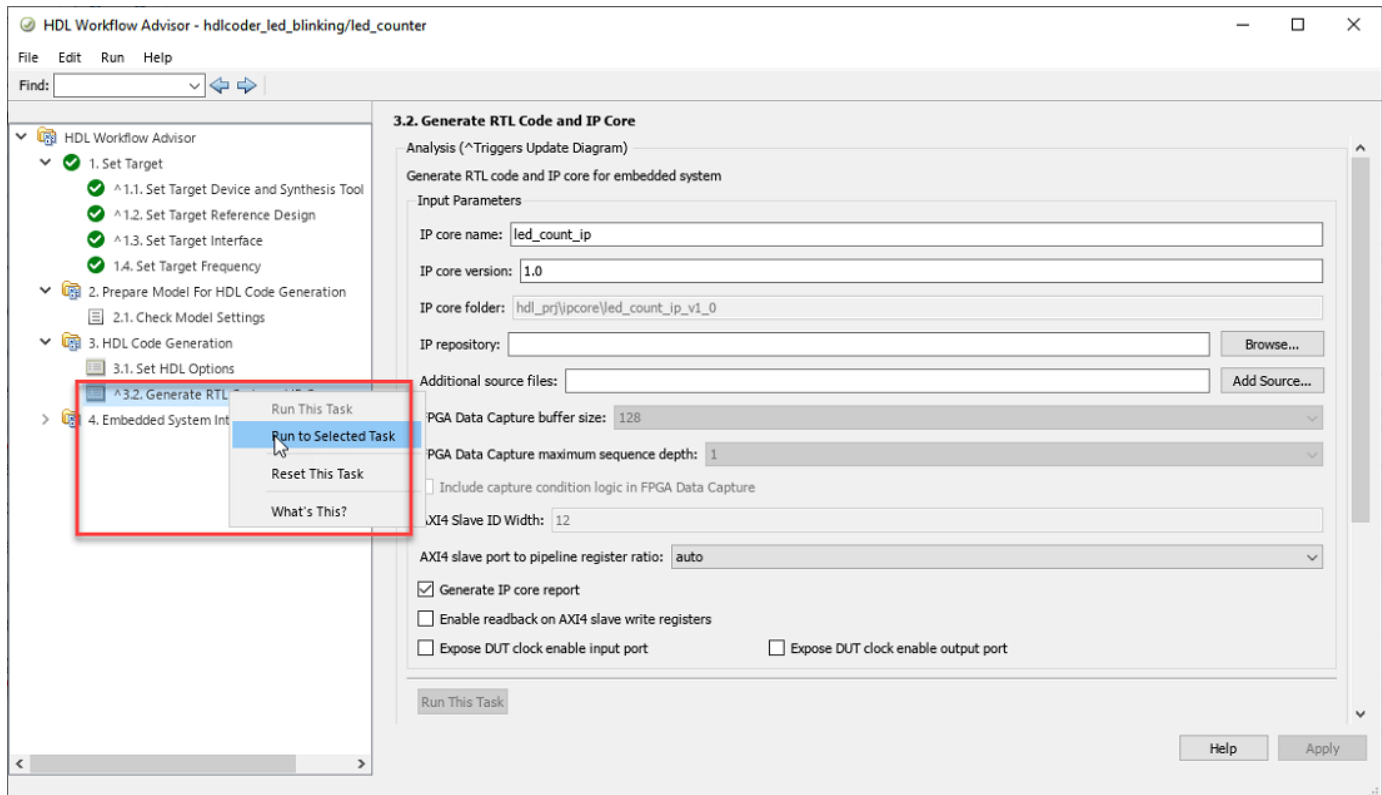

7. In the **Set Target Interface** task, set the Target Platform Interface options and click **Run This Task**.

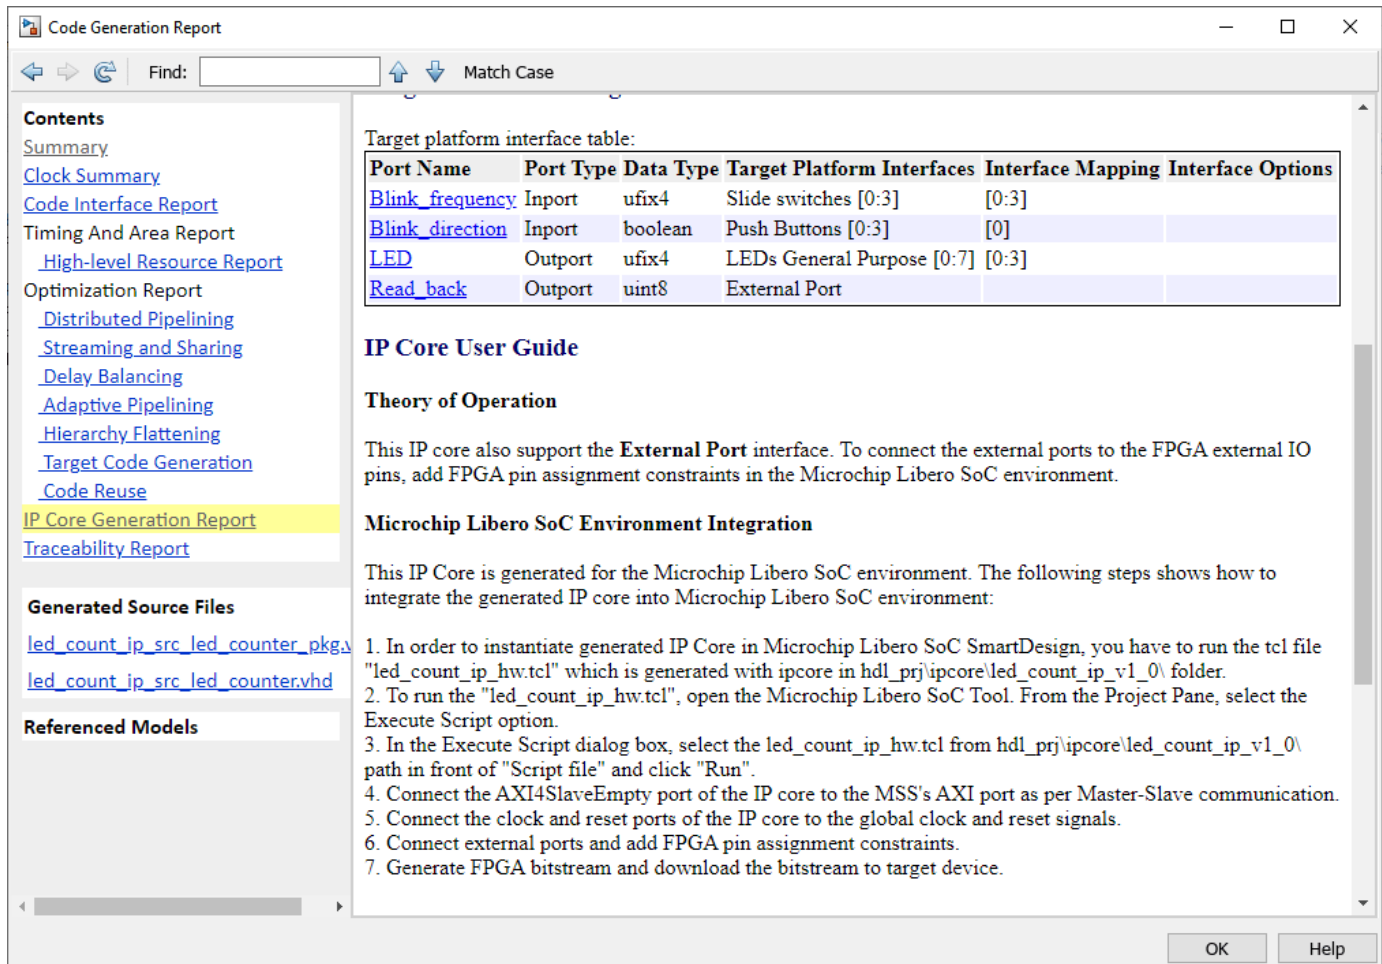

8. In the **Set Target Frequency** task, set **Target Frequency** to 50 MHz.

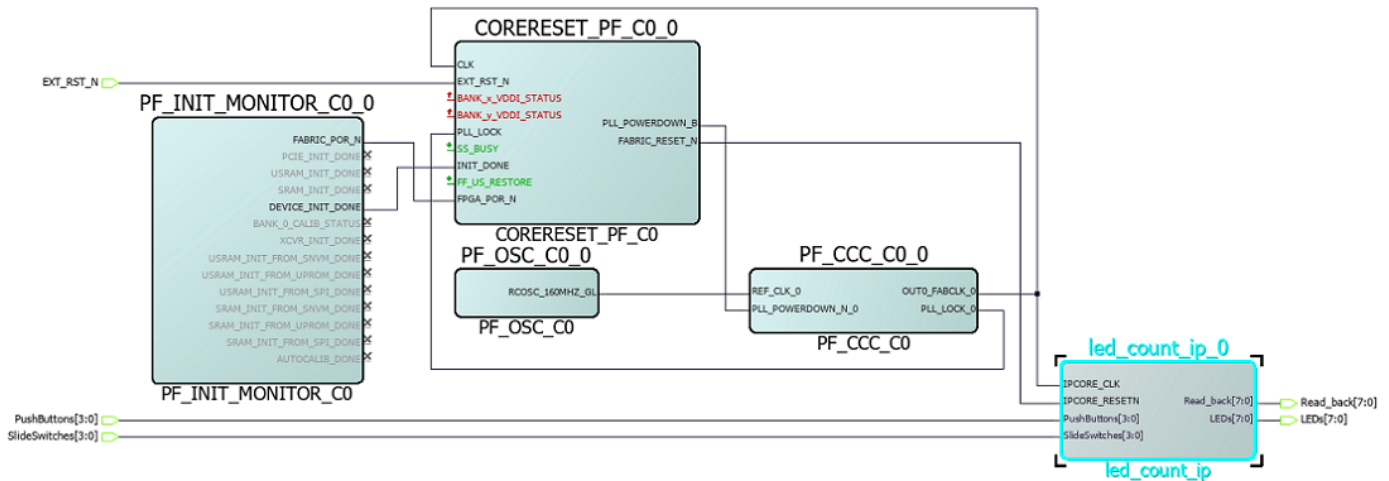

9. To generate the IP core and view the IP core generation report, right-click **Generate RTL Code and IP Core** and select **Run to Selected Task**. After you generate the custom IP core, the IP core files are in the `ipcore` folder within your project folder. An HTML custom IP core report is generated with the custom IP core. The report describes the behavior and contents of the generated custom IP core.

10. To integrate the IP core into the reference design and create the Libero project, follow step 1 of the **Integrate IP Core with Microsemi Libero SoC Environment** section in "Integrate HDL IP Core with Microchip PolarFire SoC Icicle Kit Reference Design" on page 46-155.

11. After completing the **Create Project** task under **Embedded System Integration**, examine the Microchip Libero SoC project. This figure shows the block design of the FPGA project when you highlight the HDL IP Core. Compare this block design with the previous block design used to export the custom reference design for a deeper understanding of the relationship between a custom reference design and an HDL IP Core.

12. Follow steps 2 and 3 of the **Integrate IP Core with Microsemi Libero SoC Environment** section of “Integrate HDL IP Core with Microchip PolarFire SoC Icicle Kit Reference Design” on page 46-155 to generate the FPGA bitstream and program the target device, respectively.

13. After you load the bitstream, the LEDs on the PolarFire Splash Kit start blinking. You can change the direction of LED blinking by pressing **Push Buttons[0]**.

Dynamically Create Reference Design with Master Only or Slave Only AXI4-Stream Interface

This example illustrates how to customize the reference design dynamically by using a callback function based on the reference design parameter options. Also, this example shows how you can customize the number of AXI4-Stream interface channels in your reference design to be Only AXI4-Stream Master interface, Only AXI4-Stream Slave interface or both the interfaces.

Prerequisites

To run this example, you must have the following software and hardware installed and set up:

- HDL Coder Support Package for Xilinx Zynq Platform
- Embedded Coder Support Package for Xilinx Zynq Platform
- Xilinx Vivado Design Suite, with supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Xilinx Zynq-7000 SoC ZC706 Evaluation Kit
- Latest SD image from ECoder support package setup wizard

Introduction

Instead of creating multiple reference designs that have different interface choices, data widths, or I/O plugins now you have an option of creating one reference design that has different interface choices or data widths as parameters. You can use the `CustomizeReferenceDesignFcn` method to reference the callback function that has different choices for interfaces or data widths in your reference design. For example, you can create one reference design and select the reference design parameter choice that has only AXI4-Stream Master or only AXI4-Stream Slave or both AXI4-Stream Master and AXI4-Stream Slave interfaces instead of creating three separate reference designs.

Create Reference Design Definition File and Callback Function

For this demo, you can consider Xilinx Zynq ZC706 AXI4-Stream reference design which consists of two Xilinx AXI DMAs to handle the data transfer from Processor to FPGA and vice versa using AXI4-Stream Master and Slave interfaces. In this example you customize the number of AXI4-Stream interface channels with a single reference design by creating a callback function. The different interface channels in the callback code shown below uses the different device tree. Similarly, you can modify your created reference design definition file to select different reference design parameter choices using the callback function.

The picture below shows the **Stream_Channel** reference design parameter and interface choices for the **AXI4-Stream interface with Stream channel Selection** reference design specified by using the `addParameter` method. The `CustomizeReferenceDesignFcn` method references a callback function that has the name `callback_CustomizeReferenceDesign`.

```

function hRD = plugin_rd()
hRD = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');
hRD.ReferenceDesignName = 'AXI4-Stream interface with Stream channel Selection';
hRD.BoardName = 'Xilinx Zynq ZC706 evaluation kit';
% Tool information
hRD.SupportedToolVersion = {'2018.2','2018.3','2019.1','2019.2'};
% add clock interface
hRD.addClockInterface( ...
    'ClockConnection',    'core_clkwiz/clk_out1', ...
    'ResetConnection',    'sys_core_rstgen/peripheral_aresetn',...
    'DefaultFrequencyMHz', 50,...
    'MinFrequencyMHz',    5,...
    'MaxFrequencyMHz',    500,...
    'ClockModuleInstance', 'core_clkwiz',...
    'ClockNumber',        1);
% add AXI4 and AXI4-Lite slave interfaces
hRD.addAXI4SlaveInterface( ...
    'InterfaceConnection', 'axi_cpu_interconnect/M00_AXI', ...
    'BaseAddress',         '0x40010000', ...
    'MasterAddressSpace',  'sys_cpu/Data');
hRD.addParameter( ...
    'ParameterID',        'StreamChanel', ...
    'DisplayName',        'Stream Channel', ...
    'DefaultValue',       'Both Master & Slave', ...
    'ParameterType',      hdlcoder.ParameterType.Dropdown, ...
    'Choice',             {'Master Only','Slave Only','Both Master & Slave'});
hRD.CustomizeReferenceDesignFcn = ...
    @Stream_ChannelSelection.callback_CustomizeReferenceDesign;

```

The code below shows the callback function `callback_CustomizeReferenceDesign` that has the AXI4-Stream Master or Slave Channels or both channels specified by using the `addAXI4StreamInterface` method. The `DeviceTreeName` method shown below in the callback is to specify the device tree file, which is different for different stream channels.

```

function callback_CustomizeReferenceDesign(infoStruct)
% Reference design callback run at the end of the task Set Target Reference Design

% infoStruct: information in structure format
% infoStruct.ReferenceDesignObject: current reference design registration object
% infoStruct.BoardObject: current board registration object
% infoStruct.ParameterStruct: custom parameters of the current reference design, in struct format

    'SlaveChannelConnection', 'axi_dma_mm2s/M_AXIS_MM2S', ...
    'SlaveChannelDataWidth', 32, ...
    'HasDMAConnection',      true);
hRD.DeviceTreeName = 'devicetree_axistream_SlaveOnly_io.dtb';
end
end

```

So, create the callback function like as shown above and pass the infoStruct argument to the callback function. The argument contains reference design customization information in a structure format. Save the created callback function in the reference design folder like as shown below or you can save anywhere and add the file to MATLAB path.

Generate HDL IP core with Only AXI4-Stream Master/Only AXI4-Stream Slave Interface

1. Set up the Xilinx Vivado synthesis tool path using the following command in the MATLAB command window. Use your own Vivado installation path when you run the command.

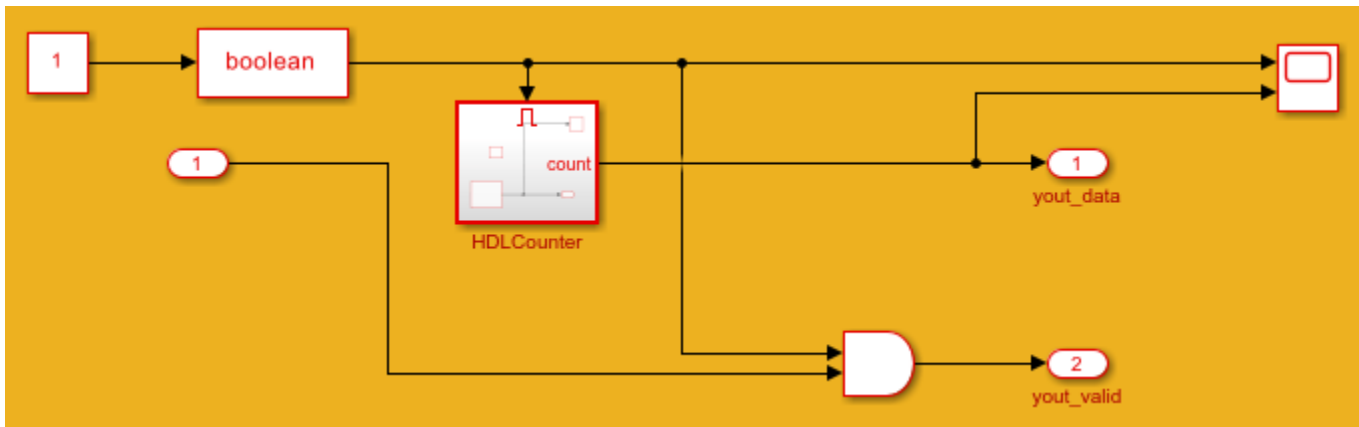

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2019.2\bin\vivado.ba
```

2. Add the demo reference design folder to the MATLAB path using following command:

```
unzip('ZC706.zip');
addpath(genpath('ZC706'));
```

3. Open AXI4-Stream Master only model using following command:

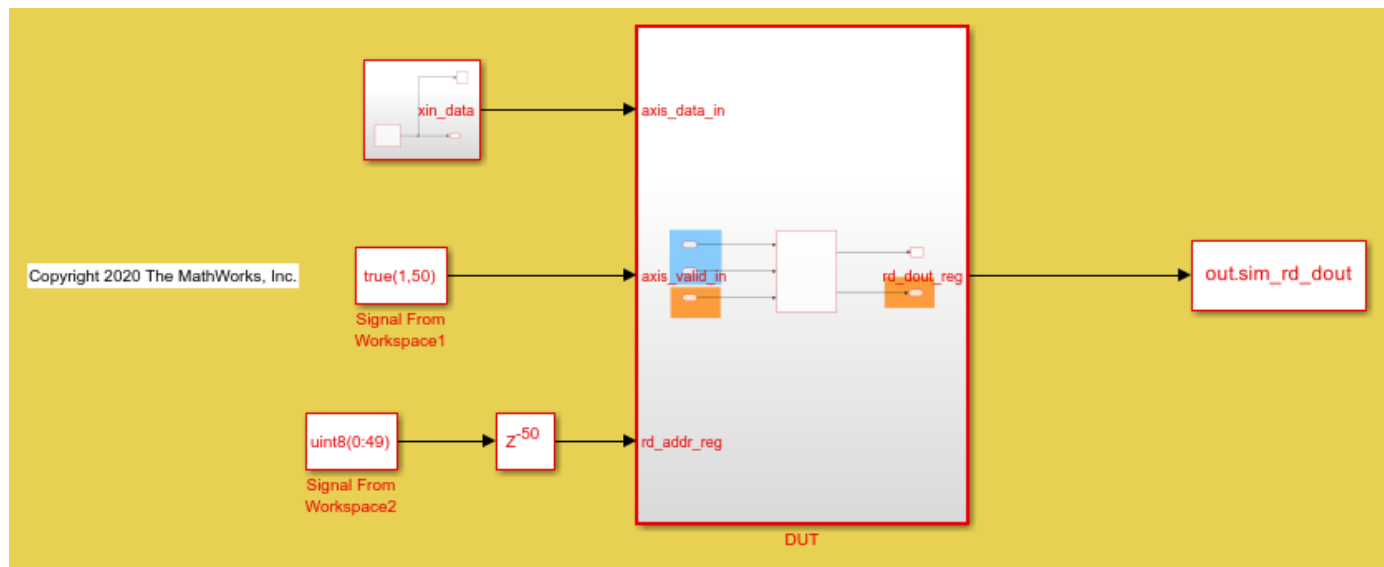

```
open_system('hdlcoder_AXI4StreamMaster');
```

The **DUT** is the hardware subsystem targeting the FPGA fabric. Inside this DUT, the **HDL Counter** subsystem acts as master. This counter counts from 1 to 50 and is connected to **yout_data** output signal which is mapped to AXI4-Stream master interface.

You can also use AXI4 Slave only model. Use the following command to open the model:

```
open_system('hdlcoder_AXI4StreamSlave');
```

As shown above **DUT** has a **Dual Port RAM** which acts as slave and receives data using AXI4-Stream Slave interface through **axis_data_in** input signal.

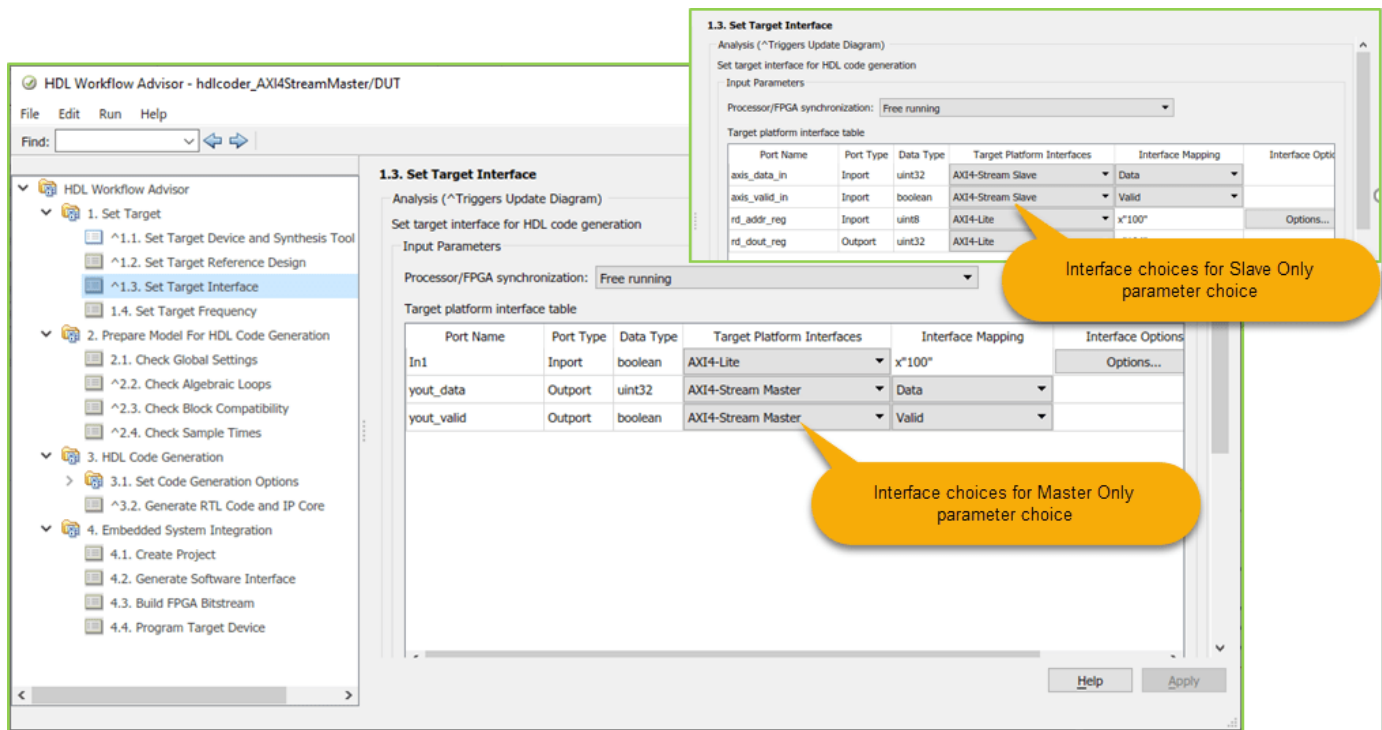

4. Start the HDL Workflow Advisor from the DUT subsystem, `hdlcoder_AXI4StreamMaster/DUT` for AXI4-Stream Master only demo. Similarly Open HDL Workflow Advisor from the DUT subsystem, `hdlcoder_AXI4StreamSlave/DUT` for AXI4-Stream Slave only demo.

The target interface settings are already saved for **ZC706** in these models, so the settings in Task 1.1 to 1.3 are automatically loaded. In Task 1.1, **IP Core Generation** is selected for Target workflow, and **Xilinx Zynq ZC706 evaluation kit** is selected for Target platform. In task 1.2, **AXI4-Stream interface with Stream channel Selection** is selected for reference design. Select **Stream Channel** reference design parameter choice as **Master Only** for AXI4-Stream Master only demo and choose **Slave Only** as parameter choice for AXI4-Stream Slave only demo.

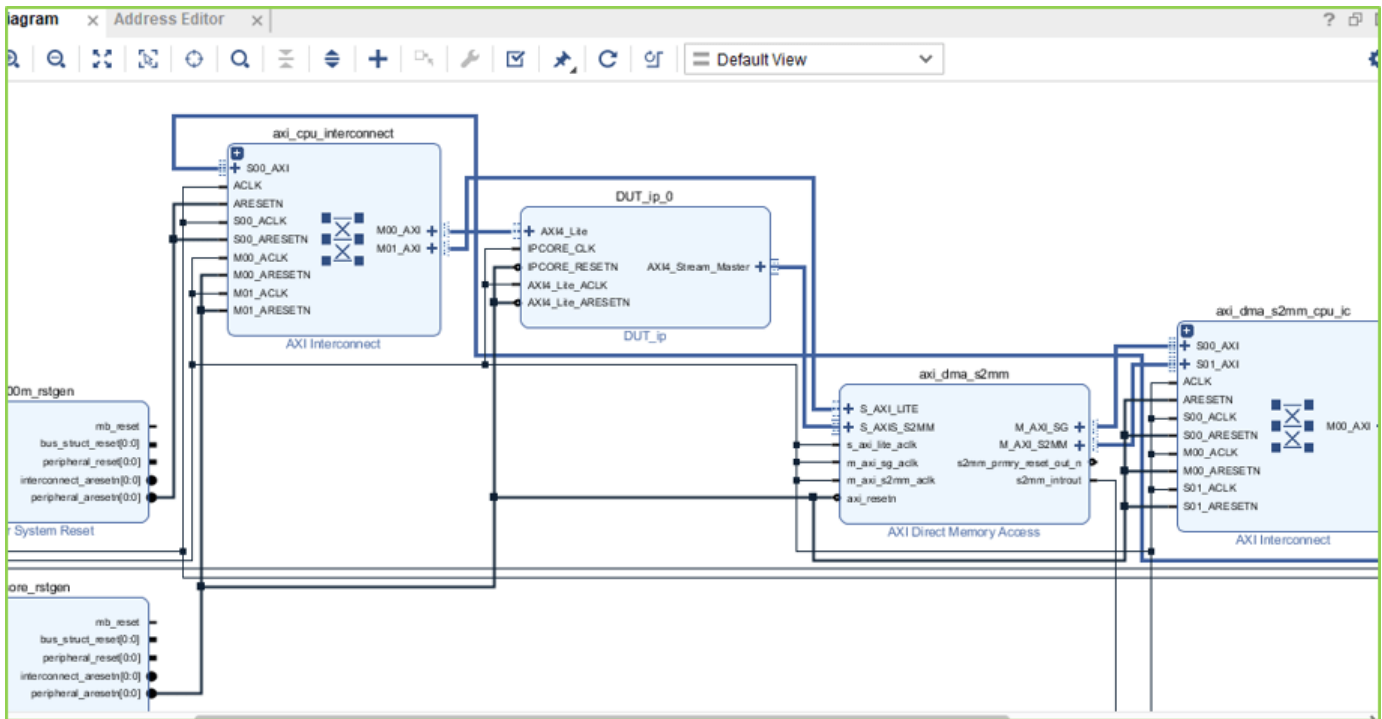

As shown in the figure above you can customize the reference design to Only AXI4-Stream Master or Only Slave or both AXI4-Stream Master and Slave by selecting the **Stream Channel** reference design parameter choice. Callback function with corresponding Tcl gets evaluated at the end of the **Set Target Reference Design** task.

5. If the parameter choice selected as **Master Only**, then the interface choice in task 1.3 shows as **AXI4 Stream Master**. Here, the AXI4-Stream interface communicates in master mode and sends data to AXI4_Stream Slave IP through **yout_data** signal. Similarly, If **Slave Only** parameter choice is selected, then the interface choice shows as **AXI4 Stream Slave**. Where, the AXI4-Stream interface communicates in slave mode and receives data through **axis_data_in** signal as shown below.

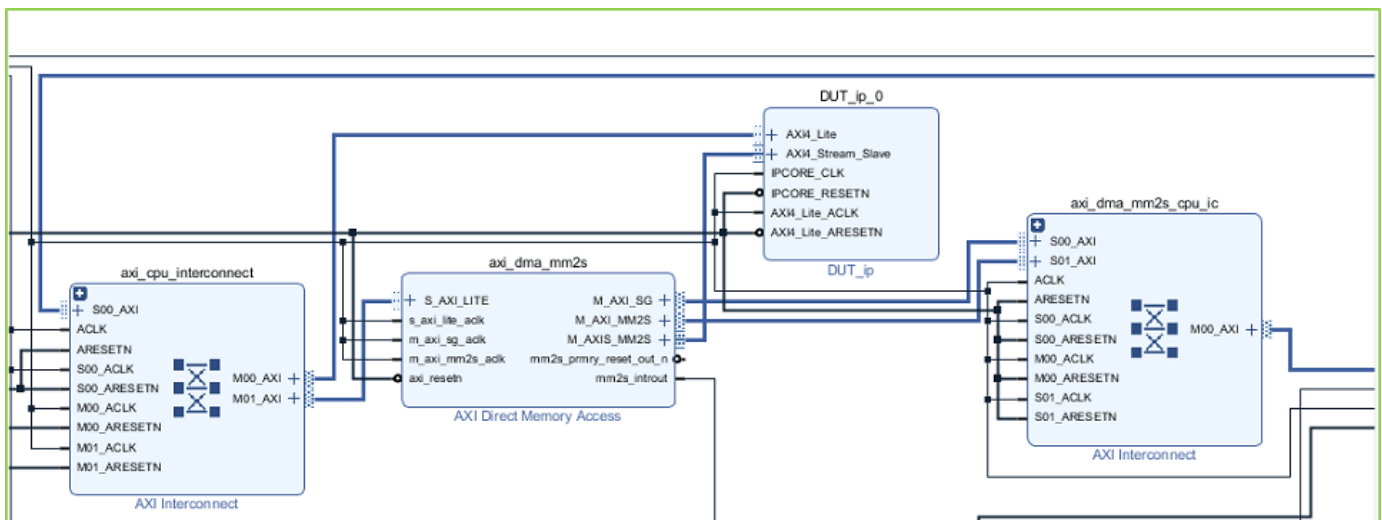

6. Right-click task 4.1, **Create Project**, and select **Run to Selected Task** to insert the generated IP core into the **AXI4-Stream interface with Stream channel Selection** reference design. The reference design contains Xilinx AXI DMA IP to handle the data streaming between FPGA fabric and processor or vice versa based on the reference design interface either Only AXI4-Stream master or only AXI4-Stream Slave.

Following diagram shows the generated vivado project with **AXI4-Stream Master only** interface choice, and you can see the connection between HDL coder generated DUT IP and slave to memory mapped Xilinx AXI DMA IP. In this reference design, DMA Controller reads the data from FPGA IP.

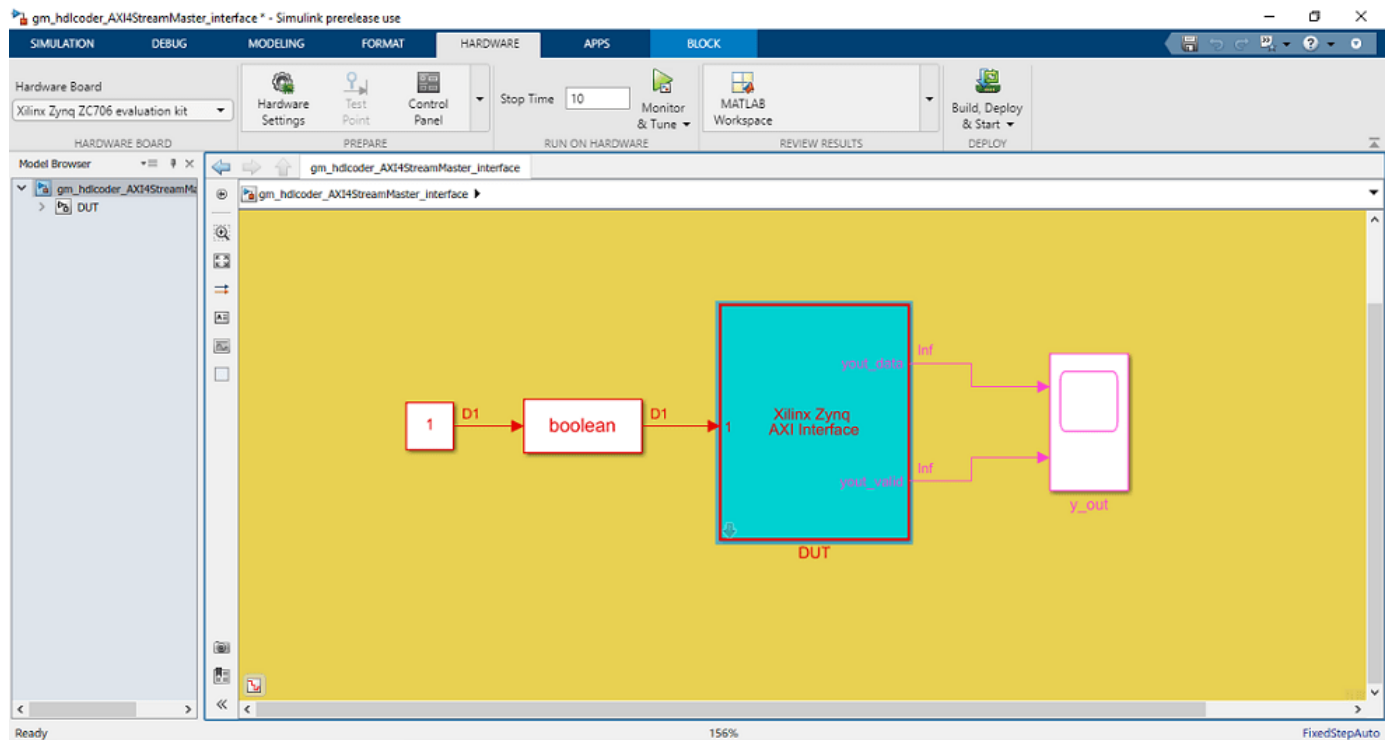

Similarly, following diagram shows the generated vivado project with **AXI4-Stream Slave only** interface choice, where the FPGA IP receives streaming data from DMA Controller.

7. In the HDL Workflow Advisor, run the rest of the tasks to generate the software interface model, and build and download the FPGA bitstream.

Generate ARM executable Using AXI4-Stream Driver Block for AXI4-Stream Master only reference design

A software interface model is generated in Task 4.2, **Generate Software Interface Model**, as shown in the following picture.

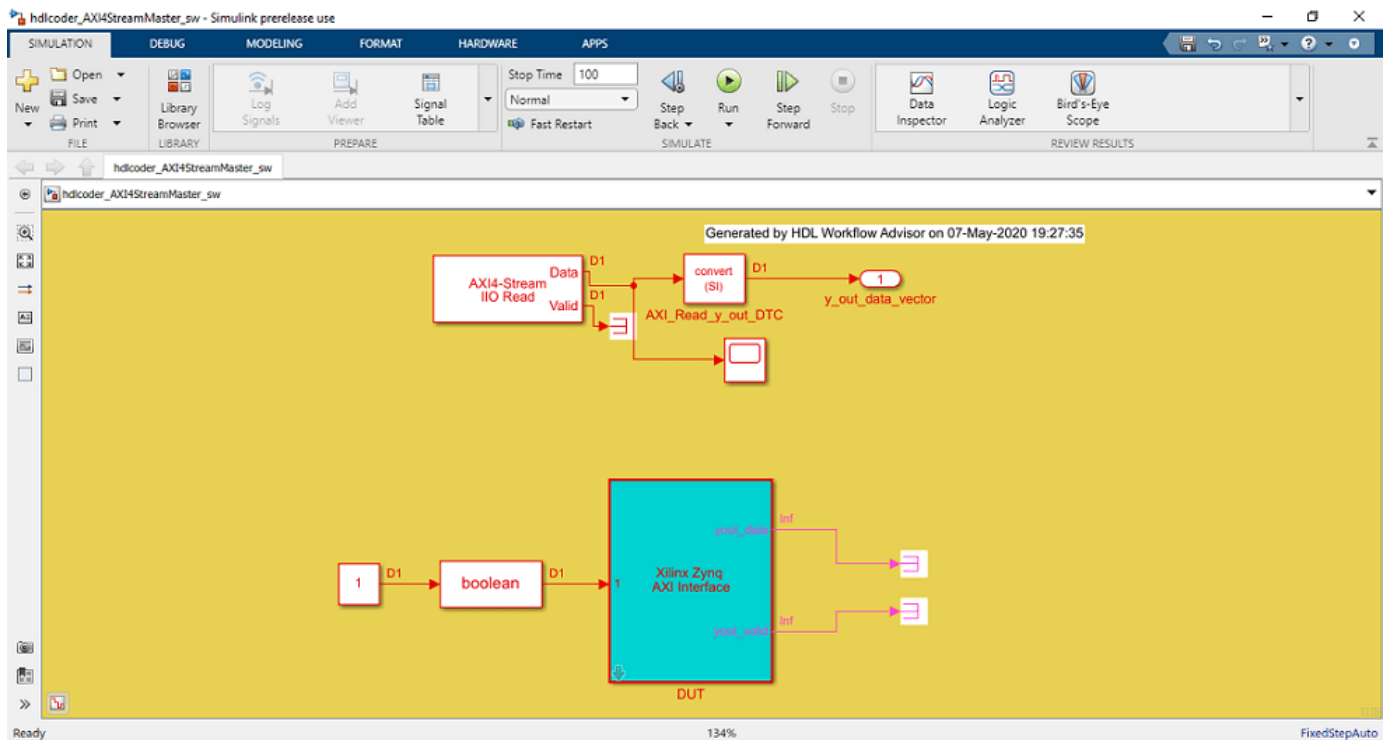

The AXI4-Stream IIO driver block cannot be automatically generated in the software interface model when a scalar port **yout_data** is mapped to AXI4-Stream interface "AXI4-Stream Master". Before you generate code from the software interface model, add the AXI4-Stream IIO Read driver block from the **Embedded Coder Support Package for Xilinx Zynq Platform** Library in the Simulink Library Browser.

The updated software interface model for AXI4-Stream Master only reference designs are provided:

```
open_system('hdlcoder_AXI4StreamMaster_sw.slx')
```

Continuous data of count 0 to 50 is used in this model, and is connected to AXI4 Stream DMA driver block.

Click the **Monitor & Tune** button on the **Hardware** tab of Simulink Toolstrip. Embedded Coder builds the model, downloads the ARM executable to the Zc706 hardware. Now, both the hardware and software parts of the design are running on Zynq hardware. The FPGA IP sends the source data through the DMA controller and the AXI4-Stream interface. The ARM processor receives the data from the FPGA IP, and sends the result data to Simulink via external mode. Observe the output from the Zynq hardware on the time Scope `y_out`.

Generate ARM executable Using AXI4-Stream Driver Block for AXI4-Stream Slave only reference design

The updated software interface model for only AXI4-Stream Slave reference design is provided:

```
open_system('hdlcoder_AXI4StreamSlave_sw.slx')
```

In this model, a counter block which generates 1 to 50 incremental data is connected to AXI4-Stream Write DMA driver block. This means the DMA controller will stream count data samples to the HDL IP core via the AXI4-Stream Slave interface.

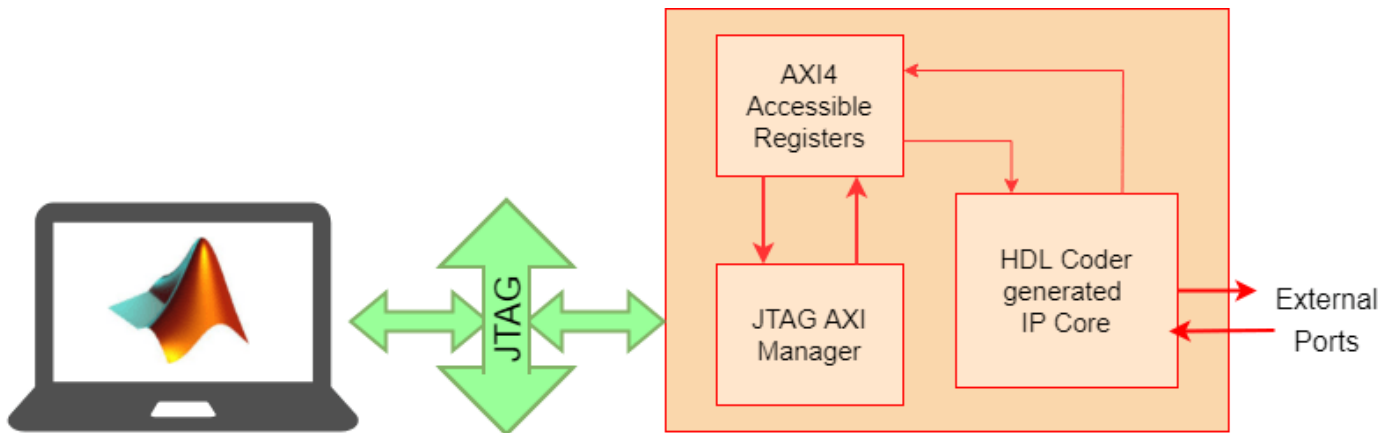

Click the **Monitor & Tune** button on the Hardware tab of model toolstrip. Embedded Coder builds the model, downloads the ARM executable to the Zc706 hardware. Now, both the hardware and software parts of the design are running on Zynq hardware. The ARM processor sends the source data to the FPGA IP, through the DMA controller and the AXI4-Stream interface. Observe the output of the IP core from the Zynq hardware on the Time Scope `y_out`.

Use JTAG AXI Manager to Control HDL Coder Generated IP Core

This example shows how to specify automatic insertion of the HDL Verifier™ AXI Manager IP into a reference design. This example also explains how to use MATLAB® or Simulink® to configure the HDL Coder™ generated FPGA IP core.

To access onboard memory locations and quickly probe or control the FPGA logic from MATLAB or Simulink, use the JTAG AXI Manager IP. The `aximanager` System object™ you create in MATLAB connects to the AXI Manager IP over a physical JTAG cable and allows you to run read and write commands to subordinate memory locations from the MATLAB command line. In Simulink, the AXI Manager Read (HDL Verifier) and AXI Manager Write (HDL Verifier) blocks drive AXI Manager IP to perform read and write operations on output and input ports of the HDL Coder generated device under test (DUT) over the JTAG interface.

This example uses ZedBoard™ to implement the FPGA design.

Requirements

- HDL Verifier™ Support Packages for Xilinx FPGA Boards
- HDL Coder™ Support Package for Xilinx FPGA Boards
- Xilinx® Vivado™ Design Suite, with the supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- ZedBoard

Generate Reference Design with AXI Manager IP

Set up the Xilinx Vivado tool path. Use your own Xilinx Vivado installation path when executing the command.

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath', ...
    'C:\Xilinx\Vivado\2020.2\bin\vivado.bat');
```

Enable Insertion of JTAG AXI Manager

1. Open the `hdlcoder_led_blinking` model by running this command at the MATLAB command prompt.

```
open_system('hdlcoder_led_blinking')
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking/led_counter')`

Launch HDL Workflow Advisor

Run Demo

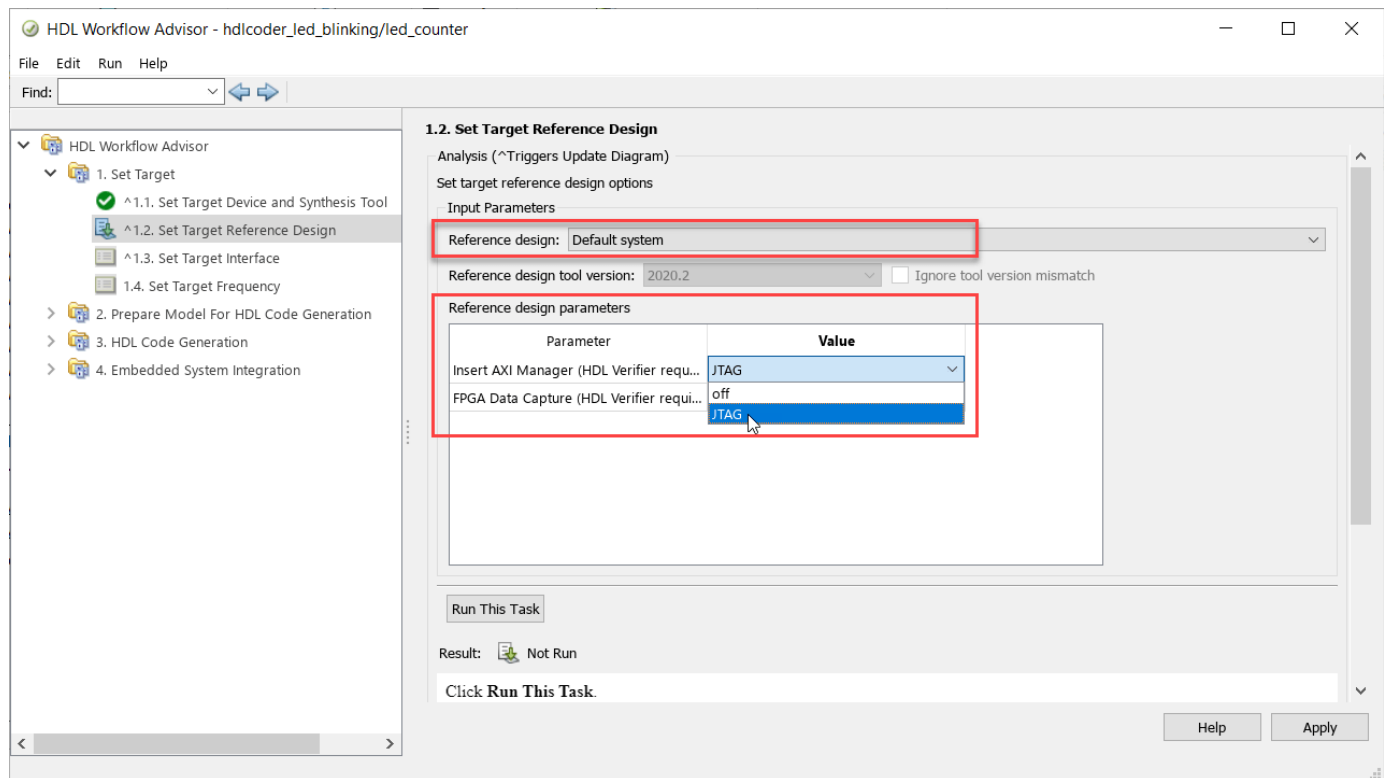

Copyright 2014 The MathWorks, Inc.

This example implements the `led_counter` subsystem on the hardware. This subsystem models a counter that causes LEDs to blink on the hardware. Two input ports, `Blink_frequency` and `Blink_direction`, are control ports that determine the LED blink frequency and direction, respectively. The output port `LED` connects to the LEDs on the hardware. You can use the output port `Read_back` to read data back to MATLAB.

2. Open the HDL Workflow Advisor from the `hdlcoder_led_blinking/led_counter` subsystem by right-clicking the `led_counter` subsystem and choosing **HDL Code > HDL Workflow Advisor**.
3. In the **Set Target > Set Target Device and Synthesis Tool** task, set **Target workflow** to IP Core Generation.
4. Set **Target platform** to ZedBoard. If you do not see this option, select **Get more** to open the Support Package Installer. In the Support Package Installer, select **Xilinx Zynq Platform** and follow the instructions provided by the Support Package Installer to complete the installation.
5. Click **Run This Task** to run the **Set Target Device and Synthesis Tool** task.

6. In the **Set Target > Set Target Reference Design** task, choose **Default system** and set the **Insert AXI Manager (HDL Verifier required)** reference design parameter to JTAG.

7. Click **Run This Task** to run the **Set Target Reference Design** task.

Generate HDL IP Core and Create Project with AXI Manager IP

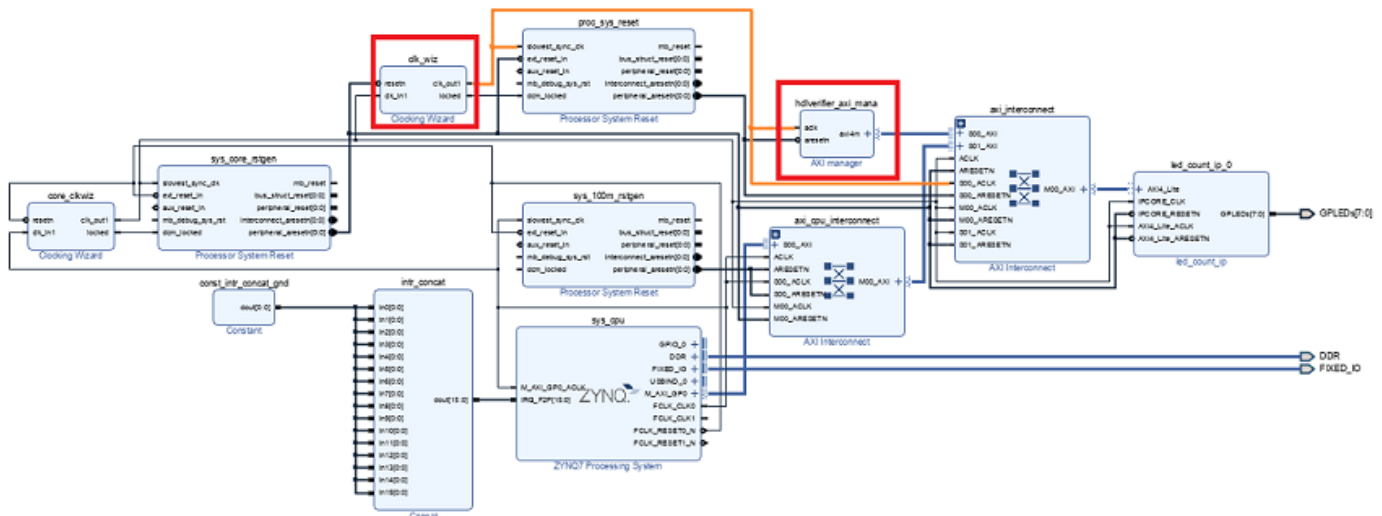

Map each port in your DUT to one of the IP core target interfaces. This example maps the **Blink_frequency** and **Blink_direction** input ports to the AXI4-Lite interface, so the HDL Coder generates registers that can be accessed through the AXI interface for these ports. This example maps the **LED** output port to an external interface, LEDs General Purpose [0:7], which connects to the LED hardware on the ZedBoard.

1. In the **Set Target > Set Target Interface** task, choose AXI4-Lite for **Blink_frequency**, **Blink_direction**, and **Read_back**.
2. Choose LEDs General Purpose [0:7] for **LED**.

3. Create the reference design project, which includes JTAG AXI Manager.

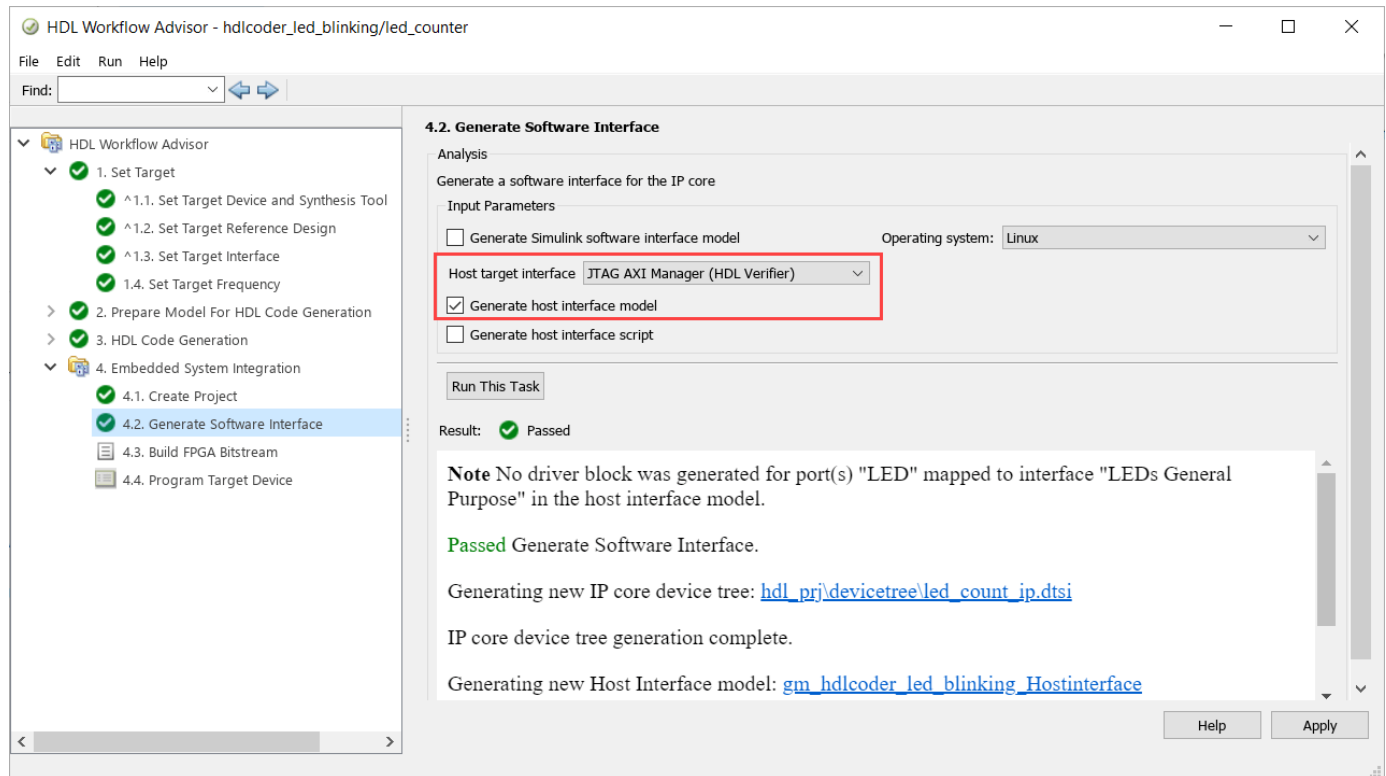

To create the project, right-click the **Create Project** task and select **Run to Selected Task**.

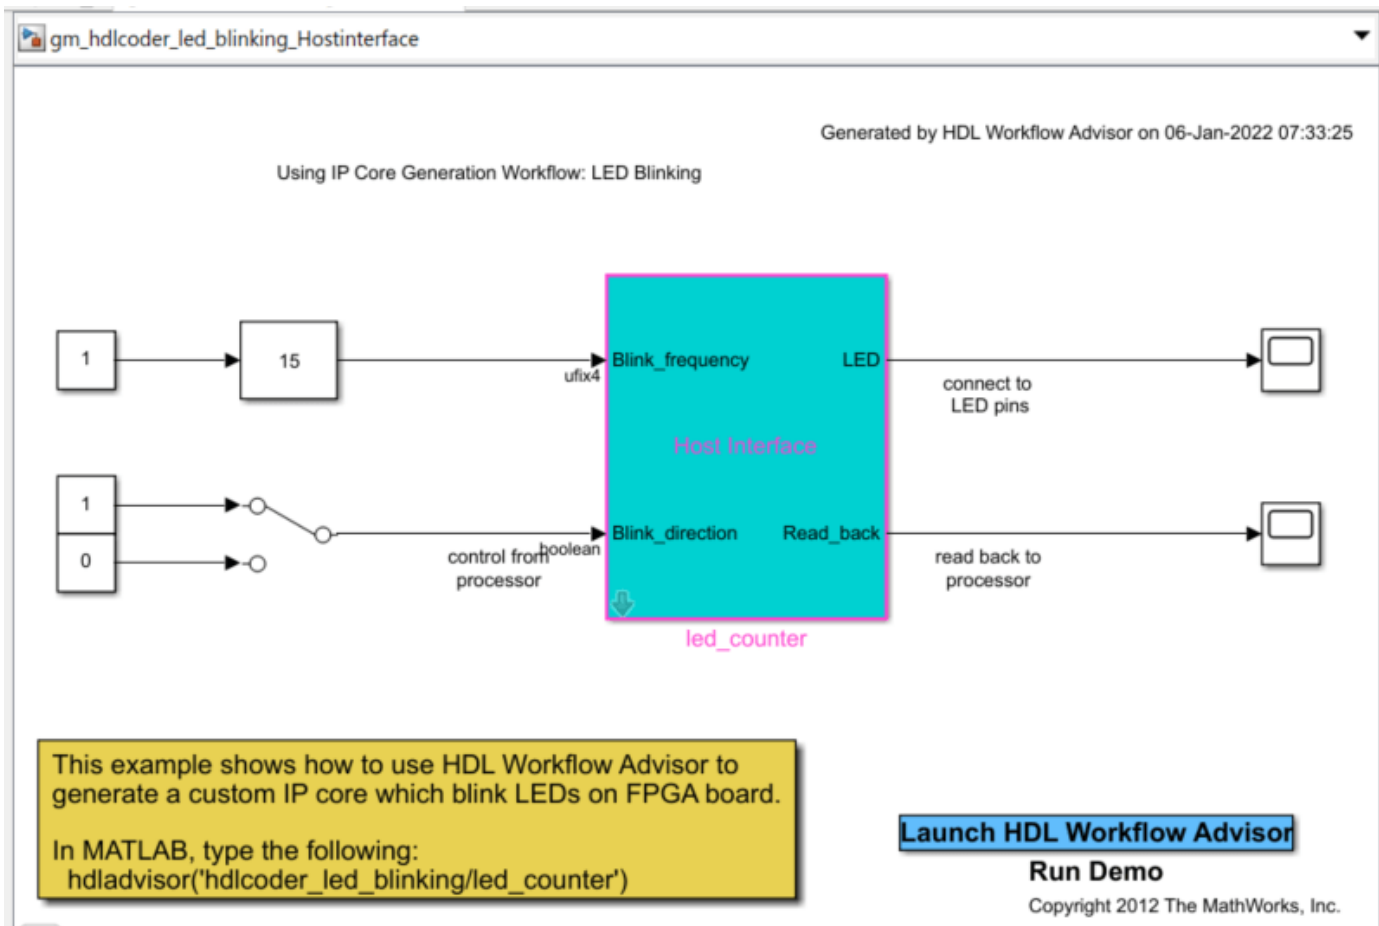

Generate Host Interface Model

Generate the host interface model by replacing the DUT with the AXI Manager Read (HDL Verifier) and AXI Manager Write (HDL Verifier) blocks in the Simulink model. Follow these steps to generate the host interface model.

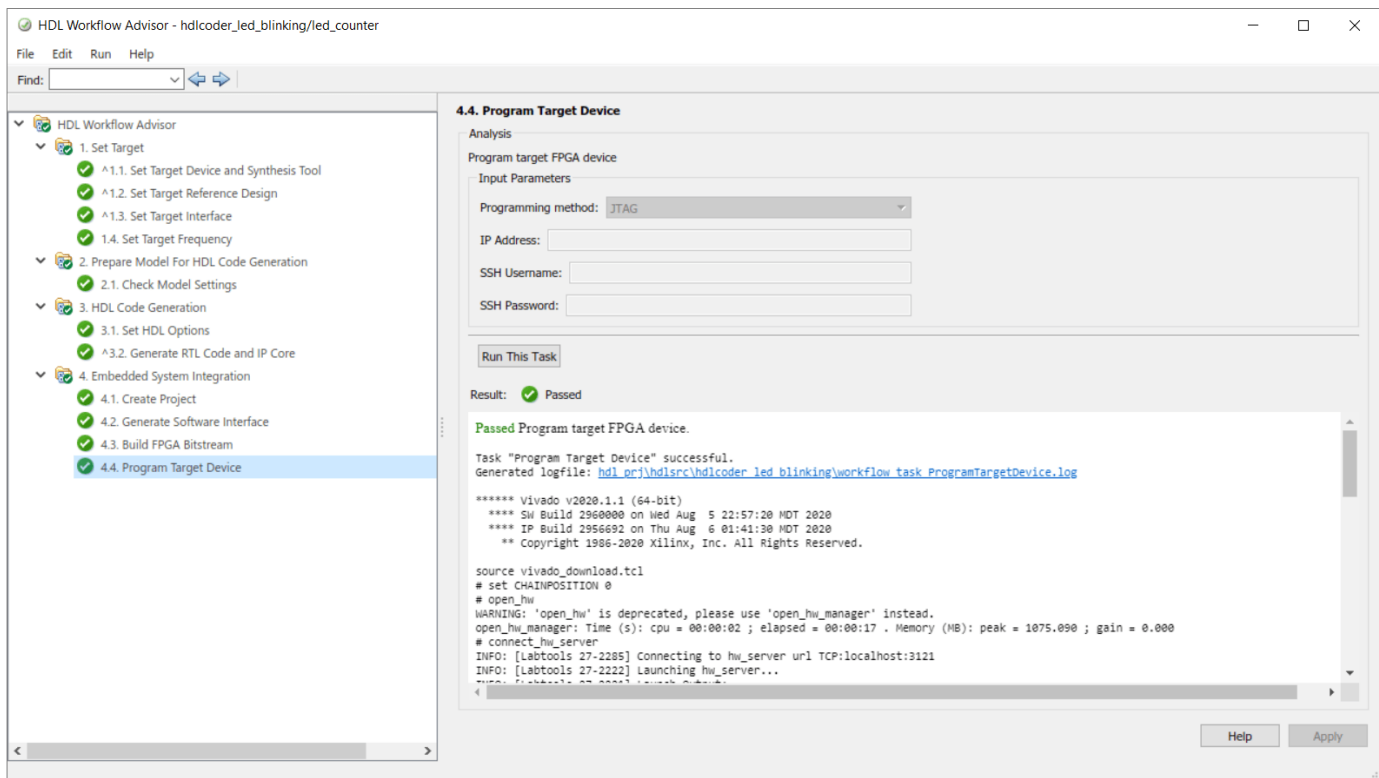

1. In the **Embedded System Integration > Generate Software Interface** task, set **Host target interface** to JTAG AXI Manager (HDL Verifier).
2. Select **Generate host interface model**.
3. Click **Run This Task**.

The following screen shot shows the `gm_hdlcoder_led_blinking_Hostinterface.slx` host interface model. You can use the host interface model as a Simulink test bench to tune DUT registers.

Run the remaining steps in the workflow to generate a bitstream and program the target device.

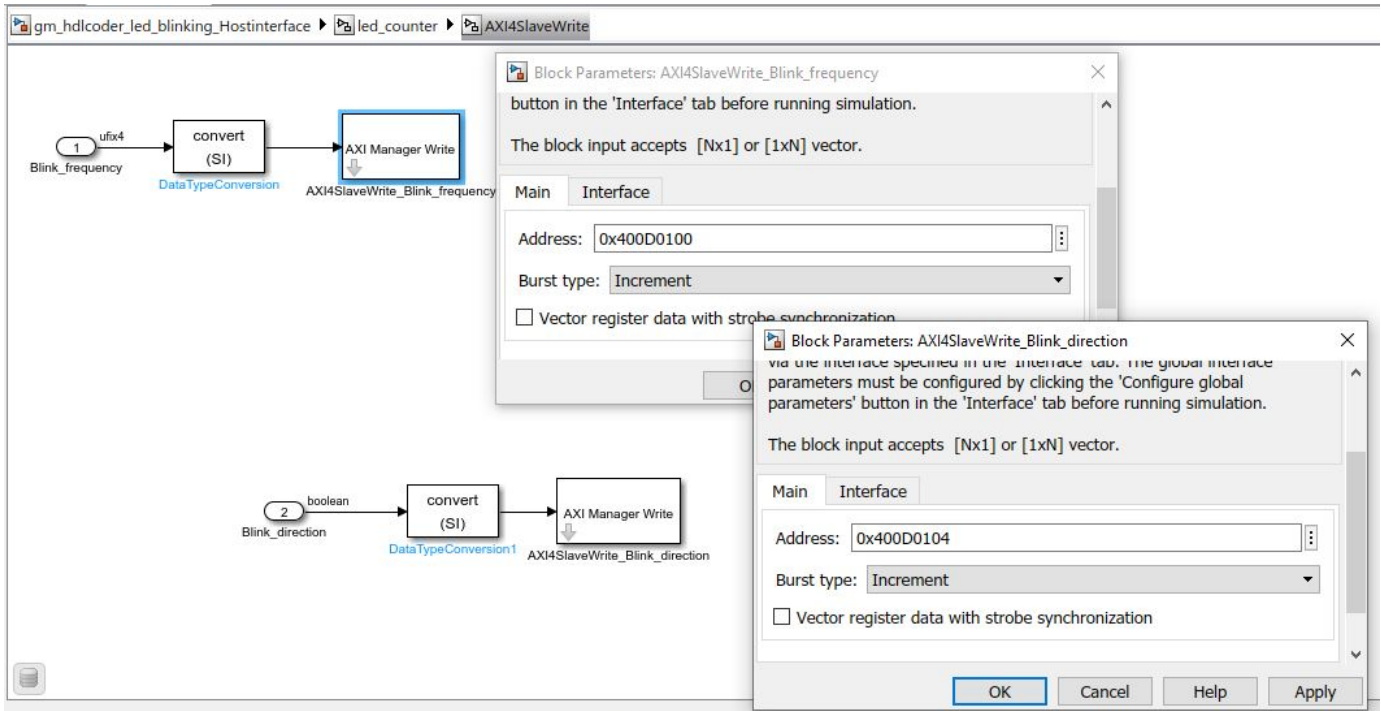

Control HDL Coder IP Core Using JTAG AXI Manager

Simulink Model to Control HDL Coder IP Core

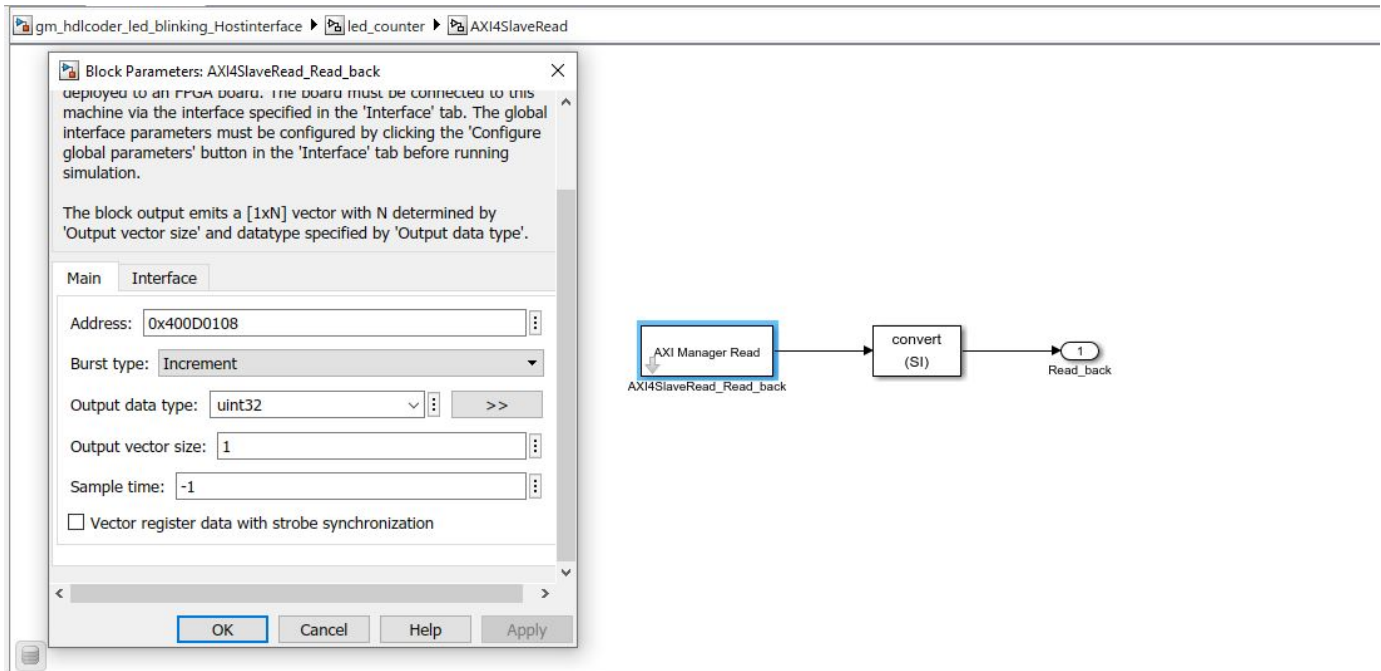

1. Open the `gm_hdlcoder_led_blinking_Hostinterface` model.
2. Go to `gm_hdlcoder_led_blinking_Hostinterface > led_counter > AXI4SlaveWrite` subsystem. Configure the AXI Manager Write (HDL Verifier) block.

This figure shows the default configuration of the AXI Manager Write block for the current HDL Workflow Advisor configuration.

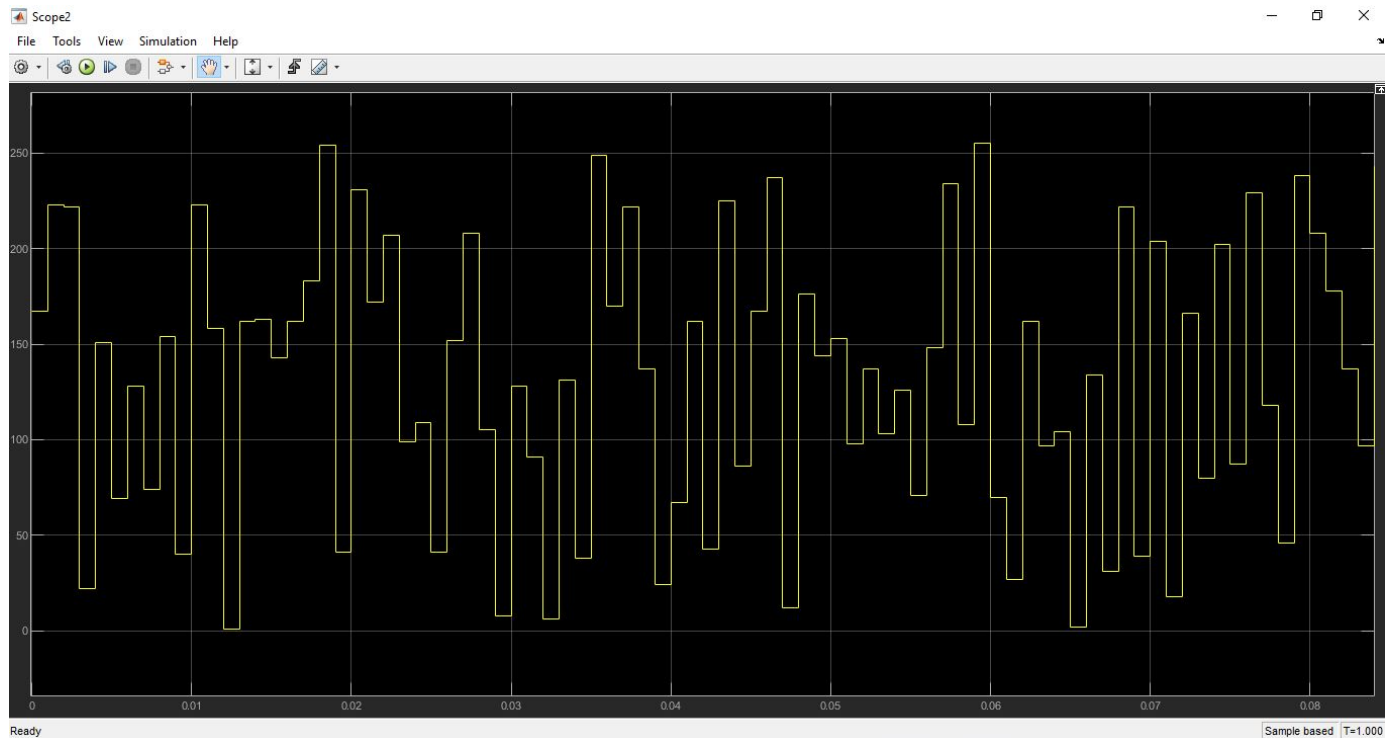

3. Go to the `gm_hdlcoder_led_blinking_Hostinterface > led_counter > AXI4SlaveRead` subsystem. Configure the AXI Manager Read (HDL Verifier) block.

This figure shows default configuration of the AXI Manager Read block for the current HDL Workflow Advisor configuration.

Run the `gm_hdlcoder_led_blinking_Hostinterface` model to perform read and write operations from Simulink.

The figure shows **Read_back** register (LED output) samples over time.

MATLAB Command Line Interface

You can also control the DUT from the MATLAB command line by creating an object for AXI Manager IP.

1. Create the AXI manager object.

```
h = aximanager('Xilinx')
```

2. Change the LED blinking frequency.

```
h.writememory('400D0100',0)
```

Observe that the LED blinking frequency is low. Change the frequency from 0 to 15 to increase the LED blinking frequency.

```
h.writememory('400D0100',15)
```

3. Read the current counter value.

```
h.readmemory('400D0108',1)
```

4. Delete the object when done to free up the JTAG resource. If you do not delete the object, any other JTAG operation fails.

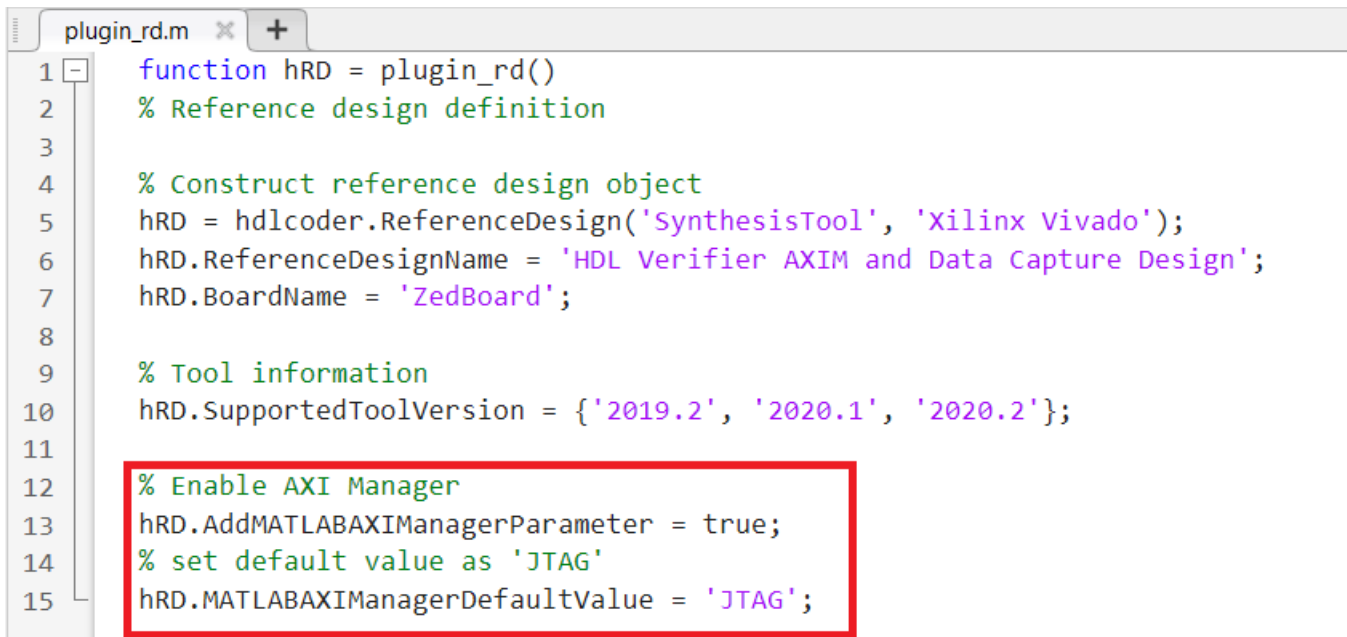

```
delete(h)
```

JTAG AXI Manager in Custom Reference Designs

The **Insert AXI Manager (HDL Verifier required)** reference design parameter is by default added to your custom reference design. The default value for the parameter is `off`. In custom reference design, you can control this parameter by using the following properties.

- “AddMATLABAXIManagerParameter” - Control visibility of the Insert AXI Manager parameter.
- “MATLABAXIManagerDefaultValue” - Specify whether to insert the AXI manager IP.

You can set the **Insert AXI Manager (HDL Verifier required)** parameter to display in **Set Target Reference Design** task and assign the default value as JTAG by adding the properties in the `plugin_rd.m` file of the custom reference design workflow shown in this figure.

```
1 function hrd = plugin_rd()
2 % Reference design definition
3
4 % Construct reference design object
5 hrd = hdlcoder.ReferenceDesign('SynthesisTool', 'Xilinx Vivado');
6 hrd.ReferenceDesignName = 'HDL Verifier AXIM and Data Capture Design';
7 hrd.BoardName = 'ZedBoard';
8
9 % Tool information
10 hrd.SupportedToolVersion = {'2019.2', '2020.1', '2020.2'};
11
12 % Enable AXI Manager
13 hrd.AddMATLABAXIManagerParameter = true;
14 % set default value as 'JTAG'
15 hrd.MATLABAXIManagerDefaultValue = 'JTAG';
```

Debug a Zynq Design Using HDL Coder and Embedded Coder

This example shows how to debug a Zynq® design using HDL Coder™ and Embedded Coder® features.

Requirements

- Xilinx® Zynq-7000 SoC ZC702 Evaluation Kit
- HDL Coder Support Package for Xilinx Zynq Platform
- Embedded Coder Support Package for Xilinx Zynq Platform
- Follow the Set up Zynq hardware and tools section in “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 to setup ZC702 hardware.

Introduction

When you are prototyping and developing an algorithm for Zynq platform, it is useful to monitor, tune, and debug the algorithm while it runs on hardware. This example shows how to use features like external mode, AXI interface and HDL FIFO blocks to probe into the Zynq design. Using the external mode feature, you can probe the internal data in the software running on the ARM® processor. And because the ARM processor is connected to the FPGA through AXI interface, you can monitor and tune the parameters on FPGA as well. Together with HDL FIFO blocks, you can capture fast FPGA data and retrieve it back to Simulink® for analysis.

Start by opening the example model.

```
open_system('hdlcoder_data_capture');
```

Data Capture In FPGA

This example shows how to use FIFO block to capture FPGA internal data and then retrieve the captured data later.

In MATLAB, type the following:
`hdladvisor('hdlcoder_data_capture/DataCapture')`

[Launch HDL Workflow Advisor](#)

[Run Demo](#)

Copyright 2012-2014 The MathWorks, Inc.

The subsystem **DataCapture** is the hardware subsystem targeting the FPGA fabric. Inside this subsystem, the **OriginalDUT** subsystem contains a **Trigonometric Function** block, which generates fast sine and cosine data streams. The **OriginalDUT** subsystem represents our algorithm design. If we want to debug this design, how do we capture and monitor this fast data stream?

The FPGA runs at a much faster clock frequency than the software code on the ARM processor. External mode can be used with the software running on the ARM processor to monitor slow-changing status parameters, such as FIFO status, but the sample rate of the software code, for example, 1KHz, is not fast enough to capture the fast-changing data in the FPGA, for example, 50MHz.

This example shows how to use a FIFO block to capture the fast FPGA data, and then use the software on the ARM processor to retrieve the captured data through the AXI interface and external mode.

For debugging purposes, we add the subsystem **Debug_FIFOs** to the DUT. This subsystem uses two HDL FIFO blocks to capture the fast data streams for future retrieval. The control signal inputs to the **Debug_FIFOs** subsystem are connected to the DUT interface, and are connected to the ARM processor via the AXI interface.

At the top level of the example model, when the **EnableCapture** switch is turned on, and **RetrieveData** switch is turned off, the **Debug_FIFOs** module will capture 1000 data samples into the **HDL FIFO** blocks. This is the data capture phase. Then, when the **EnableCapture** switch is kept on, and the **RetrieveData** switch is turned back on, the **Debug_FIFOs** module will transfer the captured data back to the ARM processor. This is the data retrieval phase. You can use the manual switches to switch between these two phases to capture and monitor the internal FPGA data.

Thus, for every signal you want to monitor, you can insert more **Debug_FIFO** modules to your design to capture and retrieve the data back to Simulink. You can also use your own control signals, or extend this example with your own triggers, or qualifiers.

The output port of the hardware subsystem, **DirectDataOut**, outputs data directly to the AXI interface. In contrast, the output ports **CapturedDataOut1** and **CapturedDataOut2** outputs captured data from the FIFOs. We will compare the results of these two outputs in the last section.

Deploy the design on Zynq hardware

Next, we will start HDL Workflow Advisor from the model and run through the Zynq HW/SW co-design workflow to deploy this design on Zynq hardware. For a detailed step by step guide, refer to the example “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

1. In the **Set Target > Set Target Device and Synthesis Tool** task, for **Target workflow**, select **IP Core Generation**. For **Target platform**, select **Xilinx Zynq ZC702 evaluation kit**. Run this task.
2. In the **Set Target > Set Target Interface** task, choose **AXI4-Lite** for all the input and output ports.

3. Then run through all the workflow steps to generate HDL IP, create an EDK project, generate the software interface model, and build and download the FPGA bitstream. The generated software interface model is shown in following picture:

4. Configure and build the software interface model for external mode:

- 1 In the generated model,click on Hardware pane and go to **Hardware settings** to open **Configuration Parameter** dialog box.
- 2 Select **Solver** and set **Stop Time** to **inf**.
- 3 From the Hardware pane, click the **Monitor and Tune** button.
- 4 Click the **Run** button on the model toolstrip. Embedded Coder builds the model, downloads the ARM executable to the Zynq ZC702 hardware, executes it, and connects the model to the executable running on the Zynq ZC702 hardware.

Capture and display data from Zynq hardware

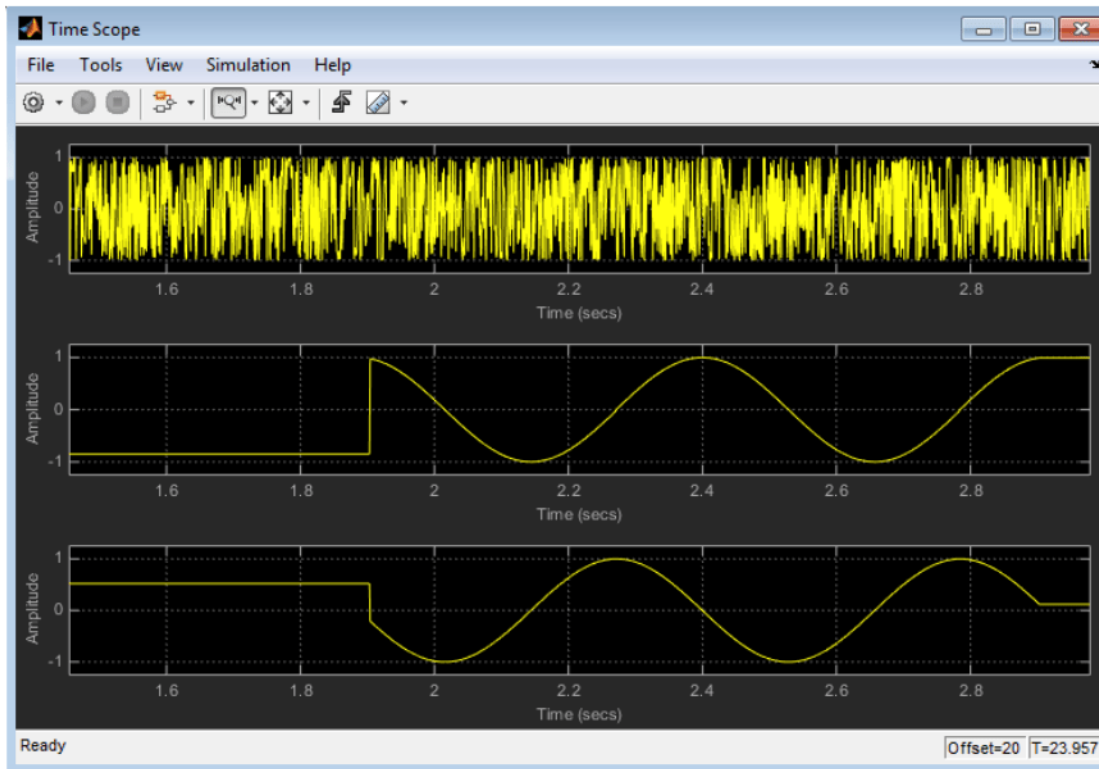

Now both the hardware and software parts of the design are running on Zynq hardware, the next step is to capture and retrieve data from the Zynq board.

Once the external mode is connected, make sure the **EnableCapture** switch is in the **1** position, and the **RetrieveData** switch is in the **0** position. Notice the **FIFONumber** display box increases to 1000 almost immediately. This means the FIFO inside the FPGA fabric started capturing data and was quickly filled with 1000 data samples.

Open the **Time Scope** block and observe the **DirectDataOut** output in the first row. Notice the received data is a seemingly random waveform between -1 and 1. This is because the FPGA is running at a much faster frequency than software is running on the ARM processor. Directly using external mode to monitor fast FPGA data means sampling a fast sine waveform at a very slow rate, which generates a random waveform between -1 and 1.

Now double-click the **RetrieveData** switch to enable data readout. The **EnableCapture** switch needs to be kept on. When the **RetrieveData** switch is turned on, the internal logic modeled in this example sends out the captured data samples one by one from FIFO to the ARM processor, through the AXI interface. These data samples are then sent from ARM processor to Simulink via external mode. Notice the **FIFONumber** display box decreases to 0.

Open the **Time Scope** block, the second and third row of the scope now shows the sine and cosine wave we captured in the FIFO. Following picture shows the scope waveforms.

Summary

This example shows how to use features like external mode, AXI interface and HDL FIFO blocks to probe into the Zynq design, capture fast FPGA data, and retrieve it back to Simulink for analysis. You can also do similar monitoring with FPGA vendor tools like ChipScope™ or SignalTap™. But the strength of this approach is that you can get all the visualization benefits of Simulink, like various scope blocks, and you can also build your own custom controls, triggers, or qualifiers in Simulink.

Debug IP Core Using FPGA Data Capture

This example shows how to debug an IP core you generate in HDL Coder™ using only FPGA Data Capture as well as both AXI Manager and FPGA Data Capture together.

Requirements

- Xilinx® Zynq® ZC702 evaluation kit. For information on setting up the ZC702 hardware, see “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.
- HDL Coder Support Package for Xilinx Zynq Platform
- HDL Verifier™ Support Package for Xilinx FPGA Boards
- Xilinx Vivado™ Design Suite, with a supported version listed in the “HDL Language Support and Supported Third-Party Tools and Hardware”
- (Optional) Embedded Coder® Support Package for Xilinx Zynq Platform
- (Optional) DSP System Toolbox

Introduction

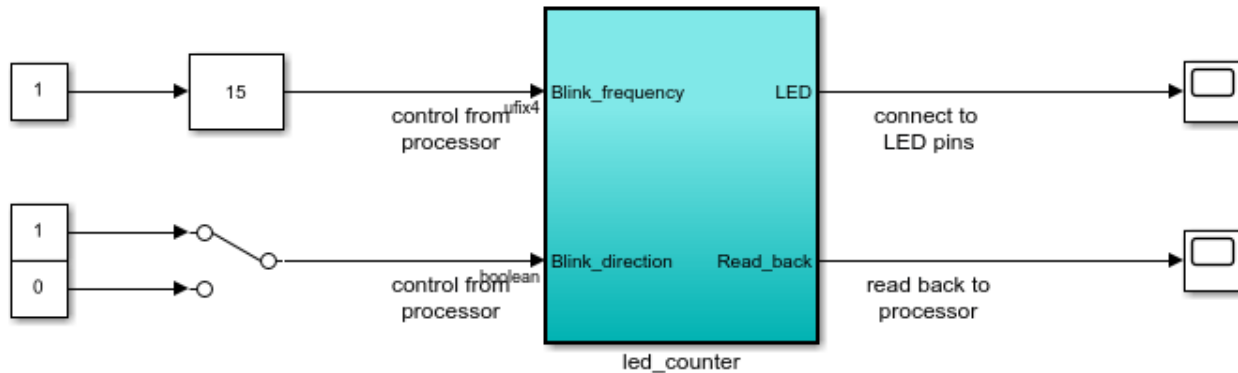

Monitoring IP core internal signals while a design is running on real hardware is useful because you can debug and analyze the design. This example illustrates how to use the FPGA Data Capture to capture internal signals of the generated IP core in MATLAB®.

This example shows how to use FPGA Data Capture in blocking and nonblocking modes. For more information on capture modes, see “CaptureMode” (HDL Verifier). Nonblocking mode allows simultaneous use of AXI Manager and FPGA Data Capture over a JTAG interface. Blocking mode suspends MATLAB execution, so you cannot use other applications when you use this mode. By contrast, nonblocking mode allows you to use AXI Manager to configure the IP core while FPGA Data Capture captures data from the hardware.

Open the model.

```
open_system('hdlcoder_led_blinking_data_capture');
```

Using IP Core Generation Workflow: LED Blinking

This example shows how to use HDL Workflow Advisor to generate a custom IP core which blink LEDs on FPGA board.

In MATLAB, type the following:
`hdladvisor('hdlcoder_led_blinking_data_capture/led_counter')`

Launch HDL Workflow Advisor

Run Demo

Copyright 2018 The MathWorks, Inc.

This example implements the `led_counter` subsystem on the hardware. This subsystem models a counter that causes LEDs to blink on the hardware. Two input ports, `Blink_frequency` and `Blink_direction`, are control ports that determine the LED blink frequency and direction, respectively. The output port `LED` connects to the LEDs on the hardware. You can use the output port `Read_back` to read data back to MATLAB.

In the `led_counter` subsystem, several internal signals are test points. HDL Coder routes those internal signals out of the DUT and into the IP core wrapper so that the signals can be connected to the FPGA Data Capture HDL IP.

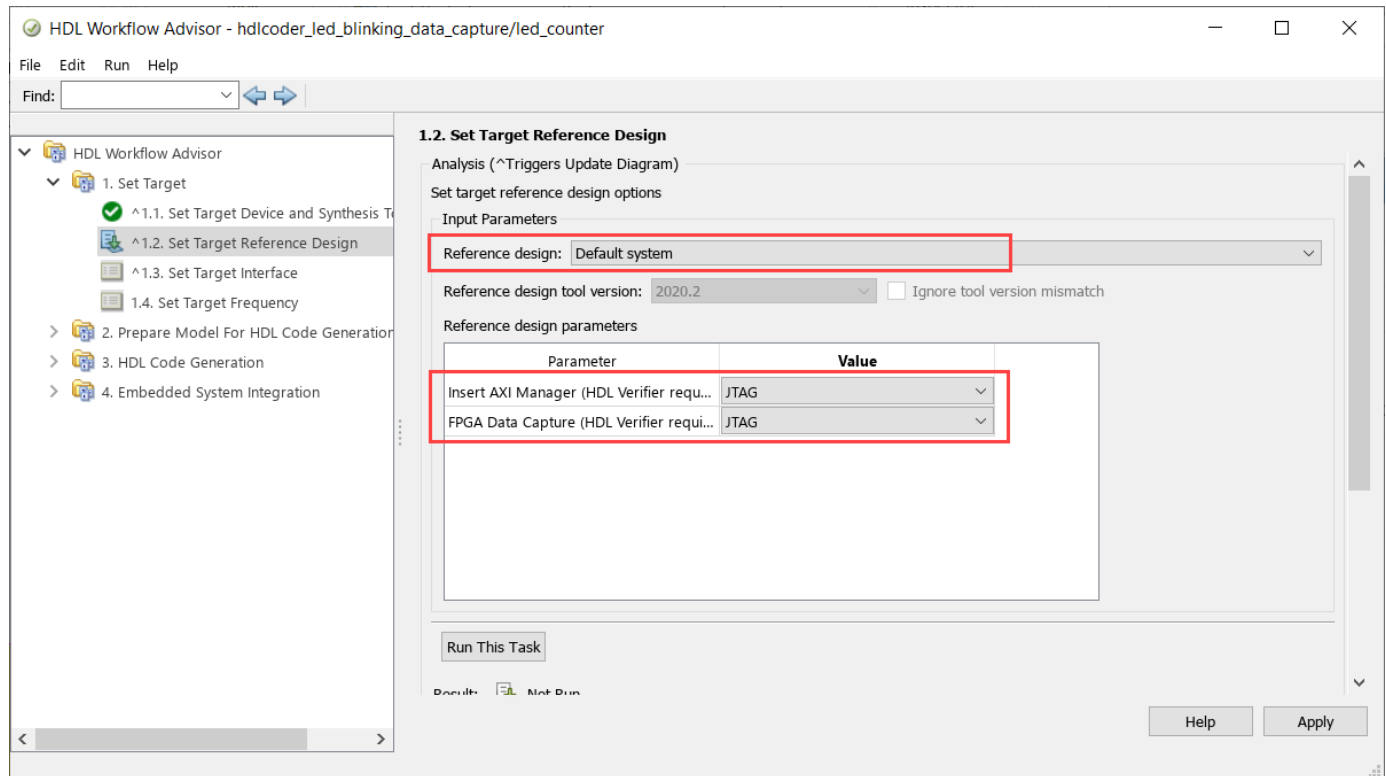

```
open_system('hdlcoder_led_blinking_data_capture/led_counter');
```

Generate HDL IP Core

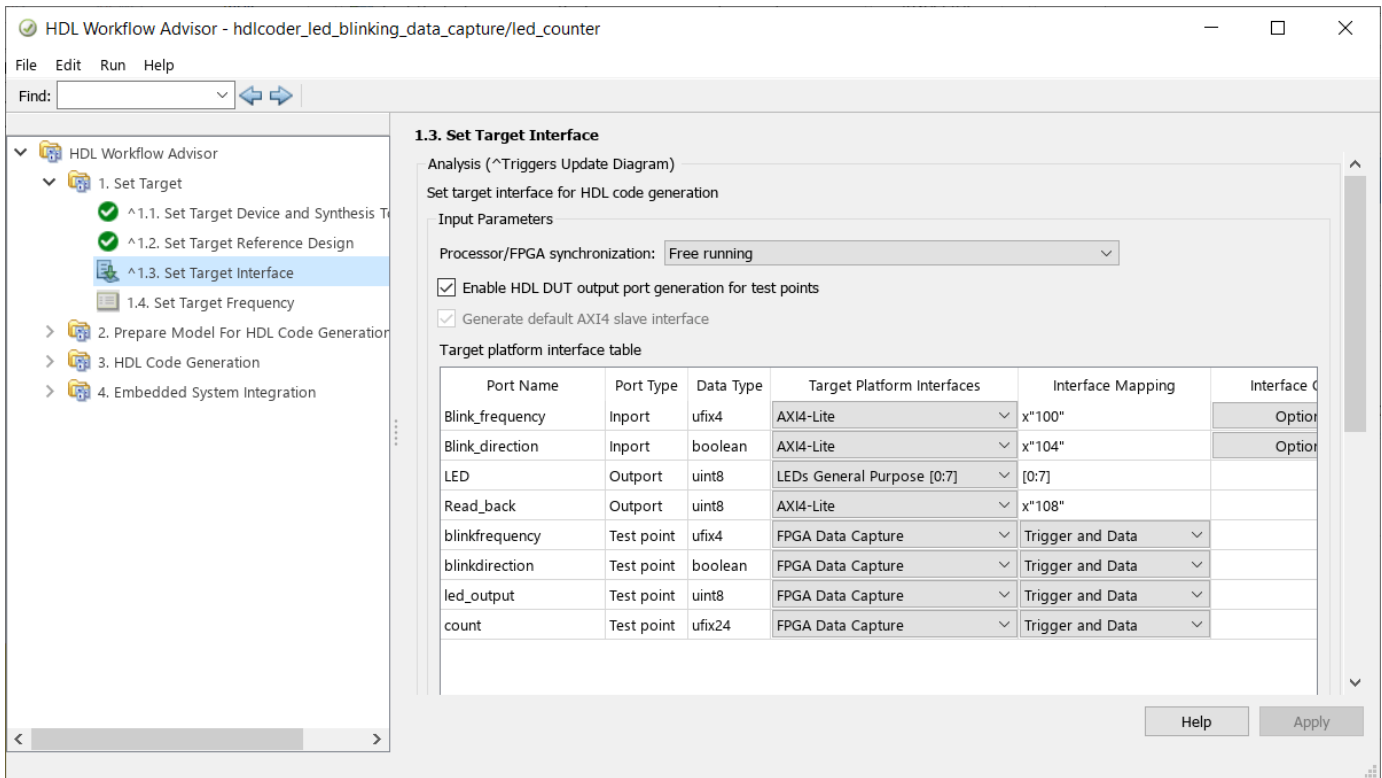

Start HDL Workflow Advisor from the model and run through the IP Core Generation workflow. For a step-by-step guide, see “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83.

1. In step 1.1, set **Target workflow** to IP Core Generation and **Target platform** to Xilinx Zynq ZC702 evaluation kit. Click **Run This Task**.
2. In step 1.2, set **Reference design** to Default system. Set **Insert AXI Manager (HDL Verifier required)** and **FPGA Data Capture (HDL Verifier required)** to JTAG. Click **Run This Task**.

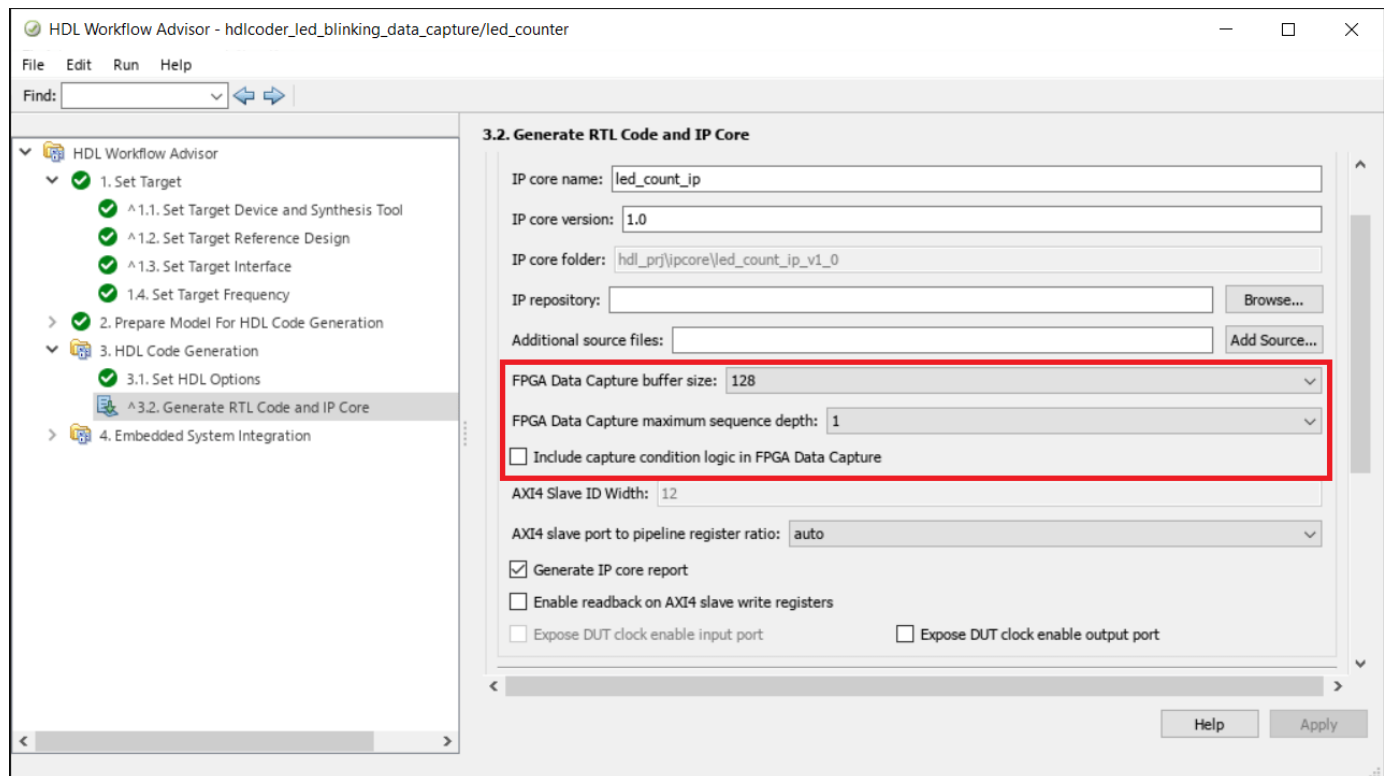

3. In step 1.3, select **Enable HDL DUT output port generation for test points**.

4. In step 1.3, set the interface of the **blinkfrequency**, **blinkdirection**, **led_output**, and **count** ports to FPGA Data Capture. Click **Run This Task**.

5. Run through the remaining workflow steps till step 3.1. In step 3.2, you can configure these FPGA Data Capture IP parameters: **FPGA Data Capture buffer size**, **FPGA Data Capture maximum sequence depth**, and **Include capture condition logic in FPGA Data Capture**. This example uses default values of these parameters. Click **Run This Task**.

6. Run through the remaining workflow steps to generate the HDL IP and program the target device.

Capture and Display Data from IP Core

Next, capture data from the Zynq board.

Locate the FPGA Data Capture launch script. For this example, the script is in your HDL code generation directory: `hdl_prj/ip_core/led_count_ip_v1_0/fpga_data_capture/launchDataCaptureApp.m`. You can also locate this script in the code generation report.

Run the `launchDataCaptureApp` script in MATLAB. Add the script directory to the MATLAB path or change the current working folder.

Capture Data in Blocking Mode

FPGA Data Capture

Description

Capture data from a design running on your FPGA board.

Specify data types for the returned data structure, and specify a logical trigger condition that defines when the data is captured.

Generate data capture IP → Integrate with existing FPGA design → Capture data

[Read more about the data capture workflow](#)

Output

Output variable name: dataCaptureOut Display data with Logic Analyzer

Trigger | Capture Condition | Data Types

Sample depth: 1024

Number of capture windows: 1 Number of trigger stages: 1

Trigger position: 0

Trigger Stage 1

Signal	Operator	Value
blinkfrequency	+	

Change operator

AND

Status: Not started Immediately Capture Data

Execute the script to launch the **FPGA Data Capture** tool. By default, FPGA Data Capture works in blocking mode. To capture data from the FPGA without setting a trigger condition, click **Capture Data**.

Alternatively, you can capture data with a trigger condition. For example, set the trigger condition `led_counter == 0` and the trigger position 32. Then, click **Capture Data** again.

Capture Data in Nonblocking Mode

Execute the script to launch the **FPGA Data Capture** tool and create the `fpgadc_obj` object in the workspace. Change the capture mode to nonblocking by executing the following command at the MATLAB command prompt.

```
fpgadc_obj.CaptureMode = 'nonblocking';
```

FPGA Data Capture in nonblocking mode allows simultaneous use of FPGA Data Capture and AXI Manager. For more information, see “Simultaneous Use of FPGA Data Capture and AXI Manager” (HDL Verifier). Now set a trigger condition where `led_blink_direction == 1` and set a trigger position of 512. Then, click **Capture Data**.

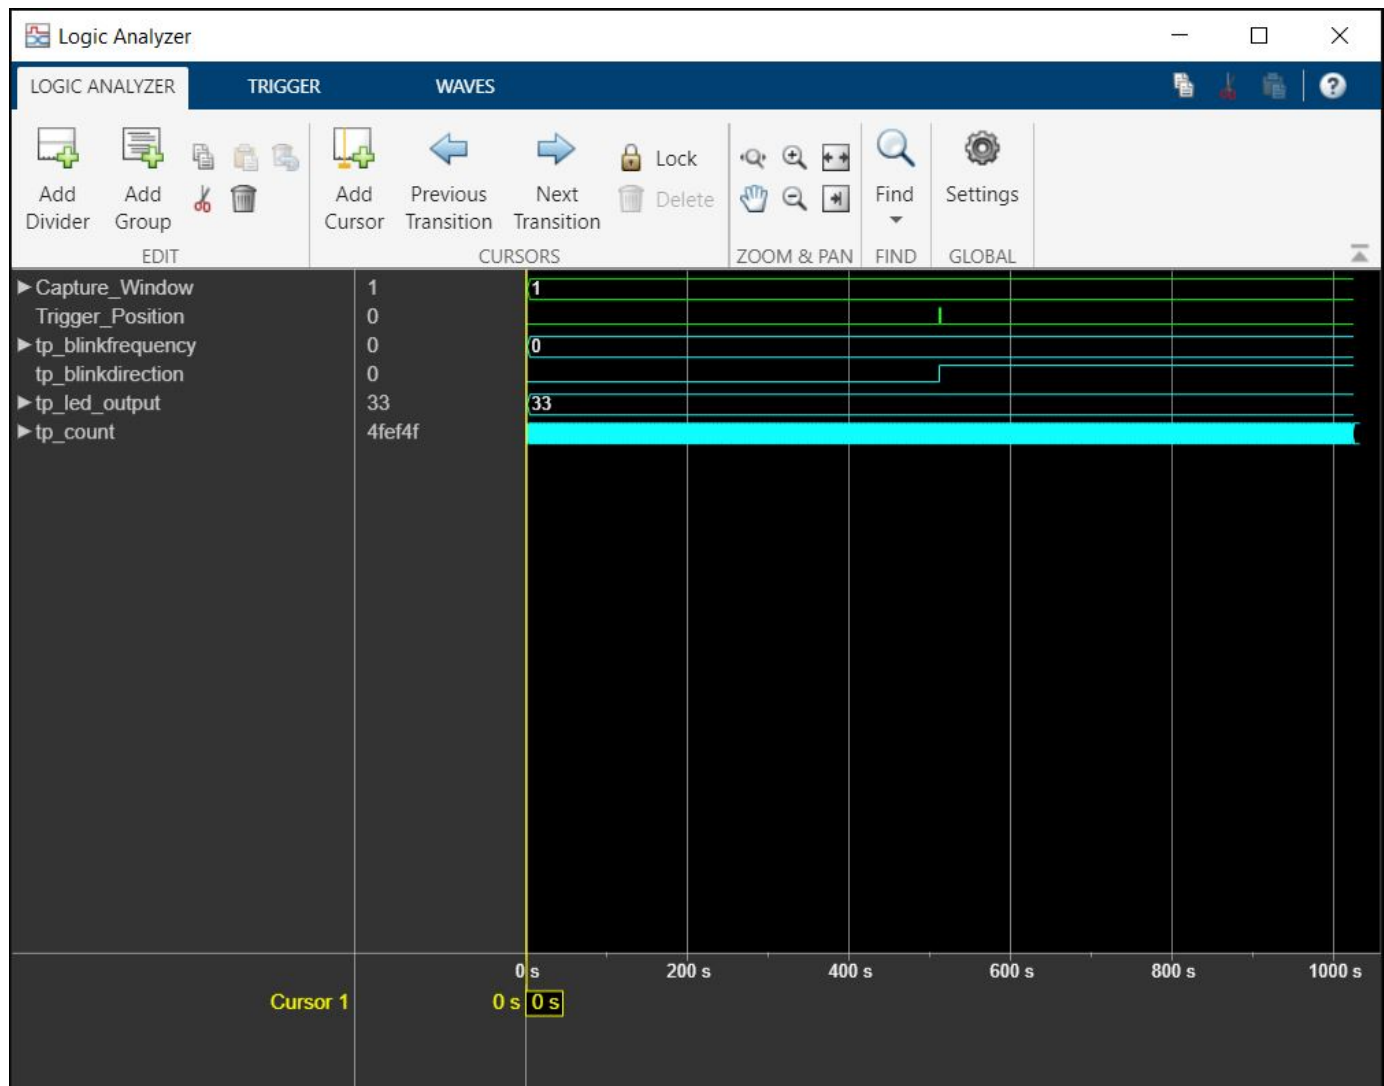

The screenshot shows the 'FPGA Data Capture' window. It includes a 'Description' section with a workflow diagram: 'Generate data capture IP' → 'Integrate with existing FPGA design' → 'Capture data'. Below this is a link to 'Read more about the data capture workflow'. The 'Output' section shows 'Output variable name: dataCaptureOut'. A modal dialog box is open, displaying 'Evaluating Trigger Stage 0. Click "Stop" to terminate data capture operation.' with a 'Stop' button. The 'Trigger' section is set to 'Capture Condition' with 'Sample depth: 1024', 'Number of capture windows: 1', and 'Number of trigger stages: 1'. The 'Trigger position' is set to 512. The 'Trigger Stage 1' configuration shows a table with columns 'Signal', 'Operator', and 'Value'. The first row is 'tp_blinkdirection == High'. Below the table, 'tp_blinkfrequency' is added with a '+' button. A 'Change operator' button and an 'AND' gate icon are also visible. The 'Status' bar at the bottom reads 'Status: Evaluating Trigger Stage 0. 0 window(s) of data has been captured.' with a 'On trigger' dropdown and a 'Capture Data' button.

FPGA Data Capture waits for the trigger condition. As FPGA Data Capture allows AXI Manager to perform read and write operations in nonblocking mode.

Next, in FPGA Data Capture, set **tp_blinkdirection** to High. Then, create an AXI Manager object in MATLAB.

```
axi_manager_obj = aximanager('Xilinx');
axi_manager_obj.writememory('0x40010104',1);
```

FPGA Data Capture captures the data in the **Logic Analyzer**. The figure shows the change in the blink direction.

Field-Oriented Control of a Permanent Magnet Synchronous Machine on a Xilinx Zynq Platform

This example models a field-oriented controller (FOC) for a permanent magnet synchronous machine (PMSM) on a Xilinx® Zynq™ - Ultrascale+™ MPSoC target. This example uses the [Trenz Electronic™ Motor Control Development kit TE0820](#). If you do not have the required hardware, you can use this example to help you develop a controller for your own hardware configuration.

Requirements

- “Install Support for Xilinx Zynq Platform” (Embedded Coder Support Package for Xilinx Zynq Platform)
- Trenz Electronic™ Motor Control Development kit TE0820

For more information about the hardware, see Trenz Electronic Motor Control Development kit support from Simulink.

Introduction

This image shows the general process of creating, simulating, and deploying a design of a controller algorithm onto an embedded hardware board.

You simulate a system test bench to gain insight into the behavior of the controller algorithm design. Explore the design to see how the algorithm is partitioned. The high-rate portion of the algorithm is

partitioned into a model that is configured for HDL code generation. The low-rate portion of the algorithm is partitioned into a model that is configured for C code generation. Generate C and HDL code from these models and learn how you can integrate this code into your design.

You can automate deployment of the algorithmic code into reference frameworks for the processor and programmable logic. Then, execute a test on the deployed application, log the results, and compare them to the simulation results.

Set up the Xilinx Zynq hardware board before starting the example. This example deploys a bitstream and ARM executable to a Xilinx Zynq device. To ensure the correct setup of your environment, complete the “Getting Started with Targeting Xilinx Zynq Platform” on page 46-83 (HDL Coder) example with your hardware configuration before starting this example.

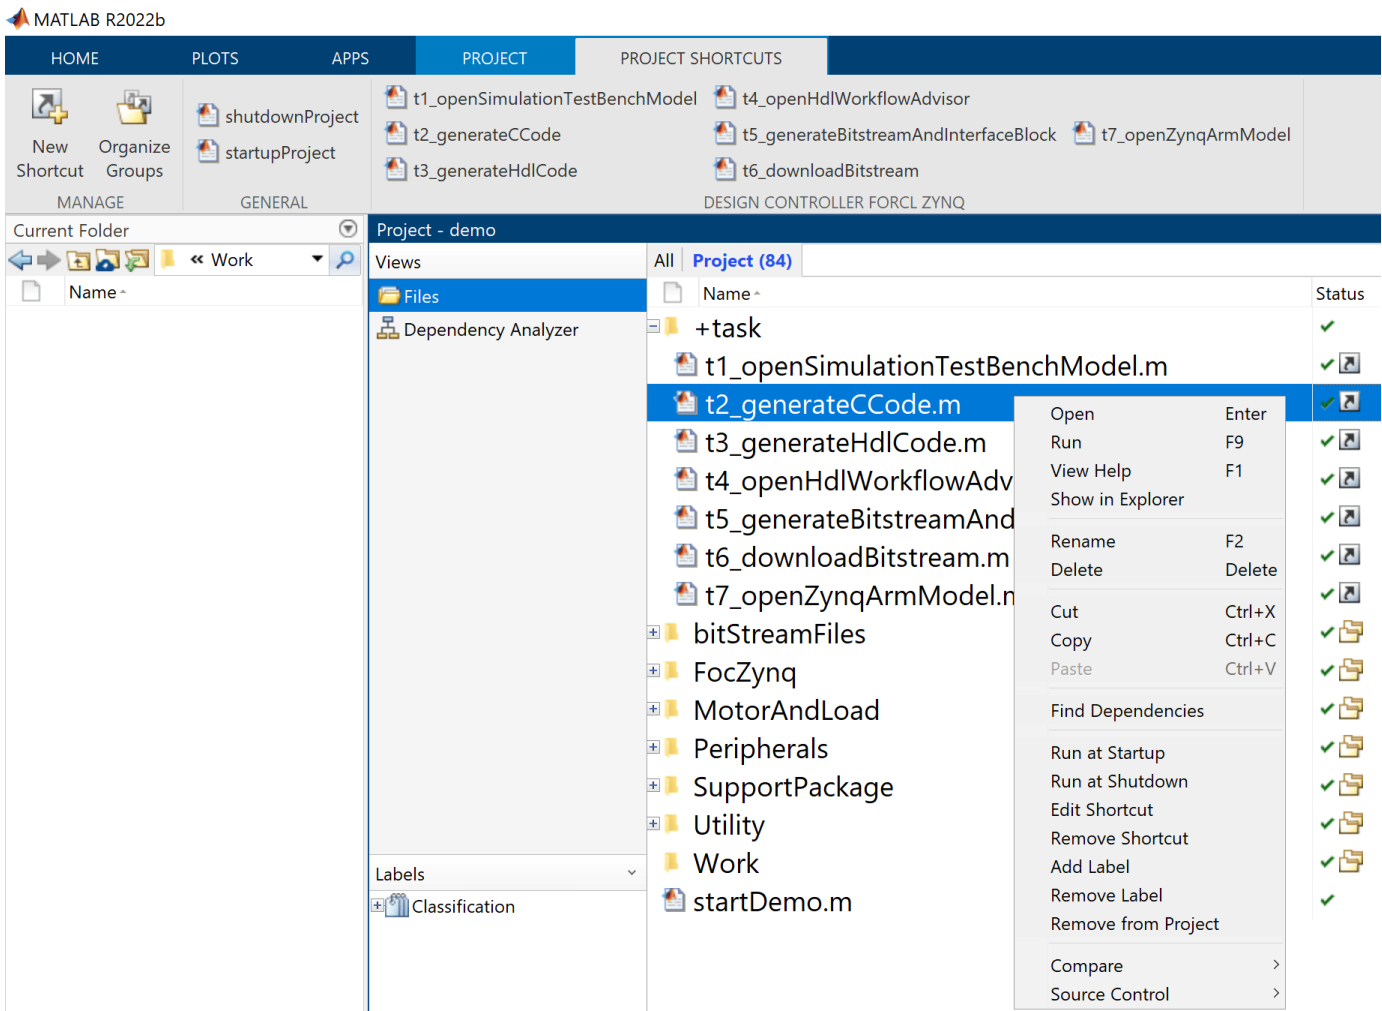

Simulate Algorithm Behavior

First, open the example project, inspect the controller models, and verify the controller behavior through simulation. This example is packaged as a project. For more information on Simulink® projects, see “What Are Projects?”

1. Open the example project by entering this command at the MATLAB command prompt.

```
zynqPMSMF0Cstart
```

2. Click the **Project Shortcuts** tab to view the shortcuts to the files and folders that this example uses.

3. Run `task.t1_openSimulationTestBenchModel` to open the `focZynqTestBench` model.

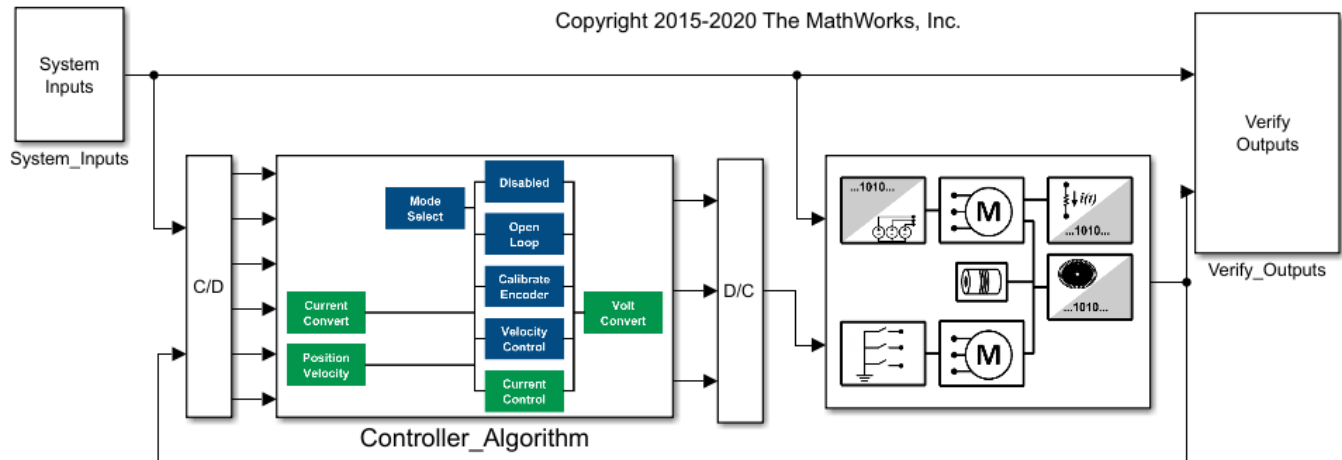

`task.t1_openSimulationTestBenchModel`

The `Motor_And_Load` subsystem consists of a mathematical model of a surface PMSM, motor load, encoder, and current sensor. The `Controller_Algorithm` subsystem includes:

- I/O engineering unit conversion
- Electrical position calculation
- Rotor velocity calculation
- Mode scheduler, and four control modes: disabled, open loop velocity control, encoder calibration, and closed loop velocity control.

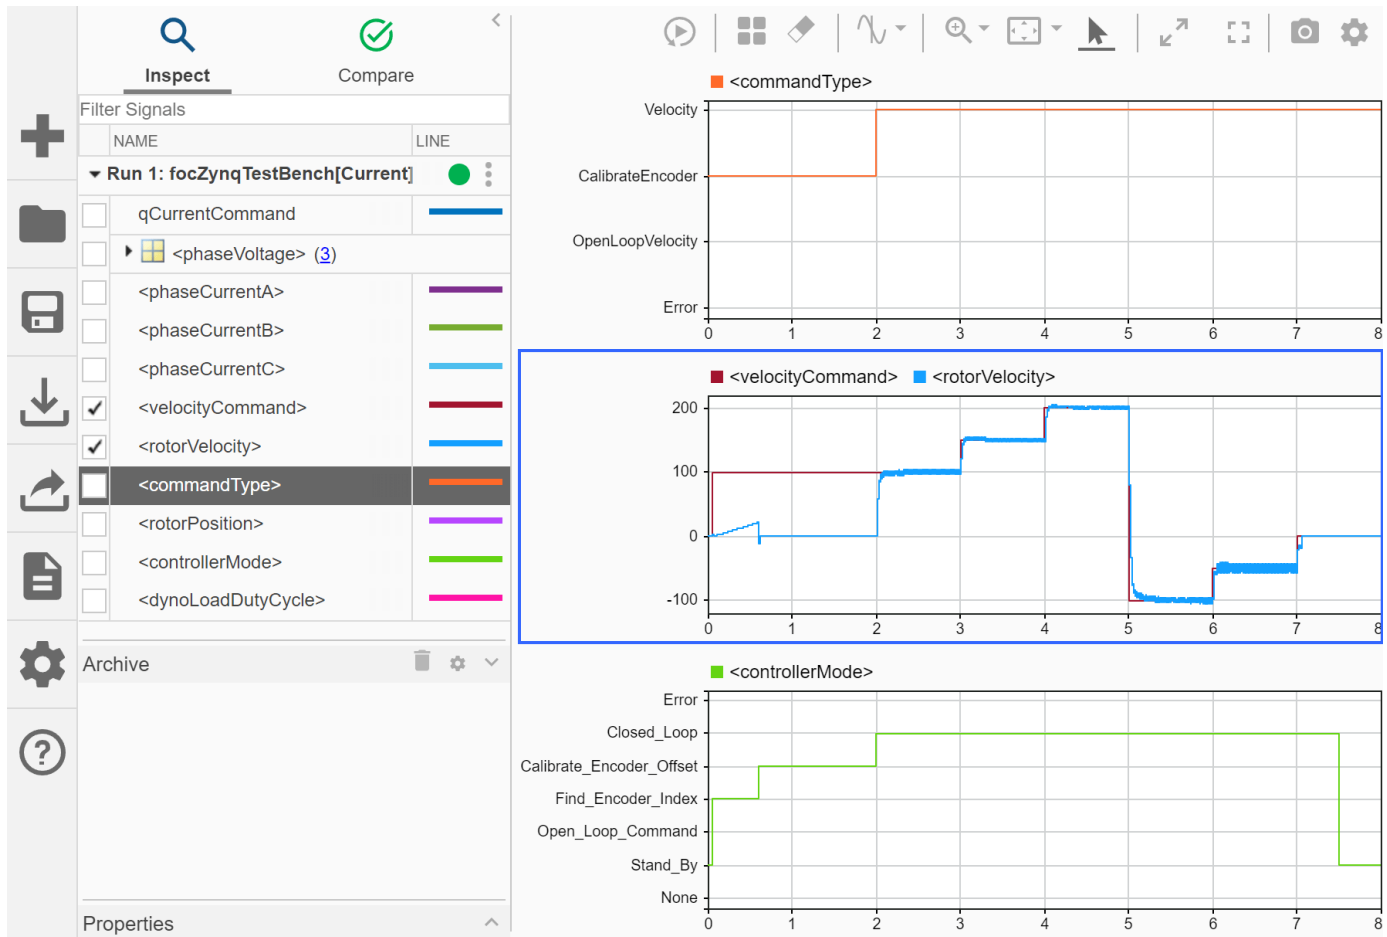

The C/D and D/C subsystems convert the data from continuous- and variable-time step solvers and floating-point data types to discrete- and fixed-time step solvers and fixed-point data types..

Field-Oriented Control of Velocity Hardware/Software Test Bench

If you do not have the Specialized Power Systems Library in Simscape Electrical™ installed, the `Motor_And_Load` subsystem contains a block that enables you to simulate the model with default motor and load parameters. In this case, you are not able to explore or modify parameters.

4. On the **Simulation** tab click **Run** to simulate the model.
5. After simulation completes, open the **Simulation Data Inspector**. On the **Simulation** tab, click **Data Inspector**. For more information on the Simulation Data Inspector, see Simulation Data Inspector.
6. In the **Simulation Data Inspector**, select the `<commandType>`, `<velocityCommand>`, `<rotorVelocity>`, and `<controllerMode>` signals.

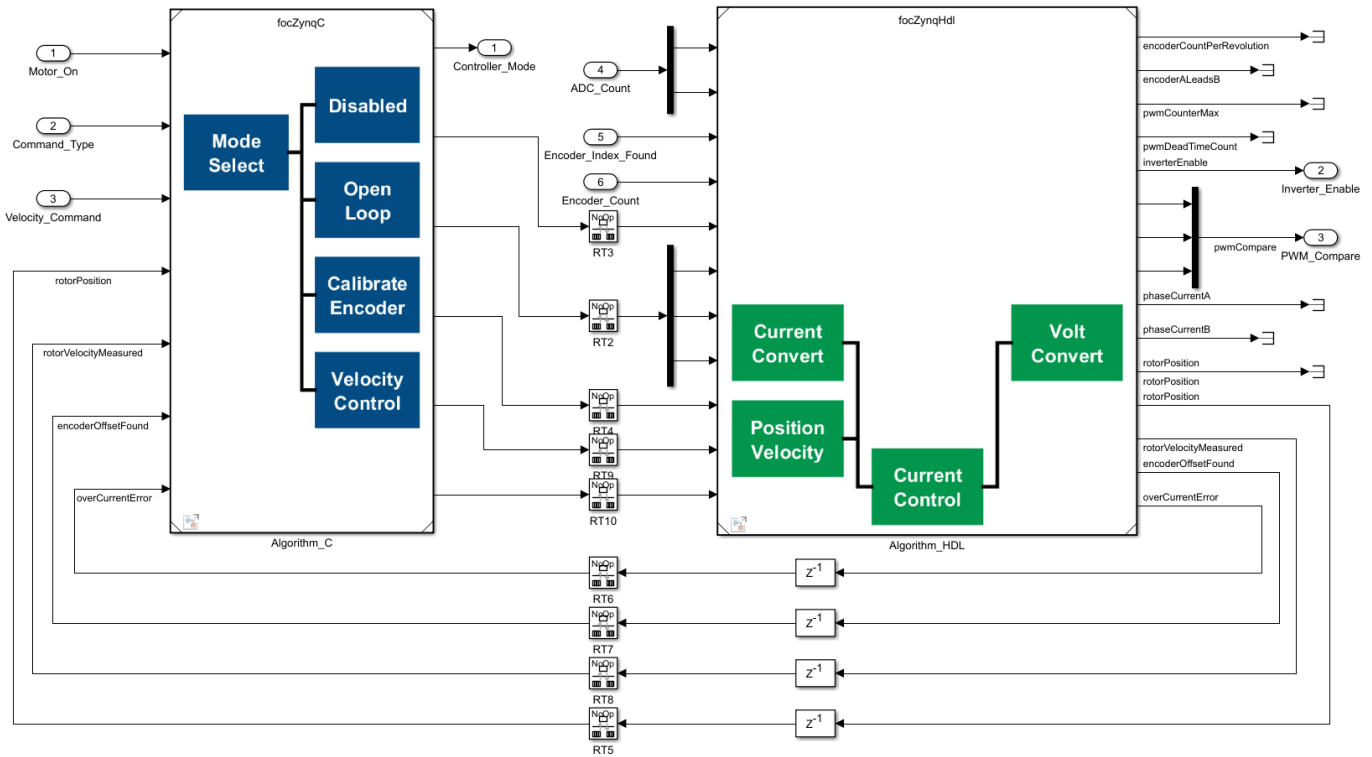

For the first two seconds, the controller receives commands to calibrate the encoder position sensor. The encoder position sensor must be calibrated before the controller can achieve closed-loop control. During the first portion of position calibration, the motor accelerates using open-loop control to identify the index pulse of the encoder. After the index is found, the controller commands and holds a zero position until the encoder offset is identified. During this period, the velocity is zero. After two seconds, the controller changes into closed-loop control and follows the commanded velocity profile. During closed-loop velocity control, the FOC regulates phase current in the PMSM.

Partition Controller Algorithm and Generate Code

Next you partition the controller algorithm into complementary software and hardware implementations by generating C and HDL code for the software and hardware implementations, respectively. The reports created during code generation show how you can integrate this code into your own embedded design.

1. In the `focZynqTestBench` model, open the `Controller_Algorithm` subsystem. The controller algorithm contains the `Algorithm_C` and `Algorithm_HDL` blocks, which reference the `focZynqC` and `focZynqHDL` models, respectively. The `focZynqC` model contains the portion of the algorithm to be implemented in software. The `focZynqHDL` model contains the portion of the algorithm to be implemented on the hardware.

Controller Algorithm

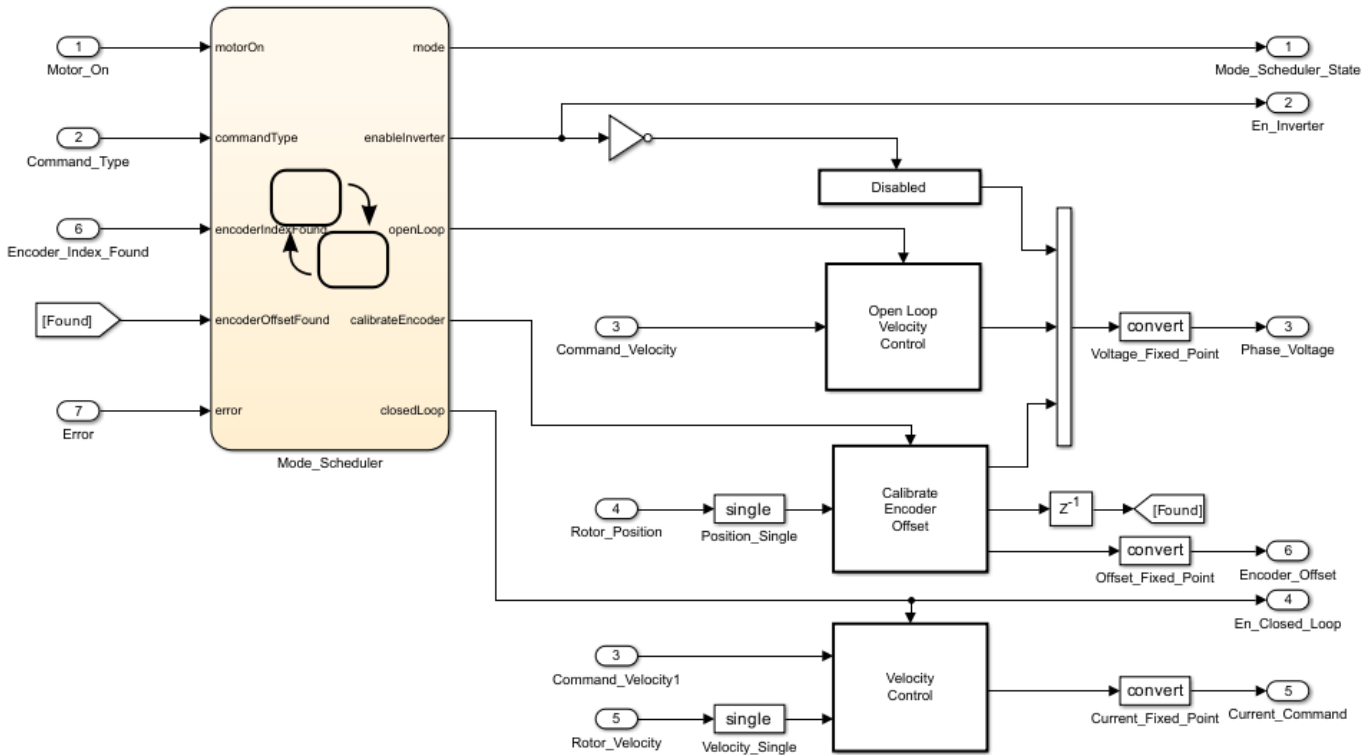

2. Run the `task.t2_generateCCode` function to open the `focZynqC` model, generate C code, and generate a report.

`task.t2_generateCCode`

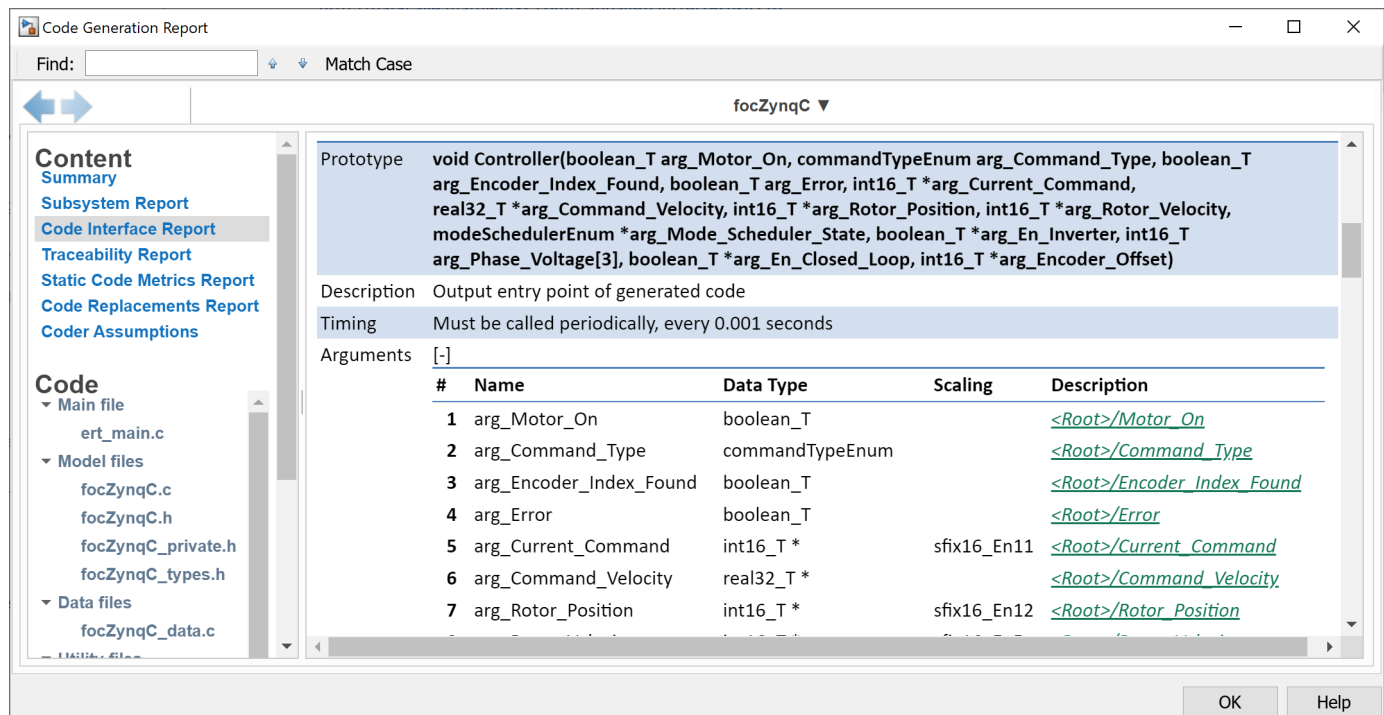

The `focZynqC` model contains the mode scheduler, velocity control loop, open-loop velocity controller, and a routine that automatically calibrates the encoder offset.

Field-Oriented Control of Velocity Zynq C Specification

Copyright 2015-2020 The MathWorks, Inc.

3. The code generation report shows how the generated code corresponds to the model. Click **Code Interface Report** to view the function interface of the code. The C code is portable and can integrate with any floating-point embedded processor that uses ANSI-C compiler. For more information on the Code Generation Report, see “Reports for Code Generation” (Embedded Coder).

4. Run the `task.t3_generateHdlCode` function to open the `focZynqHdl` model, generate HDL code, and generate a report.

```
task.t3_generateHdlCode
```

The `focZynqHdl` model contains the electrical position calculation, rotor velocity calculation, over-current checks, and the field-oriented controller.

Field-Oriented Control of Velocity Zynq HDL Specification

Copyright 2015-2020 The MathWorks, Inc.

5. The code generation report shows how the HDL code corresponds to the model. Under **Generated Source Files** select the `focZynqHdl.vhd` file, which contains the entity specification. The HDL code for the algorithm is portable and can integrate with any FPGA that supports VHDL code.

```

```

Set Up Xilinx Zynq Platform and Motor Boards

Next, set up and connect the hardware boards.

1. Run the hardware setup for the Xilinx Zynq platform. For information on the hardware setup, see “Install Support for Xilinx Zynq Platform” (Embedded Coder Support Package for Xilinx Zynq Platform). You must install both Embedded Coder® Support Package for Xilinx Zynq Platform and HDL Coder™ Support Package for Xilinx Zynq Platform.
2. Connect the Trenz board as shown in the image.

The image shows these components:

- 1 5V DC power supply
- 2 SD card
- 3 Micro USB cable for UART and JTAG
- 4 Ethernet connector
- 5 Encoder connector
- 6 24 V DC power supply
- 7 Motor power cable (A, B, C)
- 8 24 V brushless DC motor
- 9 Switch 1 (S1), which controls power to the driver board

3. Ensure that jumper J4 on the carrier module is set to SD and J3 on the motor driver card is set up for a single ended encoder.

4. Insert the encoder cable according to the picture below. For more information on the jumper settings, visit the Trenz Electronic website.

5. Download the Trenz TE0820 Linux Image, extract the ZIP archive, and copy the contents to the microSD card. Insert the microSD card in connector J8.

6. After you program FPGA bitstream, press the S1 switch located on the motor driver card once to connect the 24V to the MOSFETS. In case of any unexpected behavior from the device, use the S1 switch to disconnect the power.

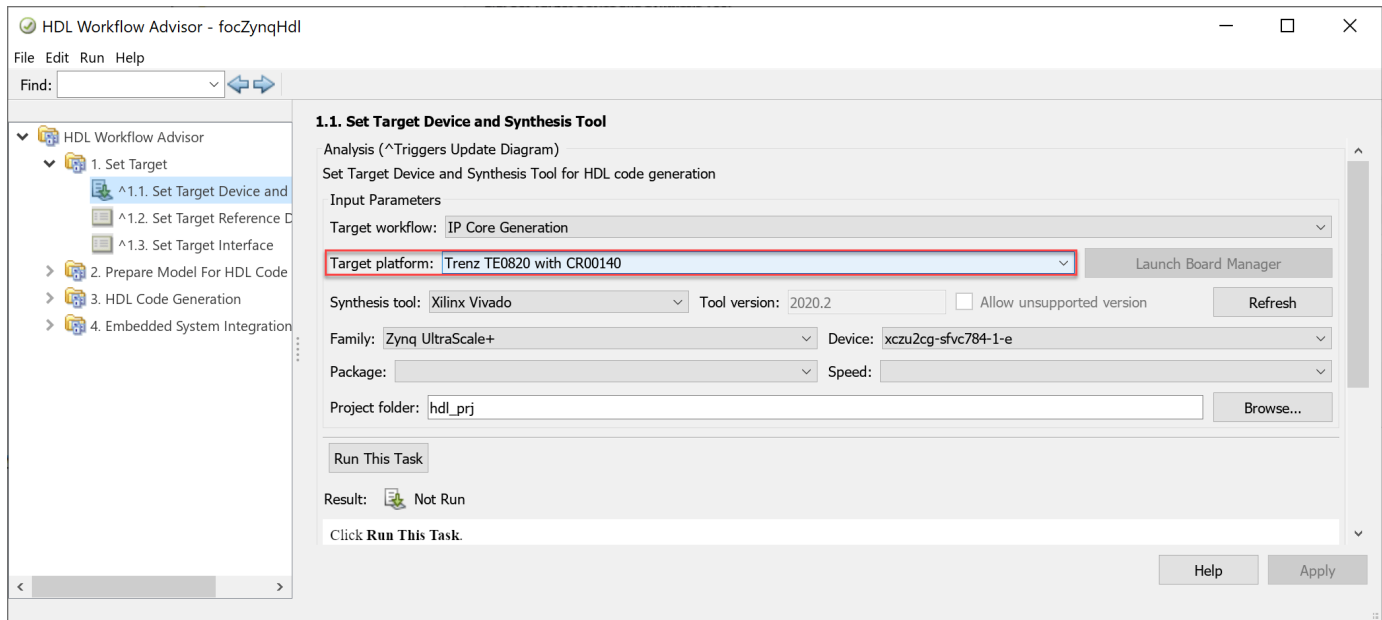

Deploy Bitstream to Programmable Logic

Next, use the HDL Workflow Advisor to generate HDL code for the algorithm, package the HDL into an IP core, integrate the IP core into a Xilinx reference design, and create a bitstream.

1. Run the `task.t4_openHdlWorkflowAdvisor` function to open HDL Workflow Advisor.

```
task.t4_openHdlWorkflowAdvisor
```

2. In the **HDL Workflow Advisor** in the **1. Set Target > 1.1 Set Target Device and Synthesis Tool** group, set the **Target platform** to Trenz TE0820 with CR00140. Trenz TE0820 with CR00140 is a Vivado® reference design that contains the ADC, encoder, and PWM components. For information on this reference design, see “Define Custom Board and Reference Design for Zynq Workflow” on page 47-231.

3. Select **1.2. Set Target Interface** to identify the ports. The entries in the **Target Platform Interfaces** column of the table that have the prefix IP refer to connections that are registered with the Trenz motor control reference design.

4. Select **4.3 Build FPGA Bitstream > Run to Selected Task** or run the task.t5_generateBitstreamAndInterfaceBlock function from the project to generate the HDL code for the algorithm and create the FPGA bitstream from the Xilinx reference design.

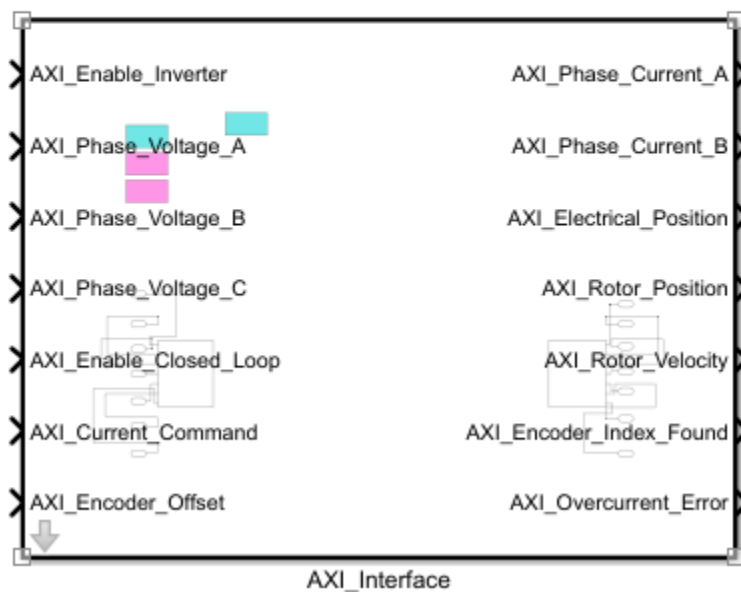

task.t5_generateBitstreamAndInterfaceBlock

5. Follow the progress of bitstream generation in the DOS Command Prompt window. In addition to generating a bitstream the customized target generates the `focZynqHdlAxiInterfaceLib` software interface library. The library contains an `AXI_Interface` block. The `AXI_Interface` block, which contains the AXI4-Lite interface components, provides connectivity from the model deployed on the ARM processor to the model deployed on the programmable logic.

AXI Interface Library

Library created on 16-Jun-2022 10:09:16

6. Run task **4.4 Program Target Device** or run the `task.t6_downloadBitstream` function from the project to program the FPGA:

```
task.t6_downloadBitstream
```

Deploy Executable to ARM processor

Next, generate C code for the controller and integrate this code with a Linux® reference framework to build, deploy, and run the model as an executable to the ARM processor. Data logged from the model running on the processor can then be compared to the results of the simulation.

1. Run the `task.t7_openZynqArmModel` function to open the `focZynqArmDeployment` model.

```
task.t7_openZynqArmModel
```

The `focZynqArmDeployment` model can generate C code, automate the integration with a Linux ARM reference framework, and deploy the executable to the ARM processor on the Xilinx Zynq platform. The deployment model references the original controller model and contains the test stimulus, scope, and AXI_Interface library block created in the Deploy Bitstream to Programmable Logic on page 47-351 section.

2. On the **Hardware** tab, click **Monitor & Tune** to build, deploy, and run the model as an executable on the ARM processor. The generated code is compiled against the reference framework to create an executable. While executing, Simulink monitors the signals and shows them in the Scope block.

3. Open the **Simulation Data Inspector** to view the logged signals and compare them to the signals logged previously from `focZynqTestBench` model. On the **Simulation** tab, click **Data Inspector**.

4. In the **Simulation Data Inspector**, select the `rotorVelocity` signal. During the encoder calibration mode, the signals initially differ because the simulated and real motors started with different rotor positions. In contrast, the closed-loop velocity control from the simulation and hardware are very similar. Differences occur because the simulation model of the motor and sensors use data sheet values and do not explicitly account for the manufacturing tolerances of the physical motor.

Deploy a Frame-Based Model with AXI4-Stream Interfaces

This example shows how to leverage the frame to sample optimization from HDL Coder™ to generate a sample-based IP core with AXI4-Stream interfaces from a frame-based Simulink® model. The generated IP core can then be deployed to hardware and verified using live streaming data from MATLAB®.

It is common to model frame-based algorithms in MATLAB and Simulink. This modeling style allows intuitive algorithm designs that process data as entire frames using frame-based operations. However, these operations are not efficient to implement on FPGA/ASIC devices, which typically process large datasets as samples. Thus, frame-based algorithms need manual conversion to their sample-based counterparts before deployment, adding time-consuming and error-prone work to the design process.

Using the frame to sample optimization, HDL Coder automates the frame to sample conversion process and generates sample-based HDL code for frame-based algorithms modeled using element-wise operations, neighborhood idioms, iterator, and reduction operations. When you use the frame to sample conversion, HDL Coder automatically transforms your frame-based algorithm into a sample-based model with valid and ready control signals and the logic to handle and align the data streams as shown below:

In this example, you:

- 1 Model a frame-based edge detection algorithm by using neighborhood processing functions.
- 2 Generate an HDL IP core with an AXI4-Stream interface.
- 3 Integrate the generated IP core into a reference design with a DMA controller.
- 4 Use a simple script to prototype the design running on hardware with live data.

Prerequisites

To run this example, you must have the following software installed and hardware boards setup:

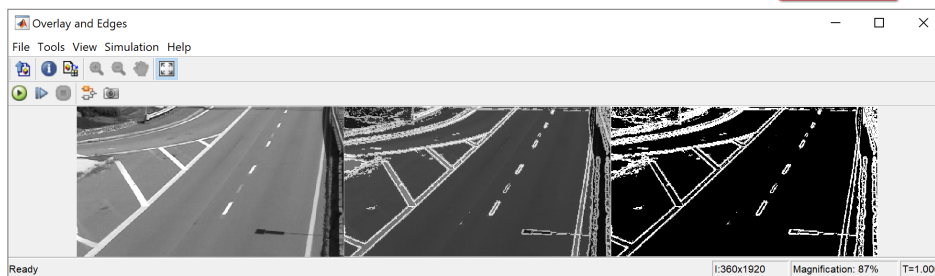

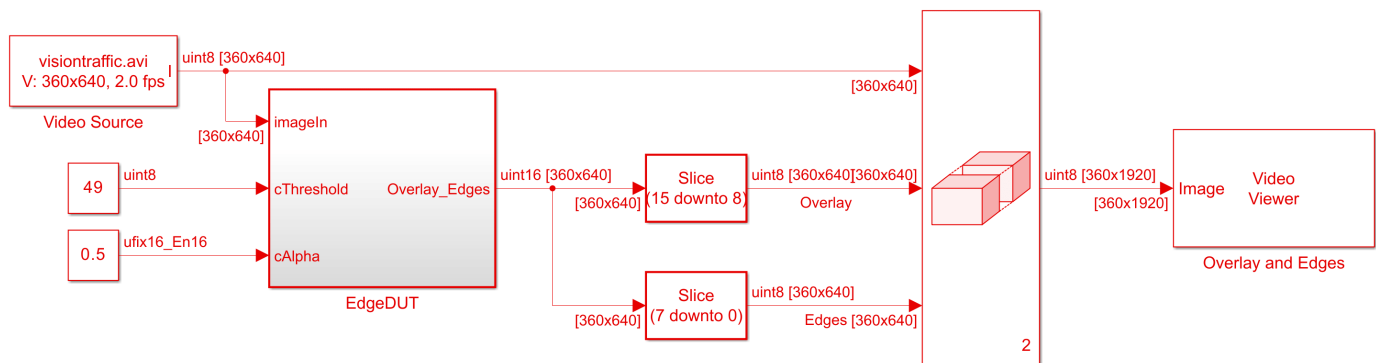

- HDL Coder Support Package for Xilinx® Zynq® Platform
- Xilinx Vivado® (To view the supported versions, see “HDL Language Support and Supported Third-Party Tools and Hardware”)
- Xilinx SoC board. This example uses the Xilinx Zynq ZC706 evaluation kit.
- MathWorks® firmware image on the SD card of the board. For help with SD card setup, see “Guided SD Card Setup” (HDL Coder Support Package for Xilinx Zynq Platform).

Model an Edge Detection Algorithm Using Neighborhood Processing Functions

Open the frame-based edge detection model.

```
open_system('hdlcoder_tunable_edge_detection')
set_param('hdlcoder_tunable_edge_detection', 'SimulationCommand', 'Update')
```

Edge Detection and Image Overlay

The model consists of the design under test (DUT) and the test bench. The DUT contains a MATLAB® Function block that models a Sobel edge detection algorithm by using the `hdl.npufun` function. The edge calculation uses scalar input parameters, `cThreshold` and `cAlpha`, with the frame input to compute the edge overlay on the original frame input. For more information, see `hdl.npufun`.

```
function [O,E] = edgeDetectionAndOverlay(I, cThreshold, cAlpha)
```

```
E = hdl.npufun(@sobel_kernel, [3 3], I, 'KernelArg', cThreshold);
O = hdl.npufun(@mix_kernel, [1 1], E, I, 'KernelArg', cAlpha);

end

function e = sobel_kernel(in,cThreshold)

u = fi(in);
hGrad = u(1) + fi(2)*u(2) + u(3) - (u(7) + fi(2)*u(8) + u(9));
vGrad = u(1) + fi(2)*u(4) + u(7) - (u(3) + fi(2)*u(6) + u(9));

hGrad = bitshift(hGrad, -3); % Divide by 8
vGrad = bitshift(vGrad, -3); % Divide by 8

thresholdValueSq = fi(cThreshold); % Edge threshold
e = (hGrad*hGrad + vGrad*vGrad) > thresholdValueSq;

end

function O = mix_kernel(E, I, cAlpha)

alpha = fi(cAlpha); % Parameter for combining images
scaleE = E*fi(255,0,8,0);
O = scaleE * (fi(1)-alpha) + I*alpha;

end
```

You can use the `hdl.npufun` function for the frame-to-sample conversion to translate the frame-based algorithm into a sample-based algorithm. You can connect the streaming I/O of your sample-based algorithm to a streaming interface. Additionally, you can map the tunable parameters to AXI4-Lite or External Ports.

When you convert this model by using the HDL Coder Workflow Advisor, you generate an AXI4-Stream interface that contains the signals in this image:

Generate HDL IP Core

Generate an IP core from the frame-based DUT by using the HDL Workflow Advisor.

1. Enable the frame-to-sample conversion by entering this command:

```
hdlset_param('hdlcoder_tunable_edge_detection','FrameToSampleConversion','on');
```

2. Enable the HDL block property ConvertToSamples for the input image to be streamed (imageIn) using this command:

```
hdlset_param('hdlcoder_tunable_edge_detection/EdgeDUT/imageIn','ConvertToSamples','on');
```

3. Set up the Xilinx Vivado synthesis tool path by using the hdlsetuptoolpath command. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath','C:\Xilinx\Vivado\2020.2\bin\vivado.bat')
```

4. Open the HDL Coder app. Click the **Apps** tab, then open **HDL Coder**. Click the **Workflow Advisor** button to open the HDL Workflow Advisor.

5. Click **1. Set Target > 1.1. Set Target device and Synthesis Tool**, then set **Target Workflow** to IP Core Generation and **Target Platform** to Xilinx Zynq ZC706 evaluation kit. If you are targeting a different Xilinx SoC, choose your board from the **Target Platform** context menu.

6. Click **1.2. Set Target Reference Design**, then set **Reference design** to Default system with AXI4-Stream interface.

7. Click **1.3. Set Target Interface**. The ports of the DUT subsystem are mapped to IP core interfaces. The AXI4-Stream interface communicates in master/slave mode, where the master device sends data

to the slave device. For this example, for the input port, **imageIn**, set **Target Platform Interfaces** to **AXI4-Stream Slave** and set the output port, **Overlay_Edges**, to **AXI4-Stream Master**. The cells in **Data Type** column that include **streamed port** indicate the ports you can map to stream interfaces. Finally, to control the tunable parameters at runtime, set **Target Platform Interfaces** to **AXI4-Lite** for the non-streamed kernel inputs, **cAlpha** and **cThreshold**.

Click **Run This Task**.

The AXI4-Stream interface contains data (**Data_In**, **Data_Out**) and control signals such as data valid (**Valid_In**, **Valid_Out**), back pressure (**Ready_In**, **Ready_Out**), and data boundary (**TLAST**). It is only required to map your frame inputs and outputs as **Data**. The **Valid**, **Ready**, and **TLAST** control signals are automatically generated. Refer to “Model Design for AXI4-Stream Interface Generation” on page 47-13 for a detailed description of the protocol signals.

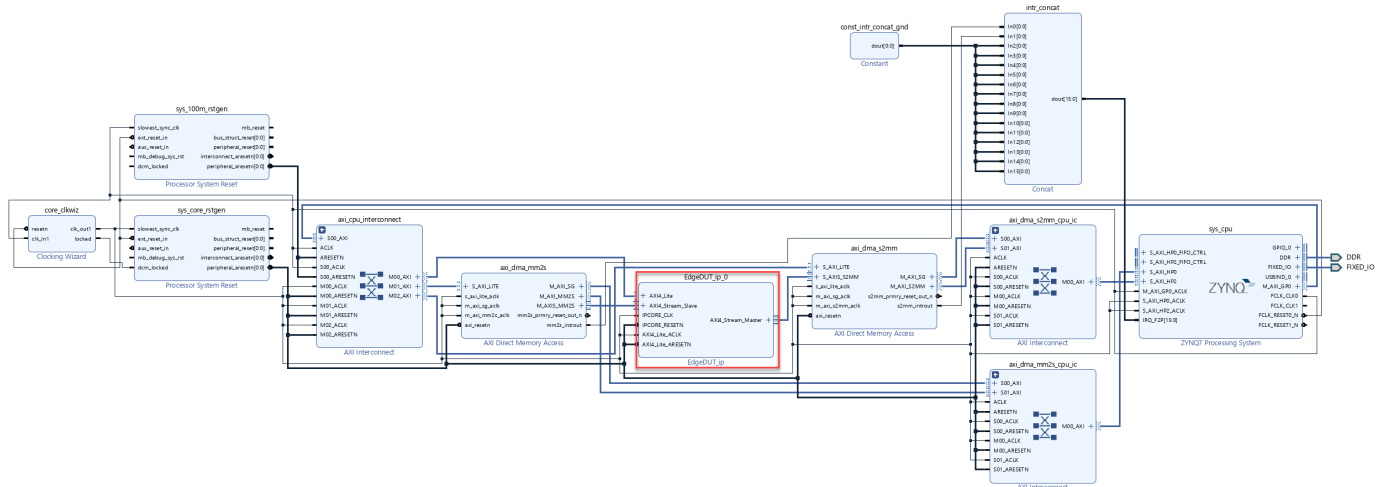

8. Right-click **3.2, Generate RTL Code and IP Core** and select **Run to Selected Task** to generate the IP core.

Integrate IP Into Reference Design Compatible with AXI4-Stream

In the HDL Workflow Advisor, run the tasks under **4.Embedded System Integration** to deploy the generated HDL IP core on Zynq hardware.

1. Click **4.1 Create Project**, then click **Run This Task**. This task inserts the generated IP core into the **Default system with AXI4-Stream interface** reference design. As shown in the IP core report, data flows from the ARM processing system through the DMA controller and the AXI4-Stream interface to the HDL Coder generated edge detection IP core. The processing system receives the processed output from the edge detection IP core.

2. Optionally, click the link in the Result pane to open the generated Vivado project. In the Vivado tool, click **Open Block Design** to view the Zynq design diagram.

Generate Interface Between Host Computer and IP Core

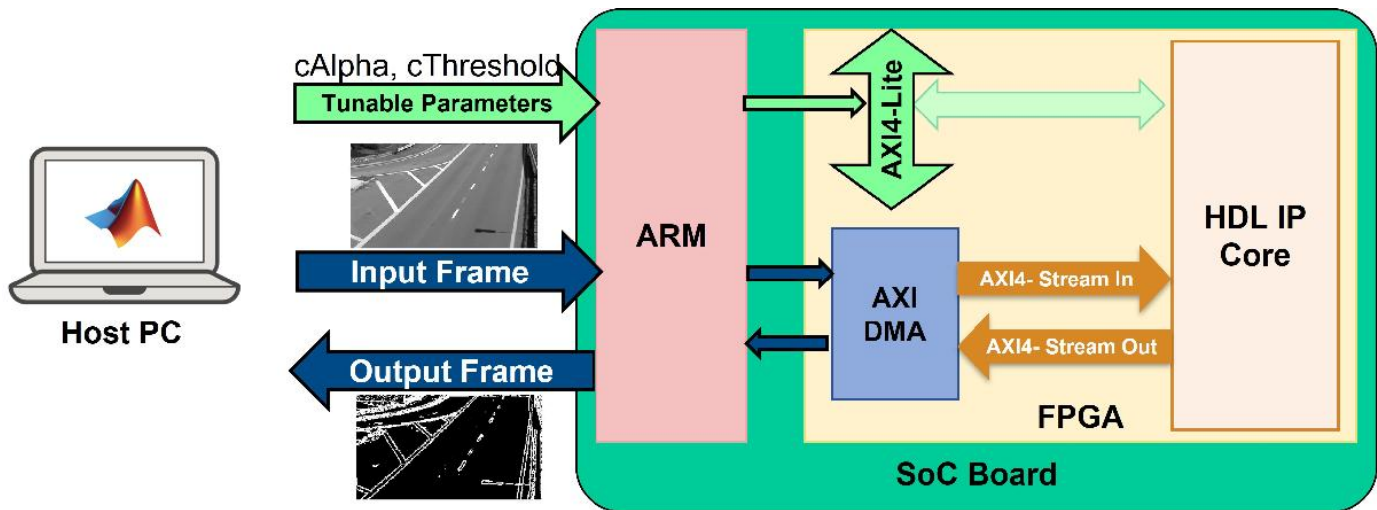

1. In the **Generate Software Interface**, select **Generate host interface script** and click **Run this Task**. The HDL Coder Workflow advisor generates two MATLAB files in your current folder that you can use to prototype your generated IP core directly from MATLAB:

- `gs_hdlcoder_tunable_edge_detection_setup.m`: This function configures the fpga hardware object with the same ports and interfaces that you mapped in the **1.3 Set Target Interface** task.
- `gs_hdlcoder_tunable_edge_detection_interface.m`: This file creates a connection to your FPGA hardware for reading and writing data.

2. In the HDL Workflow Advisor, run the rest of the tasks to build and download the FPGA bitstream.

Live Frame-Based Model Running on FPGA

You can interact with the FPGA design by reading and writing data from MATLAB on the host computer as described in the **Interact with FPGA Design from Host Computer** section of the “Prototype FPGA Design on Hardware with Live Data by Using MATLAB Commands” on page 46-234. The host computer sends and receive frames of data from the System on Chip (SoC) board as shown below in the high level architecture of the system:

This live script uses the generated script file as a starting point to test the frame-based model deployed on the FPGA.

```
open hdlcoder_frame_edge_detection_script.mlx
```

In the Write/Read DUT ports section of the `hdlcoder_frame_edge_detection_script` script, the code performs edge detection for every 20th frame for the first 200 frames of the `visiontraffic.avi` video and varies the `cAlpha` and `cThreshold` parameters as shown below

```
vidObj = VideoReader('visiontraffic.avi');
h = figure();
set(h, 'Position', [0 0 800 800])
for ii=1:20:200
    % Modify Parameters
    cThreshold = randi([20,90],1); % Vary cthreshold from 20 to 90
    % Write cThreshold value to "cThreshold" port in the DUT (AXI4-Lite)
    writePort(hFPGA, "cThreshold", cThreshold);
    cAlpha = rand(); % Vary cAlpha from 0 to 1
    % Write cAlpha value to "cAlpha" port in the DUT (AXI4-Lite)
    writePort(hFPGA, "cAlpha", cAlpha);
    % Read the iith frame of vidObj
    vidFrame = read(vidObj,ii);
    vidFrameGr = rgb2gray(vidFrame);
    % Write to inputImage DUT port (AXI4-Stream)
    wrValid = writePort(hFPGA, "imageIn", vidFrameGr);
    if wrValid
        subplot(2,2,1), imagesc(vidFrameGr); axis image; axis off; colormap(gray);
        title(sprintf('Frame %d',ii))
    end
    % Read from inputImage DUT port (AXI4-Stream)
    [outputFrame, rdValid] = readPort(hFPGA,"Overlay_Edges");
    if rdValid
        % Display the data read from the DUT
        subplot(2,2,2), imagesc(uint8(bitsliceget(fi(outputFrame),16,9))); axis image; axis off;
        title('Overlay')
        subplot(2,2,3), imagesc(uint8(bitsliceget(fi(outputFrame),8,1))); axis image; axis off;
        title('Edges')
        sgtitle(sprintf('threshold %.2f, alpha %.2f',cThreshold, cAlpha))
        drawnow
    end
end
```

```
else  
    continue;  
end  
end
```

threshold 49.00, alpha 0.54

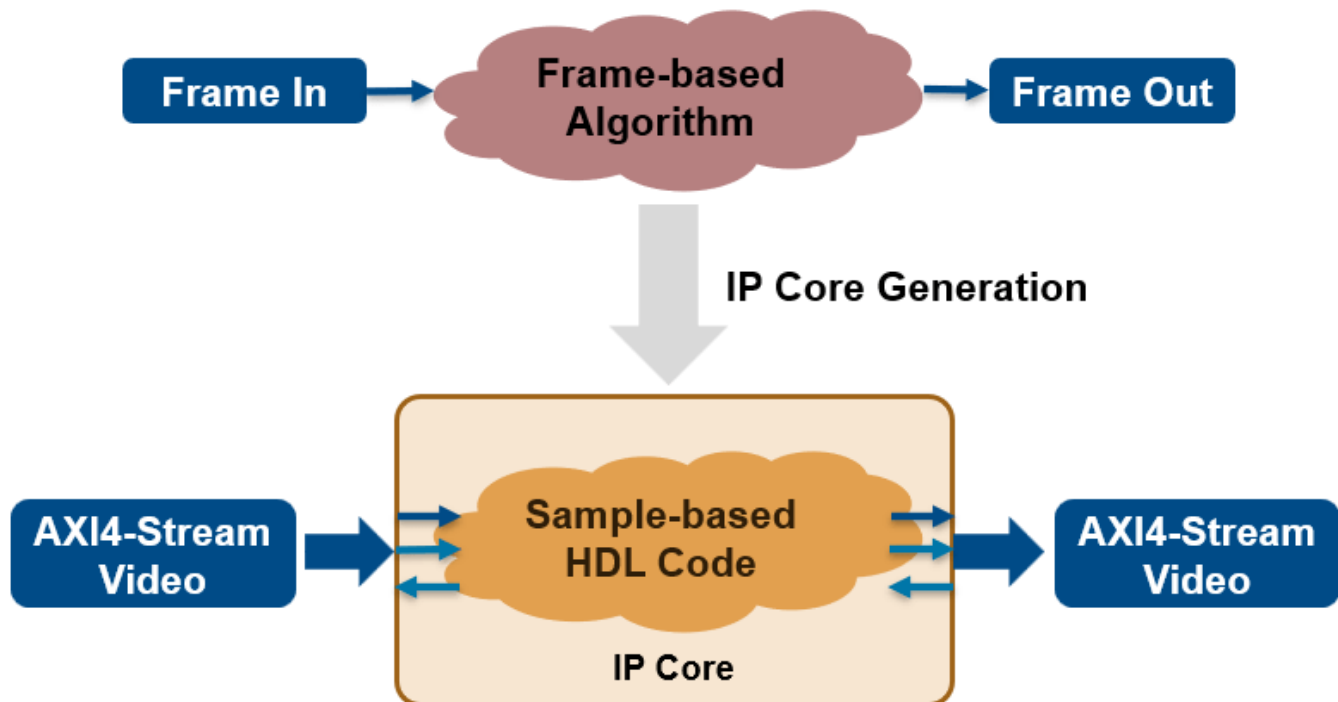

When you finish the example, run the last line of the script to release any hardware resources used by the fpga object:

```
release(hFPGA);
```

Deploy Frame-Based Models with AXI4-Stream Video Interfaces in Zynq-Based Hardware

You can use the HDL Coder™ frame-to-sample optimization to design and deploy frame-based algorithms that use AXI4-Stream Video interfaces to enable high-speed video streaming.

In this example, you:

- 1 Model a frame-based edge detection algorithm by using neighborhood processing functions.
- 2 Generate an HDL IP core with an AXI4-Stream Video interface.
- 3 Integrate the generated IP core into a Xilinx® Zynq® ZC706 reference design with access to HDMI interfaces.

Prerequisites

To run this example, you must have the following software and hardware boards setup:

- HDL Coder™ Support Package for Xilinx Zynq Platform
- Embedded Coder® Support Package for Xilinx Zynq Platform
- Vision HDL Toolbox™ Support Package for Xilinx-Zynq-Based Hardware
- Xilinx Vivado® Design Suite
- Xilinx Zynq ZC706 evaluation kit with FMC HDMI I/O card (FMC-HDMI-CAM or FMC-IMAGEON)

Set Up Hardware

1. Install the HDL Coder and Embedded Coder Support Packages for Xilinx Zynq Platform, and Vision HDL Toolbox Support Package for Xilinx Zynq-Based Hardware. To install the support packages, in MATLAB®, in the **Home** tab, click **Add-Ons > Get Hardware Support Packages**.

2. Use the SD card image provided by the Embedded Coder Support Package for Xilinx Zynq Platform.

3. Set up the Xilinx Zynq ZC706 board and the FMC HDMI I/O card as shown in the figure below. Follow these instructions for connecting the hardware:

- 1** Remove the SD card from the host computer and insert it into the Zynq board.
- 2** Plug the HDMI FMC card into the FMC connector on the Zynq board.
- 3** Connect an Ethernet cable to the board.
- 4** Connect the power cable.
- 5** Connect an HDMI video source to the FMC HDMI I/O card. The video source must be able to provide 1080p video output, such as a video camera, smart phone, tablet, or the HDMI output of your computer.
- 6** Connect a monitor to the FMC HDMI I/O card. The monitor must be able to support 1080p display.

To learn more about the ZC706 hardware setup, see Xilinx ZC706 Evaluation Board User Guide.

Model a Frame-Based Algorithm to Integrate with the Default Video System Reference Design

Open the frame-based model, `hdlcoder_frame_video_edge`, which contains an edge detection and image overlay algorithm in the device under test (DUT), `EdgeDUT`.

```
load_system('hdlcoder_frame_video_edge')
open_system('hdlcoder_frame_video_edge/EdgeDUT')
```

In the example model, the DUT subsystem, `hdlcoder_frame_video_edge/EdgeDUT`, uses the `hdl.npufun` function to implement the Sobel Edge detection algorithm and the `code.hdl.pipeline` function to pipeline the design to achieve the frequency needed to perform edge detection on live video. For more information on modeling the algorithm, see “Synthesize Code for Frame-Based Model” on page 29-26. When using the frame-to-sample optimization, you do not need to model additional control signals. The ports `ImageIn` and `Overlay` are the pixel data ports for video streams. The additional input ports, `cThreshold` and `cAlpha`, are control ports that adjust the parameters of the Sobel edge detection algorithm. You can enable the frame-to-sample conversion for this model using these commands:

```
hdlset_param('hdlcoder_frame_video_edge', 'FrameToSampleConversion', 'on');
hdlset_param('hdlcoder_frame_video_edge/EdgeDUT/ImageIn', 'ConvertToSamples', 'on');
```

Generate HDL IP Core with AXI4-Stream Video Interface

When you generate an IP core that is integrated into the Default Video System Reference Design, the video stream signals are encoded into a 32-bit representation `32'hFFRRGGBB`. To account for the data format, the subsystem `hdlcoder_frame_video_edge/EdgeDUT/IntensityCalculator` decodes the RGB 32-bit representation of the video stream to get the intensity of the frame. Additionally, the subsystem encodes the output into the same format when it calculates the overlay. For more information on the architecture of the reference design see “Default Video System Reference Design” (HDL Coder Support Package for Xilinx Zynq Platform).

To generate an IP core with the AXI4-Stream Video interface from a frame-based model:

1. Set up the Xilinx Vivado synthesis tool path by using the `hdlsetuptoolpath` command. Use your own Vivado installation path when you run the command.

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2022.1\bin\vivado.bat')
```

2. In the **1.1 Set Target Device and Synthesis Tool Task**, set **Target workflow** to IP Core Generation and set **Target platform** to Xilinx Zynq ZC706 evaluation kit. In task 1.2, set the **Reference Design** to Default video system (requires HDMI FMC module). In task 1.3, **Target Platform Interface Table** section, set the cells to these settings:

The AXI4-Stream video interface contains data (TDATA) and control signals such as TVALID, back pressure (READY), and data boundary (TDATA and TLAST). TDATA indicates the start of a video frame and TLAST indicates the end of a line. The timing diagram shows the timing for a 2x4 frame.

To use the frame-to-sample optimization, you must map your frame inputs and outputs as Pixel Data. The TVALID, READY, and TLAST control signals are automatically generated. In this example, the frame ports ImageIn and Overlay are mapped to the AXI4-Stream Video interface. The scalar ports cAlpha and cThreshold are mapped to the AXI4-Lite interface. HDL Coder generates AXI4 interface accessible registers for these ports.

3. Right-click task 3.2, **Generate RTL Code and IP Core**, and select **Run to Selected Task** to generate the IP core. You can find the register address mapping and other information for the IP core in the generated IP Core Report.

4. Right-click task 4.2 **Build FPGA Bitstream**, and select **Run to Selected Task** to generate the Vivado project and build the FPGA bitstream.

5. Run task 4.3, **Program Target Device**, to program the FPGA board.

DAC and ADC Loopback Data Capture

This example shows how to capture raw analog-to-digital converter (ADC) data using the FPGA I/O API from the Xilinx® Zynq® UltraScale+™ ZCU111 evaluation kit or Xilinx Zynq UltraScale+ ZCU216 evaluation kit. This example uses the HDL Workflow Advisor to configure an SoC model for HDL code generation. In this example, you generate the HDL code for your algorithm, build and deploy the HDL design on an RFSoc device, and run a MATLAB® script to interactively capture data from the deployed HDL design.

Requirements

- Vivado® Design Suite with a supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Xilinx Zynq UltraScale+ ZCU111 evaluation kit or Xilinx Zynq UltraScale+ ZCU216 evaluation kit
- HDL Coder
- HDL Coder Support Package for Xilinx RFSoc Devices

Introduction

Open the example project and copy the example files to a temporary directory

1. Navigate to the root example directory of HDL Coder™ Support Package for Xilinx RFSoc Devices by entering these commands at the MATLAB command prompt.

```
example_root = (hdlcoder_rfsoc_examples_root)
cd (example_root)
```

2. Copy all of the example files in the ADCDataCapture folder to a temporary directory.

This diagram depicts how the HDL design is used for this ADC capture example. The HDL Coder IP design transmits a numerically-controlled oscillator (NCO) waveform tone out of the digital-to-analog converter (DAC), which is then subsequently received by the ADC in the loopback configuration. AXI4-Stream transfers facilitate data movement back to the ARM processor in the Zynq RFSoc, which is then sent back to MATLAB over a TCP/IP connection.

Capture Logic Simulation

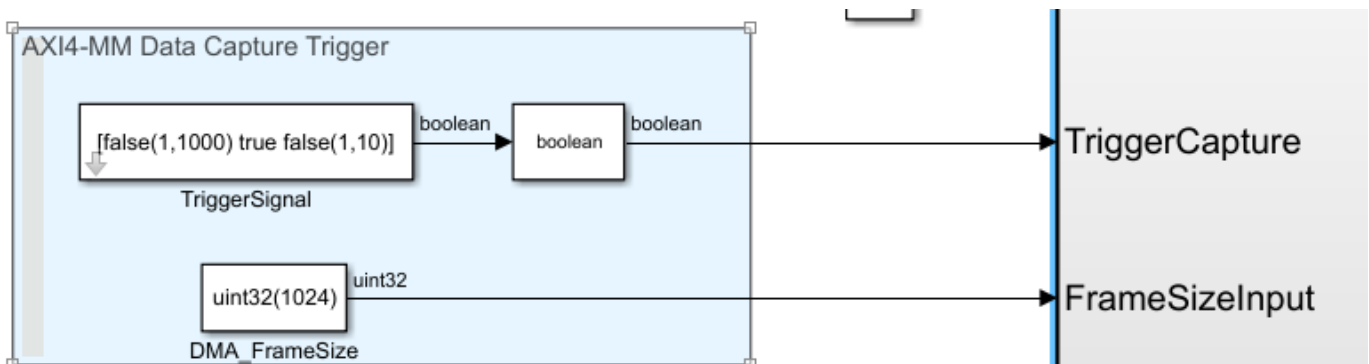

Simulate the model until the simulation terminates at the stop time. To examine the simulated captured data of the NCO waveform, open the DMA_Capture time scope plot, which this figure shows.

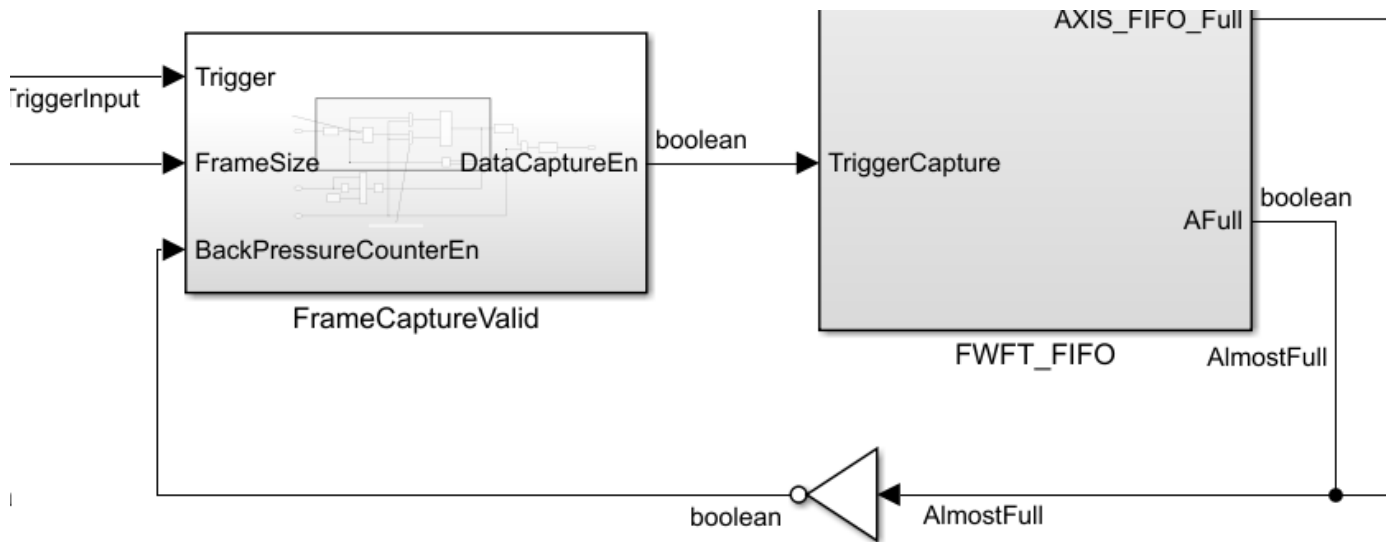

You can also view the captured data in MATLAB. The script `rfsocADCCaptureSimulationPlot.m` displays the data but uses the valid signal to extract the sample. This trimmed-down plot is what the direct memory access (DMA) transfers.

The simulation is set up such that the data movement logic moves 1024 samples of ADC samples when the trigger input is rising edge. This movement is done by using these two AXI4 register inputs.

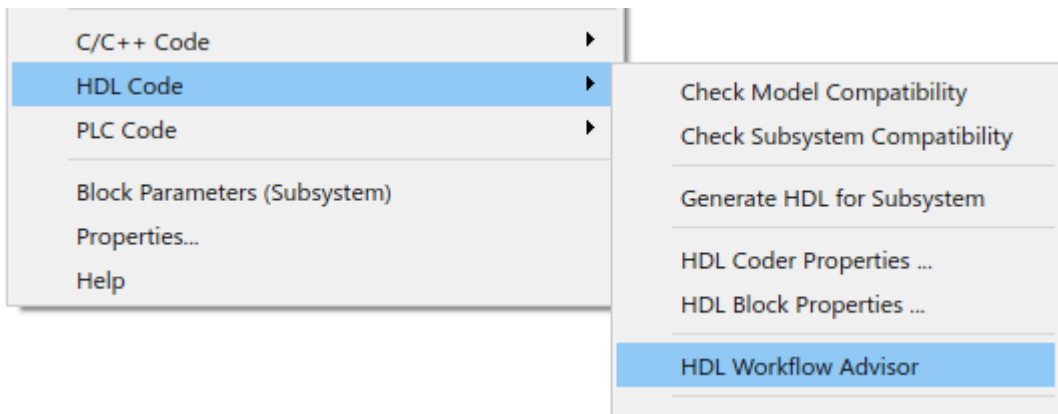

The register for the DMA frame size and the amount of data to transfer in the DMA must be equal. To examine the counter logic on how the capture is done, see this subsystem: `rf socADCCapture/ADC_Data_Capture/FrameCaptureValid`.

Generate HDL and Synthesize Bitstream

If you are running the example on a Windows® platform, copy and paste the example into a new folder with a shorter path before running this example. There are path character-length limitations that cause Vivado to error. This issue is not present on Linux® platforms.

Open the model `rfsocADCCapture.slx`, and then right-click the `ADC_Data_Capture` subsystem. Select **HDL Code**, then click **HDL Workflow Advisor**.

Follow these steps in the HDL Workflow Advisor:

Step 1: Select Target Board

In step 1.1, select **Target platform** as Xilinx Zynq Ultrascale+ RFSoc ZCU111 Evaluation Kit or Xilinx Zynq Ultrascale+ RFSoc ZCU216 Evaluation Kit.

Target workflow: IP Core Generation

Target platform: Xilinx Zynq UltraScale+ RFSoc ZCU111 Evaluation Kit Launch Board Manager

Synthesis tool: Xilinx Vivado Tool version: 2020.2 Refresh

Family: Zynq UltraScale+ RFSoc Device: xczu28dr-ffvg1517-2-e

Target workflow: IP Core Generation

Target platform: Xilinx Zynq UltraScale+ RFSoc ZCU216 Evaluation Kit Launch Board Manager

Synthesis tool: Xilinx Vivado Tool version: 2020.2 Refresh

Family: Zynq UltraScale+ RFSoc Device: xczu49dr-ffvf1760-2-e

Right-click the design under test (DUT) subsystem, and then click **Run This Task**.

Step 2: Set Target Reference Design

In step 1.2, set the **Reference design** parameter and the parameters in the **Reference design parameters** section to the indicated values in this figure.

Reference design: Real ADC/DAC Interface

Reference design tool version: 2020.2 Ignore tool

Reference design parameters

Parameter	Value
AXI4-Stream DMA data width	64
ADC sampling rate (MHz)	2048
ADC decimation mode (xN)	4
ADC samples per clock cycle	4
ADC mixer type	Bypassed
DAC sampling rate (MHz)	2048
DAC interpolation mode (xN)	4
DAC samples per clock cycle	4

These settings give an effective clock rate of 128 MHz for the HDL Coder generated IP core. This value is the result of using a decimation of 4x and four samples per clock at 2.048 giga samples per second (GSPS). This table provides the reference design parameters for the ZCU111 and ZCU216 boards. Before proceeding to the next step, set these reference design parameters to the indicated values.

- **AXI4-Stream DMA data width** to 64
- **ADC sampling rate (MHz)** to 2048
- **ADC decimation mode (xN)** to 4
- **ADC samples per clock cycle** to 4

- **ADC mixer type** to Bypassed
- **DAC sampling rate (MHz)** to 2048
- **DAC interpolation mode (xN)** to 4
- **DAC samples per clock cycle** to 4
- **DAC mixer type** to Bypassed
- **ADC/DAC NCO mixer LO (GHz)** to Disabled
- **Enable multi-tile sync** to false

If you are using a ZCU216 board, additionally set the **DAC DUC mode** parameter to Full DUC Nyquist ($0 - F_s/2$).

Click **Run This Task**.

Step 3: Set Target Interface

The target interface settings are saved in the example model. In step 1.3, these target interface settings load automatically after you successfully run the **Set Target Reference Design** task.

Target platform interface table

Port Name	Port Type	Data Type	Target Platform Interfaces	Interface Mapping
MM2S_Valid	Inport	boolean	AXI4-Stream DMA Slave	Valid
MM2S_Data	Inport	uint64	AXI4-Stream DMA Slave	Data
S2MM_Tready	Inport	boolean	AXI4-Stream DMA Master	Ready (optional)
Tile0 ADC Ch0 Data	Inport	int16 (4)	Tile0 ADC Ch0 Data [0:63]	[0:63]
Tile0 ADC Ch0 Valid	Inport	boolean	Tile0 ADC Ch0 Valid	[0]
TriggerCapture	Inport	boolean	AXI4	x"100"
FrameSizeInput	Inport	uint32	AXI4	x"104"
NCO_incr_AXI	Inport	uint16	AXI4	x"114"
NCO_DAC_Ch0_AXI	Inport	ufix16_En...	AXI4	x"11C"
S2MM_Data	Output	uint64	AXI4-Stream DMA Master	Data
S2MM_Valid	Output	boolean	AXI4-Stream DMA Master	Valid
MM2S_Ready	Output	boolean	AXI4-Stream DMA Slave	Ready (optional)

The port interface table designates the Simulink® subsystem input and outputs to an IP interface type. Options include AXI4-Stream DMA interfaces, ADC/DAC connections, and AXI4 slave registers. For more information on port interfacing, see “Set Target Interface” on page 43-6.

Step 4: Build FPGA Bitstream

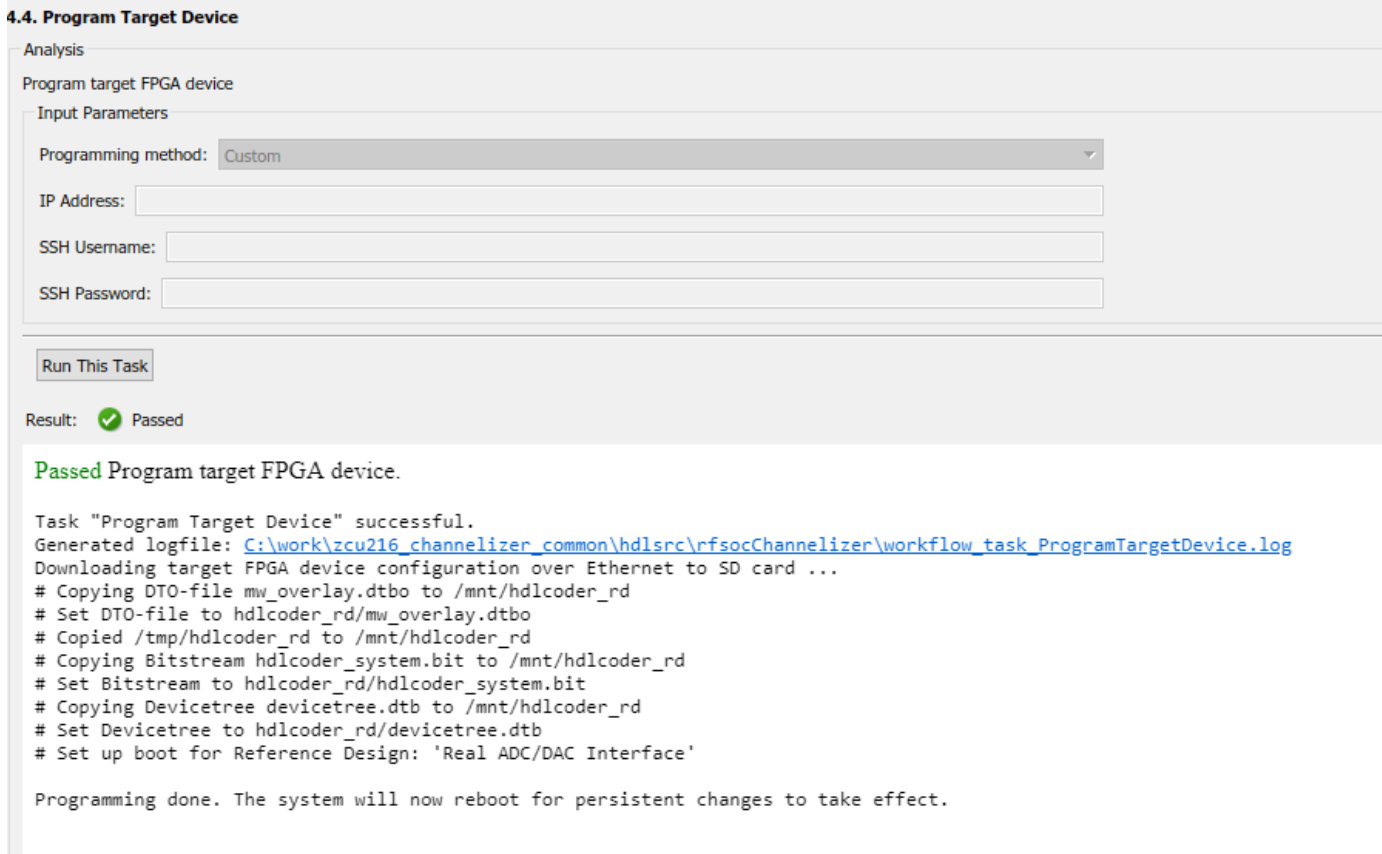

To generate a Vivado project for synthesis and bitstream creation, see “Build FPGA Bitstream” on page 43-22. A command prompt window opens to display synthesis and place and route progress. Bitstream generation takes about 20 to 30 minutes to build depending on the specifications of your computer.

In step 4.2, to generate a script that provides MATLAB connectivity to the board for interactive testing and live I/O interfacing, select **Generate host interface script**.

Program FPGA Bitstream

When the Vivado terminal reports that the FPGA bitstream has finished building, you can program the FPGA bitstream. Prior to programming the FPGA bitstream, you must ensure that the board has the correct SD card and is powered on. After Vivado programs the bit file, you see the message, which this figure shows.

The board restarts and programs the bit file to the FPGA during initialization. On the next power or boot cycle, the board continues using this bitstream repeatedly until it is reprogrammed with a new bit file or until the SD card is reformatted. You do not need to repeatedly program the same bit file because it remains persistent until a new one needs to be loaded.

If you need to swap bitstreams for different designs, programmatically script this swap out rather than using the HDL Workflow Advisor again, which can be time consuming. You can use a script that can be generated in the workflow advisor.

Select **File**, then click **Export to Script**.

After the script is generated, edit the script to download the bitstream by setting the appropriate options to false, as this figure shows.

```

290     % Set Workflow tasks to run
291 -    hWC.RunTaskGenerateRTLCodeAndIPCore = false;
292 -    hWC.RunTaskCreateProject = false;
293 -    hWC.RunTaskGenerateSoftwareInterfaceModel = false;
294 -    hWC.RunTaskBuildFPGABitstream = false;
295 -    hWC.RunTaskProgramTargetDevice = true;
  
```

Set the last task, `RunTaskProgramTargetDevice`, to true.

Now, run this script to program the FPGA. If successful, the MATLAB output window displays a message indicating success.

You can reuse the preceding script for generating a Vivado project again. If you make a change in the Simulink HDL design, you must recompile the Vivado design.

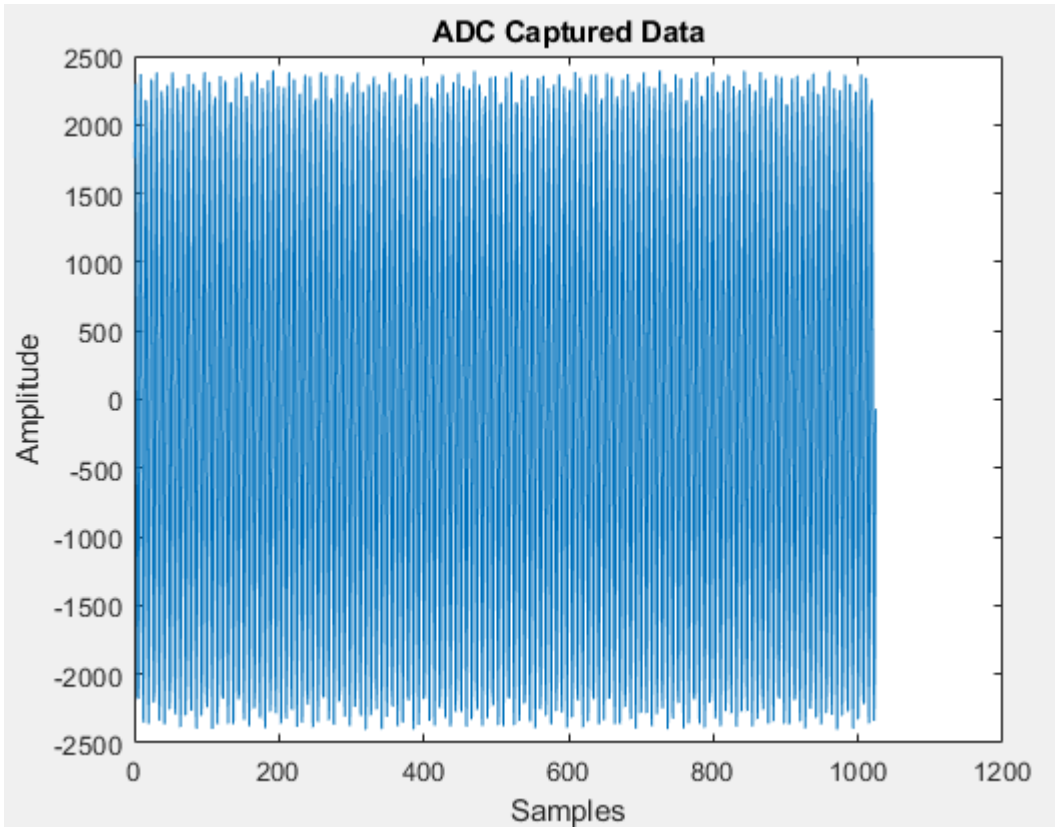

ADC Data Capture

The HDL Coder Workflow Advisor generates scripts that you can use to help with communicating to the IP design deployed to the RFSoc at run time. These scripts include AXI4-Registers and AXI4-Streaming interfaces that are specified in the previous section in the workflow advisor. For more information, see the `fpga` object.

In this example, only the stream to memory-map (S2MM) interface is used to move data from the FPGA to the ARM processor by using the DMA. Several AXI4 registers are used to control the NCO tone, which transmits to the DAC.

The generated scripts are meant to be templates, which you can then customize to fit the intended application. To perform the data captures, this example provides MATLAB script files `HostIO_rfsocADCCapture_setup.m` and `HostIO_rfsocADCCapture_interface.m`. When the board is powered on after programming, the FPGA design runs the capture script. This script displays the ADC captured data plots.

HostIO_rfsocADCCapture_interface

These time domain and spectrum plots show the resulting data captures. The script captures data in each iteration of a `while` loop while also changing the location of the NCO tone. To terminate the capture of data, close the ADC Captured Data figure. A register that is triggered by the software captures the data, and the rising edge detect logic that initiates data capture counters to move data into the AXI4-Stream S2MM.

Change Converter Settings

The RFSoc data converter contains settings and configuration options, some of which you can modify at run time. When the board is running and Linux starts, default settings are applied to the RF data converters that match the original design from the HDL Coder Workflow Advisor. This matching is accomplished with a CFG file that is uploaded to the board, and then read in during boot initialization.

To accommodate the modification of these parameters at run time, this example provides a programmatic MATLAB approach. Create the `soc.RFDataConverter` System object™ by using these commands in MATLAB.

```
rfobj = soc.RFDataConverter('ZU28DR', '192.168.1.101'); % For ZCU111 board
```

```
rfobj = soc.RFDataConverter('ZU49DR', '192.168.1.101'); % For ZCU216 board
```

This object requires the device and IP address as input arguments. Currently, RF data converter object supports these devices: ZU28DR (ZCU111) and ZU49DR (ZCU216). After creation, `rfobj` is an object in the MATLAB workspace. You can access this object further by using various object functions or properties to alter device settings.

This example provides a convenience script that gives an example of how to change the RF converter parameters. This script is autogenerated during the HDL Workflow Advisor workflow. In this ADC capture example, see the MATLAB script `ADC_Data_Capture_setup_rfsoc.m`.

```

%% Instantiate object and basic settings
IPAddr = '192.168.1.101';
rfobj = soc.RFDataConverter('ZU49DR',IPAddr);

PLLSrc = 'Internal';
ReferenceClock = 245.76; % MHz
ADCSamplingRate = 2048; % MHz
DACSamplingRate = 2048; % MHz
DecimationFactor = 4;
InterpolationFactor = 4;

%% User FPGA-logic settings
rfobj.FPGASamplesPerClock = 4;
rfobj.ConverterClockRatio = 1;

% Check if FPGA clock-rate exceeds timing used during synthesis
FPGAClockRate = ADCSamplingRate/DecimationFactor/rfobj.FPGASamplesPerC
if FPGAClockRate > 128
    warning('Selected FPGA rate %3.3f MHz exceeds the timing that was
            FPGAClockRate,128);
end

%% Establish TCP/IP connection
setup(rfobj)

```

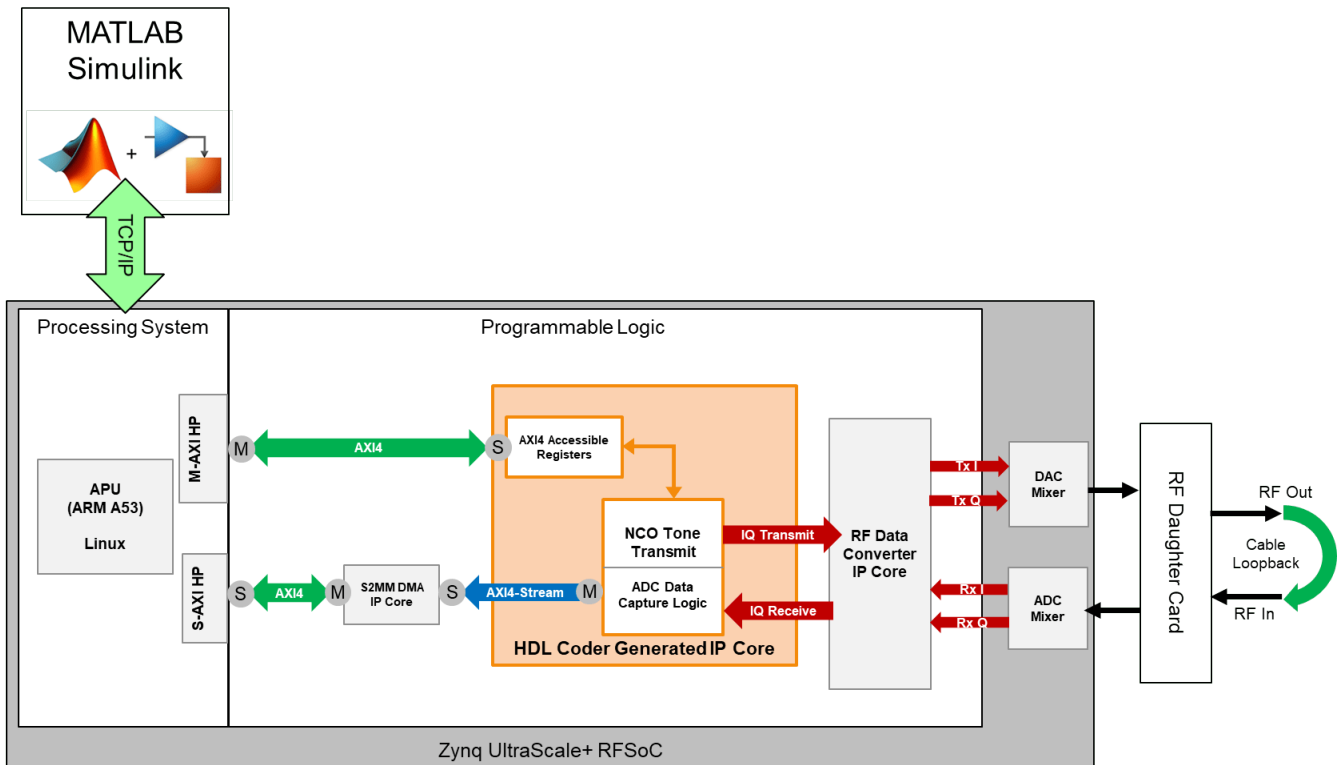

If your system is connected to the board, then running this script shows the MATLAB prompt update with messages indicating that parameters are adjusted. For this example, the sampling rate is set for 2.048 GSPS with 4x interpolation and decimation for all ADC and DAC tiles. Because you can dynamically control the converter with this script, you can rerun the script with different values, such as changing the sampling rates or interpolation modes.

For example, if you change the decimator and interpolator to 8 instead of 4, your sampling rate is cut by half. You can transmit only the DAC NCO tone to 128 MHz (F_s as 1024 and Nyquist as $F_s/2$) rather than 256 MHz. This example also provides a log file that shows the TCP/IP activity between host and target for more details on what was sent back and forth.

IQ Mixer Mode Capture

This example shows how to enable the RFSoc built-in numerically-controlled oscillator (NCO) mixer. The mixer design uses a different data format that, instead of providing real signals, provides a complex in-phase and quadrature (IQ) signal to a digital-to-analog converter (DAC) and an analog-to-digital converter (ADC). There is more data to transfer to direct memory access (DMA) and back to MATLAB® given that you need to transfer I and Q samples back. You can accommodate this larger data width by increasing the DMA data width to 128 bits.

You must configure settings such as the local oscillator (LO) mixer frequency and enable other mixer properties that are relevant to the design. To change these properties at run time, you can use the `soc.RFDataConverter` System object™. The HDL Workflow Advisor autogenerated a script to assist you with changing properties and uploads a CFG file to the board.

Requirements

- Vivado® Design Suite with a supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Xilinx® Zynq® UltraScale+™ ZCU111 evaluation kit or Xilinx Zynq UltraScale+ ZCU216 evaluation kit
- HDL Coder™
- HDL Coder Support Package for Xilinx RFSoc Devices

Open Example

Open the example project and copy the example files to a temporary directory.

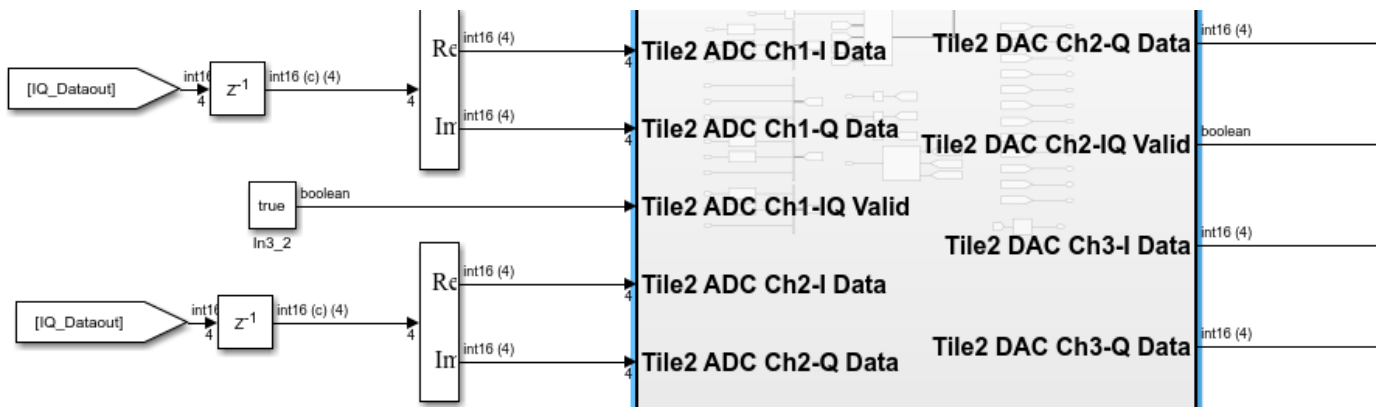

1. Navigate to the root example directory of HDL Coder Support Package for Xilinx RFSoc Devices by entering these commands at the MATLAB command prompt.

```
example_root = (hdlcoder_rfsoc_examples_root)
cd (example_root)
```

2. Copy all of the example files in the IQDataCapture folder to a temporary directory.

Generate HDL and Synthesize Bitstream

When you enable the mixer in the RFSoc, adhere to the required data formats that the IP expects. For the ADC, the IP core separates the I and Q channels. For the DAC, the IP core concatenates both I and Q channels together. For convenience, this bit concatenation is handled outside of the generated HDL and in Vivado. You need to model the I and Q channels separately for only the DAC and ADC.

This example uses four complex samples per clock cycle at 512 mega samples per second (MSPS). Each I and Q sample is 16 bits, which results in a total of 128 bits for channel I and a total of 128 bits for channel Q. From the Simulink® modeling perspective, two parts (I and Q) that exist, each with four samples per clock cycle.

To proceed with the HDL code generation, right-click the subsystem. Select **HDL Code**, then click **HDL Workflow Advisor**. In step 1.1 of the HDL Workflow Advisor, select **Target platform** as Xilinx Zynq UltraScale+ RFSoc ZCU111 Evaluation Kit or Xilinx Zynq UltraScale+ RFSoc ZCU216 Evaluation Kit.

Target workflow:	IP Core Generation	
Target platform:	Xilinx Zynq UltraScale+ RFSoc ZCU111 Evaluation Kit	Launch Board Manager
Synthesis tool:	Xilinx Vivado	Tool version: 2020.2 Refresh
Family:	Zynq UltraScale+ RFSoc	Device: xczu28dr-ffvg1517-2-e

Target workflow: IP Core Generation

Target platform: Xilinx Zynq UltraScale+ RFSoc ZCU216 Evaluation Kit Launch Board Manager

Synthesis tool: Xilinx Vivado Tool version: 2020.2 Refresh

Family: Zynq UltraScale+ RFSoc Device: xczu49dr-ffvf1760-2-e

In step 1.2, select **Reference design** as IQ ADC/DAC Interface.

Reference design: IQ ADC/DAC Interface

Reference design tool version: 2020.2 Ignore tool

Reference design parameters

Parameter	Value
AXI4-Stream DMA data width	128
ADC sampling rate (MHz)	2048
ADC decimation mode (xN)	4
ADC samples per clock cycle	4
ADC mixer type	Fine
DAC sampling rate (MHz)	2048
DAC interpolation mode (xN)	4
DAC samples per clock cycle	4

You can also specify a LO setting, which is used at board startup. The LO setting can be run-time adjustable. Before proceeding to the next step, set these reference design parameters to the indicated values.

- **AXI4-Stream DMA data width** to 128
- **ADC sampling rate (MHz)** to 2048
- **ADC decimation mode (xN)** to 4
- **ADC samples per clock cycle** to 4
- **ADC mixer type** to Fine
- **DAC sampling rate (MHz)** to 2048
- **DAC interpolation mode (xN)** to 4
- **DAC samples per clock cycle** to 4
- **DAC mixer type** to Fine
- **ADC/DAC NCO mixer LO (GHz)** to 0.5
- **Enable multi-tile sync** to false

If you are using a ZCU216 board, additionally set the **DAC DUC mode** parameter to Full DUC Nyquist ($0-F_s/2$).

To build the FPGA bitstream design, right-click **Build FPGA Bitstream** and click **Run to Selected Task**.

IQ Data Capture

To capture IQ data in this loopback test, perform a full HDL Workflow Advisor build and wait until the FPGA bitstream has been compiled. Afterward, program the board and run this capture script.

HostIO_rfsocIQDataCapture_interface.m

The capture loop triggers a register to initiate data capture logic to move IQ data into the DMA. The loop then reads the frame of IQ data and formats it to display these plots. To stop the capture, close the MATLAB plot.

Change Converter Settings: LO Mixer

You can set the LO from MATLAB by using the System object script at run time. This example provides a script to show an example of how you can use the RFSoc System to alter the mixer tone of the DAC and ADC. Open and examine this MATLAB script file:

`HostIO_ChangeLO_rfsocIQDataCapture.m`.

In this example, this script shifts the LO tone such that the DAC experiences a shift of 10 MHz relative to the ADC LO, with a center frequency of 800 MHz.

Connect to the target board.

```
rfobj = soc.RFDataConverter('zu49dr', '192.168.1.101');
setup(rfobj)
```

Specify LO Value in MHz. All tiles and channels use this LO Value.

```
LO_VALUE = 800;
```

Create a shift of 10 MHz in the DAC RF NCO.

```
rfobj.configureDACLocalOscillator(1,3,LO_VALUE+10);
```

Configure frequency of the ADC RF NCO.

```
rfobj.configureADCLocalOscillator(0,0,-LO_VALUE);
```

Disconnect the communication channel created between the `soc.RFDataConverter` System object and the `rfTool` running on the SoC device.

```
release(rfobj)
```

After running this script, run the capture script again and examine the spectrum plot.

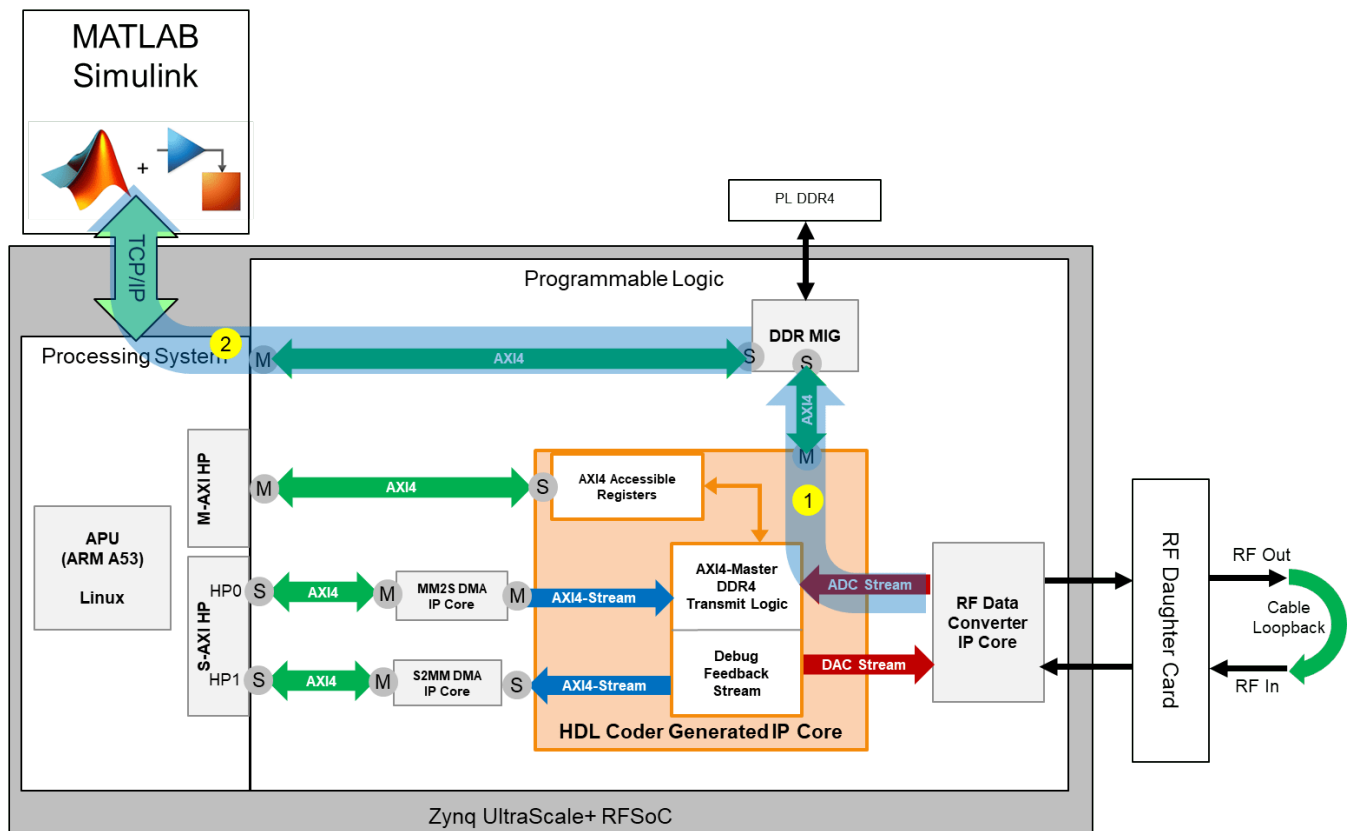

```
HostIO_ChangeLO_rfsocIQDataCapture
```

The tone, which was previously at 25 MHz, is now shifted by 10 MHz to 35 MHz.

PL-DDR4 ADC Data Capture

This example shows how to perform analog-to-digital converter (ADC) data captures with programmable logic (PL) double data rate 4 (DDR4) memory.

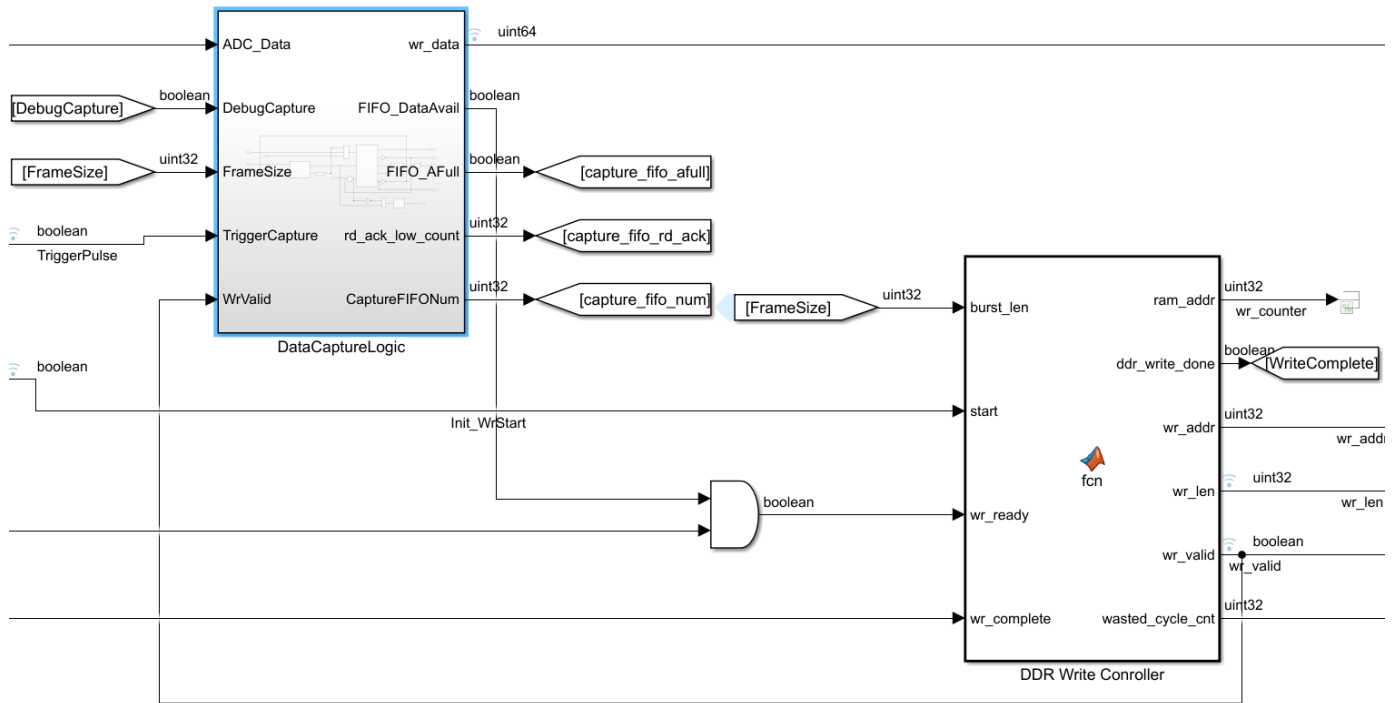

Storing data into PL-DDR4 memory can be advantageous because of the large amount of space available to read and write to. A total of 4 gigabytes is available to access from the FPGA. The HDL Coder™ reference designs provide a means for your IP design to connect to this memory interface by using AXI4-Master. AXI4-Master requires state-machine logic to perform reading and writing using multiple control signal lines.

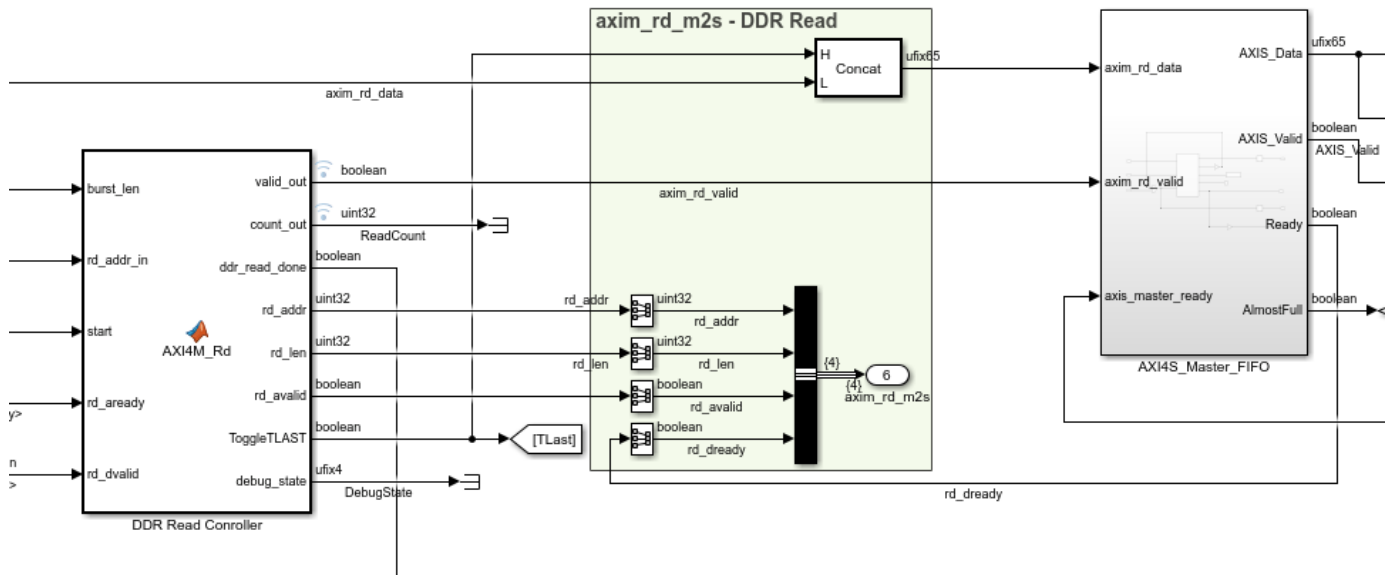

State-machine logic in the IP design helps coordinate this transfer by issuing commands originating from MATLAB® as AXI4 register writes. These register writes command the state machine to be configured in different modes. For this data capture example, these modes are broken down into two main operations.

The first arrow (labeled 1) in the first figure shows the data path connecting the ADC input stream directly into AXI4-Master to write to the memory interface generator (MIG). From MATLAB, an AXI4 register is written to the state machine to issue a command that data is ready to be written. The state machine then waits for acknowledgement from the DDR4 slave device that it is ready to accept samples. Afterward, data can flow through to the MIG. Because there is a bit of wait time on issuing burst write commands, a back pressure first in, first out (FIFO) is used to help temporarily store data during these periods. In some cases, the amount of back pressure experienced can exceed the FIFO, causing data to be lost. This example inserts several registers to help determine if this situation

arises. Typically, this issue happens if the requested data capture size is large enough to induce enough back pressure events to exceed the FIFO capacity. Constant writing to DDR4 memory can be sustained to only a certain frame length before back pressure occurs. Increasing the length of the FIFO can help alleviate this issue at the cost of more FPGA resources. This figure shows the section of the model that is responsible for writing to the digital-to-analog converter (DAC).

The second arrow (labeled 2) in the first figure shows the data path of reading from DDR4 memory and returning the frame back to MATLAB or Simulink® over the Ethernet network. Similar to the data path labeled 1, the data path labeled 2 is also controlled with a state machine that is adjustable with AXI4 registers. For each read command issued, an offset address is used to specify which spot in PL-DDR4 memory to read from. This figure shows the the read controller logic.

Requirements

- Vivado® Design Suite with a supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Xilinx® Zynq® UltraScale+™ ZCU111 evaluation kit or Xilinx Zynq UltraScale+ ZCU216 evaluation kit
- HDL Coder
- HDL Coder Support Package for Xilinx RFSoc Devices

Open Example

Open the example project and copy the example files to a temporary directory.

1. Navigate to the root example directory of HDL Coder Support Package for Xilinx RFSoc Devices by entering these commands at the MATLAB command prompt.

```
example_root = (hdlcoder_rfsoc_examples_root)
cd (example_root)
```

2. Copy all of the example files in the DDR4_ADCCapture folder to a temporary directory.

Simulate PL-DDR4 ADC Capture Model

To examine how these operations take place, open the model `rfsocADCDDR4Capture.slx` and simulate the design.

By default, the simulation uses the `debugCaptureSimMode` set to 1. With this mode, the capture logic captures counter data instead of ADC data. The goal is to validate that the counter data written to PL-DDR4 memory is the same data read out when issuing a read command later.

The other input AXI4 registers specify the amount of data to capture (**ADC_CaptureSize**), the amount of data to write back to the DMA AXI4-Stream per read (**DDR4_Rd_FrameLen**), and the offset address of where to read from in PL-DDR4 memory (**DDR4_ReadAddress**).

The model stops simulating at the end of the last sample of the frame of data that is sent over the DMA. Afterward, validate that the data written into PL-DDR4 memory is the same as the data that was read out by running the MATLAB script `simValidateADCDDR4Capture.m`.

The counter value matches expectations when read out of the DDR4 memory and accessed via the AXI4-Stream DMA. Next, disable debug mode and configure the simulation to capture ADC data instead. Open the script `rfsocADCDDR4CaptureInit.m`, and then set `debugCaptureSimMode` to `false`. Rerun the simulation, and then plot the data by running the script `simValidateADCDDR4Capture.m`.

Generate HDL and Synthesize Bitstream

Open the model `rfsocADCDDR4Capture.slx`, and then right-click the `ADC_DDR4_Data_Capture` subsystem. Select **HDL Code**, then click **HDL Workflow Advisor**.

In step 1.1 of the HDL Workflow Advisor, select **Target platform** as Xilinx Zynq Ultrascale+ RFSoc ZCU111 Evaluation Kit or Xilinx Zynq Ultrascale+ RFSoc ZCU216 Evaluation Kit.

In step 1.2, select **Reference design** as Real ADC/DAC Interface with PL-DDR4.

Before proceeding to the next step, set these reference design parameters to the indicated values.

- **AXI4-Stream DMA data width** to 64
- **ADC sampling rate (MHz)** to 2048
- **ADC decimation mode (xN)** to 4
- **ADC samples per clock cycle** to 4
- **ADC mixer type** to Bypassed
- **DAC sampling rate (MHz)** to 2048
- **DAC interpolation mode (xN)** to 4
- **DAC samples per clock cycle** to 4
- **DAC mixer type** to Bypassed
- **ADC/DAC NCO mixer LO (GHz)** to Disabled
- **Enable multi-tile sync** to false

If you are using a ZCU216 board, additionally set the **DAC DUC mode** parameter to Full DUC Nyquist ($0-F_s/2$).

Initiate the bitstream compilation. After the compilation is complete, use a programming script to program the FPGA bit file.

Collect Captured PL-DDR4 ADC Data

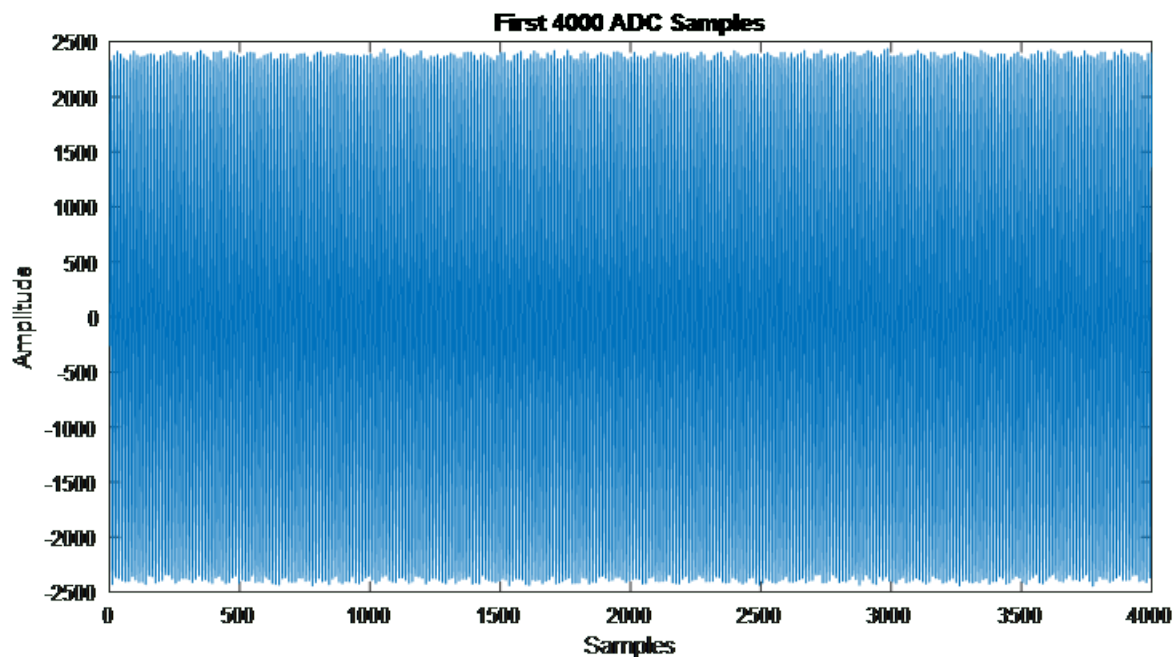

After you create and program the FPGA bit file onto the board, you can capture data.

In this capture scenario, the goal is to capture 4 million data points of ADC samples. Because the design is operating at four samples per clock, the data width of each data point written to DDR4 memory is 64 bits. Each data point has an 8 byte offset. To retrieve the samples, use the shared-memory FPGA I/O API over a TCP/IP connection.

The script performs these steps.

- 1 Initiate a data capture and store 4 million samples into DDR4 memory.
- 2 Check to see if samples were dropped in the data collection due to back pressure.
- 3 Use shared memory to directly read samples from DDR4 memory from ARM®-Linux® and transfer samples back to MATLAB.

This plot shows the first 4000 samples when the capture loop execution finishes.

In this example, a capture size of 4 million is possible. Increasing the capture size can yield results where data is missing. For instance, setting the capture length to 8 million (by changing the frame size to 2e6 rather than 1e6).

```

%% Parameters
DebugMode = 0;
incrScale = 2^14/512e6; % Used to adjust NCO frequency
Fs = 512e6;
CaptureSize = 2e6;      % Total amount of four-vector contiguous samples to store in PL-DDR4
DDR4_ReadLen = 100e3;  % Amount of four-vector samples to retrieve per read from PL-DDR4

```

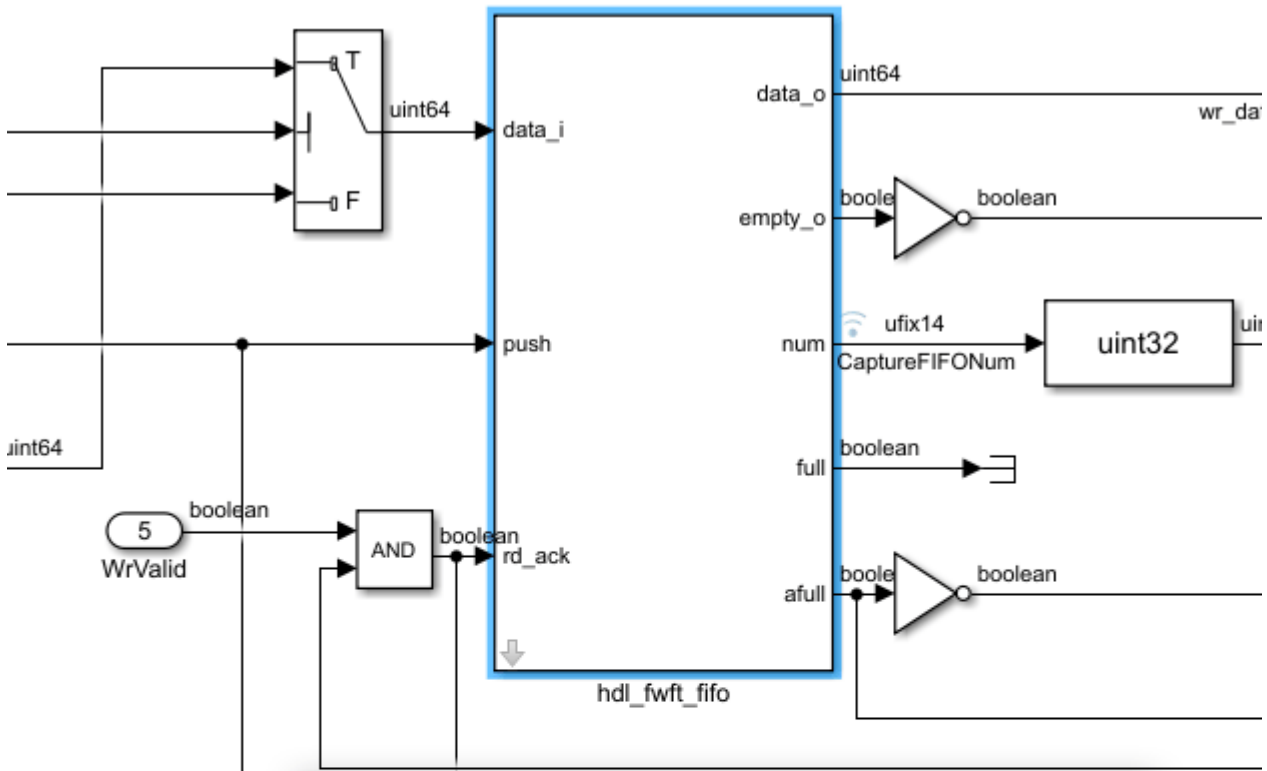

Run this script again.

```
HostIOs_rfsocADCDDR4Capture_interface
```

From these 8 million samples captured, 6329 four-vector samples were dropped, (that is, 25,316 ADC samples are missing). In plots of the captures, a missing sample is displayed as a discontinuity, which you can view by using the zoom feature of the plots.

The spectrum might not look as severely affected because many samples exist in the frame, but this many samples can still cause issues depending on your end applications. Choosing a back-pressure FIFO depth that is optimal to your design specifications is one workaround to help mitigate missing samples. For more details on where to change this FIFO depth, see this part of the model: `rfsocADCDDR4Capture/ADC_DDR4_Data_Capture/DDR_Capture_Logic/DataCaptureLogic`.

DAC PL-DDR4 Transmit

This example shows how to transmit waveforms out of the digital-to-analog converter (DAC) that is read from programmable logic (PL) double data rate 4 (DDR4) memory. Using PL-DDR4 memory offers advantages such as the ability to access 4 gigabytes of memory space. This amount of memory can help facilitate applications requiring large waveform transmissions that are not normally feasible with FPGA block random access memory (BRAM). This figure shows the relevant intellectual property (IP) interfaces and connectivity that are used in this design.

This IP design uses a shared-memory region between the Linux® operating system and PL-DDR4 memory. The memory interface uses the processing system (PS) AXI4 master high performance (HP) lines to directly access PL-DDR4 memory such that it can be accessed with reads and writes. A MATLAB® interface enables access to this shared memory region. This figure shows the flow of the data.

In this figure, the first arrow (labeled 1) shows the moving data over the Ethernet network to the PL-DDR4 memory. The second arrow (labeled 2) shows data that is read from the PL-DDR4 memory to the DAC. The PL design waits on an AXI4 register trigger from MATLAB to initiate data movement and read data out of memory to the DAC.

Requirements

- Vivado® Design Suite with a supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Xilinx® Zynq® UltraScale+™ ZCU111 evaluation kit or Xilinx Zynq UltraScale+ ZCU216 evaluation kit
- HDL Coder
- HDL Coder Support Package for Xilinx RFSoc Devices

Open Example

Open the example project and copy the example files to a temporary directory.

1. Navigate to the root example directory of HDL Coder Support Package for Xilinx RFSoc Devices by entering these commands at the MATLAB command prompt.

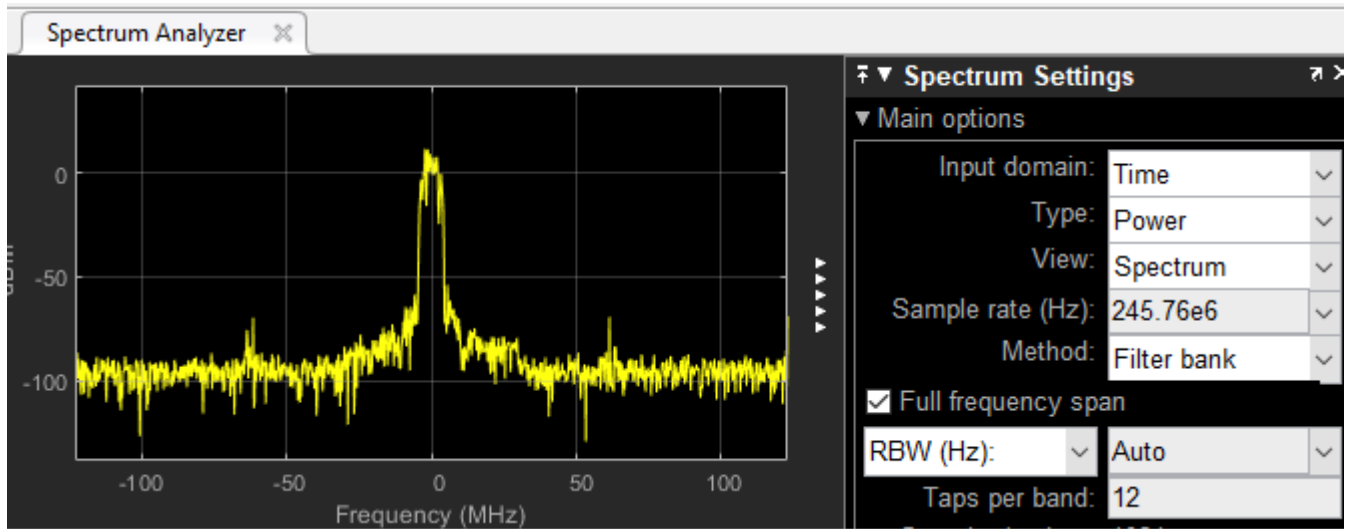

```
example_root = (hdlcoder_rfsoc_examples_root)
cd (example_root)
```

2. Copy all of the example files in the DDR4_DACWrite folder to a temporary directory.

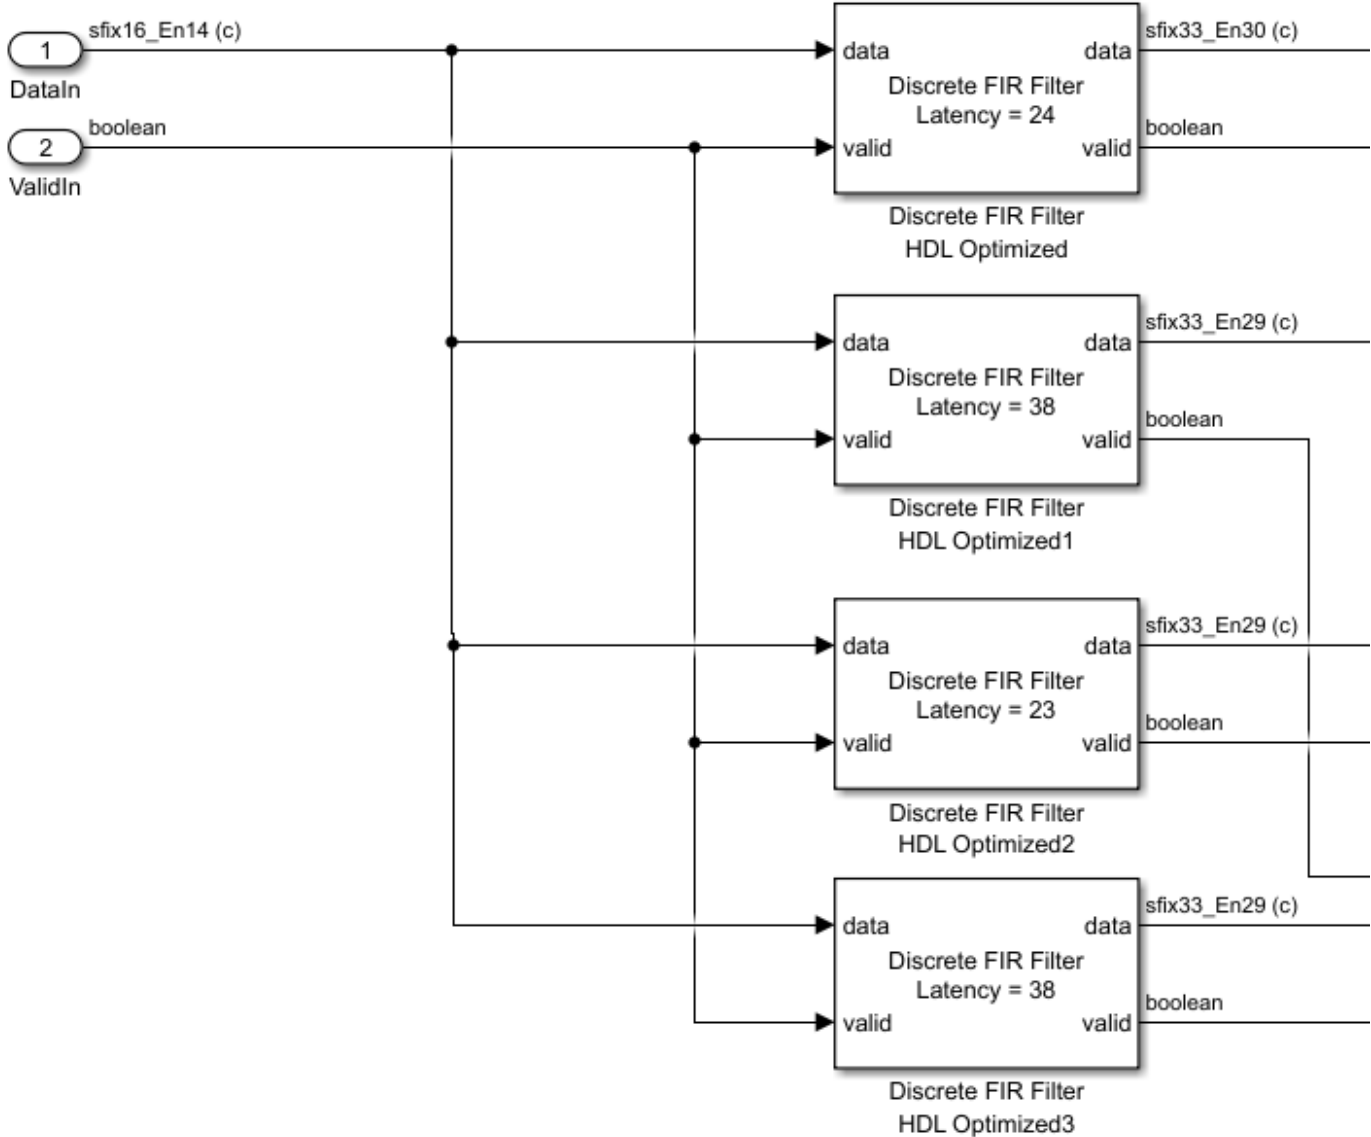

Simulate PL-DDR4 DAC Transmit Model

The HDL model for DDR4 DAC transmit is `waveformWriteDAC_DDR4.slx`. This model simulates the data transfer of using AXI4 master. The waveform that is transmitted can be either an LTE or single-tone waveform, depending on your selection. See the MATLAB script `model_init.m`.

This figure shows an LTE-transmitted waveform. To synthesize this waveform, you must have the LTE Toolbox™ product. If you do not have this toolbox the waveform that is loaded into memory for the simulation is a 15 MHz complex tone instead.

The waveform in the design is upconverted using interpolation by 4x. The waveform that is stored in memory is 61.44 MHz. Upconvert the data rate to 1966.08 MHz by using a 4x interpolator in the PL device under test (DUT) and the 8x interpolator on the RFSoc. This figure shows a vector interpolator to execute samples and produce a vector of four from a single scalar input.

See the subsystem: waveformWriteDAC_DDR4/DDR4_DAC_Transmit/Interpolation_4x/FIR_Vector_Interp. The design also implements the capture logic to collect analog-to-digital converter (ADC) samples using an AXI4-register capture.

Generate HDL and Synthesize Bitstream

Open the model waveformWriteDAC_DDR4.slx, and then right-click the DDR4_DAC_Transmit subsystem. Select **HDL Code**, then click **HDL Workflow Advisor**.

In step 1.1 of the HDL Workflow Advisor, select **Target platform** as Xilinx Zynq Ultrascale+ RFSoc ZCU111 Evaluation Kit or Xilinx Zynq Ultrascale+ RFSoc ZCU216 Evaluation Kit.

In step 1.2, select **Reference design** as IQ ADC/DAC Interface with PL-DDR4.

- **AXI4-Stream DMA data width** to 128
- **ADC sampling rate (MHz)** to 1966.08
- **ADC decimation mode (xN)** to 8
- **ADC samples per clock cycle** to 4
- **ADC mixer type** to Fine
- **DAC sampling rate (MHz)** to 1966.08
- **DAC interpolation mode (xN)** to 8
- **DAC samples per clock cycle** to 4
- **DAC mixer type** to Fine
- **ADC/DAC NCO mixer LO (GHz)** to 0.5
- **Enable multi-tile sync** to true

You can set the numerically-controlled oscillator (NCO) mixer frequency to any value and adjust it at run time from MATLAB. If you are using a ZCU216 board, additionally set the **DAC DUC mode** parameter to Full DUC Nyquist ($0-F_s/2$).

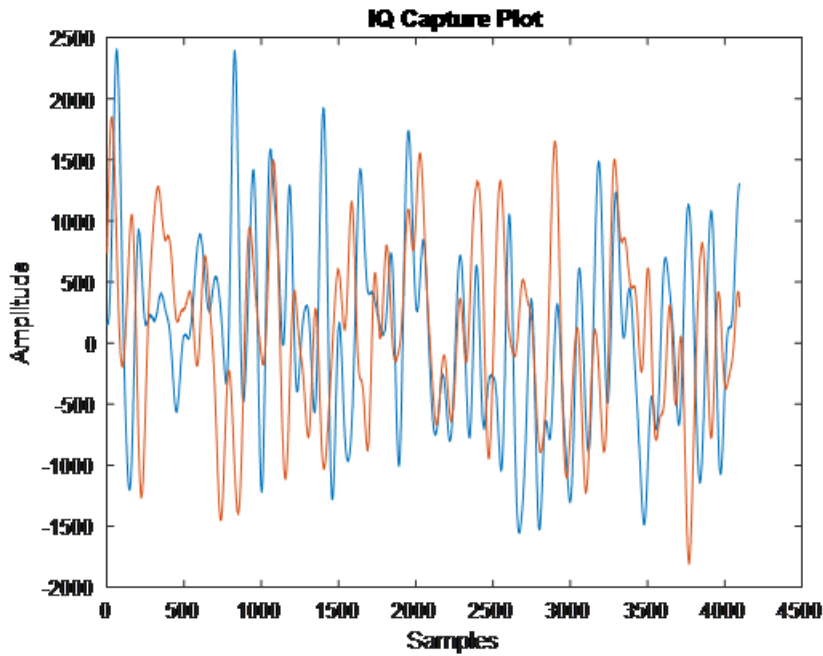

Transmit PL-DDR4 DAC Data

After you program the FPGA bitstream, run the script `fpgaio_TxWaveformAndCapture.m`. The script performs these steps.

- 1** Create a complex waveform of size 30.72e5 samples and package the waveform into a data format of `int32`.
- 2** Write the waveform into the PL-DDR4 memory and command the DUT to begin transmitting data over AXI4.
- 3** Trigger a data capture of 4096 samples to move ADC data into direct memory access (DMA).
- 4** Display the results of the captured ADC data in MATLAB by using this command.

```
fpgaio_TxWaveformAndCapture
```

Verify that the data looks as expected by checking an oscilloscope.

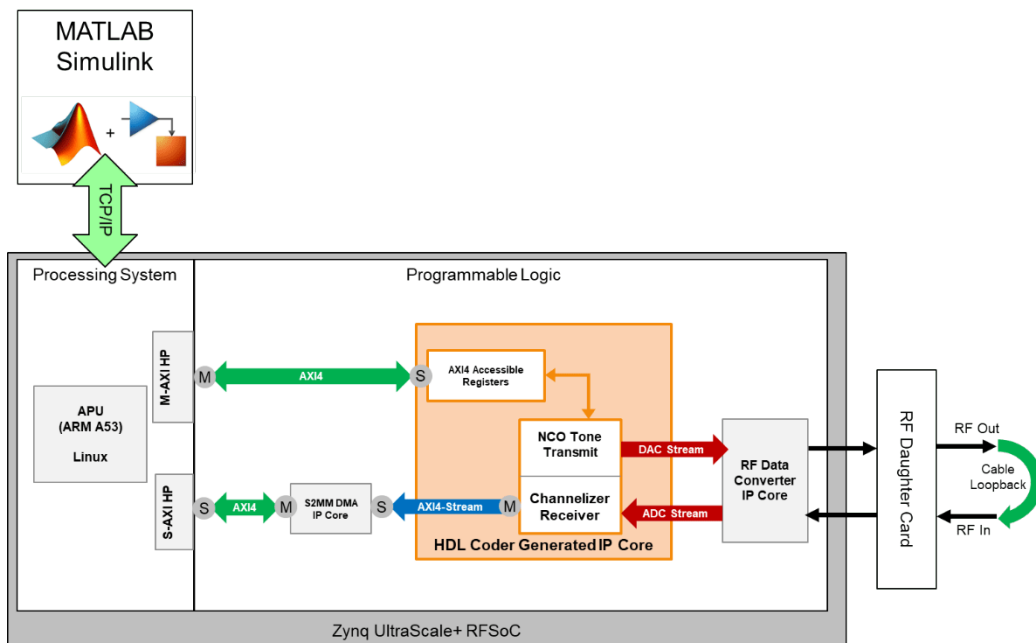

Using an oscilloscope, you can confirm the presence of the waveform by connecting to the correct channel on your RFSoc device and examining the output. For more details on which port to use, check the user guide on SMA cable connectivity. This figure shows an oscilloscope capture of a single tone value that is transmitted out of the DAC channel.

You can choose between the LTE waveform or single NCO tone by adjusting the parameters in the script `model_init.m`.

Polyphase Channelizer

This example shows how to use the HDL-optimized Channelizer block to process incoming analog-to-digital converter (ADC) samples and produce a spectrum that has 512 MHz of bandwidth. MATLAB® displays the resulting spectrum plot by using FPGA API functions over a TCP/IP connection. The channelizer data sent back is in limited bursts, which are triggered by an AXI4 register in a capture loop. The model also contains an interface to the digital-to-analog converter (DAC) by using a numerically-controlled oscillator (NCO) to drive a tone commanded at some frequency over AXI4.

Requirements

- Vivado® Design Suite with a supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Xilinx® Zynq® UltraScale+™ ZCU111 evaluation kit or Xilinx Zynq UltraScale+ ZCU216 evaluation kit
- HDL Coder™
- HDL Coder Support Package for Xilinx RFSoc Devices

Open Example

Open the example project and copy the example files to a temporary directory.

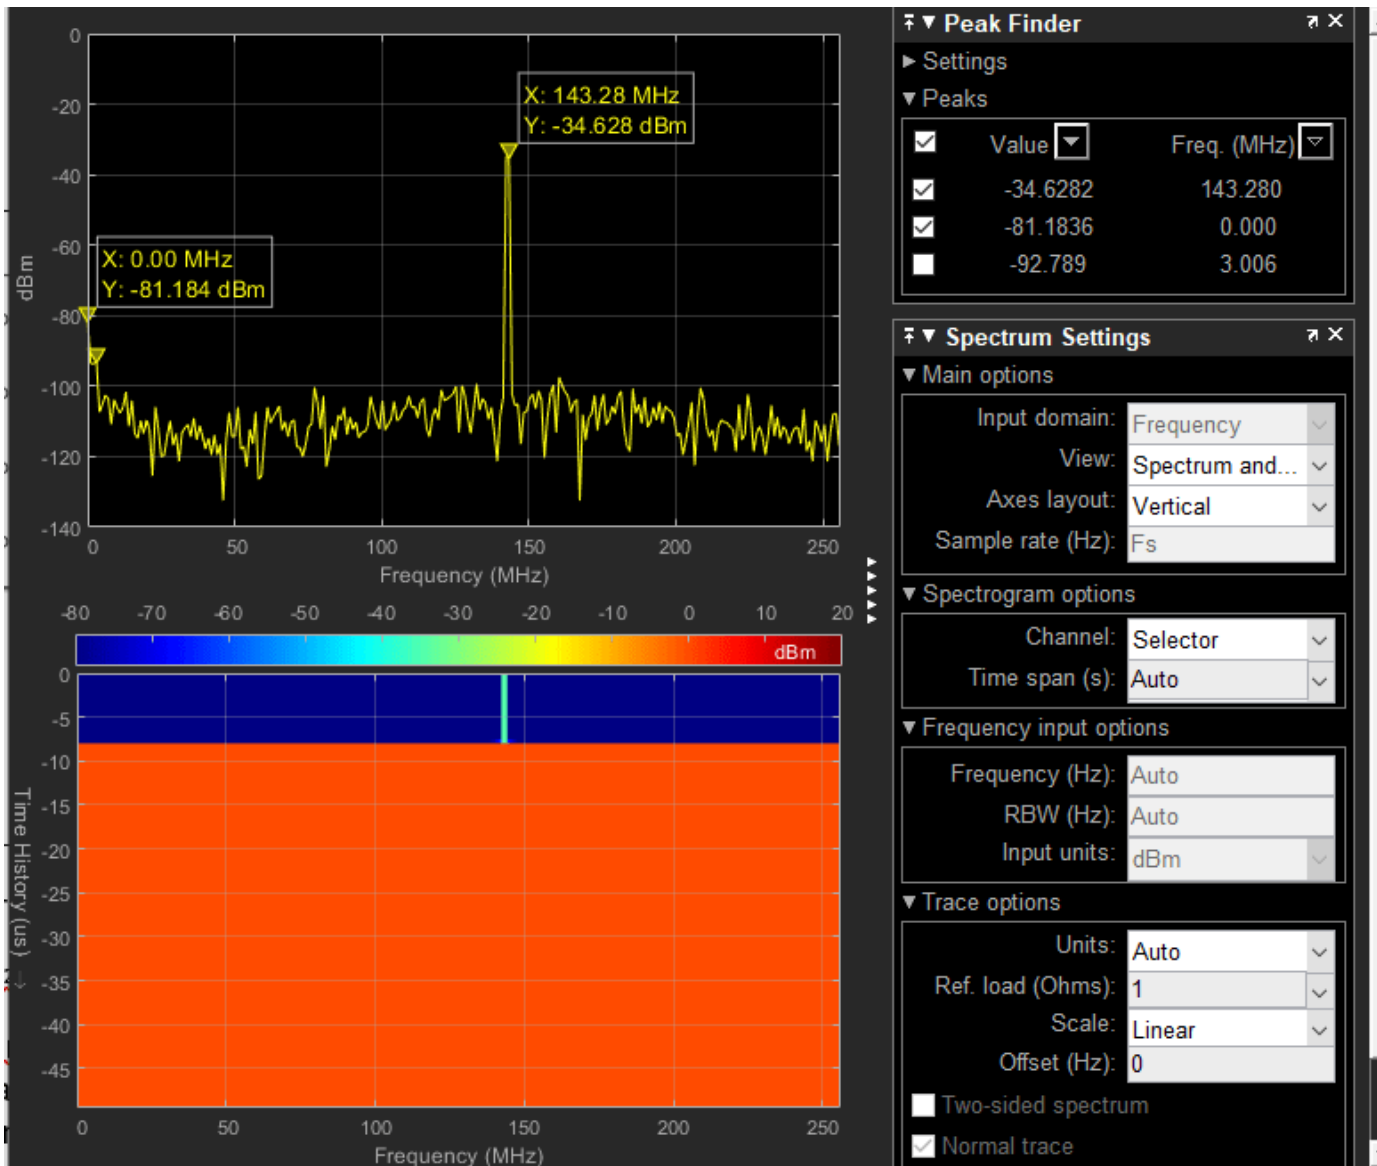

1. Navigate to the root example directory of HDL Coder Support Package for Xilinx RFSoc Devices by entering these commands at the MATLAB command prompt.

```
example_root = (hdlcoder_rfsoc_examples_root)
cd (example_root)
```

2. Copy all of the example files in the PolyphaseChannelizer folder to a temporary directory.

Simulate Channelizer Model

To understand the channelizer model in more detail, run the simulation of `rfsocChannelizer.slx` and view the power spectrum view and spectrogram.

You can see the channelizer processing inside this block: `rfsocChannelizer/PolyphaseChannelizer/Channelizer Receive Processing`. The `FFT_Capture` logic captures data based off of a trigger condition called **TriggerCapture**, which is driven by an AXI4 register. The state machine does not wait for a trigger and processes the next available frame from the channelizer to the direct memory access (DMA). The channelizer block `Start-Of-Frame` and `Valid` control lines are used to help determine when to latch onto the frame.

After the bitstream is done compiling, program the FPGA bit file if you are using an HDL Workflow Advisor script.

Channelizer Spectrum Data Capture

The FPGA returns the output of the channelizer, which is frequency domain data of the spectrum. The capture logic fetches a frame upon receiving the signal condition over AXI4. With the board programmed, run the script `hostIO_rfsocChannelizer_interface.m`.

```
% %%Data capture loop
% for ii=1:150
%     writePort(hFPGA,"TriggerCapture",false);
%     writePort(hFPGA,"TriggerCapture",true);
%     writePort(hFPGA,"TriggerCapture",false);
%
%     rd_data = readPort(hFPGA,"S2MM_Data");
%
%     idx = mod(ii,length(FrequencyArr)) + 1;
%     nco_tone = FrequencyArr(idx);
%     fprintf('Changing NCO Tx tone to %d MHz \n',nco_tone);
%     writePort(hFPGA,"AXI4_NCO_incr",uint16(incrScale*nco_tone*1e6));
%
%     fft_frame = reinterp_stream_data(rd_data);
%     spectrum = 20*log10(abs(fft_frame(1:256)));
%
%     scopeSpectrum(spectrum);
%     scopeSpectrogram(spectrum);
% end
%
% disp('Done frequency sweep');
```

Spectrogram and spectrum plots are displayed for 150 captures. The NCO is commanded with different tones from an array that is declared before the capture.

Multi-Tile Synchronization

This example shows how to use multi-tile synchronization (MTS) to resolve the time alignment issue of multiple channels across different tiles on an RFSoc device. The RFSoc has built-in features that enforce the time alignment for samples of multiple channels across different tiles. Channels in a tile alone are aligned in time but a guarantee of alignment with another channel from a different tile does not exist. You can enable multi-tile synchronization (MTS) to correct for this issue by first measuring latency across different tiles and then applying sample delays to ensure samples align correctly.

MTS for Xilinx® Zynq® UltraScale+™ RFSoc ZCU111 and Xilinx Zynq UltraScale+ RFSoc ZCU216 evaluation kits requires that you chose specific sample rates that are governed by SYSREF signals from an external clock. According to *Xilinx datasheet PG269*, the SYSREF frequency must meet these requirements.

- If synchronizing RF-ADC and RF-DAC tiles with different sample frequencies, the frequency must be an integer submultiple of: $\text{GCD}(\text{DAC_Sample_Rate}/16, \text{ADC_Sample_Rate}/16)$.
- SYSREF must also be an integer submultiple of all PL clocks that sample it. This is to ensure the periodic SYSREF is always sampled synchronously.
- Less than 10 MHz.

In the context of the ZCU111 and ZCU216 boards, the reference clock must be an integer multiple of the SYSREF frequency. For the ZCU111 board, the default SYSREF frequency produced by the LMK is 7.68 MHz. To meet the requirements, choose a sampling rate from the available provided frequencies from the LMK that is a multiple of 7.68 MHz.

In many designs, this reference clock is chosen in such a way to satisfy this requirement. For example, 245.76 MHz is a common choice when you use a ZCU216 board. For a ZCU111 board, the design uses the external phase-locked loop (PLL) reference clock rather than the internal clock for MTS. The configuration files and System object™ scripts that are generated during the HDL Workflow Advisor step complete this process.

Requirements

- Vivado® Design Suite with a supported version listed in “HDL Language Support and Supported Third-Party Tools and Hardware”
- Xilinx Zynq UltraScale+ ZCU111 evaluation kit or Xilinx Zynq UltraScale+ ZCU216 evaluation kit
- HDL Coder
- HDL Coder Support Package for Xilinx RFSoc Devices

Open Example

Open the example project and copy the example files to a temporary directory.

1. Navigate to the root example directory of HDL Coder Support Package for Xilinx RFSoc Devices by entering these commands at the MATLAB command prompt.

```
example_root = (hdlcoder_rfsoc_examples_root)
cd (example_root)
```

2. Copy all of the example files in the MTS folder to a temporary directory.

MTS Cable Setup

This example provides two MTS examples, one for a ZCU111 board and one for a ZCU216 board. These examples show that analog-to-digital converter (ADC) channel samples from different tiles are aligned after you apply MTS. By comparing one channel with the other, visual inspection can be performed.

When using Multi-Tile Synchronization, use ADC and DAC channels that are connected to the differential SMA ports on the XM500. The single-ended baluns introduce amplitude and phase offset between channels even when MTS is enabled.

For comparing channels, the ZCU111 example cable setup for the XM500 balun card is configured so that it compares two channels from differing tiles. These two figures show the cable setup.

In these figures:

- DAC 00 connects to ADC 04.
- DAC 01 connects to ADC 07.

In terms of tile connections, the setup that these figures show represents 0-based indexing.

- DAC Tile 0 Channel 0 connects to ADC Tile 2 Channel 0.
- DAC Tile 0 Channel 1 connects to ADC Tile 3 Channel 2.

Differential cables that have DC blockers are used to make use of the differential ports. The cables use a data path that does not have an analog RF cage filter, which can impose phase delays across different channels. Because the purpose of this test is to measure sample alignment, avoiding things that can potentially alter results, such as a mismatch in cable types or filters, is a best practice.

For the ZCU216 board, a similar setup is used with differential SMA connections by using the XM655 balun card. This figure shows the XM655 board with a differential cable.

ADC Setup

DAC Setup

In the DAC setup figure:

- DAC P/N 0_228 connects to ADC P/N 02_224.
- DAC P/N 0_229 connects to ADC P/N 00_225.

The next two figures show a schematic that indicates which differential connectors this example uses.

ADC

DAC

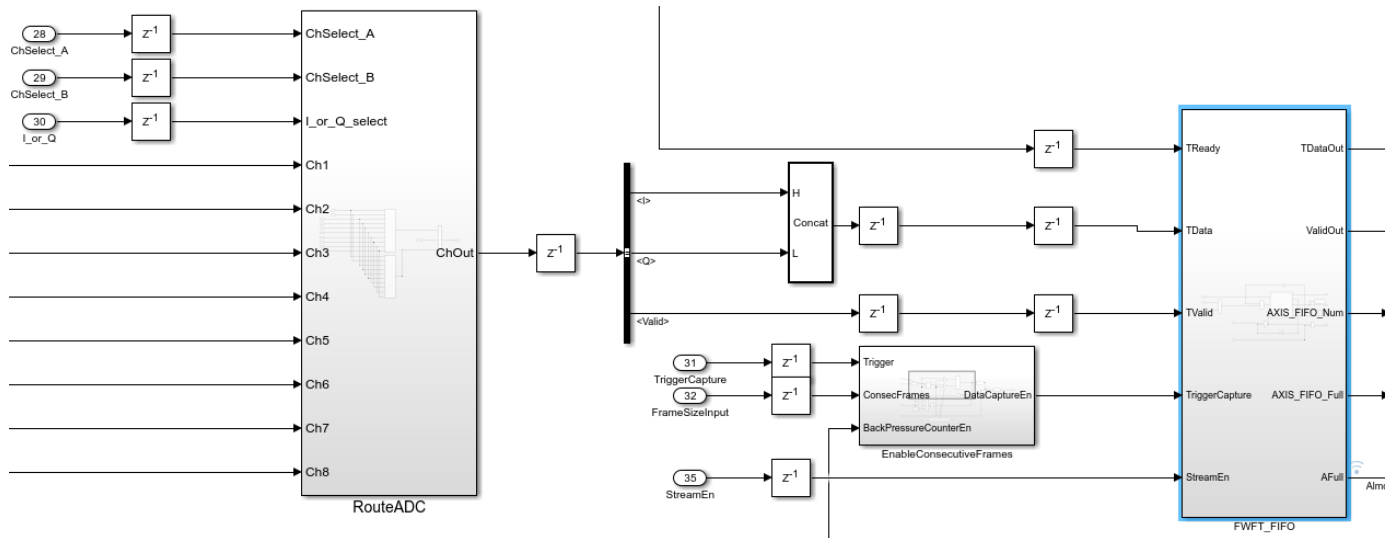

In terms of tile connections, the setup that these figures show represents 0-based indexing.

- DAC Tile 0 Channel 0 connects to ADC Tile 0 Channel 2.
- DAC Tile 1 Channel 0 connects to ADC Tile 1 Channel 2.

For more information on cable setups, see the Xilinx documentation.

HDL Model and Bitstream Synthesis

Two HDL models (`rfsoc_zcu216_MTS_iq_HDL.slx` and `rfsoc_zcu111_MTS_iq_HDL.slx` located in the example root) are provided for the ZCU216 and ZCU111 boards. The models take in two channels for data capture selected by an AXI4 register for routing. Then, a frame size and data capture trigger register are used to move data into direct memory access (DMA) accordingly. An additional mux is added to pick between inphase (I) or quadrature (Q) when comparing the channels. Because the design runs at four samples per clock for in-phase and quadrature (IQ), a limited amount of data width is available for moving data across.

To synthesize HDL, right-click the subsystem. Select **HDL Code**, then click **HDL Workflow Advisor**. In step 1.1 of the HDL Workflow Advisor, select **Target platform** as Xilinx Zynq Ultrascale+ RFSoc ZCU111 Evaluation Kit or Xilinx Zynq Ultrascale+ RFSoc ZCU216 Evaluation Kit.

In step 1.2, set these reference design parameters to the indicated values.

- **AXI4-Stream DMA data width** to 128
- **ADC sampling rate (MHz)** to 1966.08
- **ADC decimation mode (xN)** to 4
- **ADC samples per clock cycle** to 4
- **ADC mixer type** to Fine
- **DAC sampling rate (MHz)** to 1966.08
- **DAC interpolation mode (xN)** to 4
- **DAC samples per clock cycle** to 4
- **DAC mixer type** to Fine
- **ADC/DAC NCO mixer LO (GHz)** to 0.5
- **Enable multi-tile sync** to true

If you are using a ZCU216 board, additionally set the **DAC DUC mode** parameter to Full DUC Nyquist ($0 - F_s/2$).

Afterward, build the bitstream and then program the board.

Run-Time Testing of MTS Channel Alignment

After you program the board, it reboots and initializes with MTS applied when Linux® loads. To configure the RFSoc with various properties and settings, use a configuration CFG file.

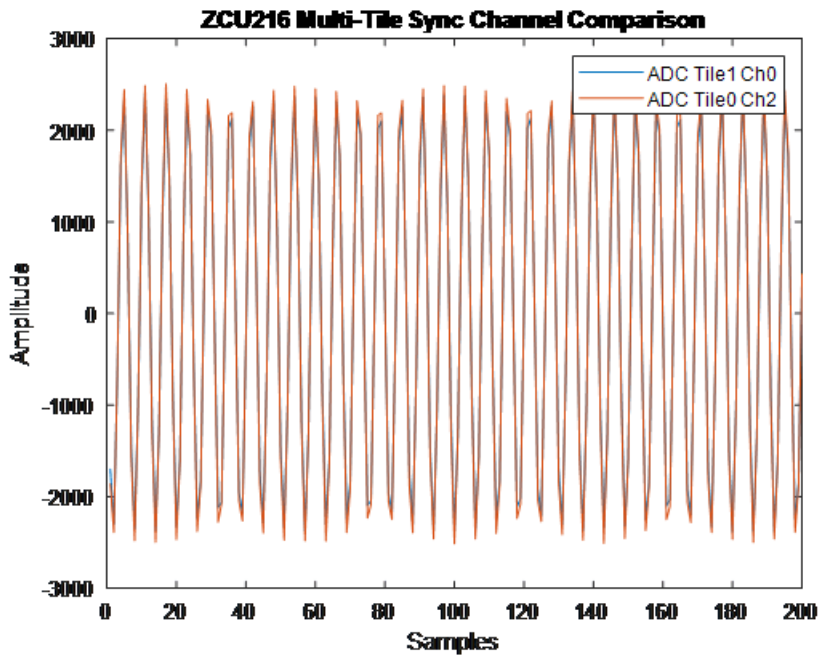

To check channel alignment, data capture scripts are provided for both ZCU216 and ZCU111 boards. If the SMA attachment cards match the setup described in the previous sections of this example, run the script. The results show near-perfect alignment of the channels.

Run whichever script matches the board that you are testing against.

```
HostIO_rfsoc_zcu216_MTS_iq_HDL_interface.m
```

```
HostIO_rfsoc_zcu111_MTS_iq_HDL_interface.m
```

A single plot shows the result of the data capture of two channels.

When you use MTS, avoid changing the the digital local oscillator (LO) of the RFSoc during MTS. The LO for each channel might not be aligned in time, which can impact alignment. The RFSoc provides ways of dealing with this issue by synchronizing the reset condition on all channels based on tile events. By setting tile events to listen to a SYSREF signal, alignment can be achieved when you use the mixer during an MTS routine. The SYSREF capture must be disabled first, then the change to the LO is applied, and then an MTS calibration is done again. To see an example of this process, run the script `ZCU216_ChangeLO.m` or `ZCU111_ChangeLO.m`.

Device Tree Generation

Generate Device Tree for IP Core

Dynamically generate device trees that include nodes for the HDL Coder generated IP core by using the HDL Coder IP Core generation workflow. The generated device tree also includes nodes for your board peripherals, reference design IP cores, and reference design interfaces that access the processing system (PS) of your target field programmable gate array (FPGA) or system on a chip (SoC) board. Program your target board with the generated device tree and bitstream.

Get Started with Device Trees

A device tree is a data structure that describes hardware devices to the operating system running on the target board. The operating system kernel uses the device tree description to manage the available hardware devices. For example, the operating system uses the device tree to load the specific device driver for a given hardware device.

The device tree has a tree data structure format consisting of nodes and properties. The image shows these components of a device tree.

In the device tree:

- Nodes represent devices in the system.
- Each node has properties specified as property-value pairs that describe the characteristics of the device.
- Each node has exactly one parent, except for the root node, which has no parent. The root node is designated by using a forward slash.

This image shows an example device tree. The left side shows the device tree source file. The right side shows a conceptual diagram of the tree structure with nodes and properties. The names of the boxes represent the node names and the text in the box represents the property-value pairs of the nodes.

Use Device Trees with IP Core Generation Workflow

When you deploy a hardware/software design to a SoC device, the device tree informs the PS about IP cores available in the bitstream. The IP cores appear to the PS as devices, which can be accessed from the software application by using device drivers. Therefore, the device tree and bitstream must be synchronized.

You can generate device tree nodes corresponding to the generated IP core by using the IP core generation workflow. The workflow keeps the device tree and bitstream in sync by updating the device tree whenever your IP core changes.

To enable generation of device tree nodes for the HDL Coder generated IP cores, HDL Coder separates the device tree into three distinct segments:

- Board segment— Device tree nodes corresponding to fixed hardware on your board, such as the central processing unit (CPU) and processor peripherals. The board device tree is typically obtained from the board vendor.
- Reference design segment— Device tree nodes corresponding to IP cores in your reference design. This segment of the device tree is typically created when you author a reference design.
- HDL Coder IP Core segment— Device tree nodes corresponding to the IP core generated by HDL Coder. This segment of the device tree does not need to be authored as it can be dynamically generated by HDL Coder.

This image shows an SoC board with its individual device tree segments.

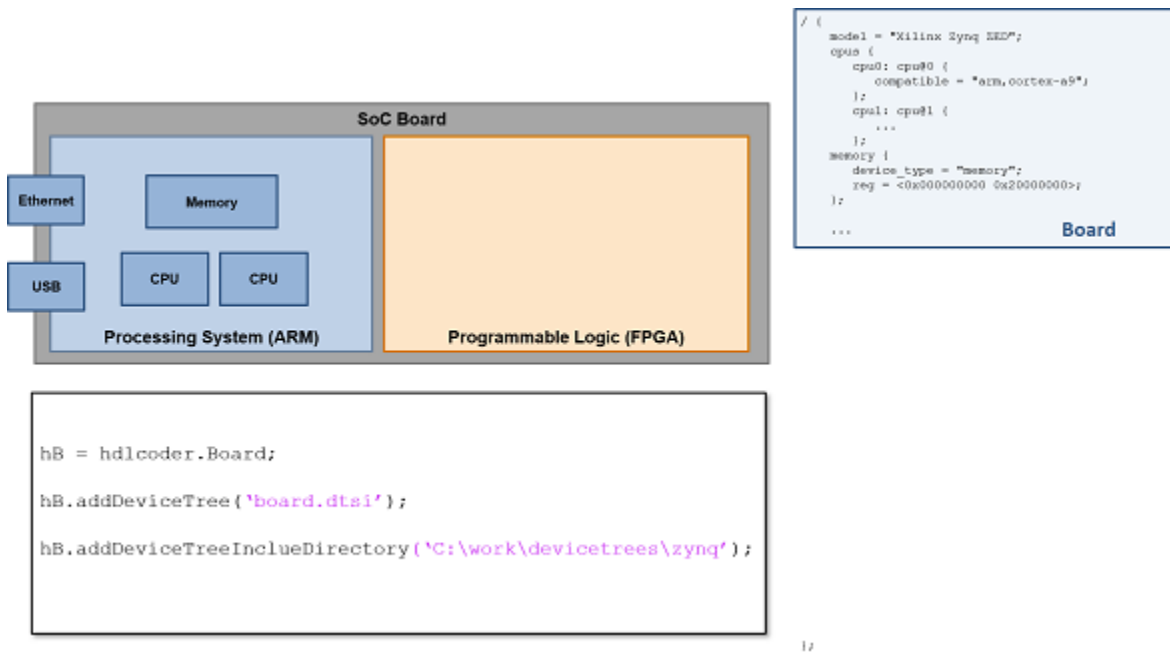

When you deploy your design to the target, HDL Coder automatically combines these segments together into a complete device tree that is used to program the target. These sections walk you through the process of registering and generating the different segments of your device tree.

Register Device Tree for Custom Board

Register the board device tree to your custom board design by using the `addDeviceTree` and `addDeviceTreeIncludeDirectory` methods of the `hdlcoder.Board` object. For more information, see `hdlcoder.Board`, `addDeviceTree`, and `addDeviceTreeIncludeDirectory`.

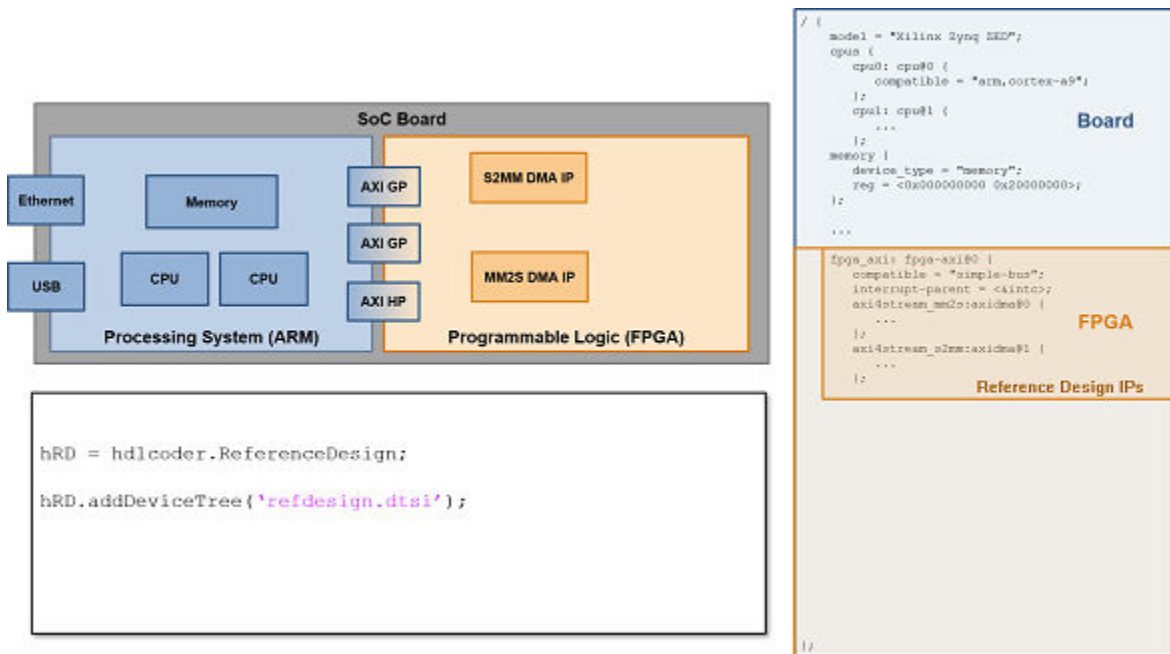

This image shows the board device tree registered to your custom board.

Register Device Tree for Custom Reference Design

Register the reference design portion of your device tree when authoring a reference design by using the `addDeviceTree` and `addDeviceTreeIncludeDirectory` methods of the `hdlcoder.ReferenceDesign` object. To register a device tree, your reference design must contain a processing system IP. Enable the `HasProcessingSystem` property of the `hdlcoder.ReferenceDesign` object. See `hdlcoder.ReferenceDesign`, `addDeviceTree`, and `addDeviceTreeIncludeDirectory`.

This image shows the reference design for a device tree registered to your custom reference design.

Generate IP Core Device Tree Node

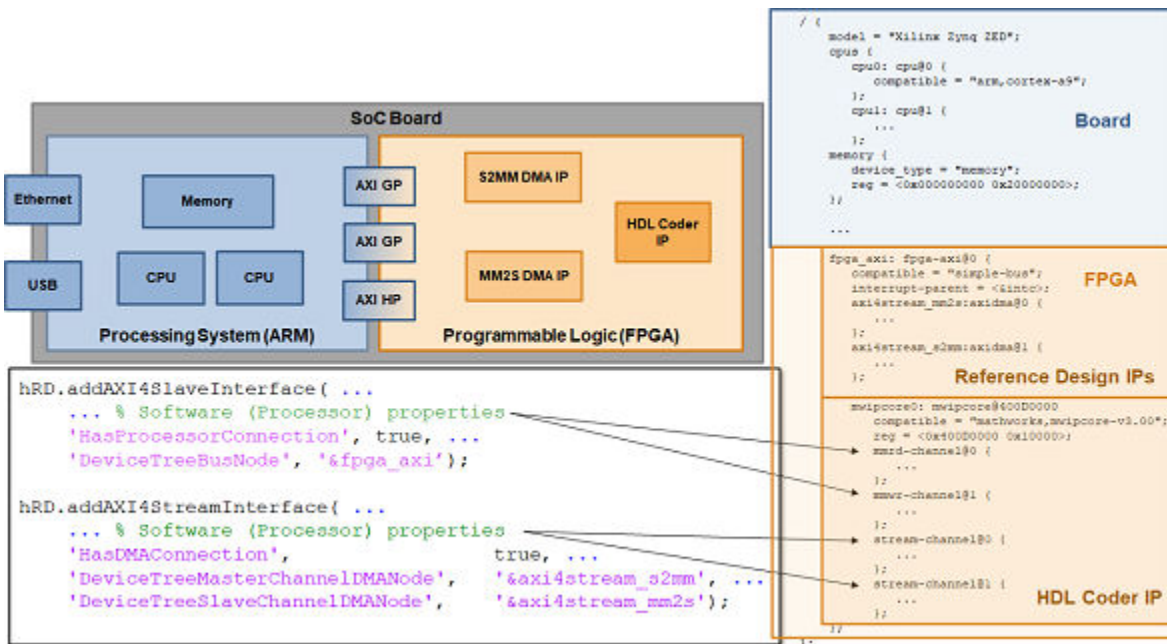

During the IP core generation workflow, HDL Coder generates an IP core and inserts it into your reference design. HDL Coder can also generate corresponding device tree nodes for this IP core and combine them with the board and reference design device trees. Generate the device tree node for your IP core by using the HDL Coder IP core generation workflow. Enable the `GenerateIPCoreDeviceTreeNodes` property of the `hdlcoder.ReferenceDesign` object to generate the device tree nodes for your IP core. See “GenerateIPCoreDeviceTreeNodes”.

This image shows the reference design for a device tree when generating and adding device tree nodes is enabled for your IP core.

To enable device tree generation for your IP core, you must specify the relevant information for the reference design interfaces that connect to the processing system. Enable the generation of device tree nodes by specifying information for the interfaces that connect to the PS on your target device. Interfaces specify references to other device tree nodes. To enable device tree generation for the AXI4 slave interface, enable the `HasProcessorConnection` property and specify the value for the `DeviceTreeNode` property of the `addAXI4SlaveInterface` method for the `hdlcoder.ReferenceDesign` object. See “`HasProcessorConnection`”, `addAXI4SlaveInterface`, and “`DeviceTreeNode`”. Enable device tree generation for the AXI4 Stream interface by enabling the `HasDMAConnection` and specifying values for the `DeviceTreeMasterChannelDMANode` and `DeviceTreeSlaveChannelDMANode`. See `addAXI4StreamInterface`, “`DeviceTreeMasterChannelDMANode`”, “`DeviceTreeSlaveChannelDMANode`”, and “`HasDMAConnection`”.

This image shows the device tree node generation enabled for the IP Core AXI4 slave and AXI4 stream interfaces.

Deploy Device Tree and Bitstream

Download the generated device tree and bitstream for your custom board, reference design, and IP core to the target device by using the HDL Coder IP core generation workflow. The IP core generation workflow compiles the board, reference design, and IP core device trees into a single device tree and then programs them onto the target device along with the generated bitstream. This image shows the generated device tree and bitstream programmed onto the target device.

During the download, HDL Coder uses the device tree compiler on the target board to combine the board device tree, reference design device tree, and IP core device tree. HDL Coder then copies the compiled device tree files back to your host computer.

The following device tree files are generated during the IP Core Generation workflow:

- `devicetree_<model-name>.dtb`— The binary device tree file used to program the board. This file is generated by the device tree compiler.
- `devicetree_<model-name>.dts`— The source device tree file provided as an input to the device tree compiler. This file is generated by HDL Coder.
- `devicetree_<model-name>.output.dts`— A combined source file which contains information for the board device tree, reference design device tree, and your IP core device tree. This file can be used for debugging, and is generated by the device tree compiler.
- `<ip-core-name>.dtsi`: The IP core segment of the device tree. This file is generated by HDL Coder.

The image shows the folder location of the generated device tree files for a sample IP core.

Sample Device Tree

The image shows your reference design file with the interface details. On the left is an example of a reference design file with interface details. On the right is the generated device tree file.

```

hRD = hdlcoder.ReferenceDesign;
hRD.addDeviceTree("refdesign.dtsi");
hRD.HasProcessingSystem = true;
hRD.GenerateIPCoreDeviceTreeNodes = true;
hRD.addAXI4StreamInterface(...
... % Hardware (FPGA) properties
'MasterChannelEnable', true,...
'SlaveChannelEnable', true, ...
'MasterChannelConnection', 'axi_dma_s2mm/S_AXIS_S2MM', ...
'SlaveChannelConnection', 'axi_dma_mm2s/M_AXIS_MM2S', ...
'MasterChannelDataWidth', 32, ...
'SlaveChannelDataWidth', 32, ...
... % Software (Processor) properties
'HasDMAConnection', true, ...
'DeviceTreeMasterChannelIDMANode', '&axi4stream_s2mm', ...
'DeviceTreeSlaveChannelIDMANode', '&axi4stream_mm2s');

```

```

&mwipcore0 {
    stream-channel@1 {
        reg = <0x1>;
        #address-cells = <1>;
        #size-cells = <0>;
        compatible = "mathworks,axi4stream-s2mm-channel-v1.00";
        dma-names = "s2mm";
        dmas = <&axi4stream_s2mm 0>;
        mathworks,dev-name = "s2mm0";
        mathworks,sample-cnt-reg = <0x8>;

        data-channel@0 {
            compatible = "mathworks,iio-data-channel-v1.00";
            mathworks,data-format = u32/32>0;
            reg = <0x0>;
        };
    };
};

```
