The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

Revision History

March 2012	Online only	New for Version 3.0 (R2012a)
September 2012	Online only	Revised for Version 3.1 (R2012b)
March 2013	Online only	Revised for Version 3.2 (R2013a)
September 2013	Online only	Revised for Version 3.3 (R2013b)
March 2014	Online only	Revised for Version 3.4 (R2014a)
October 2014	Online only	Revised for Version 3.5 (R2014b)
March 2015	Online only	Revised for Version 3.6 (R2015a)
September 2015	Online only	Revised for Version 3.7 (R2015b)
October 2015	Online only	Rereleased for Version 3.6.1 (Release 2015aSP1)
March 2016	Online only	Revised for Version 3.8 (R2016a)
September 2016	Online only	Revised for Version 3.9 (R2016b)
March 2017	Online only	Revised for Version 3.10 (Release 2017a)
September 2017	Online only	Revised for Version 3.11 (R2017b)
March 2018	Online only	Revised for Version 3.12 (Release 2018a)
September 2018	Online only	Revised for Version 3.13 (Release 2018b)
March 2019	Online only	Revised for Version 3.14 (Release 2019a)
September 2019	Online only	Revised for Version 3.15 (Release 2019b)
March 2020	Online only	Revised for Version 3.16 (Release 2020a)
September 2020	Online only	Revised for Version 3.17 (Release 2020b)
March 2021	Online only	Revised for Version 3.18 (Release 2021a)
September 2021	Online only	Revised for Version 3.19 (Release 2021b)
March 2022	Online only	Revised for Version 3.20 (Release 2022a)
September 2022	Online only	Revised for Version 4.0 (Release 2022b)
March 2023	Online only	Revised for Version 4.1 (Release R2023a)

HDL Code Generation from MATLAB

1	MATLAB Algorithm Design
Functions Supported for HDL and SystemC Code Generation	1-2
Supported MATLAB and Fixed Point Runtime Library Functions	1-2
Fixed-Point Function Limitations	1-2
Supported MATLAB Data Types, Operators, and Control Flow Statements	1-4
Supported Data Types	1-4
Supported Operators	1-6
Control Flow Statements	1-7
Persistent Variables and Persistent Array Variables	1-9
Persistent Variables	1-9
Persistent Array Variables	1-9
Complex Data Type Support	1-11
Declaring Complex Signals	1-11
Conversion Between Complex and Real Signals	1-12
Support for Vectors of Complex Numbers	1-12
Complex Data Type Support for SystemC Code Generation	1-14
Declaring Complex Signals	1-14
Conversion Between Complex and Real Signals	1-14
Support for Vectors of Complex Numbers	1-15
HDL Code Generation for System Objects	1-16
Why Use System Objects?	1-16
Predefined System Objects	1-16
User-Defined System Objects	1-16
Limitations of HDL Code Generation for System Objects	1-16
System object Examples for HDL Code Generation	1-17
HDL Code Generation from System Objects	1-18
HDL Code Generation for Streaming Matrix Inverse System Object	1-22
HDL Code Generation for Streaming Matrix Multiply System Object	1-31

HDL Code Generation from hdl.RAM System Object	1-39
HDL Code Generation from A Non-Restoring Square Root System Object	1-42
HDL Code Generation from Viterbi Decoder System Object	1-46
Predefined System Objects Supported for HDL Code Generation ..	1-50
Predefined System Objects in MATLAB Code	1-50
Predefined System Objects in the MATLAB System Block	1-51
Load constants from a MAT-File	1-52
Generate Code for User-Defined System Objects	1-53
How To Create A User-Defined System object	1-53
User-Defined System object Example	1-53
Map Matrices to ROM	1-55
Model State with Persistent Variables and System Objects	1-56
Bitwise Operations in MATLAB for HDL and SystemC Code Generation	1-58
Bit Shifting and Rotation	1-58
Bit Slicing and Bit Concatenation	1-60
Mapping of Different Rounding and Overflow Methods from MATLAB to SystemC	1-61
Guidelines for Writing MATLAB Code to Generate Efficient HDL and SystemC Code	1-63
MATLAB Design Requirements for HDL and SystemC Code Generation	1-63
Guidelines for Writing MATLAB Code	1-63
For-Loop Best Practices for HDL Code Generation	1-65
Monotonically Increasing Loop Counters	1-65
Find Indices Using Loops	1-65
Persistent Variables in Loops	1-66
Persistent Arrays in Loops	1-66
MATLAB Test Bench Requirements and Best Practices for Code Generation	1-68
What Is a MATLAB Test Bench?	1-68
MATLAB Test Bench Requirements	1-68
MATLAB Test Bench Best Practices	1-68

MATLAB to HDL Examples for Communications and Signal Processing Applications

2

HDL Code Generation for LMS Filter	2-2
Bisection Algorithm to Calculate Square Root of an Unsigned Fixed-Point Number	2-8
Timing Offset Estimation	2-12
Data Packetization	2-16
Transmit and Receive FIFO Registers	2-22
HDL Code Generation for Harris Corner Detection Algorithm	2-29
HDL Code Generation for Adaptive Median Filter	2-36
Contrast Adjustment	2-43
Image Enhancement by Histogram Equalization	2-51
HDL Code Generation for Image Format Conversion from RGB to YUV	2-56
High Dynamic Range Imaging	2-60
Accelerate Pixel-Streaming Designs Using MATLAB Coder	2-65
Enhanced Edge Detection from Noisy Color Video	2-68
Verify Sobel Edge Detection Algorithm in MATLAB-to-HDL Workflow	2-71

MATLAB Best Practices and Design Patterns for HDL Code Generation

3

Model a Counter for HDL and SystemC Code Generation	3-2
MATLAB Code for the Counter	3-2
Model a State Machine for HDL and SystemC Code Generation	3-4
MATLAB Code for the Mealy State Machine	3-4
MATLAB Code for the Moore State Machine	3-5
Generate Hardware Instances For Local Functions	3-8
MATLAB Local Functions	3-8
MATLAB Code for mlhdlc_two_counters.m	3-8

Implement RAM Using MATLAB Code	3-10
Implement RAM Using a Persistent Array or System object Properties	3-10
.....	3-11
Implement RAM Using hdl.RAM	3-11

Fixed-Point Conversion

4

Specify Type Proposal Options	4-2
Log Data for Histogram	4-5
View and Modify Variable Information	4-7
View Variable Information	4-7
Modify Variable Information	4-7
Revert Changes	4-8
Promote Sim Min and Sim Max Values	4-8
Automated Fixed-Point Conversion	4-9
License Requirements	4-9
Automated Fixed-Point Conversion Capabilities	4-9
Code Coverage	4-10
Proposing Data Types	4-12
Locking Proposed Data Types	4-14
Viewing Functions	4-14
Viewing Variables	4-14
Histogram	4-19
Function Replacements	4-20
Validating Types	4-21
Testing Numerics	4-21
Detecting Overflows	4-21
Custom Plot Functions	4-23
Edit Configuration Parameters for Fixed-Point Code Generation ..	4-24
Create and Modify Configuration Objects	4-24
Additional Functionalities	4-24
Visualize Differences Between Floating-Point and Fixed-Point Results	4-26
Inspecting Data Using the Simulation Data Inspector	4-31
What Is the Simulation Data Inspector?	4-31
Import Logged Data	4-31
Export Logged Data	4-31
Group Signals	4-31
Run Options	4-31
Create Report	4-32
Comparison Options	4-32
Enabling Plotting Using the Simulation Data Inspector	4-32
Save and Load Simulation Data Inspector Sessions	4-32

Enable Plotting Using the Simulation Data Inspector	4-33
From the UI	4-33
From the Command Line	4-33
Replacing Functions Using Lookup Table Approximations	4-34
Replace a Custom Function with a Lookup Table	4-35
Using the HDL Coder App	4-35
From the Command Line	4-38
Replace the exp Function with a Lookup Table	4-41
From the UI	4-41
From the Command Line	4-44
Data Type Issues in Generated Code	4-47
Enable the Highlight Option in a Project	4-47
Enable the Highlight Option at the Command Line	4-47
Stowaway Doubles	4-47
Stowaway Singles	4-47
Expensive Fixed-Point Operations	4-47
Working with Fixed-Point Code	4-49
Floating-Point to Fixed-Point Conversion	4-51
Fixed-Point Type Conversion and Refinement	4-61
Working with Generated Fixed-Point Files	4-68
Fixed-Point Type Conversion and Derived Ranges	4-73
Generate HDL-Compatible Lookup Table Function Replacements	
Using <code>coder.approximate</code>	4-78

Code Generation

5

Create and Set Up Your Project	5-2
Create a New Project	5-2
Open an Existing Project	5-3
Add Files to the Project	5-3
Specify Properties of Entry-Point Function Inputs	5-4
When to Specify Input Properties	5-4
Why You Must Specify Input Properties	5-4
Properties to Specify	5-4
Rules for Specifying Properties of Primary Inputs	5-5
Methods for Defining Properties of Primary Inputs	5-6
Code Generation Reports	5-7

MATLAB Variables	5-9
Additional Reports	5-10
Report Limitations	5-10
Generate Instantiable Code for Functions	5-11
How to Generate Instantiable Code for Functions	5-11
Generate Code Inline for Specific Functions	5-11
Limitations for Instantiable Code Generation for Functions	5-11
Edit Configuration Parameters for HDL Coder	5-12
Create and Modify Configuration Objects	5-12
Additional Functionalities	5-12
Integrate Custom HDL Code Into MATLAB Design	5-14
Define the hdl.BlackBox System object	5-14
Use System object In MATLAB Design Function	5-15
Generate HDL Code	5-16
Limitations for hdl.BlackBox	5-18
Enable MATLAB Function Block Generation	5-19
Requirements for MATLAB Function Block Generation	5-19
Enable MATLAB Function Block Generation	5-19
Restrictions for MATLAB Function Block Generation	5-19
Results of MATLAB Function Block Generation	5-19
System Design with HDL Code Generation from MATLAB and Simulink	5-20
Specify the Clock Enable Rate	5-23
Why Specify the Clock Enable Rate?	5-23
How to Specify the Clock Enable Rate	5-23
Specify Test Bench Clock Enable Toggle Rate	5-25
When to Specify Test Bench Clock Enable Toggle Rate	5-25
How to Specify Test Bench Clock Enable Toggle Rate	5-25
Generate an HDL Coding Standard Report from MATLAB	5-27
Using the HDL Workflow Advisor	5-27
Using the Command Line	5-29
Generate an HDL Lint Tool Script	5-30
How To Generate an HDL Lint Tool Script	5-30
Generate HDL Code from MATLAB Functions that Use Automated Lookup Table Generation	5-32
Generate Board-Independent IP Core from MATLAB Algorithm ...	5-37
Requirements and Limitations for IP Core Generation	5-37
Generate Board-Independent IP Core	5-37
Minimize Clock Enables	5-39
Using the GUI	5-39

Using the Command Line	5-39
Limitations	5-40

Verification

6

Verify Code with HDL Test Bench	6-2
Test Bench Generation	6-5
How Test Bench Generation Works	6-5
Test Bench Data Files	6-5
Test Bench Data Type Limitations	6-5
Use Constants Instead of File I/O	6-5

Deployment

7

Generate Synthesis Scripts	7-2
---	------------

Optimization

8

Map Matrices to Block RAMs to Reduce Area	8-2
Map Persistent Arrays and dsp.Delay Objects to RAM	8-6
Enable RAM Mapping	8-6
RAM Mapping Requirements for Persistent Arrays and System object Properties	8-7
RAM Mapping Requirements for dsp.Delay System Objects	8-9
RAM Mapping Comparison	8-9
Pipelining MATLAB Code	8-11
Port Registers	8-11
Input and Output Pipeline Registers	8-11
Operation Pipelining	8-11
Pipeline MATLAB Expressions	8-12
How To Pipeline a MATLAB Expression	8-12
Limitations of Pipelining for MATLAB Expressions	8-12
Distributed Pipelining	8-14
What is Distributed Pipelining?	8-14
Benefits and Costs of Distributed Pipelining	8-14
Selected Bibliography	8-14
Distributed Pipelining for Clock Speed Optimization	8-15

Optimize Clock Speed for MATLAB Code by Using Adaptive Pipelining	8-19
Optimize Feedback Loop Design and Maintain High Data Precision for HDL Code Generation	8-26
Optimize MATLAB Loops	8-29
Loop Streaming	8-29
Loop Unrolling	8-29
How to Optimize MATLAB Loops	8-29
Limitations for MATLAB Loop Optimization	8-30
Constant Multiplier Optimization	8-31
What is Constant Multiplier Optimization?	8-31
Specify Constant Multiplier Optimization	8-31
Resource Sharing of Multipliers to Reduce Area	8-33
Loop Streaming to Reduce Area	8-39
Constant Multiplier Optimization to Reduce Area	8-44

Module name prefix	21-23
Pipeline postfix	21-23
Split entity and architecture Parameters	21-25
Split entity file postfix	21-25
Split arch file postfix	21-25
Split entity and architecture	21-26
Complex Signals Postfix Parameters	21-28
Complex real part postfix	21-28
Complex imaginary part postfix	21-28
VHDL Architecture and Library Name and Code for Model Reference Parameters	21-30
VHDL architecture name	21-30
VHDL library name	21-30
Generate VHDL code for model references into a single library ..	21-31
Generate Statement and Vector and Component Instance Label Parameters	21-32
Block generate label	21-32
Output generate label	21-32
Instance generate label	21-32
Vector prefix	21-33
Instance postfix	21-33
Instance prefix	21-34
Dependency	21-34
Map file postfix	21-34
Input and Output Port and Clock Enable Output Type Parameters	21-35
Input data type	21-35
Output data type	21-35
Clock Enable output port	21-36
Minimize Clock Enables and Reset Signal Parameters	21-37
Minimize clock enables	21-37
Minimize global resets	21-38
DUT Port Configuration Parameters	21-41
Use trigger signal as clock	21-41
Enable HDL DUT port generation for tunable parameters	21-41
Balance delays for generated DUT input ports	21-42
Enable HDL DUT port generation for test points	21-43
Balance delays for generated DUT output ports	21-44
Scalarize ports	21-45
Max number of I/O pins for FPGA deployment	21-46

Check for DUT pin count exceeding I/O Threshold	21-46
RTL Annotation Parameters	21-48
Use Verilog `timescale directives	21-48
Verilog timescale specification	21-48
Code Reuse	21-49
Inline VHDL configuration	21-49
Concatenate type safe zeros	21-50
Generate obfuscated HDL code	21-51
RTL Customization Parameters for Constants and MATLAB Function	
Blocks	21-52
Inline MATLAB Function block code	21-52
Represent constant values by aggregates	21-52
RTL Customization Parameters for RAMs	21-54
Initialize all RAM blocks	21-54
RAM Architecture	21-54
No-reset registers initialization	21-56
Settings	21-56
Usage Notes	21-56
Command-Line Information	21-57
See Also	21-57
RTL Style Parameters	21-58
Use “rising_edge/falling_edge” Style for Registers	21-58
Minimize Intermediate Signals	21-59
Unroll For-Generate Loops in VHDL Code	21-59
Generate Parameterized HDL Code from Masked Subsystem	21-61
Enumerated Type Encoding Scheme	21-62
Indexing for Scalarized Port Naming	21-63
Generate Record Types for Bus	21-64
Timing Controller Settings	21-67
Optimize timing controller	21-67
Timing controller architecture	21-67
File Comment Customization Parameters	21-69
Enable Comments	21-69
Include Requirements in Block Comments	21-69
Emit Time/Date Stamp in Header	21-69
Custom File Header Comment	21-70
Custom File Footer Comment	21-71
Choose Coding Standard and Report Option Parameters	21-73
HDL coding standard	21-73
Show passing rules in coding standard report	21-74
Basic Coding Practices Parameters	21-76
Check for duplicate names	21-76
Check for HDL keywords in design names	21-77
Check module, instance, entity name length	21-77
Check signal, port, and parameter name length	21-79

RTL Description Rules for clock enables and resets Parameters	21-81
Check for clock enable signals	21-81
Detect usage of reset signals	21-82
Detect usage of asynchronous reset signals	21-83
RTL Description Rules for Conditional Parameters	21-84
Check for conditional statements in processes	21-84
Check for assignments to the same variable in multiple cascaded control regions	21-85
Check if-else statement chain length	21-85
Check if-else statement nesting depth	21-86
Other RTL Description Rule Parameters	21-88
Minimize use of variables	21-88
Check for initial statements that set RAM initial values	21-89
Check multiplier width	21-89
RTL Design Rule Parameters	21-91
Check for non-integer constants	21-91
Check line length	21-92
Model Generation Parameters for HDL Code	21-93
Generated model	21-93
Validation model	21-94
Naming and Layout Options for Model Generation	21-96
Prefix for generated model name	21-96
Suffix for validation model name	21-96
Layout Style	21-97
Auto signal routing	21-99
Inter-block horizontal scaling	21-99
Inter-block vertical scaling	21-100
Diagnostic Parameters for Optimizations	21-101
Highlight feedback loops inhibiting delay balancing and optimizations	21-101
Highlight blocks inhibiting clock-rate pipelining	21-102
Highlight blocks inhibiting distributed pipelining	21-103
Highlight lookup tables mapped to RAM	21-104
Highlight dead blocks removed in generated code	21-104
Diagnostic Parameters for Reals and Black Box Interfaces	21-106
Check for name conflicts in black box interfaces	21-106
Check for presence of reals in generated HDL code	21-107
Check for presence of unbalanced delays in generated HDL code	21-107
Code Generation Output Parameter	21-109
Generate HDL code	21-109
Suppress out of bounds access errors by generating simulation-only index checks	21-110

Report Pane Overview	22-2
See Also	22-2
Code Generation Report Parameters	22-3
Generate traceability report	22-3
Traceability style	22-4
Generate model Web view	22-5
Generate resource utilization report	22-6
Generate high-level timing critical path report	22-7
Generate optimization report	22-8
Custom Timing Database Directory	22-9

HDL Code Generation Pane: Test Bench

Test Bench Overview	23-2
Generate Test Bench Button	23-2
Test Bench Generation Output Parameters	23-3
HDL test bench	23-3
Cosimulation model	23-4
SystemVerilog DPI test bench	23-5
Simulation tool	23-6
HDL code coverage	23-7
Test Bench Postfix Parameters	23-8
Test bench name postfix	23-8
Test bench reference postfix	23-8
Test bench data file name postfix	23-9
Clock and Reset Input Parameters for Testbench	23-10
Force clock	23-10
Clock high time (ns)	23-10
Clock low time (ns)	23-11
Force clock enable	23-12
Clock enable delay (in clock cycles)	23-13
Force reset	23-14
Reset length (in clock cycles)	23-15
Setup and Hold Time Parameters for Testbench	23-17
Hold time (ns)	23-17
Setup time (ns)	23-18
Test Bench Stimulus and Output Parameters	23-20
Hold input data between samples	23-20
Initialize test bench inputs	23-21
Ignore output data checking (number of samples)	23-21
Use file I/O to read/write test bench data	23-23

Multi-File Testbench and Simulation Library Path Parameters . . .	23-25
Multi-file test bench	23-25
Simulation library path	23-26
Floating-Point Tolerance Parameters	23-28
Floating point tolerance check based on	23-28
Tolerance Value	23-28

HDL Code Generation Pane: EDA Tool Scripts

24

EDA Tool Scripts Overview	24-2
Generate EDA scripts	24-3
Settings	24-3
Command-Line Information	24-3
See Also	24-3
Compilation Script Parameters	24-4
Compile file postfix	24-4
Compile initialization	24-4
Compile command for VHDL	24-5
Compile command for Verilog	24-5
Compile termination	24-6
Simulation Script Parameters	24-7
Simulation file postfix	24-7
Simulation initialization	24-7
Simulation command	24-8
Simulation waveform viewing command	24-8
Simulation termination	24-9
Simulator flags	24-9
Synthesis Script Parameters	24-11
Choose synthesis tool	24-11
Synthesis file postfix	24-12
Synthesis initialization	24-13
Synthesis command	24-14
Synthesis termination	24-14
Additional files to add to synthesis project	24-15
Lint Script Parameters	24-17
Choose HDL lint tool	24-17
Lint initialization	24-18
Lint command	24-18
Lint termination	24-18

HDL Modeling Guidelines Severity Levels	25-2
Model Design and Compatibility Guidelines - By Numbered List	
.....	25-3
Guidelines 1.1: Basic Settings	25-3
Guidelines 1.2: DUT Subsystem and Hierarchical Modeling	25-4
Guidelines 1.3: Vectors, Matrices, and Buses	25-4
Guidelines 1.4: Clock Bundle Signals	25-5
Guidelines 1.5: Native Floating Point	25-5
Guidelines for Supported Blocks and Data Types - By Numbered List	
.....	25-6
Guidelines 2.1: HDL RAMs and HDL Operations Library	25-6
Guidelines 2.2: Logic and Bit Operations Library	25-6
Guidelines 2.3: Lookup Table and Signal Routing Blocks	25-6
Guidelines 2.4: Ports and Subsystems	25-7
Guideline 2.5: Rate Change and Constant Blocks	25-7
Guideline 2.6: Delay Blocks	25-7
Guideline 2.7: Multiplication and Accumulation Operations	25-8
Guideline 2.8: MATLAB Function Blocks	25-8
Guideline 2.9: Stateflow Charts	25-9
Guidelines 2.10: Data Types	25-9
Guidelines for Speed and Area Optimizations - By Numbered List	
.....	25-11
Guidelines 3.1: Resource Sharing and Streaming	25-11
Guidelines 3.2: Clock Rate Pipelining and Distributed Pipelining .	25-12
Basic Guidelines for Modeling HDL Algorithm in Simulink	25-13
Use HDL-Supported Blocks	25-13
Partition Model into DUT and Test Bench	25-14
Avoid Using Double-Byte Characters	25-16
Document Model Features and Attributes	25-16
Guidelines for Model Setup and Checking Model Compatibility ..	25-19
Customize hdlsetup Function Based on Target Application	25-19
Check Subsystem for HDL Compatibility	25-20
Run Model Checks for HDL Coder	25-20
Modeling with Simulink, Stateflow, and MATLAB Function Blocks	
.....	25-23
Guideline ID	25-23
Severity	25-23
Description	25-23
Terminate Unconnected Block Outputs and Usage of Commenting Blocks	25-26
Terminate Unconnected Block Outputs	25-26
Using Comment Out and Comment Through of Blocks	25-27

Identify and Programmatically Change and Display HDL Block Parameters	25-30
Adjust Sizes of Constant and Gain Blocks for Identifying Parameters	25-30
Display Parameters That Affect HDL Code Generation	25-30
Change Block Parameters by Using find_system and set_param ..	25-35
DUT Subsystem Guidelines	25-36
DUT Subsystem Considerations	25-36
Convert DUT Subsystem to Model Reference for Testbenches with Continuous Blocks	25-36
Insert Handwritten Code into Simulink Modeling Environment ..	25-38
Hierarchical Modeling Guidelines	25-40
Avoid Constant Block Connections to Subsystem Port Boundaries	25-40
Generate Parameterized HDL Code for Constant and Gain Blocks	25-41
Place Physical Signal Lines Inside a Subsystem	25-43
Design Considerations for Matrices and Vectors	25-46
Modeling Requirements for Matrices	25-46
Avoid Generating Ascending Bit Order in HDL Code From Vector Signals	25-47
Use Bus Signals to Improve Readability of Model and Generate HDL Code	25-51
Guidelines for Clock and Reset Signals	25-57
Use Global Oversampling to Create Frequency-Divided Clock	25-57
Create Multirate Model with Integer Clock Multiples by Clock Division	25-57
Use Dual Rate Dual Port RAM for Noninteger Multiple Sample Times	25-60
Asynchronous Clock Modeling in HDL Coder	25-61
Use Global Reset Type Setting Based on Target Hardware	25-63
Modeling with Native Floating Point	25-64
Guideline ID	25-64
Severity	25-64
Description	25-64
Design Considerations for RAM Blocks and Blocks in HDL Operations Library	25-67
RAM Block Access Considerations	25-67
Serial to Parallel Conversion	25-69
Usage of Blocks in Logic and Bit Operations Library	25-71
Logical and Arithmetic Bit Shift Operations	25-71
Usage of Logical Operator, Bitwise Operator, and Bit Reduce Blocks	25-73
Use Boolean Output for Compare to Constant and Relational Operator Blocks	25-75
Generate FPGA Block RAM from Lookup Tables	25-77

Recommended Block Parameter Settings of Multiport Switch Block for Numeric and Enumerated Types	25-82
Usage of Different Subsystem Types	25-86
Virtual Subsystem: Use as DUT	25-86
Atomic and Virtual Subsystems: Generate Reusable HDL Files ...	25-86
Variant Subsystem: Using Variant Subsystems for HDL Code Generation	25-87
Model References: Build Model Design Using Smaller Partitions ..	25-89
Block Settings of Enabled and Triggered Subsystems	25-91
Usage of Rate Change and Constant Blocks	25-93
Usage of Rate Conversion Blocks	25-93
Use Discrete and Finite Sample Time for Constant Block	25-94
Guidelines for Using Delays and Goto and From Blocks for HDL Code Generation	25-97
Appropriate Usage of Delay Blocks as Registers	25-97
Absorb Delays to Avoid Timing Difference	25-97
Map Large Delays to Block RAM	25-98
Required HDL Settings for Goto and From Blocks	25-99
Modeling Efficient Multiplication and Division Operations for FPGA Targeting	25-101
Designing Multipliers and Adders for Efficient Mapping to DSP Blocks on FPGA	25-101
Set ConstMultiplierOptimization HDL Block Property to auto for Gain Block	25-105
Use ShiftAdd Architecture of Divide Block for Fixed-Point Types	25-107
Using Persistent Variables and fi Objects Inside MATLAB Function Blocks for HDL Code Generation	25-108
Update Persistent Variables at End of MATLAB Function	25-108
Avoid Algebraic Loop Errors from Persistent Variables inside MATLAB Function Blocks	25-109
Use hdlfimath Setting and Specify fi Objects inside MATLAB Function Block	25-111
Guidelines for HDL Code Generation Using Stateflow Charts ...	25-114
Choose State Machine Type based on HDL Implementation Requirements	25-114
Specify Block Configuration Settings of Stateflow Chart	25-114
Insert Unconditional Transition State for Else Statement in HDL Code	25-115
Data Type Settings and Casting in Stateflow Chart for HDL Code Generation	25-118
Using Absolute Time Temporal Logic in Stateflow Charts	25-120
Modeling Error (default) State in Stateflow Charts	25-120
Enable Clock-Driven Outputs of Stateflow Charts (Moore Charts Only)	25-121
Enumeration type for active state monitoring in a Stateflow chart with no default value	25-122
Simulink Data Type Considerations	25-125
Use Boolean for Logical Data and Ufix1 for Numerical Data	25-125

Specify Data Type of Gain Blocks	25-125
Enumerated Data Type Restrictions	25-126
Resource Sharing Settings for Various Blocks	25-127
Resource Sharing of Add Blocks	25-127
Resource Sharing of Gain Blocks	25-128
Resource Sharing of Product Blocks	25-129
Resource Sharing of Multiply-Add Blocks	25-129
Resource Sharing of Subsystems and Floating-Point IPs	25-131
General Considerations for Sharing of Subsystems	25-131
Use MATLAB Datapath Architecture for Sharing with MATLAB Function Blocks	25-132
Sharing of Subsystems	25-132
Resource Sharing of Floating-Point IPs	25-133
Resource Sharing Guidelines for Vector Processing and Matrix Multiplication	25-135
Use StreamingFactor for Resource Sharing of Vector Signals . . .	25-135
Use SharingFactor and HDL Block Properties for Sharing Matrix Multiplication Operations	25-138
Distributed Pipelining and Clock-Rate Pipelining Guidelines . . .	25-140
Clock-Rate Pipelining Guidelines	25-140
Recommended Distributed Pipelining Settings	25-140
Insert Distributed Pipeline Registers for Blocks with Vector Data Type Inputs	25-143
Guideline ID	25-143
Severity	25-143
Description	25-143

Area Reduction of Filter Subsystem	28-220
Remove Redundant Logic and Unused Blocks in Generated HDL Code	28-224
Optimize Unconnected Ports in HDL Code for Simulink Models	28-246

HDL Code Generation from Frame-Based Algorithms	29-2
Generating HDL Code from a Frame-based Algorithm	29-2
Specify the Frame-to-Sample Conversion Optimization	29-3
Generate HDL Code from a Frame-Based Model Example	29-4
Hardware Considerations	29-7
Supported Blocks and Operations	29-7
Limitations	29-8
Use Neighborhood, Reduction, and Iterator Patterns with a Frame-Based Model or Function for HDL Code Generation	29-10
Generate HDL Code from Frame-Based Models by Using Neighborhood Modeling Methods	29-17
Use Sample-Based Inputs and Frame-Based Inputs in an Algorithm	29-22
Synthesize Code for Frame-Based Model	29-26
Offload Large Delays from Frame-Based Models to External Memory	29-32
Deploy Frame-Based Models with AXI4-Stream Video Interfaces in Zynq-Based Hardware	29-40
Optimize Area Usage For Frame-Based Algorithms with Tall Array Inputs	29-46
Compute Image Characteristics with a Frame-Based Model for HDL Code Generation	29-52

Code Generation Reports, HDL Compatibility Checker, Block Support Library, and Code Annotation

Create and Use Code Generation Reports	30-2
Report Generation	30-2
Code Generation Report	30-2
Timing and Area Report	30-2
Optimization Report	30-3
Navigate Between Simulink Model and HDL Code by Using Traceability	30-4
How Traceability Works	30-4
Generate Traceability Report	30-5
Report Location	30-5

Rule Summary	31-2
Rule Hierarchy	31-2
Rule and Report Customization	31-3
How to Fix Warnings and Errors	31-3
HDL Coding Standards	31-4
Generate HDL Coding Standard Report from Simulink	31-5
Using the Configuration Parameters Dialog Box	31-5
Using the Command Line	31-5
Basic Coding Practices	31-7
1.A General Naming Conventions	31-8
1.B General Guidelines for Clocks and Resets	31-13
1.C Guidelines for Initial Reset	31-14
1.D Guidelines for Clocks	31-15
1.F Guidelines for Hierarchical Design	31-16
RTL Description Rules and Checks	31-17
2.A Guidelines for Combinational Logic	31-17
2.B Guidelines for “Always” Constructs of Combinational Logic ..	31-22

2.C Guidelines for Flip-Flop Inference	31-24
2.D Guidelines for Latch Description	31-27
2.E Guidelines for Tristate Buffer	31-28
2.F Guidelines for Always/Process Construct with Circuit Structure into Account	31-29
2.G Guidelines for "IF" Statement Description	31-30
2.H Guidelines for "CASE" Statement Description	31-32
2.I Guidelines for "FOR" Statement Description	31-35
2.J Guidelines for Operator Description	31-36
2.K Guidelines for Finite State Machine Description	31-39
RTL Design Methodology Guidelines	31-41
3.A Guidelines for Creating Function Libraries	31-41
3.B Guidelines for Using Function Libraries	31-42
3.C Guidelines for Test Facilitation Design	31-43
Generate HDL Lint Tool Script	31-45
How to Generate an HDL Lint Tool Script	31-45
Cascaded Conditional Region Variable Assignments	31-47
Example Patterns that Fail the Check for Guideline 2.F.B.1.a	31-47
Example Patterns that Pass the Check for Guideline 2.F.B.1.a	31-48
Simulink Blocks and Modeling Patterns that Fail the Check for Guideline 2.F.B.1.a	31-49

Interfacing Subsystems and Models to HDL Code

32

Model Referencing for HDL Code Generation	32-2
Benefits of Model Referencing for Code Generation	32-2
How To Generate Code for a Referenced Model	32-2
Generate Code for Model Arguments	32-3
Generate Comments	32-3
Limitations	32-3
Generate Black Box Interface for Subsystem	32-4
What Is a Black Box Interface?	32-4
Requirements	32-4
Generate a Black Box Interface for a Subsystem	32-4
Generate Code for a Black Box Subsystem Implementation	32-6
Generate Black Box Interface for Referenced Model	32-8
When to Generate a Black Box Interface	32-8
How to Generate a Black Box Interface	32-8
Caveats and Limitations	32-8
Integrate Custom HDL Code by Using DocBlock	32-10
When to Use DocBlock for Integrating Custom Code	32-10
Use DocBlock to Integrate Custom Code	32-10
Restrictions	32-10
Include Custom HDL Code Using Doc Block	32-11

Customize Black Box or HDL Cosimulation Interface	32-12
Interface Parameters	32-12
Specify Bidirectional Ports	32-15
Requirements	32-15
How To Specify a Bidirectional Port	32-15
Limitations	32-15
Generate Reusable Code for Subsystems	32-17
Requirements for Generating Reusable Code for Atomic Subsystems	32-17
Requirements for Generating Reusable Code for Virtual Subsystems	32-17
Generate Reusable Code for Atomic Subsystems	32-18
Generate Reusable Code for Atomic Subsystems with Tunable Mask Parameters	32-20
Scalarization of Vector Ports in Generated VHDL Code	32-24
Create a Xilinx System Generator Subsystem	32-28
Why Use Xilinx System Generator Subsystems	32-28
Requirements for Xilinx System Generator Subsystems	32-28
Create a Xilinx System Generator Subsystem	32-28
Limitations for Code Generation from Xilinx System Generator Subsystems	32-29
Create an Altera DSP Builder Subsystem	32-30
Why Use Altera DSP Builder Subsystems?	32-30
Requirements for Altera DSP Builder Subsystems	32-30
How to Create an Altera DSP Builder Subsystem	32-30
Determine Clocking Requirements for Altera DSP Builder Subsystems	32-31
Limitations for Code Generation from Altera DSP Builder Subsystems	32-31
Using Altera DSP Builder Advanced Blockset with HDL Coder ...	32-32
Using Xilinx System Generator for DSP with HDL Coder	32-37
Choose a Test Bench for Generated HDL Code	32-40
Generate a Cosimulation Model	32-42
Requirements	32-42
What Is A Cosimulation Model?	32-42
Generating a Cosimulation Model using the Model Configuration Parameters	32-43
Structure of the Generated Model	32-45
Launching a Cosimulation	32-49
The Cosimulation Script File	32-51
Complex and Vector Signals in the Generated Cosimulation Model	32-53
Generating a Cosimulation Model from the Command Line	32-54
Naming Conventions for Generated Cosimulation Models and Scripts	32-54
Limitations for Cosimulation Model Generation	32-55

HDL Verifier Cosimulation Model Generation in HDL Coder	32-56
Verify HDL Design Using SystemVerilog DPI Test Bench	32-66
Pass-Through and No-Op Implementations	32-71
Synchronous Subsystem Behavior with the State Control Block .	32-72
What Is a State Control Block?	32-72
State Control Block Modes	32-72
Synchronous Badge for Subsystems by Using Synchronous Mode	32-73
Generate HDL Code with the State Control Block	32-74
Using the State Control Block to Generate More Efficient Code with HDL Coder	32-77
Resettable Subsystem Support in HDL Coder	32-83

Stateflow HDL Code Generation Support

33

Introduction to Stateflow HDL Code Generation	33-2
Example	33-2
Chart Initialization	33-2
Tunable Parameters	33-3
Comments in Stateflow Charts	33-3
Restrictions	33-3
Hardware Realization of Stateflow Semantics	33-6
Generate HDL for Mealy and Moore Finite State Machines	33-7
Generate HDL Code for Moore Finite State Machine	33-7
Generate HDL for Mealy Finite State Machine	33-8
Initialize Outputs Every Time Chart Wakes Up	33-10
Design Patterns Using Advanced Chart Features	33-14
Temporal Logic	33-14
Graphical Function	33-15
Hierarchy and Parallelism	33-16
Stateless Charts	33-17
Truth Tables	33-18
Initialize Persistent Variables in MATLAB Functions	33-22
MATLAB Function Block with No Direct Feedthrough	33-23
State Control Block in Synchronous Mode	33-24
Stateflow Chart Implementing Moore Semantics	33-25

34 | Generating HDL Code with the MATLAB Function Block

HDL Applications for the MATLAB Function Block	34-2
Structure of Generated HDL Code	34-2
HDL Applications	34-2
Viterbi Decoder with the MATLAB Function Block	34-4
Code Generation from a MATLAB Function Block	34-5
Counter Model Using the MATLAB Function block	34-5
Setting Up	34-7
Creating the Model and Configuring General Model Settings	34-7
Adding a MATLAB Function Block to the Model	34-8

HDL Code Advisor

44

HDL Coder Checks in Model Advisor / HDL Code Advisor Overview	44-3
---	-------------

Model configuration checks overview	44-4
Check for model parameters suited for HDL code generation	44-5
Description	44-5
Results and Recommended Actions	44-6
See Also	44-6
Check for global reset setting for Xilinx and Altera devices	44-7
Description	44-7
Results and Recommended Actions	44-7
See Also	44-7
Check inline configurations setting	44-8
Description	44-8
Results and Recommended Actions	44-8
Check algebraic loops	44-9
Description	44-9
Results and Recommended Actions	44-9
See Also	44-9
Check for visualization settings	44-10
Description	44-10
Results and Recommended Actions	44-10
See Also	44-10
Check delay balancing setting	44-11
Description	44-11
Results and Recommended Actions	44-11
See Also	44-11
Check for ports and subsystems overview	44-12
Check for invalid top level subsystem	44-13
Description	44-13
Results and Recommended Actions	44-13
Check for blocks and block settings overview	44-14
Check for infinite and continuous sample time sources	44-15
Description	44-15
Results and Recommended Actions	44-15
See Also	44-15
Check for unsupported blocks	44-16
Description	44-16
Results and Recommended Actions	44-16
Check for large matrix operations	44-17
Description	44-17
Results and Recommended Actions	44-17
See Also	44-17
Check for MATLAB Function block settings	44-18
Description	44-18

Results and Recommended Actions	44-18
See Also	44-18
Check for Stateflow chart settings	44-19
Description	44-19
Results and Recommended Actions	44-19
See Also	44-19
Check for obsolete Unit Delay Enabled/Resettable Blocks	44-20
Description	44-20
Results and Recommended Actions	44-20
Check for blocks that have nonzero output latency	44-21
Description	44-21
Results and Recommended Actions	44-21
See Also	44-21
Check for unsupported storage class for signal objects	44-22
Description	44-22
Results and Recommended Actions	44-22
Check for HDL Reciprocal block usage	44-23
Description	44-23
Results and Recommended Actions	44-23
See Also	44-23
Check for Trigonometric Function block for LUT-based approximation method	44-24
Description	44-24
Results and Recommended Actions	44-24
Capabilities and Limitations	44-24
See Also	44-24
Native Floating Point Checks Overview	44-25
Check for single datatypes in the model	44-26
Description	44-26
Results and Recommended Actions	44-26
See Also	44-26
Check for double data types in the model	44-27
Description	44-27
Results and Recommended Actions	44-27
See Also	44-27
Check for Data Type Conversion blocks with incompatible settings	44-28
Description	44-28
Results and Recommended Actions	44-28
See Also	44-28
Check for HDL Reciprocal block usage	44-29
Description	44-29
Results and Recommended Actions	44-29
See Also	44-29

Check for Relational Operator block usage	44-30
Description	44-30
Results and Recommended Actions	44-30
See Also	44-30
Check for unsupported blocks with Native Floating Point	44-31
Description	44-31
Results and Recommended Actions	44-31
See Also	44-31
Check blocks with nonzero ULP error	44-32
Description	44-32
Results and Recommended Actions	44-32

Functions Supported for HDL and SystemC Code Generation

In this section...

“Supported MATLAB and Fixed Point Runtime Library Functions” on page 1-2

“Fixed-Point Function Limitations” on page 1-2

You can generate efficient code for a subset of MATLAB built-in functions and toolbox functions that you call from MATLAB code.

Supported MATLAB and Fixed Point Runtime Library Functions

The supported functions for HDL and SystemC code generation are listed in the following tables. In these tables, a  icon before the name of a function indicates that there are specific usage notes and limitations related to HDL and SystemC code generation for that function. To view these usage notes and limitations, in the corresponding reference page, scroll down to the **Extended Capabilities** section at the bottom and expand the **HDL Code Generation** section.

The table shows HDL and SystemC code generation support for both MATLAB and fixed-point runtime library functions from the Fixed-Point Designer™ functions.

HDL and SystemC code generation support for the functions is summarized in the following tables.

- Functions Supported for HDL and SystemC Code Generation (Category List)
- Functions Supported for HDL and SystemC Code Generation (Alphabetical List)

Fixed-Point Function Limitations

In addition to function-specific limitations listed in the table, the following general limitations apply to the use of Fixed-Point Designer functions in generated HDL and SystemC code:

- `fipref` and `quantizer` objects are not supported.
- Slope and bias scaling are not supported.
- Dot notation is only supported for getting the values of `fimath` and `numericType` properties. Dot notation is not supported for `fi` objects, and it is not supported for setting properties.
- Word lengths greater than 128 bits are not supported.
- You cannot change the `fimath` or `numericType` of a given variable after that variable has been created.
- The `boolean` and `ScaledDouble` values of the `DataTypeMode` and `DataType` properties are not supported.
- For all `SumMode` property settings other than `FullPrecision`, the `CastBeforeSum` property must be set to `true`.
- The `numel` function returns the number of elements of `fi` objects in the generated code.
- General limitations of C/C++ code generated from MATLAB apply. See “MATLAB Language Features That Code Generation Does Not Support”.

Supported MATLAB Data Types, Operators, and Control Flow Statements

In this section...
“Supported Data Types” on page 1-4
“Supported Operators” on page 1-6
“Control Flow Statements” on page 1-7

When you generate HDL and SystemC code from your MATLAB algorithm, use the data types, operators, and control flow statements that HDL Coder supports.

Supported Data Types

HDL Coder does not support cell arrays and `Inf` data types. This table shows the supported subset of MATLAB data types.

Types	Supported Data Types	Restrictions
Integer	<ul style="list-style-type: none"> <code>uint8</code>, <code>uint16</code>, <code>uint32</code>, <code>uint64</code> <code>int8</code>, <code>int16</code>, <code>int32</code>, <code>int64</code> 	In Simulink®, MATLAB Function block ports must use numeric types <code>sfix64</code> or <code>ufix64</code> for 64-bit data.
Real	<ul style="list-style-type: none"> <code>double</code> <code>single</code> 	<p>HDL code generated with <code>double</code> or <code>single</code> data types in your MATLAB code can be used for simulation, but is not synthesizable. You can generate synthesizable code when you use these data types in your Simulink model. For more information, see:</p> <ul style="list-style-type: none"> “Simulink Blocks Supported by Using Native Floating Point” on page 14-142 “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116 “Signal and Data Type Support” on page 14-3 <p>Real data types are not supported for SystemC code generation.</p>
Character	<code>char</code>	-
Logical	<code>logical</code>	-
Fixed point	<ul style="list-style-type: none"> Scaled (binary point only) fixed-point numbers Custom integers (zero binary point) 	<p>Fixed-point numbers with slope (not equal to 1.0) and bias (not equal to 0.0) are not supported.</p> <p>Maximum word size for fixed-point numbers is 128 bits.</p>

Types	Supported Data Types	Restrictions
Vectors	<ul style="list-style-type: none"> unordered {N} row {1, N} column {N, 1} 	<p>The maximum number of vector elements allowed is 2^{32}.</p> <p>Before a variable is subscripted, it must be fully defined.</p>
Matrices	{N, M}	<p>Matrices are supported in the body of the design algorithm and as inputs to the top-level design function.</p> <p>Matrices are not supported with the following HDL workflows:</p> <ul style="list-style-type: none"> Cosimulation model generation FPGA-in-the-Loop IP Core Generation
Structures	<code>struct</code>	<p>Arrays of structures are not supported.</p> <p>For the FPGA Turnkey and IP Core Generation workflows, structures are supported in the body of the design algorithm, but are not supported as inputs to the top-level design function.</p> <p>Structures are not supported as inputs and outputs at the top-level DUT ports for SystemC code generation.</p>
Enumerations	<code>enumeration</code>	<p>If your target language is Verilog®, all enumeration member names must be unique within the design.</p> <p>Enumerations at the top-level DUT ports are not supported with the following workflows or verification methods:</p> <ul style="list-style-type: none"> IP Core Generation workflow FPGA Turnkey workflow FPGA-in-the-Loop HDL Cosimulation SystemC Code Generation Workflow <p>Enumerations are not supported as inputs and outputs at the top-level DUT ports for SystemC code generation.</p>

Global variables are not supported for HDL and SystemC code generation.

Supported Operators

Note HDL and SystemC code generated for large vector and matrix inputs to arithmetic operations can result in inefficient code. The code for these operators is not automatically pipelined.

Arithmetic Operators

Operation	Operator Syntax	Equivalent Function	Restrictions
Binary addition	A+B	plus(A,B)	Neither A nor B can be data type logical.
Matrix multiplication	A*B	mtimes(A,B)	HDL code generated for matrix arithmetic operations is not pipelined, and can result in inefficient code.
Arraywise multiplication	A.*B	times(A,B)	Neither A nor B can be data type logical.
Matrix power	A^B	mpower(A,B)	A and B must be scalar, and B must be an integer. HDL code generated for matrix arithmetic operations is not pipelined, and can result in inefficient code.
Arraywise power	A.^B	power(A,B)	A and B must be scalar, and B must be an integer.
Complex transpose	A'	ctranspose(A)	-
Matrix transpose	A.'	transpose(A)	
Matrix concat	[A B]	None	-
Matrix index	A(r c)	None	Before you use a variable, you must fully define it.

Logical Operators

Operation	Operator Syntax	M Function Equivalent	Notes
Logical And	A&B	and(A,B)	-
Logical Or	A B	or(A,B)	-
Logical Xor	A xor B	xor(A,B)	-
Logical And (short circuiting)	A&&B	N/A	Use short circuiting logical operators within conditionals.
Logical Or (short circuiting)	A B	N/A	Use short circuiting logical operators within conditionals.
Element complement	~A	not(A)	-

Relational Operators

Relation	Operator Syntax	Equivalent Function
Less than	A<B	lt(A,B)
Less than or equal to	A<=B	le(A,B)
Greater than or equal to	A>=B	ge(A,B)
Greater than	A>B	gt(A,B)
Equal	A==B	eq(A,B)
Not equal	A~=B	ne(A,B)

Control Flow Statements

HDL Coder supports the following control flow statements and constructs with restrictions.

Control Flow Statement	Restrictions
for	<p>Do not use for loops without static bounds. A for loop must run for a constant number of iterations, which means it cannot have control flow statements based on conditional information that changes the number of iterations for the for loop, such as break or return.</p> <p>Do not use the & and operators within conditions of a for statement. Instead, use the && and operators.</p> <p>HDL Coder does not support nonscalar expressions in the conditions of for statements. Instead, use the all or any functions to collapse logical vectors into scalars.</p>
if	<p>Do not use the & and operators within conditions of an if statement. Instead, use the && and operators.</p> <p>HDL Coder does not support nonscalar expressions in the conditions of if statements. Instead, use the all or any functions to collapse logical vectors into scalars.</p>

Control Flow Statement	Restrictions
switch	<p>The conditional expression in a switch or case statement must use only:</p> <ul style="list-style-type: none">• uint8, uint16, uint32, int8, int16, or int32 data types• Scalar data <p>If multiple case statements make assignments to the same variable, the numeric type and <code>fimath</code> specification for that variable must be the same in every case statement.</p>

The following control flow statements are not supported:

- while
- break
- continue
- return
- parfor

Avoid using the following vector functions, as they may generate loops containing break statements:

- `isequal`
- `bitrevorder`

Persistent Variables and Persistent Array Variables

Persistent Variables

Persistent variables enable you to model registers. If you need to preserve state between invocations of your MATLAB algorithm, use persistent variables.

Before you use a persistent variable, you must initialize it with a statement specifying its size and type. You can initialize a persistent variable with either a constant value or a variable, as in the following examples:

```
% Initialize with a constant
persistent p;
if isempty(p)
    p = fi(0,0,8,0);
end
```

```
% Initialize with a variable
initval = fi(0,0,8,0);

persistent p;
if isempty(p)
    p = initval;
end
```

Use a logical expression that evaluates to a constant to test whether a persistent variable has been initialized, as in the preceding examples. Using a logical expression that evaluates to a constant ensures that the generated HDL and SystemC code for the test is executed only once, as part of the reset process.

You can initialize multiple variables within a single logical expression, as in the following example:

```
% Initialize with variables
initval1 = fi(0,0,8,0);
initval2 = fi(0,0,7,0);

persistent p;
if isempty(p)
    x = initval1;
    y = initval2;
end
```

Note If persistent variables are not initialized as described above, extra sentinel variables can appear in the generated code. These sentinel variables can translate to inefficient hardware.

Persistent Array Variables

Persistent array variables enable you to model RAM.

By default, the HDL Coder software optimizes the area of your design by mapping persistent array variables to RAM. If persistent array variables are not mapped to RAM, they map to registers. RAM mapping can therefore reduce the area of your design in the target hardware.

To learn how persistent array variables map to RAM, see “Map Persistent Arrays and dsp.Delay Objects to RAM” on page 8-6 for HDL code generation and “Map Persistent Arrays to RAM” on page 13-2 for SystemC code generation.

Complex Data Type Support

In this section...

“Declaring Complex Signals” on page 1-11

“Conversion Between Complex and Real Signals” on page 1-12

“Support for Vectors of Complex Numbers” on page 1-12

Declaring Complex Signals

The following MATLAB code declares several local complex variables. `x` and `y` are declared by complex constant assignment; `z` is created using the using the `complex()` function.

```
function [x,y,z] = fcn
% create 8 bit complex constants
x = uint8(1 + 2i);
y = uint8(3 + 4j);
z = uint8(complex(5, 6));
```

The following code example shows VHDL® code generated from the previous MATLAB code.

```
ENTITY complex_decl IS
  PORT (
    clk : IN std_logic;
    clk_enable : IN std_logic;
    reset : IN std_logic;
    x_re : OUT std_logic_vector(7 DOWNTO 0);
    x_im : OUT std_logic_vector(7 DOWNTO 0);
    y_re : OUT std_logic_vector(7 DOWNTO 0);
    y_im : OUT std_logic_vector(7 DOWNTO 0);
    z_re : OUT std_logic_vector(7 DOWNTO 0);
    z_im : OUT std_logic_vector(7 DOWNTO 0));
END complex_decl;

ARCHITECTURE fsm_SFHDH OF complex_decl IS
BEGIN
  x_re <= std_logic_vector(to_unsigned(1, 8));
  x_im <= std_logic_vector(to_unsigned(2, 8));
  y_re <= std_logic_vector(to_unsigned(3, 8));
  y_im <= std_logic_vector(to_unsigned(4, 8));
  z_re <= std_logic_vector(to_unsigned(5, 8));
  z_im <= std_logic_vector(to_unsigned(6, 8));
END fsm_SFHDH;
```

As shown in the example, complex inputs, outputs and local variables declared in MATLAB code expand into real and imaginary signals. The naming conventions for these derived signals are:

- Real components have the same name as the original complex signal, suffixed with the default string `'_re'` (for example, `x_re`). To specify a different suffix, set the **Complex real part postfix** option (or the corresponding `ComplexRealPostfix` CLI property).
- Imaginary components have the same name as the original complex signal, suffixed with the string `'_im'` (for example, `x_im`). To specify a different suffix, set the **Complex imaginary part postfix** option (or the corresponding `ComplexImagPostfix` CLI property).

A complex variable declared in MATLAB code remains complex during the entire length of the program.

Conversion Between Complex and Real Signals

The MATLAB code provides access to the fields of a complex signal via the `real()` and `imag()` functions, as shown in the following code.

```
function [Re_part, Im_part]= fcn(c)
% Output real and imaginary parts of complex input signal

Re_part = real(c);
Im_part = imag(c);
```

HDL Coder supports these constructs, accessing the corresponding real and imaginary signal components in generated HDL code. In the following Verilog code example, the MATLAB complex signal variable `c` is flattened into the signals `c_re` and `c_im`. Each of these signals is assigned to the output variables `Re_part` and `Im_part`, respectively.

```
module Complex_To_Real_Imag (clk, clk_enable, reset, c_re, c_im, Re_part, Im_part );

    input clk;
    input clk_enable;
    input reset;
    input [3:0] c_re;
    input [3:0] c_im;
    output [3:0] Re_part;
    output [3:0] Im_part;

    // Output real and imaginary parts of complex input signal
    assign Re_part = c_re;
    assign Im_part = c_im;
```

Support for Vectors of Complex Numbers

You can generate HDL code for vectors of complex numbers. Like scalar complex numbers, vectors of complex numbers are flattened down to vectors of real and imaginary parts in generated HDL code.

For example in the following script `t` is a complex vector variable of base type `ufix4` and size `[1,2]`.

```
function y = fcn(u1, u2)

t = [u1 u2];
y = t+1;
```

In the generated HDL code the variable `t` is broken down into real and imaginary parts with the same two-element array .

```
VARIABLE t_re : vector_of_unsigned4(0 TO 3);
VARIABLE t_im : vector_of_unsigned4(0 TO 3);
```

The real and imaginary parts of the complex number have the same vector of type `ufix4`, as shown in the following code.

```
TYPE vector_of_unsigned4 IS ARRAY (NATURAL RANGE <>) OF unsigned(3 DOWNT0 0);
```

Complex vector-based operations (`+`, `-`, `*` etc.) are similarly broken down to vectors of real and imaginary parts. Operations are performed independently on the elements of such vectors, following MATLAB semantics for vectors of complex numbers.

In both VHDL and Verilog code generated from MATLAB code, complex vector ports are always flattened. If complex vector variables appear on inputs and outputs, real and imaginary vector components are further flattened to scalars.

In the following code, `u1` and `u2` are scalar complex numbers and `y` is a vector of complex numbers.

```
function y = fcn(u1, u2)
```

```
t = [u1 u2];  
y = t+1;
```

This generates the following port declarations in a VHDL entity definition.

```
ENTITY _MATLAB_Function IS  
  PORT (  
    clk : IN std_logic;  
    clk_enable : IN std_logic;  
    reset : IN std_logic;  
    u1_re : IN vector_of_std_logic_vector4(0 TO 1);  
    u1_im : IN vector_of_std_logic_vector4(0 TO 1);  
    u2_re : IN vector_of_std_logic_vector4(0 TO 1);  
    u2_im : IN vector_of_std_logic_vector4(0 TO 1);  
    y_re : OUT vector_of_std_logic_vector32(0 TO 3);  
    y_im : OUT vector_of_std_logic_vector32(0 TO 3));  
END _MATLAB_Function;
```

Complex Data Type Support for SystemC Code Generation

In this section...

“Declaring Complex Signals” on page 1-14

“Conversion Between Complex and Real Signals” on page 1-14

“Support for Vectors of Complex Numbers” on page 1-15

Declaring Complex Signals

The following MATLAB code declares several local complex variables. `x` and `y` are declared by complex constant assignment; `z` is created using the using the `complex()` function.

```
function [x,y,z] = fcn
% create 8 bit complex constants
x = uint8(1 + 2i);
y = uint8(3 + 4j);
z = uint8(complex(5, 6));
```

The following code example shows SystemC™ code generated from the previous MATLAB code.

```
class fcnClass
{
public:
void fcn(sc_fixed<16,3> &x_re, sc_fixed<16,3> &x_im, sc_fixed<16,4> &y_re,
        sc_fixed<16,4> &y_im, sc_fixed<16,4> &z_re, sc_fixed<16,4> &z_im)
{
    x_re = sc_fixed<16,3>(1.0);
    x_im = sc_fixed<16,3>(2.0);
    y_re = sc_fixed<16,4>(3.0);
    y_im = sc_fixed<16,4>(4.0);
    z_re = sc_fixed<16,4>(5.0);
    z_im = sc_fixed<16,4>(6.0);
}
};
```

As shown in the example, complex inputs, outputs and local variables declared in MATLAB code expand into real and imaginary signals. The naming conventions for these derived signals are:

- Real components have the same name as the original complex signal, suffixed with the default string `'_re'` (for example, `x_re`). To specify a different suffix, set the **Complex real part postfix** option (or the corresponding `ComplexRealPostfix` CLI property).
- Imaginary components have the same name as the original complex signal, suffixed with the string `'_im'` (for example, `x_im`). To specify a different suffix, set the **Complex imaginary part postfix** option (or the corresponding `ComplexImagPostfix` CLI property).

A complex variable declared in MATLAB code remains complex during the entire length of the program.

Conversion Between Complex and Real Signals

The MATLAB code provides access to the fields of a complex signal via the `real()` and `imag()` functions, as shown in the following code.

```
function [Re_part, Im_part]= fcn(c)
% Output real and imaginary parts of complex input signal

Re_part = real(c);
Im_part = imag(c);
```

HDL Coder supports these constructs, accessing the corresponding real and imaginary signal components in generated SystemC code. In the following SystemC code, the MATLAB complex signal variable `c` is flattened into the signals `c_re` and `c_im`. Each of these signals is assigned to the output variables `Re_part` and `Im_part`, respectively.

```
class fcnClass
{
public:
void fcn(sc_fixed<16,3> c_re, sc_fixed<16,3> c_im, sc_fixed<16,3> &Re_part,
        sc_fixed<16,3> &Im_part)
{
/* Output real and imaginary parts of complex input signal */
Re_part = c_re;
Im_part = c_im;
}
};
```

Support for Vectors of Complex Numbers

You can generate SystemC code for vectors of complex numbers. Like scalar complex numbers, vectors of complex numbers are flattened down to vectors of real and imaginary parts in generated SystemC code.

For example in the following script `t` is a complex vector variable of base type `ufix4` and size `[1,2]`.

```
function y = fcn(u1, u2)
t = [u1 u2];
y = t+1;
```

In the generated SystemC code the variable `t` is broken down into real and imaginary parts with the same two-element array. The real and imaginary parts of the complex number have the same vector of type `ufix4`, as shown in the following code.

```
sc_uint<4> t_re[2];
sc_uint<4> t_im[2];
```

In the above MATLAB script, `u1` and `u2` are scalar complex numbers and `y` is a vector of complex numbers. This generates the following function definition in the SystemC code.

```
void fcn(sc_uint<4> u1_re, sc_uint<4> u1_im, sc_uint<4> u2_re, sc_uint<4>
        u2_im, sc_uint<5> (&y_re)[2], sc_uint<5> (&y_im)[2])
```

Complex vector-based operations (+, -, * etc.) are similarly broken down to vectors of real and imaginary parts. Operations are performed independently on the elements of such vectors, following MATLAB semantics for vectors of complex numbers.

HDL Code Generation for System Objects

In this section...
“Why Use System Objects?” on page 1-16
“Predefined System Objects” on page 1-16
“User-Defined System Objects” on page 1-16
“Limitations of HDL Code Generation for System Objects” on page 1-16
“System object Examples for HDL Code Generation” on page 1-17

HDL Coder supports both predefined and user-defined System objects for code generation.

Why Use System Objects?

System objects provide a design advantage because:

- You can save time during design and testing by using existing System object components.
- You can design and qualify custom System objects for reuse in multiple designs.
- You can define your algorithm in a System object once, and reuse multiple instances of it in a single MATLAB design.

This idiom cannot be used with MATLAB functions that have state. For example, if the algorithm has state and requires the use of persistent variables, that function cannot be instantiated multiple times in a design. Instead, you would need to copy and rename the function for each instance.

- HDL code that you generate from System objects is modular and more readable.

Predefined System Objects

Predefined System objects that are available with MATLAB, DSP System Toolbox™, and Communications Toolbox™ are supported for HDL code generation. For a list, see “Predefined System Objects Supported for HDL Code Generation” on page 1-50.

User-Defined System Objects

You can create user-defined System objects for HDL code generation. For an example, see “Generate Code for User-Defined System Objects” on page 1-53.

Note To use a MATLAB class for HDL code generation, the class must be a System object.

Limitations of HDL Code Generation for System Objects

The following limitations apply to HDL code generation for System objects:

- Your design can call the System object only once.
- You must not call the object inside a nested conditional statement, such as a nested loop, if statement, or switch statement.

- You must not call the object inside a conditional statement that contains a matrix indexing operation.
- A System object must be declared persistent if it has state.

A System object has state when it has a tunable private or public property, or a property with the `DiscreteState` attribute.

- You can use the `dsp.Delay` System object only in feed-forward delay modeling.
- System objects in cell arrays are not supported.
- Enumerations are not supported.
- Global variables are not supported.

Supported Methods

For predefined System objects, calling the object itself is supported for HDL code generation, but no other object functions are supported.

For user-defined System objects, either the `step` method, or the `output` and `update` methods, are supported for HDL code generation.

Additional Restrictions for Predefined System Objects

Predefined System objects are not supported for HDL code generation from within a MATLAB System block.

Additional Restrictions for User-Defined System Objects

In addition to the limitations for all System objects, the following restrictions apply to user-defined System objects for HDL code generation:

- In the `setupImpl` and `resetImpl` methods, if you assign values to properties or variables, the values must be constants.
- If your design uses the `output` and `update` methods, it can call each method only once per System object.
- Initial and reset values for properties must be compile-time constant.
- User-defined System objects must not be public properties.
- A System object with multiple outputs cannot be called within a conditional statement.

System object Examples for HDL Code Generation

To learn how to use System objects for HDL code generation, view the MATLAB designs in the following examples:

- “HDL Code Generation from System Objects” on page 1-18
- “Model State with Persistent Variables and System Objects” on page 1-56
- “Generate Code for User-Defined System Objects” on page 1-53
- “Integrate Custom HDL Code Into MATLAB Design” on page 5-14

HDL Code Generation from System Objects

This example shows how to generate HDL code from MATLAB® code that contains System objects. For more information on System objects, see “HDL Code Generation for System Objects” on page 1-16.

MATLAB Design

The MATLAB code used in this example implements a simple symmetric FIR filter and uses the `hdl.Delay` System object to model state. This example also shows a MATLAB test bench that exercises the filter.

```
design_name = 'mlhdlc_sysobj_ex';
testbench_name = 'mlhdlc_sysobj_ex_tb';
```

Look at the MATLAB design.

```
type(design_name);

```

Simulate the Design

Simulate the design with the test bench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_sysobj_ex_tb
```

Create a New HDL Coder™ Project

To create a new project, enter the following command:

```
coder -hdlcoder -new mlhdlc_sysobj_prj
```

Next, add the file `mlhdlc_sysobj_ex.m` to the project as the MATLAB Function and `mlhdlc_sysobj_ex_tb.m` as the MATLAB Test Bench.

For a more complete tutorial on creating and populating MATLAB HDL Coder projects, see “Get Started with MATLAB to HDL Workflow”.

Run Fixed-Point Conversion and HDL Code Generation

Launch the Workflow Advisor. In the Workflow Advisor, right-click the **Code Generation** step. Choose the option **Run to selected task** to run all the steps from the beginning through HDL code generation.

Examine the generated HDL code by clicking the links in the log window.

Supported System objects

For a list of System objects supported for HDL code generation, see “Predefined System Objects Supported for HDL Code Generation” on page 1-50.

HDL Code Generation for Streaming Matrix Inverse System Object

This example shows how HDL Coder™ implements a streaming mode of matrix inverse operation with configurable sizes.

What is inverse of a matrix

A matrix X is invertible if there exists a matrix Y of the same size such that $XY = YX = I$, where I is the Identity matrix. The matrix Y is called inverse of X . A matrix that has no inverse is singular. A square matrix is singular only when its determinant is exactly zero.

Matrix inverse computation involves following steps:

- 1 Cofactor matrix calculation
- 2 Transpose of cofactor matrix
- 3 Multiply reciprocal of determinant of input matrix with transpose of cofactor matrix

Example:

```
A = [4 12 -16;12 37 -43;-16 -43 98];
Cofactors of 'A' will be calculated from matrix of minors
    cof(A) = [1777 488 76;488 136 20;76 20 4];

Transpose of cofactor matrix will be
    (cof(A))' = [1777 488 76;488 136 20;76 20 4];

Multiply reciprocal of determinant of 'A' with transpose of cofactor matrix
    Ainv = (1/det(A)) * (cof(A))'
          = [49.3611 -13.5556 2.1111;-13.5556 3.7778 -0.5556;2.1111 -0.5556 0.1111];
```

Matrix Inverse: Gauss-Jordan elimination

To find the inverse of matrix A using Gauss-Jordan elimination, we must find elementary row operations that reduce A to identity matrix(I) and then perform the same operations on Identity matrix(I) to obtain A_{inv} .

Computation of Matrix Inverse using Gauss-Jordan elimination: Let start with matrix A , and write it down with an Identity matrix next to it: $[A | I]$

The goal is to make A an identity matrix by applying row transformations and right-hand side matrix I also participated in the row transformations, finally reduced to A_{inv} .

Computation of A_{inv} involves following steps:

- 1 swapping rows
- 2 make the diagonal elements as 1
- 3 make the non-diagonal elements as 0

Example:

$$\begin{array}{ccc|ccc} & (A) & & & (I) & & \\ 1 & 2 & 3 & | & 1 & 0 & 0 \end{array}$$

$$[A | I] = \begin{array}{ccc|ccc} 2 & 5 & 3 & 0 & 1 & 0 \\ 1 & 0 & 8 & 0 & 0 & 1 \end{array}$$

Find the element with maximum value in the first column and swap the current row with maximum element row

swap R1 and R2 rows as R2 contains the largest values.

$$= \begin{array}{ccc|ccc} 2 & 5 & 3 & 0 & 1 & 0 \\ 1 & 2 & 3 & 1 & 0 & 0 \\ 1 & 0 & 8 & 0 & 0 & 1 \end{array}$$

Make the diagonal element in the first column as '1'

R1 --> R1/2

$$= \begin{array}{ccc|ccc} 1 & 2.5 & 1.5 & 0 & 0.5 & 0 \\ 1 & 2 & 3 & 1 & 0 & 0 \\ 1 & 0 & 8 & 0 & 0 & 1 \end{array}$$

Make the non-diagonal elements in the first column as '0'

R2 --> R2 - R1

R3 --> R3 - R1

$$= \begin{array}{ccc|ccc} 1 & 2.5 & 1.5 & 0 & 0.5 & 0 \\ 0 & -0.5 & 1.5 & 1 & -0.5 & 0 \\ 0 & -2.5 & 6.5 & 0 & -0.5 & 1 \end{array}$$

Now column 1 has diagonal elements '1' and other elements as '0'. This procedure is repeated for remaining columns and matrix A will be reduced to identity matrix, Identity matrix will be reduced to Ainv.

$$= \begin{array}{ccc|ccc} 1 & 0 & 0 & -40 & 16 & 9 \\ 0 & 1 & 0 & 13 & -5 & -3 \\ 0 & 0 & 1 & 5 & -2 & -1 \end{array}$$

(I) (Ainv)

Matrix Inverse: Cholesky decomposition

Matrix Inverse using cholesky decomposition supports only symmetric positive definite matrices. Positive definite means all the eigenvalues of the matrix should be positive.

Given a symmetric positive definite matrix A:

$$A = L * L', \quad \begin{array}{l} L \text{ is the lower triangular matrix} \\ L' \text{ is the transpose of } L \end{array}$$

$$\begin{aligned} \text{inv}(A) &= \text{inv}(L * L') \\ &= \text{inv}(L') * \text{inv}(L) \\ &= (\text{inv}(L))' * \text{inv}(L) \end{aligned}$$

$$\text{Ainv} = \text{Linv}' * \text{Linv}, \quad \begin{array}{l} \text{Linv is the inverse of lower triangular matrix} \\ \text{Ainv is the inverse of input matrix} \end{array}$$

Computation of Ainv involves following steps:

- 1 Lower triangular matrix computation(L)
- 2 Inverse of lower triangular matrix(Linv)
- 3 Multiplication of transpose of Linv with Linv

Example:

```
A = [4 12 -16;12 37 -43;-16 -43 98];
```

Lower triangular matrix(L) will be computed using cholesky decomposition

```
L = [2 0 0;6 1 0;-8 5 3];
```

Linv will be computed using forward substitution method

```
Linv = [0.5 0 0;-3 1 0;6.3333 -1.6667 0.3333];
```

Multiply transpose of Linv with Linv

```
Ainv = Linv' * Linv
```

```
= [49.3611 -13.5556 2.1111;-13.5556 3.7778 -0.5556;2.1111 -0.5556 0.1111];
```

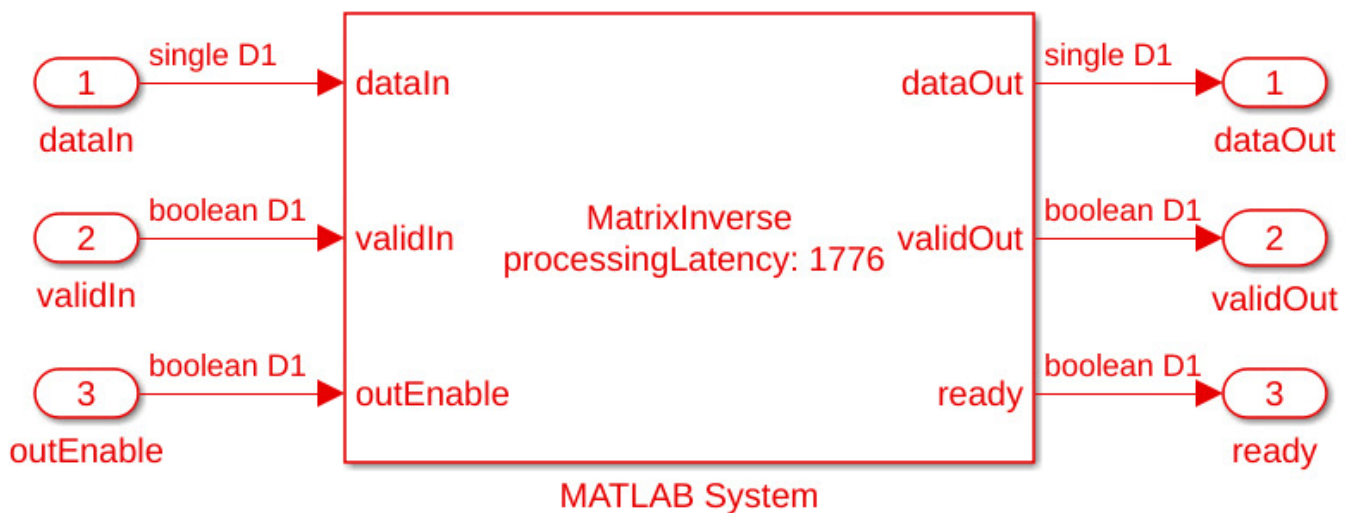

Benefits of using Gauss-Jordan Elimination

- Gauss-Jordan Elimination supports all square matrices.
- Gauss-Jordan Elimination supports both single and double data types.

Restrictions for Cholesky implementation

- Matrices for which inverse is to be computed must be symmetric positive-definite.
- Input data types of the matrices must be single and block must be used in the Native Floating Point mode.
- Input matrices must not be larger than 64-by-64 in size.

Matrix Inverse Subsystem Interface:

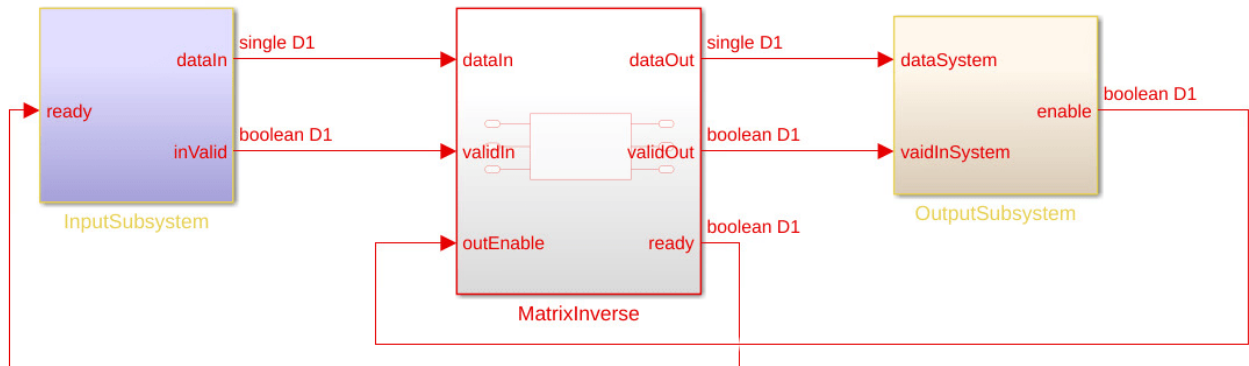

Matrix Inverse ports description:

Input ports		Output ports	
dataIn	Input data to the module	dataOut	Output data from the module
validIn	Valid signal for input data	validOut	Valid signal for output data
outEnable	Input signal that indicates downstream module is ready to take the output data from processing module	ready	Output signal that indicates processing module is ready to accept the input data in row major from upstream module

Matrix Inverse Implementation

This example shows streaming matrix inverse implementation

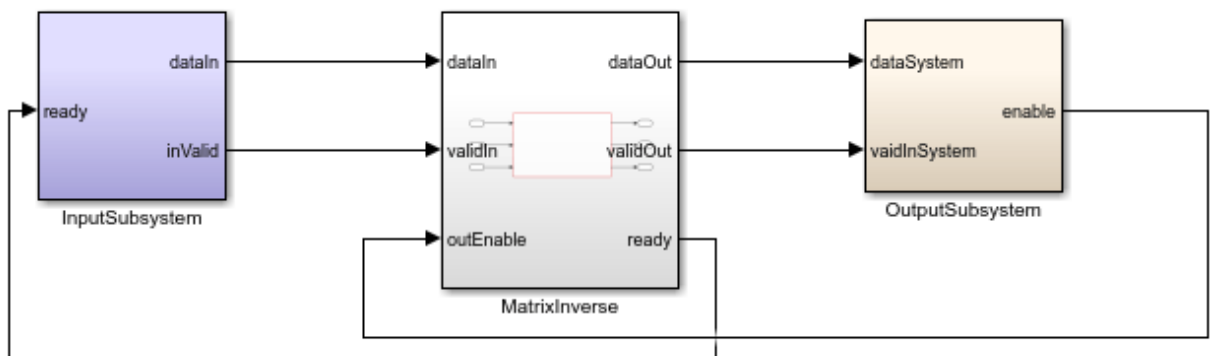

This example model contains three subsystems: InputSubsystem, MatrixInverse, and OutputSubsystem. The InputSubsystem is the upstream module that serializes the matrix input to the processing module when the ready signal is enabled. The OutputSubsystem is the downstream module that deserializes the data from the processing module to a matrix output when the outEnable signal is enabled. The MatrixInverse is a processing module that implements the matrix inverse operation.

HDL Code Generation for Streaming Matrix Multiply System Object

This example shows how HDL Coder™ implements a streaming mode of matrix multiplication with configurable sizes.

How to Multiply Matrices

Let A, B be two matrices then $C = A * B$ is the matrix multiplication of A and B. If A is an m-by-p and B is an p-by-n matrix, then C is an m-by-n matrix defined by

$$C(i,j) = A(i,1)B(1,j) + A(i,2)B(2,j) + \dots + A(i,p)B(p,j)$$

This inner definition says that $C(i,j)$ is the inner product of ith row of A with the jth column of B

For non scalar A and B, the number of columns of A must equal to the number of rows of B

Example:

$$A = [1 \ 3 \ 5; 2 \ 4 \ 7]; \quad (2 \times 3 \text{ matrix})$$

$$B = [-5 \ 8 \ 11; 3 \ 9 \ 21; 4 \ 0 \ 8]; \quad (3 \times 3 \text{ matrix})$$

After calculating inner product of rows of A with columns of B

$$C = [24 \ 35 \ 114; 30 \ 52 \ 162]; \quad (2 \times 3 \text{ matrix})$$

Introduction

Streaming Matrix Multiply supports multiplication of two matrices with configurable matrix sizes and dot product size. Dot product size is equal to the number of multipliers used for computation. This block can accept serialized input data from matrix in row major or column major format.

Matrix Multiply Interface:

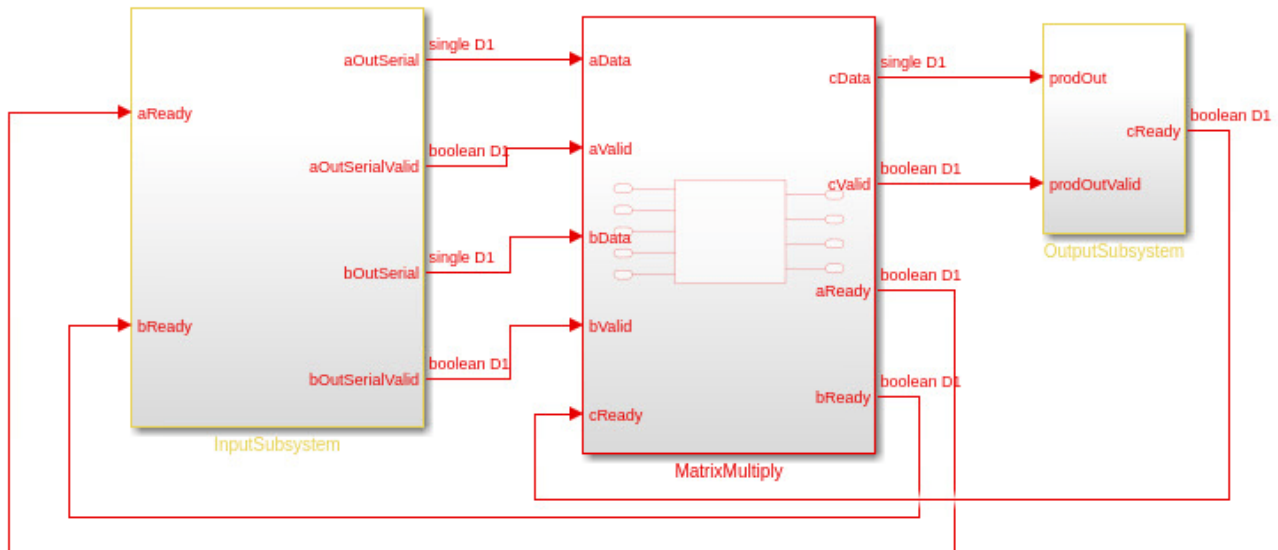

Matrix Multiply ports description:

Input ports		Output ports	
aData	Matrix-A input data to the module	cData	Matrix-C output data from processing module
aValid	Valid signal for matrix-A input data	cValid	Valid signal for matrix-C output data
bData	Matrix-B input data to the module	aReady	Output signal that indicates the processing module is ready to accept the matrix-A input data from upstream module
bValid	Valid signal for matrix-B input data	bReady	Output signal that indicates the processing module is ready to accept the matrix-B input data from upstream module
cReady	Input signal that indicates downstream module is ready to take output data from processing module		

MatrixMultiply Implementation

This example shows streaming matrix multiplication operation

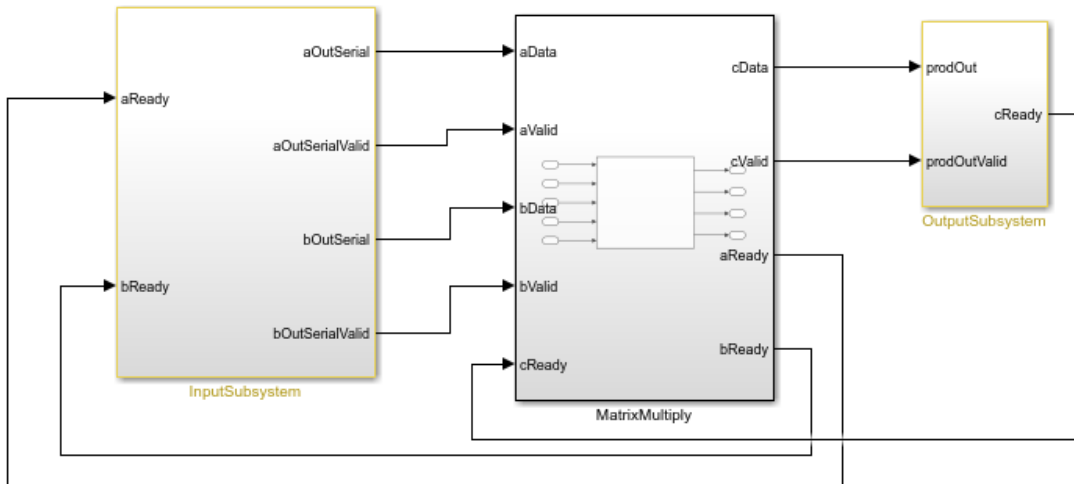

This example model contains three subsystems: InputSubsystem, MatrixMultiply and OutputSubsystem. The InputSubsystem is the upstream module that serializes the matrix inputs(A,B) to the processing module when aReady and bReady signals are enabled. The OutputSubsystem is the downstream module that deserializes the data from the processing module to matrix output(C) when the cReady signal is enabled. The MatrixMultiply is a processing module that implements the matrix multiplication.

```
open_system('hdlcoder_streaming_matrix_multiply_max_latency');
```

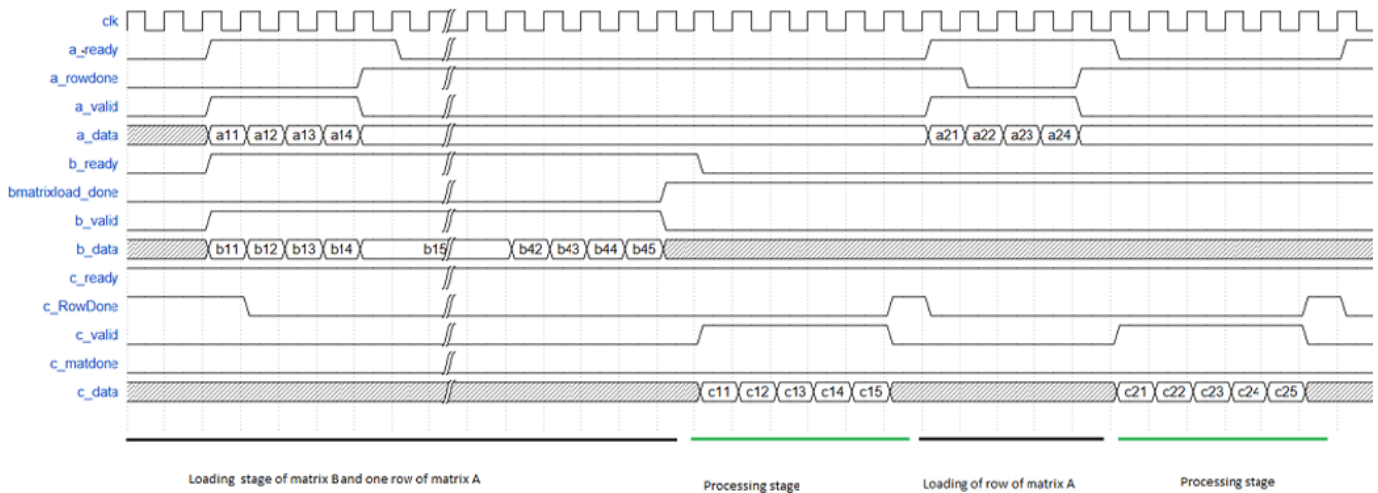

This example shows streaming matrix multiplication operation

Matrix Multiply Timing diagrams

Timing diagram

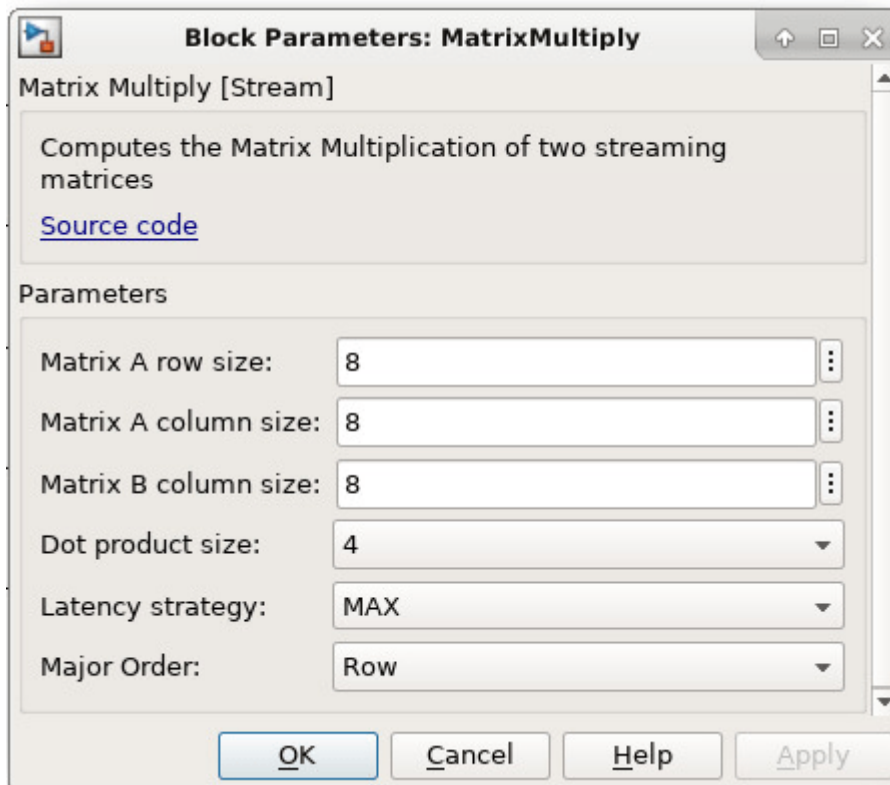

Timing diagram

Modelsim results for streaming matrix multiply

Matrix Multiply Block parameters:

Matrix-A Row Size	: Enter row size of input matrix A as a positive integer.
Matrix-A Column Size	: Enter column size of input matrix B as a positive integer which is equals to input matrix B row size.
Matrix-B Column Size	: Enter column size of input matrix B as a positive integer.
Dot product size	: Select dot product size from drop down menu(1,2,4,8,16,32,64) which should be less than input matrix A column size.
LatencyStrategy	: Select latency strategy from drop down menu ({'ZERO', 'MIN', 'MAX'}) which should be same as HDL coder latency strategy. Processing latency depends on the latency strategy.
Major Order	: Select row major or column major based on the input data streaming.

Matrix Multiply Block usage

- 1 Set block parameters of MATLAB System block.
- 2 Select input matrix sizes based on the values set in block parameters.
- 3 Generate HDL code for MatrixMultiply subsystem.

HDL Code Generation from hdl.RAM System Object

This example shows how to generate HDL code from MATLAB® code from hdl.RAM System object™ in MATLAB and infer RAM in generated hardware.

MATLAB Design

This example shows implementation of a line delay that uses a memory in a ring structure, where data is written in one position and read from another position in such a way that the data written will be read after a specific number of cycles. An efficient implementation of this architecture on Virtex FPGAs uses the on-chip Dual Port Block RAMs and an address counter. The Block RAMs can be configured as 512x8 or 256x9 synchronous Dual Port RAMs. To parameterize the delay length, the RAM write address is generated by a counter and the read address is generated by adding a constant K to the write address. If the memory size is M, the input will be read M-K clock cycles after it was written to the memory, hence implementing M-K word shift behaviour.

HDL Code Generation from A Non-Restoring Square Root System Object

This example shows how to check, generate and verify HDL code from MATLAB® code that instantiates a non-restoring square root system object.

MATLAB Design

The MATLAB code used in this example is a non-restoring square root engine suitable for implementation in an FPGA or ASIC. The engine uses a multiplier-free minimal area implementation based on [1] decision convolutional decoding, implemented as a System object. This example also shows a MATLAB test bench that tests the engine.

```
design_name = 'mlhdlc_sysobj_nonrestsqr.m';
testbench_name = 'mlhdlc_sysobj_nonrestsqr_tb.m';
sysobj_name = 'mlhdlc_msysobj_nonrestsqr.m';
```

Look at the MATLAB design.

```

Hardware Implementation of the Non-Restoring Square Root Algorithm

This algorithm implements the square root operation in a minimal area by using a single adder/subtractor with no mux (compared to a restoring algorithm that requires a mux). The square root is calculated using a series of shifts and adds/subs, so uses no multipliers (compared to other implementations which require a multiplier).

The overall architecture of the algorithm is shown below, as described in [1].

This implementation of the algorithm uses a minimal area approach that requires multiple cycles to calculate each result. The overall calculation time can be approximated as $\lceil \text{Input Word Length} / 2 \rceil$, with a few cycles of overhead to load the incoming data.

Create a New HDL Coder Project

To create a new project, enter the following command:

```
coder -hdlcoder -new mlhdlc_nonrestsqr
```

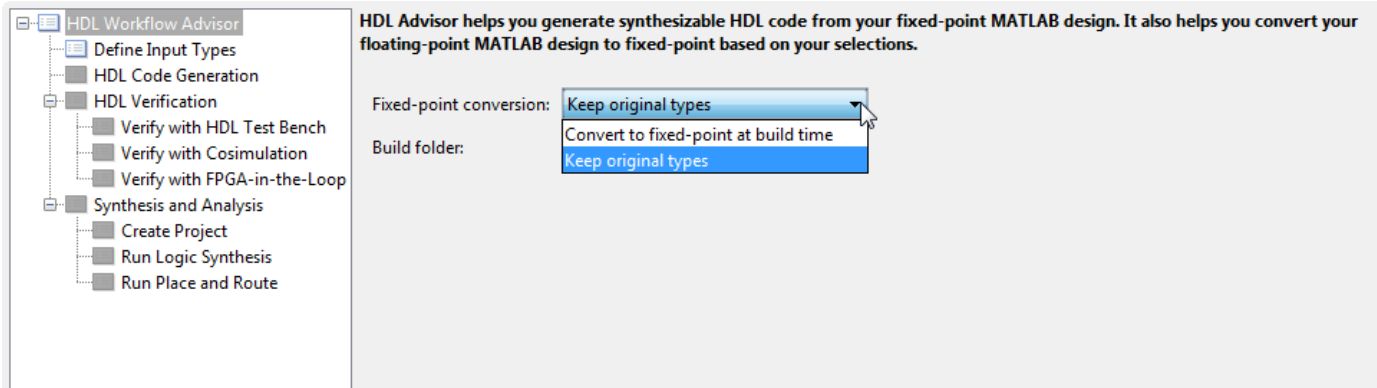

Next, add the file `mlhdlc_sysobj_nonrestsqr.m` to the project as the MATLAB function and `mlhdlc_sysobj_nonrestsqr_tb.m` as the MATLAB test bench.

For a more complete tutorial on creating and populating MATLAB HDL Coder projects, see “Get Started with MATLAB to HDL Workflow”.

Skip Fixed-Point Conversion

As the design is already in fixed-point, we do not need to perform automatic conversion.

Launch the HDL Advisor and choose `Keep original types` on the option **Fixed-point conversion**.

Run HDL Code Generation

Launch the Workflow Advisor. In the Workflow Advisor, right-click the **Code Generation** step and choose the option **Run to selected task** to run all the steps from the beginning through HDL code generation.

Examine the generated HDL code by clicking the links in the log window.

Supported System objects

For a list of System objects supported for HDL code generation, see “Predefined System Objects Supported for HDL Code Generation” on page 1-50.

Hardware Implementation of Viterbi Decoding Algorithm

There are three main components in the Viterbi decoding algorithm. They are the branch metric computation (BMC), add-compare-select (ACS), and traceback decoding. The following diagram illustrates the three units in the Viterbi decoding algorithm.

The Renormalization Method

The Viterbi decoder prevents the overflow of the state metrics in the ACS component by subtracting the minimum value of the state metrics at each time step, as shown in the following figure.

Obtaining the minimum value of all the state metric elements in one clock cycle results in a poor clock frequency for the circuit. The performance of the circuit may be improved by adding pipeline registers. However, simply subtracting the minimum value delayed by pipeline registers from the state metrics may still lead to overflow.

The hardware architecture modifies the renormalization method and avoids the state metric overflow in three steps. First, the architecture calculates values for the threshold and step parameters, based on the trellis structure and the number of soft decision bits. Second, the delayed minimum value is compared to the threshold. Last, if the minimum value is greater than or equal to the threshold value, the implementation subtracts the step value from the state metric; otherwise no adjustment is performed. The following figure illustrates the modified renormalization method.

Create a New HDL Coder Project

To create a new project, enter the following command:

```
coder -hdlcoder -new mlhdlc_viterbi
```

Next, add the file `mlhdlc_sysobj_viterbi.m` to the project as the MATLAB function and `mlhdlc_sysobj_viterbi_tb.m` as the MATLAB test bench.

For a more complete tutorial on creating and populating MATLAB HDL Coder projects, see “Get Started with MATLAB to HDL Workflow”.

Run Fixed-Point Conversion and HDL Code Generation

Launch the Workflow Advisor. In the Workflow Advisor, right-click the **Code Generation** step and choose the option **Run to selected task** to run all the steps from the beginning through HDL code generation.

Examine the generated HDL code by clicking the links in the log window.

Supported System objects

For a list of System objects supported for HDL code generation, see “Predefined System Objects Supported for HDL Code Generation” on page 1-50.

Predefined System Objects Supported for HDL Code Generation

In this section...
“Predefined System Objects in MATLAB Code” on page 1-50
“Predefined System Objects in the MATLAB System Block” on page 1-51

Predefined System Objects in MATLAB Code

HDL Coder supports the following MATLAB System objects for HDL code generation:

- `hdl.RAM`
- `hdl.BlackBox`
- `hdl.Delay`

HDL Coder also supports HDL code generation from certain System objects in DSP System Toolbox and Communications Toolbox, and from HDL-optimized algorithms implemented with System objects in DSP HDL Toolbox™ and Vision HDL Toolbox™.

You can view System objects that are supported for HDL code generation in documentation by filtering the functions reference list. Click **Functions** in the blue bar at the top of the Help window, then select the **HDL code generation** check box at the bottom of the left column. The System objects are listed in their respective products. You can use the table of contents in the left column to navigate between products and categories.

Refer to the "Extended Capabilities > HDL Code Generation" section of each block page for restrictions for HDL code generation.

The screenshot shows the MATLAB Documentation website for DSP System Toolbox Functions. The 'Functions' tab is selected and circled in red. In the left sidebar, under 'Extended Capability', 'HDL Code Generation' is checked and circled in red. The main content area shows a list of DSP functions categorized into Signal Generation, Filter Design, and Filter Implementation, with a filter set to 'HDL Code Generation'.

DSP System Toolbox — Functions

By Category | [Alphabetical List](#)

FILTERED BY HDL Code Generation x

Signal Generation, Manipulation, and Analysis

dsp.DigitalDownConverter	Translate digital signal from intermediate frequency (IF) band to baseband and decimate it
dsp.DigitalUpConverter	Interpolate digital signal and translate it from baseband to IF band
dsp.FarrowRateConverter	Polynomial sample rate converter with arbitrary conversion factor
dsp.DCBlocker	Block DC component (offset) from input signal
dsp.Delay	Delay input signal by fixed samples
dsp.VariableFractionalDelay	Delay input by time-varying fractional number of sample periods

Filter Design and Analysis

dsp.HighpassFilter	FIR or IIR highpass filter
dsp.LowpassFilter	FIR or IIR lowpass filter
dsp.CICCompensationDecimator	Compensate for CIC decimation filter using FIR decimator
dsp.CICCompensationInterpolator	Compensate for CIC interpolation filter using FIR interpolator

Filter Implementation

Single-Rate Filters

dsp.FIRFilter	Static or time-varying FIR filter
dsp.HighpassFilter	FIR or IIR highpass filter
dsp.LowpassFilter	FIR or IIR lowpass filter
dsp.BiquadFilter	IIR filter using biquadratic structures

Predefined System Objects in the MATLAB System Block

A subset of these predefined System objects are supported for code generation when you use them in a MATLAB System block. To learn more, see “HDL Code Generation” on the MATLAB System page.

Load constants from a MAT-File

You can load compile-time constants from a MAT-file with the `coder.load` function in your MATLAB design.

For example, you can create a MAT-file, `sinvals.mat`, that contains fixed-point values of `sin` by entering the following commands in MATLAB:

```
sinvals = sin(fi(-pi:0.1:pi, 1, 16,15));  
save sinvals.mat sinvals;
```

You can then generate HDL code from the following MATLAB code, which loads the constants from `sinvals.mat` into a persistent variable, `pConstStruct`, and assigns the values to a variable that is not persistent, `sv`.

```
persistent pConstStruct;  
if isempty(pConstStruct)  
    pConstStruct = coder.load('sinvals.mat');  
end  
sv = pConstStruct.sinvals;
```

Generate Code for User-Defined System Objects

In this section...

“How To Create A User-Defined System object” on page 1-53

“User-Defined System object Example” on page 1-53

How To Create A User-Defined System object

To create a user-defined System object and generate code:

- 1 Create a class that subclasses from `matlab.System`.
- 2 Define one of the following sets of methods:
 - `setupImpl` and `stepImpl`
 - `setupImpl`, `outputImpl`, and `updateImpl`
- 3 Optionally, if your System object has private state properties, define the `resetImpl` method to initialize them to zero.
- 4 Write a top-level design function that creates an instance of your System object and calls the object, or calls the `output` and `update` methods.

Note The `resetImpl` method runs automatically during System object initialization. For HDL code generation, you cannot call the public `reset` method.

- 5 Write a test bench function that exercises the top-level design function.
- 6 Generate HDL code.

User-Defined System object Example

This example shows how to generate HDL code for a user-defined System object that implements the `setupImpl` and `stepImpl` methods.

- 1 In a writable folder, create a System object, `CounterSysObj`, which subclasses from `matlab.System`. Save the code as `CounterSysObj.m`.

```
classdef CounterSysObj < matlab.System

    properties (Nontunable)
        Threshold = int32(1)
    end
    properties (Access=private)
        State
        Count
    end
    methods
        function obj = CounterSysObj(varargin)
            setProperties(obj,nargin,varargin{:});
        end
    end

    methods (Access=protected)
        function setupImpl(obj, ~)
```

```
        % Initialize states
        obj.Count = int32(0);
        obj.State = int32(0);
    end
    function y = stepImpl(obj, u)
        if obj.Threshold > u(1)
            obj.Count(:) = obj.Count + int32(1); % Increment count
        end
        y = obj.State;          % Delay output
        obj.State = obj.Count; % Put new value in state
    end
end
end
```

The `stepImpl` method implements the System object functionality. The `setupImpl` method defines the initial values for the persistent variables in the System object.

- 2 Write a function that uses this System object and save it as `myDesign.m`. This function is your DUT.

```
function y = myDesign(u)

persistent obj
if isempty(obj)
    obj = CounterSysObj('Threshold',5);
end

y = obj(u);

end
```

- 3 Write a test bench that calls the DUT function and save it as `myDesign_tb.m`.

```
clear myDesign
for ii=1:10
    y = myDesign(int32(ii));
end
```

- 4 Generate HDL code for the DUT function as you would for any other MATLAB code, but skip fixed-point conversion.

More About

- “HDL Code Generation for System Objects” on page 1-16

Map Matrices to ROM

To map a matrix constant to ROM:

- Read one matrix element at a time.
- The matrix size must be greater than or equal to the **RAM Mapping Threshold** value.

To learn how to set the RAM mapping threshold in Simulink, see the **RAM mapping threshold (bits)** section in “RAM Mapping Parameters” on page 19-6. To learn how to set the RAM mapping threshold in MATLAB, see “Enable RAM Mapping” on page 8-6.

- Read accesses to the matrix must not be within a feedback loop.

If your MATLAB code meets these requirements, HDL Coder inserts a no-reset register at the output of the matrix in the generated code. Many synthesis tools infer a ROM from this code pattern.

Model State with Persistent Variables and System Objects

This example shows how to use persistent variables and System objects to model state and delays in a MATLAB® design for HDL code generation.

Introduction

Using System objects to model delay results in concise generated code.

In MATLAB, multiple calls to a function having persistent variables do not result in multiple delays. Instead, the state in the function gets updated multiple times.

In order to reuse code implemented in a function with states, you need to duplicate functions multiple times to create multiple instances of the algorithm with delay.

Examine the MATLAB Code

Look at the implementation of the Sobel algorithm.

Examine the design to see how the delays and line buffers are modeled using:

- Persistent variables: `mlhdlc_sobel`
- System objects: `mlhdlc_sysobj_sobel`

Notice that the `filterdelay` function is duplicated with different function names in `mlhdlc_sobel` code to instantiate multiple versions of the algorithm in MATLAB for HDL code generation.

The delay line implementation is more complicated when done using MATLAB persistent variables.

Now examine the simplified implementation of the same algorithm using System objects in `mlhdlc_sysobj_sobel`.

When used within the constraints of HDL code generation, the `dsp.Delay` objects always map to registers. For persistent variables to be inferred as registers, you have to be careful to read the variable before writing to it to map it to a register.

MATLAB Design

```
demo_files = {...  
    'mlhdlc_sysobj_sobel', ...  
    'mlhdlc_sysobj_sobel_tb', ...  
    'mlhdlc_sobel', ...  
    'mlhdlc_sobel_tb'  
};
```

Known Limitations

For predefined System Objects, HDL Coder™ only supports the `step` method and does not support `output` and `update` methods.

With support for only the `step` method, delays cannot be used in modeling feedback paths. For example, the following piece of MATLAB code cannot be supported using the `dsp.Delay` System object.

```
##codegen  
function y = accumulate(u)
```

```
persistent p;  
if isempty(p)  
    p = 0;  
end  
y = p;  
p = p + u;
```

Create a New HDL Coder Project

To create a new project, enter the following command:

```
coder -hdlcoder -new mlhdlc_sobel
```

Next, add the file `mlhdlc_sobel.m` to the project as the MATLAB Function and `mlhdlc_sobel_tb.m` as the MATLAB Test Bench.

For a more complete tutorial on creating and populating MATLAB HDL Coder projects, see “Get Started with MATLAB to HDL Workflow”.

Run Fixed-Point Conversion and HDL Code Generation

Launch the Workflow Advisor and right-click the **Code Generation** step. Choose the option **Run to selected task** to run all the steps from the beginning through HDL code generation.

Examine the generated HDL code by clicking the hyperlinks in the Code Generation Log window.

Now, create a new project for the system object design:

```
coder -hdlcoder -new mlhdlc_sysobj_sobel
```

Add the file `mlhdlc_sysobj_sobel.m` to the project as the MATLAB Function and `mlhdlc_sysobj_sobel_tb.m` as the MATLAB Test Bench.

Repeat the code generation steps and examine the generated fixed-point MATLAB and HDL code.

Additional Notes:

You can model integer delay using `dsp.Delay` object by setting the `Length` property to be greater than 1. These delay objects will be mapped to shift registers in the generated code.

If the optimization option **Map persistent array variables to RAMs** is enabled, delay System objects will get mapped to block RAMs under the following conditions:

- `InitialConditions` property of the `dsp.Delay` is set to zero.
- Delay input data type is not floating-point.
- `RAMSize` (`DelayLength * InputWordLength`) is greater than or equal to the **RAM Mapping Threshold**.

Bitwise Operations in MATLAB for HDL and SystemC Code Generation

HDL Coder supports bit shift, bit rotate, bit slice operations that mimic HDL-specific and SystemC-specific operators without saturation and rounding logic.

Bit Shifting and Rotation

The following code implements a barrel shifter/rotator that performs a selected operation (based on the mode argument) on a fixed-point input operand.

```
function y = fcn(u, mode)
% Multi Function Barrel Shifter/Rotator

% fixed width shift operation
fixed_width = uint8(3);

switch mode
    case 1
        % shift left logical
        y = bitsll(u, fixed_width);
    case 2
        % shift right logical
        y = bitsrl(u, fixed_width);
    case 3
        % shift right arithmetic
        y = bitsra(u, fixed_width);
    case 4
        % rotate left
        y = bitrol(u, fixed_width);
    case 5
        % rotate right
        y = bitror(u, fixed_width);
    otherwise
        % do nothing
        y = u;
end
```

This table shows the generated VHDL, Verilog and, SystemC code.

Generated VHDL code	Generated Verilog code	Generated SystemC code
<p>In VHDL code generated for this function, the shift and rotate functions map directly to shift and rotate instructions in VHDL.</p> <pre> CASE mode IS WHEN "00000001" => -- shift left logical -- '<S2>:1:8' cr := signed(u) sll 3; y <= std_logic_vector(cr); WHEN "0000010" => -- shift right logical -- '<S2>:1:11' b_cr := signed(u) srl 3; y <= std_logic_vector(b_cr); WHEN "0000011" => -- shift right arithmetic -- '<S2>:1:14' c_cr := SHIFT_RIGHT(signed(u) , 3); y <= std_logic_vector(c_cr); WHEN "0000100" => -- rotate left -- '<S2>:1:17' d_cr := signed(u) rol 3; y <= std_logic_vector(d_cr); WHEN "0000101" => -- rotate right -- '<S2>:1:20' e_cr := signed(u) ror 3; y <= std_logic_vector(e_cr); WHEN OTHERS => -- do nothing -- '<S2>:1:23' y <= u; END CASE; </pre>	<p>The corresponding Verilog code is similar, except that Verilog does not have native operators for rotate instructions.</p> <pre> case (mode) 1 : begin // shift left logical // '<S2>:1:8' cr = u <<< 3; y = cr; end 2 : begin // shift right logical // '<S2>:1:11' b_cr = u >> 3; y = b_cr; end 3 : begin // shift right arithmetic // '<S2>:1:14' c_cr = u >>> 3; y = c_cr; end 4 : begin // rotate left // '<S2>:1:17' d_cr = {u[12:0], u[15:3]}; y = d_cr; end 5 : begin // rotate right // '<S2>:1:20' e_cr = {u[2:0], u[15:3]}; y = e_cr; end default : begin // do nothing // '<S2>:1:23' y = u; end endcase </pre>	<p>The generated SystemC code uses the native C++ bitwise operators to accomplish the shift operations. The rotate operations are written using shift operators.</p> <pre> #include "rtwtypes.hpp" class fcnClass { public: sc_ufixed<16,6> f(sc_ufixed<16,6> u, int8_T mode) { sc_ufixed<16,6> y; sc_ufixed<16,6> c; sc_ufixed<16,6> c_0; sc_ufixed<16,6> c_1; sc_ufixed<16,6> c_2; c_0 = sc_ufixed<16,6>(0.0); c_1 = sc_ufixed<16,6>(0.0); c_2 = sc_ufixed<16,6>(0.0); /* Multi Function Barrel Shifter/Rotator */ /* fixed width shift operation */ switch (mode) { case 1: /* shift left logical */ y = u << 3; break; case 2: /* shift right logical */ c_1 = u >> 3; break; case 3: /* shift right arithmetic */ c_2 = u >>> 3; break; case 4: /* rotate left */ c = (sc_ufixed<16,6>)(u << 3) (sc_ufixed- y = c; break; case 5: /* rotate right */ c_0 = (sc_ufixed<16,6>)(u >> 3) (sc_ufixe y = c_0; break; default: /* do nothing */ y = u; break; } return y; } }; </pre>

Bit Slicing and Bit Concatenation

The `bitsliceget` and `bitconcat` functions map directly to slice and concatenate operators in both VHDL and Verilog.

You can use the functions `bitsliceget` and `bitconcat` to access and manipulate bit slices (fields) in a fixed-point or integer word. As an example, consider the operation of swapping the upper and lower 4-bit nibbles of an 8-bit byte. The following example accomplishes this task without resorting to traditional mask-and-shift techniques.

```
function y = fcn(u)
% NIBBLE SWAP
y = bitconcat( ...
    bitsliceget(u, 4, 1),
    bitsliceget(u, 8, 5));
```

This table shows the generated VHDL, Verilog and, SystemC code.

Generated VHDL code	Generated Verilog code	Generated SystemC code
<p>The following listing shows the corresponding generated VHDL code.</p> <pre>ENTITY fcn IS PORT (clk : IN std_logic; clk_enable : IN std_logic; reset : IN std_logic; u : IN std_logic_vector(7 DOWNTO 0); y : OUT std_logic_vector(7 DOWNTO 0);); END nibble_swap_7b; ARCHITECTURE fsm_SFHDL OF fcn IS BEGIN -- NIBBLE SWAP y <= u(3 DOWNTO 0) & u(7 DOWNTO 4); END fsm_SFHDL;</pre>	<p>The following listing shows the corresponding generated Verilog code.</p> <pre>module fcn (clk, clk_enable, reset, input clk; input clk_enable; input reset; input [7:0] u; output [7:0] y; // NIBBLE SWAP assign y = {u[3:0], u[7:4]}; endmodule</pre>	<p>The following listing shows the corresponding generated SystemC code.</p> <pre>#pragma once #include "rtwtypes.hpp" class fcnClass { public: sc_uint<8> f(sc_ufixed<16,6> u) { sc_uint<8> y; sc_uint<16> tmp; sc_uint<16> tmp_0; /* NIBBLE SWAP */ tmp = u(); tmp_0 = u(); y = (sc_uint<8>)(sc_uint<4>)((sc_uint<16>)tmp_0) & (sc_uint<8>)(sc_uint<4>)((sc_uint<16>)tmp); return y; } };</pre>

Mapping of Different Rounding and Overflow Methods from MATLAB to SystemC

The specified fixed-point data types in MATLAB code are converted to SystemC fixed-point data types during code generation.

The tables show the mapping of different MATLAB fixed-point rounding and overflow methods to their equivalent SystemC methods.

Rounding Methods

MATLAB Fixed-Point Rounding Methods	Description	Equivalent SystemC Fixed-Point Rounding Methods
Nearest (default for MATLAB)	Rounds to the nearest representable number.	SC_RND
Zero	Rounds to the nearest representable number in the direction of zero.	SC_TRN_ZERO
Floor	Rounds to the nearest representable number in the direction of negative infinity. Equivalent to two's complement truncation.	SC_TRN (default for SystemC)
Round	Rounds to the nearest representable number.	SC_RND_INF
Convergent	Rounds to the nearest representable number.	SC_RND_CONV

Note The ceiling rounding method is not supported for SystemC code generation.

Overflow Methods

MATLAB Fixed-Point Overflow Methods	Description	Equivalent SystemC Fixed-Point Overflow Methods
Saturate (default for MATLAB)	Saturate to maximum or minimum value of the fixed-point range on overflow.	SC_SAT
Wrap	Wrap on overflow. This mode is also known as two's complement overflow.	SC_WRAP (default for SystemC)

The rounding and overflow methods are represented as typecasts on expressions in the generated SystemC code.

For example, consider the MATLAB function `exampleFun` and the generated SystemC code to understand the conversion of rounding and overflow methods.

MATLAB Code

```
function y = exampleFun(a, b)
    y = fi(a + b, 1, 5, 2, fimath('RoundingMethod', 'Nearest', 'OverflowAction', 'Saturate'));
end
```

Generated SystemC Code

```
class exampleFunClass
{
    public:
        sc_fixed<5,3> exampleFun(sc_fixed<7,3> a, sc_fixed<7,3> b)
        {
            return (sc_fixed<5,3,SC_RND,SC_SAT>)((sc_fixed<8,4>)a + (sc_fixed<8,4>)b);
        }
};
```

Guidelines for Writing MATLAB Code to Generate Efficient HDL and SystemC Code

MATLAB Design Requirements for HDL and SystemC Code Generation

When you generate HDL or SystemC code from your MATLAB design, you are converting an algorithm into an architecture that must meet hardware area and speed requirements.

Your MATLAB design has these requirements:

- MATLAB code within the design must be supported by HDL or SystemC code generation.
- Inputs and outputs must not be matrices or structures.

If you are generating code at the command line, verify your code readiness for code generation by using this command:

```
coder.screener('design_function_name')
```

If you use the HDL Workflow Advisor to generate code, this check runs automatically.

For a MATLAB language support reference, including supported functions from Fixed-Point Designer, see “Functions Supported for HDL and SystemC Code Generation” on page 1-2.

Guidelines for Writing MATLAB Code

For more efficient and faster HDL and SystemC code generation, design your MATLAB code by using these best practices:

- Serialize your input and output data. Parallel data processing structures require more hardware resources and a higher pin count.
- Use add and subtract algorithms instead of algorithms that use functions, such as sine, divide, and modulo. Add and subtract operations use fewer hardware resources.
- Avoid large arrays and matrices. Large arrays and matrices require more registers and more RAM for storage. Whenever you need to use large arrays for memory, consider using the RAM mapping optimization to map these memories to RAM.
- Convert your code from floating-point to fixed-point. Floating-point data types are inefficient for hardware realization. HDL Coder provides an automated workflow for floating-point to fixed-point conversion.
- Unroll loops to increase speed at the cost of higher area. For HDL code generation, unroll fewer loops and enable the loop streaming optimization to conserve area at the cost of lower throughput.
- Optimize generated code by reducing the number of bits used to represent a variable i.e., bitwidth of the operand inside the MATLAB code.
- Use hardware-friendly rounding and overflow methods. It can be achieved by using `hdlfimath` function in your MATLAB code.

```
function out = add(a,b)
    out = fi(a+b,1,12,4,hdlfimath);
end
```

Additional guidelines for efficient SystemC code generation:

- Modularize the design into subfunctions as much as possible. Doing so improves the readability of the code and makes it easier to specify constraints, such as `coder.hdl.constrainlatency`, on a particular region of code.
- Use a zero-based indexing scheme followed by array access with the addition of 1 as MATLAB uses 1-based indexing: for example, use `arrayVar(index+1)` instead of `arrayVar(index)`. The extra indexing logic does not need to be inserted by the code generator, thereby reducing overall area.

For-Loop Best Practices for HDL Code Generation

When you generate HDL code from your MATLAB design, you are converting an algorithm into an architecture that must meet hardware area and speed requirements. Some best practices for using loops in MATLAB code for HDL code generation are:

- Use monotonically increasing loop counters, with increments of 1, to minimize the amount of hardware generated in the HDL code.
- When implementing a loop to find an index value, use a conditional `if-else` statement inside of the loop.
- If you want to use the loop streaming optimization:
 - When assigning new values to persistent variables inside a loop, do not use other persistent variables on the right side of the assignment. Instead, use an intermediate variable.
 - If a loop modifies any elements in a persistent array, the loop should modify all of the elements in the persistent array.

Monotonically Increasing Loop Counters

By using monotonically increasing loop counters with increments of 1, you can reduce the amount of hardware in the generated HDL code. The following loop is an example of a monotonically increasing loop counter with increments of 1.

```
a=1;
for i=1:10
    a=a+1;
end
```

If a loop counter increases by an increment other than 1, the generated HDL code can require additional adders. Due to this additional hardware, do not use the following type of loop.

```
a=1;
for i=1:2:10
    a=a+1;
end
```

If a loop counter decreases, the generated HDL code can require additional adders. Due to this additional hardware, do not use the following type of loop.

```
a=1;
for i=10:-1:1
    a=a+1;
end
```

Find Indices Using Loops

When generating HDL code, control flow-like breaks are not possible, see “Supported MATLAB Data Types, Operators, and Control Flow Statements” on page 1-4. Because a `for` loop must run for a constant number of iterations, to find an index using loops, use a conditional inside the loop, such as an `if-else` statement. For example, to find the first index of a one in the array `u`, you can use this code:

```
function y = fcn(u)
```

```
y = fi(0, 0, ceil(log2(numel(u))), 0);  
for ii = cast(1:numel(u), 'like', y)  
    if y == 0 && u(ii) == true  
        y = ii;  
    end  
end  
end
```

The final value for `y` is the smallest possible fixed-point value of the index that contains a one in the array `u`.

Persistent Variables in Loops

If a loop contains multiple persistent variables, when you assign values to persistent variables, use intermediate variables that are not persistent on the right side of the assignment. This practice makes dependencies clear to the compiler and assists internal optimizations during the HDL code generation process. If you want to use the loop streaming optimization to reduce the amount of generated hardware, this practice is recommended.

In the following example, `var1` and `var2` are persistent variables. `var1` is used on the right side of the assignment. Because a persistent variable is on the right side of an assignment, do not use this type of loop:

```
for i=1:10  
    var1 = 1 + i;  
    var2 = var1 * 2;  
end
```

Instead of using `var1` on the right side of the assignment, use an intermediate variable that is not persistent. This example demonstrates this with the intermediate variable `var_intermediate`.

```
for i=1:10  
    var_intermediate = 1 + i;  
    var1 = var_intermediate;  
    var2 = var_intermediate * 2;  
end
```

Persistent Arrays in Loops

If a loop modifies elements in a persistent array, make sure that the loop modifies all of the elements in the persistent array. If all elements of the persistent array are not modified within the loop, HDL Coder cannot perform the loop streaming optimization.

In the following example, `a` is a persistent array. The first element is modified outside of the loop. Do not use this type of loop.

```
for i=2:10  
    a(i)=1+i;  
end  
a(1)=24;
```

Rather than modifying the first element outside the loop, modify all of the elements inside the loop.

```
for i=1:10  
    if i==1
```

```
        a(i)=24;  
    else  
        a(i)=1+i;  
    end  
end
```

MATLAB Test Bench Requirements and Best Practices for Code Generation

What Is a MATLAB Test Bench?

A test bench is a MATLAB script or function that you write to test the algorithm in your MATLAB design function. The test bench varies the input data to the design to simulate real world conditions. It can also check that the output data meets design specifications.

HDL Coder uses the data it gathers from running your test bench with your design to infer fixed-point data types for floating-point to fixed-point conversion. The coder also uses the data to generate HDL and SystemC test data for verifying your generated code. For more information on how to write your test bench for the best results, see “MATLAB Test Bench Requirements and Best Practices for Code Generation” on page 1-68.

MATLAB Test Bench Requirements

You can use any MATLAB data type and function in your test bench.

A MATLAB test bench has the following requirements:

- For floating-point to fixed-point conversion, the test bench must be a script or a function with no inputs. The test bench can have local helper functions that take inputs.
- The inputs and outputs in your MATLAB design interface must use the same data types, sizes, and complexity in each call site in your test bench.
- If you enable the **Accelerate test bench for faster simulation** option in the Float-to-Fixed Workflow, the MATLAB constructs in your test bench loop must be compilable.

MATLAB Test Bench Best Practices

Use the following MATLAB test bench best practices:

- *Design your test bench to cover the full numeric range of data that the design must handle.* HDL Coder uses the data that it accumulates from running the test bench to infer fixed-point data types during floating-point to fixed-point conversion.

If you call the design function multiple times from your test bench, the coder uses the accumulated data from each instance to infer fixed-point types. Both the design and the test bench can call local functions within the file or other functions on the MATLAB path. The call to the design function can be at any level of your test bench hierarchy.

- *Before trying to generate code, run your test bench in MATLAB .* If simulation is slow, accelerate your test bench. To learn how to accelerate your simulation, see “Accelerate MATLAB Algorithms”.
- If you have a loop that calls your design function, use only compilable MATLAB constructs within the loop and enable the **Accelerate test bench for faster simulation** option.
- Before each test bench simulation run, use the `clear variables` command to reset your persistent variables.

To see an example of a test bench, enter this command:

```
showdemo mlhdlc_tutorial_float2fixed_files
```

HDL Code Generation for LMS Filter

This example shows how to generate HDL code from a MATLAB® design that implements an LMS filter. The example also illustrates how to design a test bench that cancels out the noise signal by using this filter.

LMS Filter MATLAB Design

The MATLAB design used in the example is an implementation of an LMS (Least Mean Squares) filter. The LMS filter is a class of adaptive filter that identifies an FIR filter signal that is embedded in the noise. The LMS filter design implementation in MATLAB consists of a top-level function `mlhdlc_lms_fcn` that calculates the optimal filter coefficients to reduce the difference between the output signal and the desired signal.

```
design_name = 'mlhdlc_lms_fcn';
testbench_name = 'mlhdlc_lms_noise_canceler_tb';
```

Review the MATLAB design:

```
open(design_name);
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% MATLAB Design: Adaptive Noise Canceler algorithm using Least Mean Square
% (LMS) filter implemented in MATLAB
%
% Key Design pattern covered in this example:
% (1) Use of function calls
% (2) Function inlining vs instantiation knobs available in the coder
% (3) Use of system objects in the testbench to stream test vectors into the design
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

%#codegen
function [filtered_signal, y, fc] = mlhdlc_lms_fcn(input, ...
                                                desired, step_size, reset_weights)
% 'input' : The signal from Exterior Mic which records the ambient noise.
% 'desired': The signal from Pilot's Mic which includes
%            original music signal and the noise signal
% 'err_sig': The difference between the 'desired' and the filtered 'input'
%            It represents the estimated music signal (output of this block)
%
% The LMS filter is trying to retrieve the original music signal('err_sig')
% from Pilot's Mic by filtering the Exterior Mic's signal and using it to
% cancel the noise in Pilot's Mic. The coefficients/weights of the filter
% are updated(adapted) in real-time based on 'input' and 'err_sig'.

% register filter coefficients
persistent filter_coeff;
if isempty(filter_coeff)
    filter_coeff = zeros(1, 40);
end

% Variable Filter: Call 'tapped_delay_fcn' function on path to create
% 40-step tapped delay
delayed_signal = mtapped_delay_fcn(input);
```

```

% Apply filter coefficients
weight_applied = delayed_signal .* filter_coeff;

% Call treesum function on matlab path to sum up the results
filtered_signal = mtreesum_fcn(weight_applied);

% Output estimated Original Signal
td = desired;
tf = filtered_signal;
esig = td - tf;
y = esig;

% Update Weights: Call 'update_weight_fcn' function on MATLAB path to
% calculate the new weights
updated_weight = update_weight_fcn(step_size, esig, delayed_signal, ...
                                   filter_coeff, reset_weights);

% update filter coefficients register
filter_coeff = updated_weight;
fc = filter_coeff;

function y = mtreesum_fcn(u)
%Implement the 'sum' function without a for-loop
% y = sum(u);

% The loop based implementation of 'sum' function is not ideal for
% HDL generation and results in a longer critical path.
% A tree is more efficient as it results in
% delay of log2(N) instead of a delay of N delay

% This implementation shows how to explicitly implement the vector sum in
% a tree shape to enable hardware optimizations.

% The ideal way to code this generically for any length of 'u' is to use
% recursion but it is not currently supported by MATLAB Coder

% NOTE: To instruct MATLAB Coder to compile an external function,
% add the following compilation directive or pragma to the function code
%#codegen

% This implementation is hardwired for a 40tap filter.

level1 = vsum(u);
level2 = vsum(level1);
level3 = vsum(level2);
level4 = vsum(level3);
level5 = vsum(level4);
level6 = vsum(level5);
y = level6;

function output = vsum(input)

coder.inline('always');

vt = input(1:2:end);

for i = int32(1: numel(input)/2)

```

```
        k = int32(i*2);
        vt(i) = vt(i) + input(k);
    end

    output = vt;

    function tap_delay = mtapped_delay_fcn(input)
    % The Tapped Delay function delays its input by the specified number
    % of sample periods, and outputs all the delayed versions in a vector
    % form. The output includes current input

    % NOTE: To instruct MATLAB Coder to compile an external function,
    % add the following compilation directive or pragma to the function code
    %#codegen

    persistent u_d;
    if isempty(u_d)
        u_d = zeros(1,40);
    end

    u_d = [u_d(2:40), input];

    tap_delay = u_d;

    function weights = update_weight_fcn(step_size, err_sig, ...
        delayed_signal, filter_coeff, reset_weights)
    % This function updates the adaptive filter weights based on LMS algorithm

    % Copyright 2007-2022 The MathWorks, Inc.

    % NOTE: To instruct MATLAB Coder to compile an external function,
    % add the following compilation directive or pragma to the function code
    %#codegen

    step_sig = step_size .* err_sig;
    correction_factor = delayed_signal .* step_sig;
    updated_weight = correction_factor + filter_coeff;

    if reset_weights
        weights = zeros(1,40);
    else
        weights = updated_weight;
    end
end
```

The MATLAB function is modular and uses functions:

- `mtapped_delay_fcn` to calculate delayed versions of the input signal in vector form.
- `mtreesum_fcn` to calculate the sum of the applied weights in a tree structure. The individual sum is calculated by using a `vsum` function.
- `update_weight_fcn` to calculate the updated filter weights based on the least mean square algorithm.

LMS Filter MATLAB Test Bench

Review the MATLAB test bench:

```

open(testbench_name)

% Returns an adaptive FIR filter System object,
% HLMS, that computes the filtered output, filter error and the filter
% weights for a given input and desired signal using the Least Mean
% Squares (LMS) algorithm.

% Copyright 2011-2022 The MathWorks, Inc.
clear('mlhdlc_lms_fcn');

hfilt2 = dsp.FIRFilter(...
    'Numerator', fir1(10, [.5, .75]));
rng('default'); % always default to known state
x = randn(1000,1); % Noise
d = step(hfilt2, x) + sin(0:.05:49.95)'; % Noise + Signal

stepSize = 0.01;
reset_weights = false;

hSrc = dsp.SignalSource(x);
hDesiredSrc = dsp.SignalSource(d);

hOut = dsp.SignalSink;
hErr = dsp.SignalSink;
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%Call to the design
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
while (~isDone(hSrc))
    [y, e] = mlhdlc_lms_fcn(step(hSrc), step(hDesiredSrc), ...
        stepSize, reset_weights);
    step(hOut, y);
    step(hErr, e);
end

figure('Name', [mfilename, '_signal_plot']);
subplot(2,1,1), plot(hOut.Buffer), title('Noise + Signal');
subplot(2,1,2), plot(hErr.Buffer), title('Signal');

```

Test the MATLAB Algorithm

To avoid run-time errors, simulate the design with the test bench.

```
mlhdlc_lms_noise_canceler_tb
```

Create an HDL Coder Project

To generate HDL code from a MATLAB design:

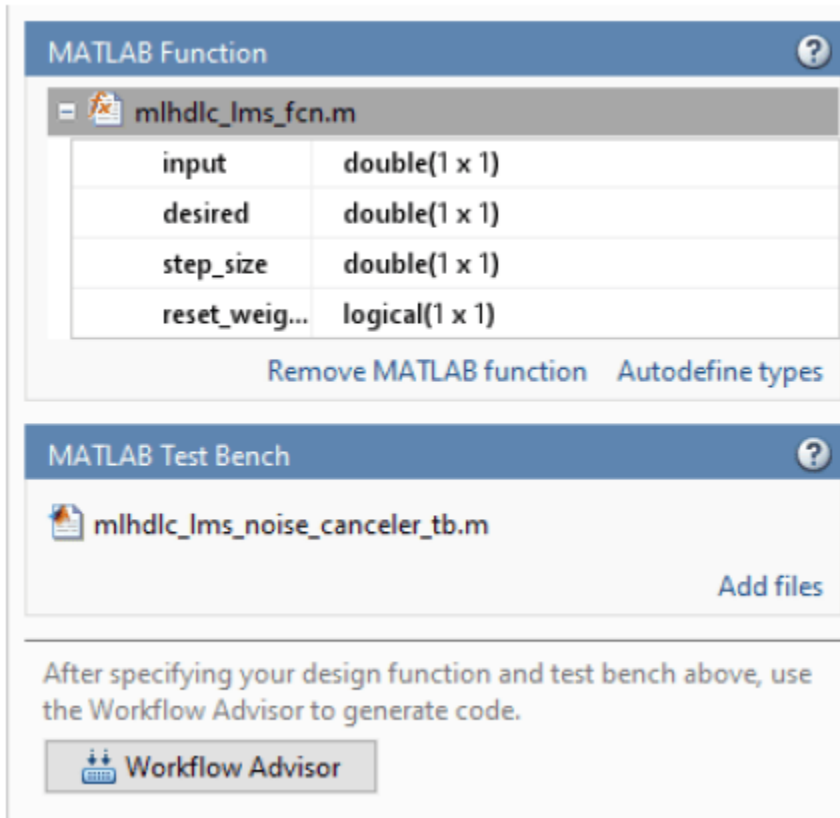

1. Create a HDL Coder project:

```
coder -hdlcoder -new mlhdlc_lms_nc
```

2. Add the file `mlhdlc_lms_fcn.m` to the project as the **MATLAB Function** and `mlhdlc_lms_noise_canceler_tb.m` as the **MATLAB Test Bench**.

3. Click **Autodefine types** to use the recommended types for the inputs and outputs of the MATLAB function `mlhdlc_lms_fcn`.

For a more complete tutorial on creating and populating MATLAB HDL Coder projects, see "Get Started with MATLAB to HDL Workflow".

Run Fixed-Point Conversion and HDL Code Generation

- 1 Click the **Workflow Advisor** button to start the Workflow Advisor.
- 2 Right click the **HDL Code Generation** task and select **Run to selected task**.

A single HDL file `mlhdlc_lms_fcn_FixPt.vhd` is generated for the MATLAB design. To examine the generated HDL code for the filter design, click the hyperlinks in the Code Generation Log window.

If you want to generate a HDL file for each function in your MATLAB design, in the **Advanced** tab of the **HDL Code Generation** task, select the **Generate instantiable code for functions** check box. See also “Generate Instantiable Code for Functions” on page 5-11.

Bisection Algorithm to Calculate Square Root of an Unsigned Fixed-Point Number

This example shows how to generate HDL code from MATLAB® design implementing a bisection algorithm to calculate the square root of a number in fixed point notation.

Same implementation, originally using n-multipliers in HDL code, for wordlength n, under sharing and streaming optimizations, can generate HDL code with only one multiplier demonstrating the power of MATLAB® HDL Coder™ optimizations.

The design of the square-root algorithm shows the pipelining concepts to achieve a fast clock rate in resulting RTL design. Since this design is already in fixed point, you don't need to run fixed-point conversion.

MATLAB Design

```
% Design Sqrt
design_name = 'mlhdlc_sqrt';

% Test Bench for Sqrt
testbench_name = 'mlhdlc_sqrt_tb';
```

Lets look at the Sqrt Design

Create a New HDL Coder Project

coder -hdlcoder -new mlhdlc_sqrt_prj

Next, add the file `mlhdlc_sqrt.m` to the project as the MATLAB Function and `mlhdlc_sqrt_tb.m` as the MATLAB Test Bench.

For a more complete tutorial on creating and populating MATLAB HDL Coder projects, see “Get Started with MATLAB to HDL Workflow”.

Run HDL Code Generation

This design is already in fixed point and suitable for HDL code generation. It is not desirable to run floating point to fixed point advisor on this design.

- 1 Launch the Workflow Advisor.
- 2 Under **Define Input Types**, choose `Keep original types` for the option **Fixed-point conversion**.
- 3 Under the **Optimizations** tab in the **RAM Mapping** box, uncheck **MAP persistent variables to RAMs**. Unchecking this option prevents the pipeline from being inferred as RAM.
- 4 Optionally, under the **Optimizations > Area Optimizations** tab, you might want to set **Resource sharing factor** equal to the wordlength (10 here) and select **Stream Loops** under the **Loop Optimizations** tab. Make sure to check **Distributed Pipelining** when you enable the optimizations.
- 5 Click on the **Code Generation** step and click **Run**.

Examine the generated HDL code by clicking on the hyperlinks in the Code Generation Log window.

Examine the Synthesis Results

- 1 Run the logic synthesis step with the following default options if you have ISE installed on your machine.
- 2 In the synthesis report, note the clock frequency reported by the synthesis tool without any optimization options enabled.
- 3 Typically the timing performance of this design, using Xilinx ISE synthesis tool for the `Virtex7` chip family, device `xc7v285t`, speed grade -3, is around 229MHz with a maximum combinatorial path delay of 0.406ns.
- 4 Optimizations for this design (loop streaming and multiplier sharing) work to reduce resource usage, with a moderate trade-off on timing. For the particular word-length size in test bench you see a reduction of `n` multipliers to one.

Timing Offset Estimation

This example shows how to generate HDL code from a basic lead-lag timing offset estimation algorithm implemented in MATLAB® code.

Introduction

In wireless communication systems, receive data is oversampled at the RF front end. This serves several purposes, including providing sufficient sampling rates for receive filtering.

However, one of the most important functions is to provide multiple sampling points on the received waveform such that data can be sampled near the maximum amplitude point in the received waveform. This example illustrates a basic lead-lag time offset estimation core, operating recursively.

The generated hardware core for this design operates at $1/os_rate$ where os_rate is the oversampled rate. That is, for 8 oversampled clock cycles this core iterates once. The output is at the symbol rate.

```
design_name = 'mlhdlc_comms_toe';
testbench_name = 'mlhdlc_comms_toe_tb';
```

Let us take a look at the MATLAB® design.

```

```

Simulate the Design

It is always a good practice to simulate the design with the testbench prior to code generation to make sure there are no runtime errors.

mlhdlc_comms_toe_tb

Create a New HDL Coder™ Project

```
coder -hdlcoder -new mlhdlc_toe
```

Next, add the file mlhdlc_comms_toe.m to the project as the MATLAB Function and mlhdlc_comms_toe_tb.m as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Run Fixed-Point Conversion and HDL Code Generation

Launch the Workflow Advisor from the Workflow Advisor button and right-click on the **Code Generation** step and choose the option **Run to selected task** to run all the steps from the beginning through the HDL code generation.

Examine the generated HDL code by clicking on the hyperlinks in the Code Generation Log window.

Data Packetization

This example shows how to generate HDL code from a MATLAB® design that packetizes a transmit sequence.

Introduction

In wireless communication systems receive data is oversampled at the RF front end. This serves several purposes, including providing sufficient sampling rates for receive filtering.

However, one of the most important functions is to provide multiple sampling points on the received waveform such that data can be sampled near the maximum amplitude point in the received waveform. This example illustrates a basic lead-lag time offset estimation core, operating recursively.

The generated hardware core for this design operates at $1/os_rate$ where os_rate is the oversampled rate. That is, for 8 oversampled clock cycles this core iterates once. The output is at the symbol rate.

```
design_name = 'mlhdlc_comms_data_packet';
testbench_name = 'mlhdlc_comms_data_packet_tb';
```

Let us take a look at the MATLAB design.

```
type(design_name);
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% MATLAB design: Data packetization
%
% Introduction:
%
% This core is meant to illustrate packetization of a transmit sequence.
% There is a "pad" data section, which allows for the transmit amplifier to
% settle. This is then followed by a 65-bit training sequence. This is
% followed by the number of symbols beginning encoded into two bytes or
% 16-bits. This is then followed by a variable length data sequence and a
% CRC. All bits can optionally be differentially encoded.
%
% Key design pattern covered in this example:
% (1) Design illustrates the use of binary operands, such as bitxor
% (2) Shows how to properly segment persistent variables for register and
% BRAM access
% (3) Illustrates the use of fi math
% (4) Shows how to properly format and store ROM data, e.g., padData

Simulate the Design

It is always a good practice to simulate the design with the testbench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_comms_data_packet_tb
```

```
Training Difference: 0 User Data Difference: 0  
CRC decoded correctly
```

Create a New HDL Coder™ Project

```
coder -hdlcoder -new mlhdlc_dpack
```

Next, add the file `mlhdlc_comms_data_packet.m` to the project as the MATLAB Function and `mlhdlc_comms_data_packet_tb.m` as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Run Fixed-Point Conversion and HDL Code Generation

Launch the Workflow Advisor from the Workflow Advisor button and right-click on the **Code Generation** step and choose the option **Run to selected task** to run all the steps from the beginning through the HDL code generation.

Examine the generated HDL code by clicking on the hyperlinks in the Code Generation Log window.

Transmit and Receive FIFO Registers

This example shows how to generate HDL code from MATLAB® code that models the data transfer between a transmit and receive first-in, first-out (FIFO) register or buffer. This example contains two functions that represent a receive FIFO buffer and a transmit FIFO buffer, and a test bench `mlhdlc_fifo_tb` that simulates the data transfer that occurs between the two buffers. Each function is hardware-ready and exhibits good practices and guidelines to follow when writing MATLAB functions to generate efficient HDL code. For more information on guidelines to follow, see “Guidelines for Writing MATLAB Code to Generate Efficient HDL and SystemC Code” on page 1-63.

View Example Functions and Test Bench

Open the MATLAB design for the test bench that exercises both designs. This test bench test both the transmit and receive FIFOs. However, when generating HDL code, because you have individual functions for the transmit and receive FIFOs, you need individual test benches to test both functions and generate code. For simulation purposes, you can use `mlhdlc_fifo_tb`, but for HDL code generation, use the receive FIFO test bench `mlhdlc_rx_fifo_tb` with the receive FIFO function `mlhdlc_rx_fifo`, and use the transmit FIFO test bench `mlhdlc_tx_fifo` with the transmit FIFO function `mlhdlc_tx_fifo`.

```
type('mlhdlc_fifo_tb');
```

Simulate the Design

Simulate the design with the test bench before generating code to ensure there are no runtime errors.

```

mlhdlc_fifo_tb
Received message correctly

ans =

    'Hello World!'

```

Create a New HDL Coder Project for the Receive FIFO

Run this command at the MATLAB command prompt to create a new HDL Coder project for the receive FIFO:

```

coder -hdlcoder -new mlhdlc_rx_fifo

```

When the **HDL Code Generation** pane opens, set the `mlhdlc_rx_fifo.m` function as the MATLAB function to generate HDL code for. Set the `mlhdlc_rx_fifo_tb.m` script as the MATLAB test bench. Click **Workflow Advisor**.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder™ projects.

Generate HDL Code for the Receive FIFO

Right-click **HDL Code Generation** and select **Run to selected task** to run all the steps from the beginning through the HDL code generation.

Examine the generated HDL code for the receive FIFO by clicking the hyperlinks in the bottom pane.

Create a New HDL Coder Project for the Transmit FIFO

```

coder -hdlcoder -new mlhdlc_tx_fifo

```

When the **HDL Code Generation** pane opens, specify `mlhdlc_tx_fifo.m` as the MATLAB function to generate HDL code for the transmit FIFO function, and `mlhdlc_tx_fifo_tb.m` as the MATLAB test bench. Click **Workflow Advisor**.

Generate HDL Code for the Transmit FIFO

Right-click **HDL Code Generation** and select **Run to selected task** to run all the steps from the beginning through the HDL code generation.

Examine the generated HDL code for the transmit FIFO by clicking on the hyperlinks in the bottom pane.

This example shows how to generate HDL code from a MATLAB® design that computes the corner metric by using Harris' technique.

Corner Detection Algorithm

A corner is a point in an image where two edges of the image intersect. The corners are robust to image rotation, translation, and illumination. Corners contain important features that you can use in many applications such as restoring image information, image registration, and object tracking.

Corner detection algorithms identify the corners by using a corner metric. This metric corresponds to the likelihood of pixels located at the corner of certain objects. Peaks of corner metric identify the corners. See also Corner Detection (Computer Vision Toolbox) in the Computer Vision Toolbox documentation. The corner detection algorithm:

1. Reads the input image.

```
Image_in = checkerboard(10);
```

2. Finds the corners.

```
cornerDetector = detectHarrisFeatures(Image_in);
```

3. Displays the results.

```
[~,metric] = step(cornerDetector,image_in);
figure;
subplot(1,2,1);
imshow(image_in);
title('Original');
subplot(1,2,2);
imshow(imadjust(metric));
title('Corner metric');
```

Corner Detection MATLAB Design

```
design_name = 'mlhdlc_corner_detection';
testbench_name = 'mlhdlc_corner_detection_tb';
```

Review the MATLAB design:

```
edit(design_name);
```

```

end

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
function cm = compute_harris_metric(gh, gv)

[g1, g2, g3] = gaussian_filter(gh, gv);
[s1, s2, s3] = reduce_matrix(g1, g2, g3);

cm = (((s1*s3) - (s2*s2)) - (((s1+s3) * (s1+s3)) * 0.04));

end

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
function [g1, g2, g3] = gaussian_filter(gh, gv)

%g=fspecial('gaussian',[5 5],1.5);
g = [0.0144    0.0281    0.0351    0.0281    0.0144
      0.0281    0.0547    0.0683    0.0547    0.0281
      0.0351    0.0683    0.0853    0.0683    0.0351
      0.0281    0.0547    0.0683    0.0547    0.0281
      0.0144    0.0281    0.0351    0.0281    0.0144];

g1 = (gh .* gh) .* g(:)';
g2 = (gh .* gv) .* g(:)';
g3 = (gv .* gv) .* g(:)';

end

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
function [s1, s2, s3] = reduce_matrix(g1, g2, g3)

s1 = sum(g1);

```

```
s2 = sum(g2);  
s3 = sum(g3);
```

```
end
```

The MATLAB function is modular and uses several functions to compute the corners of the image. The function:

- `compute_corner_metric` computes the corner metric matrix by instantiating the function `compute_harris_metric`.
- `compute_harris_metric` detects the corner features in the input image by instantiating functions `gaussian_filter` and `reduce_matrix`. The function takes outputs of `make_buffer_matrix_gh` and `make_buffer_matrix_gv` as the inputs.

Corner Detection MATLAB Test Bench

Review the MATLAB test bench:

```

Test the MATLAB Algorithm

To avoid run-time errors, simulate the design with the test bench.

```
mlhdlc_corner_detection_tb
```

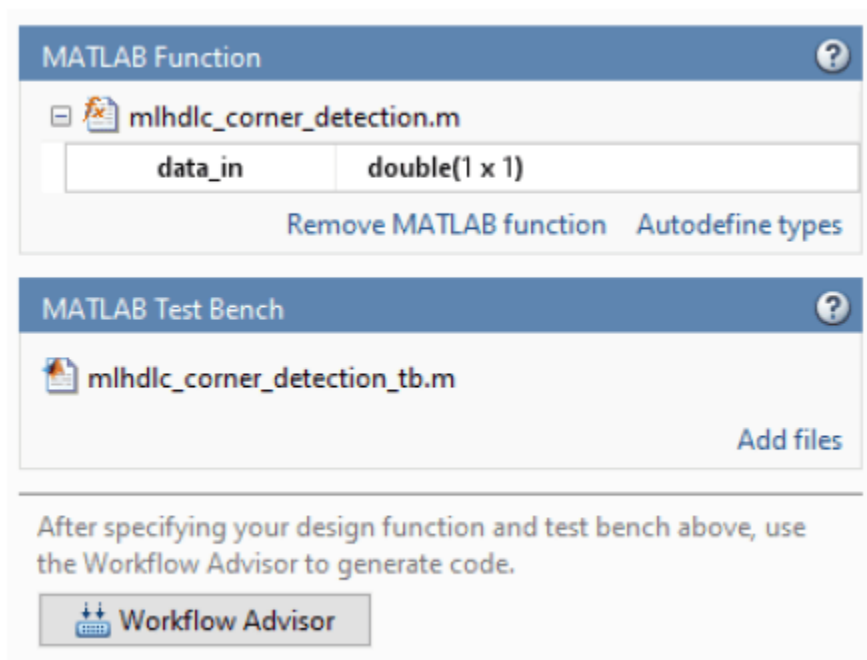

Create an HDL Coder™ Project

1. Create a HDL Coder project:

```
coder -hdlcoder -new mlhdlc_corner_detect_prj
```

2. Add the file mlhdlc_corner_detection.m to the project as the **MATLAB Function** and mlhdlc_corner_detection_tb.m as the **MATLAB Test Bench**.

3. Click **Autodefine types** to use the recommended types for the inputs and outputs of the MATLAB function mlhdlc_corner_detection.m.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Run Fixed-Point Conversion and HDL Code Generation

1 Click the **Workflow Advisor** button to start the Workflow Advisor.

2 Right click the **HDL Code Generation** task and select **Run to selected task**.

A single HDL file `mlhdlc_corner_detection_fixpt.vhd` is generated for the MATLAB design. To examine the generated HDL code for the filter design, click the hyperlinks in the Code Generation Log window.

If you want to generate a HDL file for each function in your MATLAB design, in the **Advanced** tab of the **HDL Code Generation** task, select the **Generate instantiable code for functions** check box. See also “Generate Instantiable Code for Functions” on page 5-11.

HDL Code Generation for Adaptive Median Filter

This example shows how to generate HDL code from a MATLAB® design that implements an adaptive median filter algorithm and generates HDL code.

Adaptive Filter MATLAB Design

An adaptive median filter performs spatial processing to reduce noise in an image. The filter compares each pixel in the image to the surrounding pixels. If one of the pixel values differ significantly from the majority of the surrounding pixels, the pixel is treated as noise. The filtering algorithm then replaces the noise pixel by the median values of the surrounding pixels. This process repeats until all noise pixels in the image are removed.

```
design_name = 'mlhdlc_median_filter';
testbench_name = 'mlhdlc_median_filter_tb';
```

Review the MATLAB design:

```
edit(design_name);

%#codegen

end

end

```

The MATLAB function is modular and uses several functions to filter the noise in the image.

Adaptive Filter MATLAB Test Bench

A MATLAB test bench `mlhdlc_median_filter_tb` exercises the filter design by using a representative input range.

Review the MATLAB test bench:

```
edit(testbench_name);
```

```
I = imread('mlhdlc_img_pattern_noisy.tif');
J = I;

% Copyright 2011-2019 The MathWorks, Inc.

smax = 9;
[nrows, ncols] = size(I);
ll = ceil(smax/2);
ul = floor(smax/2);

for ii=1:ncols-smax
    for jj=1:nrows-smax

        c_idx = ii;
        c_data = double(I(jj:jj+smax-1, ii));

        [pixel_val, pixel_valid] = mlhdlc_median_filter(c_data, c_idx);

        if pixel_valid
            J(jj, ii) = pixel_val;
        end
    end
end

h = figure;
set( h, 'Name', [ mfilename, '_plot' ] );
subplot( 1, 2, 1 );
imshow( I, [ ] );
subplot( 1, 2, 2 );
imshow( J, [ ] );
```

Test the MATLAB Algorithm

To avoid run-time errors, simulate the design with the test bench.

```
mlhdlc_median_filter_tb
```

Accelerating the Design for Faster Simulation

To simulate the test bench faster:

1. Create a MEX file by using MATLAB Coder™. The HDL Workflow Advisor automates these steps when running fixed-point simulations of the design.

```
codegen -o mlhdlc_median_filter -args {zeros(9,1), 0} mlhdlc_median_filter
[~, tbn] = fileparts(testbench_name);
```

2. Simulate the design by using the MEX file. When you run the test bench, HDL Coder uses the MEX file and runs the simulation faster.

```
mlhdlc_median_filter_tb
```

3. Clean up the MEX file.

```
clear mex;
rmdir('codegen', 's');
delete(['mlhdlc_median_filter', '.', mexext]);
```

Create an HDL Coder Project

1. Create an HDL Coder project:

```
coder -hdlcoder -new mlhdlc_med_filt_prj
```

2. Add the file `mlhdlc_median_filter.m` to the project as the **MATLAB Function** and `mlhdlc_median_filter_tb.m` as the **MATLAB Test Bench**.
3. Click **Autodefine types** and use the recommended types for the inputs and outputs of the MATLAB function `mlhdlc_median_filter`.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Run Fixed-Point Conversion and HDL Code Generation

- 1 Click the **Workflow Advisor** button to start the Workflow Advisor.
- 2 Right click the **HDL Code Generation** task and select **Run to selected task**.

A single HDL file `mlhdlc_median_filter_fixpt.vhd` is generated for the MATLAB design. To examine the generated HDL code for the filter design, click the hyperlinks in the Code Generation Log window.

If you want to generate a HDL file for each function in your MATLAB design, in the **Advanced** tab of the **HDL Code Generation** task, select the **Generate instantiable code for functions** check box. See also “Generate Instantiable Code for Functions” on page 5-11.

Contrast Adjustment

This example shows how to generate HDL code from a MATLAB® design that adjusts image contrast by linearly scaling pixel values.

Algorithm

Contrast adjustment adjusts the contrast of an image by linearly scaling the pixel values between upper and lower limits. Pixel values that are above or below this range are saturated to the upper or lower limit value, respectively.

MATLAB Design

```
design_name = 'mlhdlc_image_scale';
testbench_name = 'mlhdlc_image_scale_tb';
```

Look at the MATLAB design:

```
type(design_name);

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% scale.m
%
% Adjust image contrast by linearly scaling pixel values.
%
```

```

% The input pixel value range has 14bits and output pixel value range is
% 8bits.
%
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

Original Image

Scaled Image

Histogram of original Image

Histogram of equalized Image

Create a New HDL Coder™ Project

```
coder -hdlcoder -new mlhdlc_scale_prj
```

Next, add the file `mlhdlc_image_scale.m` to the project as the MATLAB Function and `mlhdlc_image_scale_tb.m` as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Run Fixed-Point Conversion and HDL Code Generation

Launch the Workflow Advisor from the Workflow Advisor button and right-click on the **Code Generation** step and choose the option **Run to selected task** to run all the steps from the beginning through the HDL code generation.

Examine the generated HDL code by clicking on the hyperlinks in the Code Generation Log window.

Image Enhancement by Histogram Equalization

This example shows how to generate HDL code from a MATLAB® design that does image enhancement using histogram equalization.

Algorithm

The Histogram Equalization algorithm enhances the contrast of images by transforming the values in an intensity image so that the histogram of the output image is approximately flat.

```
I = imread('pout.tif');  
J = histeq(I);  
subplot(2,2,1);  
imshow( I );  
subplot(2,2,2);  
imhist(I)  
subplot(2,2,3);  
imshow( J );  
subplot(2,2,4);  
imhist(J)
```

     YUV_Reg = zeros(3,1);
     x1 = 0; x2 = 0; y1 = 0; y2 = 0;
 end
```

```
 D = [.299 .587 .144; -.147 -.289 .436; .615 -.515 -.1];
 C = [0; 128; 128];
```

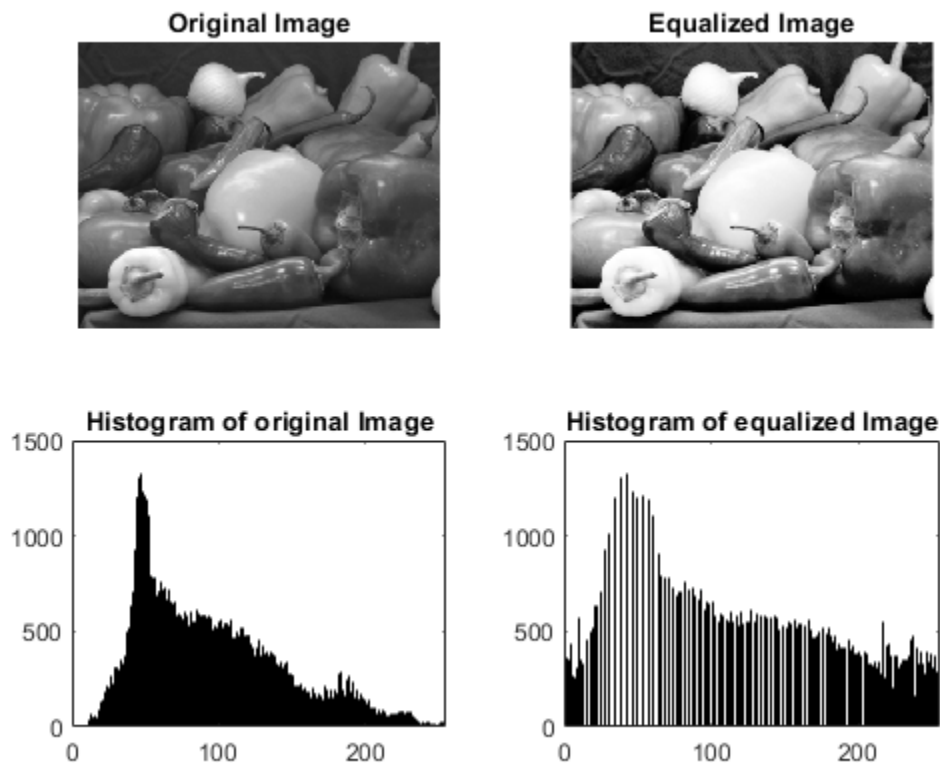

```
 RGB = [r_in; g_in; b_in];
```

```
 YUV_1 = D*RGB_Reg;
 YUV_2 = YUV_1 + C;
 RGB_Reg = RGB;
```

```
 y_data_out = round(YUV_Reg(1));
 u_data_out = round(YUV_Reg(2));
 v_data_out = round(YUV_Reg(3));
 YUV_Reg = YUV_2;
```

```
 x_out = x2; x2 = x1; x1 = x_in;
 y_out = y2; y2 = y1; y1 = y_in;
```

Review the MATLAB test bench:

```
open(testbench_name);
```

```
FRAMES = 1;
```

```

WIDTH = 752;
HEIGHT = 480;
HBLANK = 10;%748;
VBLANK = 10;%120;

% Copyright 2011-2019 The MathWorks, Inc.

vidData = double(imread('mlhdlc_img_yuv.png'));

for f = 1:FRAMES
    vidOut = zeros(HEIGHT, WIDTH, 3);

    for y = 0:HEIGHT+VBLANK-1
        for x = 0:WIDTH+HBLANK-1
            if y >= 0 && y < HEIGHT && x >= 0 && x < WIDTH
                b = vidData(y+1,x+1,1);
                g = vidData(y+1,x+1,2);
                r = vidData(y+1,x+1,3);
            else
                b = 0; g = 0; r = 0;
            end

            [xOut, yOut, yData, uData, vData] = ...
                mlhdlc_rgb2yuv(x, y, r, g, b);

            if yOut >= 0 && yOut < HEIGHT && xOut >= 0 && xOut < WIDTH
                vidOut(yOut+1,xOut+1,:) = [yData vData uData];
            end
        end
    end

    figure(1);
    subplot(1,2,1);
    imshow(uint8(vidData));
    subplot(1,2,2);
    imshow(ybcr2rgb(uint8(vidOut)));
    drawnow;
end

```

Test the MATLAB Algorithm

To avoid run-time errors, simulate the design with the test bench.

```
mlhdlc_rgb2yuv_tb
```

Create an HDL Coder™ Project

To generate HDL code from a MATLAB design:

1. Create a HDL Coder project:

```
coder -hdlcoder -new mlhdlc_rgb_prj
```

2. Add the file `mlhdlc_rgb2yuv.m` to the project as the **MATLAB Function** and `mlhdlc_rgb2yuv_tb.m` as the **MATLAB Test Bench**.

3. Click **Autodefine types** to use the recommended types for the inputs and outputs of the MATLAB function `mlhdlc_rgb2yuv`.

The screenshot shows the MATLAB HDL Coder interface. It is divided into two main sections: "MATLAB Function" and "MATLAB Test Bench".

MATLAB Function: This section contains a table of input variables for the MATLAB function `mlhdlc_rgb2yuv.m`. The variables and their types are:

<code>x_in</code>	<code>double(1 x 1)</code>
<code>y_in</code>	<code>double(1 x 1)</code>
<code>r_in</code>	<code>double(1 x 1)</code>
<code>g_in</code>	<code>double(1 x 1)</code>
<code>b_in</code>	<code>double(1 x 1)</code>

Below the table are two buttons: "Remove MATLAB function" and "Autodefine types".

MATLAB Test Bench: This section contains a single file `mlhdlc_rgb2yuv_tb.m` and an "Add files" button.

At the bottom of the interface, there is a text instruction: "After specifying your design function and test bench above, use the Workflow Advisor to generate code." Below this text is a button labeled "Workflow Advisor".

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Run Fixed-Point Conversion and HDL Code Generation

- 1 Click the **Workflow Advisor** button to start the Workflow Advisor.
- 2 Right click the **HDL Code Generation** task and select **Run to selected task**.

A HDL file `mlhdlc_rgb2yuv_fixpt.vhd` is generated for the MATLAB design. To examine the generated HDL code for the filter design, click the hyperlink to the HDL file in the Code Generation Log window.

High Dynamic Range Imaging

This example shows how to generate HDL code from a MATLAB® design that implements a high dynamic range imaging algorithm.

Algorithm

High Dynamic Range Imaging (HDRI or HDR) is a set of methods used in imaging and photography to allow a greater dynamic range between the lightest and darkest areas of an image than current standard digital imaging methods or photographic methods. HDR images can represent more accurately the range of intensity levels found in real scenes, from direct sunlight to faint starlight, and is often captured by way of a plurality of differently exposed pictures of the same subject matter.

MATLAB Design

```
design_name = 'mlhdlc_hdr';
testbench_name = 'mlhdlc_hdr_tb';
```

Use the `dbtype` function to display the contents of the MATLAB design.

```
dbtype(design_name);

1  function [valid_out, x_out, y_out, ...
2      HDR1, HDR2, HDR3] = mlhdlc_hdr(YShort1, YShort2, YShort3, ...
3      YLong1, YLong2, YLong3, ...
4      plot_y_short_in, plot_y_long_in, ...
5      valid_in, x, y)
6  %

78             HDR(y_out,x_out,3) = HDR3;
79         end
80     end
81 end
82 %% plot HDR
83 HDR_rgb = ntsc2rgb(HDR);
84 subplot(1,3,3);
85 imshow(HDR_rgb, 'InitialMagnification','fit'), title('hdr ');
```

Simulate the Design

It is always a good practice to simulate the design with the testbench prior to code generation to make sure there are no runtime errors.

mlhdlc_hdr_tb

Create a New HDL Coder™ Project

```
coder -hdlcoder -new mlhdlc_hdr_prj
```

Next, add the file 'mlhdlc_hdr.m' to the project as the MATLAB Function and 'mlhdlc_hdr_tb.m' as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Creating Constant Parameter Inputs

This example shows to use pass constant parameter inputs.

In this design the input parameters 'plot_y_short_in' and 'plot_y_long_in' are constant input parameters. You can define them accordingly by modifying the input types as 'constant(double(1x256))'

'plot_y_short_in' and 'plot_y_short_in' are LUT inputs. They are constant folded as double inputs to the design. You will not see port declarations for these two input parameters in the generated HDL code.

Note that inside the design 'mlhdlc_hdr.m' these variables are reassigned so that they get properly fixed-point converted. This is not necessary if these are purely used as constants for defining sizes of variables for example and not part of the logic.

Run Fixed-Point Conversion and HDL Code Generation

Launch HDL Advisor and right click on the 'Code Generation' step and choose the option 'Run to selected task' to run all the steps from the beginning through the HDL code generation.

Convert the Design to Fixed-Point and Generate HDL Code

The following script converts the design to fixed-point, and generate HDL code with a test bench.

```
exArgs = {0,0,0,0,0,0,coder.Constant(ones(1,256)),coder.Constant(ones(1,256)),0,0,0};  
fc = coder.config('fixpt');  
fc.TestBenchName = 'mlhdlc_hdr_tb';  
hc = coder.config('hdl');  
hc.GenerateHDLTestBench = true;  
hc.SimulationIterationLimit = 1000; % Limit number of testbench points  
codegen -float2fixed fc -config hc -args exArgs mlhdlc_hdr
```

Examine the generated HDL code by clicking on the hyperlinks in the Code Generation Log window.

Accelerate Pixel-Streaming Designs Using MATLAB Coder

This example shows how to accelerate a pixel-stream video processing algorithm in MATLAB® by using MATLAB Coder™.

You must have a MATLAB Coder license to run this example.

Acceleration with MATLAB Coder enables you to simulate large frame sizes, such as 1080p video, at practical speeds. Use this acceleration workflow after you have debugged the algorithm using a small frame size. Testing a design with a small image is demonstrated in the “Pixel-Streaming Design in MATLAB” (Vision HDL Toolbox) example.

How MATLAB Coder Works

MATLAB Coder generates C code from MATLAB code. Code generation accelerates simulation by locking-down the sizes and data types of variables. This process removes the overhead of the interpreted language checking for size and data type in every line of code. This example compiles both the test bench file `DesignAccelerationHDLTestBench.m` and the design file `DesignAccelerationHDLDesign.m` into a MEX function, and uses the resulting MEX file to speed up the simulation.

The directive (or pragma) `%#codegen` beneath the function signature indicates that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB code analyzer to help you diagnose and fix violations that would result in errors during code generation. The directive `%#codegen` does not affect interpreted simulation.

Best Practices

Debugging simulations with large frame sizes is impractical in interpreted mode due to long simulation time. However, debugging a MEX simulation is challenging due to lack of debug access into the code.

To avoid these scenarios, a best practice is to develop and verify the algorithm and test bench using a thumbnail frame size. In most cases, the HDL-targeted design can be implemented with no dependence on frame size. Once you are confident that the design and test bench are working correctly, then increase the frame size in the test bench, and use MATLAB Coder to accelerate the simulation. To increase the frame size, test bench only requires minor changes, as you can see by comparing `DesignAccelerationHDLTestBench.m` with the `PixelStreamingDesignHDLTestBench.m` in “Pixel-Streaming Design in MATLAB” (Vision HDL Toolbox).

Test Bench

In the test bench `DesignAccelerationHDLTestBench.m`, the `videoIn` object reads each frame from a video source which is converted from RGB to grayscale, and the `imresize` function interpolates this frame from 240p to 1080p. This 1080p image is passed to the `frm2pix` object, which converts the full image frame to a stream of pixels and control structures. The function `DesignAccelerationHDLDesign` is then called to process one pixel (and its associated control structure) at a time. After we process the entire pixel-stream and collect the output stream, the `pix2frm` object converts the output stream to full-frame video. The `DesignAccelerationHDLViewer` function displays the output and original images side-by-side.

The workflow above is implemented in the following lines of `DesignAccelerationHDLTestBench.m`.

```
for f = 1:numFrm
    frmFull = rgb2gray(readFrame(videoIn));           % Get a new frame
    frmIn = imresize(frmFull,[actLine actPixPerLine]); % Enlarge the frame

    [pixInVec,ctrlInVec] = frm2pix(frmIn);
    for p = 1:numPixPerFrm
        [pixOutVec(p),ctrlOutVec(p)] = DesignAccelerationHDLDesign(pixInVec(p),ctrlInVec(p));
    end
    frmOut = pix2frm(pixOutVec,ctrlOutVec);

    DesignAccelerationHDLViewer(actPixPerLine,actLine,[frmIn uint8(255*frmOut)]);
end
```

The data type of `frmIn` is `uint8` while that of `frmOut`, the edge detection output, is logical. Matrices of different data types cannot be concatenated, so `uint8(255*frmOut)` maps logical false and true to `uint8(0)` and `uint8(255)`, respectively.

Both `frm2pix` and `pix2frm` are used to convert between full-frame and pixel-stream domains. The inner for-loop performs pixel-stream processing. The rest of the test bench performs full-frame processing (i.e., `videoIn`, `scaler`, and `viewer` inside the `DesignAccelerationHDLViewer` function).

Before the test bench terminates, frame rate is displayed to illustrate the simulation speed.

Not all functions used in the test bench support C code generation. For those that do not, such as `tic`, `toc`, `fprintf`, use `coder.extrinsic` to declare them as extrinsic functions. Extrinsic functions are excluded from MEX generation. The simulation executes them in the regular interpreted mode.

Pixel-Stream Design

The function defined in `DesignAccelerationHDLDesign.m` accepts a pixel stream and five control signals, and returns a modified pixel stream and control signals. For more information on the streaming pixel protocol used by System objects from the Vision HDL Toolbox™, see “Streaming Pixel Interface” (Vision HDL Toolbox).

In this example, the function contains the Edge Detector System object.

The focus of this example is the workflow, not the algorithm design itself. Therefore, the design code is quite simple. Once you are familiar with the workflow, it is straightforward to implement advanced video algorithms by taking advantage of the functionality provided by the System objects from Vision HDL Toolbox.

Create MEX File and Simulate the Design

Generate and execute the MEX file.

```
codegen('DesignAccelerationHDLTestBench');
DesignAccelerationHDLTestBench_mex;
```

```
Code generation successful.
```

```
10 frames have been processed in 9.02 seconds.
Average frame rate is 1.11 frames/second.
```

The **viewer** displays the original video on the left, and the output on the right.

HDL Code Generation

Enter the following command to create a new HDL Coder™ project in the temporary folder

```
coder -hdlcoder -new DesignAccelerationProject
```

Then, add the file `DesignAccelerationHDLDesign.m` to the project as the MATLAB Function and `DesignAccelerationHDLTestBench.m` as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a tutorial on creating and populating MATLAB HDL Coder projects.

Launch the Workflow Advisor. In the Workflow Advisor, right-click the 'Code Generation' step. Choose the option 'Run to selected task' to run all the steps from the beginning through HDL code generation.

Examine the generated HDL code by clicking the links in the log window.

Enhanced Edge Detection from Noisy Color Video

This example shows how to develop a complex pixel-stream video processing algorithm, accelerate its simulation using MATLAB® Coder™, and generate HDL code from the design. The algorithm enhances the edge detection from noisy color video.

You must have a MATLAB Coder license to run this example.

This example builds on the “Pixel-Streaming Design in MATLAB” (Vision HDL Toolbox) and the “Accelerate Pixel-Streaming Designs Using MATLAB Coder” (Vision HDL Toolbox) examples.

Test Bench

In the `EnhancedEdgeDetectionHDLTestBench.m` file, the `videoIn` object reads each frame from a color video source, and the `imnoise` function adds salt and pepper noise. This noisy color image is passed to the `frm2pix` object, which converts the full image frame to a stream of pixels and control structures. The function `EnhancedEdgeDetectionHDLDesign.m` is then called to process one pixel (and its associated control structure) at a time. After we process the entire pixel-stream and collect the output stream, the `pix2frm` object converts the output stream to full-frame video. A full-frame reference design `EnhancedEdgeDetectionHDLReference.m` is also called to process the noisy color image. Its output is compared with that of the pixel-stream design. The function `EnhancedEdgeDetectionHDLViewer.m` is called to display video outputs.

The workflow above is implemented in the following lines of `EnhancedEdgeDetectionHDLTestBench.m`.

```

...
frmIn = zeros(actLine,actPixPerLine,3,'uint8');
for f = 1:numFrm
    frmFull = readFrame(videoIn);           % Get a new frame
    frmIn = imnoise(frmFull,'salt & pepper'); % Add noise

    % Call the pixel-stream design
    [pixInVec,ctrlInVec] = frm2pix(frmIn);
    for p = 1:numPixPerFrm
        [pixOutVec(p),ctrlOutVec(p)] = EnhancedEdgeDetectionHDLDesign(pixInVec(p,:),ctrlInVec(p));
    end
    frmOut = pix2frm(pixOutVec,ctrlOutVec);

    % Call the full-frame reference design
    [frmGray,frmDenoise,frmEdge,frmRef] = EnhancedEdgeDetectionHDLReference(frmIn);

    % Compare the results
    if nnz(imabsdiff(frmRef,frmOut))>20
        fprintf('frame %d: reference and design output differ in more than 20 pixels.\n',f);
        return;
    end

    % Display the results
    EnhancedEdgeDetectionHDLViewer(actPixPerLine,actLine,[frmGray frmDenoise uint8(255*[frmEdge
end
...

```

Since `frmGray` and `frmDenoise` are `uint8` data type while `frmEdge` and `frmOut` are logical, `uint8(255x[frmEdge frmOut])` maps logical false and true to `uint8(0)` and `uint8(255)`, respectively, so that matrices can be concatenated.

Both **frm2pix** and **pix2frm** are used to convert between full-frame and pixel-stream domains. The inner for-loop performs pixel-stream processing. The rest of the test bench performs full-frame processing.

Before the test bench terminates, frame rate is displayed to illustrate the simulation speed.

For the functions that do not support C code generation, such as `tic`, `toc`, `imnoise`, and `fprintf` in this example, use **coder.extrinsic** to declare them as extrinsic functions. Extrinsic functions are excluded from MEX generation. The simulation executes them in the regular interpreted mode. Since `imnoise` is not included in the C code generation process, the compiler cannot infer the data type and size of `frmIn`. To fill in this missing piece, we add the statement **frmIn = zeros(actLine,actPixPerLine,3,'uint8')** before the outer for-loop.

Pixel-Stream Design

The function defined in `EnhancedEdgeDetectionHDLDesign.m` accepts a pixel stream and a structure consisting of five control signals, and returns a modified pixel stream and control structure. For more information on the streaming pixel protocol used by System objects from the Vision HDL Toolbox, see the “Streaming Pixel Interface” (Vision HDL Toolbox).

In this example, the **rgb2gray** object converts a color image to grayscale, **medfil** removes the salt and pepper noise. **sobel** highlights the edge. Finally, the **mclose** object performs morphological closing to enhance the edge output. The code is shown below.

```
[pixGray,ctrlGray] = rgb2gray(pixIn,ctrlIn);           % Convert RGB to grayscale
[pixDenoise,ctrlDenoise] = medfil(pixGray,ctrlGray); % Remove noise
[pixEdge,ctrlEdge] = sobel(pixDenoise,ctrlDenoise);  % Detect edges
[pixClose,ctrlClose] = mclose(pixEdge,ctrlEdge);    % Apply closing
```

Full-Frame Reference Design

When designing a complex pixel-stream video processing algorithm, it is a good practice to develop a parallel reference design using functions from the Image Processing Toolbox™. These functions process full image frames. Such a reference design helps verify the implementation of the pixel-stream design by comparing the output image from the full-frame reference design to the output of the pixel-stream design.

The function `EnhancedEdgeDetectionHDLReference.m` contains a similar set of four functions as in the `EnhancedEdgeDetectionHDLDesign.m`. The key difference is that the functions from Image Processing Toolbox process full-frame data.

Due to the implementation difference between `edge` function and `visionhdl.EdgeDetector` System object, reference and design output are considered matching if `frmOut` and `frmRef` differ in no greater than 20 pixels.

Create MEX File and Simulate the Design

Generate and execute the MEX file.

```
codegen('EnhancedEdgeDetectionHDLTestBench');
```

```
Code generation successful.
```

```
EnhancedEdgeDetectionHDLTestBench_mex;
```

```
frame 1: reference and design output differ in more than 20 pixels.
```

The upper video player displays the original color video on the left, and its noisy version after adding salt and pepper noise on the right. The lower video player, from left to right, represents: the grayscale image after color space conversion, the de-noised version after median filter, the edge output after edge detection, and the enhanced edge output after morphological closing operation.

Note that in the lower video chain, only the enhanced edge output (right-most video) is generated from pixel-stream design. The other three are the intermediate videos from the full-frame reference design. To display all of the four videos from the pixel-stream design, you would have written the design file to output four sets of pixels and control signals, and instantiated three more **visionhdl.PixelsToFrame** objects to convert the three intermediate pixel streams back to frames. For the sake of simulation speed and the clarity of the code, this example does not implement the intermediate pixel-stream displays.

HDL Code Generation

To create a new project, enter the following command in the temporary folder

```
coder -hdlcoder -new EnhancedEdgeDetectionProject
```

Then, add the file 'EnhancedEdgeDetectionHDLDesign.m' to the project as the MATLAB Function and 'EnhancedEdgeDetectionHDLTestBench.m' as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a tutorial on creating and populating MATLAB HDL Coder projects.

Launch the Workflow Advisor. In the Workflow Advisor, right-click the 'Code Generation' step. Choose the option 'Run to selected task' to run all the steps from the beginning through HDL code generation.

Examine the generated HDL code by clicking the links in the log window.

Verify Sobel Edge Detection Algorithm in MATLAB-to-HDL Workflow

This example shows the HDL generation and verification of a MATLAB® design for the Sobel edge detection algorithm using the MATLAB HDL Coder™ Workflow Advisor. The MATLAB test bench is reused to verify the HDL using an automatically generated HDL cosimulation System object from HDL Verifier™. Any supported HDL simulator can be used, including Mentor Graphics ModelSim®/Questa®, Cadence Incisive®/Xcelium™, or Xilinx® Vivado® Simulator.

Simulate the Design

It is a good practice to simulate the design with the testbench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_sobel_tb;
```

Create a New HDL Coder Project

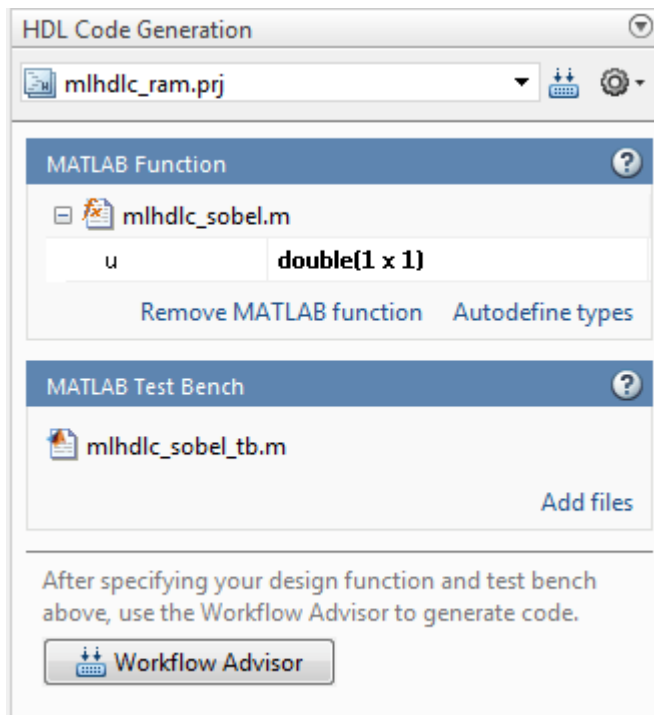

Run the following command to create the HDL code generation project.

```
coder -hdlcoder -new cosim_fil_sobel
```

This action opens a window titled **HDL Coder**.

Specify the Design and the Test Bench

- 1 Drag the file `mlhdlc_sobel.m` from the Current Folder Browser into the Entry Points tab of the HDL Coder window, under the **MATLAB Function** section.
- 2 Drag the file `mlhdlc_sobel_tb.m` into the HDL Coder window, under **MATLAB Test Bench** section.
- 3 Under the `mlhdlc_sobel_tb.m` file, specify the data type of input argument `data_in` as `double (1 x 1)`

Generate HDL Code

- 1 Click **Workflow Advisor**.
- 2 Right click on the **Code Generation** step in Workflow Advisor.
- 3 Choose option **Run to selected task** to run all steps from the beginning of the workflow through to HDL code generation.

Verify Generated HDL Code with Cosimulation

To run this step, you must have one of the HDL simulators supported by HDL Verifier. See “Cosimulation Requirements” (HDL Verifier). You may skip this step if you do not have access to a supported simulator.

- 1 Select the **Generate cosimulation test bench** option.
- 2 Select the **Log outputs for comparison plots** option. This option generates the plotting of the HDL simulator output, the reference MATLAB algorithm output, and the differences between them.
- 3 For **Cosimulate for use with:** select your HDL simulator. The HDL simulator executable must be on your system path.
- 4 To view the waveform in the HDL simulator, select **GUI mode** in the **HDL simulator run mode in cosimulation** list. For Vivado simulator there is no interactive GUI environment. To debug the HDL design, after cosimulation, open the generated file `hdlverifier_cosim_waves.wdb` in Vivado.
- 5 Select **Simulate generated cosimulation test bench**.
- 6 Click **Run**.

When the simulation is complete, check the comparison plots in MATLAB. There should be no mismatch between the HDL simulator output and the reference MATLAB algorithm output.

Verify Generated HDL Code with FPGA-in-the-Loop

To run this step, you must have one of the supported FPGA boards. See “FPGA Verification Requirements” (HDL Verifier) and “Set Up FPGA Design Software Tools” (HDL Verifier).

In the **Verify with FPGA-in-the-Loop** step, perform the following steps:

- 1 Select the **Generate FPGA-in-the-Loop test bench** option.
- 2 Select the **Log outputs for comparison plots** option. This option generates the plotting of the FPGA output, the reference MATLAB algorithm output, and the differences between them.
- 3 Select your FPGA board from the **Board Name** list. If your board is not on the list, click **Launch Board Manager** to create a new board entry. The board manager enables adding new boards in many ways including downloading add-on support packages, cloning from existing boards, or creating one from scratch. See “FPGA Board Manager” (HDL Verifier).
- 4 For boards using Ethernet connections enter your connection information in the **Board IP Address** and **Board MAC Address** fields.
- 5 Leave the **Additional Files** field empty.
- 6 Select **Simulate generated FPGA-in-the-Loop test bench**.
- 7 Click **Run**.

When the simulation is complete, check the comparison plots. There should be no mismatch between the FPGA output and the reference MATLAB algorithm output.

MATLAB Best Practices and Design Patterns for HDL Code Generation

- “Model a Counter for HDL and SystemC Code Generation” on page 3-2
- “Model a State Machine for HDL and SystemC Code Generation” on page 3-4
- “Generate Hardware Instances For Local Functions” on page 3-8
- “Implement RAM Using MATLAB Code” on page 3-10

Model a Counter for HDL and SystemC Code Generation

To write MATLAB code that models hardware and is suitable for HDL and SystemC code generation, use this design pattern.

This design pattern demonstrates best practices for writing MATLAB code for HDL and SystemC code generation:

- Initialize persistent variables to a specific value. In this example, an `if` statement and the `isempty` function initialize the persistent variable. If you do not initialize the persistent variable, then you cannot generate HDL and SystemC code.
- Inside a function, read persistent variables before they are modified so that the persistent variables are inferred as registers.

This Simulink model illustrates the MATLAB counter modeled in this example.

To learn how to model the counter in Simulink, see “Create HDL-Compatible Simulink Model”.

MATLAB Code for the Counter

The function `mlhdlc_counter` is a behavioral model of a 4-bit synchronous up counter. The input signal, `enable_ctr`, triggers the value of the count register, `count_val`, to increase by one. The counter continues to increase by one each time the input is nonzero, until the count reaches a limit of 15. After the counter reaches this limit, the counter returns to zero. A persistent variable, which is initialized to zero, represents the current value of the count. Two `if` statements determine the value of the count based on the input.

To define the `mlhdlc_counter` function, use this code:

```

%#codegen
function count = mlhdlc_counter(enable_ctr)

```

```
%four bit synchronous up counter

%persistent variable for the state
persistent count_val;
if isempty(count_val)
    count_val = 0;
end

%counting up
if enable_ctr
    count_val=count_val+1;

    %limit to four bits
    if count_val>15
        count_val=0;
    end
end

count=count_val;

end
```

Model a State Machine for HDL and SystemC Code Generation

In this section...

“MATLAB Code for the Mealy State Machine” on page 3-4

“MATLAB Code for the Moore State Machine” on page 3-5

The following design pattern shows MATLAB examples of Mealy and Moore state machines which are suitable for HDL and SystemC code generation.

The MATLAB code in these models demonstrates best practices for writing MATLAB models for HDL and SystemC code generation.

- With a `switch` block, use the `otherwise` statement to ensure that the model accounts for all conditions. If the model does not cover all conditions, the generated HDL code can contain errors.
- To designate the states in a state machine, use variables with numerical values.

MATLAB Code for the Mealy State Machine

In a Mealy state machine, the output depends on the state and the input. In a Moore state machine, the output depends only on the state.

The following MATLAB code defines the `mlhdlc_fsm_mealy` function. A persistent variable represents the current state. A `switch` block uses the current state and input to determine the output and new state. In each case in the `switch` block, an `if-else` statement calculates the new state and output.

```

%#codegen
function Z = mlhdlc_fsm_mealy(A)
% Mealy State Machine

% y = f(x,u) :
% all actions are condition actions and
% outputs are function of state and input

% define states
S1 = 0;
S2 = 1;
S3 = 2;
S4 = 3;

persistent current_state;
if isempty(current_state)
    current_state = S1;
end

% switch to new state based on the value state register
switch (current_state)

    case S1,

        % value of output 'Z' depends both on state and inputs
        if (A)
            Z = true;
            current_state = S1;

```

```

    else
        Z = false;
        current_state = S2;
    end

case S2,

    if (A)
        Z = false;
        current_state = S3;
    else
        Z = true;
        current_state = S2;
    end

case S3,

    if (A)
        Z = false;
        current_state = S4;
    else
        Z = true;
        current_state = S1;
    end

case S4,

    if (A)
        Z = true;
        current_state = S1;
    else
        Z = false;
        current_state = S3;
    end

otherwise,

    Z = false;
end

```

MATLAB Code for the Moore State Machine

The following MATLAB code defines the `mlhdlc_fsm_moore` function. A persistent variable represents the current state, and a switch block uses the current state to determine the output and new state. In each case in the switch block, an if-else statement calculates the new state and output. The value of the state is represented by numerical variables.

```

%#codegen
function Z = mlhdlc_fsm_moore(A)
% Moore State Machine

% y = f(x) :
% all actions are state actions and
% outputs are pure functions of state only

% define states
S1 = 0;

```

```
S2 = 1;
S3 = 2;
S4 = 3;

% using persistent keyword to model state registers in hardware
persistent curr_state;
if isempty(curr_state)
    curr_state = S1;
end

% switch to new state based on the value state register
switch (curr_state)

    case S1,

        % value of output 'Z' depends only on state and not on inputs
        Z = true;

        % decide next state value based on inputs
        if (~A)
            curr_state = S1;
        else
            curr_state = S2;
        end

    case S2,

        Z = false;

        if (~A)
            curr_state = S1;
        else
            curr_state = S3;
        end

    case S3,

        Z = false;

        if (~A)
            curr_state = S2;
        else
            curr_state = S4;
        end

    case S4,

        Z = true;
        if (~A)
            curr_state = S3;
        else
            curr_state = S1;
        end

    otherwise,
        Z = false;
end
```

Generate Hardware Instances For Local Functions

In this section...

“MATLAB Local Functions” on page 3-8

“MATLAB Code for mlhdlc_two_counters.m” on page 3-8

The following example shows how to use local functions in MATLAB, so that each execution of a local function corresponds to a separate hardware module in the generated HDL code.

MATLAB Local Functions

This example demonstrates best practices for writing local functions in MATLAB code that is suitable for HDL code generation.

- If your MATLAB code executes a local function multiple times, the generated HDL code does not necessarily instantiate multiple hardware modules. Rather than instantiating multiple hardware modules, multiple calls to a function typically update the state variable.
- If you want the generated HDL code to contain multiple hardware modules corresponding to each execution of a local function, specify two different local functions with the same code but different function names. If you want to avoid code duplication, consider using System objects to implement the behavior in the function, and instantiate the System object multiple times.
- If you want to specify a separate HDL file for each local function in the MATLAB code, in the Workflow Advisor, on the **Advanced** tab in the HDL Code Generation section, select **Generate instantiable code for functions**.

MATLAB Code for mlhdlc_two_counters.m

This function creates two counters and adds the output of these counters. To create two counters, there are two local functions with identical code, `counter` and `counter2`. The main method calls each of these local functions once. If the function were to call the `counter` function twice, separate hardware modules for the counters would not be generated in the HDL code.

```

%#codegen
function total_count = mlhdlc_two_counters(a,b)

%This function contains two different local functions with identical
%counters and calls each counter once.

total_count1=counter(a);

total_count2=counter2(b);

total_count=total_count1+total_count2;

function count = counter(enable_ctr)
%four bit synchronous up counter

%persistent variable for the state
persistent count_val;
if isempty(count_val)
    count_val = 0;

```

```

end

%counting up
if enable_ctr
    count_val=count_val+1;
end

%limit from four bits
if count_val>15
    count_val=0;
end

count=count_val;

function count = counter2(enable_ctr)
%four bit synchronous up counter

%persistent variable for the state
persistent count_val;
if isempty(count_val)
    count_val = 0;
end

%counting up
if enable_ctr
    count_val=count_val+1;
end

%limit from four bits
if count_val>15
    count_val=0;
end

count=count_val;

```

Implement RAM Using MATLAB Code

In this section...

“Implement RAM Using a Persistent Array or System object Properties” on page 3-10

“Implement RAM Using hdl.RAM” on page 3-11

You can write MATLAB code that maps to RAM during HDL code generation by using:

- Persistent arrays or private properties in a user-defined System object.
- `hdl.RAM` System objects.

The following examples model the same line delay in MATLAB. The line delay uses memory in a ring structure. Data is written to one location and read from another location in such a way that the data written is read after a delay of a specific number of cycles. The RAM read address is generated by a counter. The write address is generated by adding a constant value to the read address.

Implement RAM Using a Persistent Array or System object Properties

This example shows a line delay that implements the RAM behavior using a persistent array with the function `mlhdlc_hdlram_persistent`. Changing a specific value in the persistent array is equivalent to writing to the RAM. Accessing a specific value in the array is equivalent to reading from the RAM.

You can implement RAM by using user-defined System object private properties in the same way.

```

%#codegen
function data_out = mlhdlc_hdlram_persistent(data_in)

persistent hRam;
if isempty(hRam)
    hRam = zeros(128,1);
end

% read address counter
persistent rdAddrCtr;
if isempty(rdAddrCtr)
    rdAddrCtr = 1;
end

% ring counter length
ringCtrLength = 10;
ramWriteAddr = rdAddrCtr + ringCtrLength;

ramWriteData = data_in;
%ramWriteEnable = true;

ramReadAddr = rdAddrCtr;

% To write and read the memory, manipulate the values in the array

hRam(ramWriteAddr)=ramWriteData;
ramRdDout=hRam(ramReadAddr);

rdAddrCtr = rdAddrCtr + 1;

```

```
data_out = ramRdDout;
```

Implement RAM Using hdl.RAM

This example shows a line delay that implements the RAM behavior using `hdl.RAM` with the function, `mlhdlc_hdlram_sysobj`. In this function, the `step` method of the `hdl.RAM` System object reads and writes to specific locations in `hRam`. Code generation from `hdl.RAM` has the same restrictions as code generation from other System objects. For details, see “Limitations of HDL Code Generation for System Objects” on page 1-16.

```
%#codegen
function data_out = mlhdlc_hdlram_sysobj(data_in)
persistent hRam;
if isempty(hRam)
    hRam = hdl.RAM('RAMType', 'Dual port');
end

% read address counter
persistent rdAddrCtr;
if isempty(rdAddrCtr)
    rdAddrCtr = 0;
end

% ring counter length
ringCtrLength = 10;
ramWriteAddr = rdAddrCtr + ringCtrLength;

ramWriteData = data_in;
ramWriteEnable = true;

ramReadAddr = rdAddrCtr;

% To write and read the memory, call the RAM object
[~, ramRdDout] = hRam(ramWriteData, ramWriteAddr, ...
    ramWriteEnable, ramReadAddr);

rdAddrCtr = rdAddrCtr + 1;

data_out = ramRdDout;
```

Specify Type Proposal Options

Basic Type Proposal Settings	Values	Description
Fixed-point type proposal mode	Propose fraction lengths for specified word length	Use the specified word length for data type proposals and propose the minimum fraction lengths to avoid overflows.
	Propose word lengths for specified fraction length (default)	Use the specified fraction length for data type proposals and propose the minimum word lengths to avoid overflows.
Default word length	14 (default)	Default word length to use when Fixed-point type proposal mode is set to Propose fraction lengths for specified word lengths
Default fraction length	4 (default)	Default fraction length to use when Fixed-point type proposal mode is set to Propose word lengths for specified fraction lengths

Advanced Type Proposal Settings	Values	Description
When proposing types	ignore simulation ranges	Propose data types based on derived ranges.
Note Manually-entered static ranges always take precedence over simulation ranges.	ignore derived ranges	Propose data types based on simulation ranges.
	use all collected data (default)	Propose data types based on both simulation and derived ranges.
Propose target container types	Yes	Propose data type with the smallest word length that can represent the range and is suitable for C code generation (8,16,32, 64 ...). For example, for a variable with range [0 . . 7], propose a word length of 8 rather than 3.
	No (default)	Propose data types with the minimum word length needed to represent the value.
Optimize whole numbers	No	Do not use integer scaling for variables that were whole numbers during simulation.
	Yes (default)	Use integer scaling for variables that were whole numbers during simulation.

Advanced Type Proposal Settings	Values	Description
Signedness	Automatic (default)	Proposes signed and unsigned data types depending on the range information for each variable.
	Signed	Propose signed data types.
	Unsigned	Propose unsigned data types.
Safety margin for sim min/max (%)	0 (default)	Specify safety factor for simulation minimum and maximum values. The simulation minimum and maximum values are adjusted by the percentage designated by this parameter, allowing you to specify a range different from that obtained from the simulation run. For example, a value of 55 specifies that you want a range at least 55 percent larger. A value of -15 specifies that a range up to 15 percent smaller is acceptable.
Search paths	' ' (default)	Add paths to the list of paths to search for MATLAB files. Separate list items with a semicolon.

fimath Settings	Values	Description
Rounding method	Ceiling	Specify the fimath properties for the generated fixed-point data types. The default fixed-point math properties use the Floor rounding and Wrap overflow. These settings generate the most efficient code but might cause problems with overflow.
	Convergent	
	Floor (default)	
	Nearest	
	Round	
	Zero	
Overflow action	Saturate	After code generation, if required, modify these settings to optimize the generated code, or example, avoid overflow or eliminate bias, and then rerun the verification.
	Wrap (default)	
Product mode	FullPrecision (default)	For more information on fimath properties, see "fimath Object Properties".
	KeepLSB	
	KeepMSB	
	SpecifyPrecision	
Sum mode	FullPrecision (default)	For more information on fimath properties, see "fimath Object Properties".
	KeepLSB	
	KeepMSB	
	SpecifyPrecision	

Generated File Settings	Value	Description
Generated fixed-point file name suffix	_fixpt (default)	Specify the suffix to add to the generated fixed-point file names.

Plotting and Reporting Settings	Values	Description
Custom plot function	' ' (default)	Specify the name of a custom plot function to use for comparison plots.
Plot with Simulation Data Inspector	No (default)	Specify whether to use the Simulation Data Inspector for comparison plots.
	Yes	
Highlight potential data type issues	No (default)	Specify whether to highlight potential data types in the generated html report. If this option is turned on, the report highlights single-precision, double-precision, and expensive fixed-point operation usage in your MATLAB code.
	Yes	

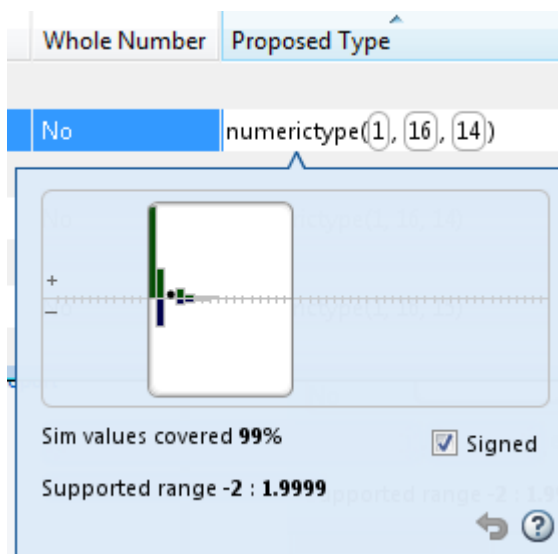

Log Data for Histogram

To log data for histograms:

- 1 In the Fixed-Point Conversion window, click **Run Simulation** and select **Log data for histogram**, and then click the Run Simulation button.

The simulation runs and the simulation minimum and maximum ranges are displayed on the **Variables** tab. Using the simulation range data, the software proposes fixed-point types for each variable based on the default type proposal settings, and displays them in the **Proposed Type** column.

- 2 To view a histogram for a variable, click the variable's **Proposed Type** field.

- 3 You can view the effect of changing the proposed data types by:
 - Selecting and dragging the white bounding box in the histogram window. This action does not change the word length of the proposed data type, but modifies the position of the binary point within the word so that the fraction length of the proposed data type changes.
 - Selecting and dragging the left edge of the bounding box to increase or decrease the word length. This action does not change the fraction length or the position of the binary point.

- Selecting and dragging the right edge to increase or decrease the fraction length of the proposed data type. This action does not change the position of the binary point. The word length changes to accommodate the fraction length.
- Selecting or clearing **Signed**. Clear **Signed** to ignore negative values.

Before committing changes, you can revert to the types proposed by the automatic conversion by clicking .

View and Modify Variable Information

View Variable Information

In the Fixed-Point Conversion tool, you can view information about the variables in the MATLAB functions. To view information about the variables for the selected function, use the **Variables** tab or pause over a variable in the code window. For more information, see “Viewing Variables” on page 4-14.

You can view the variable information:

- **Variable**

Variable name. Variables are classified and sorted as inputs, outputs, persistent, or local variables.

- **Type**

The original size, type, and complexity of each variable.

- **Sim Min**

The minimum value assigned to the variable during simulation.

- **Sim Max**

The maximum value assigned to the variable during simulation.

To search for a variable in the MATLAB code window and on the **Variables** tab, use `Ctrl+F`.

Modify Variable Information

If you modify variable information, the app highlights the modified values using bold text. You can modify the following fields:

- **Static Min**

You can enter a value for **Static Min** into the field or promote **Sim Min** information. See “Promote Sim Min and Sim Max Values” on page 4-8.

Editing this field does not trigger static range analysis, but the app uses the edited values in subsequent analyses.

- **Static Max**

You can enter a value for **Static Max** into the field or promote **Sim Max** information. See “Promote Sim Min and Sim Max Values” on page 4-8.

Editing this field does not trigger static range analysis, but the app uses the edited values in subsequent analyses.

- **Whole Number**

The app uses simulation data to determine whether the values assigned to a variable during simulation were always integers. You can manually override this field.

Editing this field does not trigger static range analysis, but the app uses the edited value in subsequent analyses.

- **Proposed Type**

You can modify the signedness, word length, and fraction length settings individually:

- On the **Variables** tab, modify the value in the **ProposedType** field.

- In the code window, select a variable, and then modify the **Proposed Type** field.

If you selected to log data for a histogram, the histogram dynamically updates to reflect the modifications to the proposed type. You can also modify the proposed type in the histogram, see “Histogram” on page 4-19.

Revert Changes

- To clear results and revert edited values, right-click the **Variables** tab and select **Reset entire table**.
- To revert the type of a selected variable to the type computed by the app, right-click the field and select **Undo changes**.
- To revert changes to variables, right-click the field and select **Undo changes for all variables**.
- To clear a static range value, right-click an edited field and select **Clear this static range**.
- To clear manually entered static range values, right-click anywhere on the **Variables** tab and select **Clear all manually entered static ranges**.

Promote Sim Min and Sim Max Values

With the app, you can promote simulation minimum and maximum values to static minimum and maximum values. This capability is useful if you have not specified static ranges and you have simulated the model with inputs that cover the full intended operating range.

To copy:

- A simulation range for a selected variable, select a variable, right-click, and then select **Copy sim range**.
- Simulation ranges for top-level inputs, right-click the Static Min or Static Max column, and then select **Copy sim ranges for all top-level inputs**.
- Simulation ranges for persistent variables, right-click the Static Min or Static Max column, and then select **Copy sim ranges for all persistent variables**.

License Requirements

Fixed-point conversion requires the following licenses:

- Fixed-Point Designer
- MATLAB Coder™

Automated Fixed-Point Conversion Capabilities

You can convert floating-point MATLAB code to fixed-point code using the Fixed-Point Conversion tool in HDL Coder projects. You can choose to propose data types based on simulation range data, derived (also known as static) range data, or both.

You can manually enter static ranges. These manually-entered ranges take precedence over simulation ranges and the tool uses them when proposing data types. In addition, you can modify and lock the proposed type so that the tool cannot change it. For more information, see “Locking Proposed Data Types” on page 4-14.

For a list of supported MATLAB features and functions, see “MATLAB Language Features Supported for Automated Fixed-Point Conversion”.

During fixed-point conversion, you can:

- Verify that your test files cover the full intended operating range of your algorithm using code coverage results.
- Propose fraction lengths based on default word lengths.
- Propose word lengths based on default fraction lengths.
- Optimize whole numbers.
- Specify safety margins for simulation min/max data.

- Validate that you can build your project with the proposed data types.
- Test numerics by running the test bench with the fixed-point types applied.
- View a histogram of bits used by each variable.
- Detect overflows.

Code Coverage

By default, the Fixed-Point Conversion tool shows code coverage results. Your test files must exercise the algorithm over its full operating range so that the simulation ranges are accurate. The quality of the proposed fixed-point data types depends on how well the test files cover the operating range of the algorithm with the accuracy that you want. Reviewing code coverage results helps you verify that your test files are exercising the algorithm adequately. If the code coverage is inadequate, modify the test files or add more test files to increase coverage. If you simulate multiple test files in one run, the tool displays cumulative coverage. However, if you specify multiple test files but run them one at a time, the tool displays the coverage of the file that ran last.

The tool displays a color-coded coverage bar to the left of the code.

```

1  function y = ex_2ndOrder_filter(x) %#codegen
2      persistent z
3      if isempty(z)
4          z = zeros(2,1);
5      end
6      % [b,a] = butter(2, 0.25)
7      b = [0.0976310729378175, 0.195262145875635, 0.0976310729378175];
8      a = [
9          1, -0.942809041582063, 0.333333333333333];
10
11     y = zeros(size(x));
12     for i=1:length(x)
13         y(i) = b(1)*x(i) + z(1);
14         z(1) = b(2)*x(i) + z(2) - a(2) * y(i);
15         z(2) = b(3)*x(i) - a(3) * y(i);
16     end
17 end

```

This table describes the color coding.

Coverage Bar Color	Indicates
Green	<p>One of the following situations:</p> <ul style="list-style-type: none"> The entry-point function executes multiple times and the code executes more than one time. The entry-point function executes one time and the code executes one time. <p>Different shades of green indicate different ranges of line execution counts. The darkest shade of green indicates the highest range.</p>
Orange	The entry-point function executes multiple times, but the code executes one time.
Red	Code does not execute.

When you pause over the coverage bar, the color highlighting extends over the code. For each section of code, the app displays the number of times that section executes.

```

1 function y = ex_2ndOrder_filter(x) %#codegen 3 calls
2     persistent z
3     if isempty(z)
4         z = zeros(2,1); 1 calls
5     end 3 calls
6     % [b,a] = butter(2, 0.25)
7     b = [0.0976310729378175, 0.195262145875635, 0.0976310729378175];
8     a = [ 1, -0.942809041582063, 0.333333333333333];
9
10
11     y = zeros(size(x));
12     for i=1:length(x) 768 calls
13         y(i) = b(1)*x(i) + z(1);
14         z(1) = b(2)*x(i) + z(2) - a(2) * y(i);
15         z(2) = b(3)*x(i) - a(3) * y(i);
16     end
17 end 3 calls

```

To verify that your test files are testing your algorithm over the intended operating range, review the code coverage results.

Coverage Bar Color	Action
Green	If you expect sections of code to execute more frequently than the coverage shows, either modify the MATLAB code or the test files.
Orange	This behavior is expected for initialization code, for example, the initialization of persistent variables. If you expect the code to execute more than one time, either modify the MATLAB code or the test files.

Coverage Bar Color	Action
Red	If the code that does not execute is an error condition, this behavior is acceptable. If you expect the code to execute, either modify the MATLAB code or the test files. If the code is written conservatively and has upper and lower boundary limits, and you cannot modify the test files to reach this code, add static minimum and maximum values. See “Computing Derived Ranges” on page 4-13.

Code coverage is on by default. Turn it off only after you have verified that you have adequate test file coverage. Turning off code coverage can speed up simulation. To turn off code coverage, in the Fixed-Point Conversion tool:

- 1 Click **Run Simulation**.
- 2 Clear Show code coverage.

Proposing Data Types

In the **Define Input Types** step, you specify a test bench that calls the MATLAB function. The tool runs the test file to analyze the code and infer the types for entry-point input arguments.

The Fixed-Point Conversion tool proposes fixed-point data types based on computed ranges and the word length or fraction length setting. The computed ranges are based on simulation range data, derived range data, or both. If you run a simulation and compute derived ranges, the conversion tool merges the simulation and derived ranges.

Note You cannot propose data types based on derived ranges for MATLAB classes.

You can manually enter static ranges. These manually-entered ranges take precedence over simulation ranges and the tool uses them when proposing data types. If you analyze ranges using derived range analysis alone, you must enter static ranges. In addition, you can modify and lock the proposed type so that the tool cannot change it. For more information, see “Locking Proposed Data Types” on page 4-14.

Running a Simulation

When you open the Fixed-Point Conversion tool, the tool generates an instrumented MEX function for your MATLAB design. If the build completes without errors, the tool displays compiled information (type, size, complexity) for functions and variables in your code. To navigate to local functions, click the **Functions** tab. If build errors occur, the tool provides error messages that link to the line of code that caused the build issues. You must address these errors before running a simulation. Use the link to navigate to the offending line of code in the MATLAB editor and modify the code to fix the issue. If your code uses functions that are not supported for fixed-point conversion, the tool displays them on the **Function Replacements** tab. See “Function Replacements” on page 4-20.

Before running a simulation, specify the test bench that you want to run. When you run a simulation, the tool runs the test bench, calling the instrumented MEX function. If you modify the MATLAB design code, the tool automatically generates an updated MEX function before running the test bench.

If the test bench runs successfully, the simulation minimum and maximum values and the proposed types are displayed on the **Variables** tab. If you manually enter static ranges for a variable, the manually-entered ranges take precedence over the simulation ranges. If you manually modify the proposed types by typing or using the histogram, the data types are locked so that the tool cannot modify them.

If the test bench fails, the errors are displayed on the **Simulation Output** tab.

The test bench should exercise your algorithm over its full operating range. The quality of the proposed fixed-point data types depends on how well the test bench covers the operating range of the algorithm with the desired accuracy.

Optionally, you can select to log data for histograms. After running a simulation, you can view the histogram for each variable. For more information, see “Histogram” on page 4-19.

Computing Derived Ranges

The advantage of proposing data types based on derived ranges is that you do not have to provide test files that exercise your algorithm over its full operating range. Running such test files often takes a very long time.

To compute derived ranges and propose data types based on these ranges, provide static minimum and maximum values or proposed data types for all input variables. To improve the analysis, enter as much static range information as possible for other variables. You can manually enter ranges or promote simulation ranges to use as static ranges. Manually-entered static ranges always take precedence over simulation ranges.

If you know what data type your hardware target uses, set the proposed data types to match this type. Manually-entered data types are locked so that the tool cannot modify them. The tool uses these data types to calculate the input minimum and maximum values and to derive ranges for other variables. For more information, see “Locking Proposed Data Types” on page 4-14.

When you select **Compute Derived Ranges**, the tool runs a derived range analysis to compute static ranges for variables in your MATLAB algorithm. When the analysis is complete, the static ranges are displayed on the **Variables** tab. If the run produces +/- Inf derived ranges, consider defining ranges for all persistent variables.

Optionally, you can select **Quick derived range analysis**. With this option, the conversion tool performs faster static analysis. The computed ranges might be larger than necessary. Select this option in cases where the static analysis takes more time than you can afford.

If the derived range analysis for your project is taking a long time, you can optionally set a timeout. The tool aborts the analysis when the timeout is reached.

Locking Proposed Data Types

You can lock proposed data types against changes by the Fixed-Point Conversion tool using one of the following methods:

- Manually setting a proposed data type in the Fixed-Point Conversion tool.
- Right-clicking a type proposed by the tool and selecting **Lock computed value**.

The tool displays locked data types in bold so that they are easy to identify. You can unlock a type using one of the following methods:

- Manually overwriting it.
- Right-clicking it and selecting **Undo changes**. This action unlocks only the selected type.
- Right-clicking and selecting **Undo changes for all variables**. This action unlocks all locked proposed types.

Viewing Functions

You can view a list of functions in your project on the **Navigation** pane. This list also includes function specializations and class methods. When you select a function from the list, the MATLAB code for that function or class method is displayed in the Fixed-Point Conversion tool code window.

After conversion, the left pane also displays a list of output files including the fixed-point version of the original algorithm. If your function is not specialized, the conversion retains the original function name in the fixed-point filename and appends the fixed-point suffix. For example, the fixed-point version of `fun_with_matlab.m` is `fun_with_matlab_fixpt.m`.

Viewing Variables

The **Variables** tab provides the following information for each variable in the function selected in the **Navigation** pane:

- **Type** — The original data type of the variable in the MATLAB algorithm.
- **Sim Min** and **Sim Max** — The minimum and maximum values assigned to the variable during simulation.

You can edit the simulation minimum and maximum values. Edited fields are shown in bold. Editing these fields does not trigger static range analysis, but the tool uses the edited values in subsequent analyses. You can revert to the types proposed by the tool.

- **Static Min** and **Static Max** — The static minimum and maximum values.

To compute derived ranges and propose data types based on these ranges, provide static minimum and maximum values for all input variables. To improve the analysis, enter as much static range information as possible for other variables.

When you compute derived ranges, the Fixed-Point Conversion tool runs a static analysis to compute static ranges for variables in your code. When the analysis is complete, the static ranges are displayed. You can edit the computed results. Edited fields are shown in bold. Editing these fields does not trigger static range analysis, but the tool uses the edited values in subsequent analyses. You can revert to the types proposed by the tool.

- **Whole Number** — Whether all values assigned to the variable during simulation are integers.

The Fixed-Point Conversion tool determines whether a variable is always a whole number. You can modify this field. Edited fields are shown in bold. Editing these fields does not trigger static range analysis, but the tool uses the edited values in subsequent analyses. You can revert to the types proposed by the tool.

- The proposed fixed-point data type for the specified word (or fraction) length. Proposed data types use the `numericType` notation. For example, `numericType(1,16,12)` denotes a signed fixed-point type with a word length of 16 and a fraction length of 12. `numericType(0,16,12)` denotes an unsigned fixed-point type with a word length of 16 and a fraction length of 12.

Because the tool does not apply data types to expressions, it does not display proposed types for them. Instead, it displays their original data types.

You can also view and edit variable information in the code pane by placing your cursor over a variable name.

You can use `Ctrl+F` to search for variables in the MATLAB code and on the **Variables** tab. The tool highlights occurrences in the code and displays only the variable with the specified name on the **Variables** tab.

Viewing Information for MATLAB Classes

The tool displays:

- Code for MATLAB classes and code coverage for class methods in the code window. Use the **Function** list in the Navigation bar to select which class or class method to view.

Variable	Type	Sim Min	Sim Max	Static Min	Static Max	Whole Number	Proposed Type
Input							
this	Counter	Unknown	Unknown			No	
this.Value	double	0	1024			Yes	numerictype(0, 11, 0)
Output							
v	double	0	1024			Yes	numerictype(0, 11, 0)

Specializations

If a function is specialized, the tool lists each specialization and numbers them sequentially. For example, consider a function, `dut`, that calls subfunctions, `foo` and `bar`, multiple times with different input types.

```

function y = dut(u, v)

tt1 = foo(u);
tt2 = foo([u v]);
tt3 = foo(complex(u,v));

ss1 = bar(u);
ss2 = bar([u v]);
ss3 = bar(complex(u,v));
    
```

```

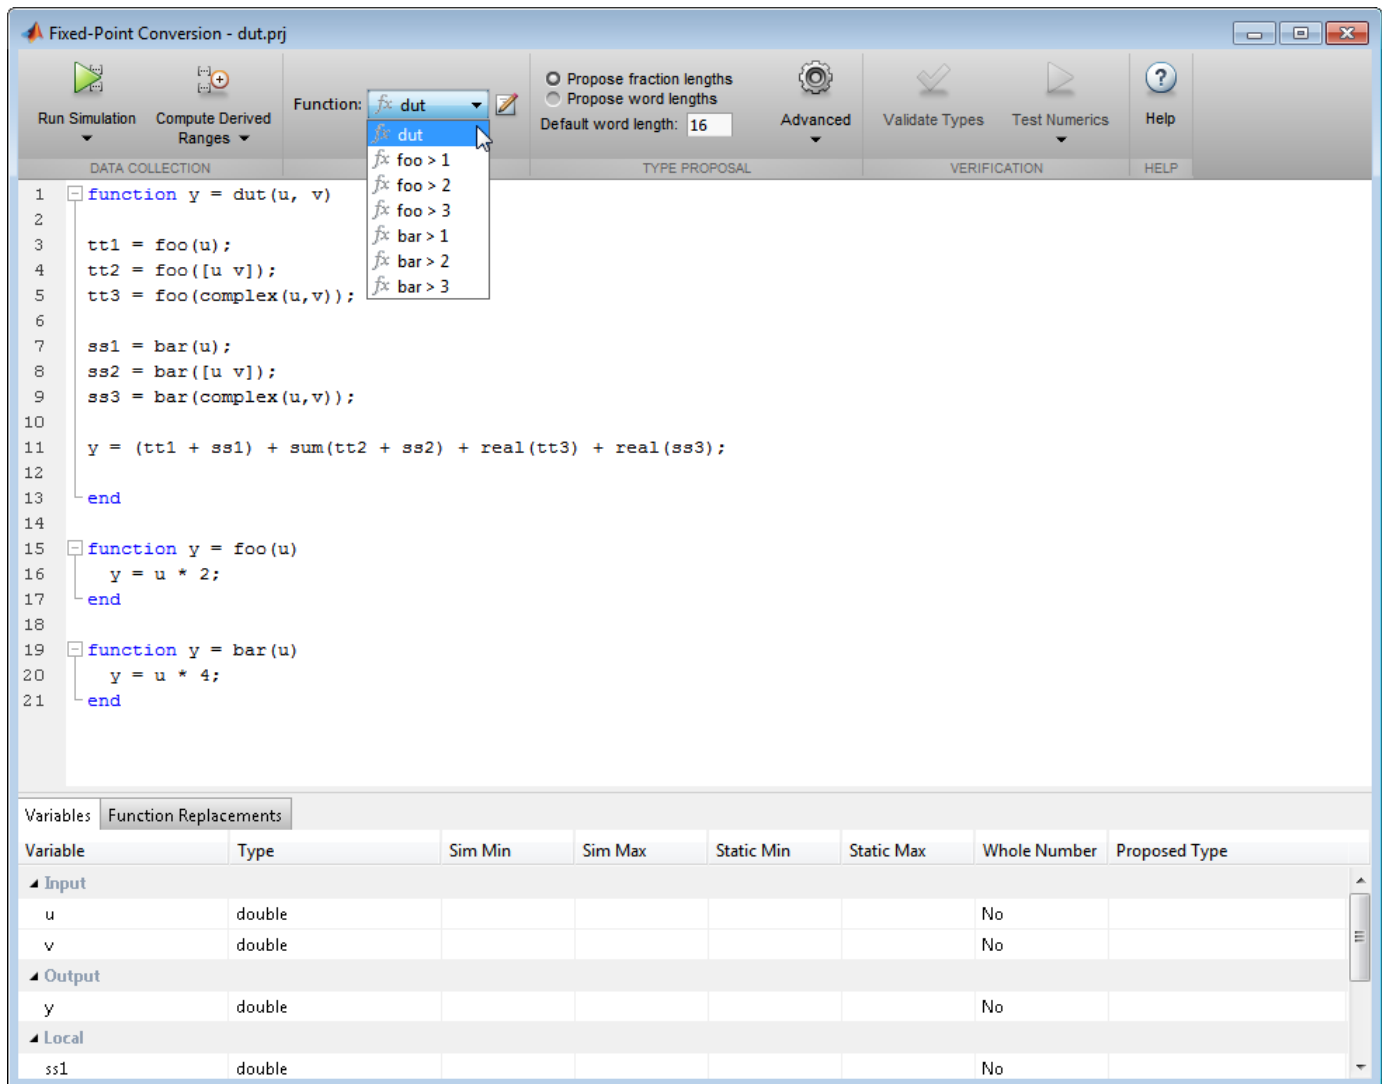

y = (tt1 + ss1) + sum(tt2 + ss2) + real(tt3) + real(ss3);

end

function y = foo(u)
    y = u * 2;
end

function y = bar(u)
    y = u * 4;
end

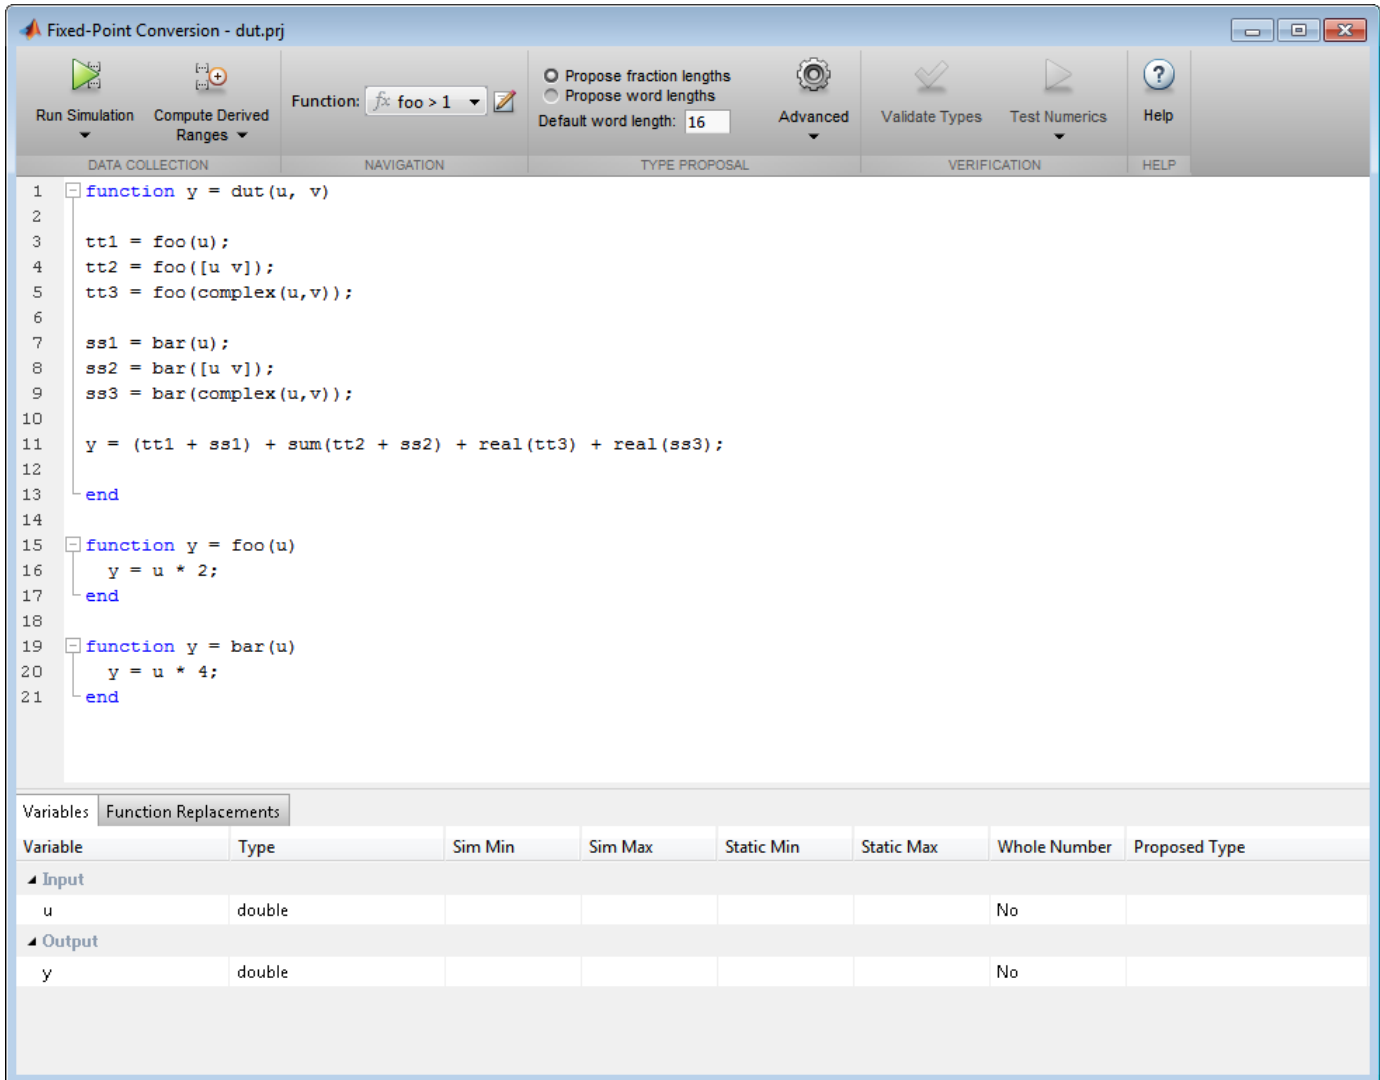

```

The screenshot shows the Fixed-Point Conversion tool interface. The 'Function:' dropdown menu is open, showing options for 'dut', 'foo > 1', 'foo > 2', 'foo > 3', 'bar > 1', 'bar > 2', and 'bar > 3'. The main code editor shows the MATLAB code from the previous block. The 'Variables' tab is active, displaying a table of variables and their types.

Variable	Type	Sim Min	Sim Max	Static Min	Static Max	Whole Number	Proposed Type
Input							
u	double					No	
v	double					No	
Output							
y	double					No	
Local							
ss1	double					No	

If you select a specialization, the app displays only the variables used by the specialization.

The screenshot shows the 'Fixed-Point Conversion - dut.prj' window. The top toolbar includes buttons for 'Run Simulation', 'Compute Derived Ranges', 'Function: foo > 1', 'Propose fraction lengths', 'Propose word lengths', 'Default word length: 16', 'Advanced', 'Validate Types', 'Test Numerics', and 'Help'. Below the toolbar are tabs for 'DATA COLLECTION', 'NAVIGATION', 'TYPE PROPOSAL', 'VERIFICATION', and 'HELP'. The main area displays source code for three functions: 'dut', 'foo', and 'bar'. The 'Function Replacements' table at the bottom shows the mapping of variables to their types and proposed fixed-point types.

```

1 function y = dut(u, v)
2
3     tt1 = foo(u);
4     tt2 = foo([u v]);
5     tt3 = foo(complex(u,v));
6
7     ss1 = bar(u);
8     ss2 = bar([u v]);
9     ss3 = bar(complex(u,v));
10
11     y = (tt1 + ss1) + sum(tt2 + ss2) + real(tt3) + real(ss3);
12
13 end
14
15 function y = foo(u)
16     y = u * 2;
17 end
18
19 function y = bar(u)
20     y = u * 4;
21 end

```

Variable	Type	Sim Min	Sim Max	Static Min	Static Max	Whole Number	Proposed Type
Input							
u	double					No	
Output							
y	double					No	

In the generated fixed-point code, the number of each fixed-point specialization matches the number in the Source Code list which makes it easy to trace between the floating-point and fixed-point versions of your code. For example, the generated fixed-point function for `foo > 1` is named `foo_s1`.

```

1  %%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
2  %
3  %       Generated by MATLAB 8.4 and Fixed-Point Designer 4.3
4  %
5  %%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
6  %#codegen
7  function y = dut_fixpt(u, v)
8
9      fm = fimath('RoundingMethod', 'Floor', 'OverflowAction', 'Wrap', 'ProductMode', 'FullPrecision', 'MaxProductWordLength', 128, 'SumMode', 'Full
10
11      tt1 = fi(foo_s1(u), 0, 5, 0, fm);
12      tt2 = fi(foo_s2([fi(u, 0, 5, 0, fm) v]), 0, 6, 0, fm);
13      tt3 = fi(foo_s3(complex(u,v)), 0, 6, 0, fm);
14
15      ss1 = fi(bar_s1(u), 0, 6, 0, fm);
16      ss2 = fi(bar_s2([fi(u, 0, 5, 0, fm) v]), 0, 7, 0, fm);
17      ss3 = fi(bar_s3(complex(u,v)), 0, 7, 0, fm);
18
19      y = fi((tt1 + ss1) + sum(tt2 + ss2) + real(tt3) + real(ss3), 0, 9, 0, fm);
20
21  end
22
23  function y = foo_s1(u)
24      fm = fimath('RoundingMethod', 'Floor', 'OverflowAction', 'Wrap', 'ProductMode', 'FullPrecision', 'MaxProductWordLength', 128, 'SumMode', 'Fu
25
26      y = fi(u * fi(2, 0, 2, 0, fm), 0, 5, 0, fm);
27  end
28
29  function y = foo_s2(u)
30      fm = fimath('RoundingMethod', 'Floor', 'OverflowAction', 'Wrap', 'ProductMode', 'FullPrecision', 'MaxProductWordLength', 128, 'SumMode', 'Fu
31
32      y = fi(u * fi(2, 0, 2, 0, fm), 0, 6, 0, fm);
33  end
34

```

Histogram

To log data for histograms, in the Fixed-Point Conversion window, click **Run Simulation** and select **Log data for histogram**, and then click the **Run Simulation** button.

After simulation, to view the histogram for a variable, on the **Variables** tab, click the **Proposed Type** field for that variable.

The histogram provides the range of the proposed data type and the percentage of simulation values that the proposed data type covers. The bit weights are displayed along the X-axis, and the percentage of occurrences along the Y-axis. Each bin in the histogram corresponds to a bit in the binary word. For example, this histogram displays the range for a variable of type `numericity(1,16,14)`.

You can view the effect of changing the proposed data types by:

- Dragging the edges of the bounding box in the histogram window to change the proposed data type.

- Selecting or clearing **Signed**.

To revert to the types proposed by the automatic conversion, in the histogram window, click .

Function Replacements

If your MATLAB code uses functions that do not have fixed-point support, the tool lists these functions on the **Function Replacements** tab. You can choose to replace unsupported functions with a custom function replacement or with a lookup table.

Variables		Function Replacements		Simulation Output		
Enter a function to replace					Custom Function	+ -
Function or Operator	Replacement					
▲ Custom Function	<i>Function Name</i>					
foo	foo_fixedpoint					
▲ Lookup Table	<i>Interpolation Method</i>	<i>Design Min</i>	<i>Design Max</i>	<i>Number of Points</i>		
exp	None	Auto	Auto	1000		

You can add and remove function replacements from this list. If you enter a function replacements for a function, the replacement function is used when you build the project. If you do not enter a replacement, the tool uses the type specified in the original MATLAB code for the function.

Note Using this table, you can replace the names of the functions but you cannot replace argument patterns.

Validating Types

Selecting **Validate Types** validates the build using the proposed fixed-point data types. If the validation is successful, you are ready to test the numerical behavior of the fixed-point MATLAB algorithm.

If the errors or warnings occur during validation, they are displayed on the **Type Validation Output** tab. If errors or warning occur:

- On the **Variables** tab, inspect the proposed types and manually modified types to verify that they are valid.
- On the **Function Replacements** tab, verify that you have provided function replacements for unsupported functions.

Testing Numerics

After validating the proposed fixed-point data types, select **Test Numerics** to verify the behavior of the fixed-point MATLAB algorithm. By default, if you added a test bench to define inputs or run a simulation, the tool uses this test bench to test numerics. The tool compares the numerical behavior of the generated fixed-point MATLAB code with the original floating-point MATLAB code. If you select to log inputs and outputs for comparison plots, the tool generates an additional plot for each scalar output. This plot shows the floating-point and fixed-point results and the difference between them. For non-scalar outputs, only the error information is shown.

If the numerical results do not meet your desired accuracy after fixed-point simulation, modify fixed-point data type settings and repeat the type validation and numerical testing steps. You might have to iterate through these steps multiple times to achieve the desired results.

Detecting Overflows

When testing numerics, selecting **Use scaled doubles to detect overflows** enables overflow detection. When this option is selected, the conversion tool runs the simulation using scaled double versions of the proposed fixed-point types. Because scaled doubles store their data in double-

precision floating-point, they carry out arithmetic in full range. They also retain their fixed-point settings, so they are able to report when a computation goes out of the range of the fixed-point type. .

If the tool detects overflows, on its Overflow tab, it provides:

- A list of variables and expressions that overflowed
- Information on how much each variable overflowed
- A link to the variables or expressions in the code window

Variables	Function Replacements	Overflows	
	Function	Line	Description
	overflow_fixpt	7	Overflow error in expression 'x'.
	overflow_fixpt	7	Overflow error in expression 'y'.
	overflow_fixpt	10	Overflow error in expression 'z'.
	overflow_fixpt	10	Overflow error in expression 'z = fi(x*y, 0, 8, 0, fm)'.
	overflow_fixpt	10	Overflow error in expression 'fi(x*y, 0, 8, 0, fm)'.
	overflow_fixpt	10	Overflow error in expression 'x'.
	overflow_fixpt	10	Overflow error in expression 'x*y'.
	overflow_fixpt	10	Overflow error in expression 'y'.
	overflow_fixpt	11	Overflow error in expression 'z'.

If your original algorithm uses scaled doubles, the tool also provides overflow information for these expressions.

“Detect Overflows”

Custom Plot Functions

The Fixed-Point Conversion tool provides a default time series based plotting function. The conversion process uses this function at the test numerics step to show the floating-point and fixed-point results and the difference between them. However, during fixed-point conversion you might want to visualize the numerical differences in a view that is more suitable for your application domain. For example, plots that show eye diagrams and bit error differences are more suitable in the communications domain and histogram difference plots are more suitable in image processing designs.

You can choose to use a custom plot function at the test numerics step. The Fixed-Point Conversion tool facilitates custom plotting by providing access to the raw logged input and output data before and after fixed-point conversion. You supply a custom plotting function to visualize the differences between the floating-point and fixed-point results. If you specify a custom plot function, the fixed-point conversion process calls the function for each input and output variable, passes in the name of the variable and the function that uses it, and the results of the floating-point and fixed-point simulations.

Your function should accept three inputs:

- A structure that holds the name of the variable and the function that uses it.

Use this information to:

- Customize plot headings and axes.
- Choose which variables to plot.
- Generate different error metrics for different output variables.
- A cell array to hold the logged floating-point values for the variable.

This cell array contains values observed during floating-point simulation of the algorithm during the test numerics phase. You might need to reformat this raw data.

- A cell array to hold the logged values for the variable after fixed-point conversion.

This cell array contains values observed during fixed-point simulation of the converted design.

For example, function `customComparisonPlot(varInfo, floatVarVals, fixedPtVarVals)`.

To use a custom plot function, in the Fixed-Point Conversion tool, select **Advanced**, and then set **Custom plot function** to the name of your plot function.

In the programmatic workflow, set the `coder.FixPtConfig` configuration object `PlotFunction` property to the name of your plot function. See “Visualize Differences Between Floating-Point and Fixed-Point Results” on page 4-26.

Edit Configuration Parameters for Fixed-Point Code Generation

In this section...

“Create and Modify Configuration Objects” on page 4-24

“Additional Functionalities” on page 4-24

After you have created a fixed-point code generation configuration object at the command line, you can modify the properties of the object interactively by using the Fixed-point configuration setting dialog box.

Create and Modify Configuration Objects

- 1 Create a fixed-point configuration object.

```
cfg = coder.config('fixpt');
```

- 2 Open the fixed-point configuration settings dialog box by using one of these methods:

- In the MATLAB workspace, double-click the configuration object `cfg`.
- At the MATLAB command prompt, open the configuration object `cfg`.

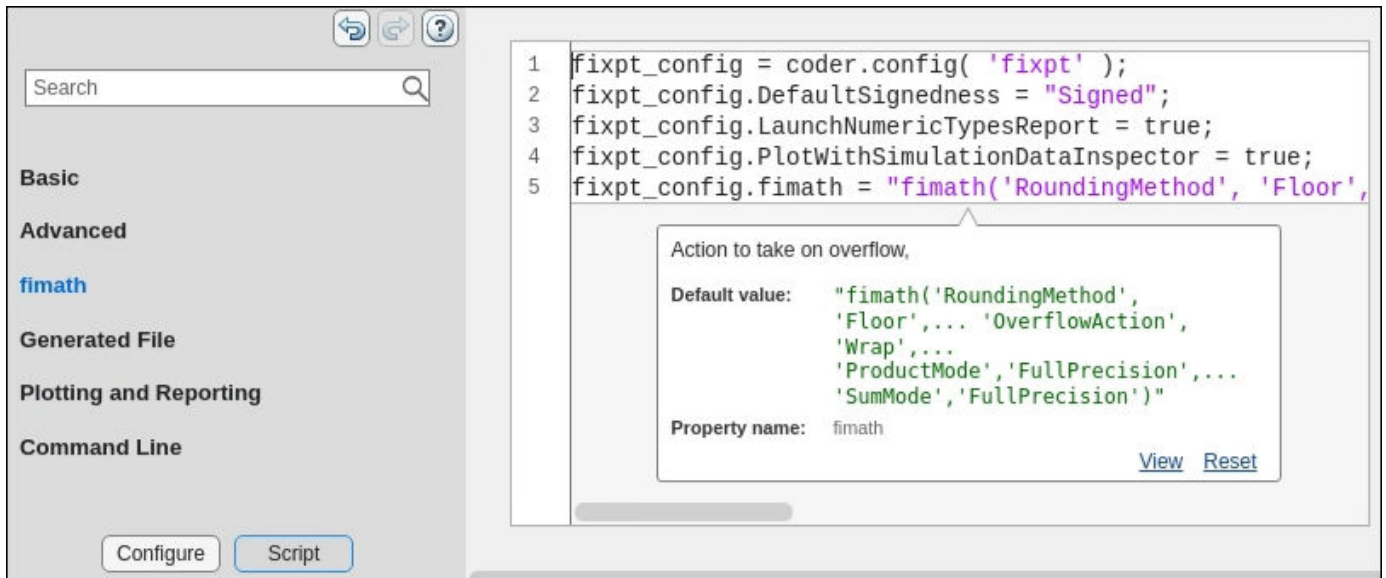

```
open cfg
```

- 3 In the dialog box, modify configuration parameters as required.

Additional Functionalities

Fixed-point configuration settings dialog box provides these functionalities.

- *Search*: When you search for a string, you see the filtered results across all settings categories. The search string might be present in a setting name, the name of an option for a setting, or in a tooltip.
- *Informative tooltips*: The tooltip for each setting contains the configuration object property name, a **Help** link for that property, and the name of any additional products that are required for using the property. If the property is disabled, the tooltip also contains links to other properties that you must set to enable this property. You can make that change in the tooltip itself.
- *Settings with nondefault values*: The dialog box shows settings that have nondefault values in bold font. To reset such a setting to its default values, click the **Reset** button in the tooltip.
- *Generate equivalent script*: You can view the command-line script that produces your current settings by clicking the **Script** button located at the bottom of the list of categories on the left side of the window. You can switch from script mode back to interactive mode by clicking the **Configure** button.

Visualize Differences Between Floating-Point and Fixed-Point Results

To complete this example, you must install the following products:

- MATLAB
- Fixed-Point Designer
- C compiler

See https://www.mathworks.com/support/compilers/current_release/.

You can use `mex -setup` to change the default compiler. See “Change Default Compiler”.

Inspect Example Files

Type	Name	Description
Function code	<code>myFilter.m</code>	Entry-point MATLAB function
Test file	<code>myFilterTest.m</code>	MATLAB script that tests <code>myFilter.m</code>
Plotting function	<code>plotDiff.m</code>	Custom plot function
MAT-file	<code>filterData.mat</code>	Data to filter.

The `myFilter` Function

```
function [y, ho] = myFilter(in)

persistent b h;
if isempty(b)
    b = complex(zeros(1,16));
    h = complex(zeros(1,16));
    h(8) = 1;
end

b = [in, b(1:end-1)];
y = b*h.';

errf = 1-sqrt(real(y)*real(y) + imag(y)*imag(y));
update = 0.001*conj(b)*y*errf;

h = h + update;
h(8) = 1;
ho = h;

end
```

The `myFilterTest` File

```
% load data
data = load('filterData.mat');
d = data.symbols;

for idx = 1:4000
    y = myFilter(d(idx));
end
```

The plotDiff Function

```

% varInfo - structure with information about
% the variable. It has the following fields
%         i) name
%         ii) functionName
% floatVals - cell array of logged original values
% for the 'varInfo.name' variable
% fixedVals - cell array of logged values for
% the 'varInfo.name' variable after Fixed-Point conversion.
function plotDiff(varInfo, floatVals, fixedVals)
    varName = varInfo.name;
    fcnName = varInfo.functionName;

    % escape the '_'s because plot titles treat these as subscripts
    escapedVarName = regexp(varName, '_', '\\_');
    escapedFcnName = regexp(fcnName, '_', '\\_');

    % flatten the values
    flatFloatVals = floatVals(1:end);
    flatFixedVals = fixedVals(1:end);

    % build Titles
    floatTitle = [escapedFcnName ' > ' 'float : ' escapedVarName];
    fixedTitle = [escapedFcnName ' > ' 'fixed : ' escapedVarName];

    data = load('filterData.mat');

    switch varName
        case 'y'
            x_vec = data.symbols;

            figure('Name', 'Comparison plot', 'NumberTitle', 'off');

            % plot floating point values
            y_vec = flatFloatVals;
            subplot(1, 2, 1);
            plotScatter(x_vec, y_vec, 100, floatTitle);

            % plot fixed point values
            y_vec = flatFixedVals;
            subplot(1, 2, 2);
            plotScatter(x_vec, y_vec, 100, fixedTitle);

        otherwise
            % Plot only output 'y' for this example, skip the rest
    end
end

function plotScatter(x_vec, y_vec, n, figTitle)
    % plot the last n samples
    x_plot = x_vec(end-n+1:end);
    y_plot = y_vec(end-n+1:end);

    hold on
    scatter(real(x_plot), imag(x_plot), 'bo');

```

```
hold on
scatter(real(y_plot),imag(y_plot), 'rx');

title(figTitle);
end
```

Set Up Configuration Object

- 1 Create a `coder.FixptConfig` object.

```
fxptcfg = coder.config('fixpt');
```

- 2 Specify the test file name and custom plot function name. Enable logging and numerics testing.

```
fxptcfg.TestBenchName = 'myFilterTest';
fxptcfg.PlotFunction = 'plotDiff';
fxptcfg.TestNumerics = true;
fxptcfg.LogIOForComparisonPlotting = true;
fxptcfg.DefaultWordLength = 16;
```

Convert to Fixed Point

Convert the floating-point MATLAB function, `myFilter`, to fixed-point MATLAB code. You do not need to specify input types for the `codegen` command because it infers the types from the test file.

```
codegen -args {complex(0, 0)} -float2fixed fxptcfg myFilter
```

The conversion process generates fixed-point code using a default word length of 16 and then runs a fixed-point simulation by running the `myFilterTest.m` function and calling the fixed-point version of `myFilter.m`.

Because you selected to log inputs and outputs for comparison plots and to use the custom plotting function, `plotDiff.m`, for these plots, the conversion process uses this function to generate the comparison plot.

The plot shows that the fixed-point results do not closely match the floating-point results.

Increase the word length to 24 and then convert to fixed point again.

```
fxptcfg.DefaultWordLength = 24;  
codegen -args {complex(0, 0)} -float2fixed fxptcfg myFilter
```

The increased word length improved the results. This time, the plot shows that the fixed-point results match the floating-point results.

4 Fixed-Point Conversion

Inspecting Data Using the Simulation Data Inspector

In this section...

“What Is the Simulation Data Inspector?” on page 4-31
“Import Logged Data” on page 4-31
“Export Logged Data” on page 4-31
“Group Signals” on page 4-31
“Run Options” on page 4-31
“Create Report” on page 4-32
“Comparison Options” on page 4-32
“Enabling Plotting Using the Simulation Data Inspector” on page 4-32
“Save and Load Simulation Data Inspector Sessions” on page 4-32

What Is the Simulation Data Inspector?

The Simulation Data Inspector allows you to view data logged during the fixed-point conversion process. You can use it to inspect and compare the inputs and outputs to the floating-point and fixed-point versions of your algorithm.

For fixed-point conversion, there is no programmatic interface for the Simulation Data Inspector.

Import Logged Data

Before importing data into the Simulation Data Inspector, you must have previously logged data to the base workspace or to a MAT-file.

Export Logged Data

The Simulation Data Inspector provides the capability to save data collected by the fixed-point conversion process to a MAT-file that you can later reload. The format of the MAT-file is different from the format of a MAT-file created from the base workspace.

Group Signals

You can customize the organization of your logged data in the Simulation Data Inspector **Runs** pane. By default, data is first organized by run. You can then organize your data by logged variable or no hierarchy.

Run Options

You can configure the Simulation Data Inspector to:

- Append New Runs

In the Run Options dialog box, the default is set to add new runs to the bottom of the run list. To append new runs to the top of the list, select **Add new runs at top**.

- Specify a Run Naming Rule

To specify run naming rules, in the Simulation Data Inspector toolbar, click **Run Options**.

Create Report

You can create a report of the runs or comparison plots. Specify the name and location of the report file. By default, the Simulation Data Inspector overwrites existing files. To preserve existing reports, select **If report exists, increment file name to prevent overwriting**.

Comparison Options

To change how signals are matched when runs are compared, specify the **Align by** and **Then by** parameters and then click **OK**.

Enabling Plotting Using the Simulation Data Inspector

To enable the Simulation Data Inspector, see “Enable Plotting Using the Simulation Data Inspector” on page 4-33.

Save and Load Simulation Data Inspector Sessions

If you have data in the Simulation Data Inspector and you want to archive or share the data to view in the Simulation Data Inspector later, save the Simulation Data Inspector session. When you save a Simulation Data Inspector session, the MAT-file contains:

- All runs, data, and properties from the **Runs** and **Comparisons** panes.
- Check box selection state for data in the **Runs** pane.

Save a Session to a MAT-File

- 1 On the **Visualize** tab, click **Save**.
- 2 Browse to where you want to save the MAT-file to, name the file, and click **Save**.

Load a Saved Simulation Data Inspector Simulation

- 1 On the **Visualize** tab, click **Open**.
- 2 Browse, select the MAT-file saved from the Simulation Data Inspector, and click **Open**.
- 3 If data in the session is plotted on multiple subplots, on the **Format** tab, click **Subplots** and select the subplot layout.

Enable Plotting Using the Simulation Data Inspector

In this section...

“From the UI” on page 4-33

“From the Command Line” on page 4-33

From the UI

You can use the Simulation Data Inspector to inspect and compare floating-point and fixed-point logged input and output data. In the Fixed-Point Conversion tool:

- 1 Click **Advanced**.
- 2 In the Advanced Settings dialog box, set **Plot with Simulation Data Inspector** to Yes.
- 3 At the Test Numerics stage in the conversion process, click **Test Numerics**, select Log inputs and outputs for comparison plots, and then click .

For an example, see “Propose Fixed-Point Data Types Based on Derived Ranges”.

From the Command Line

You can use the Simulation Data Inspector to inspect and compare floating-point and fixed-point input and output data logged using the function. At the MATLAB command line:

- 1 Create a fixed-point configuration object and configure the test file name.

```
fixptcfg = coder.config('fixpt');
fixptcfg.TestBenchName = 'dti_test';
```
- 2 Select to run the test file to verify the generated fixed-point MATLAB code. Log inputs and outputs for comparison plotting and select to use the Simulation Data Inspector to plot the results.

```
fixptcfg.TestNumerics = true;
fixptcfg.LogIOForComparisonPlotting = true;
fixptcfg.PlotWithSimulationDataInspector = true;
```

- 3 Generate fixed-point MATLAB code using codegen.

```
codegen -float2fixed fixptcfg -config cfg dti
```

For an example, see “Propose Fixed-Point Data Types Based on Derived Ranges”.

Replacing Functions Using Lookup Table Approximations

The software provides an option to generate lookup table approximations for continuous and stateless single-input, single-output functions in your original MATLAB code. These functions must be on the MATLAB path.

You can use this capability to handle functions that are not supported for fixed point and to replace your own custom functions. The fixed-point conversion process infers the ranges for the function and then uses an interpolated lookup table to replace the function. You can control the interpolation method and number of points in the lookup table. By adjusting these settings, you can tune the behavior of replacement function to match the behavior of the original function as closely as possible.

The fixed-point conversion process generates one lookup table approximation per call site of the function that needs replacement.

To use lookup table approximations, see:

- `coder.approximation`
- “Replace the exp Function with a Lookup Table” on page 4-41
- “Replace a Custom Function with a Lookup Table” on page 4-35

Replace a Custom Function with a Lookup Table

In this section...

“Using the HDL Coder App” on page 4-35

“From the Command Line” on page 4-38

With HDL Coder, you can generate lookup table approximations for functions that do not support fixed-point types, and replace your own functions. To replace a custom function with a Lookup Table, use the HDL Coder app, or the `fiaccel` codegen function.

Using the HDL Coder App

This example shows how to replace a custom function with a Lookup Table using the **HDL Coder** app.

Create Algorithm and Test Files

In a local, writable folder:

- 1 Create a MATLAB function, `custom_fcn`, which is the function that you want to replace.

```
function y = custom_fcn(x)
    y = 1./(1+exp(-x));
end
```

- 2 Create a wrapper function that calls `custom_fcn`.

```
function y = call_custom_fcn(x)
    y = custom_fcn(x);
end
```

- 3 Create a test file, `custom_test`, which uses `call_custom_fcn`.

```
close all

x = linspace(-10,10,1e3);
for itr = 1e3:-1:1
    y(itr) = call_custom_fcn( x(itr) );
end
plot( x, y );
```

Create and Set up a HDL Coder Project

- 1 Navigate to the work folder that contains the file for this example.
- 2 To open the **HDL Coder** app, in the MATLAB command prompt, enter `hdlcoder`. Set **Name** to `custom_project.prj` and click **OK**. The project opens in the MATLAB workspace.
- 3 In the project window, on the **MATLAB Function** tab, click the **Add MATLAB function** link. Browse to the file `call_custom_fcn.m`, and then click **OK** to add the file to the project.

Define Input Types

- 1 To define input types for `call_custom_fcn.m`, on the **MATLAB Function** tab, click **Autodefine types**.
- 2 Add `custom_test` as a test file, and then click **Run**.

From the test file, HDL Coder determines that `x` is a scalar double.

- 3 Click **Use These Types**.

Replace custom_fcn with Lookup Table

- 1 To open the HDL Workflow Advisor, click **Workflow Advisor**, and in the Workflow Advisor window, click **Fixed-Point Conversion**.
- 2 To replace custom_fcn with a Lookup Table, on the **Function Replacements** tab, enter custom_fcn, select Lookup Table, and then click +.

By default, the lookup table uses linear interpolation, 1000 points, and design minimum and maximum values that the app detects by running a simulation or computing derived ranges.

- 3 Under **Run Simulation**, select Log data for histogram, and then click **Run Simulation**. Verify that custom_test file is selected as the test file.

The simulation runs and the tool displays simulation minimum and maximum ranges on the **Variables** tab. HDL Coder plots the simulation results in the MATLAB Editor.

Validate Fixed-Point Types

- 1 In the **Proposed Type** column, verify that the fixed-point types proposed by software cover the full simulation range. To view logged histogram data for a variable, click its **Proposed Type** field.

The histogram provides range information and the percentage of simulation range that the proposed data type covers.

Variable	Type	Sim Min	Sim Max	Static Min	Static Max	Whole Nu...	Proposed Type
Input							
x	double	-10	10			No	numerictype(1, 14, 9)
Output							
y	double	0	1				

Sim values covered **100%** Signed
 Supported range **-16 : 15.998**

- 2 To validate the build by using the proposed types, click **Validate Types**.

The software validates the proposed types and generates a fixed-point code, `call_custom_fcn_fixpt`.

- 3 To view the generated fixed-point code, click the `call_custom_fcn_fixpt` link.

The generated fixed-point function, `call_custom_fcn_fixpt.m`, calls this approximation instead of calling `custom_fcn`.

```
function y = call_custom_fcn_fixpt(x)
    fm = get_fimath();

    y = fi(replacement_custom_fcn(x), 0, 14, 14, fm);
end

function fm = get_fimath()
    fm = fimath('RoundingMethod', 'Floor',...
               'OverflowAction', 'Wrap',...
               'ProductMode', 'FullPrecision',...
               'MaxProductWordLength', 128,...
               'SumMode', 'FullPrecision',...
               'MaxSumWordLength', 128);
end
```

From the Command Line

Prerequisites

To complete this example, you must install the following products:

- MATLAB
- Fixed-Point Designer
- C compiler

See https://www.mathworks.com/support/compilers/current_release/.

You can use `mex -setup` to change the default compiler. See “Change Default Compiler”.

Create a MATLAB function, `custom_fcn.m`. This is the function that you want to replace.

```
function y = custom_fcn(x)
    y = 1./(1+exp(-x));
end
```

Create a wrapper function that calls `custom_fcn.m`.

```
function y = call_custom_fcn(x)
    y = custom_fcn(x);
end
```

Create a test file, `custom_test.m`, that uses `call_custom_fcn.m`.

```
close all

x = linspace(-10,10,1e3);
for itr = 1e3:-1:1
```

```

    y(itr) = call_custom_fcn( x(itr) );
end
plot( x, y );

```

Create a function replacement configuration object to approximate `custom_fcn`. Specify the function handle of the custom function and set the number of points to use in the lookup table to 50.

```

q = coder.approximation('Function','custom_fcn',...
    'CandidateFunction',@custom_fcn,...
    'NumberOfPoints',50);

```

Create a `coder.FixptConfig` object, `fixptcfg`. Specify the test file name and enable numerics testing. Associate the function replacement configuration object with the fixed-point configuration object.

```

fixptcfg = coder.config('fixpt');
fixptcfg.TestBenchName = 'custom_test';
fixptcfg.TestNumerics = true;
fixptcfg.addApproximation(q);

```

Generate fixed-point MATLAB code.

```

codegen -float2fixed fixptcfg call_custom_fcn

```

`codegen` generates fixed-point MATLAB code in `call_custom_fcn_fixpt.m`.

To view the generated fixed-point code, click the link to `call_custom_fcn_fixpt`.

The generated code contains a lookup table approximation, `replacement_custom_fcn`, for the `custom_fcn` function. The fixed-point conversion process infers the ranges for the function and then uses an interpolated lookup table to replace the function. The lookup table uses 50 points as specified. By default, it uses linear interpolation and the minimum and maximum values detected by running the test file.

The generated fixed-point function, `call_custom_fcn_fixpt`, calls this approximation instead of calling `custom_fcn`.

```

function y = call_custom_fcn_fixpt(x)
    fm = get_fimath();

    y = fi(replacement_custom_fcn(x), 0, 14, 14, fm);
end

```

You can now test the generated fixed-point code and compare the results against the original MATLAB function. If the behavior of the generated fixed-point code does not match the behavior of the original code closely enough, modify the interpolation method or number of points used in the lookup table and then regenerate code.

More About

- “Replacing Functions Using Lookup Table Approximations” on page 4-34

Replace the exp Function with a Lookup Table

With HDL Coder, you can handle functions that are not supported for fixed point and replace your own functions. To replace a custom function with a Lookup Table, use the HDL Coder App, or the `fiaccel` codegen function.

From the UI

This example shows how to replace a custom function with a Lookup Table using the **HDL Coder** app.

Create Algorithm and Test Files

In a local, writable folder:

- 1 Create a MATLAB function, `custom_fcn`, which is the function that you want to replace.

```
function y = custom_fcn(x)
    y = 1./(1+exp(-x));
end
```

- 2 Create a wrapper function that calls `custom_fcn`.

```
function y = call_custom_fcn(x)
    y = custom_fcn(x);
end
```

- 3 Create a test file, `custom_test`, which uses `call_custom_fcn`.

```
close all

x = linspace(-10,10,1e3);
for itr = 1e3:-1:1
    y(itr) = call_custom_fcn( x(itr) );
end
plot( x, y );
```

Create and Set up a HDL Coder Project

- 1 Navigate to the work folder that contains the file for this example.
- 2 To open the **HDL Coder** app, in the MATLAB command prompt, enter `hdlcoder`. Set **Name** to `custom_project.prj` and click **OK**. The project opens in the MATLAB workspace.
- 3 In the project window, on the **MATLAB Function** tab, click the **Add MATLAB function** link. Browse to the file `call_custom_fcn.m`, and then click **OK** to add the file to the project.

Define Input Types

- 1 To define input types for `call_custom_fcn.m`, on the **MATLAB Function** tab, click **Autodefine types**.
- 2 Add `custom_test` as a test file, and then click **Run**.

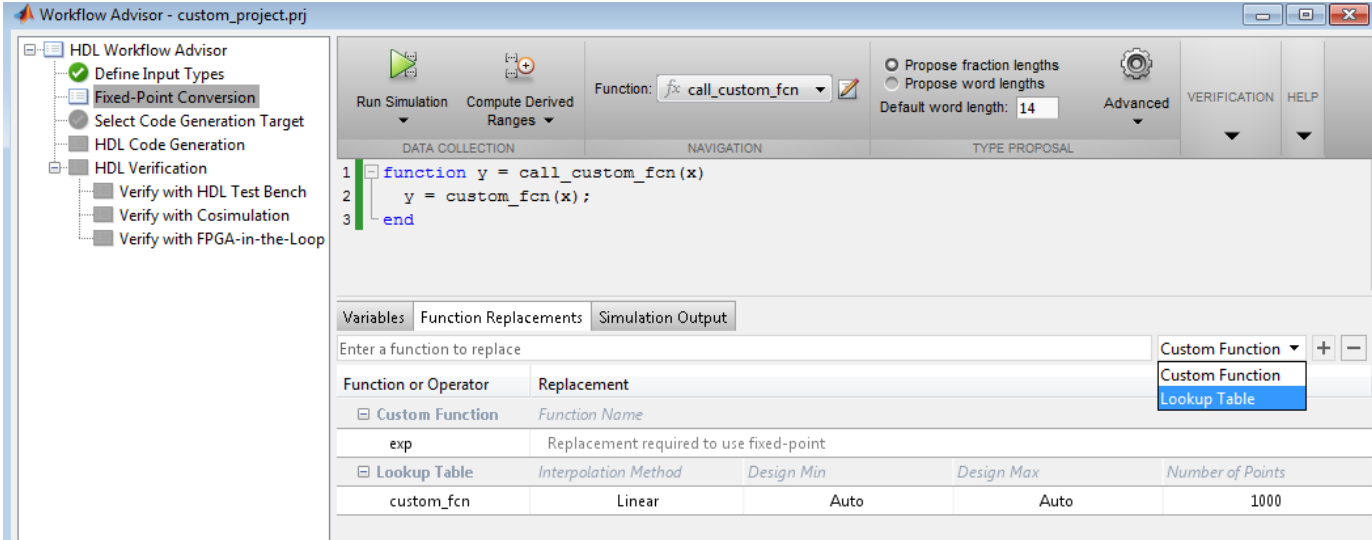

From the test file, HDL Coder determines that `x` is a scalar double.

- 3 Click **Use These Types**.

Replace custom_fcn with Lookup Table

- 1 To open the HDL Workflow Advisor, click **Workflow Advisor**, and in the Workflow Advisor window, click **Fixed-Point Conversion**.
- 2 To replace custom_fcn with a Lookup Table, on the **Function Replacements** tab, enter custom_fcn, select Lookup Table, and then click +.

By default, the lookup table uses linear interpolation, 1000 points, and design minimum and maximum values that the app detects by running a simulation or computing derived ranges.

The screenshot shows the HDL Workflow Advisor interface for a project named 'custom_project.pj'. The 'Fixed-Point Conversion' step is selected in the workflow tree. The main workspace displays the following code:

```

1 function y = call_custom_fcn(x)
2   y = custom_fcn(x);
3 end

```

Below the code, the 'Function Replacements' tab is active. It shows a search for 'custom_fcn' and a dropdown menu with 'Lookup Table' selected. A table below lists the replacement details:

Function or Operator	Replacement	Interpolation Method	Design Min	Design Max	Number of Points
exp	Replacement required to use fixed-point				
custom_fcn	Lookup Table	Linear	Auto	Auto	1000

- 3 Under **Run Simulation**, select Log data for histogram, and then click **Run Simulation**. Verify that custom_test file is selected as the test file.

The simulation runs and the tool displays simulation minimum and maximum ranges on the **Variables** tab. HDL Coder plots the simulation results in the MATLAB Editor.

Validate Fixed-Point Types

- 1 In the **Proposed Type** column, verify that the fixed-point types proposed by software cover the full simulation range. To view logged histogram data for a variable, click its **Proposed Type** field.

The histogram provides range information and the percentage of simulation range that the proposed data type covers.

Variable	Type	Sim Min	Sim Max	Static Min	Static Max	Whole Nu...	Proposed Type
Input							
x	double	-10	10			No	numerictype(1, 14, 9)
Output							
y	double	0	1				

Sim values covered **100%** Signed
 Supported range **-16 : 15.998**

- 2 To validate the build by using the proposed types, click **Validate Types**.

The software validates the proposed types and generates a fixed-point code, `call_custom_fcn_fixpt`.

- 3 To view the generated fixed-point code, click the `call_custom_fcn_fixpt` link.

The generated fixed-point function, `call_custom_fcn_fixpt.m`, calls this approximation instead of calling `custom_fcn`.

```
function y = call_custom_fcn_fixpt(x)
    fm = get_fimath();

    y = fi(replacement_custom_fcn(x), 0, 14, 14, fm);
end

function fm = get_fimath()
    fm = fimath('RoundingMethod', 'Floor',...
               'OverflowAction', 'Wrap',...
               'ProductMode', 'FullPrecision',...
               'MaxProductWordLength', 128,...
               'SumMode', 'FullPrecision',...
               'MaxSumWordLength', 128);
end
```

From the Command Line

This example shows how to replace the `exp` function with a lookup table approximation in the generated fixed-point code using the function.

Prerequisites

To complete this example, you must install the following products:

- MATLAB
- Fixed-Point Designer
- C compiler

See https://www.mathworks.com/support/compilers/current_release/.

You can use `mex -setup` to change the default compiler. See “Change Default Compiler”.

Create Algorithm and Test Files

- 1 Create a MATLAB function, `my_fcn.m`, that calls the `exp` function.

```
function y = my_fcn(x)
    y = exp(x);
end
```

- 2 Create a test file, `my_fcn_test.m`, that uses `my_fcn.m`.

```
close all

x = linspace(-10,10,1e3);
for itr = 1e3:-1:1
    y(itr) = my_fcn( x(itr) );
end
```

```
end
plot( x, y );
```

Configure Approximation

Create a function replacement configuration object to approximate the `exp` function, using the default settings of linear interpolation and 1000 points in the lookup table.

```
q = coder.approximation('exp');
```

Set Up Configuration Object

Create a `coder.FixptConfig` object, `fixptcfg`. Specify the test file name and enable numerics testing. Associate the function replacement configuration object with the fixed-point configuration object.

```
fixptcfg = coder.config('fixpt');
fixptcfg.TestBenchName = 'my_fcn_test';
fixptcfg.TestNumerics = true;
fixptcfg.DefaultWordLength = 16;
fixptcfg.addApproximation(q);
```

Convert to Fixed Point

Generate fixed-point MATLAB code.

```
codegen -float2fixed fixptcfg my_fcn
```

View Generated Fixed-Point Code

To view the generated fixed-point code, click the link to `my_fcn_fixpt`.

The generated code contains a lookup table approximation, `replacement_exp`, for the `exp` function. The fixed-point conversion process infers the ranges for the function and then uses an interpolated lookup table to replace the function. By default, the lookup table uses linear interpolation, 1000 points, and the minimum and maximum values detected by running the test file.

The generated fixed-point function, `my_fcn_fixpt`, calls this approximation instead of calling `exp`.

```
function y = my_fcn_fixpt(x)
    fm = get_fimath();

    y = fi(replacement_exp(x), 0, 16, 1, fm);
end
```

You can now test the generated fixed-point code and compare the results against the original MATLAB function. If the behavior of the generated fixed-point code does not match the behavior of the original code closely enough, modify the interpolation method or number of points used in the lookup table and then regenerate code.

Data Type Issues in Generated Code

Within the fixed-point conversion report, you have the option to highlight MATLAB code that results in double, single, or expensive fixed-point operations. Consider enabling these checks when trying to achieve a strict single, or fixed-point design.

These checks are disabled by default.

Enable the Highlight Option in a Project

- 1 Open the **Settings** menu.
- 2 Under **Plotting and Reporting**, set **Highlight potential data type issues** to Yes.

Enable the Highlight Option at the Command Line

- 1 Create a fixed-point code configuration object:

```
cfg = coder.config('fixpt');
```
- 2 Set the `HighlightPotentialDataTypeIssues` property of the configuration object to `true`.

```
cfg.HighlightPotentialDataTypeIssues = true;
```

Stowaway Doubles

When trying to achieve a strict-single or fixed-point design, manual inspection of code can be time-consuming and error prone. This check highlights all expressions that result in a double operation.

Stowaway Singles

This check highlights all expressions that result in a single operation.

Expensive Fixed-Point Operations

The expensive fixed-point operations check identifies optimization opportunities for fixed-point code. It highlights expressions in the MATLAB code that require cumbersome multiplication or division, expensive rounding, expensive comparison, or multiword operations. For more information on optimizing generated fixed-point code, see "Tips for Making Generated Code More Efficient".

Cumbersome Operations

Cumbersome operations most often occur due to insufficient range of output. Avoid inputs to a multiply or divide operation that has word lengths larger than the base integer type of your processor. Operations with larger word lengths can be handled in software, but this approach requires much more code and is much slower.

Expensive Rounding

Traditional handwritten code, especially for control applications, almost always uses "no effort" rounding. For example, for unsigned integers and two's complement signed integers, shifting right and dropping the bits is equivalent to rounding to floor. To get results comparable to, or better than, what you expect from traditional handwritten code, use the `floor` rounding method. This check identifies expensive rounding operations in multiplication and division.

Expensive Comparison Operations

Comparison operations generate extra code when a casting operation is required to do the comparison. For example, when comparing an unsigned integer to a signed integer, one of the inputs must first be cast to the signedness of the other before the comparison operation can be performed. Consider optimizing the data types of the input arguments so that a cast is not required in the generated code.

Multiword Operations

Multiword operations can be inefficient on hardware. When an operation has an input or output data type larger than the largest word size of your processor, the generated code contains multiword operations. You can avoid multiword operations in the generated code by specifying local `fimath` properties for variables. You can also manually specify input and output word lengths of operations that generate multiword code.

Working with Fixed-Point Code

This example shows HDL code generation from a fixed-point MATLAB® design that is ready for code generation.

Introduction

The MATLAB code used in the example is an implementation of viterbi decoder modeled using fixed-point constructs.

```
design_name = 'mlhdlc_viterbi';
testbench_name = 'mlhdlc_viterbi_tb';
```

- 1 MATLAB Design: mlhdlc_viterbi
- 2 MATLAB testbench: mlhdlc_viterbi_tb

Open the design function mlhdlc_viterbi by clicking on the above link to notice the use of Fixed-Point Designer functions:

- 1 use of 'fi', 'numerictype', and 'fimath' for modeling fixed-point data types
- 2 use of 'bitget', 'bitsliceget', 'bitconcat' for modeling bit-wise operations

Create a New HDL Coder™ Project

```
coder -hdlcoder -new fixpt_codegen
```

Next, add the file 'mlhdlc_viterbi.m' to the project as the MATLAB Function and 'mlhdlc_viterbi_tb.m' as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Skip Fixed-Point Conversion

Launch the HDL Advisor and choose 'Keep original types' on the option 'Fixed-point conversion:'.

The Floating-point to fixed-point conversion related step is removed from the workflow tree when we skip the conversion.

If your design is in floating-point, follow the instructions in “Floating-Point to Fixed-Point Conversion” on page 4-51 and convert your design to fixed-point before moving onto the HDL code generation steps.

Run HDL Code Generation

Right click on the 'Code Generation' step and choose the option 'Run this task' to run all code generation step directly.

Examine the generated HDL code by clicking on the hyperlinks in the Code Generation Log window.

Try More Code Generation Options

As this is a large design with considerable number of functions you can try the option 'Generate instantiable code for functions' in the Advanced tab.

Re-examine the generated HDL code and compare it with the previous step.

Floating-Point to Fixed-Point Conversion

This example shows how to start with a floating-point design in MATLAB®, iteratively converge on an efficient fixed-point design in MATLAB, and verify the numerical accuracy of the generated fixed-point design.

Signal processing applications for reconfigurable platforms require algorithms that are typically specified using floating-point operations. However, for power, cost, and performance reasons, they are usually implemented with fixed-point operations either in software for DSP cores or as special-purpose hardware in FPGAs. Fixed-point conversion can be very challenging and time-consuming, typically demanding 25 to 50 percent of the total design and implementation time. Automated tools can simplify and accelerate the conversion process.

For software implementations, the aim is to define an optimized fixed-point specification which minimizes the code size and the execution time for a given computation accuracy constraint. This optimization is achieved through the modification of the binary point location (for scaling) and the selection of the data word length according to the different data types supported by the target processor.

For hardware implementations, the complete architecture can be optimized. An efficient implementation will minimize both the area used and the power consumption. Thus, the conversion process goal typically is focused around minimizing the operator word length.

The floating-point to fixed-point workflow is currently integrated in the HDL Workflow Advisor as described in “Get Started with MATLAB to HDL Workflow”.

Introduction

The floating-point to fixed-point conversion workflow in HDL Coder™ includes the following steps:

- 1 Verify that the floating-point design is compatible with code generation.
- 2 Compute fixed-point types based on the simulation of the testbench.
- 3 Generate readable and traceable fixed-point MATLAB code by applying proposed types.
- 4 Verify the generated fixed-point design.
- 5 Compare the numerical accuracy of the generated fixed-point code with the original floating point code.

MATLAB Design

The MATLAB code used in this example is a simple second-order direct-form 2 transposed filter. This example also contains a MATLAB testbench that exercises the filter.

```
design_name = 'mlhdlc_df2t_filter';
testbench_name = 'mlhdlc_df2t_filter_tb';
```

Examine the MATLAB design.

```
type(design_name);

%#codegen
function y = mlhdlc_df2t_filter(x)
```

```
% Copyright 2011-2015 The MathWorks, Inc.

persistent z;
if isempty(z)
    % Filter states as a column vector
    z = zeros(2,1);
end

% Filter coefficients as constants
b = [0.29290771484375    0.585784912109375    0.292907714843750];
a = [1.0                0.0                0.171600341796875];

y    = b(1)*x + z(1);
z(1) = (b(2)*x + z(2)) - a(2) * y;
z(2) = b(3)*x - a(3) * y;

end
```

For the floating-point to fixed-point workflow, it is desirable to have a complete testbench. The quality of the proposed fixed-point data types depends on how well the testbench covers the dynamic range of the design with the desired accuracy.

For details on requirements for floating-point design and the testbench, see **Floating-Point Design Structure** structure section of “Working with Generated Fixed-Point Files” on page 4-68.

```
type(testbench_name);
```

```
%
```

```

```

```
Fs = 256;           % Sampling frequency
Ts = 1/Fs;         % Sample time
t = 0:Ts:1-Ts;    % Time vector from 0 to 1 second
f1 = Fs/2;        % Target frequency of chirp set to Nyquist
in = sin(pi*f1*t.^2); % Linear chirp from 0 to Fs/2 Hz in 1 second
out = zeros(size(in)); % Output the same size as the input

for ii=1:length(in)
    out(ii) = mlhdlc_df2t_filter(in(ii));
end

% Plot
figure('Name', [mfilename, '_plot']);
subplot(2,1,1);
plot(in);
xlabel('Time')
ylabel('Amplitude')
title('Input Signal (with Noise)')

subplot(2,1,2);
plot(out);
xlabel('Time')
ylabel('Amplitude')
title('Output Signal (filtered)')
```

Simulate the Design

Simulate the design with the test bench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_df2t_filter_tb
```

Create a New HDL Coder Project

To create a new project, enter the following command:

```
coder -hdlcoder -new flt2fix_project
```

Next, add the file 'mlhdlc_filter.m' to the project as the MATLAB Function and 'mlhdlc_filter_tb.m' as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Fixed-Point Code Generation Workflow

The floating-point to fixed-point conversion workflow allows you to:

- Verify that the floating-point design is code generation compliant
- Propose fixed-point types based on simulation data and word length settings
- Allow the user to manually adjust the proposed fixed-point types

- Validate the proposed fixed-point types
- Verify that the generated fixed-point MATLAB code has the desired numeric accuracy

Step 1: Launch Workflow Advisor

- 1 Click on the Workflow Advisor button to launch the HDL Workflow Advisor.
- 2 Choose **Convert to fixed-point at build time** for the option **Fixed-point conversion**.

Step 2: Define Input Types

In this step you can define input types manually or by specifying and running the testbench.

- 1 Click **Run** to execute this step.

After simulation notice that the input variable `x` is defined as scalar double, `double(1x1)`.

Step 3: Run Simulation

- 1 Click on the **Fixed-Point Conversion** step.

The design is compiled with the input types defined in the previous step and after the compilation is successful the variable table shows inferred types for all the functions in the design.

In this step, the original design is instrumented so that the minimum and maximum values for all variables in the design are collected during simulation.

The screenshot shows the MATLAB Workflow Advisor interface for a project named 'flt2fix_project.prj'. The 'Fixed-Point Conversion' step is selected in the left-hand navigation pane. The main workspace displays the MATLAB code for the 'mlhdlc_df2t_filter' function. Below the code, a table summarizes the variables and their proposed fixed-point types based on simulation data.

Variable	Type	Sim Min	Sim Max	Whole...	Proposed Type	Log	Error (%)
Input							
x	double			No		✓	
Output							
y	double			No		✓	
Persistent							
z	2 x 1 double			No			
Local							
b	1 x 3 double			No			
a	1 x 3 double			No			

1 Click on the 'Analyze' button.

Notice that the 'Sim Min' and 'Sim Max' table is now populated with simulation ranges. Fixed-point types are proposed based on the default word length settings.

The screenshot shows the HDL Workflow Advisor interface for a project named 'flt2fix_project.prj'. The 'Fixed-Point Conversion' step is selected in the workflow tree. The main window displays the MATLAB code for the function 'mlhdlc_df2t_filter'. Below the code is a table showing the proposed fixed-point types for various variables based on simulation data.

Variable	Type	Sim Min	Sim Max	Whole...	Proposed Type	Log	Error (%)
Input							
x	double	-1	1	No	numerictype(1, 14, 12)	✓	
Output							
y	double	-0.99	1	No	numerictype(1, 14, 13)	✓	
Persistent							
z	2 x 1 double	-0.8	0.8	No	numerictype(1, 14, 13)		
Local							
b	1 x 3 double	0.29	0.59	No	numerictype(0, 14, 14)		
a	1 x 3 double	0	1	No	numerictype(0, 14, 13)		

At this stage, based on computed simulation ranges for all variables, you can compute:

- Fraction lengths for a given fixed word length setting, or
- Word lengths for a given fixed fraction length setting.

The type table contains the following information for each variable existing in the floating-point MATLAB design, organized by function:

- Sim Min: The minimum value assigned to the variable during simulation.
- Sim Max: The maximum value assigned to the variable during simulation.
- Whole Number: Whether all values assigned during simulation are integers.

The type proposal step uses the above information and combines it with the user-specified word length settings to propose a fixed-point type for each variable.

You can also enable the **Log histogram data** option in the **Analyze** button drop-down menu to enable logging of histogram data.

The screenshot shows the HDL Workflow Advisor interface for a project named 'fit2fix_project.prj'. The 'Fixed-Point Conversion' step is active. The main window displays the MATLAB code for the 'mlhdlc_df2t_filter' function. Below the code is a table of variables and their proposed fixed-point types. A histogram window is overlaid on the table, showing the distribution of simulation values for variable 'x'.

Variable	Type	Sim Min	Sim Max	Whole...	Proposed Type	Log	Error (%)
Input							
x	double	-1	1	No	numerictype(1, 14, 12)	✓	
Output							
y	double	-0.99				✓	
Persistent							
z	2 x 1 double	-0.8					
Local							
b	1 x 3 double	0.29					
a	1 x 3 double	0					

The histogram window shows the distribution of simulation values for variable 'x'. The x-axis represents bit weights and the y-axis represents the number of occurrences. The proposed numeric type information is overlaid on top of this graph and is editable. Moving the bounding white box left or right changes the position of binary point. Moving the right or left edges correspondingly change fraction length or wordlength. All the changes made to the proposed type are saved in the project.

The histogram view concisely gives information about dynamic range of the simulation data for a variable. The x-axis correspond to bit weights and y-axis represents number of occurrences. The proposed numeric type information is overlaid on top of this graph and is editable. Moving the bounding white box left or right changes the position of binary point. Moving the right or left edges correspondingly change fraction length or wordlength. All the changes made to the proposed type are saved in the project.

Step 4: Validate types

In this step, the fixed-point types from the previous step are used to generate a fixed-point MATLAB design from the original floating-point implementation.

- 1 Click on the **Validate Types** button.

The screenshot shows the HDL Workflow Advisor interface for a project named 'flt2fix_project.prj'. The workflow is at the 'Fixed-Point Conversion' step. The main editor displays the MATLAB code for the 'mlhdlc_df2t_filter' function. The code includes comments for code generation, persistent variables, and filter coefficients. The output window shows the results of the conversion, including the generation of a type proposal report, fixed-point MATLAB code, and a design wrapper.

```

1  %#codegen
2  function y = mlhdlc_df2t_filter(x)
3
4  % Copyright 2011-2015 The MathWorks, Inc.
5
6  persistent z;
7  if isempty(z)
8      % Filter states as a column vector
9      z = zeros(2,1);
10 end
11
12 % Filter coefficients as constants
13 b = [0.29290771484375  0.585784912109375  0.292907714843750];
14 a = [1.0              0.0              0.171600341796875];
15
16 y = b(1)*x + z(1);

```

Output window content:

```

10
11  fm = get_fimath();
12
13  persistent z;
14  if isempty(z)
15      % Filter states as a column vector
16      z = fi(zeros(2,1), 1, 14, 13, fm);
17  end
18
19  % Filter coefficients as constants
20  b = fi([0.29290771484375  0.585784912109375  0.292907714843750], 0, 14, 14, fm);
21  a = fi([1.0  0.0  0.171600341796875], 0, 14, 13, fm);
22
23  y = fi(b(1)*x + z(1), 1, 14, 13, fm);
24  z(1) = fi_signed((b(2)*x + z(2))) - a(2) * y;
25  z(2) = fi_signed(b(3)*x) - a(3) * y;
26

```

Step 5: Test Numerics

- 1 Click on the **Test Numerics** button.

In this step, the generated fixed-point code is executed using MATLAB Coder.

If you enable the **Log all inputs and outputs for comparison plots** option on the **Test Numerics** pane, an additional plot is generated for each scalar output that shows the floating point and fixed point results, as well as the difference between the two. For non-scalar outputs, only the error information is shown.

Step 6: Iterate on the Results

If the numerical results do not meet your desired accuracy after fixed-point simulation, you can return to the **Propose Fixed-Point Types** step in the Workflow Advisor. Adjust the word length settings or individually modify types as desired, and repeat the rest of the steps in the workflow until you achieve your desired results.

Refer to “Fixed-Point Type Conversion and Refinement” on page 4-61 for more details on how to iterate and refine the numerics of the algorithm in the generated fixed-point code.

Fixed-Point Type Conversion and Refinement

This example shows how to achieve your desired numerical accuracy when converting fixed-point MATLAB® code to floating-point code using the HDL Workflow Advisor.

Introduction

The floating-point to fixed-point conversion workflow in HDL Coder™ includes the following steps:

- 1 Verify the floating-point design is compatible for code generation.
- 2 Compute fixed-point types based on the simulation of the testbench.
- 3 Generate readable and traceable fixed-point MATLAB® code.
- 4 Verify the generated fixed-point design.

This tutorial uses Kalman filter suitable for HDL code generation to illustrate some key aspects of fixed-point conversion workflow, specifically steps 2 and 3 in the above list.

MATLAB Design

The MATLAB code used in this example implements a simple Kalman filter. This example also contains a MATLAB testbench that exercises the filter.

Kalman filter implementation suitable for HDL code generation

```
design_name = 'mlhdlc_kalman_hdl';  
testbench_name = 'mlhdlc_kalman_hdl_tb';  
  
edit('mlhdlc_kalman_hdl')  
edit('mlhdlc_kalman_hdl_tb')
```

Simulate the Design

Simulate the design with the testbench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_kalman_hdl_tb
```

```
Running -----> mlhdlc_kalman_hdl_tb
```

```
Current plot held  
Current plot released
```

Create a New HDL Coder Project

To create a new project, enter the following command:

```
coder -hdlcoder -new flt2fix_project
```

Next, add the file `mlhdlc_kalman_hdl.m` to the project as the MATLAB Function and `mlhdlc_kalman_hdl_tb.m` as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Fixed-Point Code Generation Workflow

Perform the following tasks before moving on to the fixed-point type proposal step:

- 1 Click the **Workflow Advisor** button to launch the HDL Workflow Advisor.
- 2 Choose **Convert to fixed-point at build time** for the **Fixed-point conversion** option.
- 3 Click **Run** button to define input types for the design from the testbench.
- 4 Select the **Fixed-Point Conversion** workflow step.
- 5 Click **Analyze** to execute the instrumented floating-point simulation.

Refer to “Floating-Point to Fixed-Point Conversion” on page 4-51 for a more complete tutorial on these steps.

Determine the Initial Fixed Point Types

After instrumented floating-point simulation completes, Fixed-Point Types are proposed based on the simulation results.

At this stage of the conversion proposes fixed-point types for each variable in the design based on the recorded min/max values of the floating point variables and user input.

At this point, for all variables, you can (re)compute and propose:

- Fraction lengths for a given fixed word length setting, or
- Word lengths for a given fixed fraction length setting.

Choose the Word Length Setting

When you are starting with a floating-point design and going through the floating-point to fixed-point conversion for the first time, it is a good practice to start by specifying a 'Default Word Length' setting based on the largest dynamic range of all the variables in the design.

In this example, we start with a default word length of 22 and run the 'Propose Fixed-Point Types' step.

The screenshot shows the HDL Workflow Advisor interface for a project named 'flt2fix_project.prj'. The 'Fixed-Point Conversion' step is highlighted in the task list. The main window displays the MATLAB code for the 'mldlc_kalman_hdl' function. A red box highlights the 'Propose Fixed-Point Types' settings, showing 'Propose word lengths' selected and 'Default word length: 14'. Below the code, a table lists the proposed fixed-point types for various variables.

Variable	Type	Sim Min	Sim Max	Whole...	Proposed Type	Log	Error (%)
Input							
z	2 x 1 double	-0.98	1.01	No	numerictype(1, 14, 12)	✓	
Output							
y1	double	-1.14	1.01	No	numerictype(1, 14, 12)	✓	
y2	double	-0.98	0.98	No	numerictype(1, 14, 13)	✓	
dv_out_q	double	0	1	Yes	numerictype(0, 1, 0)	✓	
Persistent							
state	double	1	5	Yes	numerictype(0, 3, 0)		

Explore the Proposed Fixed-Point Type Table

The type table contains the following information for each variable, organized by function, existing in the floating-point MATLAB design:

- Sim Min: The minimum value assigned to the variable during simulation.
- Sim Max: The maximum value assigned to the variable during simulation.
- Whole Number: Whether all values assigned during simulation are integer.

The type proposal step uses the above information and combines it with the user-specified word length settings to propose a fixed-point type for each variable.

You can also use **Compute Derived Range Analysis** to compute derived ranges and that is covered in detail in this tutorial “Fixed-Point Type Conversion and Derived Ranges” on page 4-73.

Interpret the Proposed Numeric Types for Variables

Based on the simulation range (min & max) values and the default word length setting, a numeric type is proposed for each variable.

The following table shows numeric type proposals for a **Default word length** of 22 bits.

Variable	Type	Sim Min	Sim Max	Whole...	Proposed Type	Log	Error (%)
Input							
z	2 x 1 double	-0.98	1.01	No	numerictype(1, 14, 12)	✓	
Output							
y1	double	-1.14	1.01	No	numerictype(1, 14, 12)	✓	
y2	double	-0.98	0.98	No	numerictype(1, 14, 13)	✓	
dv_out_q	double	0	1	Yes	numerictype(0, 1, 0)	✓	
Persistent							
state	double	1	5	Yes	numerictype(0, 3, 0)		
x_est	6 x 1 double	-1.14	1.01	No	numerictype(1, 14, 12)		
p_est	6 x 6 double	0	472.78	No	numerictype(0, 14, 5)		
y	2 x 1 double	-1.14	1.01	No	numerictype(1, 14, 12)		
x_prd	6 x 1 double	-1.35	1.17	No	numerictype(1, 14, 12)		
p_prd	6 x 6 double	0	896.74	No	numerictype(0, 14, 4)		
z_prd	2 x 1 double	-1.35	1.17	No	numerictype(1, 14, 12)		
S	2 x 2 double	0	1896.74	No	numerictype(0, 14, 3)		
B	2 x 6 double	0	896.74	No	numerictype(0, 14, 4)		
klm_gain	6 x 2 double	0	0.47	No	numerictype(0, 14, 15)		
dv_out	double	0	1	Yes	numerictype(0, 1, 0)		
backslash_dv_out	double	0	1	Yes	numerictype(0, 1, 0)		
Local							
dt	double	1	1	Yes	numerictype(0, 1, 0)		
A	6 x 6 double	0	1	Yes	numerictype(0, 1, 0)		
H	2 x 6 double	0	1	Yes	numerictype(0, 1, 0)		
Q	6 x 6 double	0	1	Yes	numerictype(0, 1, 0)		
R	2 x 2 double	0	1000	Yes	numerictype(0, 10, 0)		

Examine the types proposed in the above table for variables instrumented in the top-level design.

Floating-Point Range for variable B:

- Simulation Info: SimMin: 0, SimMax: 896.74., Whole Number: No
- Type Proposed: numerictype(0,22,12) (Signedness: Unsigned, WordLength: 22, FractionLength: 12)

The floating-point range:

- Has the same number of bits as the **Default word length**.
- Uses the minimum number of bits to completely represent the range.
- Uses the rest of the bits to represent the precision.

Integer Range for variable A:

- Simulation Info: SimMin: 0, SimMax: 1, Whole Number: Yes
- Type Proposed: numerictype(0,1,0) (Signedness: Unsigned, WordLength: 1, FractionLength: 0)

The integer range:

- Has the minimum number of bits to represent the whole integer range.
- Has no fractional bits.

All the information in the table is editable, persists across iterations, and is saved with your code generation project.

Generate Fixed-Point Code and Verify the Generated Code

Based on the numeric types proposed for a default word length of 22, continue with fixed-point code generation and verification steps and observe the plots.

- 1 Click on **Validate Types** to apply computed fixed-point types.
- 2 Next choose the option **Log inputs and outputs for comparison plots** and then click on the **Test Numerics** to rerun the testbench on the fixed-point code.

The plot on the left is generated from testbench during the simulation of floating-point code, the one on the right is generated from the simulation of the generated fixed-point code. Notice, the plots do not match.

Having chosen comparison plots option you will see additional plots that compare the floating and fixed point simulation results for each output variable.

Examine the error graph for each output variable. It is very high for this particular design.

Iterate on the Results

One way to reduce the error is to increase **Default word length** and repeat the fixed-point conversion.

In this example design, when a word length of 22 bits is chosen there is a lot of truncation error when representing the precision. More bits are required to the right of the binary point to reduce the truncation errors.

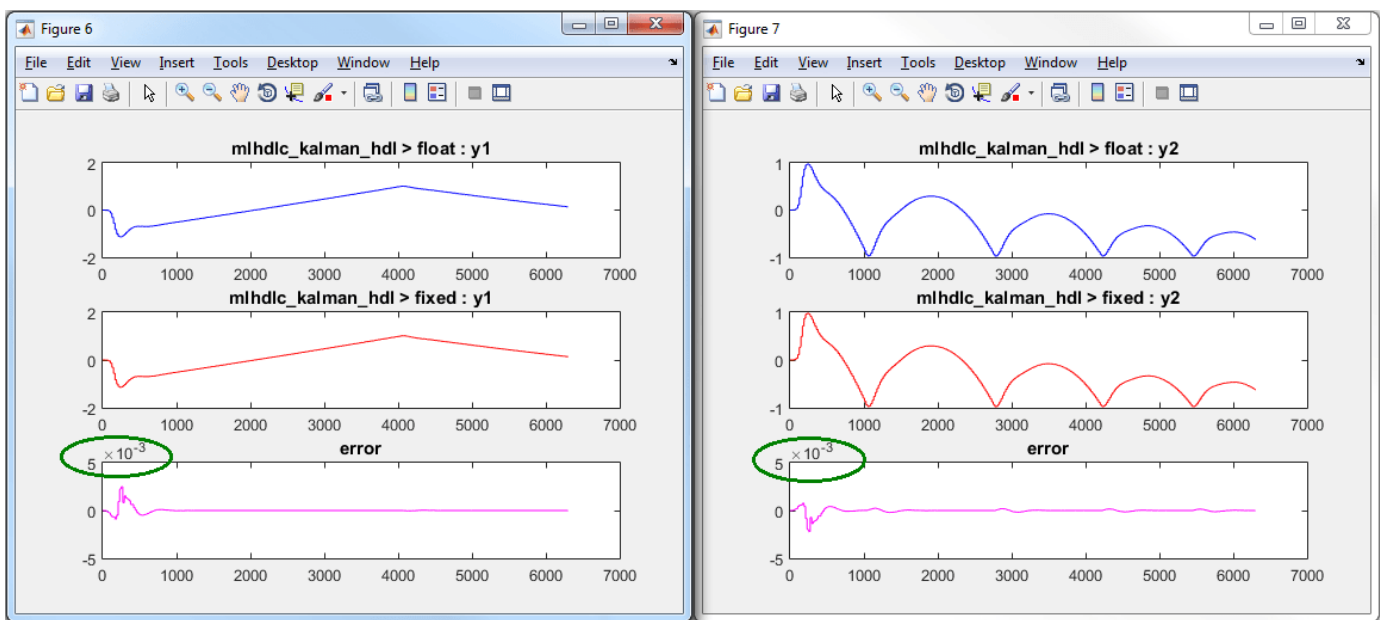

Let us now increase the default word length to 28 bits and repeat the type proposal and validation steps.

- 1 Select a **Default word length** of 28.

Changing default word length automatically triggers the type proposal step and new fixed-point types are proposed based on the new word length setting. Also notice that type validation needs to be rerun and numerics need to be verified again.

- 1 Click on **Validate Types**.
- 2 Click on **Test Numerics** to rerun the testbench on the fixed-point code.

Once these steps are complete, re-examine the comparison plots and notice that the error is now roughly three orders of magnitude smaller.

Working with Generated Fixed-Point Files

This example shows how to work with the files generated during floating-point to fixed-point conversion.

Introduction

This tutorial uses a simple filter implemented in floating-point and an associated testbench to illustrate the file structure of the generated fixed-point code.

```
design_name = 'mlhdlc_filter';  
testbench_name = 'mlhdlc_filter_tb';
```

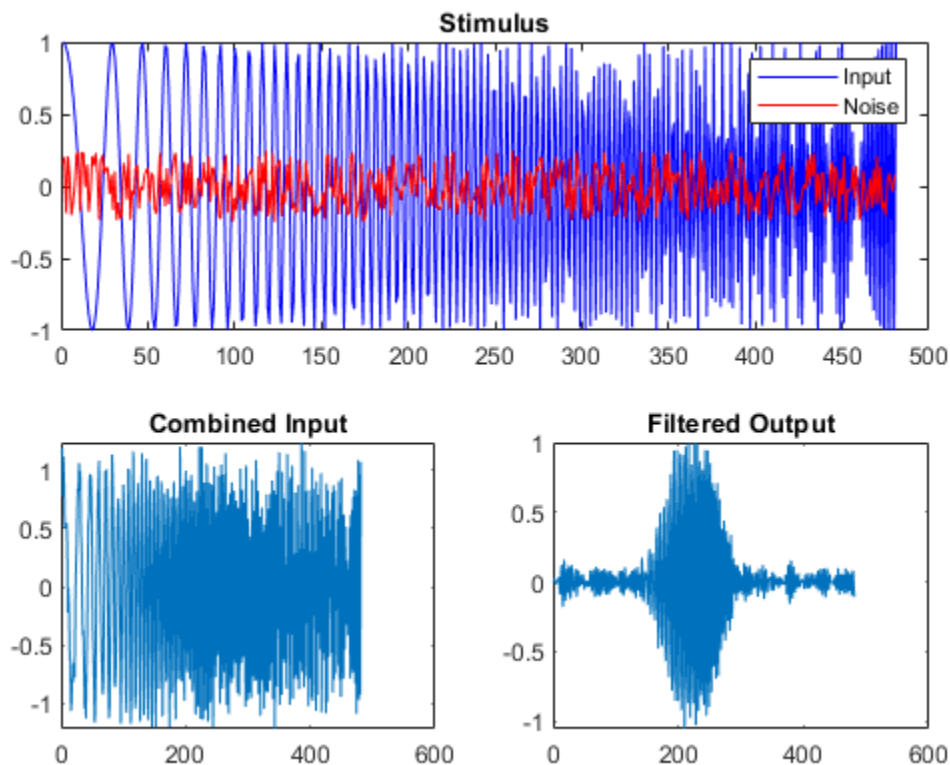

MATLAB® Code

- 1 MATLAB Design: mlhdlc_filter
- 2 MATLAB testbench: mlhdlc_filter_tb

Simulate the Design

Simulate the design with the testbench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_filter_tb
```

Create a New HDL Coder™ Project

To create a new project, enter the following command:

```
coder -hdlcoder -new flt2fix_project
```

Next, add the file 'mlhdlc_filter' to the project as the MATLAB Function and 'mlhdlc_filter_tb' as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Fixed-Point Code Generation Workflow

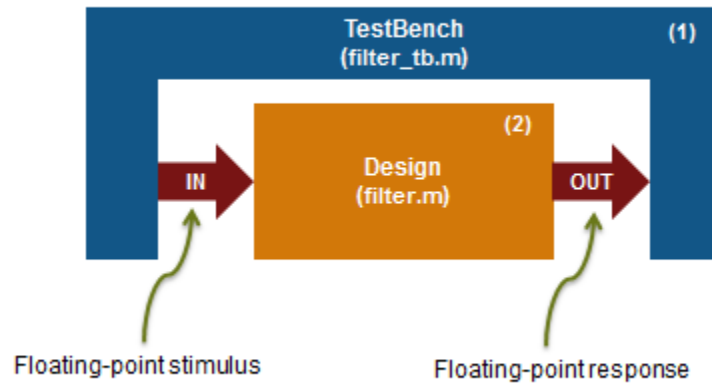

Perform the following tasks in preparation for the fixed-point code generation step:

- 1 Click the **Workflow Advisor** button to launch the Workflow Advisor.
- 2 Choose Convert to fixed-point at build time for the option **Fixed-point conversion**.
- 3 Right-click the **Fixed-Point Conversion** step and select **Run to Selected Task** to execute the instrumented floating-point simulation.

Refer to “Floating-Point to Fixed-Point Conversion” on page 4-51 for a more complete tutorial on these steps.

Floating-Point Design Structure

The original floating-point design and testbench have the following relationship.

For floating-point to fixed-point conversion, the following requirements apply to the original design and the testbench:

- The testbench 'mlhdlc_filter_tb.m' (1) must be a script or a function with no inputs. The test bench can have local helper functions that take inputs.
- The design 'mlhdlc_filter.m' (2) must be a function.
- There must be at least one call to the design from the testbench. All call sites contribute when determining the proposed fixed-point types.
- Both the design and testbench can call other sub-functions within the file or other functions on the MATLAB path. Functions that exist within matlab/toolbox are not converted to fixed-point.

In the current example, the MATLAB testbench 'mlhdlc_filter_tb' has a single call to the design function 'mlhdlc_filter'. The testbench calls the design with floating-point inputs and accumulates the floating-point results for plotting.

Validate Types

During the type validation step, fixed-point code is generated for this design and compiled to verify that there are no errors when applying the types. The output files will have the following structure.

The following steps are performed during fixed-point type validation process:

- 1** The design file 'mlhdlc_filter.m' is converted to fixed-point to generate fixed-point MATLAB code, 'mlhdlc_filter_fixpt.m' (3).
- 2** All user-written functions called in the floating-point design are converted to fixed point and included in the generated design file.
- 3** A new design wrapper file is created, called 'mlhdlc_filter_wrapper_fixpt.m' (2). This file converts the floating-point data values supplied by the testbench to the fixed-point types determined for the design inputs during the conversion step. These fixed point values are fed into the converted fixed-point design, 'mlhdlc_filter_fixpt.m'.
- 4** 'mlhdlc_filter_fixpt.m' will be used for HDL code generation.
- 5** All the generated fixed-point files are stored in the output directory 'codegen/mlhdlc_filter/fixpt'.

The screenshot shows the Workflow Advisor interface for a project named 'fft2fix_project.prj'. The left sidebar indicates the workflow steps: Define Input Types, Fixed-Point Conversion (highlighted), Select Code Generation Target, HDL Code Generation, and HDL Verification (with sub-steps: Verify with HDL Test Bench, Verify with Cosimulation, and Verify with FPGA-in-the-Loop). The main window displays the MATLAB code for the 'mldlc_filter' function, which includes comments for clearing the tap delay line and initializing coefficients. The output log at the bottom shows the simulation completion time (1.8038 sec) and the generation of type proposal reports and wrappers for the 'mldlc_filter' function.

```

10
11 function out=mldlc_filter(in)
12 persistent td c;
13 % Clear tap delay line at beginning
14 if isempty(c)
15     c = equiripple31_coeffs(); % initialize coefficients only once
16     td = zeros(1,length(c));
17 end
18 % inner product
19 out = td * c;
20 % shift tap delay line
21 td= [in td(1:end-1)];
22
23
24
25 function coefficients = equiripple31_coeffs()
26

```

Click the links to the generated code in the Workflow Advisor log Window to examine the generated fixed-point design and wrapper.

Fixed-Point Type Conversion and Derived Ranges

This example shows how to achieve your desired numerical accuracy when converting fixed-point MATLAB® code to floating-point code using static range analysis which helps to compute derived ranges of the variables from design ranges.

Introduction

The floating-point to fixed-point conversion workflow in HDL Coder™ includes the following steps:

- 1 Verify the floating-point design is compatible for code generation.
- 2 Compute fixed-point types based on the simulation of the testbench.
- 3 Generate readable and traceable fixed-point MATLAB® code.
- 4 Verify the generated fixed-point design.

However, the fixed-point types proposed from the simulation depends on the quality of the testbench. Sometimes it is hard to write testbenches which completely cover paths of the design representing full design ranges of all the variables. Static analysis based workflow can be used in such cases to compute derived ranges from design ranges.

This tutorial uses a symmetric FIR filter whose output signal is integrated over time.

MATLAB Design

The MATLAB code used in this example implements a simple Kalman filter. This example also contains a MATLAB testbench that exercises the filter.

```
design_name = 'mlhdlc_dti';  
testbench_name = 'mlhdlc_dti_tb';
```

- 1 MATLAB Design: mlhdlc_dti
- 2 MATLAB testbench: mlhdlc_dti_tb

Simulate the Design

Simulate the design with the testbench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_dti_tb
```

Create a New HDL Coder Project

To create a new project, enter the following command:

```
coder -hdlcoder -new flt2fix_project_dmm
```

Next, add the file 'mlhdlc_dti.m' to the project as the MATLAB Function and 'mlhdlc_dti_tb.m' as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Fixed-Point Code Generation Workflow

Perform the following tasks before moving on to the fixed-point type proposal step:

- 1 Click the 'Workflow Advisor' button to launch the HDL Workflow Advisor.
- 2 Choose 'Convert to fixed-point at build time' for the 'Fixed-point conversion' option.
- 3 Click 'Run' button to define input types for the design from the testbench.
- 4 Select the 'Fixed-Point Conversion' workflow step.
- 5 Click 'Analyze' to execute the instrumented floating-point simulation.

Refer to “Floating-Point to Fixed-Point Conversion” on page 4-51 for a more complete tutorial on these steps.

Determine the Initial Fixed Point Types

After instrumented floating-point simulation completes, you will see 'Fixed-Point Types are proposed' based on the simulation results.

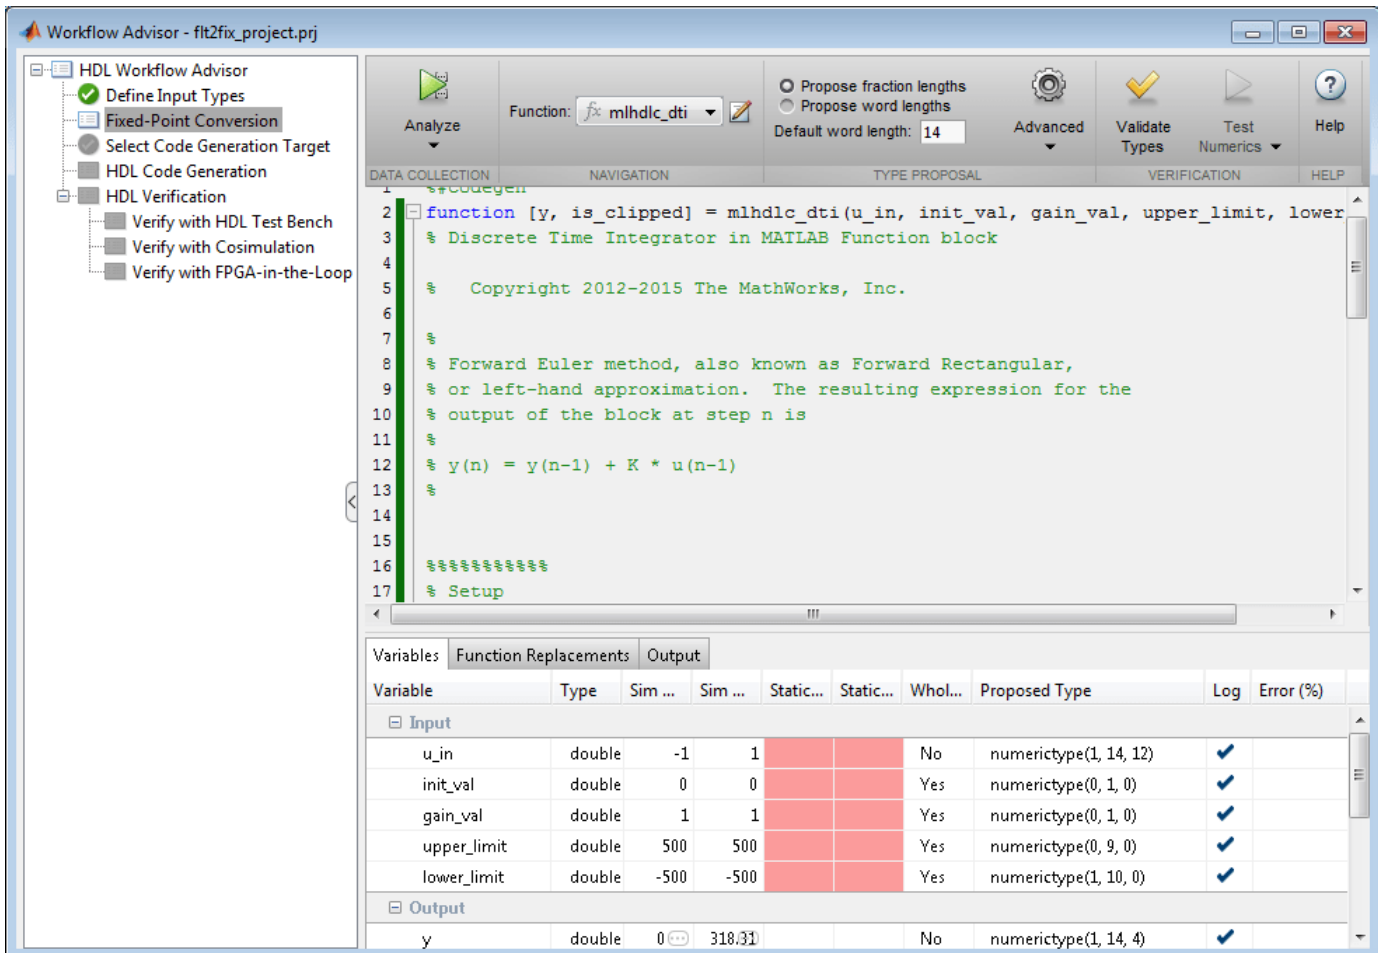

At this step fixed-point types for each variable in the design based on the recorded min/max values of the floating point variables and user input.

Observe the simulation range of the variable 'is_clipped' in the function 'mlhdlc_dti'. You will notice that the simulation range of this variable is a constant value 0. However, if you can observe the code to see that the variable can take values from -1 to -1.

The ranges for the variable can be fixed by updating the testbench. However, it may be desirable to compute program ranges through static analysis.

Entering Design Ranges and Computing Derived Ranges

In this step you can specify design ranges and compute derived ranges through static analysis. Enable derived range analysis by clicking the 'analyze ranges using derived range analysis' checkbox in the 'Analyze' button's menu. The tool will then prompt you to specify design ranges for the inputs variables in the Static Min and Static Max columns.

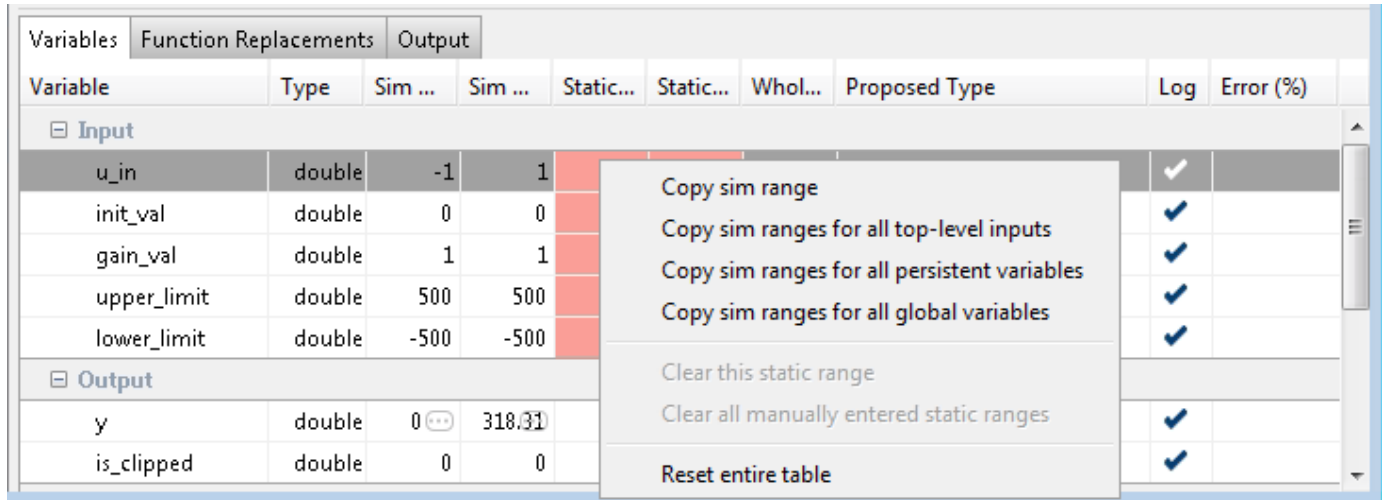

The screenshot shows the Workflow Advisor interface for the 'fit2fix_project.prj'. The 'Fixed-Point Conversion' step is active. The main window displays the MATLAB code for the 'mlhdlc_dti' function. Below the code is a table showing the proposed fixed-point types for variables.

Variable	Type	Sim ...	Sim ...	Static...	Static...	Whol...	Proposed Type	Log	Error (%)
Input									
u_in	double	-1	1			No	numerictype(1, 14, 12)	✓	
init_val	double	0	0			Yes	numerictype(0, 1, 0)	✓	
gain_val	double	1	1			Yes	numerictype(0, 1, 0)	✓	
upper_limit	double	500	500			Yes	numerictype(0, 9, 0)	✓	
lower_limit	double	-500	-500			Yes	numerictype(1, 10, 0)	✓	
Output									
y	double	0	318.31			No	numerictype(1, 14, 4)	✓	

There are multiple ways you can enter design ranges.

- 1 You can manually edit the 'Static Min' and 'Static Max' entries in the table and specify design ranges.
- 2 You can copy the Sim Min and Sim Max for a variable via right-clicking on the table cell (or)
- 3 You can Lock or Specify the Output type to be used as the design range

Once all the necessary design ranges are specified you can click on the 'Analyze' button to use derived range analysis.

Variable	Type	Sim ...	Sim Max	Static Min	Static Max	Whole N...	Proposed Type	Log	Error (...)
Input									
u_in	double	-1	1	-1	1	No	numerictype(1, 14, 12)	✓	
init_val	double	0	0	0	0	Yes	numerictype(0, 1, 0)	✓	
gain_val	double	1	1	1	1	Yes	numerictype(0, 1, 0)	✓	
upper_limit	double	500	500	500	500	Yes	numerictype(0, 9, 0)	✓	
lower_limit	double	-500	-500	-500	-500	Yes	numerictype(1, 10, 0)	✓	
Output									
y	double	0	318.31	-500	500	No	numerictype(1, 14, 4)	✓	
is_clipped	double	0	0	-1	1	Yes	numerictype(1, 2, 0)	✓	
Persistent									

Notice that the derived range of the variable now includes values taken in all paths of the control flow.

Insufficient design ranges

Sometimes specifying ranges for input variables alone may not be sufficient for certain designs. For example in a MATLAB design implementing a counter using a persistent variable, the range of the variable depends on number of times the design is called. In such situations you will see computed

derived static ranges for the variable reported as -Inf or +Inf. When these imprecise ranges appear please consider specifying ranges for such persistent variables.

Generate HDL-Compatible Lookup Table Function Replacements Using `coder.approximate`

This example shows MATLAB® code generation from a floating-point MATLAB design that is not ready for code generation. Use `coder.approximate` function to generate a lookup table based MATLAB function. This newly generated function is ready for HDL code generation (not shown in this demo).

Introduction

The MATLAB code used in the example is sigmoid function, which is used for threshold detection and decision making problems. For example, neural networks use sigmoid functions with appropriate thresholds to train systems for learning patterns.

MATLAB Design

```
design_name = 'mlhdlc_approximate_sigmoid';  
testbench_name = 'mlhdlc_approximate_sigmoid_tb';
```

This function call displays the file contents of `design_name`.

```
dbtype(design_name)
```

```
1     function y = mlhdlc_approximate_sigmoid( x )  
2     %  
3  
4     %   Copyright 2014-2015 The MathWorks, Inc.  
5  
6         y = 1./(1+exp(-x));  
7     end
```

Simulate the Design

It is always a good practice to simulate the design with the testbench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_approximate_sigmoid_tb
```

- 1 MATLAB Design: `mlhdlc_approximate_sigmoid`
- 2 MATLAB testbench: `mlhdlc_approximate_sigmoid_tb`

Use `coder.approximate` to generate a lookup-table based replacement function for `mlhdlc_approximate_sigmoid`.

Generate fixed-point lookup-table replacements

```
repCfg = coder.approximation('Function','mlhdlc_approximate_sigmoid','CandidateFunction',@mlhdlc_
                           'NumberOfPoints',50,'InputRange',[-10,10],'FunctionNamePrefix','repsig_
coder.approximate(repCfg);
```

First the fixed-point conversion completes with appropriate function replacements, and following console message,

```
### Generating approximation for 'sigmoid' : repsiglookuptable.m
### Generating testbench for 'sigmoid' : repsiglookuptable_tb.m
### LookupTable replacement for function 'sigmoid' used 50 data points
```

This should generate the MATLAB files `repsig_lookuptable_tb`, and `repsig_lookuptable` containing the testbench and design respectively.

Test the replacement functions

To visually see the degree of match between lookup-table based replacement function and the original function use the testbench,

```
repsig_lookuptable_tb();
```

Code Generation

Create and Set Up Your Project

In this section...

“Create a New Project” on page 5-2

“Open an Existing Project” on page 5-3

“Add Files to the Project” on page 5-3

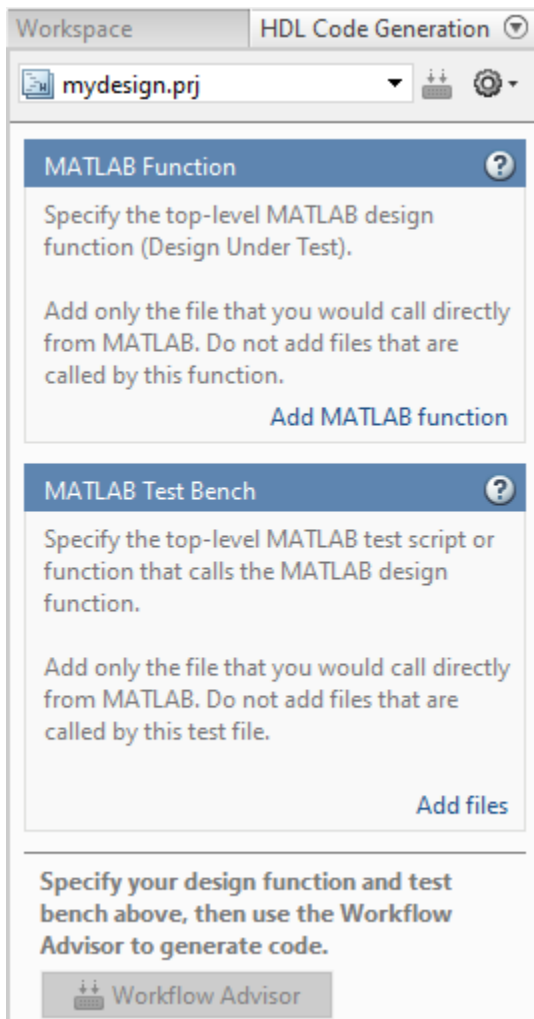

Create a New Project

- 1 At the MATLAB command line, enter:

```
hdlcoder
```

- 2 Enter a project name in the project dialog box and click **OK**.

HDL Coder creates the project in the local working folder, and, by default, opens the project in the right side of the MATLAB workspace.

Alternatively, you can create a new HDL Coder project from the apps gallery:

- 1 On the **Apps** tab, on the far right of the **Apps** section, click the arrow ▾.
- 2 Under **Code Generation**, click **HDL Coder**.
- 3 Enter a project name in the project dialog box and click **OK**.

Open an Existing Project

At the MATLAB command line, enter:

```
open project_name
```

where *project_name* specifies the full path to the project file.

Alternatively, navigate to the folder that contains your project and double-click the `.prj` file.

Add Files to the Project

Add the MATLAB Function (Design Under Test)

First, you must add the MATLAB file from which you want to generate code to the project. Add only the top-level function that you call from MATLAB (the Design Under Test). Do not add files that are called by this file. Do not add files that have spaces in their names. The path must not contain spaces, as spaces can lead to code generation failures in certain operating system configurations.

To add a file, do one of the following:

- In the project pane, under **MATLAB Function**, click the **Add MATLAB function** link and browse to the file.
- Drag a file from the current folder and drop it in the project pane under **MATLAB Function**.

If the functions that you added have inputs, and you do not specify a test bench, you must define these inputs. See “Specify Properties of Entry-Point Function Inputs” on page 5-4.

Add a MATLAB Test Bench

You must add a MATLAB test bench unless your design does not need fixed-point conversion and you do not want to generate an RTL test bench. If you do not add a test bench, you must define the inputs to your top-level MATLAB function. For more information, see “Specify Properties of Entry-Point Function Inputs” on page 5-4.

To add a test bench, do one of the following:

- In the project panel, under **MATLAB Test Bench**, click the **Add MATLAB test bench** link and browse to the file.
- Drag a file from the current folder and drop it in the project pane under **MATLAB Test Bench**.

Specify Properties of Entry-Point Function Inputs

In this section...

“When to Specify Input Properties” on page 5-4

“Why You Must Specify Input Properties” on page 5-4

“Properties to Specify” on page 5-4

“Rules for Specifying Properties of Primary Inputs” on page 5-5

“Methods for Defining Properties of Primary Inputs” on page 5-6

When to Specify Input Properties

If you supply a test bench for your MATLAB algorithm, you do not need to specify the primary function inputs manually. The HDL Coder software uses the test bench to infer the data types.

Why You Must Specify Input Properties

HDL Coder must determine the properties of all variables in the MATLAB files at compile time. To infer variable properties in MATLAB files, HDL Coder must be able to identify the properties of the inputs to the *primary* function, also known as the *top-level* or *entry-point* function. Therefore, if your primary function has inputs, you must specify the properties of these inputs, to HDL Coder. If your primary function has no input parameters, HDL Coder can compile your MATLAB file without modification. You do not need to specify properties of inputs to local functions or external functions called by the primary function.

Note Your primary function cannot be within a package. Create a wrapper function as the primary function outside the package. Call the desired function within the new function as the primary function.

If you use the tilde (~) character to specify unused function inputs in an HDL Coder project, and you want a different type to appear in the generated code, specify the type. Otherwise, the inputs default to real, scalar doubles.

Properties to Specify

If your primary function has inputs, you must specify the following properties for each input.

For	Specify properties				
	Class	Size	Complexity	numerictype	fimath
Fixed-point inputs	✓	✓	✓	✓	✓
Other inputs	✓	✓	✓		

The following data types are not supported for primary function inputs, although you can use them within the primary function:

- structure
- matrix

Variable-size data is not supported in the test bench or the primary function.

Default Property Values

HDL Coder assigns the following default values for properties of primary function inputs.

Property	Default
class	double
size	scalar
complexity	real
numerictype	No default
fimath	hdlfimath

Supported Classes

The following table presents the class names supported by HDL Coder.

Class Name	Description
logical	Logical array of true and false values
char	Character array
int8	8-bit signed integer array
uint8	8-bit unsigned integer array
int16	16-bit signed integer array
uint16	16-bit unsigned integer array
int32	32-bit signed integer array
uint32	32-bit unsigned integer array
single	Single-precision floating-point or fixed-point number array
double	Double-precision floating-point or fixed-point number array
embedded.fi	Fixed-point number array

Rules for Specifying Properties of Primary Inputs

When specifying the properties of primary inputs, follow these rules:

- You must specify the class of all primary inputs. If you do not specify the size or complexity of primary inputs, they default to real scalars.
- For each primary function input whose class is fixed point (fi), you must specify the input numerictype and fimath properties.

Methods for Defining Properties of Primary Inputs

Method	Advantages	Disadvantages
<p>“Define Input Properties by Example at the Command Line”</p> <hr/> <p>Note If you define input properties programmatically in the MATLAB file, you cannot use this method</p>	<ul style="list-style-type: none"> • Easy to use • Does not alter original MATLAB code • Designed for prototyping a function that has a few primary inputs 	<ul style="list-style-type: none"> • Must be specified at the command line every time you invoke (unless you use a script) • Not efficient for specifying memory-intensive inputs such as large structures and arrays
<p>“Define Input Properties Programmatically in the MATLAB File”</p>	<ul style="list-style-type: none"> • Integrated with MATLAB code; no need to redefine properties each time you invoke HDL Coder • Provides documentation of property specifications in the MATLAB code • Efficient for specifying memory-intensive inputs such as large structures 	<ul style="list-style-type: none"> • Uses complex syntax • HDL Coder project files do not currently recognize properties defined programmatically. If you are using a project, you must reenter the input types in the project.

Code Generation Reports

In this section...
"Report Generation" on page 5-7
"Report Location" on page 5-7
"Errors and Warnings" on page 5-8
"Files and Functions" on page 5-8
"MATLAB Source" on page 5-8
"MATLAB Variables" on page 5-9
"Additional Reports" on page 5-10
"Report Limitations" on page 5-10

HDL Coder produces a code generation report that helps you to:

- Debug code generation issues and verify that your MATLAB code is suitable for code generation.
- View generated HDL code.
- See how the code generator determines and propagates type information for variables and expressions in your MATLAB code.
- Access additional reports.

Report Generation

When you enable report generation, the code generator produces a code generation report. To control generation and opening of a code generation report, use app settings, codegen options, or configuration object properties.

In the HDL Coder app:

- 1 Open the HDL Coder Workflow Advisor.
- 2 In the HDL Code Generation step options, on the **Coding Style** tab, under **Generated Code Comments**, select the **Generate report** check box.

At the command line, use codegen options:

- To generate a report, use the `-report` option.
- To generate and open a report, use the `-launchreport` option.

Alternatively, use configuration object properties:

- To generate a report, set `GenerateReport` to `true`.
- If you want codegen to open the report for you, set `LaunchReport` to `true`.

Report Location

The code generation report is named `report.mldatx`. It is located in the `html` subfolder of the code generation output folder. If you have MATLAB R2018a or later, you can open the `report.mldatx` file by double-clicking it.

Errors and Warnings

View code generation error, warning, and information messages on the **All Messages** tab. To highlight the source code for an error or warning, click the message. It is a best practice to address the first message because subsequent errors and warnings can be related to the first message.

Files and Functions

The report lists MATLAB source functions and generated files. In the **MATLAB Source** pane, the **Function List** view organizes functions according to the containing file. To visualize functions according to the call structure, use the **Call Tree** view.

To view a function in the code pane of the report, click the function in the list. Clicking a function opens the file that contains the function. To edit the selected file in the MATLAB Editor, click **Edit in MATLAB** or click a line number in the code pane.

Specialized Functions or Classes

When a function is called with different types of inputs or a class uses different types for its properties, the code generator produces specializations. In the **MATLAB Source** pane, numbered functions (or classes) indicate specializations. For example:

```
fx fcn > 1
fx fcn > 2
```

MATLAB Source

To view a MATLAB function in the code pane, click the name of the function in the **MATLAB Source** pane. In the code pane, when you pause on a variable or expression, a tooltip displays information about its size, type, and complexity. Additionally, syntax highlighting helps you to identify MATLAB syntax elements and certain code generation attributes, such as whether a function is extrinsic or whether an argument is constant.

Extrinsic Functions

The report identifies an extrinsic function with purple text. The tooltip indicates that the function is extrinsic.

```
Function: callMyExtrinsic
1 function z = callMyExtrinsic(a,b)
2 %#codegen
3 coder.extrinsic('myExtrinsic');
4 z = 0;
5 z = myExtrinsic(a,b);
6 disp(z);
7 end
8
```

EXPRESSION INFO

myExtrinsic(a,b)

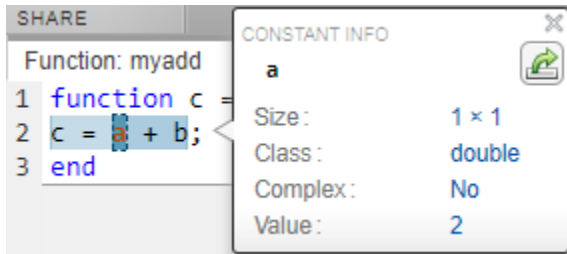

Size: 1 x 1

Class: mxArray

myExtrinsic is an extrinsic function.

Constant Arguments

Orange text indicates a compile-time constant argument to an entry-point function or a specialized function. The tooltip includes the constant value.

Knowing the value of a constant argument helps you to understand the generated function signatures. It also helps you to see when code generation creates function specializations for different constant argument values.

To export the value to a variable in the workspace, click the Export icon .

MATLAB Variables

The **Variables** tab provides information about the variables for the selected MATLAB function. To select a function, click the function in the **MATLAB Source** pane.

The variables table shows:

- Class, size, and complexity
- Properties of fixed-point types

This information helps you to understand type propagation and identify type mismatch errors.

Visual Indicators on the Variables Tab

This table describes the symbols, badges, and other indicators in the variables table.

Column in the Variables Table	Indicator	Description
Name	expander	Variable has elements or properties that you can see by clicking the expander.
Name	{:}	Heterogeneous cell array (all elements have the same properties)
Name	{n}	nth element of a heterogeneous cell array

Column in the Variables Table	Indicator	Description
Class	$v > n$	v is reused with a different class, size, and complexity. The number n identifies each unique reuse (a reuse with a unique set of properties). When you pause over a renamed variable, the report highlights only the instances of this variable that share the class, size, and complexity.
Class	complex prefix	Complex number
Class		Fixed-point type To see the fixed-point properties, click the badge.

Additional Reports

The **Summary** tab can have links to these additional reports:

- Conformance report
- Resource report
- “HDL Coding Standard Report” on page 31-2

Report Limitations

- The entry-point summary shows the individual elements of `varargin` and `varargout`, but the variables table does not show them.
- The report does not show full information for unrolled loops. It displays data types of one arbitrary iteration.
- The report does not show information about dead code.

Generate Instantiable Code for Functions

In this section...

“How to Generate Instantiable Code for Functions” on page 5-11

“Generate Code Inline for Specific Functions” on page 5-11

“Limitations for Instantiable Code Generation for Functions” on page 5-11

You can use the **Generate instantiable code for functions** option to generate a VHDL entity or Verilog module for each function. The software generates code for each entity or module in a separate file.

How to Generate Instantiable Code for Functions

To enable instantiable code generation for functions in the UI:

- 1 In the HDL Workflow Advisor, select the **HDL Code Generation** task.
- 2 In the **Advanced** tab, select **Generate instantiable code for functions**.

To enable instantiable code generation for functions programmatically, in your `coder.HdlConfig` object, set the `InstantiateFunctions` property to true. For example, to create a `coder.HdlConfig` object and enable instantiable code generation for functions:

```
hdlcfg = coder.config('hdl');
hdlcfg.InstantiateFunctions = true;
```

Generate Code Inline for Specific Functions

If you want to generate instantiable code for some functions but not others, enable the option to generate instantiable code for functions, and use `coder.inline`. See `coder.inline` for details.

Limitations for Instantiable Code Generation for Functions

The software generates code inline when:

- Function calls are within conditional code or `for` loops.
- Any function is called with a nonconstant `struct` input.
- The function has state, such as a persistent variable, and is called multiple times.
- There is an enumeration anywhere in the design function.

Edit Configuration Parameters for HDL Coder

In this section...

“Create and Modify Configuration Objects” on page 5-12

“Additional Functionalities” on page 5-12

After you have created a HDL Coder code generation configuration object at the command line, you can modify the properties of the object interactively by using the HDL Coder Configuration dialog box.

Create and Modify Configuration Objects

- 1 Create a HDL Coder configuration object.

```
cfg = coder.config('hdl')
```

- 2 Open the HDL Coder Configuration dialog box by using one of these methods:

- In the MATLAB command window, click the **Edit Configuration Object** hyperlink.
- Double-click the configuration object `cfg` in the MATLAB workspace.
- At the MATLAB command prompt, open the configuration object `cfg`.

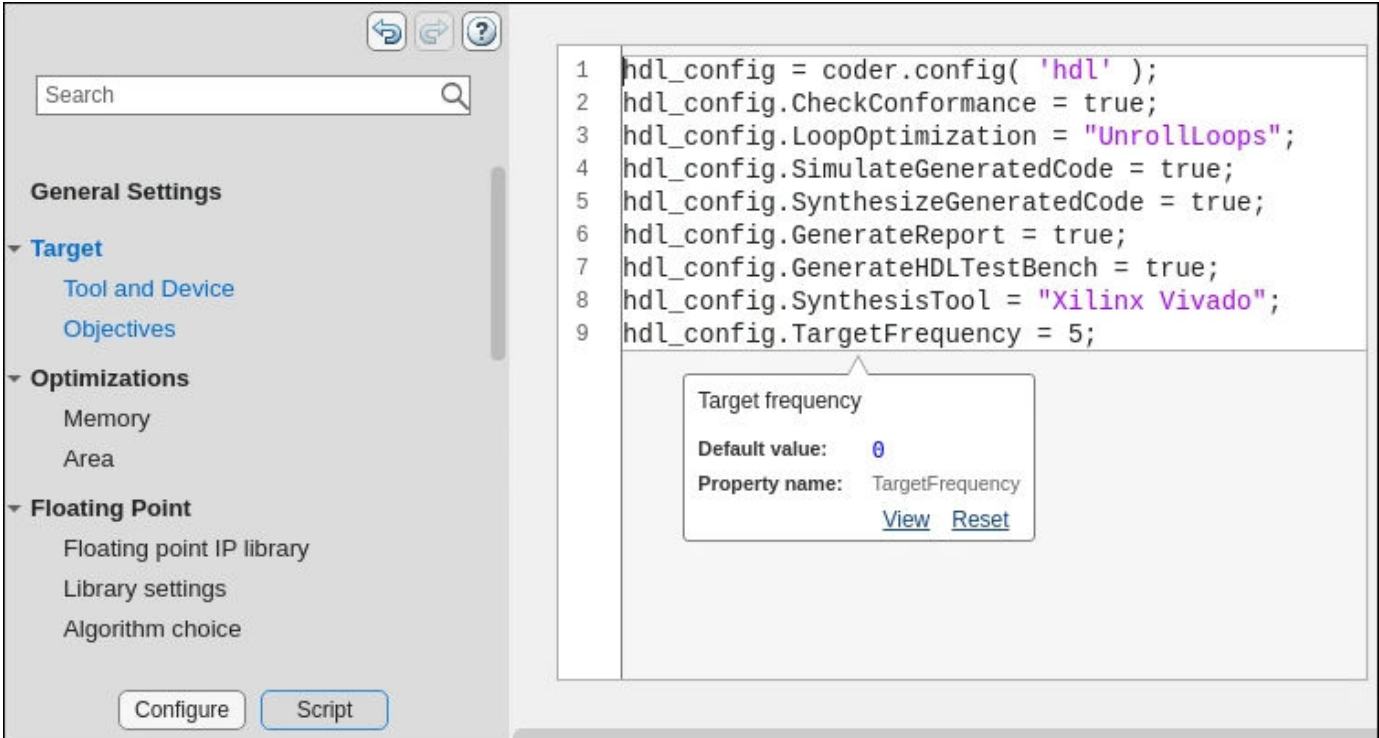

```
open cfg
```

- 3 In the dialog box, modify configuration parameters as required.

Additional Functionalities

HDL Coder Configuration dialog box provides these functionalities.

- *Search*: When you search for a string, you see the filtered results across all settings categories. The search string might be present in a setting name, the name of an option for a setting, or in a tooltip.
- *Informative tooltips*: The tooltip for each setting contains the configuration object property name, a **Help** link for that property, and the name of any additional products that are required for using the property. If the property is disabled, the tooltip also contains links to other properties that you must set to enable this property. You can make that change in the tooltip itself.
- *Settings with nondefault values*: The dialog box shows settings that have nondefault values in bold font. To reset such a setting to its default values, click the **Reset** button in the tooltip.
- *Generate equivalent script*: You can view the command-line script that produces your current settings by clicking the **Script** button located at the bottom of the list of categories on the left side of the window. You can switch from script mode back to interactive mode by clicking the **Configure** button.

The screenshot displays the HDL Coder configuration interface. On the left is a sidebar with a search bar and a tree view of settings categories: General Settings, Target (with sub-items Tool and Device and Objectives), Optimizations (with sub-items Memory and Area), and Floating Point (with sub-items Floating point IP library, Library settings, and Algorithm choice). At the bottom of the sidebar are 'Configure' and 'Script' buttons. The main area on the right contains a code editor with the following MATLAB code:

```
1 hdl_config = coder.config( 'hdl' );
2 hdl_config.CheckConformance = true;
3 hdl_config.LoopOptimization = "UnrollLoops";
4 hdl_config.SimulateGeneratedCode = true;
5 hdl_config.SynthesizeGeneratedCode = true;
6 hdl_config.GenerateReport = true;
7 hdl_config.GenerateHDLTestBench = true;
8 hdl_config.SynthesisTool = "Xilinx Vivado";
9 hdl_config.TargetFrequency = 5;
```

A tooltip is visible over the value '5' in line 9, showing the property name 'TargetFrequency', a default value of '0', and links for 'View' and 'Reset'.

Integrate Custom HDL Code Into MATLAB Design

`hdl.BlackBox` provides a way to include custom HDL code, such as legacy or handwritten HDL code, in a MATLAB design intended for HDL code generation.

When you create a user-defined System object that inherits from `hdl.BlackBox`, you specify a port interface and simulation behavior that matches your custom HDL code.

HDL Coder simulates the design in MATLAB using the behavior you define in the System object. During code generation, instead of generating code for the simulation behavior, the coder instantiates a module with the port interface you specify in the System object.

To use the generated HDL code in a larger system, you include the custom HDL source files with the rest of the generated code.

In this section...

“Define the `hdl.BlackBox` System object” on page 5-14

“Use System object In MATLAB Design Function” on page 5-15

“Generate HDL Code” on page 5-16

“Limitations for `hdl.BlackBox`” on page 5-18

Define the `hdl.BlackBox` System object

- 1 Create a user-defined System object that inherits from `hdl.BlackBox`.
- 2 Configure the black box interface to match the port interface for your custom HDL code by setting `hdl.BlackBox` properties in the System object.
- 3 Define the `step` method such that its simulation behavior matches the custom HDL code.

Alternatively, the System object you define can inherit from `hdl.BlackBox` class, and you can define `output` and `update` methods to match the custom HDL code simulation behavior.

Example Code

For example, the following code defines a System object, `CounterBbox`, that inherits from `hdl.BlackBox` and represents custom HDL code for a counter that increments until it reaches a threshold. The `CounterBbox` `reset` and `step` methods model the custom HDL code behavior.

```
classdef CounterBbox < hdl.BlackBox % derive from hdl.BlackBox class
    %Counter: Count up to a threshold.
    %
    % This is an example of a discrete-time System object with state
    % variables.
    %
    properties (Nontunable)
        Threshold = 1
    end

    properties (DiscreteState)
        % Define discrete-time states.
        Count
    end
end
```

```

methods
    function obj = CounterBbox(varargin)
        % Support name-value pair arguments
        setProperties(obj,nargin,varargin{:});
        obj.NumInputs = 1; % define number of inputs
        obj.NumOutputs = 1; % define number of inputs
    end
end

methods (Access=protected)
    % Define simulation behavior.
    % For code generation, the coder uses your custom HDL code instead.
    function resetImpl(obj)
        % Specify initial values for DiscreteState properties
        obj.Count = 0;
    end

    function myout = stepImpl(obj, myin)
        % Implement algorithm. Calculate y as a function of
        % input u and state.
        if (myin > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        myout = obj.Count;
    end
end
end
end

```

Use System object In MATLAB Design Function

After you define your System object, use it in the MATLAB design function by creating an instance and calling its `step` method.

To generate code, you also need to create a test bench function that exercises the top-level design function.

Example Code

The following example code shows a top-level design function that creates an instance of the `CounterBbox` and calls its `step` method.

```

function [y1, y2] = topLevelDesign(u)

persistent mybboxObj myramObj
if isempty(mybboxObj)
    mybboxObj = CounterBbox; % instantiate the black box
    myramObj = hdl.RAM('RAMType', 'Dual port');
end

y1 = step(mybboxObj, u); % call the system object step method
[~, y2] = step(myramObj, uint8(10), uint8(0), true, uint8(20));

```

The following example code shows a test bench function for the `topLevelDesign` function.

```

clear topLevelDesign
y1 = zeros(1,200);
y2 = zeros(1,200);

```

```

for ii=1:200
    [y1(ii), y2(ii)] = topLevelDesign(ii);
end
plot([1:200], y2)

```

Generate HDL Code

Generate HDL code using the design function and test bench code.

When you use the generated HDL code, include your custom HDL code with the generated HDL files.

Example Code

In the following generated VHDL code for the CounterBbox example, you can see that the CounterBbox instance in the MATLAB code maps to an HDL component definition and instantiation, but HDL code is not generated for the step method.

```

LIBRARY IEEE;
USE IEEE.std_logic_1164.ALL;

Enable MATLAB Function Block Generation

In this section...

“Requirements for MATLAB Function Block Generation” on page 5-19

“Enable MATLAB Function Block Generation” on page 5-19

“Restrictions for MATLAB Function Block Generation” on page 5-19

“Results of MATLAB Function Block Generation” on page 5-19

Requirements for MATLAB Function Block Generation

During HDL code generation, your MATLAB algorithm must go through the floating-point to fixed-point conversion process, even if it is already a fixed-point algorithm.

Enable MATLAB Function Block Generation

Using the GUI

To enable MATLAB Function block generation using the HDL Workflow Advisor:

- 1 In the HDL Workflow Advisor, on the left, click **Code Generation**.
- 2 In the **Advanced** tab, select the **Generate MATLAB Function Black Box** option.

Using the Command Line

To enable MATLAB Function block generation, at the command line, enter:

```
hdlcfg = coder.config('hdl');  
hdlcfg.GenerateMLFcnBlock = true;
```

Restrictions for MATLAB Function Block Generation

The top-level MATLAB design function cannot have input or output arguments with the `struct` data type.

Results of MATLAB Function Block Generation

After you generate HDL code, an untitled model opens containing a MATLAB Function block.

You can use the MATLAB Function block as part of a larger model in Simulink for simulation and further HDL code generation.

To learn more about generating a MATLAB Function block from a MATLAB algorithm, see “System Design with HDL Code Generation from MATLAB and Simulink” on page 5-20.

System Design with HDL Code Generation from MATLAB and Simulink

This example shows how to generate a MATLAB Function block from a MATLAB® design for system simulation, code generation, and FPGA programming in Simulink®.

Introduction

HDL Coder can generate HDL code from both MATLAB and Simulink. The coder can also generate a Simulink component, the MATLAB Function block, from your MATLAB code.

This capability enables you to:

- 1 Design an algorithm in MATLAB;
- 2 Generate a MATLAB Function block from your MATLAB design;
- 3 Use the MATLAB component in a Simulink model of the system;
- 4 Simulate and optimize the system model;
- 5 Generate HDL code; and
- 6 Program an FPGA with the entire system design.

In this example, you will generate a MATLAB Function block from MATLAB code that implements a FIR filter.

MATLAB Design

The MATLAB code used in the example is a simple FIR filter. The example also shows a MATLAB testbench that exercises the filter.

```
design_name = 'mlhdlc_fir';  
testbench_name = 'mlhdlc_fir_tb';
```

- 1 Design: mlhdlc_fir
- 2 Test Bench: mlhdlc_fir_tb

Simulate the Design

To simulate the design with the test bench prior to code generation to make sure there are no runtime errors, enter the following command:

```
mlhdlc_fir_tb
```

Create a New Project

To create a new HDL Coder project, enter the following command:

```
coder -hdlcoder -new fir_project
```

Next, add the file `mlhdlc_fir.m` to the project as the MATLAB Function and `mlhdlc_fir_tb.m` as the MATLAB Test Bench.

Click the **Workflow Advisor** button to launch the HDL Workflow Advisor.

Enable the MATLAB Function Block Option

To generate a MATLAB Function block from a MATLAB HDL design, you must have a Simulink license. If the following command returns 1, Simulink is available:

```
license('test', 'Simulink')
```

In the HDL Workflow Advisor, select the **HDL Code Generation** task. On the right-side, click the **Advanced** tab and select the check box **Generate Simulink model (Simulink license is required)**.

Run Floating-Point to Fixed-Point Conversion and Generate Code

To generate a MATLAB Function block, convert your design from floating-point to fixed-point.

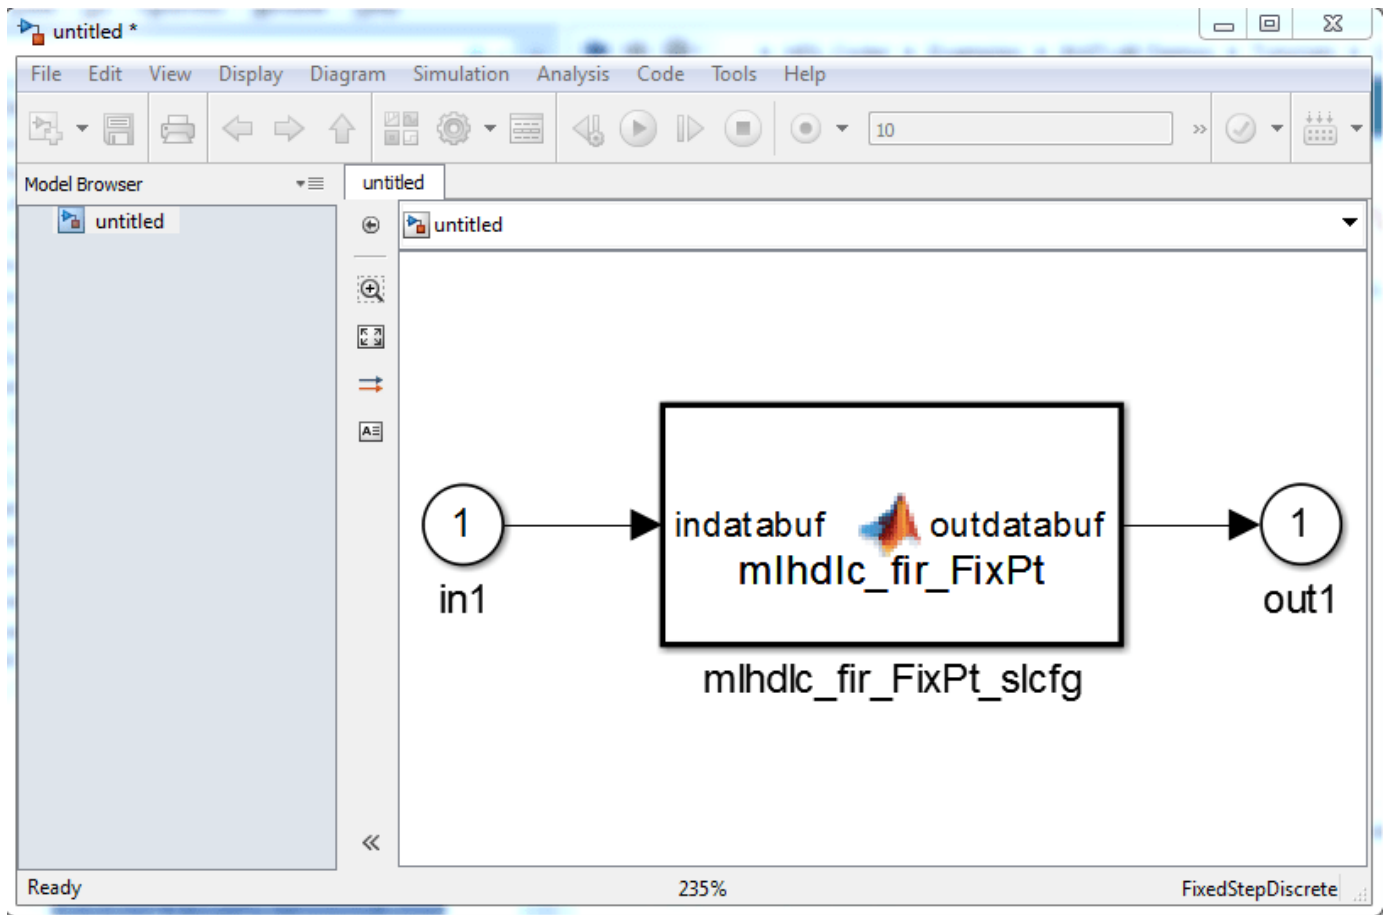

Right-click the **HDL Code Generation** step and choose the option **Run to selected task** to run all the steps from the beginning through HDL code generation.

Examine the Generated MATLAB Function Block

An untitled model opens after HDL code generation. It has a MATLAB Function block containing the fixed-point MATLAB code from your MATLAB HDL design. HDL Coder automatically applies settings to the model and MATLAB Function block so that they can simulate in Simulink and generate HDL code.

To generate HDL code from the MATLAB Function block, enter the following command:

```
makehdl('untitled');
```

You can rename and save the new block to use in a larger Simulink design.

Specify the Clock Enable Rate

In this section...

“Why Specify the Clock Enable Rate?” on page 5-23

“How to Specify the Clock Enable Rate” on page 5-23

Why Specify the Clock Enable Rate?

When HDL Coder performs area optimizations, it might upsample parts of your design (DUT), and thereby introduce an increase in your required DUT clock frequency.

If the coder upsamples your design, it generates a message indicating the ratio between the new clock frequency and your original clock frequency. For example, the following message indicates that your design’s new required clock frequency is 4 times higher than the original frequency:

```
The design requires 4 times faster clock with respect to the base rate = 1
```

This frequency increase introduces a rate mismatch between your input clock enable and output clock enable, because the output clock enable runs at the slower original clock frequency.

With the **Drive clock enable at** option, you can choose whether to drive the input clock enable at the faster rate (**DUT base rate**) or at a rate that is less than or equal to the original clock enable rate (**Input data rate**).

How to Specify the Clock Enable Rate

- 1 In the HDL Workflow Advisor, select **MATLAB to HDL Workflow > Code Generation**. Click the **Clocks & Ports** tab.
- 2 For the **Drive clock enable at** option, select **Input data rate** or **DUT base rate**.

Drive clock enable at Option	Clock Enable Behavior
Input data rate (default)	<p>Each assertion of the input clock enable produces an output clock enable assertion.</p> <p>You can assert the input clock enable at a maximum rate of once every N clocks. N = the upsampled clock rate / original clock rate.</p> <p>For example, if you see the message, “The design requires 4 times faster clock with respect to the base rate = 1”, your maximum input clock enable rate is once every 4 clocks.</p>

Drive clock enable at Option	Clock Enable Behavior
DUT base rate	<p>Input clock enable rate does not match the output clock enable rate. You must assert the input clock enable with your input data N times to get 1 output clock enable assertion. N = the upsampled clock rate / original clock rate.</p> <p>For example, if you see the message, "The design requires 4 times faster clock with respect to the base rate = 1", you must assert the input clock enable 4 times to get 1 output clock enable assertion.</p>

Specify Test Bench Clock Enable Toggle Rate

In this section...

“When to Specify Test Bench Clock Enable Toggle Rate” on page 5-25

“How to Specify Test Bench Clock Enable Toggle Rate” on page 5-25

When to Specify Test Bench Clock Enable Toggle Rate

When you want the test bench to drive your input data at a slower rate than the maximum input clock enable rate, specify the test bench clock enable toggle rate.

This specification can help you to achieve better test coverage, and to simulate the real world input data rate.

Note The maximum input clock enable rate is once every N clock cycles. N = the upsampled clock rate / original clock rate. Refer to the clock enable behavior for **Input data rate**, in “Specify the Clock Enable Rate” on page 5-23.

How to Specify Test Bench Clock Enable Toggle Rate

To set your test bench clock enable toggle rate:

- 1 In the HDL Workflow Advisor, select **MATLAB to HDL Workflow > Code Generation**.
- 2 In the **Clocks & Ports** tab, for the **Drive clock enable at** option, select **Input data rate**.
- 3 In the **Test Bench** tab, for **Input data interval**, enter 0 or an integer greater than the maximum input clock enable interval.

Input data interval, I	Test Bench Clock Enable Behavior
I = 0 (default)	Asserts at the maximum input clock enable rate, or once every N cycles. N = the upsampled clock rate / original clock rate.
I < N	Not valid; generates an error.
I = N	Same as I = 0.
I > N	Asserts every I clock cycles.

For example, this timing diagram shows clock enable behavior with **Input data interval** = 0. Here, the maximum input clock enable rate is once every 2 cycles.

The following timing diagram shows the same test bench and DUT with **Input data interval** = 3.

Generate an HDL Coding Standard Report from MATLAB

In this section...
“Using the HDL Workflow Advisor” on page 5-27
“Using the Command Line” on page 5-29

You can generate an HDL coding standard report that shows how well your generated code follows industry standards. You can optionally customize the coding standard report and the coding standard rules.

Using the HDL Workflow Advisor

To generate an HDL coding standard report using the HDL Workflow Advisor:

- 1 In the **HDL Code Generation** task, select the **Coding Standards** tab.
- 2 For **HDL coding standard**, select **Industry**.

Target	Coding Style	Coding Standards	Clocks & Ports	Optimizations	Advanced	Script Options
Choose coding standard						
HDL coding standard:		Industry				
Report options						
<input type="checkbox"/> Do not show passing rules in coding standard report						
Basic coding rules						
<input checked="" type="checkbox"/> Check for duplicate names						
<input checked="" type="checkbox"/> Check for HDL keywords in design names						
<input checked="" type="checkbox"/> Check module, instance, entity name length						
Minimum:			2			
Maximum:			32			
<input checked="" type="checkbox"/> Check signal, port, parameter name length						
Minimum:			2			
Maximum:			40			
RTL description rules						
<input type="checkbox"/> Check for clock enable signals						
<input type="checkbox"/> Check for reset signals						
<input checked="" type="checkbox"/> Check for asynchronous reset signals						
<input type="checkbox"/> Minimize use of variables						
<input checked="" type="checkbox"/> Check for initial statements that set RAM initial values						
<input checked="" type="checkbox"/> Check number of conditional regions						
Length:			1			
<input checked="" type="checkbox"/> Check if-else statement chain length						
Length:			7			
<input checked="" type="checkbox"/> Check if-else statement nesting depth						
Depth:			3			
<input checked="" type="checkbox"/> Check multiplier width						
Maximum:			16			
RTL design rules						
<input checked="" type="checkbox"/> Check for non-integer constants						
<input checked="" type="checkbox"/> Check line wrap length						

- 3 Optionally, using the other options in the **Coding Standards** tab, customize the coding standard rules.
- 4 Click **Run** to generate code.

After you generate code, the message window shows a link to the HTML compliance report.

Using the Command Line

To generate an HDL coding standard report using the command line interface, set the `HDLCodingStandard` property to `Industry` in the `coder.HdlConfig` object.

For example, to generate HDL code and an HDL coding standard report for a design, `mlhdlc_sfir`, with a testbench, `mlhdlc_sfir_tb`, enter the following commands:

```
hdlcfg = coder.config('hdl');
hdlcfg.TestBenchName = 'mlhdlc_sfir_tb';
hdlcfg.HDLCodingStandard='Industry';
codegen -config hdlcfg mlhdlc_sfir

### Generating Resource Utilization Report resource_report.html
### Generating default Industry script file mlhdlc_sfir_mlhdlc_sfir_default.prj
### Industry Compliance report with 0 errors, 8 warnings, 4 messages.
### Generating Industry Compliance Report mlhdlc_sfir_Industry_report.html
```

To open the report, click the report link.

You can customize the coding standard report and coding standard rule checks by specifying an HDL coding standard customization object. For example, suppose you have a design, `mlhdlc_sfir`, and testbench, `mlhdlc_sfir_tb`. You can create an HDL coding standard customization object, `cso`, set the maximum if-else statement chain length to 5 by using the `IfElseChain` property, and generate code:

```
hdlcfg = coder.config('hdl');
hdlcfg.TestBenchName = 'mlhdlc_sfir_tb';
hdlcfg.HDLCodingStandard='Industry';
cso = hdlcoder.CodingStandard('Industry');
cso.IfElseChain.length = 5;
hdlcfg.HDLCodingStandardCustomizations = cso;
codegen -config hdlcfg mlhdlc_sfir
```

Generate an HDL Lint Tool Script

You can generate a lint tool script to use with a third-party lint tool to check your generated HDL code.

HDL Coder can generate Tcl scripts for the following lint tools:

- Ascent Lint
- HDL Designer
- Leda
- SpyGlass
- Custom

If you specify one of the supported third-party lint tools, you can either generate a default tool-specific script, or customize the script by specifying the initialization, command, and termination names as a character vector. If you want to generate a script for a custom lint tool, you must specify the initialization, command, and termination names.

HDL Coder writes the initialization, command, and termination names to a Tcl script that you can use to run the third-party tool.

How To Generate an HDL Lint Tool Script

Using the HDL Workflow Advisor

- 1 In the HDL Workflow Advisor, select the **HDL Code Generation** task.
- 2 In the **Script Options** tab, select **Lint**.
- 3 For **Choose lint tool**, select **Ascent Lint**, **HDL Designer**, **Leda**, **SpyGlass**, or **Custom**.
- 4 Optionally, enter text to customize the **Lint script initialization**, **Lint script command**, and **Lint script termination** fields. For a custom tool, you must specify these fields.

After you generate code, the command window shows a link to the lint tool script.

Using the Command Line

To generate an HDL lint tool script from the command line, set the `HDLLintTool` property to `AscentLint`, `HDLDesigner`, `Leda`, `SpyGlass` or `Custom` in your `coder.HdlConfig` object.

To disable HDL lint tool script generation, set the `HDLLintTool` property to `None`.

For example, to generate a default SpyGlass lint script using a `coder.HdlConfig` object, *hdlcfg*, enter:

```
hdlcfg.HDLLintTool = 'SpyGlass';
```

After you generate code, the command window shows a link to the lint tool script.

To generate an HDL lint tool script with custom initialization, command, and termination strings, use the `HDLLintTool`, `HDLLintInit`, `HDLLintCmd`, and `HDLLintTerm` properties.

For example, you can use the following command to generate a custom Leda lint script for a DUT subsystem, `sfir_fixed\symmetric_fir`, with custom initialization, termination, and command strings:

```
hdlcfg.HDLLintTool = 'Leda';
hdlcfg.HDLLintInit = 'myInitialization';
hdlcfg.HDLLintCmd = 'myCommand %s';
hdlcfg.HDLLintTerm = 'myTermination';
```

After you generate code, the command window shows a link to the lint tool script.

Custom Lint Tool Command Specification

If you want to generate a lint tool script for a custom lint tool, you must use `%s` as a placeholder for the HDL file name in the generated Tcl script.

For **Lint script command** or `HDLLintCmd`, specify the lint command in the following format:

```
custom_lint_tool_command -option1 -option2 %s
```

For example, to set the `HDLLintCmd` for a `coder.HdlConfig` object, `hdlcfg`, where the lint command is `custom_lint_tool_command -option1 -option2`, enter:

```
hdlcfg.HDLLintCmd = 'custom_lint_tool_command -option1 -option2 %s';
```

Generate HDL Code from MATLAB Functions that Use Automated Lookup Table Generation

This example shows how to generate HDL code from a floating-point MATLAB® design that is not ready for code generation. Use the fixed-point conversion process by using the `float2fixed` setting with the `codegen` function to generate a lookup table based MATLAB function replacement. Use the new MATLAB replacement function to generate the HDL code.

The MATLAB code in the example is an implementation of a variable exponent function.

Specify Design and Test Bench

Specify the MATLAB design that you are generating HDL code for and the test bench script that simulates and tests the MATLAB function. The `mlhdlc_replacement_exp.m` file contains the design and the exponent function calculations. The MATLAB test bench is in the file `mlhdlc_replacement_exp_tb.m`.

```
design_name = 'mlhdlc_replacement_exp';  
testbench_name = 'mlhdlc_replacement_exp_tb';
```

Examine the MATLAB design. The use of the function `exp` is not a supported fixed-point function for HDL code generation. By using automated lookup table generation in the following steps, you can convert the `exp` function to a lookup table that is supported for HDL code generation. For a list of supported functions, see “Functions Supported for HDL and SystemC Code Generation” on page 1-2.

```
dbtype(design_name)
```

```
1     function y = mlhdlc_replacement_exp(u)  
2     %  
3  
4     %   Copyright 2014-2015 The MathWorks, Inc.  
5  
6     y = exp(u);  
7  
8     end
```

Simulate the Design

Simulate the design with the test bench to ensure there are no run-time errors.

```
mlhdlc_replacement_exp_tb
```

Generate HDL Code by Using Implicit Fixed-Point Conversion

Create a new script called, copy and paste the following code into the script, and save the file as `runme.m`. The runme executes the automated lookup table conversion and generates HDL code by using implicit fixed-point conversion.

Set up the path to your installed synthesis tool. This example uses Vivado(R).

```
hdlsetuptoolpath('ToolName', 'Xilinx Vivado', 'ToolPath', 'C:\Xilinx\Vivado\2019.1\bin\vivado.l
```

```
clear design_name testbench_name fxCfg hdlcfg interp_degree
```

```
design_name = 'mlhdlc_replacement_exp';
```

```
testbench_name = 'mlhdlc_replacement_exp_tb';
```

```
interp_degree = 0;
```

```
%% fixed point converter config
```

```
fxCfg = coder.config('fixpt');
```

```
fxCfg.TestBenchName = 'mlhdlc_replacement_exp_tb';
```

```
fxCfg.TestNumerics = true;
```

```
% specify this - for optimized HDL
```

```
fxCfg.DefaultWordLength = 10;
```

```
%% exp - replacement config
```

```
mathFcnGenCfg = coder.approximation('exp');
```

```
% generally use to increase accuracy; specify this as power of 2 for optimized HDL
```

```
mathFcnGenCfg.NumberOfPoints = 1024;
```

```
mathFcnGenCfg.InterpolationDegree = interp_degree; % can be 0,1,2, or 3
```

```
fxCfg.addApproximation(mathFcnGenCfg);
```

```

%% HDL config object
hdlcfg = coder.config('hdl');

hdlcfg.TargetLanguage = 'Verilog';

hdlcfg.DesignFunctionName = design_name;
hdlcfg.TestBenchName = testbench_name;
hdlcfg.GenerateHDLTestBench=true;

hdlcfg.SimulateGeneratedCode=true;

%If you choose VHDL set the ModelSim compile options as well
% hdlcfg.TargetLanguage = 'Verilog';
% hdlcfg.HDLCompileVHDLCmd = 'vcom %s %s -noindexcheck \n';

hdlcfg.ConstantMultiplierOptimization = 'auto'; %optimize out any multipliers from interpolation
hdlcfg.PipelineVariables = 'y u idx_bot x x_idx';%

hdlcfg.InputPipeline = 2;
hdlcfg.OutputPipeline = 2;
hdlcfg.RegisterInputs = true;
hdlcfg.RegisterOutputs = true;

hdlcfg.SynthesizeGeneratedCode = true;
hdlcfg.SynthesisTool = 'Xilinx Vivado';
hdlcfg.SynthesisToolChipFamily = 'Virtex7';
hdlcfg.SynthesisToolDeviceName = 'xc7vh580t';
hdlcfg.SynthesisToolPackageName = 'hcg1155';
hdlcfg.SynthesisToolSpeedValue = '-2G';

%codegen('-config',hdlcfg)

codegen('-float2fixed',fxpCfg,'-config',hdlcfg,'mlhdlc_replacement_exp')

%If you only want to do fixed point conversion and stop/examine the
%intermediate results you can use,

%only F2F conversion
codegen('-float2fixed',fxpCfg,'mlhdlc_replacement_exp')

```

Generate a Circuit with a High Clock Rate

To generate a high clock rate circuit for the generated lookup table replacement function, follow these recommendations:

- Use the number of points for the replacement function as a power.
- Set the **ConstantMultiplierOptimization** to Auto to allow HDL Coder™ to choose which Constant Multiplier Optimization yields the most area-efficient implementation in the generated HDL code. For more information, see “Constant Multiplier Optimization” on page 8-31.
- Use pipelined variables to minimize the clock delays and improve circuit frequency in the generated HDL code.

Output and Iterative Improvements

Run the `runme.m` script. After the fixed-point conversion completes the function replacements, the script outputs:

```

===== Step1: Analyze floating-point code =====

```

Input types not specified, inferring types by simulating the test bench.

===== Step1a: Verify Floating Point =====

```
### Analyzing the design 'mlhdlc_replacement_exp'
### Analyzing the test bench(es) 'mlhdlc_replacement_exp_tb'
### Begin Floating Point Simulation (Instrumented)
### Floating Point Simulation Completed in 1.8946 sec(s)
### Elapsed Time: 2.8361 sec(s)
```

===== Step2: Propose Types based on Range Information =====

===== Step3: Generate Fixed Point Code =====

```
### Generating Fixed Point MATLAB Code <a href="matlab:edit('codegen/mlhdlc_replacement_exp/fixpt/fxp'
### Generating Fixed Point MATLAB Design Wrapper <a href="matlab:edit('codegen/mlhdlc_replacement_exp/fixpt/fxp'
### Generating Mex file for 'mlhdlc_replacement_exp_wrapper_fixpt'
Code generation successful: To view the report, open('codegen/mlhdlc_replacement_exp/fixpt/fxp'
### Generating Type Proposal Report for 'mlhdlc_replacement_exp' <a href="matlab:web('codegen/mlhdlc_replacement_exp'>report
```

===== Step4: Verify Fixed Point Code =====

```
### Begin Fixed Point Simulation : mlhdlc_replacement_exp_tb
### Fixed Point Simulation Completed in 1.9497 sec(s)
### Generating Type Proposal Report for 'mlhdlc_replacement_exp_fixpt' <a href="matlab:web('codegen/mlhdlc_replacement_exp_fixpt'>report

Generate Board-Independent IP Core from MATLAB Algorithm

In this section...

“Requirements and Limitations for IP Core Generation” on page 5-37

“Generate Board-Independent IP Core” on page 5-37

When you open the HDL Workflow Advisor and run the IP Core Generation workflow for your Simulink model, you can specify a generic Xilinx® platform or a generic Intel® platform. The workflow then generates a generic IP core that you can integrate into any target platform of your choice. For IP core integration, define and register a custom reference design for your target board.

Requirements and Limitations for IP Core Generation

You cannot generate an HDL IP core without any AXI4 slave interface. At least one DUT port must map to an AXI4 or AXI4-Lite interface. To generate an HDL IP core without any AXI4 slave interfaces, use the Simulink IP core generation workflow. For more information, see “Generate Board-Independent HDL IP Core from Simulink Model” on page 46-26.

In the same IP core, you cannot map to both an AXI4 interface and AXI4-Lite interface.

AXI4-Lite Interface Restrictions

- The inputs and outputs must have a bit width less than or equal to 32 bits.
- The input and outputs must be scalar.

AXI4-Stream Video Interface Restrictions

- Ports must have a 32-bit width.
- Ports must be scalar.
- You can have a maximum of one input video port and one output video port.
- The AXI4-Stream Video interface is not supported in **Coprocessing - blocking Processor/FPGA synchronization** must be set to Free running mode. Coprocessing – blocking mode is not supported.

Generate Board-Independent IP Core

To generate a board-independent IP core to use in an embedded system integration environment, such as Intel Qsys, Xilinx EDK, or Xilinx IP Integrator:

- 1 Create an HDL Coder project containing your MATLAB design and test bench, or open an existing project.
- 2 In the HDL Workflow Advisor, define input types and perform fixed-point conversion.

To learn how to convert your design to fixed-point, see “Basic HDL Code Generation and FPGA Synthesis from MATLAB”.

- 3 In the HDL Workflow Advisor, in the **Select Code Generation Target** task:
 - **Workflow:** Select IP Core Generation.
 - **Platform:** Select Generic Xilinx Platform or Generic Altera Platform.

Depending on your selection, the code generator automatically sets the **Synthesis tool**. For example, if you select Generic Xilinx Platform, **Synthesis tool** automatically changes to Xilinx Vivado.

- **Additional source files:** If you are using an `hdl.BlackBox` System object to include existing Verilog or VHDL code, enter the file names. Enter each file name manually, separated with a semicolon (;), or by using the ... button.
- 4 In the **Set Target Interface** step, for each port, select an option from the **Target Platform Interfaces** drop-down list.

Port Name	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
Inport			
Blink_frequency_1	numerictype(0, 4, 0)	AXI4	x"100"
Blink_direction	numerictype(0, 1, 0)	AXI4	x"104"
Outport			
LED	numerictype(0, 8, 0)	External Port	
Read_back	numerictype(0, 8, 0)	AXI4	x"108"

- 5 In the **HDL Code Generation** step, optionally specify code generation options, then click **Run**.

In the HDL Workflow Advisor message pane, click the IP core report link to view detailed documentation for your generated IP core.

Minimize Clock Enables

In this section...

“Using the GUI” on page 5-39

“Using the Command Line” on page 5-39

“Limitations” on page 5-40

By default, HDL Coder generates code in a style that is intended to map to registers with clock enables, and the DUT has a top-level clock enable port.

If you do not want to generate registers with clock enables, you can minimize the clock enable logic. For example, if your target hardware contains registers without clock enables, you can save hardware resources by minimizing the clock enable logic.

The following VHDL code shows the default style of generated code, which uses clock enables. The `enb` signal is the clock enable:

```
Unit_Delay_process : PROCESS (clk, reset)
BEGIN
  IF reset = '1' THEN
    Unit_Delay_out1 <= to_signed(0, 32);
  ELSIF clk'EVENT AND clk = '1' THEN
    IF enb = '1' THEN
      Unit_Delay_out1 <= In1_signed;
    END IF;
  END IF;
END PROCESS Unit_Delay_process;
```

The following VHDL code shows the style of code you generate if you minimize clock enables:

```
Unit_Delay_process : PROCESS (clk, reset)
BEGIN
  IF reset = '1' THEN
    Unit_Delay_out1 <= to_signed(0, 32);
  ELSIF clk'EVENT AND clk = '1' THEN
    Unit_Delay_out1 <= In1_signed;
  END IF;
END PROCESS Unit_Delay_process;
```

Using the GUI

To minimize clock enables, in the HDL Workflow Advisor, on the **HDL Code Generation > Clocks & Ports** tab, select **Minimize clock enables**.

Using the Command Line

To minimize clock enables, in the `coder.HdlConfig` configuration object, set the `MinimizeClockEnables` property to `true`. For example:

```
hdlCfg = coder.config('hdl')
hdlCfg.MinimizeClockEnables = true;
```

Limitations

If you specify area optimizations that the coder implements by increasing the clock rate in certain regions of the design, you cannot minimize clock enables. The following optimizations prevent clock enable minimization:

- Resource sharing
- RAM mapping
- Loop streaming

Clock enable minimization is also prevented by setting **RAM architecture** to **Generic RAM without clock enable** in the HDL Workflow Advisor on the **HDL Code Generation > Advanced** tab.

Verification

- “Verify Code with HDL Test Bench” on page 6-2
- “Test Bench Generation” on page 6-5

Verify Code with HDL Test Bench

Simulate the generated HDL design under test (DUT) with test vectors from the test bench using the specified simulation tool.

- 1 Start the MATLAB to HDL Workflow Advisor.

- 2 At step **HDL Verification**, click **Verify with HDL Test Bench**.
- 3 Select **Generate HDL test bench**.

This option enables HDL Coder to generate HDL test bench code from your MATLAB test script.

- 4 Optionally, select **Simulate generated HDL test bench**. This option enables MATLAB to simulate the HDL test bench with the HDL DUT.

If you select this option, you must also select the **Simulation tool**.

- 5 For **Test Bench Options**, select and set the optional parameters according to the descriptions in the following table.

HDL Test Bench Parameter	Description
Test bench name postfix	Specify the postfix for the test bench name.

HDL Test Bench Parameter	Description
Force clock	Enable for test bench to force clock input signals.
Clock high time (ns)	Specify the number of nanoseconds the clock is high.
Clock low time (ns)	Specify the number of nanoseconds the clock is low.
Hold time (ns)	Specify the hold time for input signals and forced reset signals.
Force clock enable	Enable to force clock enable.
Clock enable delay (in clock cycles)	Specify time (in clock cycles) between deassertion of reset and assertion of clock enable.
Force reset	Enable for test bench to force reset input signals.
Reset length (in clock cycles)	Specify time (in clock cycles) between assertion and deassertion of reset.
Hold input data between samples	Enable to hold substrate signals between clock samples.
Input data interval	Specifies the number of clock cycles between assertions of clock enable. For more information, see “Specify Test Bench Clock Enable Toggle Rate” on page 5-25.
Initialize test bench inputs	Enable to initialize values on inputs to test bench before test bench drives data to DUT.
Multi file test bench	Enable to divide generated test bench into helper functions, data, and HDL test bench code.
Test bench data file name postfix	Specify the character vector to append to name of test bench data file when generating multi-file test bench.
Test bench reference postfix	Specify the character vector to append to names of reference signals in test bench code.
Ignore data checking (number of samples)	Specify the number of samples at the beginning of simulation during which output data checking is suppressed.
Simulation iteration limit	Specify the maximum number of test samples to use during simulation of generated HDL code.

- 6 Optionally, select **Skip this step** if you don't want to use the HDL test bench to verify the HDL DUT.
- 7 Click **Run**.

If the test bench and simulation is successful, you should see messages similar to these in the message pane:

```
### Begin TestBench generation.  
### Collecting data...  
### Begin HDL test bench file generation with logged samples  
### Generating test bench: mlhdlc_sfir_fixpt_tb.vhd  
### Creating stimulus vectors...  
### Simulating the design 'mlhdlc_sfir_fixpt' using 'ModelSim'.  
### Generating Compilation Report mlhdlc_sfir_fixpt_vsim_log_compile.txt  
### Generating Simulation Report mlhdlc_sfir_fixpt_vsim_log_sim.txt  
### Simulation successful.  
### Elapsed Time: 113.0315 sec(s)
```

If there are errors, those messages appear in the message pane. Fix errors and click **Run**.

Test Bench Generation

In this section...

“How Test Bench Generation Works” on page 6-5

“Test Bench Data Files” on page 6-5

“Test Bench Data Type Limitations” on page 6-5

“Use Constants Instead of File I/O” on page 6-5

How Test Bench Generation Works

HDL Coder writes the DUT stimulus and reference data from your MATLAB or Simulink simulation to data files (.dat).

During HDL simulation, the HDL test bench reads the saved stimulus from the .dat files. The test bench compares the actual DUT output with the expected output, which is also saved in .dat files. After you generate code, the message window displays links to the test bench data files.

Reference data is delayed by one clock cycle in the waveform viewer compared to default test bench generation due to the delay in reading data from files.

Test Bench Data Files

The coder saves stimulus and reference data for each DUT input and output in a separate test bench data file (.dat), with the following exceptions:

- Two files are generated for the real and imaginary parts of complex data.
- Constant DUT input data is written to the test bench as constants.

Vector input or output data is saved as a single file.

Test Bench Data Type Limitations

If you have double, single, or enumeration data types at the DUT inputs and outputs, the simulation data is generated as constants in the test bench code, instead of writing the simulation data to files.

Use Constants Instead of File I/O

You can generate test bench stimulus and reference data as constants in the test bench code instead of using file I/O. However, simulating a long running test bench that uses constants requires more memory than a test bench that uses file I/O.

Test bench generation automatically generates data as constants if your DUT inputs or outputs use data types that are not supported for file I/O. For details, see “Test Bench Data Type Limitations” on page 6-5.

To generate a test bench that uses constants instead of file I/O:

- 1 In the HDL Workflow Advisor, select the **HDL Verification > Verify with HDL Test Bench** task.
- 2 In the **Test bench Options** tab, disable the **Use file I/O for test bench** option.

Deployment

Generate Synthesis Scripts

You can generate customized synthesis scripts for the following tools:

- Xilinx Vivado®
- Xilinx ISE
- Microchip Libero
- Mentor Graphics® Precision
- Altera® Quartus II
- Synopsys® Synplify Pro®
- Intel Quartus® Pro

You can also generate a synthesis script for a custom tool by specifying the fields manually.

To generate a synthesis script:

- 1** In the HDL Workflow Advisor, select the **HDL Code Generation** task.
- 2** In the **Script Options** tab, select **Synthesis**.
- 3** For **Choose synthesis tool**, select a tool option.
- 4** If you want to customize your script, use the **Synthesis file postfix**, **Synthesis initialization**, **Synthesis command**, and **Synthesis termination** text fields to do so.

After you generate code, your synthesis Tcl script (.tcl) is in the same folder as your generated HDL code.

Map Matrices to Block RAMs to Reduce Area

This example shows how to use the RAM mapping optimization in HDL Coder™ to map persistent matrix variables to block RAMs in hardware.

Introduction

One of the attractive features of writing MATLAB code is the ease of creating, accessing, modifying and manipulating matrices in MATLAB.

When processing such MATLAB code, HDL Coder maps these matrices to wires or registers in HDL. For example, local temporary matrix variables are mapped to wires, whereas persistent matrix variables are mapped to registers.

The latter tends to be an inefficient mapping when the matrix size is large, since the number of register resources available is limited. It also complicates synthesis, placement and routing.

Modern FPGAs feature block RAMs that are designed to have large matrices. HDL Coder takes advantage of this feature and automatically maps matrices to block RAMs to improve area efficiency. For certain designs, mapping these persistent matrices to RAMs is mandatory if the design is to be realized. State-of-the-art synthesis tools may not be able to synthesize designs when large matrices are mapped to registers, whereas the problem size is more manageable when the same matrices are mapped to RAMs.

MATLAB Design

```
design_name = 'mlhdlc_sobel';  
testbench_name = 'mlhdlc_sobel_tb';
```

- MATLAB Design: mlhdlc_sobel
- MATLAB Testbench: mlhdlc_sobel_tb
- Input Image: stop_sign

Simulate the Design

Simulate the design with the test bench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_sobel_tb
```

Create a New HDL Coder™ Project

Run the following command to create a new project.

```
coder -hdlcoder -new mlhdlc_ram
```

Next, add the file 'mlhdlc_sobel.m' to the project as the MATLAB function, and 'mlhdlc_sobel_tb.m' as the MATLAB test bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Turn On the RAM Mapping Optimization

Launch the Workflow Advisor.

The checkbox 'Map persistent array variables to RAMs' needs to be turned on to map persistent variables to block RAMs in the generated code.

Run Fixed-Point Conversion and HDL Code Generation

In the Workflow Advisor, right-click the 'Code Generation' step. Choose the option 'Run to selected task' to run all the steps from the beginning through HDL code generation.

Examine the Generated Code

Examine the messages in the log window to see the RAM files generated along with the design.

```

### Begin VHDL Code Generation
### Working on mlhdlc_sobel_FixPt/u_d_ram/DualPortRAM_128x9b as DualPortRAM\_128x9b.vhd
### Working on mlhdlc_sobel_FixPt/u_d_ram as u\_d\_ram.vhd
### Working on mlhdlc_sobel_FixPt/u_d_ram/DualPortRAM_128x9b as DualPortRAM\_128x9b\_block.vhd
### Working on mlhdlc_sobel_FixPt/u_d_ram as u\_d\_ram\_block.vhd
### Working on mlhdlc_sobel_FixPt as mlhdlc\_sobel\_FixPt.vhd
### Generating package file mlhdlc\_sobel\_FixPt\_pkg.vhd
### The DUT requires an initial pipeline setup latency. Each output port experiences these
additional delays
### Output port 0: 4 cycles
### Output port 1: 4 cycles
### Generating Resource Utilization Report resource\_report.html
### Elapsed Time: 33.1382 sec(s)

```

A warning message appears for each persistent matrix variable not mapped to RAM.

Examine the Resource Report

Take a look at the generated resource report, which shows the number of RAMs inferred, by following the 'Resource Utilization report...' link in the generated code window.

Multipliers	0
Adders/Subtractors	19
Registers	29
RAMs	2
Multiplexers	5

Additional Notes on RAM Mapping

- Persistent matrix variable accesses must be in unconditional regions, i.e., outside any if-else, switch case, or for-loop code.
- MATLAB functions can have any number of RAM matrices.
- All matrix variables in MATLAB that are declared persistent and meet the threshold criteria get mapped to RAMs.
- A warning is shown when a persistent matrix does not get mapped to RAM.
- Read-dependent write data cycles are not allowed: you cannot compute the write data as a function of the data read from the matrix.

- Persistent matrices cannot be copied as a whole or accessed as a sub matrix: matrix access (read/write) is allowed only on single elements of the matrix.
- Mapping persistent matrices with non-zero initial values to RAMs is not supported.

Map Persistent Arrays and dsp.Delay Objects to RAM

In this section...

“Enable RAM Mapping” on page 8-6

“RAM Mapping Requirements for Persistent Arrays and System object Properties” on page 8-7

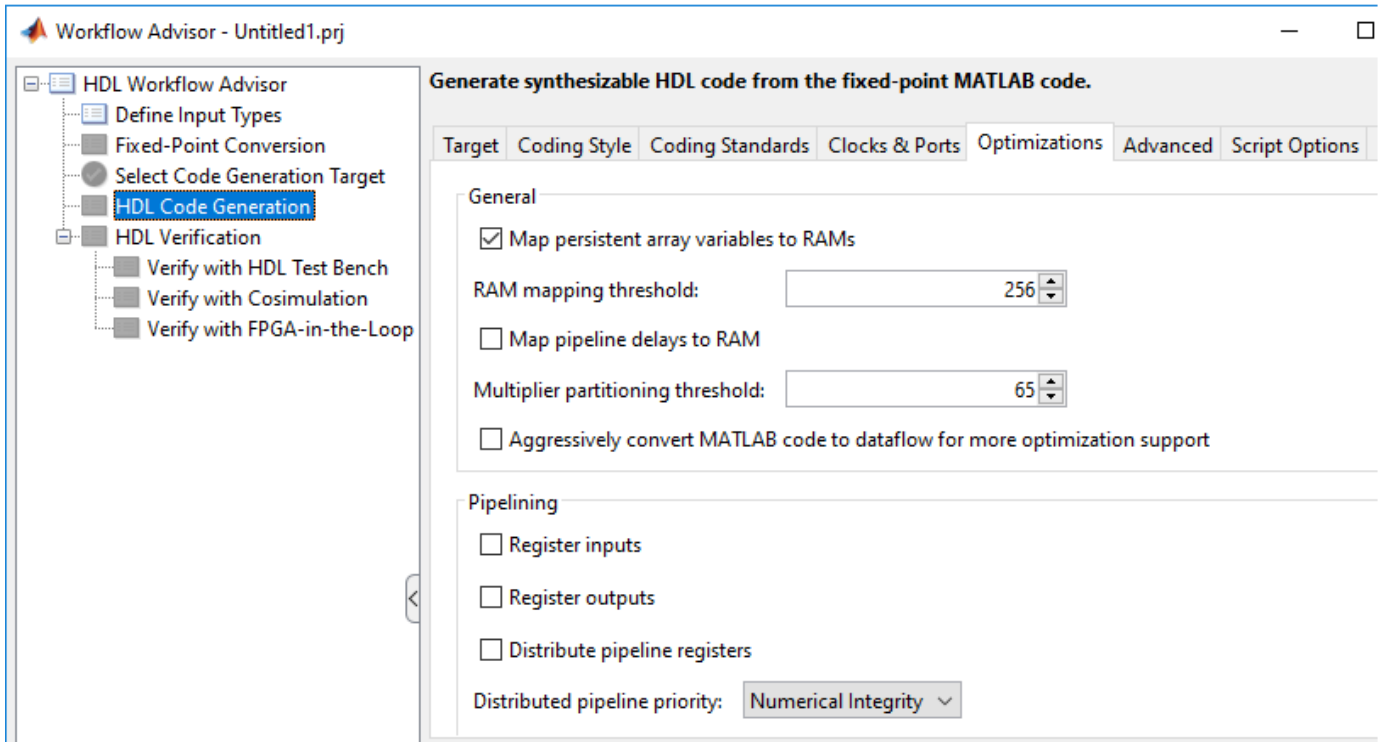

“RAM Mapping Requirements for dsp.Delay System Objects” on page 8-9

“RAM Mapping Comparison” on page 8-9

Map persistent arrays and `dsp.Delay` objects to RAM on hardware to reduce the area used on your target device. For more information on general RAM mapping, see “Apply RAM Mapping to Optimize Area” on page 28-122.

Enable RAM Mapping

- 1 In the HDL Workflow Advisor, in the left pane, click **HDL Workflow Advisor > HDL Code Generation**. Then click the **Optimizations** tab.
- 2 Select **Map persistent array variables to RAMs**.
- 3 Set the **RAM mapping threshold** to either:
 - An integer that specifies the RAM size of the smallest persistent array, user-defined System object private property, or `dsp.Delay` object that you want to map to RAM.
 - A string of format `MxN` that specifies two thresholds to define the shape of the data to map to RAM, where `M` is the delay length (for delays) or array size (for persistent array variables) and `N` is the word length or bit width of the data type. Setting both thresholds excludes delays or persistent arrays from being mapped to RAM that inefficiently map to block RAM on your target hardware.

RAM Mapping Requirements for Persistent Arrays and System object Properties

The following table shows a summary of the RAM mapping behavior for persistent arrays and private properties of a user-defined System object.

Map Persistent Array Variables to RAMs Setting	Mapping Behavior
on	Map to RAM. For restrictions, see “RAM Mapping Restrictions” on page 8-7.
off	Map to registers in the generated HDL code.

RAM Mapping Restrictions

When you enable RAM mapping, a persistent array or user-defined System object private property maps to a block RAM when all of these conditions are true:

- Each read or write access is for a single element only. For example, submatrix access and array copies are not supported.
- Address computation logic is not read-dependent. For example, computation of a read or write address using the data read from the array is not supported.
- Persistent variables or user-defined System object private properties are initialized to 0 if they have a cyclic dependency. For example, if you have two persistent variables, A and B, you have a cyclic dependency if A depends on B, and B depends on A.

- If an access is within a conditional statement, the conditional statement uses only simple logic expressions (&&, ||, ~) or relational operators. For example, in this code, `r1` does not map to RAM:

```
if (mod(i,2) > 0)
    a = r1(u);
else
    r1(i) = u;
end
```

You can rewrite complex conditions, such as conditions that call functions, by assigning them to temporary variables, and using the temporary variables in the conditional statement. For example, to map `r1` to RAM, rewrite the previous code as:

```
temp = mod(i,2);
if (temp > 0)
    a = r1(u);
else
    r1(i) = u;
end
```

- The persistent array or user-defined System object private property value depends on external inputs.

For example, in the following code, `bigarray` does not map to RAM because it does not depend on `u`:

```
function z = foo(u)

persistent cnt bigarray
if isempty(cnt)
    cnt = fi(0,1,16,10,hdlfimath);
    bigarray = uint8(zeros(1024,1));
end
z = u + cnt;
idx = uint8(cnt);
temp = bigarray(idx+1);
cnt(:) = cnt + fi(1,1,16,0,hdlfimath) + temp;
bigarray(idx+1) = idx;
```

- The RAM size is greater than or equal to the `RAMMappingThreshold` value. The RAM size is the product of `Array Size * Word Length * Complexity`, where:
 - `Array Size` is the number of elements in the array.
 - `Word Length` is the number of bits that represent the data type of the array.
 - `Complexity` is 2 for a complex data type or 1 for a real datatype.
- Access to the persistent variable that you are mapping to RAM is not in a loop, such as a `for` loop, unless the loop is unrolled. For more information, see `coder.unroll`.
- Access to the persistent variable that you are mapping to RAM is not in a nested conditional statement, such as a nested `if` statement or nested `switch` statement.

If any of the above conditions is false, the persistent array or user-defined System object private property maps to a register in the HDL code.

RAM Mapping Requirements for dsp.Delay System Objects

This table describes the dsp.Delay System object RAM mapping behavior:

Map Persistent Array Variables to RAMs Option	Mapping Behavior
on	<p>A dsp.Delay System object maps to a block RAM when all of the following conditions are true:</p> <ul style="list-style-type: none"> • Length property is greater than 4. • InitialConditions property is 0. • The delay input data type is one of these types: <ul style="list-style-type: none"> • Real scalar with a non-floating-point data type • Complex scalar with real and imaginary parts that are non-floating-point • Vector where each element is either a non-floating-point real scalar or complex scalar • The RAM size is greater than or equal to the RAM Mapping Threshold value. The RAM size is the product of DelayLength * WordLength * VectorLength * Complexity, where <ul style="list-style-type: none"> • DelayLength is the number of delays. • WordLength is the number of bits that represent the input data type. • VectorLength is the vector length of the input to the delay. • Complexity is 2 for a complex data type or 1 for a real datatype. <p>If any of the conditions are false, the dsp.Delay System object maps to registers in the HDL code.</p>
off	A dsp.Delay System object maps to registers in the generated HDL code.

RAM Mapping Comparison

hdl.RAM objects, dsp.Delay objects, persistent array variables, and user-defined System object private properties can map to RAM, but have different attributes. This table summarizes the differences.

Attribute	hdl . RAM Objects	dsp . Delay Objects	Persistent Arrays and User-Defined System object Properties
RAM mapping criteria	Unconditionally maps to RAM	Maps to RAM in HDL code under specific conditions. See “RAM Mapping Requirements for dsp.Delay System Objects” on page 8-9.	Maps to RAM in HDL code under specific conditions. See “RAM Mapping Requirements for Persistent Arrays and System object Properties” on page 8-7.
Address generation and port mapping	User specified	Automatic	Automatic
Access scheduling	User specified	Automatically inferred	Automatically inferred
Overclocking	None	None	Local multirate, if the access schedule requires it.
Latency with respect to simulation in MATLAB.	0	0	2 cycles if local multirate; 1 cycle otherwise.
RAM type	User specified	Dual port	Dual port

- “Map Matrices to Block RAMs to Reduce Area” on page 8-2

Pipelining MATLAB Code

Pipelining helps achieve a higher maximum clock rate by inserting registers at strategic points in the hardware to break the critical path. However, the higher clock rate comes at the expense of increased chip area and increased initial latency.

Port Registers

Input and output port registers for modules help partition a larger design so the critical path does not extend across module boundaries. Having a port register at each input and output port is a good design practice for synchronous interfaces. Distributed pipelining does not affect port registers. To insert input or output port registers:

- 1 In the HDL Workflow Advisor, select the **HDL Code Generation** task and select the **Optimizations** tab.
- 2 Enable **Register inputs**, **Register outputs**, or both.

Input and Output Pipeline Registers

You can insert multiple input and output pipeline stages. Distributed pipelining can move these input and output pipeline registers to help reduce your critical path within the module. If you insert input and output pipeline stages without applying distributed pipelining, the registers stay at the DUT inputs and outputs.

To insert input or output pipeline register stages:

- 1 In the HDL Workflow Advisor, select the **HDL Code Generation** task and select the **Optimizations** tab.
- 2 For **Input pipelining**, **Output pipelining**, or both, enter the number of pipeline register stages.

Operation Pipelining

Operation pipelining inserts one or more registers at the output of a specific expression in your MATLAB code. If you know a specific expression is part of the critical path, you can add a pipeline register at its output to reduce your critical path.

To learn how to insert a pipeline register at the output of a MATLAB expression, see “Pipeline MATLAB Expressions” on page 8-12.

Pipeline MATLAB Expressions

In this section...

“How To Pipeline a MATLAB Expression” on page 8-12

“Limitations of Pipelining for MATLAB Expressions” on page 8-12

With the `coder.hdl.pipeline` pragma, you can specify the placement and number of pipeline registers in the HDL code generated for a MATLAB expression.

If you insert pipeline registers and enable distributed pipelining, HDL Coder automatically moves the pipeline registers to break the critical path.

How To Pipeline a MATLAB Expression

To insert pipeline registers at the output of an expression in MATLAB code, place the expression in the `coder.hdl.pipeline` pragma. Specify the number of registers.

You can insert pipeline registers in the generated HDL code:

- At the output of the entire right side of an assignment statement.

The following code inserts three pipeline registers at the output of a MATLAB expression, $a + b * c$:

```
y = coder.hdl.pipeline(a + b * c, 3);
```

- At an intermediate stage within a longer MATLAB expression.

The following code inserts five pipeline registers after the computation of $b * c$ within a longer expression, $a + b * c$:

```
y = a + coder.hdl.pipeline(b * c, 5);
```

- By nesting multiple instances of the pragma.

The following code inserts five pipeline registers after the computation of $b * c$, and two pipeline registers at the output of the whole expression, $a + b * c$:

```
y = coder.hdl.pipeline(a + coder.hdl.pipeline(b * c, 5), 2);
```

Alternatively, to insert one pipeline register instead of multiple pipeline registers, you can omit the second argument in the pragma:

```
y = coder.hdl.pipeline(a + b * c);
```

```
y = a + coder.hdl.pipeline(b * c);
```

```
y = coder.hdl.pipeline(a + coder.hdl.pipeline(b * c));
```

Limitations of Pipelining for MATLAB Expressions

Note When you use the MATLAB code inside a MATLAB Function block and select the MATLAB Datapath architecture, these limitations do not apply.

HDL Coder cannot insert a pipeline register at the output of a MATLAB expression if any of the variables in the expression are:

- In a loop.
- A persistent variable that maps to a state element, like a state register or RAM.
- An output of a function. For example, in the following code, you cannot add a pipeline register for an expression containing `y`:

```
function [y] = myfun(x)
y = x + 5;
end
```

- In a data feedback loop. For example, in the following code, you cannot pipeline an expression containing the `t` or `pvar` variables:

```
persistent pvar;
t = u + pvar;
pvar = t + v;
```

You cannot use `coder.hdl.pipeline` to insert a pipeline register for a single variable or other no-op expression. To learn how to insert a pipeline register for a function input variable, see “Port Registers” on page 8-11.

Distributed Pipelining

In this section...
“What is Distributed Pipelining?” on page 8-14
“Benefits and Costs of Distributed Pipelining” on page 8-14
“Selected Bibliography” on page 8-14

What is Distributed Pipelining?

Distributed pipelining, or register retiming, is a speed optimization that moves existing delays in a design to reduce the critical path while preserving functional behavior. This optimization moves the delays within a subsystem while preserving the hierarchy.

The HDL Coder software uses an adaptation of the Leiserson-Saxe retiming algorithm.

Benefits and Costs of Distributed Pipelining

Distributed pipelining can reduce your design’s critical path, enabling you to use a higher clock rate and increase throughput.

However, distributed pipelining requires your design to contain a number of delays. If you need to insert additional delays in your design to enable distributed pipelining, this increases the area and the initial latency of your design.

Selected Bibliography

Leiserson, C.E, and James B. Saxe. “Retiming Synchronous Circuitry.” *Algorithmica*. Vol. 6, Number 1, 1991, pp. 5-35.

Distributed Pipelining for Clock Speed Optimization

This example shows how to use the distributed pipelining and loop unrolling optimizations in HDL Coder to optimize clock speed.

Introduction

Distributed pipelining is a design-wide optimization supported by HDL Coder for improving clock frequency. When you turn on the 'Distribute Pipeline Registers' option in HDL Coder, the coder redistributes the input and output pipeline registers of the top level function along with other registers in the design in order to minimize the combinatorial logic between registers and thus maximize the clock speed of the chip synthesized from the generated HDL code.

Consider the following example design of a FIR filter. The combinatorial logic from an input or a register to an output or another register contains a sum of products. Loop unrolling and distributed pipelining moves the output registers at the design level to reduce the amount of combinatorial logic, thus increasing clock speed.

MATLAB® Design

The MATLAB code used in the example is a simple FIR filter. The example also shows a MATLAB test bench that exercises the filter.

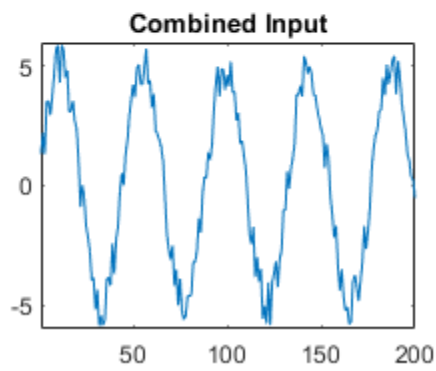

```
design_name = 'mlhdlc_fir';  
testbench_name = 'mlhdlc_fir_tb';
```

- 1 Design: mlhdlc_fir
- 2 Test Bench: mlhdlc_fir_tb

Simulate the Design

Simulate the design with the testbench prior to code generation to make sure there are no run-time errors.

```
mlhdlc_fir_tb
```

Create a Fixed-Point Conversion Config Object

To perform fixed-point conversion, you need a 'fixpt' config object.

Create a 'fixpt' config object and specify your test bench name:

```
close all;
fixptcfg = coder.config('fixpt');
fixptcfg.TestBenchName = 'mlhdlc_fir_tb';
```

Create an HDL Code Generation Config Object

To generate code, you must create an 'hdl' config object and set your test bench name:

```
hdlcfg = coder.config('hdl');
hdlcfg.TestBenchName = 'mlhdlc_fir_tb';
```

Distributed Pipelining

To increase the clock speed, the user can set a number of input and output pipeline stages for any design. In this particular example Input pipelining option is set to '1' and Output pipelining option is set to '20'. Without any additional options turned on these settings will add one input pipeline register at all input ports of the top level design and 20 output pipeline registers at each of the output ports.

If the option 'Distribute pipeline registers' is enabled, HDL Coder tries to reposition the registers to achieve the best clock frequency.

In addition to moving the input and output pipeline registers, HDL Coder also tries to move the registers modeled internally in the design using persistent variables or with system objects like `dsp.Delay`.

Additional opportunities for improvements become available if you unroll loops. The 'Unroll Loops' option unrolls explicit for-loops in MATLAB code in addition to implicit for-loops that are inferred for vector and matrix operations. 'Unroll Loops' is necessary for this example to do distributed pipelining.

```
hdlcfg.InputPipeline = 1;  
hdlcfg.OutputPipeline = 20;  
hdlcfg.DistributedPipelining = true;  
hdlcfg.LoopOptimization = 'UnrollLoops';
```

Examine the Synthesis Results

If you have ISE installed on your machine, run the logic synthesis step

```
hdlcfg.SynthesizeGeneratedCode = true;  
codegen -float2fixed fixptcfg -config hdlcfg mlhdlc_fir
```

View the result report

```
edit codegen/mlhdlc_fir/hdlsrc/ise_prj/mlhdlc_fir_fixpt_syn_results.txt
```

In the synthesis report, note the clock frequency reported by the synthesis tool. When you synthesize the design with the loop unrolling and distributed pipelining options enabled, you see a significant clock frequency increase with pipelining options turned on.

Optimize Clock Speed for MATLAB Code by Using Adaptive Pipelining

This example shows how to use the adaptive pipelining optimization in HDL Coder™ to optimize clock speed for a MATLAB® design.

Introduction

Certain patterns of code that have registers can improve the achievable clock frequency and reduce the area usage on FPGA boards. The adaptive pipelining optimization creates these patterns by inserting pipeline registers in your design. To determine the optimal number of pipeline registers to insert in your design, the target device, target frequency, and multiplier word lengths are considered.

You can also use adaptive pipelining for:

- Automatically pipelining multiply operations for optimized Digital Signal Processors (DSP) mapping.
- Other optimizations, such as resource sharing, which saves area and timing because HDL Coder shares resources and inserts adaptive pipeline registers.

To insert adaptive pipelining into your design:

- Specify the target device by specifying a synthesis tool.
- Set your target frequency to be greater than zero.

Enable Adaptive Pipelining in a MATLAB Design

- Set adaptive pipelining by using an HDL code configuration object. For example, this MATLAB code creates an HDL code configuration object and sets the adaptive pipelining property to `true`:

```
hdlcfg = coder.config('hdl');
hdlcfg.AdaptivePipelining = true;
```

For more information, see `coder.HdlConfig`.

- Enable adaptive pipelining in the **HDL Workflow Advisor > HDL Code Generation** task > **Optimization** tab.

Adaptive Pipelining Example

Consider the following example design of a simple symmetric FIR filter. Adaptive pipelining inserts pipelines to reduce the amount of combinatorial logic and increase the clock speed. The example also shows a MATLAB test bench that exercises the filter.

```
design_name = 'mlhdlc_sfir';
testbench_name = 'mlhdlc_sfir_tb';
```

Review the MATLAB design.

```
open(design_name);
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% MATLAB design: Symmetric FIR Filter
```

```
%
% Introduction:
%
% We can reduce the complexity of the FIR filter by leveraging its symmetry.
% Symmetry for an n-tap filter implies, coefficient h0 = coefficient hn-1,
% coefficient, h1 = coefficient hn-2, etc. In this case, the number of
% multipliers can be approximately halved. The key is to add the
% two data values that need to be multiplied with the same coefficient
% prior to performing the multiplication.
%
% Key Design pattern covered in this example:
% (1) Filter states represented using the persistent variables
% (2) Filter coefficients passed in as parameters

% Copyright 2011-2019 The MathWorks, Inc.

%#codegen
function [y_out, delayed_xout] = mlhdlc_sfir(x_in,h_in1,h_in2,h_in3,h_in4)
% Symmetric FIR Filter

% declare and initialize the delay registers
persistent ud1 ud2 ud3 ud4 ud5 ud6 ud7 ud8;
if isempty(ud1)
    ud1 = 0; ud2 = 0; ud3 = 0; ud4 = 0; ud5 = 0; ud6 = 0; ud7 = 0; ud8 = 0;
end

% access the previous value of states/registers
a1 = ud1 + ud8; a2 = ud2 + ud7;
a3 = ud3 + ud6; a4 = ud4 + ud5;

% multiplier chain
m1 = h_in1 * a1; m2 = h_in2 * a2;
m3 = h_in3 * a3; m4 = h_in4 * a4;

% adder chain
a5 = m1 + m2; a6 = m3 + m4;

% filtered output
y_out = a5 + a6;

% delayout input signal
delayed_xout = ud8;

% update the delay line
ud8 = ud7;
ud7 = ud6;
ud6 = ud5;
ud5 = ud4;
ud4 = ud3;
ud3 = ud2;
ud2 = ud1;
ud1 = x_in;
end
```

Simulate the Design

Before you generate code, simulate the design by using the test bench to make sure there are no run-time errors.

```
mlhdlc_sfir_tb
```

Set Up Synthesis Tool Path

Before you use HDL Coder to generate code, set up your synthesis tool path to synthesize the generated HDL code. Use the `hdlsetuptoolpath` function. For example, if your synthesis tool is Xilinx Vivado:

```
hdlsetuptoolpath('ToolName','Xilinx Vivado','ToolPath',...
    'C:\Xilinx\Vivado\2018.3\bin\vivado.bat');
```

You must have already installed Xilinx Vivado. To check your Xilinx Vivado synthesis tool setup, start the tool by running this command:

```
!vivado
```

Create an HDL Coder Project

1. Create a project by running this command:

```
coder -hdlcoder -new fir_project
```

2. For **MATLAB Function**, add the MATLAB design `mlhdlc_sfir`. Add `mlhdlc_sfir_tb.m` as the MATLAB test bench.

3. Click **Autodefine types** and use the recommended types for the MATLAB design. HDL Coder infers data types by running the test bench.

Create Fixed-Point Versions of Algorithm and Test Bench

- 1 Click the **Workflow Advisor** button to open the Workflow Advisor. The **Define Input Types** task has passed.
- 2 Run the **Fixed-Point Conversion** task. The **Fixed-Point Conversion** tool opens in the right pane. For more information, see “Floating-Point to Fixed-Point Conversion” on page 4-51.

Select Code Generation Options

Before you generate HDL code, to deploy the code onto a target platform and use adaptive pipelining for your design, specify a synthesis tool. In the **Code Generation Target** task, leave **Workflow** set to **Generic ASIC/FPGA** and specify **Xilinx Vivado** as the **Synthesis Tool**. If you do not see the synthesis tool, click **Refresh list**. Specifying the **Synthesis tool** sets default values for the target hardware, such as **Chip family**, **Device**, **Package**, and **Speed**. Set **Speed** to -1. Leave the rest of the target hardware properties at their defaults.

To show the effects of adaptive pipelining, specify a target frequency that you are trying to achieve for your target device. For this example, set the **Target frequency (MHz)** to 200. Run this task.

In the **HDL Code Generation** task, by using the tabs on the right side of this task, you can specify additional code generation options. For this example, in the **HDL Code Generation** task > **Optimization** tab:

- Specify 1 for **Input pipelining** and **Output pipelining**.
- Set **Loop Optimizations** to **Loop Unroll**. It is good practice to enable this option whenever you are using adaptive pipelining.
- For before and after comparison of adaptive pipelining effects on your design, keep the **Adaptive Pipelining** check box clear.
- Click **Run** to generate HDL code.

Examine the log window and click the links to explore the generated code and the reports. In the log window, the report shows two cycles of latency, one cycle each for the input pipeline and output pipeline added.

Synthesize Generated Code for Nonoptimized Design

After generating HDL code, in this example, go to **Synthesis and Analysis** and clear **skip this task** so that synthesis and implementation can be run on your design by using your specified **Synthesis Tool**, Xilinx Vivado. HDL Coder synthesizes the HDL code on the target platform and generates area and timing reports for your design based on the target device that you specify.

To synthesize the generated HDL code and generate a timing report from synthesis:

1. Go to the **Create project** task and add the `clock_constraint.xdc` file from the example folder by either:
 - Providing the path to the file manually in the **Additional Project Files** option.

- By selecting the file using the ellipsis on the right-side of the **Additional Project Files** option. Click the right side of the drop-down list for another ellipsis that opens your file explorer window. Navigate to the folder containing `clock_constraint.xdc`, double-click the file, and click **OK**.

If you adjust your target frequency, adjust the clock constraint file accordingly. For example, because the target frequency is 200 MHz, and the clock constraint file requires the period in nanoseconds, the period is set to $1/200 \text{ MHz} = 5 \text{ ns}$.

2. Run the **Create project** task.

This task creates a Xilinx Vivado synthesis project for the HDL code. HDL Coder uses this project in the next task to synthesize the design.

3. Select and run the **Run Synthesis** task.

This task starts the synthesis tool in the background, opens the synthesis project, compiles the HDL code, synthesizes the design, and generates netlists and area and timing reports. The timing reports take into account the `clock_constraint.xdc` file you previously specified to calculate slack between your required path delay and your actual path delay.

3. Select and run the **Run Implementation** task.

This task starts the synthesis tool in the background, runs place and route on the design, and generates pre- and post-route timing information for use in critical path analysis and back annotation of your source model.

The timing report in the output window of the **Run Implementation** task has the synthesis results show a negative slack of -2.47 ns, indicating that timing constraints are not met, and the clock frequency is 133 MHz, below the target frequency 200 MHz.

This figure shows how the algorithm is implemented in hardware when running synthesis on the generated code without adaptive pipelining. The input and output pipelines are shown in orange.

Generate and Synthesize Code for Optimized Design with Adaptive Pipelining

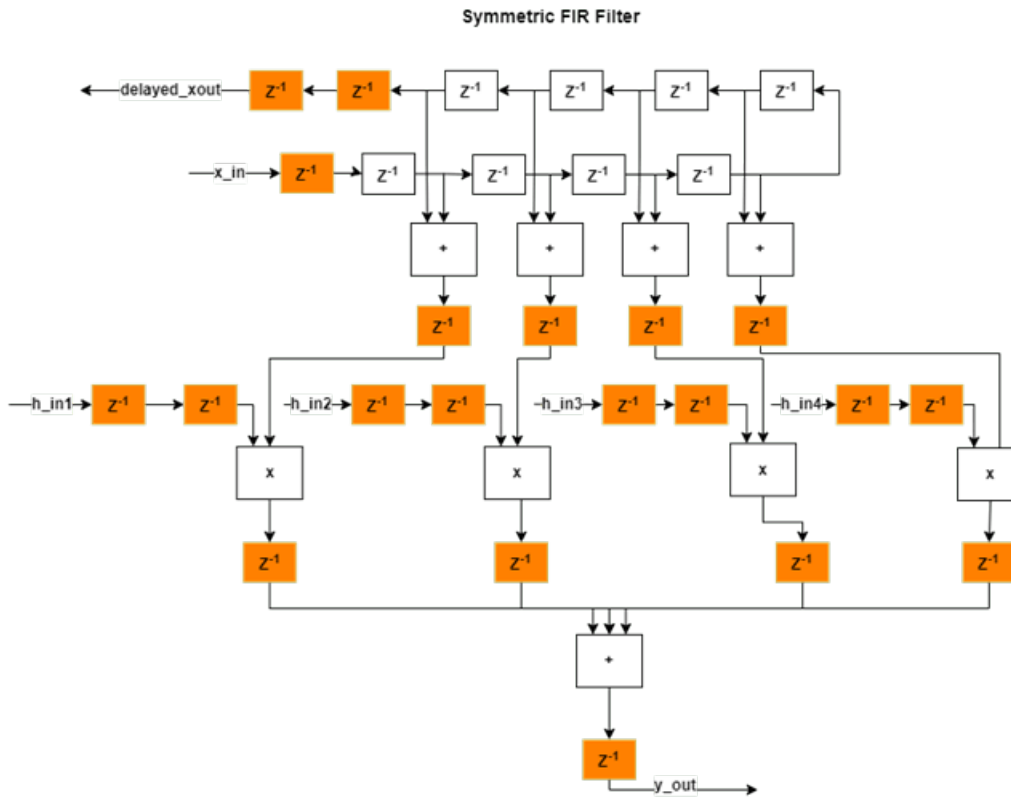

To generate HDL code with adaptive pipelining enabled, go to the **HDL Code Generation** task > **Optimization** tab, enable **Adaptive Pipelining**, and click **Run**.

In the log window, the report now shows four cycles of latency per output port, indicating that adaptive pipelining adds extra delays in the design.

When you run this task again, the subsequent tasks are reset. Because you have already specified your clock constraint file, right-click the **Synthesis and Analysis** task and select **Run This task** to run through the entire project creation, synthesis, and implementation workflow.

The timing report in the output window of the **Run Implementation** task has the synthesis results show a positive slack of .874 ns, indicating that timing constraints are now met as a result of enabling adaptive pipelining. The clock frequency is 242 MHz, above the target frequency 200 MHz.

This figure shows how the algorithm is implemented in hardware when running synthesis on the generated code with adaptive pipelining on. The additional delays added from adaptive pipelining and delay balancing are shown in orange, along with the original input and output pipelines.

Limitations

While adaptive pipelining can improve clock frequency and reduce area usage for your design, multiply operations might not be pipelined when adaptive pipelining is enabled if:

- The multiply operation is in a `for` loop that is not unrolled.
- The multiply operation is in a subfunction and **Generate instantiable code for functions** is not enabled. **Generate instantiable code for functions** is located in the **HDL Code Generation** task > **Advanced** tab.
- The multiply operation is in a subfunction and the function contains `coder.inline('never')`.

Optimize Feedback Loop Design and Maintain High Data Precision for HDL Code Generation

Optimize a feedback loop design and maintain high data precision for HDL code generation by using native floating point and clock-rate pipelining when generating HDL code from a MATLAB® design.

Open the MATLAB Code

The MATLAB function `feedback_fcn` describes a feedback loop that keeps track of the previous state value and adds it to the current value.

```
open('feedback_fcn')

function y = feedback_fcn(u)
persistent state;
if isempty(state)
    state = 0;
end
y = u + state + 1;
state = y;
```

Create HDL Code Generation Configuration Object and Apply Clock-Rate Pipelining

The variable `state` is a persistent variable. In HDL code generation, persistent variables act as delays and map to a register. As a result, persistent variables introduce latency in the feedback loop. To compensate for this latency in the generated HDL code, you can use clock-rate pipelining. For more information on clock-rate pipelining, see “Clock-Rate Pipelining” on page 28-149.

To programmatically apply clock-rate pipelining, first create a `coder.HDLConfig` object.

```
hdlcfg = coder.config('hdl');
```

Set the `DesignFunctionName` property to the MATLAB function and the `TestBenchName` property to the test bench script, `feedback_fcn_tb`.

```
hdlcfg.DesignFunctionName = 'feedback_fcn';
hdlcfg.TestBenchName = 'feedback_fcn_tb';
```

Enable `GenerateHDLTestBench` to generate HDL test bench code from `feedback_fcn_tb`.

```
hdlcfg.GenerateHDLTestBench = true;
```

Enable clock-rate pipelining and set an oversampling factor based on the amount of latency introduced in the design. In this example, the design requires a 22x faster clock than the base rate. Set the oversampling factor to 22.

```
hdlcfg.ClockRatePipelining = true;
hdlcfg.Oversampling = 22;
```

Use Native Floating Point for HDL Code Generation

The test bench function `feedback_fcn_tb` uses the `double` data type as the input to `feedback_fcn`.

```
open('feedback_fcn_tb')

for ii = 1:10
    y = feedback_fcn(ii);
end
```

Using a `double` data type as the input for HDL code generation produces non-synthesizable code unless you either convert the input to fixed-point or use native floating point. To maintain high data precision, use native floating point. The trade-off is that more hardware resources are needed to store floating-point values than fixed-point values.

To enable native floating point, first enable the `AggressiveDataflowConversion` property. This property transforms the control flow algorithm of the MATLAB code inside the MATLAB function to a dataflow representation, which native floating point uses.

```
hdlcfg.AggressiveDataflowConversion = true;
```

Use native floating point for HDL code generation by setting the `FloatingPointLibrary` property to `NativeFloatingPoint`. Set the diagnostic option `TreatRealsInGeneratedCodeAs` to `Error` in order to produce an error during HDL code generation if there is any real type in the HDL code.

```
hdlcfg.FloatingPointLibrary = 'NativeFloatingPoint';
hdlcfg.TreatRealsInGeneratedCodeAs = "Error";
```

Generate a Simulink® model that contains Simulink blocks that is functionally equivalent to your MATLAB function design. The Simulink model performs the algorithm designed in your MATLAB function. This property requires a Simulink license.

```
hdlcfg.GenerateMLFcnBlock = true;
```

Generate HDL Code

Generate HDL code with an HDL code generation report by using the `codegen` function.

```
codegen -report -config hdlcfg
```

Optimize MATLAB Loops

In this section...

“Loop Streaming” on page 8-29

“Loop Unrolling” on page 8-29

“How to Optimize MATLAB Loops” on page 8-29

“Limitations for MATLAB Loop Optimization” on page 8-30

With loop optimization, you can stream or unroll loops in generated code. Loop streaming is an area optimization, and loop unrolling is a speed optimization. To optimize loops for MATLAB code that is inside a MATLAB Function block, use the MATLAB Function architecture. When you use the MATLAB Datapath architecture, the code generator unrolls loops irrespective of the loop optimization setting.

Loop Streaming

HDL Coder streams a loop by instantiating the loop body once and using that instance for each loop iteration. The code generator oversamples the loop body instance to keep the generated loop functionally equivalent to the original loop.

If you stream a loop, the advantage is decreased hardware resource usage because the loop body is instantiated fewer times. The disadvantage is the hardware implementation runs at a lower speed.

You can partially stream a loop. A partially streamed loop instantiates the loop body more than once, so it uses more area than a fully streamed loop. However, a partially streamed loop also uses less oversampling than a fully streamed loop.

Loop Unrolling

HDL Coder unrolls a loop by instantiating multiple instances of the loop body in the generated code. You can also partially unroll a loop. The generated code uses a loop statement that contains multiple instances of the original loop body and fewer iterations than the original loop.

The distributed pipelining and resource sharing can optimize the unrolled code. Distributed pipelining can increase speed. Resource sharing can decrease area.

When loop unrolling creates multiple instances, these instances are likely to increase area. Loop unrolling also makes the code harder to read.

How to Optimize MATLAB Loops

You can specify a global loop optimization by using the HDL Workflow Advisor, or at the command line.

You can also specify a local loop optimization for a specific loop by using the `coder.hdl.loopspec` pragma in the MATLAB code. If you specify both a global and local loop optimization, the local loop optimization overrides the global setting.

Global Loop Optimization

To specify a loop optimization in the Workflow Advisor:

- 1 In the HDL Workflow Advisor left pane, select **HDL Workflow Advisor > HDL Code Generation**.
- 2 In the **Optimizations** tab, for **Loop Optimizations**, select **None**, **Unroll Loops**, or **Stream Loops**.

To specify a loop optimization at the command line in the MATLAB to HDL workflow, specify the `LoopOptimization` property of the `coder.HdlConfig` object. For example, for a `coder.HdlConfig` object, `hdlcfg`, enter one of the following commands:

```
hdlcfg.LoopOptimization = 'UnrollLoops'; % unroll loops
hdlcfg.LoopOptimization = 'StreamLoops'; % stream loops
hdlcfg.LoopOptimization = 'LoopNone'; % no loop optimization
```

Local Loop Optimization

To learn how to optimize a specific MATLAB loop, see `coder.hdl.loopspec`.

Note If you specify the `coder.unroll` pragma, this pragma takes precedence over `coder.hdl.loopspec`. `coder.hdl.loopspec` has no effect.

Limitations for MATLAB Loop Optimization

HDL Coder cannot stream a loop if:

- The loop index counts down. The loop index must increase by 1 on each iteration.
- There are two or more nested loops at the same level of hierarchy within another loop.
- Any particular persistent variable is updated both inside and outside a loop.
- A persistent variable that is initialized to a nonzero value is updated inside the loop.

HDL Coder can stream a loop when the persistent variable is:

- Updated inside the loop and read outside the loop.
- Read within the loop and updated outside the loop.

You cannot use the `coder.hdl.loopspec('stream')` pragma:

- In a subfunction. You must specify it in the top-level MATLAB design function.
- For a loop that is nested within another loop.
- For a loop containing a nested loop, unless the streaming factor is equal to the number of iterations.

Constant Multiplier Optimization

In this section...
“What is Constant Multiplier Optimization?” on page 8-31
“Specify Constant Multiplier Optimization” on page 8-31

What is Constant Multiplier Optimization?

The **Constant multiplier optimization** option enables you to specify use of canonical signed digit (CSD) or factored CSD (FCSD) optimizations for processing coefficient multiplier operations.

The following table shows the **Constant multiplier optimization** values.

Constant Multiplier Optimization Value	Description
None (default)	By default, HDL Coder does not perform CSD or FCSD optimizations. Code generated for the Gain block retains multiplier operations.
CSD	When you specify this option, the generated code decreases the area used by the model while maintaining or increasing clock speed, using canonical signed digit (CSD) techniques. CSD replaces multiplier operations with add and subtract operations. CSD minimizes the number of addition operations required for constant multiplication by representing binary numbers with a minimum count of nonzero digits.
FCSD	This option uses factored CSD (FCSD) techniques, which replace multiplier operations with shift and add/subtract operations on certain factors of the operands. These factors are generally prime but can also be a number close to a power of 2, which favors area reduction. This option lets you achieve a greater area reduction than CSD, at the cost of decreasing clock speed.
Auto	When you specify this option, HDL Coder chooses between the CSD or FCSD optimizations. The coder chooses the optimization that yields the most area-efficient implementation, based on the number of adders required. HDL Coder does not use multipliers, unless conditions are such that CSD or FCSD optimizations are not possible (for example, if the design uses floating-point arithmetic).

Specify Constant Multiplier Optimization

To specify constant multiplier optimization:

- 1 In the HDL Workflow Advisor, select the **HDL Code Generation** task and select the **Optimizations** tab.

- 2** For **Constant multiplier optimization**, select **CSD**, **FCSD**, or **Auto**.

Resource Sharing of Multipliers to Reduce Area

This example shows how to use the resource sharing optimization in HDL Coder™. This optimization identifies functionally equivalent multiplier operations in MATLAB® code and shares them in order to optimize design area. You have control over the number of multipliers to be shared in the design.

Introduction

Resource sharing is a design-wide optimization supported by HDL Coder™ for implementing area-efficient hardware.

This optimization enables users to share hardware resources by mapping N functionally-equivalent MATLAB operators, in this case multipliers, to a single operator.

The user specifies N using the `Resource Sharing Factor` option in the optimization panel.

Consider the following example model of a symmetric FIR filter. It contains 4 product blocks that are functionally equivalent and which are mapped to 4 multipliers in hardware. The Resource Utilization Report shows the number of multipliers inferred from the design.

In this example you run fixed-point conversion on the MATLAB design `mlhdlc_sharing` followed by HDL Coder. This prerequisite step normalizes all the multipliers used in the fixed-point code. You input proposed-type settings during this fixed-point conversion phase.

MATLAB Design

The MATLAB code used in the example is a simple symmetric FIR filter written in MATLAB and also has a testbench that exercises the filter.

```
design_name = 'mlhdlc_sharing';
testbench_name = 'mlhdlc_sharing_tb';
```

Look at the MATLAB design.

```
type(design_name);

clear mlhdlc_sharing;

% input signal with noise
x_in = cos(3.*pi.*(0:0.001:2).*(1+(0:0.001:2).*75)).';

len = length(x_in);
y_out = zeros(1,len);
x_out = zeros(1,len);

% Define a regular MATLAB constant array:
%
% filter coefficients
h = [-0.1339 -0.0838 0.2026 0.4064];

for ii=1:len
    data = x_in(ii);
    % call to the design 'mlhdlc_sfir' that is targeted for hardware
    [y_out(ii), x_out(ii)] = mlhdlc_sharing(data, h);
end

figure('Name', [mfilename, '_plot']);
plot(1:len,y_out);
```

Create a New HDL Coder Project

Run the following command to create a new project:

```
coder -hdlcoder -new mlhdlc_sfir_sharing
```

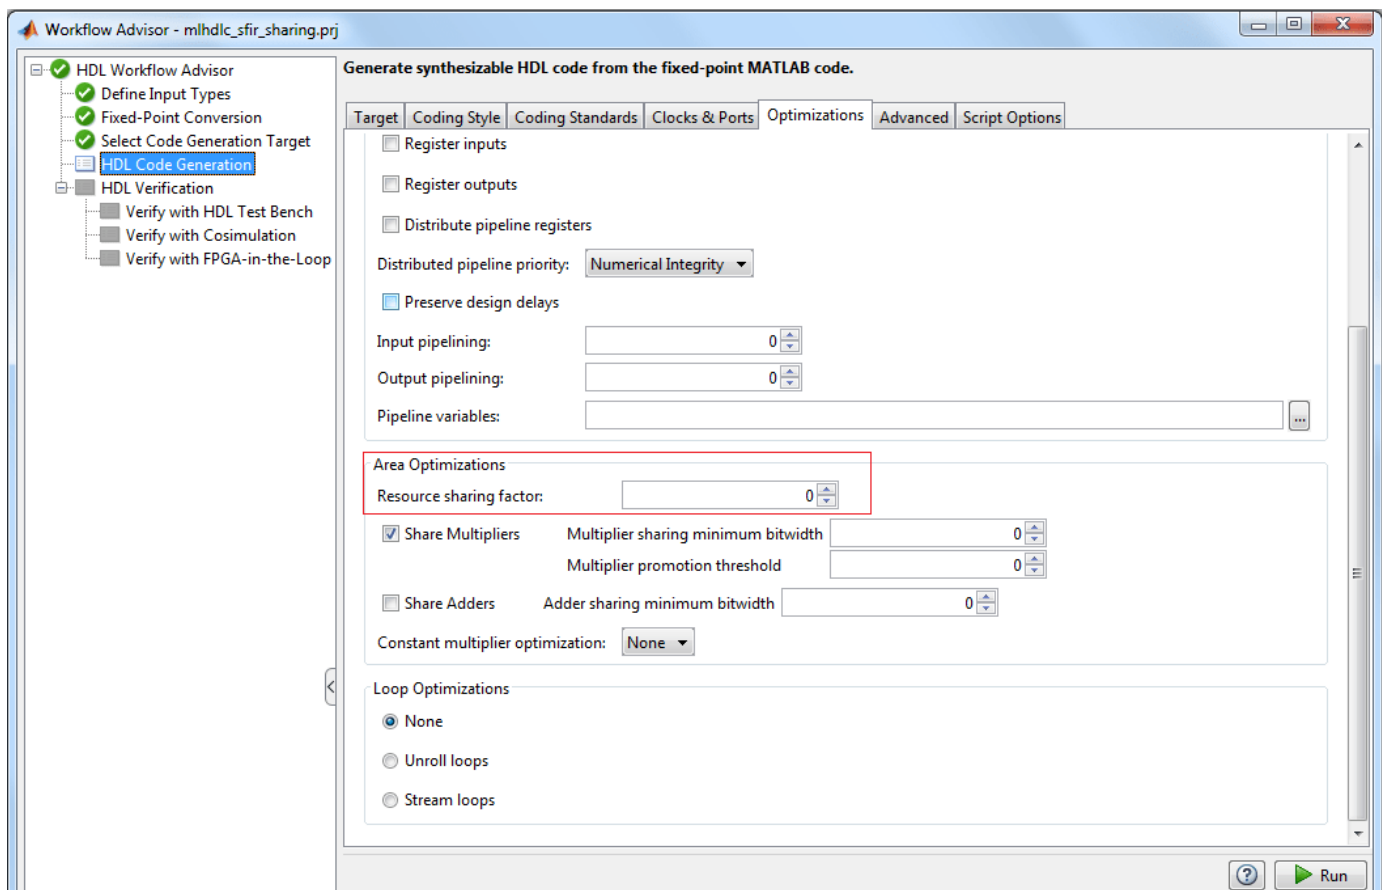

Next, add the file `mlhdlc_sharing.m` to the project as the MATLAB Function and `mlhdlc_sharing_tb.m` as the MATLAB Test Bench.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Realize an N-to-1 Mapping of Multipliers

Turn on the resource sharing optimization by setting the 'Resource Sharing Factor' to a positive integer value.

This parameter specifies N in the N-to-1 hardware mapping. Choose a value of $N > 1$.

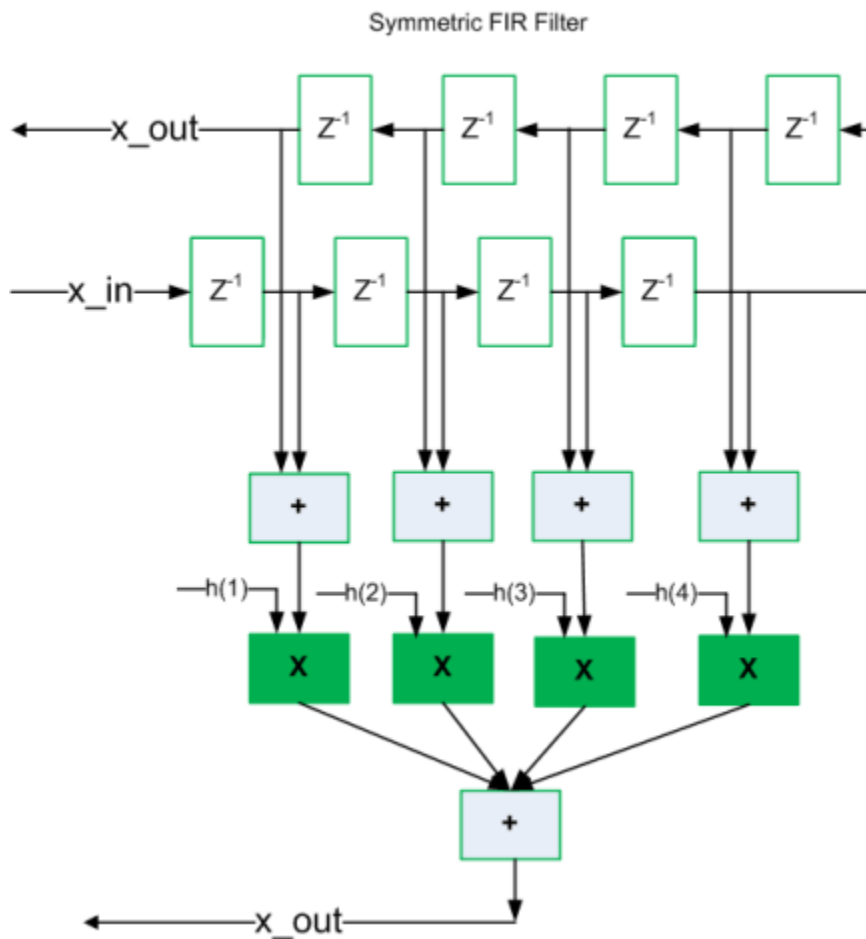

Examine the Resource Report

There are 4 multiplication operators in this example design. Generating HDL with a SharingFactor of 4 will result in only one multiplier in the generated code.

Multipliers	1
Adders/Subtractors	7
Registers	29
RAMs	0
Multiplexers	12

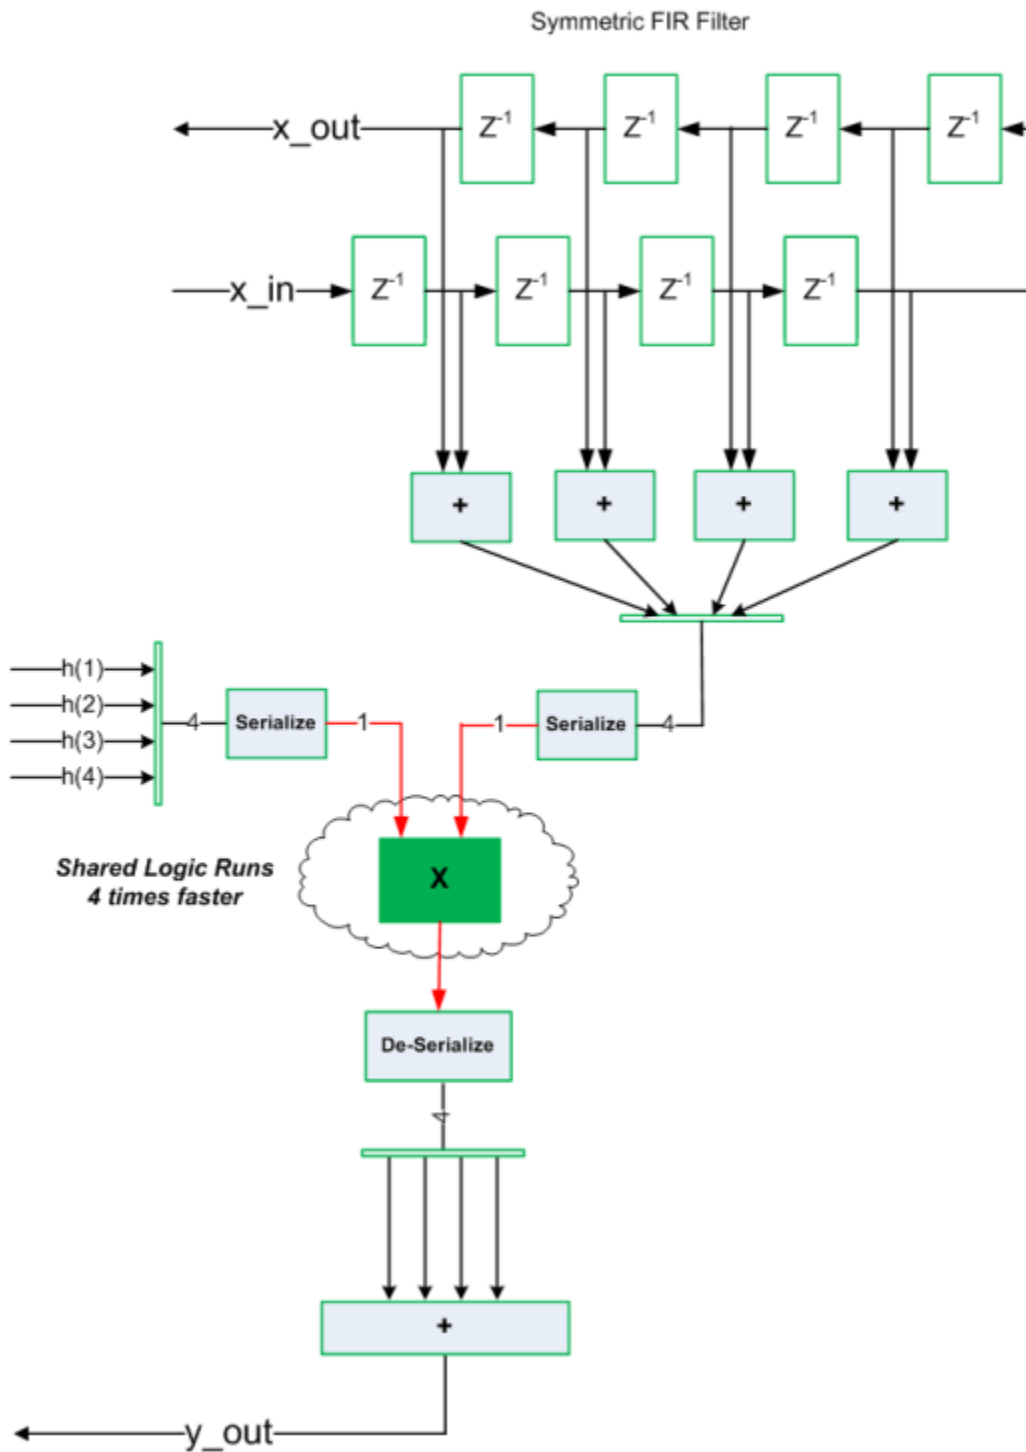

Sharing Architecture

The following figure shows how the algorithm is implemented in hardware when we synthesize the generated code without turning on the sharing optimization.

The following figure shows the sharing architecture automatically implemented by HDL Coder when the sharing optimization option is turned on.

The inputs to the shared multiplier are time-multiplexed at a faster rate (in this case 4x faster and denoted in red). The outputs are then routed to the respective consumers at a slower rate (in green).

Run Fixed-Point Conversion and HDL Code Generation

Launch the Workflow Advisor and right-click the **Code Generation** step. Choose the option **Run to selected task** to run all the steps from the beginning through the HDL code generation.

The detailed example “Fixed-Point Type Conversion and Derived Ranges” on page 4-73 provides a tutorial for updating the type proposal settings during fixed-point conversion.

Note that to share multipliers of different word-length, in the Optimization -> Resource Sharing tab of HDL Configuration Parameters, specify the **Multiplier promotion threshold**.

Run Synthesis and Examine Synthesis Results

Synthesize the generated code from the design with this optimization turned off, then with it turned on, and examine the area numbers in the resource report.

Loop Streaming to Reduce Area

This example shows how to use the design-level loop streaming optimization in HDL Coder™ to optimize area.

Introduction

A MATLAB® for loop generates a FOR_GENERATE loop in VHDL. Such loops are always spatially unrolled for execution in hardware. In other words, the body of the software loop is replicated as many times in hardware as the number of loop iterations. This results in inefficient area usage.

The loop streaming optimization creates an alternative implementation of a software loop, where the body of the loop is shared in hardware. Instead of spatially replicating copies of the loop body, HDL Coder™ creates a single hardware instance of the loop body that is time-multiplexed across loop iterations.

MATLAB Design

The MATLAB code used in this example implements a simple FIR filter. This example also shows a MATLAB testbench that exercises the filter.

```
design_name = 'mlhdlc_fir';  
testbench_name = 'mlhdlc_fir_tb';
```

- 1 Design: mlhdlc_fir
- 2 Test Bench: mlhdlc_fir_tb

Simulate the Design

Simulate the design with the testbench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_fir_tb
```

Creating a New Project From the Command Line

To create a new project, enter the following command:

```
coder -hdlcoder -new fir_project
```

Next, add the file `mlhdlc_fir.m` to the project as the MATLAB Function and `mlhdlc_fir_tb.m` as the MATLAB Test Bench.

Launch the Workflow Advisor.

Refer to “Get Started with MATLAB to HDL Workflow” for a more complete tutorial on creating and populating MATLAB HDL Coder projects.

Turn On Loop Streaming

The loop streaming optimization in HDL Coder converts software loops (either written explicitly using a for-loop statement, or inferred loops from matrix/vector operators) to area-friendly hardware loops.

Run Fixed-Point Conversion and HDL Code Generation

Right-click the **Code Generation** step. Choose the option **Run to selected task** to run all the steps from the beginning through HDL code generation.

Examine the Generated Code

When you synthesize the design with the loop streaming optimization, you see a reduction in area resources in the resource report. Try generating HDL code with and without the optimization.

The resource report without the loop streaming optimization:

Multipliers	16
Adders/Subtractors	31
Registers	106
RAMs	0
Multiplexers	0

The resource report with the loop streaming optimization enabled:

Multipliers	1
Adders/Subtractors	17
Registers	448
RAMs	0
Multiplexers	5

Limitations

Loops will be streamed only if they are regular nested loops. A regular nested loop structure is defined as one where:

- None of the loops in any level of nesting appear in a conditional flow region, i.e. no loop can be embedded within if-else or switch-else regions.
- Loop index variables are monotonically increasing.
- Total number of iterations of the loop structure is non-zero.
- There are no back-to-back loops at the same level of the nesting hierarchy.

Constant Multiplier Optimization to Reduce Area

This example shows how to perform a design-level area optimization in HDL Coder™ by converting constant multipliers into shifts and adds using canonical signed digit (CSD) techniques. The CSD representation of multiplier constants for example, in gain coefficients or filter coefficients) significantly reduces the area of the hardware implementation.

Canonical Signed Digit (CSD) Representation

A signed digit (SD) representation is an augmented binary representation with weights 0,1 and -1. -1 is represented in HDL Coder generated code as 1'.

$$X_{10} = \sum_{r=0}^{B-1} x_r \cdot 2^r$$

where

$$x_r = 0, 1, -1(\bar{1})$$

For example, here are a couple of signed digit representations for 93:

$$X_{10} = 64 + 16 + 13 = 01011101$$

$$X_{10} = 128 - 32 - 2 - 1 = 10\bar{1}000\bar{1}\bar{1}$$

Note that the signed digit representation is non-unique. A canonical signed digit (CSD) representation is an SD representation with the minimum number of nonzero elements.

Here are some properties of CSD numbers:

- 1 No two consecutive bits in a CSD number are nonzero
- 2 CSD representation uses minimum number of nonzero digits
- 3 CSD representation of a number is unique

CSD Multiplier

Let us see how a CSD representation can yield an implementation requiring a minimum number of adders.

Let us look at CSD example:

```

y = 231 * x
  = (11100111) * x           % 231 in binary form
  = (1001'01001') * x       % 231 in signed digit form
  = (256 - 32 + 8 - 1) * x   %
  = (x << 8) - (x << 5) + (x << 3) - x % cost of CSD: 3 Adders

```

HDL Coder CSD Implementation

HDL Coder uses a CSD implementation that differs from the traditional CSD implementation. This implementation preferentially chooses adders over subtractors when using the signed digit representation. In this representation, sometimes two consecutive bits in a CSD number can be nonzero. However, similar to the CSD implementation, the HDL Coder implementation uses the minimum number of nonzero digits. For example:

In the traditional CSD implementation, the number 1373 is represented as:

$$1373 = 0101'01'01'001'01$$

This implementation does not have two consecutive nonzero digits in the representation. The cost of this implementation is 1 adder and 4 subtractors.

In the HDL Coder CSD implementation, the number 1373 is represented as:

$$1373 = 00101011001'01$$

This implementation has two consecutive nonzero digits in the representation but uses the same number of nonzero digits as the previous CSD implementation. The cost of this implementation is 4 adders and 1 subtractor which shows that adders are preferred to subtractors.

FCSD Multiplier

A combination of factorization and CSD representation of a constant multiplier can lead to further reduction in hardware cost (number of adders).

FCSD can further reduce the number of adders in the above constant multiplier:

```

y = 231 * x
y = (7 * 33) * x
y_tmp = (x << 5) + x
y = (y_tmp << 3) - y_tmp           % cost of FCSD: 2 Adders

```

CSD/FCSD Costs

This table shows the costs (C) of all 8-bit multipliers.

C	Coefficient
0	1, 2, 4, 8, 16, 32, 64, 128, 256

MATLAB® Design

The MATLAB code used in this example implements a simple FIR filter. The example also shows a MATLAB test bench that exercises the filter.

```
design_name = 'mlhdlc_csd';
testbench_name = 'mlhdlc_csd_tb';
```

- 1 Design: mlhdlc_csd
- 2 Test Bench: mlhdlc_csd_tb

Simulate the Design

Simulate the design with the test bench prior to code generation to make sure there are no runtime errors.

```
mlhdlc_csd_tb
```

Create a Fixed-Point Conversion Config Object

To perform fixed-point conversion, you need a 'fixpt' config object.

Create a 'fixpt' config object and specify your test bench name:

```
close all;
fixptcfg = coder.config('fixpt');
fixptcfg.TestBenchName = 'mlhdlc_csd_tb';
```

Create an HDL Code Generation Config Object

To generate code, you must create an 'hdl' config object and set your test bench name:

```
hdlcfg = coder.config('hdl');
hdlcfg.TestBenchName = 'mlhdlc_csd_tb';
```

Generate Code without Constant Multiplier Optimization

```
hdlcfg.ConstantMultiplierOptimization = 'None';
```

Enable the 'Unroll Loops' option to inline multiplier constants.

```
hdlcfg.LoopOptimization = 'UnrollLoops';
codegen -float2fixed fixptcfg -config hdlcfg mlhdlc_csd
```

Examine the generated code.

```
329 -- filtered output
330 --'mlhdlc_csd_FixPt:40' y_out = fi((h( 1 )*a1 + h( 2 )*a2) + (h( 3 )*a3 + h( 4 )*a4), 1, 14, 12, fm);
331 p22y_out_mul_temp <= (-2194) * a1;
332 p22y_out_add_cast <= resize(p22y_out_mul_temp, 29);
333 p22y_out_mul_temp_1 <= (-1373) * a2;
334 p22y_out_add_cast_1 <= resize(p22y_out_mul_temp_1, 29);
335 p22y_out_add_temp <= p22y_out_add_cast + p22y_out_add_cast_1;
336 p22y_out_add_cast_2 <= resize(p22y_out_add_temp, 30);
337 p22y_out_mul_temp_2 <= 3319 * a3;
338 p22y_out_add_cast_3 <= resize(p22y_out_mul_temp_2, 29);
339 p22y_out_mul_temp_3 <= 6658 * a4;
340 p22y_out_add_cast_4 <= resize(p22y_out_mul_temp_3, 29);
341 p22y_out_add_temp_1 <= p22y_out_add_cast_3 + p22y_out_add_cast_4;
342 p22y_out_add_cast_5 <= resize(p22y_out_add_temp_1, 30);
343 p22y_out_add_temp_2 <= p22y_out_add_cast_2 + p22y_out_add_cast_5;
344 y_out_1 <= p22y_out_add_temp_2(26 DOWNT0 13);
345
```

Take a look at the resource report for adder and multiplier usage without the CSD optimization.

Multipliers	4
Adders/Subtractors	7
Registers	23
RAMs	0
Multiplexers	0

Generate Code with CSD Optimization

```
hdlcfg.ConstantMultiplierOptimization = 'CSD';
```

Enable the 'Unroll Loops' option to inline multiplier constants.

```
hdlcfg.LoopOptimization = 'UnrollLoops';  
codegen -float2fixed fixptcfg -config hdlcfg mlhdlc_csd
```

Examine the generated code.

```
329 -- filtered output  
330 --'mlhdlc_csd_FixPt:40' y_out = fi((h( 1 )*a1 + h( 2 )*a2) + (h( 3 )*a3 + h( 4 )*a4), 1, 14, 12, fm);  
331 -- CSD Encoding (2194) : 0100010010010; Cost (Adders) = 3  
332 p22y_out_mul_temp <= - (((resize(a1 & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0', 28) + resize(a1 & '0' & '0'  
333 p22y_out_add_cast <= resize(p22y_out_mul_temp, 29);  
334 -- CSD Encoding (1373) : 0101011001'01; Cost (Adders) = 5  
335 p22y_out_mul_temp_1 <= - (((((resize(a2 & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0', 28) + resize(a2 & '0' & '0'  
336 p22y_out_add_cast_1 <= resize(p22y_out_mul_temp_1, 29);  
337 p22y_out_add_temp <= p22y_out_add_cast + p22y_out_add_cast_1;  
338 p22y_out_add_cast_2 <= resize(p22y_out_add_temp, 30);  
339 -- CSD Encoding (3319) : 0110100001'001'; Cost (Adders) = 4  
340 p22y_out_mul_temp_2 <= (((resize(a3 & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0', 28) + resize(a3 & '0' & '0'  
341 p22y_out_add_cast_3 <= resize(p22y_out_mul_temp_2, 29);  
342 -- CSD Encoding (6658) : 01101000000010; Cost (Adders) = 3  
343 p22y_out_mul_temp_3 <= ((resize(a4 & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0' & '0', 28) + resize(a4 & '0' & '0'  
344 p22y_out_add_cast_4 <= resize(p22y_out_mul_temp_3, 29);  
345 p22y_out_add_temp_1 <= p22y_out_add_cast_3 + p22y_out_add_cast_4;  
346 p22y_out_add_cast_5 <= resize(p22y_out_add_temp_1, 30);  
347 p22y_out_add_temp_2 <= p22y_out_add_cast_2 + p22y_out_add_cast_5;  
348 y_out_1 <= p22y_out_add_temp_2(DOWNT0 13);
```

Examine the code with comments that outline the CSD encoding for all the constant multipliers.

Look at the resource report and notice that with the CSD optimization, the number of multipliers is reduced to zero and multipliers are replaced by shifts and adders.

Multipliers	0
Adders/Subtractors	24
Registers	23
RAMs	0
Multiplexers	0

Generate Code with FCSD Optimization

```
hdlcfg.ConstantMultiplierOptimization = 'FCSD';
```

Enable the 'Unroll Loops' option to inline multiplier constants.

```
hdlcfg.LoopOptimization = 'UnrollLoops';  
codegen -float2fixed fixptcfg -config hdlcfg mlhdlc_csd
```

Examine the generated code.

HDL Workflow Advisor Reference

- “HDL Workflow Advisor” on page 9-2
- “MATLAB to HDL Code and Synthesis” on page 9-6

HDL Workflow Advisor

The screenshot shows the HDL Workflow Advisor interface. The main window displays a MATLAB function named `m1hdlc_sfir`. The code includes comments and logic for a symmetric FIR filter, including declaring delay registers (`ud1` through `ud8`) and calculating the output `y_out` and `delayed_xout` based on input `x_in` and filter coefficients `h_in1` through `h_in4`.

Below the code, there is a table with three tabs: **Variables**, **Function Replacements**, and **Output**. The **Variables** tab is active, showing a list of variables categorized into **Input**, **Output**, and **Persistent**.

Variable	Type	Sim Min	Sim Max	Whol...	Proposed Type	Lo...	Max Diff
Input							
<code>x_in</code>	double			No			
<code>h_in1</code>	double			No			
<code>h_in2</code>	double			No			
<code>h_in3</code>	double			No			
<code>h_in4</code>	double			No			
Output							
<code>y_out</code>	double			No			
<code>delayed_xout</code>	double			No			
Persistent							
<code>ud1</code>	double			No			
<code>ud2</code>	double			No			

Overview

The HDL Workflow Advisor is a tool that supports a suite of tasks covering the stages of the ASIC and FPGA design process, including converting floating-point MATLAB algorithms to fixed-point algorithms. Some tasks perform code validation or checking; others run the HDL code generator or third-party tools. Each folder at the top level of the HDL Workflow Advisor contains a group of related tasks that you can select and run.

Use the HDL Workflow Advisor to:

- Convert floating-point MATLAB algorithms to fixed-point algorithms.

If you already have a fixed-point MATLAB algorithm, set **Design needs conversion to Fixed Point?** to No to skip this step.

- Generate HDL code from fixed-point MATLAB algorithms.
- Simulate the HDL code using a third-party simulation tool.
- Synthesize the HDL code and run a mapping process that maps the synthesized logic design to the target FPGA.
- Run a Place and Route process that takes the circuit description produced by the previous mapping process, and emits a circuit description suitable for programming an FPGA.

HDL Workflow Advisor is not available in Simulink Online™.

Procedures

Automatically Run Tasks

To automatically run the tasks within a folder:

- 1 Click the **Run** button. The tasks run in order until a task fails.

Alternatively, right-click the folder to open the context menu. From the context menu, select Run to run the tasks within the folder.

- 2 If a task in the folder fails:
 - a Fix the failure using the information in the results pane.
 - b Continue the run by clicking the **Run** button.

Run Individual Tasks

To run an individual task:

- 1 Click the **Run** button.

Alternatively, right-click the task to open the context menu. From the context menu, select Run to run the selected task.

- 2 Review Results. The possible results are:
 - Pass:** Move on to the next task.
 - Warning:** Review results, decide whether to move on or fix.
 - Fail:** Review results, do not move on without fixing.
- 3 If required, fix the issue using the information in the results pane.
- 4 Once you have fixed a **Warning** or **Failed** task, rerun the task by clicking **Run**.

Run to Selected Task

To run the tasks up to and including the currently selected task:

- 1 Select the last task that you want to run.
- 2 Right-click this task to open the context menu.
- 3 From the context menu, select Run to Selected Task.

Note If a task before the selected task fails, the Workflow Advisor stops at the failed task.

Reset a Task

To reset a task:

- 1 Select the task that you want to reset.
- 2 Right-click this task to open the context menu.
- 3 From the context menu, select **Reset Task** to reset this and subsequent tasks.

Reset All Tasks in a Folder

To reset a task:

- 1 Select the folder that you want to reset.
- 2 Right-click this folder to open the context menu.

- 3 From the context menu, select **Reset Task** to reset the tasks this folder and subsequent folders.

MATLAB to HDL Code Conversion

The **MATLAB to HDL Workflow** task in the HDL Workflow Advisor generates HDL code from fixed-point MATLAB code, and simulates and verifies the HDL against the fixed-point algorithm. HDL Coder then runs synthesis, and optionally runs place and route to generate a circuit description suitable for programming an ASIC or FPGA.

Code Generation: Target Tab

Select target hardware and language and required outputs.

Input Parameters

Target

Target hardware. Select from the list:

- Generic ASIC/FPGA
- Xilinx
- Altera
- Simulation

Language

Select the language (VHDL or Verilog) in which code is generated. The selected language is referred to as the target language.

Default: VHDL

Check HDL Conformance

Enable HDL conformance checking.

Default: Off

Generate HDL

Enable generation of HDL code for the fixed-point MATLAB algorithm.

Default: On

Generate HDL Test Bench

Enable generation of HDL code for the fixed-point test bench.

Default: Off

Generate EDA Scripts

Enable generation of script files for third-party electronic design automation (EDA) tools. These scripts let you compile and simulate generated HDL code and synthesize generated HDL code.

Default: On

Code Generation: Coding Style Tab

Parameters that affect the style of the generated code.

Input Parameters

Preserve MATLAB code comments

Include MATLAB code comments in generated code.

Default: On

Include MATLAB source code as comments

Include MATLAB source code as comments in the generated code. The comments precede the associated generated code. Includes the function signature in the function banner.

Default: On

Generate Report

Enable a code generation report.

Default: Off

VHDL File Extension

Specify the file name extension for generated VHDL files.

Default: .vhd

Verilog File Extension

Specify the file name extension for generated Verilog files.

Default: .v

Comment in header

Specify comment lines in header of generated HDL and test bench files.

Default: None

Text entered in this field as a character vector generates a comment line in the header of the generated code. The code generator adds leading comment characters for the target language. When newlines or linefeeds are included in the text, the code generator emits single-line comments for each newline.

Package postfix

HDL Coder applies this option only if a package file is required for the design.

Default: _pkg

Entity conflict postfix

Specify the character vector to resolve duplicate VHDL entity or Verilog module names in generated code.

Default: `_block`

Reserved word postfix

Specify a character vector to append to value names, postfix values, or labels that are VHDL or Verilog reserved words.

Default: `_rsvd`

Clocked process postfix

Specify a character vector to append to HDL clock process names.

Default: `_process`

Complex real part postfix

Specify a character vector to append to real part of complex signal names.

Default: `'_re'`

Complex imaginary part postfix

Specify a character vector to append to imaginary part of complex signal names.

Default: `'_im'`

Pipeline postfix

Specify a character vector to append to names of input or output pipeline registers.

Default: `'_pipe'`

Enable prefix

Specify the base name as a character vector for internal clock enables and other flow control signals in generated code.

Default: `'enb'`

Code Generation: Clocks and Ports Tab

Clock and port settings

Input Parameters**Reset type**

Specify whether to use asynchronous or synchronous reset logic when generating HDL code for registers.

Default: Asynchronous

Reset Asserted level

Specify whether the asserted (active) level of reset input signal is active-high or active-low.

Default: Active-high

Reset input port

Enter the name for the reset input port in generated HDL code.

Default: reset

Clock input port

Specify the name for the clock input port in generated HDL code.

Default: clk

Clock enable input port

Specify the name for the clock enable input port in generated HDL code.

Default: clk

Oversampling factor

Specify frequency of global oversampling clock as a multiple of the design under test (DUT) base rate (1).

Default: 1

Input data type

Specify the HDL data type for input ports.

For VHDL, the options are:

- `std_logic_vector`
Specifies VHDL type `STD_LOGIC_VECTOR`
- `signed/unsigned`
Specifies VHDL type `SIGNED` or `UNSIGNED`

Default: `std_logic_vector`

For Verilog, the options are:

- In generated Verilog code, the data type for all ports is 'wire'. Therefore, **Input data type** is disabled when the target language is Verilog.

Default: wire

Output data type

Specify the HDL data type for output data types.

For VHDL, the options are:

- Same as input data type
Specifies that output ports have the same type specified by Input data type.
- `std_logic_vector`
Specifies VHDL type `STD_LOGIC_VECTOR`
- `signed/unsigned`
Specifies VHDL type `SIGNED` or `UNSIGNED`

Default: Same as input data type

For Verilog, the options are:

- In generated Verilog code, the data type for all ports is 'wire'. Therefore, Output data type is disabled when the target language is Verilog.

Default: wire

Clock enable output port

Specify the name for the clock enable input port in generated HDL code.

Default: clk_enable

Code Generation: Test Bench Tab

Test bench settings.

Input Parameters

Test bench name postfix

Specify a character vector appended to names of reference signals generated in test bench code.

Default: '_tb'

Force clock

Specify whether the test bench forces clock enable input signals.

Default: On

Clock High time (ns)

Specify the period, in nanoseconds, during which the test bench drives clock input signals high (1).

Default: 5

Clock low time (ns)

Specify the period, in nanoseconds, during which the test bench drives clock input signals low (0).

Default: 5

Hold time (ns)

Specify a hold time, in nanoseconds, for input signals and forced reset input signals.

Default: 2 (given the default clock period of 10 ns)

Setup time (ns)

Display setup time for data input signals.

Default: 0

Force clock enable

Specify whether the test bench forces clock enable input signals.

Default: On

Clock enable delay (in clock cycles)

Define elapsed time (in clock cycles) between deassertion of reset and assertion of clock enable.

Default: 1

Force reset

Specify whether the test bench forces reset input signals.

Default: On

Reset length (in clock cycles)

Define length of time (in clock cycles) during which reset is asserted.

Default: 2

Hold input data between samples

Specify how long substrate signal values are held in valid state.

Default: On

Initialize testbench inputs

Specify initial value driven on test bench inputs before data is asserted to device under test (DUT).

Default: Off

Multi file testbench

Divide generated test bench into helper functions, data, and HDL test bench code files.

Default: Off

Test bench data file name postfix

Specify suffix added to test bench data file name when generating multi-file test bench.

Default: '_data'

Test bench reference post fix

Specify a character vector to append to names of reference signals generated in test bench code.

Default: '_ref'

Ignore data checking (number of samples)

Specify number of samples during which output data checking is suppressed.

Default: 0

Use fiaccel to accelerate test bench logging

To generate a test bench, HDL Coder simulates the original MATLAB code. Use the Fixed-Point Designer `fiaccel` function to accelerate this simulation and accelerate test bench logging.

Default: On

Code Generation: Optimizations Tab

Optimization settings

Input Parameters

Map persistent array variables to RAMs

Select to map persistent array variables to RAMs instead of mapping to shift registers.

Default: Off

Dependencies:

- **RAM Mapping Threshold**
- **Persistent variable names for RAM Mapping**

RAM Mapping Threshold

Specify the minimum RAM size required for mapping persistent array variables to RAMs.

Default: 256

Persistent variable names for RAM Mapping

Provide the names of the persistent variables to map to RAMs.

Default: None

Input Pipelining

Specify number of pipeline registers to insert at top level input ports. Can improve performance and help to meet timing constraints.

Default: 0

Output Pipelining

Specify number of pipeline registers to insert at top level output ports. Can improve performance and help to meet timing constraints.

Default: 0

Distribute Pipeline Registers

Reduces critical path by changing placement of registers in design. Operates on all registers, including those inserted using the **Input Pipelining** and **Output Pipelining** parameters, and internal design registers.

Default: Off

Sharing Factor

Number of additional sources that can share a single resource, such as a multiplier. To share resources, set **Sharing Factor** to 2 or higher; a value of 0 or 1 turns off sharing.

In a design that performs identical multiplication operations, HDL Coder can reduce the number of multipliers by the sharing factor. This can significantly reduce area.

Default: 0

Simulation and Verification

Simulates the generated HDL code using the selected simulation tool.

Input Parameters

Simulation tool

Lists the available simulation tools.

Default: None

Skip this step

Default: Off

Results and Recommended Actions

Conditions	Recommended Action
No simulation tool available on system path.	Add your simulation tool path to the MATLAB system path, then restart MATLAB. For more information, see “Synthesis Tool Path Setup”.

Synthesis and Analysis

This folder contains tasks to create a synthesis project for the HDL code. The task then runs the synthesis and, optionally, runs place and route to generate a circuit description suitable for programming an ASIC or FPGA.

Input Parameters**Skip this step**

Default: Off

Skip this step if you are interested only in simulation or you do not have a synthesis tool.

Create Project

Create synthesis project for supported synthesis tool.

Description

This task creates a synthesis project for the selected synthesis tool and loads the project with the HDL code generated for your MATLAB algorithm.

You can select the family, device, package, and speed that you want.

When the project creation is complete, the HDL Workflow Advisor displays a link to the project in the right pane. Click this link to view the project in the synthesis tool's project window.

Input Parameters**Synthesis Tool**

Select from the list:

- Altera Quartus II

Generate a synthesis project for Altera Quartus II. When you select this option, HDL Coder sets:

- **Chip Family** to Stratix II
- **Device Name** to EP2S60F1020C4

You can manually change these settings.

- Xilinx ISE

Generate a synthesis project for Xilinx ISE. When you select this option, HDL Coder:

- Sets **Chip Family** to Virtex4
- Sets **Device Name** to xc4vsx35
- Sets **Package Name** to ff6...
- Sets **Speed Value** to -...

You can manually change these settings.

Default: No Synthesis Tool Specified

When you select **No Synthesis Tool Specified**, HDL Coder does not generate a synthesis project. It clears and disables the fields in the **Synthesis Tool Selection** pane.

Chip Family

Target device family.

Default: None

Device Name

Specific target device, within selected family.

Default: None

Package Name

Available package choices. The family and device determine these choices.

Default: None

Speed Value

Available speed choices. The family, device, and package determine these choices.

Default: None

Results and Recommended Actions

Conditions	Recommended Action
Synthesis tool fails to create project.	Read the error message returned by synthesis tool, then check the synthesis tool version, and check that you have write permission for the project folder.
Synthesis tool does not appear in dropdown list.	Add your synthesis tool path to the MATLAB system path, then restart MATLAB. For more information, see "Synthesis Tool Path Setup".

Run Logic Synthesis

Launch selected synthesis tool and synthesize the generated HDL code.

Description

This task:

- Launches the synthesis tool in the background.
- Opens the previously generated synthesis project, compiles HDL code, synthesizes the design, and emits netlists and related files.
- Displays a synthesis log in the **Result** subpane.

Results and Recommended Actions

Conditions	Recommended Action
Synthesis tool fails when running place and route.	Read the error message returned by the synthesis tool, modify the MATLAB code, then rerun from the beginning of the HDL Coder workflow.

Run Place and Route

Launches the synthesis tool in the background and runs a Place and Route process.

Description

This task:

- Launches the synthesis tool in the background.
- Runs a Place and Route process that takes the circuit description produced by the previous mapping process, and emits a circuit description suitable for programming an FPGA.
- Displays a log in the Result subpane.

Input Parameters**Skip this step**

If you select **Skip this step**, the HDL Workflow Advisor executes the workflow, but omits the Perform Place and Route, marking it Passed. You might want to select **Skip this step** if you prefer to do place and route work manually.

Default: Off

Results and Recommended Actions

Conditions	Recommended Action
Synthesis tool fails when running place and route.	Read the error message returned by the synthesis tool, modify the MATLAB code, then rerun from the beginning of the HDL Coder workflow.

SystemC Code Generation from MATLAB

SystemC Code Generation for LMS Filter

This example shows how to generate SystemC code from a MATLAB® design that implements an LMS filter. The example also illustrates how to design a test bench that cancels out the noise signal by using this filter.

LMS Filter MATLAB Design

The MATLAB design used in the example is an implementation of an LMS (Least Mean Squares) filter. The LMS filter is a class of adaptive filter that identifies an FIR filter signal that is embedded in the noise. The LMS filter design implementation in MATLAB consists of a top-level function `mlhdlc_lms_fcn` that calculates the optimal filter coefficients to reduce the difference between the output signal and the desired signal.

```
design_name = 'mlhdlc_lms_fcn';
testbench_name = 'mlhdlc_lms_noise_canceler_tb';
```

Review the MATLAB design:

```
open(design_name);
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% MATLAB Design: Adaptive Noise Canceler algorithm using Least Mean Square
% (LMS) filter implemented in MATLAB
%
% Key Design pattern covered in this example:
% (1) Use of function calls
% (2) Function inlining vs instantiation knobs available in the coder
% (3) Use of system objects in the testbench to stream test vectors into the design
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

%#codegen
function [filtered_signal, y, fc] = mlhdlc_lms_fcn(input, ...
                                                desired, step_size, reset_weights)
% 'input' : The signal from Exterior Mic which records the ambient noise.
% 'desired': The signal from Pilot's Mic which includes
%             original music signal and the noise signal
% 'err_sig': The difference between the 'desired' and the filtered 'input'
%             It represents the estimated music signal (output of this block)
%
% The LMS filter is trying to retrieve the original music signal('err_sig')
% from Pilot's Mic by filtering the Exterior Mic's signal and using it to
% cancel the noise in Pilot's Mic. The coefficients/weights of the filter
% are updated(adapted) in real-time based on 'input' and 'err_sig'.

% register filter coefficients
persistent filter_coeff;
if isempty(filter_coeff)
    filter_coeff = zeros(1, 40);
end

% Variable Filter: Call 'tapped_delay_fcn' function on path to create
% 40-step tapped delay
delayed_signal = mtapped_delay_fcn(input);
```

```

% Apply filter coefficients
weight_applied = delayed_signal .* filter_coeff;

% Call treesum function on matlab path to sum up the results
filtered_signal = mtreesum_fcn(weight_applied);

% Output estimated Original Signal
td = desired;
tf = filtered_signal;
esig = td - tf;
y = esig;

% Update Weights: Call 'update_weight_fcn' function on MATLAB path to
% calculate the new weights
updated_weight = update_weight_fcn(step_size, esig, delayed_signal, ...
    filter_coeff, reset_weights);

% update filter coefficients register
filter_coeff = updated_weight;
fc = filter_coeff;

function y = mtreesum_fcn(u)
%Implement the 'sum' function without a for-loop
% y = sum(u);

% The loop based implementation of 'sum' function is not ideal for
% HDL generation and results in a longer critical path.
% A tree is more efficient as it results in
% delay of log2(N) instead of a delay of N delay

% This implementation shows how to explicitly implement the vector sum in
% a tree shape to enable hardware optimizations.

% The ideal way to code this generically for any length of 'u' is to use
% recursion but it is not currently supported by MATLAB Coder

% NOTE: To instruct MATLAB Coder to compile an external function,
% add the following compilation directive or pragma to the function code
%#codegen

% This implementation is hardwired for a 40tap filter.

level1 = vsum(u);
level2 = vsum(level1);
level3 = vsum(level2);
level4 = vsum(level3);
level5 = vsum(level4);
level6 = vsum(level5);
y = level6;

function output = vsum(input)

coder.inline('always');

vt = input(1:2:end);

for i = int32(1: numel(input)/2)

```

```
        k = int32(i*2);
        vt(i) = vt(i) + input(k);
    end

    output = vt;

    function tap_delay = mtapped_delay_fcn(input)
    % The Tapped Delay function delays its input by the specified number
    % of sample periods, and outputs all the delayed versions in a vector
    % form. The output includes current input

    % NOTE: To instruct MATLAB Coder to compile an external function,
    % add the following compilation directive or pragma to the function code
    %#codegen

    persistent u_d;
    if isempty(u_d)
        u_d = zeros(1,40);
    end

    u_d = [u_d(2:40), input];

    tap_delay = u_d;

    function weights = update_weight_fcn(step_size, err_sig, ...
        delayed_signal, filter_coeff, reset_weights)
    % This function updates the adaptive filter weights based on LMS algorithm

    % Copyright 2007-2022 The MathWorks, Inc.

    % NOTE: To instruct MATLAB Coder to compile an external function,
    % add the following compilation directive or pragma to the function code
    %#codegen

    step_sig = step_size .* err_sig;
    correction_factor = delayed_signal .* step_sig;
    updated_weight = correction_factor + filter_coeff;

    if reset_weights
        weights = zeros(1,40);
    else
        weights = updated_weight;
    end
end
```

The MATLAB function is modular and uses functions:

- `mtapped_delay_fcn` to calculate delayed versions of the input signal in vector form.
- `mtreesum_fcn` to calculate the sum of the applied weights in a tree structure. The individual sum is calculated by using a `vsum` function.
- `update_weight_fcn` to calculate the updated filter weights based on the least mean square algorithm.

LMS Filter MATLAB Test Bench

Review the MATLAB test bench:

```

open(testbench_name)

% Returns an adaptive FIR filter System object,
% HLMS, that computes the filtered output, filter error and the filter
% weights for a given input and desired signal using the Least Mean
% Squares (LMS) algorithm.

% Copyright 2011-2022 The MathWorks, Inc.
clear('mlhdlc_lms_fcn');

hfilt2 = dsp.FIRFilter(...
    'Numerator', fir1(10, [.5, .75]));
rng('default'); % always default to known state
x = randn(1000,1); % Noise
d = step(hfilt2, x) + sin(0:.05:49.95)'; % Noise + Signal

stepSize = 0.01;
reset_weights = false;

hSrc = dsp.SignalSource(x);
hDesiredSrc = dsp.SignalSource(d);

hOut = dsp.SignalSink;
hErr = dsp.SignalSink;
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%Call to the design
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
while (~isDone(hSrc))
    [y, e] = mlhdlc_lms_fcn(step(hSrc), step(hDesiredSrc), ...
        stepSize, reset_weights);
    step(hOut, y);
    step(hErr, e);
end

figure('Name', [mfilename, '_signal_plot']);
subplot(2,1,1), plot(hOut.Buffer), title('Noise + Signal');
subplot(2,1,2), plot(hErr.Buffer), title('Signal');

```

Test the MATLAB Algorithm

To avoid run-time errors, simulate the design by using the HDL test bench.

```
mlhdlc_lms_noise_canceler_tb
```

Create HDL Coder™ Coder Project

To generate SystemC code from a MATLAB design:

1. Create a HDL Coder project:

```
coder -hdlcoder -new mlhdlc_lms_nc
```

2. Add the file `mlhdlc_lms_fcn.m` to the project as the **MATLAB Function** and `mlhdlc_lms_noise_canceler_tb.m` as the **MATLAB Test Bench**.

3. Click **Autodefine types** to use the recommended types for the inputs and outputs of the MATLAB function `mlhdlc_lms_fcn`.

For more information, see “Get Started with MATLAB to SystemC Workflow Using the Command Line Interface” on page 11-11 or “Get Started with MATLAB to SystemC Workflow Using HDL Coder App” on page 11-2.

Run Fixed-Point Conversion and SystemC Code Generation

To generate SystemC code from a MATLAB design:

1. At the MATLAB command line, setup the path for SystemC code generation by using the function `hdlsetuiphlstoopath`.
2. Start the Workflow Advisor by clicking the **Workflow Advisor** button.
3. In the **HDL Workflow Advisor** step, select **Code Generation Workflow** as **MATLAB to SystemC**.
4. Select **Cadence Stratus** as the **Synthesis tool** for **Select Code Generation Target**.
5. Right-click the **SystemC Code Generation** and choose the option **Run to selected task** to run all the steps from the beginning through the SystemC code generation.

A single SystemC file `mlhdlc_lms_fcn_fixptClass.hpp` is generated for the MATLAB design. To examine the generated SystemC code for the filter design, click the hyperlinks in the Code Generation Log window.

SystemC Code Generation for Bisection Algorithm

You can generate SystemC™ code from a MATLAB® design that implements a bisection algorithm to calculate the square root of a number in fixed-point notation.

MATLAB Design

First, set up the sqrt model.

```
mlhdlc_demo_setup('sqrt');

% Design Sqrt
design_name = 'mlhdlc_sqrt';

% Test Bench for Sqrt
testbench_name = 'mlhdlc_sqrt_tb';
```

Review the sqrt design

```
dbtype(design_name)
```

```
1      %%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
2      % MATLAB design: Pipelined Bisection Square root algorithm
3      %
4      % Introduction:
5      %
6      % Implement SQRT by the bisection algorithm in a pipeline, for unsigned fixed
7      % point numbers (also why you don't need to run fixed-point conversion for this design).
8      % The demo illustrates the usage of a pipelined implementation for numerical algorithms.
9      %
10     % Key Design pattern covered in this example:
11     % (1) State of the bisection algorithm is maintained with persistent variables
12     % (2) Stages of the bisection algorithm are implemented in a pipeline
13     % (3) Code is written in a parameterized fashion, i.e. word-length independent, to work for

```

Create HDL Coder™ Project

Create an HDL Coder project.

```
coder -hdlcoder -new mlhdlc_sqrt_prj
```

Add the file mlhdlc_sqrt.m to the project as the MATLAB Function. Add the file mlhdlc_sqrt_tb.m as the MATLAB Test Bench.

For more information, see “Get Started with MATLAB to SystemC Workflow Using the Command Line Interface” on page 11-11 or “Get Started with MATLAB to SystemC Workflow Using HDL Coder App” on page 11-2.

SystemC Code Generation

This design is already in fixed point and suitable for SystemC code generation. You do not need to run floating point to fixed point conversion on this design.

To generate SystemC code from the MATLAB design:

1. At the MATLAB command line, set up the path for SystemC code generation by using the function `hdlsetu-phl-stoolpath`.
2. Start the Workflow Advisor by clicking the **Workflow Advisor** button.
3. In the **HDL Workflow Advisor**, select **Code Generation Workflow** as **MATLAB to SystemC**.
4. In the **Select Code Generation Target** step, from the **Synthesis tool** list, select **Cadence Stratus**.
5. Right-click the **SystemC Code Generation** task and select **Run to selected task** to run all the steps from the beginning through the SystemC code generation.

Examine the generated SystemC code by clicking the hyperlinks in the **SystemC Code Generation** log window.

SystemC Code Generation for Data Packetization

This example shows how to generate SystemC code from a MATLAB® design that packetizes a transmit sequence.

Introduction

In wireless communication, systems receive data that is oversampled at the radio frequency (RF) front end. This data serves several purposes, including providing sufficient sampling rates for receive filtering.

One of the most important functions is to provide multiple sampling points on the received waveform such that data can be sampled near the maximum amplitude point in the received waveform. This example illustrates a basic lead-lag time offset estimation core, operating recursively.

The generated hardware core for this design operates at $1/os_rate$, where os_rate is the oversampled rate. That is, for 8 oversampled clock cycles, this core iterates once. The output is at the symbol rate.

```
design_name = 'mlhdlc_comms_data_packet';
testbench_name = 'mlhdlc_comms_data_packet_tb';
```

Review the MATLAB design.

```
type(design_name);
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% MATLAB design: Data packetization
%
% Introduction:
%
% This core is meant to illustrate packetization of a transmit sequence.
% There is a "pad" data section, which allows for the transmit amplifier to
% settle. This is then followed by a 65-bit training sequence. This is
% followed by the number of symbols beginning encoded into two bytes or
% 16-bits. This is then followed by a variable length data sequence and a
% CRC. All bits can optionally be differentially encoded.
%
% Key design pattern covered in this example:
% (1) Design illustrates the use of binary operands, such as bitxor
% (2) Shows how to properly segment persistent variables for register and
% BRAM access
% (3) Illustrates the use of fi math
% (4) Shows how to properly format and store ROM data, e.g., padData
%

fprintf(fid,'y = [\n');

```

```
fprintf(fid, '%1.0e\n', x);
fprintf(fid, '];\n');
fclose(fid);
```

Simulate the Design

Before code generation, simulate the design by using the test bench to make sure that there are no run-time errors.

```
mlhdlc_comms_data_packet_tb
```

```
Training Difference: 0 User Data Difference: 0
CRC decoded correctly
```

Create HDL Coder™ Project

```
coder -hdlcoder -new mlhdlc_dpack
```

Add the file `mlhdlc_comms_data_packet.m` to the project as the MATLAB Function and `mlhdlc_comms_data_packet_tb.m` as the MATLAB Test Bench.

For more information, see “Get Started with MATLAB to SystemC Workflow Using the Command Line Interface” on page 11-11 or “Get Started with MATLAB to SystemC Workflow Using HDL Coder App” on page 11-2.

Run Fixed-Point Conversion and SystemC Code Generation

To generate SystemC code from a MATLAB design:

1. At the MATLAB command line, setup the path for SystemC code generation by using the function `hdlsetuPhlStoolPath`.
2. Start the Workflow Advisor by clicking the **Workflow Advisor** button.
3. In the **HDL Workflow Advisor**, select **Code Generation Workflow** as **MATLAB to SystemC**.
4. Select **Cadence Stratus** as the **Synthesis tool** for **Select Code Generation Target**.
5. Right-click the **SystemC Code Generation** and choose the option **Run to selected task** to run all the steps from the beginning through the SystemC code generation.

Examine the generated SystemC code by clicking the hyperlinks in the Code Generation Log window.

SystemC Code Generation for DF2T Filter

You can generate SystemC code from MATLAB® design for direct-form II transposed filter.

MATLAB Design

Set up the `df2t_filter` model and test bench for this example.

```
mlhdlc_demo_setup('df2t_filter');  
  
% Design Sqrt  
design_name = 'mlhdlc_df2t_filter';  
  
% Test Bench for Sqrt  
testbench_name = 'mlhdlc_df2t_filter_tb';
```

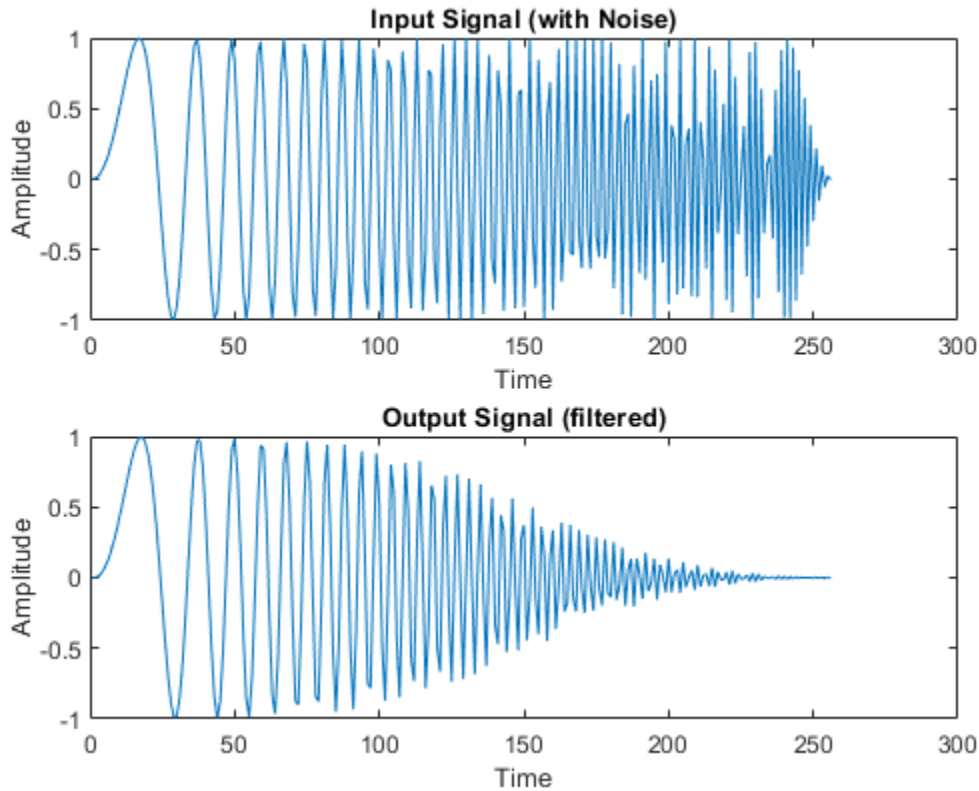

Review the `df2t_filter` design

```
dbtype(design_name)  
  
1   %#codegen  
2   function y = mlhdlc_df2t_filter(x)  
3  
4   %   Copyright 2011-2015 The MathWorks, Inc.  
5  
6   persistent z;  
7   if isempty(z)  
8       % Filter states as a column vector  
9       z = zeros(2,1);  
10  end  
11  
12  % Filter coefficients as constants  
13  b = [0.29290771484375    0.585784912109375    0.292907714843750];  
14  a = [1.0                0.0                0.171600341796875];  
15  
16  y    = b(1)*x + z(1);  
17  z(1) = (b(2)*x + z(2)) - a(2) * y;  
18  z(2) = b(3)*x - a(3) * y;  
19  
20  end
```

Simulate the Design

It is a best practice to simulate the design with the test bench prior to code generation to check for run-time errors.

```
mlhdlc_df2t_filter_tb
```

Create a HDL Coder™ Project

Create an HDL Coder project.

```
coder -hdlcoder -new mlhdlc_df2t_prj
```

Next, add the file `mlhdlc_df2t_filter.m` to the project as the MATLAB Function and `mlhdlc_df2t_filter_tb.m` as the MATLAB Test Bench.

Run Fixed-Point Conversion and SystemC Code Generation

To generate SystemC code from the MATLAB design:

1. At the MATLAB command line, set up the path for SystemC code generation by using the function `hdlsetuph1stoolpath`.
2. Start the Workflow Advisor by clicking the **Workflow Advisor** button.
3. In the **HDL Workflow Advisor**, select **Code Generation Workflow** as **MATLAB to SystemC**.
4. Select **Cadence Stratus** as the **Synthesis tool** for **Select Code Generation Target**.
5. Right-click the **SystemC Code Generation** task and select **Run to selected task** to run all the steps from the beginning through the SystemC code generation.

Examine the generated SystemC code by clicking the hyperlinks in the SystemC Code Generation log window. For more information, see “Get Started with MATLAB to SystemC Workflow Using HDL Coder App” on page 11-2.

SystemC Code Generation For Transmit and Receive FIFO Registers

This example shows how to generate SystemC™ code from MATLAB® code that models the data transfer between a transmit and receive first-in, first-out (FIFO) register or buffer. This example contains two functions that represent a receive FIFO buffer and a transmit FIFO buffer, and a test bench `mlhdlc_fifo_tb` that simulates the data transfer that occurs between the two buffers. Each function is hardware-ready and exhibits good practices and guidelines to follow when writing MATLAB functions to generate efficient SystemC code. For more information on guidelines to follow, see “Guidelines for Writing MATLAB Code to Generate Efficient HDL and SystemC Code” on page 1-63.

View Example Functions and Test Bench

You can set up the model and open the MATLAB design for the transmit FIFO and the receive FIFO.

```
mlhdlc_demo_setup('rx_fifo');
type('mlhdlc_rx_fifo');

function [dout, empty, byte_ready, full, bytes_available] = ...
    mlhdlc_rx_fifo(get_byte, store_byte, byte_in, reset_fifo, fifo_enable)
%
% Copyright 2014-2015 The MathWorks, Inc.
%

    end
end

```

```
dout = byte_out;
dbg_fifo_enable = fifo_enable;
end
```

Open the MATLAB design for the test bench that exercises both designs. This test bench test both the transmit and receive FIFOs. However, when generating SystemC code, because you have individual functions for the transmit and receive FIFOs, you need individual test benches to test both functions and generate code. For simulation purposes, you can use `mlhdlc_fifo_tb`, but for SystemC code generation, use the receive FIFO test bench `mlhdlc_rx_fifo_tb` with the receive FIFO function `mlhdlc_rx_fifo`, and use the transmit FIFO test bench `mlhdlc_tx_fifo` with the transmit FIFO function `mlhdlc_tx_fifo`.

```
type('mlhdlc_fifo_tb');
```

```

```

Simulate the Design

Simulate the design with the test bench before generating code to ensure there are no runtime errors.

```

mlhdlc_fifo_tb
Received message correctly

ans =

    'Hello World!'

```

Create HDL Coder™ Project for the Receive FIFO

At the MATLAB command line, set up the path for SystemC code generation by using the function `hdlsetuiphlstoopath`.

Create a HDL Coder project for the receive FIFO.

```

coder -hdlcoder -new mlhdlc_rx_fifo

```

Add the file `mlhdlc_rx_fifo.m` to the project as the MATLAB Function and `mlhdlc_rx_fifo_tb.m` as the MATLAB Test Bench and then click **Workflow Advisor**.

Generate SystemC Code for the Receive FIFO

In the **HDL Workflow Advisor**, select **MATLAB to SystemC** as the **Code Generation Workflow** and **Cadence Stratus** as the **Synthesis tool** in **Select Code Generation Target** step.

Run all the steps from the beginning through the SystemC code generation. Examine the generated SystemC code for the receive FIFO by clicking the hyperlinks in the bottom pane.

For more information, see “Get Started with MATLAB to SystemC Workflow Using HDL Coder App” on page 11-2.

Create HDL Coder Project for the Transmit FIFO

At the MATLAB command line, set up the path for SystemC code generation by using the function `hdlsetuiphlstoopath`.

Create a HDL Coder project.

```
coder -hdlcoder -new mlhdlc_tx_fifo
```

Add `mlhdlc_tx_fifo.m` to the project as the MATLAB Function and `mlhdlc_tx_fifo_tb.m` as the MATLAB Test Bench and then click **Workflow Advisor**.

Generate SystemC Code for the Transmit FIFO

In the **HDL Workflow Advisor**, select **MATLAB to SystemC** as the **Code Generation Workflow** and **Cadence Stratus** as the **Synthesis tool** in **Select Code Generation Target** step.

Run all the steps from the beginning through the SystemC code generation. Examine the generated SystemC code for the transmit FIFO by clicking on the hyperlinks in the bottom pane.

SystemC Code Generation for Contrast Adjustment

This example shows how to generate SystemC code from a MATLAB® design that adjusts image contrast by linearly scaling pixel values.

Algorithm

Contrast adjustment adjusts the contrast of an image by linearly scaling the pixel values between upper and lower limits. Pixel values that are above or below this range are saturated to the upper or lower limit value, respectively.

MATLAB Design

```
design_name = 'mlhdlc_image_scale';
testbench_name = 'mlhdlc_image_scale_tb';
```

Review the MATLAB design:

```
type(design_name);
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% scale.m
%
% Adjust image contrast by linearly scaling pixel values.
%
```

```

% The input pixel value range has 14bits and output pixel value range is
% 8bits.
%
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

frame: 2
```

Original Image

Scaled Image

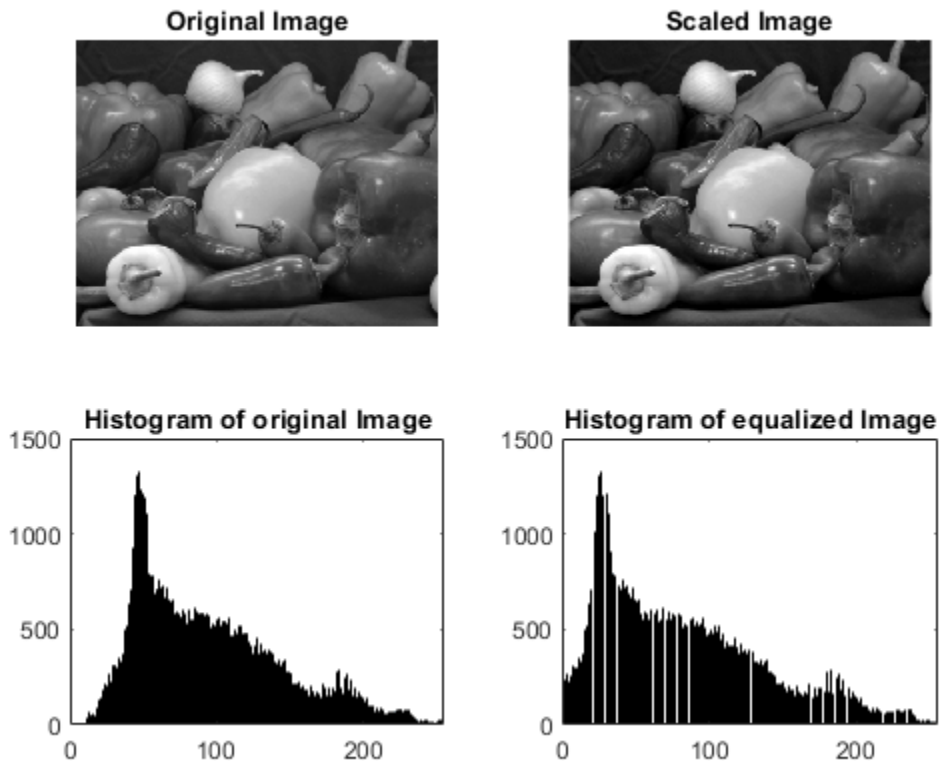

Histogram of original Image

Histogram of equalized Image

Create HDL Coder™ Project

```
coder -hdlcoder -new mlhdlc_scale_prj
```

Add the file `mlhdlc_image_scale.m` to the project as the MATLAB Function and `mlhdlc_image_scale_tb.m` as the MATLAB Test Bench.

For more information, see “Get Started with MATLAB to SystemC Workflow Using the Command Line Interface” on page 11-11 or “Get Started with MATLAB to SystemC Workflow Using HDL Coder App” on page 11-2.

Run Fixed-Point Conversion and SystemC Code Generation

To generate SystemC code from a MATLAB design:

1. At the MATLAB command line, setup the path for SystemC code generation by using the function `hdlsetuptoolpath`.
2. Start the Workflow Advisor by clicking the **Workflow Advisor** button.
3. In the **HDL Workflow Advisor**, select **Code Generation Workflow** as **MATLAB to SystemC**.
4. Select **Cadence Stratus** as the **Synthesis tool** for **Select Code Generation Target**.
5. Right-click the **SystemC Code Generation** and choose the option **Run to selected task** to run all the steps from the beginning through the SystemC code generation.

Examine the generated SystemC code by clicking the hyperlinks in the Code Generation Log window.

SystemC Code Generation for Image Format Conversion from RGB to YUV

This example shows how to generate SystemC™ code from a MATLAB® design that converts the image format from RGB to YUV.

MATLAB Design and Test Bench

Set up the Rgb2yuv model for this example.

```
mlhdlc_demo_setup('Rgb2yuv');
design_name = 'mlhdlc_rgb2yuv';
testbench_name = 'mlhdlc_rgb2yuv_tb';
```

Review the Rgb2yuv design.

```
open(design_name)

function [x_out, y_out, y_data_out, u_data_out, v_data_out] = ...
    mlhdlc_rgb2yuv(x_in, y_in, r_in, g_in, b_in)
%#codegen

% Copyright 2011-2019 The MathWorks, Inc.

persistent RGB_Reg YUV_Reg
persistent x1 x2 y1 y2

if isempty(RGB_Reg)
    RGB_Reg = zeros(3,1);
    YUV_Reg = zeros(3,1);
    x1 = 0; x2 = 0; y1 = 0; y2 = 0;
end

D = [.299 .587 .144; -.147 -.289 .436; .615 -.515 -.1];
C = [0; 128; 128];

RGB = [r_in; g_in; b_in];

YUV_1 = D*RGB_Reg;
YUV_2 = YUV_1 + C;
RGB_Reg = RGB;

y_data_out = round(YUV_Reg(1));
u_data_out = round(YUV_Reg(2));
v_data_out = round(YUV_Reg(3));
YUV_Reg = YUV_2;

x_out = x2; x2 = x1; x1 = x_in;
y_out = y2; y2 = y1; y1 = y_in;
```

Review the Rgb2yuv test bench:

```
open(testbench_name);
```

```
FRAMES = 1;
WIDTH = 752;
HEIGHT = 480;
HBLANK = 10;%748;
VBLANK = 10;%120;

% Copyright 2011-2019 The MathWorks, Inc.

vidData = double(imread('mlhdlc_img_yuv.png'));

for f = 1:FRAMES
    vidOut = zeros(HEIGHT, WIDTH, 3);

    for y = 0:HEIGHT+VBLANK-1
        for x = 0:WIDTH+HBLANK-1
            if y >= 0 && y < HEIGHT && x >= 0 && x < WIDTH
                b = vidData(y+1,x+1,1);
                g = vidData(y+1,x+1,2);
                r = vidData(y+1,x+1,3);
            else
                b = 0; g = 0; r = 0;
            end

            [xOut, yOut, yData, uData, vData] = ...
                mlhdlc_rgb2yuv(x, y, r, g, b);

            if yOut >= 0 && yOut < HEIGHT && xOut >= 0 && xOut < WIDTH
                vidOut(yOut+1,xOut+1,:) = [yData vData uData];
            end
        end
    end

    figure(1);
    subplot(1,2,1);
    imshow(uint8(vidData));
    subplot(1,2,2);
    imshow(ycbcr2rgb(uint8(vidOut)));
    drawnow;
end
```

Test the MATLAB Algorithm

To avoid run-time errors, simulate the design with the test bench.

```
mlhdlc_rgb2yuv_tb
```

Create HDL Coder™ Project

To generate SystemC code from a MATLAB design:

1. Create a HDL Coder project:

```
coder -hdlcoder -new mlhdlc_rgb_prj
```

2. Add the file `mlhdlc_rgb2yuv.m` to the project as the **MATLAB Function** and `mlhdlc_rgb2yuv_tb.m` as the **MATLAB Test Bench**.

3. Click **Autodefine types** to use the recommended types for the inputs and outputs of the MATLAB function `mlhdlc_rgb2yuv`.

For more information, see “Get Started with MATLAB to SystemC Workflow Using the Command Line Interface” on page 11-11 or “Get Started with MATLAB to SystemC Workflow Using HDL Coder App” on page 11-2.

Run Fixed-Point Conversion and SystemC Code Generation

To generate SystemC code from the MATLAB design:

1. At the MATLAB command line, set up the path for SystemC code generation by using the function `hdlsetuuph1stoolpath`.
2. Start the Workflow Advisor by clicking the **Workflow Advisor** button.

3. In the **HDL Workflow Advisor**, select **Code Generation Workflow** as **MATLAB to SystemC**.
4. In the **Select Code Generation Target** step, from the **Synthesis tool** list, select Cadence Stratus.
5. Right-click the **SystemC Code Generation** task and select **Run to selected task** to run all the steps from the beginning through the SystemC code generation.

Examine the generated SystemC code by clicking the hyperlinks in the **SystemC Code Generation** task log window.

SystemC Code Generation for Advanced Encryption Standard

This example shows how to generate SystemC code from MATLAB® code that implements an AES (Advanced Encryption Standard) algorithm.

AES MATLAB Design

AES is a symmetric block cipher that encrypts and decrypts confidential data using the same cipher key. You can design complicated algorithms such as AES using MATLAB code and then generate their equivalent System C code.

In this example, the `mlhdlc_aes` function implements the AES encryption algorithm. This function accepts plain text to encrypt and a cipher key as inputs and outputs encrypted text. The `mlhdlc_aesd` function decrypts the encrypted text to plain text.

Set up the AES model for this example.

```
mlhdlc_demo_setup('aes');
```

To review the MATLAB code for encryption and decryption of text, open the files `mlhdlc_aes.m` and `mlhdlc_aesd.m`.

```
open('mlhdlc_aes');
open('mlhdlc_aesd');
```

You can also review the MATLAB test bench file.

```
open('mlhdlc_aes_tb')
```

Test the MATLAB Algorithm

To avoid run-time errors, simulate the design by using the test bench.

```

Generate SystemC Code by Using HDL Workflow Advisor

SystemC code generation with the HDL Workflow Advisor has the following basic steps:

- 1** At the MATLAB command line, set up the high-level synthesis (HLS) tool path for SystemC code generation by using the function `hdlsetuphls_toolpath`.
- 2** Create a HDL Coder project by adding the `mlhdlc_aes.m` design file and `mlhdlc_aes_tb.m` test bench file to the HDL workflow advisor.
- 3** Launch the HDL Workflow Advisor to generate SystemC code. Do not run floating point to fixed point conversion on this design, as the AES MATLAB code is already in fixed point and suitable for SystemC code generation.

For detailed information about these steps, see “Get Started with MATLAB to SystemC Workflow Using the Command Line Interface” on page 11-11 or “Get Started with MATLAB to SystemC Workflow Using HDL Coder App” on page 11-2.

Get Started with MATLAB to SystemC Workflow Using HDL Coder App

This example shows how to create an HDL Coder™ project and generate SystemC code from a MATLAB® design for a symmetric finite impulse response (FIR) filter.

Set up the FIR model and test bench for this example.

```
mlhdlc_demo_setup('sfir');
```

FIR Filter MATLAB Design

The MATLAB design `mlhdlc_sfir` is a simple symmetric FIR filter.

```
design_name = 'mlhdlc_sfir';
testbench_name = 'mlhdlc_sfir_tb';
```

Review the design.

```
open(design_name);
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% MATLAB design: Symmetric FIR Filter
%
% Introduction:
%
% We can reduce the complexity of the FIR filter by leveraging its symmetry.
% Symmetry for an n-tap filter implies, coefficient h0 = coefficient hn-1,
% coefficient, h1 = coefficient hn-2, etc. In this case, the number of
% multipliers can be approximately halved. The key is to add the
% two data values that need to be multiplied with the same coefficient
% prior to performing the multiplication.
%
% Key Design pattern covered in this example:
% (1) Filter states represented using the persistent variables
% (2) Filter coefficients passed in as parameters
%
% Copyright 2011-2019 The MathWorks, Inc.

%#codegen
function [y_out, delayed_xout] = mlhdlc_sfir(x_in,h_in1,h_in2,h_in3,h_in4)
% Symmetric FIR Filter

% declare and initialize the delay registers
persistent ud1 ud2 ud3 ud4 ud5 ud6 ud7 ud8;
if isempty(ud1)
    ud1 = 0; ud2 = 0; ud3 = 0; ud4 = 0; ud5 = 0; ud6 = 0; ud7 = 0; ud8 = 0;
end

% access the previous value of states/registers
a1 = ud1 + ud8; a2 = ud2 + ud7;
a3 = ud3 + ud6; a4 = ud4 + ud5;

% multiplier chain
m1 = h_in1 * a1; m2 = h_in2 * a2;
```

```

m3 = h_in3 * a3; m4 = h_in4 * a4;

% adder chain
a5 = m1 + m2; a6 = m3 + m4;

% filtered output
y_out = a5 + a6;

% delayout input signal

Test MATLAB Algorithm

To avoid run-time errors, simulate the design by using the test bench.

```
mlhdlc_sfir_tb
```

Generate SystemC Code by Using HDL Workflow Advisor

SystemC code generation with the HDL Workflow Advisor has the following basic steps:

- 1 At the MATLAB command line, set up the high-level synthesis (HLS) tool path for SystemC code generation by using the function `hdlsetuphlsstoolpath`.
- 2 Create a MATLAB HDL Coder project.
- 3 Add the design and test bench files to the project.
- 4 Start the HDL Workflow Advisor for the MATLAB design.
- 5 Run fixed-point conversion and SystemC code generation.

Create HDL Coder Project and Assign Files

To create an HDL Coder project:

1. In the MATLAB Editor, on the **Apps** tab, select **HDL Coder**. Enter `sfir_project` as the **Name** of the project.

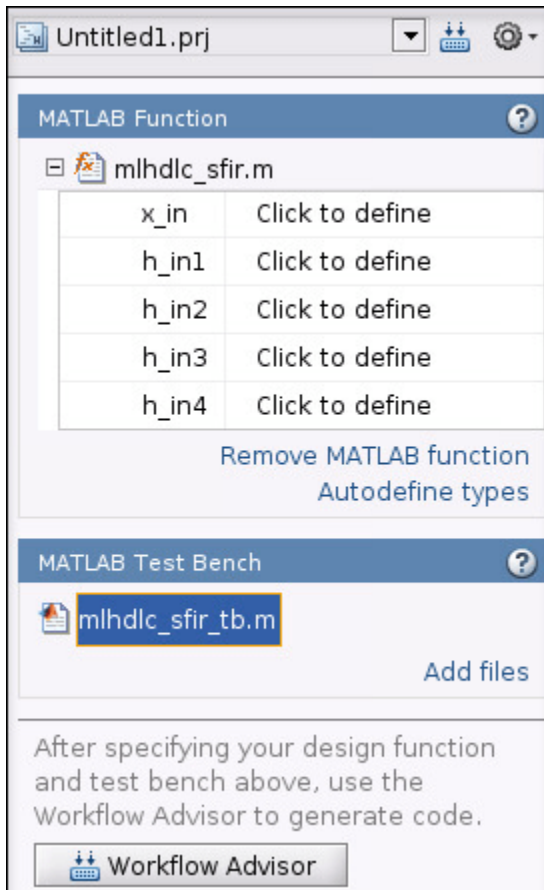

To create a project at the MATLAB command prompt, run the command:

```
coder -hdlcoder -new sfir_project
```

A `sfir_project.prj` file is created in the current folder.

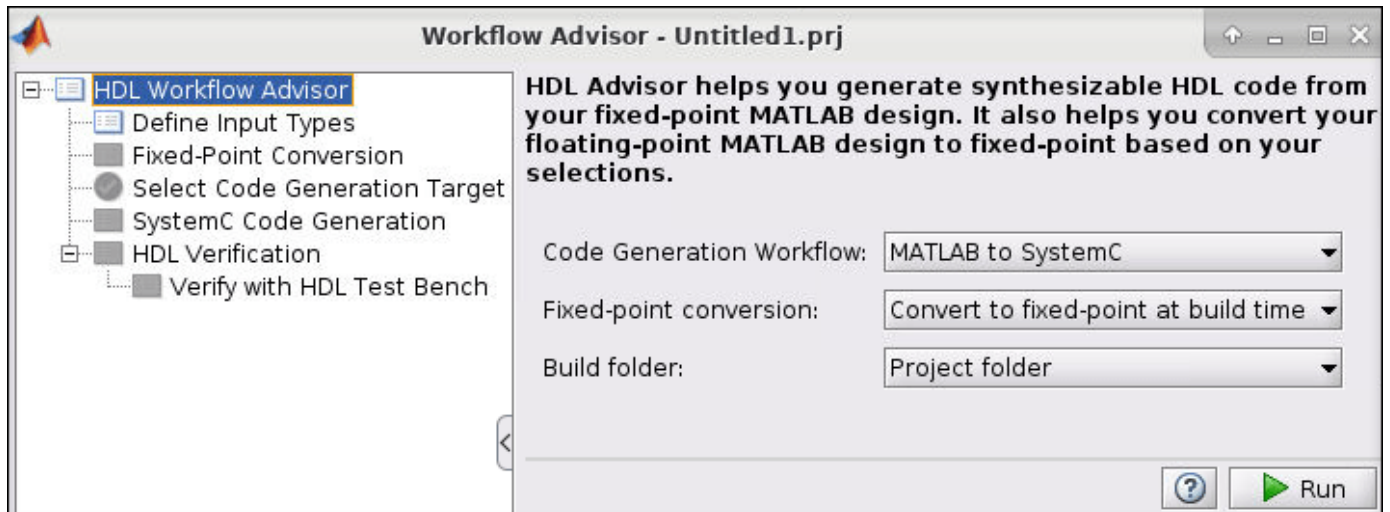

2. For **MATLAB Function**, click the **Add MATLAB function** link and select the FIR filter MATLAB design `mlhdlc_sfir`. Under the **MATLAB Test Bench** section, click **Add files** and add the MATLAB test bench `mlhdlc_sfir_tb.m`.

3. Click **Autodefine types** and use the recommended types for the MATLAB design. The code generator infers the input types from the MATLAB test bench.

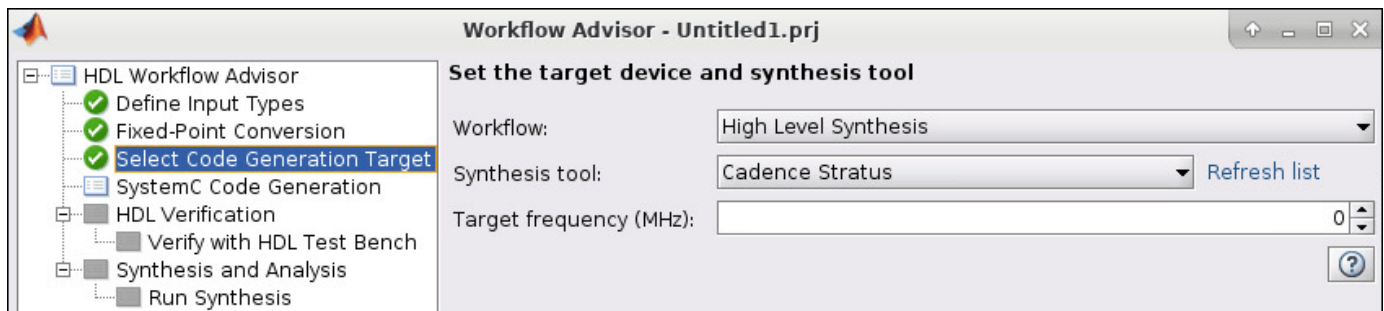

Run Fixed-Point Conversion and SystemC Code Generation in HDL Workflow Advisor

1. To start the HDL Workflow Advisor, click the **Workflow Advisor** button.
2. In **HDL Workflow Advisor** step, specify **Code Generation workflow** as **MATLAB to SystemC**.

3. If your design does not use fixed-point types and functions, then translate your floating-point MATLAB design to a fixed-point design. To examine the generated fixed-point code from the floating-point design, click the **Fixed-Point Conversion** task. The generated fixed-point MATLAB code opens in the MATLAB editor. For details, see “Floating-Point to Fixed-Point Conversion” on page 4-51.

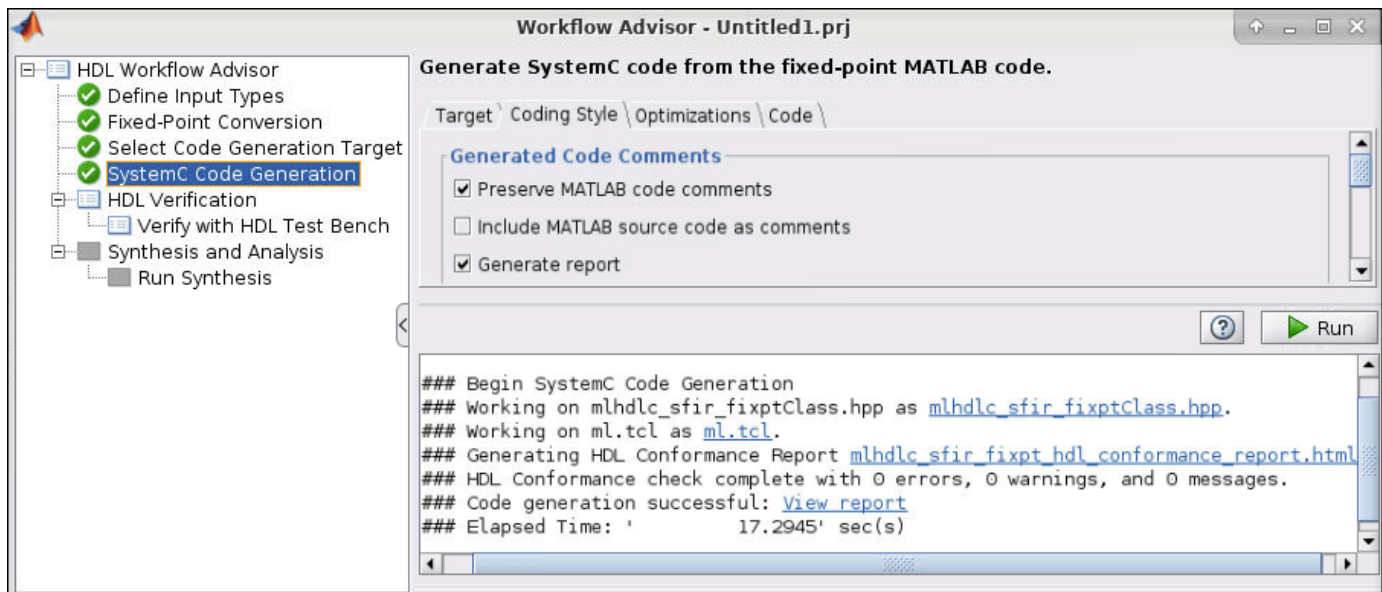

4. In **Select Code Generation Target** step, specify **Workflow** as **High Level Synthesis** and **Synthesis tool** as **Cadence Stratus**.

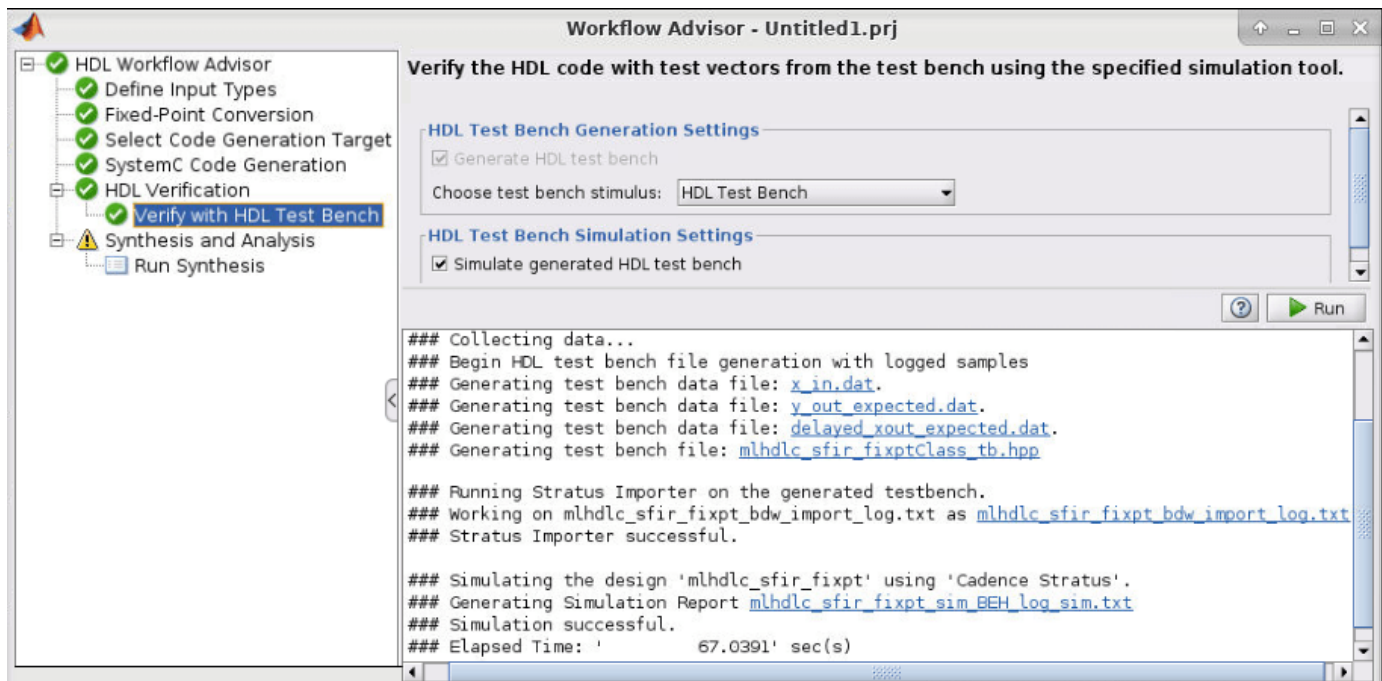

5. Right-click the **SystemC Code Generation** task and select **Run to selected task**.

The code generator runs the Workflow Advisor tasks to generate SystemC code for the filter design.

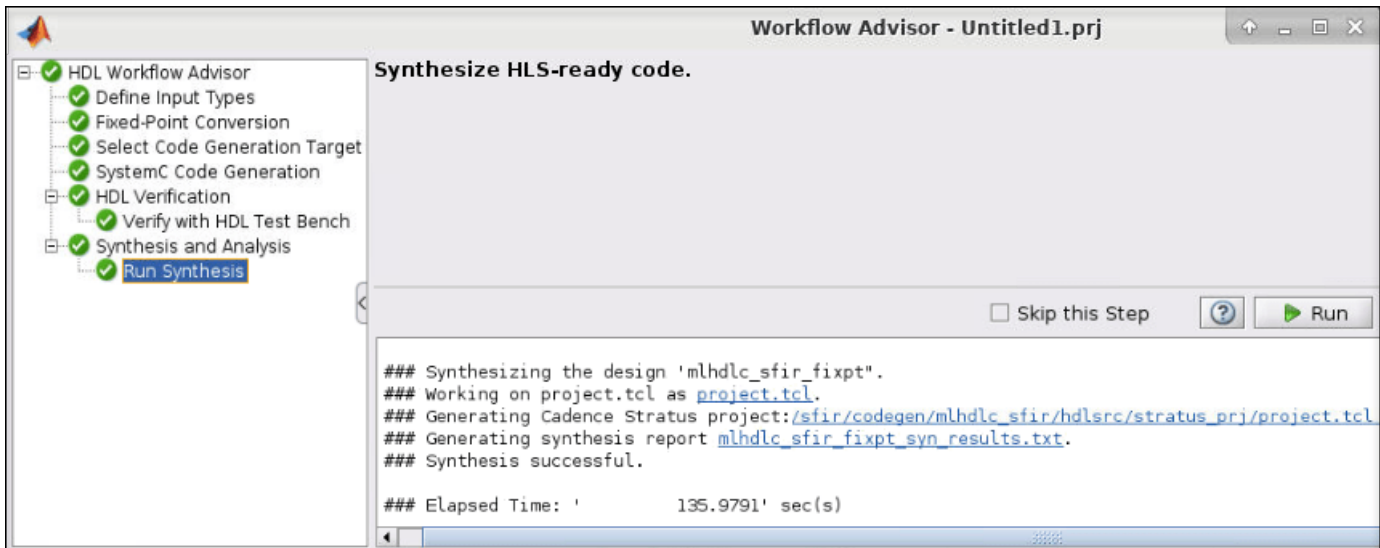

To examine the generated SystemC code, click the hyperlink to `mlhdlc_sfir_fixptClass.hpp` in the **SystemC Code Generation** log window.

6. You can compare the output of the generated SystemC code to that of the MATLAB code in the **Verify with HDL Test Bench** step. This step also generates SystemC test bench files and creates the Cadence Stratus project.

7. Synthesis is the final step in the code generation process. In the **Run Synthesis** step, the generated SystemC code is synthesized using the HLS tool and Verilog or VHDL code is generated.

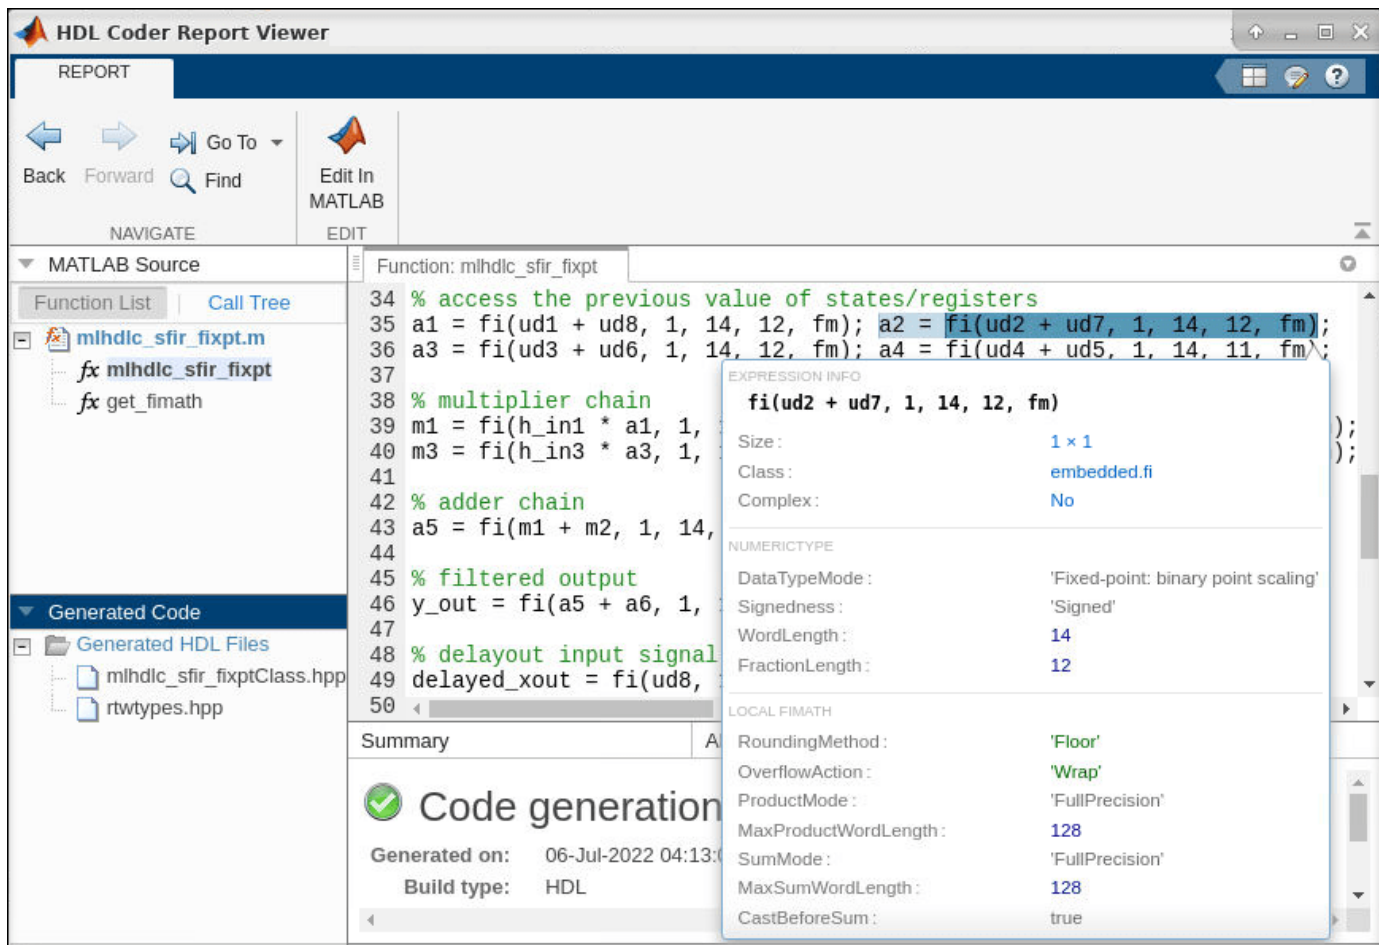

SystemC Code Generation Report

At the **SystemC Code Generation** step, you can check the code generation report by clicking **View Report** in the log window.

The code generation report helps you to:

- Debug code generation issues and verify that your MATLAB code is suitable for code generation.
- View generated SystemC code.
- Access additional reports like a conformance report.
- See how the code generator determines and propagates type information for variables and expressions in your MATLAB code.

To view a MATLAB function in the code pane, click the name of the function in the MATLAB Source pane. In the code pane, when you pause on a variable or expression, a tooltip displays information about its size, type, and complexity.

Limitations

- Only Cadence Stratus is supported as the high level synthesis tool. Cadence Stratus supports only point to point (p2p) communication for SystemC code generation.
- Generating SystemC code that runs on multiple threads is not supported.
- Real data types and Systems objects are not supported for SystemC code generation.
- Structures and enumerations are not supported as inputs and outputs at the top-level DUT ports for SystemC code generation.

Get Started with MATLAB to SystemC Workflow Using the Command Line Interface

This example shows how to use the HDL Coder™ command-line interface to generate SystemC code from MATLAB® code, including floating-point to fixed-point conversion.

Overview

SystemC code generation using the command-line interface has the following basic steps:

- 1 Set up the high-level synthesis (HLS) tool path for SystemC code generation by using the function `hdlsetuptoolpath`.
- 2 Create a `fixpt` coder configuration object.
- 3 Create an `hdl` coder configuration object.
- 4 Set configuration object parameters.
- 5 Run the `codegen` command to generate SystemC code.

The HDL Coder command-line interface can use two coder configuration objects with the `codegen` command. The `fixpt` coder configuration object configures the floating-point to fixed-point conversion of your MATLAB code. The `hdl` coder configuration object configures SystemC code generation and programming options.

The example code implements a simple symmetric finite impulse response (FIR) filter and its test bench. Using this example, you can configure floating-point to fixed-point conversion and generate SystemC code.

Set up the FIR model and test bench for this example.

```
mlhdlc_demo_setup('sfir');
```

Create Floating-Point to Fixed-Point Conversion Configuration Object

If your design already uses fixed-point types and functions, then you can skip the fixed-point conversion step.

To perform floating-point to fixed-point conversion, you need a `fixpt` configuration object.

Create a `fixpt` configuration object and specify your test bench name.

```
fixptcfg = coder.config('fixpt');  
fixptcfg.TestBenchName = 'mlhdlc_sfir_tb';
```

Fixed-Point Conversion Type Proposal Options

The code generator can propose fixed-point types based on your choice of either word length or fraction length. These two options are mutually exclusive.

Base the proposed types on a word length of 24:

```
fixptcfg.DefaultWordLength = 24;  
fixptcfg.ProposeFractionLengthsForDefaultWordLength = true;
```

Alternatively, you can base the proposed fixed-point types on fraction lengths. The following code configures the coder to propose types based on a fraction length of 10:

```
fixptcfg.DefaultFractionLength = 10;  
fixptcfg.ProposeWordLengthsForDefaultFractionLength = true;
```

Safety Margin

The code generator increases the simulation data range on which it bases its fixed-point type proposal by the safety margin percentage. For example, the default safety margin is 4, which increases the simulation data range used for fixed-point type proposal by 4%.

Set the `SafetyMargin` to 10%:

```
fixptcfg.SafetyMargin = 10;
```

Data Logging

The code generator runs the test bench with the design before and after a floating-point to fixed-point conversion. You can enable simulation data logging to plot the quantization effects of the new fixed-point data types.

Enable data logging in the `fixpt` configuration object:

```
fixptcfg.LogIOForComparisonPlotting = true;
```

Numeric Type Proposal Report

Configure the code generator to start the type proposal report once the fixed-point types have been proposed:

```
fixptcfg.LaunchNumericTypesReport = true;
```

Create SystemC Code Generation Configuration Object

To generate SystemC code, you must create an `hdl` configuration object and set your test bench name:

```
hdlcfg = coder.config('hdl');  
hdlcfg.TestBenchName = 'mlhdlc_sfir_tb';
```

Target Language and Synthesis Tool

To generate SystemC code, specify the target language as SystemC and the synthesis tool as Cadence Stratus.

```
hdlcfg.TargetLanguage = 'SystemC';  
hdlcfg.SynthesisTool = 'Cadence Stratus';
```

Generation of SystemC Test Bench Code

Configure the code generator to generate a SystemC test bench from your MATLAB® test bench:

```
hdlcfg.GenerateHDLTestBench = true;
```

Simulation of the Generated SystemC Code

If you want to simulate your generated SystemC code, you must also configure the code generator to generate a SystemC test bench.

```
hdlcfg.SimulateGeneratedCode = true;
```

Synthesis Tool for Generated SystemC Code

You can synthesize your generated SystemC code by using the synthesis tool **Cadence Stratus**. Configure the code generator to use this tool.

```
hdlcfg.SynthesizeGeneratedCode = true;
```

Run SystemC Code Generation

Now that you have your `fixpt` and `hdl` configuration objects set up, run the `codegen` command to perform floating-point to fixed-point conversion and generate SystemC code:

```
codegen -float2fixed fixptcfg -config hdlcfg mlhdlc_sfir -report
```

SystemC Code Generation Report

At the MATLAB command line window, you can check the code generation report by clicking **View Report**.

The code generation report helps you to:

- Debug code generation issues and verify that your MATLAB code is suitable for code generation.
- View generated SystemC code.
- Access additional reports like a conformance report.
- See how the code generator determines and propagates type information for variables and expressions in your MATLAB code.

To view a MATLAB function in the code pane, click the name of the function in the MATLAB Source pane. In the code pane, when you pause on a variable or expression, a tooltip displays information about its size, type, and complexity.

The screenshot displays the HDL Coder Report Viewer interface. The main window shows MATLAB source code for a function named `mlhdlc_sfir_fixpt`. The code includes comments and function calls for fixed-point arithmetic. A popup window titled "EXPRESSION INFO" is open over the expression `fi(ud2 + ud7, 1, 14, 12, fm)`. The popup provides the following details:

- Size:** 1 × 1
- Class:** embedded.fi
- Complex:** No
- NUMERICTYPE:**
 - DataTypeMode:** 'Fixed-point: binary point scaling'
 - Signedness:** 'Signed'
 - WordLength:** 14
 - FractionLength:** 12
- LOCAL FIMATH:**
 - RoundingMethod:** 'Floor'
 - OverflowAction:** 'Wrap'
 - ProductMode:** 'FullPrecision'
 - MaxProductWordLength:** 128
 - SumMode:** 'FullPrecision'
 - MaxSumWordLength:** 128
 - CastBeforeSum:** true

At the bottom of the viewer, a "Code generation" summary is shown with a green checkmark, indicating successful generation. The generated code is dated 06-Jul-2022 04:13:00 and is of type HDL.

Limitations

- Only Cadence Stratus is supported as the high level synthesis tool. Cadence Stratus supports only point to point (p2p) communication for SystemC code generation.
- Generating SystemC code that runs on multiple threads is not supported.
- Real data types and Systems objects are not supported for SystemC code generation.
- Structures and enumerations are not supported as inputs and outputs at the top-level DUT ports for SystemC code generation.

Replace Arithmetic Operation to Generate Efficient SystemC Code

Best practices when using division operation in your MATLAB code for SystemC code generation.

Division Operation

One of the fundamental arithmetic operation, division is found in many applications including vector normalization and matrix decomposition. The example starts with floating-point division operation and use fixed-point conversion to map division into efficient implementations before generating SystemC code.

Division Using Cordic Algorithm

Cordic algorithm is one of the hardware efficient algorithms for division operations that require only shift-add operations. You can use `fixed.cordicDivide` method supported for fixed-point data type in MATLAB to generate efficient SystemC code.

To facilitate automatic replacement of division operation with `fixed.cordicDivide` function:

- Write the division operation into a separate function called `divide_op`.

```
function y = divide_example(u, v)
    y = divide_op(u, v);
end
```

```
function y = divide_op(u, v)
    y = u / v;
end
```

- Replace the `divide_op` function with `CordicDivideFcn` when converting from floating-point type to fixed-point data type.

```
function y = CordicDivideFcn(a, b)
    y = fixed.cordicDivide(a, b, numerictype(0,14,14));
end
```

Perform fixed-point conversion and generate SystemC code by using these commands.

```
% Create HDL configuration object
hdlcfg = coder.config('hdl');
hdlcfg.Workflow = 'High Level Synthesis';
hdlcfg.TargetLanguage = 'SystemC';
hdlcfg.DesignFunctionName = 'divide_example';
hdlcfg.TestBenchName = 'divide_example_tb';

% Create float to fixed configuration object
cfg = coder.config('fixpt');
cfg.TestBenchName = { 'divide_example_tb.m' };
cfg.LogIOForComparisonPlotting = true;
cfg.TestNumerics = true;
cfg.PlotWithSimulationDataInspector = true;

% Replace divide_op with cordic divide function
cfg.addFunctionReplacement('divide_op', 'CordicDivideFcn');
```

```
% Invoke fixed-point conversion and generate SystemC code
codegen -float2fixed cfg divide_example -config hdlcfg -args {0,0}
```

```

Code generation successful.
```

In the HDL workflow advisor, function replacements are done in the fixed-point converter step using the **Function Replacements** tab.

Division Using Shift-Add

Non-restoring division algorithm uses only shifts and addition operations and is advantageous to use in hardware. You can use a custom implementation of this division algorithm for fixed-point data types in function `shift_add_divider`. Write division operation in a separate function which can be replaced after fixed-point conversion with our custom implementation function `shift_add_divider`.

```
function y = divide_example(u, v)
    y = divide_op(u, v);
end
```

```
function y = divide_op(u, v)
    y = u / v;
end
```

Perform fixed-point conversion and generate SystemC code by using these commands.

```
% Create configuration object of class 'coder.HdlConfig'.
hdlcfg = coder.config('hdl');
hdlcfg.Workflow = 'High Level Synthesis';
hdlcfg.TargetLanguage = 'SystemC';
hdlcfg.DesignFunctionName = 'divide_example';
hdlcfg.TestBenchName = 'divide_example_tb';

% Create configuration object of class 'coder.FixPtConfig'.
cfg = coder.config('fixpt');
cfg.TestBenchName = { 'divide_example_tb.m' };
cfg.LogIOForComparisonPlotting = true;
cfg.TestNumerics = true;
cfg.PlotWithSimulationDataInspector = true;
```

```

% Replace divide_op with shift-add divide function
cfg.addTypeSpecification('divide_example', 'u', numerictype(0,14,10));
cfg.addTypeSpecification('divide_op', 'u', numerictype(0,14,10));
cfg.addFunctionReplacement('divide_op', 'shift_add_divider');

% Invoke fixed-point conversion and generate SystemC

Division Using Lookup Table

When the output of division does not have high dynamic range, use lookup table approach to compute reciprocal and then multiply the reciprocal with numerator to perform division operation.

For using a 1-D lookup table, split the division operation into a reciprocal operation and a multiplication. Implement the reciprocal using the lookup table.

```
function y = recip_example(u, v)
    recip = reciprocal_op(v);
    y = u * recip;
end
```

The function `reciprocal_op` need to be in a separate file so that the fixed-point converter can use the results of this function to create lookup table data.

```
function y = reciprocal_op(v)
    y = 1 / v;
end
```

Perform fixed-point conversion and generate SystemC code by using these commands.

```
% HDL Configuration
hdlcfg = coder.config('hdl');
hdlcfg.Workflow = 'High Level Synthesis';
hdlcfg.TargetLanguage = 'SystemC';
hdlcfg.DesignFunctionName = 'recip_example';
hdlcfg.TestBenchName = 'recip_example_tb';

% Fixpt conversion configuration
cfg = coder.config('fixpt');
cfg.TestBenchName = { 'recip_example_tb.m' };
cfg.LogIOForComparisonPlotting = true;
cfg.TestNumerics = true;
cfg.PlotWithSimulationDataInspector = true;

cfg.addTypeSpecification('recip_example', 'v', numerictype(0,6,0));

% Lookup table specification
approxConfig = coder.approximation('reciprocal_op');
approxConfig.CandidateFunction = 'reciprocal_op';
approxConfig.InterpolationDegree = 1;
approxConfig.NumberOfPoints = 1000;
cfg.addApproximation(approxConfig);

% Invoke code generation

In the HDL workflow advisor, lookup table replacements are done in the fixed-point converter step using the **Function Replacements** tab. Lookup table parameters like table size and interpolation method can be customized in the workflow advisor.

Function Replacements						
Enter a function to replace					Custom Function ▾	+ -
Function or Operator	Replacement					
Custom Function						
<input type="checkbox"/> Lookup Table	Interpolation Method	Design Min	Design Max	Number of Points		
reciprocal_op	Linear	Auto	Auto	1000		

Summary

The above examples showed three different ways of implementing division operation that are suitable for hardware.

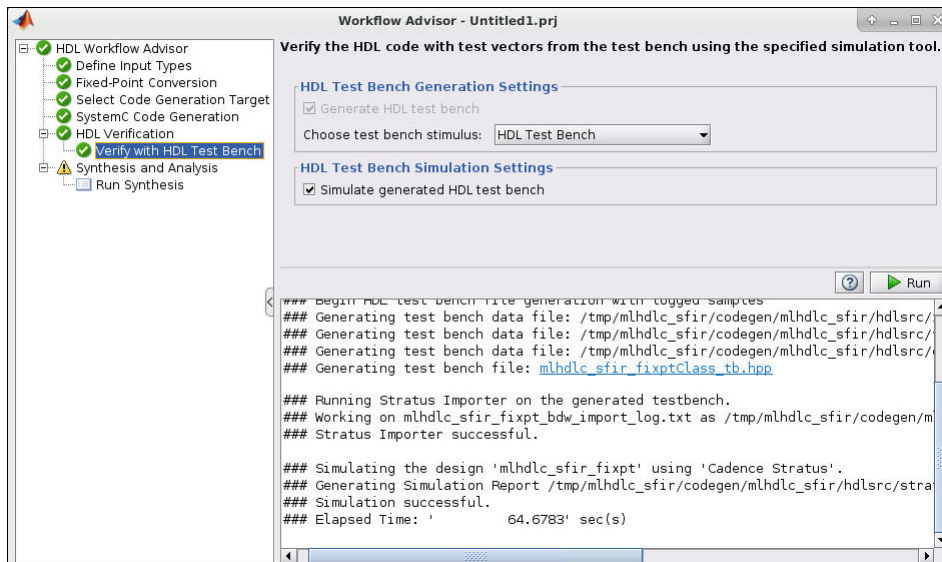

Verification

- “Verify SystemC Code That Has an HDL Test Bench” on page 12-2
- “MATLAB to SystemC Code Conversion Options” on page 12-4

Verify SystemC Code That Has an HDL Test Bench

Simulate the generated SystemC design under test (DUT) with test vectors from the test bench files.

- 1 Start the MATLAB to HDL Workflow Advisor.
- 2 In the **HDL Workflow Advisor**, select **MATLAB to SystemC** as the **Code generation workflow**.
- 3 Select the **Workflow** as **High Level Synthesis** and **Synthesis tool** as **Cadence Stratus** in the **Select Code Generation Target** step.
- 4 For **HDL Verification**, click **Verify with HDL Test Bench**.

- 5 Optionally, select **Simulate generated HDL test bench**. This option enables MATLAB to simulate the SystemC test bench by using the SystemC DUT.
- 6 Click **Run**.

If the test bench and simulation executes without error, you see messages similar to these messages in the message pane:

```

### Begin TestBench generation.
Code generation successful.

### Collecting data...
### Begin HDL test bench file generation with logged samples
### Generating test bench data file: /tmp/mlhdlc_sfir/codegen/mlhdlc_sfir/hdlsrc/x_in.dat.
### Generating test bench data file: /tmp/mlhdlc_sfir/codegen/mlhdlc_sfir/hdlsrc/y_out_expected.dat.
### Generating test bench data file: /tmp/mlhdlc_sfir/codegen/mlhdlc_sfir/hdlsrc/delayed_xout_expected.dat.
### Generating test bench file: mlhdlc_sfir_fixptClass_tb.hpp

### Running Stratus Importer on the generated testbench.
### Working on mlhdlc_sfir_fixpt_bdw_import_log.txt as /tmp/mlhdlc_sfir/codegen/mlhdlc_sfir/hdlsrc/stratus_prj/mlhdlc_sfir_fixpt_bdw_import_log.txt
### Stratus Importer successful.

### Simulating the design 'mlhdlc_sfir_fixpt' using 'Cadence Stratus'.
### Generating Simulation Report /tmp/mlhdlc_sfir/codegen/mlhdlc_sfir/hdlsrc/stratus_prj/mlhdlc_sfir_fixpt_sim_BEH_1
### Simulation successful.
### Elapsed Time: ' 64.6783' sec(s)

```

If the errors appear in the message pane, fix the errors and click **Run**.

Additional Notes

- After clicking **Run**, the test bench generation starts generating the `.dat` files, such as `x_in.dat` and `y_out_expected.dat`, that contains the input and the expected output values to the top-level DUT and a test bench class file.
- When the test bench files are generated, the Stratus Importer is run by using Cadence Stratus HLS tool. It generates a Stratus HLS project in the current working folder.
- The simulation compiles and executes the generated SystemC code and test bench with input values stored in the `x_in.dat` file. The simulation can verify the numeric match of the generated SystemC code to the MATLAB code by comparing the SystemC output with the expected output values stored in the `y_out_expected.dat` file.

MATLAB to SystemC Code Conversion Options

In this section...

“MATLAB to SystemC Code Conversion” on page 12-4

“SystemC Code Generation: Target Tab” on page 12-4

“SystemC Code Generation: Coding Style Tab” on page 12-4

“SystemC Code Generation: Optimizations Tab” on page 12-5

MATLAB to SystemC Code Conversion

The **MATLAB to SystemC Workflow** task in the HDL Workflow Advisor generates SystemC code from fixed-point MATLAB code. It simulates and verifies the SystemC against the fixed-point algorithm.

SystemC Code Generation: Target Tab

Select target hardware and language and required outputs.

Input Parameters

Check HDL Conformance

Enable HDL conformance checking.

Default: Off

SystemC Code Generation: Coding Style Tab

Parameters that affect the style of the generated code.

Input Parameters

Preserve MATLAB code comments

Include MATLAB code comments in generated code.

Default: On

Include MATLAB source code as comments

Include MATLAB source code as comments in the generated code. The comments precede the associated generated code. Includes the function signature in the function banner.

Default: On

Generate Report

Enable a code generation report.

Default: Off

Emit time/date stamp in the header

Enable to include time and date in output file header..

Default: Off

Comment in header

Specify comment lines in header of generated SystemC and test bench files.

Default: None

Text entered in this field as a character vector generates a comment line in the header of the generated code. The code generator adds leading comment characters for the target language. When newlines or linefeeds are included in the text, the code generator emits single-line comments for each newline.

Complex real part postfix

Specify a character vector to append to the real part of complex signal names.

Default: '_re'

Complex imaginary part postfix

Specify a character vector to append to the imaginary part of complex signal names.

Default: '_im'

Reserved word postfix

Specify a character vector to append to value names, postfix values, or labels that are SystemC reserved words.

Default: '_rsvd'

SystemC Code Generation: Optimizations Tab

Optimization settings

Input Parameters**Map persistent array variables to RAMs**

Select to map persistent array variables to RAMs instead of mapping to shift registers.

Default: Off

Dependencies:

- **RAM Mapping Threshold**
- **Persistent variable names for RAM Mapping**

RAM Mapping Threshold

Specify the minimum RAM size required for mapping persistent array variables to RAMs.

Default: 256

Initialize Block Ram

Enable to initialize the RAM elements to zero.

Default: off

SystemC Optimizations

- “Map Persistent Arrays to RAM” on page 13-2
- “Pipelining of for-Loops” on page 13-4
- “Map Persistent Variables to RAM for Histogram Equalization” on page 13-9

Map Persistent Arrays to RAM

In this section...

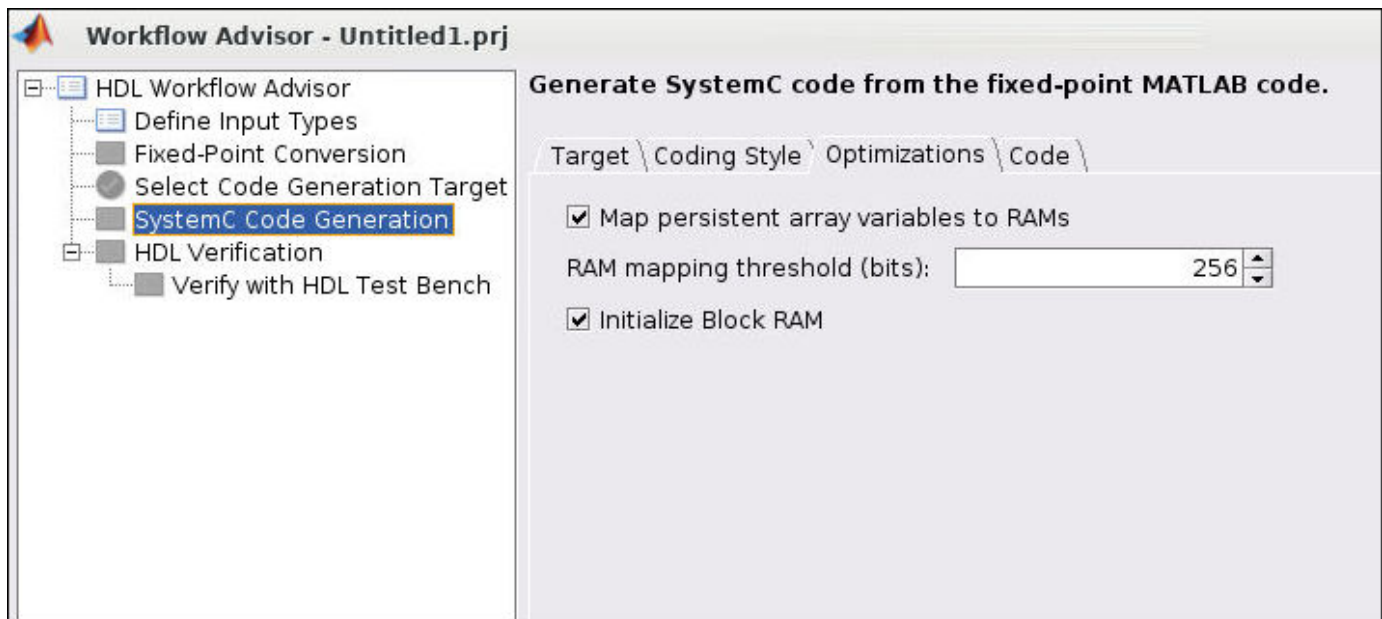

“Enable RAM Mapping” on page 13-2

“RAM Mapping Requirements for Persistent Arrays” on page 13-2

To map the persistent variables to RAMs in the generated SystemC code use the **RAM Mapping** optimization. Without this optimization, the variables are mapped to registers. RAM mapping is an area optimization. It reduces the area of your design in the target hardware.

Enable RAM Mapping

- 1 In the HDL Workflow Advisor, select **MATLAB to SystemC Workflow > SystemC Code Generation > Optimizations** tab.
- 2 Select the **Map persistent array variables to RAMs** option.
- 3 Set the **RAM mapping threshold** to the size (in bits) of the smallest persistent array that you want to map to RAM.

RAM Mapping Requirements for Persistent Arrays

This table lists a summary of the RAM mapping behavior for persistent arrays.

Map Persistent Array Variables to RAMs Setting	Mapping Behavior
on	Map to RAM in the generated SystemC code.
off	Map to registers in the generated SystemC code.

Additional Notes

- The large persistent arrays whose size in bits is greater than or equal to **RAM mapping threshold** are mapped to RAM. The size in bits is calculated as `NumElements * WordLength`.
 - `NumElements` is the number of elements in the array.
 - `WordLength` is the number of bits that represent the data type of the array.
- The list of RAM variables is populated inside the `ml.tcl` metadata file generated during **SystemC Code Generation**. This metadata file is read by the Stratus HLS tool during project creation and maps these variables to RAM.
- If **Initialize Block RAM** option is turned off, the RAM variables that have a zero initial value are not initialized inside `initialize_ram_vars()` method.
- If the initial value of the variables is nonzero, then those RAM variables are initialized inside the `initialize_ram_vars()` method, irrespective of the **Initialize Block RAM** option value.

More About

- “Map Persistent Variables to RAM for Histogram Equalization” on page 13-9

Pipelining of for-Loops

Pipelining allows concurrent execution of multiple iterations. The next iteration of a loop can begin execution before the previous iteration completes its execution. Pipelining optimises the execution speed and improves the throughput of the code at the expense of increased resources.

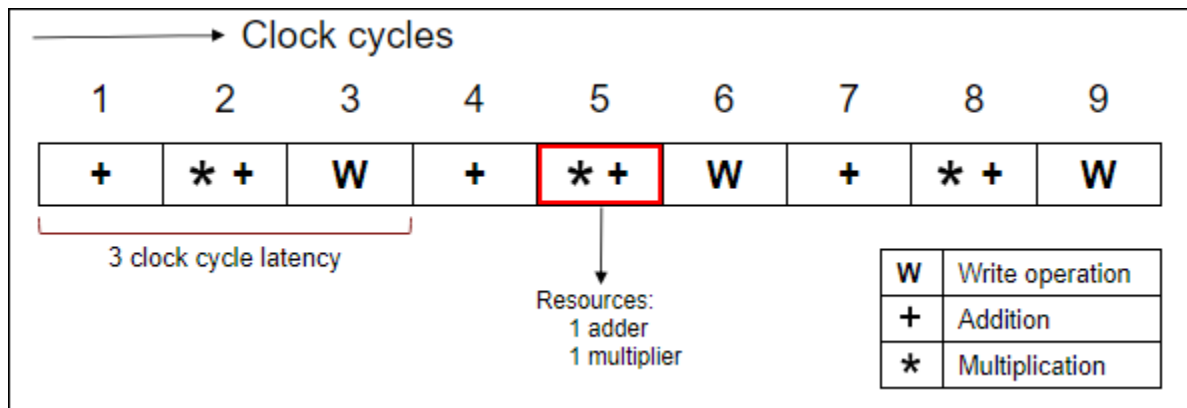

In MATLAB you can pipeline for-loops by using `coder.hdl.loopspec('pipeline')` or `coder.hdl.loopspec('pipeline',initiation_interval)`.

To understand the concept of pipelining of for-loops, consider the following MATLAB code. It consists of a for-loop and a persistent array `arr`, mapped to RAM during code generation.

```
for i = 1:20
    tmp = fi((a + b) * c + tmp, 0, 32, 0, hdlfimath);
    arr(i) = tmp;
end
```

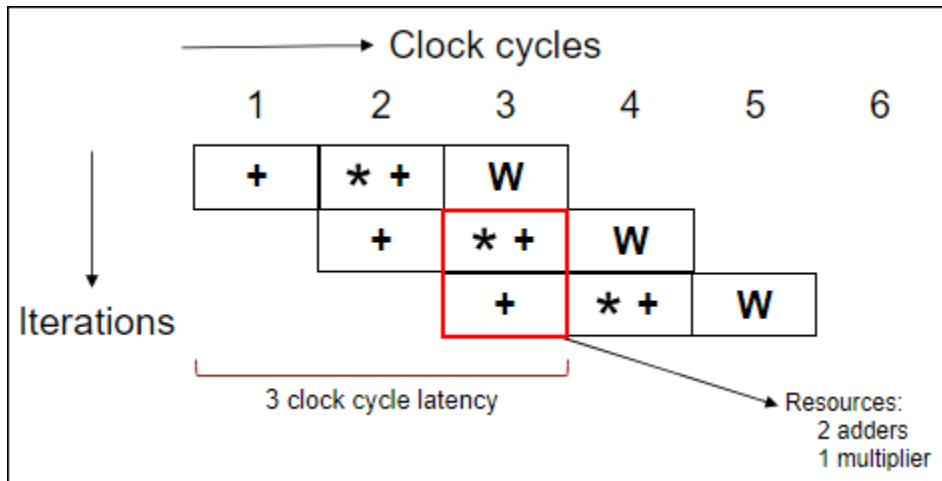

- **Non-pipelined for-loop**

In a non-pipelined loop, all the iterations of the for-loop are scheduled serially. The next iteration executes after the previous iteration completes its execution. Also, there is no overlap in the execution of the iterations in a non-pipelined loop. The following diagram shows the schedule of a non-pipelined for-loop.

- **Pipelined for-loop**

In a pipelined loop, the next iteration starts its execution with a gap of an initiation interval. This can lead to overlap in the execution of the iterations. The initiation interval represents the number of clock cycles before the start of the next iteration of the for-loop. The following diagram shows the schedule of a pipelined for-loop with an initiation interval of 1.

In the above schedules, a non-pipelined for-loop takes 9 clock cycles to complete 3 iterations whereas a pipelined for-loop takes only 5 clock cycles for 3 iterations. This shows the impact of pipelining in improving the throughput of the code at the expense of additional resources.

Issues with Pipelined for-Loops

Pipelining enables resource sharing between multiple iterations, thus leading to the following hazards:

1 Conflicting Read and Write Operations

If a pipelined for-loop is performing read and write operations in the same iteration, it can lead to overlapping of these operations. The memory read operation in the next iteration can be scheduled before the memory write operation in the current iteration. This leads to reading of incorrect values between the for-loop iterations of the shared resources.

Consider the following MATLAB code and its testbench. The code consists of a pipelined for-loop with an `initiation_interval` of 1, that performs both read and write operations in each iteration.

MATLAB Code	Generated SystemC Code
<pre>function out = f(in) persistent arr1; if isempty(arr1) arr1 = zeros(1,102); end coder.hdl.loopspec('pipeline',1); for i = 4:100 y = arr1(i-3); arr1(i) = in; end out = y; end % MATLAB Testbench a = fi(4,0,3,0); for i = 1:100 out(i) = f(a); end</pre>	<pre>class f_fixptClass { public: sc_uint<3> f_fixpt_arr1[102]; void f_fixpt_initialize_ram_vars() { int32_T t_0; L1: for (t_0 = 0; t_0 < 102; t_0 = t_0 + 1) { f_fixpt_arr1[t_0] = sc_uint<3>(0.0); } } sc_uint<3> f_fixpt(sc_uint<3> in) { sc_uint<3> out; L2: for (int32_T i = 0; i < 97; i = i + 1) { HLS_PIPELINE_LOOP(HARD_STALL, 1, "L2"); out = f_fixpt_arr1[i]; f_fixpt_arr1[i + 3] = in; } return out; } };</pre>

During synthesis, the high level synthesis (HLS) tool throws an error stating: Unable to guarantee the safety of the schedule in the pipelined loop.

Solution:

To overcome the conflicting read and write operations, you can use any one of the following solution based on your design requirement.

- Use `coder.hdl.arraydistance(arr1, 'max', 1)`, which ensures that read and write operations enclosed in the `for`-loop are separated with a maximum array distance of one clock cycle.

```
coder.hdl.loopspec('pipeline',1);
for i = 4:100
    coder.hdl.arraydistance(arr1, 'max', 1);
    y = arr1(i-3);
    arr1(i) = in;
end
```

- Alternatively, you can update the value of `initiation_interval` to 2 in the `coder.hdl.loopspec` pragma.

```
coder.hdl.loopspec('pipeline',2);
for i = 4:100
    y = arr1(i-3);
    arr1(i) = in;
end
```

2 Limited Memory Access

In many designs, it is common to have a single loop performing two or more accesses to a single memory (RAM). If such a loop is pipelined with `initiation_interval` as 1, these memory

accesses occur simultaneously during each clock cycle. Dual-port RAMs have two ports at maximum, so at most two parallel independent accesses can be scheduled to the memory in a single clock cycle.

However, with a pipelined for-loop, more than two memory accesses can occur in a single clock cycle. This scenario leads to a limited memory access issue.

Consider the following MATLAB code and its testbench. It has a persistent array `arr1` that is mapped to RAM. The for-loop is pipelined with an `initiation_interval` of 1, and three write operations are performed on the RAM mapped variable `arr1` inside the for-loop body.

MATLAB Code	Generated SystemC Code
<pre>function out = f(in1, in2) persistent arr1; if isempty(arr1) arr1 = zeros(1,102); end coder.hdl.loopspec('pipelined', t_0); for i = 1:100 arr1(i) = in1+in2; arr1(i+1) = in1*2; arr1(i+2) = in1+in2-2; end out = sum(arr1); end % MATLAB Testbench a = int8(4); b = int8(5); out = f(a,b);</pre>	<pre>class f_fixptClass { public: sc_uint<4> f_fixpt_arr1[102]; void f_fixpt_initialize_ram_vars() { int32_T t_0; L1: for (t_0 = 0; t_0 < 102; t_0 = t_0 + 1) { f_fixpt_arr1[t_0] = sc_uint<4>(0.0); } } sc_uint<10> f_fixpt(sc_uint<3> in1, sc_uint<3> in2) { sc_uint<10> out; sc_uint<11> Y; L2: for (int32_T i = 0; i < 100; i = i + 1) { HLS_PIPELINE_LOOP(HARD_STALL, 1, "L2"); f_fixpt_arr1[i] = (sc_uint<4>)in1 + (sc_uint<4>)in2; f_fixpt_arr1[i + 1] = (sc_uint<4>)(in1 * sc_uint<2>(2.0)); f_fixpt_arr1[i + 2] = ((sc_uint<4>)in1 + (sc_uint<4>)in2) sc_uint<5>(2.0); } Y = (sc_uint<11>)f_fixpt_arr1[0]; L3: for (int32_T k = 0; k < 101; k = k + 1) { Y = (sc_uint<11>)((sc_uint<12>)Y + (sc_uint<12>)f_fixpt_a } out = (sc_uint<10>)Y; return out; } };</pre>

During synthesis, the HLS tool throws an error stating: Unable to produce a valid schedule, found 1 Violation(s).

Solution:

To overcome the limited memory access create a pipelined for-loop with an `initiation_interval` of 2. This action ensures that two memory accesses occur in each iteration of the for-loop.

```
coder.hdl.loopspec('pipeline',2);  
for i = 1:100  
    arr1(i) = in1+in2;  
    arr1(i+1) = in1*2;  
    arr1(i+2) = in1+in2-2;  
end
```

Map Persistent Variables to RAM for Histogram Equalization

This example shows how to use the RAM mapping optimization in HDL Coder™ to map persistent matrix variables to block RAMs in hardware.

Introduction

In MATLAB, you can easily create, access, modify, and manipulate matrices.

When processing such MATLAB code, HDL Coder maps these matrices to wires or registers in hardware. For example, local temporary matrix variables are mapped to wires, whereas persistent matrix variables are mapped to registers.

The latter tends to be an inefficient mapping when the matrix size is large because the number of register resources available is limited. It also complicates synthesis, placement, and routing.

Modern FPGAs feature block RAMs that are designed to have large matrices. HDL Coder takes advantage of this feature and maps matrices to block RAMs to improve area efficiency. For certain designs, mapping these persistent matrices to RAMs is mandatory if the design is to be realized. State-of-the-art synthesis tools might not be able to synthesize designs when large matrices are mapped to registers, whereas the size is more manageable when the same matrices are mapped to RAMs.

Algorithm

The Histogram Equalization algorithm enhances the contrast of images by transforming the values in an intensity image so that the histogram of the output image is approximately flat.

```
I = imread('pout.tif');
J = histeq(I);
subplot(2,2,1);
imshow( I );
subplot(2,2,2);
imhist(I)
subplot(2,2,3);
imshow( J );
subplot(2,2,4);
imhist(J)
```

MATLAB Design

```
design_name = 'mlhdlc_heq';
testbench_name = 'mlhdlc_heq_tb';
```

Review the MATLAB design

```
type(design_name);

end
```

Simulate the Design

Before code generation, simulate the design by using the HDL test bench to make sure that there are no run-time errors.

```
mlhdlc_heq_tb
```

```
working on frame: 1
working on frame: 2
```

Setup for the Example

To copy the required files into a temporary folder, run this code:

```
mlhdlc_demo_dir = fullfile(matlabroot, 'toolbox', 'hdlcoder', 'hdlcoderdemos', 'matlabhdlcoderdemo');
mlhdlc_temp_dir = [tempdir 'mlhdlc_heq'];
```

```
% create a temporary folder and copy the MATLAB files
```

```
cd(tempdir);
[~, ~, ~] = rmdir(mlhdlc_temp_dir, 's');
mkdir(mlhdlc_temp_dir);
cd(mlhdlc_temp_dir);
```

```
% copy files to the temp dir
```

```
copyfile(fullfile(mlhdlc_demo_dir, [design_name, '.m*']), mlhdlc_temp_dir);
copyfile(fullfile(mlhdlc_demo_dir, [testbench_name, '.m*']), mlhdlc_temp_dir);
copyfile(fullfile(mlhdlc_demo_dir, 'mlhdlc_img_peppers.png'), mlhdlc_temp_dir);
```

Create HDL Coder™ Project

```
coder -hdlcoder -new mlhdlc_heq_prj
```

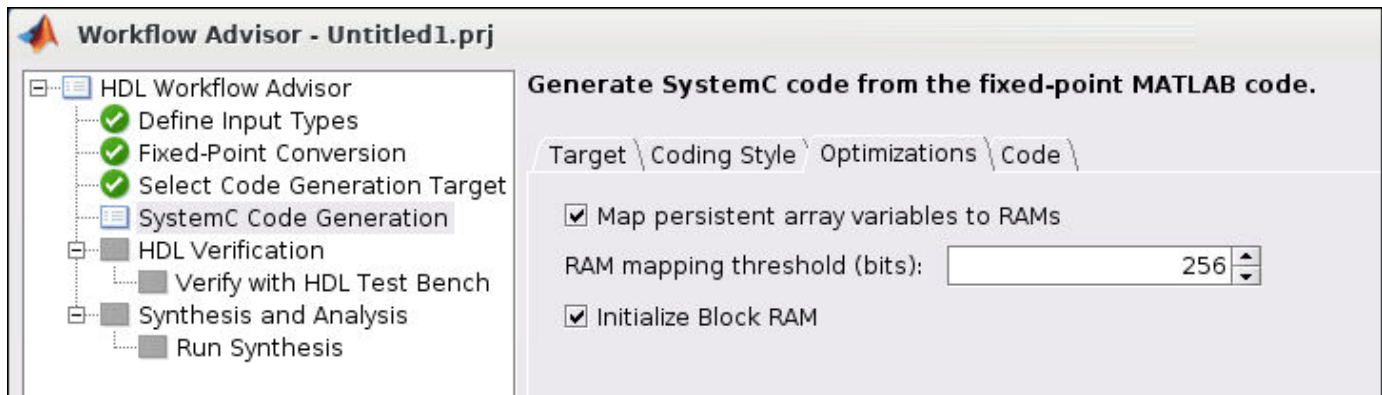

Add the file `mlhdlc_heq.m` to the project as the MATLAB Function and `mlhdlc_heq_tb.m` as the MATLAB Test Bench.

For more information, see “Get Started with MATLAB to SystemC Workflow Using the Command Line Interface” on page 11-11 or “Get Started with MATLAB to SystemC Workflow Using HDL Coder App” on page 11-2.

SystemC Code Generation by Using RAM Mapping Optimization

To generate SystemC code from a MATLAB design:

1. At the MATLAB command line, setup the high-level synthesis (HLS) tool path for SystemC code generation by using the function `hdlsetuptoolpath`.
2. Start the HDL Workflow Advisor.
3. Select as **MATLAB to SystemC** as the **Code Generation Workflow**.
4. In **Select Code Generation Target** step, select **Workflow** as **High Level Synthesis** and **Synthesis tool** as **Cadence Stratus**.
5. To map persistent variables to block RAMs in the generated code. Select **Map persistent array variables to RAMs** check box in the **Optimizations** tab of the **SystemC Code Generation** step.

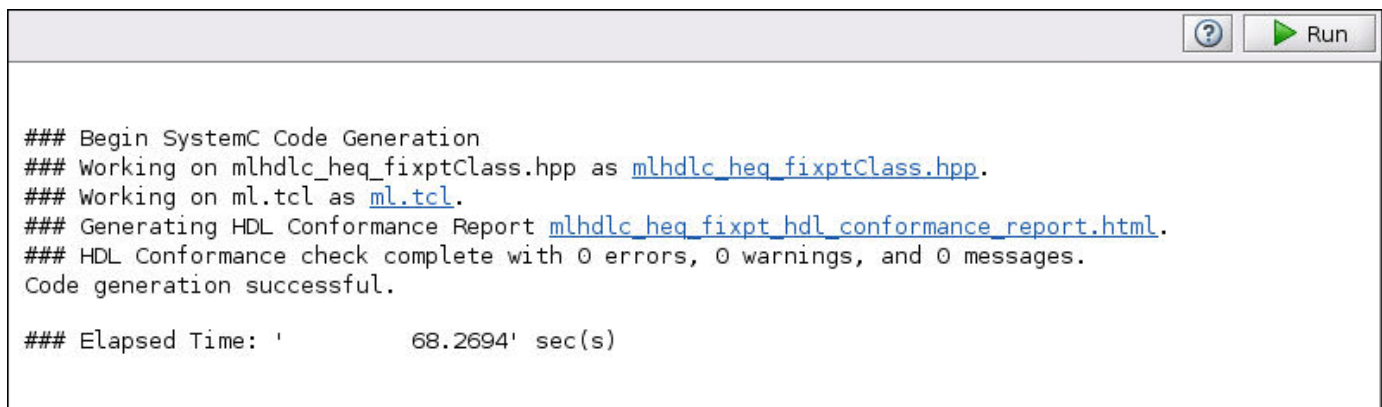

6. Right-click **SystemC Code Generation** and choose the option **Run to selected task** to run all the steps from the beginning through the SystemC code generation.

Examine the generated SystemC code by clicking the hyperlinks in the Code Generation Log window.

Examine the Generated Code

Examine the messages in the log window to see the RAM files generated with the design.

Examine the Resource Report

Examine the generated resource report, which shows the number of RAMs inferred, by following the `mlhdlc_heq_fixpt_syn_results.txt` link in the generated code window.

The **Allocation Report** highlights the variables mapped to RAM.

```

Additional Notes on RAM Mapping

- MATLAB functions can have any number of RAM matrices.
- All matrix variables in MATLAB that are declared persistent and meet the threshold criteria get mapped to RAMs.

Signal and Data Type Support

In this section...

“Buses” on page 14-3

“Enumerations” on page 14-4

“Matrices” on page 14-4

“Unsupported Signal and Data Types” on page 14-7

HDL Coder supports code generation for Simulink signal types and data types with a few special cases.

Buses

If your DUT or other blocks in your model have many input or output signals, you can create bus signals to improve the readability of your model. A bus signal or bus is a composite signal that consists of other signals that are called elements.

You can generate HDL code for designs that use virtual and nonvirtual buses. For example, you can generate code for designs that contain:

- DUT subsystem ports connected to buses.
- Simulink and Stateflow® blocks that support buses and HDL code generation.

Supported Blocks with Buses

Bus-capable blocks are blocks that can accept bus signals as input and produce bus signals as outputs. For a list of bus-capable blocks that Simulink supports, see “Bus-Capable Blocks”. HDL Coder supports code generation for bus-capable blocks in the **HDL Coder** block library. For more details, see the “HDL Code Generation” section of each block page. The supported blocks include:

- Bus Assignment
- Bus Creator
- Bus Selector
- Constant
- Delay
- Multiplex Switch
- Rate Transition
- Signal Conversion
- Signal Specification
- Switch
- Unit Delay
- Vector Concatenate, Matrix Concatenate
- Zero-Order Hold

In addition, subsystems, models, and these user-defined functions support buses for simulation and HDL code generation:

- Subsystem, Atomic Subsystem, CodeReuse Subsystem
- Model references, see “Model Referencing for HDL Code Generation” on page 32-2.
- Stateflow Chart
- MATLAB Function blocks
- MATLAB System blocks
- Vision HDL Toolbox blocks that accept a pixelcontrol bus for control input

Bus Support Limitations

Buses are not supported in the IP Core Generation workflow. In addition, you cannot generate code for designs that use:

- A Black box model reference connected to a bus.
- A bus input to a Delay block with nonzero **Initial condition**.

Enumerations

You can generate code for Simulink, MATLAB, or Stateflow enumerations within your design.

Requirements

- The enumeration strings must have unique names and must not use a reserved keyword in the Verilog or VHDL language.
- If your target language is Verilog, all enumeration member names must be unique within the design.

Restrictions

Enumerations at the top-level DUT ports are not supported with the following workflows or verification methods:

- IP Core Generation workflow
- FPGA Turnkey workflow
- Simulink Real-Time FPGA I/O workflow
- Customization for the USRP Device workflow
- FPGA-in-the-loop
- HDL Cosimulation

Matrices

You can use matrix types with these blocks in your design. For more details, see the "HDL Code Generation" section of each block page.

HDL Coder Block Library	Supported blocks
Discontinuities	These blocks are supported: <ul style="list-style-type: none"> • Dead Zone • Relay • Saturation
Discrete	These blocks are supported: <ul style="list-style-type: none"> • Delay • Discrete-Time Integrator • Memory • Tapped Delay • Unit Delay • Unit Delay Enabled Synchronous • Unit Delay Enabled Resettable Synchronous • Unit Delay Resettable Synchronous • Zero-Order Hold
HDL Floating Point Operations	The Rounding Function block is supported.
HDL Operations	All blocks in this library are supported.
HDL RAMs	Blocks in this library are not supported.
HDL Subsystems	Blocks in this library are not supported.
Logic and Bit Operations	These blocks are supported: <ul style="list-style-type: none"> • Bit Clear • Bit Concat • Bit Reduce • Bit Rotate • Bit Set • Bit Shift • Bit Slice • Extract Bits • Logical Operator • Relational Operator • Shift Arithmetic
Lookup Tables	Blocks in this library are not supported.

HDL Coder Block Library	Supported blocks
Math Operations	<p>These blocks are supported:</p> <ul style="list-style-type: none"> • Abs • Add • Assignment • Bias • Complex to Real-Imag • Gain • Product, including matrix multiplication. • Matrix Concatenate • Math Function • Real-Imag to Complex • Reshape • Sign • Sum • Unary Minus • Increment Stored Integer • Increment Real World • Decrement Stored Integer • Decrement Real World • Sum of Elements • Product of Elements
Model Verification	All blocks in this library are supported.
Model-Wide Utilities	The DocBlock is supported. The Model Info block does not support matrix data types.
Ports & Subsystems	The Subsystem, Atomic Subsystem, CodeReuse Subsystem block is supported.
Signal Attributes	<p>These blocks are supported:</p> <ul style="list-style-type: none"> • Data Type Conversion • Data Type Duplicate • Probe • Rate Transition • Signal Conversion • Signal Specification

HDL Coder Block Library	Supported blocks
Signal Routing	These blocks are supported: <ul style="list-style-type: none"> • Mux • Multiport Switch • Selector • Switch
Sources	These blocks are supported: <ul style="list-style-type: none"> • Constant • Enumerated Constant • Inport
Sinks	These blocks are supported: <ul style="list-style-type: none"> • Display • Outport • Scope • To Workspace • To File
User-Defined Functions	The MATLAB Function block is supported.

Unsupported Signal and Data Types

- Arrays stored in row-major layout are not supported for HDL code generation
- Variable-size signals are not supported for code generation.

Use Simulink Templates for HDL Code Generation

In this section...

“Create Model Using HDL Coder Model Template” on page 14-8

“HDL Coder Model Templates” on page 14-8

HDL Coder model templates in Simulink provide you with design patterns and best practices for models intended for HDL code generation. Models you create from one of the HDL Coder model templates have their configuration parameters and solver settings set up for HDL code generation. To configure an existing model for HDL code generation, use `hdlsetup`.

Create Model Using HDL Coder Model Template

To model hardware for efficient HDL code generation, create a model using an HDL Coder model template.

- 1 Open the Simulink Start Page. In the MATLAB Home tab, select the **Simulink** button. Alternatively, at the command line, enter:
- 2 In the **HDL Coder** section, you see templates that are preconfigured for HDL code generation. Selecting the template opens a blank model in the Simulink Editor. To save the model, select **File > Save As**.
- 3 To open the Simulink Library Browser and then open the **HDL Coder** Block Library, select the **Library Browser** button in the Simulink Editor. Alternatively, at the command line, enter

```
simulink
```

```
sLibraryBrowser
```

To filter the Simulink Library Browser to show the block libraries that support HDL code generation, use the `hdlLib` function:

```
hdlLib
```

HDL Coder Model Templates

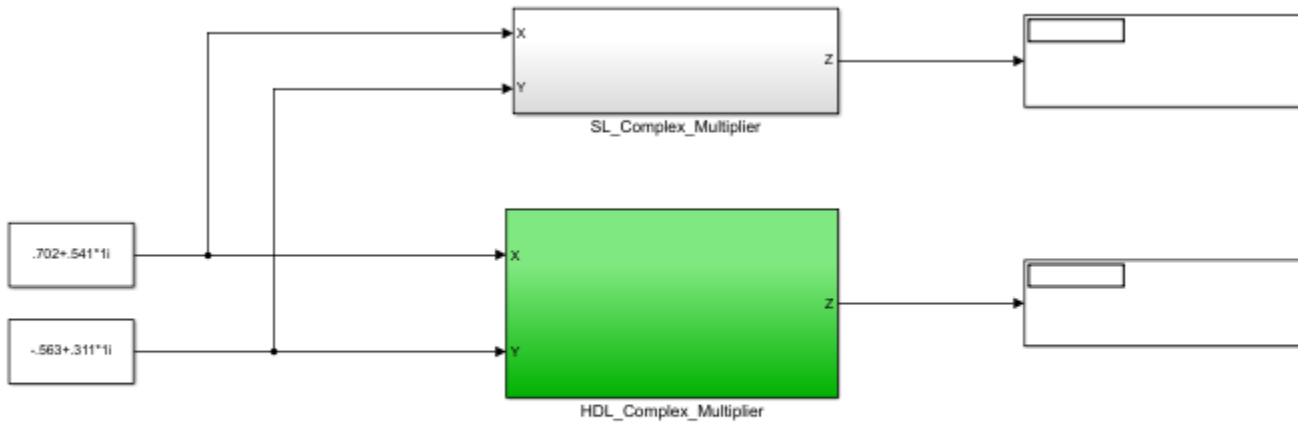

Complex Multiplier

The Complex Multiplier template shows how to model a complex multiplier-accumulator and manually pipeline the intermediate stages. The hardware implementation of complex multiplication uses four multipliers and two adders.

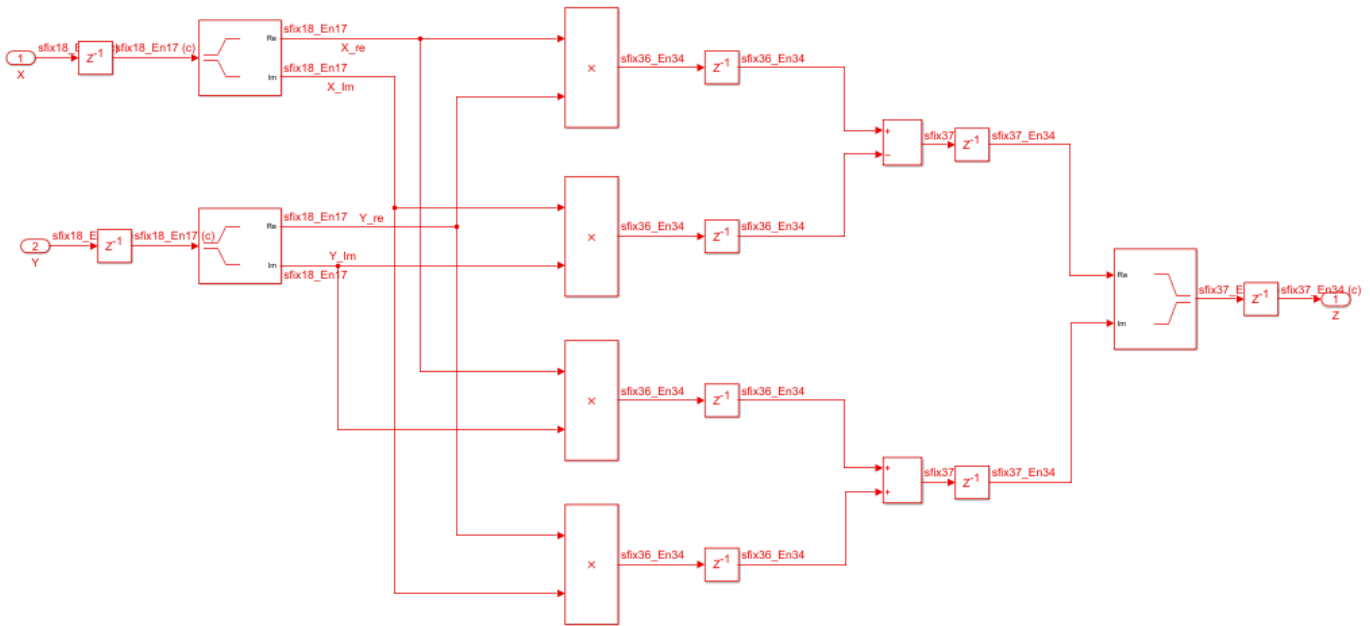

The template applies the following best practices:

- In the Configuration Parameters dialog box, in **HDL Code Generation > Global Settings**, **Reset type** is set to **Synchronous**.
- To improve speed, Delay blocks, which map to registers in hardware, are at the inputs and outputs of the multipliers and adders.
- To support the output data of a full-precision complex multiplier, the output data word length is manually specified to be $(operand_word_length * 2) + 1$.

For example, in the template, the operand word length is 18, and the output word length is 37.

Copyright 2014-2016 The MathWorks, Inc.

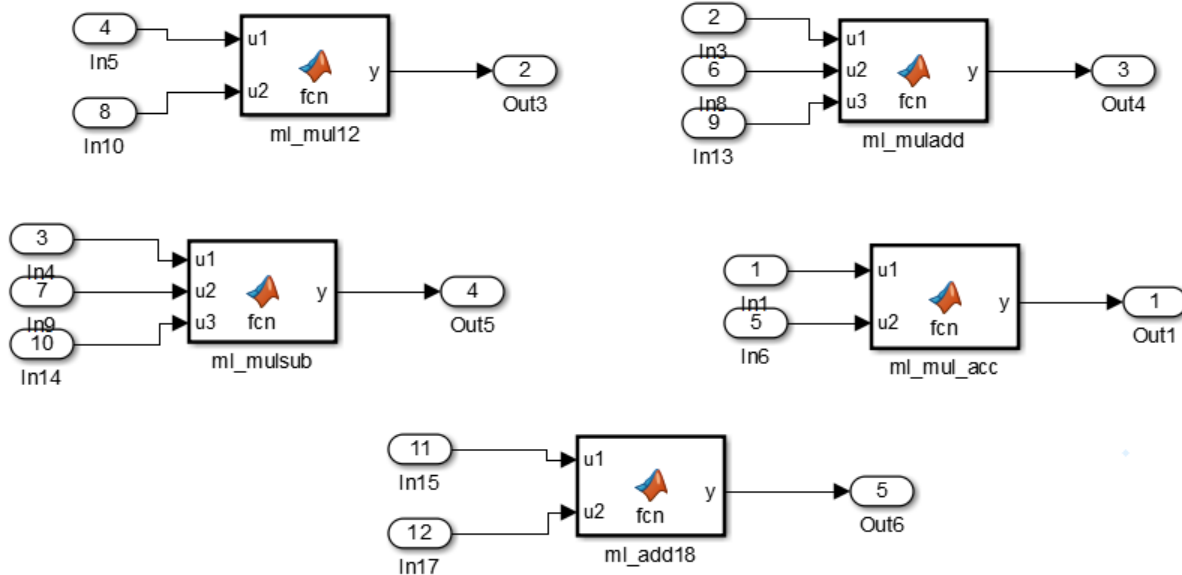

MATLAB Arithmetic

The MATLAB Arithmetic template contains MATLAB arithmetic operations that infer DSP48s in hardware.

Copyright 2014-2016 The MathWorks, Inc.

untitled ▶ EML_DSP48_Patterns

For example, the `ml_mul_acc` MATLAB Function block shows how to write a multiply-accumulate operation in MATLAB. `hdlfimath` on page 34-23 applies fixed-point math settings for HDL code generation.

```

function y = fcn(u1, u2)

% design of a 6x6 multiplier
% same reset on inputs and outputs
% followed by an adder

nt = numerictype(0,6,0);
nt2 = numerictype(0,12,0);
fm = hdlfimath;

persistent u1_reg u2_reg mul_reg add_reg;
if isempty(u1_reg)
    u1_reg = fi(0, nt, fm);
    u2_reg = fi(0, nt, fm);
    mul_reg = fi(0, nt2, fm);
    add_reg = fi(0, nt2, fm);
end

mul = mul_reg;
mul_reg = u1_reg * u2_reg;
add = add_reg;
add_reg(:) = mul+add;
u1_reg = u1;
u2_reg = u2;

y = add;

```

ROM

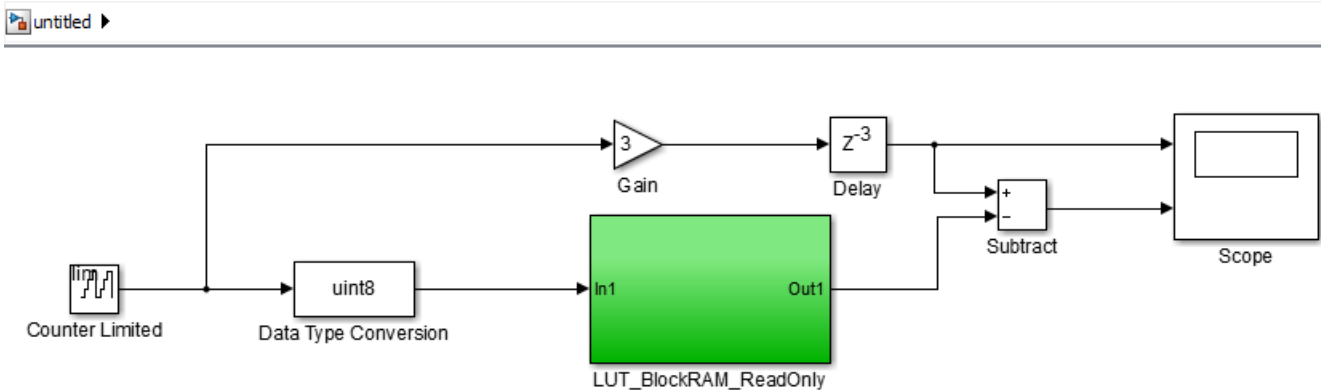

The ROM template is a design pattern that maps to a ROM in hardware.

The template applies the following best practices:

- At the output of the lookup table, there is a Delay block with `ResetType = none`.
- The lookup table is structured such that the spacing between breakpoints is a power of two.

Using table dimensions that are a power of two enables HDL Coder to generate shift operations instead of division operations. If necessary, pad the table with zeros.

- The number of lookup table entries is a power of two. For some synthesis tools, a lookup table that has a power-of-two number of entries maps better to ROM. If necessary, pad the table with zeros.

untitled ▶ LUT_BlockRAM_ReadOnly ▶ HDL ROM

```
x=(0:99);
Scale_by_3_LUT=3*x;
pad=2^nextpow2(length(Scale_by_3_LUT))-length(Scale_by_3_LUT);
Scale_by_3_LUT_pad=[Scale_by_3_LUT,zeros(pad,1)];
```

Register

The Register template shows how to model hardware registers:

- In Simulink, using the Delay block.
- In MATLAB, using persistent variables.

This design pattern also shows how to use `cast` to propagate data types automatically.

untitled ▶

The MATLAB code in the MATLAB Function block uses a persistent variable to model the register.

```
function y = fcn(u)
% Unit delay implementation that maps to a register in hardware

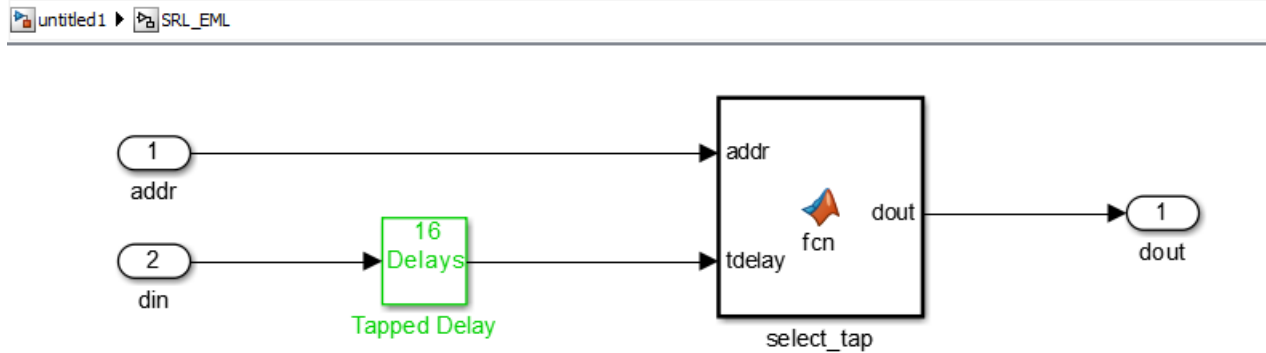

persistent u_d;
if isempty(u_d)
    % defines initial value driven by unit delay at time step 0
    u_d = cast(0, 'like', u);
end

% return delayed input from last sample time hit
y = u_d;

% store the current input
u_d = u;
```

SRL

The SRL template shows how to implement a shift register that maps to an SRL16 in hardware. You can use a similar pattern to map to an SRL32.

To map to SRL16/32:

- Set ResetType = none for the tapped delay
- Use ML fcn block to create mux logic
- Flatten hierarchy for the subsystem to inline the ML code
- Do not use "include current input in output vector" option for the tapped delay

In the shift register subsystem, the Tapped Delay implements the shift operation, and the MATLAB Function, select_tap, implements the output mux.

In select_tap, the zero-based address, addr increments by 1 because MATLAB indices are one-based.

```
function dout = fcn(addr, tdelay)
%#codegen
```

```
addr1 = fi(addr+1,0,5,0);
dout = tdelay(addr1);
```

In the generated code, HDL Coder automatically omits the increment because Verilog and VHDL are zero-based.

The template also applies the following best practices for mapping to an SRL16 in hardware:

- For the Tapped Delay block:
 - In the Block Parameters dialog box, **Include current input in output vector** is not enabled.
 - In the HDL Block Properties dialog box, **ResetType** is set to none.
- For the Subsystem block, in the HDL Block Properties dialog box, **FlattenHierarchy** is set to on.

Simulink Hardware Patterns

The Simulink Hardware Patterns template contains design patterns for common hardware operations:

- Serial-to-parallel shift register
- Detect rising edge
- Detect falling edge
- SR latch
- RS latch

untitled2 ▶

untitled ▶ Subsystem ▶

For example, the design patterns for rising edge detection and falling edge detection:

untitled ▶ Subsystem ▶ detect_rising_edge

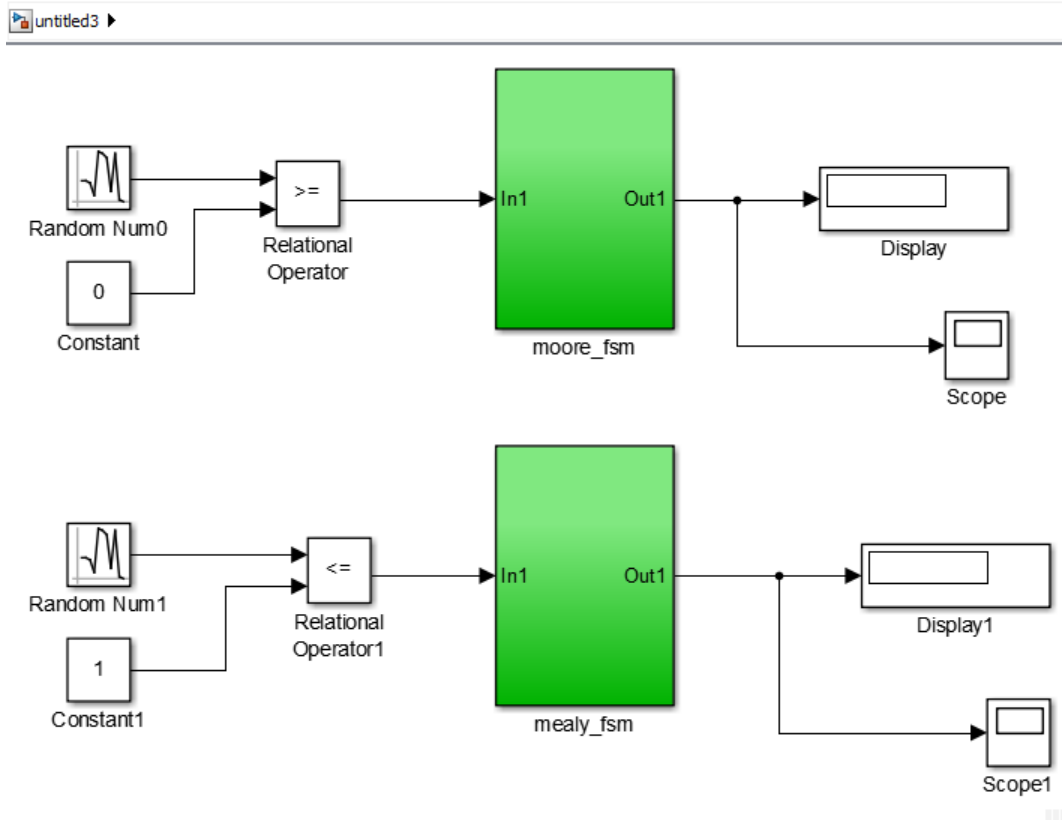

untitled ▶ Subsystem ▶ detect_falling_edge

State Machine in MATLAB

The State Machine in MATLAB template shows how to implement Mealy and Moore state machines using the MATLAB Function block.

To learn more about best practices for modeling state machines, see “Model a State Machine for HDL and SystemC Code Generation” on page 3-4.

Generate DUT Ports for Tunable Parameters

In this section...

“Prerequisites” on page 14-18

“Create and Add Tunable Parameter That Maps to DUT Ports” on page 14-18

“Generated Code” on page 14-19

“Limitations” on page 14-19

“Use Tunable Parameter in Other Blocks” on page 14-19

Tunable parameters that you use to adjust your model behavior during simulation can map to top-level DUT ports in your generated HDL code. HDL Coder generates one DUT port per tunable parameter.

You can generate a DUT port for a tunable parameter by using it in one of these blocks:

- Gain
- Constant
- MATLAB Function
- MATLAB System
- Chart
- Truth Table
- State Transition Table

These blocks with the tunable parameter can be at any level of the DUT hierarchy, including within a model reference.

You cannot use HDL cosimulation with a DUT that uses tunable parameters in any of these blocks. If you use a tunable parameter in a block other than these blocks, code is generated inline and does not map to DUT ports. To use the value of a tunable parameter in a Chart or Truth Table block, see “Use Tunable Parameter in Other Blocks” on page 14-19.

You can define and store the tunable parameters in the base workspace or a Simulink data dictionary. However, a Simulink data dictionary provides more capabilities. For details, see “What Is a Data Dictionary?”.

Prerequisites

- The Simulink compiled data type for all instances of a tunable parameter must be the same.
- Simulink blocks that use tunable parameters with the same name must operate at the same data rate.

To learn more about Simulink compiled data types, see “Control Block Parameter Data Types”.

Create and Add Tunable Parameter That Maps to DUT Ports

To generate a DUT port for a tunable parameter:

- 1 Create a tunable parameter with `StorageClass` set to `ExportedGlobal`.

For example, to create a tunable parameter, *myParam*, and initialize it to 5, at the command line, enter:

```
myParam = Simulink.Parameter;
myParam.Value = 5;
myParam.CoderInfo.StorageClass = 'ExportedGlobal';
```

Alternatively, using the Model Explorer, create a tunable parameter and:

- In the **Storage Class** column of the **Contents** pane, click the **configure** link.
- In the **Dialog** pane, click **Configure in Coder App**. Set **Storage Class** to `ExportedGlobal`.

See “Create Data Objects from Built-In Data Class Package Simulink”.

2 In your Simulink design, use the tunable parameter as the:

- **Constant value** in a Constant block.
- **Gain** parameter in a Gain block.
- MATLAB function argument in a MATLAB Function block.

Generated Code

The following VHDL code is an example of code that HDL Coder generates for a Gain block with its **Gain** field set to a tunable parameter, *myParam*. You see that the code generator creates a DUT port and adds a comment to indicate that the port corresponds to a tunable parameter.

```
ENTITY s IS
  PORT( In1      : IN    std_logic_vector(15 DOWNTO 0); -- sfix16_En5
        myParam  : IN    std_logic_vector(15 DOWNTO 0); -- sfix16_En5 Tunable port
        Out1     : OUT   std_logic_vector(31 DOWNTO 0) -- sfix32_En10
      );
END s;

ARCHITECTURE rtl OF s IS

  -- Signals
  SIGNAL myParam_signed : signed(15 DOWNTO 0); -- sfix16_En5
  SIGNAL In1_signed     : signed(15 DOWNTO 0); -- sfix16_En5
  SIGNAL Gain_out1      : signed(31 DOWNTO 0); -- sfix32_En10

BEGIN
  myParam_signed <= signed(myParam);

  In1_signed <= signed(In1);

  Gain_out1 <= myParam_signed * In1_signed;

  Out1 <= std_logic_vector(Gain_out1);

END rtl;
```

Limitations

Make sure that the “Use trigger signal as clock” on page 21-41 check box is left cleared by default.

Use Tunable Parameter in Other Blocks

To use the value of a tunable parameter in a Chart or Truth Table block:

- 1 Create the tunable parameter and use it in a Constant block. on page 14-18
- 2 Add an input port to the block where you want to use the tunable parameter.
- 3 Connect the output of the Constant block to the new input port.

Generate Parameterized Code for Referenced Models

In this section...

“Parameterize Referenced Model for HDL Code Generation” on page 14-21

“Restrictions” on page 14-21

To generate parameterized code for referenced models, use model arguments. You can use model arguments in a masked or unmasked Model block.

HDL Coder generates a single VHDL entity or Verilog module for the referenced model, even if the DUT has multiple instances of the referenced model. In the generated code, each model argument is a VHDL generic or a Verilog parameter.

Parameterize Referenced Model for HDL Code Generation

- 1 In the referenced model, create one or more model arguments.

To learn how to create a model argument, see “Specify a Different Value for Each Instance of a Reusable Model”.

- 2 In the referenced model, use each model argument parameter in a Gain or Constant block.
- 3 In the DUT, for each model reference, in the **Model arguments** table, enter values for each model argument.

Alternatively, create a model mask for the referenced model. In the DUT, for each model reference, enter values for each model argument.

- 4 Generate code for the DUT.

Restrictions

Model argument values:

- Must be scalar.
- Cannot be complex.
- Cannot be enumerated data.

Generating HDL Code for Subsystems with Array of Buses

In this section...

“How HDL Coder Generates Code for Array of Buses” on page 14-22

“Array of Buses Limitations” on page 14-24

An array of buses is an array whose elements are buses. Each element in an array of buses must be nonvirtual and must have the same data type.

The array of buses represents structured data compactly. The array:

- Reduces the model complexity
- Reduces maintenance by organizing and routing signals in your Simulink model for vectorized algorithms

For more information, see “Group Nonvirtual Buses in Arrays of Buses”.

You can generate HDL code for virtual and nonvirtual blocks that Simulink supports with an array of buses. For more information, see “Bus-Capable Blocks”.

How HDL Coder Generates Code for Array of Buses

HDL Coder expands the array of buses in your Simulink model into the corresponding scalar signals in the generated code.

This Simulink model has an array of buses signal at the DUT interface.

The array of buses combines two nonvirtual bus elements, each having scalars a and b of types uint16 and int32 respectively.

The resulting HDL code expands the array of buses into scalars, and contains four scalar input and output ports.

In the generated code, the array of bus expansion results in four scalar signals at the input and output ports. For the first bus object, the input ports are In_1_a and In_1_b. For the second bus object, they are In_2_a and In_2_b. At the output, for the first bus object, they are Out_1_a and Out_1_b. For the second bus object, they are Out_2_a and Out_2_b.

```

ENTITY DUT IS
  PORT( In1_1_a : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        In1_1_b : IN    std_logic_vector(31 DOWNTO 0); -- int32
        In1_2_a : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        In1_2_b : IN    std_logic_vector(31 DOWNTO 0); -- int32
  );

```

```
    Out1_1_a : OUT  std_logic_vector(15 DOWNT0 0); -- uint16
    Out1_1_b : OUT  std_logic_vector(31 DOWNT0 0); -- int32
    Out1_2_a : OUT  std_logic_vector(15 DOWNT0 0); -- uint16
    Out1_2_b : OUT  std_logic_vector(31 DOWNT0 0)  -- int32
  );
END DUT;
```

HDL Coder generates code in accordance with the order in which you specify the bus elements and the array elements in your Simulink model. If you specify the VHDL target language for your Simulink model that contains a bus object with arrays, HDL Coder preserves the arrays in the generated code, and does not expand into scalars.

Array of Buses Limitations

- Do not use the array of buses inside other data types. You cannot use a bus signal that contains an array of buses.
- MATLAB System and MATLAB Function blocks that contain System objects are not supported with an array of buses.

Generate VHDL Code with Record Types for Bus Signals

In this section...

“Requirements and Considerations” on page 14-25

“Use Record Types for Bus in HDL Code Generation” on page 14-26

“Generate Record Types for Bus Signals at Subsystem Interface” on page 14-26

“Generate Record Types for Array of Bus” on page 14-28

“Limitations” on page 14-29

For a Simulink model that contains the bus signals at the subsystem interface, you can generate code with a VHDL construct record type for those bus signals. Use the record type to simplify your VHDL code. The record type is especially useful for simplifying interfaces and maintaining a large number of signals at the entity level.

To generate code with record types for bus signals, enable the **Generate Record types for Bus** parameter. This parameter is available in the Configuration Parameter dialog box, in the **HDL Code Generation > Global Settings > Coding Style > RTL Style** section.

HDL Coder generates record types for:

- Bus signals at design-under-test (DUT) interfaces
- Bus signals at different subsystem-level interfaces
- Bus signal at the model reference interfaces
- Bus signals at black box interfaces
- Bus signals at controlled subsystem interfaces
- Array of Bus
- Nested bus signals
- Bus signals that have different data types

Requirements and Considerations

- To generate code with record types, set the target language to VHDL. Specify the **Target language** option in the **HDL Code Generation** pane of the Configuration Parameter dialog box.
- When you create a bus in your model, the Bus object must be specified. You can create the Bus object by using the **Type Editor** tool. To open **Type Editor**, run this command in the MATLAB Command Window:

```
typeeditor
```

After you create a Bus object and specify its attributes, you can associate it with any block that needs to use the bus definition that the object provides. To associate a block with a bus, in the Block Parameters dialog box, set **Output data type** or **Data type** to Bus: <object name>, replacing <object name> with the Bus object name. For more information, see “Specify Bus Properties with Simulink.Bus Object Data Types”.

- When you use **Generate Record types for Bus** option to generate record for bus signal, you must turn off **Scalarize ports** option for your model. If **Scalarize ports** option is enabled, then HDL Coder does not generate record types for bus signal due to the scalarization of bus ports. For more information, see “Scalarize ports” on page 21-45.

- To generate record types for bus signal at model reference interface, enable **Generate VHDL code for model references into a single library** option. For more information, see “Generate VHDL code for model references into a single library” on page 21-31.

Use Record Types for Bus in HDL Code Generation

By default, the **Generate Record types for Bus** option is disabled. The generated code does not have record types. The bus signals are flattened at the interface and are defined as individual ports in an entity in the generated code.

If your model contains the bus signals at the DUT interface or different subsystem-level interface, you can generate the VHDL code with record types for those bus signals.

To generate record types for the bus signals in the HDL code of your DUT subsystem:

- 1 Create a Bus object by using the **Type Editor** tool.
- 2 Specify **Output data type** as the Bus object in the Bus Creator block. For more information, see “Create and Specify Simulink.Bus Objects”.
- 3 Specify **Target language** as VHDL.
- 4 Enable the generation of record types for bus. In the configuration parameter dialog box, go to the **HDL Code Generation > Global Settings > Coding Style > RTL Style** section, select **Generate Record types for Bus**.
- 5 Generate HDL code for the DUT subsystem. In the **HDL Code** tab, set **Code for** subsystem to the DUT subsystem, and then click the **Generate HDL Code** button.

You can also generate HDL code for your DUT with record types by setting the `GenerateRecordType` argument of the `makehdl` function to "on".

```
makehdl (<DUT>,GenerateRecordType="on");
```

Generate Record Types for Bus Signals at Subsystem Interface

This example shows how to generate VHDL code with record types for a model that has bus signals at the design under test (DUT) interface. The **Generate Record types for Bus** configuration option enables you to generate code with record types for the bus signals. Use the record type to simplify your VHDL code. The record type is especially useful for simplifying interfaces and maintaining a large number of signals at the entity level.

Open Model

The Simulink® model `BusSignalWithRecordTypes` has a bus signal at the DUT interface. The DUT subsystem consists of a Unit Delay block. The input and output of the DUT subsystem is a bus. This bus has two bus elements with the `double` datatype. The Bus Creator block uses bus object `BusRecordObj` for creating bus signals. To load the bus object `BusRecordObj`, run:

```
run('BusRecordInput.m')
```

Load and open the `BusSignalWithRecordTypes` model by running these commands:

```
load_system("BusSignalWithRecordTypes");
set_param("BusSignalWithRecordTypes", 'SimulationCommand', 'Update')
open_system("BusSignalWithRecordTypes");
```

The bus object "BusRecordObj" is loaded from PreLoadFcn model callback.

Copyright 2023 The MathWorks Inc.

Generate HDL code

You can generate the HDL code for a model by using HDL Coder™. To generate HDL code for DUT subsystem with record types by setting the GenerateRecordType argument of the makehdl to "on":

```
makehdl("BusSignalWithRecordTypes/DUT", GenerateRecordType="on")
```

Generated VHDL Code for DUT Subsystem

HDL Coder defines the record type for bus signals in the VHDL package file. HDL Coder uses this package file for the port declaration of the bus signals in an entity. This code snippet shows the VHDL code of a package file that specifies record types for two bus signal. The package file defines the record BusRecordObj_record, which consists of two bus elements with the double data type.

```
-----
LIBRARY IEEE;
IEEE.std_logic_1164.ALL;
USE IEEE.numeric_std.ALL;

PACKAGE DUT_pkg IS
    TYPE BusRecordObj_record IS RECORD
        signal1      : std_logic_vector(63 DOWNTO 0);
        signal2      : std_logic_vector(63 DOWNTO 0);
    END RECORD BusRecordObj_record;
END DUT_pkg;
```

These VHDL code of the DUT subsystem uses these record types for port and signals declaration of the bus signals. This code snippet shows VHDL code for a DUT subsystem which uses record types for the bus signals:

```
-----
LIBRARY IEEE;
IEEE.std_logic_1164.ALL;
USE IEEE.numeric_std.ALL;
USE work.Subsystem_pkg.ALL;

ENTITY DUT IS
    PORT( clk          : IN    std_logic;
          reset        : IN    std_logic;
          clk_enable   : IN    std_logic;
          In1          : IN    BusRecordObj_record; -- record {double,double}
    );
END DUT;
```

```

        ce_out          : OUT   std_logic;
        Out1            : OUT   BusRecordObj_record -- record {double,double}
    );
END DUT;

ARCHITECTURE rtl OF Subsystem IS

    -- Signals
    SIGNAL enb          : std_logic;
    SIGNAL In1_signal1  : std_logic_vector(63 DOWNTO 0); -- ufix64
    SIGNAL In1_signal2  : std_logic_vector(63 DOWNTO 0); -- ufix64
    SIGNAL signal1      : std_logic_vector(63 DOWNTO 0); -- ufix64
    SIGNAL signal2      : std_logic_vector(63 DOWNTO 0); -- ufix64
    SIGNAL Unit_Delay_out1 : BusRecordObj_record; -- record {double,double}

```

Generate Record Types for Array of Bus

This example shows model that has array of bus signal at the design under test (DUT) interface. Using **Generate Record types for Bus** configuration option, you can generate code with array of record types for the array of bus signals.

Open Model

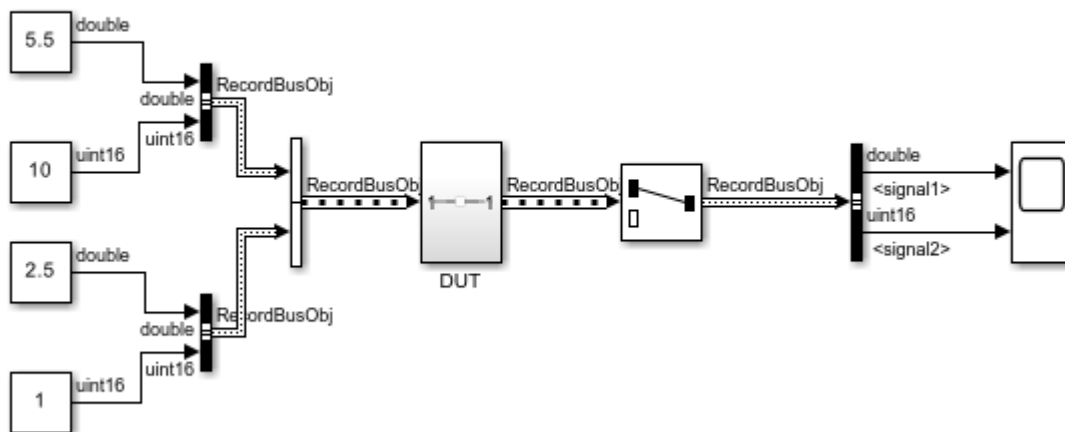

The model `ArrayOfBusSignalWithRecordTypes` has array of bus signal at the DUT interface. The Bus Creator block uses bus object `RecordBusObj` for creating bus signals. This bus object has two bus elements of datatypes, `double` and `uint16`. To load the bus object `RecordBusObj`, run:

```
run('RecordArrayOfBusInput.m')
```

Load and open the `BusSignalWithRecordTypes` model by running these commands:

```
load_system("ArrayOfBusSignalWithRecordTypes");
set_param("ArrayOfBusSignalWithRecordTypes", 'SimulationCommand', 'Update')
open_system("ArrayOfBusSignalWithRecordTypes");
```

The bus object "RecordBusObj" is loaded from PreLoadFcn model callback.

Copyright 2023 The MathWorks Inc.

The Vector Concatenate block generates an array of bus signal by concatenating two bus signals from the Bus Creator blocks.

Generated VHDL Code with Record Types for Array of Bus

Enable **Generate Record types for Bus** option and generate HDL code for DUT subsystem by using this command.

```
makehdl("ArrayOfBusSignalWithRecordTypes/DUT",GenerateRecordType="on")
```

HDL Coder generates an array of record for array of bus signals in the VHDL package file. This code snippet shows the VHDL code of a package file that specifies RecordBusObj record types and vector of record for the array of bus signal.

```
-----
LIBRARY IEEE;
USE IEEE.std_logic_1164.ALL;
USE IEEE.numeric_std.ALL;

PACKAGE DUT_pkg IS
TYPE RecordBusObjlogicType_record IS RECORD
    signal1          : std_logic_vector(63 DOWNTO 0);
    signal2          : std_logic_vector(15 DOWNTO 0);
END RECORD RecordBusObjlogicType_record;

TYPE vector_of_RecordBusObjlogicType_record IS ARRAY (NATURAL RANGE <>) OF RecordBusObjlogicType_record;
TYPE RecordBusObj_record IS RECORD
    signal1          : std_logic_vector(63 DOWNTO 0);
    signal2          : unsigned(15 DOWNTO 0);
END RECORD RecordBusObj_record;

TYPE vector_of_RecordBusObj_record IS ARRAY (NATURAL RANGE <>) OF RecordBusObj_record;
END DUT_pkg;
```

These VHDL code of the DUT subsystem uses these vector record for port declaration of the bus array. This code snippet shows VHDL code for a DUT subsystem which uses vector record for the bus array:

```
-----
LIBRARY IEEE;
USE IEEE.std_logic_1164.ALL;
USE IEEE.numeric_std.ALL;
USE work.DUT_pkg.ALL;

ENTITY DUT IS
    PORT(
        clk          : IN    std_logic;
        reset        : IN    std_logic;
        clk_enable   : IN    std_logic;
        In1          : IN    vector_of_RecordBusObjlogicType_record(
        ce_out       : OUT   std_logic;
        Out1        : OUT   vector_of_RecordBusObjlogicType_record(
        );
END DUT;
```

Limitations

- HDL test bench generation does not support the record type when you disable the **Use file I/O to read/write test bench data** option.

- HDL test bench generation does not support the record type when you enable the **SystemVerilog DPI test bench** option.
- You cannot generate a cosimulation model for record types.
- Target IP core generation does not support ports with the record type.
- When your model contains the bus elements of complex or enumerated types, HDL Coder generates code without record types for these buses.

Implement Control Signal-Based Mathematical Functions by Using HDL Coder

HDL Coder™ provides HDLMathLib blocks that have control signal-based fixed-point mathematical functions. The blocks have control signals that indicate whether the input and output data are valid. You can also simulate these block with latency.

HDLMathLib Library With Control Ports for Mathematical Functions

To see all the mathematical function blocks in the HDLMathLib library, open the library by using this command.

```
open_system('HDLMathLib')
```

Copyright 2020-2022 The MathWorks, Inc.

HDLMathLib include these blocks:

- Sqrt
- rSqrt
- Atan2
- Sin
- Cos

- SinCos
- Cos+jSin
- Reciprocal
- Divide

These blocks are a masked subsystem that contains a MATLAB Function block, LumpLatency. This MATLAB Function block is used to compute the latency. To see the latency computation for a block, view inside the masked subsystem and open LumpLatency block.

Implement Sqrt Block With Control Signals

This example shows how to implement the control-signal based Square root block and use it to generate HDL code.

Open and Run the Simulink Model

Specify the input data as a linear sweep. You can change these values according to your requirements.

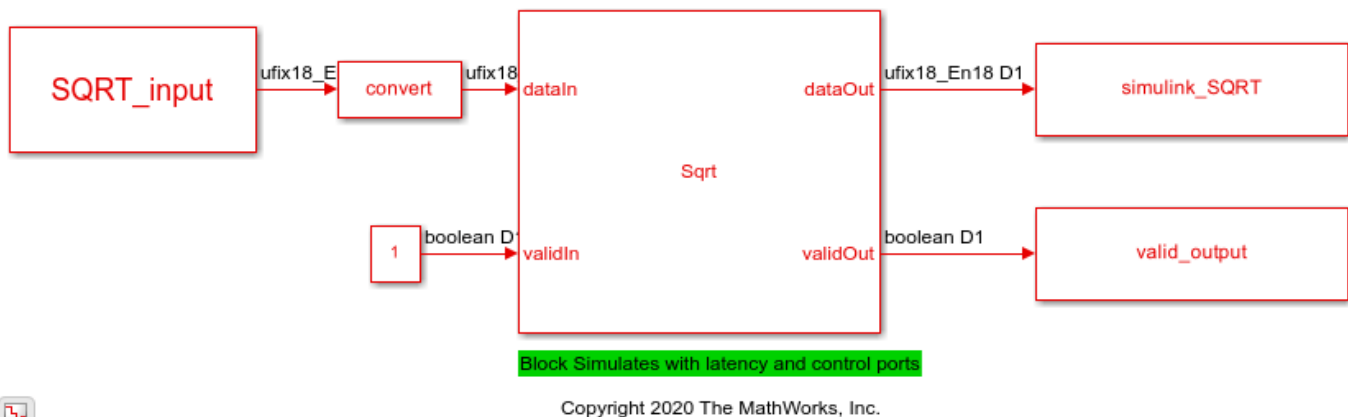

```
SQRT_input = fi(1/2^17:1/2^17:1,0,18,17)';
```

Specify the word length for fixed-point datatypes and the latency for the model.

```
WL = 18; latency = 20;
```

Open the `hdlcoder_sqrt_bitset_control` model and specify a stop time sufficient to process all the input combinations.

```
stoptime = length(SQRT_input)-1+latency;
open_system('hdlcoder_sqrt_bitset_control')
sim('hdlcoder_sqrt_bitset_control')
```

This figure shows the simulation waveform for the model. You can see that `dataOut` output is valid when `validOut` is 1.

Validate Simulink Output by Using Reference Output

To validate the output of the Simulink model, compare this output to a reference values. To obtain the reference values, use the `sqrt` function. Compute the reference output by using the `sqrt` function.

```
ref_SQRT = sqrt(double(SQRT_input));
```

Use logical indexing to extract valid output.

```
implementation_SQRT = simulink_SQRT(valid_output);
```

Plot the comparison results by using the `comparison_plot_sqrt` function. The maximum error value is significantly smaller than the output of the model.

```
comparison_plot_sqrt(ref_SQRT,implementation_SQRT,1,'SQRT linear input');
```

```
Maximum Error SQRT linear input 3.814697e-06
Maximum PctError SQRT linear input 3.803159e-02
```

Generate HDL Code for Square Root Implementation

Check the HDL settings saved of the model by using the `hdlsaveparams` function.

```
hdlsaveparams('hdlcoder_sqrt_bitset_control')
```

```
% Set Model 'hdlcoder_sqrt_bitset_control' HDL parameters
hdlset_param('hdlcoder_sqrt_bitset_control', 'Backannotation', 'on');
hdlset_param('hdlcoder_sqrt_bitset_control', 'HDLSubsystem', 'hdlcoder_sqrt_bitset_control/Sqrt');
hdlset_param('hdlcoder_sqrt_bitset_control', 'ResetType', 'Synchronous');
hdlset_param('hdlcoder_sqrt_bitset_control', 'ResourceReport', 'on');
hdlset_param('hdlcoder_sqrt_bitset_control', 'SynthesisTool', 'Xilinx Vivado');
hdlset_param('hdlcoder_sqrt_bitset_control', 'SynthesisToolChipFamily', 'Virtex7');
hdlset_param('hdlcoder_sqrt_bitset_control', 'SynthesisToolDeviceName', 'xc7v2000t');
hdlset_param('hdlcoder_sqrt_bitset_control', 'SynthesisToolPackageName', 'fhg1761');
hdlset_param('hdlcoder_sqrt_bitset_control', 'SynthesisToolSpeedValue', '-2');
```

```

hdlset_param('hdlcoder_sqrt_bitset_control', 'TargetDirectory', 'hdl_prj\hdlsrc');
hdlset_param('hdlcoder_sqrt_bitset_control', 'TargetFrequency', 500);
hdlset_param('hdlcoder_sqrt_bitset_control', 'Traceability', 'on');

% Set SubSystem HDL parameters
hdlset_param('hdlcoder_sqrt_bitset_control/Sqrt', 'FlattenHierarchy', 'on');

hdlset_param('hdlcoder_sqrt_bitset_control/Sqrt/LumpLatency', 'Architecture', 'MATLAB Datapath');
% Set SubSystem HDL parameters
hdlset_param('hdlcoder_sqrt_bitset_control/Sqrt/LumpLatency', 'FlattenHierarchy', 'on');

% Set Sqrt HDL parameters
hdlset_param('hdlcoder_sqrt_bitset_control/Sqrt/Sqrt', 'LatencyStrategy', 'Max');

hdlset_param('hdlcoder_sqrt_bitset_control/Sqrt/ValidLine', 'Architecture', 'MATLAB Datapath');
% Set SubSystem HDL parameters
hdlset_param('hdlcoder_sqrt_bitset_control/Sqrt/ValidLine', 'FlattenHierarchy', 'on');

```

To generate HDL code for the Sqrt block in the model, use the `makehdl` function.

```

makehdl('hdlcoder_sqrt_bitset_control/Sqrt')
close_system('hdlcoder_sqrt_bitset_control')
close all;

Implement Divide Block With Control Signals

This example shows how to implement the control-signal based Divide block and use it to generate HDL code.

Open and Run Simulink Model

Specify the input data as a linear sweep. You can change these values according to your requirements.

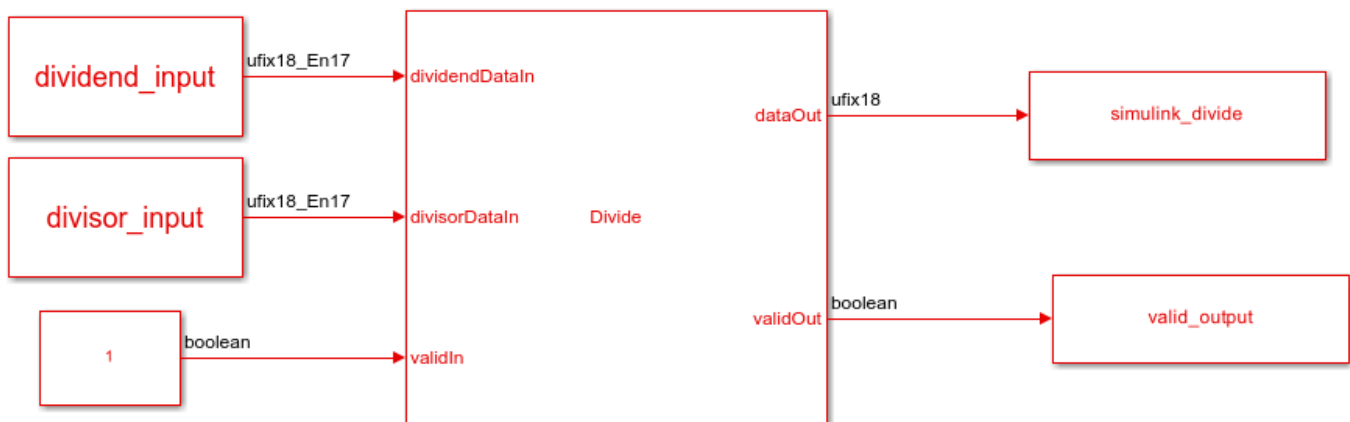

```
dividend_input = fi(1/2^17:1/2^17:1,0,18,17)';
divisor_input = fi(1/2^17:1/2^17:1,0,18,17)';
```

Specify the word length for fixed-point datatypes and the latency for the model.

```
WL_divide = 18; divide_latency = 22;
```

Open the `hdlcoder_divide_shiftadd_control` model and specify a stop time sufficient to process all the input combinations.

```
stoptime_divide = length(dividend_input)-1+divide_latency;
open_system('hdlcoder_divide_shiftadd_control')
sim('hdlcoder_divide_shiftadd_control')
```

Copyright 2020 The MathWorks, Inc.

The figure shows waveform when you simulate the above model. The `dataOut` output is valid when `validOut` is 1.

Validate Simulink Output By Using Reference Output

To validate the output of the Simulink model, compare this output with a reference value. Compute the reference output by using the `divide` function.

```
ref_divide = double(dividend_input)./double(divisor_input);
```

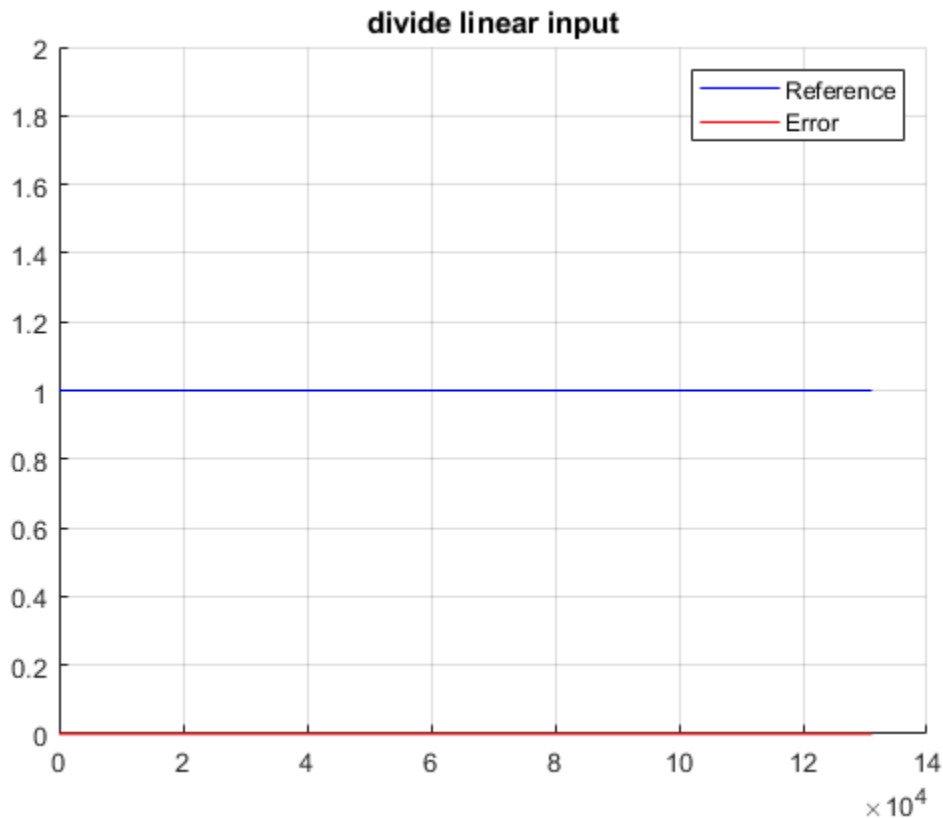

Use logical indexing to extract valid output.

```
implementation_divide = simulink_divide(valid_output);
```

Plot the comparison results by using the `comparison_plot_divide` function. The maximum error value is significantly smaller than the output of the model.

```
comparison_plot_divide(ref_divide,implementation_divide,11,'divide linear input');
```

```
Maximum Error divide linear input 0
Maximum PctError divide linear input 0
```

Generate HDL Code for Divide Implementation

Check the HDL settings of the model by using the `hdlsaveparams` function.

```
hdlsaveparams('hdlcoder_divide_shiftadd_control')
```

```
%% Set Model 'hdlcoder_divide_shiftadd_control' HDL parameters
hdlset_param('hdlcoder_divide_shiftadd_control', 'Backannotation', 'on');
hdlset_param('hdlcoder_divide_shiftadd_control', 'HDLSubsystem', 'hdlcoder_divide_shiftadd_control');
```

```

hdlset_param('hdlcoder_divide_shiftadd_control', 'ResetType', 'Synchronous');
hdlset_param('hdlcoder_divide_shiftadd_control', 'ResourceReport', 'on');
hdlset_param('hdlcoder_divide_shiftadd_control', 'SynthesisTool', 'Xilinx Vivado');

460	70	292	1087

Implement Sine and Cosine Block With Control Signals

This example shows how to implement the control-signal based SinCos block and use it generate HDL code.

Open and Run Simulink Model

Specify the input data as a linear sweep through values in the range $[-\pi, \pi]$. You can change these values according to your requirements.

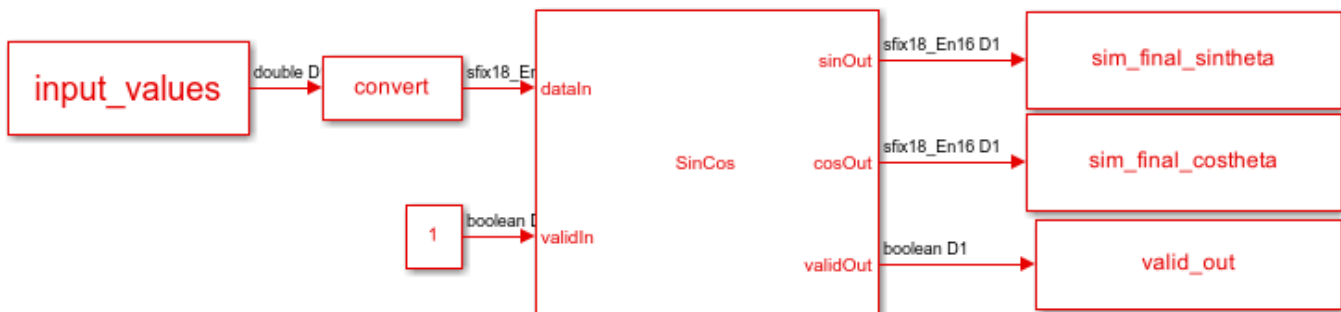

```
input_values = (-pi:.01/(2*pi):pi)';
```

Specify the word length for fixed-point datatypes and the latency for the model. The latency depends up on the number of iterations.

```
WL_SinCos = 18; latency_SinCos = 12;
```

Open the `hdlcoder_sincos_control` model and specify a stop time sufficient to process all the input combinations. The model has SinCos block that implements the SinCos using CORDIC algorithm. The other trigonometric function blocks, such as Sin, Cos, and Cos + jSin, use the same CORDIC approximation method.

```
stoptime_sincos = length(input_values)-1+latency_SinCos;
open_system('hdlcoder_sincos_control')
sim('hdlcoder_sincos_control')
```

Copyright 2020 The MathWorks, Inc.

This figure shows the waveform when you simulate the above model. The `dataOut` output is valid when `validOut` is 1.

Validate Simulink Output By Using Reference Output

To validate the output of the Simulink model, compare the this output with a reference value. To obtain the reference values, use the `sin` and `cos` function. Compute the reference value for Sine output by using the `sin` function.

```
comparison_plot_sincos(sin(input_values),sim_final_sintheta(valid_out),5,'sin');
```

Maximum Error sin 1.005291e-03

Compute the reference value for Cosine output by using the `cos` function. The maximum error value is significantly smaller than the output of the model.

```
comparison_plot_sincos(cos(input_values),sim_final_costheta(valid_out),6,'cos');
```

Maximum Error cos 1.036532e-03

Generate HDL Code for SinCos Implementation

Check the HDL settings of the model by using the `hdlsaveparams` function.

```
hdlsaveparams('hdlcoder_sincos_control')
```

```
%% Set Model 'hdlcoder_sincos_control' HDL parameters
hdlset_param('hdlcoder_sincos_control', 'HDLSubsystem', 'hdlcoder_sincos_control/SinCos');
hdlset_param('hdlcoder_sincos_control', 'ResetType', 'Synchronous');
hdlset_param('hdlcoder_sincos_control', 'SynthesisTool', 'Xilinx Vivado');
hdlset_param('hdlcoder_sincos_control', 'SynthesisToolChipFamily', 'Virtex7');
hdlset_param('hdlcoder_sincos_control', 'SynthesisToolDeviceName', 'xc7v2000t');
hdlset_param('hdlcoder_sincos_control', 'SynthesisToolPackageName', 'fhg1761');
hdlset_param('hdlcoder_sincos_control', 'SynthesisToolSpeedValue', '-2');
hdlset_param('hdlcoder_sincos_control', 'TargetDirectory', 'hdl_prj\hdlsrc');
hdlset_param('hdlcoder_sincos_control', 'TargetFrequency', 500);

hdlset_param('hdlcoder_sincos_control/SinCos/LumpLatency', 'Architecture', 'MATLAB Datapath');
% Set SubSystem HDL parameters
hdlset_param('hdlcoder_sincos_control/SinCos/LumpLatency', 'FlattenHierarchy', 'on');

hdlset_param('hdlcoder_sincos_control/SinCos/LumpLatency1', 'Architecture', 'MATLAB Datapath');
% Set SubSystem HDL parameters
hdlset_param('hdlcoder_sincos_control/SinCos/LumpLatency1', 'FlattenHierarchy', 'on');

hdlset_param('hdlcoder_sincos_control/SinCos/SinCos', 'Architecture', 'Cordic');

hdlset_param('hdlcoder_sincos_control/SinCos/ValidLine', 'Architecture', 'MATLAB Datapath');
```

```
% Set SubSystem HDL parameters
hdlset_param('hdlcoder_sincos_control/SinCos/ValidLine', 'FlattenHierarchy', 'on');
```

To generate HDL code for the SinCos block in the model, use the `makehdl` function.

```
makehdl('hdlcoder_sincos_control/SinCos')
close_system('hdlcoder_sincos_control')
close_all;

Implement Atan2 Block With Control Signals

This example shows how to implement the control-signal based Atan2 block and use it to generate HDL code.

Open and Run Simulink Model

Specify the input data as a linear sweep through values in the range $[-\pi, \pi]$. You can change these values according to your requirements.

```
input_values = (-pi:.01/(2*pi):pi)';
RADIUS = 10.^(-2.5:.25:0);
```

Specify the word length for fixed-point data types and the latency for the model. The latency depends on the number of iterations.

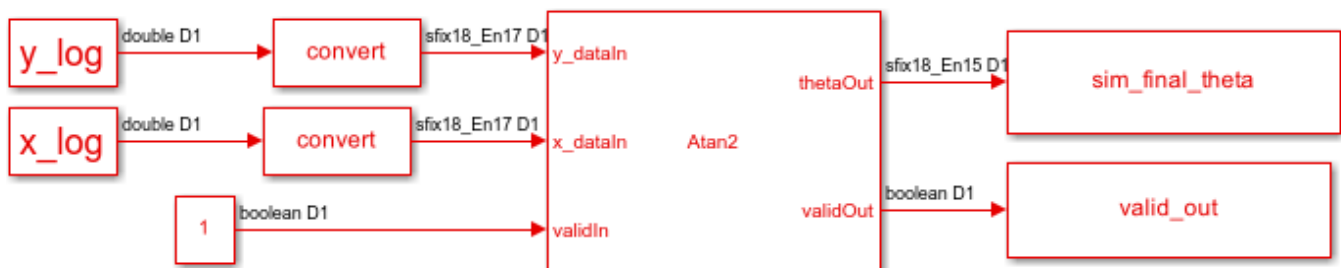

```
WL_atan2 = 18; latency_atan2 = 14;
```

Map the input data to x- and y-coordinate values.

```
x_log = zeros(length(input_values)*length(RADIUS),1);
y_log = zeros(length(input_values)*length(RADIUS),1);
for outerindex = 0:length(RADIUS)-1
    for index = 1:length(input_values)
        input = input_values(index); % access current value
        y = RADIUS(outerindex+1)*sin(input); % compute y
        x = RADIUS(outerindex+1)*cos(input); % compute x
        addr = outerindex*length(input_values)+index;
        y_log(addr) = y;
        x_log(addr) = x;
    end
end
```

Open the `hdlcoder_atan2_control` model and specify a stop time sufficient to process all the input combinations. The model has an Atan2 block that implements the four-quadrant arctangent operation using the CORDIC algorithm.

```
stoptime_atan2 = length(x_log)-1+latency_atan2;
close all
open_system('hdlcoder_atan2_control')
sim('hdlcoder_atan2_control')
```

Using ForEach Subsystems in HDL Coder

This example shows how you can use a For Each Subsystem to implement a streaming square root algorithm by cascading identical CORDIC iterations. You can then generate code for the algorithm by using HDL Coder™.

Using CORDIC Algorithm for Hardware Functions

CORDIC is an iterative algorithm that can be used to approximate fixed-point mathematics such as trigonometric functions, square root, and divide. The iterative core is composed of simple shift and add operations, allowing the algorithm to be implemented efficiently on FPGA or ASIC hardware. For low data rate applications, a single core can be reused to perform all iterations and achieve a very small area footprint. For applications requiring a new data sample to be processed at each clock cycle, a separate core can be used to calculate each iteration in a cascaded chain, as shown in the following diagram.

While it is straightforward to manually cascade the cores in Simulink®, the ability to automatically adjust the number of cores based on a parameter value would be highly desirable. You can do exactly that using a For Each Subsystem.

Cascade CORDIC Iterations Using For Each Subsystem

In this model, the iterative core is placed into a For Each Subsystem to be repeated N times, where N is the number of iterations defined in the upper-level block mask. The N core outputs form a vector at the For Each Subsystem output, where they are pipelined, and then fed back into the For Each Subsystem inputs. Outputs from core $(1:N-1)$ are connected to inputs of core $(2:N)$, exactly the same as in the manually cascaded model.

A valid signal path is included to handle intermittent input data, and tested by inserting random gaps between valid data samples.

```
open_system('hdlcoder_foreach_cordic')
open_system('hdlcoder_foreach_cordic/For Each Cordic Sqrt','force')
```

Copyrights 2019-2022 The MathWorks, Inc.

Compare Output to CORDIC Square Root Reference

Using a 14-bit signed input in the range of $[0.5, 2)$, the output of the Simulink model matches the `cordicsqrt` reference function exactly. Input range outside of $[0.5, 2)$ is not expected to work because the example lacks a normalizer stage.

In addition, the final gain adjustment in the model uses an 18-bit gain parameter for optimal FPGA DSP mapping; while the `cordicsqrt` function matches the gain parameter word length to that of the gain input. This results in slight differences between the Simulink model output and the `cordicsqrt` function when other input data types are used.

```
slout = sim('hdlcoder_foreach_cordic');
data_out = slout.logout.getElement('data out').Values.Data;
valid_out = slout.logout.getElement('valid out').Values.Data;
data_out = data_out(valid_out);

ref_cordic = double(cordicsqrt(v_fix, niter));
data_in = double(v_fix);
data_out = double(data_out);

figure;
subplot(211);
plot(data_in, data_out, 'r.', data_in, ref_cordic, 'b-');
legend('ForEach', 'MATLAB CORDICSQRT', 'Location', 'SouthEast');
title('ForEach Model and MATLAB CORDICSQRT Reference Results');
subplot(212);
absErr = abs(ref_cordic - data_out);
plot(data_in, absErr);
title('Absolute Differences (vs. MATLAB CORDICSQRT Reference)');
```

Additional Modeling Guidelines

Observe the following guidelines when cascading blocks in your algorithm using For Each Subsystem:

- Since For Each Subsystem is atomic, the connection between output of block X and input of block X+1 creates an artificial algebraic loop. To break this loop, place pipeline registers between cascading blocks outside of the For Each Subsystem, as demonstrated in this example.
- A mux block is used to concatenate external input and outputs of block (1:N-1) to form the inputs of the For Each Subsystem. This requires the cascading blocks to use the same input and output data types.

Generate HDL Code for Blocks Inside For Each Subsystem

This example shows how to use blocks inside a For Each Subsystem in your Simulink® model, and then generate HDL code.

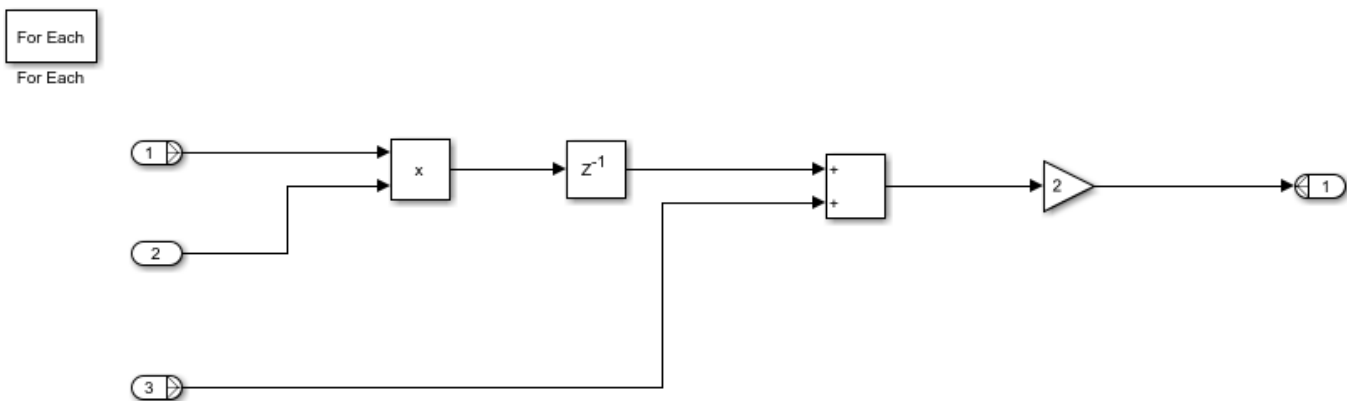

Why Use a For Each Subsystem?

To repeatedly perform the same algorithm on individual elements or subarrays of the input signals, use the For Each Subsystem block. The set of blocks within the Subsystem replicate the algorithm that is applied to individual elements or equally divided subarrays of the input signals. Using the For Each Subsystem block, you do not have to create and connect replicas of a Subsystem block to model the same algorithm. The For Each Subsystem:

- Supports vector or 2-D matrix processing, which reduces the simulation time of your model. You can process individual elements or subarrays of an input signal simultaneously.
- Improves code readability by using a for-generate loop in the generated HDL code. The for-generate loop reduces the number of lines of code, which can otherwise result in hundreds of lines of code for large vector signals.
- Supports HDL code generation for all data types, Simulink blocks, and predefined and user-defined system objects.
- Supports optimizations on and inside the block, such as resource sharing and pipelining. The parallel processing capability of the For Each Subsystem block combined with the optimizations that you specify produces high performance on the target FPGA device.

Modeling With the For Each Subsystem

Open the `foreach_subsystem_example1` model. You see this simple algorithm modeled inside a For Each Subsystem block.

When you simulate the model, you see that the input signals In1 and In3 are partitioned into subarrays. To see this partitioning, double-click the For Each block. The block parameters **Partition Dimension** and **Partition Width** specify the dimension through which the input signal is partitioned and the width of each partition slice respectively. Based on the input signal sizes and the partitioning that you specify, the For Each Subsystem determines the number of iterations that it requires to compute the algorithm.

In this example, the input signals In1 and In3 of size 8 are partitioned into four subarrays, each of size 2. The input signal In2 of size 2 is not partitioned. To compute the algorithm, the For Each

Subsystem requires four iterations, with each iteration repeating the algorithm on each of the four subarrays of In1 and In3.

The For Each Subsystem simplifies modeling of vectorized algorithms. This figure shows how you can model the same algorithm by creating multiple subsystem instances. This model can become graphically complex and difficult to maintain.

Using Matrix Input Signals

The For Each Subsystem supports 2-D matrix input for HDL code generation. For example, the `foreach_subsystem_example2` model shows a simple multi-channel filter operation. HDL code generation is not supported for matrices at the input and output ports of the HDL DUT, so the model separates the channels at the DUT subsystem boundary.

The For Each subsystem averages the samples on each channel. The generated HDL code will contain three copies of the logic inside the For Each Subsystem, and each operates on a 4x1 vector.

Using Complex Data Signals

The block does not support complex data types as inputs for HDL code generation. To input a complex signal, you can convert this signal to an array of signals, and then input to the block.

To perform the same algorithm on both real and imaginary parts of the signal:

- 1 Separate the signal into real and imaginary parts by using a Complex to Real-Imag block.
- 2 Create a vector signal that consists of the real and imaginary parts by using a Mux block.

You can then input this vector to the For Each Subsystem block and replicate the same computation on both the real and imaginary parts. At the output of the For Each Subsystem, you can convert the vector output back to a complex signal. Use a Demux block to separate the real and imaginary scalar parts, and then input the scalars to the Real-Imag to Complex block.

Generate HDL Code

To generate HDL code, in the `foreach_subsystem_example1` model, right-click the `Subsystem_Foreach` block and select **HDL Code > Generate HDL for Subsystem**.

To see the generated HDL code for the `Subsystem_Foreach` block, in the MATLAB® Command Window, click the `Subsystem_Foreach.vhd` file. In the VHDL® code snippet, you see this for-generate loop in the HDL code. This loop creates four subsystem instances, with each instance performing the algorithm on size 2 subarrays of inputs `In1` and `In3`.

```

BEGIN
  -- <S2>/For Each Subsystem
  GEN_LABEL: FOR k IN 0 TO 3 GENERATE
    u_For_Each_Subsystem : For_Each_Subsystem
      PORT MAP( clk => clk,
               reset => reset,
               enb => clk_enable,
               In1 => In1(2*k TO 2*(k+1) - 1), -- uint16 [2]
               In2 => In2, -- uint16 [2]
               In3 => In3(2*k TO 2*(k+1) - 1), -- uint16 [2]
               Out1 => For_Each_Subsystem_out1(2*k TO 2*(k+1) - 1)
            );
  END GENERATE;

```

You can specify optimizations that change the contents of the subsystems that the For Each Subsystem instantiates. In such cases, the code generator does not use for-generate loops in the HDL code. The HDL code does not contain for-generate loops if you have:

- Bus or complex input signals.
- Resource sharing and streaming optimizations on the subsystem.
- Vector inputs that get partitioned into nonscalar signals in the Verilog® code. To obtain for-generate loops in the Verilog code, partition the vector signal to scalars.

Optimize the For Each Subsystem Algorithm

To optimize the algorithm contained within the For Each Subsystem, you can enable optimizations such as resource sharing and streaming on the DUT that contains the For Each Subsystem. For example, by using the resource sharing optimization, you can share multiple Subsystem instances that are created by the For Each Subsystem. This optimization reuses the algorithm modeled by the Subsystem across multiple instances and reduces the area usage on the target device.

Note: When you enable optimizations on the For Each Subsystem, the generated HDL code does not contain for-generate loops.

This example shows how to use the resource sharing optimization on the For Each Subsystem. To share resources, select the Subsystem block that contains the For Each Subsystem and then specify the **Sharing Factor**. In this example, right-click the Subsystem_Foreach block and select **HDL Code > HDL Block Properties**. Set the **Sharing Factor** to 4, because the For Each Subsystem generates four Subsystem instances. Then, generate HDL code for the Subsystem_Foreach block.

To see the effect of the resource sharing optimization, at the command-line, enter `gm_foreach_subsystem_example1` to open the generated model. In the generated model, you see that the optimization shared the four subsystem instances generated by the For Each Subsystem into one Subsystem For Each Subsystem_Instance1.

If you double-click the For Each Subsystem_Instance1 block, you see the algorithm computed for the size 2 subarrays of inputs In1 and In3.

To learn more about the resource sharing optimization, see “Resource Sharing” on page 28-45.

For Each Subsystem

Field-Oriented Control of a Permanent Magnet Synchronous Machine

In this example you will review a Field-Oriented Control (FOC) algorithm for a Permanent Magnet Synchronous Machine (PMSM). You will test the control algorithm with closed loop system simulation then generate HDL code for the control algorithm. You will also see how tunable parameter data is specified and how corresponding HDL port entities are generated.

Introduction

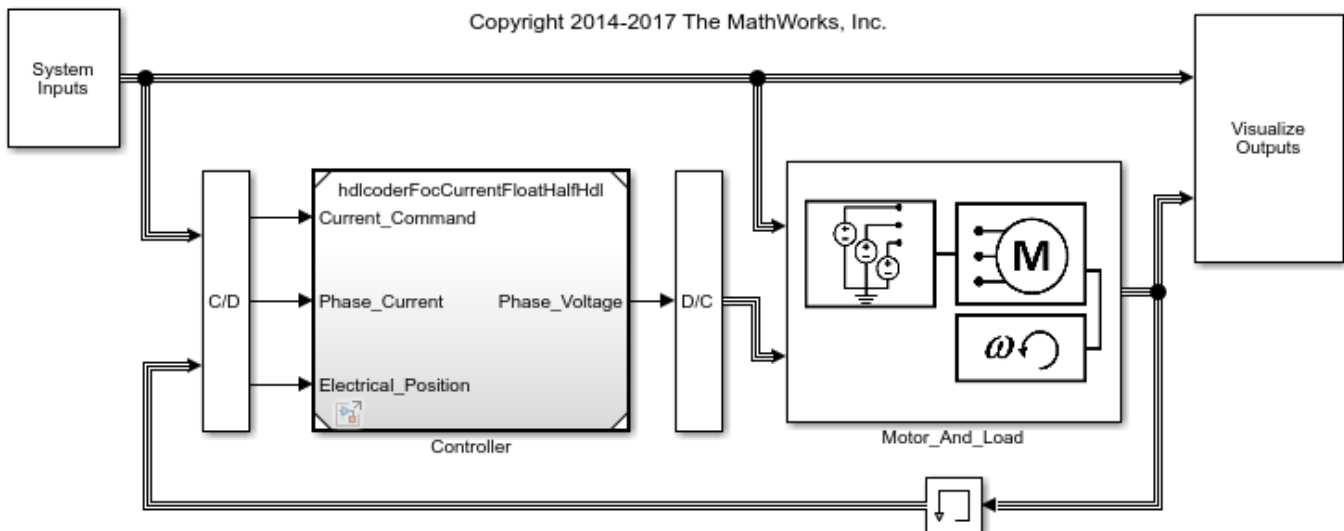

The example is partitioned such that you can generate code for the control algorithm as well as verify the behavior of the control algorithm using a simulation test bench. Simscape (TM) Electrical (TM) is required to run the system simulation test bench model `hdlcoderFocCurrentTestBench.slx` but is not required to generate code from the control algorithm model `hdlcoderFocCurrentFixptHdl.slx`.

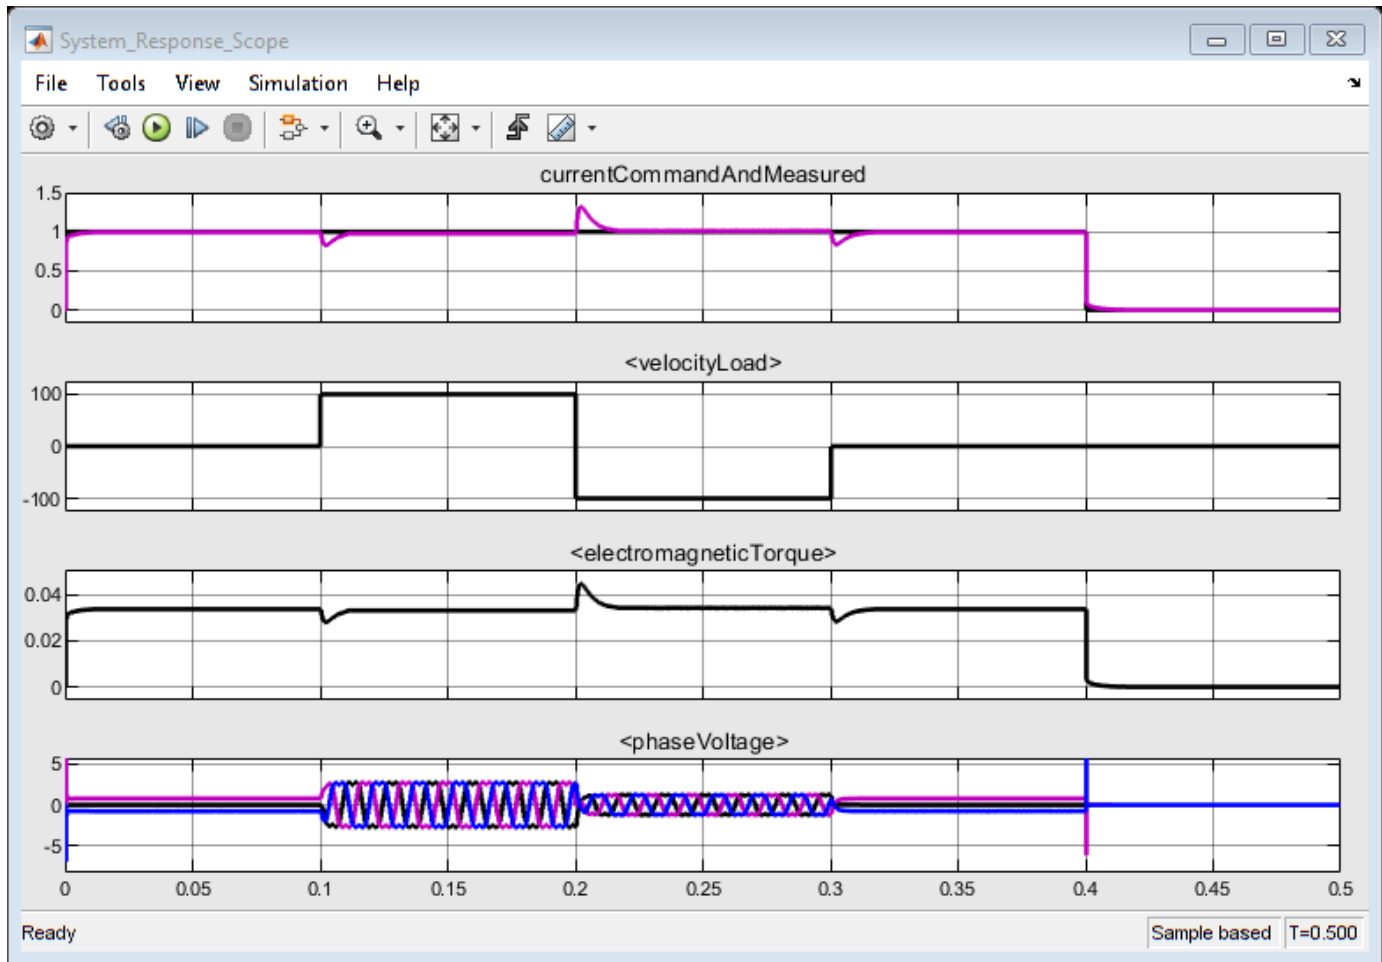

Verify Behavior through Simulation

In this example FOC is used to regulate phase current to control torque of an electric machine. You can simulate a test bench to explore the behavior of the system. During the simulation, the solver may generate warnings related to zero crossing when the velocity load changes abruptly. You can disable these warnings during the simulation.

```
hasSimPowerSystems = license ('test', 'Power_System_Blocks');
if hasSimPowerSystems
    open_system('hdlcoderFocCurrentTestBench')
    set_param('hdlcoderFocCurrentTestBench', 'IgnoredZcDiagnostic', 'none');
    sim('hdlcoderFocCurrentTestBench')
    set_param('hdlcoderFocCurrentTestBench', 'IgnoredZcDiagnostic', 'warn');
end
```

Field-Oriented Control Current Control Test Bench

The scope shows that a 1 Amp step current command is requested and the load velocity changes between locked rotor (zero), +100 rad/sec, and -100 rad/sec. The current command represents a quadrature current command to a non-salient PMSM. (The controller regulates the direct current to zero.) Note that for this motor and controller, the electromagnetic torque closely follows the measured quadrature current of the motor.

Explore Plant Specification

In the Motor_And_Load subsystem you will see a mathematical model of the components being controlled. An average model of the inverter is used to drive a constant parameter dq voltage equation model of a PMSM which is connected to a velocity load.

```
if hasSimPowerSystems
    open_system('hdlcoderFocCurrentTestBench/Motor_And_Load')
end
```

Motor And Load

Explore Control Algorithm Specification

The FOC current control algorithm is specified in a separate model. In the control algorithm, the electrical equations of the machine are projected from the three-phase stationary reference frame onto a two phase rotating reference frame using Clarke and Park transforms. This simplifies the control by removing time and position dependencies. Space Vector Modulation enables the controller to achieve greater voltage across the phases than if just the sinusoidal outputs of the inverse Clarke transform were used.

```
load_system('hdlcoderFocCurrentFixptHdl');
open_system('hdlcoderFocCurrentFixptHdl/FOC_Current_Control')
```

Explore Data Specification

Both the controller and the plant (i.e. motor and load) reference data from the MATLAB workspace. A data definition file creates this data and is automatically run within the PreLoadFcn callback of the system test bench model.

```
%edit('hdlcoderFocCurrentFixptHdlData.m')
%
```

When you review this file, notice that the parameters paramCurrentControlP and paramCurrentControlI are specified as Simulink.Parameters whose storage class is set to

`ExportedGlobal`. This tells HDL Coder to generate entity ports for these parameters instead of constant values.

Generate HDL Code for Control Algorithm

Before generating HDL code, it is important to ensure that the model adheres to certain important settings for HDL code generation. Below are some of the main steps:

- Create a DUT subsystem: For HDL code generation it is always better to create a DUT (Design Under Test) subsystem from which HDL code is generated. This subsystem serves several purposes including being a place-holder for HDL optimization settings.
- Setup for HDL: In order to get ready for HDL code generation, certain solver settings and model settings must be in place. The `hdlsetup` command takes care of all these settings and should be run before HDL code-generation.
- Checking sample times: Applying HDL optimizations requires all block sample times to be inferred as discrete. The main block-type to be cautious of are constants, which derive an 'inf' sample time, by default. We can find these blocks and explicitly set their sample-times to -1 so they get the correct back-propagated sample times.

% You can generate and review the HDL code for the controller.

```
makehdl('hdlcoderFocCurrentFixptHdl/FOC_Current_Control');
```

Model and Debug Test Point Signals with HDL Coder

This example shows how you can mark signals as test points in your Simulink® model and, after HDL code generation, debug the signals at the top level using the generated model or a test bench.

Why Use Test Points?

Test points are signals that you can use to easily debug and observe the simulation results at various points in your Simulink model. You can observe signals designated as test points with a Floating Scope block in a model. In Simulink, you can designate any signal in a model as a test point.

After code generation, you can observe test point signals at the DUT output ports and further debug the generated code in downstream workflows. This capability makes debugging your design easier because the code generator can propagate test point signals deep within the subsystem hierarchy to the DUT output ports.

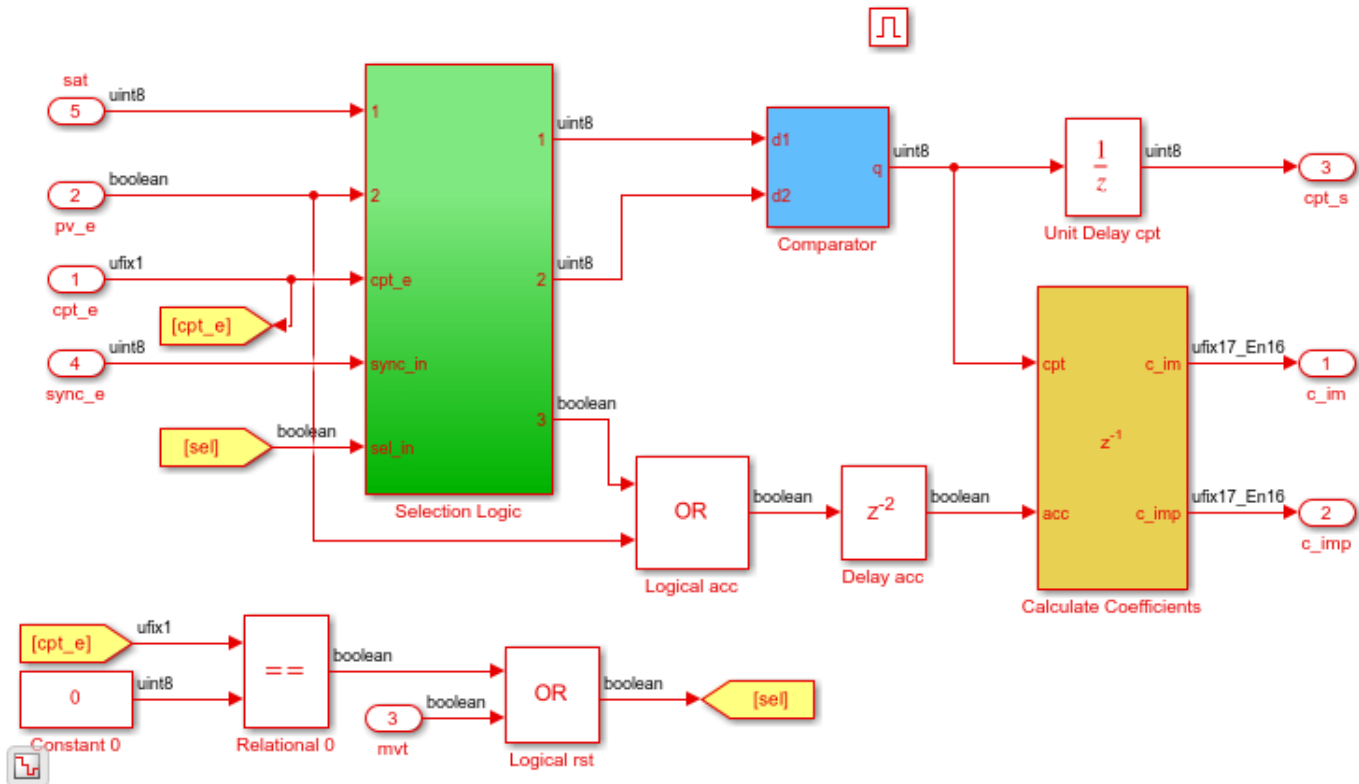

Create HDL-Compatible Model

Before you designate signals as test points and generate HDL code, make sure that the model you create is compatible for HDL code generation. See “Create HDL-Compatible Simulink Model”.

For this example, open the `hdlcoder_test_points` model that has been prepared for HDL code generation. The DUT is an Enabled Subsystem that calculates two coefficients based on inputs from a Selection Logic and a Comparator.

```

load_system('hdlcoder_test_points')
open_system('hdlcoder_test_points/DUT/MaJ Counter')
set_param('hdlcoder_test_points', 'SimulationCommand', 'update');
  
```

Designate Signals as Test Points

To debug internal signals in this model, mark them as test points in either of these ways:

- In the Simulink Editor, to open the Signal Properties dialog box, right-click the signal, and select **Properties**. Then, select **Test Point**.
- At the command line, get the handle to the output port of a block, and then set the port parameter `TestPoint` to on.

For example, enter these commands to designate the output signal from the Logical acc block that performs the OR operation as a test point.

```
portHandles = get_param('hdlcoder_test_points/DUT/MaJ Counter/Logical acc', 'portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle, 'TestPoint', 'on');
```

If a block has more than one output port, specify the outport handle that you want to designate as testpoint. For example, to designate the second output of a Demux block as a test point, enter this command:

```
set_param(outportHandle(2), 'TestPoint', 'on');
```

Simulink displays an indicator on each signal for which you enable the **Test point** setting. If you navigate the model, you see three additional test points. These test points are inside the Selection Logic subsystem, the Comparator Subsystem, and the Calculate Coefficients Subsystem blocks.

To learn more, see “Configure Signals as Test Points”.

Enable DUT Output Port Generation for Test Points

Before you generate HDL code, to debug signals that are designated as test points, enable HDL DUT port generation for the signals. When you generate code for the model, HDL Coder™ propagates these signals to the DUT as an additional output port.

To enable DUT output port generation for the `hdlcoder_simulink_test_points` model:

- In the Configuration Parameters dialog box, on the **HDL Code Generation > Global Settings > Ports** tab, select **Enable HDL DUT port generation for test points**.
- At the command line, use the `EnableTestpoints` property.

```
hdlset_param('hdlcoder_test_points', 'EnableTestpoints', 'on')
```

To learn more about this parameter, see “Enable HDL DUT port generation for test points” on page 21-43.

When you enable DUT output port generation for test points, you can disable delay balancing for the generated DUT output ports by using the Configuration Parameters dialog box and disabling **Balance delays for generated DUT output ports** or by using the command line and setting `BalanceDelaysForTestpoints` to `off`. To learn more about this parameter, see “Balance delays for generated DUT output ports” on page 21-44.

You can also treat a manually added output port as a test point and disable the HDL block property **BalanceDelays** on the DUT-level Output block.

After you enable DUT port generation, you can run either of these workflows:

- Generate HDL code. To deploy the code onto a target FPGA, use the **Generic ASIC/FPGA** workflow in the HDL Workflow Advisor.
- Map test point ports to target platform interfaces, and generate an HDL IP core by using the **IP Core Generation** or **Simulink Real-Time FPGA I/O** workflows that use Xilinx Vivado or Altera Quartus II as the synthesis tools.

HDL Code Generation and FPGA Targeting

If you want to see the mapping between test point ports in the HDL code and the test point signals in your model, enable generation of the code generation report. The report displays the test point ports with links to the corresponding test point signals in your Simulink model.

For example, to enable report generation for the `hdlcoder_simulink_test_points` model:

- In the Configuration Parameters dialog box, on the **HDL Code Generation** pane, select **Generate resource utilization report**.
- To specify this setting at the command line, use the `ResourceReport` property.

```
hdlset_param('hdlcoder_test_points', 'ResourceReport', 'on')
```

To learn more about report generation, see “Create and Use Code Generation Reports” on page 30-2.

To generate HDL code:

- Right-click the DUT Subsystem and select **HDL Code > Generate HDL for Subsystem**.

- At the command line, run `makehdl` on the DUT Subsystem.

To deploy the code onto a target platform, use the Generic ASIC/FPGA workflow. In the HDL Workflow Advisor, on the **Set Target Device and Synthesis Tool** task, for **Target workflow**, select Generic ASIC/FPGA, specify the **Synthesis tool**, and then run the workflow.

When generating code, HDL Coder opens the Code Generation report. The Code Interface Report section contains links to the test point ports in the Output Ports section.

Output ports

Port Name	Datatype	Bits
<code>ce_out</code>	boolean	1
c_imp	ufix17_En16	17
c_imp	ufix17_En16	17
cpt_s	uint8	8
tp_Sum_C_out1	ufix17_En16	17
tp_Relational_out1	boolean	1
tp_Sum_out1	uint8	8
tp_Logical_acc_out1	boolean	1
tp_Relational_0_out1	boolean	1

When you click the links in the test point ports, the code generator highlights the corresponding signals that you designated as test points in your Simulink model. Therefore, you can use the report to trace back from the test point port in the generated code to the test point signals in your Simulink model.

To see the test point ports in the generated HDL code, open the `DUT.v` file.

```
output [16:0] c_imp; // ufix17_En16
output [7:0] cpt_s; // uint8
output [16:0] tp_Sum_C_out1; // ufix17_En16 Testpoint port
output tp_Relational_out1; // Testpoint port
output [7:0] tp_Sum_out1; // uint8 Testpoint port
output tp_Logical_acc_out1; // Testpoint port
output tp_Relational_0_out1; // Testpoint port
```

You can see the test point ports at the top level module declaration. These ports have the prefix `tp_` and a comment to indicate that they correspond to test point ports. If you specify VHDL® as the target language, you can see the test point ports in the entity declaration.

IP Core Generation and SoC Targeting

To generate an HDL IP core, open the HDL Workflow Advisor. In the Advisor:

- 1 On the **Set Target Device and Synthesis Tool** task, for **Target workflow**, select IP Core Generation, and specify a **Target platform** that uses Xilinx Vivado or Altera Quartus

II as the **Synthesis tool**. If you use the Simulink Real-Time FPGA I/O workflow, specify a **Target platform** that uses Xilinx Vivado as the **Synthesis tool**

- 2 On the **Set Target Reference Design** task, you can specify the HDL Coder default reference designs, or a custom reference design that you want to integrate the HDL IP core into. If you do not specify unique names for test point signals, running this task can fail. To fix this error, in the **Result** subpane, select the link to generate unique names for test point signals. To verify that the task passes, rerun the task.
- 3 On the **Set Target Interface** task, you can enable HDL DUT port generation for testpoints by selecting the **Enable HDL DUT port generation for testpoints** checkbox and see the test point ports in the **Target platform interface table**. You can map the ports to AXI4, AXI4-Lite, or External Port interfaces. After you run this task, the code generator stores this testpoint interface mapping information on the DUT. To see this information, in the HDL Block Properties for the DUT Subsystem, on the **Target Specification** tab, look for the **TestPointMapping** block property. You can reload this information for the DUT across subsequent runs of the workflow.
- 4 On the **Generate RTL Code and IP Core** task, right-click and select **Run to Selected Task** to generate the IP core. The code generator opens an IP Core Generation report that displays the mapping of test point ports to interfaces.

Target platform interface table:

Port Name	Port Type	Data Type	Target Platform Interfaces	Bit Range / Address / FPGA Pin
cpt_e	Inport	ufix1	AXI4-Lite	x"100"
pv_e	Inport	boolean	AXI4-Lite	x"104"
mvt	Inport	boolean	AXI4-Lite	x"108"
sync_e	Inport	uint8	AXI4-Lite	x"110"
sat	Inport	uint8	DIP Switches [0:7]	[0:7]
Enable_In	Inport	boolean	AXI4-Lite	x"11C"
c_im	Outport	ufix17_En16	External Port	
c_imp	Outport	ufix17_En16	External Port	
cpt_s	Outport	uint8	AXI4-Lite	x"10C"
TestPoint_3	Test point	boolean	AXI4-Lite	x"114"
TestPoint	Test point	ufix17_En16	External Port	
TestPoint_1	Test point	boolean	AXI4-Lite	x"118"
TestPoint_2	Test point	uint8	LEDs General Purpose [0:7]	[0:7]

When you click the links in the test point ports, the code generator highlights the corresponding signals that you designated as test points in your Simulink model.

If you open the generated HDL source file, you see the test point signals connected to the IP core wrapper.

```

MaJCounte_ip_axi_lite u_MaJCounte_ip_axi_lite_inst (...
    ...
    .read_TestPoint_3(tp_TestPoint_3_sig), // ufix1
    .read_TestPoint_1(tp_TestPoint_1_sig), // ufix1
    ...
    ...
);

MaJCounte_ip_dut u_MaJCounte_ip_dut_inst (...
    ...
    .tp_TestPoint(tp_TestPoint_sig), // ufix17_En16
    .tp_TestPoint_1(tp_TestPoint_1_sig), // ufix1
    .tp_TestPoint_2(tp_TestPoint_2_sig), // ufix8
    .tp_TestPoint_3(tp_TestPoint_3_sig) // ufix1
);

```

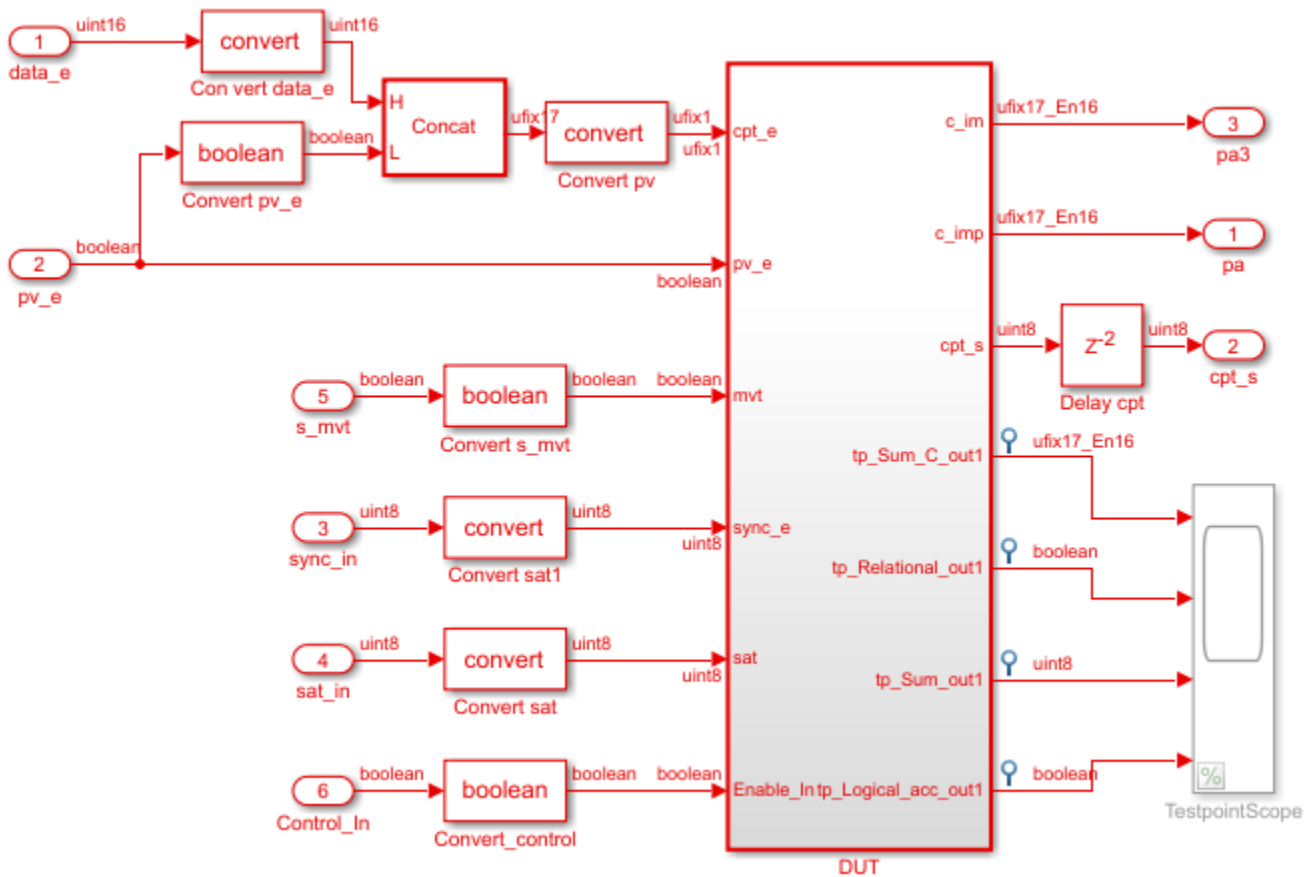

Run the workflow to generate the Software Interface model and integrate the IP core into the target reference design that you specified in the **Set Target Reference Design** task.

To learn more about the IP Core Generation workflow, see “Custom IP Core Generation” on page 46-16 and “Custom IP Core Report” on page 46-19.

Debug Test Point Signals

After you generate HDL code or generate an IP core, you can debug the test point signals.

If you generated HDL code for your model or ran the Generic ASIC/FPGA workflow, to debug the test point signals, generate a HDL test bench, or use the generated model. To open the generated model, at the command line, enter `gm_hdlcoder_test_points`.

In the generated model, you see the test points at the DUT output ports connected to a Scope block that is commented out. To observe the simulation results for these signals, uncomment the Scope block, and then run the simulation. If you navigate the generated model, you can see that the code generator creates an output port at the point where you designated the signal as a test point. HDL Coder then propagates these ports to the DUT as additional output ports.

If you run the IP Core Generation workflow to the **Generate Software Interface Model** task, the code generator opens the Software Interface model.

To observe the data on test point signals from the ARM® processor, uncomment the Scope block, and then run the Software Interface model.

Considerations

- Test point ports are considered similar to other output ports in the code generation process. Test point port generation works with all optimizations such as resource sharing, streaming, and distributed pipelining. To learn about various optimizations, see “Speed and Area Optimization”.
- If you generate a validation model, you see that the code generator does not compare the test point signals with the test point ports at the output. You can still observe the test point signals by uncommenting the Scope block and by running the simulation. To learn more about generated model and validation model, see “Generated Model and Validation Model” on page 28-10.
- If you generate a cosimulation model, you see the test point ports connected to a Terminator block. To observe the test points, remove the Terminator blocks, and connect the output ports to a Scope block, and then run cosimulation. You can also observe the waveforms in the HDL simulator that you run cosimulation with. To learn more about cosimulation, see “Generate a Cosimulation Model” on page 32-42.
- If you open the generated model, you see the Scope block commented out for performance considerations.
- You cannot specify the port ordering for the DUT test point ports. HDL Coder determines the port ordering when you generate code.
- **Target workflow** must be Generic ASIC/FPGA, IP Core Generation, or Simulink Real-Time FPGA I/O.
- If you use IP Core Generation or Simulink Real-Time FPGA I/O workflows, the **Synthesis tool** must be Xilinx Vivado or Altera Quartus II. Xilinx ISE is not supported.

- If you use IP Core Generation or Simulink Real-Time FPGA I/O workflows, you map the test point ports to AXI4, AXI4-Lite, or External Port interfaces. You cannot map the ports to AXI4-Stream or AXI4-Stream Video interfaces.

Allocate Sufficient Delays for Floating-Point Operations

In this section...

“Problem” on page 14-79

“Cause” on page 14-79

“Solution” on page 14-80

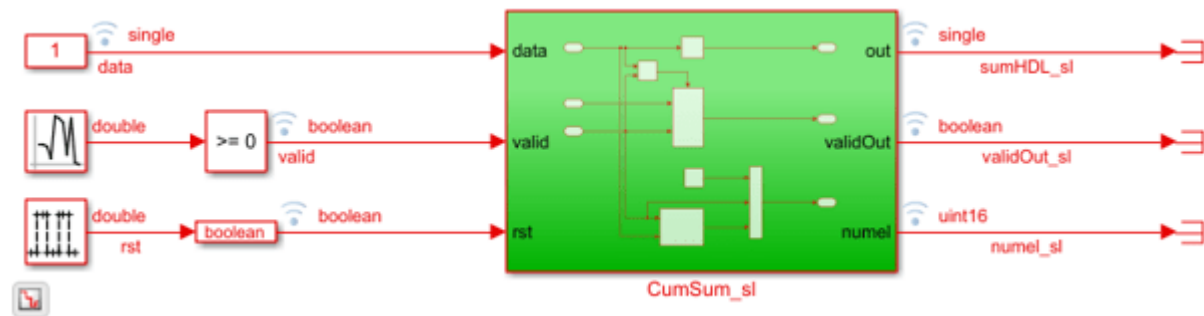

Problem

Sometimes, when generating code from your floating-point algorithm in Simulink, HDL Coder generates an error that it is unable to allocate sufficient number of delays.

Cause

This error message generally occurs when you have Simulink® blocks performing floating-point operations inside a feedback loop. These blocks have a latency. HDL Coder™ is unable to allocate delays to compensate for the latency, because the code generator needs to add delays and balance them to maintain numerical accuracy.

If you open this example model `RunningSum.slx`, you see a Simulink model that uses single data types.

To generate HDL code for the `CumSum_sl` Subsystem, right-click the subsystem and select **HDL Code > Generate HDL for Subsystem**. During code generation, HDL Coder generates an error:

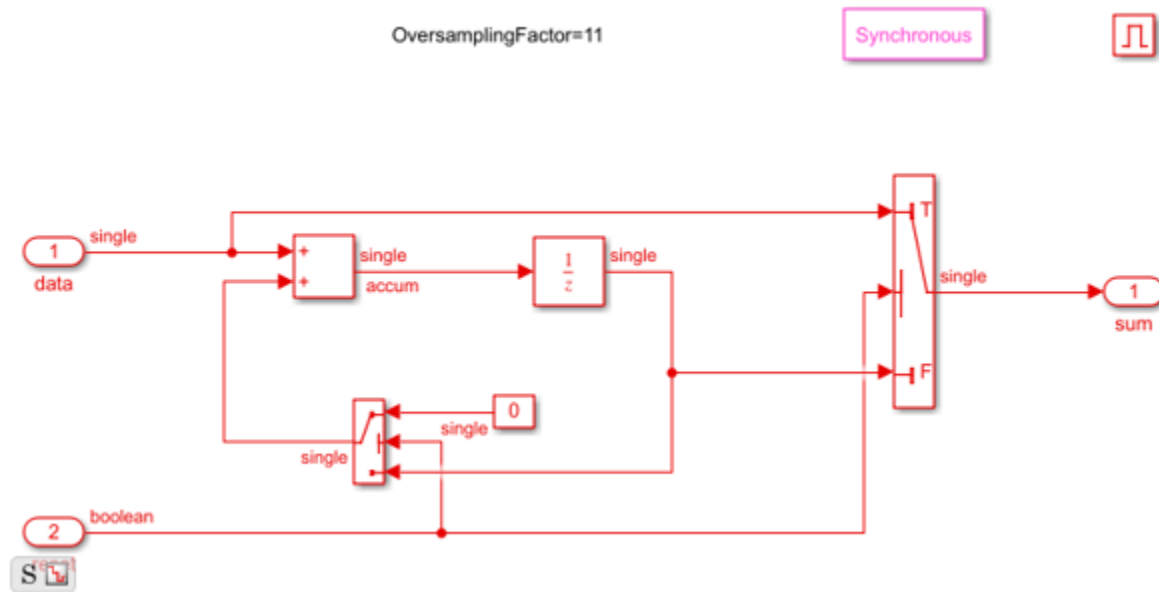

HDL Code Generation Check Report for 'RunningSum/CumSum_sl' open model
'RunningSum/CumSum_sl'
 Generated on 2021-12-21 11:08:29

HDL check for 'RunningSum' complete with 2 errors, 0 warnings, and 2 messages.

The following table describes blocks for which errors, warnings or messages were reported.

Simulink Blocks and resources	Level	Description
RunningSum/CumSum_sl/Subsystem/Add	Error	Unable to allocate delays to compensate for the 11 delays of the Native Floating Point operator in a feedback loop. Consider either setting the 'Latency Strategy' to 'Zero', or utilizing Clock-Rate Pipelining. If Clock-Rate Pipelining is already requested, please refer to 'highlightClockRatePipelining.m' for further diagnostics. More information
RunningSum	Error	Native floating-point code generation cannot complete for the following reason(s): 'Unable to allocate delays to compensate for the 11 delays of the Native Floating Point operator in a feedback loop. Consider either setting the 'Latency Strategy' to 'Zero', or utilizing Clock-Rate Pipelining. If Clock-Rate Pipelining is already requested, please refer to 'highlightClockRatePipelining.m' for further diagnostics. More information '.
RunningSum	Message	'AdaptivePipelining' is set to 'Off' for the model. 'AdaptivePipelining' can improve the achievable clock frequency and reduce the area usage on FPGA boards. To enable adaptive pipelining, please set the option to 'On'. When adaptive pipelining is enabled, it inserts pipeline registers to create patterns that efficiently map blocks to DSP units on the target FPGA device.
RunningSum	Message	'LUTMapToRAM' is set to 'On' for the model. This option is used to map lookup tables to a block RAM in hardware. To disable pipeline insertion for mapping lookup tables to RAM, please set the option to 'Off'.

By using the path to the block mentioned in the error message, navigate to the Add block in the model. This block is inside a feedback loop.

The Add block has a latency of 11. When generating code, HDL Coder cannot allocate 11 delays for the block, because it cannot add matching delays to other paths.

This model serves as an example to illustrate the various strategies to solve this problem.

Solution

Strategy 1: Global Oversampling

This modeling paradigm uses the clock-rate pipelining optimization to oversample your design to a clock-rate much faster than the DUT sample rate. To enable this optimization, specify a global

oversampling factor for your Simulink model. The floating-point delays then operate at the faster clock-rate and can be allocated successfully. For more information, see “Clock-Rate Pipelining” on page 28-149.

- 1 Specify an oversampling factor that is equal to or greater than the latency of the floating-point operators that are unable to allocate delays. For the RunningSum model, specify an oversampling factor at least equal to 12. To learn about the latency values of the floating-point operators, see “Simulink Blocks Supported by Using Native Floating Point” on page 14-142.

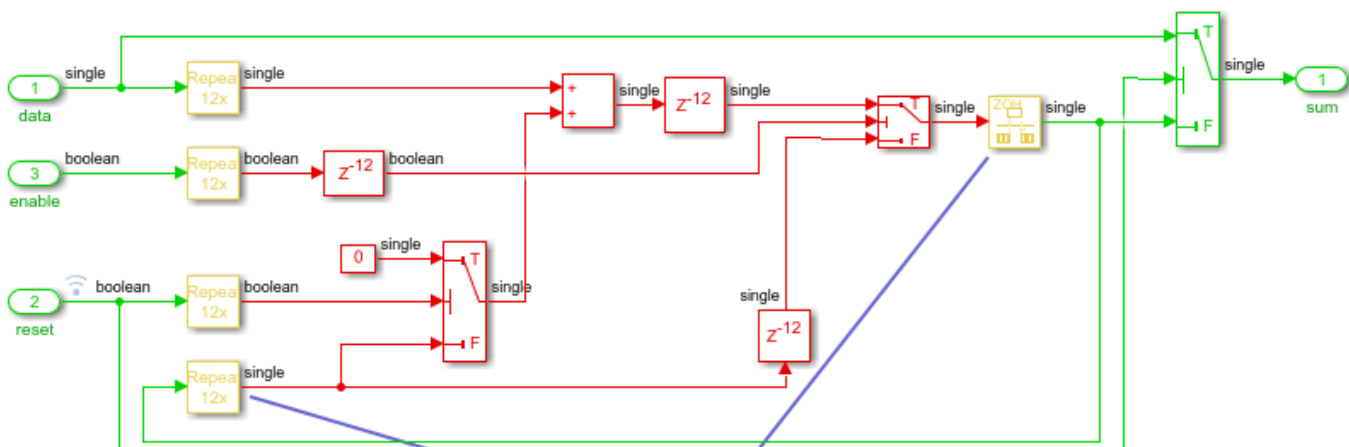

To specify the oversampling factor:

- a In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
 - b Click **Settings**. In the **HDL Code Generation > Global Settings** tab, set **Oversampling factor** to 12.
- 2 Enable hierarchy flattening on the DUT and make sure that subsystems inside the DUT inherit this setting. For the RunningSum model, select the CumSum_sl subsystem and click **HDL Block Properties** on the **HDL Code** tab, and then set **FlattenHierarchy** to on.

Strategy 2: Local Oversampling

To model your design at the data rate and selectively increase the sample rate of blocks for which HDL Coder™ is unable to allocate delays, use local oversampling. These blocks then operate at the faster clock rate and can accommodate the required number of delays.

If you open the RunningSum_OSmanual model and navigate to the Add block, it shows how you can increase the sample rate of the Add block and allocate delays.

use of repeat and zoh blocks to deal with floating-point latency in feedback loop instead of oversampling the whole design

- The blocks that are within the boundary of the Repeat and Zero Order Hold blocks operate at the clock rate that is 12 times faster than the sample rate of the model.
- The subsystem has a Delay block of length 12 at the output of the Add block. When generating code, the Add block absorbs this Delay block, which compensates for the latency of the operator. To balance delays, the subsystem contains Delay blocks of length 12 in other paths.

You can now generate HDL code for the CumSum_sl subsystem. To generate HDL code for the CumSum_sl Subsystem, right-click the subsystem and select **HDL Code > Generate HDL for Subsystem**.

Strategy 3: Delay Blocks

Use this modeling paradigm to model your entire design at the Simulink data rate. For blocks that are unable to accommodate the required number of delays, add a Delay block with a sufficient **Delay length** at the output of the blocks. Specify a **Delay length** that is equal to the latency of the floating-point operator. Make sure that you add matching delays in other paths.

For the RunningSum model, you can add a Delay block of length 12 at the output of the Add block. When generating code, the Add block absorbs this delay, because the block has a latency of 12.

For more information, see “Latency Considerations with Native Floating Point” on page 14-109.

Strategy 4: Use Custom Latency

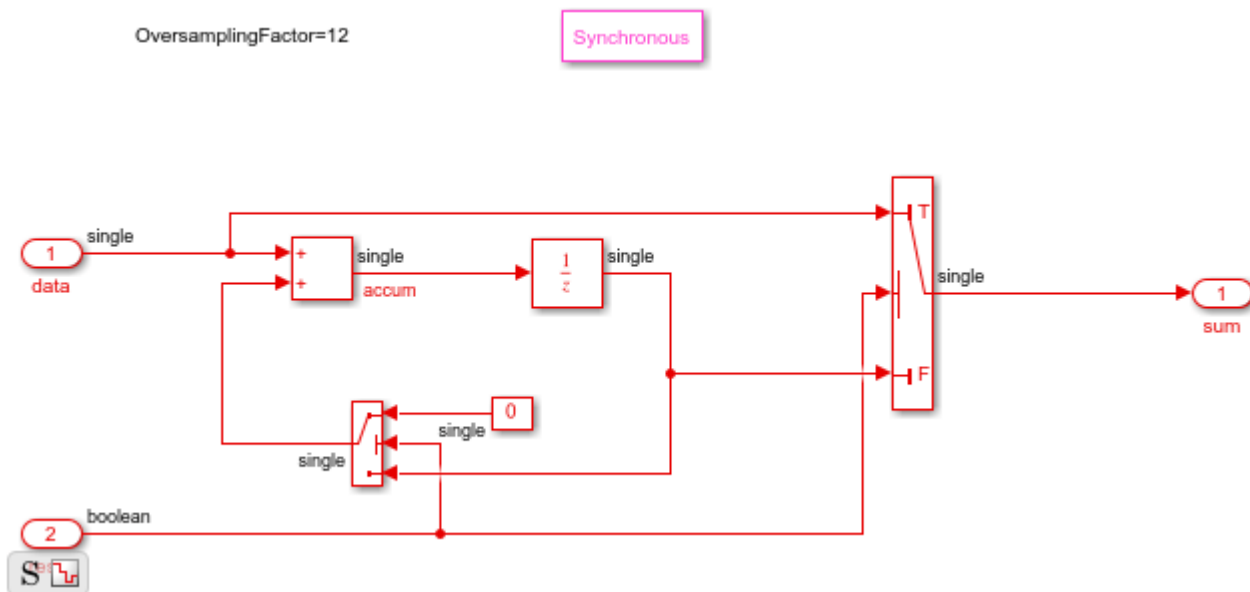

You can use the **Latency Strategy** for various blocks to specify a custom latency value and absorb the additional delays. Using this strategy can optimize your design for trade-offs between:

- Clock frequency and power consumption.
- Oversampling factor and sampling frequency.

To learn more about the trade-offs and blocks for which you can specify a custom latency, see “LatencyStrategy” on page 26-34.

Note: When you use the custom latency strategy, make sure that the Subsystem that contains the block for which native floating-point is unable to allocate delays is not a conditional subsystem. That is, the Subsystem must not contain trigger, reset, or enable ports.

To see how using a custom latency can resolve the delay allocation issue, open the model RunningSum_Custom.slx.

The model is similar to the original `RunningSum` model but does not have the `Enable` block. Using the `Enable` block can prevent the custom latency strategy from absorbing delays. Specify a custom latency of one for the `Add` block. The `Add` block can then absorb the Unit Delay adjacent to the `Add` block.

You can now generate HDL code for the `CumSum_sl` subsystem.

Strategy 5: Zero Latency

You can use the zero latency strategy setting for blocks in your design for which native floating point is unable to allocate delays. By default, blocks in your design inherit the native floating-point settings that you specify in the Configuration Parameters dialog box. To specify a zero latency strategy setting for a block, in the HDL Block Properties dialog box for that block, on the **Native Floating Point** tab, set **LatencyStrategy** to Zero.

For the `RunningSum` example, set the **LatencyStrategy** of the `Add` block to Zero. To choose the native floating point library and specify zero latency strategy, at the command line, enter:

```
fc = hdlcoder.createFloatingPointTargetConfig('NativeFloatingPoint');
hdlset_param('RunningSum/CumSum_sl/Subsystem/Add', ...
             'LatencyStrategy', 'Zero');
```

Note To obtain good performance on the target FPGA device, it is not recommended to set **Latency Strategy** to Zero from the Configuration Parameters dialog box.

Optimize Generated HDL Code for Multirate Designs with Large Rate Differentials

In this section...

“Issue” on page 14-84

“Description” on page 14-84

“Recommendations” on page 14-86

Issue

When generating HDL code from your multirate algorithm in Simulink, HDL Coder might generate a large number of pipeline registers that can prevent the HDL design from fitting into an FPGA. This issue occurs due to modeling patterns that might result in large rate differentials. You can address this issue by using modeling techniques to manage sample time ratios.

Description

This issue occurs when your Simulink® model has a significantly large difference in sample rates or uses certain block implementations or optimizations that result in different clock-rate paths, such as:

- Multicycle block implementations
- Input and output pipelining
- Distributed pipelining
- Floating-point library mapping
- Native floating-point HDL code generation
- Fixed-point math functions such as reciprocal, sqrt, or divide
- Resource sharing
- Streaming

The additional pipelines result in a latency overhead that requires the insertion of matching delays across multiple signal paths operating at different rates. If the ratio of the fastest to the slowest clock rate is quite large, the code generator can potentially introduce a large number of registers in the resulting HDL code. The large number of pipeline registers can increase the size of the generated HDL files, and can prevent the design from fitting into an FPGA.

To see an example of how this issue occurs, open this Simulink model.

```
open_system('hdlcoder_multirate_high_differential')
```

Copyright 2017-2021 The MathWorks, Inc.

When you compile the model and double-click the `hdlcoder_multirate_high_differential` Subsystem, you can see that the model has a floating-point Gain block, a multicycle operator, in the fast clock-rate region.

Sample Time Legend

Help

Generate HDL code for the `hdlcoder_multirate_high_differential` Subsystem and check the output log.

```

### Generating HDL for 'hdlcoder_multirate_high_differential/hdlcoder_multirate_high_differential'.
### Using the config set for model hdlcoder_multirate_high_differential for HDL code generation parameters.
### Starting HDL check.
### The code generation and optimization options you have chosen have introduced additional pipeline delays.
### The delay balancing feature has automatically inserted matching delays for compensation.
### The DUT requires an initial pipeline setup latency. Each output port experiences these additional delays.
### Output port 0: 100000 cycles.
### Output port 1: 1 cycles.
### Begin VHDL Code Generation for 'hdlcoder_multirate_high_differential'.
### Working on hdlcoder_multirate_high_differential/hdlcoder_multirate_high_differential/nfp_mul_comp as hdlsrc/hdlcoder_multirate_high_differential/nfp_mul_comp.vhd.
### Working on hdlcoder_multirate_high_differential/hdlcoder_multirate_high_differential/hdlcoder_multirate_high_differential_tc.vhd.
### Working on hdlcoder_multirate_high_differential/hdlcoder_multirate_high_differential as hdlsrc/hdlcoder_multirate_high_differential/hdlcoder_multirate_high_differential.vhd.
### Generating package file hdlsrc/hdlcoder_multirate_high_differential/hdlcoder_multirate_high_differential_pkg.vhd.
### Creating HDL Code Generation Check Report hdlcoder_multirate_high_differential_report.html
### HDL check for 'hdlcoder_multirate_high_differential' complete with 0 errors, 0 warnings, and 0 messages.
### HDL code generation complete.

```

Open the generated model. At the command line, enter `gm_hdlcoder_multirate_high_differential`. When you compile the model and double-click the `hdlcoder_multirate_high_differential` Subsystem, the model looks as displayed by the sample time legend.

The large output latency on the fast clock rate region of the design is introduced by the code generator to balance delays across multiple output paths of the system. This large latency increases the size of the generated HDL files and reduces the efficiency of the generated code.

Recommendations

Recommendation 1: Use a Single-Rate Model

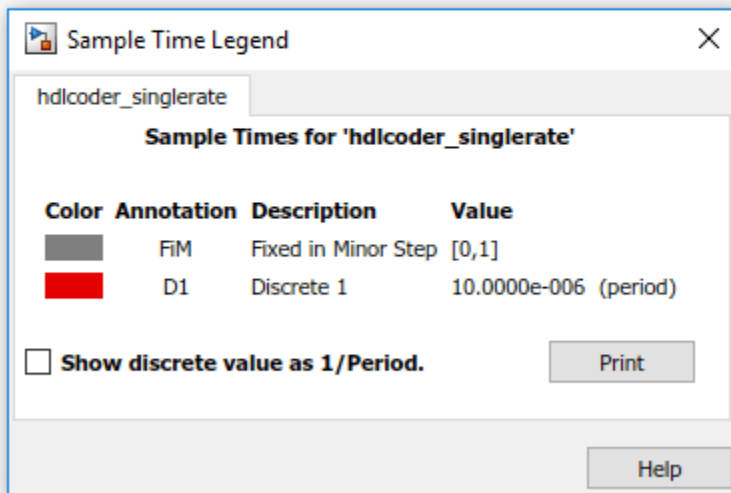

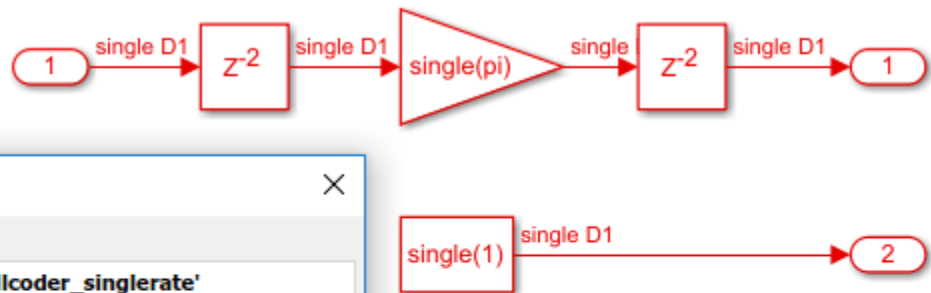

Most applications that you target the HDL code for might not require such a large rate differential. In that case, it is recommended that you use a single-rate model. In this example, you can change the sample rate of the Constant block inside the `hdlcoder_multirate_high_differential` subsystem to be the same as that of the base model.

Open this model that has the sample time of the Constant block changed to $10E-06$, which is the same sample time as the base sample time of the model.

```
open_system('hdlcoder_singlerate')
```

When you compile the model and double-click the `hdlcoder_singlerate` Subsystem, you see that the signal paths in the model operate at the same sample time of $10\text{E}-06$.

Set `UseFloatingPoint` property to `on` for the `hdlcoder_singlerate` model by using the `hdlset_param` function. Generate HDL code for the `hdlcoder_singlerate` subsystem and check the output log.

```
### Generating HDL for 'hdlcoder_singlerate/hdlcoder_singlerate'.
### Using the config set for model hdlcoder\_singlerate for HDL code generation parameters.
### Starting HDL check.
### The code generation and optimization options you have chosen have introduced additional pipeline delays.
### The delay balancing feature has automatically inserted matching delays for compensation.
### The DUT requires an initial pipeline setup latency. Each output port experiences these additional delays.
### Output port 0: 6 cycles.
### Output port 1: 6 cycles.
### Begin VHDL Code Generation for 'hdlcoder_singlerate'.
### Working on hdlcoder_singlerate/hdlcoder_singlerate/nfp_mul_comp as hdlsrc/hdlcoder\_singlerate/nfp\_mul\_comp.vhd.
### Working on hdlcoder_singlerate/hdlcoder_singlerate as hdlsrc/hdlcoder\_singlerate/hdlcoder\_singlerate.vhd.
### Generating package file hdlsrc/hdlcoder\_singlerate/hdlcoder\_singlerate\_pkg.vhd.
### Creating HDL Code Generation Check Report hdlcoder\_singlerate\_report.html
### HDL check for 'hdlcoder_singlerate' complete with 0 errors, 0 warnings, and 0 messages.
### HDL code generation complete.
```

You see that the output latency has decreased significantly. Now open the generated model. At the MATLAB® command line, enter `gm_hdlcoder_singlerate`. When you compile the model and double-click the `hdlcoder_singlerate` Subsystem, the model looks as displayed by the sample time legend.

The generated HDL code is now optimal and uses few registers. Therefore, you can deploy the design to target FPGA platforms.

Recommendation 2: Reduce the Rate Differential

If you want to use a multirate model, it is recommended that you reduce the rate differential. Rate differential corresponds to the ratio of the fastest to the slowest clock rate in your design. If your target application requires two signal paths such that one signal path runs in time units of nanoseconds (ns) and the other signal path runs in time units of microseconds (us), you can choose to retain the multirate paths in your model. Be aware that delay balancing can introduce a significantly large number of registers to balance the signal paths.

In this example, you can change the sample rate of the Constant block inside the `hdlcoder_multirate_high_differential` Subsystem to reduce the rate differential.

Open this model that has the sample time of the Constant block changed to 0.01.

```
open_system('hdlcoder_multirate_medium_differential')
```

Copyright 2017-2021 The MathWorks, Inc.

When you compile the model and double-click the `hdlcoder_multirate_medium_differential` Subsystem, you see that the rate differential between the two signal paths is equal to 1000.

Sample Time Legend

hdlcoder_multirate_medium_differential

Sample Times for 'hdlcoder_multirate_medium_differential'

Color	Annotation	Description	Value
	FIM	Fixed in Minor Step	[0,1]
	D1	Discrete 1	10.0000e-006 (period)
	D2	Discrete 2	0.01 (period)
	H	Hybrid	N/A

Show discrete value as 1/Period. Print

Help

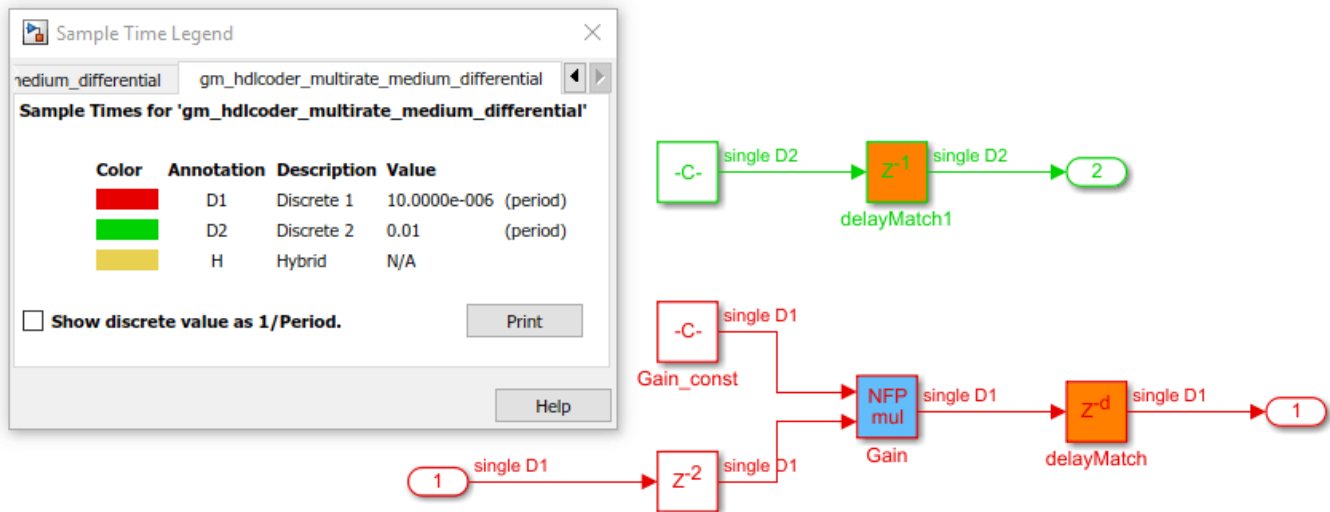

Generate HDL code for the `hdlcoder_multirate_medium_differential` Subsystem and check the output log.

```

### Generating HDL for 'hdlcoder_multirate_medium_differential/hdlcoder_multirate_medium_differential'.
### Using the config set for model hdlcoder_multirate_medium_differential for HDL code generation parameters.

### The delay balancing feature has automatically inserted matching delays for compensation.
### The DUT requires an initial pipeline setup latency. Each output port experiences these additional delays.
### Output port 0: 1000 cycles.
### Output port 1: 1 cycles.
### Begin VHDL Code Generation for 'hdlcoder_multirate_medium_differential'.
### Working on hdlcoder_multirate_medium_differential/hdlcoder_multirate_medium_differential/nfp_mul_comp as hdlsrc\hdlcoder_multirate_medium_differential\nfp_mul_comp.vhd.
### Working on hdlcoder_multirate_medium_differential_cc as hdlsrc\hdlcoder_multirate_medium_differential\hdlcoder_multirate_medium_differential_cc.vhd.
### Working on hdlcoder_multirate_medium_differential/hdlcoder_multirate_medium_differential as hdlsrc\hdlcoder_multirate_medium_differential\hdlcoder_multirate_medium_differential.vhd.
### Generating package file hdlsrc\hdlcoder_multirate_medium_differential\hdlcoder_multirate_medium_differential_pkg.vhd.
### Creating HDL Code Generation Check Report hdlcoder_multirate_medium_differential_report.html
### HDL check for 'hdlcoder_multirate_medium_differential' complete with 0 errors, 0 warnings, and 0 messages.
### HDL code generation complete.

```

Open the generated model. At the MATLAB® command line, enter `gm_hdlcoder_multirate_medium_differential`. When you compile the generated model and double-click the `hdlcoder_multirate_medium_differential` Subsystem, the model is as displayed by the sample time legend.

The model has a large number of registers, approximately 1000, in the fast clock rate path. The additional cost of registers is expected when you have a control logic that runs at a sample rate that is 1000 times faster than the sample rate of the system. When you deploy the generated code to a target platform, be aware of the constraints in hardware resources on the target platform. This recommendation offers a trade-off between generating optimal HDL code and targeting practical FPGA applications that might require an extremely large rate differential.

Recommendation 3: Map Pipeline Delays to RAM

To optimize the number of registers that your design uses on the target FPGA device, you can use the **Map Pipeline Delays to RAM** setting. This setting is a trade-off of the pipeline registers that are inserted in the HDL code with RAM resources to save area footprint on the target FPGA device. You can enable this setting in the **HDL Code Generation > Optimizations > General** tab of the Configuration Parameters dialog box.

You can also specify this setting at the command line by using the `MapPipelineDelaysToRAM` property with `hdlset_param` or `makehdl`. You can view the property value by using `hdlget_param`. Use either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('hdlcoder_multirate_high_differential/hdlcoder_multirate_high_differential', ...  
        'MapPipelineDelaysToRAM','on')
```

- When you use `hdlset_param`, you can set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('hdlcoder_multirate_high_differential', ...  
            'MapPipelineDelaysToRAM','on')  
makehdl('hdlcoder_multirate_high_differential/hdlcoder_multirate_high_differential')
```

Use this setting in combination with the previous recommendations to further improve the efficiency of the generated HDL code and for deploying the code to the target platform.

Getting Started with HDL Coder Native Floating-Point Support

In this section...

“Key Features” on page 14-92

“Numeric Considerations and IEEE-754 Standard Compliance” on page 14-92

“Floating Point Types” on page 14-93

“Data Type Considerations” on page 14-94

Native floating-point support in HDL Coder enables you to generate code from your floating-point design. If your design has complex math and trigonometric operations or has data with a large dynamic range, use native floating point. You can use native floating point with a Simulink model or a MATLAB function.

Key Features

In your Simulink model or MATLAB function:

- You can have half-precision, single-precision, and double-precision floating-point data types and operations.
- You can have a combination of integer, fixed-point, and floating-point operations. By using Data Type Conversion blocks, you can perform conversions between floating-point and fixed-point data types.

The generated code:

- Complies with the IEEE-754 standard of floating-point arithmetic.
- Is target-independent. You can deploy the code on any generic FPGA or an ASIC.
- Does not require floating-point processing units or hard floating-point DSP blocks on the target ASIC or FPGA.

HDL Coder supports:

- Math and trigonometric functions
- Large subset of Simulink blocks
- Denormal numbers
- Customizing the latency of the floating-point operator

Numeric Considerations and IEEE-754 Standard Compliance

Native floating point technology in HDL Coder adheres to IEEE standard of floating-point arithmetic. For basic arithmetic operations such as addition, subtraction, multiplication, division, and reciprocal, when you generate HDL code in native floating-point mode, the numeric results obtained match the original Simulink model or MATLAB function.

Certain advanced math operations such as exponential, logarithm, and trigonometric operators have machine-specific implementation behaviors because these operators use recurring Taylor series and Remez expression based implementations. When you use these operators in native floating-point mode, the generated HDL code can have relatively small numeric differences from the Simulink

model or MATLAB function. These numeric differences are within a tolerance range and therefore indicate compliance with the IEEE-754 standard.

To generate code that complies with the IEEE-754 standard, HDL Coder supports:

- Round to nearest rounding mode
- Denormal numbers
- Exceptions such as NaN (Not a Number), Inf, and Zero
- Customization of ULP (Units in the Last Place) and relative accuracy

For more information, see “Numeric Considerations for Native Floating-Point” on page 14-96.

Floating Point Types

Single Precision

In the IEEE 754-2008 standard, the single-precision floating-point number is 32-bits. The 32-bit number encodes a 1-bit sign, an 8-bit exponent, and a 23-bit mantissa.

This graph is the normalized representation for floating-point numbers. You can compute the actual value of a normal number as:

$$value = (-1)^{sign} * (1 + \sum_{i=1}^{23} b_{23-i} 2^{-i}) * 2^{(e-127)}$$

The exponent field represents the exponent plus a bias of 127. The size of the mantissa is 24 bits. The leading bit is a 1, so the representation encodes the lower 23 bits.

Use single-precision types for applications that require larger dynamic range than half-precision types. Single-precision operations consume less memory and has lower latency than double-precision types.

Double Precision

In the IEEE 754-2008 standard, the single-precision floating-point number is 64-bits. The 64-bit number encodes a 1-bit sign, an 11-bit exponent, and a 52-bit mantissa.

The exponent field represents the exponent plus a bias of 1023. The size of the mantissa is 53 bits. The leading bit is a 1, so the representation encodes the lower 52 bits.

Use double-precision types for applications that require larger dynamic range, accuracy, and precision. These operations consume larger area on the FPGA and lower target frequency.

Half Precision

In the IEEE 754-2008 standard, the half-precision floating-point number is 16-bits. The 16-bit number encodes a 1-bit sign, a 5-bit exponent, and a 10-bit mantissa.

The exponent field represents the exponent plus a bias of 15. The size of the mantissa is 11 bits. The leading bit is a 1, so the representation encodes the lower 10 bits.

Use half-precision types for applications that require smaller dynamic range, consumes much less memory, has lower latency, and saves FPGA resources.

When using `half` types, you might want to explicitly set the **Output data type** of the blocks to `half` instead of the default setting `Inherit: Inherit via internal rule`. To learn how to change the parameters programmatically, see “Set HDL Block Parameters for Multiple Blocks Programmatically” on page 26-53.

Data Type Considerations

With native floating-point support, HDL Coder supports code generation from Simulink models or MATLAB functions that contain floating-point signals and fixed-point signals. You can model your design with floating-point types to:

- Implement algorithms that have a large or unknown dynamic range that can fall outside the range of representable fixed-point types.
- Implement complex math and trigonometric operations that are difficult to design in fixed point.
- Obtain a higher precision and better accuracy.

Floating-point designs can potentially occupy more area on the target hardware. In your Simulink model or MATLAB function, it is recommended to use floating-point data types in the algorithm data path and fixed-point data types in the algorithm control logic. This figure shows a section of a Simulink model that uses `single` and fixed-point types. By using Data Type Conversion blocks, you can perform conversions between the single and fixed-point types.

Numeric Considerations for Native Floating-Point

In this section...

“Nearest Even Digit Rounding” on page 14-96
 “Denormal Numbers” on page 14-96
 “Exception Handling” on page 14-97
 “Relative Accuracy and ULP Considerations” on page 14-97

Native floating-point technology can generate HDL code from your floating-point design. Floating-point designs have better precision, a higher dynamic range, and a shorter development cycle than fixed-point designs. If your design has complex mathematical operations, use native floating-point technology.

HDL Coder generates code that complies with the IEEE® 754 standard for floating-point arithmetic. HDL Coder native floating-point supports:

- Rounding numbers to the nearest even digit
- Denormal numbers
- Exceptions such as NaN values, Inf values, and zero
- Customization of units in the last place (ULP) and relative accuracy

Nearest Even Digit Rounding

HDL Coder native floating-point supports rounding to the nearest even digit. This mode resolves all ties by rounding to the nearest even digit.

This rounding method requires at least three trailing bits after the 23 bits of the mantissa. The MSB is called Guard bit, the middle bit is called the Round bit, and the LSB is called the Sticky bit. The table shows the rounding action that HDL Coder performs based on different values of the three trailing bits. x denotes a *don't care* value and can take either a 0 or a 1.

Rounding bits	Rounding Action
0xx	No action performed.
100	A tie. If the mantissa bit that precedes the Guard bit is a 1, round up, otherwise no action is performed.
101	Round up.
11x	Round up.

Denormal Numbers

Denormal numbers are numbers that have an exponent field equal to zero and a nonzero mantissa field. The leading bit of the mantissa is zero.

$$value = (-1)^{sign} * (0 + \sum_{i=1}^{23} b_{23-i} 2^{-i}) * 2^{-126}$$

Denormal numbers have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. The presence of denormal numbers indicates a

loss of significant digits that can accumulate over multiple operations and result in unexpected values.

The logic that HDL Coder uses to handle denormal numbers involves counting the number of leading zeros and performing a left shift operation to obtain the normalized representation. Addition of this logic increases the area footprint on the target device and can affect the timing of your design.

When you use native floating-point support, you can specify your design handles denormal numbers.

Exception Handling

If you perform operations such as division by zero or computing the logarithm of a negative number, HDL Coder detects and reports exceptions. This table summarizes the mapping from the encoding of a floating-point number to the value of the number for different exceptions. An x denotes a don't care value, which can be a 0 or 1 without affecting the mapping.

Sign	Exponent	Significand	Value	Description
x	0xFF	0x00000000	$value = (-1)^{S_{\infty}}$	Infinity
x	0xFF	A nonzero value	$value = NaN$	Not a Number
x	0x00	0x00000000	$value = 0$	Zero
x	0x00	A nonzero value	$value = (-1)^{sign} * (0 + \sum_{i=1}^{23} b_{23-i} 2^{-i}) * 2^{-126}$	Denormal
x	0x00 < E < 0xFF	x	$value = (-1)^{sign} * (1 + \sum_{i=1}^{23} b_{23-i} 2^{-i}) * 2^{(e-127)}$	Normal

Relative Accuracy and ULP Considerations

The representation of infinite real numbers with a finite number of bits requires an approximation. This approximation can result in rounding errors in floating-point computation. To measure the rounding errors, the floating-point standard uses a relative error and a ULP error.

ULP

If the exponent range is not upper-bounded, a ULP value of a floating-point number x is the distance between the two closest straddling floating-point numbers a and b nearest to x . The IEEE 754 standard requires that the result of an elementary arithmetic operation such as addition, multiplication, or division is correctly rounded. A correctly rounded result means that the rounded result is within 0.5 ULP of the exact result.

ULP value of 1 means adding a 1 to the decimal value of the stored integer. This table shows the approximation of π to nine decimal digits and how the ULP value of 1 changes the approximate value.

Floating-point number	Decimal Value of Stored Integer	IEEE-754 representation for Single Types
3.141592741	1078530011	0 10000000 10010010000111111011011
3.141592979	1078530012	0 10000000 10010010000111111011100

The gap between two consecutively representable floating-point numbers varies according to magnitude.

Floating-point number	Decimal Value of Stored Integer	IEEE-754 representation for Single Types
1234567	1234613304	0 10010011 00101101011010000111000
1234567.125	1234613305	0 10010011 00101101011010000111001

Relative Error

Relative error measures the relative difference between a floating-point number and the approximation of the real number. The relative error between the real numbers a and b is the ratio of absolute difference between numbers a and b to the maximum of a and b .

This table shows the relative error between two consecutive floating-point values that has a ULP value of 1.

Floating-point number	Decimal Value of Stored Integer	IEEE-754 representation for Single Types	Relative error
1234567	1234613304	0 10010011 00101101011010000111000	1.0125e-07
1234567.125	1234613305	0 10010011 00101101011010000111001

ULP Considerations of Native Floating-Point Operators

In this section...

“Adherence of Native Floating Point Operators to IEEE-754 Standard” on page 14-99

“ULP Values of Floating Point Operators” on page 14-99

“Considerations” on page 14-101

The representation of infinitely real numbers with a finite number of bits requires an approximation. This approximation can result in rounding errors in floating-point computation. To measure the rounding errors, the floating-point standard uses relative error and ULP (Units in the Last Place) error. To learn about relative error, see “Relative Accuracy and ULP Considerations” on page 14-97.

If the exponent range is not upper-bounded, Units in Last Place (ULP) of a floating-point number x is the distance between two closest straddling floating-point numbers a and b nearest to x . The IEEE-754 standard requires that the result of an elementary arithmetic operation such as addition, multiplication, and division is correctly round. A correctly rounded result means that the rounded result is within 0.5 ULP of the exact result.

Adherence of Native Floating Point Operators to IEEE-754 Standard

Native floating point technology in HDL Coder follows IEEE standard of floating-point arithmetic. Basic arithmetic operations such as addition, subtraction, multiplication, division, and reciprocal are mandated by IEEE to have zero ULP error. When you perform these operations in native floating-point mode, the numerical results obtained from the generated HDL code match the original Simulink model.

Certain advanced math operations such as exponential, logarithm, and trigonometric operators have machine-specific implementation behaviors because these operators use recurring Taylor series and Remez expression based implementations. When you use these operators in native floating-point mode, there can be relatively small differences in numerical results between the Simulink model and the generated HDL code.

You can measure the difference in numerical results as a relative error or ULP. A nonzero ULP for these operators does not mean noncompliance with the IEEE standard. A ULP of one is equivalent to a relative error of 10^{-7} . You can ignore such relatively small errors by specifying a custom tolerance value for the ULP when generating a HDL test bench. For example, you can specify a custom floating-point tolerance of one ULP to ignore the error when verifying the generated code. For more information, see “Floating-Point Tolerance Parameters” on page 23-28.

ULP Values of Floating Point Operators

The table enumerates the ULP of floating-point operators that have a nonzero ULP. In addition to these operators, the HDL Reciprocal block has a ULP of five.

Math Functions

Simulink Blocks	Data Type	Units in the Last Place (ULP) error
exp	Single	1
	Half	1
log	Double	1
	Single	1
	Half	1
log10	Single	1
	Half	1
10 ^u	Single	1
pow	Single	1
hypot	Single	1

Math Operations

Simulink Blocks	Data Type	Units in the Last Place (ULP) error
HDL Reciprocal	Single	5
Reciprocal Sqrt	Double	1

Trigonometric Functions

Simulink Blocks	Data Type	Units in the Last Place (ULP) error
sin	Double	1
	Single	2
	Half	1
cos	Double	1
	Single	2
	Half	1
tan	Single	3
asin	Single	2
acos	Single	2
atan	Single	2
atan2	Single	5
sinh	Single	1
cosh	Single	1
tanh	Single	1
asinh	Single	2
acosh	Single	2
atanh	Single	3
sincos	Single	2

Considerations

For certain floating-point input values, some blocks can produce simulation results that vary from the MATLAB simulation results. To see the difference in results, before you generate code, enable generation of the validation model. In the Configuration Parameters dialog box, on the **HDL Code Generation** pane, select the **Generate validation model** check box.

- If you perform computations that involve complex numbers and an exception such as `Inf` or `NaN`, the HDL simulation result with native floating point can potentially vary from the Simulink simulation result. For example, if you multiply a complex input with `Inf`, the Simulink simulation result is `Inf i` whereas the HDL simulation result is `NaN+Inf i`.
- HDL Coder does not generate a mismatch error between reference and native floating-point values if both values are `NaN` irrespective of the sign.
- If you compute the square root or logarithm of a negative number, the HDL simulation result with native floating point is `0`. This result matches the simulation result when you verify the design with a SystemVerilog DPI test bench. In Simulink, the result obtained is `NaN`. According to the IEEE-754 standard, if you compute the square root or logarithm of a negative number, the result is that number itself.
- If the input to the Direct Lookup Table (n-D) is of floating-point data type, but the elements of the table use a smaller data type, the generated HDL code can be potentially incorrect. For example, the input is of `single` type and the elements use `uint8` type. To obtain accurate HDL simulation results, use the same data type for the input signal and the elements of the lookup table.

- If you use the Cosine block with the inputs $-7.729179E28$ or $7.729179E28$, the generated HDL code has a ULP of 4. For all other inputs, the ULP is 2.
- When you use a Math Function block to compute $\text{mod}(a, b)$ or $\text{rem}(a, b)$, where a is the dividend and b is the divisor, the simulation result in native floating-point mode varies from the MATLAB simulation result in these cases:
 - If b is integer and $\frac{a}{b} > 2^{32}$, the simulation result in native floating-point mode is zero. For such significant difference in magnitude between the numbers a and b , this implementation saves area on the target FPGA device.
 - If $\frac{a}{b}$ is close to 2^{23} , the simulation result in native floating-point mode can potentially vary from the MATLAB simulation results.

Latency Values of Floating-Point Operators

In this section...

“Math Operations” on page 14-103

“Trigonometric Operations” on page 14-105

“Comparisons and Conversions” on page 14-106

HDL Coder native floating-point support can generate HDL code from your floating-point design. HDL Coder supports several Simulink blocks, Math and Trigonometric Functions blocks in native floating-point mode. The tables list the default latency values of these floating-point operations.

You can customize the latency settings for the blocks and design for trade-offs between latency and maximum frequency. For more information, see “NFPCustomLatency” on page 26-36.

You can also set the global custom latency of native floating-point IPs. Use the keywords listed in the tables to specify the global custom latency of the floating-point IPs. For more information on setting the custom latency of floating-point IPs, see “Latency Considerations with Native Floating Point” on page 14-109.

You can see the latency of these floating-point operators in MATLAB by entering these commands.

```
nfpconfig = hdlcoder.createFloatingPointTargetConfig('NativeFloatingPoint');
nfpconfig.IPConfig
```

Math Operations

This table shows the list of basic math operations that are supported with native floating-point in HDL Coder and their latency information. The basic math operations include addition, subtraction, multiplication, and so on. You can use most of these blocks with both `single` and `double` data types. If you do not see an entry of `double` data type corresponding to a block, it means that the block does not support `double` types.

Basic Math Operators

Simulink Blocks	Keywords	Data Type	Minimum Output Latency	Maximum Output Latency	Custom Latency Support
Add	ADDSUB	Double	6	11	Yes
		Single	6	11	
		Half	4	8	
Subtract	ADDSUB	Double	6	11	Yes
		Single	6	11	
		Half	4	8	
Product or Gain	MUL	Double	6	9	Yes
		Single	6	8	
		Half	4	7	
Divide	DIV	Double	31	61	Yes
		Single	17	32	
		Half	10	19	
Reciprocal	RECIP	Double	30	60	Yes
		Single	16	31	
		Half	10	19	
Multiply-Add	MULTADD	Single	8	14	No
Sqrt	SQRT	Double	33	58	Yes
		Single	16	28	
		Half	6	12	
HDL Reciprocal	HDLRECIP	Single	14	21	No
Rounding Function	ROUNDING	Double	3	5	Yes
		Single	3	5	
Gain(Power of 2)	GAINPOW2	Double	1	2	Yes
		Single	1	2	
		Half	1	4	

This table shows the math functions that are supported with native floating-point in HDL Coder and their latency information. You can select the function using the **Function** setting of the Math Function block.

Math Functions

Simulink Blocks	Keywords	Data Type	Minimum Output Latency	Maximum Output Latency	Custom Latency Support
Rem	REM	Single	15	24	No
Mod	MOD	Single	16	26	No
Reciprocal Sqrt	RSQRT	Single	16	30	Yes
Hypot	HYPOT	Single	17	33	No
Magnitude Square	-	Double	6	9	Yes
		Single	6	8	

This table shows the exponential operations that are supported with native floating-point in HDL Coder and their latency information. You can select the function using the **Function** setting of the Math Function block. You can use these blocks with `single` data types. `Double` types are unsupported for the blocks except Log.

Exponent/Logarithm/Power

Simulink Blocks	Keywords	Data Type	Minimum Output Latency	Maximum Output Latency	Custom Latency Support
Exp	EXP	Single	16	26	No
Pow	POW	Single	33	54	No
Pow10	POW10	Single	16	26	No
Log	LOG	Double	34	44	No
		Single	20	27	
		Half	9	17	
Log10	LOG10	Single	17	27	No
		Half	10	18	

Trigonometric Operations

This table shows the trigonometric operations that are supported with native floating-point in HDL Coder and their latency information. You can select the function using the **Function** setting of the Trigonometric Function block. You can use these blocks with `single` data types.

Trigonometric Functions

Simulink Blocks	Keywords	Data Type	Minimum Output Latency	Maximum Output Latency	Custom Latency Support
Sin	SIN	Double	34	34	No
		Single	27	27	
		Half	8	14	
Cos	COS	Double	48	48	No
		Single	27	27	
		Half	9	14	
Tan	TAN	Single	33	33	No
Sincos	SINCOS	Single	27	27	No
Asin	ASIN	Single	17	23	No
Acos	ACOS	Single	17	23	No
Atan	ATAN	Single	36	36	No
Atan2	ATAN2	Single	42	42	No
Sinh	SINH	Single	18	30	No
Cosh	COSH	Single	17	27	No
Tanh	TANH	Single	25	43	No
Asinh	ASINH	Single	94	94	No
Acosh	ACOSH	Single	93	93	No
Atanh	ATANH	Single	67	67	No

Comparisons and Conversions

This table shows operations related to relational operators and data type conversions that are supported with native floating-point in HDL Coder and their latency information. You can use these blocks with both `single` and `double` data types except for the `MinMax` block. This block does not support `double` data type. For the `Data Type Conversion` block, you can convert between `double`, `half`, and `single` data types, and between floating-point and other fixed-point data types.

Comparisons and Conversions

Simulink Blocks	Keywords	Data Type	Minimum Output Latency	Maximum Output Latency	Custom Latency Support
Data Type Conversion	CONVERT	DOUBLE_TO_NUMERICTYPE	3	6	Yes
		DOUBLE_TO_SINGLE	3	6	
		HALF_TO_NUMERICTYPE	2	3	
		HALF_TO_SINGLE	1	2	
		NUMERICTYPE_TO_DOUBLE	3	6	
		NUMERICTYPE_TO_HALF	2	4	
		NUMERICTYPE_TO_SINGLE	6	6	
		SINGLE_TO_DOUBLE	3	5	
		SINGLE_TO_HALF	2	3	
		SINGLE_TO_NUMERICTYPE	6	6	
Relational Operator	RELOP	Double	1	3	Yes
		Single	1	3	
		Half	1	2	
MinMax	MINMAX	Single	3	3	No

Latency Considerations with Native Floating Point

HDL Coder™ native floating-point technology can generate HDL code from your floating-point design. Native floating-point operators have a latency. When you generate HDL code, the code generator figures out this latency and adds matching delays to balance parallel paths.

View Latency of a Floating-Point Operator

Open the `hdlcoder_nfp_delay_allocation` Simulink® model. The model uses `single` data types and computes the square root. The model has a parallel path to illustrate how the code generator balances delays.

```
load_system('hdlcoder_nfp_delay_allocation')
open_system('hdlcoder_nfp_delay_allocation/DUT')
```

To generate HDL code:

- 1 Right-click the DUT Subsystem and select **HDL Code > Generate HDL for Subsystem**.
- 2 To see the generated model after HDL code generation, at the command line, enter `gm_hdlcoder_nfp_delay_allocation`.

The `NFP_sqrt` block is the floating-point operator corresponding to the `Sqrt` block in your model, and has a latency of 28. The code generator determines this latency and adds a matching delay of length 28 in the parallel path. To see the latency of the square root operation, double-click the `NFP_sqrt` block. The **Delay length** of the `Sqrt_pd1` block corresponds to the operator latency.

You can customize the latency of your design. Use custom latency settings to design for trade-offs between latency and throughput. You can then optimize your design implementation on the target FPGA device for area and speed. Customize the latency by using:

- Latency Strategy setting: Specify whether to map your entire Simulink model or individual blocks in your model to maximum, minimum, or zero latency of the floating-point operator.
- Custom Latency: You can specify a custom latency for certain blocks that you use in your Simulink model. The custom latency setting can take values from zero to the maximum latency of the floating-point operator.
- Oversampling factor: Increasing the **Oversampling factor** operates the design at a faster clock rate and absorbs the clock-rate pipelines with the latency of the floating-point operator.
- Delay blocks in the model: If your Simulink model has a latency, HDL Coder can absorb some or all of the latency with the native floating-point implementation.

Latency Strategy Setting for Model

You can specify the latency strategy setting for an entire model or for individual blocks in your model.

To specify this setting for a model:

- 1 In the `hdlcoder_nfp_delay_allocation` model, right-click the DUT Subsystem and select **HDL Code > HDL Coder Properties**.
- 2 On the **HDL Code Generation > Floating Point**, select **Use Floating Point**.
- 3 For **Latency Strategy**, select **MAX**, **MIN**, or **ZERO**.

To specify this setting from the command line:

1. Create a `hdlcoder.FloatingPointTargetConfig` object for native floating point by using the `hdlcoder.createFloatingPointTargetConfig` function.

```
nfpconfig = hdlcoder.createFloatingPointTargetConfig("NativeFloatingPoint");
hdlset_param('hdlcoder_nfp_delay_allocation', 'FloatingPointTargetConfiguration', nfpconfig);
```

2. Specify the latency strategy by using the `LatencyStrategy` property of the `nfpconfig` object.

```
nfpconfig.LibrarySettings.LatencyStrategy = 'MAX'
```

```
nfpconfig =
```

```
    FloatingPointTargetConfig with properties:
```

```
        Library: 'NATIVEFLOATINGPOINT'
    LibrarySettings: [1x1 fpconfig.NFPLatencyDrivenMode]
        IPConfig: [1x1 hdlcoder.FloatingPointTargetConfig.IPConfig]
        VendorLibrary: []
    VendorLibrarySettings: []
        VendorIPConfig: []
```

To see the latency information, generate HDL code and then open the generated model. To open the generated model, enter the command `gm_hdlcoder_nfp_delay_allocation`.

Custom Latency Strategy for Blocks

For blocks in your Simulink model, you can selectively customize the latency strategy. By default, the blocks inherit the latency strategy setting you specify for the model. For certain blocks, you can specify a custom latency value that is between zero and the maximum latency of the floating-point operator.

By specifying a custom latency, you can customize your design for trade-offs between:

- Clock frequency and power consumption: A higher latency value increases the maximum clock frequency (Fmax) that you can achieve, which increases the dynamic power consumption.
- Oversampling factor and sampling frequency: A combination of higher latency value and higher oversampling factor increases the Fmax that you can achieve but reduces the sampling frequency.

To learn more about this setting and how to specify the latency strategy for a block, see “LatencyStrategy” on page 26-34.

For example, if you have an Add block in the parallel path in your model, you can specify a custom latency value of 2 for the Add block by entering these commands.

```
load_system('hdlcoder_nfp_delay_allocation_custom')
open_system('hdlcoder_nfp_delay_allocation_custom')
hdlset_param('hdlcoder_nfp_delay_allocation_custom/DUT/Add','LatencyStrategy','Custom')
hdlset_param('hdlcoder_nfp_delay_allocation_custom/DUT/Add','NFPCustomLatency',2)
```

Copyright 2018-2021 The MathWorks, Inc.

To see the latency information, generate HDL code and then open the generated model. To open the generated model, enter the command `gm_hdlcoder_nfp_delay_allocation_custom`. In the generated model, you see that the NFP Add block has a latency of 2.

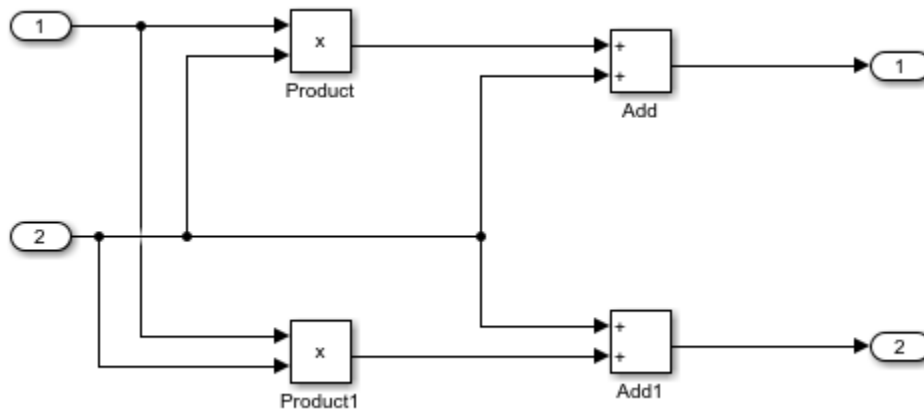

Custom Latency Settings for Native Floating-Point IPs

For a model that has a large number of floating-point operators, you can customize the latency for native floating-point IPs by setting the global custom latency for NFP operators. The customization applies to all operators in the model.

For example, if you have a model that has multiple add and product blocks, by default, the block inherits the latency strategy settings specified for the model. By using these commands, you can customize the latency of all the NFP add blocks to 4 and all the NFP mul blocks to 3.

```
load_system('hdlcoder_nfp_delay_allocation_global_custom')
open_system('hdlcoder_nfp_delay_allocation_global_custom/Sample_DUT');
hdlset_param('hdlcoder_nfp_delay_allocation_global_custom', 'FloatingPointTargetConfiguration',
hdlcoder.createFloatingPointTargetConfig('NativeFloatingPoint', 'IPConfig', ...
{{ 'ADDSUB', 'SINGLE', 'CustomLatency', 4} ...
, { 'ADDSUB', 'DOUBLE', 'CustomLatency', 4} ...
, { 'MUL', 'SINGLE', 'CustomLatency', 3} ...
, { 'MUL', 'DOUBLE', 'CustomLatency', 3}}))
```

To see the latency information, generate HDL code and then open the generated model. To open the generated model, enter the command `gm_hdlcoder_nfp_delay_allocation_global_custom`. In the generated model, you see that the all the NFP Add block has a latency of 4 and all the NFP mul blocks has latency of 3.

For the list of keywords to use for native floating-point IPs in the API in the command, refer to the table in “Latency Values of Floating-Point Operators” on page 14-103.

Oversampling Factor

When you design the blocks in your Simulink model at the data rate, specify an **Oversampling factor** greater than one. The **Oversampling factor** inserts pipeline registers at a faster clock rate,

which improves clock frequency and reduces area usage. To learn more about clock-rate pipelining, see “Clock-Rate Pipelining” on page 28-149.

To see the effect of **Oversampling factor** on the model, in the `hdlcoder_nfp_delay_allocation` model:

- 1 Add a Delay block with a **Delay length** of 1 at the output of the Sqrt block.
- 2 Right-click the DUT and select **HDL Code > HDL Coder Properties**.
- 3 On the **HDL Code Generation > Global Settings** pane, enter a value of 40 for **Oversampling factor**.

After HDL code generation, the generated model shows the NFP Sqrt block operating at a clock rate that is 40 times faster than the Sqrt block in your model. The NFP Sqrt block absorbed the Delay block in your Simulink model. The Delay block now operates at the clock rate. This implementation saves area by absorbing the additional latency, and improves timing by operating at the faster clock rate.

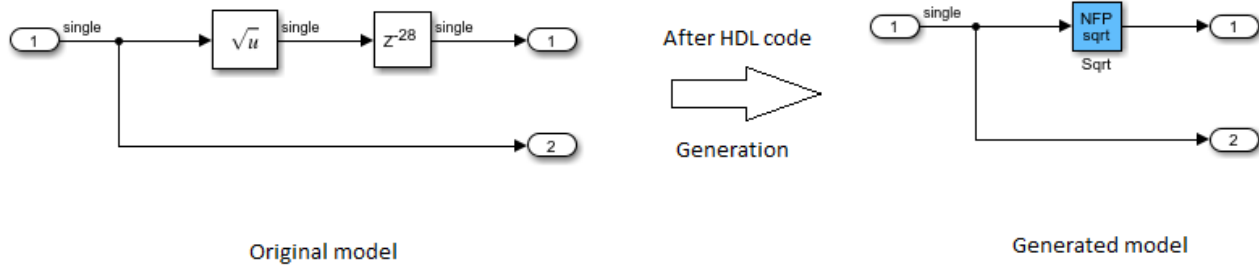

Delay Absorption in the Model

If your Simulink model has a Delay block with sufficient **Delay length** adjacent to an operator or separated from the operator by only a component that does not take zero input and output a non-zero value, such as a NOT Logical Operator block, HDL Coder absorbs the delays as part of the operator latency.

If the **Delay length** is equal to the latency of the floating-point operator, HDL Coder absorbs the delays and does not introduce any additional latency.

In the `hdlcoder_nfp_delay_allocation` model:

- 1 Double-click the Delay block at the output of the Sqrt block and change the **Delay length** to 28.
- 2 Generate HDL code for the DUT Subsystem.
- 3 After HDL code generation, at the command line, enter `gm_hdlcoder_nfp_delay_allocation` to open the generated model.

In the generated model, you see that the NFP Sqrt block absorbs the Delay block adjacent to the Sqrt block in your original model. This delay absorption occurs because the operator latency is equal to the **Delay length**. The code generator therefore avoids the additional latency in your model.

If the **Delay length** is less than the operator latency, HDL Coder absorbs the available delays and balances parallel paths by adding matching delays.

In the `hdlcoder_nfp_delay_allocation` model:

- 1 Double-click the Delay block at the output of the Sqrt block and change the **Delay length** to 21.
- 2 Generate HDL code for the DUT Subsystem.
- 3 After HDL code generation, at the command line, enter `gm_hdlcoder_nfp_delay_allocation` to open the generated model.

You see that the NFP Sqrt block absorbed a Delay of length 21 and added a matching delay of length 7 in the parallel path because the square root operation requires 28 delays.

If the delay length is greater than the operator latency, the code generator absorbs a certain number of delays equal to the latency and the excess delays appear outside the operator.

In the `hdlcoder_nfp_delay_allocation` model:

- 1 Double-click the Delay block at the output of the Sqrt block and change the **Delay length** to 34.
- 2 Generate HDL code for the DUT Subsystem.
- 3 After HDL code generation, at the command-line, enter `gm_hdlcoder_nfp_delay_allocation` to open the generated model.

The NFP Sqrt block absorbed 28 delays because the square root operation has a latency of 28. The excess latency of 6 is outside the operator.

Generate Target-Independent HDL Code with Native Floating-Point

In this section...

“How HDL Coder Generates Target-Independent HDL Code” on page 14-116

“Enable Native Floating Point and Generate Code” on page 14-117

“View Code Generation Report” on page 14-118

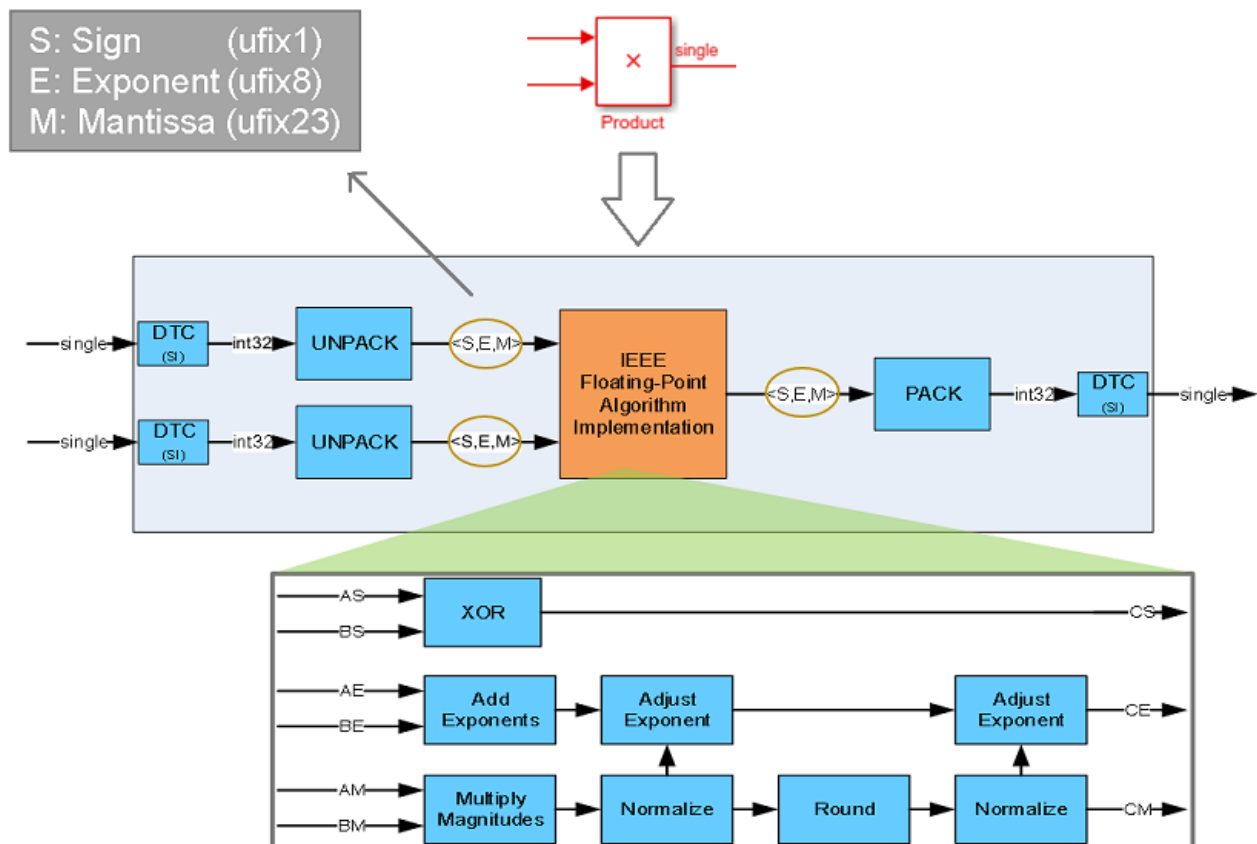

“Analyze Results” on page 14-119

“Limitation” on page 14-121

HDL Coder native floating-point technology can generate target-independent HDL code from your floating-point design. You can synthesize your floating-point design on any generic FPGA or ASIC. Floating-point designs have better precision, higher dynamic range, and a shorter development cycle than fixed-point designs. If your design has complex math and trigonometric operations, use native floating-point technology.

How HDL Coder Generates Target-Independent HDL Code

This figure shows how HDL Coder generates code with the native floating-point technology.

The **Unpack** and **Pack** blocks convert the floating-point types to the sign, exponent, and mantissa. In the figure, *S*, *E*, and *M* represent the sign, exponent, and mantissa respectively. This interpretation is based on the IEEE-754 standard of floating-point arithmetic.

The **Floating-Point Algorithm Implementation** block performs computations on the *S*, *E*, and *M*. With this conversion, the generated HDL code is target-independent. You can deploy the design on any generic FPGA or an ASIC.

Enable Native Floating Point and Generate Code

You can enable native floating point and generate HDL code from a Simulink model or MATLAB function.

Specify Native Floating Point for a Simulink Model

You can specify the native floating-point settings for HDL code generation in the Configuration Parameters dialog box or at the command line.

To specify the native floating-point settings and generate HDL code in the Configuration Parameters dialog box:

- 1 In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
- 2 Click **Settings**. In the **HDL Code Generation > Floating Point** pane, select **Use Floating Point**.
- 3 Specify the **Latency Strategy** to map your design to maximum or minimum latency or no latency. See “Latency Strategy” on page 20-6.
- 4 If you have denormal numbers in your design, select **Handle Denormals**. Denormal numbers are numbers that have an exponent field equal to zero and a nonzero mantissa field. See “Handle Denormals” on page 20-7.
- 5 If your design has multipliers, to specify how you want HDL Coder to implement the multiplication operation, use the **Mantissa Multiplier Strategy**. See “Mantissa Multiplier Strategy” on page 20-8.
- 6 To share floating-point resources, on the **HDL Code Generation > Optimizations > Resource Sharing** tab, make sure that you select **Floating-point IPs**. The number of blocks that get shared depends on the **SharingFactor** that you specify for the subsystem.
- 7 Click **Apply**. In the **HDL Code** tab, click **Generate HDL Code**.

To apply native floating point at the command line for HDL code generation, use the `hdlcoder.createFloatingPointTargetConfig` function. You can use this function to create an `hdlcoder.FloatingPointTargetConfig` object for the native floating-point library.

```
nfpconfig = hdlcoder.createFloatingPointTargetConfig('NATIVEFLOATINGPOINT');
hdlset_param('sfir_single', 'FloatingPointTargetConfiguration', nfpconfig);
```

Optionally, you can specify the latency strategy and whether you want HDL Coder to handle denormal numbers in your design:

```
nfpconfig.LibrarySettings.HandleDenormals = 'on';
nfpconfig.LibrarySettings.LatencyStrategy = 'MAX';
```

To learn how you can verify the generated code, see “Verify the Generated Code from Native Floating-Point” on page 14-138.

Specify Native Floating Point for a MATLAB Function

You can specify the native floating-point settings for HDL code generation by using the MATLAB HDL Workflow Advisor or the command line.

To specify the native floating-point settings in the MATLAB HDL Workflow Advisor:

- 1 Open the MATLAB HDL Workflow Advisor. To get started with the MATLAB HDL Workflow Advisor, see “Basic HDL Code Generation and FPGA Synthesis from MATLAB”.
- 2 In the left pane, click the **HDL Code Generation** task. In the right pane, navigate to the **Floating Point** tab and set **Library** to Native Floating Point.
- 3 Click the **Clocks & Ports** tab and set **Oversampling factor** to a value greater than one.
- 4 Set **Latency Strategy** to MIN, MAX, or ZERO to map your design to minimum, maximum, or no latency, respectively. See “Latency Strategy” on page 20-6.
- 5 If you have denormal numbers in your design, select **Handle Denormals**. Denormal numbers are numbers that have an exponent field equal to zero and a nonzero mantissa field. See “Handle Denormals” on page 20-7.
- 6 If your design has multipliers, specify how you want HDL Coder to implement the multiplication operation by using the **Mantissa Multiplier Strategy** parameter. See “Mantissa Multiplier Strategy” on page 20-8.
- 7 In the left pane, right-click on the **HDL Code Generation** task and select **Run to Selected Task**.

To apply native floating point at the command line for HDL code generation, use the `coder.config` function to create a `coder.HdlConfig` object for HDL code generation and the `hdlcoder.createFloatingPointTargetConfig` function to create an `hdlcoder.FloatingPointTargetConfig` object for the native floating-point library.

```
hdlcfg = coder.config("hdl");
nfpconfig = hdlcoder.createFloatingPointTargetConfig('NATIVEFLOATINGPOINT');
hdlcfg.FloatingPointLibrary = 'NativeFloatingPoint';
hdlcfg.FloatingPointTargetConfiguration = nfpconfig;
```

Optionally, you can specify the latency strategy and whether you want HDL Coder to handle denormal numbers in your design.

```
nfpconfig.LibrarySettings.HandleDenormals = 'on';
nfpconfig.LibrarySettings.LatencyStrategy = 'MAX';
```

View Code Generation Report

To view the code generation reports of floating-point library mapping, before you begin code generation, enable generation of the Resource Utilization Report and Optimization Report. To enable the reports, on the **HDL Code** tab, click **Settings > Report Options** in the Configuration Parameters dialog box, on the **HDL Code Generation** pane, enable **Generate resource utilization report** and **Generate optimization report**. For more information, see “Create and Use Code Generation Reports” on page 30-2.

To see the list of native floating-point operators that HDL Coder supports and the floating-point operators to which your Simulink blocks mapped to, in the Code Generation Report, select **Native Floating-Point Resource Report**.

Native Floating-Point Resource Report for sfir_single

Summary of single precision native floating-point operators

adders	7
multipliers	4

A detailed report shows the various resources that the floating-point blocks use on the target device that you specify. HDL code generation from a native floating point design uses dynamic shift operations for aligning mantissa based on exponent values. Because these dynamic shifters are resource-expensive in the model, they are reported separately from static shift operators. For more information on dynamic and static shifters, see “Timing and Area Report” on page 30-2.

Detailed Report

Module nfp_add_comp

(Latency = "Max")

Multipliers	0
Adders/Subtractors	8
Registers	91
Total 1-Bit Registers	839
RAMs	0
Multiplexers	109
Static Shift operators	0
Dynamic Shift operators	2

To see the native floating-point settings that you applied to the model and whether HDL Coder successfully generated HDL code, in the Code Generation Report, select **Target Code Generation**.

Analyze Results

Floating point operators have a latency. If your Simulink model does not have delays, when you generate HDL code, the code generator figures out the operator latency and delay balances parallel paths. Consider this Simulink model that has two single inputs and gives a single output.

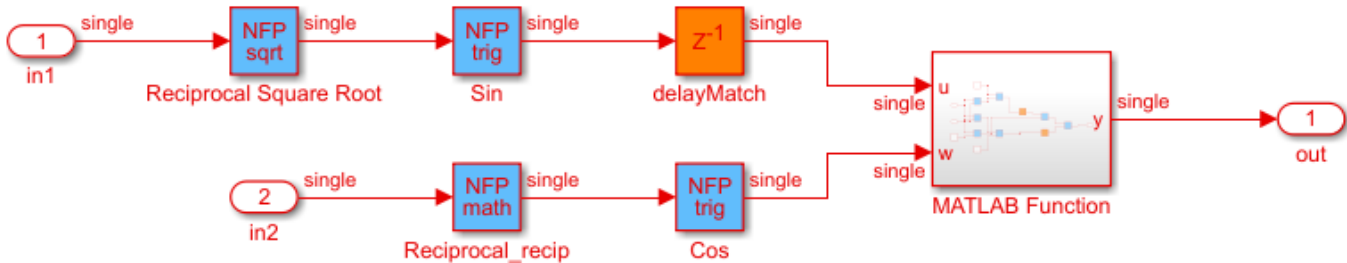

The MATLAB Function block in the Simulink model contains this code.

```
function y = fcn(u, w)
%#codegen

y1 = (u+w) * 20;
y2 = w^16;
y3 = (u-w) / 10;
y = y1 + y2 - y3;
```

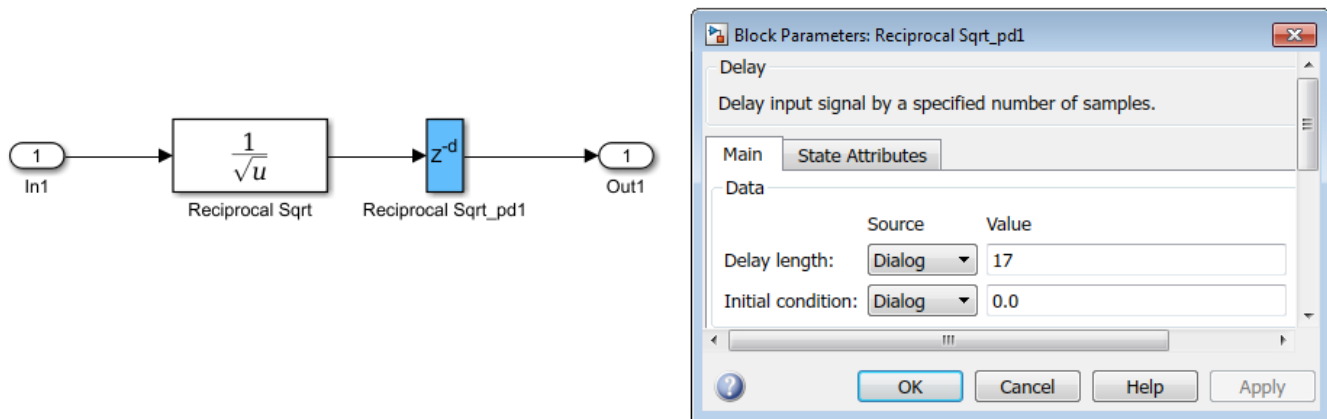

When you generate HDL code, the code generator maps the blocks in your Simulink model to synthesizable native floating-point operators. To see how the code generator implemented the floating-point operations, open the generated model. The blocks **NFP math**, **NFP Sqrt**, and **NFP trig** correspond to the floating-point implementation of the Reciprocal Sqrt, Reciprocal, sin, and cos blocks respectively in your original model.

Every floating-point operator has a latency. The code generator inserted an additional matching delay because the latency of the Reciprocal Sqrt is 30 and latency of Reciprocal is 31. The operator latency is equal to the **Delay length** of the Delay block inside that NFP block. For example, if you double-click the **NFP sqrt** block, you can get the latency by looking at the **Delay length** of the Delay block. See “Latency Values of Floating-Point Operators” on page 14-103.

When you use MATLAB Function blocks with floating-point data types, HDL Coder uses the MATLAB Datapath architecture. This architecture treats the MATLAB Function block like a regular Subsystem block. When you generate code, the code generator maps the basic operations such as addition and multiplication to the corresponding native floating-point operators. Open the MATLAB Function subsystem to see how the code generator implemented the MATLAB Function block.

To learn more about the generated model, see “Generated Model and Validation Model” on page 28-10.

Limitation

To generate HDL code in native floating-point mode, use discrete sample times. Blocks operating at a continuous sample time are not supported.

Floating Point Support: Field-Oriented Control Algorithm

In this example you review a Field-Oriented Control (FOC) algorithm for a Permanent Magnet Synchronous Machine (PMSM) implemented using single-precision and half-precision floating-point types.

Introduction

You have seen the fixed-point version of this design in “Field-Oriented Control of a Permanent Magnet Synchronous Machine” on page 14-66 that takes a deep dive into how to implement current control algorithm using fixed-point types. The model was converted to fixed-point before generating HDL code.

You can use floating-point single-precision types in your design and generate HDL code natively without converting to fixed-point types. This example shows design considerations when generating code from floating-point single-precision and half-precision variants of the fixed point model `hdlcoderFocCurrentFixptHdl`.

The testbench model `hdlcoderFocCurrentTestBench` has a reference block pointing to the DUT implemented in fixed-point or floating-point.

Salient features of Native Floating Point support

- Vendor independent and target agnostic RTL for FPGA and/or ASIC design
- Full range of IEEE-754 features including support for rounding modes, inf and nan data types, and optional support for denormal numbers.
- Extensive math block (add, mul, div, recip, log, exp, sqrt, rsqrt) and trigonometric block (sin, cos, sincos, atan, atan2) support.

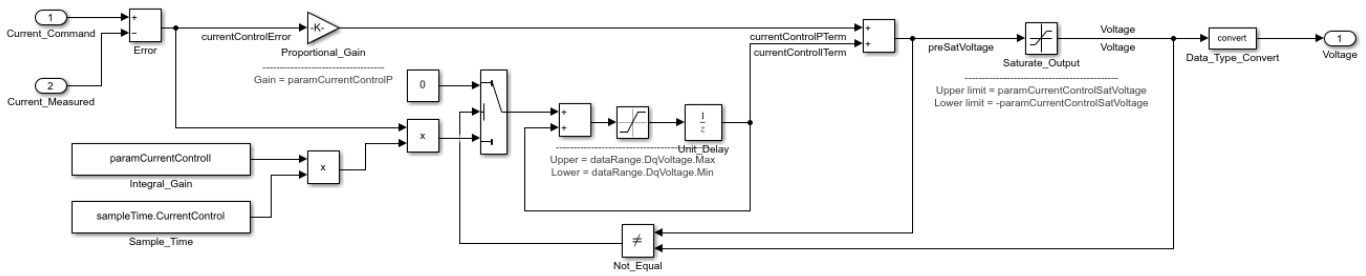

Why Use Floating-Point Types

Sometimes you might want to start in floating-point and stay in floating-point to target HDL, rather than convert to fixed-point, for the following reasons:

- Your algorithms have large or unknown dynamic ranges (for example integrators in feedback loops)
- Your algorithm uses operations that are difficult to design in fixed-point (ex: atan2)

In the fixed-point version of the example `hdlcoderFocCurrentFloatHDL.slx` you notice that several fixed-point rounding and saturation decisions are made to preserve the numerical behavior of the algorithm. For example the block `hdlcoderFocCurrentFixptHdl/FOC_Current_Control/DQ_Current_Control/D_Current_Control/Saturate` which is a saturation block has been placed in the integrator loop so that results do not overflow due to accumulation in the loop.

```
open_system('hdlcoderFocCurrentFixptHdl');
open_system('hdlcoderFocCurrentFixptHdl/FOC_Current_Control/DQ_Current_Control/D_Current_Control/
```

Sometimes, the task of fixed-point conversion could take several weeks to months with multiple levels of algorithm re-validation. It may also lead to undesirable loss of precision which might not be acceptable for some mission critical applications requiring very high accuracy.

In these situations, you can choose to use native floating point synthesis features available in HDL Coder.

Single-Precision FOC Model

To open the single-precision version of the algorithm, run these commands:

```
load_system('hdlcoderFocCurrentFloatHdl');
open_system('hdlcoderFocCurrentFloatHdl/FOC_Current_Control')
```

In comparison to the fixed-point algorithm, the single-precision model does not require additional rounding and saturation blocks and settings as can be seen in the floating-point version of the model `hdlcoderFocCurrentFloatHdl/FOC_Current_Control/DQ_Current_Control/D_Current_Control`

```
open_system('hdlcoderFocCurrentFloatHdl/FOC_Current_Control/DQ_Current_Control/D_Current_Control')
```

To verify the behavior through simulation, run these commands:

```

hasSimPowerSystems = license ('test', 'Power_System_Blocks');

Half-Precision FOC Model

For applications that require smaller dynamic range, you can use `half` types without having to convert your design to use fixed-point types. Using `half` types consumes much less memory, has lower latency, and saves FPGA resources.

Advantages of half-precision floating point types in hardware perspective:

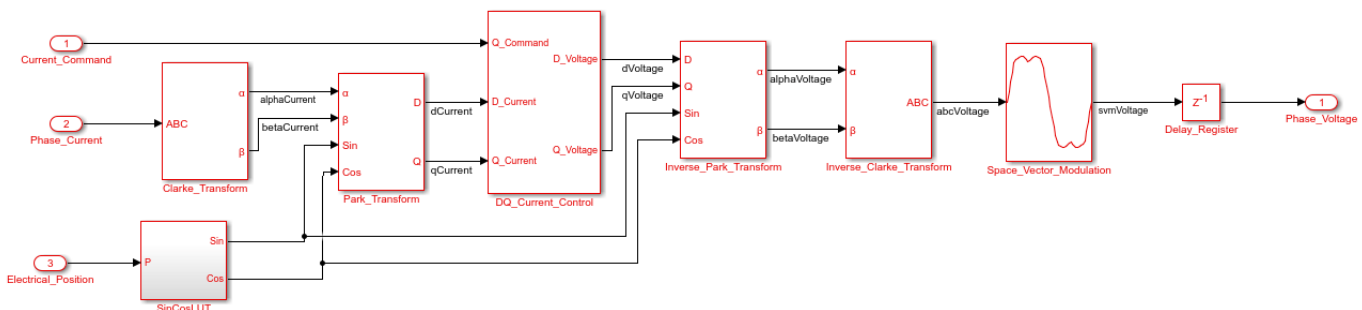

- Low latency
- Low Area
- High speed
- 16-bit floating point behavior which will be useful for optimal storage
- Wider dynamic range compared to integer or fixed point data types of same size

Half-precision types have same features as single- and double-precision floating-point types. Supported operators include basic arithmetic operators (EX: Add/Sub, Mul, Div/Recip) and Gain, Relational operators, Data type conversions.

```

load_system('hdlcoderFocCurrentFloatHalfHdl');
open_system('hdlcoderFocCurrentFloatHalfHdl/FOC_Current_Control')

```

To verify the behavior through simulation, run these commands:

```

hasSimPowerSystems = license('test', 'Power_System_Blocks');
if hasSimPowerSystems
    open_system('hdlcoderFocCurrentTestBench')

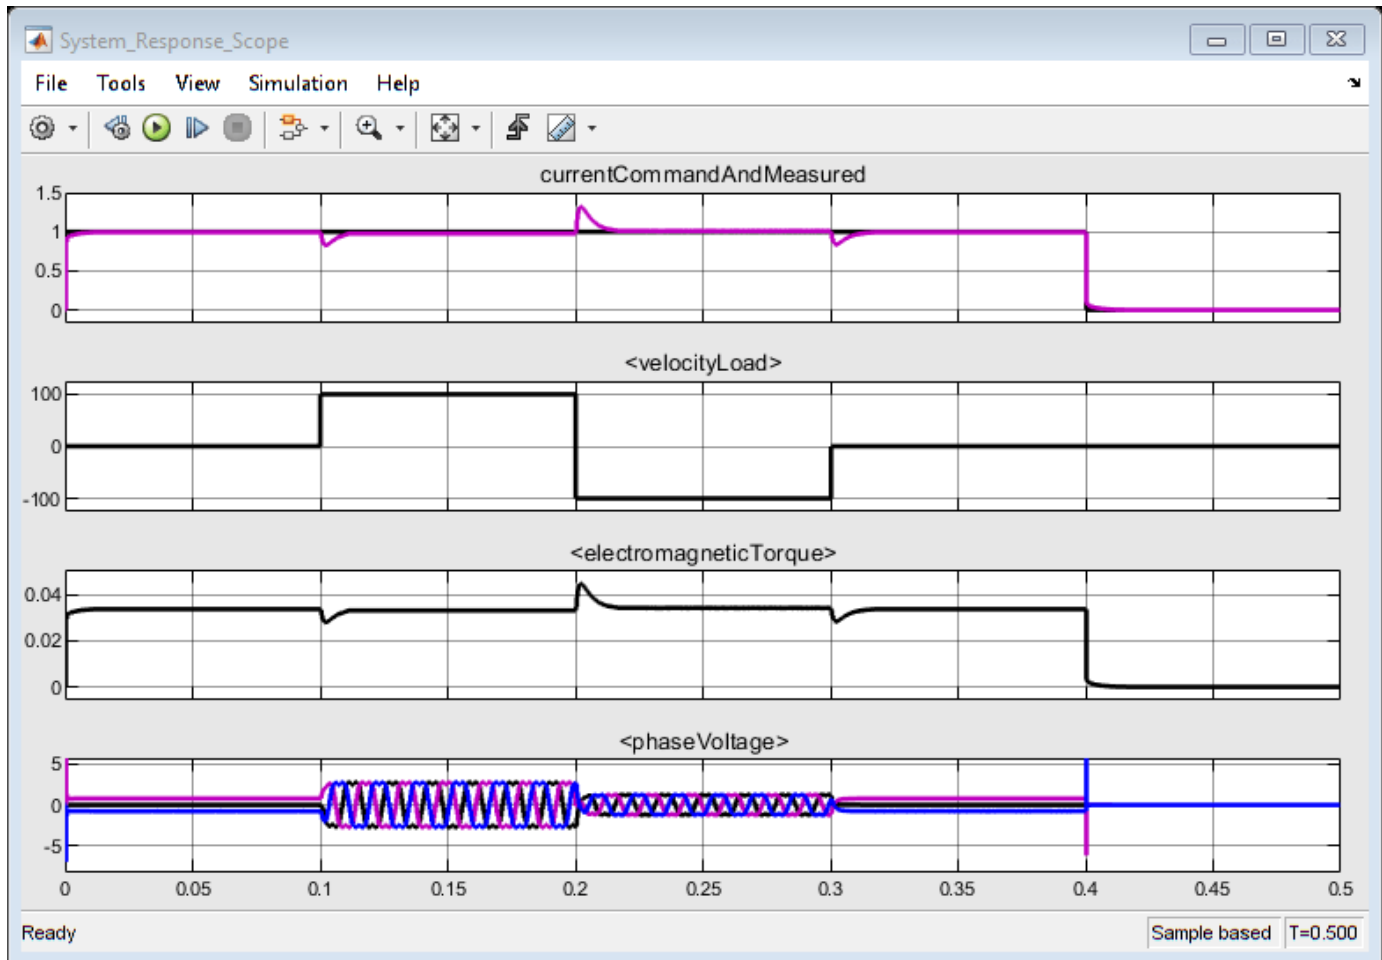

```

```

% set half-precision floating-point model in the testbench
set_param('hdlcoderFocCurrentTestBench/Controller', 'ModelName', 'hdlcoderFocCurrentFloatHalfHdl');

set_param('hdlcoderFocCurrentTestBench', 'IgnoredZcDiagnostic', 'none');
sim('hdlcoderFocCurrentTestBench')
set_param('hdlcoderFocCurrentTestBench', 'IgnoredZcDiagnostic', 'warn');
end

```

You can generate HDL code and view the generated code for the controller.

```

hdlset_param('hdlcoderFocCurrentFloatHalfHdl', 'FloatingPointTargetConfiguration', hdlcoder.createFloatingPointTargetConfiguration('float'));
makehdl('hdlcoderFocCurrentFloatHalfHdl/FOC_Current_Control');

```

You can refer to documentation for full native floating-point capabilities available in HDL Coder. See link in the “Getting Started with HDL Coder Native Floating-Point Support” on page 14-92.

Design Model by Using HDL Coder Native Floating Point and Intel Hard Floating Point

This example shows how to create a model design that uses both HDL Coder™ native floating-point (NFP) and Intel® hard floating-point (HFP) IP. Using the NFP and HFP blocks together in a mixed design offers better FPGA resource utilizations. For complex models, this mixed design allows you to have bigger design into the FPGA fabric.

Generate HDL Code for Model with NFP Library

1. Set the synthesis tool path by using the function `hdlsetuptoolpath`. For this example, use Intel Quartus Pro as your synthesis tool. To set up tools in your environment, run the `hdlsetuptoolpath` command using the synthesis tool path on your computer. For example, the function `quartuspath` returns the Intel Quartus Pro synthesis tool path.

```
hdlsetuptoolpath('ToolName', 'Intel Quartus Pro', 'ToolPath', quartuspropath);
```

Prepending following Intel Quartus Pro path(s) to the system path:
B:\share\apps\HDLTools\Altera\21.3-mw-0_pro\Windows\quartus\bin64

2. Open the Simulink® model `hdlcoder_mixed_nfp_hfp`. The model consists of a Tanh, Multiply, and Add block. The input data type is single.

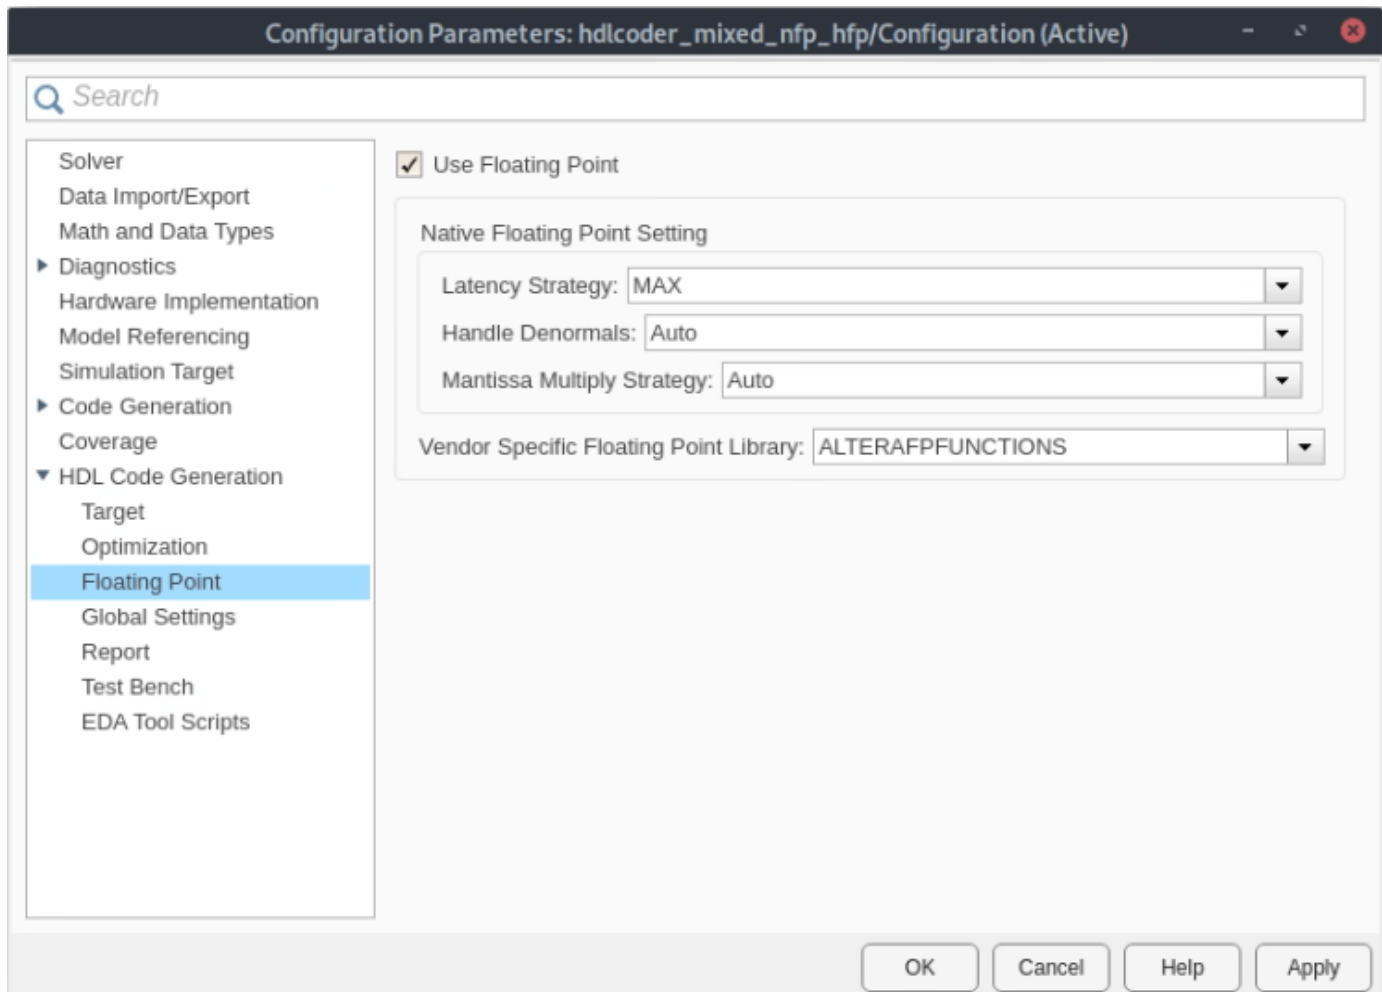

```
open_system('hdlcoder_mixed_nfp_hfp.slx');
```

3. Open the Configuration Parameters dialog box. In the **HDL Code Generation > Target** pane, set **Synthesis Tool** to Intel Quartus Pro, set **Family** to Arria 10, and set **Device** to 10AS016C3U19E2LG.

4. In the **Floating Point** pane, select **Use Floating Point** to map the design to the native floating-point library. To map the design to a vendor-specific floating point library, set the **Vendor Specific Floating Point Library** to the library that aligns with your target hardware. In this example, the **Vendor Specific Floating Point Library** is set to ALTERAFPFUNCTIONS.

Click **OK** to save the changes.

5. To compile and simulate the generated code with QuestaSim, at the command line, set the Altera simulation library path by using the `hdlsetup_param` function. In this example, that path is saved in variable `alterasimulationlibpath`. For example, the simulation path can be `C:\HDLTools\Altera\Questa_SimLibs\15.1\`.

```
hdlset_param('hdlcoder_mixed_nfp_hfp', 'SimulationLibPath', alterasimulationlibpath);
```

6. Generate HDL code for the DUT subsystem, `hdlcoder_mixed_nfp_hfp/DUT`, by using the `makehdl` function.

```
makehdl('hdlcoder_mixed_nfp_hfp/DUT')
```

```

### HDL TestBench generation complete.

```

7. After makehdl runs, the **HDL Code** pane opens and displays the VHDL code for the components of the model. The generated DUT.vhd file shows the trigonometric function component tanh maps to a native floating-point component, and the Multiply and Add components map to hard floating-point components.

8. Open the generated model file gm_hdlcoder_mixed_nfp_hfp.slx. The blocks that map to native floating-point components are light blue and display NFP on the block mask. The blocks that map to the vendor-specific floating point components are cyan and have initials associated with the specified vendor library on the block mask. In this example, the blocks that map to vendor-specific floating point IP from the ALTERAFPFUNCTIONS library display the initials ALT. The Tanh block maps to a native floating-point component and the Multiply and Add blocks map to hard floating-point components.

HDL Coder adds matching delays to balance the added latency from the floating-point operator blocks. Double-click each floating-point block to see the latency added for each. For more information on latency with floating-point operators, see “Latency Considerations with Native Floating Point” on page 14-109.

9. The `makehdl` function generates the `DUT_compile.do` file that contains these commands to compile generated HDL files.

- `vlib work`
- `vmap -c`
- `vmap -c -modelsimini /mathworks/devel/src/commercial/HDLTools/Altera/Questa_SimLibs/18.1_20.2/modelsim.ini`

- vcom nfp_tanh_single.vhd
- vcom DUT.vhd
- vcom DUT_tb_pkg.vhd
- vcom DUT_tb.vhd

11. The `makehdltb` function generates the `DUT_tb_sim.do` file that contains these commands for simulation when using the ModelSim® software.

- onbreak resume
- onerror resume
- vsim -t lps -L lpm -L altera_mf -voptargs=+acc work.DUT_tb
- add wave sim:/DUT_tb/u_DUT/clock
- add wave sim:/DUT_tb/u_DUT/reset
- add wave sim:/DUT_tb/u_DUT/clock_enable
- add wave sim:/DUT_tb/u_DUT/In1
- add wave sim:/DUT_tb/u_DUT/In2
- add wave sim:/DUT_tb/u_DUT/In3
- add wave sim:/DUT_tb/u_DUT/ce_out
- add wave sim:/DUT_tb/u_DUT/Out1
- add wave sim:/DUT_tb/Out1_ref
- run -all

Verify Functionality by Using ModelSim Simulation

Open ModelSim and navigate to the folder containing the DO files.

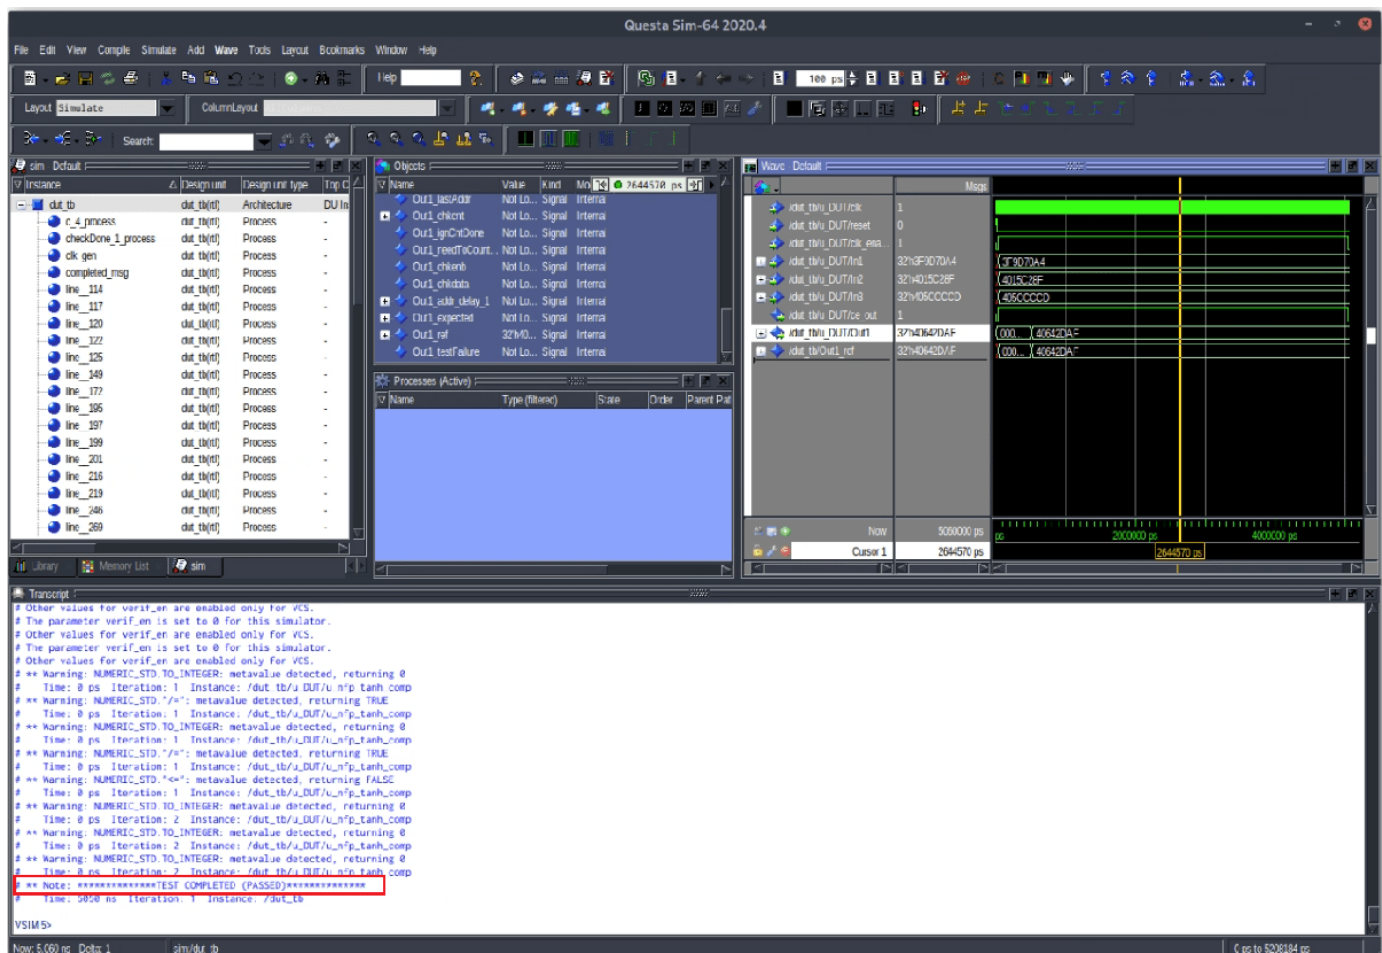

Run the DO files in this order:

do DUT_compile.do

do DUT_tb_compile.do

do DUT_tb_sim.do

This figure shows the ModelSim simulation with the a message at the end of the log to indicate that the tests passed.

Design Synthesis in Intel Quartus Pro

To perform design synthesis of the mixed NFP and HFP design in Intel Quartus Pro software, follow these steps:

1. Open Intel Quartus Pro and create a project.
2. Add the generated HDL files to the Quartus project, including the top module DUT and the other supporting files.
3. Set DUT as top module in the Quartus project.

4. Perform design synthesis by following the Intel Quartus Pro workflow.

Verify the Generated Code from Native Floating-Point

In this section...

- “Specify the Tolerance Strategy” on page 14-138
- “Verify the Generated Code with HDL Test Bench” on page 14-139
- “Verify the Generated Code with Cosimulation” on page 14-139
- “Limitation” on page 14-141

HDL Coder native floating-point technology can generate target-independent HDL code from your floating-point design. You can synthesize your floating-point design on any generic FPGA or ASIC. Floating-point designs have better precision, higher dynamic range, and a shorter development cycle than fixed-point designs. If your design has complex math and trigonometric operations, use native floating-point technology.

When representing infinitely real numbers with a finite number of bits, there can be rounding errors with the correct rounding range of values that the IEEE-754 standard specifies. To measure the rounding errors, you can specify the floating-point tolerance check based on `relative error` or `ulp error`. For more information about these rounding errors, see “Relative Accuracy and ULP Considerations” on page 14-97.

Specify the Tolerance Strategy

Before generating the testbench, specify the floating-point tolerance check for verifying the generated code.

To specify the tolerance check in the Configuration Parameters dialog box:

- 1 In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears.
- 2 Click **Settings**. In the **HDL Code Generation > Testbench** pane, for **Floating point tolerance check based on**, specify `relative error` or `ulp error`.

Test bench data file name postfix:

Test bench reference postfix:

Use file I/O to read/write test bench data:

Ignore output data checking (number of samples):

Floating point tolerance check based on:

- ulp error
- relative error
- ulp error

Tolerance Value:

Simulation library path:

- 3 Enter the **Tolerance Value** and click **Apply**. If you choose `relative error`, the default is a tolerance value of `1e-07`. If you choose `ulp error`, the default tolerance value is zero. To learn more, see “Numeric Considerations for Native Floating-Point” on page 14-96.

To specify the tolerance strategy at the command-line, use:

- 1 Specify the floating point tolerance check setting by using `FPToleranceStrategy`.

```
% check for floating-point tolerance based on relative error
hdlset_param('sfir_single', 'FPToleranceStrategy', 'Relative');
```

```
% check for floating-point tolerance based on the ULP error
hdlset_param('sfir_single', 'FPToleranceStrategy', 'ULP');
```

- 2 Based on the `FPToleranceStrategy` setting, enter the tolerance value by using `FPToleranceValue`.

```
% if using relative error, enter custom tolerance value
hdlset_param('FP_test_16a', 'FPToleranceValue', 1e-06);
```

```
% if using ULP error, enter tolerance value greater
% than or equal to 1
hdlset_param('FP_test_16a', 'FPToleranceValue', 1);
```

Verify the Generated Code with HDL Test Bench

To generate an HDL test bench for verifying the generated code:

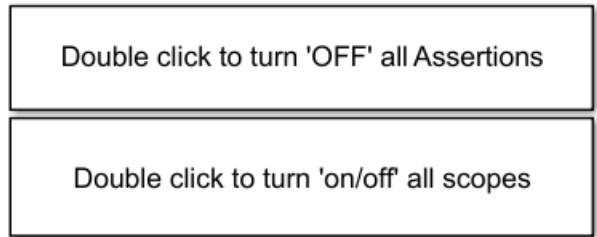

- 1 In the Configuration Parameters dialog box, on the **HDL Code Generation > Test Bench** pane, in the Test Bench Generation Output section, select **HDL test bench**.
- 2 In the Configuration section, make sure that **Use file I/O to read/write test bench data** is enabled. To generate a test bench that uses constants instead of file I/O, clear **Use file I/O to read/write test bench data**.
- 3 Click **Apply**, and then click **Generate Test Bench**.

To learn more about how HDL test bench generation works, see “Test Bench Generation” on page 6-5.

Verify the Generated Code with Cosimulation

To generate a cosimulation model for verifying the generated code:

- 1 In the Configuration Parameters dialog box, on the **HDL Code Generation > Test Bench** pane, for **Cosimulation model for use with**, select the cosimulation tool.
- 2 Click **Apply**, and then click **Generate Test Bench**.
- 3 After test bench generation, save the cosimulation model. In the model, double-click the Compare subsystem.

- 4 If you double-click the Assert_Out1 block, the block parameters show the **Tolerance Value** that you specify.
- 5 To look inside the Assert_Out1 block, click the mask. If you specify the floating-point tolerance check based on `ulp` error, the model shows a ULPChecker block.

The ULPChecker has a MATLAB Function block that shows how HDL Coder accounts for the ULP error when checking for numerical accuracy.

If you specify the floating-point tolerance check based on `relative` error, the model shows a `RelErrCheck` block.

RelerrCheck has a MATLAB Function block that shows how HDL Coder accounts for the relative error when checking for numerical accuracy.

- 6 In the Simulink Editor for the model, start simulation. At the end of cosimulation, check the compare: Out1 scope.

The scope compares the difference between the result signal from the cosimulation block and the reference signal from the DUT.

See also “Generate a Cosimulation Model” on page 32-42.

Limitation

When verifying the generated code, constructs that use IEEE standards prior to VHDL-2008 are not supported with native floating-point.

Simulink Blocks Supported by Using Native Floating Point

In this section...

“HDL Floating Point Operations Library” on page 14-142

“Supported Simulink Blocks in Math Operations Library” on page 14-143

“Supported Functions in Math Function Block” on page 14-144

“Supported Simulink Blocks in Other Libraries” on page 14-144

“Simulink Block Restrictions” on page 14-146

HDL Coder native floating point can generate target-independent HDL code from your floating-point design. You can synthesize your floating-point design on any generic FPGA or ASIC. Floating-point designs have better precision, higher dynamic range, and a shorter development cycle than fixed-point designs. If your design has complex math and trigonometric operations, use native floating-point technology.

HDL Coder supports several Simulink blocks, including math and trigonometric blocks by using native floating-point technology.

HDL Floating Point Operations Library

In the **HDL Floating Point Operations** library, HDL Coder supports blocks that have single and double data types in the Native Floating Point mode. For certain blocks, such as Discrete-Time Integrator and Discrete PID Controller, use zero latency strategy. These blocks contain inherent feedback loops and using a non-value for the latency strategy can result in the code generator not allocating delays. For more information, see “Allocate Sufficient Delays for Floating-Point Operations” on page 14-79.

When you use half types, these blocks are supported in Native Floating Point mode.

- Add
- Bus to Vector
- Divide
- Dot Product
- Float Typecast
- Gain
- Logical Operator
- Multiply-Add
- Probe
- Product
- Product of Elements
- Reciprocal
- Relational Operator
- Subtract
- Sum of Elements
- Signal Conversion

- Terminator
- Transpose
- Unary Minus

Supported Simulink Blocks in Math Operations Library

In the Math Operations library, these blocks are supported for HDL code generation:

Block Name	Supported by Half Data Types	Supported by Single Data Types	Supported by Double Data types	Complex Data Support	Remarks
Abs	No	Yes	Yes	Yes	Not Applicable
Add	Yes	Yes	Yes	Yes	Not applicable
Assignment	No	Yes	Yes	Yes	Not applicable
Bias	No	Yes	Yes	Yes	Not applicable
Complex to Real-Imag	No	Yes	Yes	Yes	Not applicable
Divide	Yes	Yes	Yes	No	Not applicable
Dot Product	Yes	Yes	Yes	No	Not applicable
Gain	Yes	Yes	Yes	Yes	Not applicable
MinMax	No	Yes	Yes	No	Not applicable
Multiply-Add	Yes	Yes	Yes	Yes	Not applicable
Product	Yes	Yes	Yes	Yes	If you configure the block to perform matrix multiplication by setting the Multiplication block parameter to Matrix(*) , the DotProductStrategy must be set to Fully Parallel .
Product of Elements	Yes	Yes	Yes	Yes	Not applicable
Real-Imag to Complex	No	Yes	Yes	No	Not applicable
Reciprocal Sqrt	No	Yes	Yes	No	Not applicable
Reshape	Yes	Yes	Yes	Yes	Not applicable
Sqrt	No	Yes	Yes	No	Not applicable
Subtract	Yes	Yes	Yes	Yes	Not applicable
Sum	Yes	Yes	Yes	Yes	Not applicable
Sum of Elements	Yes	Yes	Yes	Yes	Not applicable
Trigonometric Function	No	Yes	No	No	Not applicable
Unary Minus	Yes	Yes	Yes	Yes	Not applicable

Block Name	Supported by Half Data Types	Supported by Single Data Types	Supported by Double Data types	Complex Data Support	Remarks
Vector Concatenate, Matrix Concatenate	Yes	Yes	Yes	Yes	Not applicable

Supported Functions in Math Function Block

In the Math Function block, these functions are supported for HDL code generation:

Math Functions	Supported Floating-Point Datatypes			Complex Data Support
	Half	Single	Double	
exp	No	Yes	No	No
log	No	Yes	Yes	No
10 ^u	No	Yes	No	No
log10	No	Yes	No	No
magnitude ²	No	Yes	Yes	Yes
square	No	Yes	No	Yes
pow	No	Yes	No	No

Model-Wide Utilities	Blocks in this library are not supported.	All blocks are supported.	All blocks are supported.
Ports & Subsystems	Enable, reset, input, and output ports, model references, and subsystem blocks are supported.	Enable, reset, input, and output ports, model references, and subsystem blocks are supported.	Enable, reset, input, and output ports, model references, and subsystem blocks are supported.

Block Library	Supported by Half Data Types	Supported by Single Data Types	Supported by Double Data Types
Signal Attributes	Supported blocks include: <ul style="list-style-type: none"> • Data Type Conversion • Data Type Duplicate • Rate Transition • Signal Specification • Signal Conversion • Bus to Vector • Probe 	All blocks are supported.	All blocks are supported.
Signal Routing	All blocks are supported.	All blocks are supported.	All blocks are supported.
Sources	The supported blocks include Inport, Constant, and Ground blocks.	The supported blocks include Inport, Constant, and Ground blocks.	The supported blocks include Inport, Constant, and Ground blocks.
Sinks	All blocks are supported.	All blocks are supported.	All blocks are supported.
User-Defined Functions	MATLAB Function blocks are supported.	MATLAB Function blocks are supported.	MATLAB Function blocks are supported.

Simulink Block Restrictions

In native floating-point mode, the code generator does not support these blocks or block architectures:

- Biquad Filter.
- Sum of Elements with complex input types.
- MATLAB System blocks.
- Dot Product in complex mode with **Architecture** as Tree or Linear.
- Discrete FIR Filter with **Architecture** other than Fully Parallel.
- Dead Zone and Dead Zone Dynamic.
- Polar to Cartesian.
- For the Data Type Conversion block:
 - Stored Integer (SI) mode for **Input and output to have equal** setting is not supported.
 - The **Saturate on integer overflow** check box must be left cleared.

Synthesis Benchmark of Common Native Floating Point Operators

This example shows how to access and generate synthesis benchmarks for common native floating-point operators with Xilinx® Vivado® and Intel® Quartus® tool.

Access Generated Synthesis Results from a MAT File

Perform synthesis and timing analysis on common operators with Xilinx Vivado and Intel Quartus tool. These operators include basic math operators such as addition and subtraction, as well as more complex operators such as log, sin, cos, and atan. In this example, you configure the Simulink® models used for synthesis with native floating-point mode in single precision with different latency strategies. The strategies include maximum, minimum, zero, and custom latency values from zero to the maximum latency of the floating-point operator.

In this example, you use benchmarking data that has already been generated for the `hdl_nfp_single_ops_benchmark` model. The benchmarking data is in the `hdlcoder_synthesis_benchmark` MAT file. The MAT file contains the data for subsystems whose names start with `op_`. Each subsystem corresponds to a device under test (DUT).

Open the Simulink model.

```
addpath(fullfile(matlabroot, 'toolbox', 'hdlcoder', 'hdlcoder', 'hdlutils', 'hdlBenchMarking'))
open_system('hdl_nfp_single_ops_benchmark')
```

To generate the synthesis result from the MAT file:

1. Make a copy of the Simulink model in a directory for which you have write permission.
2. Run the runBenchmarkNFPSingle function by running these commands.

```
addpath(fullfile(matlabroot, 'toolbox', 'hdlcoder', 'hdlcoder', 'hdlutils', 'hdlBenchMarking'))
Results = runBenchmarkNFPSingle;
```

Generating synthesis benchmarks with the `hdl_nfp_single_ops_benchmark` model takes several days to finish benchmarking.

To view the MAT file that contains synthesis results.

```
load('hdlcoder_synthesis_benchmark.mat')
NFPSynthesisResults
```

```
NFPSynthesisResults =
    struct with fields:
        Vivado: [1x1 struct]
        Quartus: [1x1 struct]
```

The MAT file contains a structure named `NFPSynthesisResults`, which has two fields. The `Vivado` field contains the synthesis results of the Xilinx Vivado. The `Quartus` field contains the synthesis results of the Intel Quartus. View synthesis results of Vivado tool.

```
NFPSynthesisResults.Vivado
```

```
ans =
    struct with fields:
        HardwareDetails: [1x1 struct]
        MaxLatency: [82x13 table]
        MinLatency: [82x13 table]
        ZeroLatency: [82x13 table]
        TargetFrequency: 500
        CustomLatency: [369x13 table]
```

`NFPSynthesisResults.Vivado` and `NFPSynthesisResults.Quartus` contains these fields:

- `HardwareDetails` - Structure containing tool and device information
- `MaxLatency` - Table of synthesis results using the MAX latency strategy
- `MinLatency` - Table of synthesis results using the MIN latency strategy
- `ZeroLatency` - Table of synthesis results using the ZERO latency strategy
- `TargetFrequency` - Target frequency in MHz
- `CustomLatency` - Table of synthesis results using the latency values from zero to the maximum latency

The `NFPSynthesisResults.Vivado.CustomLatency` and `NFPSynthesisResults.Quartus.CustomLatency` contains list of performance and resource utilization of the floating-point operators for latency values from zero to max latency. View the complete list of performance and resource utilization results for Xilinx Vivado:

```
NFPSynthesisResults.Vivado.CustomLatency
```

```
ans =
```

Generate Synthesis Results

To generate synthesis results for other Simulink models or different settings, you can pass input arguments to the `runBenchmarkNFPSingle` function. Specify name-value arguments, where name is the argument name and value is the corresponding value.

- **ModelName** - Simulink model name, specified as a character vector. The default value is `hdl_nfp_single_ops_benchmark`. The name of the subsystems in a model must start with `op_`.
- **TargetFrequency** - Target frequency in MHz. The default value is 500 MHz.
- **HardwareTool** - Hardware applications for generating results, specified as a cell array of character vectors. The default value is `{'Vivado','Quartus'}`.
- **LatencyStrategy** - Latency strategy, specified as a cell array of character vectors. The default value is `{'Min','Max','Zero','Custom'}`.
- **VivadoHardwareDetails** or **QuartusHardwareDetails** - Hardware details, specified as a structure containing these five fields:

Tool - Synthesis tool name, specified as character vector.

ChipFamily - Chip family, specified as character vector.

DeviceName - Device name, specified as character vector.

PackageName - Package name, specified as character vector.

SpeedValue - Hardware speed, specified as character vector.

For example, set the hardware details for Xilinx Vivado and Altera Quartus II.

```
vivado_hardware_details.Tool = 'Xilinx Vivado';
vivado_hardware_details.ChipFamily = 'Virtex7';
vivado_hardware_details.DeviceName = 'xc7v2000t';
vivado_hardware_details.PackageName = 'fhg1761';
vivado_hardware_details.SpeedValue = '-2';
vivado_hardware_details =
```

struct with fields:

```
Tool: 'Xilinx Vivado'
ChipFamily: 'Virtex7'
DeviceName: 'xc7v2000t'
PackageName: 'fhg1761'
SpeedValue: '-2'
```

```
quartus_hardware_details.Tool = 'Altera QUARTUS II';
quartus_hardware_details.ChipFamily = 'Stratix V';
quartus_hardware_details.DeviceName = '5SGSMD4E1H29C1';
quartus_hardware_details.PackageName = '';
quartus_hardware_details.SpeedValue = '';
quartus_hardware_details =
```

struct with fields:

```
Tool: 'Altera QUARTUS II'
ChipFamily: 'Stratix V'
DeviceName: '5SGSMD4E1H29C1'
PackageName: ''
SpeedValue: ''
```

Call the `runNFPBenchmarkResults` function for the specified hardware.

```
runNFPBenchmarkResults = runBenchmarkNFPSingle('ModelName','myModel',...
                                              'TargetFrequency',500,...
                                              'VivadoHardwareDetails', vivado_hardware_details,
                                              'QuartusHardwareDetails', quartus_hardware_details,
                                              'HardwareTool',{'Vivado','Quartus'},...
                                              'LatencyStrategy',{'Min','Max','Zero','Custom'});
```

Customize Synthesis Results

Generating synthesis benchmarks with the `hdl_nfp_single_ops_benchmark` model takes several days to finish benchmarking. To generate benchmarks for only a subset of the operators, make a copy of the model and delete any DUTs for which you do not require data.

To generate benchmark synthesis results with your own model using the `runBenchmarkNFPSingle` function, ensure that:

- Each DUT or subsystem name starts with `op_`.
- For custom latency benchmarking, each DUT name contains characters required to get the list of operators that support custom latency. Please see `purgeDutList` function in `runBenchmarkNFPSingle_Vivado` and `runBenchmarkNFPSingle_Quartus`. To view the list of blocks that supports custom latency, see “Latency Values of Floating-Point Operators” on page 14-103.

Supported Data Types

HDL Coder supports the following subset of MATLAB data types.

Types	Supported Data Types	Restrictions
Integer	<ul style="list-style-type: none"> uint8, uint16, uint32, uint64 int8, int16, int32, int64 	In Simulink, MATLAB Function block ports must use numeric types <code>sfix64</code> or <code>ufix64</code> for 64-bit data.
Real	<ul style="list-style-type: none"> double single 	<p>HDL code generated with <code>double</code> or <code>single</code> data types can be used for simulation, but is not synthesizable.</p> <p>When you have floating-point data types, to generate synthesizable HDL code, use:</p> <ul style="list-style-type: none"> HDL Coder native floating-point when you want to deploy the generated code on any generic ASIC or FPGA. To learn more, see “Getting Started with HDL Coder Native Floating-Point Support” on page 14-92. FPGA floating-point target libraries when you want to map the Simulink model to an Intel or Xilinx FPGA. To learn more, see “Generate HDL Code for Vendor-Specific FPGA Floating-Point Target Libraries” on page 36-20.
Character	<code>char</code>	
Logical	<code>logical</code>	
Fixed point	<ul style="list-style-type: none"> Scaled (binary point only) fixed-point numbers Custom integers (zero binary point) 	<p>Fixed-point numbers with slope (not equal to 1.0) and bias (not equal to 0.0) are not supported.</p> <p>Maximum word size for fixed-point numbers is 128 bits.</p>
Vectors	<ul style="list-style-type: none"> unordered {N} row {1, N} column {N, 1} 	<p>The maximum number of vector elements allowed is 2^{32}.</p> <p>Before a variable is subscripted, it must be fully defined.</p>

Types	Supported Data Types	Restrictions
Matrices	{N, M}	<p>Matrices are supported in the body of the design algorithm and as inputs to the top-level design function.</p> <p>Matrices are not supported with the following HDL workflows:</p> <ul style="list-style-type: none"> • Cosimulation model generation • FPGA-in-the-Loop • IP Core Generation
Structures	struct	<p>Arrays of structures are not supported.</p> <p>For the FPGA Turnkey and IP Core Generation workflows, structures are supported in the body of the design algorithm, but are not supported as inputs to the top-level design function.</p>
Enumerations	enumeration	<p>If your target language is Verilog, all enumeration member names must be unique within the design.</p> <p>Enumerations at the top-level DUT ports are not supported with the following workflows or verification methods:</p> <ul style="list-style-type: none"> • IP Core Generation workflow • FPGA Turnkey workflow • FPGA-in-the-Loop • HDL Cosimulation

Unsupported Data Types

The following data types are not supported:

- Cell array
- Inf

Scope for Variables

Global variables are not supported for HDL code generation.

Import Verilog Code and Generate Simulink Model

In this section...

“HDL Import” on page 14-162
“HDL Import Requirements” on page 14-162
“Import HDL Code” on page 14-162
“Model Location” on page 14-163
“Errors and Warnings” on page 14-163
“Limitations of Verilog HDL Import” on page 14-164

To import synthesizable HDL code into the Simulink modeling environment, use HDL import. HDL import parses the input HDL file and generates a Simulink model. The model is a block diagram environment that visually represents the HDL code in terms of functionality and behavior. By importing the HDL code into Simulink, you can verify the functionality of the HDL code by compiling and running simulation on the model in a model-based simulation environment. You can also debug internal signals by logging the signals as test points.

HDL Import

Roundtrip code generation with HDL import is not recommended. Do not use HDL import to import the HDL code that was previously generated from a Simulink model by using the HDL Coder software. The Simulink model that you create is typically at a higher abstraction level. The model generated by HDL import might be at a lower abstraction level. The HDL code you generate from this model might not be usable for production code.

To generate production HDL code, develop your algorithm by using Simulink blocks, MATLAB code, or Stateflow charts. Then, use HDL Coder to generate code.

HDL Import Requirements

To generate a Simulink model, make sure that the HDL file you import:

- Is free of syntax errors.
- Is synthesizable.
- Uses supported Verilog constructs for the import.

Import HDL Code

To import the HDL code, in the MATLAB Command Window, run the `importhdl` function. The function parses the HDL input file that you specified and generates the corresponding Simulink model, and provides a link to open the model.

For example, consider a Verilog code of a comparator,

```
// File Name: comparator.v
// This module implements a simple comparator module

`define value 12
module comparator (clk, rst, a, b);
```

```

input clk, rst;
input [1:0] a;
output reg [1:0] b;

parameter d = 2'b11;

always@(posedge clk) begin
    if (rst)
        b <= 0;
    else if (a < `value)
        b <= a + 1;
end

endmodule

```

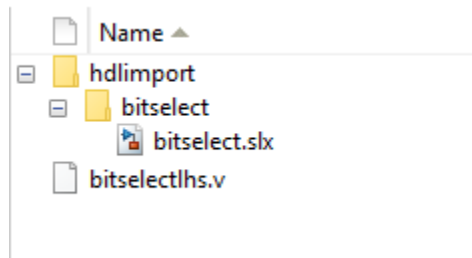

To generate a Simulink model, run the `importhdl` function and specify the HDL input file name. The file name can be specified in different ways, see input argument 'FileNames' in `importhdl`.

```
importhdl('comparator.v')
```

The constructs that you use in the HDL code can infer simple Simulink blocks, such as Add and Product, to RAM blocks, such as Dual Rate Dual Port RAM. For more examples that illustrate various Simulink models that are inferred, see `importhdl`.

Model Location

The generated Simulink model is named after the top module in the input HDL file that you specify. The model is saved in the `hdlimport/TopModule` path relative to the current working folder. For example, if you input a file named `bitselectlhs.v` to the `importhdl` function that has `bitselect` as the top module name, the generated Simulink model has the name `bitselect.slx`, and is saved in the `hdlimport/bitselect` path relative to the current folder.

Errors and Warnings

When you run the `importhdl` function, HDL import verifies the syntax and semantics of the input HDL code. Semantic verification checks for module instantiation constructs, unused ports in the module definition, the sensitivity list of an `always` block, and so on. If HDL import fails, `importhdl` provides an error message and a link to the file name and line number.

For example, consider this Verilog code for a `bitselect` module:

```
module bitselect(a,c);  
  
input [1:0] a;  
output [1:0] c;  
  
c[0] = 0;  
assign c[1] = a[2];  
  
endmodule
```

When you run the `importhdl` function, HDL import generates an error message:

```
Parser Error: bitselectlhs.v:6:2: error: Syntax Error near '['..
```

The error message indicates that there is a syntax error in line 6. To fix this error, change the syntax to an assignment statement.

```
assign c[0] = 0;
```

Limitations of Verilog HDL Import

HDL import does not support:

- Importing of VHDL files.
- On Mac Platforms.
- Importing of Verilog files from a read-only folder.
- Generation of the preprocessing files in a read-only file system that parses the HDL code you input to the `importhdl` function.
- Attribute instances and comments, which are ignored.
- (`#`)delay values, such as `#25`, which are ignored.
- Enumeration data types.
- More than one clock signal.
- Modules that are multirate.
- Recursive module instantiation.
- Multiport Switch inference with more than 1024 inputs. If you specify more than 1024 inputs to a Multiport Switch block that gets inferred from the Verilog code, Verilog import generates an error. The error is generated because the Simulink modeling environment does not support more than 1024 inputs for the block.
- ROM detection from the Verilog code.
- Importing of HDL files that use unsupported Verilog constructs. See “Supported Verilog Constructs for HDL Import” on page 14-166.
- Importing of HDL files that use unsupported dataflow modeling patterns. See “Unsupported Verilog Dataflow Patterns” on page 14-173.

"Other Constructs" on page 14-169

Use HDL import to import synthesizable HDL code into the Simulink modeling environment. To import the HDL code, use the `importhdl` function. Make sure that the constructs used in the HDL code are supported by HDL import.

These tables list the supported Verilog constructs that you can use when you import your HDL code. If you use an unsupported construct, HDL import generates an error when parsing the input HDL file. Verilog HDL import can sometimes ignore the presence of certain constructs in the HDL code. To learn more, see the **Comments** section of the table.

Module Definition and Instantiations

Verilog Constructs	Supported?	Comments
Library declaration	No	-
Configuration declaration	No	-
Module declaration	Yes	Multiple sample rates and multiple clock inputs are not supported.
Module parameter port list	Yes	-
Port declarations	Yes	INOUT ports are not supported.
Module without ports	No	-
Local parameter declaration	Yes	-
Parameter declaration	Yes	You can use parameters and constants that have a maximum size of 64 bits. By default, the parameter size is 32 bits.

Verilog Constructs	Supported?	Comments
Module instantiation	Yes	<ul style="list-style-type: none"> Unconnected ports in the instantiated modules are removed when importing the Verilog code. Recursive module instantiation is not supported. <p>Instead, if your top module instantiates modules that are defined in recursive subfolders, <code>importhdl</code> parses all Verilog files. For example, in this figure, <code>importhdl</code> can parse both <code>DFF_Instantiation.v</code> and <code>TFF_Instantiation.v</code> that are instantiated in <code>DFF.v</code>.</p> 

Data Types and Vectors

Verilog Constructs	Supported?	Comments
Net declaration (Wire, Supply0, Supply1)	Yes	-
Real declaration	No	-
String declaration	No	-
Vector declaration	Yes	-
Array support and array indexing	Yes	-
Reg declaration	Yes	-
Integer declaration	Yes	-

Identifiers and Comments

Verilog Constructs	Supported?	Comments
Lexical tokens (Whitespace, operator, comment)	Yes	-
Identifiers (Simple, Escaped)	Yes	-
System Functions (\$signed, \$unsigned)	Yes	-

Verilog Constructs	Supported?	Comments
Attribute instances	No	HDL import ignores these constructs.
Comments	No	HDL import ignores these constructs.
Numbers (Decimal, Binary, Hexadecimal, and Octal)	Yes	-
Compiler directives (<code>`define</code> , <code>`undef</code> , <code>`ifndef</code> , <code>`else if</code>)	Yes	-

Assignments

Verilog Constructs	Supported?	Comments
Continuous assignment	Yes	-
Blocking assignment	Yes	--
Nonblocking assignment	Yes	-
Procedural assignment (Always block)	Yes	-

Operators

Verilog Constructs	Supported?	Comments
Arithmetic operators (+, -, *, **, /, <<<, >>>)	Yes	-
Logical operators (<<, >>, !, &&, , ==, !=)	Yes	-
Relational operators (>, <, >=, <=, ==, !=)	Yes	-
Bitwise operators (~, &, , ^, ~^, ^~)	Yes	-
Unary operators (+, -)	Yes	Supported for restricted data types
Power operators	Yes	Supported for restricted data types
Conditional operators (?:)	Yes	-
Concatenation	Yes	-
Bit Select	Yes	-
Reduction operators (&, ~&, , ~ , ^, ~^, or ^~)	Yes	-

For an example that illustrates how to use different operators, see “Generate Simulink Model from Verilog Code for Various Operators”.

Conditional and Looping Statements

Verilog Constructs	Supported?	Comments
If-else statement	Yes	-
Conditional operators (?:)	Yes	-
For loop	Yes	-
Loop Generate construct	Yes	Supports loop generate constructs such as for-generate, case-generate, and if-generate constructs.
Conditional Generate construct	No	-
Generate region	No	-
Genvar declaration	No	-
Case statement	Yes	casex and casez statements are also supported.

Procedural Blocks and Events

Verilog Constructs	Supported?	Comments
Task declaration	No	-
Initial construct (ROM modeling)	No	-
Sequential blocks	Yes	-
Block declarations	Yes	-
Event control statements	Yes	-
Function calls	Yes	HDL import does not support recursive function calls.
Task enable	No	-
Always construct	Yes	-
Function declaration	Yes	-

Other Constructs

Verilog Constructs	Supported?	Comments
Gate instantiation	No	-
Specparams	No	-
Specify block	No	-
Semantic verification (unused ports, correct module instantiation)	Yes	-

Verilog Constructs	Supported?	Comments
Clock bundle identification	Yes	Multiple sample rates and multiple clock signals are not supported.
Register inference	Yes	-
Compare to Constant block inference	Yes	-
Gain block inference	Yes	-
RAM inference	Yes	-
ROM inference	No	-
Counter inference	No	-
Drive strength	No	-

Verilog Dataflow Modeling with HDL Import

In this section...

“Supported Verilog Dataflow Patterns” on page 14-171

“Unsupported Verilog Dataflow Patterns” on page 14-173

Use HDL import to import synthesizable HDL code into the Simulink modeling environment. To import the HDL code, use the `importhdl` function. Make sure that the constructs used in the HDL code are supported by HDL import.

These tables list the supported Verilog HDL dataflow patterns that you can use when importing the HDL code. If your code uses an unsupported dataflow model such as code that infers a latch, `importhdl` generates an error message with a link to the file name and line number. You can then update the code as illustrated in the preceding examples.

Supported Verilog Dataflow Patterns

Verilog Dataflow Model	Example Verilog Code
Blocking assignments in sequential always blocks and nonblocking assignments in combinational always blocks.	<p>For example, this Verilog code uses a sequential assignment for the variable <code>temp</code> in a combinational always block.</p> <pre> module dataconv(clk,a,b,c); input clk; integer i; input wire [7:0] a, b; output wire [7:0] c; reg [1:0] temp [0:7]; always @(*) begin for (i=0;i<=7;i=i+1) begin temp[i] <= a[i] + b[i]; end end assign c = temp; endmodule </pre>

Verilog Dataflow Model	Example Verilog Code
<p>Multiple assignments to the same signal. You can use partial and complete assignments to that signal.</p>	<p>This example shows the Verilog code that performs both partial assignment and complete assignment to the variable out1_reg.</p> <pre> module testPartialAndCompleteAssign (input [2:0] in1, in2, input cond, clk, output [2:0] out1); reg [2:0] out1_reg; always@(posedge clk) begin if(cond) begin out1_reg[0] = 1'b0; out1_reg[1] = 1'b0; out1_reg[2] = 1'b0; end else begin out_reg = in1 & in2; end end assign out1 = out1_reg; endmodule </pre>
<p>Multiple assignments to the same variable in the true or false path of a Switch block that gets inferred.</p>	<p>For example, this Verilog code performs multiple assignments to the variable out1 inside both the if and else conditions of the always block.</p> <pre> module testSwitchMuxing (input [2:0] in1, input cond, output reg [2:0] out1); always@(*) begin if (cond) begin out1 = in1; end else begin out1 = 3'd2; out1 = 3'd1; end end endmodule </pre>

Verilog Dataflow Model	Example Verilog Code
<p>Bit select, part select, and array indexing operations with signals. A Multiplex Switch is inferred when array indexing is performed at the RHS. An array indexing operation on the LHS is inferred as an Assign block.</p>	<p>For example, this Verilog code uses multiple assignments to the variable out1 in the false branch, which is not supported.</p> <pre> module ArrayIndexing (In1, In2, In3, In4, Sel1, Sel2, Out1, Out2, Out3); parameter w = 7; input [w:0] In1, In2, In3, In4; input [1:0] Sel1, Sel2; output [w:0] Out1; output [1:0] Out2; output Out3; wire [w:0] v[3:0]; assign v[0] = In1; assign v[1] = In2; assign v[2] = In3; assign v[3] = In4; //Array indexing with signal Sel1 assign Out1 = v[Sel1]; //Part select on array index with signal Sel2 assign Out2 = v[Sel2][7:2]; //Bit select on array index with signal Sel assign Out3 = v[Sel2][4]; endmodule </pre>

Unsupported Verilog Dataflow Patterns

These dataflow constructs are unsupported when you import the Verilog code. The *Description and Example Scenarios* column describes each scenario with an example and illustrates how you can avoid this scenario.

Verilog Dataflow Model	Description and Example Scenarios
Latch detection from the Verilog code.	<p>Presence of latches in the HDL code can result in algebraic loops in the generated Simulink model and result in model compilation failures. To avoid latch inference, specify all branches in if-else conditions and in case statements.</p> <p>For example, when you import this Verilog code, the if-condition is inferred as a Switch block. The block has a true path that is specified in the code. The output of the Switch block is fed back directly as input to the false path which results in an algebraic loop.</p> <pre> module testAlgebraicLoop(input cond, input [2:0] in1, output reg [2:0] out1); // causes latch inference - unsupported always@(*) begin if (cond) begin out1 = in1; end end // Specify else branch to avoid latch inference // always@(*) begin // if (cond) begin // out1 = in1; // end // else begin // out1 = in1 + 1; // end // end endmodule </pre>

Verilog Dataflow Model	Description and Example Scenarios
<p>Performing operations on clock, reset, or clock enable signals in the Verilog code.</p>	<p>When you define signals using names such as <code>clk</code>, <code>rst</code>, and <code>enb</code>, HDL import infers these signals to be the clock, global reset, and clock enable signals.</p> <p>For example, this Verilog code uses an explicit assignment with the clock signal <code>clk</code>. This construct is not supported.</p> <pre> module testOperationOnClkBundLe (input [2:0] in1, input clk, output reg [2:0] out1, output out2); reg [2:0] out1_reg; always@(posedge clk) begin out1_reg <= in1; end assign out2 = clk && 1'b1; endmodule </pre> <p>Make sure that your Verilog code does not perform operations on any of the signals in the clock bundle. In addition, for signals that you use for performing computations in your code, make sure that the signal names do not match any of the names that are inferred as clock, reset, or enable signals. See the <code>clockBundle</code> name-value pair of the <code>importhdl</code> function for possible signal names that are inferred as signals in the clock bundle.</p>

Verilog Dataflow Model	Description and Example Scenarios
<p>Sensitivity of clock or reset signal to different clock edges or different reset edges inside the same module.</p>	<p>You cannot have one <code>always</code> block with the clock signal sensitive to the positive edge and the other <code>always</code> block with the clock signal sensitive to the negative edge inside the same module.</p> <p>For example, this Verilog code uses the positive and negative edges of the same clock, which is not supported.</p> <pre> module testMultipleClockEdges (input [2:0] in1, in2, input clk, output [2:0] out1, out2); reg [2:0] out1_reg, out2_reg; /* clk sensitivity to posedge */ always@(posedge clk) begin out1_reg <= in1 && in2; end /* clk sensitivity to negedge */ always@(negedge clk) begin out2_reg <= in1 in2; end assign out1 = out1_reg; assign out2 = out2_reg; endmodule </pre> <p>Make sure that your Verilog code does not use both edges of the clock or reset signal in the same module. Use either <code>posedge</code> or <code>negedge</code> of the clock.</p>

Verilog Dataflow Model	Description and Example Scenarios
Realization of synchronous and asynchronous circuits inside the same module.	<p>You cannot use Verilog code realizes both circuits in the same module as shown in the code below. Use different modules for realization of asynchronous and synchronous circuits.</p> <pre>module testSynchronousAsynchronous (input [2:0] in1, in2, input clk, reset, output [2:0] out1, out2); reg [2:0] out1_reg, out2_reg; /* synchronous always block */ always@(posedge clk) begin out1_reg <= in1 && in2; end /* asynchronous always block */ always@(posedge clk or posedge reset) begin out2_reg <= in1 in2; end assign out1 = out1_reg; assign out2 = out2_reg; endmodule</pre>

Verilog Dataflow Model	Description and Example Scenarios
<p>Initialization of multiple RAMs that are inferred in the same module.</p>	<p>For example, this Verilog code infers <code>sample_store0</code> and <code>sample_store1</code> as RAMs. This construct is not supported. Separate each RAM inference into a single module.</p> <pre> module testMultipleRAMs (input [2:0] in1, in2, input clk, reset, output reg [2:0] read_data0, read_data1); reg [2:0] out1_reg, out2_reg; /* Inference of RAM sample_store0 */ always@(posedge clk) begin if (write_enable) begin sample_store0[write_address] <= write_data; end read_data0 = sample_store0[read_address0] end /* Inference of RAM sample_store1 */ always@(posedge clk) begin if (write_enable) begin sample_store1[write_address] <= write_data; end read_data1 = sample_store0[read_address1] end endmodule </pre>

Verilog Dataflow Model	Description and Example Scenarios
Usage of certain constructs when reading initial values from an <code>initial</code> block.	<p>An <code>initial</code> block does not support constructs other than assignment statements or for loops with assignments. The RHS of the assignment statement must use only</p> <p>For example, this Verilog code uses an if-else condition to assign a value to the variable <code>dout_a</code> and assigns a variable <code>write_data</code> to <code>dout_c</code>, which are not supported.</p> <pre> module testInitial (input cond, input [3:0] write_data output reg [3:0] dout_a, dout_b, doutc); parameter AddrWidth = 3; integer i; reg [3:0] ram [7:0]; initial begin for (i=0; i<=2**AddrWidth - 1; i=i+1) begin ram[i] = 0; end dout_b = 0; // if-else condition - not supported if (cond) begin dout_a = 0; end else begin dout_a = 4; end end // Variable assignment to RHS - not supported dout_a = write_data; // Use assignment statements instead for // dout_a and dout_c // dout_a = 4; // dout_c = 32; // end // end endmodule </pre>

Verilog Dataflow Model	Description and Example Scenarios
<p>All dimensions of signals not referenced at time of usage.</p>	<p>Use all dimensions of a signal in the input Verilog code. If you specify an additional dimension, it creates an indexed bit select.</p> <p>For example, this Verilog code creates an 8-bit variable temp. The assignment inside the always block generates an error because it does not use both dimensions of the variable.</p> <pre> module dataconv(clk,a,b,c); input clk; input wire [1:0] a, b; output wire [1:0] c; reg [7:0] temp_reg [1:0][1:0]; // temp_reg is not indexed // with both dimensions - not supported always @(posedge clk) begin temp_reg [0] <= a[0] + b[0]; temp_reg [1] <= a[1] + b[1]; end // Use both dimensions when indexing a variable // always @(posedge clk) begin // temp_reg [0][0] <= a[0] + b[0]; // temp_reg [0][1] <= a[0] + b[1]; // temp_reg [1][0] <= a[1] + b[0]; // temp_reg [1][1] <= a[1] + b[1]; // You can also perform indexed bit select // temp_reg [1][0][1] = 1'b0; // end assign c = temp_reg; endmodule </pre>

Simulate and Generate HDL Code for the Float Typecast Block

This example shows how you can use the Float Typecast block to extract the sign, exponent, and mantissa bits from a floating-point input, and then convert the bits back to a floating-point output after performing any computations.

Open the `hdlcoder_float_typecast_example` model.

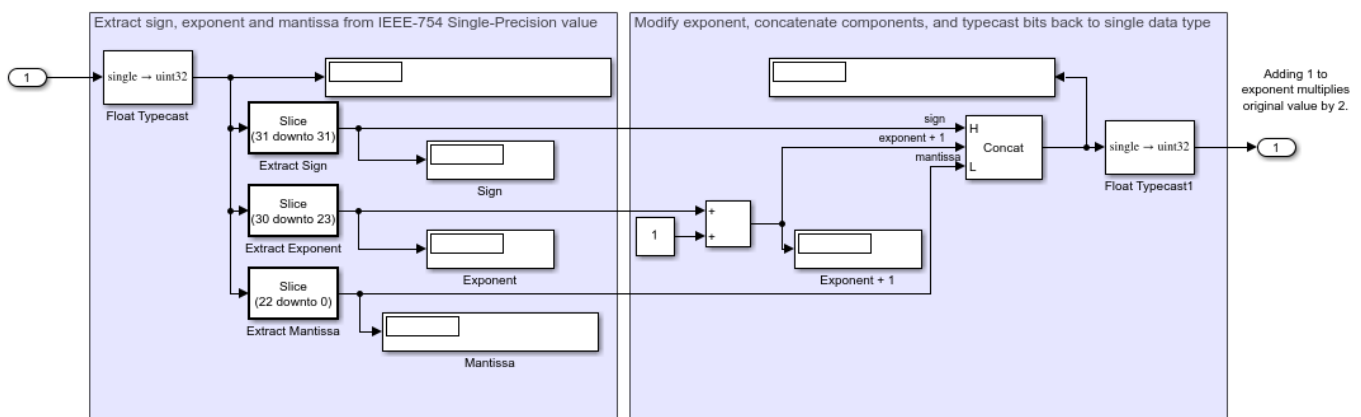

```
open_system('hdlcoder_float_typecast_example')
```

Copyright 2020 The MathWorks, Inc.

The model multiplies the floating-point input by two to produce the floating-point output. To multiply the input, the algorithm increments the exponent by one. Open the `HDL_DUT` subsystem.

```
open_system('hdlcoder_float_typecast_example/HDL_DUT')
```

The model is already configured for HDL compatibility by using the `hdlsetup` function. Simulate the model.

```
sim('hdlcoder_float_typecast_example')
open_system('hdlcoder_float_typecast_example')
```

Copyright 2020 The MathWorks, Inc.

Before you generate HDL code, enable the Native Floating Point mode.

```
nfpcfg = hdlcoder.createFloatingPointTargetConfig('NATIVEFLOATINGPOINT');
hdlset_param('hdlcoder_float_typecast_example', ...
    'FloatingPointTargetConfiguration', nfpcfg);
```

Generate HDL code for the `HDL_DUT` subsystem.

```
makehdl('hdlcoder_float_typecast_example')
```

Generate Simulink Model From CORDIC Atan2 Verilog Code

This example shows how you can import a file containing Verilog® code and generate the corresponding Simulink® model by using the `importhdl` function. `importhdl` imports and parses the specified Verilog files to generate the corresponding Simulink model. The Verilog code in this example contains a CORDIC atan2 algorithm.

CORDIC 2-Argument Arctangent (atan2) Verilog Design

This Verilog input file implements a CORDIC atan2 algorithm.

```
cordic_atan2_verilog_file = fullfile(matlabroot, 'toolbox', 'hdlcoder', 'hdlcoderdemos', 'cordic_
type(cordic_atan2_verilog_file);
```

```
`timescale 1ns / 1ps

This Verilog design contains various commonly used Verilog constructs such as:

- Continuous assignments
- Always blocks
- Conditional Statements
- Module instantiation
- Generate Constructs
- For Loop

Import HDL File Containing CORDIC atan2 Algorithm

To import the Verilog file, specify the file name as an argument to the `importhdl` function.

```

importhdl(cordic_atan2_verilog_file);

```

`importhdl` parses the input file and displays messages of the import process in the MATLAB™ Command Window. The import provides a link to the generated Simulink model `cordic_atan2.slx`. The generated model uses the same name as the top module in the input Verilog file.

Examine Generated Simulink Model

To open the generated Simulink model, click the link in the Command Window. The model is saved in the `hdlimport/cordic_atan2` path relative to the current folder. You can simulate the model and observe the simulation results.

```

open_system('hdlimport/cordic_atan2/cordic_atan2')
Simulink.BlockDiagram.arrangeSystem('cordic_atan2')
set_param('cordic_atan2', 'UnconnectedOutputMsg', 'None');
sim('hdlimport/cordic_atan2/cordic_atan2.slx');

```

Generated Module instances

The Verilog code instantiates 15 kernel modules by using the generate construct. In the generated Simulink model, 15 kernel modules are seen.

```
generate
  for (i = 0; i<15; i =i+1)
    begin
      Kernel cordic_iterator (.clk(clk),
                             .reset(reset),
                             .enable(enable),
                             .itr_num(i),
                             .x_in(x_k[i]),
                             .y_in(y_k[i]),
                             .z_in(z_k[i]),
                             .lut_constant(LUT[i]),
                             .x_out(x_k[i+1]),
                             .y_out(y_k[i+1]),
                             .z_out(z_k[i+1]));
    end
endgenerate
```

Simulink model for the Kernel Module

```

Programmable FIR Filter for FPGA

This example shows how to implement a programmable FIR filter for hardware. You can program the filter to the required response by loading the coefficients into internal registers using a memory-style interface.

This example implements a bank of two filters, each with a different response. Both filters have the same length and symmetry of coefficients. This pattern of coefficients allows the block to share multipliers for symmetric coefficients in the same way for both filters. The same filter hardware can be programmed with new coefficients to obtain a different filter response.

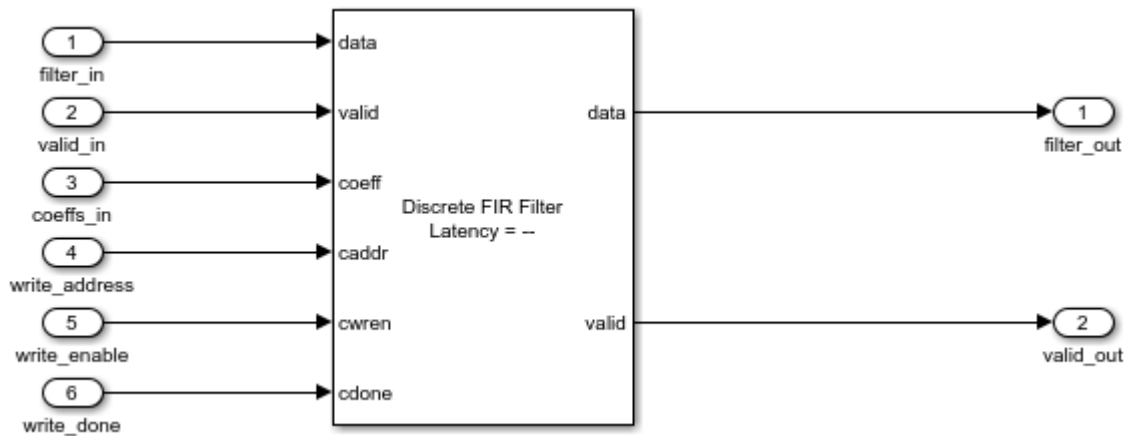

Model Programmable FIR Filter

This example implements two FIR filters, one with a lowpass response and the other with a highpass response. The coefficients are specified in the Model Properties>Callbacks>InitFcn function.

The Programmable FIR(Memory Interface) subsystem contains the Discrete FIR Filter block, with the **Coefficients source** parameter set to `Input port (Memory interface)`. This configuration enables a memory-style set of ports where you can write the coefficients into the filter. First, the Host Behavioral Model subsystem loads the lowpass coefficients to the FIR filter. The model delays the input chirp samples until the first coefficient write is complete. Then the Host Behavioral Model subsystem loads the highpass coefficients.

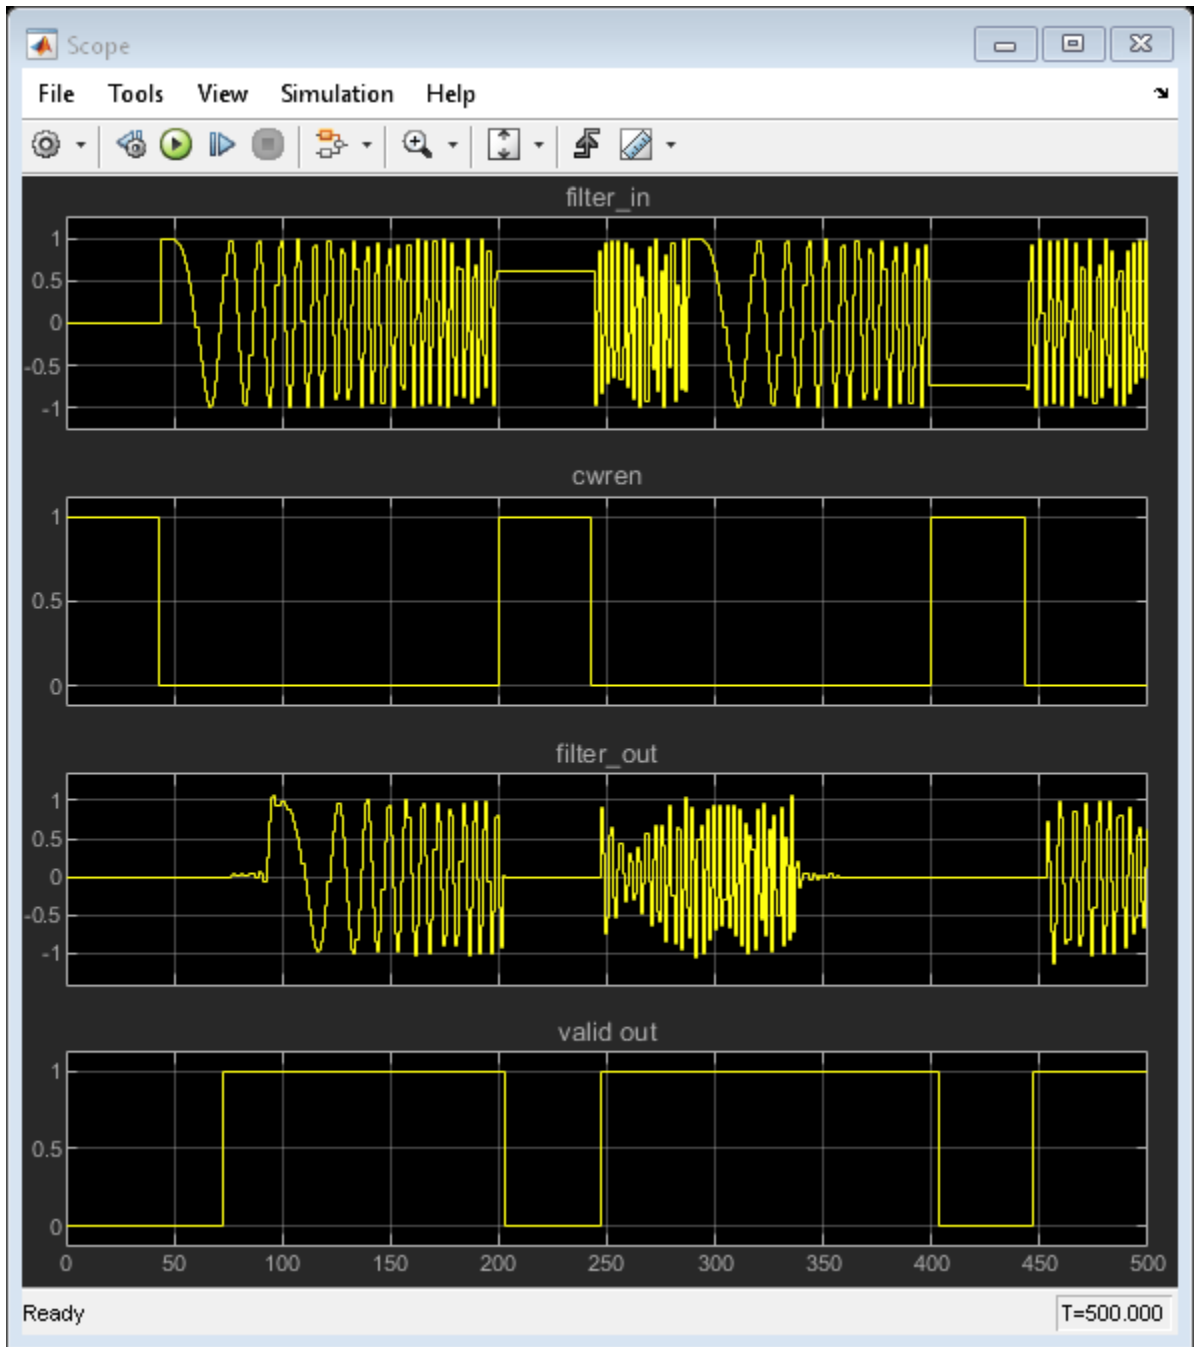

While you write coefficients to the filter, the filter ignores any input data samples. This model stops sending input data while the coefficients are changing. You can also use the output valid signal to determine when the output data is valid.

The Discrete FIR Filter block in this model is configured to use a fully parallel direct form systolic architecture. The block also supports using the memory-style programmable coefficients when the block uses the parallel transposed or serial architectures. The **Coefficient prototype** parameter is set to one of the coefficient vectors. This setting enables the block to optimize hardware resources based on the symmetry and position of zero-valued coefficients. When you specify a prototype, all input coefficient sets must match the prototype in symmetry and location of zero-valued coefficients. For more detail about how to use the prototype to optimize filter resources, see “Optimize Programmable FIR Filter Resources” (DSP HDL Toolbox).

Simulink Simulation Results

To view the input and output data and the signals of the coefficient interface, open the Scope and run the example model.

Using the Logic Analyzer

You can also view the signals from the model in the Logic Analyzer. The Logic Analyzer enables you to view multiple signals in one window and lets you find the transitions in the signals and measure the latency between signals.

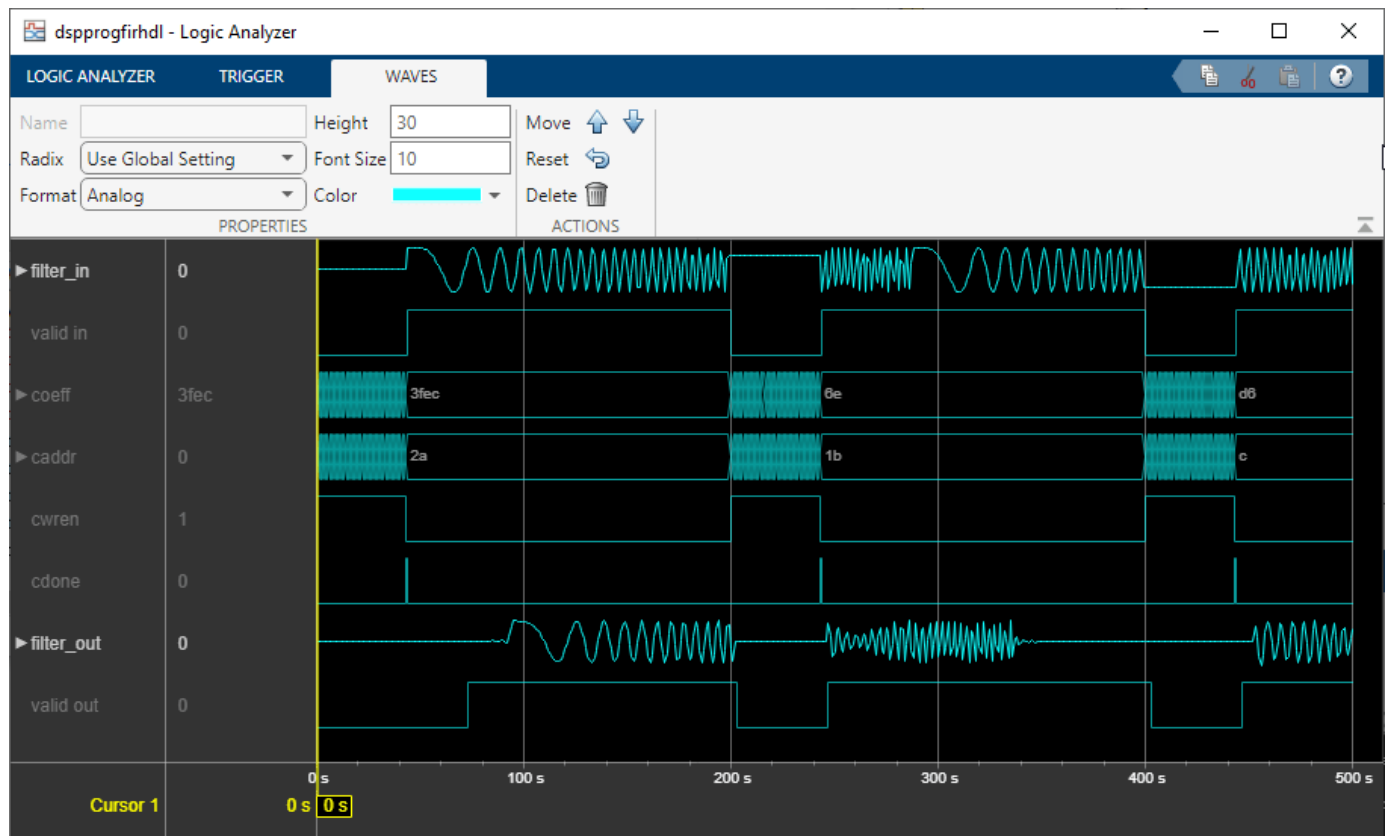

Launch the Logic Analyzer from the model's toolstrip.

The model already has some signals of interest (input coefficients, write address, write enable, write done, filter in, filter out, and valid signals) added to the Logic Analyzer for observation.

The Logic Analyzer display can also be controlled on a per-wave or per-divider basis. To modify an individual wave or divider, select a wave or divider and then click the **Waves** tab. A useful mode of visualization in the Logic Analyzer is the **Analog** format.

For more information, see Logic Analyzer (DSP System Toolbox).

Generate HDL Code and Test Bench

You must have an HDL Coder™ license to generate HDL code for this example model. Use this command to generate HDL code.

```
systemname = [modelName '/Programmable FIR(Memory Interface)'];
makehdl(systemname);
```

Use this command to generate a test bench that compares the results of an HDL simulation against the Simulink simulation behavior.

```
makehdltb(systemname);
```

Multichannel FIR Filter for FPGA

This example shows how to implement a discrete FIR filter with multiple input data streams for hardware.

In many DSP applications, multiple data streams are filtered by the same filter. The straightforward solution is to implement a separate filter for each channel. You can create a more area-efficient structure by sharing one filter implementation across multiple channels. The resulting hardware requires a faster clock rate compared to the clock rate used for a single channel filter.

Model Multichannel FIR Filter

```
modelName = 'dspmultichannelhdl';
open_system(modelName);
```

Launch HDL Dialog

Copyright 2012 The MathWorks, Inc.

The model contains a two-channel FIR filter. The input data vector includes two streams of sinusoidal signal with different frequencies. The input data streams are processed by a lowpass filter whose coefficients are specified by the Model Properties `InitFcn` Callback function.

Select a fully parallel architecture for the Discrete FIR Filter block, and enable resource sharing across multiple channels.

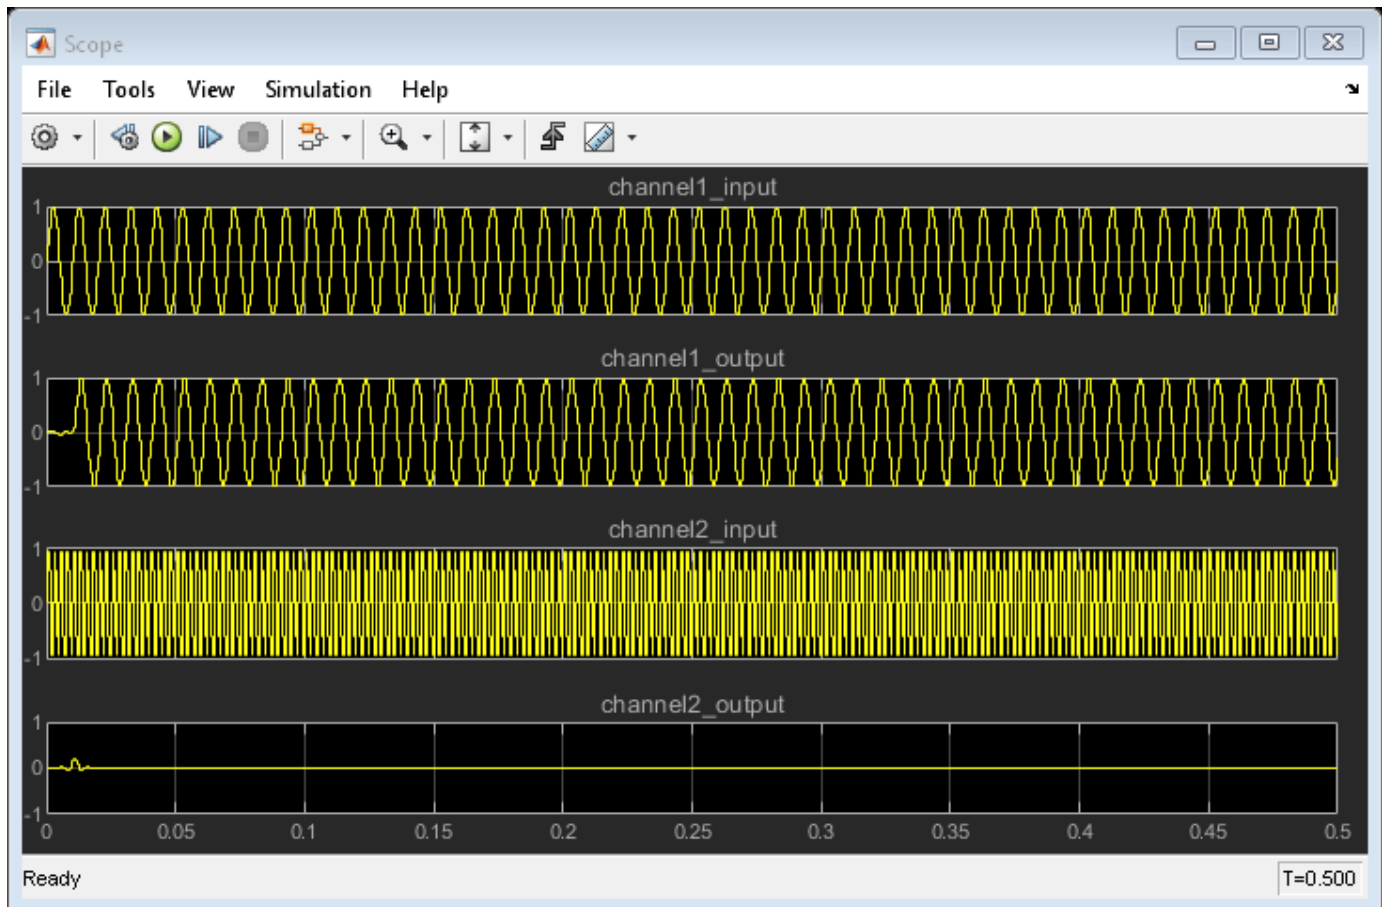

```
systemname = [modelName '/Multichannel FIR Filter'];
blockname = [systemname '/Discrete FIR Filter'];
set_param(blockname, 'FilterStructure', 'Direct form symmetric');
hdlset_param(blockname, 'Architecture', 'Fully Parallel');
hdlset_param(blockname, 'ChannelSharing', 'On');
```

You can alternatively specify these settings on the **HDL Block Properties** menu, which you access by right-clicking a block and selecting **HDL Code > HDL Block Properties**.

Simulation Results

Run the example model and open the scope to compare the two data streams.

```
sim(modelname);
open_system([modelname '/Scope']);
```

Generate HDL Code and Test Bench

You must have an HDL Coder™ license to generate HDL code for this example model. Use this command to generate HDL code for the Multichannel FIR Filter subsystem. Enable the resource use report.

```
makehdl(systemname, 'resource', 'on');
```

Use this command to generate a test bench that compares the HDL simulation results with the Simulink model results.

```
makehdltb(systemname);
```

Compare Resource Utilization

To compare resource use with and without sharing, you can disable sharing resources across channels and generate HDL code again, then compare the resource use reports.

```
hdlset_param(blockname, 'ChannelSharing', 'Off');  
makehdl(systemname, 'resource', 'on');
```

High-Throughput Channelizer for FPGA

This example shows how to implement a high-throughput, gigasamples-per-second (GSPS), channelizer for hardware by using a polyphase filter bank.

High speed signal processing is a requirement for applications such as radar, broadband wireless, and backhaul communication. Modern ADCs can sample signals at sample rates up to several GSPS, but the clock speeds for the fastest FPGA fall short of this sample rate. FPGAs typically run at hundreds of MHz. To perform GSPS processing on an FPGA, you can move from scalar processing to vector processing and process multiple samples in parallel at a much lower clock rate. Many modern FPGAs support the JESD204B standard interface, which accepts scalar input at a GHz clock rate and produces a vector of samples at a lower clock rate.

This example shows how to design a signal processing application that supports GSPS throughput. These Simulink® models assume that the input data is vectorized by using a JESD204B interface, and is available at a lower clock rate in the FPGA. The algorithm processes four samples at a time. Both models have a polyphase filter bank that consists of a filter and an FFT. The polyphase filter bank technique minimizes leakage and scalloping loss from the FFT. For more information about polyphase filter banks, see “High Resolution Spectral Analysis in MATLAB” (DSP System Toolbox).

The first part of the example uses the Channelizer (DSP HDL Toolbox) block from the DSP HDL Toolbox™ library, configured for a 12-tap filter. The Channelizer block uses the polyphase filter bank technique and automatically chooses data types, applies pipelining, and uses other optimizations for hardware performance and resource use. With this block, you can easily explore variations on your design.

The second part of the example implements a polyphase filter bank that has a 4-tap filter. This second part uses basic Simulink blocks. It shows the polyphase filter bank architecture, and the challenges of filter design for hardware, such as choosing data types and inserting pipeline stages.

Implement Channelizer with 12-Tap Filter

This model uses the Channelizer block, configured with a 12-tap filter, that results in good spectrum performance. Using the Channelizer block from the DSP HDL Toolbox library makes it easy to change design parameters such as coefficients, vector size, and FFT length. The block also automatically shares multipliers, calculates fixed-point data types, and pipelines the filter.

The model uses these workspace variables to configure the FFT and filter. The input vector size for this model is 4 samples. The model uses a 512-point FFT and a 12-tap filter for each band. The number of coefficients for the channelizer is 512 frequency bands times 12 taps per frequency band. Generate all the coefficients by using the `tf(h)` function.

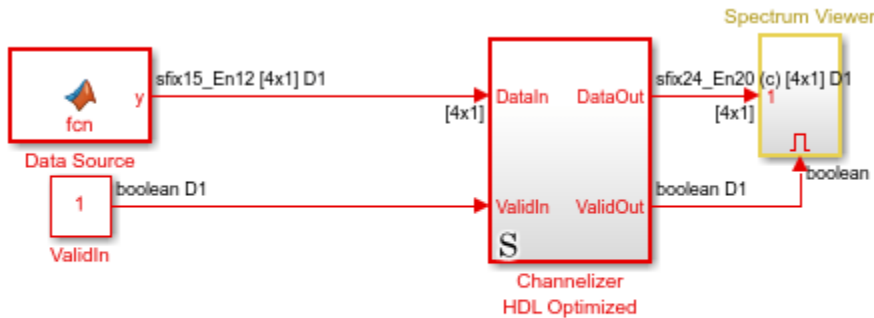

```
FFTLength = 512;
InVect = 4;
hc = dsp.Channelizer;
hc.NumTapsPerBand = 12;
hc.NumFrequencyBands = FFTLength;
hc.StopbandAttenuation = 60;
coef12Tap = tf(hc);
```

The input data consists of two sine waves, 200 kHz and 206.5 kHz. The frequencies are close to each other to illustrate the spectrum resolution of the channelizer.

The Channelizer HDL Optimized subsystem contains the Channelizer block and a synchronous State Control block that generates hardware-optimized code for the enable logic within the channelizer.

The block implements pipeline stages around the multipliers so that the logic fits into FPGA DSP blocks, and implements the coefficient banks inside the channelizer with ROM blocks. These hardware-friendly options are the default behavior for the DSP HDL Toolbox blocks.

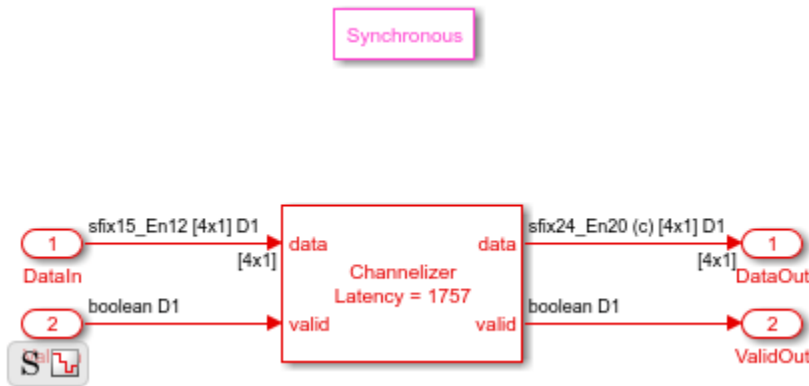

```
modelName = 'PolyphaseFilterBankHDLExample_HDLChannelizer';
open_system(modelName);
set_param(modelName, 'SimulationCommand', 'Update');
```

Copyright 2016-2021 The MathWorks, Inc.

This model diagram shows the Channelizer block inside the subsystem.

```
open_system([modelName, '/Channelizer HDL Optimized'])
```

The block has parameters to configure the filter coefficients, FFT length, and other settings that enable you to explore different hardware implementations of the algorithm.

View Simulation Results

To visualize the spectrum result, open the spectrum viewer and run the model.

```
open_system([modelName, '/Spectrum Viewer/Power Spectrum viewer (Channelizer_12tap)']);
sim(modelname);
```

The spectrum viewer shows that the 12-tap filter separates the spectrum of the two signals. Zoom in between 100 kHz and 300 kHz to see where the channelizer detects two peaks. Two peaks is the expected result because the input signal has two frequency components.

Generate HDL Code

You must have the HDL Coder™ product to generate HDL code for this example model. Use this command to generate HDL code.

```
makehdl([modelName, '/Channelizer HDL Optimized']);
```

Use this command to generate a test bench that compares the results of an HDL simulation against the Simulink simulation behavior.

```
makehdltb([modelName, '/Channelizer HDL Optimized']);
```

The design was synthesized for Xilinx Virtex 7 (xc7vx550t-ffg1158, speed grade 2). The design achieves a clock frequency of 361 MHz. At 4 samples per clock, this frequency results in 1.4 GSPS throughput.

The **Minimize clock enable** HDL code generation option is on in this model. The clock enable signal is a global signal, which is not recommended for high speed designs. In the model Configuration

Parameters, choose **HDL Code Generation, Global settings, Ports**, and then select **Minimize clock enable**. This option is supported when the model is single rate.

The FFT block uses 56 DSP blocks on the FPGA, and the filter uses 48 DSP blocks.

```
T = table(...
    categorical({'LUT'; 'LUT RAM'; 'FF'; 'BRAM'; 'DSP'}), ...
    [26641; 14585; 24816; 2; 104], ...
    'VariableNames',{'Resource','Usage'});

disp(T);
```

Resource	Usage

LUT RAM	14585
FF	24816
BRAM	2
DSP	104

Implement 4-Tap Polyphase Filter Bank

To show the internal implementation of a polyphase filter bank, the second example model implements a 512-point FFT by using the DSP HDL Toolbox FFT block and a 4-tap filter for each band by using basic Simulink blocks. The 4-tap filter has lower frequency resolution than the 12-tap filter in the first model, but it is easier to see the structure of the filter. These MATLAB variables configure the blocks in the model. Use the `dsp.Channelizer` (DSP System Toolbox) System object™ to generate the coefficients. The `polyphase` method of the channelizer object generates a 512-by-4 matrix. Each row represents the coefficients for one band. Cast the coefficients to fixed-point types that have the same word length as the input signal.

```
h = dsp.Channelizer;
h.NumTapsPerBand = 4;
h.NumFrequencyBands = FFTLength;
h.StopbandAttenuation = 60;
coef4Tap = fi(polyphase(h),1,15,14,'RoundingMethod','Convergent');
```

The algorithm requires 512 filters (one filter for each band). For a vector input of 4 samples, the model implements four parallel 4-tap filters. Each filter applies 128 sets of coefficients.

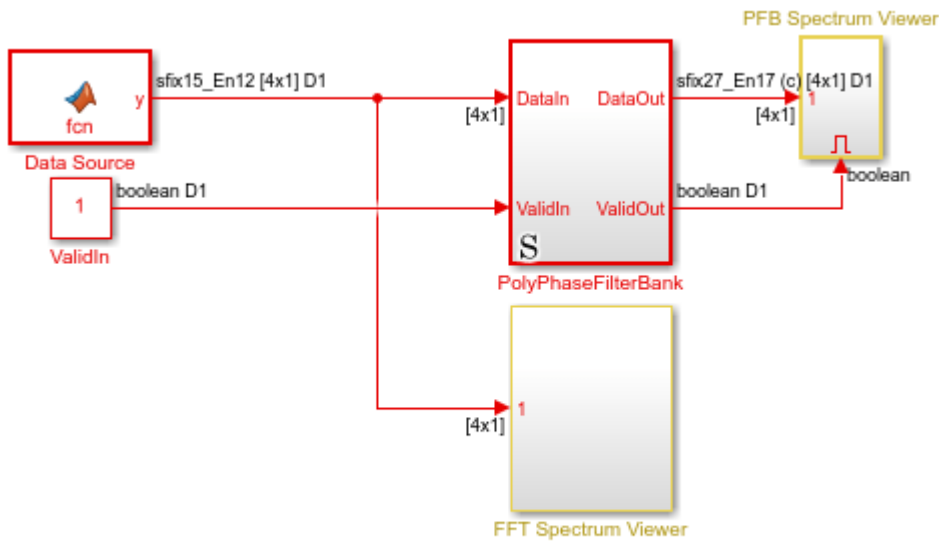

```
ReuseFactor = FFTLength/InVect;
```

These variables configure the model to pipeline the multipliers and the coefficient bank to fit the logic into DSP blocks on the FPGA. Using the DSP blocks enables synthesis to a higher clock rate.

```
Multiplication_Pipeline = 2;
CoefBank_Pipeline = 1;
```

The input data consists of two sine waves, 200 kHz and 250 kHz. These two frequencies are farther apart than the previous model because the smaller filter has lower spectrum performance. The input and output of the `PolyPhaseFilterBank` subsystem are 4-by-1 vectors.

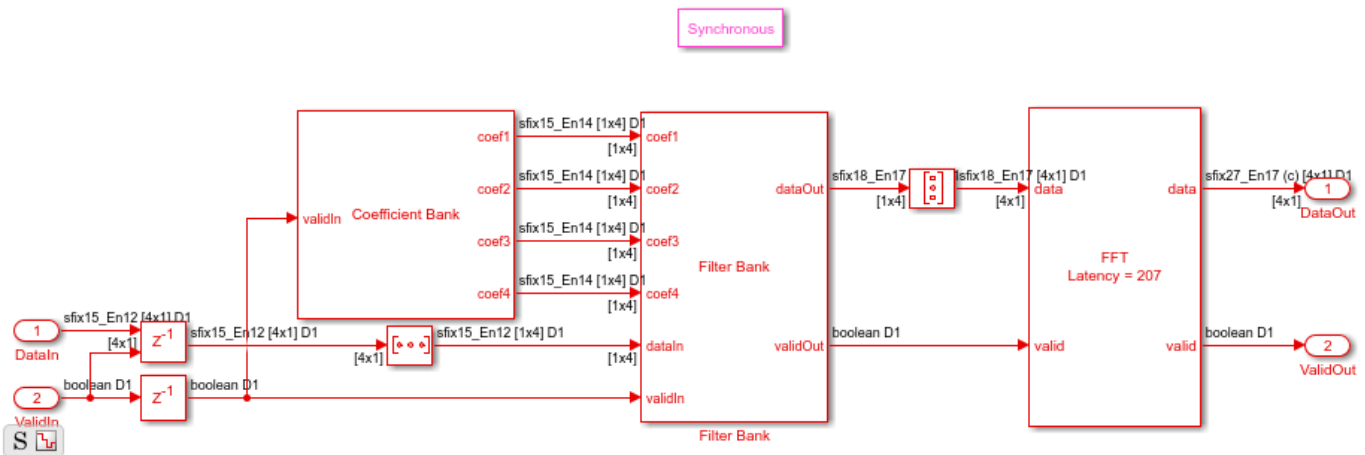

```
modelName = 'PolyphaseFilterBankHDLExample_4tap';
open_system(modelName);
set_param(modelName,'SimulationCommand','Update');
```

Copyright 2016-2021 The MathWorks, Inc.

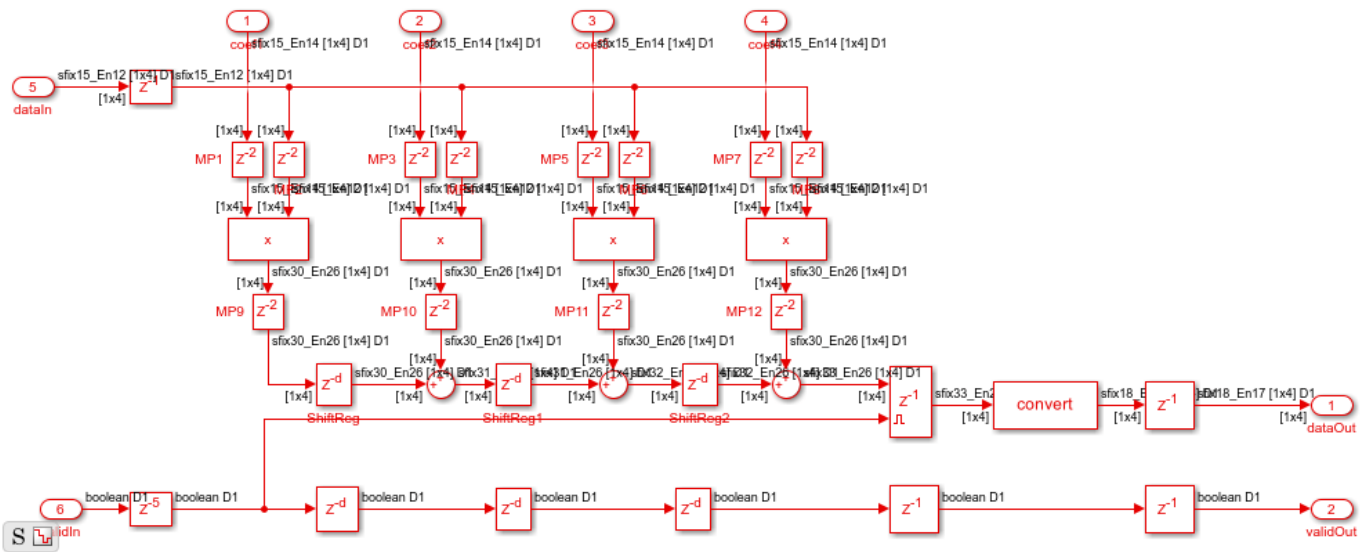

The PolyPhaseFilterBank subsystem contains the Coefficient Bank subsystem that rotates over the coefficient sets. The Filter Bank subsystem accepts vectors of coefficients and data and returns a vector of filtered data. The FFT block also accepts and returns a vector of 4 samples, and implements a hardware-optimized architecture.

```
open_system([modelName, '/PolyPhaseFilterBank'])
```

This model diagram shows the pipelined 4-tap filter implementation.

```
open_system([modelName, '/PolyPhaseFilterBank/Filter Bank'])
```

View Simulation Results

To visualize the result of the simulation, open the spectrum viewers and run the model.

```
open_system([modelName, '/FFT Spectrum Viewer/Power Spectrum viewer (FFT)']);
open_system([modelName, '/PFB Spectrum Viewer/Power Spectrum viewer (PFB)']);
sim(modelname);
```

The polyphase filter bank spectrum viewer shows the improvement in the power spectrum and minimization of frequency leakage and scalloping compared with using only an FFT. By comparing the two spectrums, and zooming in between 100 kHz and 300 kHz, you can see that the polyphase filter bank has fewer peaks over -40 dB than the classic FFT.

Considerations for Optimized Hardware

Data Type

Data word length affects both the accuracy of the result and the resources used in the hardware. This 4-tap filter uses full precision. With an input data type of `fixdt(1, 15, 13)`, the output is `fixdt(1, 18, 17)`. The absolute values of the filter coefficients are all smaller than 1, so the data does not grow after each multiplication operation. Each addition adds one bit to the data type. To keep the accuracy in the FFT, the data type grows one bit for each stage. This growth makes the twiddle factor multiplication larger at each stage. For many FPGAs, a multiplication size smaller than 18-by-18 is desirable. Because a 512-point FFT has 9 stages, the input of the FFT cannot be more than 11 bits. The first 8 binary digits of the maximum coefficient in this case are zero. Therefore, this example casts the coefficients to `fixdt(1, 7, 14)` instead of `fixdt(1, 15, 14)`. Also, the maximum value of the Datatype block output inside the polyphase filter bank has 7 leading zeros after the binary point, so the model casts the filter output to `fixdt(1, 11, 17)`. These adjustments keep the FFT internal multiplier size smaller than 18-by-18 and save hardware resources.

Design for Speed

The model uses these settings to enable the generated HDL code to synthesize to a faster clock rate.

- 1 Synchronous State Control block — Implements hardware-friendly enable logic for Delay blocks.

- 2 Minimize clock enable — Avoids implementing a global clock enable signal that could decrease the synthesized clock rate.
- 3 Use DSP block in FPGA — Maps multipliers into DSP blocks in the FPGA by including 2 delays before each multiplier and 2 delays after. These pipeline registers cannot have a reset signal. Set the reset type to none for each pipeline by right-clicking the Delay block and selecting **HDL Code > HDL Block Properties**, then setting **Reset Type** to None.
- 4 Use ROM in FPGA — Map the combinatorial logic inside the Coefficient MATLAB Function block (inside the Coefficient Bank subsystem) to a ROM by adding a register after the block. The delay length is set by CoefBank_PipeLine. Set the reset type for these delays to none.

Generate HDL Code

You must have the HDL Coder™ product to generate HDL code for this example model. Use this command to generate HDL code.

```
makehdl([modelName, 'PolyPhaseFilterBank']);
```

Use this command to generate a test bench that compares the results of an HDL simulation against the Simulink simulation behavior.

```
makehdltb([modelName, 'PolyPhaseFilterBank']);
```

When the design is synthesized for Xilinx® Virtex 7 (xc7vx550t-ffg1158, speed grade 2), the design achieves a clock frequency of 324 MHz (before place and route). At 4 samples per clock, this frequency results in 1.3 GSPS throughput.

The FFT block uses 56 DSP blocks in the FPGA, and the filter uses 16 DSP blocks.

```
T = table(...
    categorical({'LUT'; 'LUT RAM'; 'FF'; 'BRAM'; 'DSP'}), ...
    [14713; 3570; 21514; 2; 72], ...
    'VariableNames', {'Resource', 'Usage'});

disp(T);
```

Resource	Usage
LUT	14713
LUT RAM	3570
FF	21514
BRAM	2
DSP	72

Conclusion

The first part of the example shows how the Channelizer block from the DSP HDL Toolbox library makes it easy to implement an algorithm for hardware, and provides quick exploration of design options.

The second part of the example shows design considerations when implementing filters for hardware without using a hardware-optimized library block, such as choosing data types and inserting pipeline stages. When you use the library blocks from DSP HDL Toolbox, you do not have to consider these

factors yourself. The blocks implement hardware-optimized algorithms that are ready for HDL code generation and deployment to FPGAs or ASICs.

Implement Digital Downconverter for FPGA

This example shows how to design a digital downconverter (DDC) for radio communication applications such as LTE, and generate HDL code.

Introduction

DDCs are widely used in digital communication receivers to convert radio frequency (RF) or intermediate frequency (IF) signals to baseband. The DDC operation shifts the signal to a lower frequency and reduces its sampling rate to facilitate subsequent processing stages. The DDC in this example performs complex frequency translation followed by sample rate conversion using a four-stage filter chain. The example starts by designing the DDC with DSP System Toolbox™ functions in floating point. Then, each stage is converted to fixed point, and used in a Simulink® model that generates synthesizable HDL code. The example uses these two test signals to demonstrate and verify the DDC operation:

- A sinusoid that is modulated onto a 32 MHz IF carrier.
- An LTE downlink signal with a bandwidth of 1.4 MHz modulated onto a 32 MHz IF carrier.

The example compares the signal quality at the output of the floating-point DDC with the signal quality at the output of the fixed-point DDC.

Finally, the example presents an implementation of the filter chain for FPGAs, and synthesis results.

This example uses `DDCTestUtils`, a helper class that contains functions for generating stimulus and analyzing the DDC output. For more information, see the `DDCTestUtils.m` file.

DDC Structure

The DDC consists of a numerically controlled oscillator (NCO), mixer, and decimating filter chain. The filter chain consists of a cascade integrator-comb (CIC) decimator, CIC gain correction, a CIC compensation decimator (FIR), a halfband FIR decimator, and a final FIR decimator.

The overall response of the filter chain is equivalent to that of a single decimation filter with the same specification. However, splitting the filter into multiple decimation stages results in a more efficient design that uses fewer hardware resources.

The CIC decimator provides a large initial decimation factor, which enables subsequent filters to work at lower rates. The CIC compensation decimator improves the spectral response by compensating for the CIC droop while decimating by two. The halfband is an intermediate decimator, and the final decimator implements the precise F_{pass} and F_{stop} characteristics of the DDC. The lower sampling rates near the end of the chain mean the later filters can optimize resource use by sharing multipliers.

This figure shows a block diagram of the DDC.

The sample rate of the input to the DDC is 122.88 Msps, and the output sample rate is 1.92 Msps. These rates give an overall decimation factor of 64. LTE receivers use 1.92 Msps as the typical sampling rate for cell search and master information block (MIB) recovery. The DDC filters are designed to suit this application. The DDC is optimized to run at a clock rate of 122.88 MHz.

DDC Design

This section explains how to design the DDC using floating-point operations and filter-design functions in MATLAB®.

DDC Parameters

This example designs the DDC filter characteristics to meet these specifications for the given input sampling rate and carrier frequency.

```
FsIn = 122.88e6;    % Sampling rate of DDC input
FsOut = 1.92e6;    % Sampling rate of DDC output
Fc = 32e6;        % Carrier frequency
Fpass = 540e3;    % Passband frequency, equivalent to 36x15kHz LTE subcarriers
Fstop = 700e3;    % Stopband frequency
Ap = 0.1;        % Passband ripple
Ast = 60;        % Stopband attenuation
```

CIC Decimator

The first filter stage is a CIC decimator because of its ability to efficiently implement a large decimation factor. The response of a CIC filter is similar to a cascade of moving average filters, but a CIC filter uses no multiplication or division. As a result, the CIC filter has a large DC gain.

```
cicParams.DecimationFactor = 8;
cicParams.DifferentialDelay = 1;
cicParams.NumSections = 3;
cicParams.FsOut = FsIn/cicParams.DecimationFactor;

cicFilt = dsp.CICDecimator(cicParams.DecimationFactor, ...
    cicParams.DifferentialDelay,cicParams.NumSections) %#ok<*NOPTS>
cicGain = gain(cicFilt)
```

```
cicFilt =
```

```
    dsp.CICDecimator with properties:
```

```
    DecimationFactor: 8
```

```
DifferentialDelay: 1
  NumSections: 3
FixedPointDataType: 'Full precision'
```

```
cicGain =
    512
```

Because the CIC gain is a power of two, a hardware implementation can easily correct for the gain factor by using a shift operation. For analysis purposes, the example represents the gain correction in MATLAB with a one-tap `dsp.FIRFilter` System object™.

```
cicGainCorr = dsp.FIRFilter('Numerator',1/cicGain)
```

```
cicGainCorr =
```

```
  dsp.FIRFilter with properties:
    Structure: 'Direct form'
  NumeratorSource: 'Property'
    Numerator: 0.0020
  InitialConditions: 0
```

```
Use get to show all properties
```

Display the magnitude response of the CIC filter with and without gain correction by using `fvtool`. For analysis, combine the CIC filter and the gain correction filter into a `dsp.FilterCascade` System object. CIC filters use fixed-point arithmetic internally, so `fvtool` plots both the quantized and unquantized responses.

```
ddcPlots.cicDecim = fvtool(...
    cicFilt, ...
    dsp.FilterCascade(cicFilt,cicGainCorr), ...
    'Fs',[FsIn,FsIn]);
legend(ddcPlots.cicDecim, ...
    'CIC No Correction', ...
    'CIC With Gain Correction');
```

CIC Droop Compensation Filter

Because the magnitude response of the CIC filter has a significant *droop* within the passband region, the example uses a FIR-based droop compensation filter to flatten the passband response. The droop compensator has the same properties as the CIC decimator. This filter implements decimation by a factor of two, so you must also specify bandlimiting characteristics for the filter. Use the design function to return a filter System object with the specified characteristics.

```

compParams.R = 2; % CIC compensation decimation factor
compParams.Fpass = Fstop; % CIC compensation passband frequency
compParams.FsOut = cicParams.FsOut/compParams.R; % New sampling rate
compParams.Fstop = compParams.FsOut - Fstop; % CIC compensation stopband frequency
compParams.Ap = Ap; % Same passband ripple as overall filter
compParams.Ast = Ast; % Same stopband attenuation as overall filter

compSpec = fdesign.decimator(compParams.R,'ciccomp', ...
    cicParams.DifferentialDelay, ...
    cicParams.NumSections, ...
    cicParams.DecimationFactor, ...
    'Fp,Fst,Ap,Ast', ...
    compParams.Fpass,compParams.Fstop,compParams.Ap,compParams.Ast, ...
    cicParams.FsOut);
compFilt = design(compSpec,'SystemObject',true)

compFilt =

```

`dsp.FIRDecimator` with properties:

```
Main
DecimationFactor: 2
NumeratorSource: 'Property'
    Numerator: [-0.0398 -0.0126 0.2901 0.5258 0.2901 -0.0126 -0.0398]
    Structure: 'Direct form'
```

Use `get` to show all properties

Plot the combined response of the CIC filter (with gain correction) and droop compensation.

```
ddcPlots.cicComp = fvtool(...
    dsp.FilterCascade(cicFilt,cicGainCorr,compFilt), ...
    'Fs',FsIn,'Legend','off');
```

Halfband Decimator

The halfband filter provides efficient decimation by two. Halfband filters are efficient because approximately half of their coefficients are equal to zero, and those multipliers are excluded from the hardware implementation.

```
hbParams.FsOut = compParams.FsOut/2;
hbParams.TransitionWidth = hbParams.FsOut - 2*Fstop;
hbParams.StopbandAttenuation = Ast;
```

```
hbSpec = fdesign.decimator(2,'halfband',...
```

```

    'Tw,Ast', ...
    hbParams.TransitionWidth, ...
    hbParams.StopbandAttenuation, ...
    compParams.FsOut);
hbFilt = design(hbSpec,'SystemObject',true)

hbFilt =

    dsp.FIRDecimator with properties:

    Main
    DecimationFactor: 2
    NumeratorSource: 'Property'
        Numerator: [0.0089 0 -0.0565 0 0.2977 0.5000 0.2977 0 -0.0565 ... ]
        Structure: 'Direct form'

    Use get to show all properties

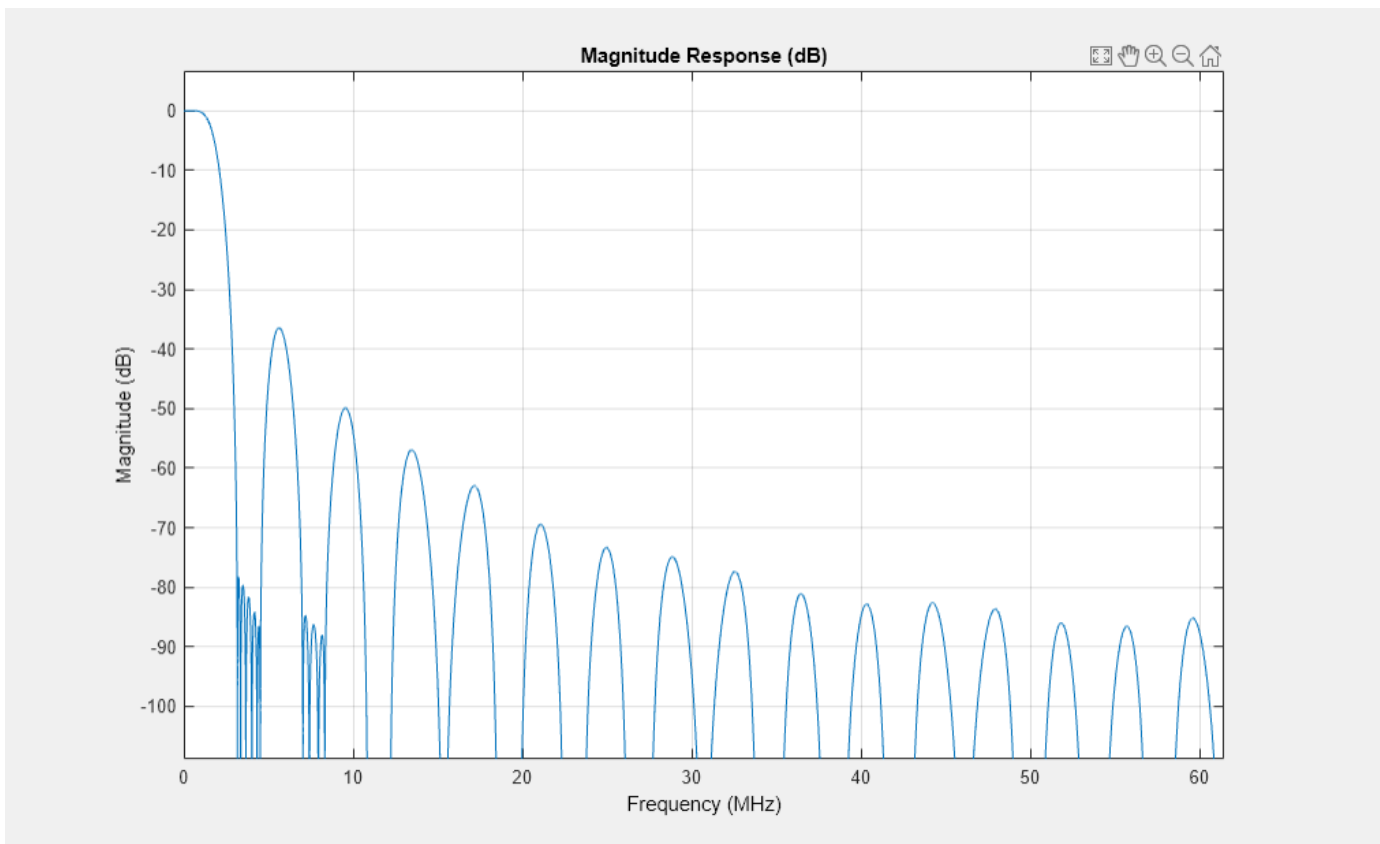

```

Plot the response of the DDC up to the halfband filter output.

```

ddcPlots.halfbandFIR = fvtool(...
    dsp.FilterCascade(cicFilt,cicGainCorr,compFilt,hbFilt), ...
    'Fs',FsIn,'Legend','off');

```

Final FIR Decimator

The final FIR implements the detailed passband and stopband characteristics of the DDC. This filter has more coefficients than the earlier FIR filters, but because it operates at a lower sampling rate it can use resource sharing for an efficient hardware implementation.

Add 3 dB of headroom to the stopband attenuation so that the DDC still meets the specification after fixed-point quantization. This value was found empirically by using `fvtool`.

```
finalSpec = fdesign.decimator(2,'lowpass', ...  
    'Fp,Fst,Ap,Ast',Fpass,Fstop,Ap,Ast+3,hbParams.FsOut);  
finalFilt = design(finalSpec,'equiripple','SystemObject',true)
```

```
finalFilt =
```

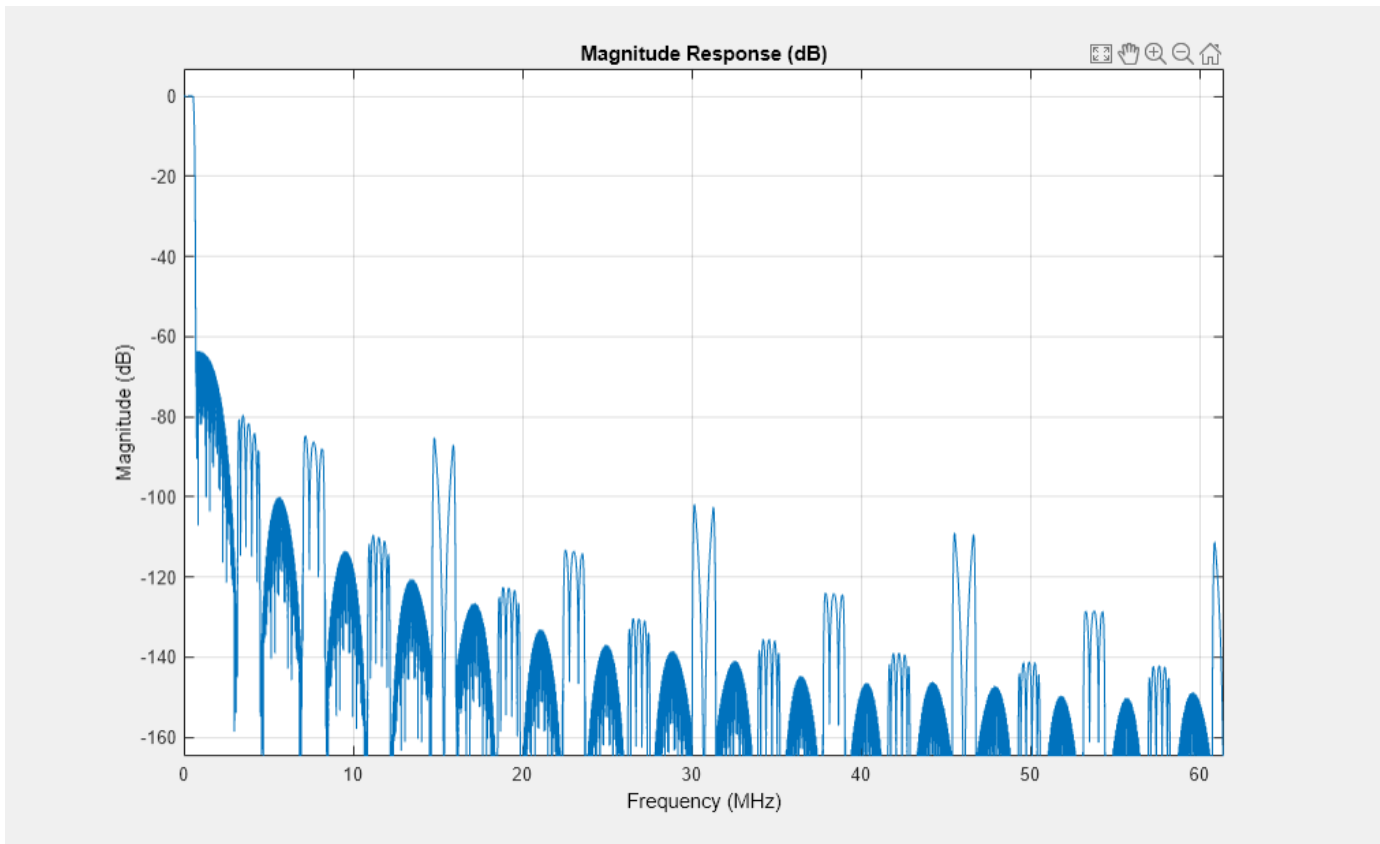

```
    dsp.FIRDecimator with properties:
```

```
    Main  
    DecimationFactor: 2  
    NumeratorSource: 'Property'  
        Numerator: [9.3365e-04 0.0013 9.3466e-04 -5.3189e-04 -0.0022 ... ]  
        Structure: 'Direct form'
```

```
Use get to show all properties
```

Visualize the overall magnitude response of the DDC.

```
ddcFilterChain = dsp.FilterCascade(cicFilt,cicGainCorr,compFilt,hbFilt,finalFilt);  
ddcPlots.overallResponse = fvtool(ddcFilterChain,'Fs',FsIn,'Legend','off');
```

Fixed-Point Conversion

The frequency response of the floating-point DDC filter chain now meets the specification. Next, quantize each filter stage to use fixed-point types and analyze them to confirm that the filter chain still meets the specification.

Filter Quantization

This example uses 16-bit coefficients, which are sufficient to meet the specification. Using fewer than 18 bits for the coefficients minimizes the number of DSP blocks that are required for an FPGA implementation. The input to the DDC filter chain is 16-bit data with 15 fractional bits. The filter outputs are 18-bit values, which provide extra headroom and precision in the intermediate signals.

For the CIC decimator, choosing the 'Minimum section word lengths' fixed-point data type option automatically optimizes the internal wordlengths based on the output wordlength and other CIC parameters.

```
cicFilt.FixedPointDataType = 'Minimum section word lengths';
cicFilt.OutputWordLength = 18;
```

Configure the fixed-point properties of the gain correction and FIR-based System objects. The object uses the default RoundingMethod and OverflowAction property values ('Floor' and 'Wrap' respectively).

```
% CIC Gain Correction
cicGainCorr.FullPrecisionOverride = false;
cicGainCorr.CoefficientsDataType = 'Custom';
```

```
cicGainCorr.CustomCoefficientsDataType = numerictype(fi(cicGainCorr.Numerator,1,16));
cicGainCorr.OutputDataType = 'Custom';
cicGainCorr.CustomOutputDataType = numerictype(1,18,16);

% CIC Droop Compensation
compFilt.FullPrecisionOverride = false;
compFilt.CoefficientsDataType = 'Custom';
compFilt.CustomCoefficientsDataType = numerictype([],16,15);
compFilt.ProductDataType = 'Full precision';
compFilt.AccumulatorDataType = 'Full precision';
compFilt.OutputDataType = 'Custom';
compFilt.CustomOutputDataType = numerictype([],18,16);

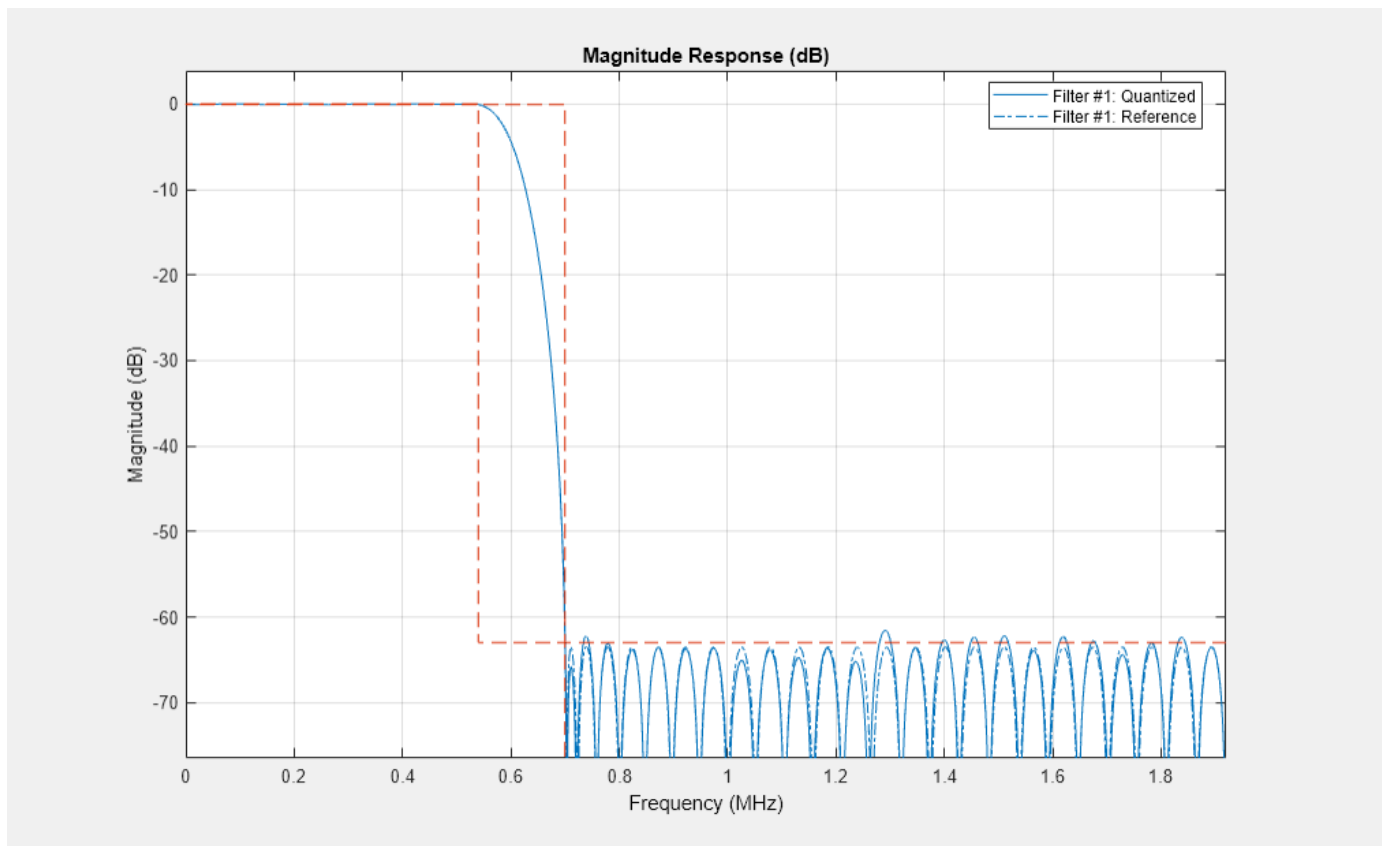

% Halfband
hbFilt.FullPrecisionOverride = false;
hbFilt.CoefficientsDataType = 'Custom';
hbFilt.CustomCoefficientsDataType = numerictype([],16,15);
hbFilt.ProductDataType = 'Full precision';
hbFilt.AccumulatorDataType = 'Full precision';
hbFilt.OutputDataType = 'Custom';
hbFilt.CustomOutputDataType = numerictype([],18,16);

% FIR
finalFilt.FullPrecisionOverride = false;
finalFilt.CoefficientsDataType = 'Custom';
finalFilt.CustomCoefficientsDataType = numerictype([],16,15);
finalFilt.ProductDataType = 'Full precision';
finalFilt.AccumulatorDataType = 'Full precision';
finalFilt.OutputDataType = 'Custom';
finalFilt.CustomOutputDataType = numerictype([],18,16);
```

Fixed-Point Analysis

Inspect the quantization effects with `fvtool`. You can analyze the filters individually or in a cascade. `fvtool` shows the quantized and unquantized (reference) responses overlaid. For example, this figure shows the effect of quantizing the final FIR filter stage.

```
ddcPlots.quantizedFIR = fvtool(finalFilt, ...
    'Fs',hbParams.FsOut,'arithmetic','fixed');
```

Redefine the `ddcFilterChain` cascade object to include the fixed-point properties of the individual filters. Then, use `fvtool` to analyze the entire filter chain and confirm that the quantized DDC still meets the specification.

```
ddcFilterChain = dsp.FilterCascade(cicFilt, ...
    cicGainCorr, compFilt, hbFilt, finalFilt);
ddcPlots.quantizedDDCResponse = fvtool(ddcFilterChain, ...
    'Fs',FsIn,'Arithmetic','fixed');

legend(ddcPlots.quantizedDDCResponse, ...
    'DDC filter chain');
```

HDL-Optimized Simulink Model

The next step in the design flow is to implement the DDC in Simulink using blocks that support HDL code generation.

Model Configuration

The model relies on variables in the MATLAB workspace to configure the blocks and settings. It uses the same filter chain variables defined earlier in the example. Next, define the NCO characteristics and the input signal. The example uses these characteristics to configure the NCO block.

Specify the desired frequency resolution and calculate the number of accumulator bits that are required to achieve the desired resolution. Set the desired spurious free dynamic range, and then define the number of quantized accumulator bits. The NCO uses the quantized output of the accumulator to address the sine lookup table. Also compute the phase increment that the NCO uses to generate the specified carrier frequency. The NCO applies phase dither to those accumulator bits that are removed during quantization.

```
nco.Fd = 1;
nco.AccWL = nextpow2(FsIn/nco.Fd)+1;
SFDR = 84;
nco.QuantAccWL = ceil((SFDR-12)/6);
nco.PhaseInc = round((-Fc*2^nco.AccWL)/FsIn);
nco.NumDitherBits = nco.AccWL-nco.QuantAccWL;
```

The input to the DDC comes from the `ddcIn` variable. For now, assign a dummy value for `ddcIn` so that the model can compute its data types. During testing, `ddcIn` provides input data to the model.

```
ddcIn = 0; %#ok<NASGU>
```

You can create a sample-based signal by setting up the FrameSize to 1, and output each individual sample as it is received. For a higher input sampling frequency or power reducing consideration, this design could also realize frame-based processing, and the FrameSize should be modified accordingly. In this case, we're showing a case for the FrameSize of 4.

```
FrameSize = 4;
```

Model Structure

This figure shows the top level of the DDC Simulink model. The model imports the ddcIn variable from the MATLAB workspace by using a Signal From Workspace block, converts the input signal to 16-bit values, and applies the signal to the DDC. You can generate HDL code from the HDL_DDC subsystem.

```
modelName = 'DDCforLTEHDL';
open_system(modelName);
set_param(modelName, 'SimulationCommand', 'Update');
set_param(modelName, 'Open', 'on');
```

Implementation of a Digital Down-Converter for LTE in HDL

The HDL_DDC subsystem implements the DDC filter. First, the NCO block generates a complex phasor at the carrier frequency. This signal goes to a mixer that multiplies the phasor with the input signal. Then, the output of the mixer is passed to the filter chain and decimated to 1.92 Msps.

```
set_param([modelName '/HDL_DDC'], 'Open', 'on');
```

NCO Block Parameters

The NCO block in the model is configured with the parameters defined in the nco structure. This figure shows both tabs of the NCO block parameters dialog.

CIC Decimation and Gain Correction

The first filter stage is a CIC Decimator that is implemented with a CIC Decimator block. The block parameters are set to the `cicParams` structure values. To implement the gain correction, the model selects the **Gain correction** parameter. The image shows the block parameters for the CIC Decimator block.

The model configures the filters by using the properties of the corresponding System objects. The CIC compensation, halfband decimation, and final decimation filters operate at effective sample rates that are lower than the clock rate by factors of 8, 16, and 32, respectively. The model implements these sample rates by using the **valid** input signal to indicate which samples are valid at each rate. The signals in the filter chain all have the same Simulink sample time.

The CIC Compensation, Halfband Decimation, and Final Decimation filters are each implemented by an FIR Decimator. By setting the **Minimum number of cycles between valid input samples** parameter, we can use the invalid cycles between input samples. For example, the spacing between every input of CIC Compensation Decimator is 8, which equals the decimation factor. So the CIC Compensation Decimator has the **Minimum number of cycles between valid input samples** set to `ceil(cicParams.DecimationFactor/FrameSize)`, which equals 2 cycles. The image shows the block parameters for the CIC Compensation Decimation block.

The FIR Decimator block fully reuses the multipliers in time over the number of clock cycles you specify. For `FrameSize` is 4, the CIC Compensation Decimation filter with complex input data would use 4 multipliers. The Halfband Decimation uses 4 multipliers, and the Final Decimation uses 12 multipliers. For `FrameSize` is 1, since the inputs spacing of CIC Compensation Decimation and Halfband Decimation are larger than their filter length, those two decimators only require 2 multipliers. And the Final Decimation needs 4 multipliers at that time.

Sinusoid on Carrier Test and Verification

To test the DDC, modulate a 40 kHz sinusoid onto the carrier frequency and pass the modulated sine wave through the DDC. Then, measure the spurious-free dynamic range (SFDR) of the resulting tone and the SFDR of the NCO output. Plot the SFDR of the NCO and the fixed-point DDC output.

```
% Initialize random seed before executing any simulations.
rng(0);

% Generate a 40 kHz test tone, modulated onto the carrier.
ddcIn = DDCTestUtils.GenerateTestTone(40e3, Fc);

% Demodulate the test signal with the floating-point DDC.
ddcOut = DDCTestUtils.DownConvert(ddcIn, FsIn, Fc, ddcFilterChain);
release(ddcFilterChain);

% Demodulate the test signal by running the Simulink model.
out = sim(modelName);
```

```

% Measure the SFDR of the NCO, floating-point DDC outputs, and fixed-point
% DDC outputs.
results.sfdrNCO = sfdr(real(out.ncoOut),FsIn);
results.sfdrFloatDDC = sfdr(real(ddcOut),FsOut);
results.sfdrFixedDDC = sfdr(real(out.ddcFixedOut),FsOut);

disp('SFDR Measurements');
disp([' Floating-point DDC SFDR: ',num2str(results.sfdrFloatDDC) ' dB']);
disp([' Fixed-point NCO SFDR: ',num2str(results.sfdrNCO) ' dB']);
disp([' Optimized fixed-point DDC SFDR: ',num2str(results.sfdrFixedDDC) ' dB']);
fprintf(newline);

% Plot the SFDR of the NCO and fixed-point DDC outputs.
ddcPlots.ncoOutSFDR = figure;
sfdr(real(out.ncoOut),FsIn);

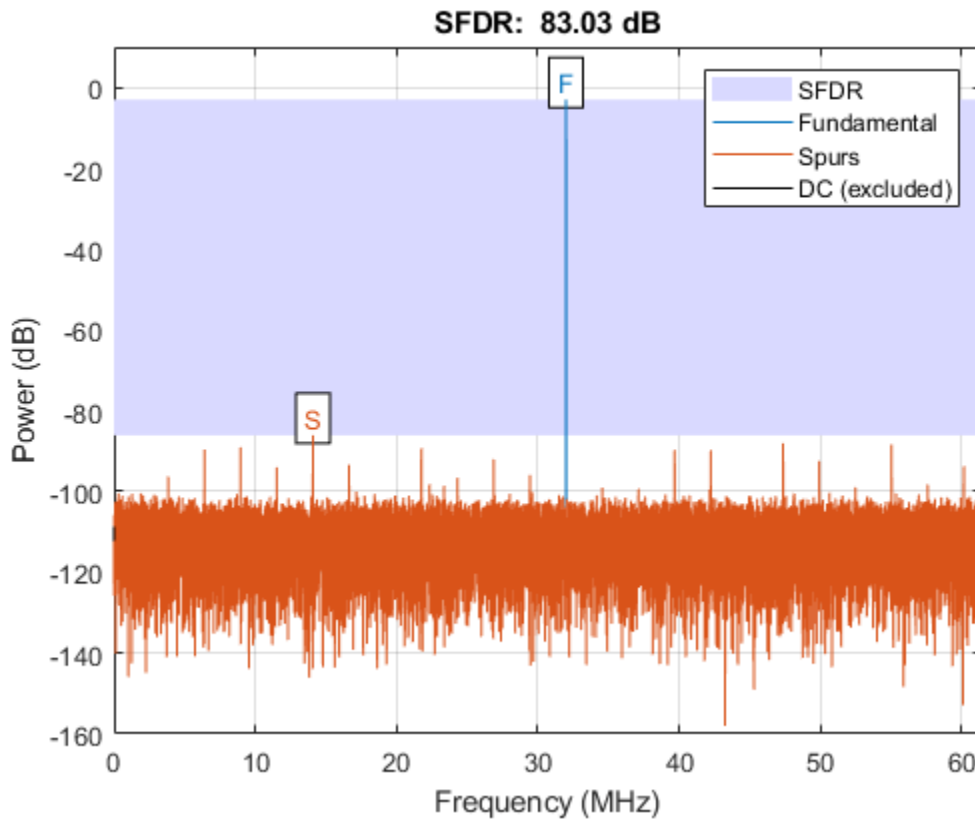

ddcPlots.OptddcOutSFDR = figure;
sfdr(real(out.ddcFixedOut),FsOut);

```

```

SFDR Measurements
Floating-point DDC SFDR: 291.4188 dB
Fixed-point NCO SFDR: 83.0306 dB
Optimized fixed-point DDC SFDR: 110.386 dB

```

LTE Signal Test

You can use an LTE test signal to perform more rigorous testing of the DDC. Generate a standard-compliant LTE waveform by using LTE Toolbox™ functions. Then, downconvert the waveform with the DDC model. Use LTE Toolbox functions to measure the error vector magnitude (EVM) of the resulting signals.

```
rng(0);
% Execute this test only if you have the LTE Toolbox product.
if license('test','LTE_Toolbox')

    % Generate a modulated LTE test signal by using the LTE Toolbox functions.
    [ddcIn,sigInfo] = DDCTestUtils.GenerateLTETestSignal(Fc);

    % Downconvert the signal with the floating-point DDC.
    ddcOut = DDCTestUtils.DownConvert(ddcIn,FsIn,Fc,ddcFilterChain);
    release(ddcFilterChain);

    % Downconvert the signal with the Simulink model, then measure and plot the
    % EVM of the floating-point and fixed-point results. Pad the input with zeros
    % to represent propagation latency and return the complete result.
    ddcIn = [ddcIn;zeros(2480*FrameSize,1)];
    out = sim(modelName);

    results.evmFloat = DDCTestUtils.MeasureEVM(sigInfo,ddcOut);
    results.evmFixed = DDCTestUtils.MeasureEVM(sigInfo,out.ddcFixedOut(1:length(ddcOut)));
```

```

disp('LTE Error Vector Magnitude (EVM) Measurements');
disp([' Floating-point DDC RMS EVM: ' num2str(results.evmFloat.RMS*100,3) '%']);
disp([' Floating-point DDC Peak EVM: ' num2str(results.evmFloat.Peak*100,3) '%']);
disp([' Fixed-point DDC RMS EVM: ' num2str(results.evmFixed.RMS*100,3) '%']);
disp([' Fixed-point DDC Peak EVM: ' num2str(results.evmFixed.Peak*100,3) '%']);
fprintf(newline);

```

end

```

LTE Error Vector Magnitude (EVM) Measurements
Floating-point DDC RMS EVM: 0.633%
Floating-point DDC Peak EVM: 2.44%
Fixed-point DDC RMS EVM: 0.731%
Fixed-point DDC Peak EVM: 2.69%

```

HDL Code Generation and FPGA Implementation

To generate the HDL code for this example you must have the HDL Coder™ product. Use the `makehdl` and `makehdltb` commands to generate HDL code and an HDL test bench for the HDL_DDC subsystem. The DDC was synthesized on a Xilinx® Zynq®-7000 ZC706 evaluation board. The table shows the post place-and-route resource utilization results. The design met timing with a clock frequency of 331 MHz.

```

T = table(...
    categorical({'LUT'; 'LUTRAM'; 'FF'; 'BRAM'; 'DSP'}),...
    categorical({'4341'; '383'; '8248'; '2.0'; '36'}),...
    'VariableNames',{'Resource','Usage'})

```

T =

5x2 table

Resource	Usage
LUT	4341
LUTRAM	383
FF	8248
BRAM	2.0
DSP	36

Implement Digital Upconverter for FPGA

This example shows how to design a digital upconverter (DUC) for radio communication applications such as LTE, and generate HDL code.

Introduction

DUCs are widely used in digital communication transmitters to convert baseband signals to radio frequency (RF) or intermediate frequency (IF) signals. The DUC operation increases the sample rate of the signal and shifts it to a higher frequency to facilitate subsequent processing stages. The DUC in this example performs sample rate conversion using a four-stage filter chain followed by complex frequency translation. The example starts by designing the DUC with DSP System Toolbox™ functions in floating point. Then, each stage is converted to fixed point, and used in a Simulink® model that generates synthesizable HDL code. The example uses these two test signals to demonstrate and verify the DUC operation:

- A sinusoid that is modulated onto a 32 MHz IF carrier.
- An LTE downlink signal with a bandwidth of 1.4 MHz, modulated onto a 32 MHz IF carrier.

The example downconverts the outputs of the floating-point and fixed-point DUCs, and compares the signal quality of the two outputs.

Finally, the example presents an implementation of the filter chain for FPGAs, and synthesis results.

This example uses `DUCTestUtils`, a helper class that contains functions for generating stimulus and analyzing the DUC output. For more information, see the `DUCTestUtils.m` file.

DUC Structure

The DUC consists of an interpolating filter chain, numerically controlled oscillator (NCO), and mixer. The filter chain consists of a lowpass interpolator, halfband interpolator, CIC compensation interpolator (FIR), CIC interpolator, and CIC gain correction.

The overall response of the filter chain is equivalent to that of a single interpolation filter with the same specification. However, splitting the filter into multiple interpolation stages results in a more efficient design that uses fewer hardware resources.

The first lowpass interpolator implements the precise F_{pass} and F_{stop} characteristics of the DUC. The halfband filter is an intermediate interpolator. The lower sampling rates at the beginning of the chain mean the earlier filters can optimize resource use by sharing multipliers. The CIC compensation interpolator improves the spectral response by compensating for the later CIC droop while interpolating by two. The CIC interpolator provides a large interpolation factor, which meets the filter chain upsampling requirements.

This figure shows a block diagram of the DUC.

The sample rate of the input to the DUC is 1.92 Msps, and the output sample rate is 122.88 Msps. These rates give an overall interpolation factor of 64. LTE receivers use 1.92 Msps as the typical sampling rate for cell search and master information block (MIB) recovery. The DUC filters are designed to suit this application. The DUC is optimized to run at a clock rate of 122.88 MHz.

DUC Design

This section explains how to design the DUC using floating-point operations and filter-design functions in MATLAB®. The DUC object enables you to specify several characteristics that define the response of the cascade for the four filters, including passband and stopband frequencies, passband ripple, and stopband attenuation.

DUC Parameters

This example designs the DUC filter characteristics to meet these desired response values for the given input sampling rate and carrier frequency.

```
FsIn = 1.92e6;      % Sampling rate at input to DUC
FsOut = 122.88;    % Sampling rate at the output
Fc = 32e6;         % Carrier frequency
Fpass = 540e3;     % Passband frequency, equivalent to 36*15kHz LTE subcarriers
Fstop = 700e3;     % Stopband frequency
Ap = 0.1;         % Passband ripple
Ast = 60;         % Stopband attenuation
```

First Lowpass Interpolator

This filter interpolates by two, and operates at the lowest sampling rate of the filter chain. The low sample rate means this filter can use resource sharing for an efficient hardware implementation.

```
lowpassParams.FsIn = FsIn;
lowpassParams.InterpolationFactor = 2;
lowpassParams.FsOut = FsIn*lowpassParams.InterpolationFactor;

lowpassSpec = fdesign.interpolator(lowpassParams.InterpolationFactor, ...
    'lowpass', 'Fp, Fst, Ap, Ast', Fpass, Fstop, Ap, Ast, lowpassParams.FsOut);
lowpassFilt = design(lowpassSpec, 'SystemObject', true)
```

```
lowpassFilt =
```

```
    dsp.FIRInterpolator with properties:
```

```
    InterpolationFactor: 2
    NumeratorSource: 'Property'
    Numerator: [0.0020 0.0021 4.9115e-04 -0.0027 -0.0050 ... ]
```

Use `get` to show all properties

Display the magnitude response of the lowpass filter without gain correction.

```
ducPlots.lowpass = fvtool(lowpassFilt,'Fs',FsIn*2,'Legend','off');
```

Second Halfband Interpolator

The halfband filter provides efficient interpolation by two. Halfband filters are efficient for hardware because approximately half of their coefficients are equal to zero, and those multipliers are excluded from the hardware implementation.

```
hbParams.FsIn = lowpassParams.FsOut;
hbParams.InterpolationFactor = 2;
hbParams.FsOut = lowpassParams.FsOut*hbParams.InterpolationFactor;
hbParams.TransitionWidth = hbParams.FsIn - 2*Fstop;
hbParams.StopbandAttenuation = Ast;
```

```
hbSpec = fdesign.interpolator(hbParams.InterpolationFactor,'halfband', ...
    'TW,Ast', ...
    hbParams.TransitionWidth, ...
    hbParams.StopbandAttenuation, ...
    hbParams.FsOut);
```

```
hbFilt = design(hbSpec,'SystemObject',true)
```

```

hbFilt =
    dsp.FIRInterpolator with properties:
        InterpolationFactor: 2
        NumeratorSource: 'Property'
        Numerator: [0.0178 0 -0.1129 0 0.5953 1 0.5953 0 -0.1129 0 ... ]

Use get to show all properties

```

Visualize the magnitude response of the halfband interpolation.

```

ducFilterChain = dsp.FilterCascade(lowpassFilt,hbFilt);
ducPlots.hbFilt = fvtool(lowpassFilt,hbFilt,ducFilterChain, ...
    'Fs',[FsIn*2,FsIn*4,FsIn*4]);

legend(ducPlots.hbFilt, ...
    'Lowpass Interpolator', ...
    'Halfband Interpolator', ...
    'Lowpass+Halfband');

```

CIC Compensation Interpolator

Because the magnitude response of the last CIC filter has a significant *droop* within the passband region, the example uses an FIR-based droop compensation filter to flatten the passband response.

The droop compensator has the same properties as the CIC interpolator. This filter implements interpolation by a factor of two, so you must also specify handlimiting characteristics for the filter. Also, specify the CIC interpolator properties that are used for this compensation filter as well as the later CIC interpolator.

Use the `design` function to return a filter System object with the specified characteristics.

```
compParams.FsIn = hbParams.FsOut;
compParams.InterpolationFactor = 2; % CIC compensation interpolation factor
compParams.FsOut = compParams.FsIn*compParams.InterpolationFactor; % New sampling rate
compParams.Fpass = 1/2*compParams.FsIn + Fpass; % CIC compensation passband
compParams.Fstop = 1/2*compParams.FsIn + 1/4*compParams.FsIn; % CIC compensation stopband
compParams.Ap = Ap; % Same passband ripple as original
compParams.Ast = Ast; % Same stopband attenuation as original
N = 31; % 32 tap filter to take advantage of symmetry

cicParams.InterpolationFactor = 8; % CIC interpolation factor
cicParams.DifferentialDelay = 1; % CIC interpolator differential delay
cicParams.NumSections = 3; % CIC interpolator number of integrator and comb sections

compSpec = fdesign.interpolator(compParams.InterpolationFactor,'ciccomp', ...
    cicParams.DifferentialDelay, ...
    cicParams.NumSections, ...
    cicParams.InterpolationFactor, ...
    'N,Fp,Ap,Ast', ...
    N,compParams.Fpass,compParams.Ap,compParams.Ast, ...
    compParams.FsOut);
compFilt = design(compSpec,'SystemObject',true)
```

```
compFilt =
```

```
    dsp.FIRInterpolator with properties:
```

```
    InterpolationFactor: 2
    NumeratorSource: 'Property'
    Numerator: [-6.9876e-04 -0.0099 0.0038 0.0134 -0.0255 ... ]
```

```
    Use get to show all properties
```

Plot the response of the CIC compensation interpolator.

```
ducFilterChain = dsp.FilterCascade(lowpassFilt,hbFilt,compFilt);
ducPlots.cicComp = fvtool(lowpassFilt,hbFilt,compFilt,ducFilterChain, ...
    'Fs',[FsIn*2,FsIn*4,FsIn*8,FsIn*8]);

legend(ducPlots.cicComp, ...
    'Lowpass Interpolator', ...
    'Halfband Interpolator', ...
    'CIC Comp Interpolator', ...
    'Lowpass+Halfband+CIC Comp');
```

CIC Interpolator

The last filter stage is implemented as a CIC interpolator because of this type of filter's ability to efficiently implement a large decimation factor. The response of a CIC filter is similar to a cascade of moving average filters, but a CIC filter uses no multiplication or division. As a result, the CIC filter has a large DC gain.

```
cicParams.FsIn = compParams.FsOut;
cicParams.FsOut = cicParams.FsIn*cicParams.InterpolationFactor;

cicFilt = dsp.CICInterpolator(cicParams.InterpolationFactor, ...
    cicParams.DifferentialDelay,cicParams.NumSections) %#ok<*NOPTS>
```

```
cicFilt =
```

```
    dsp.CICInterpolator with properties:
```

```
    InterpolationFactor: 8
    DifferentialDelay: 1
    NumSections: 3
    FixedPointDataType: 'Full precision'
```

Visualize the magnitude response of the CIC interpolation. CIC filters use fixed-point arithmetic internally, so `fvtool` plots both the quantized and unquantized responses.

```

ducFilterChain = dsp.FilterCascade(lowpassFilt,hbFilt,compFilt,cicFilt);
ducPlots.cicInter = fvtool(lowpassFilt,hbFilt,compFilt,cicFilt,ducFilterChain, ...
    'Fs',[FsIn*2,FsIn*4,FsIn*8,FsIn*64,FsIn*64]);

legend(ducPlots.cicInter, ...
    'First Halfband Interpolator', ...
    'Second Halfband Interpolator', ...
    'CIC Compensation Interpolator', ...
    'CIC Interpolator: Quantized',...
    'CIC Interpolator: Reference');

```

Every interpolator has a DC gain that is determined by its interpolation factor. The CIC interpolator has a larger gain than other filters. Call the `gain` function to get the gain factor of this filter.

Because the CIC gain is a power of two, a hardware implementation can easily correct for the gain factor by using a shift operation. For analysis purposes, the example represents the gain correction by using a one-tap `dsp.FIRFilter` System object. Combine the filter chain and the gain correction filter into a `dsp.FilterCascade` System object.

```

cicGain = gain(cicFilt)
Gain = lowpassParams.InterpolationFactor* ...
    hbParams.InterpolationFactor*compParams.InterpolationFactor* ...
    cicParams.InterpolationFactor*cicGain;
GainCorr = dsp.FIRFilter('Numerator',1/Gain)

```

```

cicGain =

```

64

GainCorr =

```

dsp.FIRFilter with properties:
    Structure: 'Direct form'
    NumeratorSource: 'Property'
    Numerator: 2.4414e-04
    InitialConditions: 0

```

```
Use get to show all properties
```

Plot the overall chain response with and without gain correction.

```

ducPlots.overallResponse = fvtool(ducFilterChain,dsp.FilterCascade(ducFilterChain,GainCorr), ...
    'Fs',[FsIn*64,FsIn*64]);
legend(ducPlots.overallResponse, ...
    'Overall Response: No Gain Correction',...
    'Overall Response: Gain Correction');

```

Fixed-Point Conversion

The frequency response of the floating-point DUC filter chain now meets the specification. Next, quantize each filter stage to use fixed-point types and analyze them to confirm that the filter chain still meets the specification.

Filter Quantization

This example uses 16-bit coefficients, which are sufficient to meet the specification. Using fewer than 18 bits for the coefficients minimizes the number of DSP blocks that are required for an FPGA implementation. The input to the DUC filter chain is 16-bit data with 15 fractional bits. The filter outputs are 18-bit values, which provide extra headroom and precision in the intermediate signals.

```
% First Lowpass Interpolator
lowpassFilt.FullPrecisionOverride = false;
lowpassFilt.CoefficientsDataType = 'Custom';
lowpassFilt.CustomCoefficientsDataType = numerictype([],16,15);
lowpassFilt.ProductDataType = 'Full precision';
lowpassFilt.AccumulatorDataType = 'Full precision';
lowpassFilt.OutputDataType = 'Custom';
lowpassFilt.CustomOutputDataType = numerictype([],18,14);

% Halfband
hbFilt.FullPrecisionOverride = false;
hbFilt.CoefficientsDataType = 'Custom';
hbFilt.CustomCoefficientsDataType = numerictype([],16,14);
hbFilt.ProductDataType = 'Full precision';
hbFilt.AccumulatorDataType = 'Full precision';
hbFilt.OutputDataType = 'Custom';
hbFilt.CustomOutputDataType = numerictype([],18,14);

% CIC Compensation Interpolator
compFilt.FullPrecisionOverride = false;
compFilt.CoefficientsDataType = 'Custom';
compFilt.CustomCoefficientsDataType = numerictype([],16,14);
compFilt.ProductDataType = 'Full precision';
compFilt.AccumulatorDataType = 'Full precision';
compFilt.OutputDataType = 'Custom';
compFilt.CustomOutputDataType = numerictype([],18,14);
```

For the CIC interpolator, choosing the 'Minimum section word lengths' fixed-point data type option automatically optimizes the internal wordlengths based on the output wordlength and other CIC parameters.

```
cicFilt.FixedPointDataType = 'Minimum section word lengths';
cicFilt.OutputWordLength = 18;
```

Configure the fixed-point properties of the gain correction and FIR-based System objects. The object uses the default RoundingMethod and OverflowAction property values ('Floor' and 'Wrap' respectively).

```
% CIC Gain Correction
GainCorr.FullPrecisionOverride = false;
GainCorr.CoefficientsDataType = 'Custom';
GainCorr.CustomCoefficientsDataType = numerictype(fi(GainCorr.Numerator,1,16));
GainCorr.OutputDataType = 'Custom';
GainCorr.CustomOutputDataType = numerictype(1,18,14);
```

Fixed-Point Analysis

Inspect the quantization effects with `fvtool`. You can analyze the filters individually or in a cascade. `fvtool` shows the quantized and unquantized (reference) responses overlaid. For example, this figure shows the effect of quantizing the first FIR filter stage.

```
ducPlots.quantizedFIR = fvtool(lowpassFilt,'Fs',lowpassParams.FsIn*2,'arithmetic','fixed');
legend(ducPlots.quantizedFIR, ...
       'Lowpass Interpolator');
```

Redefine the `ducFilterChain` cascade object to include the fixed-point properties of the individual filters. Then use `fvtool` to analyze the entire filter chain and confirm that the quantized DUC still meets the specification.

```
ducFilterChain = dsp.FilterCascade(lowpassFilt,hbFilt,compFilt,cicFilt,GainCorr);
ducPlots.quantizedDUCResponse = fvtool(ducFilterChain, ...
    'Fs',FsIn*64,'Arithmetic','fixed');

legend(ducPlots.quantizedDUCResponse, ...
       'DUC filter chain');
```

HDL-Optimized Simulink Model

The next step in the design flow is to implement the DUC in Simulink using blocks that support HDL code generation.

Model Configuration

The model relies on variables in the MATLAB workspace to configure the blocks and settings. The filter blocks are configured by using the filter chain objects defined earlier in the example.

The input to the DUC comes from the `ducIn` variable. For now, assign a dummy value for `ducIn` so that the model can compute its data types. During testing, `ducIn` provides input data to the model.

```
ducIn = 0; %#ok<NASGU>
```

The `outputFrame` parameter sets the frame size of the output based on the DAC requirement. `outputFrame` affects the input vector size and valid sample spacing, and it should be a power of two.

```
outputFrame = 4;
```

Model Structure

This figure shows the top level of the DUC Simulink model. The model imports the `ducIn` variable from the MATLAB workspace by using a **Signal From Workspace** block, converts the signal to 16-bit values, and applies the signal to the DUC. The design is single rate, and uses a *valid* signal to convey the rate change from block to block. To simulate the input running 64 times slower than the clock, it is upsampled by 64 with zero insertion. You can generate HDL code from the `HDL_DUC` subsystem.

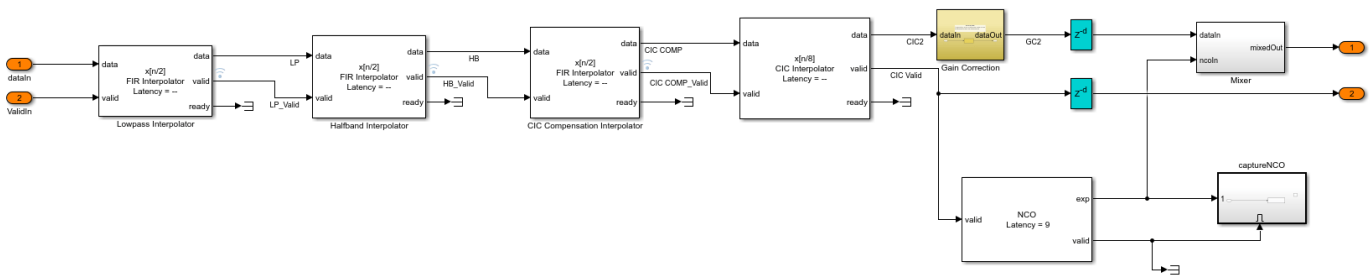

```
modelName = 'DUCforLTEHDL';
open_system(modelName);
set_param(modelName, 'Open', 'on');
```

Implementation of a Digital Up-Converter for LTE in HDL

The DUC implementation is inside the HDL_DUC subsystem.

```
set_param([modelName '/HDL_DUC'], 'Open', 'on');
```

Filter Block Parameters

All of the filters are configured to inherit the coefficients of the corresponding System objects. Each block also has a "Minimum number of cycles between valid input" parameter that is used to optimize the resulting HDL code. The lowpass, halfband, and CIC compensation filters have cycles between valid inputs that can be used for resource sharing - 64, 32, and 16 cycles, respectively.

For example, because the sample rate of the input to the Lowpass Interpolation block is $F_{clk}/64$, 64 clock cycles are available to process each input sample.

The first filter interpolates by 2. Each polyphase branch is implemented by a separate FIR Filter. Because the number of cycles between valid input samples is greater than 1, each FIR is implemented using the partly serial systolic architecture. The filter has 69 coefficients in total, and after polyphase decomposition each branch has 35 coefficients. There are 64 cycles available for sharing, so each branch is implemented with a fully serial FIR. With complex input, each branch uses 2 multipliers, for a total of 4 multipliers in this filter.

The second filter is a halfband interpolator. This filter can also take advantage of cycles between valid input to perform resource sharing. These cycles are available because each interpolator output has idle cycles between valid samples. The first filter has 64 cycles and interpolates by 2. Therefore, it will output data every 32 cycles. The second filter has 6 coefficients per polyphase branch and so it can be implemented as a fully serial FIR. In this filter, the second branch only contains one non-zero coefficient, and it is a power of 2. The FIR Interpolator block implements this branch as a shift rather than a multiplier. The second filter then has only 2 multipliers.

The third filter is a CIC compensation filter which interpolates by 2. It has 32 coefficients in total, which we specified when designing the filter. The filter is implemented using 2 fully serial complex FIRs, giving a total of 4 multipliers for this filter.

Gain Correction

The gain correction divides the output by 4096, which is equivalent to shifting right by 12 bits. Because the input and output signals of the gain correction each are expressed with 18 bits, the model implements this shift by reinterpreting the data type of the output signal. The Conversion block reinterprets the 12-bit number to have 20 fractional bits rather than 8 fractional bits.

```
set_param([modelName '/HDL_DUC/Gain Correction'], 'Open', 'on');
```

Divide by 4096
To right-shift by 12 bits, reinterpret the number to have
20 fractional bits rather than 8 fractional bits.

NCO Block Parameters

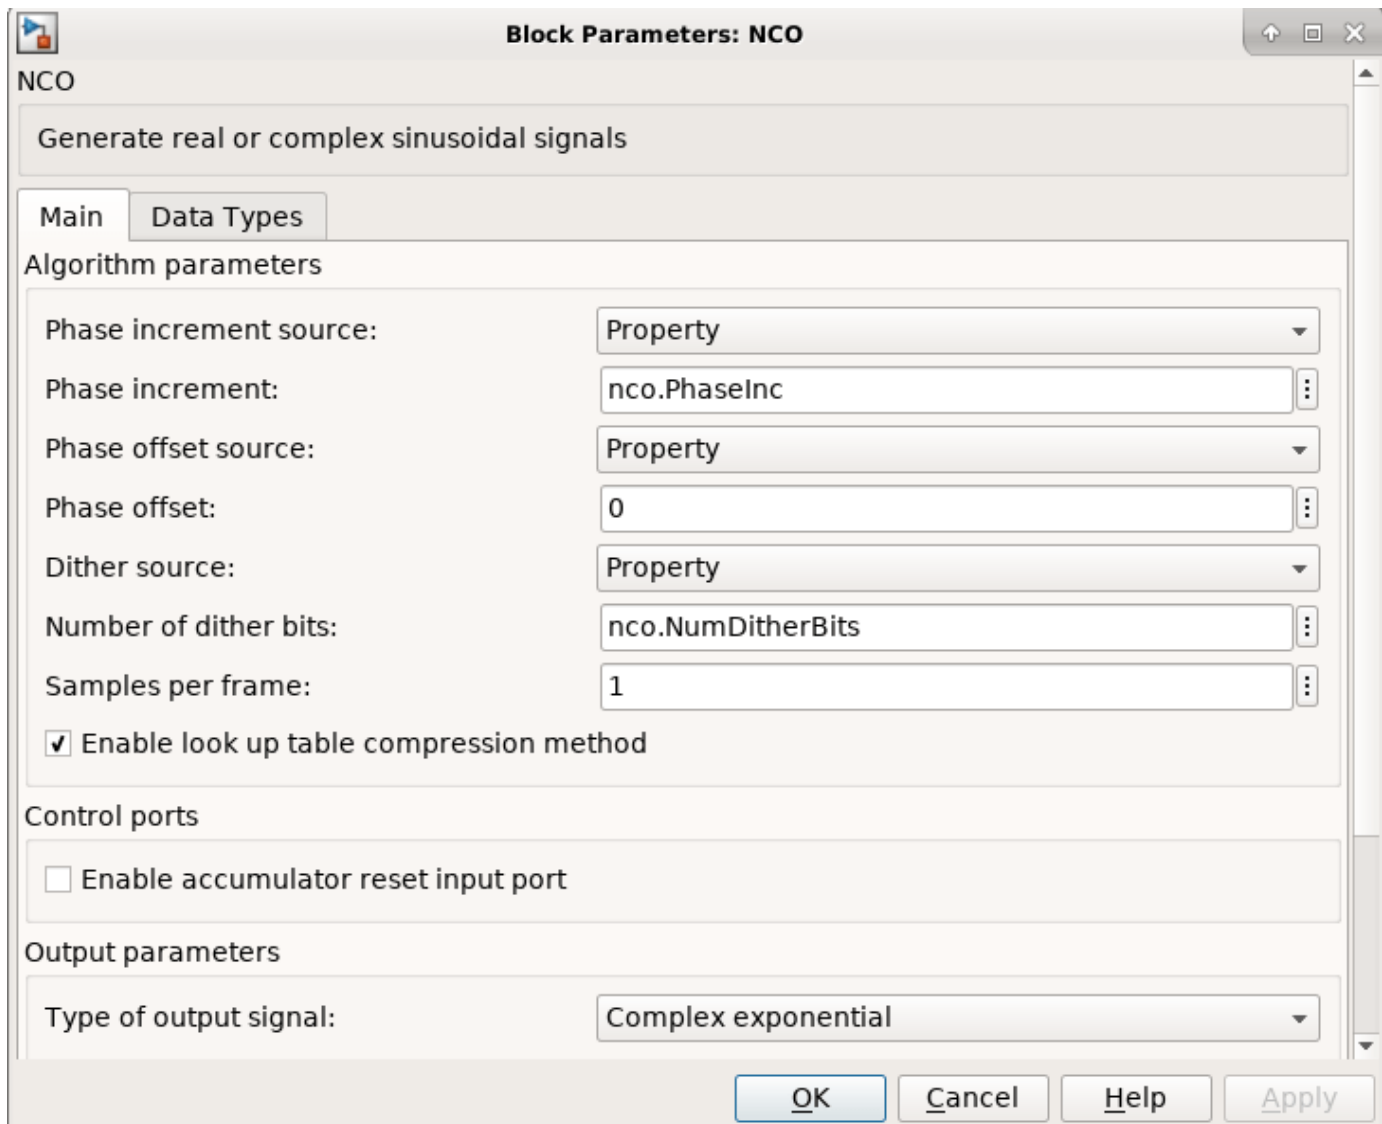

The NCO block generates a complex phasor at the carrier frequency. This signal goes to a mixer that multiplies the phasor with the output signal. The output of the mixer is sampled at 122.88 Msp/s.

Specify the desired frequency resolution, then calculate the number of accumulator bits required to achieve the desired resolution, and define the number of quantized accumulator bits. The NCO uses the quantized output of the accumulator to address the sine lookup table. Also compute the phase increment the NCO must use to generate the specified carrier frequency. The NCO applies phase dither to the accumulator bits that are removed during quantization.

```

nco.Fd = 1;
nco.AccWL = nextpow2(FsIn*64/nco.Fd) + 1;
nco.QuantAccWL = 12;
nco.PhaseInc = round((Fc*2^nco.AccWL)/(FsIn*64));
nco.NumDitherBits = nco.AccWL - nco.QuantAccWL;
  
```

The NCO block in the model is configured with the parameters defined in the nco structure. This figure shows the NCO block parameters dialog.

Mixer

The Mixer subsystem performs a complex multiply of the filter output and NCO.

```
set_param([modelName '/HDL_DUC/Mixer'], 'Open', 'on');
```

To map the mixer to DSP slices on FPGA, the mixer is pipelined and the blocks have specific settings. The delay blocks in the mixer are configured to have reset turned off as shown in the image. There are 2 pipeline stages at the input, 1 between the multiplier and adder, and another post-adder. Also, the multipliers and adders are configured to use full-precision output. These blocks use Floor rounding method, and the saturate on overflow logic is disabled.

Sinusoid on Carrier Test

To test the DUC, pass a 40kHz sinusoid through the DUC and modulate the output signal onto the carrier frequency. Demodulate and resample the signal. Then measure the spurious free dynamic range (SFDR) of the resulting tone and the SFDR of the NCO output.

```
% Initialize random seed before executing any simulations.
rng(0);
```

```
% Generate a 40kHz test tone.
```

```
ducIn = DUCTestUtils.GenerateTestTone(40e3);

% Upconvert the test signal with the floating-point DUC.
ducTx = DUCTestUtils.UpConvert(ducIn,FsIn*64,Fc,ducFilterChain);
release(ducFilterChain);

% Down convert the output of DUC.
ducRx = DUCTestUtils.DownConvert(ducTx,FsIn*64,Fc);

% Upconvert the test signal by running the fixed-point Simulink model.
simOut = sim(modelName);

% Downconvert the output of DUC.
simTx = simOut.ducOut;
simRx = DUCTestUtils.DownConvert(simTx,FsIn*64,Fc);

% Measure the SFDR of the NCO, floating point DUC, and fixed-point DUC outputs.
results.sfdrNCO = sfdr(real(simOut.ncoOut),FsIn);
results.sfdrFloatDUC = sfdr(real(ducRx),FsIn);
results.sfdrFixedDUC = sfdr(real(simRx),FsIn);

disp('SFDR Measurements');

Fixed-point NCO SFDR: 86.2454 dB
Fixed-point DUC SFDR: 89.5756 dB
```

LTE Signal Test

You can use an LTE test signal to perform more rigorous testing of the DUC. Generate a standard-compliant LTE waveform by using LTE Toolbox™ functions. Then, upconvert the waveform with the DUC model. Use LTE Toolbox functions to measure the error vector magnitude (EVM) of the resulting signals.

```

rng(0);
% Execute this test only if you have the LTE Toolbox product.
if license('test','LTE_Toolbox')

    % Generate an LTE test signal by using LTE Toolbox functions.
    [ducIn, sigInfo] = DUCTestUtils.GenerateLTETestSignal();

    % Upconvert the signal with the floating-point DUC and modulate onto carrier.
    ducTx = DUCTestUtils.UpConvert(ducIn,FsIn*64,Fc,ducFilterChain);
    release(ducFilterChain);

    % Add noise to the transmit signal.
    ducTxAddNoise = DUCTestUtils.AddNoise(ducTx);

    % Downconvert the received signal.
    ducRx = DUCTestUtils.DownConvert(ducTxAddNoise,FsIn*64,Fc);

    % Upconvert the signal by using the Simulink model.
    simOut = sim(modelName);

```

```

% Add noise to the transmit signal.
simTx = simOut.ducOut;
simTxAddNoise = DUCTestUtils.AddNoise(simTx);

% Downconvert the received signal.
simRx = DUCTestUtils.DownConvert(simTxAddNoise,FsIn*64,Fc);

results.evmFloat = DUCTestUtils.MeasureEVM(sigInfo,ducRx);
results.evmFixed = DUCTestUtils.MeasureEVM(sigInfo,simRx);

disp('LTE EVM Measurements');
disp([' Floating-point DUC RMS EVM: ' num2str(results.evmFloat.RMS*100,3) '%']);
disp([' Floating-point DUC Peak EVM: ' num2str(results.evmFloat.Peak*100,3) '%']);

Floating-point DUC Peak EVM: 2.53%
Fixed-point DUC RMS EVM: 0.816%
Fixed-point DUC Peak EVM: 2.82%

```

HDL Code Generation and FPGA Implementation

To generate the HDL code for this example you must have the HDL Coder™ product. Use the `makehdl` and `makehdltb` commands to generate HDL code and an HDL test bench for the HDL_DUC subsystem. The DUC was synthesized on a Xilinx® Zynq®-7000 ZC706 evaluation board. The table shows the post place-and-route resource utilization results for outputFrame of size 4. The design met timing with a clock frequency of 335 MHz.

```

T = table(...
    categorical({'LUT'; 'LUTRAM'; 'FF'; 'BRAM'; 'DSP'}),...
    categorical({'4708'; '654'; '6849'; '2'; '32'}),...
    'VariableNames',{'Resource','Usage'})

```

```
T =
```

```
5x2 table
```

Resource	Usage
LUT	4708
LUTRAM	654
FF	6849
BRAM	2
DSP	32

HDL QAM Transmitter and Receiver

This example shows how to use Simulink® blocks that support HDL code generation to implement a 64-QAM transmitter and receiver for HDL code generation and hardware implementation.

The HDL QAM Tx subsystem generates a complex valued, 64-QAM modulated constellation. A floating-point channel model, Channel, is used to add attenuation, channel noise, carrier frequency offset, and fractional delay in order to demonstrate the operation of the receiver subsystem. The HDL QAM Rx subsystem implements a practical digital receiver to mitigate the channel impairments using coarse frequency recovery, timing recovery, frame synchronization, and magnitude and phase recovery. The Text Message Decoding subsystem then receives the data packets, decodes the packets, and prints them to the MATLAB® Command Window.

Structure of the Example

To open the model, enter:

```
modelName = 'commqamtxrxhdl';
open_system(modelName);
set_param(modelName, 'Open', 'on');
```

This image shows the top-level structure of the QAM receiver model. The QAM Tx HDL and QAM Rx HDL subsystems are optimized for HDL code generation.

Copyright 2014-2021 The MathWorks, Inc.

To open the QAM Tx HDL subsystem, enter:

```
set_param(modelName, 'Open', 'off');
set_param([modelName '/QAM Tx HDL'], 'Open', 'on');
```

This image shows the detailed structure of the QAM Tx HDL subsystem.

The QAM Tx HDL subsystem contains these components, which are described in more detail in the **HDL QAM Transmitter** section.

- **Data Generation & Packetization** - Generates the packets to be transmitted, grouping the bits for mapping to symbols
- **Symbol Mapping** - Maps the bits output from the **Data Generation & Packetization** subsystem to QAM symbols
- **Pulse Shaping** - Performs pulse shaping and upsampling of the symbols using an interpolating RRC (Root Raised Cosine) filter prior to transmission

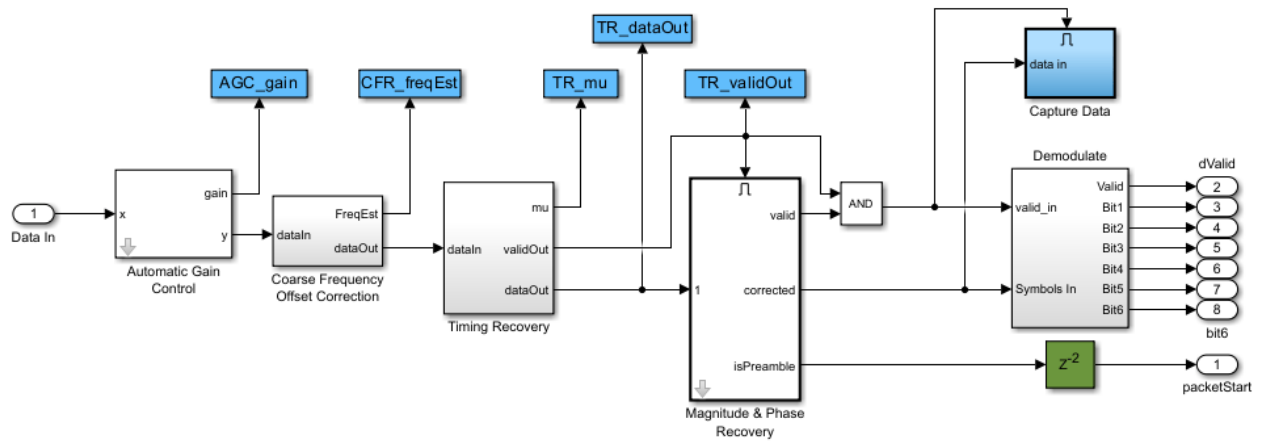

```
set_param([modelName '/QAM Tx HDL'], 'Open', 'off');
set_param([modelName '/Channel'], 'Open', 'on');
```

The structure of the Channel subsystem can be seen below. As the Channel subsystem is intended to be a rough approximation of a AWGN channel with attenuation and frequency offset it is intended to be run in software. As a result blocks which are not supported for HDL code generation can be used here, such as the **Phase/Frequency Offset** block. The **Phase/Frequency Offset** block does not support fixed point data types, hence the conversion to double at the input of the Channel subsystem. The signal is converted back to fixed point before being output from the Channel subsystem. A fractional delay and AWGN are applied to the transmitted signal and the **Gain** block attenuates the signal.

```
set_param([modelName '/Channel'], 'Open', 'off');
set_param([modelName '/QAM Rx HDL'], 'Open', 'on');
```

This image shows the detailed structure of the QAM Rx HDL subsystem.

The QAM Rx HDL subsystem contains these components:

- **Automatic Gain Control** - Normalizes the received signal power.
- **Coarse Frequency Offset Correction** - Estimates the approximate frequency offset and corrects. The subsystem also contains the **Root Raised Cosine Receive Filter** block which downsamples by two.
- **Timing Recovery** - Resamples the input signal according to a recovered timing strobe so that symbol decisions are made at the optimum sampling instants.
- **Magnitude & Phase Recovery** - Performs packet detection, fine-grained phase and amplitude correction.
- **Demodulate** - Demodulates the signal and demaps symbols to bits.

```
set_param([modelName '/QAM Rx HDL'], 'Open', 'off');
set_param([modelName '/Text Message Decoding'], 'Open', 'on');
```

This image shows the structure of the Text Message Decoding subsystem.

This subsystem is designed to be run in software, therefore, the subsystem uses frame-based signals to speed up the computation. The Text Message Decoding subsystem has eight sample-based Boolean input signals: `dValid`, `packetStart` and signals `bit1` to `bit6`. The `dataframer` MATLAB Function block converts the sample-based signals to frame-based signals. The demodulated bits are valid only when `dValid` is set high. The `dataframer` block uses the `dValid` signal to fill up a delay line with the received bits and the `newPacket` signal to forward the data stored in the delay line to the output and reset the delay line.

The `Descramble and Print` subsystem processes the received data only when its enable signal goes high. This occurs when either the delay line accumulates 336 valid demodulated bits or the `newPacket` signal is high. This will cause the `dataframer` block to set the `RxGo` signal high. While the simulation is running, the `Descramble and Print` subsystem outputs the string "Hello world! ~64QAM test string~ ###" to the MATLAB Command Window, where '###' is a repeating sequence of '000', '001', '002', ..., '099'. Every 50 packets the subsystem outputs the the bit error rate of the data in the last 50 successfully received packets to the MATLAB Command Window.

HDL QAM Transmitter

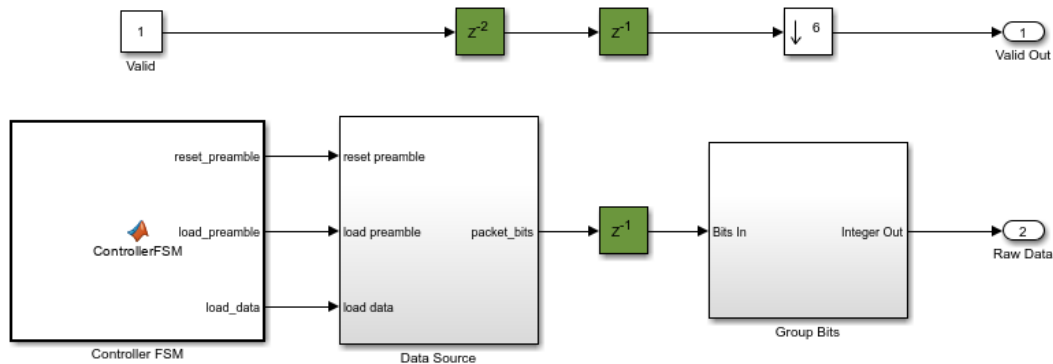

The HDL QAM Tx contains the Data Generation & Packetization, Symbol Mapping, and Pulse Shaping blocks.

Data Generation & Packetization

The `Controller FSM` and `Data Source` subsystems generate the preamble bits, data bits, performs scrambling and builds the packets. Each packet consists of an 84-bit Barker code preamble and 252 bits of scrambled data. The `Group Bits` block converts the input data bit stream into a six-bit integer at 1/6th of the input sampling rate, as required by the symbol mapper.

The Data Source subsystem has a pipeline delay of two samples. In addition, there is a pipeline delay between the data source and the bit pairing subsystem. The valid signal is therefore delayed to match the pipeline delay of the data path. The Group Bits subsystem reduces the sample rate by a factor of six. Placing a downsample by six in the valid control path ensures that the sample rate matches that of the signal path.

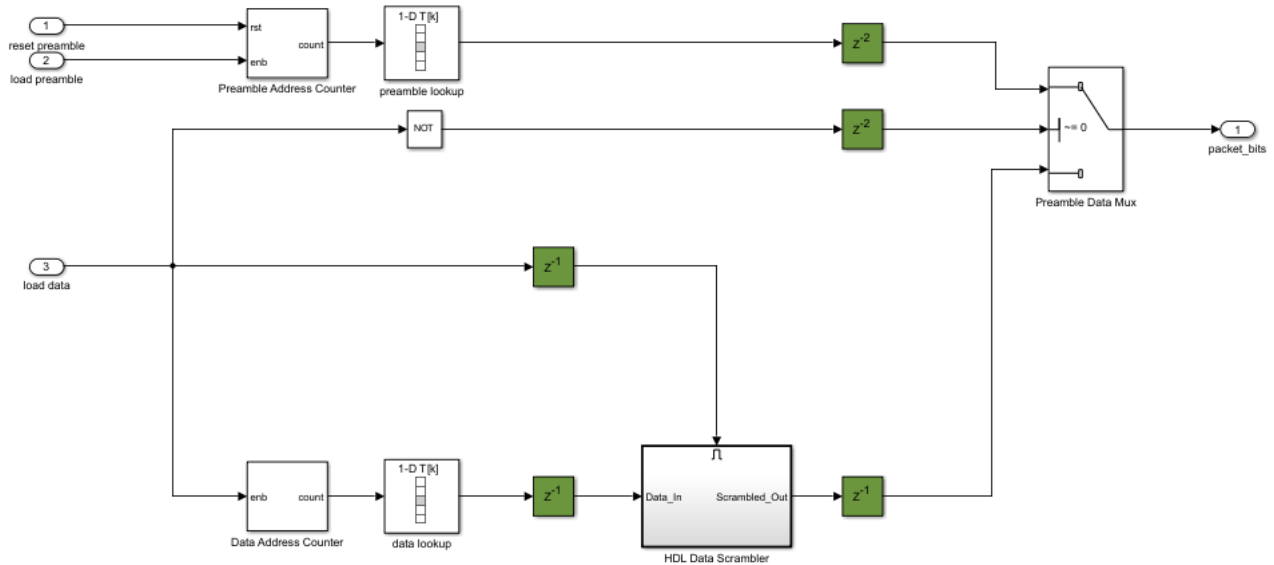

```
set_param([modelName '/Text Message Decoding'],'Open','off');
set_param([modelName '/QAM Tx HDL/Data Generation & Packetization'],'Open','on');
```

Controller FSM - The Controller FSM block is a MATLAB Function block that implements a control state machine. The FSM has two states, Pack_Preamble and Append_Data. The Pack_Preamble state asserts the load_preamble signal and de-asserts the reset_preamble and the load_data signals. The FSM remains in this state for 84 clock cycles. Then the FSM moves into the Append_Data state, asserts the load_data signal and the reset_preamble signal while releasing the load_preamble signal. The FSM remains in this state for 252 clock cycles. The load_preamble and reset_preamble are Boolean and are used to control the Preamble Address Counter which manages the load of the preamble at the start of each packet. The load_data signal is Boolean and enables the Data Address Counter which controls the loading of data into the packet.

Data Source - The Data Source subsystem contains two lookup tables (LUTs), storing the preamble and data bits. The Preamble Address Counter subsystem, which is controlled by the reset_preamble and load_preamble signals generated by the Controller FSM block, addresses the preamble lookup LUT. The Data Access Counter, which is enabled by the load_data signal generated by the Controller FSM block, addresses the data lookup LUT. The Preamble Address Counter subsystem has a reset signal, generated by the Controller FSM block, as the same preamble is inserted at the start of each packet. The Data Address Counter subsystem does not have a reset signal as the data address sequence is much longer and varies for each packet as different data bits are placed within each packet. In addition to enabling the counter for the data LUT, the load_data input controls when the HDL Data Scrambler component enables selection of preamble or data bits via the Preamble Data Mux block.

```
set_param([modelName '/QAM Tx HDL/Data Generation & Packetization'],'Open','off');
set_param([modelName '/QAM Tx HDL/Data Generation & Packetization/Data Source'],'Open','on');
```

HDL Data Scrambler - To view the HDL Data Scrambler block, enter:

```
set_param([modelName '/QAM Tx HDL/Data Generation & Packetization/Data Source'], 'Open', 'off');
set_param([modelName '/QAM Tx HDL/Data Generation & Packetization/Data Source/HDL Data Scrambler'], 'Open', 'off');
```

This image shows the HDL Data Scrambler subsystem. The subsystem uses XOR gates (for modulo 2 addition) and registers. The enabled subsystem ensures that the scrambler is only enabled when there is new input data to be processed.

Group Bits - The Group Bits subsystem groups six individual bits into a six-bit unsigned integer output which is the format expected by the symbol mapping component. The delays are used to align

six bits at the input of the **Bit Concat** block, which concatenates into a six-bit unsigned output. This output is then downsampled to select the correct grouping of bits.

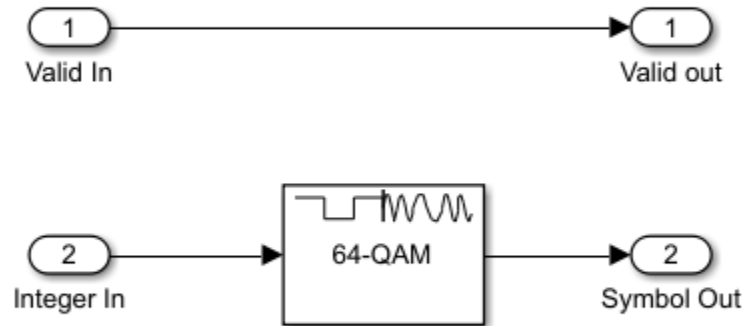

```
set_param([modelName '/QAM Tx HDL/Data Generation & Packetization/Data Source/HDL Data Scrambler']
set_param([modelName '/QAM Tx HDL/Data Generation & Packetization/Group Bits'],'Open','on');
```

Symbol Mapping

The Symbol Mapping subsystem uses the **Rectangular QAM Modulator Baseband** block to map the integer input value onto the appropriate 64-QAM complex valued symbol. The block uses a Gray mapping scheme.

```
set_param([modelName '/QAM Tx HDL/Data Generation & Packetization/Group Bits'],'Open','off');
set_param([modelName '/QAM Tx HDL/Symbol Mapping'],'Open','on');
```

Pulse Shaping

The Pulse Shaping subsystem uses the **RRC Interpolation Filter** block with an upsampling factor of four. A matched filter is implemented in the receiver. The filter is pipelined.

```
set_param([modelName '/QAM Tx HDL/Symbol Mapping'], 'Open', 'off');
set_param([modelName '/QAM Tx HDL/Pulse Shaping'], 'Open', 'on');
```

HDL QAM Receiver

The HDL QAM Rx contains the Automatic Gain Control, Coarse Frequency Offset Correction, Timing Recovery, Magnitude & Phase Recovery, and Demodulate blocks.

Automatic Gain Control

The Automatic Gain Control subsystem ensures that the amplitude of the input of the Coarse Frequency Compensation is normalized to the range 1 to -1.

```
set_param([modelName '/QAM Tx HDL/Pulse Shaping'], 'Open', 'off');
set_param([modelName '/QAM Rx HDL/Automatic Gain Control'], 'Open', 'on');
```

This image shows the Automatic Gain Control subsystem structure with pipeline registers in green throughout the model.

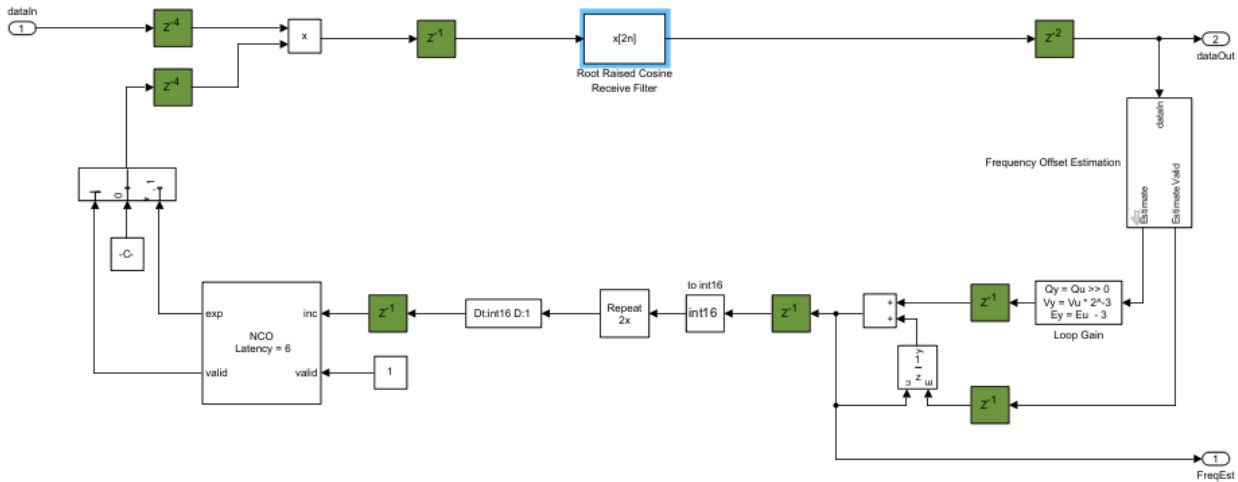

Coarse Frequency Offset Correction

The Coarse Frequency Offset Correction subsystem estimates and corrects for the frequency offset by using the Luise-Reggiannini algorithm [1 on page 15-77]. The **Frequency Offset Estimation** subsystem makes an estimate based on the output of the **Root Raised Cosine Receive Filter** block, then frequency offset correction based on this estimate is applied at the input to the **Root Raised Cosine Receive Filter**. This ensures that the desired portion of the received signal bandwidth is better aligned with the receiver filter frequency response, which improves the SNR compared to correcting at the output of the **Root Raised Cosine Receive Filter** block.

Because the estimation and correction algorithm is operating in a closed loop, and makes iterative updates to the previous estimates of the frequency offset, the system gradually converges towards a result. The **Loop Gain** averages the estimates. This architecture is described in [1 on page 15-77]. The **Root Raised Cosine Receive Filter** block implements a downsampling operation so it is necessary to upsample the feedback signal, using the repeat block, to match the rate at the input to the filter.

Note that there is a residual frequency offset at the output of the **Coarse Frequency Offset Correction** subsystem that varies over time, even if the frequency offset at the input to the subsystem remains the same as the Coarse Frequency Offset Correction subsystem makes new estimates. The **Magnitude and Phase Recovery** subsystem makes fine-grained correction of the residual offset.

```
set_param([modelName '/QAM Rx HDL/Automatic Gain Control'],'Open','off');
set_param([modelName '/QAM Rx HDL/Coarse Frequency Offset Correction'],'Open','on');
```

Frequency Offset Estimation: The **Frequency Offset Estimation** subsystem implements the Luise-Reggiannini algorithm, described in [1 on page 15-77]. The subsystem raises the signal to the power four to implement a fourth power phase estimator as described in [2 on page 15-77]. Two cascaded product blocks, with pipelining added to improve hardware performance implement the estimator. The **Discrete FIR Filter** implements the filter with rectangular weights, made up of all ones, described in [1 on page 15-77]. The **FIR Scale** scales the FIR output to account for the filter gain. The **Complex To Magnitude-Angle HDL Optimized** block is used to implement the *angle* function, as required by the Luise-Reggiannini algorithm. This block computes the phase using the hardware friendly CORDIC algorithm. For more information, see the Complex to Magnitude-Angle (DSP HDL Toolbox) block. Before the **Frequency Offset Estimation** subsystem output, the signal is scaled as required by the Luise-Reggiannini algorithm and, in addition, is scaled to match the word length of the NCO.

```
set_param([modelName '/QAM Rx HDL/Coarse Frequency Offset Correction'],'Open','off');
set_param([modelName '/QAM Rx HDL/Coarse Frequency Offset Correction/Frequency Offset Estimation
```

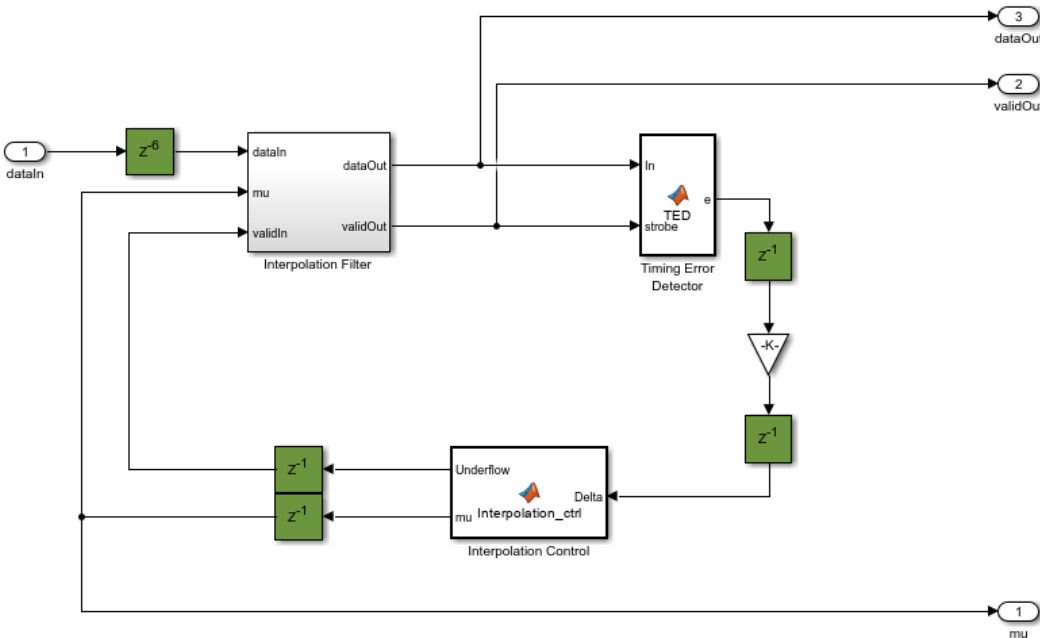

Timing Recovery

To open the Timing Recovery subsystem, enter:.

```
set_param([modelName '/QAM Rx HDL/Coarse Frequency Offset Correction/Frequency Offset Estimation
set_param([modelName '/QAM Rx HDL/Timing Recovery'], 'Open', 'on');
```

This image shows the **Timing Recovery** subsystem.

The **Timing Recovery** subsystem implements a PLL, described in Chapter 8 of [3 on page 15-77], to correct the timing error in the received signal. On average, the **Timing Recovery** subsystem generates one output sample for every two input samples.

The **Interpolation Control** block implements a decremting modulo-1 counter, described in Chapter 8.4.3 of [3 on page 15-77], to generate the control signal to facilitate the selection of the interpolants of the **Interpolation Filter**. This control signal also enables the **Timing Error Detector (TED)**, so that it calculates the timing errors at the correct timing instants. The **Interpolation Control** subsystem updates the timing difference, **mu**, for the **Interpolation Filter**, generating interpolants at optimum sampling instants.

The **Interpolation Filter** is a Farrow parabolic filter with $\alpha = 0.5$ as described in Chapter 8.4.2 of [3 on page 15-77]. The filter uses an α of 0.5 so that all the filter coefficients become 1, $-1/2$ and $3/2$, which significantly simplifies the interpolator structure. Based on the interpolants the **Timing Error Detector**, generates timing errors during a zero crossing as described in Chapter 8.4.1 of [3 on page 15-77].

The **Interpolation Filter** introduces a fractional delay to the signal in order to compensate for the timing error. The fractional delay is controlled by the **mu** input signal. When the timing error (delay) reaches symbol boundaries, there is one extra or missing interpolant in the output. The **Timing Error Detector** implements bit stuffing or skipping to handle the extra or missing interpolants.

Refer to Chapter 8.4.4 of [3 on page 15-77] for details of bit stuffing and skipping. The timing recovery loop normally generates one output symbol for every two input samples. It also outputs a

timing strobe (**validOut** signal) that runs at the input sample rate. Under normal circumstances, the strobe value is simply a sequence of alternating ones and zeros. However, this occurs only when the relative delay between transmitter and receiver contains some fractional part of one symbol period and the integer part of the delay (in symbols) remains constant. If the integer part of the relative delay changes, the strobe value can have two consecutive zeros or two consecutive ones.

Magnitude & Phase Recovery

The **Magnitude & Phase Recovery** subsystem performs packet synchronization, fine grained frequency recovery and fine grained amplitude recovery.

```
set_param([modelName '/QAM Rx HDL/Timing Recovery'], 'Open', 'off');
set_param([modelName '/QAM Rx HDL/Magnitude & Phase Recovery'], 'Open', 'on');
```

Packet Synchronization: The **Preamble Matched Filter** subsystem uses the time-reversed complex conjugate of the preamble as the filter weights. The modulus of the output of the **Preamble Matched Filter** subsystem is calculated using the **Modulus** subsystem. The output of the **Modulus** subsystem is then compared to a threshold to detect the preamble at the start of a packet. The MATLAB function block generates a signal, **isPreamble**, which is held high for the duration of the preamble of each packet. The MATLAB function block also generates the **dvalid** signal which is set high for the duration of the packet when a preamble has been detected.

Fine Grained Magnitude and Phase Recovery : The **1-Tap DLMS** (Delayed Least Mean Squares) filter subsystem, adapting over the preamble and using the reference signal generated by **Desired Signal Source**, corrects for both phase and magnitude errors. The **isPreamble** signal, generated by the MATLAB function block and set high for the 14 preamble symbols once a packet has been detected, is used to enable the desired signal source and to enable the **Adapt** input of the **1-Tap DLMS**. When the **isPreamble** signal is low, the weight in the **1-Tap DLMS** is held and the **Desired Signal Source** is reset. The Delayed LMS (DLMS) [4 on page 15-77] algorithm is used here to allow for more pipelining to be introduced and, therefore, reduce the critical path in the filter and increase the maximum clock rate achievable after being implemented in hardware.

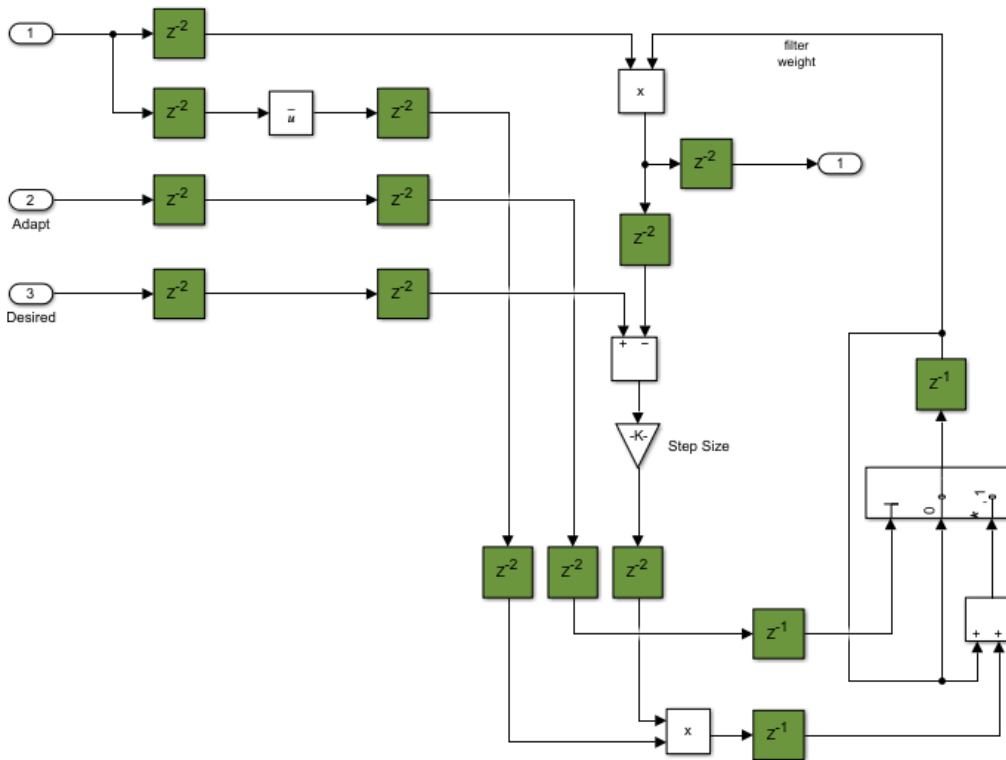

The internal structure of the **Desired Signal Source** subsystem is shown below. The **data lookup** LUT contains the preamble symbols.

```
set_param([modelName '/QAM Rx HDL/Magnitude & Phase Recovery'], 'Open', 'off');
set_param([modelName '/QAM Rx HDL/Magnitude & Phase Recovery/Desired Signal Source'], 'Open', 'on');
```

The internal structure of the **1-Tap DLMS** subsystem is shown below.

```
set_param([modelName '/QAM Rx HDL/Magnitude & Phase Recovery/Desired Signal Source'],'Open','off')
set_param([modelName '/QAM Rx HDL/Magnitude & Phase Recovery/1-Tap DLMS'],'Open','on');
```

Demodulate

The **Demodulate** subsystem maps each 64-QAM input symbol to bits, outputting 6 bits for each input symbol. To generate HDL for the **Rectangular QAM Demodulator Baseband** block, the minimum distance between symbols must be set to 2. This is 8 times larger than the distance between the symbols generated in the transmitter. As a result, the symbols input to the **Demodulate** subsystem

must be scaled up appropriately. This is done using the **Shift Arithmetic** block which shifts the binary point left by 3 bits to achieve the required multiplication by 8.

```
set_param([modelName '/QAM Rx HDL/Magnitude & Phase Recovery/1-Tap DLMS'], 'Open', 'off');
set_param([modelName '/QAM Rx HDL/Demodulate'], 'Open', 'on');
```

Results and Displays

During the simulation, the model displays successfully received packets in the MATLAB Command Window. At every 50 packets, the MATLAB Command Windows displays the bit error rate of the data in the last 50 successfully received packets.

After running the simulation, the model displays six different figures that illustrate different aspects of the receiver performance. These are shown below, along with an explanation of each plot. The first five plots show the adaption, over the simulation duration, of the **Automatic Gain Control**, **Frequency Offset Estimation**, **Timing Recovery** position estimate, the real part of the constellation at the output of the **Timing Recovery** subsystem, and at the output of the **Magnitude & Phase Recover** subsystem. The last plot shows the constellation diagram at the output of **Magnitude & Phase Recovery** subsystem after any adaption has taken place.

```
set_param([modelName '/QAM Rx HDL/Demodulate'], 'Open', 'off');
print_cap = evalc('sim(modelname)'); %#ok<NASGU>
clear print_cap;
tscope1.hide;
tscope2.hide;
tscope3.hide;
constDiag1.hide;
constDiag2.hide;
constDiag3.hide;
```

Automatic Gain Control Plot

This plot illustrates the **Automatic Gain Control** subsystem adapting over time to normalize the output. A balance must be struck between how quickly the automatic gain control adapts and how

much ripple there is after the gain has reached a relatively constant level. Using a larger automatic gain control loop gain adapts faster, but the amplitude after adaption varies more. Using a smaller loop gain slows the adaption of the automatic gain control, smooths the level after adaption but takes longer to adapt.

```
tscope1.show;
```

Frequency Offset Estimate Plot

This plot illustrates how the coarse frequency offset gradually adapts towards the frequency offset introduced by the system, as indicated by the blue horizontal line. This image shows that while the estimate comes close to the actual frequency offset, there is still a residual error that must be addressed later in the system.

```
tscope1.hide;
tscope2.show;
```

Timing Recovery Position Plot

This plot shows the **mu** input to the **Interpolation Filter**. Note that **mu** converges to a steady state, with some ripple over time as the channel delay does not vary during the simulation.

```
tscope2.hide;
tscope3.show;
```

Real Part of Timing Recovery Output Plot

This plot illustrates how the real part of the **Timing Recovery** subsystem output is beginning to converge towards the eight distinct amplitude levels expected for 64QAM. However, as the residual frequency offset remaining after the coarse frequency recovery has not yet been corrected at this point in the receiver, the quality of the signal varies with the distinct amplitude levels more clearly visible at some points than at others. The constellation still has some rotation at this point in the receiver.

```
tscope3.hide;
constDiag1.show;
```

Real Part of Symbol Estimates Plot

This plot shows how the real part of output of the **Magnitude & Phase Recovery** subsystem adapts over time. Unlike the previous plot, this diagram is generated after the fine frequency recovery, therefore the constellation should not be rotating. There are no samples initially as the output from the block is not valid, and then eight clear amplitude levels should be seen - representing the eight real amplitude levels of the 64-QAM constellation.

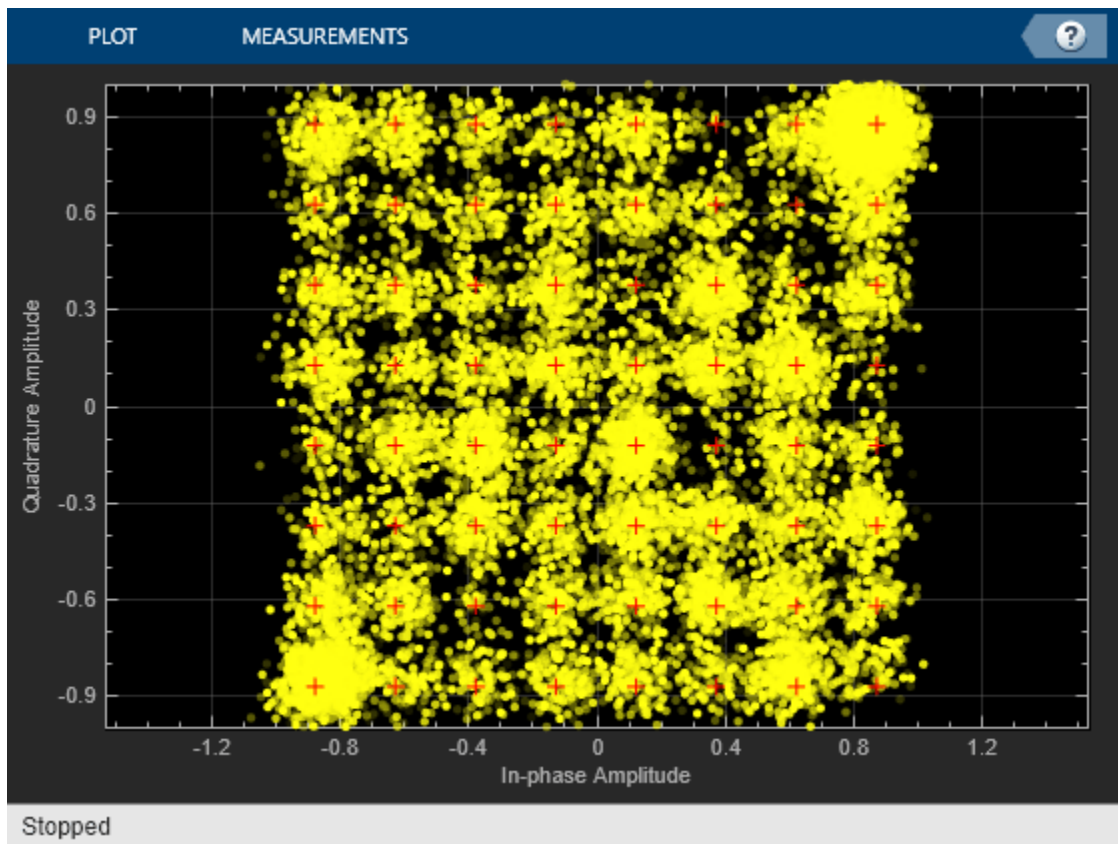

```
constDiag1.hide;
constDiag2.show;
```

Recovered Constellation Plot

This plot shows the constellation at the output of the **Magnitude & Phase Recovery** subsystem after the system has had time to adapt to the channel. Reducing the channel noise should reduce the size of each of the constellation points; increasing the channel noise begins to merge the distinct constellation points together. If the system has not successfully corrected for the frequency offset, then rotation of the constellation is visible here.

```
constDiag2.hide;  
constDiag3.show;
```

Airplane Tracking with ADS-B Captured Data

This example shows how to implement the Automatic Dependent Surveillance - Broadcast (ADS-B) receiver for HDL code generation and hardware implementation. This example decodes ADS-B extended squitter messages which can be used to track the airplane. The HDL-optimized model in this example uses Simulink® blocks that support HDL code generation to implement the ADS-B Receiver. This example model is used for real-time processing in “HW/SW Co-Design Implementation of ADS-B Receiver Using Analog Devices AD9361/AD9364” (Communications Toolbox Support Package for Xilinx Zynq-Based Radio), which requires the Communications Toolbox™ Support Package for Xilinx® Zynq®-Based Radio.

Introduction

ADS-B is an air traffic management and control surveillance system. The broadcast messages (approximately once per second) contain the flight information including position and velocity. For introduction on ADS-B technology and modes of transmission, see [1]. The **HDLRx** subsystem is optimized for HDL code generation. The captured received signal is streamed into the receiver (**HDLRx** subsystem) front end. The streaming output of the receiver is buffered and passed to the **MapResults** MATLAB® function to view the output.

Structure of the Example

The model supports both Normal and Accelerator modes. The top-level structure of the ADS-B receiver model is shown in the following figure.

Copyright 2018 The MathWorks, Inc.

The receiver input data is captured using “HW/SW Co-Design Implementation of ADS-B Receiver Using Analog Devices AD9361/AD9364” (Communications Toolbox Support Package for Xilinx Zynq-Based Radio) running on the Zynq® platform. The captured data represents the baseband received signal with a sampling rate of 4 MHz. The data contains 8 frames of extended squitter messages. The

ADS-B transmitter modulates the 112-bit extended squitter messages using 2-bit pulse-position modulation, and adds a 16-bit prefix. Then, to generate 4 MHz data, each 240-bit message is zero-padded and upsampled by 2.

This diagram shows the detailed structure of the **HDLRx** subsystem.

The subsystems listed here are described further in the following sections.

1. **Magnitude Calculation** - Finds the complex modulus of the received input signal
2. **Threshold Calculation** - Calculates the threshold value based on received input signal strength
3. **Correlation with Preamble** - Correlates the received signal with reference signal to detect the preamble
4. **Timing Control** - Provides timing synchronization for the receiver
5. **Bit Process** - Decodes symbols using PPM demodulation
6. **Compute CRC and Frame Validation** - Validates the frame by checking for CRC errors

HDL Optimized ADS-B Receiver

1. Magnitude Calculation

The inputs to the **Magnitude Calculation** subsystem are the in-phase (real) and quadrature (imaginary) phase samples. This subsystem outputs the modulus of the complex number. The $\sqrt{I^2 + Q^2}$ can be approximated by the " $|L| + 0.4 * |S|$ algorithm" described on page 238 of [2].

$$\sqrt{I^2 + Q^2} = |L| + 0.4 * |S|$$

where

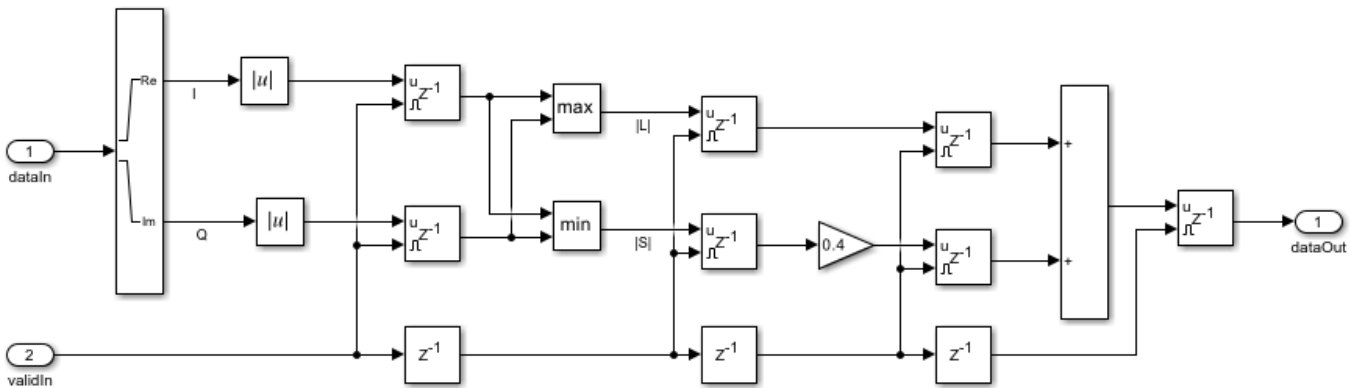

$|L|$ is the larger value of $|I|$ or $|Q|$

$|S|$ is the smaller value of $|I|$ or $|Q|$.

The Gain block converts received input from 12-bit to 16-bit word length.

For the implementation of " $|L|+0.4|S|$ algorithm", see the following model.

2. Threshold Calculation

The **Threshold Calculation** subsystem calculates the signal energy and applies a scaling factor to create a threshold for preamble detection. Moving Average Filter is a serial FIR filter architecture with 32 coefficients that operates on the magnitude values. The coefficients of the FIR filter are selected to find the average energy of the received signal. This example scales the signal energy by 5 to detect valid ADS-B preambles. For details on FIR filter, see Discrete FIR Filter.

3. Correlation with Preamble

The **Correlation with Preamble** subsystem correlates the received signal with the ADS-B reference/preamble sequence [1 0 1 0 0 0 1 0 1 0 0 0 0 0] using a peak detection filter. The peak detection filter is a serial FIR Filter architecture, configured with coefficients that match the preamble sequence. Preamble correlation identifies potential ADS-B transmissions and aligns our bit detection algorithm with the first message bit. The preamble is detected if the peak amplitude exceeds the scaled threshold value. Once the preamble is detected, the correlation value is passed on as input(SyncCorr) to the **Timing Control** block.

4. Timing Control

The **Timing Control** block is a state machine that detects the preamble and generates the control signals ActivateBP and Reset, that indicate the start of frame, end of frame and reset status to the **Bit Process** and **Compute CRC and Frame Validation** blocks.

5. Bit Process

The **Bit Process** subsystem demodulates and down converts the 4 MHz received signal to a 1 MHz bit sequence. Each data bit is represented by four PPM bits. To demodulate, the block finds the sum of the first two bits and the last two bits of each quadruplet. Then, it compares the sums to determine the original bit value. The output valid signal is asserted every fourth cycle to align with 1 MHz bit sequence.

6. Compute CRC and Frame Validation

This subsystem checks for mismatches in the 24-bit checksum of each 88-bit message. The CRC block needs an indication of the frame boundaries to determine which bits are the checksum. The rising edge of the ActivateBP signal generated from the **Timing Control** block indicates the start of frame, and the falling edge indicates the end of the frame. The start signal is delayed to match the demod latency. When the block output err signal is zero, the frame is a valid ADS-B message. The subsystem buffers the message bits until the message is confirmed to have no CRC error.

Launch Map and Log Data

You can launch the map and start text file logging using the two slider switches (Launch Map and Data Logging).

Launch Map - Launch the map where the tracked flights can be viewed. **NOTE:** You must have a Mapping Toolbox™ license to use this feature.

Data Logging - Save the captured data in a TXT file. You can use the saved data for later for post processing.

Results and Displays

The **HDLRx** subsystem demodulates and decodes the ADS-B data and the output is streamed through **Deserializer1D** block and **MapResults** MATLAB function, which produces hexadecimal output information about the aircraft. Each extended squitter Mode S packet contains partial information (any of Aircraft ID, Flight ID, Altitude, Speed, and Location) about the aircraft and the table is built up from multiple messages. The output is obtained as shown in the following diagram. The packet statistics include the number of detected packets, the number of correctly decoded packets, and packet error rate (PER). These aircraft details match the transmitted values from the “HW/SW Co-Design Implementation of ADS-B Receiver Using Analog Devices AD9361/AD9364” (Communications Toolbox Support Package for Xilinx Zynq-Based Radio) example.

HDL Code Generation and Synthesis Results

Pipeline registers have been added to the model to make sure that **HDLRx** subsystem does not have a long critical path. The HDL code generated from the **HDLRx** subsystem was synthesized using Xilinx® Vivado® on a **Zynq** FPGA with the device 7z045ffg900-2, and the design achieves **264.2 MHz** clock frequency, which is sufficient to decode the real-time ADS-B signals. The generated HDL code is tested and verified in the real-time example “HW/SW Co-Design Implementation of ADS-B Receiver Using Analog Devices AD9361/AD9364” (Communications Toolbox Support Package for Xilinx Zynq-Based Radio). To check and generate the HDL code referenced in this example, you must have an HDL Coder™ license. The following table shows the synthesis results of this example.

Synthesis Frequency	264.2 MHz	
Resources	Used	Utilization in %
Slice LUTs	831	0.38
Slice Registers	1689	0.39
DSP48E1	2	0.22
F7 Muxes	24	0.02
F8 Muxes	8	0.01

You can use the commands `makehdl` and `makehdltb` to generate HDL code and a test bench for the HDLRx subsystem. To generate the HDL code, use the following command:

```
makehdl('commdsbrxhdl/HDLRx')
```

To generate a test bench, use the following command:

```
makehdltb('commdsbrxhdl/HDLRx')
```

HDL Code Generation for Viterbi Decoder

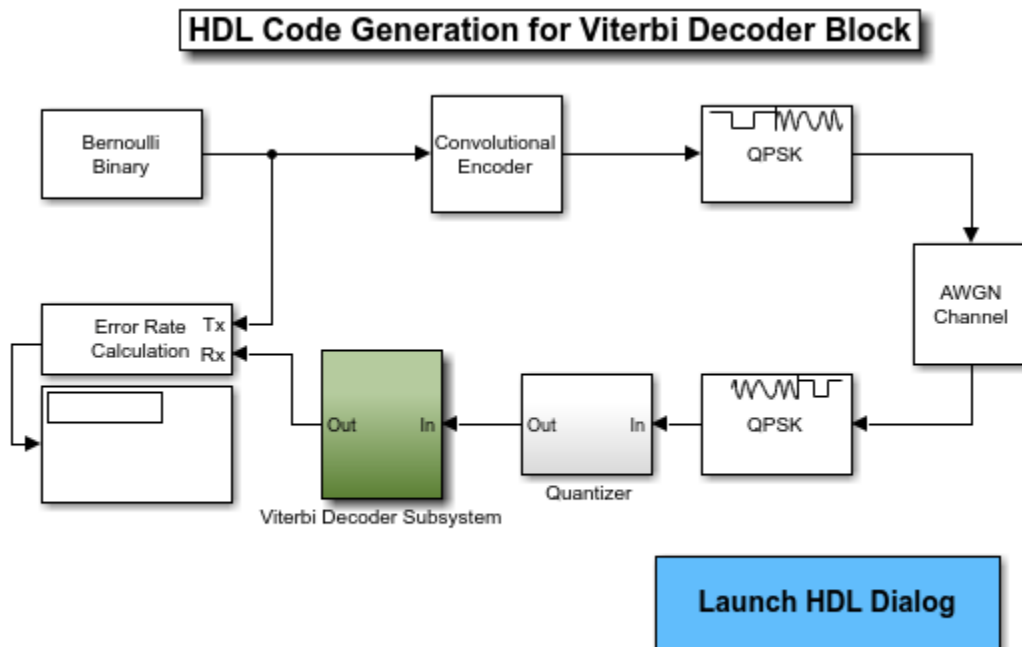

This example shows HDL code generation support for the Viterbi Decoder block. It shows how to check, generate, and verify the HDL code you generate from a fixed-point Viterbi Decoder model. This example also discusses the settings you can use to alter the HDL code you generate.

Introduction

The model shows HDL code generation for a fixed-point Viterbi Decoder block used in soft decision convolutional decoding. To learn more about HDL support for Viterbi Decoder, refer to the “HDL Code Generation” (Communications Toolbox) section of the block page in documentation.

To open the model, run the following commands:

```
modelname = 'hdlcoder_comm_viterbi';
open_system(modelname);
```

Copyright 2014 The MathWorks, Inc.

In this model, the top-level subsystem *Viterbi Decoder Subsystem* contains the Viterbi Decoder block. To open this subsystem, run the following commands:

```
systemname = [modelname '/Viterbi Decoder Subsystem'];
open_system(systemname);
```

The Viterbi Decoding Algorithm

There are three main components to the Viterbi decoding algorithm. They are the branch metric computation (BMC), add-compare-select (ACS), and traceback decoding. The following diagram illustrates the three units in the Viterbi decoding algorithm:

The Renormalization Method

The Viterbi Decoder prevents the overflow of the state metrics in the ACS component by subtracting the minimum value of the state metrics at each time step, as shown in the following figure:

Obtaining the minimum value of all the state metric elements in one clock cycle results in a poor clock frequency for the circuit. The performance of the circuit may be improved by adding pipeline registers. However, simply subtracting the minimum value delayed by pipeline registers from the state metrics may still lead to overflow. The hardware architecture modifies the renormalization method and avoids the state metric overflow in three steps. First, the architecture calculates values for the threshold and step parameters, based on the trellis structure and the number of soft decision bits. Second, the delayed minimum value is compared to the threshold. Last, if the minimum value is greater than or equal to the threshold value, the implementation subtracts the step value from the state metric; otherwise no adjustment is performed. The following figure illustrates the modified renormalization method:

Optimal State Metric Word Length Calculation

The hardware implementation calculates the optimal word length of the state metric and compares it with the value you specify for the block. The hardware architecture uses the optimal value if it is smaller than the one you specify. A message is displayed to show the value during HDL code

generation. If the calculated value is larger than the value you specify, an error message is reported and the optimal value is displayed.

Applying the calculated optimal state metric word length in the hardware implementation may significantly reduce the hardware resource if the value you specify is too large. For example, if you set 16 bits as the state metric word length but only 9 bits are required to achieve the same numerical results, applying the calculated optimal state metric word length in the hardware architecture saves approximately 40 percent of the register resources. The calculated optimal state metric word length for some typical trellises is displayed in the following table:

Decoding rate	Free distance	Example Trellis	Number of soft decision bits	Optimal word length
1/2	10	7, [171 133]	3	8
1/2	10	7, [171 133]	1	5
1/3	15	7, [171 133 165]	3	9
1/3	15	7, [171 133 165]	1	6
1/4	24	9,[463 535 733 745]	3	9
1/4	24	9,[463 535 733 745]	1	7

Check and Generate Code for a Fixed-point Viterbi Model

This model decodes a DVB rate 1/2 , constraint length 7,(171,133) convolutional code with 3 bits soft decision. The decoder runs at continuous mode with the traceback depth of 32. The state metric word length is set to 16 bits. To validate the parameter settings of the Viterbi Decoder block, you can run the following commands:

- `workingdir = tempname;`
- `checkhdl(systemname,'TargetDirectory',workingdir);`

Running `checkhdl` generates messages that report:

- the default value of **TracebackStagesPerPipeline**. More information on this parameter can be found in the section **Pipelining the register-based traceback unit**,
- the state metric word length used in the HDL code compared with the one set on the block mask,
- the total delay introduced by the pipeline registers with respect to the original Viterbi block.

To generate HDL for the subsystem containing the Viterbi Decoder block, run the following commands: `workingdir = tempname; makehdl(systemname,'TargetDirectory',workingdir);`

The top level VHDL file name matches the name of the block in the model. The `Viterbi_Decoder` component generated in the `Viterbi_Decoder.vhd` contains three components: `BranchMetric`, `ACS`, and `Traceback`. The `ACS` and `Traceback` components instantiate components `ACSUnit` and `TracebackUnit` multiple times respectively. Data type definitions are included in the package file `Viterbi_Decoder_Subsystem_pkg.vhd`.

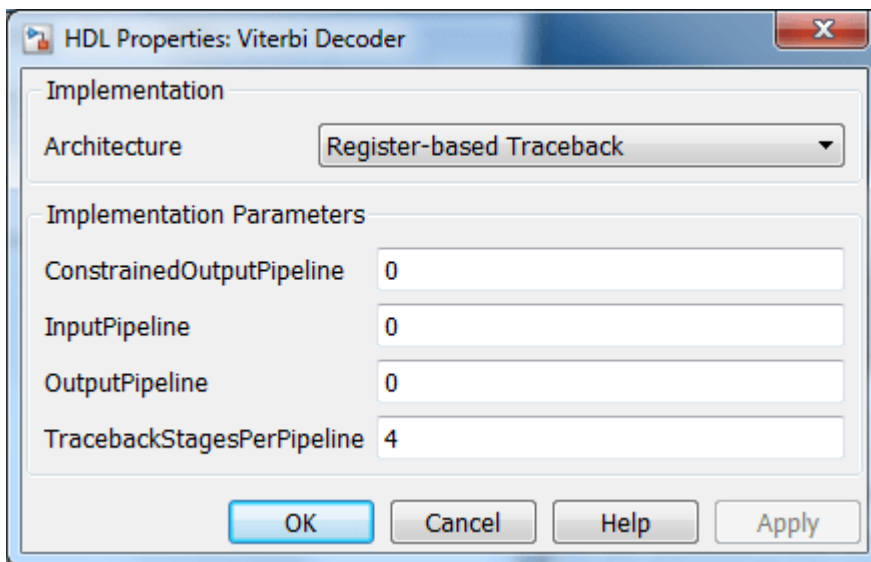

To generate a testbench for the subsystem containing the Viterbi Decoder block, run the following command: `makehdltb(systemname,'TargetDirectory',workingdir);`

Optimization of The Traceback Unit

They are two methods to optimize the traceback unit: pipelining the register-based traceback or using the RAM-based traceback architecture.

- **Pipelining the register-based traceback unit**

The Viterbi Decoder block decodes every bit by tracing back through a traceback depth you define for the block. Because the block implements a complete traceback for each decision bit, registers are used to store the minimum state index and branch decision in the Traceback Decoding unit. This unit may be pipelined in order to improve the performance of the generated circuit. Pipeline registers can be added to the traceback unit by specifying the number of traceback stages per pipeline register. This can be done by setting the **TracebackStagesPerPipeline** implementation parameter for the Viterbi Decoder in the HDL block properties dialog. Right click the Viterbi Decoder block to navigate to the **HDL Block Properties** menu.

Setting the property value to 4 results in the insertion of a pipeline register for every four traceback units in the model, as illustrated in the following figure:

The **TracebackStagesPerPipeline** implementation parameter provides you a way of balancing the circuit performance based on system requirements. A smaller parameter value indicates the requirement to add more registers to increase the speed of the traceback circuit. Increasing the number results in a lower usage of registers along with a decrease in the circuit speed. In our experiment with the rate 1/2, constraint length 7, (171,133) convolutional code, adjusting the **TracebackStagesPerPipeline** parameter from 4 to 8 reduces the pipeline register usage in half, with the circuit speed changing from 173MHz to 94 MHz.

- **RAM-based traceback**

Instead of using registers, you can choose to use RAMs to save the survivor branch information. This can be done by setting the HDL Architecture property of the Viterbi Decoder block to RAM-based Traceback.

There are two major differences between the register-based and the RAM-based traceback architectures.

Firstly, the register-based implementation combines the traceback and decode operations into one step and uses the best state found from the minimum operation as the decoding initial state. The RAM-based implementation traces back through one set of data to find the initial state to decode the previous set of data.

Secondly, the register-based implementation decodes one bit after a complete traceback; while the RAM-based implementation traces back through M samples, decodes the previous M bits in reverse order, and releases one bit in order at each clock cycle.

Due to the differences in the two traceback algorithms, the RAM-based implementation produces different numerical results than the register-based traceback. A longer traceback depth, for example, 10 times of constraint length, is recommended in the RAM-based traceback to achieve a similar bit error rate (BER) as the register-based implementation.

The size of RAM required for the implementation depends on the trellis and the traceback depth. The following table summarizes the RAM usage for some typical trellis structures.

Constraint length	Example trellis	Traceback depth	Memory size(bits)	Block RAMs
3	3,[5 7]	30	3x30x4	1
4	4,[15 17])	40	3x40x8	1
5	5,[37 27 33 25 35]	50	3x50x16	1
6	6,[73 75 55 65 47 57]	60	3x60x32	1
7	7,[171 133]	70	3x70x64	2
8	(8,[225 331 367])	80	3x80x128	4
9	9,[463 535 733 745]	90	3x90x256	8

Our experiment with the rate 1/2, constraint length 7, (171, 133) convolutional code shows that the RAM-based traceback unit uses 90% fewer registers than the register-based traceback unit (with pipelining every 4 stages)) using similar clock constraints in synthesis. The two implementations provide a register-RAM tradeoff that can be tailored to the individual design.

Design Video Processing Algorithms for HDL in Simulink

This example shows how to design a hardware-targeted image filter using Vision HDL Toolbox™ blocks. It also uses Computer Vision Toolbox™ blocks.

The key features of a model for hardware-targeted video processing in Simulink® are:

- **Streaming pixel interface:** Blocks in Vision HDL Toolbox use a streaming pixel interface. Serial processing is efficient for hardware designs, because less memory is required to store pixel data for computation. The serial interface allows the block to operate independently of image size and format and makes the design more resilient to video timing errors. For further information, see “Streaming Pixel Interface” (Vision HDL Toolbox).
- **Subsystem targeted for HDL code generation:** Design a hardware-friendly pixel-streaming video processing model by selecting blocks from the Vision HDL Toolbox libraries. The part of the design targeted for HDL code generation must be in a separate subsystem.
- **Conversion to frame-based video:** For verification, you can display frame-based video or compare the result of your hardware-compatible design with the output of a Simulink behavioral model. Vision HDL Toolbox provides a block that allows you to deserialize the output of your design.

Open Model Template

This tutorial uses a Simulink model template to get started.

Click the Simulink button, or type `simulink` at the MATLAB® command prompt. On the Simulink start page, find the Vision HDL Toolbox section, and click the Basic Model template.

The template creates a new model that you can customize. Save the model with a new name.

The model shows three video streams on the video viewers.

1. The first video viewer displays the input video stream.
2. The input video is passed through the Behavioral Algorithm subsystem which represents the full-frame model of the algorithm to be ported to HDL. The output of the Behavioral Algorithm subsystem is displayed on the Behavioral Video Viewer.
3. On the third stream, the input video is converted to a streaming pixel format using the Frame to Pixels blocks, passed through the HDL Algorithm subsystem and then converted back to a frame using the Pixels to Frame block.
4. The model is configured for HDL code generation using the `hdlsetup` function.
5. The video format is defined by Model Simulation Callback Parameters (File -> Model Properties -> Model Properties -> Callbacks -> InitFcn).
6. To run this model, you must have a license for the Computer Vision Toolbox™.

You can

1. Add blocks to the Behavioral Algorithm and HDL algorithm subsystems.
2. Change the video format by changing the settings in the Video source, Frame to Pixels and Pixels to Frame blocks.
3. Generate HDL code for the HDL Algorithm subsystem by right-clicking on the subsystem -> HDL Coder -> Generate HDL for Subsystem.

Copyright 2019-2020 The MathWorks, Inc.

Import Data

The template includes a Video Source block that contains a 240p video sample. Each pixel is a scalar `uint8` value representing intensity. A best practice is to design and debug your design using a small frame size for quick debug cycles, before scaling up to larger image sizes. You can use this 240p source to debug a design targeted for 1080p video.

Serialize Data

The Frame To Pixels block converts framed video to a stream of pixels and control structures. This block provides input for a subsystem targeted for HDL code generation, but it does not itself support HDL code generation.

The template includes an instance of this block. To simulate with a standard video format, choose a predefined video padding format to match your input source. To simulate with a custom-size image, choose the dimensions of the inactive regions that you want to surround the image with. This tutorial uses a standard video format.

Open the Frame To Pixels block dialog box to view the settings. The source video is in 240p grayscale format. A scalar integer represents the intensity value of each pixel. To match the input video, set **Number of components** to 1, and the **Video format** to 240p.

Note: The sample time of the video source must match the total number of pixels in the frame size you select in the Frame to Pixels block. Set the sample time to **Total pixels per line** × **Total lines**.

In the `InitFcn` callback, the template creates a workspace variable, `totalPixels`, for the sample time of a 240p frame.

Design HDL-Compatible Model

Design a subsystem targeted for HDL code generation, by modifying the HDL Algorithm subsystem. The subsystem input and output ports use the streaming pixel format described in the previous section. Open the HDL Algorithm subsystem to edit it.

In the Simulink Library Browser, click Vision HDL Toolbox. You can also open this library by typing `visionhdllib` at the MATLAB command prompt.

Select an image processing block. This example uses the Image Filter (Vision HDL Toolbox) block from the Filtering sublibrary. You can also access this library by typing `visionhdlfilter` at the MATLAB command prompt. Add the Image Filter block to the HDL Algorithm subsystem and connect the ports.

Open Image Filter block and make the following changes:

- Set **Filter coefficients** to `ones(4,4)/16` to implement a 4×4 blur operation.
- Set **Padding method** to `Symmetric`.
- Set **Line buffer size** to a power of 2 that accommodates the active line size of the largest required frame format. This parameter does not affect simulation speed, so it does not need to be reduced when simulating with a small test image. The default, 2048, accommodates 1080p video format.
- On the **Data Types** tab, under **Data Type**, set **Coefficients** to `fixdt(0,1,4)`.

Design Behavioral Model

You can visually or mathematically compare your HDL-targeted design with a behavioral model to verify the hardware design and monitor quantization error. The template includes a Behavioral Model subsystem with frame-based input and output ports for this purpose. Double-click on the Behavioral Model to edit it.

For this tutorial, add the 2-D FIR Filter (Computer Vision Toolbox) block from Computer Vision Toolbox™. This block filters the entire frame at once.

Open the 2-D FIR Filter block and make the following changes to match the configuration of the Image Filter block from Vision HDL Toolbox:

- Set **Coefficients** to `ones(4,4)/16` to implement a 4×4 blur operation.
- Set **Padding options** to `Symmetric`.
- On the **Data Types** tab, under **Data Type**, set **Coefficients** to `fixdt(0,2,4)`.

Deserialize Filtered Pixel Stream

Use the Pixels To Frame block included in the template to deserialize the data for display.

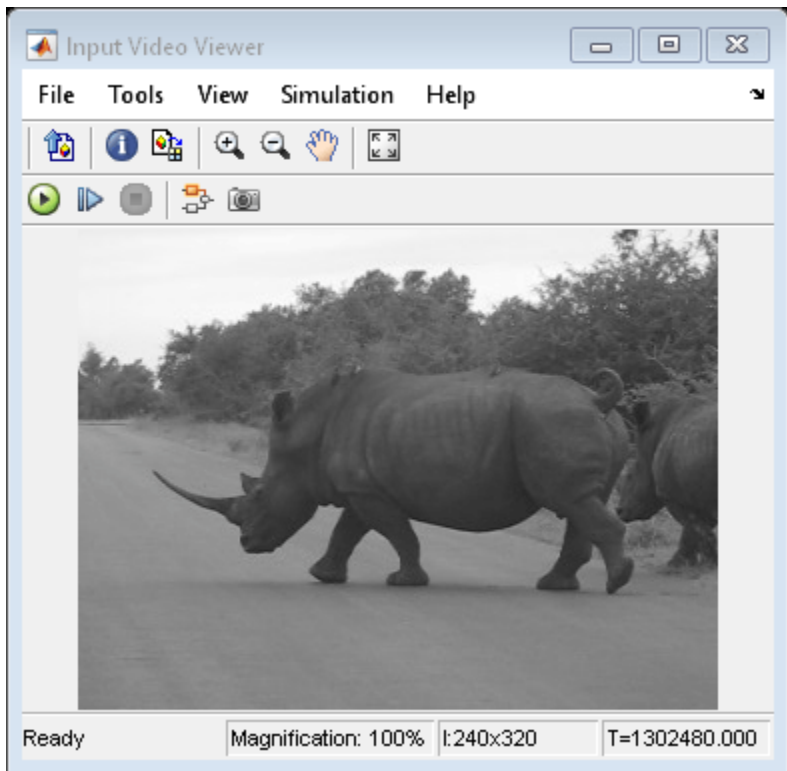

Open the Pixels To Frame block. Set the image dimension properties to match the input video and the settings you specified in the Frame To Pixels block. For this tutorial, the **Number of components** is

set to 1 and the **Video format** is set to 240p. The block converts the stream of output pixels and control signals back to a matrix representing a frame.

Display Results and Compare to Behavioral Model

Use the Video Viewer blocks included in the template to compare the output frames visually. The `validOut` signal of the Pixels To Frame block is connected to the `Enable` port of the viewer. Run the model to display the results.

Generate HDL Code

Once your design is working in simulation, you can use HDL Coder™ to generate HDL code for the HDL Algorithm subsystem. See “Generate HDL Code from Simulink” (Vision HDL Toolbox).

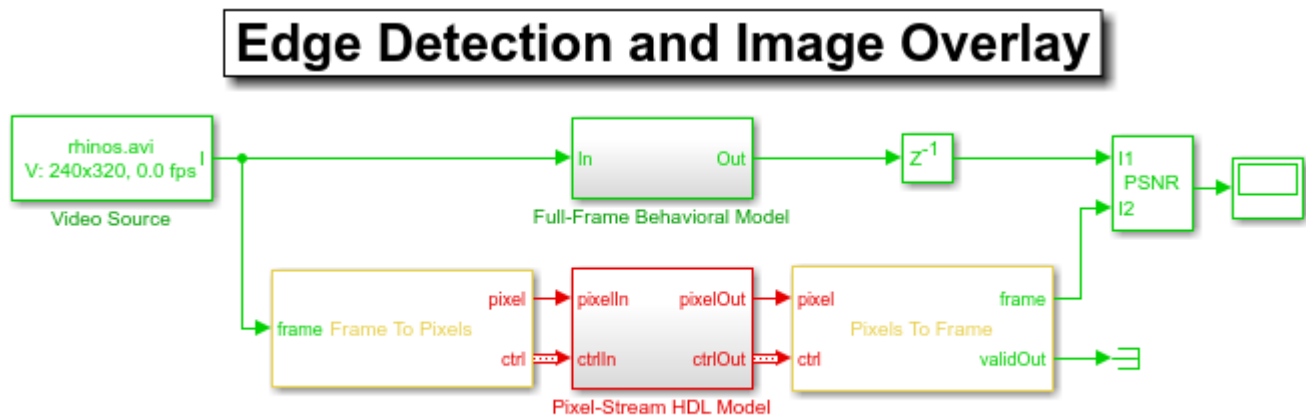

Edge Detection and Image Overlay

This example shows how to detect and highlight object edges in a video stream. The behavior of the pixel-stream Sobel Edge Detector block, video stream alignment, and overlay, is verified by comparing the results with the same algorithm calculated by the full-frame blocks from the Computer Vision Toolbox™.

This example model provides a hardware-compatible algorithm. You can implement this algorithm on a board using a Xilinx® Zynq® reference design. See “Developing Vision Algorithms for Zynq-Based Hardware” (Vision HDL Toolbox Support Package for Xilinx Zynq-Based Hardware).

Structure of the Example

The EdgeDetectionAndOverlayHDL.slx system is shown below.

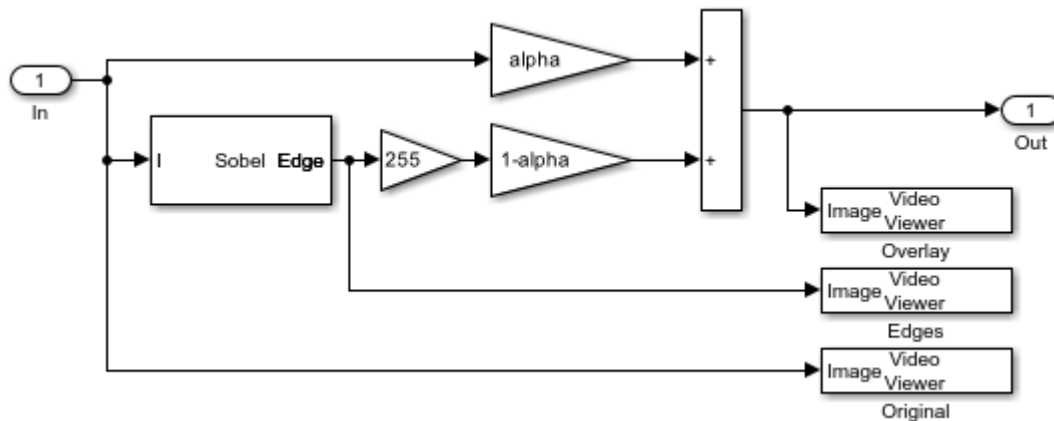

Copyright 2015-2022 The MathWorks, Inc.

The difference in the color of the lines feeding the **Full-Frame Behavioral Model** and **Pixel-Stream HDL Model** subsystems indicates the change in the image rate on the streaming branch of the model. This rate transition is because the pixel stream is sent out in the same amount of time as the full video frames and therefore it is transmitted at a higher rate.

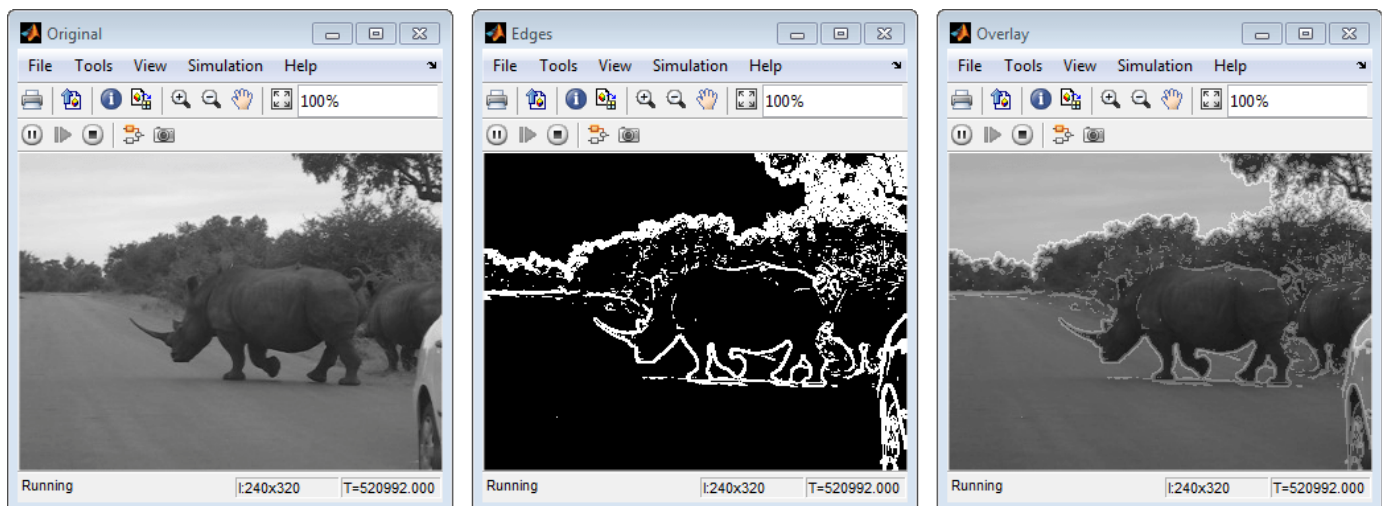

Full-Frame Behavioral Model

The following diagram shows the structure of the **Full-Frame Behavioral Model** subsystem, which employs the frame-based **Edge Detection** block.

Given that the frame-based **Edge Detection** block does not introduce latency, image overlay is performed by weighting the source image and the **Edge Detection** output image, and adding them together in a straightforward manner.

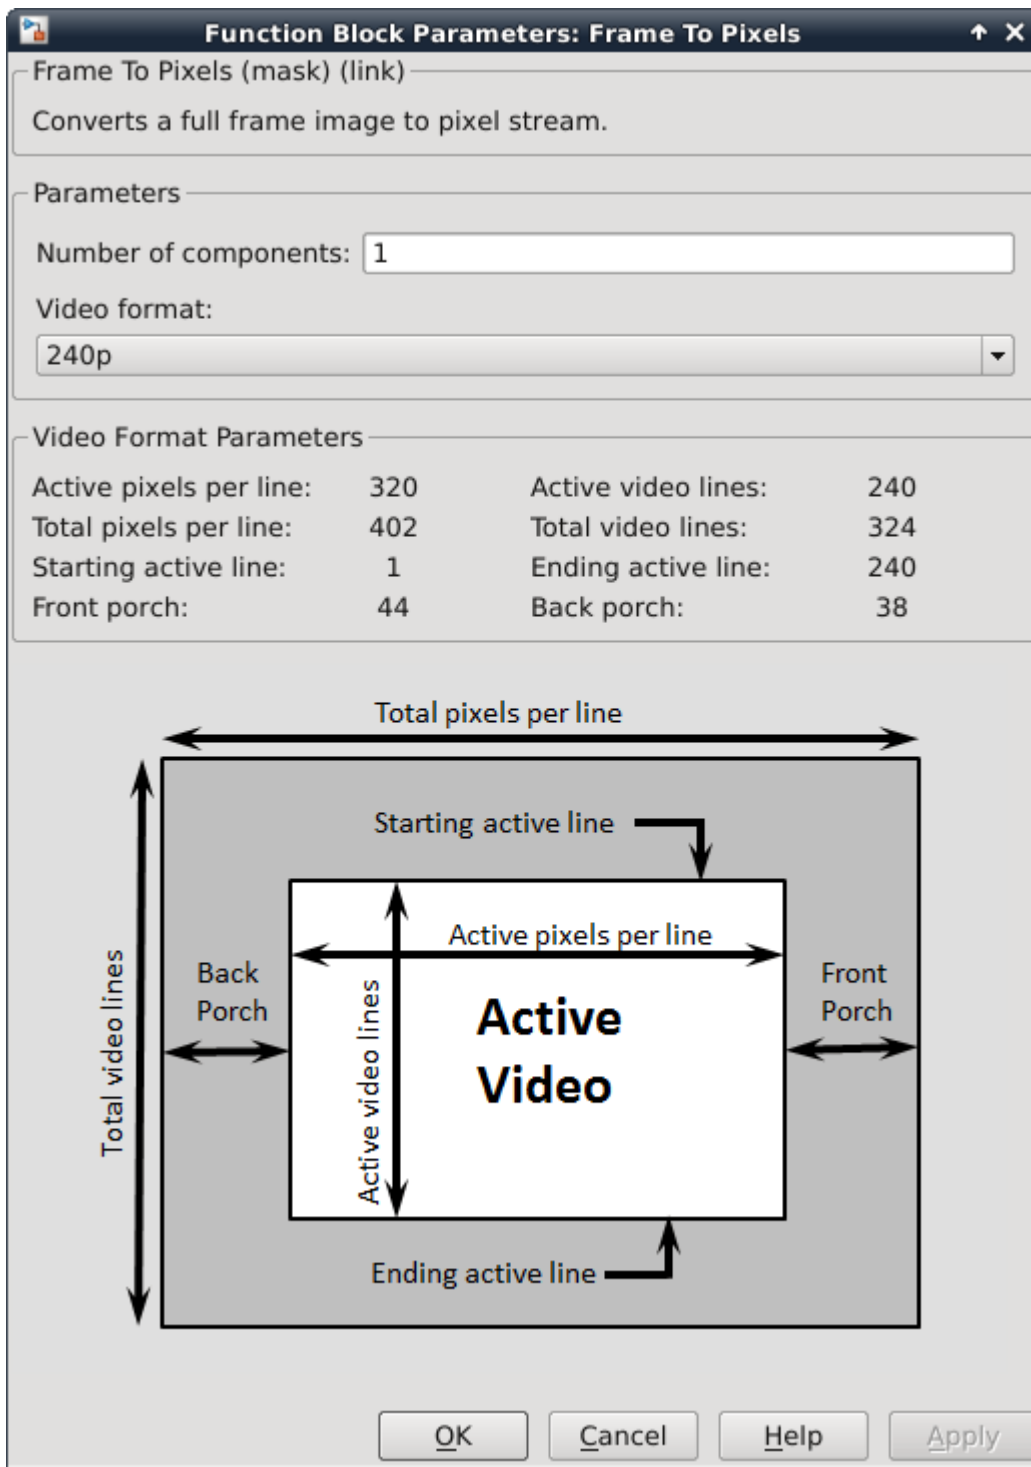

One frame of the source video, the edge detection result, and the overlaid image are shown from left to right in the diagram below.

It is a good practice to develop a behavioral system using blocks that process full image frames, the **Full-Frame Behavioral Model** subsystem in this example, before moving forward to working on an FPGA-targeting design. Such a behavioral model helps verify the video processing design. Later on, it can serve as a reference for verifying the implementation of the algorithm targeted to an FPGA. Specifically, the **PSNR** (peak signal-to-noise ratio) block at the top level of the model compares the results from full-frame processing with those from pixel-stream processing.

Frame To Pixels: Generating a Pixel Stream

The task of the **Frame To Pixels** is to convert a full frame image to pixel stream. To simulate the effect of horizontal and vertical blanking periods found in real life hardware video systems, the active image is augmented with non-image data. For more information on the streaming pixel protocol, see “Streaming Pixel Interface” (Vision HDL Toolbox). The **Frame To Pixels** block is configured as shown:

The **Number of components** field is set to 1 for grayscale image input, and the **Video format** field is 240p to match that of the video source.

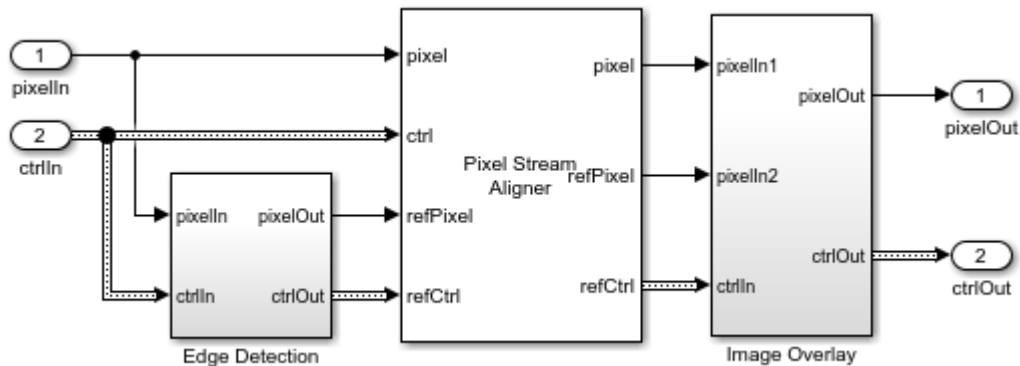

In this example, the Active Video region corresponds to the 240x320 matrix of the dark image from the upstream **Corruption** block. Six other parameters, namely, **Total pixels per line**, **Total video**

lines, **Starting active line**, **Ending active line**, **Front porch**, and **Back porch** specify how many non-image data will be augmented on the four sides of the Active Video. For more information, see the **Frame To Pixels** (Vision HDL Toolbox) block reference page.

Note that the sample time of the **Video Source** is determined by the product of **Total pixels per line** and **Total video lines**.

Pixel-Stream Edge Detection and Image Overlay

The **Pixel-Stream HDL Model** subsystem is shown in the diagram below. You can generate HDL code from this subsystem.

Due to the nature of pixel-stream processing, unlike the **Edge Detection** block in the **Full-Frame Behavioral Model**, the **Edge Detector** block from the Vision HDL Toolbox™ will introduce latency. The latency prevents us from directly weighting and adding two images to obtain the overlaid image. To address this issue, the **Pixel Stream Aligner** block is used to synchronize the two pixel streams before the sum.

To properly use this block, **refPixel** and **refCtrl** must be connected to the **pixel** and **control** bus that are associated with a delayed pixel stream. In our example, due to the latency introduced by the **Edge Detector**, the pixel stream coming out of the **Edge Detection** subsystem is delayed with respect to that feeding into it. Therefore, the upstream source of **refPixel** and **refCtrl** are the **pixelOut** and **ctrlOut** signals from the **Edge Detection** subsystem.

Pixels To Frame: Converting Pixel Stream Back to Full Frame

As a companion to **Frame To Pixels** that converts a full image frame to pixel stream, the **Pixels To Frame** block, reversely, converts the pixel stream back to the full frame by making use of the synchronization signals. Since the output of the **Pixels To Frame** block is a 2-D matrix of a full image, there is no need to further carry on the bus containing five synchronization signals.

The **Number of components** field and the **Video format** fields of both **Frame To Pixels** and **Pixels To Frame** are set at 1 and 240p, respectively, to match the format of the video source.

Verifying the Pixel Stream Processing Design

While building the streaming portion of the design, the **PSNR** block continuously verifies results against the original full-frame design. The **Delay** block on the top level of the model time-aligns the 2-D matrices for a fair comparison. During the course of the simulation, the **PSNR** block should give **inf** output, indicating that the output image from the **Full-Frame Behavioral Model** matches the image generated from the stream processing **Pixel-Stream HDL Model**.

Exploring the Example

The example allows you to experiment with different threshold and alpha values to examine their effect on the quality of the overlaid images. Specifically, two workspace variables *thresholdValue* and *alpha* with initial values 7 and 0.8, respectively, are created upon opening the model. You can modify their values using the MATLAB® command line as follows:

```
thresholdValue=8  
alpha=0.5
```

The updated *thresholdValue* will be propagated to the **Threshold** field of the **Edge Detection** block inside the **Full-Frame Behavioral Model** and the **Edge Detector** block inside **Pixel-Stream HDL Model/Edge Detection**. The *alpha* value will be propagated to the **Gain1** block in the **Full-Frame Behavioral Model** and **Pixel-Stream HDL Model/Image Overlay**, and the value of $1 - \alpha$ goes to **Gain2** blocks. Closing the model clears both variables from your workspace.

In this example, the valid range of *thresholdValue* is between 0 and 256, inclusive. Setting *thresholdValue* equal to or greater than 257 triggers a message **Parameter overflow occurred for 'threshold'**. The higher you set the *thresholdValue*, the smaller the amount of edges the example finds in the video.

The valid range of *alpha* is between 0 and 1, inclusive. It determines the weights for edge detection output image and the original source image before adding them. The overlay operation is a linear interpolation according to the following formula.

$$\text{overlaid image} = \alpha * \text{source image} + (1 - \alpha) * \text{edge image}.$$

Therefore, when *alpha* = 0, the overlaid image is the edge detection output, and when *alpha* = 1 it becomes the source image.

Generate HDL Code and Verify Its Behavior

To check and generate the HDL code referenced in this example, you must have an HDL Coder™ license.

To generate the HDL code, use the following command:

```
makehdl('EdgeDetectionAndOverlayHDL/Pixel-Stream HDL Model');
```

To generate a test bench, use the following command:

```
makehdltb('EdgeDetectionAndOverlayHDL/Pixel-Stream HDL Model');
```

Lane Detection

This example shows how to implement a lane-marking detection algorithm for FPGAs.

Lane detection is a critical processing stage in Advanced Driving Assistance Systems (ADAS). Automatically detecting lane boundaries from a video stream is computationally challenging and therefore hardware accelerators such as FPGAs and GPUs are often required to achieve real time performance.

In this example model, an FPGA-based lane candidate generator is coupled with a software-based polynomial fitting engine, to determine lane boundaries.

Download Input File

This example uses the `visionhdl_caltech.avi` file as an input. The file is approximately 19 MB in size. Download the file from the MathWorks website and unzip the downloaded file.

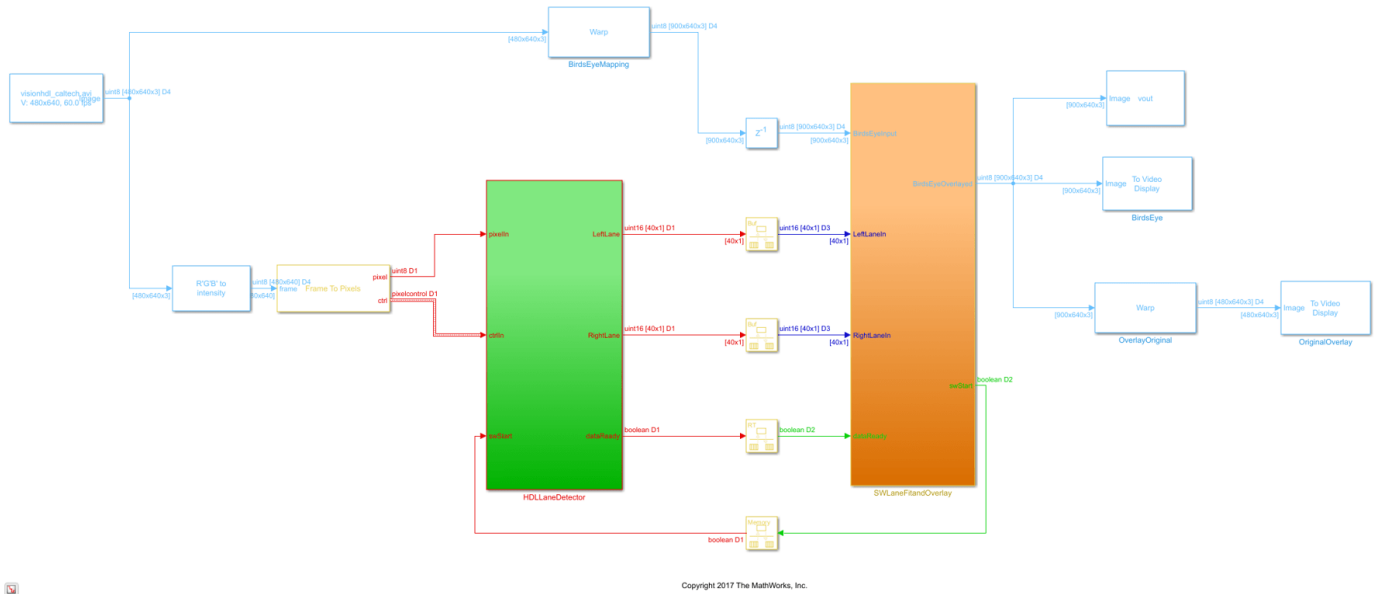

```
laneZipFile = matlab.internal.examples.downloadSupportFile('visionhdl_hdlcoder','caltech_dataset');
[outputFolder,~,~] = fileparts(laneZipFile);
unzip(laneZipFile,outputFolder);
caltechVideoFile = fullfile(outputFolder,'caltech_dataset');
addpath(caltechVideoFile);
```

System Overview

The LaneDetectionHDL.slx system is shown below. The HDLLaneDetector subsystem represents the hardware accelerated part of the design, while the SWLaneFitandOverlay subsystem represent the software based polynomial fitting engine. Prior to the Frame to Pixels block, the RGB input is converted to intensity color space.

```
modelName = 'LaneDetectionHDL';
open_system(modelName);
set_param(modelName,'SampleTimeColors','on');
set_param(modelName,'SimulationCommand','Update');
set_param(modelName,'Open','on');
set(allchild(0),'Visible','off');
```

Lane Detection

HDL Lane Detector

The HDL Lane Detector represents the hardware-accelerated part of the design. This subsystem receives the input pixel stream from the front-facing camera source, transforms the view to obtain the birds-eye view, locates lane marking candidates from the transformed view and then buffers them into a vector to send to the software side for curve fitting and overlay.

```
set_param(modelname, 'SampleTimeColors', 'off');
open_system([modelname '/HDLLaneDetector'], 'force');
```

Birds-Eye View

The Birds-Eye View block transforms the front-facing camera view to a birds-eye perspective. Working with the images in this view simplifies the processing requirements of the downstream lane detection algorithms. The front-facing view suffers from perspective distortion, causing the lanes to converge at the vanishing point. The perspective distortion is corrected by applying an inverse perspective transform.

The Inverse Perspective Mapping (IPM) is given by the following expression:

$$(\hat{x}, \hat{y}) = \text{round} \left(\frac{h_{11}x + h_{12}y + h_{13}}{h_{31}x + h_{32}y + h_{33}}, \frac{h_{21}x + h_{22}y + h_{23}}{h_{31}x + h_{32}y + h_{33}} \right)$$

The homography matrix, h , is derived from four intrinsic parameters of the physical camera setup, namely the focal length, pitch, height, and principle point (from a pinhole camera model). For more details, refer to the Computer Vision Toolbox™ documentation.

You can estimate the homography matrix by using the Computer Vision Toolbox™ `estgeotform2d` function or the Image Processing Toolbox™ `fitgeotform2d` function to create a `projtform2d` object. These functions require a set of matched points between the source frame and birds-eye view frame. The source frame points are taken as the vertices of a trapezoidal region of interest, and can extend past the source frame limits to capture a larger region. For the trapezoid shown the point mapping is:

$$\text{sourcePoints} = [c_x, c_y; d_x, d_y; a_x, a_y; b_x, b_y]$$

$$\text{birdsEyePoints} = [1, 1; bAPPL, 1; 1, bAVL; bAPPL, bAVL]$$

Where $bAPPL$ and $bAVL$ are the birds-eye view active pixels per line and active video lines respectively.

Direct evaluation of the source (front-facing) to destination (birds-eye) mapping in real time on FPGA/ASIC hardware is challenging. The requirement for division along with the potential for non-sequential memory access from a frame buffer mean that the computational requirements of this part of the design are substantial. Therefore instead of directly evaluating the IPM calculation in real time, an offline analysis of the input to output mapping has been performed and used to pre-compute a mapping scheme. This is possible as the homography matrix is fixed after factory calibration/installation of the camera, due to the camera position, height and pitch being fixed.

In this particular example, the birds-eye output image is a frame of [700x640] dimensions, whereas the front-facing input image is of [480x640] dimensions. There is not sufficient blanking available in order to output the full birds-eye frame before the next front-facing camera input is streamed in. The Birds-Eye view block will therefore not accept any new frame data until it has finished processing the current birds-eye frame.

```
open_system([modelName '/HDLLaneDetector'], 'force');
```

Line Buffering and Address Computation

A full sized projective transformation from input to output would result in a [900x640] output image. This requires that the full [480x640] input image is stored in memory, while the source pixel location is calculated using the source location and homography matrix. Ideally on-chip memory should be used for this purpose, removing the requirement for an off-chip frame buffer.

You can determine the number of lines to buffer on-chip by performing inverse row mapping using the homography matrix. The following script calculates the homography matrix from the point mapping, using it to an inverse transform to map the source frame rows to birds-eye view rows.

```
% Source & Birds-Eye Frame Parameters
% AVL: Active Video Lines, APPL: Active Pixels Per Line

Source Video Frame

Birds-Eye View Inverse Row Mapping

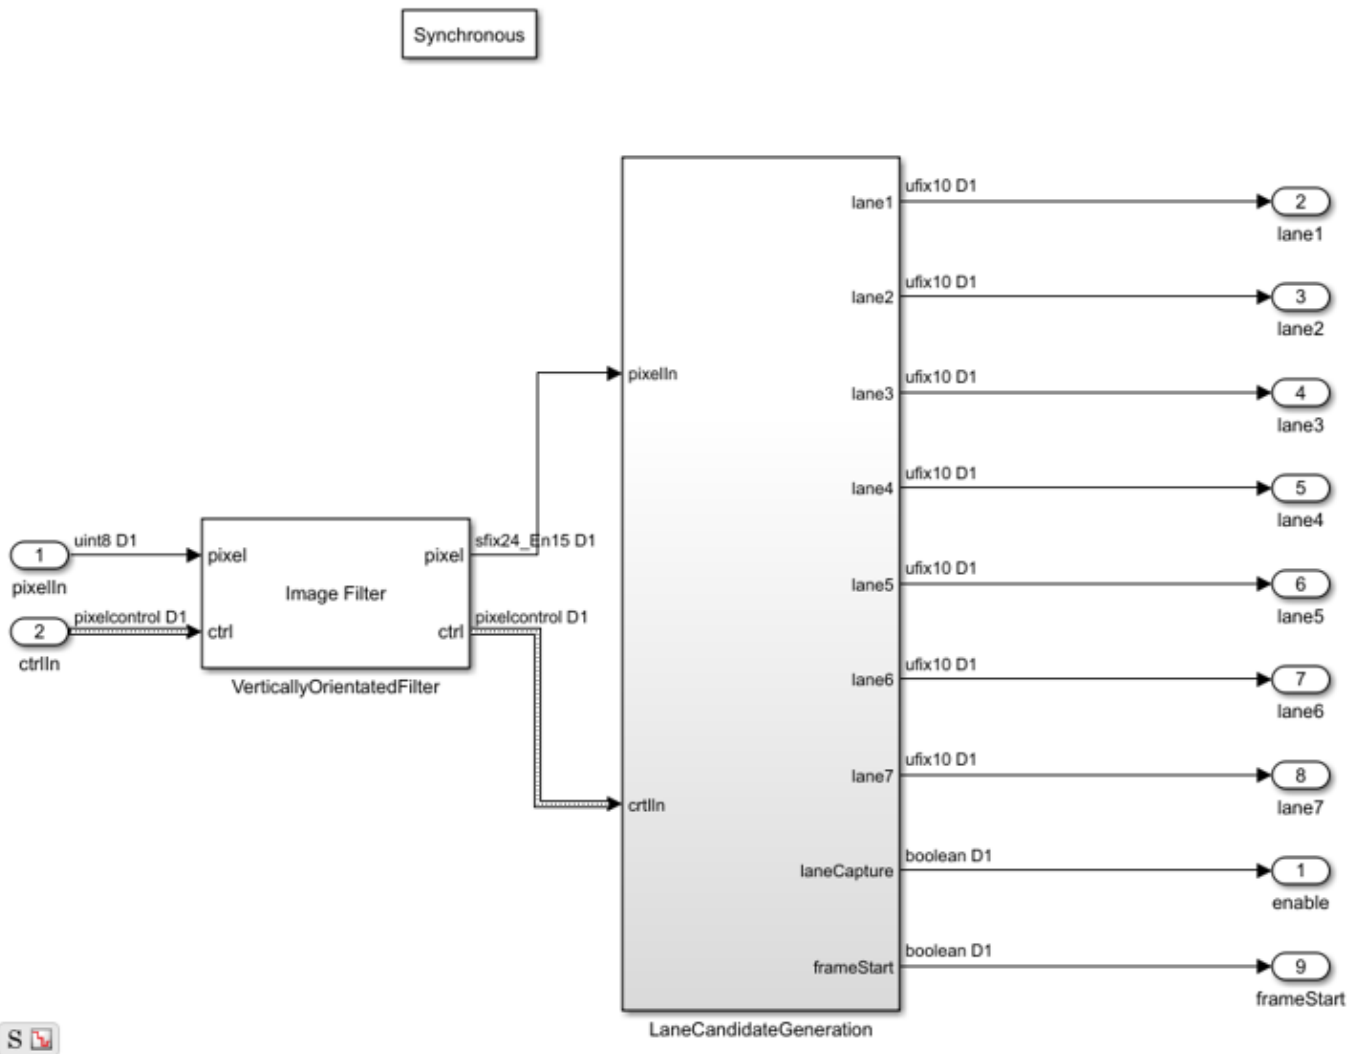

The plot shows the mapping of input line to output line revealing that in order to generate the first 700 lines of the top down birds eye output image, around 50 lines of the input image are required. This is an acceptable number of lines to store using on-chip memory.

Lane Detection

With the birds-eye view image obtained, the actual lane detection can be performed. There are many techniques which can be considered for this purpose. To achieve an implementation which is robust, works well on streaming image data and which can be implemented in FPGA/ASIC hardware at reasonable resource cost, this example uses the approach described in [1]. This algorithm performs a full image convolution with a vertically oriented first order Gaussian derivative filter kernel, followed by sub-region processing.

```
open_system([modelName '/HDLLaneDetector/LaneDetection'], 'force');
```

Vertically Oriented Filter Convolution

Immediately following the birds-eye mapping of the input image, the output is convolved with a filter designed to locate strips of high intensity pixels on a dark background. The width of the kernel is 8

pixels, which relates to the width of the lines that appear in the birds-eye image. The height is set to 16 which relates to the size of the dashed lane markings which appear in the image. As the birds-eye image is physically related to the height, pitch etc. of the camera, the width at which lanes appear in this image is intrinsically related to the physical measurement on the road. The width and height of the kernel may need to be updated when operating the lane detection system in different countries.

The output of the filter kernel is shown below, using jet colormap to highlight differences in intensity. Because the filter kernel is a general, vertically oriented Gaussian derivative, there is some response from many different regions. However, for the locations where a lane marking is present, there is a strong positive response located next to a strong negative response, which is consistent across columns. This characteristic of the filter output is used in the next stage of the detection algorithm to locate valid lane candidates.

Lane Candidate Generation

After convolution with the Gaussian derivative kernel, sub-region processing of the output is performed in order to find the coordinates where a lane marking is present. Each region consists of 18 lines, with a ping-pong memory scheme in place to ensure that data can be continuously streamed through the subsystem.

```
%Seeing as  
open_system([modelName '/HDLLaneDetector/LaneDetection/LaneCandidateGeneration'], 'force');
```

Histogram Column Count

Firstly, HistogramColumnCount counts the number of thresholded pixels in each column over the 18 line region. A high column count indicates that a lane is likely present in the region. This count is performed for both the positive and the negative thresholded images. The positive histogram counts are offset to account for the kernel width. Lane candidates occur where the positive count and negative counts are both high. This exploits the previously noted property of the convolution output where positive tracks appear next to negative tracks.

Internally, the column counting histogram generates the control signalling that selects an 18 line region, computes the column histogram, and outputs the result when ready. A ping-pong buffering scheme is in place which allows one histogram to be reading while the next is writing.

Overlap and Multiply

As noted, when a lane is present in the birds-eye image, the convolution result will produce strips of high-intensity positive output located next to strips of high-intensity negative output. The positive and negative column count histograms locate such regions. In order to amplify these locations, the positive count output is delayed by 8 clock cycles (an intrinsic parameter related to the kernel width), and the positive and negative counts are multiplied together. This amplifies columns where the positive and negative counts are in agreement, and minimizes regions where there is disagreement between the positive and negative counts. The design is pipelined in order to ensure high throughput operation.

Zero Crossing Filter

At the output of the Overlap and Multiply subsystem, peaks appear where there are lane markings present. A peak detection algorithm determines the columns where lane markings are present. Because the SNR is relatively high in the data, this example uses a simple FIR filtering operation followed by zero crossing detection. The Zero Crossing Filter is implemented using the Discrete FIR Filter block from DSP System Toolbox™. It is pipelined for high-throughput operation.

Store Dominant Lanes

The zero crossing filter output is then passed into the Store Dominant Lanes subsystem. This subsystem has a maximum memory of 7 entries, and is reset every time a new batch of 18 lines is reached. Therefore, for each sub-region 7 potential lane candidates are generated. In this subsystem, the Zero Crossing Filter output is streamed through, and examined for potential zero crossings. If a zero crossing does occur, then the difference between the address immediately prior to zero crossing and the address after zero crossing is taken in order to get a measurement of the size of the peak. The subsystem stores the zero crossing locations with the highest magnitude.

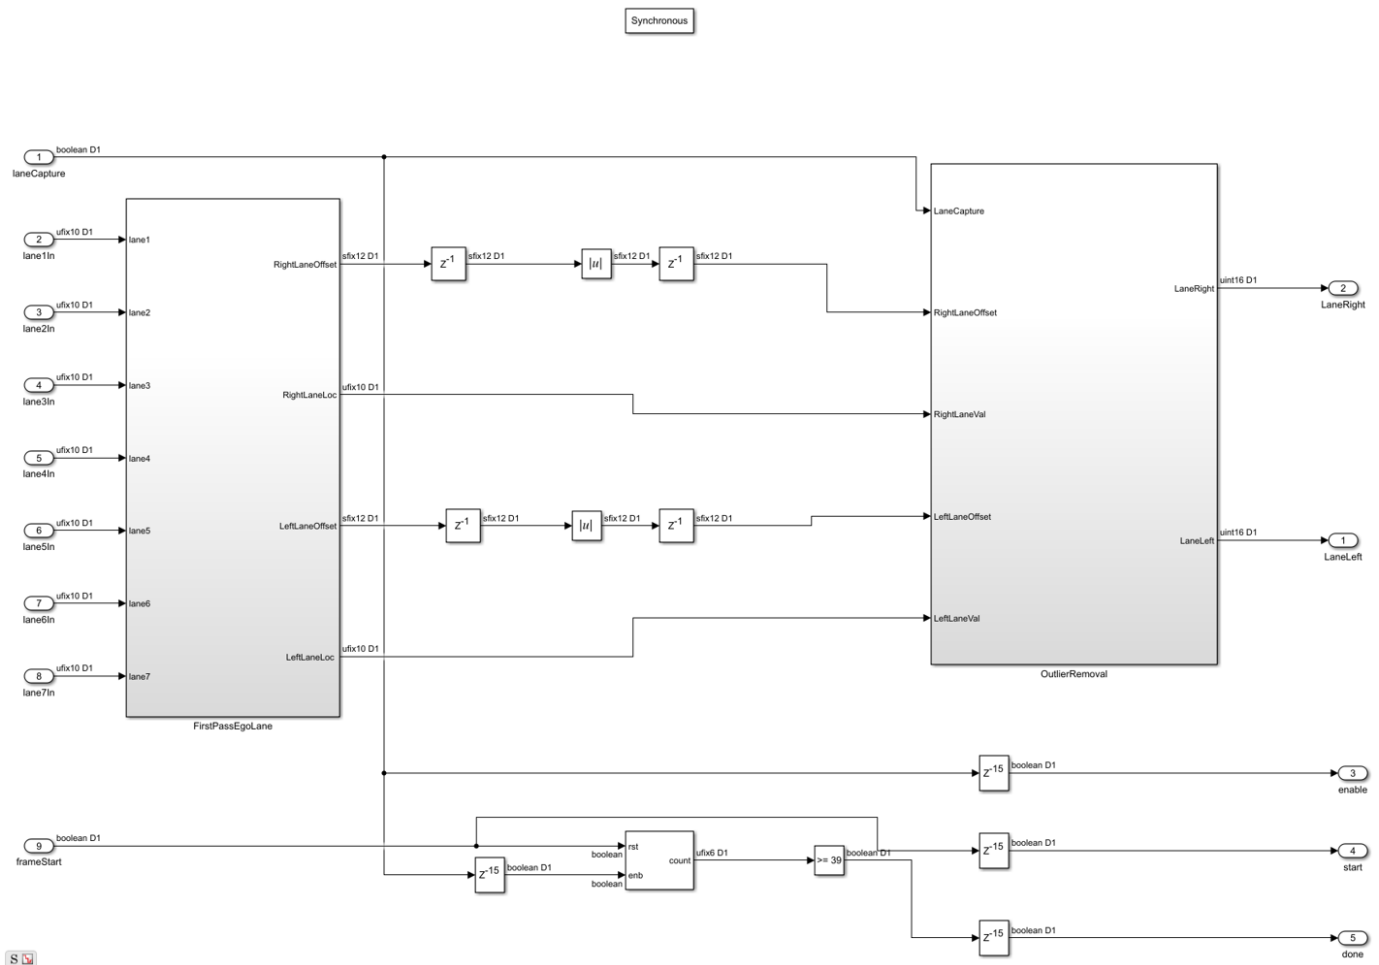

```
open_system([modelName '/HDLLaneDetector/LaneDetection/LaneCandidateGeneration/StoreDominantLanes
```

Compute Ego Lanes

The Lane Detection subsystem outputs the 7 most viable lane markings. In many applications, we are most interested in the lane markings that contain the lane in which the vehicle is driving. By computing the so called "Ego-Lanes" on the hardware side of the design, we can reduce the memory bandwidth between hardware and software, by sending 2 lanes rather than 7 to the processor. The Ego-Lane computation is split into two subsystems. The FirstPassEgoLane subsystem assumes that the centre column of the image corresponds to the middle of the lane, when the vehicle is correctly operating within the lane boundaries. The lane candidates which are closest to the center are therefore assumed as the ego lanes. The Outlier Removal subsystem maintains an average width of the distance from lane markings to centre coordinate. Lane markers which are not within tolerance of the current width are rejected. Performing early rejection of lane markers gives better results when performing curve fitting later on in the design.

```
open_system([modelName '/HDLLaneDetector/ComputeEgoLanes'], 'force');
```

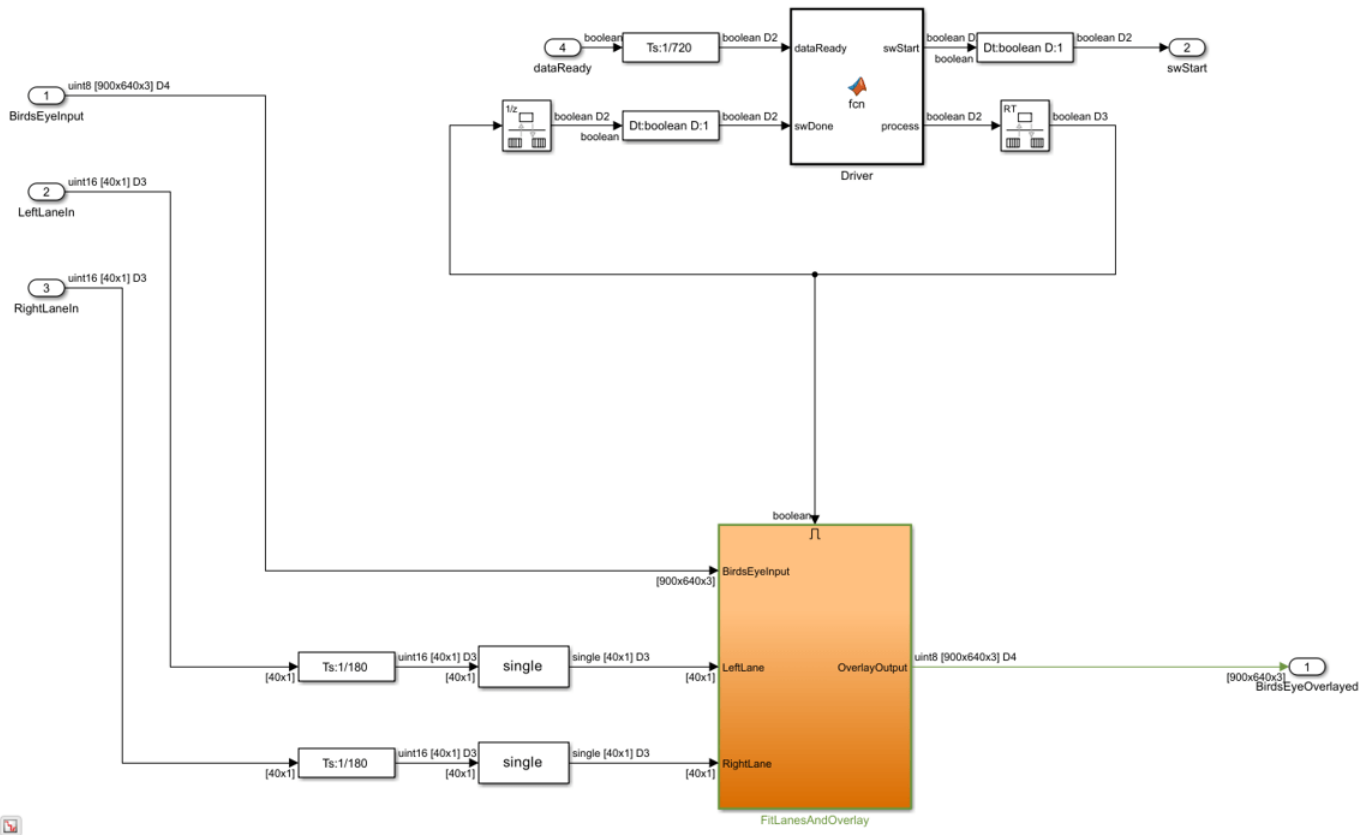

Control Interface

Finally, the computed ego lanes are sent to the CtrlInterface MATLAB function subsystem. This state machine uses the four control signal inputs - enable, hwStart, hwDone, and swStart to determine when to start buffering, accept new lane coordinate into the 40x1 buffer and finally indicate to the software that all 40 lane coordinates have been buffered and so the lane fitting and overlay can be performed. The dataReady signal ensures that software will not attempt lane fitting until all 40 coordinates have been buffered, while the swStart signal ensures that the current set of 40 coordinates will be held until lane fitting is completed.

Software Lane Fit and Overlay

The detected ego-lanes are then passed to the SW Lane Fit and Overlay subsystem, where robust curve fitting and overlay is performed. Recall that the birds-eye output is produced once every two frames or so rather than on every consecutive frame. The curve fitting and overlay is therefore placed in an enabled subsystem, which is only enabled when new ego lanes are produced.

```
open_system([modelName '/SWLaneFitandOverlay'], 'force');
```

Driver

The Driver MATLAB Function subsystem controls the synchronization between hardware and software. Initially it is in a polling state, where it samples the `dataReady` input at regular intervals per frame to determine when hardware has buffered a full [40x1] vector of lane coordinates. Once this occurs, it transitions into software processing state where `swStart` and `process` outputs are held high. The Driver remains in the software processing state until `swDone` input is high. Seeing as the `process` output loops back to `swDone` input with a rate transition block in between, there is effectively a constant time budget specified for the `FitLanesandOverlay` subsystem to perform the fitting and overlay. When `swDone` is high, the Driver will transition into a synchronization state, where `swStart` is held low to indicate to hardware that processing is complete. The synchronization between software and hardware is such that hardware will hold the [40x1] vector of lane coordinates until the `swStart` signal transitions back to low. When this occurs, `dataReady` output of hardware will then transition back to low.

Fit Lanes and Overlay

The Fit Lanes and Overlay subsystem is enabled by the Driver. It performs the necessary arithmetic required in order to fit a polynomial onto the lane coordinate data received at input, and then draws the fitted lane and lane coordinates onto the Birds-Eye image.

Fit Lanes

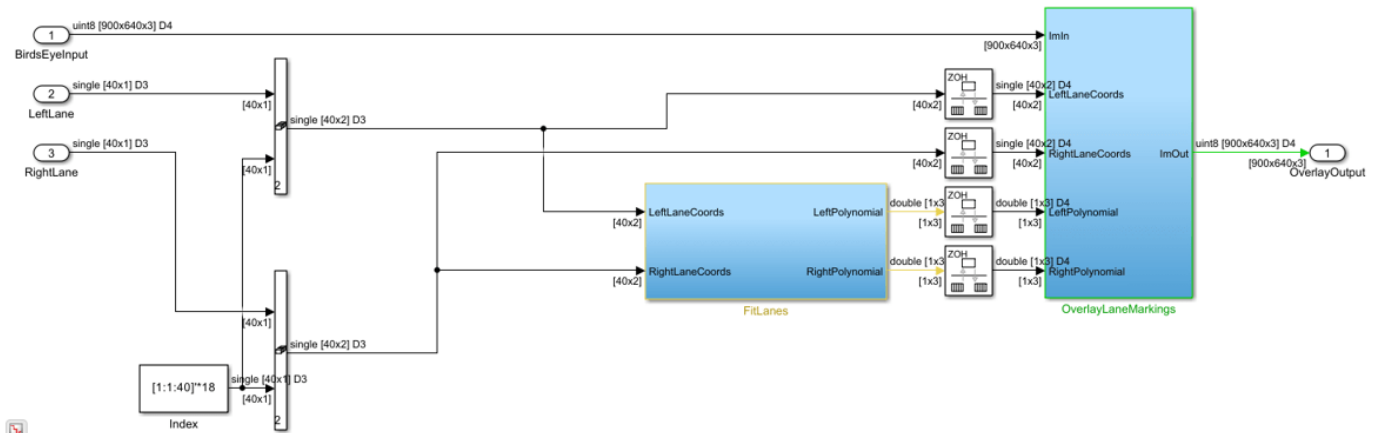

The Fit Lanes subsystem runs a RANSAC based line-fitting routine on the generated lane candidates. RANSAC is an iterative algorithm which builds up a table of inliers based on a distance measure

between the proposed curve, and the input data. At the output of this subsystem, there is a $[3 \times 1]$ vector which specifies the polynomial coefficients found by the RANSAC routine.

Overlay Lane Markings

The Overlay Lane Markings subsystem performs image visualization operations. It overlays the ego lanes and curves found by the lane-fitting routine.

```
open_system([modelName '/SWLaneFitandOverlay/FitLanesAndOverlay'],'force');
```

Results of the Simulation

The model includes two video displays shown at the output of the simulation results. The **BirdsEye** display shows the output in the warped perspective after lane candidates have been overlaid, polynomial fitting has been performed and the resulting polynomial overlaid onto the image. The **OriginalOverlay** display shows the **BirdsEye** output warped back into the original perspective.

Due to the large frame sizes used in this model, simulation can take a relatively long time to complete. If you have an HDL Verifier™ license, you can accelerate simulation speed by directly running the HDL Lane Detector subsystem in hardware using FPGA in the Loop.

HDL Code Generation

To check and generate the HDL code referenced in this example, you must have an HDL Coder™ license.

To generate the HDL code, use the following command.

```
makehdl('LaneDetectionHDL/HDLLaneDetector')
```

To generate the test bench, use the following command. Note that test bench generation takes a long time due to the large data size. You may want to reduce the simulation time before generating the test bench.

```
makehdltb('LaneDetectionHDL/HDLLaneDetector')
```

For faster test bench simulation, you can generate a SystemVerilog DPIC test bench using the following command.

```
makehdltb('LaneDetectionHDL/HDLLaneDetector', 'GenerateSVPITestBench', 'ModelSim')
```

Conclusion

This example has provided insight into the challenges of designing ADAS systems in general, with particular emphasis paid to the acceleration of critical parts of the design in hardware.

HDL QPSK Transmitter and Receiver

This example shows how to implement a QPSK transmitter and receiver in Simulink® that is optimized for HDL code generation and hardware implementation.

The model shown in this example modulates data based on quadrature phase shift keying (QPSK). The goal of this example is to model an HDL QPSK communication system that can transmit and recover information for a real-time system. The receiver implements symbol timing synchronization and carrier frequency and phase synchronization, which are essential in a single-carrier communication system.

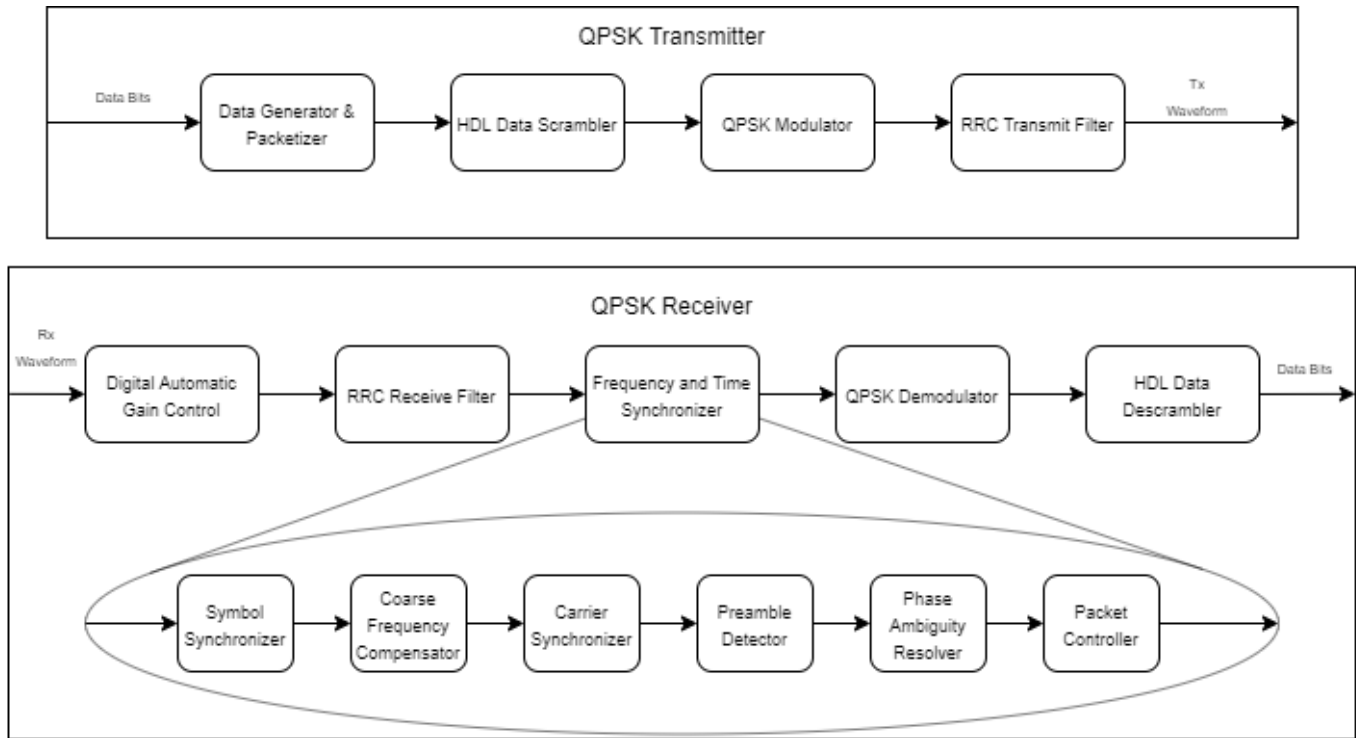

System Specifications

This section explains the specifications of the transmitter and receiver used in this example. The frame format is packet based. Each packet has a preamble of length 26 bits. Each bit of the 13 bit Barker sequence is repeated twice to generate a preamble sequence such that the same bit is modulated in the in phase and quadrature phase by the QPSK Modulator. The preamble sequence is followed by 2240 bits of payload data. The transmitter runs using a root raised cosine (RRC) pulse-shaping filter with a roll-off factor of 0.5, resulting in a bandwidth of 1.5 times the symbol rate and four samples per symbol (sample rate of four times the symbol rate). The RRC impulse response spans over four adjacent symbols. The bit rate is twice the symbol rate. The effective average bit rate is the bit rate times the frame efficiency. The frame efficiency is $(2240/(2240+26)) = 0.9885$.

The default symbol rate is set to 1.92 Mbaud, which results in a bandwidth of 1.5 times 1.92e6, which equals 2.88 MHz, and a sample rate of 4 times 1.92e6, which equals 7.68 Msps, bit rate of 2 times 1.92e6, which equals 3.84 Mbps. The effective average bit rate supported by this system is 0.9885 times 3.84e6, which equals 3.7959 Mbps. These specifications change with a change in the symbol rate.

Model Architecture

This section explains the high-level architecture of the QPSK transmitter and receiver as in the block diagram. The QPSK transmitter samples the input at a bit rate of twice the symbol rate. The Data Generator & Packetizer collects the data bits, generates the preamble bits, and forms the packet bits. The HDL Data Scrambler scrambles the data bits of each packet to increase bit transitions and avoid long running sequences of the same bit. The QPSK Modulator modulates the packet bits to generate QPSK symbols. The RRC Transmit Filter upsamples and pulse-shapes the QPSK symbols to generate the Tx Waveform at a sample rate of four times that of the symbol rate. The QPSK receiver samples the input at the transmission rate. The Digital AGC performs gain control to the desired amplitude level of the received waveform. The RRC Receive Filter performs matched filtering on the AGC output. The Frequency and Time Synchronizer performs synchronization operations and generates QPSK symbols for each packet. The QPSK Demodulator demodulates the QPSK symbols to generate packet bits. The HDL Data Descrambler descrambles the packet data bits that stream out of the receiver.

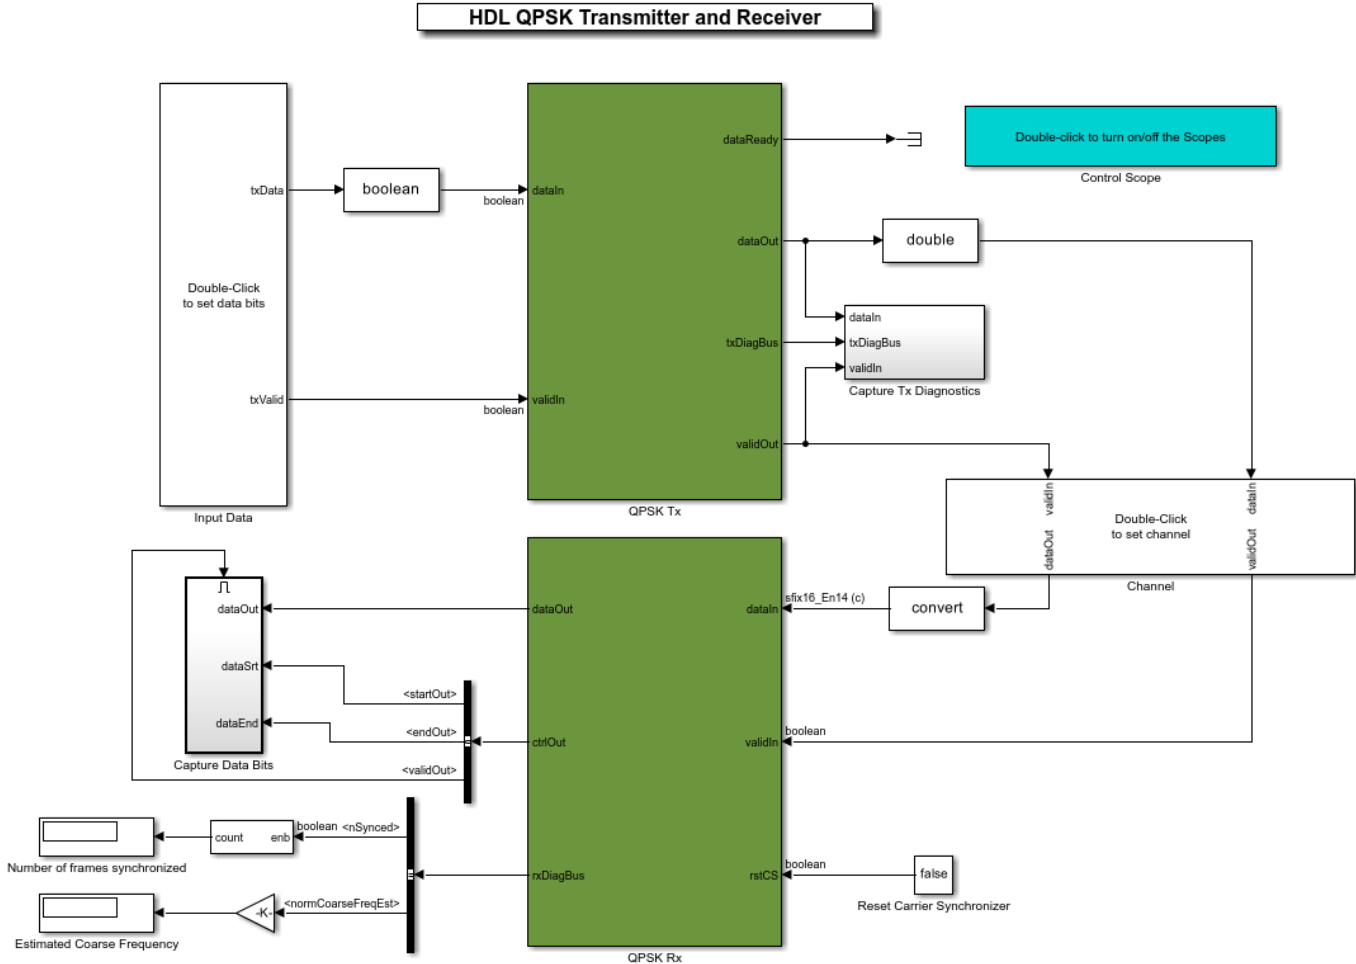

File Structure

One Simulink model and three MATLAB® files construct this example.

- `commhdlQPSKTxRx.slx` — Top-level Simulink model
- `commhdlQPSKTxRxParameters.m` — Generates parameters for QPSK Tx and QPSK Rx required for initialization
- `commhdlQPSKTxRxModelInit.m` — Initializes the model `commhdlQPSKTxRx.slx`
- `generateHelloWorldMsgBits.m` — Generates "Hello world xxx " message bits. xxx refers to values from 000 to 100

System Interface

This figure shows the top-level model of the QPSK transmitter and receiver system.

Transmitter Inputs

- **dataIn** — Input data, specified as a Boolean scalar.
- **validIn** — Control signal to validate the **dataIn**, specified as a Boolean scalar.

Transmitter Outputs

- **dataOut** — Output transmitted waveform, returned as 16-bit complex data at a sample rate four times that of the symbol rate.
- **validOut** — Control signal to validate the **dataOut**, returned as a Boolean scalar.
- **txDiagBus** — Status signal with diagnostic outputs, returned as a Bus signal.
- **dataReady** — Signal to indicate a ready for the input signals, returned as a Boolean scalar.

The transmitter enables the **dataReady** signal to indicate that it is ready to accept input bits. The transmitter constructs a packet after it accepts all the data bits corresponding to that packet. If all the data bits corresponding to that packet are not received, the transmitter generates dummy packets. For a dummy packet, the Barker sequence is not used for the preamble and the data bits are generated randomly internally. As long as the input bit rate is less than or equal to the effective bit

rate, the **dataReady** signal remains high so that the input does not get any back pressure from **dataReady**.

Receiver Inputs

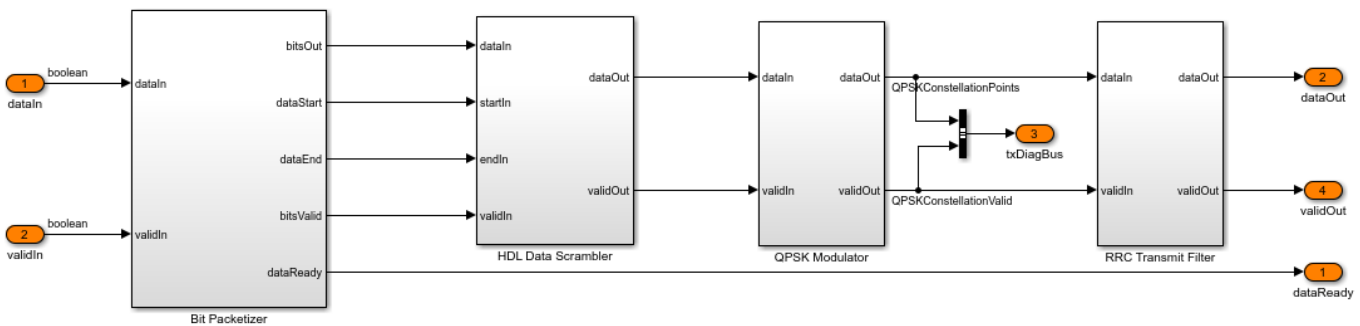

- **dataIn** — Input data, specified as a 16-bit complex data with sample rate as the transmitter output.
- **validIn** — Control signal to validate the **dataIn**, specified as a Boolean scalar.

Receiver Outputs

- **dataOut** — Decoded output data bits, returned as a Boolean scalar.
- **ctrlOut** — Bus signal with start, end, and valid signals, returned as a bus signal.
- **rxDiagBus** — Status signal with diagnostic outputs, returned as a bus signal.

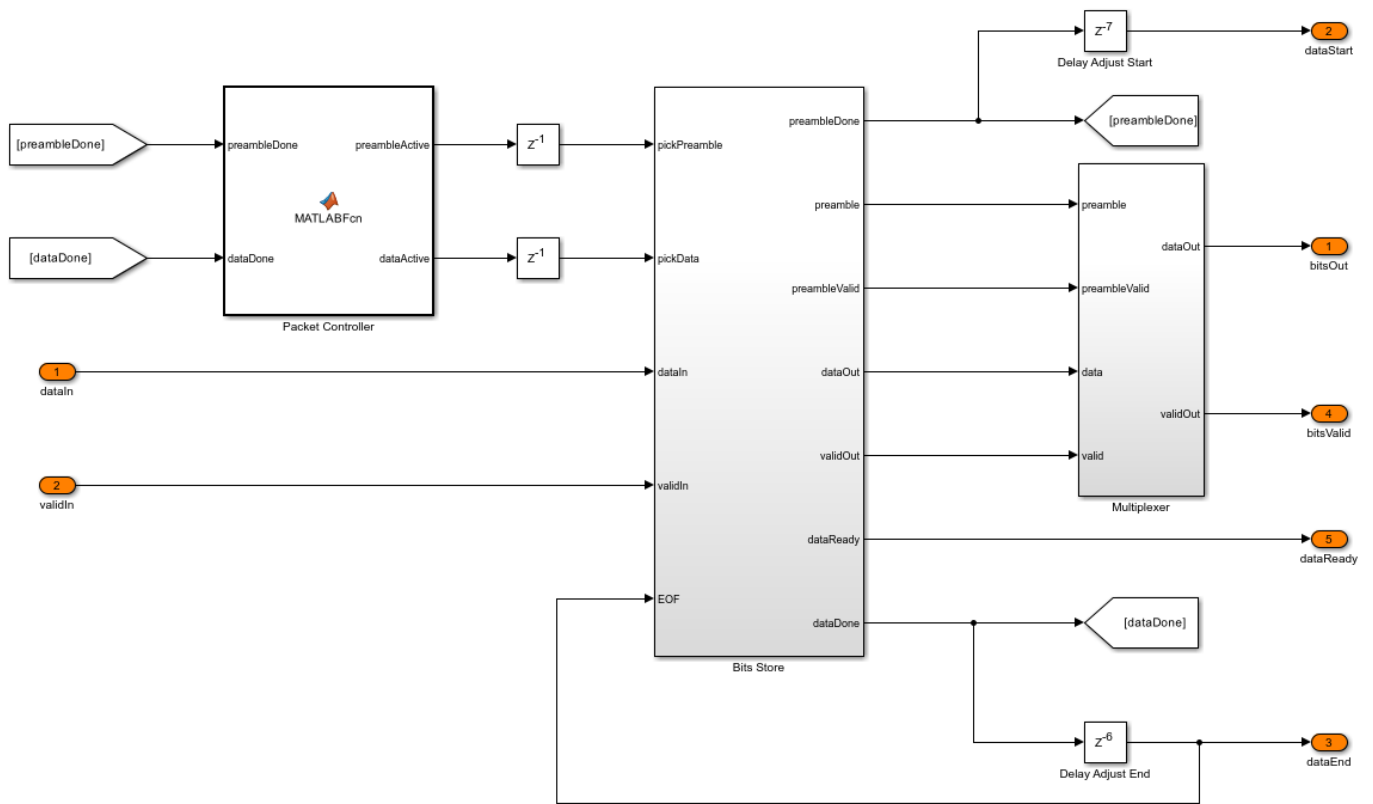

Transmitter Structure

This figure shows the top-level model of the QPSK Tx subsystem.

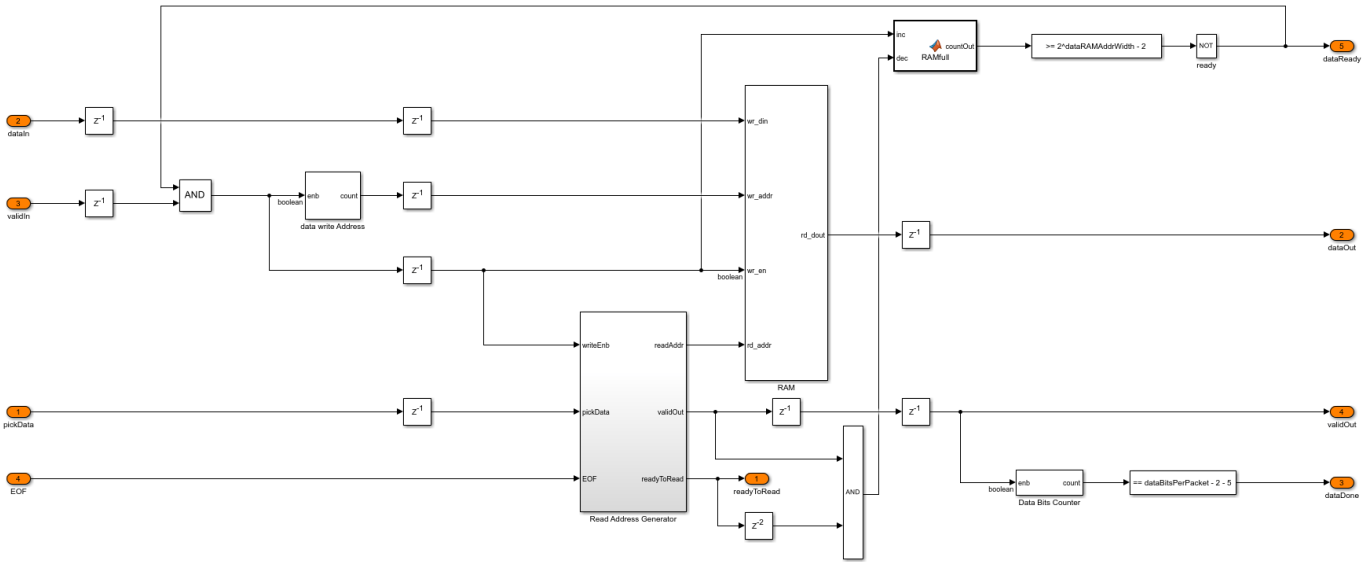

Bit Packetizer

The Bit Packetizer subsystem consists of a Packet Controller MATLAB function, a Bits Store, and a Multiplexer subsystem. The preamble sequence is stored in a look up table (LUT) inside the Preamble Bits Store subsystem. The data bits stream into the Bits Store subsystem and are stored in a RAM inside the Data Bits Store subsystem. The Packet Controller MATLAB function reads the preamble sequence followed by the data bits stored in the RAM for each packet. The Multiplexer subsystem streamlines the preamble bits and the data bits.

The Data Bits Store subsystem consists of a RAM that can store two packets. This RAM provides the flexibility to operate the transmitter with a discrete valid input. The Packet Controller MATLAB function reads data from the RAM only if the RAM contains a minimum of one packet of the data bits. The read and write logic is designed in such a way that the RAM does not overflow. When the RAM does not contain a minimum of one packet of the data bits, the transmitter generates a dummy packet. The Preamble does not use the Barker sequence for a dummy packet so that preamble detection does not detect it.

HDL Data Scrambler

The HDL Data Scrambler subsystem scrambles the data bits in each packet by using the control signals generated by the Bits Generator subsystem.

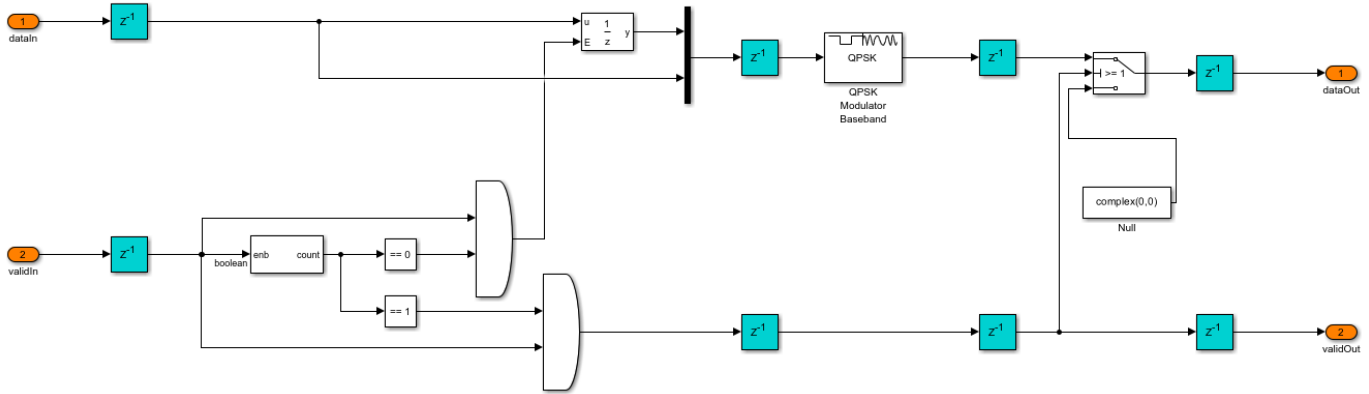

QPSK Modulator

The QPSK Modulator subsystem uses the QPSK Modulator Baseband (Communications Toolbox) block to modulate the preamble and data bits to generate QPSK symbols. It uses a gray mapping as described in this table.

Bits	Mapping

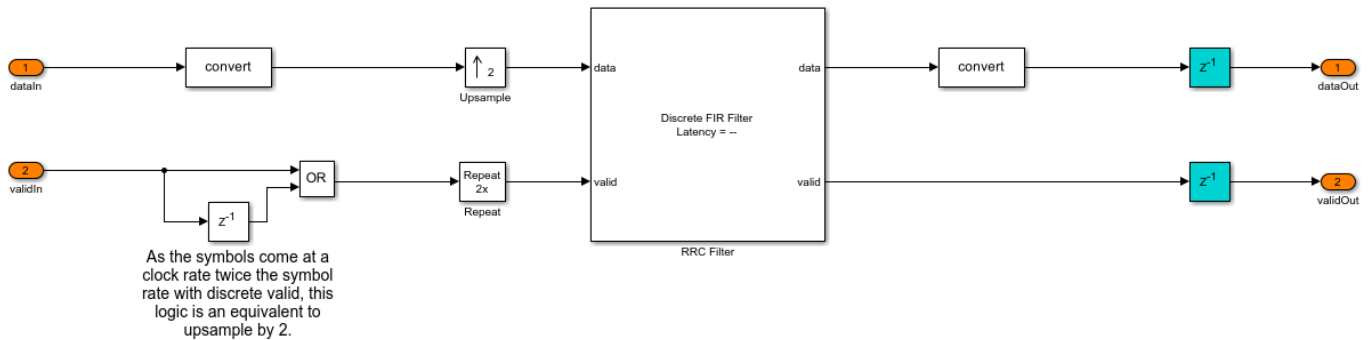

```

00  0.70711+0.70711i
01  -0.70711+0.70711i
11  -0.70711-0.70711i
10  0.70711-0.70711i
    
```

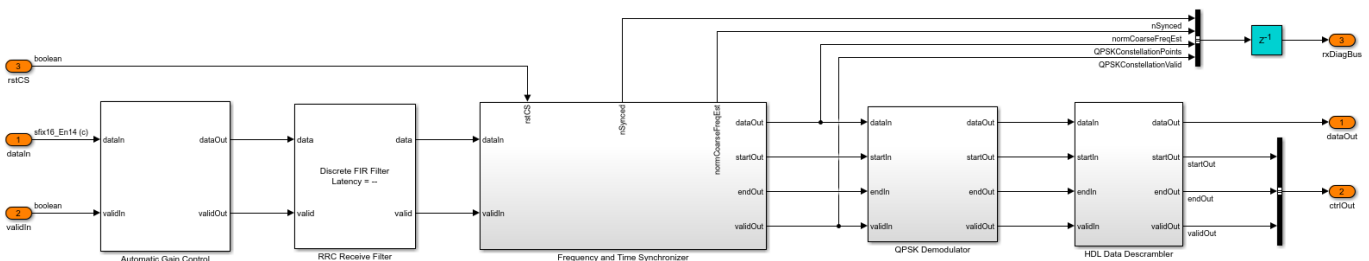

RRC Transmit Filter

The RRC Transmit Filter subsystem upsamples the input by a factor of four and uses the Discrete FIR Filter (DSP HDL Toolbox) block with an RRC impulse response to pulse-shape the transmitter waveform. The receive filter in the QPSK Receiver forms a matched filter to this transmit filter.

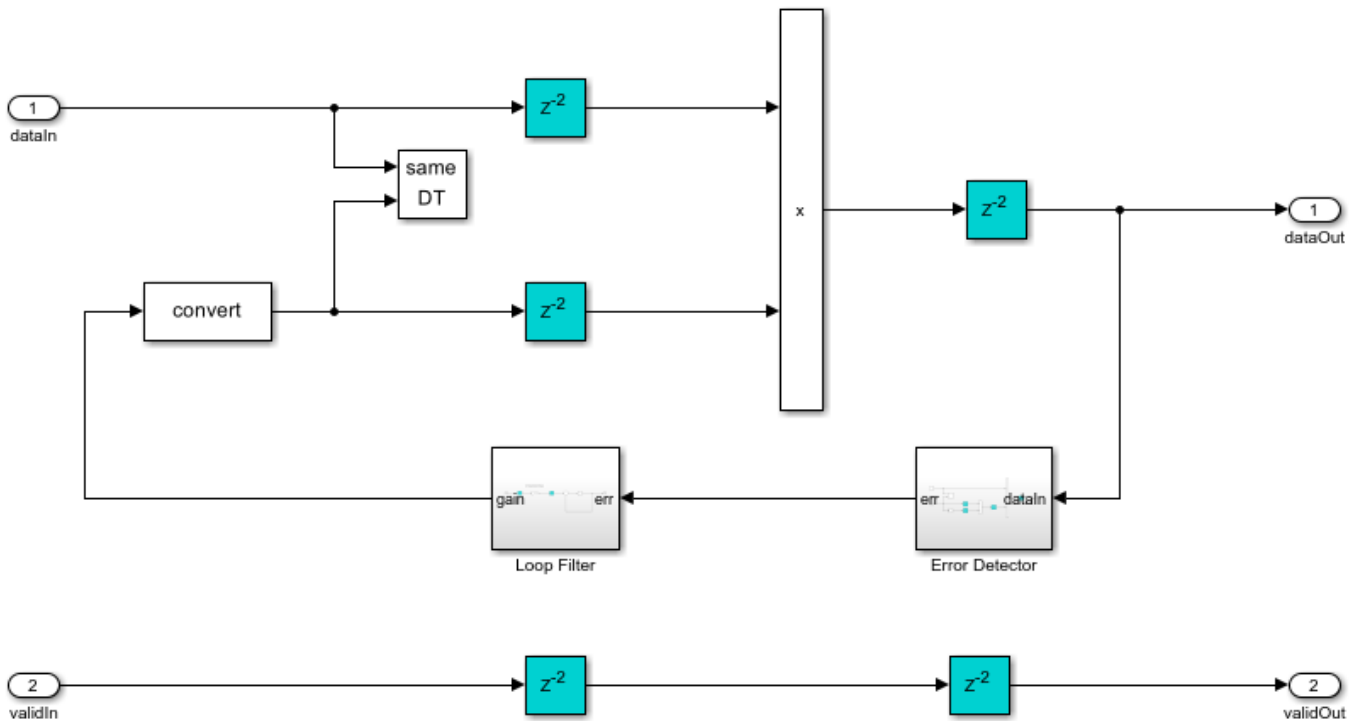

Receiver Structure

This figure shows the top-level model of the QPSK Rx subsystem.

Automatic Gain Control

As the input signal amplitude affects the symbol and carrier synchronizer phase-locked loop (PLL) performance, the Automatic Gain Control subsystem is placed ahead of them. The magnitude squared output is compared with the AGC reference to generate an amplitude error. This error is multiplied with the loop gain and passed through an integrator to calculate the required gain. The resulted gain is multiplied with the AGC input to generate the AGC output. For more information, see Chapter 9.5 of [1].

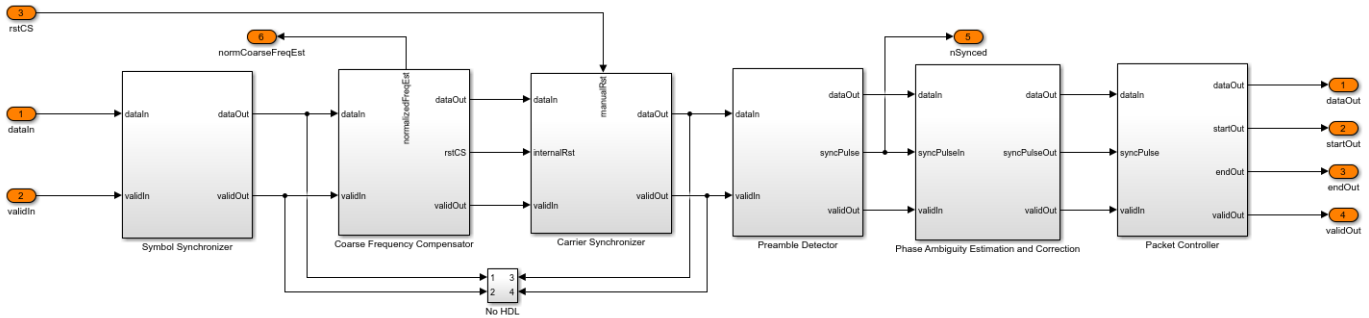

RRC Receive Filter

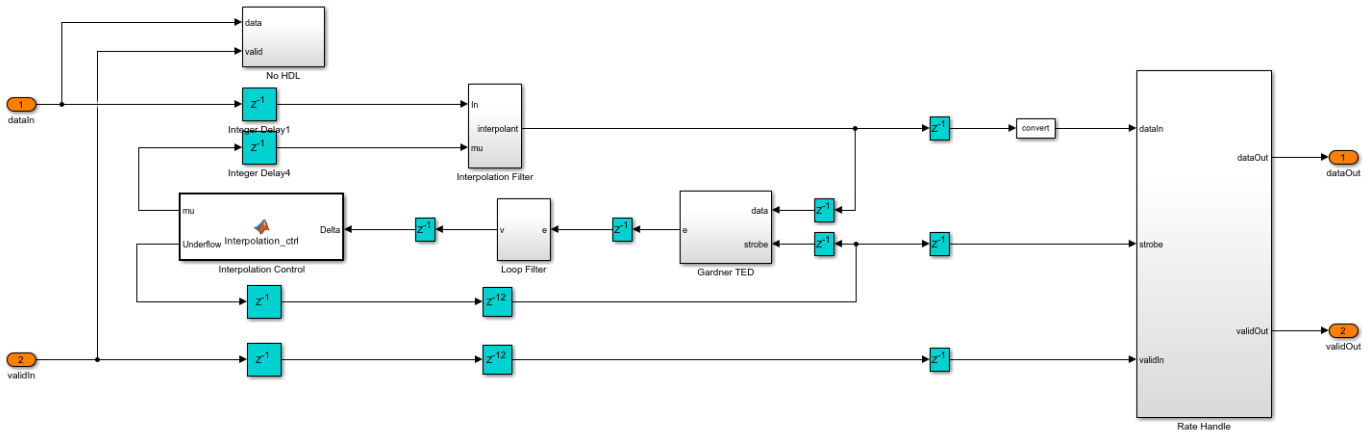

The RRC Receive Filter is a Discrete FIR Filter (DSP HDL Toolbox) block with matched filter coefficients of the filter used for pulse-shaping in the transmitter. The RRC matched filtering generates an RC pulse-shaped waveform, which has zero ISI characteristics at maximum eye opening in the eye diagram of the waveform. Also, the matched filtering process maximizes the signal to noise power ratio (SNR) of the filter output.

Frequency and Time Synchronizer

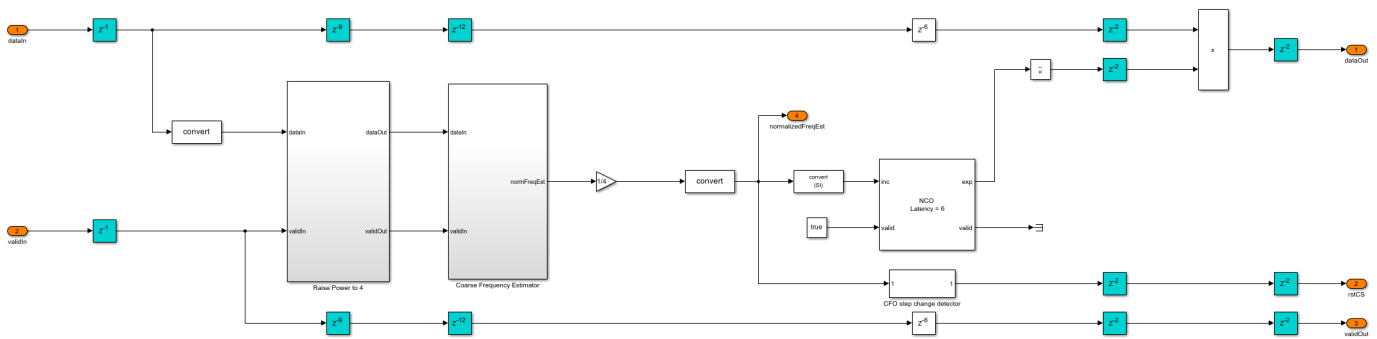

The Frequency and Time Synchronizer subsystem performs symbol synchronization, coarse frequency compensation, carrier synchronization, and preamble detection for packet synchronization. It also estimates and resolves the phase ambiguity that is left uncorrected in carrier synchronization.

The Symbol Synchronizer subsystem is a PLL-based implementation. It generates samples at the optimum time instant (maximum eye opening instant) as described in Chapter 8.5 of [1]. The subsystem generates one output sample for every four input samples. The Interpolation Filter subsystem implements a piecewise parabolic interpolator with a hardware resource efficient farrow structure as described in Chapter 8.4.2, and the farrow coefficients are tabulated in Table 8.4.1 (the free parameter α of the coefficients is taken as 0.5) of [1]. This filter introduces fractional delays in the input waveform. The Gardner TED subsystem implements a Gardner timing error detector. The timing error detector is described in Chapter 8.4.1 of [1]. The loop filter filters the timing error and the timing error is passed on to the Interpolation Control MATLAB function block. This block implements a mod-1 decrementing counter to calculate fractional delays based on the loop filtered timing error as described in Chapter 8.4.3 of [1] to generate interpolants at optimum sampling instants. The Rate Handle subsystem selects the required interpolant indicated by the strobe. This sample corresponds to the maximum eye opening of the eye diagram before symbol synchronization.

The Coarse Frequency Compensator subsystem raises the input sequence to a power of 4 in the Raise Power to 4 subsystem. This eliminates the QPSK phase mapping dependency in the input sequence but reduces the estimation range by a factor of 4. This sequence streams into the Coarse Frequency Estimator subsystem. The estimate obtained from the Coarse Frequency Estimator subsystem is divided by 4 to remove the factor 4 due to raising to power 4 and get the normalized coarse frequency estimate. This estimate drives the NCO (DSP HDL Toolbox) block to generate complex exponential phase that is conjugated and multiplied with the input sequence to correct the frequency offset.

The Coarse Frequency Estimator subsystem differentially detect the input sequence and extract the complex frequency offset estimate in the input. This estimate is averaged for 2^{15} consecutive estimates in the Integrator subsystem to get the final complex estimate. The Complex to Magnitude-Angle (DSP HDL Toolbox) block extracts the frequency from the complex estimate in the Extract Frequency subsystem.

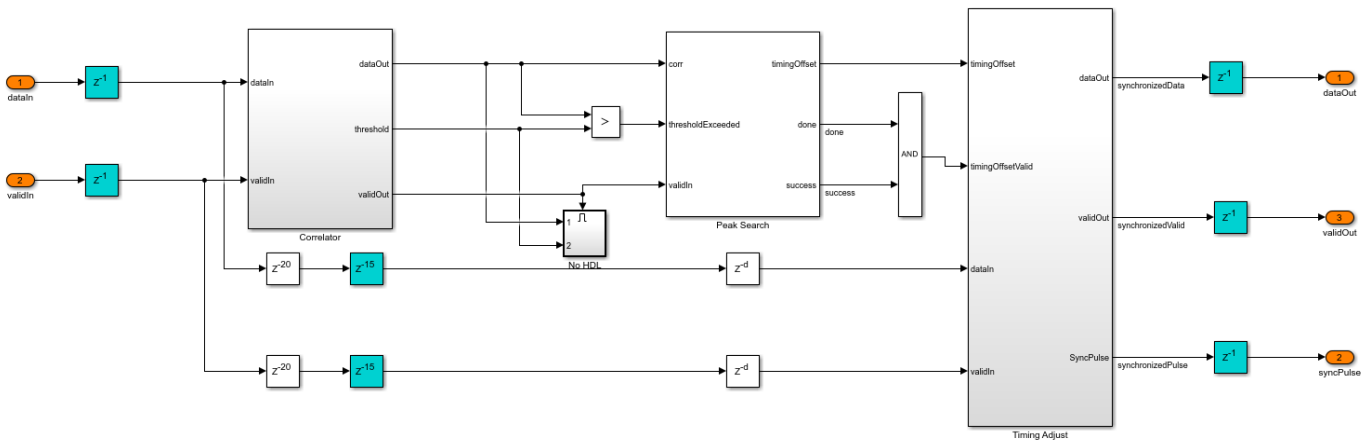

The frequency estimator estimates a normalized frequency (with respect to symbol rate) range of -0.125 to 0.125 which corresponds to a frequency offset range of -240 KHz to 240 KHz for a symbol rate of 1.92 Mbaud. The estimation accuracy is such that the residual frequency offset after coarse frequency offset correction is with in the normalized frequency range of -0.0016 to 0.0016 which corresponds to a frequency offset range of -3 KHz to 3 KHz for a symbol rate of 1.92 Mbaud that the Carrier Synchronizer PLL converge.

The Carrier Synchronizer subsystem is a TYPE II PLL with a sinusoidal phase error detector, which operates at a 45 degrees operating point. The phase error detector is described in Chapter 7.2.2, and the design equations are described in the Appendix C of [1]. A detailed analysis of TYPE II PLL with a zero operating point sinusoidal phase detector is described in Chapter 4 of [2]. The sign function of the phase detector in the real and imaginary parts converts all of the angles in the 4 quadrants into a first-quadrant angle (0 to 90 degrees), which creates an ambiguity of 90,180,270 degrees for second (90 to 180 degrees), third (-180 to -90 degrees) and fourth (-90 to 0 degrees) quadrant angles, respectively. The phase error is calculated as a deviation from the operating point (45 degrees) of the phase detector. The proportional plus integrator filter in the Loop Filter subsystem filters the phase error. The loop filter sets the normalized loop bandwidth (normalized by the sample rate) and the loop damping factor. The default normalized loop bandwidth is set to 0.005, and the default damping factor is set to 0.7071. The filtered error is given as a phase increment source to the Direct Digital Synthesis subsystem, which uses the NCO (DSP HDL Toolbox) block for complex exponential phase generation. The complex exponential phase is used to correct the frequency and phase of the input. A detailed analysis of direct digital synthesis is described in Chapter 9.2.2 of [1].

The Preamble Detector subsystem performs continuous correlation for the input with the Barker sequence. The correlation is implemented as convolution with the reversed Barker sequence as coefficients for the Discrete FIR Filter (DSP HDL Toolbox) block, and the magnitude of the correlated output is found using the Complex to Magnitude-Angle (DSP HDL Toolbox) block inside the Correlator subsystem. The magnitude of the correlation is compared with a threshold. The Peak Search subsystem begins searching for the maximum correlation peak that exceeded the threshold for every one frame duration and records the timing offset. The Timing Adjust subsystem synchronizes packet timing based on the timing offset to generate **syncPulse** signal, which indicates a packet synchronized sample to the subsequent subsystem.

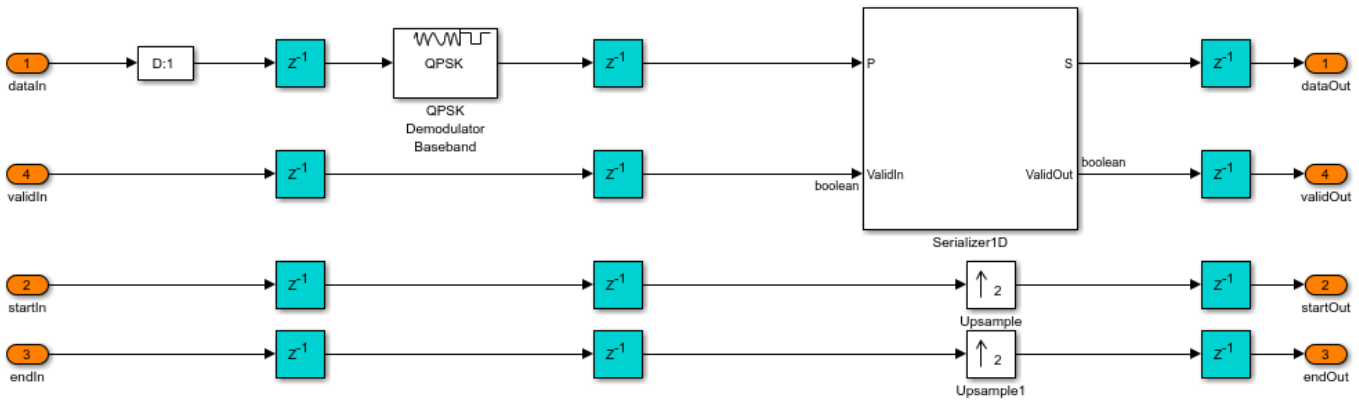

The Phase Ambiguity Estimation and Correction subsystem works based on the unique word method for phase ambiguity resolution described in Chapter 7.7.1 of [1]. This method uses the preamble sequence as the reference sequence. The reference sequence is conjugated and multiplied with the preamble sequence in the input, and the residual phase is extracted as the phase ambiguity estimate. This estimate is used to correct the ambiguity by rotating the constellation in the opposite direction of ambiguity.

The Packet Controller subsystem generates control signals for the packet boundaries.

QPSK Demodulator

The QPSK Demodulator subsystem uses the QPSK Demodulator Baseband (Communications Toolbox) block to demodulate the packet synchronized symbols and generate bits.

HDL Data Descrambler

The HDL Data Descrambler subsystem descrambles the demodulated bits to generate the user bits. This subsystem is same as the scrambler used at the transmitter side.

Run the Model

Run the commhdlQPSKTxRx.slx Model to simulate it. You can set custom data on the Input Data subsystem Mask and set channel configuration on the Channel subsystem Mask. The QPSKTxRxVerification.m script describes a procedure to verify the commhdlQPSKTxRx.slx model. This verification script generates a reference waveform within the script, compares the

reference waveform with the transmitter output, and compares the transmitted bits with the receiver decoded user bits.

Verification and Results

Run `sim commhdlQPSKTxRx` to run the model.

```
>> sim commhdlQPSKTxRx;
```

```
Simulation completed  
Running the verification script
```

```
QPSK Tx:  
Maximum absolute symbol error: Real:1.4496e-05 Imaginary:1.4496e-05
```

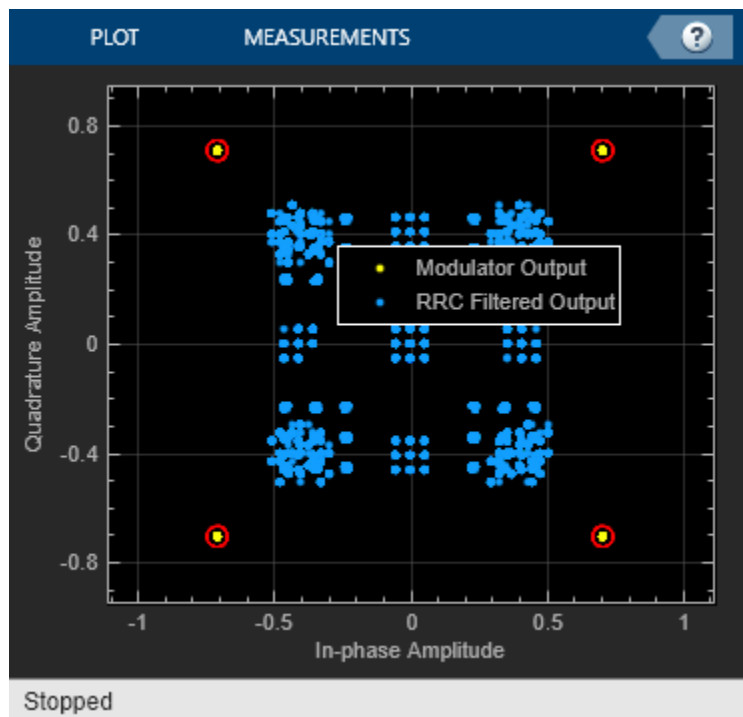

```
Maximum absolute RRC output error: Real:7.8708e-05 Imaginary:7.8708e-05
```

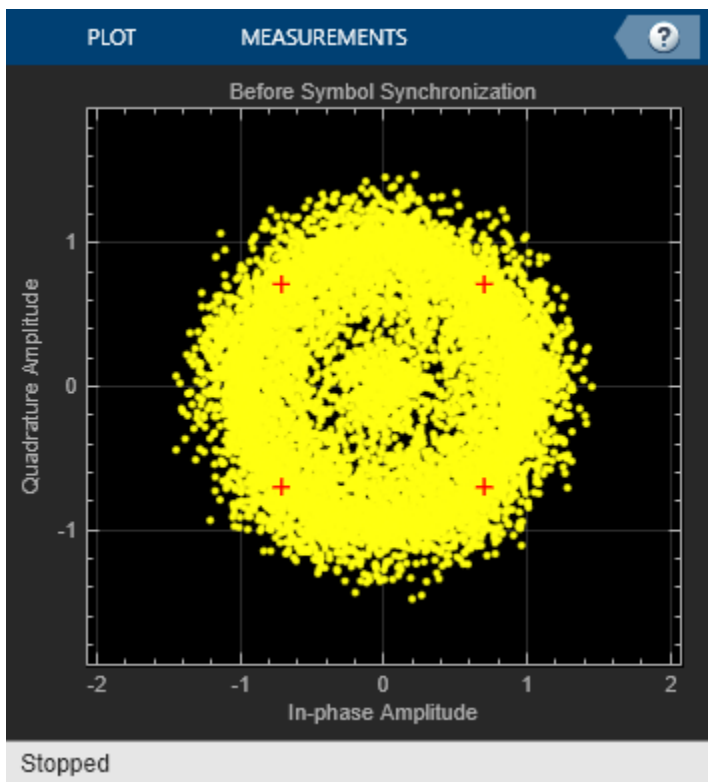

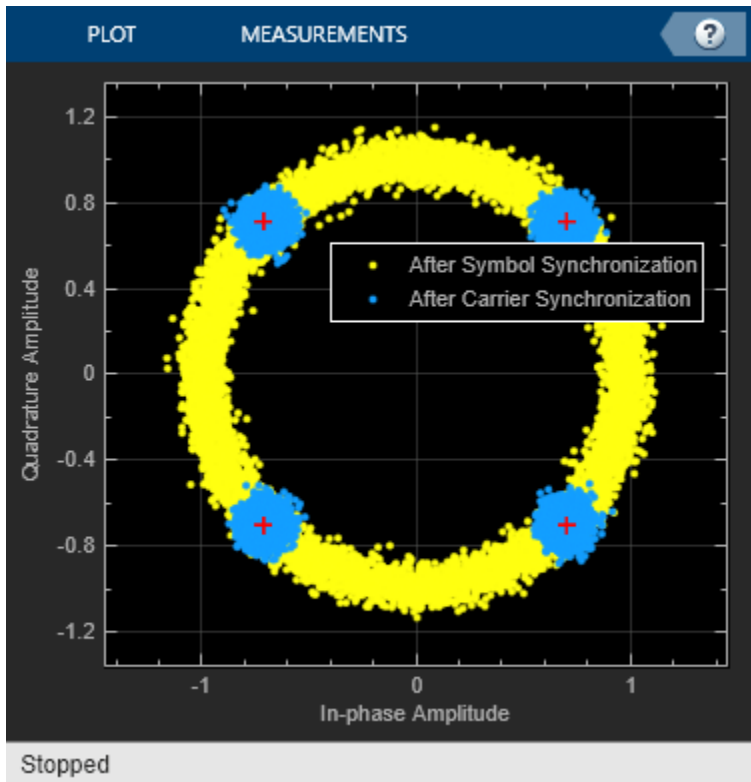

```
QPSK Rx:  
Initial frames not compared : 29
```

```
Number of packets missed = 0 out of 30
```

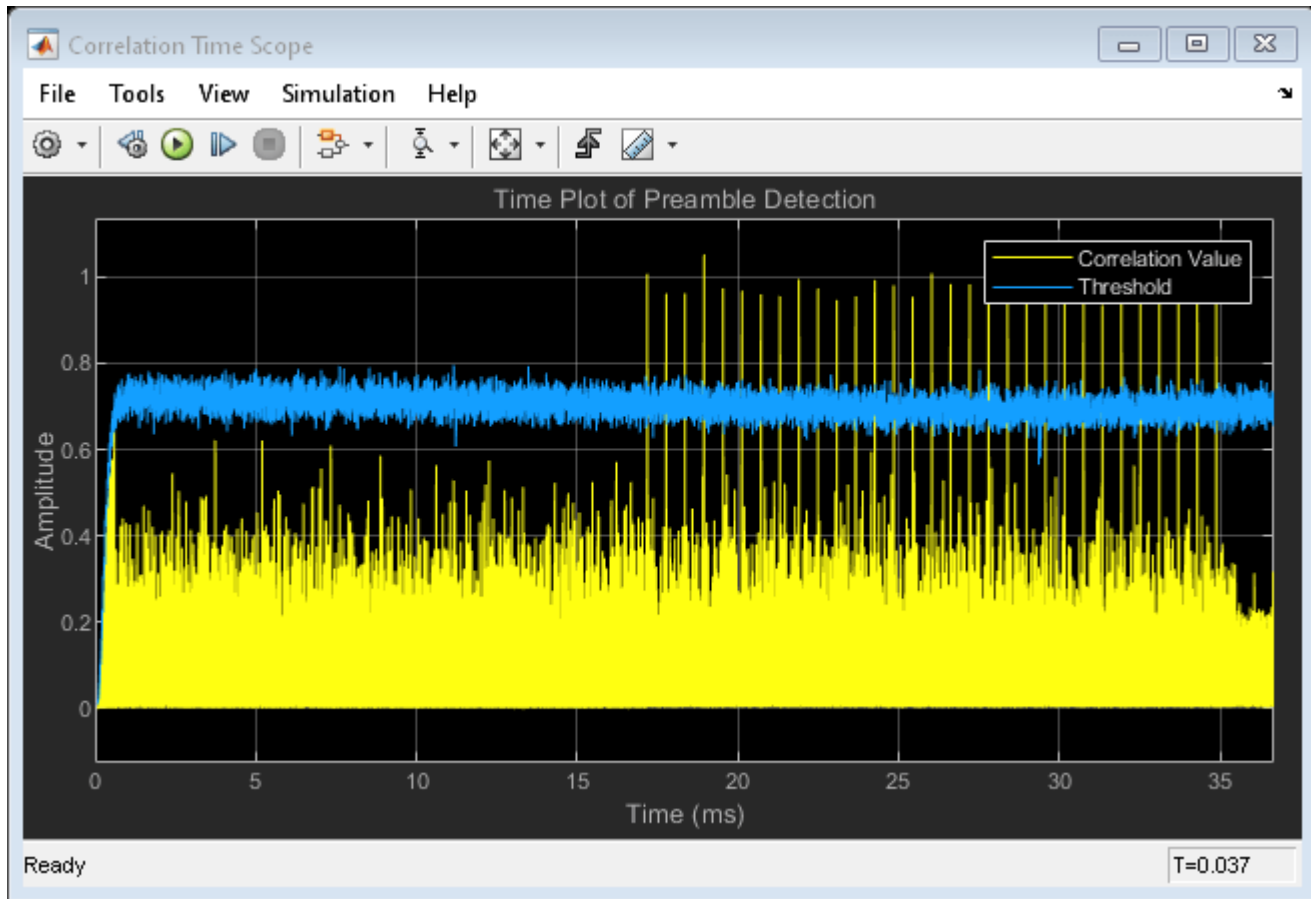

```
Number of packets false detected = 0 out of 30
```

```
Number of bits errored = 0 out of 67200
```

HDL Code Generation

Pipeline registers (shown in cyan) are added throughout the model to make sure the transmitter and receiver subsystems do not have a long critical path.

To check and generate the HDL code referenced in this example, you must have the HDL Coder™ product.

To generate the HDL code for transmitter and receiver subsystems, update the models and use the following command:

```
makehdl('commhdlQPSKTxRx/QPSK Tx') and makehdl('commhdlQPSKTxRx/QPSK Rx')
```

To generate test bench, use the following command:

```
makehdltb('commhdlQPSKTxRx/QPSK Tx') and makehdltb('commhdlQPSKTxRx/QPSK Rx')
```

Test bench generation time depends on the simulation time.

The resulting HDL code is synthesized for the Xilinx® Zynq®-7000 ZC706 evaluation board. The post place and route resource utilization is shown in this table. The maximum frequency of operation is 276 MHz for the transmitter and 198 MHz for the receiver.

Resources	Tx Usage	Rx Usage

Slice Registers	321	10496
Slice LUT	160	7483
RAMB36	0	10
RAMB18	1	1
DSP48	18	118

Further Exploration

You can modify the channel conditions by tuning the variables listed in this table on the Channel subsystem mask in the `commhdlQPSKTxRx.slx` model and run the model.

Variable Name	Description
<code>dataBits</code>	Data bits to the transmitter
<code>Rsym</code>	Symbol rate specified in symbols per second
<code>fractionalTimingOffset</code>	Normalized timing phase offset specified in the range ≥ 0 and < 1
<code>timingFrequencyOffset</code>	Timing frequency offset specified in PPM
<code>EbN0dB</code>	Energy per information bit to single sided noise power spectral density
<code>CFO</code>	Carrier frequency offset specified in Hz
<code>CPO</code>	Carrier phase offset specified in degrees

Set HDL Code Generation Options

In this section...

“HDL Code Generation Options in the Configuration Parameters Dialog Box” on page 16-2

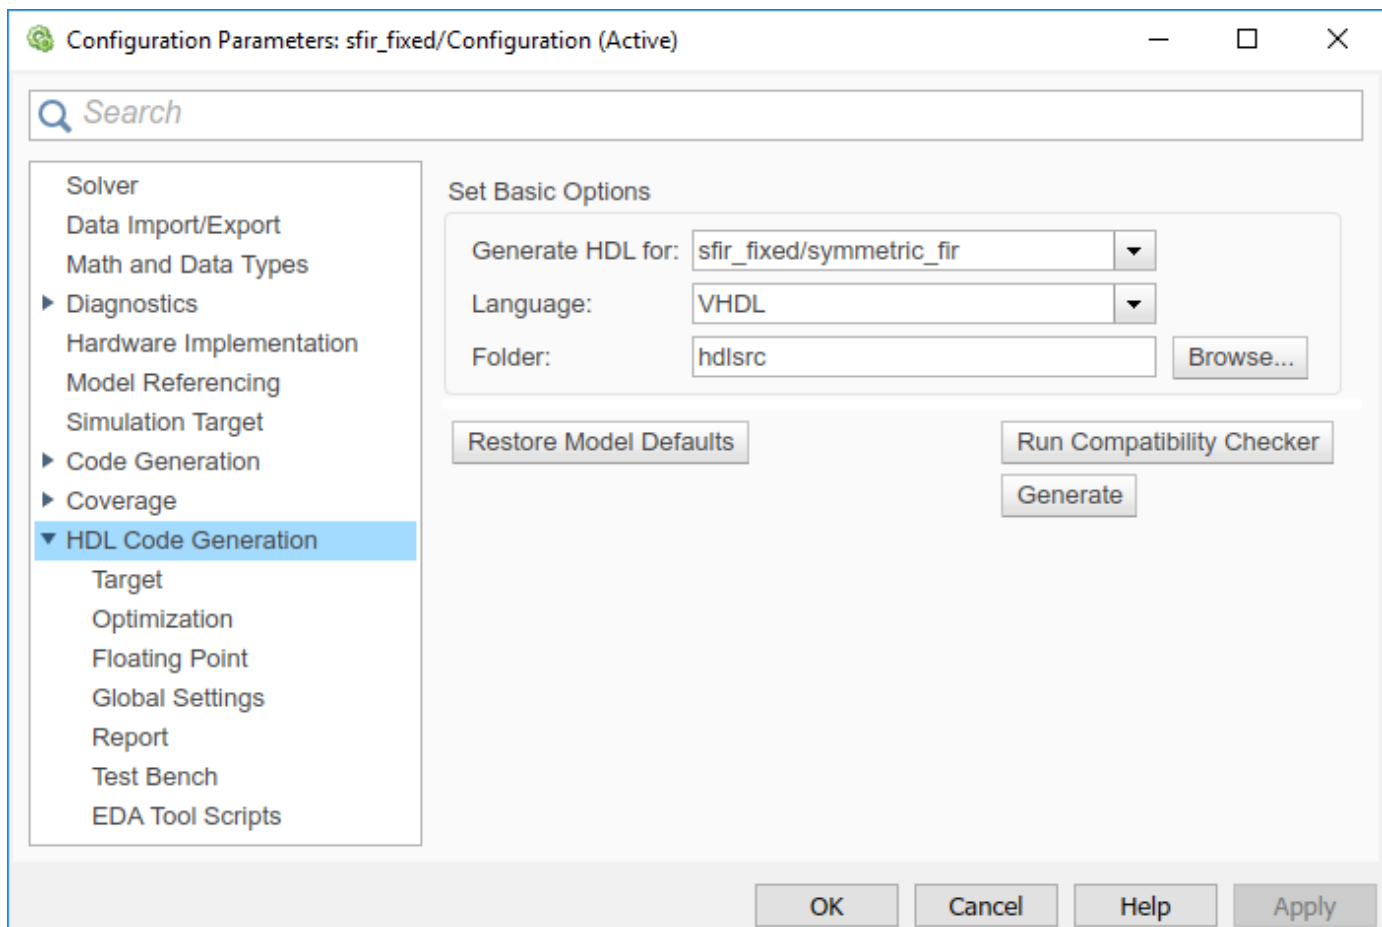

“HDL Code Tab in Simulink Toolstrip” on page 16-3

“HDL Code Options in the Block Context Menu” on page 16-4

“The HDL Block Properties Dialog Box” on page 16-5

HDL Code Generation Options in the Configuration Parameters Dialog Box

The following figure shows the top-level **HDL Code Generation** pane in the Configuration Parameters dialog box. To open this dialog box, in the Apps gallery, click **HDL Coder**. The **HDL Code** tab appears. In the **Prepare** section, click **Settings**.

Note When the **HDL Code Generation** pane of the Configuration Parameters dialog box appears, clicking the **Help** button displays general help for the Configuration Parameters dialog box.

For more information, see “HDL Code Generation Options in Configuration Parameters Dialog Box” on page 16-6.

HDL Code Tab in Simulink Toolstrip

The Simulink Toolstrip contains contextual tabs that appear only when you need to access them. To access the **HDL Code** tab, open the **HDL Coder** app from the **Apps** tab on the Simulink Toolstrip.

The **HDL Code** tab provides shortcuts to the HDL code generation options. You can also use this tab to initiate code generation.

Options include:

- **Workflow Advisor:** Open the HDL Workflow Advisor.
- **HDL Block Properties:** Open the HDL-compatible block library in the Simulink Library Browser or open the HDL Block Properties dialog box for a block that you select in your model.

Note After you open the HDL-compatible block library, to restore the Library Browser to the default view, in the Library Browser, click the  button.

- **HDL Code Advisor:** Open the HDL Code Advisor for the model or the selected Subsystem.
- **Settings:** Open the **HDL Code Generation** pane in the Configuration Parameters dialog box.
 - **Report Options:** Open the **HDL Code Generation > Report** pane.
 - **Remove HDL Configuration from Model:** The HDL configuration component is internal data that HDL Coder creates and attaches to a model. This component lets you view the **HDL Code Generation** pane in the Configurations Parameters dialog box, and use the **HDL Code Generation** pane to set HDL code generation options. To remove the HDL Code Generation configuration component to or from a model, select this option. For more information, see “Add or Remove the HDL Configuration Component” on page 30-27.
- **Code for:** Select the top-level Subsystem or model for which you want to generate HDL code. This option corresponds to the **Generate HDL for** option in the **HDL Code Generation** pane of the Configuration Parameters dialog box.
- **Generate HDL Code:** Initiate HDL code generation; equivalent to the **Generate HDL Code** check box in the **HDL Code Generation > Global Settings > Advanced** tab of the Configuration Parameters dialog box.
- **Navigate to Code:** Select a block in your model and navigate to the HDL code generated for that block. To use this setting, you must have generated a traceability report.
- **Open Report:** Opens the Code Generation Report if this report exists on the path. Otherwise, this button opens the HDL Check Report.
- **Generate Test Bench:** Initiate test bench code generation; equivalent to the **Generate Test Bench** button in the Configuration Parameters dialog box. To use this button, you If you do not

select a subsystem in the **Generate HDL for** menu, the **Generate Test Bench** menu option is not available.

If you have HDL Verifier™ installed, you can generate a HDL cosimulation model or a SystemVerilog DPI component.

- **Share:** Generate a protected model that you can share with a third party without revealing the intellectual property of the model.

HDL Code Options in the Block Context Menu

When you right-click a block that HDL Coder supports, the context menu for the block includes an **HDL Code** submenu. The code generator enables items in the submenu according to:

- The block type: for subsystems, the menu enables some options that are specific to subsystems.
- Whether or not code and traceability information has been generated for the block or subsystem.

Note You can also access the options in the context menu from the **HDL Code** tab in the Simulink Toolstrip. To access this tab, open the **HDL Coder** app from the **Apps** tab.

The following summary describes the **HDL Code** submenu options.

Option	Description	Availability
Check Subsystem Compatibility	Runs the HDL compatibility checker (checkhdl) on the subsystem.	Available only for subsystems.
Generate HDL for Subsystem	Runs the HDL code generator (makehdl) and generates code for the subsystem.	Available only for subsystems.
HDL Coder Properties	Opens the Configuration Parameters dialog box, with the top-level HDL Code Generation pane selected.	Available for blocks or subsystems.
HDL Block Properties	Opens a block properties dialog box for the block or subsystem. See “Set and View HDL Model and Block Parameters” on page 26-53 for more information.	Available for blocks or subsystems.
HDL Workflow Advisor	Opens the HDL Workflow Advisor for the subsystem.	Available only for subsystems.
Navigate to Code	Activates the HTML code generation report window, displaying the beginning of the code generated for the selected block or subsystem. For more information, see “Navigate Between Simulink Model and HDL Code by Using Traceability” on page 30-4.	Enabled when both code and a traceability report have been generated for the block or subsystem.

The HDL Block Properties Dialog Box

HDL Coder provides selectable alternate block implementations for many block types. Each implementation is optimized for different characteristics, such as speed or chip area. The HDL Properties dialog box lets you choose the implementation for a selected block.

Most block implementations support a number of implementation parameters that let you control further details of code generation for the block. The HDL Properties dialog box lets you set implementation parameters for a block.

The following figure shows the HDL Properties dialog box for a block.

There are a number of ways to specify implementations and implementation parameters for individual blocks or groups of blocks. See “Set and View HDL Model and Block Parameters” on page 26-53.

The following figure shows the top-level **HDL Code Generation** pane in the Configuration Parameters dialog box. To open this dialog box, in the Apps gallery, click **HDL Coder**. The **HDL Code** tab appears. In the **Prepare** section, click **Settings**.

The **HDL Code Generation** pane consists of basic options that specify the DUT that you want to generate code for, target language, and folder settings. The **Generate HDL for** setting is synchronized with the **Code for** menu in the **HDL Code** tab. You can also use the buttons in this pane

to initiate code generation and perform compatibility checking. The **HDL Code Generation** pane consists of various subpanes.

To learn more about the parameters in this pane, see “Target Language and Folder Selection Parameters” on page 17-3.

HDL Code Generation Pane: Target

The **HDL Code Generation > Target** pane consists of parameters that you can use to specify the target device and synthesis tool. You can also specify the target frequency value in MHz.

To learn more about the parameters in this pane, see “Tool and Device Parameters” on page 18-3 and “Target Frequency Parameter” on page 18-8.

HDL Code Generation Pane: Optimization

The **HDL Code Generation > Optimization** pane consists of parameters that you can use to specify various area and speed optimizations to optimize your design. You can also specify use of multicycle path constraints as timing requirement for synthesis tools to meet.

To learn more about the parameters in this pane, see:

- “General Optimization Parameters” on page 19-3
- “RAM Mapping Parameters” on page 19-6
- “Pipelining Parameters” on page 19-9
- “Resource Sharing Settings for Various Blocks” on page 25-127
- “Resource Sharing of Subsystems and Floating-Point IPs” on page 25-131
- “Multicycle Path Constraints Parameters” on page 19-31

HDL Code Generation Pane: Floating Point

The **HDL Code Generation > Floating Point** pane consists of parameters that you can use to specify the floating-point IP library and additional options depending on whether to use native floating-point support and map to target floating-point IP libraries.

To learn more about the parameters in this pane, see:

- “Floating Point IP Library Parameters” on page 20-3
- “Native Floating-Point Parameters” on page 20-6

HDL Code Generation Pane: Global Settings

The **HDL Code Generation > Global Settings** pane enables you to specify detailed characteristics of the generated code, such as clock settings, HDL element naming, coding style, whether you want the HDL code to conform to coding standards, and diagnostics and additional options for model generation and HDL code generation.

To learn more about the top-level parameters in the **Clock Settings** section of this pane, see:

HDL Code Generation Pane: Report

The **HDL Code Generation > Report** pane consists of parameters that you can use to specify generation of a Code Generation Report with the HDL code. In addition to the summary and clock information, you can specify whether the Code Generation Report report should include sections that display high-level resource utilization, traceability information, effect of various optimizations, and floating-point resource consumption.

To learn more about the parameters in this pane, see “Code Generation Report Parameters” on page 22-3.

HDL Code Generation Pane: Testbench

The **HDL Code Generation > Testbench** pane consists of parameters that you can use to specify generation of a testbench to verify the HDL code. You can also specify various testbench options related to clock and reset input signals, setup and hold time, and testbench tolerance parameters.

To learn more about the parameters in this pane, see:

- “Test Bench Generation Output Parameters” on page 23-3
- “Test Bench Postfix Parameters” on page 23-8

Generate HDL Code from Simulink Model Using Configuration Parameters

In this section...

“FIR Filter Model” on page 16-11

“Create a Folder and Copy Relevant Files” on page 16-12

“Open HDL Code Generation Pane of Configuration Parameters Dialog Box” on page 16-13

“Generate HDL Code” on page 16-13

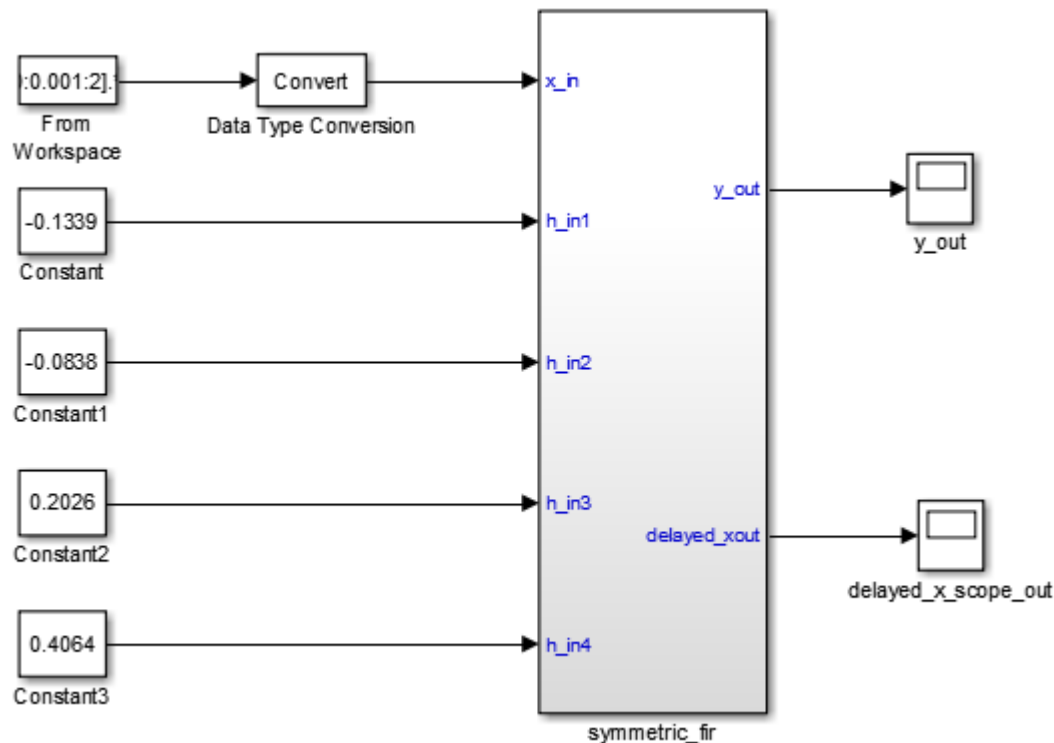

You can view and edit options and parameters that affect HDL code generation in the Configuration Parameters dialog box, or in the Model Explorer. This example illustrates how you can use the Configuration Parameters dialog box to generate HDL code for the Symmetric FIR filter model.

FIR Filter Model

Before you generate HDL code, the model must be compatible for HDL code generation. To check and update your model for HDL compatibility, see “Check HDL Compatibility of Simulink Model Using HDL Code Advisor” on page 45-2.

This example uses the Symmetric FIR filter model that is compatible for HDL code generation. To open this model at the command line, enter:

```
sfir_fixed
```

The model uses a division of labor that is suitable for HDL design.

```
mkdir C:\work\sl_hdlcoder_work
```

sl_hdlcoder_work stores a local copy of the example model and folders and generated HDL code. Use a folder location that is not within the MATLAB folder tree.

- 2 Make the sl_hdlcoder_work folder your working folder, for example:

```
cd C:\work\sl_hdlcoder_work
```

- 3 Save a local copy of the sfir_fixed model to your current working folder. Leave the model open.

Open HDL Code Generation Pane of Configuration Parameters Dialog Box

This figure shows the top-level **HDL Code Generation** pane of the Configuration Parameters dialog box. To open this dialog box, in the Apps gallery, click **HDL Coder**. The **HDL Code** tab appears. In the **Prepare** section, click **Settings**.

The **HDL Code Generation** pane consists of basic options that specify the DUT that you want to generate code for, target language, and folder settings. The **Generate HDL for** setting is synchronized with the **Code for** menu in the **HDL Code** tab. You can also use the buttons in this pane to initiate code generation and perform compatibility checking. The **HDL Code Generation** pane consists of various subpanes that you can use to specify various settings related to clock and reset signals to reporting and optimization settings.

In the **HDL Code Generation** pane

- The **Generate HDL for** field specifies the sfir_fixed/symmetric_fir subsystem for code generation.
- The **Language** field specifies generation of VHDL code.
- The **Folder** field specifies a target folder that stores generated code files and scripts.

To learn more about the various parameters in the **HDL Code Generation** pane, see “HDL Code Generation Options in Configuration Parameters Dialog Box” on page 16-6.

Generate HDL Code

To generate code, click the **Generate** button. By default, HDL Coder generates VHDL code in the target hdlsrc folder.

To generate Verilog code for the model:

- 1 In the **HDL Code** tab, click **Settings**.
- 2 In the **HDL Code Generation** pane, for **Language**, select Verilog. Leave other settings to the default. Click **Apply** and then click **Generate**.

HDL Coder compiles the model before generating code. Depending on model display options such as port data types, the model can change in appearance after code generation. As code generation proceeds, HDL Coder displays progress messages in the MATLAB command line with:

- Link to the Configuration Set that indicates the model for which the Configuration Parameters are applied.

- Links to the generated files. To view the files in the MATLAB Editor, click the links.
 - `symmetric_fir.vhd`: VHDL code. This file contains an entity definition and RTL architecture implementing the `symmetric_fir.vhd` filter.
 - `symmetric_fir_compile.do`: Mentor Graphics ModelSim® compilation script (vcom command) to compile the generated VHDL code.
 - `symmetric_fir_synplify.tcl`: Synplify® synthesis script.
 - `symmetric_fir_map.txt`: This report maps generated entities to the subsystems that generated them. See “Trace Code Using the Mapping File” on page 30-24

The process completes with the message:

```
### HDL Code Generation Complete.
```

More About

- “Set HDL Code Generation Options” on page 16-2
- “HDL Code Generation Options in Configuration Parameters Dialog Box” on page 16-6

Generate HDL Code from Simulink Model from Command Line

In this section...

“FIR Filter Model” on page 16-15

“Create a Folder and Copy Relevant Files” on page 16-16

“Generate HDL Code” on page 16-17

You can customize and edit HDL code generation options and then generate code at the command line. This example illustrates how you can use the Configuration Parameters dialog box to generate HDL code for the Symmetric FIR filter model.

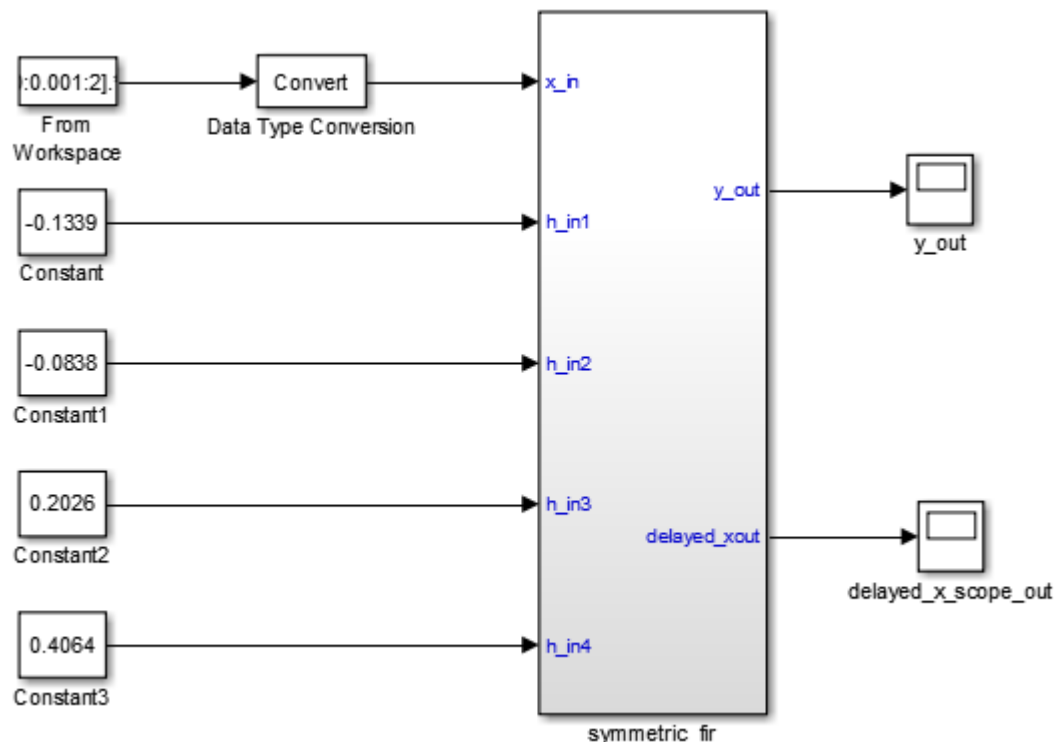

FIR Filter Model

Before you generate HDL code, the model must be compatible for HDL code generation. To check and update your model for HDL compatibility, see “Check HDL Compatibility of Simulink Model Using HDL Code Advisor” on page 45-2. You can also customize the model parameters by using the `hdlsetup` function.

```
hdlsetup(gcs)
```

This example uses the Symmetric FIR filter model that is compatible for HDL code generation. To open this model at the command line, enter:

```
sfir_fixed
```

The model uses a division of labor that is suitable for HDL design.

- The `symmetric_fir` subsystem, which implements the filter algorithm, is the device under test (DUT). An HDL entity is generated from this subsystem.
- The top-level model components that drive the subsystem work as a test bench.

The top-level model generates 16-bit fixed-point input signals for the `symmetric_fir` subsystem. The Signal From Workspace block generates a test input (stimulus) signal for the filter. The four Constant blocks provide filter coefficients. The Scope blocks are used for simulation and are not used for HDL code generation.

To navigate to the `symmetric_fir` subsystem, enter:

```
open_system('sfir_fixed/symmetric_fir')
```

Create a Folder and Copy Relevant Files

In MATLAB:

- 1 Create a folder named `sl_hdlcoder_work`, for example:

```
mkdir C:\work\sl_hdlcoder_work
```

sl_hdlcoder_work stores a local copy of the example model and folders and generated HDL code. Use a folder location that is not within the MATLAB folder tree.

- 2 Make the sl_hdlcoder_work folder your working folder, for example:

```
cd C:\work\sl_hdlcoder_work
```

- 3 Save a local copy of the sfir_fixed model to your current working folder. Leave the model open.

Generate HDL Code

To generate HDL code for the DUT, you use the makehdl function. For example, to generate HDL code for the symmetric_fir subsystem, enter:

```
makehdl('sfir_fixed/symmetric_fir')
```

To specify the customizations before you generate HDL code, use the hdlset_param function. You can also specify various name-value pair arguments with the makehdl function to customize HDL code generation options while generating HDL code. For example, to generate Verilog code, use the TargetLanguage property.

```
makehdl('sfir_fixed/symmetric_fir', 'TargetLanguage', 'Verilog')
```

Alternatively, if you are using hdlset_param, set this parameter on the model and then run the makehdl function.

```
hdlset_param('sfir_fixed', 'TargetLanguage', 'Verilog')
makehdl('sfir_fixed/symmetric_fir')
```

HDL Coder compiles the model before generating code. Depending on model display options such as port data types, the model can change in appearance after code generation. As code generation proceeds, HDL Coder displays progress messages in the MATLAB command line with:

- Link to the Configuration Set that indicates the model for which the Configuration Parameters are applied.
- Links to the generated files. To view the files in the MATLAB Editor, click the links.
 - symmetric_fir.vhd: VHDL code. This file contains an entity definition and RTL architecture implementing the symmetric_fir.vhd filter.
 - symmetric_fir_compile.do: Mentor Graphics ModelSim compilation script (vcom command) to compile the generated VHDL code.
 - symmetric_fir_synplify.tcl: Synplify synthesis script.
 - symmetric_fir_map.txt: This report maps generated entities to the subsystems that generated them. See “Trace Code Using the Mapping File” on page 30-24

The process completes with the message:

```
### HDL Code Generation Complete.
```

More About

- “Set HDL Code Generation Options” on page 16-2
- “HDL Code Generation Options in Configuration Parameters Dialog Box” on page 16-6

HDL Code Generation Pane: General

- “HDL Code Generation Top-Level Pane Overview” on page 17-2
- “Target Language and Folder Selection Parameters” on page 17-3

HDL Code Generation Top-Level Pane Overview

The top-level **HDL Code Generation** pane contains settings for target language and the model that you want to generate code for, and buttons that initiate code generation and compatibility checking, and sets code generation parameters.

Buttons in the HDL Code Generation Top-Level Pane

The buttons in the **HDL Code Generation** pane perform functions related to code generation. These buttons are:

Generate: Initiates code generation for the system selected in the **Generate HDL for** menu. See also `makehdl`.

Run Compatibility Checker: Invokes the compatibility checker to examine the system selected in the **Generate HDL for** menu for compatibility problems. See also `checkhdl`.

Browse: Lets you navigate to and select the target folder to which generated code and script files are written. The path to the target folder is entered into the **Folder** field.

Restore Model Defaults: Sets model parameters to their default values.

Target Language and Folder Selection Parameters

In this section...

“Generate HDL for” on page 17-3

“Language” on page 17-3

“Folder” on page 17-4

“Restore Model Defaults” on page 17-5

“Run Compatibility Checker” on page 17-5

“Generate” on page 17-6

This page describes configuration parameters in the **HDL Code Generation** pane of the Configuration Parameters dialog box. By using these parameters, you can specify the Subsystem that you want to generate HDL code for, the target HDL language, and the target folder into which code is generated.

Generate HDL for

Select the subsystem or model from which code is generated. The list includes the path to the root model and to subsystems in the model. When you specify this parameter and click the **Generate** button, HDL Coder generates code for the Subsystem that you specify. By default, the HDL code is generated in VHDL language and into the `hdlsrc` folder.

Settings

Default: The top level subsystem in the root model is selected.

Command-Line Information

Property: HDLSubsystem

Type: character vector

Value: A valid path to your subsystem

Default: Path to the top level subsystem in root model

For example, you can generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Specify the subsystem using the property `HDLSubsystem` as an argument to `makehdl`.

```
makehdl('sfir_fixed', 'HDLSubsystem', 'sfir_fixed/symmetric_fir')
```

- Pass in the path to the subsystem as a first argument to `makehdl`.

```
makehdl('sfir_fixed/symmetric_fir')
```

See also `makehdl`.

Language

Select the language (VHDL or Verilog) in which code is generated. The selected language is referred to as the target language. When you specify the **Language** and click the **Generate** button, HDL Coder generates code in that language for the Subsystem that is specified by the **Generate HDL for** parameter. By default, the HDL code is generated in VHDL language and into the `hdlsrc` folder.

The generated HDL code complies with these standards:

- VHDL-1993 (IEEE 1076-1993)
- Verilog-2001 (IEEE 1364-2001)

Settings

Default: VHDL

VHDL

Generate VHDL code.

Verilog

Generate Verilog code.

Command-Line Information

Property: TargetLanguage

Type: character vector

Value: 'VHDL' | 'Verilog'

Default: 'VHDL'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to generate Verilog code for the `symmetric_fir` subsystem inside the `sfir_fixed` model, use either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', 'TargetLanguage', 'Verilog')
```

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'TargetLanguage', 'Verilog')  
makehdl('sfir_fixed/symmetric_fir')
```

See also `makehdl`.

Folder

Enter a path to the folder into which code is generated. Alternatively, click **Browse** to navigate to and select a folder. The selected folder is referred to as the target folder. When you specify the **Folder** and click the **Generate** button, HDL Coder generates code into that folder for the Subsystem that is specified by the **Generate HDL for** parameter. By default, the HDL code is generated in VHDL language and into the `hdlsrc` folder.

Settings

Default: The default target folder is a subfolder of your working folder, named `hdlsrc`. HDL Coder writes the generated files into this subfolder. The folder name can be a complete path name, specified as a character vector.

Command-Line Information

Property: TargetDirectory

Type: character vector

Value: A valid path to your target folder

Default: 'hdlsrc'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to generate HDL code into a custom target folder for the `symmetric_fir` subsystem inside the `sfir_fixed` model, use either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','TargetDirectory','C:/Temp/hdlsrc')
```

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','TargetDirectory','C:/Temp/hdlsrc')
makehdl('sfir_fixed/symmetric_fir')
```

See also `makehdl`.

Restore Model Defaults

This button resets the model-level HDL settings to the default values. The block settings are not changed. To clear the block settings, use `hdlrestoreparams`.

Note If you clear the model-level settings, you cannot restore the previous settings. To restore the settings, close the model without saving and then reopen the model.

Command-Line Information

Function: `hdlrestoreparams`

Type: character vector

Value: model name

Default: ''

Run Compatibility Checker

This setting checks whether the Subsystem that you specify by using **Generate HDL for** is compatible for HDL code generation. The setting generates a HDL Check Report that displays errors, warnings, and messages. See “Check Subsystem for HDL Compatibility” on page 25-20.

Command-Line Information

Function: `checkhdl`

Type: character vector

Value: subsystem or model name

Default: ''

See Also

`checkhdl`

Generate

This setting generates HDL code for the Subsystem that you specify by using **Generate HDL for**. If the Subsystem is not HDL-compatible, the code generator displays errors in the HDL Check Report.

Command-Line Information

Function: makehdl

Type: character vector

Value: subsystem or model name

Default: ''

See Also

makehdl

HDL Code Generation Pane: Target

- “Target Overview” on page 18-2
- “Tool and Device Parameters” on page 18-3
- “Target Frequency Parameter” on page 18-8

Target Overview

The **Target** pane enables you to specify the target hardware settings. You can specify the tool and device settings and the target frequency.

Tool and Device Parameters

In this section...

“Synthesis Tool” on page 18-3

“Family” on page 18-4

“Device” on page 18-5

“Package” on page 18-6

“Speed” on page 18-6

This page describes configuration parameters in the **Tool and Device** section of the **HDL Code Generation > Target** pane of the Configuration Parameters dialog box. By using the parameters in this section, you can specify the synthesis tool, and then select the **Family**, **Device**, **Package**, and **Speed** for your synthesis target.

Synthesis Tool

Specify the synthesis tool for targeting the generated HDL code. To use HDL Coder with one of the supported third-party FPGA synthesis tools, add the tool to the system path using the `hdlsetuptoolpath` function. When you specify the **Synthesis Tool**, HDL Coder populates the **Family**, **Device**, **Package**, and **Speed** with default values for that tool.

Settings

Default: No synthesis tool specified

The options are:

No synthesis tool specified

Select this option if you do not want to perform logic synthesis. You can generate HDL code from your design.

Xilinx Vivado

Specify Xilinx Vivado as the synthesis tool.

Xilinx ISE

Specify Xilinx ISE as the synthesis tool.

Altera Quartus II

Specify Altera Quartus II as the synthesis tool.

Microchip Libero SoC

Specify Microchip Libero[®] SoC as the synthesis tool.

Intel Quartus Pro

Specify Intel Quartus Pro as the synthesis tool.

If your synthesis tool is not one of the **Synthesis tool** options, see “Synthesis Tool Path Setup”.

Command-Line Information

Property: `SynthesisTool`

Type: character vector

Value: '' | 'Xilinx Vivado' 'Xilinx ISE' 'Altera Quartus II'
Default: ''

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify `Altera Quartus II` as the `SynthesisTool` when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'SynthesisTool', 'Altera Quartus II')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'SynthesisTool', 'Altera Quartus II')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`
- `hdlsetuptoolpath`
- “Tool Setup”

Family

Specify the target device chip family for your model as a character vector. When you specify the **Synthesis Tool**, HDL Coder populates the **Family**, **Device**, **Package**, and **Speed** with default values for that tool. To find the chip family for your target device, at the MATLAB command line, enter `hdlcoder.supportedDevices`. Then, open the linked report and find your target device details.

Settings

Default: ''

Specify the target device chip family for your Simulink model as a character vector.

Command-Line Information

Property: `SynthesisToolChipFamily`

Type: character vector

Value: A valid chip family for the target device

Default: ''

For example, if your `SynthesisTool` is `Xilinx Vivado`, you can specify `Virtex7` as the `SynthesisToolChipFamily` when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'SynthesisToolChipFamily', 'Virtex7')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','SynthesisToolChipFamily', 'Virtex7')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`
- `hdlsetuptoolpath`
- “Tool Setup”

Device

Specify the target device name for your model as a character vector. When you specify the **Synthesis Tool**, HDL Coder populates the **Family**, **Device**, **Package**, and **Speed** with default values for that tool. To find the device name for your target device, at the MATLAB command line, enter `hdlcoder.supportedDevices`. Then, open the linked report and find your target device details.

Settings

Default: ''

Specify the target device name for your Simulink model as a character vector.

Command-Line Information

Property: `SynthesisToolDevicename`

Type: character vector

Value: A valid device name for the synthesis tool

Default: ''

You can get the `SynthesisToolDeviceName` when you specify the `SynthesisTool` for your model. Consider that the `SynthesisTool` is set to Xilinx Vivado and the `SynthesisToolChipFamily` is set to `Virtex7`.

- To get the default device name, pass the property as an argument to the `hdlget_param` function.

```
hdlget_param('sfir_fixed', ...
    'SynthesisToolDeviceName')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','SynthesisToolDeviceName', 'xc7v2000t')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`
- `hdlsetuptoolpath`

Package

Specify the target device package name for your model as a character vector. When you specify the **Synthesis Tool**, HDL Coder populates the **Family**, **Device**, **Package**, and **Speed** with default values for that tool. To find the device name for your target device, at the MATLAB command line, enter `hdlcoder.supportedDevices`. Then, open the linked report and find your target device details.

Settings

Default: ''

Specify the target device package name for your Simulink model as a character vector.

Command-Line Information

Property: `SynthesisToolPackageName`

Type: character vector

Value: A valid package name for the synthesis tool

Default: ''

You can get the `SynthesisToolPackageName` when you specify the `SynthesisTool` for your model. Consider that the `SynthesisTool` is set to `Xilinx Vivado` and the `SynthesisToolChipFamily` is set to `Virtex7`.

- To get the default device name, pass the property as an argument to the `hdlget_param` function.

```
hdlget_param('sfir_fixed', ...
    'SynthesisToolPackageName')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'SynthesisToolPackageName', 'fhg1761')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`

Speed

Specify the target device speed value for your model as a character vector. When you specify the **Synthesis Tool**, HDL Coder populates the **Family**, **Device**, **Package**, and **Speed** with default values for that tool. To find the chip family for your target device, at the MATLAB command line, enter `hdlcoder.supportedDevices`. Then, open the linked report and find your target device details.

Settings

Default: ''

Specify the target device speed value for your Simulink model as a character vector.

Command-Line Information**Property:** SynthesisToolSpeedValue**Type:** character vector**Value:** A valid speed value for the target device**Default:** ''

You can get the SynthesisToolSpeedValue when you specify the SynthesisTool for your model. Consider that the SynthesisTool is set to Xilinx Vivado and the SynthesisToolChipFamily is set to Virtex7.

- To get the default device name, pass the property as an argument to the hdlget_param function.

```
hdlget_param('sfir_fixed', ...  
            'SynthesisToolSpeedValue')
```

- When you use hdlset_param, you can set the parameter on the model and then generate HDL code using makehdl.

```
hdlset_param('sfir_fixed', 'SynthesisToolSpeedValue', '-1')  
makehdl('sfir_fixed/symmetric_fir')
```

Target Frequency Parameter

This configuration parameter resides in the **Objectives Settings** section of the **HDL Code Generation > Target** pane of the Configuration Parameters dialog box. By using this parameter, you can specify the target frequency in MHz for multiple features and workflows. Before setting the target frequency, make sure that you specify the **Synthesis Tool**.

Settings

Default: 0

This setting is the target frequency in MHz for multiple features and workflows that HDL Coder supports. The supported features are:

- **FPGA floating-point target library mapping:** Specify the target frequency that you want the IP to achieve when you use ALTERA MEGAFUNCTION (ALTERA FP FUNCTIONS). If you do not specify the target frequency, HDL Coder sets the target frequency to a default value of 200 MHz. See also “Generate HDL Code for Vendor-Specific FPGA Floating-Point Target Libraries” on page 36-20.
- **Adaptive pipelining:** If your design uses multipliers, specify the synthesis tool and the target frequency. Based on these settings, HDL Coder estimates the number of pipelines that can be inserted to improve area and timing on the target platform. If you do not specify the target frequency, HDL Coder uses a target frequency of 0 MHz and does not insert adaptive pipelines. See also “Adaptive Pipelining” on page 28-181.

You can also set the target frequency by using the **Target Frequency (MHz)** setting in the **Set Target Frequency** task in the HDL Workflow Advisor.

Specify the target frequency for these workflows-

- **Generic ASIC/FPGA:** To specify the target frequency that you want your design to achieve. HDL Coder generates a timing constraint file for that clock frequency. It adds the constraint to the FPGA synthesis tool project that you create in the **Create Project** task. If the target frequency is not achievable, the synthesis tool generates an error.
- **IP Core Generation:** To specify the target frequency for HDL Coder to modify the clock module setting in the reference design to produce the clock signal with that frequency. Enter a target frequency value that is within the **Frequency Range (MHz)**. If you do not specify the target frequency, HDL Coder uses the **Default (MHz)** target frequency.
- **Simulink Real-Time FPGA I/O:** For Speedgoat I/O modules that are supported with Xilinx ISE, specify the target frequency to generate the clock module to produce the clock signal with that frequency.

The Speedgoat I/O modules that are supported with Xilinx Vivado use the IP Core Generation workflow infrastructure. Specify the target frequency for HDL Coder to modify the clock module setting in the reference design to produce the clock signal with that frequency. Enter a target frequency value that is within the **Frequency Range (MHz)**. If you do not specify the target frequency, HDL Coder uses the **Default (MHz)** target frequency.

- **FPGA Turnkey:** To generate the clock module to produce the clock signal with that frequency automatically.

Command-Line Information

Property: TargetFrequency

Type: integer

Value: integer greater than or equal to 0

Default: 0

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify the `TargetFrequency` when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...  
        'TargetFrequency', '300')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'TargetFrequency', '300')  
makehdl('sfir_fixed/symmetric_fir')
```

HDL Code Generation Pane: Optimization

- “Optimization Overview” on page 19-2
- “General Optimization Parameters” on page 19-3
- “RAM Mapping Parameters” on page 19-6
- “Pipelining Parameters” on page 19-9
- “Resource Sharing Parameters for Adders and Multipliers” on page 19-18
- “Resource Sharing Parameters for Subsystems and Floating-Point IPs” on page 19-27
- “Multicycle Path Constraints Parameters” on page 19-31
- “Frame to Sample Conversion Parameters” on page 19-34

Optimization Overview

The **Optimization** pane enables you to specify various optimizations such as delay balancing, resource sharing and pipelining. To improve the area and timing of your design on the target hardware, specify these settings. This pane also contains a **Multicycle Path Constraints** section. Use the settings in this section to specify the timing requirements that the Synthesis tool must meet for your design.

General Optimization Parameters

In this section...

“Transform non zero initial value delay” on page 19-3

“Remove Unused Ports” on page 19-4

“Balance delays” on page 19-4

This page describes configuration parameters that reside in the **HDL Code Generation > Optimization > General** tab of the Configuration Parameters dialog box. Using the parameters in this section, you can optimize your design for HDL code generation.

Transform non zero initial value delay

Settings

Default: On

On

Transform Delay blocks with nonzero **Initial condition** in your Simulink model to Delay blocks with zero **Initial condition** and some additional logic in the generated HDL code.

By using this transformation, HDL Coder can perform optimizations such as sharing, distributed pipelining, and clock-rate pipelining more effectively, and prevent an assertion from being triggered in the validation model.

Off

Do not transform Delay blocks with nonzero **Initial condition** in your Simulink model.

Command-Line Information

Property: TransformNonZeroInitValDelay

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can set the `TransformNonZeroInitValDelay` property to on when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'TransformNonZeroInitValDelay', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'TransformNonZeroInitValDelay', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

makehdl

Remove Unused Ports**Settings****Default:** On On

Removes ports in your design that are unused from the generated HDL code. This optimization preserves unused ports at the top-level DUT subsystem. All other unused ports are removed from the HDL code.

 Off

Do not remove unused ports from the HDL code.

Command-Line Information**Property:** DeleteUnusedPorts**Type:** character vector**Value:** 'on' | 'off'**Default:** 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can set the `DeleteUnusedPorts` property to `off` when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'DeleteUnusedPorts','off')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','DeleteUnusedPorts','on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “Remove Redundant Logic and Unused Blocks in Generated HDL Code” on page 28-224
- “Optimize Unconnected Ports in HDL Code for Simulink Models” on page 28-246
- `makehdl`

Balance delays

When you enable certain optimizations such as pipelining or resource sharing, or specify certain block implementations and generate code, HDL Coder introduces pipeline delays along certain signal

paths in your model. By default, the delay balancing is on for the model. HDL Coder detects these pipeline delays introduced along one path and then inserts matching delays on other paths. For more information, see “Delay Balancing” on page 28-81.

To make sure that the generated model after HDL code generation is functionally equivalent to the original Simulink model, leave this setting enabled. If you disable this setting, HDL Coder generates a warning that numerical differences can occur in the validation model. To fix this warning, run the model check “Check delay balancing setting” on page 44-11.

Compatibility Considerations

It is not recommended to disable delay balancing for your entire model. The delay balancing model option is removed from the **HDL Code Generation > Optimization > General** tab of the Configuration Parameters dialog box. For recommendations on delay balancing, see “Delay Balancing Considerations” on page 28-83. You can still enable this option in the MATLAB command-line interface by using `hdlset_param` or `makehdl` commands.

Command-Line Information

Property: BalanceDelays

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can enable the `BalanceDelays` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'BalanceDelays', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'BalanceDelays', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

RAM Mapping Parameters

In this section...

“Map pipeline delays to RAM” on page 19-6

“RAM mapping threshold” on page 19-7

This page describes configuration parameters that reside in the **HDL Code Generation > Optimization > General** tab of the Configuration Parameters dialog box. Using the parameters in this section, you can reduce the area usage on the target device by trading-off block RAMs for registers. The parameters specify whether you want to map pipeline registers in the generated code to RAM, and the minimum RAM size for mapping to block RAMs on the FPGA.

Map pipeline delays to RAM

Map pipeline registers in the generated HDL code to RAM. Certain speed or area optimizations such as pipelining and resource sharing, or certain block implementations that you specify can insert pipeline registers in the generated HDL code. You can save area on the target device by mapping these pipeline registers to RAM.

Settings

Default: Off

On

Map pipeline registers in the generated HDL code to RAM. To map these registers to block RAMs, the RAM size must be greater than or equal to the RAM mapping threshold in bits. To calculate the total RAM size for delays, use this formula:

$$\text{RAMSize} = \text{Delay length} * \text{Word length} * \text{Vector length} * \text{Complexity}$$

Complexity is 2 for a complex data type or 1 for a real datatype.

Off

Do not map pipeline registers in the generated HDL code to RAM.

Command-Line Information

Property: MapPipelineDelaysToRAM

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can enable the `MapPipelineDelaysToRAM` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'MapPipelineDelaysToRAM', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','MapPipelineDelaysToRAM','on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`
- “UseRAM” on page 26-25
- “Apply RAM Mapping to Optimize Area” on page 28-122

RAM mapping threshold

Specify the minimum RAM size for mapping to block RAMs. HDL Coder determines whether to use registers or RAM resources on the FPGA by comparing the RAM size of your design with the RAM mapping threshold that you specify.

You can specify the RAM mapping threshold by using either:

- A single integer to map any delay or persistent array greater than the threshold bit size to RAM.
- A string of format $M \times N$ that specifies two thresholds where M is the delay length (for delays) or array size (for persistent array variables) and N is the word length or bit width of the data type. Setting both thresholds excludes delays or persistent arrays that inefficiently map to block RAM on your target hardware. For more information, see “Use the RAM Mapping Threshold” on page 28-123.

Settings

Default: 256

The RAM mapping threshold must be:

- An integer greater than or equal to zero.
- A string that has the format $M \times N$, where M is the delay length or array size and N is the word length.

HDL Coder uses the threshold to determine whether or not to map the following elements to block RAMs instead of to registers:

- Delay blocks
- Persistent arrays in MATLAB Function blocks

Command-Line Information

Property: `RAMMappingThreshold`

Type: integer, string

Value: integer greater than or equal to 0, string of $M \times N$ format

Default: 256

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can set the `RAMMappingThreshold` to 1024 when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...  
        RAMMappingThreshold=1024)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', RAMMappingThreshold=1024)  
makehdl('sfir_fixed/symmetric_fir')
```

For example, you can set the `RAMMappingThreshold` to a delay length of 500 cycles and a word length of 50 bits, "500x50", when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...  
        RAMMappingThreshold="500x50")
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', RAMMappingThreshold="500x50");  
makehdl('sfir_fixed/symmetric_fir')
```

Pipelining Parameters

In this section...
“Clock-rate pipelining” on page 19-9
“Allow clock-rate pipelining of DUT output ports” on page 19-10
“Balance clock-rate pipelined DUT output ports” on page 19-11
“Distributed pipelining” on page 19-12
“Distributed pipelining priority” on page 19-13
“Preserve design delays” on page 19-14
“Use synthesis estimates for distributed pipelining” on page 19-14
“Adaptive pipelining” on page 19-15
“Map lookup tables to RAM” on page 19-16

This documentation page describes configuration parameters that reside in the **HDL Code Generation > Optimization > Pipelining** tab of the Configuration Parameters dialog box. Using the parameters in this section, you can improve the timing of your design on the target device.

Clock-rate pipelining

If your design contains multicycle paths, use clock-rate pipelining to insert pipeline registers at a clock rate that is faster than the data rate. This optimization improves the clock frequency and reduces the area usage without introducing additional latency. Clock-rate pipelining does not affect existing design delays in your model. It is an alternative to using multicycle path constraints with your synthesis tool.

Settings

Default: On

On

Insert pipeline registers at the clock rate for multi-cycle paths.

Off

Insert pipeline registers at the data rate for multi-cycle paths.

Dependency

If you specify an **Oversampling factor** greater than one, make sure that you select the **Clock-rate pipelining** check box. Clock-rate pipelining identifies regions in your model that run at the same slow data rate and are delimited by Delay blocks or blocks that introduce a rate transition. The code generator converts these regions to the faster clock rate by introducing Repeat blocks at the input of the region and Rate Transition blocks at the output of the region.

Command-Line Information

Property: ClockRatePipelining

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `ClockRatePipelining` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ClockRatePipelining', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'ClockRatePipelining', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “Clock-Rate Pipelining” on page 28-149

Allow clock-rate pipelining of DUT output ports

Produce the DUT outputs as soon as possible by passing the outputs from the DUT at the clock rate rather than the data rate.

Settings

Default: Off

On

Produce the DUT outputs as soon as possible at the clock rate.

Off

Produce the DUT outputs at the data rate.

Dependency

When you specify this parameter, make sure that you select the **Clock-rate pipelining** check box.

Command-Line Information

Property: `ClockRatePipelineOutputPorts`

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `ClockRatePipelineOutputPorts` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ClockRatePipelineOutputPorts', 'on')
```

- When you use `hdlset_param`, set the parameter on the model and then generate HDL code by using the `makehdl` function.

```
hdlset_param('sfir_fixed', 'ClockRatePipelineOutputPorts', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

Balance clock-rate pipelined DUT output ports

Synchronize the DUT outputs while satisfying the highest-latency requirements of the outputs. Apply this option when interfacing your logic with a valid signal interface to align the output of the logic path and valid signal path.

Settings

Default: Off

On

Synchronize the DUT outputs.

Off

Produce the DUT outputs as soon as possible, without synchronization.

Dependency

To enable this parameter, select the **Allow clock-rate pipelining of DUT output ports** check box.

Command-Line Information

Property: `BalanceClockRateOutputPorts`

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `BalanceClockRateOutputPorts` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'BalanceClockRateOutputPorts', 'on')
```

- When you use `hdlset_param`, set the parameter on the model and then generate HDL code by using the `makehdl` function.

```
hdlset_param('sfir_fixed', 'BalanceClockRateOutputPorts', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

Distributed pipelining

Enable pipeline register distribution, which is a speed optimization that increases the clock speed by moving existing delays in a design to reduce the critical path. This optimization moves the delays within a subsystem while preserving the hierarchy. For more information, see “Distributed Pipelining” on page 28-131.

Settings

Default: Off

On

Distribute pipelines in your design. To distribute pipelines, you must have pipelines already specified in your design.

Off

Do not distribute pipelines in your design.

Dependency

Your design must contain delays that can be redistributed. You can insert delays manually or by using the HDL block properties **InputPipeline** or **OutputPipeline** on a subsystem or block.

Command-Line Information

Property: DistributedPipelining

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `DistributedPipelining` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'DistributedPipelining', 'on')
```

- When you use `hdlset_param`, set the parameter on the model and then generate HDL code by using the `makehdl` function.

```
hdlset_param('sfir_fixed','DistributedPipelining','on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`
- “DistributedPipelining” on page 26-9

Distributed pipelining priority

Specify the priority for your distributed pipelining algorithm.

Settings

Default: Numerical Integrity

Numerical Integrity

Prioritize numerical integrity when distributing pipeline registers.

This option uses a conservative retiming algorithm that does not move registers across a component if the functional equivalence to the original design is unknown.

Performance

Prioritize performance over numerical integrity.

Use this option if your design requires a higher clock frequency and the Simulink behavior does not need to strictly match the generated code behavior. This option uses a more aggressive retiming algorithm that moves registers across a component even if the modified design’s functional equivalence to the original design is unknown. You can also use this option to reduce area by preventing distributed pipelining from inserting pipeline registers on stable paths.

Command-Line Information

Property: DistributedPipeliningPriority

Type: character vector

Value: 'NumericalIntegrity' | 'Performance'

Default: 'NumericalIntegrity'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `DistributedPipeliningPriority` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'DistributedPipeliningPriority','Performance')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','DistributedPipeliningPriority','Performance')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

Preserve design delays

Settings

Default: Off

On

Prevent distributed pipelining from moving design delays.

Off

Do not prevent distributed pipelining from moving design delays.

Command-Line Information

Property: PreserveDesignDelays

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `PreserveDesignDelays` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'PreserveDesignDelays','on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','PreserveDesignDelays','on')
makehdl('sfir_fixed/symmetric_fir')
```

Use synthesis estimates for distributed pipelining

To determine more accurate propagation delays for each component, use synthesis timing estimates for distributed pipelining. Different weights are assigned to varying components, which more

accurately reflects how the components function on hardware. When you enable this parameter, HDL Coder can better distribute pipelines in your design for HDL code generation and hardware deployment to maximize the clock frequency for your target device.

Settings

Default: Off

On

Use synthesis timing estimates for calculating propagation delays for each component in your design for distributed pipelining.

Off

Use equal weights for calculating propagation delays for each component in your design for distributed pipelining.

Dependency

Distributed pipelining must be enabled for at least one subsystem in your model to use this parameter.

Command-Line Information

Property: `UseSynthesisEstimatesForDistributedPipelining`

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can enable the `UseSynthesisEstimatesForDistributedPipelining` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'UseSynthesisEstimatesForDistributedPipelining','on')
```

- When you use `hdlset_param`, set the parameter on the model, and then generate HDL code by using the `makehdl` function.

```
hdlset_param('sfir_fixed','UseSynthesisEstimatesForDistributedPipelining','on')
makehdl('sfir_fixed/symmetric_fir')
```

Adaptive pipelining

Use this parameter to insert pipeline registers to the blocks in your design, reduce the area usage, and maximize the achievable clock frequency on the target FPGA device.

Settings

Default: Off

On

Insert adaptive pipeline registers in your design. For HDL Coder to insert adaptive pipelines, you must specify the synthesis tool.

Off

Do not insert adaptive pipeline registers.

Dependency

When you specify this parameter, in the **HDL Code Generation > Target** pane, specify the **Synthesis Tool**. If your design has multipliers, specify the **Synthesis Tool** and the **Target Frequency (MHz)** for adaptive pipeline insertion.

Command-Line Information

Property: AdaptivePipelining

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `AdaptivePipelining` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'AdaptivePipelining', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'AdaptivePipelining', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

Map lookup tables to RAM

Use this parameter to map lookup tables in your design to block RAM and reduce area usage on the target FPGA device.

Settings

Default: On

On

Map lookup tables in your design to RAM.

Off

Do not map lookup tables in your design to RAM.

Command-Line Information

Property: LUTMapToRAM

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the LUTMapToRAM setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...  
        'LUTMapToRAM', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed', 'LUTMapToRAM', 'on')  
makehdl('sfir_fixed/symmetric_fir')
```

Resource Sharing Parameters for Adders and Multipliers

In this section...

“Share Multiply-Add blocks” on page 19-24

“Multiply-Add block sharing minimum bitwidth” on page 19-25

This page describes configuration parameters that reside in the **HDL Code Generation > Optimization > Resource sharing** tab of the Configuration Parameters dialog box. Enable these parameters to save resources on the target device by specifying whether to share adders and multipliers in your design, and the minimum sharing bitwidth.

Share Adders

Enable this parameter to share adders with the resource sharing optimization. Resource sharing identifies Add or Sum blocks in your design that have two inputs and replaces them with a single Add or Sum block. This optimization saves area on the target FPGA device.

Settings

Default: Off

On

When resource sharing is enabled, this optimization shares adders with a bit width greater than or equal to the **Adder sharing minimum bitwidth**.

Off

Do not share adders.

Dependency

- To share adders in your design, in the HDL Block Properties for the DUT Subsystem, specify the **SharingFactor**.
- When you specify the **Adder sharing minimum bitwidth**, the code generator shares adders that have a bit width greater than or equal to the minimum bit width. The default minimum bit width for sharing adders is zero.

Command-Line Information

Property: ShareAdders

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `ShareAdders` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ShareAdders', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'ShareAdders', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

Adder sharing minimum bitwidth

Use this parameter to specify the minimum bit width that is required to share adders with the resource sharing optimization.

Settings

Default: 0

01

No minimum bit width for shared adders.

N, where N is an integer greater than 1

When resource sharing and adder sharing are enabled, share adders with a bit width greater than or equal to N.

Dependency

To share adders in your design:

- In the **Resource Sharing** tab, enable the **Adders** setting.
- In the HDL Block Properties for the DUT Subsystem, specify the **SharingFactor**.

Command-Line Information

Property: AdderSharingMinimumBitwidth

Type: integer

Value: integer greater than or equal to 0

Default: 0

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `AdderSharingMinimumBitwidth` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'AdderSharingMinimumBitwidth', 16)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'AdderSharingMinimumBitwidth', 16)
makehdl('sfir_fixed/symmetric_fir')
```

See Also

Share Multipliers

Enable this parameter to share multipliers with the resource sharing optimization. Resource sharing identifies Product or Gain blocks in your design that have two inputs and replaces them with a single Product or Gain block. This optimization saves area on the target FPGA device. Share multipliers with the resource sharing optimization.

Settings

Default: On

On

When resource sharing is enabled, share multipliers with a bit width greater than or equal to the **Multiplier sharing minimum bitwidth**. For successfully sharing multipliers, the input fixed-point data types must have the same wordlength. The fraction lengths and signs of the fixed-point data types can be different.

Off

Do not share multipliers.

Dependency

- To share multipliers in your design, in the HDL Block Properties for the DUT Subsystem, specify the **SharingFactor**.
- When you specify the **Multiplier sharing minimum bitwidth**, the code generator shares multipliers that have a bit width greater than or equal to the minimum bit width. The default minimum bit width for sharing multipliers is zero.

Command-Line Information

Property: ShareMultipliers

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `ShareMultipliers` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ShareMultipliers', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'ShareMultipliers', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “SharingFactor” on page 26-23

Multiplier sharing minimum bitwidth

Use this parameter to specify the minimum bit width that is required to share multipliers with the resource sharing optimization.

Settings

Default: 0

01

No minimum bit width for shared multipliers.

N, where N is an integer greater than 1

When resource sharing and multiplier sharing are enabled, share multipliers with a bit width greater than or equal to N.

Dependency

To share multipliers in your design:

- In the **Resource Sharing** tab, make sure that the **Multipliers** check box is selected.
- In the HDL Block Properties for the DUT Subsystem, specify the **SharingFactor**.

Command-Line Information

Property: MultiplierSharingMinimumBitwidth

Type: integer

Value: integer greater than or equal to 0

Default: 0

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `MultiplierSharingMinimumBitwidth` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'MultiplierSharingMinimumBitwidth', 16)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'MultiplierSharingMinimumBitwidth', 16)
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “SharingFactor” on page 26-23
- “Resource Sharing” on page 28-45

Multiplier promotion threshold

To share smaller multipliers with other larger multipliers by using the resource sharing optimization, specify the multiplier promotion threshold. This threshold specifies the maximum word length by which HDL Coder promotes a multiplier for sharing with other multipliers. For example, if you have a multiplier whose input word lengths sum to 28 bits and you want to share that multiplier with another multiplier whose input word lengths sum to 34 bits, subtract the total bits from each other, and set the multiplier promotion threshold to at least as large as the difference. In this example, the difference is 6 bits.

Settings

Default: 0

0

No difference in word length between the multipliers, meaning that HDL Coder shares multipliers that have the same word length.

N, where N is an integer greater than 0

Maximum word length by which HDL Coder promotes a multiplier for sharing with other multipliers. If the difference in word lengths is less than or equal to N, HDL Coder promotes and shares multipliers that have different word lengths.

To determine N:

- Calculate the sum of the input word lengths for the multipliers that you want to share.
- Set N to be at least as large as the difference between the summation of input word lengths for the different multipliers.

Dependency

To share multipliers in your design:

- In the **Resource Sharing** tab, make sure that you select the **Multipliers** check box.

- In the HDL Block Properties for the DUT Subsystem, specify the **SharingFactor**.

Command-Line Information

Property: MultiplierPromotionThreshold

Type: integer

Value: integer greater than or equal to 0

Default: 0

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `MultiplierPromotionThreshold` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'MultiplierPromotionThreshold',8)
```

- When you use `hdlset_param`, you can set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','MultiplierPromotionThreshold',8)
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “SharingFactor” on page 26-23
- “Resource Sharing” on page 28-45

Multiplier partitioning threshold

Settings

Default: Inf

N, where N is an integer greater than or equal to 2

Partition multipliers so that N is the maximum multiplier input bit width.

This parameter specifies the maximum input bit width for a multiplier. If at least one of the inputs to the multiplier has a bit width greater than the threshold value, the code generator splits the multiplier into smaller multipliers.

To improve hardware mapping results, set the multiplier partitioning threshold to the input bit width of the DSP or multiplier hardware on your target device.

Inf

Do not partition multipliers.

Command-Line Information

Property: MultiplierPartitioningThreshold

Type: integer

Value: integer greater than or equal to 0

Default: Inf

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can set the `MultiplierPartitioningThreshold` to 16 when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'MultiplierPartitioningThreshold', 16)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'MultiplierPartitioningThreshold', 16)
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`

Share Multiply-Add blocks

Share Multiply-Add blocks with the resource sharing optimization.

Settings**Default:** On

On

When resource sharing is enabled, share Multiply-Add blocks with a bit width greater than or equal to **Multiply-Add block sharing minimum bitwidth**.

Off

Do not share Multiply-Add blocks.

Dependency

- To share Multiply-Add blocks in your design, in the HDL Block Properties for the DUT Subsystem, specify the **SharingFactor**.
- When you specify the **Multiply-Add block sharing minimum bitwidth**, the code generator shares Multiply-Add blocks that have a bit width greater than or equal to the minimum bit width. The default minimum bit width for sharing Multiply-Add blocks is zero.

Command-Line Information

Property: ShareMultiplyAdds

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `ShareMultiplyAdds` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ShareMultiplyAdds', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'ShareMultiplyAdds', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

Multiply-Add block sharing minimum bitwidth

Use this parameter to specify the minimum bit width that is required to share Multiply-Add with the resource sharing optimization.

Settings

Default: 0

01

No minimum bit width for shared Multiply-Add blocks.

N, where N is an integer greater than 1

When resource sharing and Multiply-Add block sharing are enabled, share Multiply-Add blocks with a bit width greater than or equal to N.

Dependency

To share Multiply-Add blocks in your design:

- In the **Resource Sharing** tab, make sure that the **Multiply-Add blocks** check box is selected.
- In the HDL Block Properties for the DUT Subsystem, specify the **SharingFactor**.

Command-Line Information

Property: `MultiplierAddSharingMinimumBitwidth`

Type: integer

Value: integer greater than or equal to 0

Default: 0

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `MultiplierAddSharingMinimumBitwidth` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...  
        'MultiplierAddSharingMinimumBitwidth',16)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','MultiplierAddSharingMinimumBitwidth',16)  
makehdl('sfir_fixed/symmetric_fir')
```

Resource Sharing Parameters for Subsystems and Floating-Point IPs

In this section...

“Share Atomic subsystems” on page 19-27

“Share MATLAB Function blocks” on page 19-28

“Share Floating-Point IPs” on page 19-29

This page describes configuration parameters that reside in the **HDL Code Generation > Optimization > Resource sharing** tab of the Configuration Parameters dialog box. Enable these parameters to save resources on the target device by specifying whether to share atomic subsystems, MATLAB Function blocks, and floating-point IPs in your design.

Share Atomic subsystems

Share Atomic Subsystem blocks with the resource sharing optimization.

Settings

Default: On

On

When you enable resource sharing, HDL Coder shares atomic subsystems.

Off

Do not share atomic subsystems.

Dependency

To share Atomic Subsystem blocks in your design, in the HDL Block Properties for the parent DUT Subsystem, specify the **SharingFactor**.

Command-Line Information

Property: ShareAtomicSubsystems

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `ShareAtomicSubsystems` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ShareAtomicSubsystems', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','ShareAtomicSubsystems','on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “Resource Sharing of Subsystems and Floating-Point IPs” on page 25-131

- “Resource Sharing” on page 28-45

Share MATLAB Function blocks

Share MATLAB Function blocks with the resource sharing optimization.

Settings

Default: On

On

When you enable resource sharing, HDL Coder shares MATLAB Function blocks.

Off

Do not share MATLAB Function blocks.

Dependency

To share MATLAB Function blocks in your design, in the HDL Block Properties for the parent DUT Subsystem, specify the **SharingFactor**.

Command-Line Information

Property: ShareMATLABBlocks

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `ShareMATLABBlocks` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ShareMATLABBlocks','on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','ShareMATLABBlocks','on')
makehdl('sfir_fixed/symmetric_fir')
```

Share Floating-Point IPs

Settings

Default: On

On

When you enable resource sharing, HDL Coder shares floating-point IP blocks.

Off

Do not share floating-point IP blocks.

Dependency

To share floating-point IPs:

- In the HDL Block Properties for the parent DUT Subsystem, specify the **SharingFactor**. The number of floating-point IP blocks that get shared depends on the **SharingFactor** that you specify for the subsystem.
- In the Configuration Parameters dialog box, in the **HDL Code Generation > Floating Point Target** pane, select **Use Floating Point**.

Command-Line Information

Property: ShareFloatingPointIP

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `ShareFloatingPointIP` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ShareFloatingPointIP', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'ShareFloatingPointIP', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

Multicycle Path Constraints Parameters

In this section...

“Enable-based constraints” on page 19-31

“Register-to-register path info” on page 19-32

This page describes configuration parameters that reside in the **HDL Code Generation > Optimization > General** tab of the Configuration Parameters dialog box. Synthesis tools require that data propagates from a source register to a destination register within one clock cycle. Multicycle paths cannot complete their execution within one clock cycle and cannot meet the timing requirements. To meet the timing requirement of multicycle paths, use the multicycle path constraints parameters to generate a register-to-register path information file or to generate enable-based constraints that use the timing controller enable signals.

Enable-based constraints

To meet the timing requirement of the multicycle path in your model, use enable-based constraints. The constraints are applied to a model that has **Clock inputs** set to **Single**. This option is useful for a multirate model to create a constraint file for relaxing timing of the slow-rate regions.

Enable-based constraints relax the timing requirement by enabling multiple clock cycles for data to propagate between the registers. The constraints use the timing controller enable signals to create enable-based register groups that have registers in each group driven by the same clock enable.

Settings

Default: Off

On

When you enable this setting and generate HDL code, HDL Coder generates a constraints file with the naming convention `dutname_constraints`. The format of the file name depends on the synthesis tool that you specify. The constraints file defines the timing requirements of multicycle paths. The file contains information about the clock multiples for calculating the setup and hold time information.

Off

Do not generate a multicycle path constraints file.

Dependency

- When you select the **Enable-based constraints** check box, make sure that **Clock-rate pipelining** is **Off**. Using enable-based multicycle path constraints is an alternative to the clock-rate pipelining optimization. You can clear the clock-rate pipelining check box in the **HDL Code Generation > Optimization > Pipelining** tab.
- Set the **Clock inputs** to **Single**. You can set the clock input in the **HDL Code Generation > Global settings > Clock settings > Clock inputs**.
- To generate multicycle path constraints file, oversampling factor must be greater than 1. You can specify the Oversampling value in the **HDL Code Generation > Global settings > Clock settings > Oversampling**.

Command-Line Information**Parameter:** MulticyclePathConstraints**Type:** character vector**Value:** 'on' | 'off'**Default:** 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can enable the `MulticyclePathConstraints` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('<model_name>', ...
        'MulticyclePathConstraints', 'on')
```

- When you use `hdlset_param`, set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('<model_name>', 'MulticyclePathConstraints', 'on')
makehdl('<model_name>')
```

See Also

- “Meet Timing Requirements Using Enable-Based Multicycle Path Constraints” on page 27-37
- “Use Multicycle Path Constraints to Meet Timing for Slow Paths” on page 27-43

Register-to-register path info

Generate a text file that reports multicycle path constraint information. The text file describes one or more multicycle path constraints that are agnostic to the synthesis tool. You must convert this information to the format required by the synthesis tool. It is recommended that you use the enable-based constraints setting instead to meet the timing requirements of multicycle paths. When you use that setting, the generated constraints are more robust for name changes in synthesis tools, and are supported on Xilinx Vivado, Xilinx ISE, and Altera Quartus II.

Settings**Default:** Off

On

Generate a text file that reports multicycle path constraint information for use with synthesis tools.

The file name for the multicycle path information file is derived from the name of the DUT and the postfix `'_constraints'`,

```
DUTname_constraints.txt
```

For example, if the DUT name is `symmetric_fir`, the name of the multicycle path information file is `symmetric_fir_constraints.txt`.

Off

Do not generate a multicycle path information file.

Command-Line Information

Parameter: MulticyclePathInfo

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can enable the `MulticyclePathInfo` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('<model_name>', ...
        'MulticyclePathInfo', 'on')
```

- When you use `hdlset_param`, set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('<model_name>', 'MulticyclePathInfo', 'on')
makehdl('<model_name>')
```

Compatibility Considerations

Starting in R2021b, it is not recommended to use **Register-to-register path info** for generating multicycle path information. This option is removed from the **HDL Code Generation > Optimization** tab in HDL Coder Properties. It is recommended to use Enable-based constraints for generating multicycle path information. You can still enable this option in the MATLAB command-line interface by using `hdlset_param` or `makehdl` commands.

- “Generate Multicycle Path Information Files” on page 27-30

Frame to Sample Conversion Parameters

You can use the configuration parameters in the **Frame to Sample Conversion** tab of the **HDL Code Generation > Optimization** pane of the Configuration Parameters dialog box to convert matrix inputs to smaller sized samples to reduce the amount of I/O that handles large input signals for HDL code generation.

Enable frame to sample conversion

Select this parameter to enable frame-to-sample conversion. If your model is not synthesizable because it requires a large amount of I/O, this optimization can reduce the I/O in the design and generate synthesizable HDL code. The frame-to-sample conversion converts matrix inputs to smaller samples by streaming the input signal for HDL code generation to reduce the I/O that handles a large input signal.

Settings

Default: Off

On

Stream input signals attached to Inport blocks that have the HDL block property **ConvertToSamples** enabled.

Off

Do not stream input signals.

Dependency

Enable the HDL block property **ConvertToSamples** for at least one Inport block on your DUT that has an incoming matrix signal to be streamed.

Command-Line Information

Property: FrameToSampleConversion

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `FrameToSampleConversion` setting when you generate HDL code for a DUT subsystem in a model using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('<model_name/DUT_name>', ...
        'FrameToSampleConversion', 'on')
```

- When you use `hdlset_param`, set the parameter on the model and then generate HDL code by using the `makehdl` function.

```
hdlset_param('<model_name>', 'FrameToSampleConversion', 'on')
makehdl('<model_name/DUT_name>')
```

See Also

- `makehdl`

Samples per cycle

Use this parameter to specify the size of the signals after the frame-to-sample conversion streams them. The streamed input signal is either a scalar (one sample per cycle) or 1-D vectors with N elements (N samples per cycle).

Settings**Default:** 1

Enter an integer with a value greater than or equal to one. When you use the default value, the streamed input signal is one sample per cycle or a scalar signal. When you use an integer N , where N is an integer greater than one, the streamed input signal is N samples per cycle or a 1-D vector with N elements.

Dependency

To enable this parameter, select **Enable frame to sample conversion**.

Command-Line Information

Property: `SamplesPerCycle`

Type: integer

Value: integer greater than or equal to 1

Default: 1

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `SamplesPerCycle` setting when you generate HDL code for a DUT subsystem in a model using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('<model_name/DUT_name>', ...
        'SamplesPerCycle', '2')
```

- When you use `hdlset_param`, set the parameter on the model and then generate HDL code by using the `makehdl` function.

```
hdlset_param('<model_name>', 'SamplesPerCycle', '2')
makehdl('<model_name/DUT_name>')
```

See Also

- `makehdl`

Input FIFO size

Use this parameter to specify the register size of the generated input FIFOs around the streaming matrix partitions. The frame-to-sample conversion generates an input FIFO for every input port in the DUT that has a streaming matrix input signal. The **Input FIFO size** parameter must be greater than equal to four, the minimum size of the HDL FIFO block.

Settings

Default: 10

Dependency

To enable this parameter, select **Enable frame to sample conversion**.

Command-Line Information

Property: InputFIFOSize

Type: integer

Value: integer greater than or equal to 4

Default: 10

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `InputFIFOSize` setting when you generate HDL code for a DUT subsystem in a model using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('<model_name/DUT_name>', ...
        'InputFIFOSize', '20')
```

- When you use `hdlset_param`, set the parameter on the model and then generate HDL code by using the `makehdl` function.

```
hdlset_param('<model_name>', 'InputFIFOSize', '20')
makehdl('<model_name/DUT_name>')
```

See Also

- `makehdl`
- HDL FIFO

Output FIFO size

Use this parameter to specify the register size of the generated output FIFOs around the streaming matrix partitions. The frame-to-sample conversion generates an output FIFO for every output port in the DUT that is connected to a streaming matrix output signal. The **Output FIFO size** parameter must be greater than equal to four, the minimum size of the HDL FIFO block.

Settings

Default: 10

Dependency

To enable this parameter, select **Enable frame to sample conversion**.

Command-Line Information**Property:** OutputFIFOSize**Type:** integer**Value:** integer greater than or equal to 4**Default:** 10

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `OutputFIFOSize` setting when you generate HDL code for a DUT subsystem in a model using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('<model_name/DUT_name>', ...
        'OutputFIFOSize','20')
```

- When you use `hdlset_param`, set the parameter on the model and then generate HDL code by using the `makehdl` function.

```
hdlset_param('<model_name>', 'OutputFIFOSize', '20')
makehdl('<model_name/DUT_name>')
```

- `makehdl`
- HDL FIFO

Input processing order

Use this parameter to choose between row-major and column-major ordering for the frame inputs that the frame-to-sample conversion optimization converts to sample inputs. This setting affects how the data is streamed into the device under test (DUT), but does not change the behavior of the generated DUT.

Settings**Default:** RowMajor**RowMajor**

Traverse the input frame data for the frame-to-sample conversion using row-major ordering, which traverses the data from left to right and then top to bottom across the frame-based input matrix.

ColumnMajor

Traverse the input frame data for the frame-to-sample conversion using column-major ordering, which traverses the data from top to bottom and then left to right across the frame-based input matrix.

Dependency

To enable this parameter, select **Enable frame to sample conversion**.

Command-Line Information**Property:** InputProcessingOrder**Type:** character vector**Value:** 'RowMajor' | 'ColumnMajor'**Default:** 'RowMajor'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can use the `InputProcessingOrder` setting when you generate HDL code for a DUT subsystem in a model using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('<model_name/DUT_name>', 'InputProcessingOrder', 'ColumnMajor')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code by using `makehdl`.

```
hdlset_param('<model_name>', 'InputProcessingOrder', 'ColumnMajor')
makehdl('<model_name/DUT_name>')
```

Delay size threshold for external memory

Use this parameter to specify a threshold size in bits to map large integer delays to input and output DUT ports and offload large delays to external memory outside of your FPGA. Offloading to external memory is useful when a design requires an input frame be delayed and operated on and the delay does not fit on the chip block RAM. For example, if your design requires a comparison between two different frames, which creates a large delay, set this threshold parameter to save resources on your FPGA that would otherwise be used to store the delay.

Settings**Default:** 100000000

Enter an integer N with a value greater than or equal to one to map delays greater than or equal to the threshold value N to external memory by using input and output DUT ports. When you use the default value 100000000, HDL Coder maps delays with a register size of 100000000 bits or greater to external memory.

Dependency

To enable this parameter, select **Enable frame to sample conversion**.

Command-Line Information**Property:** DelaySizeThreshold**Type:** integer**Value:** integer greater than or equal to 1**Default:** 100000000

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

You can set the `DelaySizeThreshold` property using a real integer number or the scientific notation version of the integer. For example, you can use `DelaySizeThreshold` to offload the memory required for a 4k frame, 66 megabits of external memory storage, by setting the `DelaySizeThreshold` value to `66000000`, `66e6`, or `6.6e7`.

You can then use `DelaySizeThreshold` when you generate HDL code for a DUT subsystem in a model using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('<model_name/DUT_name>', ...  
        'DelaySizeThreshold',66e6)
```

- When you use `hdlset_param`, set the parameter on the model and then generate HDL code by using the `makehdl` function.

```
hdlset_param('<model_name>', 'DelaySizeThreshold',66000000)  
makehdl('<model_name/DUT_name>')
```

HDL Code Generation Pane: Floating Point

- “Floating Point Overview” on page 20-2
- “Floating Point IP Library Parameters” on page 20-3
- “Native Floating-Point Parameters” on page 20-6
- “FPGA Floating-Point Library Targeting Properties” on page 20-10

Floating Point Overview

The **Floating Point** pane enables you to specify the floating point IP libraries. You can specify whether to generate code with native floating point support in HDL Coder or with native floating point support and a third-party Intel or Xilinx floating-point library.

Floating Point IP Library Parameters

You can access the floating-point parameters in the **HDL Code Generation > Floating Point** pane in the Configuration Parameters dialog box.

Use Floating Point

Use the native floating-point library in your design. You can specify the latency strategy and whether to handle denormal numbers in your design. See “Native Floating-Point Parameters” on page 20-6.

Settings

Default: Off

On

Map your design to the native floating-point target library.

Off

Do not map your design to the native floating-point target library.

Command-Line Information

Parameter: UseFloatingPoint

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can enable the `UseFloatingPoint` setting when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_single` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_single/symmetric_fir', ...
        'UseFloatingPoint','on')
```

- When you use `hdlset_param`, set the parameter on the model and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_single','UseFloatingPoint','on')
makehdl('sfir_single/symmetric_fir')
```

See Also

- “Native Floating-Point Parameters” on page 20-6
- “Getting Started with HDL Coder Native Floating-Point Support” on page 14-92
- “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116

Vendor Specific Floating Point Library

Select a vendor-specific floating-point library in your design, based on the setting of the **Synthesis Tool** parameter and use the library in combination with a native floating-point (NFP) library. Using a NFP and vendor-specific floating point library together in a mixed design more efficiently uses resources on the FPGA, such as hardened DSP floating point adder or multiplier primitives, which allows you to fit a bigger design into the FPGA fabric.

Settings

Default: None

The options are:

None

Use only the native floating-point mode to target ASIC devices or generate vendor-independent code that you can use on different FPGA or SoC devices.

ALTERAFPFUNCTIONS

Specify Altera Megafunctions (ALTERA FP FUNCTIONS) as the floating-point target library. You can provide the IP target frequency.

ALTFP

Specify Altera Megafunctions (ALTFP) as the floating-point target library. You can provide the objective and latency strategy for the IP.

XILINXLOGICORE

Specify Xilinx LogiCORE® as the floating-point target library. You can provide the objective and latency strategy for the IP.

Dependency

To specify this parameter, set the **Synthesis Tool** parameter to your target tool and select **Use Floating Point**. The options for **Vendor Specific Floating Point Library** depend on the synthesis tool you select.

Command-Line Information

To set the vendor-specific floating-point library:

- 1 Use the `hdlcoder.createFloatingPointTargetConfig` function to create a floating-point IP configuration object, `hdlcoder.FloatingPointTargetConfig`, for the floating-point library. For example, to create a mixed-mode floating-point target configuration with the native floating point library and the ALTERA FP FUNCTIONS library as the vendor-specific floating point library, use this command:

```
fpconfig = hdlcoder.createFloatingPointTargetConfig("NativeFloatingPoint", ...
    VendorFloatingPointLibrary = "AlteraFPFunctions");
```

- 2 Set the floating-point target configuration on the model and generate HDL code. For example, to set the configuration on the `sfir_single` model and generate HDL code for the `symmetric_fir` subsystem, enter:

```
hdlset_param("sfir_single", FloatingPointTargetConfiguration = fpconfig);
makehdl('sfir_single/symmetric_fir')
```

To get the floating point target configuration object from the model, enter:

```
fpconfig = hdlget_param("sfir_single", 'FloatingPointTargetConfiguration')
```

See Also

- `createFloatingPointTargetConfig`
- `hdlcoder.FloatingPointTargetConfig`
- “Generate HDL Code for Vendor-Specific FPGA Floating-Point Target Libraries” on page 36-20
- “Design Model by Using HDL Coder Native Floating Point and Intel Hard Floating Point” on page 14-130

Native Floating-Point Parameters

You can access the floating-point parameters in the **HDL Code Generation > Floating Point** pane in the Configuration Parameters dialog box. Use these parameters to specify the latency strategy, whether to handle denormal numbers in your design, and how to perform mantissa multiplication. To specify these settings, **Use Floating Point** must be selected.

Latency Strategy

Specify whether you want the design to map to minimum or maximum latency with native floating-point libraries.

Settings

Default: MAX

The options are:

MIN

Maps to minimum latency for the native floating-point libraries.

MAX

Maps to maximum latency for the native floating-point libraries.

ZERO

Does not use any latency for the native floating-point libraries.

Dependency

To specify this parameter, select **Use Floating Point**.

Command-Line Information

To specify the latency strategy:

- 1 Create a floating-point target configuration object for **Native Floating Point** as the floating-point library.

```
fpconfig = hdlcoder.createFloatingPointTargetConfig('NativeFloatingPoint');
```

- 2 Specify the **LatencyStrategy** property of the **LibrarySettings** attribute of the floating-point target configuration object.

```
fpconfig.LibrarySettings.LatencyStrategy = 'MIN';
```

- 3 Set the floating-point target configuration on the model and then generate HDL code. This example shows how to set the configuration on the `sfir_single` model and generate HDL code for the `symmetric_fir` subsystem:

```
hdlset_param('sfir_single', 'FloatingPointTargetConfig', fpconfig)
makehdl('sfir_single/symmetric_fir')
```

See also

- “LatencyStrategy” on page 26-34

- `createFloatingPointTargetConfig`
- “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116
- “Latency Considerations with Native Floating Point” on page 14-109

Handle Denormals

Specify whether you want to handle denormal numbers in your design. Denormal numbers are nonzero numbers that are smaller than the smallest normal number.

Settings

Default: Auto

Auto

Controls the insertion of additional logic to handle the denormal numbers based on a floating-point data type used in your design. This option inserts a denormal logic if your design uses the half-precision data types. While using single or double data types, denormal logic is not added in your design.

On

Inserts additional logic to handle the denormal numbers in your design.

Off

Does not add additional logic to handle the denormal numbers in your design. If the input is a denormal value, HDL Coder treats the value as zero before performing computation.

Dependency

To specify this parameter, select **Use Floating Point**.

Command-Line Information

To specify the latency strategy:

- 1 Create a floating-point target configuration object for **Native Floating Point** as the floating-point library.

```
fpconfig = hdlcoder.createFloatingPointTargetConfig('NativeFloatingPoint');
```

- 2 Specify the `HandleDenormals` property of the `LibrarySettings` attribute of the floating-point target configuration object.

```
fpconfig.LibrarySettings.HandleDenormals = 'on';
```

- 3 Set the floating-point target configuration on the model and then generate HDL code. This example shows how to set the configuration on the `sfir_single` model and generate HDL code for the `symmetric_fir` subsystem:

```
hdlset_param('sfir_single', 'FloatingPointTargetConfig', fpconfig)
makehdl('sfir_single/symmetric_fir')
```

Considerations

- Insertion of an denormal logic in your design provides an ability to handle the denormal numbers with an overhead of increasing hardware resources. Hence, you can enable or disable the **Handle Denormals** option based on your requirements.

- For some of the floating-point blocks, HDL Coder generates the code that has denormal logic enabled by default. These blocks are:
 - Add
 - Subtract
 - Data Type Conversion

These blocks can handle the denormal numbers with minimal impact on the hardware resources. The generated code for these blocks is not affected by **Handle Denormals** settings.

See also

- “HandleDenormals” on page 26-32
- `createFloatingPointTargetConfig`
- “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116
- “Numeric Considerations for Native Floating-Point” on page 14-96

Mantissa Multiplier Strategy

Specify how you want HDL Coder to implement the mantissa multiplication operation when you have Product blocks in your design.

Settings

Default: Auto

The options are:

Auto

This default option automatically determines how to implement the mantissa multiplication depending on the **Synthesis tool** that you specify.

- If you do not specify a **Synthesis tool**, this setting selects the Full Multiplier implementation by default.
- If you specify Altera Quartus II as the **Synthesis tool**, this setting selects the Full Multiplier implementation.
- If you specify Xilinx Vivado or Xilinx ISE as the **Synthesis tool**, this setting selects the Part Multiplier Part AddShift implementation.

Full Multiplier

Specify this option to use only multipliers for implementing the mantissa multiplication. The multipliers can utilize DSP units on the target device.

Part Multiplier Part AddShift

Specify this option to split the implementation into two parts. One part is implemented with multipliers. The other part is implemented with a combination of adders and shifters. The multipliers can utilize the DSP units on the target device. The combination of adders and shifters does not utilize the DSP.

No Multiplier Full AddShift

Select this option to use a combination of adders and multipliers to implement the mantissa multiplication. This option does not utilize DSP units on the target device. You can also use this option if your target device does not contain DSP units.

Dependency

To specify this parameter, select **Use Floating Point**.

Command-Line Information

To specify the latency strategy:

- 1 Create a floating-point target configuration object for **Native Floating Point** as the floating-point library.

```
fpconfig = hdlcoder.createFloatingPointTargetConfig('NativeFloatingPoint');
```

- 2 Specify the `MantissaMultiplyStrategy` property of the `LibrarySettings` attribute of the floating-point target configuration object.

```
fpconfig.LibrarySettings.MantissaMultiplyStrategy = 'PartMultiplierPartAddShift';
```

- 3 Set the floating-point target configuration on the model and then generate HDL code. This example shows how to set the configuration on the `sfir_single` model and generate HDL code for the `symmetric_fir` subsystem:

```
hdlset_param('sfir_single', 'FloatingPointTargetConfig', fpconfig)
makehdl('sfir_single/symmetric_fir')
```

See also

- “MantissaMultiplyStrategy” on page 26-37
- `createFloatingPointTargetConfig`
- “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116

FPGA Floating-Point Library Targeting Properties

Use these properties to specify the latency strategy, objective, and whether to initialize the pipeline registers in the floating-point target IP to zero. Set these properties by creating a floating-point configuration object, `hdlcoder.FloatingPointTargetConfig` using the `createFloatingPointTargetConfig` function.

Initialize IP Pipelines To Zero

Inserts additional logic during HDL code generation to initialize the values of pipeline registers in the Altera floating-point target IP to zero. If you do not select this check box, HDL Coder reports a warning during HDL code generation.

Settings

Default: On

On

Inserts additional logic to initialize pipeline registers in the floating-point target IP to zero.

Off

Does not add additional logic to initialize pipeline registers in the floating-point target IP to zero.

Dependency

To specify this parameter, set the **Floating Point IP Library** to Altera Megafunctions (ALTERA FP FUNCTIONS). Before you set the floating-point library, specify the path to your synthesis tool by using the `hdlsetuptoolpath` function.

Command-Line Information

To specify this setting:

- 1 Create a floating-point target configuration object with Altera Megafunctions (ALTERA FP FUNCTIONS) as the floating-point target library.

```
fpconfig = hdlcoder.createFloatingPointTargetConfig('AlteraFPFunctions');
```

- 2 Specify the `InitializeIPPipelinesToZero` property of the `LibrarySettings` attribute of the floating-point target configuration object.

```
fpconfig.LibrarySettings.InitializeIPPipelinesToZero = 0;
```

- 3 Set the floating-point target configuration on the model and then generate HDL code. This example shows how to set the configuration on the `sfir_single` model and generate HDL code for the `symmetric_fir` subsystem:

```
hdlset_param('sfir_single', 'FloatingPointTargetConfig', fpconfig)
makehdl('sfir_single/symmetric_fir')
```

See Also

- `createFloatingPointTargetConfig`
- “Target Frequency Parameter” on page 18-8

- “Generate HDL Code for Vendor-Specific FPGA Floating-Point Target Libraries” on page 36-20

Latency Strategy

Specify whether you want the design to map to minimum or maximum latency with Xilinx LogiCORE or ALTFP Altera megafunction IPs.

Settings

Default: MIN

The options are:

MIN

Maps to minimum latency for the specified floating-point target IP.

MAX

Maps to maximum latency for the specified floating-point target IP.

Dependency

To specify this parameter, set the **Floating Point IP Library** to Altera Megafunctions (ALTFP) or Xilinx LogiCORE. Before you set the floating-point library, specify the path to your synthesis tool by using the `hdlsetuptoolpath` function.

Command-Line Information

To specify this setting:

- 1 Create a floating-point target configuration object with Altera Megafunctions (ALTERA FP FUNCTIONS) as the floating-point target library.
- 2 Specify the `LatencyStrategy` property of the `LibrarySettings` attribute of the floating-point target configuration object.

```
fpconfig = hdlcoder.createFloatingPointTargetConfig('ALTFP');
```

- 3 Set the floating-point target configuration on the model and then generate HDL code. This example shows how to set the configuration on the `sfir_single` model and generate HDL code for the `symmetric_fir` subsystem:

```
hdlset_param('sfir_single', 'FloatingPointTargetConfig', fpconfig)
makehdl('sfir_single/symmetric_fir')
```

See also

- `createFloatingPointTargetConfig`
- “Generate HDL Code for Vendor-Specific FPGA Floating-Point Target Libraries” on page 36-20
- “Customize Floating-Point IP Configuration” on page 36-38

Objective

Specify whether you want to optimize the design for speed or area when mapping to floating-point target libraries.

Settings

Default: SPEED

The options are:

NONE

Select this option if you do not want to optimize the design for speed or area.

SPEED

Select this option to optimize the design for speed.

AREA

Select this option to optimize the design for area.

Dependency

To specify this parameter, set the **Floating Point IP Library** to Altera Megafunctions (ALTFP) or Xilinx LogiCORE. Before you set the floating-point library, specify the path to your synthesis tool by using the `hdlsetuptoolpath` function.

Command-Line Information

To specify this setting:

- 1 Create a floating-point target configuration object with Altera Megafunctions (ALTERA FP FUNCTIONS) as the floating-point target library.

```
fpconfig = hdlcoder.createFloatingPointTargetConfig('ALTFP');
```

- 2 Specify the `Objective` property of the `LibrarySettings` attribute of the floating-point target configuration object.

```
fpconfig.LibrarySettings.Objective = 'AREA';
```

- 3 Set the floating-point target configuration on the model and then generate HDL code. This example shows how to set the configuration on the `sfir_single` model and generate HDL code for the `symmetric_fir` subsystem:

```
hdlset_param('sfir_single','FloatingPointTargetConfig',fpconfig)  
makehdl('sfir_single/symmetric_fir')
```

See also

- “Customize Floating-Point IP Configuration” on page 36-38

IP Settings

The **IP Settings** section has an IP configuration table with the IP names and data types and additional options to specify a custom latency and any extra arguments.

The options in the IP configuration table depend on the library that you specify.

- If you specify the ALTERA MEGAFUNCTION (ALTERA FP FUNCTIONS) library, HDL Coder infers the latency value from the **Target Frequency (MHz)** value.
- If you specify the ALTERA MEGAFUNCTION (ALTFP) or XILINX LOGICORE libraries, HDL Coder infers the IP latency from the **Latency Strategy** setting. The IP configuration table has two additional columns, **MinLatency** and **MaxLatency**, that contain the minimum and maximum latency values for each IP in the table.

The IP configuration table has these sections:

- **Name:** Contains a list of IP names that HDL Coder map the Simulink blocks to, such as ABS, ADDSUB, and CONVERT.
- **Data Type:** Contains a list of IP data types for each IP in the table. These are mostly SINGLE and DOUBLE data types. The CONVERT IP blocks can have DOUBLE_TO_NUMERICTYPE, NUMERICTYPE_TO_DOUBLE data types, and so on.
- **Latency:** The default latency value of -1 means that the IP inherits the latency value from the target frequency or the latency strategy setting depending on the library that you choose. To customize the latency of the IP that your Simulink blocks map to, enter your own custom value for the latency.
- **ExtraArgs:** Specify any additional settings that is specific to the IP.

For example, if you have an Add block with Single data types in your Simulink model, HDL Coder maps the block to the **ADDSUB** IP. If you want to specify a custom latency value, say 8, for the IP, enter the value in the **Latency** column for the IP.

– IP Settings

Customize data type conversion IP for:

Name	Data Type	MinLatency	MaxLatency	Latency	ExtraArgs
ADDSUB	DOUBLE	12	12	-1	
ADDSUB	SINGLE	12	12	8	CSET c_mult_usage=...
CONVERT	DOUBLE_TO_N...	6	6	-1	
CONVERT	NUMERICTYPE_...	6	6	-1	

cmultusage is a parameter that you can specify with the Xilinx LogiCORE libraries.

Dependency

To specify this parameter, set the **Floating Point IP Library** to Altera Megafunctions (ALTFP) or Xilinx LogiCORE. Before you set the floating-point library, specify the path to your synthesis tool by using the `hdlsetuptoolpath` function.

Command-Line Information

To specify this setting:

- 1 Create a floating-point target configuration object with Altera Megafunctions (ALTERA FP FUNCTIONS) as the floating-point target library.

```
fpconfig = hdlcoder.createFloatingPointTargetConfig('ALTFP');
```

- 2 To view the floating-point IP configuration, use the `IPConfig` object.

```
fpconfig.IPConfig
```

- 3 To customize the latency or specify additional arguments, use the `customize` method.

```
fpconfig.IPConfig.customize('ADDSUB','Single','Latency',6);
```

- 4 Set the floating-point target configuration on the model and then generate HDL code. This example shows how to set the configuration on the `sfir_single` model and generate HDL code for the `symmetric_fir` subsystem:

```
hdlset_param('sfir_single','FloatingPointTargetConfig',fpconfig)  
makehdl('sfir_single/symmetric_fir')
```

Global Settings Overview

The **Global Settings** pane enables you to specify detailed characteristics of the generated code, such as HDL element naming, coding style, whether you want the HDL code to conform to coding standards, and diagnostics and additional options for model generation and HDL code generation.

Clock Settings and Timing Controller Postfix Parameters

This page describes configuration parameters that reside in the **Clock settings** section of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Use these parameters to specify the clock signal name, the number of clock inputs, the active clock edge, and the postfix for the clock process and the timing controller.

Clock input port

Specify the name for the clock input port in generated HDL code.

Settings

Default: clk

Enter the clock signal name in generated HDL code as a character vector.

For a generated entity `my_filter`, if you specify `'filter_clock'` as the clock signal name, the entity declaration is as shown in this code snippet:

```
ENTITY my_filter IS
  PORT( filter_clock : IN std_logic;
        clk_enable   : IN std_logic;
        reset        : IN std_logic;
        my_filter_in : IN std_logic_vector (15 DOWNT0 0); -- sfix16_En15
        my_filter_out: OUT std_logic_vector (15 DOWNT0 0); -- sfix16_En15
        );
END my_filter;
```

If you specify a VHDL or Verilog reserved word, the code generator appends a reserved word postfix string to form a valid VHDL or Verilog identifier. For example, if you specify the reserved word `signal`, the resulting name string would be `signal_rsvd`.

Command-Line Information

Property: ClockInputPort

Type: character vector

Value: A valid identifier in the target language

Default: 'clk'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','ClockInputPort','system_clk')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','ClockInputPort','system_clk')
```

See Also

makehdl

Clock inputs

Specify generation of single or multiple clock inputs.

Settings

Default: Single

Single

Generates a single clock input for the DUT. If the DUT is multirate, the input clock is the primary clock rate, and a timing controller is synthesized to generate additional clocks as required. It is recommended that you use a single clock signal in your design.

Multiple

Generates a unique clock for each Simulink rate in the DUT. The number of timing controllers generated depends on the contents of the DUT. The oversample factor must be 1 (default) to specify multiple clocks.

For a multirate model, to generate clock for each Simulink rate, make sure to include sequential logic block, such as delay block, at each Simulink rate. If the sequential logic is not present for a particular Simulink rate, HDL Coder do not generate the clock signal for that rate.

Command-Line Information

Property: ClockInputs

Type: character vector

Value: 'Single' | 'Multiple'

Default: 'Single'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','ClockInputs','Multiple')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','ClockInputs','Multiple')
```

See Also

- `makehdl`
- “Check clock settings” on page 44-44
- “Using Multiple Clocks in HDL Coder” on page 27-13

Clock edge

Specify the active clock edge that triggers Verilog always blocks or VHDL process blocks in the generated HDL code.

Settings

Default: Rising.

Rising

The rising edge, or 0-to-1 transition, is the active clock edge.

Falling

The falling edge, or 1-to-0 transition, is the active clock edge.

Command-Line Information

Property: ClockEdge

Type: character vector

Value: 'Rising' | 'Falling'

Default: 'Rising'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','ClockEdge','Falling')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','ClockEdge','Falling')
```

See Also

- `makehdl`
- “Check clock settings” on page 44-44

Clocked process postfix

Specify the postfix as a character vector. The code generator appends this postfix to HDL clock process names.

Settings

Default: `_process`

HDL Coder uses process blocks for register operations. The label for each of these blocks is derived from a register name and the postfix `_process`. For example, the code generator derives the label `delay_pipeline_process` in the following block declaration from the register name `delay_pipeline` and the default postfix `_process`.

```

delay_pipeline_process : PROCESS (clk, reset)
BEGIN
  .
  .
  .

```

Command-Line Information

Property: ClockProcessPostfix

Type: character vector

Default: '_process'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```

hdlset_param('sfir_fixed', 'ClockProcessPostfix', 'delay_postfix')
makehdl('sfir_fixed/symmetric_fir')

```

- Pass the property as an argument to the `makehdl` function.

```

makehdl('sfir_fixed/symmetric_fir', 'ClockProcessPostfix', 'delay_postfix')

```

See Also

`makehdl`

Timing controller postfix

Specify the postfix as a character vector. The code generator appends this suffix to the DUT name to form the timing controller name.

Settings

Default: '_tc'

A timing controller file is generated if the design uses multiple rates, for example:

- When code is generated for a multirate model.
- When an area or speed optimization, or block architecture, introduces local multirate.

The timing controller name is based on the name of the DUT. For example, if the name of your DUT is `my_test`, by default, HDL Coder adds the postfix `_tc` to form the timing controller name, `my_test_tc`.

Command-Line Information

Property: TimingControllerPostfix

Type: character vector

Default: '_tc'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Reset Settings and Parameters

This page describes parameters in the **Clock Settings** section of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Using these parameters, you can specify the reset name, whether to use a synchronous or asynchronous reset, and whether the reset is asserted active-high or active-low.

Reset type

Specify whether to use asynchronous or synchronous reset logic when generating HDL code for registers. It is recommended that you specify the **Reset type** as **Synchronous** when you use a Xilinx device and **Asynchronous** when you use an Altera device.

Settings

Default: Asynchronous

Asynchronous

Use asynchronous reset logic. This reset logic samples the reset independent of the clock signal.

The following process block, generated by a Unit Delay block, illustrates the use of asynchronous resets. When the reset signal is asserted, the process block performs a reset, without checking for a clock event.

```
Unit_Delay1_process : PROCESS (clk, reset)
BEGIN
  IF reset = '1' THEN
    Unit_Delay1_out1 <= (OTHERS => '0');
  ELSIF clk'event AND clk = '1' THEN
    IF clk_enable = '1' THEN
      Unit_Delay1_out1 <= signed(x_in);
    END IF;
  END IF;
END PROCESS Unit_Delay1_process;
```

Synchronous

Use synchronous reset logic. This reset logic samples the reset with respect to the clock signal.

The following process block, generated by a Unit Delay block, checks for a clock event, the rising edge, before performing a reset:

```
Unit_Delay1_process : PROCESS (clk)
BEGIN
  IF rising_edge(clk) THEN
    IF reset = '1' THEN
      Unit_Delay1_out1 <= (OTHERS => '0');
    ELSIF clk_enable = '1' THEN
      Unit_Delay1_out1 <= signed(x_in);
    END IF;
  END IF;
END PROCESS Unit_Delay1_process;
```

Command-Line Information

Property: ResetType

Type: character vector

Value: 'async' | 'sync'

Default: 'async'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify `sync` as the `ResetType` when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
       'ResetType', 'async')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'ResetType', 'async')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`
- “Check for global reset setting for Xilinx and Altera devices” on page 44-7

Reset asserted level

Specify whether the asserted or active level of the reset input signal is active-high or active-low.

Settings

Default: Active-high

Active-high

Specify that the asserted level of reset input signal is active-high. For example, the following code fragment checks whether reset is active high before populating the `delay_pipeline` register:

```
Delay_Pipeline_Process : PROCESS (clk, reset)
BEGIN
  IF reset = '1' THEN
    delay_pipeline(0 TO 50) <= (OTHERS => (OTHERS => '0'));
  .
  .
  .
```

Active-low

Specify that the asserted level of reset input signal is active-low. For example, the following code fragment checks whether reset is active low before populating the `delay_pipeline` register:

```
Delay_Pipeline_Process : PROCESS (clk, reset)
BEGIN
  IF reset = '0' THEN
    delay_pipeline(0 TO 50) <= (OTHERS => (OTHERS => '0'));
  .
  .
  .
```

Dependency

If you input a logic high value to the **Reset input port**, to reset the registers in your design, set **Reset asserted level** to Active-high. If you input a logic low value to the **Reset input port**, to reset the registers in your design, set **Reset asserted level** to Active-low.

Command-Line Information

Property: ResetAssertedLevel

Type: character vector

Value: 'active-high' | 'active-low'

Default: 'active-high'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','ResetAssertedLevel','active-high')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','ResetAssertedLevel','active-high')
```

See Also

- `makehdl`
- “Reset input port” on page 21-10

Reset input port

Enter the name for the reset input port in generated HDL code.

Settings

Default: reset

Enter a character vector for the reset input port name in generated HDL code.

For example, if you override the default with 'chip_reset' for the generating system `myfilter`, the generated entity declaration might look as follows:

```
ENTITY myfilter IS
  PORT( clk           : IN  std_logic;
        clk_enable   : IN  std_logic;
        chip_reset    : IN  std_logic;
        myfilter_in   : IN  std_logic_vector (15 DOWNTO 0);
        myfilter_out  : OUT std_logic_vector (15 DOWNTO 0);
        );
END myfilter;
```

If you specify a VHDL or Verilog reserved word, the code generator appends a reserved word postfix string to form a valid VHDL or Verilog identifier. For example, if you specify the reserved word `signal`, the resulting name string would be `signal_rsvd`.

Dependency

If you specify active-high for **Reset asserted level**, the reset input signal is asserted active-high. To reset the registers in the entity, the input value to the **Reset input port** must be high. If you specify active-low for **Reset asserted level**, the reset input signal is asserted active-low. To reset the registers in the entity, the input value to the **Reset input port** must be low.

Command-Line Information

Property: ResetInputPort

Type: character vector

Value: A valid identifier in the target language

Default: 'reset'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify `sync` as the `ResetType` when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ResetInputPort', 'rstx')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'ResetInputPort', 'rstx')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`
- “Reset asserted level” on page 21-9

Clock Enable Settings and Parameters

This page describes configuration parameters in the **Clock Settings** section of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Using these parameters, you can specify the name of the clock enable input port and for internal clock enable signals in the generated code.

Clock enable input port

Specify the name for the clock enable input port in generated HDL code.

Settings

Default: `clk_enable`

Enter the clock enable input port name in generated HDL code as a character vector.

For example, if you specify `'filter_clock_enable'` for the generating subsystem `filter_subsys`, the generated entity declaration might look as follows:

```
ENTITY filter_subsys IS
  PORT( clk
        filter_clock_enable : IN std_logic;
        reset                : IN std_logic;
        filter_subsys_in     : IN std_logic_vector (15 DOWNTO 0);
        filter_subsys_out    : OUT std_logic_vector (15 DOWNTO 0);
        );
END filter_subsys;
```

The clock enable input signal is asserted active-high (1). Thus, the input value must be high for the generated entity's registers to be updated.

If you specify a VHDL or Verilog reserved word, the code generator appends a reserved word postfix string to form a valid VHDL or Verilog identifier. For example, if you specify the reserved word `signal`, the resulting name string would be `signal_rsvd`.

Command-Line Information

Property: `ClockEnableInputPort`

Type: character vector

Value: A valid identifier in the target language

Default: `'clk_enable'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
       'ClockEnableInputPort', 'clken')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'ClockEnableInputPort', 'clken')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- makehdl
- “Clock Enable output port” on page 21-36
- “Clock input port” on page 21-4
- “Reset input port” on page 21-10

Enable prefix

Specify the base name as a character vector for internal clock enables and other flow control signals in generated code.

Settings

Default: 'enb'

Where only a single clock enable is generated, **Enable prefix** specifies the signal name for the internal clock enable signal.

In some cases, the code generator can generate multiple clock enable signals. For example, if you specify a cascade block implementation for certain blocks, multiple clock enable signals are generated. In such cases, **Enable prefix** specifies a base signal name for the first clock enable that is generated. For other clock enable signals, numeric tags are appended to **Enable prefix** to form unique signal names. For example, the following code fragment illustrates two clock enables that were generated when **Enable prefix** was set to 'test_clk_enable':

```
COMPONENT mysys_tc
  PORT( clk           : IN    std_logic;
        reset        : IN    std_logic;
        clk_enable    : IN    std_logic;
        test_clk_enable : OUT  std_logic;
        test_clk_enable_5_1_0 : OUT std_logic
      );
END COMPONENT;
```

Command-Line Information

Property: EnablePrefix

Type: character vector

Default: 'enb'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'EnablePrefix', 'int_enable')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','EnablePrefix','int_enable')  
makehdl('sfir_fixed/symmetric_fir')
```

- “Clock enable input port” on page 21-12

Oversampling factor

This configuration parameter resides in the **Clock Settings** section of the **HDL Code Generation > Global Settings** pane in the Configuration Parameters dialog box. Use this parameter to specify the frequency of the global oversampling clock as a multiple of the model base rate.

Settings

Default: 1.

Oversampling factor specifies the factor by which the global clock signal is a multiple of the base rate at which the model operates. Use the **Oversampling factor** to integrate the DUT with a larger system that supplies timing signals to other components in the system at the global oversampling clock.

By default, HDL Coder does not generate a global oversampling clock. To generate a global oversampling clock, specify an integer greater than one. If you use a multirate DUT, make sure that other rates in the DUT divide evenly into the global oversampling rate.

Generation of the global oversampling clock affects the generated HDL code. It does not affect the simulation behavior of your model.

Dependency

- if you use multiple clocks, the **Oversampling factor** must be set to one. If you want to use an **Oversampling factor** greater than one, set **Clock inputs** to **Single**.
- If you specify an **Oversampling factor** greater than one, make sure that the clock-rate pipelining optimization is enabled. You can specify this setting in the **HDL Code Generation > Target and Optimizations > Pipelining** tab.

Clock-rate pipelining uses the **Oversampling factor** to convert the slow regions in your model that operate at the base sample rate to the faster clock rate.

Command-Line Information

Property: Oversampling

Type: int

Value: integer greater than or equal to 1

Default: 1

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'Oversampling',5)
```

- When you use `hdlset_param`, you can set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','Oversampling',5)
makehdl('sfir_fixed/symmetric_fir')
```

Comment in header

This parameter resides in the **Comments** tab of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Use this parameter to specify comment lines in header of generated HDL and test bench files.

Settings

Default: None

Text entered in this field generates a comment line in the header of generated model and test bench files. The code generator adds leading comment characters for the target language. When newlines or linefeeds are included, the code generator emits single-line comments for each newline.

For example, if you specify this comment 'This is a comment line.\nThis is a second line.' for the `symmetric_fir` subsystem inside the `sfir_fixed` model and generate HDL code, the resulting header comment block appears as follows:

```

-----
--
-- Module: symmetric_fir
-- Simulink Path: sfir_fixed/symmetric_fir
-- Created: 2006-11-20 15:55:25
-- Hierarchy Level: 0
--
-- This is a comment line.
-- This is a second line.
--
-- Simulink model description for sfir_fixed:
-- This model shows how to use HDL Coder to check, generate,
-- and verify HDL for a fixed-point symmetric FIR filter.
--
-----

```

Command-Line Information

Property: UserComment

Type: character vector

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
    'UserComment','This is a comment line.\nThis is a second line.')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', ...
    'UserComment','This is a comment line.\nThis is a second line.')
makehdl('sfir_fixed/symmetric_fir')
```

Language-Specific File Extension Parameters

Verilog file extension

Specify the file name extension for generated Verilog files.

Settings

Default: .v

This field specifies the file name extension for generated Verilog files.

Dependency

To enable this option, set the target language to Verilog. You can specify the target language by using the **Language** parameter in the **HDL Code Generation** pane.

Command-Line Information

Property: VerilogFileExtension

Type: character vector

Default: '.v'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'VerilogFileExtension', '.v')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'VerilogFileExtension', '.v')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- `makehdl`
- “Target Language and Folder Selection Parameters” on page 17-3

VHDL file extension

Specify the file name extension for generated VHDL files.

Settings

Default: .vhd

This field specifies the file name extension for generated VHDL files.

Dependency

To enable this option, set the target language to VHDL. You can specify the target language by using the **Language** parameter in the **HDL Code Generation** pane.

Command-Line Information

Property: VHDLFileExtension

Type: character vector

Default: '.vhd'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...  
        'VHDLFileExtension', '.vhd')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'VHDLFileExtension', '.vhd')  
makehdl('sfir_fixed/symmetric_fir')
```

Language-Specific Identifiers and Postfix Parameters

This section contains parameters in the **Clock Settings** section of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Using these parameters, you can specify the entity, module, and package name postfix, and the prefix for module names.

Entity conflict postfix

Specify the text as a character vector to resolve duplicate VHDL entity or Verilog module names in generated code.

Settings

Default: `_block`

The specified postfix resolves duplicate VHDL entity or Verilog module names.

For example, if HDL Coder detects two entities with the name `MyFilter`, the coder names the first entity `MyFilter` and the second entity `MyFilter_block`.

Command-Line Information

Property: `EntityConflictPostfix`

Type: character vector

Value: A valid character vector in the target language

Default: `'_block'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'EntityConflictPostfix', '_entity')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'EntityConflictPostfix', '_entity')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

`makehdl`

Package postfix

Specify a text as a character vector to append to the model or subsystem name to form name of a package file.

Settings

Default: `_pkg`

HDL Coder applies this option only if a package file is required for the design.

Dependency

- This option is enabled when the target language (specified by the **Language** option) is VHDL.
- This option is enabled when the target language (specified by the **Language** option) is Verilog, and the **Multi-file test bench** option is selected.
- This option is ignored, when the **HDL Coding Standard** is set to Industry.

Command-Line Information

Property: `PackagePostfix`

Type: character vector

Value: A character vector that is legal in a VHDL package file name

Default: `'_pkg'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...  
        'PackagePostfix', '_pkg')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'PackagePostfix', '_pkg')  
makehdl('sfir_fixed/symmetric_fir')
```

Reserved word postfix

Specify a text as a character vector to append to value names, postfix values, or labels that are VHDL or Verilog reserved words.

Settings

Default: `_rsvd`

The reserved word postfix is applied to identifiers (for entities, signals, constants, or other model elements) that conflict with VHDL or Verilog reserved words. For example, if your generating model contains a signal named `mod`, HDL Coder adds the postfix `_rsvd` to form the name `mod_rsvd`.

Command-Line Information

Property: `ReservedWordPostfix`

Type: character vector

Default: `'_rsvd'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'ReservedWordPostfix', '_reserved')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed', 'ReservedWordPostfix', '_reserved')
makehdl('sfir_fixed/symmetric_fir')
```

Module name prefix

Specify a prefix for every module or entity name in the generated HDL code.

Settings

Default: ''

Specify a prefix for every module or entity name in the generated HDL code. HDL Coder also applies this prefix to generated script file names.

You can specify the module name prefix to avoid name collisions if you plan to instantiate the generated HDL code multiple times in a larger system.

Command-Line Information

Property: `ModulePrefix`

Type: character vector

Default: ''

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Suppose you have a DUT, `myDut`, containing an internal module, `myUnit`. You can prefix the modules within your design with `unit1_` by using either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('myDUT', ...
        'ModulePrefix', 'unit1_')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('myUnit/myDUT', 'ModulePrefix', 'unit1_')
makehdl('myDUT')
```

In the generated code, your HDL module names are `unit1_myDut` and `unit1_myUnit`, with corresponding HDL file names. Generated script file names also have the `unit1_` prefix.

Pipeline postfix

Specify the postfix as a character vector to append to names of input or output pipeline registers generated for pipelined block implementations.

Settings

Default: '_pipe'

You can specify a generation of input and/or output pipeline registers for selected blocks. The **Pipeline postfix** option defines a character vector that HDL Coder appends to names of input or output pipeline registers when generating code.

Command-Line Information

Property: PipelinePostfix

Type: character vector

Default: '_pipe'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Suppose you specify a pipelined output implementation for a Product block in a model, as in the following code:

```
hdlset_param('sfir_fixed/symmetric_fir/Product','OutputPipeline', 2)
```

To append a postfix 'testpipe' to the generated pipeline register names, use either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl(gcb,'PipelinePostfix','testpipe')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param(gcs,'PipelinePostfix','testpipe')
makehdl('myDUT')
```

The following excerpt from generated VHDL code shows process the `PROCESS` code, with postfixed identifiers, that implements two pipeline stages:

```
Product_outtestpipe_process : PROCESS (clk, reset)
BEGIN
  IF reset = '1' THEN
    Product_outtestpipe_reg <= (OTHERS => to_signed(0, 33));
  ELSIF clk'EVENT AND clk = '1' THEN
    IF enb = '1' THEN
      Product_outtestpipe_reg(0) <= Product_out1;
      Product_outtestpipe_reg(1) <= Product_outtestpipe_reg(0);
    END IF;
  END IF;
END PROCESS Product_outtestpipe_process;
```

Split entity and architecture Parameters

These settings correspond to the parameters in the **HDL Code Generation > Global Settings > General** tab of the Configuration Parameters dialog box. The parameters determine whether to split the entity and architecture into separate files.

Split entity file postfix

Enter a character vector to be appended to the model name to form the name of a generated VHDL entity file.

You can specify an empty character vector for either the **Split entity file postfix** or the **Split arch file postfix**. Both VHDL entity and architecture files cannot have empty postfix values. When you specify both values, make sure that you use different values for the **Split entity file postfix** and the **Split arch file postfix**.

If you input special characters for **Split entity file postfix**, the code generator changes the entity name to a valid HDL name before generating code.

Settings

Default: `_entity`

Dependency

This parameter is enabled by selecting the **Split entity and architecture** check box. When you select this check box, HDL Coder places the VHDL entity and architecture code in separate files.

Command-Line Information

Property: `SplitEntityFilePostfix`

Type: character vector

Default: `'_entity'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example:

- Pass the property as an argument to the `makehdl` function.

```
makehdl(gcb, 'SplitEntityFilePostfix', '_ent')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param(gcs, 'SplitEntityFilePostfix', '_ent')
makehdl('myDUT')
```

Split arch file postfix

Enter a character vector to be appended to the model name to form the name of a generated VHDL architecture file.

You can specify an empty character vector for either the **Split arch file postfix** or the **Split entity file postfix**. Both VHDL entity and architecture files cannot have empty postfix values. When you specify both values, make sure that you use different values for the **Split entity file postfix** and the **Split arch file postfix**.

If you input special characters for **Split arch file postfix**, the code generator changes the architecture name to a valid HDL name before generating code.

Settings

Default: `_arch`

Dependency

This parameter is enabled by selecting the **Split entity and architecture** check box. When you select this check box, HDL Coder places the VHDL entity and architecture code in separate files.

Command-Line Information

Property: `SplitArchFilePostfix`

Type: character vector

Default: `'_arch'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example:

- Pass the property as an argument to the `makehdl` function.
- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
makehdl(gcb, 'SplitArchFilePostfix', '_arch1')
```

```
hdlset_param(gcs, 'SplitArchFilePostfix', '_arch1')
makehdl('myDUT')
```

Split entity and architecture

Specify whether generated VHDL entity and architecture code is written to a single VHDL file or to separate files.

Settings

Default: Off

On

VHDL entity and architecture definitions are written to separate files.

Off

VHDL entity and architecture code is written to a single VHDL file.

Tips

The names of the entity and architecture files derive from the base file name (as specified by the generating model or subsystem name). By default, postfix strings identifying the file as an entity

(`_entity`) or architecture (`_arch`) are appended to the base file name. You can override the default and specify your own postfix as a character vector.

For example, instead of all generated code residing in `MyFIR.vhd`, you can specify that the code reside in `MyFIR_entity.vhd` and `MyFIR_arch.vhd`.

Dependency

This option is enabled when the target language (specified by the **Language** option) is VHDL.

Selecting this option enables the following parameters:

- **Split entity file postfix**
- **Split architecture file postfix**

You can specify an empty character vector for either the **Split arch file postfix** or the **Split entity file postfix**. Both VHDL entity and architecture files cannot have empty postfix values. When you specify both values, make sure that you use different values for the **Split entity file postfix** and the **Split arch file postfix**.

If you input special characters for the **Split entity file postfix** or the **Split arch file postfix**, the code generator changes the entity name or the architecture name to a valid HDL name before generating code.

Command-Line Information

Property: `SplitEntityArch`

Type: character vector

Value: `'on'` | `'off'`

Default: `'off'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example:

- Pass the property as an argument to the `makehdl` function.

```
makehdl(gcb, 'SplitEntityArch', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param(gcs, 'SplitEntityArch', 'on')
makehdl('myDUT')
```

Complex Signals Postfix Parameters

This page describes parameters that reside in the **HDL Code Generation > Global Settings > General** tab of the Configuration Parameters dialog box.

Complex real part postfix

Specify the character vector to append to real part of complex signal names.

Settings

Default: `'_re'`

Enter a text to be appended to the names generated for the real part of complex signals.

Command-Line Information

Property: `ComplexRealPostfix`

Type: character vector

Default: `'_re'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

To append a postfix `'_repart'` to the generated pipeline register names, use either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl(gcb, 'ComplexRealPostfix', '_repart')
```
- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param(gcs, 'ComplexRealPostfix', '_repart')  
makehdl('myDUT')
```

Complex imaginary part postfix

Specify character vector to append to imaginary part of complex signal names.

Settings

Default: `'_im'`

Enter a character vector to be appended to the names generated for the imaginary part of complex signals.

Command-Line Information

Property: `ComplexImagPostfix`

Type: character vector

Default: `'_im'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

To append a postfix `'_impart'` to the generated pipeline register names, use either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl(gcb, 'ComplexImagPostfix', '_impart')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param(gcs, 'ComplexImagePostfix', '_impart')  
makehdl('myDUT')
```

VHDL Architecture and Library Name and Code for Model Reference Parameters

This page describes parameters that reside in the **HDL Code Generation > Global Settings > General** tab of the Configuration Parameters dialog box.

VHDL architecture name

Specify the architecture name for your DUT in the generated HDL code.

Settings

Default: 'rtl'

Specify the VHDL architecture name for your DUT in the generated HDL code as a character vector.

Command-Line Information

Property: VHDLArchitectureName

Type: character vector

Default: 'rtl'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example:

- Pass the property as an argument to the `makehdl` function.

```
makehdl(gcb, 'VHDLArchitectureName', '_rtl2')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param(gcs, 'VHDLArchitectureName', '_rtl2')  
makehdl('myDUT')
```

VHDL library name

Specify the target library name for the generated VHDL code.

Settings

Default: 'work'

Target library name for generated VHDL code.

Command-Line Information

Property: VHDLLibraryName

Type: character vector

Default: 'work'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example:

- Pass the property as an argument to the `makehdl` function.

```
makehdl(gcb, 'VHDLLibraryName', '__work1')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param(gcs, 'VHDLLibraryName', '__work1')
makehdl('myDUT')
```

Generate VHDL code for model references into a single library

Specify whether VHDL code generated for model references is in a single library, or in separate libraries.

Settings

Default: Off

On

Generate VHDL code for model references into a single library.

Off

For each model reference, generate a separate VHDL library.

Dependency

This option is enabled when the target language (specified by the **Language** option) is VHDL.

Command-Line Information

Property: `UseSingleLibrary`

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example:

- Pass the property as an argument to the `makehdl` function.

```
makehdl(gcb, 'UseSingleLibrary', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param(gcs, 'UseSingleLibrary', 'on')
makehdl('myDUT')
```

Generate Statement and Vector and Component Instance Label Parameters

This page describes parameters that reside in the **HDL Code Generation > Global Settings > General** tab of the Configuration Parameters dialog box.

Block generate label

Specify postfix to block labels used for HDL GENERATE statements.

Settings

Default: '_gen'

Specify the postfix as a character vector. HDL Coder appends the postfix to block labels used for HDL GENERATE statements.

Command-Line Information

Property: BlockGenerateLabel

Type: character vector

Default: '_gen'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Output generate label

Specify postfix to output assignment block labels for VHDL GENERATE statements.

Settings

Default: 'outputgen'

Specify the postfix as a character vector. HDL Coder appends this postfix to output assignment block labels in VHDL GENERATE statements.

Command-Line Information

Property: OutputGenerateLabel

Type: character vector

Default: 'outputgen'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Instance generate label

Specify text to append to instance section labels in VHDL GENERATE statements.

Settings

Default: '_gen'

Specify the postfix as a character vector. HDL Coder appends the postfix to instance section labels in VHDL GENERATE statements.

Command-Line Information

Property: InstanceGenerateLabel

Type: character vector

Default: '_gen'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Vector prefix

Specify prefix to vector names in generated code.

Settings

Default: 'vector_of_'

Specify the prefix as a character vector. HDL Coder appends this prefix to vector names in generated code.

Command-Line Information

Property: VectorPrefix

Type: character vector

Default: 'vector_of_'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Instance postfix

Specify postfix to generated component instance names.

Settings

Default: '' (no postfix appended)

Specify the postfix as a character vector. HDL Coder appends the postfix to component instance names in generated code.

Command-Line Information

Property: InstancePostfix

Type: character vector

Default: ''

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Instance prefix

Specify prefix to generated component instance names.

Settings

Default: 'u_'

Specify the prefix as a character vector. HDL Coder appends the prefix to component instance names in generated code.

Command-Line Information

Property: InstancePrefix

Type: character vector

Default: 'u_'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Dependency

Instance prefix option is disabled when you select the **HDL coding standard** configuration parameter to **Industry**.

Map file postfix

Specify postfix appended to file name for generated mapping file.

Settings

Default: '_map.txt'

Specify the postfix as a character vector. HDL Coder appends the postfix to file name for generated mapping file.

For example, if the name of the device under test is `my_design`, HDL Coder adds the postfix `_map.txt` to form the name `my_design_map.txt`.

Command-Line Information

Property: HDLMapFilePostfix

Type: character vector

Default: '_map.txt'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Input and Output Port and Clock Enable Output Type Parameters

This page describes parameters that reside in the **HDL Code Generation > Global Settings > Ports** tab of the Configuration Parameters dialog box.

Input data type

Specify the HDL data type for the input ports of the model.

Settings

For VHDL, the options are:

Default: `std_logic_vector`

`std_logic_vector`

Specifies VHDL type `STD_LOGIC_VECTOR`.

`signed/unsigned`

Specifies VHDL type `SIGNED` or `UNSIGNED`.

For Verilog, the options are:

Default: `wire`

In generated Verilog code, the data type for all ports is `'wire'`, and cannot be modified. Therefore, **Input data type** is disabled when the target language is Verilog.

Dependency

This option is enabled when the target language (specified by the **Language** option) is VHDL.

Command-Line Information

Property: `InputType`

Type: character vector

Value: (for VHDL) `'std_logic_vector'` | `'signed/unsigned'`

(for Verilog) `'wire'`

Default: (for VHDL) `'std_logic_vector'`

(for Verilog) `'wire'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Output data type

Specify the HDL data type for the output ports of the model.

Settings

For VHDL, the options are:

Default: Same as input data type

Same as input data type

Specifies that output ports of the model have the same type specified by **Input data type**.

std_logic_vector

Specifies VHDL type STD_LOGIC_VECTOR as the data type of the output port.

signed/unsigned

Specifies VHDL type SIGNED or UNSIGNED as the data type of the output port.

For Verilog, the options are:

Default: wire

In generated Verilog code, the data type for all ports is 'wire', and cannot be modified. Therefore, **Output data type** is disabled when the target language is Verilog.

Dependency

This option is enabled when the target language (specified by the **Language** option) is VHDL.

Command-Line Information

Property: OutputType

Type: character vector

Value: (for VHDL) 'std_logic_vector' | 'signed/unsigned'
(for Verilog) 'wire'

Default: If the property is left unspecified, output ports have the same type specified by InputType.

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Clock Enable output port

Specify the name for the generated clock enable output port as a character vector.

Settings

Default: ce_out

A clock enable output is generated when the design requires one.

Command-Line Information

Property: ClockEnableOutputPort

Type: character vector

Default: 'ce_out'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

“Clock Enable Settings and Parameters” on page 21-12

Minimize Clock Enables and Reset Signal Parameters

This page describes parameters that reside in the **HDL Code Generation > Global Settings > Ports** tab of the Configuration Parameters dialog box.

Minimize clock enables

Omit generation of clock enable logic for single-rate designs.

Settings

Default: Off

On

For single-rate models, omit generation of clock enable logic wherever possible. The following VHDL code example does not define or examine a clock enable signal. When the clock signal (clk) goes high, the current signal value is output.

```
Unit_Delay_process : PROCESS (clk, reset)
BEGIN
  IF reset = '1' THEN
    Unit_Delay_out1 <= to_signed(0, 32);
  ELSIF clk'EVENT AND clk = '1' THEN
    Unit_Delay_out1 <= In1_signed;
  END IF;
END PROCESS Unit_Delay_process;
```

Off

Generate clock enable logic. The following VHDL code extract represents a register with a clock enable (enb)

```
Unit_Delay_process : PROCESS (clk, reset)
BEGIN
  IF reset = '1' THEN
    Unit_Delay_out1 <= to_signed(0, 32);
  ELSIF clk'EVENT AND clk = '1' THEN
    IF enb = '1' THEN
      Unit_Delay_out1 <= In1_signed;
    END IF;
  END IF;
END PROCESS Unit_Delay_process;
```

Exceptions

In some cases, HDL Coder emits clock enables even when **Minimize clock enables** is selected. These cases are:

- Registers inside Enabled, State-Enabled, and Triggered subsystems.
- Multirate models.
- The coder always emits clock enables for the following blocks:
 - commseqgen2/PN Sequence Generator

- dspdigops/NCO

Note HDL support for the NCO block will be removed in a future release. Use the NCO HDL Optimized block instead.

- dspsrcs4/Sine Wave
- hlldemolib/HDL FFT
- built-in/DiscreteFir
- dspmlti4/CIC Decimation
- dspmlti4/CIC Interpolation
- dspmlti4/FIR Decimation
- dspmlti4/FIR Interpolation
- dspadpt3/LMS Filter
- dsparch4/Biquad Filter

Note If your design uses a RAM block such as a Dual Rate Dual Port RAM with the **RAM Architecture** set to Generic RAM without Clock Enable, the code generator ignores the **Minimize clock enables** setting.

Command-Line Information

Property: MinimizeClockEnables

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to minimize Clock Enable signals when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model, use either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...  
        'MinimizeClockEnables','on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','MinimizeClockEnables','on')  
makehdl('sfir_fixed/symmetric_fir')
```

Dependency

This option is ignored, when the **HDL Coding Standard** is set to Industry.

Minimize global resets

Omit generation of reset logic in the HDL code.

Settings

Default: Off

On

When you enable this setting, the code generator tries to minimize or remove the global reset logic from the HDL code. This code snippet corresponds to the Verilog code generated for a Delay block in the Simulink model. The code snippet shows that HDL Coder removed the reset logic.

```
always @(posedge clk)
begin : Delay_Synchronous_process
  if (enb) begin
    Delay_Synchronous_out1 <= DataIn;
  end
end
```

Off

When you disable this parameter, HDL Coder generates the global reset logic in the HDL code. This Verilog code snippet shows the reset logic generated for the Delay block.

```
always @(posedge clk or posedge reset)
begin : Delay_Synchronous_process
  if (reset == 1'b1) begin
    Delay_Synchronous_out1 <= 1'b0;
  end
  else begin
    if (enb) begin
      Delay_Synchronous_out1 <= DataIn;
    end
  end
end
```

Dependency

If you select **Minimize global resets**, the generated HDL code contains registers that do not have a reset port. If you do not initialize these registers, there can be potential numerical mismatches in the HDL simulation results. To avoid simulation mismatches, you can initialize the registers by using the “No-reset registers initialization” on page 21-56 setting.

By default, the **No-reset registers initialization** setting has the value `Generate initialization inside module`, which means that the code generator initializes the registers as part of the HDL code generated for the DUT. To initialize the registers with the script, set **No-reset registers initialization** to `Generate an external script`. You must use a zero initial value for the blocks in your Simulink model.

Exceptions

Sometimes, when you select **Minimize global resets**, HDL Coder generates the reset logic, if you have:

- Blocks with state that have a nonzero initial value, such as a Delay block with non-zero **Initial Condition**.

- Enumerated data types for blocks with state.
- Subsystem blocks with `BlackBox` HDL architecture where you request a reset signal.
- Multirate models with **Timing controller architecture** set to default.

If you set **Timing controller architecture** to `resettable`, HDL Coder generates a reset port for the timing controller. If you set **Minimize global reset signals** to `'on'`, the code generator removes this reset port.

- Truth Table
- Chart
- MATLAB Function block

Command-Line Information

Property: `MinimizeGlobalResets`

Type: character vector

Value: `'on' | 'off'`

Default: `'off'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to minimize global reset signals when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model, use either of these methods.

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...  
        'MinimizeGlobalResets','on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','MinimizeGlobalResets','on')  
makehdl('sfir_fixed/symmetric_fir')
```

Dependency

This option is ignored, when the **HDL Coding Standard** is set to `Industry`.

DUT Port Configuration Parameters

These parameters reside in **HDL Code Generation > Global Settings**, in the **Ports** tab in the Configuration Parameters dialog box.

Use trigger signal as clock

This setting is a parameter in the **HDL Code Generation > Global Settings > Ports** tab in the Configuration Parameters dialog box.

Settings

Default: Off

On

For triggered subsystems, use the trigger input signal as a clock in the generated HDL code. Make sure that the **Clock edge** setting in the Configuration Parameters dialog box matches the **Trigger type** of the Trigger block inside the triggered subsystem.

Off

For triggered subsystems, do not use the trigger input signal as a clock in the generated HDL code.

Command-Line Information

Property: TriggerAsClock

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to generate HDL code that uses the trigger signal as clock for triggered subsystems within the `sfir_fixed/symmetric_fir` DUT subsystem, use either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl ('sfir_fixed/symmetric_sfir', 'TriggerAsClock', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed', 'TriggerAsClock', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

Enable HDL DUT port generation for tunable parameters

Disable this setting to prevent creation of DUT input ports for tunable parameters in the generated HDL code.

Settings

Default: On

On

The code generator creates DUT input ports for the tunable parameters signals in the generated HDL code.

Off

The code generator preserves the tunable parameters and does not create DUT input ports in the generated HDL code. Selecting `off` might speed up code generation.

Command-Line Information

Property: GenDUTPortForTunableParam

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, after you designate signals as tunable parameters for the `sfir_fixed/symmetric_fir` DUT subsystem, to generate DUT input ports in the HDL code, use either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_sfir','GenDUTPortForTunableParam','on')
```

- When you use `hdlset_param`, you can set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','GenDUTPortForTunableParam','on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

“Generate DUT Ports for Tunable Parameters” on page 14-18

Balance delays for generated DUT input ports

Enable this setting to insert matching delays on generated DUT inport port paths. Disable this setting to prevent HDL Coder from inserting matching delays on paths with stable inputs. Disable this setting if you do not intend to change the tunable parameter associated with the generated DUT input port while running your design on hardware. Preventing matching delays on stable paths in the DUT reduces the amount of resources needed for your design.

Settings

Default: On

On

HDL Coder inserts matching delays on the path of generated DUT input ports for tunable parameters signals in the generated HDL code.

Off

HDL Coder does not insert matching delays on the path of generated DUT input ports for tunable parameters signals in the generated HDL code.

Dependency

To disable this parameter, select the **Enable HDL DUT input port generation for tunable parameters** check box.

Command-Line Information

Property: BalanceDelaysForTunableParam

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, after you designate signals as tunable parameters for the `sfir_fixed/symmetric_fir` DUT subsystem, to prevent matching delays on the generated DUT input port path in the HDL code, use either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_sfir',...
        'BalanceDelaysForTunableParam','off')
```

- When you use `hdlset_param`, you can set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','BalanceDelaysForTunableParam','off')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

“Generate DUT Ports for Tunable Parameters” on page 14-18

Enable HDL DUT port generation for test points

Enable this setting to create DUT output ports for the test point signals in the generated HDL code.

Settings

Default: Off

On

When you enable this setting, the code generator creates DUT output ports for the test point signals in the generated HDL code. You can observe the test point signals and debug your design by connecting a Scope block to the output ports corresponding to these signals.

Off

When you disable this setting, the code generator preserves the test point signals and does not create DUT output ports in the generated HDL code.

Note When you designate test points for states inside a Stateflow Chart, the code generator ignores this setting.

Command-Line Information

Property: EnableTestpoints

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, after you designate signals as testpoints for the `sfir_fixed/symmetric_fir` DUT subsystem, to generate DUT output ports in the HDL code, use either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_sfir','EnableTestpoints','on')
```

- When you use `hdlset_param`, you can set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','EnableTestpoints','on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

“Model and Debug Test Point Signals with HDL Coder” on page 14-70

Balance delays for generated DUT output ports

Enable this setting to insert matching delays on generated DUT output port paths. Disable this setting to prevent HDL Coder from inserting matching delays on paths to output ports generated for test points. Preventing matching delays on test point output port paths in the DUT reduces the amount of resources needed for your design and reduces the latency of test points. Disable this property to probe hardware directly without added latency to the test point signal.

Note Disabling this property affects the simulation behavior of test points in the original model.

Settings

Default: On

On

HDL Coder inserts matching delays on the path of DUT output ports generated for test point signals in the generated HDL code.

Off

HDL Coder does not insert matching delays on the path of DUT output ports generated for test point signals in the generated HDL code.

Dependency

To disable this parameter, select the **Enable HDL DUT output port generation for test points** check box.

Command-Line Information

Property: BalanceDelaysForTestpoints

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, after you designate signals as testpoints for the `sfir_fixed/symmetric_fir` DUT subsystem, to prevent matching delays on the generated DUT output port path in the HDL code, use either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_sfir',...
        'BalanceDelaysForTestpoints','off')
```

- When you use `hdlset_param`, you can set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','BalanceDelaysForTestpoints','off')
makehdl('sfir_fixed/symmetric_fir')
```

“Model and Debug Test Point Signals with HDL Coder” on page 14-70

Scalarize ports

Flatten vector ports into a structure of scalar ports in VHDL code.

Settings

Default: Off

On

When generating code for a vector port, generate a structure of scalar ports.

Off

When generating code for a vector port, generate a type definition and port declaration for the vector port.

dutlevel

When generating code for a vector port, generate a structure of scalar ports for vector ports that are at only DUT level. The DUT subsystem does not have to be at the top level of your model.

Dependency

When the target language (specified by the **Language** option) is VHDL, this option is enabled.

Command-Line Information**Property:** ScalarizePorts**Type:** character vector**Value:** 'on' | 'off' | 'dutlevel'**Default:** 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

“Scalarization of Vector Ports in Generated VHDL Code” on page 32-24

Max number of I/O pins for FPGA deployment

Specify the maximum number of I/O pins for your target FPGA.

Settings**Default:** 5000

If the DUT pin count in the generated code exceeds the value of this parameter, HDL Coder generates the message type specified by the **Check for DUT pin count exceeding I/O Threshold** parameter in the HDL Code Generation Check Report.

Command-Line Information**Property:** IOThreshold**Type:** int32**Value:** positive integer**Default:** 5000

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- `coder.HdlConfig`
- “Check for DUT pin count exceeding I/O Threshold” on page 21-46

Check for DUT pin count exceeding I/O Threshold

Specify the type of message generated when the DUT pin count in the generated code exceeds the maximum number of I/O pins set by the **Max number of I/O pins for FPGA deployment** parameter.

Settings**Default:** Error**Error**

HDL Coder generates an error in the HDL Code Generation Check Report if the DUT pin count in the generated code exceeds the maximum number of I/O pins.

Warning

HDL Coder generates a warning in the HDL Code Generation Check Report if the DUT pin count in the generated code exceeds the maximum number of I/O pins.

None

There is no message in the HDL Code Generation Check Report if the DUT pin count in the generated code exceeds the maximum number of I/O pins.

Command-Line Information

Property: TreatIOThresholdAs

Type: character vector

Value: 'Error' | 'Warning' | 'None'

Default: 'Error'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- `coder.HdlConfig`
- “Max number of I/O pins for FPGA deployment” on page 21-46

RTL Annotation Parameters

This page describes parameters that reside in the **HDL Code Generation > Global Settings > Coding Style** tab of the Configuration Parameters dialog box.

Use Verilog ``timescale` directives

Specify use of compiler ``timescale` directives in generated Verilog code.

Settings

Default: On

On

Use compiler ``timescale` directives in generated Verilog code.

Off

Suppress the use of compiler ``timescale` directives in generated Verilog code.

Tip

The ``timescale` directive provides a way of specifying different delay values for multiple modules in a Verilog file. This setting does not affect the generated test bench.

Dependency

This option is enabled when the target language (specified by the **Language** option) is Verilog.

Command-Line Information

Property: UseVerilogTimescale

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Verilog timescale specification

Specify the timescale that you want to use in the generated Verilog code.

Settings

Default: ``timescale 1 ns/1 ns`

HDL Coder applies this option to the timescale directive in the generated Verilog code. You can customize the default timescale and specify a valid, compilable timescale directive. The Verilog language uses this directive to determine the time units and the precision for calculating delay values.

By default, both the time units and precision are 1ns. For example, if you customized the timescale to ``timescale 1 ns/1 ps`, a delay unit becomes 1ns and the value is precise to the nearest 1 ps.

Dependency

This option is enabled when:

- The target language (specified by the **Language** option) is Verilog.
- The **Use Verilog `timescale directives** option is enabled.

Command-Line Information

Property: Timescale

Type: character vector

Value: A character vector that is a valid timescale value

Default: ``timescale 1 ns/1 ns`

Code Reuse

Specify whether to generate a single reusable file to represent the subsystem logic for your model subsystem.

Settings

Default: Atomic only

Atomic only

Generate reusable code for only atomic subsystems.

Atomic and Virtual

Generate a single reusable file for multiple identical subsystems.

Off

Suppress the generation of a single reusable file that represents the subsystem logic.

Command Line Information

Property: SubsystemReuse

Type: character vector

Value: 'Atomic only' | 'Atomic and Virtual' | 'off'

Default: 'Atomic only'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to generate a single reusable system for your entire project, enter

```
hdlset_param('myHDLModel', 'SubsystemReuse', 'Atomic and Virtual')
```

To set the option for a DUT component in your project, enter:

```
makehdl(<DUT system>, 'SubsystemReuse', 'Atomic and Virtual')
```

Inline VHDL configuration

Specify whether generated VHDL code includes inline configurations.

Settings

Default: On

On

Include VHDL configurations in files that instantiate a component.

Off

Suppress the generation of configurations and require user-supplied external configurations. Use this setting if you are creating your own VHDL configuration files.

Tip

HDL configurations can be either inline with the rest of the VHDL code for an entity or external in separate VHDL source files. By default, HDL Coder includes configurations for a model within the generated VHDL code. If you are creating your own VHDL configuration files, suppress the generation of inline configurations.

Dependency

This option is enabled when the target language (specified by the **Language** option) is VHDL.

Command-Line Information

Property: InlineConfigurations

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Concatenate type safe zeros

Specify use of syntax for concatenated zeros in generated VHDL code.

Settings

Default: On

On

Use the type-safe syntax, '0' & '0', for concatenated zeros. Typically, this syntax is preferred.

Off

Use the syntax "000000. . ." for concatenated zeros. This syntax can be easier to read and more compact, but it can lead to ambiguous types.

Dependency

This option is enabled when the target language (specified by the **Language** option) is VHDL.

Command-Line Information**Property:** SafeZeroConcat**Type:** character vector**Value:** 'on' | 'off'**Default:** 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Generate obfuscated HDL code

Specify generation of obfuscated HDL code. By using obfuscation, you can share the HDL code with a third-party without revealing the intellectual property. Obfuscation reduces readability of the code. The generated HDL code does not have comments, newlines or spaces, and replaces identifier names with other random names.

Settings**Default:** Off On

Generate obfuscated HDL code.

 Off

Do not generate obfuscated HDL code.

Dependency

To enable this parameter, the **Generate HDL Code** check box must be selected.

Command-Line Information**Property:** ObfuscateGeneratedHDLCode**Type:** character vector**Value:** 'on' | 'off'**Default:** 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

- To generate obfuscated HDL code by using `makehdl`:

```
makehdl('dutname', 'ObfuscateGeneratedHDLCode', 'on')
```

- To generate obfuscated HDL code by using `hdlset_param`:

```
hdlset_param('modelname', 'ObfuscateGeneratedHDLCode', 'on')
makehdl('dutname')
```

RTL Customization Parameters for Constants and MATLAB Function Blocks

This page describes parameters that reside in the **HDL Code Generation > Global Settings > Coding Style** tab of the Configuration Parameters dialog box.

Inline MATLAB Function block code

Inline HDL code for MATLAB Function blocks.

Settings

Default: Off

On

Inline HDL code for MATLAB Function blocks to avoid instantiation of code for custom blocks.

Off

Instantiate HDL code for MATLAB Function blocks and do not inline.

Command-Line Information

Property: InlineMATLABBlockCode

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to enable inlining of the code:

```
mdl = 'my_custom_block_model';  
hdlset_param(mdl, 'InlineMATLABBlockCode', 'on');
```

For example, to enable instantiation of HDL code:

```
mdl = 'my_custom_block_model';  
hdlset_param(mdl, 'InlineMATLABBlockCode', 'off');
```

Represent constant values by aggregates

Specify whether constants in VHDL code are represented by aggregates, including constants that are less than 32 bits. This option does not affect generated HDL code for MATLAB Function blocks.

Settings

Default: Off

On

HDL Coder represents constants as aggregates. The following VHDL constant declarations show a scalar less than 32 bits represented as an aggregate:

```
GainFactor_gainparam <= (14 => '1', OTHERS => '0');
```

 Off

The coder represents constants less than 32 bits as scalars and constants greater than or equal to 32 bits as aggregates. The following VHDL code was generated by default for a value less than 32 bits:

```
GainFactor_gainparam <= to_signed(16384, 16);
```

Dependency

This option is enabled when the target language (specified by the **Language** option) is VHDL.

Command-Line Information

Property: UseAggregatesForConst

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

RTL Customization Parameters for RAMs

This page describes parameters that reside in the **HDL Code Generation > Global Settings > Coding Style** tab of the Configuration Parameters dialog box.

Initialize all RAM blocks

Enable or suppress generation of initial signal value for RAM blocks. If you specify a nonzero initial value for the RAM, this setting is ignored.

Settings

Default: On

On

For RAM blocks, generate initial values of '0' for both the RAM signal and the output temporary signal.

Off

For RAM blocks, do not generate initial values for either the RAM signal or the output temporary signal.

Tip

This parameter applies to these RAM blocks in the **HDL Coder > HDL RAMs** Block Library in the Simulink Library Browser:

- Dual Port RAM
- Simple Dual Port RAM
- Single Port RAM
- Dual Rate Dual Port RAM

Command-Line Information

Property: InitializeBlockRAM

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

RAM Architecture

Select RAM architecture with clock enable, or without clock enable, for all RAMs in DUT subsystem.

Settings

Default: RAM with clock enable

Select one of the following options from the menu:

- RAM with clock enable: Generate RAMs with clock enable.
- Generic RAM without clock enable: Generate RAMs without clock enable.

Command-Line Information

Property: RAMArchitecture

Type: character vector

Value: 'WithClockEnable' | 'WithoutClockEnable'

Default: 'WithClockEnable'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

No-reset registers initialization

Specify whether you want to initialize registers without reset and the mode of initialization.

Settings

Default: Generate initialization inside module

The options are:

Do not initialize

HDL Coder does not initialize the registers without a reset port.

Generate an external script

HDL Coder generates a script to initialize registers that do not have a reset port in the generated code.

Generate initialization inside module

HDL Coder initializes the registers that do not have a reset port as part of the HDL code generated for the DUT. In Verilog, an `initial` construct in the corresponding module definition initializes the no-reset registers. In VHDL, the initialization code is part of the signal declaration statements.

Usage Notes

If you have blocks with **ResetType** on page 26-21 set to none in your Simulink model or specify the adaptive pipelining optimization, the generated HDL code can contain registers without a reset port. If you do not initialize these registers, there can be potential numerical mismatches in the HDL simulation results, because the registers are insensitive to the global reset logic. To avoid simulation mismatches, use this setting to initialize these registers in the generated code. For better simulation results, if you have registers without a reset port at the boundaries of the DUT, select **Initialize test bench inputs** in the **Test Bench** pane. Setting this property provides an initial value for the data driven to the DUT, and initializes the registers with these values.

Functionality	Script	None value	InsideModule
Generated HDL code for DUT	The script is generated externally and does not affect the HDL code for the DUT.	HDL Coder does not initialize the registers in the generated code.	The code for initializing the registers is part of the HDL code for the DUT.

Functionality	Script	None value	InsideModule
HDL simulator support	The syntax of the script is compliant with ModelSim 10.2c or later. Other HDL simulators or older ModelSim versions do not support the syntax of the initialization script. This mode does not support enumeration types, and initializing the registers with non zero values.	There can be numerical mismatches in the HDL simulation results, because this mode does not initialize the registers that do not have a reset port.	All HDL simulators support this initialization mode, and initialize the no-reset registers with appropriate values.
Synthesis tool support	As the script does not affect the HDL code generated for the DUT, all synthesis tools support this initialization mode.	Synthesis tools do not initialize the no-reset registers in this mode.	Later versions of synthesis tools support the initialization constructs in the generated code. However, it is possible that older versions do not synthesize the initialization constructs. To avoid such issues, make sure that synthesis tools can synthesize the generated code.

Command-Line Information

Property: NoResetInitializationMode

Type: character vector

Value: 'InsideModule' | 'None' | 'Script'

Default: 'InsideModule'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

“Minimize global resets” on page 21-38

RTL Style Parameters

You access the register transfer logic (RTL) style parameters in the **HDL Code Generation > Global Settings > Coding Style** tab in the Configuration Parameters dialog box.

Use “rising_edge/falling_edge” Style for Registers

Specify whether generated code uses the VHDL `rising_edge` function or the `falling_edge` function to detect clock transitions.

Settings

Default: Off

On

Generated code uses either the `rising_edge` function or the `falling_edge` function.

For example, this following code generated from a Unit Delay block uses the `rising_edge` function to detect positive clock transitions:

```
Unit_Delay1_process : PROCESS (clk, reset)
BEGIN
  IF reset = '1' THEN
    Unit_Delay1_out1 <= (OTHERS => '0');
  ELSIF rising_edge(clk) THEN
    IF clk_enable = '1' THEN
      Unit_Delay1_out1 <= signed(x_in);
    END IF;
  END IF;
END PROCESS Unit_Delay1_process;
```

Off

Generated code uses the `'event` syntax.

For example, this code generated from a Unit Delay block uses `clk'event AND clk = '1'` to detect positive clock transitions:

```
Unit_Delay1_process : PROCESS (clk, reset)
BEGIN
  IF reset = '1' THEN
    Unit_Delay1_out1 <= (OTHERS => '0');
  ELSIF clk'event AND clk = '1' THEN
    IF clk_enable = '1' THEN
      Unit_Delay1_out1 <= signed(x_in);
    END IF;
  END IF;
END PROCESS Unit_Delay1_process;
```

Dependency

This option is enabled when the target language is VHDL.

Command-Line Information

Property: UseRisingEdge

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Minimize Intermediate Signals

Specify whether to optimize HDL code for debuggability or code coverage.

Settings

Default: Off

On

Optimize the code coverage by minimizing intermediate signals. For example, with this setting as *off*, suppose that the generated code is:

```
const3 <= to_signed(24, 7);
subtractor_sub_cast <= resize(const3, 8);
subtractor_sub_cast_1 <= resize(delayout, 8);
subtractor_sub_temp <= subtractor_sub_cast - subtractor_sub_cast_1;
```

With this setting as *on*, HDL Coder optimizes the output to:

```
subtractor_sub_temp <= 24 - (resize(delayout, 8));
```

The code generator removes the intermediate signals `const3`, `subtractor_sub_cast`, and `subtractor_sub_cast_1`.

Off

Optimize the code for debuggability by preserving intermediate signals.

Command-Line Information

Property: `MinimizeIntermediateSignals`

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Unroll For-Generate Loops in VHDL Code

Specify whether VHDL FOR and GENERATE loops are unrolled and omitted from generated VHDL code.

Settings

Default: Off

On

Unroll and omit FOR and GENERATE loops from the generated VHDL code. (In Verilog code, loops are always unrolled.)

 Off

Include FOR and GENERATE loops in the generated VHDL code.

Command-Line Information**Property:** LoopUnrolling**Type:** character vector**Value:** 'on' | 'off'**Default:** 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For some Simulink blocks, by default, the HDL code is generated by using a FOR-GENERATE loop construct when you set the target language to VHDL. These Simulink blocks are:

- Reshape
- Vector Concatenate, Matrix Concatenate
- For Each Subsystem
- Serializer1D
- Deserializer1D
- Selector

The code generated by using a FOR-GENERATE loop has better code readability, reduced lines of code, and reduced code generation time. For example, consider the VHDL code generated for reshaping a 2-D matrix into a 1-D matrix. The example shows the code generated for the Reshape block with and without FOR-GENERATE loops.

- Reshape block without FOR-GENERATE loop (**Unroll for Generate Loops for VHDL code** is enabled):

```
Reshape_output : PROCESS (In1_signed)
BEGIN
Reshape_out1(0) <= In1_signed(0, 0);
Reshape_out1(1) <= In1_signed(1, 0);
Reshape_out1(2) <= In1_signed(2, 0);
Reshape_out1(3) <= In1_signed(3, 0);
Reshape_out1(4) <= In1_signed(4, 0);
Reshape_out1(5) <= In1_signed(5, 0);
Reshape_out1(6) <= In1_signed(6, 0);
Reshape_out1(7) <= In1_signed(7, 0);
Reshape_out1(8) <= In1_signed(8, 0);
Reshape_out1(9) <= In1_signed(9, 0);
Reshape_out1(10) <= In1_signed(0, 1);
...

```

- Reshape block with a FOR-GENERATE loop (**Unroll for Generate Loops for VHDL code** is disabled):

```
Reshape_out1GEN_LABEL1: FOR d1 IN 0 TO 1 GENERATE
  Reshape_out1GEN_LABEL: FOR d0 IN 0 TO 9 GENERATE

```

```

    Reshape_out1(d0 + (d1*10)) <= In1_signed(d0, d1);
  END GENERATE;
END GENERATE;

```

Tips

- If you are using an electronic design automation (EDA) tool that does not support GENERATE loops, select the loop unrolling option to omit loops from your generated VHDL code.
- Setting the loop unrolling option does not affect results obtained from simulation or synthesis of generated VHDL code.

Dependency

This option is enabled when the target language is VHDL.

Generate Parameterized HDL Code from Masked Subsystem

Generate reusable HDL code for subsystems that have the same tunable mask parameters, but with different values.

Settings

Default: Off

On

Generate one reusable HDL file for multiple masked subsystems that have different values for the mask parameters. HDL Coder supports scalar, vector, and matrix values as mask parameters. HDL Coder detects subsystems that have tunable mask parameters, which are sharable.

Inside the subsystem, you can use the mask parameter only in the blocks and parameters listed in the table.

Block	Parameter	Limitation
Constant	Constant value on the Main tab in the dialog box	None
Gain	Gain on the Main tab in the dialog box	Parameter data type must be the same for all Gain blocks.

Off

Generate a separate HDL file for each masked subsystem.

Command-Line Information

Property: MaskParameterAsGeneric

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Restrictions for Mask Parameter Values

- Each value must be a scalar, vector, or matrix.
- Values must not be complex.
- Values must not be enumerated data.

See Also

“Generate Reusable Code for Subsystems” on page 32-17

Enumerated Type Encoding Scheme

Specify the encoding scheme to represent enumeration types in the generated HDL code.

Settings

Default: default

Use a default, onehot, twohot, or binary encoding scheme to represent enumerated types in the generated HDL code.

default

The code generator uses decimal encoding in Verilog and VHDL-native enumerated types in VHDL. This example shows the Verilog code snippet of this encoding scheme for a Stateflow Chart that has four states.

```
parameter
is_Chart_IN_s_idle = 2'd0,
is_Chart_IN_s_rx = 2'd1,
is_Chart_IN_s_wait_0 = 2'd2,
is_Chart_IN_s_wait_tb = 2'd3;
```

onehot

The code generator uses a one-hot encoding scheme where a single bit is high to represent each enumeration value. This example shows the Verilog code snippet of this encoding scheme for a Stateflow Chart that has four states.

```
parameter
is_Chart_IN_s_idle = 4'b0001,
is_Chart_IN_s_rx = 4'b0010,
is_Chart_IN_s_wait_0 = 4'b0100,
is_Chart_IN_s_wait_tb = 4'b1000;
```

This encoding scheme does not support more than 64 enumeration values or numbers of states.

twohot

The code generator uses a two-hot encoding scheme where two bits are high to represent each enumeration value. This example shows the Verilog code snippet of this encoding scheme for a Stateflow Chart that has four states.

```
parameter
is_Chart_IN_s_idle = 4'b0011,
is_Chart_IN_s_rx = 4'b0101,
```

```
is_Chart_IN_s_wait_0 = 4'b0110,
is_Chart_IN_s_wait_tb = 4'b1001;
```

binary

The code generator uses a binary encoding scheme to represent each enumeration value. This example shows the Verilog code snippet of this encoding scheme for a Stateflow Chart that has four states.

```
parameter
is_Chart_IN_s_idle = 2'b00,
is_Chart_IN_s_rx = 2'b01,
is_Chart_IN_s_wait_0 = 2'b10,
is_Chart_IN_s_wait_tb = 2'b11;
```

In VHDL, the generated code uses `CONSTANT` types to encode nondefault enumeration values in the generated code. For example, this code snippet shows the generated VHDL code when you use the two-hot state encoding for a Stateflow Chart that has four states.

```
PACKAGE s_pkg IS
-- Constants
-- Two-hot encoded enumeration values for type state_type_is_Chart
CONSTANT IN_s_idle      : std_logic_vector(3 DOWNTO 0) :=
  "0011";
CONSTANT IN_s_rx       : std_logic_vector(3 DOWNTO 0) :=
  "0101";
CONSTANT IN_s_wait_0   : std_logic_vector(3 DOWNTO 0) :=
  "0110";
CONSTANT IN_s_wait_tb  : std_logic_vector(3 DOWNTO 0) :=
  "1001";

END s_pkg;
```

Command-Line Information

Property: EnumEncodingScheme

Type: character vector

Value: 'default' | 'onehot' | 'twohot' | 'binary'

Default: 'default'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Indexing for Scalarized Port Naming

Specify the starting index for the names of scalarized vector ports. For an example, see “Scalarization of Vector Ports in Generated VHDL Code” on page 32-24.

Settings

Default: Zero-based

Zero-based

The starting index for the names of scalarized vector ports is 0. For example, if you have an input `u` that is a 1x10 vector of type `uint16` that has been scalarized, the generated HDL code snippet might look like this code:

```

ENTITY Subsystem IS
  PORT( u_0      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_1      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_2      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_3      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_4      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_5      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_6      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_7      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_8      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_9      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        );
END Subsystem;

```

One-based

The starting index for the names of scalarized vector ports is 1. For example, if you have an input `u` that is a `1x10` vector of type `uint16` that has been scalarized, the generated HDL code snippet might look like this code:

```

ENTITY Subsystem IS
  PORT( u_1      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_2      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_3      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_4      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_5      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_6      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_7      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_8      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_9      : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        u_10     : IN    std_logic_vector(15 DOWNTO 0); -- uint16
        );
END Subsystem;

```

Dependency

This option is applied when the model configuration parameter **Scalarize ports** is set to on or DUT Level. For more information, see the Scalarize ports section of “DUT Port Configuration Parameters” on page 21-41.

Command-Line Information

Property: ScalarizedPortIndexing

Type: character vector

Value: 'Zero-based' | 'One-based'

Default: 'Zero-based'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Generate Record Types for Bus

Generate code with VHDL construct record types for bus signals at design-under-test (DUT) interfaces and different subsystem-level interfaces. For more information, see “Generate VHDL Code with Record Types for Bus Signals” on page 14-25.

Settings

Default: Off

On

Generate record types for bus signals in your VHDL code. For example, this code snippet shows the generated VHDL code for a subsystem where In1 and Out1 are the bus ports that are defined using the record types.

```
ENTITY Subsystem IS
  PORT( clk      : IN    std_logic;
        reset    : IN    std_logic;
        In1      : IN    BusObject_record; -- record {double,double}
        Out1     : OUT   BusObject_record -- record {double,double}
        );
END Subsystem;
```

The package file defines the record BusObject_record, which consists of two bus elements with data type double.

```
PACKAGE Subsystem_pkg IS
  TYPE BusObject_record IS RECORD
    signal1      : std_logic_vector(63 DOWNTO 0);
    signal2      : std_logic_vector(63 DOWNTO 0);
  END RECORD BusObject_record;
END Subsystem_pkg;
```

Off

HDL Coder flattens the bus elements ports at the subsystem interface. This code snippet shows the generated VHDL code for the subsystem without record types:

```
ENTITY Subsystem IS
  PORT( clk      : IN    std_logic;
        reset    : IN    std_logic;
        In1_signal1 : IN    std_logic_vector(63 DOWNTO 0); -- double
        In1_signal2 : IN    std_logic_vector(63 DOWNTO 0); -- double
        Out1_signal1 : OUT   std_logic_vector(63 DOWNTO 0); -- double
        Out1_signal2 : OUT   std_logic_vector(63 DOWNTO 0) -- double
        );
END Subsystem;
```

Command-Line Information

Property: GenerateRecordType

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Dependency

To enable this parameter, set **Target language** to VHDL.

See Also

“Generate VHDL Code with Record Types for Bus Signals” on page 14-25

Timing Controller Settings

This page describes parameters that reside in the **HDL Code Generation > Global Settings > Coding Style** tab of the Configuration Parameters dialog box.

Optimize timing controller

Optimize timing controller entity for speed and code size by implementing separate counters per rate.

Settings

Default: On

On

HDL Coder generates multiple counters (one counter for each rate in the model) in the timing controller code. The benefit of this optimization is that it generates faster logic, and the size of the generated code is usually much smaller.

Off

The coder generates a timing controller that uses one counter to generate all rates in the model.

Command-Line Information

Property: OptimizeTimingController

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- **Timing controller architecture**
- “Timing Controller for Multirate Models” on page 27-4

Timing controller architecture

Specify the architecture of the generated timing controller. HDL Coder generates a timing controller in the DUT if this parameter is set to `default` or `resettable` and a timing controller is required by the design. For example, a timing controller is required by the design when:

- You generate HDL code for a multirate model.
- You specify a cascade block implementation for certain blocks.

HDL Coder generates a separate timing controller code file that contains a module that defines timing signals, such as clock, reset, external clock enable inputs and clock enable output. In a multirate model, the timing controller module generates the required rates from a single primary clock using one or more counters and multiple clock enables. For more information, see “Timing Controller for Multirate Models” on page 27-4.

Settings

Default: default

default

Generate a timing controller in the DUT without a reset. This setting generates a timing controller code file as its own HDL file and instantiates the timing controller in the DUT at the top level.

resettable

Generate a timing controller in the DUT with a reset port. This setting generates a timing controller code file as its own HDL file and instantiates the timing controller in the DUT at the top level. If you select this option, the **Clock inputs** value must be Single.

external

Move the timing controller externally and expose the clock enable signals from the top-level design. This setting prevents the creation of a timing controller inside the DUT and does not generate a timing controller code file during HDL code generation, which allows you to integrate your own custom external timing controller into the design. If you select this option, the **Clock inputs** value must be Single.

Note When generating a test bench to validate your design, a timing controller file is generated to drive the DUT timing controller inputs for test bench validation. HDL Coder still keeps the clock enable signals exposed at the top-level design for external timing controller integration.

Command-Line Information

Property: TimingControllerArch

Type: character vector

Value: 'default' | 'resettable' | 'external'

Default: 'default'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

“Timing Controller for Multirate Models” on page 27-4

File Comment Customization Parameters

You can access the file comment customization parameters in the Configuration Parameters dialog box. Select **Settings > HDL Code Generation > Global Settings > Comments** tab.

Enable Comments

While generating HDL code, enable or disable comments.

Settings

Default: On

On

Include requirements as comments in code or code generation reports. See “Requirements Comments and Hyperlinks” on page 30-17.

Off

Do not include requirements as comments in code or code generation reports.

Include Requirements in Block Comments

Enable or disable generation of requirements comments as comments in code or code generation reports.

Settings

Default: On

On

Include requirements as comments in code or code generation reports. See “Requirements Comments and Hyperlinks” on page 30-17.

Off

Do not include requirements as comments in code or code generation reports.

Command-Line Information

Property: RequirementComments

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Emit Time/Date Stamp in Header

Specify whether or not to include time and date information in the generated HDL file header.

Settings

Default: On

On

Include the date and time stamp in the generated HDL file header.

```
-- -----  
--  
-- File Name: hdlsrc\symmetric_fir.vhd  
-- Created: 2011-02-14 07:21:36  
--
```

Off

Omit the date and time stamp in the generated HDL file header.

```
-- -----  
--  
-- File Name: hdlsrc\symmetric_fir.vhd  
--
```

By omitting the date and time stamp in the file header, you can easily determine if two HDL files contain identical code. You can also avoid redundant revisions of the same file when checking in HDL files to a source code management (SCM) system.

Command-Line Information

Property: DateComment

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Dependency

To use this option, **Custom File Header Comment** text box must be empty. While using the custom file header comment, use date and time stamp macros for adding the date and time in the generated HDL code.

Note After clearing the **Custom File Header Comment** text box, reopen the Configuration Parameter dialog box to view the applied changes.

Custom File Header Comment

Specify a custom file header comment in the generated HDL code.

Default: '' (Empty)

With **Custom File Header Comment**, you can enter custom comments to appear as a header in the generated HDL file for your design.

For example, you can specify arguments such as title, author, modified date, and so on. To include the date, time, and timestamp in your generated HDL file, use macros such as '`__DATE__`', '`__TIME__`', and '`__TIMESTAMP__`' in the custom file header comment.

Macro Syntax: `__<Parameter>__` (two underscores in the beginning and end of the parameter)

Macro Parameter: DATE, TIME, TIMESTAMP (Case Sensitive)

```
// =====
// Project: Your_Project_Title
// Author: Author_Name
//
// Date: __DATE__
// Time: __TIME__
// Timestamp: __TIMESTAMP__
// =====
```

To view the header comment, generate HDL code, and then open the generated HDL file. The custom file header comment is added in your generated HDL code.

```
// =====
// Project: Your_Project_Title
// Author: Author_Name
//
// Date: 11-05-2021
// Time: 05:20:58
// Timestamp: 11-05-2021 05:20:58
// =====
```

Command-Line Information

Property: CustomFileHeaderComment

Type: character vector

Default: ''

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to include the date and time in the custom file header comment using timestamp macro, set the parameter on the model using the `hdlset_param` function, and then generate HDL code.

```
hdlset_param('sfir_fixed', 'CustomFileHeaderComment', 'Created: __DATE__; __TIME__; __TIMESTAMP__')
```

Custom File Footer Comment

Specify a custom file footer comment in the generated HDL code.

Default: '' (Empty)

With **Custom File Footer Comment**, you can enter custom comments to appear as a footer in the generated HDL file for your design.

For example, you can specify arguments such as revision, generated log file, revision number, and so on.

```
//=====
// xxxxxx
//=====
// Log
// Revision 1.2  __TIMESTAMP__
// Initial revision
//
//=====
```

Use macros such as '__DATE__', '__TIME__', and '__TIMESTAMP__' in your custom file footer comment for including the date, time and timestamp in your generated HDL code. To view the footer comment, generate HDL code, and then open the generated HDL file.

```
//=====
// xxxxxx
//=====
// Log
// Revision 1.2  11-05-2021 05:20:58
// Initial revision
//
//=====
```

Command-Line Information

Property: CustomFileFooterComment

Type: character vector

Default: ''

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Choose Coding Standard and Report Option Parameters

This section contains parameters in the **Coding standards** tab of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Use these parameters to generate HDL code that adheres to the guidelines recommended by Industry coding standards.

HDL coding standard

Specify whether to enable the Industry coding standard guidelines that the generated HDL code must conform to.

Settings

Default: None

None

Generate generic synthesizable HDL code. The generated code need not conform with the Industry standard guidelines.

Industry

Generate synthesizable HDL code that follows the industry standard rules supported by HDL Coder. When you specify the **Industry** setting, the code generator enables the **Report options** check box and rules that you can customize in the **Coding Standards** tab.

When you specify the **Industry** setting and generate code, HDL Coder generates a standards compliance report. The report displays errors, warnings, messages, and lists the corresponding rules. To filter the report such that the passing rules do not appear, clear the **Report options** check box.

Command-Line Information

Property: HDLCodingStandard

Type: character vector

Value: 'None' | 'Industry'

Default: 'None'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can enable the Industry standard guidelines compliance for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','HDLCodingStandard','Industry')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','HDLCodingStandard','Industry')
```

Dependency

When you set the **HDLCodingStandard** to `Industry`, configuration parameters such as `PackagePostfix`, `MinimizeClockEnables`, `MinimizeGlobalResets`, and `InstancePrefix` are ignored.

See Also

- `makehdl`
- “HDL Coding Standards” on page 31-4
- HDL Coding Standard Customization Properties

Show passing rules in coding standard report

Specify whether to filter the coding standard report such that the passing rules do not appear. By default, the report displays pass, errors, warnings, messages, and lists the corresponding rules.

Settings

Default: Off

On

Show all rules in the report including the messages and passing rules.

Off

Shows rules with errors or warnings. The code generator filters out messages and passing rules from the report.

Dependency

To clear the **Report options** check box, set the **HDL coding standard** parameter to `Industry`.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```
- 2 Set the `ShowPassingRules` property of the HDL coding standard customization object.

For example, to omit passing rules from the report, enter:

```
cso.ShowPassingRules.enable = false;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard', 'Industry', ...  
        'HDLCodingStandardCustomizations', cso);
```

See Also

- `makehdl`
- “HDL Coding Standards” on page 31-4
- `hdlcoder.CodingStandard`
- HDL Coding Standard Customization

Basic Coding Practices Parameters

These parameters belong to the **Basic coding rules** section of the **Coding standards** tab of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Use these parameters to customize basic coding rules that are specified by the Industry standard guidelines. These rules correspond to naming conventions that your design uses.

Check for duplicate names

Specify whether to check for duplicate names in the design. This check corresponds to CGSL-1.A.A.5 of the Industry standard guidelines.

Settings

Default: On

On

Check for duplicate names.

Off

Do not check for duplicate names.

Dependency

To clear the **Check for duplicate names** check box, set the **HDL coding standard** parameter to Industry.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the DetectDuplicateNamesCheck property of the HDL coding standard customization object.

For example, to disable the check for duplicate names, enter:

```
cso.DetectDuplicateNamesCheck.enable = false;
```

- 3 Set the HDLCodingStandardCustomizations property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...
        'HDLCodingStandardCustomizations',cso);
```

See Also

- `makehdl`
- “Basic Coding Practices” on page 31-7

- `hdlcoder.CodingStandard`
- HDL Coding Standard Customization

Check for HDL keywords in design names

Specify whether to check for HDL keywords in design names. This check corresponds to CGSL-1.A.A.3 of the Industry standard guidelines.

Settings

Default: On

On

Check for HDL keywords in design names.

Off

Do not check for HDL keywords in design names.

Dependency

To clear the **Check for HDL keywords in design names** check box, set the **HDL coding standard** parameter to `Industry`.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `HDLKeywords` property of the HDL coding standard customization object.

For example, to disable the check for HDL keywords in design names, enter:

```
cso.HDLKeywords.enable = false;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard', 'Industry', ...
        'HDLCodingStandardCustomizations', cso);
```

- HDL Coding Standard Customization

Check module, instance, entity name length

Specify whether to check module, instance, and entity name length. This check corresponds to CGSL-1.A.C.3 of the Industry standard guidelines.

Settings

Default: On

On

Check module, instance, and entity name length.

Minimum

Minimum name length, specified as a positive integer. The default is 2.

Maximum

Maximum name length, specified as a positive integer. The default is 32.

Off

Do not check module, instance, and entity name length.

Dependency

To clear the **Check module, instance, entity name length** check box, set the **HDL coding standard** parameter to **Industry**.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `ModuleInstanceEntityNameLength` property of the HDL coding standard customization object.

For example, to enable the check for module, instance, and entity name length, with 5 as the minimum length and 30 as the maximum length, enter:

```
cso.ModuleInstanceEntityNameLength.enable = true;  
cso.ModuleInstanceEntityNameLength.length = [5 30];
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...  
       'HDLCodingStandardCustomizations',cso);
```

Check signal, port, and parameter name length

Specify whether to check signal, port, and parameter name length. This check corresponds to CGSL-1.A.B.1 of the Industry standard guidelines.

Settings

Default: On

On

Check signal, port, and parameter name length.

Minimum

Minimum name length, specified as a positive integer. The default is 2.

Maximum

Maximum name length, specified as a positive integer. The default is 40.

Off

Do not check signal, port, and parameter name length.

Dependency

To clear the **Check signal, port, and parameter name length** check box, set the **HDL coding standard** parameter to **Industry**.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```
- 2 Set the `SignalPortParamNameLength` property of the HDL coding standard customization object.

For example, to enable the check for signal, port, and parameter name length, with 5 as the minimum length and 30 as the maximum length, enter:

```
cso.SignalPortParamNameLength.enable = true;
cso.SignalPortParamNameLength.length = [5 30];
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...
        'HDLCodingStandardCustomizations',cso);
```

RTL Description Rules for clock enables and resets Parameters

These parameters belong to the **RTL description rules** section of the **Coding standards** tab of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Use these parameters to customize RTL description rules for clock enable and reset signals that are specified by the Industry standard guidelines.

Check for clock enable signals

Specify whether to check for clock enable signals in the generated code. This check corresponds to CGSL-2.C.C.4 of the Industry standard guidelines.

Settings

Default: Off

On

Minimize clock enables during code generation, then check for clock enable signals in the generated code.

Off

Do not check for clock enable signals in the generated code.

Dependency

To select the **Check for clock enable signals** check box, set the **HDL coding standard** parameter to Industry.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `MinimizeClockEnableCheck` property of the HDL coding standard customization object.

For example, to minimize clock enables and check for clock enable signals in the generated code, enter:

```
cso.MinimizeClockEnableCheck.enable = true;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard', 'Industry', ...
        'HDLCodingStandardCustomizations',cso);
```

See Also

- HDL Coding Standard Customization

Detect usage of reset signals

Specify whether to check for reset signals in the generated code. This check corresponds to CGSL-2.C.C.5 of the Industry standard guidelines.

Settings

Default: Off

On

Minimize reset signals in the generated code, then check for reset signals after code generation.

Off

Do not check for reset signals in the generated code.

Dependency

To select the **Detect usage of reset signals** check box, set the **HDL coding standard** parameter to Industry.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `RemoveResetCheck` property of the HDL coding standard customization object.

For example, to check for reset signals, enter:

```
cso.RemoveResetCheck.enable = true;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard', 'Industry', ...  
       'HDLCodingStandardCustomizations', cso);
```

- `hdlcoder.CodingStandard`
- HDL Coding Standard Customization

Detect usage of asynchronous reset signals

Specify whether to check for asynchronous reset signals in the generated code. This check corresponds to CGSL-2.C.C.6 of the Industry standard guidelines.

Settings

Default: Off

On

Check for asynchronous reset signals in the generated code.

Off

Do not check for asynchronous reset signals in the generated code.

Dependency

To clear the **Detect usage of asynchronous reset signals** check box, set the **HDL coding standard** parameter to `Industry`.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `AsynchronousResetCheck` property of the HDL coding standard customization object.

For example, to minimize use of variables, enter:

```
cso.AsynchronousResetCheck.enable = true;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...
        'HDLCodingStandardCustomizations',cso);
```

RTL Description Rules for Conditional Parameters

These parameters belong to the **RTL description rules** section of the **Coding standards** tab of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Use these parameters to customize RTL description rules for conditional and if-else statements that are specified by the Industry standard guidelines.

Check for conditional statements in processes

Specify whether to check for length of conditional statements that are described separately within a process. This check corresponds to CGSL-2.F.B.1 of the Industry standard guidelines.

Settings

Default: On

On

Check for length of conditional statements in a process. The default length is 1.

Off

Do not check for length of conditional statements in a process.

Dependency

To clear the **Check for conditional statements in processes** check box, set the **HDL coding standard** parameter to **Industry**.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `ConditionalRegionCheck` property of the HDL coding standard customization object.

For example, to check for four conditional statements in a process, enter:

```
cso.ConditionalRegionCheck.enable = true;
cso.ConditionalRegionCheck.length = 4;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...
        'HDLCodingStandardCustomizations',cso);
```

Check for assignments to the same variable in multiple cascaded control regions

Specify whether to check if there are assignments to the same variable in multiple cascaded control regions within the same process block. This check corresponds to CGSL-2.F.B.1.a of the industry standard guidelines.

Settings

Default: Off

On

Check for assignments to the same variable in multiple cascaded control regions.

Off

Do not check for assignments to the same variable in multiple cascaded control regions.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```
- 2 Set the `CascadedConditionalAssignmentCheck` property of the HDL coding standard customization object.

```
cso.CascadedConditionalAssignmentCheck.enable = true;
```
- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object. Specify the coding standard and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...
        'HDLCodingStandardCustomizations',cso);
```

See Also

Check if-else statement chain length

Specify whether to check if-else statement chain length. This check corresponds to CGSL-2.G.C.1c of the Industry standard guidelines.

Settings

Default: On

On

Check if-else statement chain length.

Length

Maximum if-else statement chain length, specified as a positive integer. The default is 7.

Off

Do not check if-else statement chain length.

Dependency

To clear the **Check if-else statement chain length** check box, set the **HDL coding standard** parameter to `Industry`.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `IfElseChain` property of the HDL coding standard customization object.

For example, to check for if-else statement chains with length greater than 5, enter:

```
cso.IfElseChain.enable = true;  
cso.IfElseChain.length = 5;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard', 'Industry', ...  
        'HDLCodingStandardCustomizations', cso);
```

See Also

Check if-else statement nesting depth

Specify whether to check if-else statement nesting depth. This check corresponds to CGSL-2.G.C.1a of the Industry standard guidelines.

Settings

Default: On

On

Check if-else statement nesting depth.

Depth

Maximum if-else statement nesting depth, specified as a positive integer. The default is 3.

Off

Do not check if-else statement nesting depth.

Dependency

To clear the **Check if-else statement nesting depth** check box, set the **HDL coding standard** parameter to `Industry`.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `IfElseNesting` property of the HDL coding standard customization object.

For example, to enable the check for if-else statement nesting depth with a maximum depth of 5, enter:

```
cso.IfElseNesting.enable = true;
cso.IfElseNesting.depth = 5;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard', 'Industry', ...
        'HDLCodingStandardCustomizations', cso);
```

Other RTL Description Rule Parameters

These parameters belong to the **RTL description rules** section of the **Coding standards** tab of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Use these parameters to customize RTL description rules of the Industry standard guidelines. These rules pertain to checking the multiplier width, whether to minimize use of variables, and initial statements to provide initial value for RAMs.

Minimize use of variables

Specify whether to minimize use of variables. This check corresponds to CGSL-2.G of the Industry standard guidelines.

Settings

Default: Off

On

Minimize use of variables.

Off

Do not minimize use of variables.

Dependency

To select the **Minimize use of variables** check box, set the **HDL coding standard** parameter to Industry.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.
- 2 Set the `MinimizeVariableUsage` property of the HDL coding standard customization object.

For example, to minimize use of variables, enter:

```
cso.MinimizeVariableUsage.enable = true;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...
        'HDLCodingStandardCustomizations',cso);
```

Check for initial statements that set RAM initial values

Specify whether to check for initial statements that set RAM initial values. This check corresponds to CGSL-2.C.D.1 of the Industry standard guidelines.

Settings

Default: On

On

Check for initial statements that set RAM initial values

Off

Do not check for initial statements that set RAM initial values.

Dependency

To clear the **Check for initial statements that set RAM initial values** check box, set the **HDL coding standard** parameter to `Industry`.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.
- 2 Set the `InitialStatements` property of the HDL coding standard customization object.

For example, to disable the check for initial statements that set RAM initial values, enter:

```
cso.InitialStatements.enable = false;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard', 'Industry', ...
        'HDLCodingStandardCustomizations', cso);
```

- HDL Coding Standard Customization

Check multiplier width

Specify whether to check multiplier bit width. This check corresponds to CGSL-2.J.F.5 of the Industry standard guidelines.

Settings

Default: On

On

Check multiplier width.

Maximum

Maximum multiplier bit width, specified as a positive integer. The default is 16.

Off

Do not check multiplier width.

Dependency

To clear the **Check multiplier width** check box, set the **HDL coding standard** parameter to Industry.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `MultiplierBitWidth` property of the HDL coding standard customization object.

For example, to enable the check for multiplier width with a maximum bit width of 32, enter:

```
cso.MultiplierBitWidth.enable = true;  
cso.MultiplierBitWidth.width = 32;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...  
        'HDLCodingStandardCustomizations',cso);
```

RTL Design Rule Parameters

This section contains configuration parameters in the **RTL design rules** section of the **Coding standards** tab of the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. Use these parameters to check for presence of non-integer constants and the line wrap length in the generated HDL code.

Check for non-integer constants

Specify whether to check for non-integer constants. This check corresponds to CGSL-3.B.D.1 of the Industry standard guidelines.

Settings

Default: On

On
Check for non-integer constants.

Off
Do not check for non-integer constants.

Dependency

To clear the **Check for non-integer constants** check box, set the **HDL coding standard** parameter to Industry.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.
`cso = hdlcoder.CodingStandard('Industry');`
- 2 Set the `NonIntegerTypes` property of the HDL coding standard customization object.

For example, to disable the check for non-integer constants, enter:

```
cso.NonIntegerTypes.enable = false;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...  
        'HDLCodingStandardCustomizations',cso);
```

See Also

- `makehdl`
- “RTL Design Rule Parameters” on page 21-91

- HDL Coding Standard Customization

Check line length

Specify whether to check line lengths in the generated HDL code. This check corresponds to CGSL-3.A.D.5 of the Industry standard guidelines.

Settings

Default: On

On

Check line length.

Maximum

Maximum number of characters in a line, specified as a positive integer. The default is 110.

Off

Do not check line length.

Dependency

To clear the **Check line length** check box, set the **HDL coding standard** parameter to **Industry**.

Command-Line Information

To set this property:

- 1 Create an HDL coding standard customization object.

```
cso = hdlcoder.CodingStandard('Industry');
```

- 2 Set the `LineLength` property of the HDL coding standard customization object.

For example, to enable the check line length with a maximum character length of 80, enter:

```
cso.HDLKeywordsLineLength.enable = true;  
cso.HDLKeywordsLineLength.length = 80;
```

- 3 Set the `HDLCodingStandardCustomizations` property to the HDL coding standard customization object, specify the coding standard, and generate code.

For example, if your DUT is `sfir_fixed/symmetric_fir`, enter:

```
makehdl('sfir_fixed/symmetric_fir', 'HDLCodingStandard','Industry', ...  
        'HDLCodingStandardCustomizations',cso);
```

See Also

- `makehdl`

Model Generation Parameters for HDL Code

In the Configuration Parameter dialog box, you can select the types of the model that you want to generate. Select **HDL Code Generation > Global Settings > Model Generation**.

You can customize the name and layout of the generated model and the validation model by using “Naming and Layout Options for Model Generation” on page 21-96.

Generated model

Enable or disable generation of the generated model that shows latency and numeric differences between your Simulink DUT and the generated HDL code. Delays that the coder inserts are highlighted in the generated model.

Note When you select **Generated model**, the **Naming options** and **Layout options** become available.

Settings

Default: On

On

Select this setting to generate the generated model. By default, HDL Coder generates code and the generated model. To generate only the generated model, clear the **Generate HDL code** check box.

Off

Clear this setting when you do not want to generate the generated model. When you click the **Generate** button, HDL Coder generates code for the model.

Command-Line Information

Property: GenerateModel

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

By default, the `GenerateHDLCode` property is enabled. You can use this property in conjunction with the `GenerateModel` property to specify whether to generate the generated model and the HDL code. To generate the code and the generated model, run `makehdl`.

```
makehdl('sfir_fixed/symmetric_fir')
```

If you want to generate only the generated model, disable the `GenerateHDLCode` property and run `makehdl`.

```
hdlset_param('sfir_fixed', 'GenerateModel','on');
hdlset_param('sfir_fixed', 'GenerateHDLCode','off');
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “Balance delays” on page 19-4
- “Generated Model and Validation Model” on page 28-10
- “Prefix for generated model name” on page 21-96

Validation model

Enable or disable generation of a validation model that verifies the functional equivalence of the original model with the generated model. The validation model contains the original and the generated DUT models. You can use the generated DUT model to observe the effect of block settings and optimizations such as resource sharing, streaming, and delay balancing.

If you enable generation of a validation model, make sure that delay balancing is enabled on the model (its default). Delay balancing keeps the generated DUT model synchronized with the original DUT model. Validation fails when there is a mismatch between delays in the original DUT model and delays in the generated DUT model. See

Settings

Default: Off

On

Select this setting to generate the validation model. By default, HDL Coder generates code and the validation model. To generate only the validation model, clear the **Generate HDL code** check box.

Off

Clear this setting when you do not want to generate the validation model. When you click the **Generate** button, HDL Coder generates code for the model.

Command-Line Information

Property: GenerateValidationModel

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

By default, the `GenerateHDLCode` property is enabled. You can use this property in conjunction with the `GenerateValidationModel` property to specify whether to generate the validation model and the HDL code. To generate the code and the validation model, enable the `GenerateValidationModel` property with `makehdl`.

```
hdlset_param('sfir_fixed', 'GenerateValidationModel','on');  
makehdl('sfir_fixed/symmetric_fir')
```

If you want to generate only the validation model, disable the `GenerateHDLCode` property and enable the `GenerateValidationModel` property with `makehdl`.

```
hdlset_param('sfir_fixed', 'GenerateValidationModel','on');  
hdlset_param('sfir_fixed', 'GenerateHDLCode',off);  
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “Balance delays” on page 19-4
- “Generated Model and Validation Model” on page 28-10
- “Suffix for validation model name” on page 21-96

Naming and Layout Options for Model Generation

Following are the different naming options available in **HDL Code Generation > Global Settings** pane under the **Model Generation** tab. You can control the prefix for the generated model name and the suffix for the validation model name.

Prefix for generated model name

Specify the prefix of the generated model name.

Settings

Default: 'gm_'

Specify the prefix as a character vector. HDL Coder appends the prefix to name of generated model.

Command-Line Information

Property: GeneratedModelNamePrefix

Type: character vector

Default: 'gm_'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to indicate that you are using the generated model as a software interface model, you can use the prefix `sm_`. Specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'GeneratedModelNamePrefix','sm_')
```

- When you use `hdlset_param`, set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','GeneratedModelNamePrefix','sm_')
makehdl('sfir_fixed/symmetric_fir')
```

Dependency

To specify **Prefix for generated model**, select **Generated model**.

See Also

- “Generated Model” on page 28-10
- “Suffix for validation model name” on page 21-96
- “Generated Model and Validation Model” on page 28-10

Suffix for validation model name

Specify the suffix of the validation model name.

Settings

Default: '_vnl'

Specify the suffix as a character vector. HDL Coder appends the suffix to name of validation model.

Command-Line Information

Property: ValidationModelNameSuffix

Type: character vector

Default: '_vnl'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, to indicate that you are using the generated model as a software interface model, you can use the suffix `_sm` for the validation model name. Specify this property when you generate HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','ValidationModelNameSuffix','_sm')
```

- When you use `hdlset_param`, set the parameter on the model, and then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','ValidationModelNameSuffix','_sm');
makehdl('sfir_fixed/symmetric_fir');
```

Dependency

To specify **Suffix for validation model**, select **Generated model** and **Validation model**.

See Also

- “Validation model” on page 21-94
- “Prefix for generated model name” on page 21-96
- “Generated Model and Validation Model” on page 28-10

Layout Style

Select the layout style of the generated HDL model for better layout visualization.

Layout Style	Description
None	When you set the Layout style to None , the generated model has no layout. Use this layout style when you want to test only functionality. The code generation time is significantly reduced.

Layout Style	Description
Default	<p>When you set the Layout style to Default, the model is generated using default HDL coder layout. Use this layout style when you want to verify the configured optimizations on the input model by using optimization reports.</p> <p>You can set the Auto signal routing to on or off based on the layout visualization and code generation time.</p> <p>When the design complexity is high, the layout process might not succeed. Code generation does not proceed after the '### Begin model generation' message in the command log. In such a scenario, you can switch layout option to None or change the style to AutoArrange.</p>
AutoArrange	<p>When you set the Layout style to AutoArrange, the model is generated by using a Simulink layout. Use this layout style when you want to verify the configured optimizations on the input model by using optimization reports.</p>

Note For an input model that has no optimizations configured, you cannot observe the layout effect of these layout styles. The generated model appears the same as the input model.

Settings

Default: Default

Command-Line Information

Property: LayoutStyle

Type: character vector

Value: 'None' | 'Default' | 'AutoArrange'

Default: 'Default'

To set this property, use `hdlset_param`,

```
hdlset_param(gcs, 'LayoutStyle', 'Default')
```

Tips

- Consider introducing hierarchy in the model to reduce the complexity and number of blocks to be placed in a single level. Such model refactoring helps improve the layout computation process.
- The code generation time increases when you change the layout style to **Default** or **AutoArrange**.

Dependency

To select **Layout style**, first select **Generated model**.

See Also

“Model Generation Parameters for HDL Code” on page 21-93

Auto signal routing

Specify automatic routing of signals in the generated model.

Settings

Default: on

Command-Line Information

Property: autoroute

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use `hdlset_param`:

```
hdlset_param(gcs, 'autoroute', 'on')
```

Dependency

To select **Auto signal routing**, first select **Layout style** to Default.

See Also

“Model Generation Parameters for HDL Code” on page 21-93

Inter-block horizontal scaling

Scale the generated model horizontally. You can use this setting for **Inter-block vertical scaling** depending on how tightly or loosely packed you want the model to appear.

Settings

Default: 1.7

Command-Line Information

Property: InterBlkHorzScale

Type: positive integer | positive double

Default: 1.7

To set this property, use `hdlset_param`:

```
hdlset_param(gcs, 'InterBlkHorzScale', 1.7)
```

Dependency

To select **Inter-block horizontal scaling**, set **Layout style** to Default.

See Also

“Model Generation Parameters for HDL Code” on page 21-93

Inter-block vertical scaling

Scale the generated model vertically. You can use this setting for **Inter-block horizontal scaling** depending on how tightly or loosely packed you want the model to appear.

Settings

Default: 1.2

Command-Line Information

Property: InterBlkVertScale

Type: positive integer | positive double

Default: 1.2

To set this property, use `hdlset_param`:

```
hdlset_param(gcs, 'InterBlkVertScale', 1.2)
```

Dependency

To select **Inter-block vertical scaling**, set **Layout style** to Default.

“Model Generation Parameters for HDL Code” on page 21-93

Diagnostic Parameters for Optimizations

This section contains parameters in the **Diagnostics** section of the **HDL Code Generation > Global Settings > Advanced** tab in the Configuration Parameters dialog box. To highlight blocks and feedback loops that inhibit delay balancing, distributed pipelining, clock-rate pipelining, and other optimizations, use these parameters.

Highlight feedback loops inhibiting delay balancing and optimizations

Feedback loops in your Simulink model can inhibit delay balancing and optimizations such as resource sharing and streaming. Use this setting to generate a script that highlights feedback loops.

When you generate the feedback loop highlighting script, HDL Coder generates another script that clears the highlighting of feedback loops in your model. To turn off highlighting, click the link to the [clearhighlighting](#) script.

Settings

Default: On

On

Generate a MATLAB script that highlights feedback loops in the original model and the generated model. When you run the script, the code generator highlights the feedback loops using different colors. The highlighting script is saved in the same target folder as the generated HDL code.

It is recommended that you leave this setting enabled so that you can identify the feedback loops and further optimize your design.

Off

Do not generate a script to highlight feedback loops.

Command-Line Information

Property: HighlightFeedbackLoops

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','HighlightFeedbackLoops','off')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','HighlightFeedbackLoops','off')
```

See Also

- “Generated Model and Validation Model” on page 28-10

Highlight blocks inhibiting clock-rate pipelining

Certain blocks in your Simulink model can inhibit clock-rate pipelining and therefore delimit clock-rate pipelining regions. Use this setting to generate a script to highlight the blocks.

When you generate the clock-rate pipelining highlighting script, HDL Coder generates another script that clears the highlighting. To turn off highlighting, click the link to the `clearhighlighting` script.

Settings

Default: On

On

Generate a MATLAB script that highlights blocks in the original model and the generated model that are inhibiting clock-rate pipelining.

It is recommended that you leave this setting enabled so that you can identify the blocks that delimit the clock-rate pipelining regions and further optimize your design.

Off

Do not generate a script to highlight blocks that are inhibiting clock-rate pipelining.

Command-Line Information

Property: `HighlightClockRatePipeliningDiagnostic`

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','HighlightClockRatePipeliningDiagnostic','off')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','HighlightClockRatePipeliningDiagnostic','off')
```

See Also

- “Pipelining Parameters” on page 19-9

- “Generated Model and Validation Model” on page 28-10

Highlight blocks inhibiting distributed pipelining

Certain blocks in your Simulink model can act as barriers for the distributed pipelining optimization. Use this setting to generate a script to highlight the blocks that are inhibiting distributed pipelining.

When you generate the highlighting script that displays distributed pipelining barriers, HDL Coder generates another script that clears the highlighting. To turn off highlighting, click the link to the [clearhighlighting](#) script.

Settings

Default: On

On

Generate a MATLAB script that highlights blocks that are inhibiting distributed pipelining in the original model and the generated model.

It is recommended that you leave this setting enabled so that you can identify the blocks that are barriers for distributed pipelining and further optimize your design.

Off

Do not generate a script to highlight blocks that are inhibiting distributed pipelining.

Command-Line Information

Property: DistributedPipeliningBarriers

Type: character vector

Value: 'on' | 'off'

Default: 'on'

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','DistributedPipeliningBarriers','off')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','DistributedPipeliningBarriers','off')
```

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Pipelining Parameters” on page 19-9
- “Diagnostic Parameters for Reals and Black Box Interfaces” on page 21-106
- “Generated Model and Validation Model” on page 28-10

Highlight lookup tables mapped to RAM

Use this setting to generate a script to highlight the Lookup Table blocks in your model that are mapped to RAM.

When you generate the highlighting script that displays lookup tables mapped to RAM, HDL Coder generates another script that clears the highlighting. To turn off highlighting, click the link to the [clearhighlighting](#) script.

Settings

Default: On

On

Generate a MATLAB script that highlights Lookup Table blocks that are mapped to RAM.

It is recommended that you leave this setting enabled so that you can identify the Lookup Table blocks that are mapped to RAM.

Off

Do not generate a script to highlight Lookup Table blocks that are mapped to RAM.

Command-Line Information

Property: HighlightLUTPipeliningDiagnostic

Type: character vector

Value: 'on' | 'off'

Default: 'on'

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','HighlightLUTPipeliningDiagnostic','off')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','HighlightLUTPipeliningDiagnostic','off')
```

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Highlight dead blocks removed in generated code

Use this setting to generate a script to highlight the unused blocks in your model that are removed during HDL code generation. The unused blocks are typically in upstream logic connected to a Terminator block. HDL Coder removes upstream logic connected to Terminator blocks because it does not contribute to the output.

HDL Coder generates the highlighting script and a script that clears the highlighting. To highlight the unused blocks, click the link to the `highlightRemovedDeadBlocks.m` script. To turn off highlighting, click the link to the `clearHighlightingRemovedDeadBlocks.m` script.

Settings

Default: On

On

Generate a MATLAB script that highlights dead blocks removed in generated code. HDL Coder generates this script only if there are components removed during HDL code generation.

Off

Do not generate a script to highlight dead blocks removed in generated code.

Command-Line Information

Property: `HighlightRemovedDeadBlocks`

Type: character vector

Value: 'on' | 'off'

Default: 'on'

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Use `hdlset_param` to set the parameter on the model. Then, generate HDL code by using `makehdl`.

```
hdlset_param('sfir_fixed','HighlightRemovedDeadBlocks','on')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','HighlightRemovedDeadBlocks','on')
```

To generate the highlighting script, add logic that connects to a Terminator block in the DUT subsystem `sfir_fixed/symmetric_fir`.

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

Diagnostic Parameters for Reals and Black Box Interfaces

This section contains parameters in the **Diagnostics** option under **Advanced** tab in the Configuration Parameters dialog box. Select **HDL Code Generation > Global Settings**. To check for name conflicts in black box interfaces and for the presence of reals in the generated HDL code, use these parameters.

Check for name conflicts in black box interfaces

Specify whether to check for duplicate module or entity names in generated HDL code and black box interface HDL code.

Settings

Default: Warning

None

Do not check for black box subsystems that have the same HDL module name as a generated HDL module name.

Warning

Check for black box subsystems that have the same HDL module name as a generated HDL module name. Display a warning if matching names are found.

Error

Check for black box subsystems that have the same HDL module name as a generated HDL module name. Display an error if matching names are found.

Command-Line Information

Property: DetectBlackBoxNameCollision

Type: character vector

Value: 'None' | 'Warning' | 'Error'

Default: 'Warning'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','DetectBlackBoxNameCollision','None')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','DetectBlackBoxNameCollision','None')
```

See Also

- `makehdl`
- “Generate Black Box Interface for Subsystem” on page 32-4

- “Diagnostic Parameters for Optimizations” on page 21-101

Check for presence of reals in generated HDL code

Specify whether to check for reals in the generated HDL code.

Settings

Default: Error

None

Do not check for reals in the generated HDL code.

Warning

Checks and warns of presence of real data types in the generated HDL code. Real data types in the generated HDL code are not synthesizable on target FPGA devices.

Error

Checks and generates an error if the generated HDL code uses real data types. If you are generating code for simulation purposes and not for synthesizing your design, you can change this setting to Warning or None. To generate synthesizable HDL code, select the model configuration parameter **Use Floating Point**.

Command-Line Information

Property: TreatRealsInGeneratedCodeAs

Type: character vector

Value: 'None' | 'Warning' | 'Error'

Default: 'Error'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','TreatRealsInGeneratedCodeAs','Warning')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','TreatRealsInGeneratedCodeAs','Warning')
```

See Also

- `makehdl`
- “Getting Started with HDL Coder Native Floating-Point Support” on page 14-92
- “Diagnostic Parameters for Optimizations” on page 21-101

Check for presence of unbalanced delays in generated HDL code

Specify whether to check for unbalanced delays in the generated HDL code.

Settings

Default: Error

None

Do not check for unbalanced delays in the generated HDL code.

Warning

Checks and warns of presence of unbalanced delays in the generated HDL code.

Error

Checks and generates an error if the generated HDL code uses unbalanced delays. If you are generating code for simulation purposes and not for synthesizing your design, you can change this setting to Warning or None.

Command-Line Information

Property: TreatBalanceDelaysOffAs

Type: character vector

Value: 'None' | 'Warning' | 'Error'

Default: 'Error'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code using `makehdl`.

```
hdlset_param('sfir_fixed','TreatBalanceDelaysOffAs','Warning')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir','TreatBalanceDelaysOffAs','Warning')
```

Code Generation Output Parameter

You can specify whether or not to generate HDL code by using the **Generate HDL code** parameter. In the Configuration Parameters dialog box, select **HDL Code Generation > Global Settings > Advanced > Code generation output**.

Generate HDL code

Enable or disable HDL code generation for the model or Subsystem. To specify the Subsystem that you want to generate HDL code for, use the **Generate HDL for** parameter. Then, click the **Generate** button in the **HDL Code Generation** pane. By default, the HDL code is generated in VHDL language and put into the `hdlsrc` folder.

Settings

Default: On

On

Select this setting to generate HDL code.

Off

When you clear this setting, you cannot generate HDL code for the model.

Command-Line Information

Property: GenerateHDLCode

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

By default, the `GenerateHDLCode` property is selected. To generate code, use the `makehdl` function. For example, this command generates HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model.

```
makehdl('sfir_fixed/symmetric_fir')
```

Control Code Generation Output

Property: CodeGenerationOutput

Type: character vector

Value: 'GenerateHDLCode' |
'GenerateHDLCodeAndDisplayGeneratedModel' 'DisplayGeneratedModelOnly'

Default: 'GenerateHDLCode'

By default, HDL Coder creates a model called the generated model when you generate HDL code. The generated model uses HDL-specific block implementations, and it implements the area and speed optimizations that you specify in your Simulink model. The code generator creates the generated model but does not display the model by default. To control display of the generated model, use the `CodeGenerationOutput` property.

This example shows how to generate HDL code, and then display the generated model by using `makehdl`.

```
makehdl('sfir_fixed/symmetric_fir', ...
        'CodeGenerationOutput', 'GenerateHDLCodeAndDisplayGeneratedModel')
```

If you specify `DisplayGeneratedModelOnly`, the code generator displays the generated model but does not proceed to code generation.

Suppress out of bounds access errors by generating simulation-only index checks

Enable or disable whether to generate additional logic that runs during simulation time to prevent array indices from going out of bounds. This option is available only when the **Language** option is set to VHDL. When you enable this option, a function is generated that uses a pragma to perform checks at simulation time. When the function encounters arrays, a function call is generated with the lower bound (zero) and the upper bound (size of array - 1) as the function parameters.

Settings

Default: Off

On

Generate additional logic that runs during simulation time to prevent array indices from going out of bounds.

Off

Do not generate additional logic that runs during simulation time to prevent array indices from going out of bounds.

Command-Line Information

Property: `SimIndexCheck`

Type: character vector

Value: 'on' | 'off'

Default: 'on'

For example, you can specify this property while generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model by using either of these methods:

- Use `hdlset_param` to set the parameter on the model. Then generate HDL code by using the `makehdl` function.

```
hdlset_param('sfir_fixed', 'SimIndexCheck', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

- Pass the property as an argument to the `makehdl` function.

```
makehdl('sfir_fixed/symmetric_fir', 'SimIndexCheck', 'on')
```

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

HDL Code Generation Pane: Report

- “Report Pane Overview” on page 22-2
- “Code Generation Report Parameters” on page 22-3

Report Pane Overview

When you use the parameters in the **Report** pane, HDL Coder creates a Code Generation Report when generating HDL code for your model or Subsystem. The Code Generation Report contains a **Summary**, a **Code Interface Report**, and one or more of these reports.

- A traceability report that you can use to trace from the generated HDL code to the model and from the model to HDL code.
- A resource utilization report that contains the number of hardware resources used in the HDL code.
- An optimization report that displays the result of optimizations such as streaming, sharing, distributed pipelining, and floating-point target-specific information that was implemented in the generated code.
- A web view of the model that you can use to navigate between the generate code and your Simulink model.
- A timing report that displays the critical path delay and generates a highlighting script as a link that you can click to highlight the estimated critical path in the generated model. If your design contains blocks without timing information, the report displays the link to another highlighting script that is generated to highlight those blocks.

Code Generation Report Parameters

In this section...
"Generate traceability report" on page 22-3
"Traceability style" on page 22-4
"Generate model Web view" on page 22-5
"Generate resource utilization report" on page 22-6
"Generate high-level timing critical path report" on page 22-7
"Generate optimization report" on page 22-8
"Custom Timing Database Directory" on page 22-9

This page describes configuration parameters that reside in the **HDL Code Generation > Report** pane of the Configuration Parameters dialog box. Enable these parameters to see the **Summary**, **Code Interface Report**, and reports that display traceability information, resource utilization, and effect of optimizations on your design.

Generate traceability report

Enable or disable generation of an HTML code generation report with hyperlinks from code to model and model to code. The report provides line-level traceability for each block in your Simulink model. When you click the hyperlink beside a certain line of code in the report, HDL Coder highlights the corresponding block in your Simulink model. When you select a certain block in your model, the report highlights all lines of code corresponding to that block.

Settings

Default: Off

On

Create and display a traceability report section in the HTML code generation report. To generate the report, after you enable this setting, click the **Generate** button. The code generation report contains a summary section and a code interface report along with the traceability report.

Off

Do not create an HTML code generation report.

Dependency

When you select this check box, you can select the **Traceability style**. By default, the **Traceability style** is **Line Level**.

Command-Line Information

Property: Traceability

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can generate a traceability report when generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass in the `Traceability` property as an argument to `makehdl`.

```
makehdl('sfir_fixed/symmetric_fir','Traceability','on')
```

- Enable the `Traceability` property using `hdlset_param` and then use `makehdl`.

```
hdlset_param('sfir_fixed','Traceability','on')
makehdl('sfir_fixed/symmetric_fir')
```

You can use the `RequirementComments` property to generate hyperlinked requirements comments within the HTML code generation report. The requirements comments link to the corresponding requirements documents for your model.

See Also

- “Create and Use Code Generation Reports” on page 30-2
- “Navigate Between Simulink Model and HDL Code by Using Traceability” on page 30-4
- `makehdl`

Traceability style

You can use **Traceability style** to specify whether you want to generate line-level or comment-based hyperlinks in the traceability report.

Settings

Default: Line Level

The options are:

Line Level

By default, HDL Coder generates a line-level traceability report that contains hyperlinks from each line of HDL code to the corresponding block in your Simulink model. The traceability report that is generated by using this style does not contain hyperlinked comments above the HDL code corresponding to a certain block. When you select a certain block and navigate to the HDL code, the code generator highlights all lines of code corresponding to that block.

Comment Based

If you specify generation of a comment-based traceability report, the report contains hyperlinked comments above a block of HDL code. The comments contain a traceability tag that contains a searchable pattern of the format `<system>/blockname`. `<system>` is the root model or a Subsystem inside the model, and `blockname` is the name of the block inside that model or Subsystem.

For example, if you have a model, `foo`, that has a Subsystem, `outer`, and a nested Subsystem, `Inner`, then the `<System>` tag is:

- `<Root>`: `foo`
- `<S1>`: `foo/outer`
- `<S2>`: `foo/outer/inner`

Dependency

To specify this setting, select the **Generate traceability report** check box.

Command-Line Information

Property: TraceabilityStyle

Type: character vector

Value: 'Line Level' | 'Comment Based'

Default: 'Line Level'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, when you generate a traceability report for the `symmetric_fir` subsystem inside the `sfir_fixed` model, specify the `TraceabilityStyle` by using either of these methods:

- Pass in the `TraceabilityStyle` property as an argument to `makehdl`.

```
makehdl('sfir_fixed/symmetric_fir','Traceability','on',...
        'TraceabilityStyle','Comment Based')
```

- Enable the `TraceabilityStyle` property using `hdlset_param`, and then use `makehdl`.

```
hdlset_param('sfir_fixed','Traceability','on')
hdlset_param(gcs,'TraceabilityStyle','Comment Based')
makehdl('sfir_fixed/symmetric_fir')
```

- `makehdl`

Generate model Web view

Include the model Web view in the HDL Code Generation report to navigate between the code and model within the same window. With a model Web view, you can click a link in the generated code to highlight the corresponding block in the model. Using this capability, you can review, analyze, and debug the generated HDL code. You can share your model and generated code outside of the MATLAB environment.

Settings

Default: Off

On

Include model Web view in the Code Generation report. To generate the report, after you enable this setting, click the **Generate** button. The code generation report contains a summary section and a code interface report along with the model web view.

Off

Do not include model Web view in the Code Generation report.

Dependencies

To include a Web view (Simulink Report Generator) of the model in the Code Generation report, you must have Simulink Report Generator™ installed.

Command-Line Information

Parameter: HDLGenerateWebview

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use `hdlset_param` or `makehdl`. To view the property value, use `hdlget_param`.

For example, you can generate a model web view when generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass in the `HDLGenerateWebview` property as an argument to `makehdl`.

```
makehdl('sfir_fixed/symmetric_fir', 'HDLGenerateWebview', 'on')
```

- Enable the `HDLGenerateWebview` property using `hdlset_param` and then use `makehdl`.

```
hdlset_param('sfir_fixed', 'HDLGenerateWebview', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “Create and Use Code Generation Reports” on page 30-2
- “Web View of Model in Code Generation Report” on page 30-13
- `makehdl`

Generate resource utilization report

Enable or disable generation of an HTML resource utilization report. The report contains a summary and detailed information about the number of hardware resources, such as multipliers, adders, and registers that are used in the generated HDL code. If you have floating-point data types in your model, you can generate HDL code with native floating point support or map your design to native floating-point libraries and Intel or Xilinx FPGA floating-point libraries. The resource utilization report displays a target-specific report corresponding to FPGA floating-point library mapping and a resource report corresponding to HDL code in native floating-point mode.

Settings

Default: Off

On

Create and display an HTML resource utilization report. To generate the report, after you enable this setting, click the **Generate** button. The code generation report contains a summary section and a code interface report along with the resource utilization report.

Off

Do not create an HTML resource utilization report.

Command-Line Information**Property:** ResourceReport**Type:** character vector**Value:** 'on' | 'off'**Default:** 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can generate a resource utilization report when generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass in the `ResourceReport` property as an argument to `makehdl`.

```
makehdl('sfir_fixed/symmetric_fir','ResourceReport','on')
```

- Enable the `ResourceReport` property using `hdlset_param` and then use `makehdl`.

```
hdlset_param('sfir_fixed','ResourceReport','on')
makehdl('sfir_fixed/symmetric_fir')
```

Generate high-level timing critical path report

Specify whether to generate a highlighting script that shows the estimated critical path. The report displays the critical path delay and generates a highlighting script as a link that you can click to highlight the estimated critical path in the generated model. If your design contains blocks without timing information, the report displays the link to another highlighting script that is generated to highlight those blocks.

Settings**Default:** Off On

Generate a highlighting script that shows the estimated critical path. To generate the report, after you enable this setting, click the **Generate** button. The code generation report contains a summary section and a code interface report along with the critical path estimation report.

To estimate the critical path for single-precision floating-point models, use the **Native Floating Point** mode. In the Configuration Parameters dialog box, in the **HDL Code Generation > Floating Point** pane, select **Use Floating Point**.

 Off

Do not calculate the estimated critical path.

Command-Line Information**Property:** CriticalPathEstimation**Type:** character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can generate a critical path estimation report when generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass in the `CriticalPathEstimation` property as an argument to `makehdl`.

```
makehdl('sfir_fixed/symmetric_fir','CriticalPathEstimation','on')
```

- Enable the `CriticalPathEstimation` property using `hdlset_param` and then use `makehdl`.

```
hdlset_param('sfir_fixed','CriticalPathEstimation','on')
makehdl('sfir_fixed/symmetric_fir')
```

See Also

- “Getting Started with HDL Coder Native Floating-Point Support” on page 14-92
- `makehdl`

Generate optimization report

Enable or disable generation of an HTML optimization report. The report contains information about the results of distributed pipelining, streaming, sharing, delay balancing, and adaptive pipelining optimizations that are implemented in the generated code. The report includes hyperlinks back to referenced blocks, subsystems, or validation models. If you have floating-point data types in your model, you can generate HDL code with native floating point support or map your design to native floating-point libraries and Intel or Xilinx FPGA floating-point libraries. When you map to FPGA floating-point libraries, the optimization report displays a target code generation section that displays the target device summary and a link to the generated model.

Settings

Default: Off

On

Create and display an HTML optimization report. To generate the report, after you enable this setting, click the **Generate** button. The code generation report contains a summary section and a code interface report along with the optimization report.

Off

Do not create an HTML optimization report.

Command-Line Information

Property: OptimizationReport

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

For example, you can generate an optimization report when generating HDL code for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass in the `OptimizationReport` property as an argument to `makehdl`.

```
makehdl('sfir_fixed/symmetric_fir', 'OptimizationReport', 'on')
```

- Enable the `OptimizationReport` property using `hdlset_param` and then use `makehdl`.

```
hdlset_param('sfir_fixed', 'OptimizationReport', 'on')
makehdl('sfir_fixed/symmetric_fir')
```

Custom Timing Database Directory

Specify the path to load your custom timing `.mat` files.

Settings

Default: ' '

Specify the path to load your custom timing `.mat` files.

Dependency

This option is disabled if you do not select the **Generate high-level timing critical path report**.

Command-Line Information

Property: `TimingDatabaseDirectory`

Type: character vector

Default: ' '

To set this property, use `hdlset_param` or `makehdl`. To view the property value, use `hdlget_param`.

For example, if you want to set the path to your custom timing database file, enter:

```
myDUT = gcb;
timingpath = '/timingfiles/customtimingreport.mat';

hdlset_param(myDUT, 'TimingDatabaseDirectory', timingpath);

makehdl(myDUT)
```

- “Test Bench Stimulus and Output Parameters” on page 23-20
- “Multi-File Testbench and Simulation Library Path Parameters” on page 23-25
- “Floating-Point Tolerance Parameters” on page 23-28

Test Bench Overview

The **Test Bench** pane lets you set options that determine characteristics of generated test bench code.

Generate Test Bench Button

The **Generate Test Bench** button initiates test bench generation for the system selected in the **Generate HDL for** menu on the parent HDL Code Generation pane. Make sure that the system selected is the DUT. Testbench generation is disabled if you select the entire model. See also `makehdltb`.

Test Bench Generation Output Parameters

To specify the type of test bench to generate for verifying the HDL code in a simulation tool, use the Test Bench Generation Output parameters setting. You can specify the configuration parameters for the test bench generation in **HDL Code Generation > Test Bench > Test Bench Generation Output**. This setting is enabled when you select the subsystem in your model. Select the subsystem in your model from the **Generate HDL for** menu on the parent **HDL Code Generation** pane, and then initiate the test bench generation for the subsystem. This setting is unavailable if you select the entire model.

HDL test bench

Enable or disable HDL test bench generation.

Settings

Default: selected

On

Enable generation of HDL test bench code. The code generator creates a HDL test bench by running a Simulink simulation to capture input vectors and expected output data for your DUT.

This test bench is the default test bench that HDL Coder generates for your model. If you have not already generated code for your model, running HDL test bench generation also generates code for your DUT.

Specify your HDL simulator in the **Simulation tool** menu. HDL Coder generates build-and-run scripts for the simulator that you specify.

Off

Suppress generation of HDL test bench code. You can use this option when you use an alternate test bench.

Dependencies

Make sure that the system selected is the DUT. This option is disabled if you select the entire model.

This check box enables the options in the **Configuration** section of the **Test Bench** pane. Select a **Simulation tool** to generate scripts to build and run the test bench.

Command-Line Information

Property: GenerateHDLTestBench

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, to generate a HDL test bench for the `sfir_fixed/symmetric_fir` Subsystem, pass the DUT as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir')
```

Cosimulation model

Enable or disable generation of a model including a HDL Cosimulation block. This option requires an HDL Verifier license. After you select this check box, specify your **Simulation tool**. You can select Mentor Graphics ModelSim, Cadence Incisive®, or Xilinx Vivado Simulator for cosimulation. Custom script settings are not supported with this test bench.

The code generator configures the generated HDL Cosimulation blocks to conform to the port and data type interface of the DUT selected for code generation. By connecting an HDL Cosimulation block to your model in place of the DUT, you can cosimulate your design with the desired simulator.

The coder appends the character vector that the `CosimLibPostfix` property specifies to the names of the generated HDL Cosimulation blocks.

Settings

Default: not selected

Dependencies

Make sure that the system selected is the DUT. This option is disabled if you select the entire model.

Command-Line Information

Property: `GenerateCoSimBlock`

Type: character vector

Value: 'on' | 'off'

Default: 'off'

Property: `GenerateCoSimModel`

Type: character vector

Value: 'ModelSim' | 'Incisive' | 'Vivado Simulator' | 'None'

Default: 'ModelSim'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can enable the `GenerateCoSimModel` property when you generate a testbench for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'GenerateCoSimModel', 'ModelSim')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'GenerateCoSimModel', 'ModelSim')
makehdltb('sfir_fixed/symmetric_fir')
```

SystemVerilog DPI test bench

Enable or disable generation of SystemVerilog DPI test bench. Select your HDL simulator at **Simulation tool**. For SystemVerilog DPI test bench you can select Mentor Graphics ModelSim, Cadence Incisive, Synopsys , or Xilinx Vivado. The command line option also includes a VCS® simulator. Custom script settings are not supported with this test bench.

When you set this property, the code generator generates a direct programming interface (DPI) component for your entire Simulink model, including your DUT and data sources. Your entire model must support C code generation with Simulink Coder. The code generator generates a SystemVerilog test bench that compares the output of the DPI component with the output of the HDL implementation of your DUT. The coder also builds shared libraries and generates a simulation script for the simulator you select.

Consider using this option if the default HDL test bench takes a long time to generate or simulate. Generation of a DPI test bench is sometimes faster than the default version because it does not run a full Simulink simulation to create the test bench data. Simulation of a DPI test bench with a large data set is faster than the default version because it does not store the input or expected data in a separate file.

To use this capability, you must have HDL Verifier and Simulink Coder. To run the SystemVerilog test bench with generated VHDL code, you must have a mixed-language simulation license for your HDL simulator.

Settings

Default: not selected

Dependencies

Make sure that the system selected is the DUT. This option is disabled if you select the entire model.

Limitations

Your DUT subsystem must meet the following conditions:

- Input and output data types of the DUT cannot be larger than 64 bits.
- Input and output ports of the DUT cannot use enumerated data types.
- Input and output ports cannot be single-precision or double-precision data types.
- The DUT cannot have multiple clocks. You must set the **Clock inputs** code generation option to Single.
- **Use trigger signal as clock** must not be selected.
- If the DUT uses vector ports, you must use **Scalarize vector ports** to flatten the interface.

Command-Line Information

Property: GenerateSVDPIBench

Type: character vector

Value: 'ModelSim' | 'Incisive' | 'Custom' | 'VCS' | 'Vivado Simulator'

Default: 'ModelSim'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can enable the `GenerateCoSimModel` property when you generate a testbench for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'GenerateSVDPICTestBench', 'ModelSim')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'GenerateSVDPICTestBench', 'ModelSim')
makehdltb('sfir_fixed/symmetric_fir')
```

Simulation tool

Simulator where you run the generated test benches. The tool generates a script to build and run your HDL code and test bench.

Settings

- **Mentor Graphics ModelSim:** This option is the default. HDL Coder generates the selected types of test benches for use with Mentor Graphics ModelSim.
- **Cadence Incisive:** The coder generates the selected types of test benches for use with Cadence Incisive.
- **Xilinx Vivado Simulator:** The coder generates the selected types of test benches for use with Xilinx Vivado simulator.
- **Custom:** Selecting this option enables the custom script options on the **EDA Tool Scripts** pane.
- **VCS:** This simulator is supported only for **SystemVerilog DPI test bench**.

Dependencies

Make sure that the system selected is the DUT. This option is disabled if you select the entire model.

Command-Line Information

For HDL test bench, use the `SimulationTool` property. For cosimulation, use the `GenerateCosimModel` property. For SystemVerilog DPI test bench, use the `GenerateSVDPICTestbench` property.

Property: `SimulationTool`

Type: character vector

Value: 'Mentor Graphics ModelSim' | 'Cadence Incisive' | 'Xilinx Vivado Simulator' | 'Custom'

Default: 'Mentor Graphics ModelSim'
Property: GenerateCosimModel
Type: character vector
Value: 'ModelSim' | 'Incisive' | 'Vivado Simulator' | 'None'
Default: 'ModelSim'
Property: GenerateSVDPIITestbench
Type: character vector
Value: 'ModelSim' | 'Incisive' | 'Custom' | 'VCS' | 'Vivado'
Default: 'ModelSim'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

HDL code coverage

Enable or disable HDL code coverage flags in the generated simulator scripts

With this option enabled, when you run the HDL simulation, code coverage is collected for your generated test bench. Specify your HDL simulator in the `SimulationTool` property. The coder generates build-and-run scripts for the simulator you specify.

Settings

Default: not selected

Dependencies

Make sure that the system selected is the DUT. This option is disabled if you select the entire model.

This option is ignored when `GenerateCoSimBlock` is selected and `SimulationTool` is set to 'Xilinx Vivado Simulator'.

Command-Line Information

Property: HDLCodeCoverage
Type: character vector
Value: 'on' | 'off'
Default: 'off'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can enable the `HDLCodeCoverage` property when you generate a testbench for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'HDLCodeCoverage', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'HDLCodeCoverage', 'on')
makehdltb('sfir_fixed/symmetric_fir')
```

Test Bench Postfix Parameters

This page describes configuration parameters that reside in the **HDL Code Generation > Test Bench** tab of the Configuration Parameters dialog box. Using the parameters in this tab, you can customize the postfix for the test bench name, data file, and test bench reference.

Test bench name postfix

Specify a suffix appended to the test bench name.

Settings

Default: `_tb`

For example, if the name of your DUT is `my_test`, HDL Coder adds the default postfix `_tb` to form the name `my_test_tb`.

Dependencies

Make sure that the system selected is the DUT. This option is disabled if you select the entire model.

Command-Line Information

Property: `TestBenchPostFix`

Type: character vector

Default: `'_tb'`

To set this property, use `hdlset_param` or `makehdl.tb`. To view the property value, use `hdlget_param`.

Test bench reference postfix

Specify a character vector to be appended to names of reference signals generated in test bench code.

Settings

Default: `'_ref'`

Reference signal data is represented as arrays in the generated test bench code. The character vector specified by **Test bench reference postfix** is appended to the generated signal names.

Dependencies

Make sure that the system selected is the DUT. This option is disabled if you select the entire model.

Command-Line Information

Parameter: `TestBenchReferencePostFix`

Type: character vector

Default: `'_ref'`

To set this property, use `hdlset_param` or `makehdl.tb`. To view the property value, use `hdlget_param`.

Test bench data file name postfix

Specify suffix added to test bench data file name when generating multi-file test bench.

Settings

Default: '_data'

HDL Coder applies the **Test bench data file name postfix** character vector only when generating a multi-file test bench (i.e., when **Multi-file test bench** is selected).

For example, if the name of your DUT is `my_test`, and **Test bench name postfix** has the default value `_tb`, the coder adds the postfix `_data` to form the test bench data file name `my_test_tb_data`.

Dependency

This parameter is enabled by **Multi-file test bench**.

Command-Line Information

Property: TestBenchDataPostFix

Type: character vector

Default: '_data'

To set this property, use `hdlset_param` or `makehdl.tb`. To view the property value, use `hdlget_param`.

Clock and Reset Input Parameters for Testbench

This page describes configuration parameters that reside in the **HDL Code Generation > Test Bench** tab of the Configuration Parameters dialog box. Using the parameters in this tab, you can specify the clock high time, clock low time, and whether you want the test bench to force clock, reset, and clock enable input signals.

Force clock

Specify whether the test bench forces clock input signals.

Settings

Default: On

On

The test bench forces the clock input signals. When this option is selected, the clock high and low time settings control the clock waveform.

Off

A user-defined external source forces the clock input signals.

Dependencies

This property enables the **Clock high time** and **Clock low time** options. This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Property: ForceClock

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
         'ForceClock', 'off')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'ForceClock', 'off')
makehdltb('sfir_fixed/symmetric_fir')
```

Clock high time (ns)

Specify the period, in nanoseconds, during which the test bench drives clock input signals high (1).

Settings

Default: 5

Specify a positive integer value. The **Clock high time** and **Clock low time** properties define the period and duty cycle for the clock signal. Using the defaults, the clock signal is a square wave (50% duty cycle) with a period of 10 ns.

Dependency

This parameter is enabled when **Force clock** is selected.

Command-Line Information

Property: ClockHighTime

Type: integer

Value: positive integer

Default: 5

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'ClockHighTime', 2)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'ClockHighTime', 2)
makehdltb('sfir_fixed/symmetric_fir')
```

Clock low time (ns)

Specify the period, in nanoseconds, during which the test bench drives clock input signals low (0).

Settings

Default: 5

The **Clock high time** and **Clock low time** properties define the period and duty cycle for the clock signal. Using the defaults, the clock signal is a square wave (50% duty cycle) with a period of 10 ns.

Dependency

This parameter is enabled when **Force clock** is selected.

Command-Line Information

Property: ClockLowTime

Type: integer
Value: positive integer
Default: 5

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
         'ClockLowTime', 2)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'ClockLowTime', 2)
makehdltb('sfir_fixed/symmetric_fir')
```

Force clock enable

Specify whether the test bench forces clock enable input signals.

Settings

Default: On

On

The test bench forces the clock enable input signals to active-high (1) or active-low (0), depending on the setting of the clock enable input value.

Off

A user-defined external source forces the clock enable input signals.

Dependencies

This property enables the **Clock enable delay (in clock cycles)** option.

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Property: ForceClockEnable

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'ForceClockEnable', 'off')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'ForceClockEnable', 'off')
makehdltb('sfir_fixed/symmetric_fir')
```

Clock enable delay (in clock cycles)

Define elapsed time (in clock cycles) between deassertion of reset and assertion of clock enable.

Settings

Default: 1

The **Clock enable delay (in clock cycles)** property defines the number of clock cycles elapsed between the time the reset signal is deasserted and the time the clock enable signal is first asserted. In the figure below, the reset signal (active-high) deasserts after 2 clock cycles and the clock enable asserts after a clock enable delay of 1 cycle (the default).

In the figure below, the reset signal (active-high) de-asserts after the interval labelled **Hold Time**. The clock enable asserts after a further interval labelled **Clock enable delay**.

Dependency

This parameter is enabled when **Force clock enable** is selected.

Command-Line Information

Property: TestBenchClockEnableDelay

Type: integer

Default: 1

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'TestBenchClockEnableDelay', 2)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'TestBenchClockEnableDelay', 2)
makehdltb('sfir_fixed/symmetric_fir')
```

Force reset

Specify whether the test bench forces reset input signals.

Settings

Default: On

On

The test bench forces the reset input signals.

Off

A user-defined external source forces the reset input signals.

Tips

If you select this option, you can use the **Hold time** option to control the timing of a reset.

Dependency

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Property: ForceReset

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'ForceReset', 'off')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'ForceReset', 'off')
makehdltb('sfir_fixed/symmetric_fir')
```

Reset length (in clock cycles)

Define length of time (in clock cycles) during which reset is asserted.

Settings

Default: 2

The **Reset length (in clock cycles)** property defines the number of clock cycles during which reset is asserted. **Reset length (in clock cycles)** must be an integer greater than or equal to 0. The following figure illustrates the default case, in which the reset signal (active-high) is asserted for 2 clock cycles.

Dependency

This parameter is enabled when **Force reset** is selected.

Command-Line Information

Property: Resetlength

Type: integer

Default: 2

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
         'Resetlength', 4)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'Resetlength', 4)  
makehdltb('sfir_fixed/symmetric_fir')
```

Setup and Hold Time Parameters for Testbench

This page describes configuration parameters that reside in the **HDL Code Generation > Test Bench** tab of the Configuration Parameters dialog box. Using the parameters in this tab, you can specify the setup time for data input and hold time for data input and forced reset signal signals.

Hold time (ns)

Specify a hold time, in nanoseconds, for input signals and forced reset input signals.

Settings

Default: 2 (given the default clock period of 10 ns)

The hold time defines the number of nanoseconds that reset input signals and input data are held past the clock rising edge. The hold time is expressed as a positive integer or double (with a maximum of 6 significant digits after the decimal point).

Tips

- The specified hold time must be less than the clock period (specified by the **Clock high time** and **Clock low time** properties).
- This option applies to reset input signals only if **Force reset** is selected.

Usage Notes

Hold Time for Reset Input Signals

The hold time is the amount of time that reset input signals and input data are held past the clock rising edge. The following figures show the application of a hold time (t_{hold}) for reset and data input signals when the signals are forced to active high and active low.

Hold Time for Data Input Signals

Note A reset signal is always asserted for two cycles plus t_{hold} .

Dependencies

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Property: HoldTime

Type: integer

Value: positive integer

Default: 2

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
         'HoldTime', 4)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'HoldTime', 4)
makehdltb('sfir_fixed/symmetric_fir')
```

Setup time (ns)

Display setup time for data input signals.

Settings

Default: None

This is a display-only field, showing a value computed as $(\text{clock period} - \text{HoldTime})$ in nanoseconds.

Dependency

The value displayed in this field depends on the clock rate and the values of the **Hold time** property.

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Because this is a display-only field, a corresponding command-line property does not exist.

Test Bench Stimulus and Output Parameters

This page describes configuration parameters that reside in the **HDL Code Generation > Test Bench** tab of the Configuration Parameters dialog box. Using the parameters in this tab, you can specify whether to ignore data checking, and hold input data between samples.

Hold input data between samples

Specify how long subrate signal values are held in valid state.

Settings

Default: On

On

Data values for subrate signals are held in a valid state across N base-rate clock cycles, where N is the number of base-rate clock cycles that elapse per subrate sample period. (N >= 2.)

Off

Data values for subrate signals are held in a valid state for only one base-rate clock cycle. For the subsequent base-rate cycles, data is in an unknown state (expressed as 'X') until leading edge of the next subrate sample period.

Tip

In most cases, the default (On) is the best setting for **Hold input data between samples**. This setting matches the behavior of a Simulink simulation, in which subrate signals are held valid through each base-rate clock period.

In some cases (for example modeling memory or memory interfaces), it is desirable to clear **Hold input data between samples**. In this way you can obtain diagnostic information about when data is in an invalid ('X') state.

Dependency

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Property: HoldInputDataBetweenSamples

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'HoldInputDataBetweenSamples', 'off')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'HoldInputDataBetweenSamples', 'off')
makehdltb('sfir_fixed/symmetric_fir')
```

Initialize test bench inputs

Specify initial value driven on test bench inputs before data is asserted to DUT.

Settings

Default: Off

On

Initial value driven on test bench inputs is '0'.

Off

Initial value driven on test bench inputs is 'X' (unknown).

Dependency

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Property: InitializeTestBenchInputs

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'InitializeTestBenchInputs', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'InitializeTestBenchInputs', 'on')
makehdltb('sfir_fixed/symmetric_fir')
```

Ignore output data checking (number of samples)

Specify number of samples during which output data checking is suppressed.

Settings

Default: 0

The value must be a positive integer.

When the value of **Ignore output data checking (number of samples)**, N, is greater than zero, the test bench suppresses output data checking for the first N output samples after the clock enable output (`ce_out`) is asserted.

When using pipelined block implementations, output data may be in an invalid state for some number of samples. To avoid spurious test bench errors, determine this number and set **Ignore output data checking (number of samples)** accordingly.

Be careful to specify N as a number of samples, not as a number of clock cycles. For a single-rate model, these are equivalent, but they are not equivalent for a multirate model.

You should use **Ignore output data checking (number of samples)** in cases where there is a state (register) initial condition in the HDL code that does not match the Simulink state, including the following specific cases:

- When you set the `DistributedPipelining` property to 'on' for the MATLAB Function block (see “Use Distributed Pipelining Optimization in Models with MATLAB Function Blocks” on page 34-32)
- When you set the `ResetType` property to 'None' for the following blocks:
 - `commcnvintrlv2/Convolutional Deinterleaver`
 - `commcnvintrlv2/Convolutional Interleaver`
 - `commcnvintrlv2/General Multiplexed Deinterleaver`
 - `commcnvintrlv2/General Multiplexed Interleaver`
 - `dpsigops/Delay`
 - `simulink/Additional Math & Discrete/Additional Discrete/Unit Delay Enabled`
 - `simulink/Commonly Used Blocks/Unit Delay`
 - `simulink/Discrete/Delay`
 - `simulink/Discrete/Memory`
 - `simulink/Discrete/Tapped Delay`
 - `simulink/User-Defined Functions/MATLAB Function`
 - `sflib/Chart`
 - `sflib/Truth Table`
- When generating a black box interface to existing manually written HDL code

Dependency

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information**Property:** IgnoreDataChecking**Type:** integer**Default:** 0

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'IgnoreDataChecking', 2)
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'IgnoreDataChecking', 2)
makehdltb('sfir_fixed/symmetric_fir')
```

Use file I/O to read/write test bench data

Create and use data files for reading and writing test bench input and output data.

Settings**Default:** On On

Create and use data files for reading and writing test bench input and output data.

 Off

Use constants in the test bench for DUT stimulus and reference data.

Dependency

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information**Property:** UseFileIOInTestBench**Type:** character vector**Value:** 'on' | 'off'**Default:** 'on'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...  
         'UseFileIOInTestBench', 'off')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'UseFileIOInTestBench', 'off')  
makehdltb('sfir_fixed/symmetric_fir')
```

Multi-File Testbench and Simulation Library Path Parameters

This page describes configuration parameters that reside in the **HDL Code Generation > Test Bench** tab of the Configuration Parameters dialog box. Using the parameters in this tab, you can specify the simulation library path and whether to generate a multi-file testbench.

Multi-file test bench

Divide generated test bench into helper functions, data, and HDL test bench code files.

Description

You can use this setting to specify how you want to divide files that contain the test bench code, data, and helper functions.

The file names are derived from the name of the DUT, the **Test bench name postfix** property, and the **Test bench data file name postfix** property as:

DUTname_TestBenchPostfix_TestBenchDataPostfix

For example, if the DUT name is `symmetric_fir`, and the target language is VHDL, the default test bench file names are:

- `symmetric_fir_tb.vhd`: test bench code
- `symmetric_fir_tb_pkg.vhd`: helper functions package
- `symmetric_fir_tb_data.vhd`: data package

If the DUT name is `symmetric_fir` and the target language is Verilog, the default test bench file names are:

- `symmetric_fir_tb.v`: test bench code
- `symmetric_fir_tb_pkg.v`: helper functions package
- `symmetric_fir_tb_data.v`: test bench data

Settings

Default: Off

On

Write three separate HDL files. There is a separate file for test bench code, helper functions, and test bench data.

Off

Write two separate HDL files. One file contains the HDL test bench code. The other file contains the helper functions package and test bench data.

Dependency

When this property is selected, **Test bench data file name postfix** is enabled.

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Property: MultifileTestBench

Type: character vector

Value: 'on' | 'off'

Default: 'off'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, you can specify this parameter for the `symmetric_fir` subsystem inside the `sfir_fixed` model using either of these methods.

- Pass the property as an argument to the `makehdltb` function.

```
makehdltb('sfir_fixed/symmetric_fir', ...
          'MultifileTestBench', 'on')
```

- When you use `hdlset_param`, you can set the parameter on the model and then generate HDL code using `makehdltb`.

```
hdlset_param('sfir_fixed', 'MultifileTestBench', 'on')
makehdltb('sfir_fixed/symmetric_fir')
```

Simulation library path

Specify the path to your compiled Altera or Xilinx simulation libraries.

Settings

Default: ''

Specify the path to the compiled Altera or Xilinx simulation libraries. Altera provides the simulation model files in `\quartus\eda\sim_lib` folder.

Dependency

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Property: SimulationLibPath

Type: character vector

Default: ''

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, if you want to set the path to the compiled Xilinx Simulation library, enter:

```
myDUT = gcb;
```

```
libpath = '/apps/Xilinx_ISE/XilinxISE-13.4/Linux/ISE_DS/ISE/vhdl/
```

```
    mti_se/6.6a/lin64/xilinxcorelib';  
hdlset_param (myDUT, 'SimulationLibPath', libpath);  
makehdltb(myDUT)
```

Floating-Point Tolerance Parameters

This page describes configuration parameters that reside in the **HDL Code Generation > Test Bench** tab of the Configuration Parameters dialog box. Using the parameters in this tab, you can specify the floating-point tolerance strategy and the tolerance value.

Floating point tolerance check based on

When you map your design to the native floating-point libraries or the floating-point target libraries, specify the floating-point tolerance check option.

Settings

Default: relative error

Select one of these options from the drop-down menu:

- **relative error:** This is the default option. When you verify the generated code by using HDL Testbench, HDL Coder checks for the floating-point tolerance of the native floating-point library or the floating-point target library that your design mapped to based on the relative error.
- **ulp error:** When you verify the generated code by using HDL Testbench, HDL Coder checks for the floating-point tolerance of the native floating-point library or the floating-point target library that your design mapped to based on the ULP error.

Dependency

This option is disabled if you select the entire model. Select the DUT instead for **Generate HDL for** setting.

Command-Line Information

Property: FPToleranceStrategy

Type: character vector

Value: 'relative' | 'ULP'

Default: 'relative'

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, to specify the floating-point tolerance value for a model, use the `hdlset_param` function to specify the tolerance strategy, and then enter the tolerance value. For example, to check the floating-point tolerance based on ULP error and enter the tolerance value:

```
% Check for floating-point tolerance based on ULP
hdlset_param('sfir_single', 'FPToleranceStrategy', 'ULP');

% When using ULP, optionally enter tolerance value >= 0
hdlset_param('FP_test_16a', 'FPToleranceValue', 1);

% Generate HDL testbench with specified tolerance setting
makehdltb('sfir_single/symmetric_fir')
```

Tolerance Value

Enter the tolerance value based on the floating-point tolerance check setting that you specify.

Settings

Default: 1e-07

The value must be a positive integer or a double data type.

The default tolerance value depends on the floating-point tolerance check setting that you specify. When you set the **Floating point tolerance check based on** to:

- **relative error**, the default is a **Tolerance Value** of 1e-07. When you use this floating-point tolerance check setting, specify the tolerance value as a double data type. You can specify a **Tolerance Value**, N, that is less than or equal to 1e-07.
- **ulp error**, the default is a **Tolerance Value** of 0. When you use this floating-point tolerance check setting, specify the tolerance value as an integer. You can specify a **Tolerance Value**, N, that is greater than or equal to 0.

Command-Line Information

Property: FPToleranceValue

Type: double | integer

Default: 1e-07

To set this property, use `hdlset_param` or `makehdltb`. To view the property value, use `hdlget_param`.

For example, to specify the floating-point tolerance value for a model, use the `hdlset_param` function to specify the tolerance strategy, and then enter the tolerance value. For example, to check the floating-point tolerance based on ULP error and enter the tolerance value:

```
% Check for floating-point tolerance based on ULP
hdlset_param('sfir_single', 'FPToleranceStrategy', 'ULP');

% When using ULP, optionally enter tolerance value >= 0
hdlset_param('FP_test_16a', 'FPToleranceValue', 1);

% Generate HDL testbench with specified tolerance setting
makehdltb('sfir_single/symmetric_fir')
```

HDL Code Generation Pane: EDA Tool Scripts

- “EDA Tool Scripts Overview” on page 24-2
- “Generate EDA scripts” on page 24-3
- “Compilation Script Parameters” on page 24-4
- “Simulation Script Parameters” on page 24-7
- “Synthesis Script Parameters” on page 24-11
- “Lint Script Parameters” on page 24-17

EDA Tool Scripts Overview

The **EDA Tool Scripts** pane lets you set the options that control generation of script files for third-party HDL simulation and synthesis tools.

Generate EDA scripts

Enable generation of script files for third-party electronic design automation (EDA) tools. These scripts let you compile and simulate generated HDL code and/or synthesize generated HDL code.

Settings

Default: On

On

Generation of script files is enabled.

Off

Generation of script files is disabled.

Command-Line Information

Parameter: EDAScriptGeneration

Type: character vector

Value: 'on' | 'off'

Default: 'on'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Compilation Script Parameters

This page describes configuration parameters that reside in the **HDL Code Generation > EDA Tool Scripts > Compilation Script** tab of the Configuration Parameters dialog box.

Compile file postfix

Specify a postfix to append to the DUT or test bench name to form the compilation script file name.

Settings

Default: `_compile.do`

For example, if the name of the device under test or test bench is `my_design`, HDL Coder adds the postfix `_compile.do` to form the name `my_design_compile.do`.

Command-Line Information

Property: `HDLCompileFilePostfix`

Type: character vector

Default: `'_compile.do'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Compile initialization

Format name passed to `fprintf` to write the Init section of the compilation script.

Settings

Default: `vlib %s\n`

The Init phase of the script performs required setup actions, such as creating a design library or a project file.

The implicit argument, `%s`, is the contents of the `'VHDLLibraryName'` property, which defaults to `'work'`. You can override the default Init string (`'vlib work\n'`) by changing the value of `'VHDLLibraryName'`.

Command-Line Information

Property: `HDLCompileInit`

Type: character vector

Default: `'vlib %s\n'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Compile command for VHDL

Format name passed to `fprintf` to write the `Cmd` section of the compilation script for VHDL files.

Settings

Default: `vcom %s %s\n`

The command-per-file phase (`Cmd`) of the script is called iteratively, once per generated HDL file. On each call, a different file name is passed in.

The two implicit arguments in the compile command are the contents of the `SimulatorFlags` property and the file name of the current entity or module. To omit the flags, set `SimulatorFlags` to `' '` (the default).

Command-Line Information

Property: `HDLCompileVHDLCmd`

Type: character vector

Default: `'vcom %s %s\n'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Compile command for Verilog

Format name passed to `fprintf` to write the `Cmd` section of the compilation script for Verilog files.

Settings

Default: `vlog %s %s\n`

The command-per-file phase (`Cmd`) of the script is called iteratively, once per generated HDL file. On each call, a different file name is passed in.

The two implicit arguments in the compile command are the contents of the `SimulatorFlags` property and the file name of the current entity or module. To omit the flags, set `SimulatorFlags` property to `' '` (the default).

Command-Line Information

Property: `HDLCompileVerilogCmd`

Type: character vector

Default: 'vlog %s %s\n'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Compile termination

Format name passed to `fprintf` to write the termination portion of the compilation script.

Settings

Default: empty character vector

The termination phase (`Term`) is the final execution phase of the script. One application of this phase is to execute a simulation of HDL code that was compiled in the `Cmd` phase. The `Term` phase does not take arguments.

Command-Line Information

Property: `HDLCompileTerm`

Type: character vector

Default: ''

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Simulation Script Parameters

This page describes configuration parameters that reside in the **HDL Code Generation > EDA Tool Scripts > Simulation Script** tab of the Configuration Parameters dialog box.

Simulation file postfix

Specify a postfix to append to the DUT or test bench name to form the simulation script file name.

Settings

Default: `_sim.do`

For example, if the name of the device under test or test bench is `my_design`, HDL Coder adds the postfix `_sim.do` to form the name `my_design_sim.do`.

Command-Line Information

Property: `HDLSimFilePostfix`

Type: character vector

Default: `'_sim.do'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Simulation initialization

Format name passed to `fprintf` to write the initialization section of the simulation script.

Settings

Default: The default is

```
['onbreak resume\nonerror resume\n']
```

The `Init` phase of the script performs required setup actions, such as creating a design library or a project file.

Command-Line Information

Property: `HDLSimInit`

Type: character vector

Default: `['onbreak resume\nonerror resume\n']`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Simulation command

Format name passed to `fprintf` to write the simulation command.

Settings

Default: `vsim -voptargs=+acc %s.%s\n`

The first implicit argument, `%s`, is the library name. The second implicit argument is the top-level module or entity name. If your target language is VHDL, the library name is the value of “VHDL library name” on page 21-30. If your target language is Verilog, the library name is 'work' and cannot be changed.

If you compile your filter design with code from other libraries, update **VHDL library name** to avoid library name conflicts.

Note Prior to R2020b, the default simulation command was `vsim -novopt %s.%s\n`. Mentor Graphics ModelSim versions prior to 10.7 support the former syntax. If you use a more recent Mentor Graphics ModelSim version, use the `vsim -voptargs=+acc %s.%s\n` syntax.

Command-Line Information

Property: HDLSimCmd

Type: character vector

Default: `'vsim -novopt %s.%s\n'`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Simulation waveform viewing command

Specify the waveform viewing command written to simulation script.

Settings

Default: `add wave sim:%s\n`

The implicit argument, `%s`, adds the signal paths for the DUT top-level input, output, and output reference signals.

Command-Line Information**Property:** HDLSimViewWaveCmd**Type:** character vector**Default:** 'add wave sim:%s\n'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Simulation termination

Format name passed to `fprintf` to write the termination portion of the simulation script.

Settings**Default:** `run -all\n`

The termination phase (Term) is the final execution phase of the script. One application of this phase is to execute a simulation of HDL code that was compiled in the Cmd phase. The Term phase does not take arguments.

Command-Line Information**Property:** HDLSimTerm**Type:** character vector**Default:** 'run -all\n'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Simulator flags

Specify simulator flags to apply to generated compilation scripts.

Settings**Default:** '' (no simulator flags)

Specify simulator flags to apply to generated compilation scripts as a character vector. The simulator flags are specific to your application and the simulator you are using. For example, if you must use the 1076-1993 VHDL compiler, specify the flag `-93`.

The flags you specify with this option are added to the compilation command in generated compilation scripts. The simulation command is specified by the HDLCompileVHDLCmd or HDLCompileVerilogCmd properties.

Command-Line Information

Property: SimulatorFlags

Type: character vector

Default: ''

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Synthesis Script Parameters

This page describes configuration parameters that reside in the **HDL Code Generation > EDA Tool Scripts > Synthesis Script** tab of the Configuration Parameters dialog box.

Choose synthesis tool

Enable or disable generation of synthesis scripts, and select the synthesis tool for which HDL Coder generates scripts.

Settings

Default: None

None

When you select **None**, HDL Coder does not generate a synthesis script. The coder clears and disables the fields in the **Synthesis script** pane.

Xilinx ISE

Generate a synthesis script for Xilinx ISE. When you select this option, the coder:

- Enables the fields in the **Synthesis script** pane.
- Sets **Synthesis file postfix** to `_ise.tcl`
- Fills in the **Synthesis initialization**, **Synthesis command** and **Synthesis termination** fields with TCL script code for the tool.

Microchip Libero

Generate a synthesis script for Microchip Libero. When you select this option, the coder:

- Enables the fields in the **Synthesis script** pane.
- Sets **Synthesis file postfix** to `_libero.tcl`
- Fills in the **Synthesis initialization**, **Synthesis command** and **Synthesis termination** fields with TCL script code for the tool.

Mentor Graphics Precision

Generate a synthesis script for Mentor Graphics Precision. When you select this option, the coder:

- Enables the fields in the **Synthesis script** pane.
- Sets **Synthesis file postfix** to `_precision.tcl`
- Fills in the **Synthesis initialization**, **Synthesis command** and **Synthesis termination** fields with TCL script code for the tool.

Altera Quartus II

Generate a synthesis script for Altera Quartus II. When you select this option, the coder:

- Enables the fields in the **Synthesis script** pane.
- Sets **Synthesis file postfix** to `_quartus.tcl`
- Fills in the **Synthesis initialization**, **Synthesis command** and **Synthesis termination** fields with TCL script code for the tool.

Synopsys Synplify Pro

Generate a synthesis script for Synopsys Synplify Pro. When you select this option, the coder:

- Enables the fields in the **Synthesis script** pane.
- Sets **Synthesis file postfix** to `_synplify.tcl`
- Fills in the **Synthesis initialization**, **Synthesis command** and **Synthesis termination** fields with TCL script code for the tool.

Xilinx Vivado

Generate a synthesis script for Xilinx Vivado. When you select this option, the coder:

- Enables the fields in the **Synthesis script** pane.
- Sets **Synthesis file postfix** to `_vivado.tcl`
- Fills in the **Synthesis initialization**, **Synthesis command** and **Synthesis termination** fields with TCL script code for the tool.

Custom

Generate a custom synthesis script. When you select this option, the coder:

- Enables the fields in the **Synthesis script** pane.
- Sets **Synthesis file postfix** to `_custom.tcl`
- Fills in the **Synthesis initialization**, **Synthesis command** and **Synthesis termination** fields with example TCL script code.

Command-Line Information

Property: HDLSynthTool

Type: character vector

Value: 'None' | 'ISE' | 'Libero' | 'Precision' | 'Quartus' | 'Synplify' | 'Vivado' | 'Custom'

Default: 'None'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Synthesis file postfix

Specify a postfix to append to file name for generated synthesis scripts.

Settings

Default: None.

Your choice of synthesis tool (from the **Choose synthesis tool** pulldown menu) sets the postfix for generated synthesis file names to one of the following:

```

_ise.tcl
_libero.tcl
_precision.tcl
_quartus.tcl
_synplify.tcl
_vivado.tcl
_custom.tcl

```

For example, if the DUT name is `my_design` and the choice of synthesis tool is Synopsys Synplify Pro, HDL Coder adds the postfix `_synplify.tcl` to form the name `my_design_synplify.tcl`.

Dependency

To use this setting, the **Choose synthesis tool** or `HDLSynthTool` property must be set to a value other than `None`.

Command-Line Information

Property: `HDLSynthFilePostfix`

Type: character vector

Default: none

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Synthesis initialization

Format name passed to `fprintf` to write the initialization section of the synthesis script.

Settings

Default: none.

Your choice of synthesis tool (from the **Choose synthesis tool** pulldown menu) sets the **Synthesis initialization** string. The content of the string is specific to the selected synthesis tool.

The default is a synthesis project creation command passed as a format string to `fprintf` to write the `Init` section of the synthesis script. The implicit argument, `%s`, is the top-level module or entity name.

Dependency

To use this setting, the **Choose synthesis tool** or `HDLSynthTool` property must be set to a value other than `None`.

Command-Line Information

Property: `HDLSynthInit`

Type: character vector

Default: none

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Synthesis command

Format name passed to `fprintf` to write the synthesis command.

Settings

Default: none.

Your choice of synthesis tool (from the **Choose synthesis tool** menu) sets the **Synthesis command** string. The content of the string is specific to the selected synthesis tool.

The default is a format string passed to `fprintf` to write the `Cmd` section of the synthesis script. The implicit argument, `%s`, is the file name of the entity or module. The command is iterated for each generated file.

To avoid issues when generating synthesis scripts for various tools, retain both format specifiers (`%s`).

Dependency

To use this setting, the **Choose synthesis tool** or `HDLSynthTool` property must be set to a value other than `None`.

Command-Line Information

Property: `HDLSynthCmd`

Type: character vector

Default: none

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Synthesis termination

Specify a format name that is passed to `fprintf` to write the termination portion of the synthesis script.

Settings

Default: none

Your choice of synthesis tool (from the **Choose synthesis tool** pulldown menu) sets the **Synthesis termination** string. The content of the string is specific to the selected synthesis tool.

The default is a format name passed to `fprintf` to write the Term section of the synthesis script. The termination string does not take arguments.

Dependency

To use this setting, the **Choose synthesis tool** or `HDLSynthTool` property must be set to a value other than `None`.

Command-Line Information

Property: `HDLSynthTerm`

Type: character vector

Default: none

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

- “Generate Scripts for Compilation, Simulation, and Synthesis” on page 35-2
- “Configure Compilation, Simulation, Synthesis, and Lint Scripts” on page 35-7

Additional files to add to synthesis project

Include additional HDL or constraint files in synthesis project.

Settings

Default: `''` (no files added)

Additional project files, such as HDL source files (`.v`, `.vhd`) or constraint files (`.ucf`), that you want to include in your synthesis project, specified as a character vector. Separate file names with a semicolon (`;`).

You cannot use this setting to include Tcl files. To specify synthesis project Tcl files, use the `AdditionalProjectCreationTclFiles` property of the `hdlcoder.WorkflowConfig` object.

Command-Line Information

Property: `SynthesisProjectAdditionalFiles`

Type: character vector

Default: `''`

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

To include a source file, `src_file.vhd`, and a constraint file, `constraint_file.ucf`, in the synthesis project for a DUT subsystem, `myDUT`:

```
hdlset_param (myDUT, 'SynthesisProjectAdditionalFiles', ...  
              'L:\src_file.vhd;L:\constraint_file.ucf;')
```

Lint Script Parameters

This page describes configuration parameters that reside in the **HDL Code Generation > EDA Tool Scripts > Lint Script** tab of the Configuration Parameters dialog box.

Choose HDL lint tool

Enable or disable generation of an HDL lint script, and select the HDL lint tool for which HDL Coder generates a script.

After you select an HDL lint tool, the **Lint initialization**, **Lint command** and **Lint termination** fields are enabled.

Dependencies

If you set the HDL lint tool to one of the supported third-party tools, you can generate a Tcl script without setting **Lint initialization**, **Lint command**, and **Lint termination** to nondefault values. If the **Lint initialization**, **Lint command**, and **Lint termination** have default values, HDL Coder automatically writes tool-specific default initialization, command, and termination strings to the Tcl script.

Settings

Default: None

None

When you select **None**, the coder does not generate a lint script. The coder clears and disables the fields in the **Lint script** pane.

Ascent Lint

Generate a lint script for Real Intent Ascent Lint.

HDL Designer

Generate a lint script for Mentor Graphics HDL Designer.

Leda

Generate a lint script for Synopsys Leda.

SpyGlass

Generate a lint script for Atrenta SpyGlass.

Custom

Generate a custom synthesis script.

Command-Line Information

Property: HDLLintTool

Type: character vector

Value: 'None' | 'AscentLint' | 'Leda' | 'SpyGlass' | 'Custom'

Default: 'None'

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

“Generate HDL Lint Tool Script” on page 31-45

Lint initialization

Enter an initialization text for your HDL lint script.

Dependencies

If **Lint initialization** is set to the default value, ' ', and you set HDLLintCmd to one of the supported third-party tools, HDL Coder automatically inserts a tool-specific default termination string in the Tcl script.

Command-Line Information

Property: HDLLintInit

Type: character vector

Default: none

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

See Also

“Generate HDL Lint Tool Script” on page 31-45

Lint command

Enter the command for your HDL lint script.

Command-Line Information

Property: HDLLintCmd

Type: character vector

Default: none

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

If you set HDLLintTool to Custom, you must use %s as a placeholder for the HDL file name in the generated Tcl script. Specify HDLLintCmd using the following format:

```
custom_lint_tool_command -option1 -option2 %s
```

See Also

“Generate HDL Lint Tool Script” on page 31-45

Lint termination

Enter a termination character vector for your HDL lint script.

Dependencies

If **Lint termination** is set to the default value, ' ', and you set HDLLintCmd to one of the supported third-party tools, HDL Coder automatically inserts a tool-specific default termination string in the Tcl script.

Command-Line Information

Property: HDLLintTerm

Type: character vector

Default: none

To set this property, use the functions `hdlset_param` or `makehdl`. To view the property value, use the function `hdlget_param`.

HDL Modeling Guidelines Severity Levels

Each modeling guideline for HDL code generation has a different level of severity that indicates the levels of compliance requirements. This table illustrates what each severity level indicates.

Severity Levels

Category	Mandatory	Strongly Recommended	Recommended	Informative
Definition	Guidelines that are absolutely essential to follow. Models created must conform to these guidelines to 100%.	Guidelines that are agreed upon to be a good practice. Models created should conform to these guidelines to the greatest extent possible, but does not have to be 100%.	Guidelines that are recommended to improve the generated code and optimize the code on the target device, but are not critical	Guidelines that are meant to understand some modeling recommendations and best practices.
Impact	If you violate these guidelines, you cannot generate code and synthesize your design on the target hardware.	If you violate these guidelines, you get poor quality of results.	Violating these guidelines may impact the efficiency or ease of using the generated code with downstream synthesis tools	None

Model Design and Compatibility Guidelines - By Numbered List

The HDL modeling guidelines are a set of recommended guidelines that you can follow when creating Simulink model for code generation with HDL Coder. The model design and compatibility guidelines consist of guidelines for basic block usage, clock and reset signals, buses and vectors, and subsystem and hierarchical designing. Each modeling guideline for HDL code generation has a different level of severity that indicates the levels of compliance requirements. To learn more about these severity levels, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

These tables list the model design and compatibility guidelines in HDL Coder. These guidelines start from 1.1 and are divided into subsections. In the table, you see that certain guidelines have an associated model check. You can follow the modeling pattern recommended for these guidelines by running that check in the HDL Code Advisor. To learn more about the HDL Code Advisor, see “Check HDL Compatibility of Simulink Model Using HDL Code Advisor” on page 45-2.

Guidelines 1.1: Basic Settings

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
1.1.1	“Use HDL-Supported Blocks” on page 25-13	Recommended	None
1.1.2	“Partition Model into DUT and Test Bench” on page 25-14	Recommended	None
1.1.3	“Avoid Using Double-Byte Characters” on page 25-16	Mandatory	None
1.1.4	“Document Model Features and Attributes” on page 25-16	Recommended	None
1.1.5	“Customize hdlsetup Function Based on Target Application” on page 25-19	Recommended	Model Check: “Check for model parameters suited for HDL code generation” on page 44-5
1.1.6	“Check Subsystem for HDL Compatibility” on page 25-20	Recommended	None
1.1.7	“Run Model Checks for HDL Coder” on page 25-20	Recommended	None
1.1.8	“Modeling with Simulink, Stateflow, and MATLAB Function Blocks” on page 25-23	Informative	None
1.1.9	“Terminate Unconnected Block Outputs” on page 25-26	Mandatory	None
1.1.10	“Using Comment Out and Comment Through of Blocks” on page 25-27	Informative	None
1.1.11	“Adjust Sizes of Constant and Gain Blocks for Identifying Parameters” on page 25-30	Recommended	None

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
1.1.12	“Display Parameters That Affect HDL Code Generation” on page 25-30	Recommended	None
1.1.13	“Change Block Parameters by Using find_system and set_param” on page 25-35	Informative	None

Guidelines 1.2: DUT Subsystem and Hierarchical Modeling

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
1.2.1	“DUT Subsystem Considerations” on page 25-36	Strongly Recommended	Model Check: “Check for invalid top level subsystem” on page 44-13
1.2.2	“Convert DUT Subsystem to Model Reference for Testbenches with Continuous Blocks” on page 25-36	Strongly Recommended	None
1.2.3	“Insert Handwritten Code into Simulink Modeling Environment” on page 25-38	Informative	None
1.2.4	“Avoid Constant Block Connections to Subsystem Port Boundaries” on page 25-40	Mandatory	None
1.2.5	“Generate Parameterized HDL Code for Constant and Gain Blocks” on page 25-41	Recommended	None
1.2.6	“Place Physical Signal Lines Inside a Subsystem” on page 25-43	Mandatory	None

Guidelines 1.3: Vectors, Matrices, and Buses

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
1.3.1	“Modeling Requirements for Matrices” on page 25-46	Mandatory	None
1.3.2	“Avoid Generating Ascending Bit Order in HDL Code From Vector Signals” on page 25-47	Strongly Recommended	None
1.3.3	“Use Bus Signals to Improve Readability of Model and Generate HDL Code” on page 25-51	Informative	None

Guidelines 1.4: Clock Bundle Signals

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
1.4.1	“Use Global Oversampling to Create Frequency-Divided Clock” on page 25-57	Informative	None
1.4.2	“Create Multirate Model with Integer Clock Multiples by Clock Division” on page 25-57	Mandatory	None
1.4.3	“Use Dual Rate Dual Port RAM for Noninteger Multiple Sample Times” on page 25-60	Mandatory	None
1.4.4	“Asynchronous Clock Modeling in HDL Coder” on page 25-61	Recommended	None
1.4.5	“Use Global Reset Type Setting Based on Target Hardware” on page 25-63	Strongly Recommended	Model check: “Check for global reset setting for Xilinx and Altera devices” on page 44-7

Guidelines 1.5: Native Floating Point

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
1.5.1	“Modeling with Native Floating Point” on page 25-64	Recommended	None

Guidelines for Supported Blocks and Data Types - By Numbered List

The HDL modeling guidelines are a set of recommended guidelines that you can follow when creating Simulink model for code generation with HDL Coder. The guidelines for supported blocks and data types consist of guidelines for using various blocks in the HDL Coder block library, and about the supported data types. Each modeling guideline for HDL code generation has a different level of severity that indicates the levels of compliance requirements. To learn more about these severity levels, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

These tables list the guidelines for supported data types in HDL Coder and for various blocks in the HDL Coder block library. The guidelines start from 2.1 and are divided into subsections. In the table, you see that certain guidelines have an associated model check. You can follow the modeling pattern recommended for these guidelines by running that check in the HDL Code Advisor. To learn more about the HDL Code Advisor, see “Check HDL Compatibility of Simulink Model Using HDL Code Advisor” on page 45-2.

Guidelines 2.1: HDL RAMs and HDL Operations Library

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.1.1	“RAM Block Access Considerations” on page 25-67	Recommended	None
2.1.2	“Serial to Parallel Conversion” on page 25-69	Recommended	None

Guidelines 2.2: Logic and Bit Operations Library

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.2.1	“Logical and Arithmetic Bit Shift Operations” on page 25-71	Informative	None
2.2.2	“Usage of Logical Operator, Bitwise Operator, and Bit Reduce Blocks” on page 25-73	Informative	None
2.2.3	“Use Boolean Output for Compare to Constant and Relational Operator Blocks” on page 25-75	Strongly Recommended	None

Guidelines 2.3: Lookup Table and Signal Routing Blocks

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.3.1	“Generate FPGA Block RAM from Lookup Tables” on page 25-77	Strongly Recommended	None

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.3.2	“Recommended Block Parameter Settings of Multiport Switch Block for Numeric and Enumerated Types” on page 25-82	Recommended	None

Guidelines 2.4: Ports and Subsystems

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.4.1	“Virtual Subsystem: Use as DUT” on page 25-86	Mandatory	Model Check: “Check for invalid top level subsystem” on page 44-13
2.4.2	“Atomic and Virtual Subsystems: Generate Reusable HDL Files” on page 25-86	Recommended	None
2.4.3	“Variant Subsystem: Using Variant Subsystems for HDL Code Generation” on page 25-87	Mandatory	None
2.4.4	“Model References: Build Model Design Using Smaller Partitions” on page 25-89	Recommended	None
2.4.5	“Block Settings of Enabled and Triggered Subsystems” on page 25-91	Mandatory	None

Guideline 2.5: Rate Change and Constant Blocks

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.5.1	“Usage of Rate Conversion Blocks” on page 25-93	Recommended	None
2.5.2	“Use Discrete and Finite Sample Time for Constant Block” on page 25-94	Recommended	Model Check: “Check for infinite and continuous sample time sources” on page 44-15

Guideline 2.6: Delay Blocks

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.6.1	“Appropriate Usage of Delay Blocks as Registers” on page 25-97	Recommended	“Check for obsolete Unit Delay Enabled/Resettable Blocks” on page 44-20

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.6.2	“Absorb Delays to Avoid Timing Difference” on page 25-97	Recommended	None
2.6.3	“Map Large Delays to Block RAM” on page 25-98	Recommended	None
2.6.4	“Required HDL Settings for Goto and From Blocks” on page 25-99	Mandatory	None

Guideline 2.7: Multiplication and Accumulation Operations

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.7.1	“Designing Multipliers and Adders for Efficient Mapping to DSP Blocks on FPGA” on page 25-101	Strongly Recommended	None
2.7.2	“Set ConstMultiplierOptimization HDL Block Property to auto for Gain Block” on page 25-105	Recommended	None
2.7.3	“Use ShiftAdd Architecture of Divide Block for Fixed-Point Types” on page 25-107	Recommended	None

Guideline 2.8: MATLAB Function Blocks

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.8.1	“Update Persistent Variables at End of MATLAB Function” on page 25-108	Strongly Recommended	None
2.8.2	“Avoid Algebraic Loop Errors from Persistent Variables inside MATLAB Function Blocks” on page 25-109	Mandatory	None
2.8.3	“Use hdlfmath Setting and Specify fi Objects inside MATLAB Function Block” on page 25-111	Strongly Recommended	“Check for MATLAB Function block settings” on page 44-18

Guideline 2.9: Stateflow Charts

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.9.1	“Choose State Machine Type based on HDL Implementation Requirements” on page 25-114	Strongly Recommended	None
2.9.2	“Specify Block Configuration Settings of Stateflow Chart” on page 25-114	Strongly Recommended	“Check for Stateflow chart settings” on page 44-19
2.9.3	“Insert Unconditional Transition State for Else Statement in HDL Code” on page 25-115	Recommended	None
2.9.4	“Data Type Settings and Casting in Stateflow Chart for HDL Code Generation” on page 25-118	Informative	None
2.9.5	“Using Absolute Time Temporal Logic in Stateflow Charts” on page 25-120	Mandatory	None
2.9.6	“Modeling Error (default) State in Stateflow Charts” on page 25-120	Informative	None
2.9.7	“Enable Clock-Driven Outputs of Stateflow Charts (Moore Charts Only)” on page 25-121	Informative	None
2.9.8	“Enumeration type for active state monitoring in a Stateflow chart with no default value” on page 25-122	Informative	None

Guidelines 2.10: Data Types

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
2.10.1	“Use Boolean for Logical Data and Ufix1 for Numerical Data” on page 25-125	Mandatory	None
2.10.2	“Specify Data Type of Gain Blocks” on page 25-125	Recommended	None
2.10.3	“Enumerated Data Type Restrictions” on page 25-126	Mandatory	None

Guidelines for Speed and Area Optimizations - By Numbered List

The HDL modeling guidelines are a set of recommended guidelines that you can follow when creating Simulink model for code generation with HDL Coder. In addition to providing architectural guidance, because the generated code targets hardware platforms such as FPGAs, ASICs, and SoCs, you can use these guidelines to optimize your design for speed or area on the target hardware.. Each modeling guideline for HDL code generation has a different level of severity that indicates the levels of compliance requirements. To learn more about these severity levels, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

These tables list the guidelines for speed and area optimizations in HDL Coder. The guidelines start from 3.1 and are divided into subsections. These guidelines do not have an associated model check. You can follow the modeling pattern recommended for these guidelines by running that check in the HDL Code Advisor. To learn more about the HDL Code Advisor, see “Check HDL Compatibility of Simulink Model Using HDL Code Advisor” on page 45-2.

Guidelines 3.1: Resource Sharing and Streaming

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
3.1.1	“Resource Sharing of Add Blocks” on page 25-127	Recommended	None
3.1.2	“Resource Sharing of Gain Blocks” on page 25-128	Recommended	None
3.1.3	“Resource Sharing of Product Blocks” on page 25-129	Recommended	None
3.1.4	“Resource Sharing of Multiply-Add Blocks” on page 25-129	Recommended	None
3.1.5	“General Considerations for Sharing of Subsystems” on page 25-131	Recommended	None
3.1.6	“Use MATLAB Datapath Architecture for Sharing with MATLAB Function Blocks” on page 25-132	Recommended	None
3.1.7	“Sharing of Subsystems” on page 25-132	Recommended	None
3.1.8	“Resource Sharing of Floating-Point IPs” on page 25-133	Recommended	None
3.1.9	“Use StreamingFactor for Resource Sharing of Vector Signals” on page 25-135	Informative	None

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
3.1.10	“Use SharingFactor and HDL Block Properties for Sharing Matrix Multiplication Operations” on page 25-138	Informative	None

Guidelines 3.2: Clock Rate Pipelining and Distributed Pipelining

Guideline ID	Title	Severity	Associated Model Check/ Coding Standard Rule
3.2.1	“Clock-Rate Pipelining Guidelines” on page 25-140	Informative	None
3.2.2	“Recommended Distributed Pipelining Settings” on page 25-140	Recommended	None
3.2.3	“Insert Distributed Pipeline Registers for Blocks with Vector Data Type Inputs” on page 25-143	Informative	None

Basic Guidelines for Modeling HDL Algorithm in Simulink

In this section...

“Use HDL-Supported Blocks” on page 25-13
 “Partition Model into DUT and Test Bench” on page 25-14
 “Avoid Using Double-Byte Characters” on page 25-16
 “Document Model Features and Attributes” on page 25-16

Use these guidelines to develop your HDL algorithm in Simulink. The guidelines include using HDL-supported blocks when modeling your design and how to partition your design when developing the algorithm.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Use HDL-Supported Blocks

Guideline ID

1.1.1

Severity

Strongly Recommended

Description

When you create your Simulink model, use blocks from the **Simulink Library Browser > HDL Coder** library. Several blocks in this library are pre-configured for HDL code generation. Blocks in this library are available with Simulink. If you do not have HDL Coder, you can simulate the blocks in your model, but cannot generate HDL code.

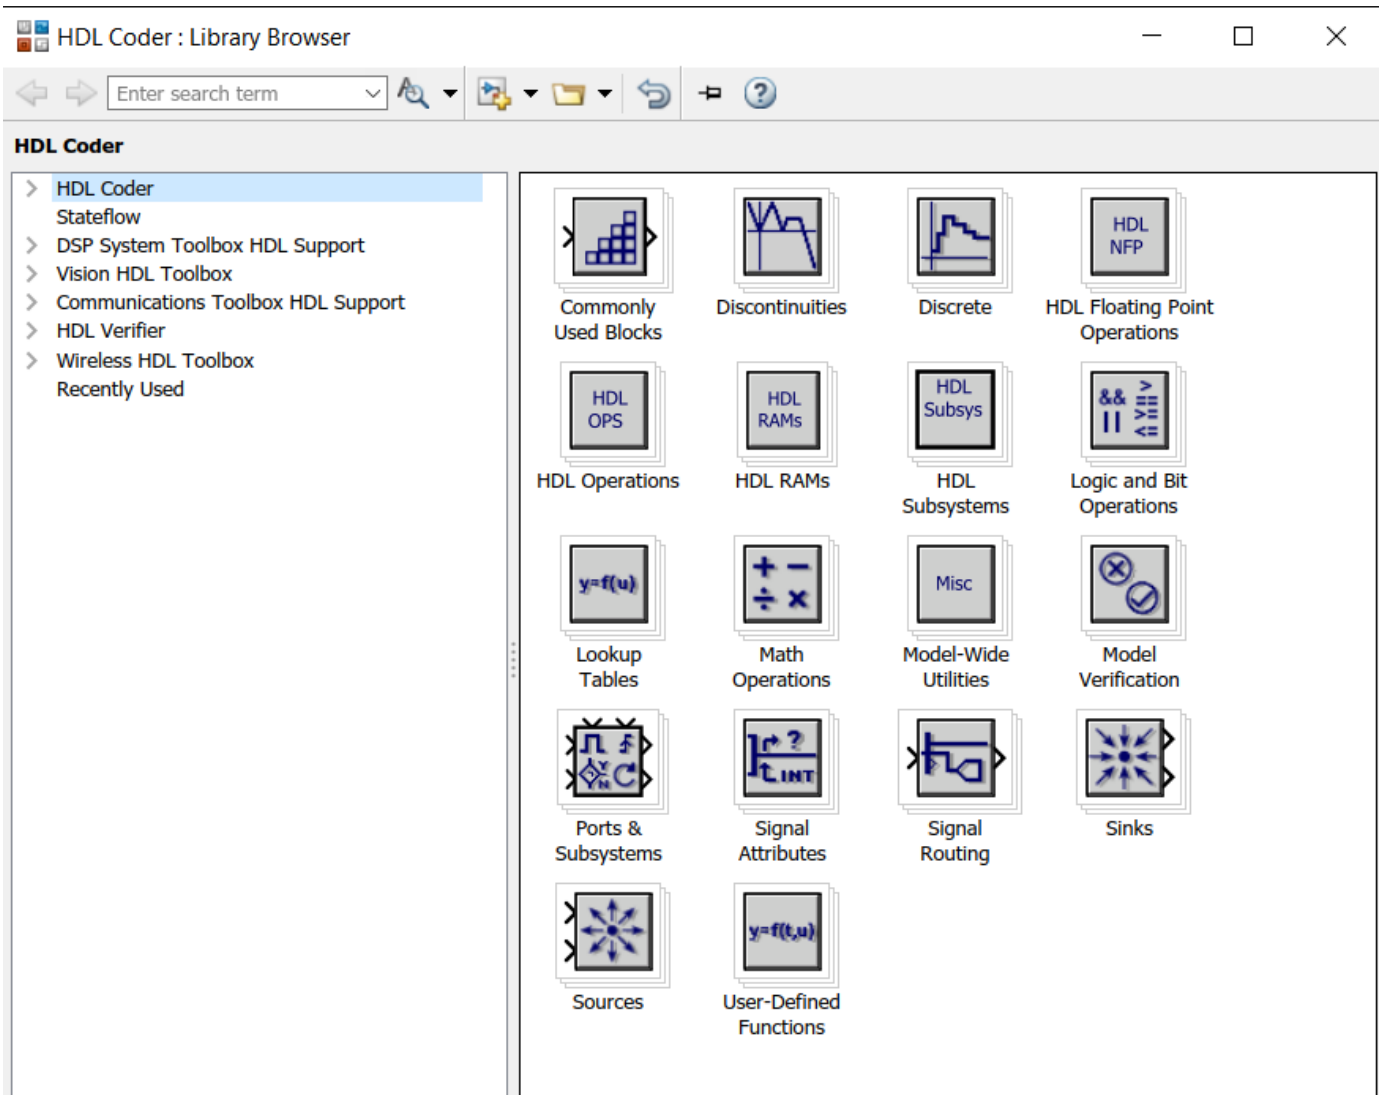

You can find additional HDL-supported blocks in these Simulink block libraries:

- **DSP System Toolbox HDL Support**
- **Communications Toolbox HDL Support**
- **Vision HDL Toolbox**
- **Wireless HDL Toolbox**

To display only HDL-supported blocks in the Library Browser:

- in the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select **HDL Block Properties > Open HDL Block Library**.
- Alternatively, at the MATLAB Command Window, enter `hdllib`.

```
hdllib
```

To restore the library browser to the default view, enter this command:

```
hdllib('off')
```

Note The set of supported blocks will change in future releases, so you should rebuild your supported blocks library each time you install a new version of this product.

Partition Model into DUT and Test Bench

Guideline ID

1.1.1.2

Severity

Recommended

Description

When you create your Simulink model for HDL code generation, the Subsystem that you want to generate HDL code for is the Design-Under-Test (DUT). This Subsystem contains Simulink blocks that can be implemented on your target FPGA or ASIC device. You can further partition the logic inside the DUT into smaller subsystems based on functionality, sample rates in your design, and so on. When you generate HDL code, the DUT becomes the top-level module or entity, and the Subsystems inside the DUT become submodules or smaller entities.

Blocks outside the DUT Subsystem become part of the test bench. The test bench can consist of blocks that are not supported for HDL code generation. Simulate the test bench to:

- Verify the functionality of the DUT in your Simulink model.
- Verify functional equivalence of the generated model with your original model.

For example, if you open the Simulink model template **Blank_DUT**, this model opens in the Simulink Editor.

Note: This model is configured with 'hdlsetup'

Add your design targeted for ASIC/FPGA inside HDL_DUT and then run the following command:
makehdl('HDL_DUT')

In this model, **HDL_DUT** Subsystem is the DUT and blocks outside this Subsystem form the test bench. You can develop your HDL algorithm inside the **HDL_DUT** Subsystem. This template model is preconfigured for HDL code generation.

Note You can also generate HDL code for the entire model instead of the DUT Subsystem. Replace the input signals and Constant blocks with Inport blocks. Replace the output signals and Scope blocks with Outport blocks.

Avoid Using Double-Byte Characters

Guideline ID

1.1.3

Severity

Strongly Recommended

Description

Downstream synthesis and simulation tools do not support double-byte characters such as Japanese and Chinese characters. HDL Coder does not support using:

- Double-byte characters in model and block names.
- Reserved words of your Operating System in model and block names such as CR, con, prn, aux, ptr, null, ipt1, ipt2, ipt3, and ipt4, com1, com2, com3, and com4.
- Double-byte characters in comments because the comments are propagated to the generated code. Use English comments instead.

Document Model Features and Attributes

Guideline ID

1.1.4

Severity

Recommended

Description

To make the generated HDL code easier to manage, you can document reference information as part of your model settings in these ways:

- **Custom File Headers and Footer Comments in HDL Code for Design and Testbench**

In the **HDL Code Generation > Global Settings > Coding Style** tab of the Configuration Parameters dialog box, by using the **Custom File Header Comment** and **Custom File Footer Comment** parameters, you can enter your own custom comments to appear as headers or footers in all generated HDL files. To learn more, see “File Comment Customization Parameters” on page 21-69.

- **Model and Block Annotations, Text Comments, and Requirement Comments**

You can add annotations in the form of model annotations, text comments, or requirement comments to the generated code. For example, you can enter text directly on the block diagram as Simulink annotations, or insert text comments by placing a DocBlock in your model. To relate annotations in the block diagram to blocks in your model, use lines to connect the annotations to those blocks. These annotations appear as comments beside the blocks in the generated code. To learn more, see “Generate Code with Annotations or Comments” on page 30-16.

- **Block Features and Attributes as Custom Header Comments for Each File**

In the **Description** section of the Block Properties for subsystems that you use in your design. This information appears as comment headers in the HDL code. For example, this figure illustrates block comments added for a **Vector FFT Subsystem** in your design.

The block comments appear as headers in the generated HDL code.

```
-- Simulink subsystem description for vector_fft_implementation_example/Vector_FFT:
--
-- Created by: John
-- Function: Vector FFT
-- This model shows...
-- Revision 1.0
-- Revision 1.1 added functionality to...
--
--
-----

Guidelines for Model Setup and Checking Model Compatibility

In this section...

“Customize hdlsetup Function Based on Target Application” on page 25-19

“Check Subsystem for HDL Compatibility” on page 25-20

“Run Model Checks for HDL Coder” on page 25-20

Use these guidelines to setup your Simulink model for HDL code generation compatibility and verify that your design is ready to generate code.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Customize hdlsetup Function Based on Target Application

Guideline ID

1.1.5

Severity

Strongly Recommended

Description

Before generating code, configure the model for HDL code generation by using `hdlsetup`. The `hdlsetup` function uses the `set_param` function to set up models for HDL code generation. To view the settings that `hdlsetup` function saves on the model, enter:

```
edit hdlsetup.m
```

You can customize the `hdlsetup.m` file to only edit parameters required for your target application. For example, you can disable some of the solver settings in the Configuration Parameters and enable certain model parameters such as displaying port data types.

```
% following config parameters are disabled.
%   'Solver',                'fixedstepdiscrete', ...
%   'SaveTime',              'off', ...
%   'SaveOutput',            'off', ...
%   'DataTypeOverride',      'ForceOff',...

% Following model parameters are enabled.
set_param(model, 'ShowLineDimensions', 'on')
set_param(model, 'ShowPortDataTypes', 'on')
set_param(model, 'SampleTimeColors', 'on')
set_param(model, 'WideLines', 'on')
```

To view a custom `hdlsetup` function, enter:

```
edit myhdlsetup.m
```

myhdlsetup saves some HDL-specific parameters by using `hdlset_param` on the model.

Check Subsystem for HDL Compatibility

Guideline ID

1.1.6

Severity

Strongly Recommended

Description

The compatibility checker generates a report specified system for compatibility problems, such as use of unsupported blocks, illegal data type usage, and so on.

To run the check for HDL compatibility:

- From the UI, right-click the DUT Subsystem and select **HDL Code > Check Subsystem for HDL compatibility**.
- At the command line, use the `checkhdl` function. Select the DUT Subsystem and then enter this command:

```
checkhdl(gcb)
```

See also “Check Your Model for HDL Compatibility” on page 30-19.

When you run this command, the HDL compatibility checker generates an HDL Code Generation Check Report. The report is stored in the target `hdlsrc` folder. If the report does not display any errors, it indicates that your model is compatible for HDL code generation.

```
### Starting HDL Check.  
### HDL Check Complete with 0 errors, warnings and messages.
```

Note `checkhdl` does not detect all compatibility issues. Even if HDL check completes without any errors or warnings, HDL Coder can generate errors during code generation.

Run Model Checks for HDL Coder

Guideline ID

1.1.7

Severity

Strongly Recommended

Description

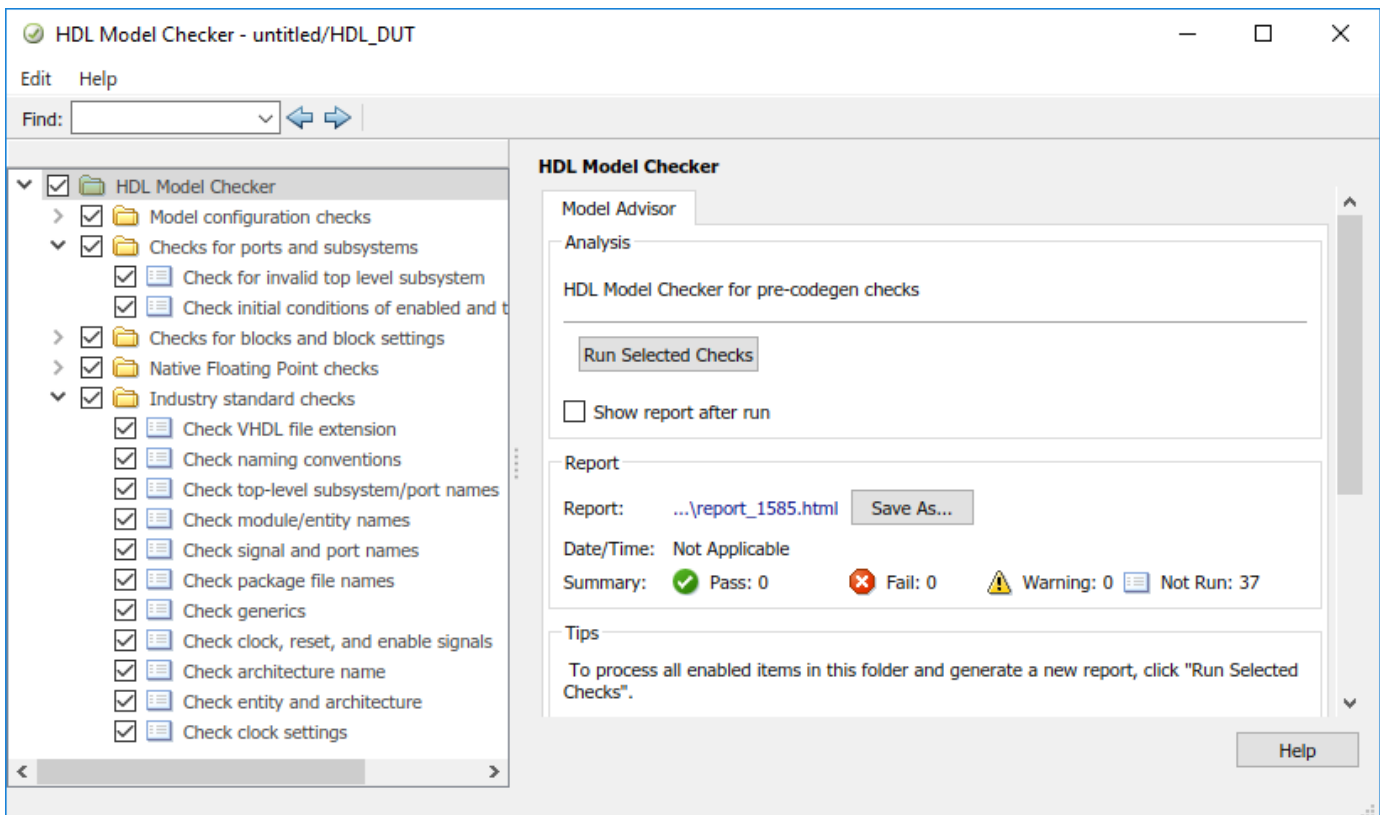

To see whether your DUT Subsystem is compatible for HDL code generation, run the checks in the HDL Code Advisor or the Simulink Model Advisor checks for **HDL Coder**.

To open the HDL Code Advisor:

- From the UI, in the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select the DUT Subsystem and then click **HDL Code Advisor**.
- To run the model checks for the Subsystem you want to analyze, right-click that Subsystem, and in the context menu, select **HDL Code > HDL Code Advisor**.
- At the command line, use the `hdlcodeadvisor` function:

```
hdlcodeadvisor(gcf)
```

When you run this command, the HDL Code Advisor appears.

You may not have to run all checks in the HDL Code Advisor. For example, if your model does not have single or double data types, you do not have to run the checks in the **Native Floating Point checks** folder. To learn more about each check and whether to run the check for your model, right-click that check and select **What's This?**.

Modeling with Simulink, Stateflow, and MATLAB Function Blocks

In this section...

“Guideline ID” on page 25-23

“Severity” on page 25-23

“Description” on page 25-23

You can follow this guideline as a general practice for modeling your design with various blocks in the Simulink Library Browser.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Guideline ID

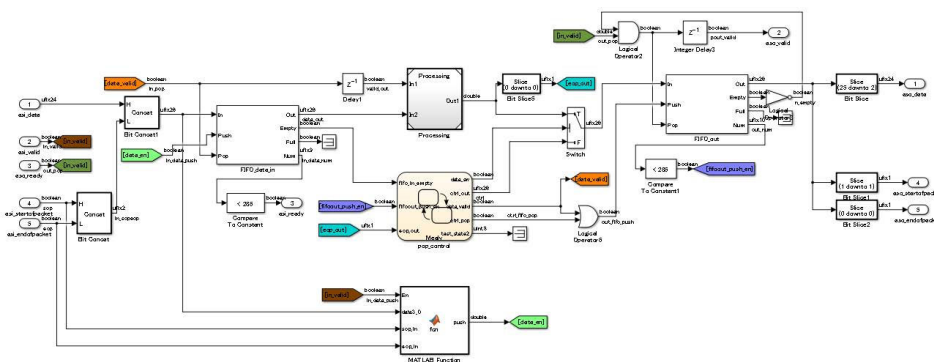

1.1.8

Severity

Informative

Description

When you create a Simulink model for HDL code generation, use Simulink blocks, MATLAB Function blocks, and Stateflow blocks based on the application. This figure shows an example of how you can use the various blocks inside your DUT.

Simulink Blocks

Use Simulink blocks to model arithmetic algorithms that perform numerical processing or contains feedback loops.

MATLAB Function Blocks

Use MATLAB Function blocks to model the control logic, conditional branches such as if-else statements, and simple state machines. You can also use MATLAB Function blocks to model an IP that is written using MATLAB code.

Stateflow Blocks

Use these Stateflow blocks to model your algorithm:

- **State Transition Table:** Use these blocks to model state machines that control the output using knowledge of the past and the present.
- **Chart:** Use these blocks to model flow charts using conditional if-else branches and state machines that control the output using knowledge of the past and the present.
- **Truth Table:** Use these blocks to model conditional if-else branches.

You can model combinational logic using Stateflow blocks. For more complex operations and operations that change timing such as pipeline insertion and processing, use Simulink blocks. You can then use the Stateflow logic to process the result calculated from the Simulink blocks

Model References

For significantly large algorithms that have complex computations, you can partition the design into a hierarchy of smaller designs. Use this partitioning for reuse, modular development, and accelerated simulation. You can reuse models by including them as Model blocks inside a top model. The model that reuses this block is called the top model and the block that is reused or included in the top model is called the referenced model.

Note When you generate HDL code for a Subsystem that is not at the top level of the model, HDL Coder converts the Subsystem to a model reference.

A referenced model is treated similar to an Atomic Subsystem. In some cases, an algebraic loop can potentially occur, and can prevent HDL code generation. To generate code, either remove the algebraic loop in your design, or, in the Configuration Parameters dialog box, specify the **Minimize algebraic loop occurrences** setting.

BlackBox Subsystems

For subsystems that you want to simulate in your design and to include the HDL code that you authored, use BlackBox subsystems. To create a **BlackBox** Subsystem, set the HDL Architecture of a Subsystem or Model reference to **BlackBox**. You can use this architecture to incorporate handwritten HDL code into a Simulink model. For more information, see “Verify the Combination of Hand-Written and Generated HDL Code” (HDL Verifier).

If you generate a Simulink model using the HDL code that you authored, use HDL import. To learn more, see “Import Verilog Code and Generate Simulink Model” on page 14-162.

HDL Cosimulation Blocks

If you have a HDL simulator such as Mentor Graphics ModelSim or Cadence Incisive, you can use HDL Cosimulation blocks to simulate the HDL code for the DUT and instantiate this HDL code in the generated code.

Terminate Unconnected Block Outputs and Usage of Commenting Blocks

You can follow these guidelines as recommended modeling practices such as making sure that block outputs are terminated and how you can comment out blocks for HDL code generation.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Terminate Unconnected Block Outputs

Guideline ID

1.1.9

Severity

Mandatory

Description

If you generate HDL code for a Subsystem that has unconnected output ports, HDL Coder™ generates an error. For output ports that are not connected to downstream logic, connect them to a Terminator block.

This model illustrates a DUT0 Subsystem that has an unconnected output port Out2.

```
open_system('hdlcoder_terminateout')
```

Copyright 2018-2021 The MathWorks, Inc.

If you generate HDL code for this Subsystem, HDL Coder™ generates this error:

```
error in validation model generation: Failed to find source for output 2 on
'DUT0' Please create a fully connected subsystem when generating the
cosimulation model.
```

```
close_system('hdlcoder_terminateout')
```

You can use the `addterms` function to add Terminator blocks to unconnected ports in your model.

```
load_system('hdlcoder_terminateout')
addterms('hdlcoder_terminateout')
open_system('hdlcoder_terminateout')
```

Copyright 2018-2021 The MathWorks, Inc.

Using Comment Out and Comment Through of Blocks

Guideline ID

1.1.10

Severity

Informative

Description

To exclude blocks in your model from simulation without physically removing the blocks from your model, use **Comment Out** or **Comment Through**. When you use **Comment Out**, the signals are terminated and grounded. When you use **Comment Through**, the signals are passed through.

When you generate HDL code, you can use this capability to exclude certain blocks such as blocks that are not supported for HDL code generation.

Open the model `hdlcoder_comment_through_out`.

```
open_system('hdlcoder_comment_through_out')
```

The code generator supports blocks that are comment out when the output signals are unused. The generated code assigns a constant value of 0 to the signal at the output. The `Dut_CommentOut` subsystem contains blocks that are commented out.

```
open_system('hdlcoder_comment_through_out/DUT_CommentOut/Generated_CommentOut')
```

When you generate code, this VHDL® code generated for the `DUT_CommentOut` subsystem indicates a constant zero value assigned to `Out1`.

```
ARCHITECTURE rtl OF Generated IS
```

```
-- Signals
SIGNAL TmpGroundAtData_Type_DuplicateInport1_out1 : signed(15 DOWNT0 0); -- sfix16_En6
```

```
BEGIN
```

```
-- Unsupported Block
```

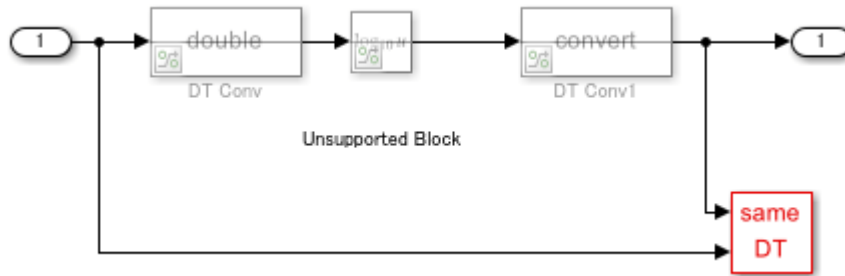

```
TmpGroundAtData_Type_DuplicateInport1_out1 <= to_signed(16#0000#, 16);
```

```
Out1 <= std_logic_vector(TmpGroundAtData_Type_DuplicateInport1_out1);
```

```
END rtl;
```

The code generator supports blocks that are comment through. The generated code passes the input signal through to the output. The Dut_CommentThrough subsystem contains blocks that are comment through.

`open_system('hdlcoder_comment_through_out/DUT_CommentThrough/Generated_CommentThrough')`

When you generate code for Dut_CommentThrough subsystem, the VHDL code shows In1 passed through to Out1.

```
ARCHITECTURE rtl OF Generated_CommentThrough IS
```

```
BEGIN
```

```
-- Unsupported Block
```

```
Out1 <= In1;
```

```
END rtl;
```

Identify and Programmatically Change and Display HDL Block Parameters

You can follow these guidelines to learn how you can identify block parameters in your design and programmatically update some of the parameters so that the model is compatible for HDL code generation. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Adjust Sizes of Constant and Gain Blocks for Identifying Parameters

Guideline ID

1.1.11

Severity

Recommended

Description

For Constant blocks and Gain blocks that have significantly large values or use parameter values, the **Constant** or **Gain** values may not be visible in the block mask. To increase readability, adjust the size of the block so that the parameter value can be displayed as shown in figure.

Display Parameters That Affect HDL Code Generation

Guideline ID

1.1.12

Severity

Recommended

Description

Certain HDL block properties such as `DistributedPipelining` and `SharingFactor` can significantly affect HDL code generation. If the block properties are enabled for a certain block or Subsystem, it is recommended that you annotate the block properties beside that block in the Simulink® diagram. When you annotate the model, use delimiters such as `--HDL--` to separate the annotation from the block name.

For example, open the model `hdlcoder_block_annotation_HDL_params.slx`.

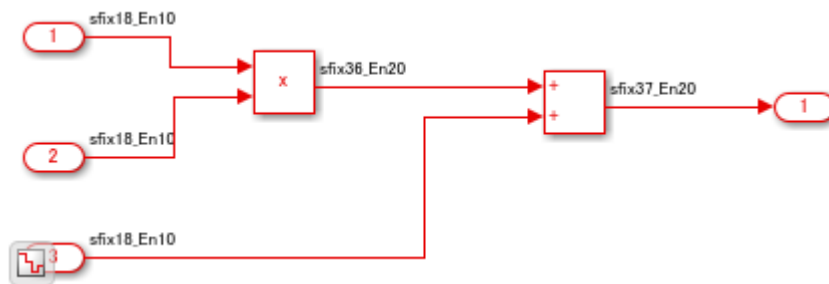

```
open_system('hdlcoder_block_annotation_HDL_params')
set_param('hdlcoder_block_annotation_HDL_params','SimulationCommand','Update')
```

Copyright 2018–2021 The MathWorks, Inc.

The DUT Subsystem performs a simple multiply-add operation.

```
open_system('hdlcoder_block_annotation_HDL_params/DUT')
```

There are HDL model and block parameters saved on the model. To see the non-default parameters, use the `hdlsaveparams` function.

```
hdlsaveparams('hdlcoder_block_annotation_HDL_params/DUT')
```

```
%% Set Model 'hdlcoder_block_annotation_HDL_params' HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params', 'GenerateCoSimModel', 'ModelSim');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'GenerateValidationModel', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'MaskParameterAsGeneric', 'on');
```

```

hdlset_param('hdlcoder_block_annotation_HDL_params', 'MinimizeClockEnables', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'MinimizeIntermediateSignals', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'OptimizationReport', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'ResetType', 'Synchronous');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'ResourceReport', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'TargetLanguage', 'Verilog');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'Traceability', 'on');

% Set SubSystem HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT', 'DistributedPipelining', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT', 'InputPipeline', 1);
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT', 'OutputPipeline', 3);

% Set Sum HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Add', 'InputPipeline', 1);
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Add', 'OutputPipeline', 1);

% Set Product HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Product', 'InputPipeline', 2);
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Product', 'OutputPipeline', 1);

```

To annotate the blocks in the model with the non-default HDL block parameters saved and to display the non-default HDL model and block properties in the MATLAB® command window, use the `showHdlParams` script attached with the example.

```

showHdlParams('hdlcoder_block_annotation_HDL_params/DUT', 'on')

%% Set Model 'hdlcoder_block_annotation_HDL_params' HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params', 'GenerateCoSimModel', 'ModelSim');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'GenerateValidationModel', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'MaskParameterAsGeneric', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'MinimizeClockEnables', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'MinimizeIntermediateSignals', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'OptimizationReport', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'ResetType', 'Synchronous');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'ResourceReport', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'TargetLanguage', 'Verilog');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'Traceability', 'on');

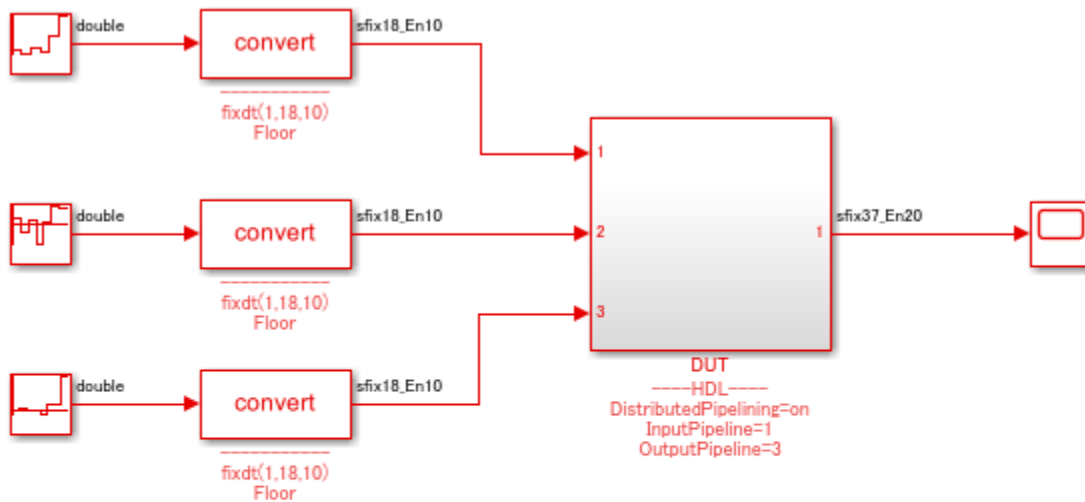

% Set SubSystem HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT', 'DistributedPipelining', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT', 'InputPipeline', 1);
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT', 'OutputPipeline', 3);

% Set Sum HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Add', 'InputPipeline', 1);
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Add', 'OutputPipeline', 1);

% Set Product HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Product', 'InputPipeline', 2);
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Product', 'OutputPipeline', 1);

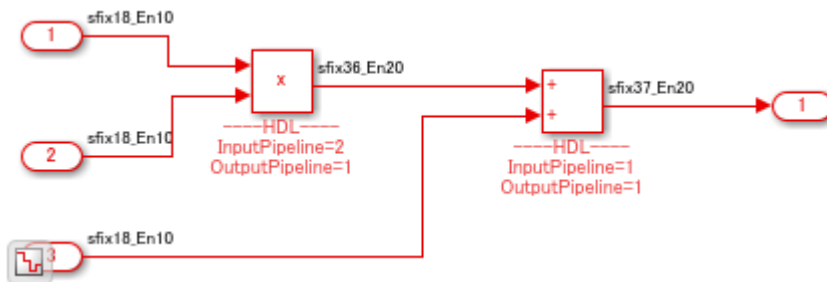

open_system('hdlcoder_block_annotation_HDL_params')

```

Copyright 2018–2021 The MathWorks, Inc.

```
open_system('hdlcoder_block_annotation_HDL_params/DUT')
```

To remove the HDL block parameters annotation from the model, run the `showHdlParams` set to off.

```
showHdlParams('hdlcoder_block_annotation_HDL_params/DUT','off')
```

```

% Set Model 'hdlcoder_block_annotation_HDL_params' HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params', 'GenerateCoSimModel', 'ModelSim');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'GenerateValidationModel', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'MaskParameterAsGeneric', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'MinimizeClockEnables', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'MinimizeIntermediateSignals', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'OptimizationReport', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'ResetType', 'Synchronous');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'ResourceReport', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'TargetLanguage', 'Verilog');
hdlset_param('hdlcoder_block_annotation_HDL_params', 'Traceability', 'on');

```

```

% Set SubSystem HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT', 'DistributedPipelining', 'on');
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT', 'InputPipeline', 1);
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT', 'OutputPipeline', 3);

% Set Sum HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Add', 'InputPipeline', 1);
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Add', 'OutputPipeline', 1);

% Set Product HDL parameters
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Product', 'InputPipeline', 2);
hdlset_param('hdlcoder_block_annotation_HDL_params/DUT/Product', 'OutputPipeline', 1);

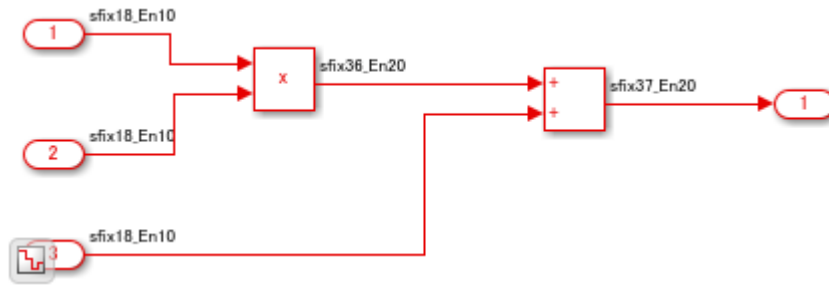

open_system('hdlcoder_block_annotation_HDL_params')

```

Copyright 2018–2021 The MathWorks, Inc.

```
open_system('hdlcoder_block_annotation_HDL_params/DUT')
```

Change Block Parameters by Using `find_system` and `set_param`

Guideline ID

1.1.13

Severity

Informative

Description

To modify the parameters of certain blocks, you can use the function `find_system` with the function `set_param`. For example, this script that detects all Constant blocks with a **Sample time** of `inf` and modifies it to `-1`:

```

modelname = 'sfir_fixed';
open_system(modelname)

% Detect all Constant blocks in the model
blockConstant = find_system(bdroot, 'blocktype', 'Constant')

% Detect the Constant blocks with sample time [inf], and change to [-1]
for n = 1:numel(blockConstant)
    sTime = get_param(blockConstant{n}, 'SampleTime')
    if strcmp(lower(sTime), 'inf')
        set_param(blockConstant{n}, 'SampleTime', '-1')
    end
end

```

- “Specify Block Properties”

DUT Subsystem Guidelines

You can follow these guidelines to learn some best practices on how you can model the DUT for HDL code and testbench generation. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

DUT Subsystem Considerations

Guideline ID

1.2.1

Severity

Strongly Recommended

Description

The DUT is the Subsystem that contains the algorithm for which you want to generate code. Generally, you specify the top-level Subsystem as the DUT. See also “Partition Model into DUT and Test Bench” on page 25-14.

Consider using these recommended settings when you design the DUT Subsystem for HDL code generation.

- Make sure that the DUT is not a conditionally-executed subsystem, such as an Enabled Subsystem or a Triggered Subsystem. To verify that you are using a valid top-level Subsystem as the DUT, you can run this HDL model check “Check for invalid top level subsystem” on page 44-13.
- Make sure that the **HDL Architecture** of the DUT is not specified as a BlackBox. See “BlackBox Subsystems” on page 25-24.
- Connect output signals that are unconnected to a Terminator block. To learn more, see “Terminate Unconnected Block Outputs” on page 25-26.
- For a nontop DUT, specify the DUT as a nonvirtual Subsystem before generating HDL code to avoid numerical mismatches in the simulation results. To learn more, see “Usage of Different Subsystem Types” on page 25-86.

Convert DUT Subsystem to Model Reference for Testbenches with Continuous Blocks

Guideline ID

1.2.2

Severity

Strongly Recommended

Description

In some cases, parts of the Simulink™ testbench can contain Simscape™ blocks or other blocks from the Simulink library that operate at a continuous sample time. To simulate these blocks, you must

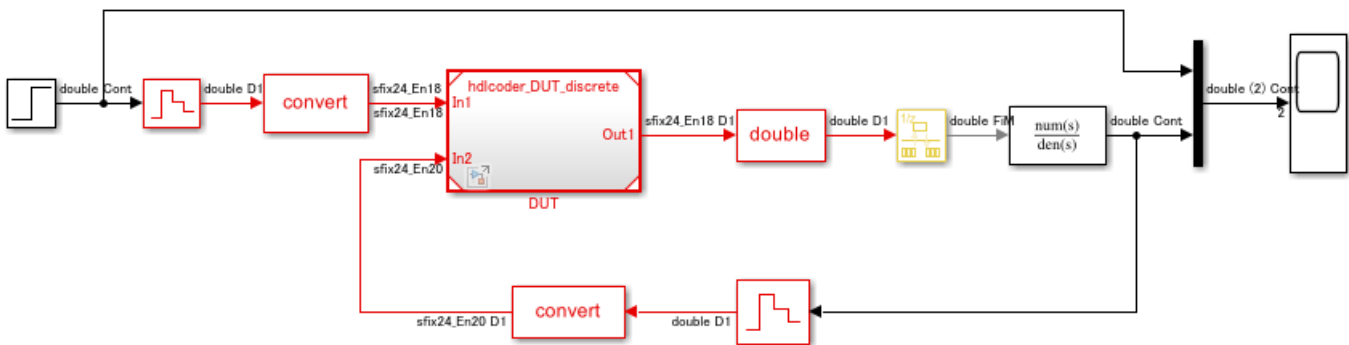

specify a continuous solver setting for your model. The solver settings that you specify applies to all blocks in your model. This means that the DUT Subsystem uses a continuous solver, which is not supported for HDL code generation. To generate HDL code, convert the DUT Subsystem to a model reference, and then use a fixed-step discrete solver for the referenced model. As the parent model and the referenced model use different solver settings, you must convert the sample time by inserting Zero-Order Hold and Rate Transition blocks at the DUT boundary.

For example, open the model `hdlcoder_testbench_continuous.slx`. The model uses `ode45`, which is a continuous solver setting. You see that the DUT is a Model block. Zero-Order Hold and Rate Transition blocks at the boundary convert the sample time.

```
open_system('hdlcoder_testbench_continuous')
set_param('hdlcoder_testbench_continuous', 'SimulationCommand', 'Update')
get_param('hdlcoder_testbench_continuous', 'Solver')
```

ans =

'ode45'

Copyright 2018-2021 The MathWorks, Inc.

To see the referenced model `hdlcoder_DUT_discrete`, double-click the DUT block. You see that the DUT uses a discrete solver setting.

```
open_system('hdlcoder_testbench_continuous/DUT')
get_param('hdlcoder_DUT_discrete', 'Solver')
```

ans =

'FixedStepDiscrete'

Copyright 2018–2021 The MathWorks, Inc.

Insert Handwritten Code into Simulink Modeling Environment

Guideline ID

1.2.3

Severity

Informative

Description

You can reuse a pre-verified RTL IP or insert your handwritten HDL code into the Simulink modeling environment by using these methods:

- **Verilog HDL Import**

If you have handwritten Verilog code, you can import the code into the Simulink environment. The import process generates a Simulink model that is functionally equivalent to your handwritten HDL code.

HDL import supports a subset of Verilog constructs that you can use for importing your design to create the Simulink model. To learn more, see:

- “Supported Verilog Constructs for HDL Import” on page 14-166
- “Limitations of Verilog HDL Import” on page 14-164

- **BlackBox Subsystems**

You can use BlackBox subsystems to insert your handwritten HDL code for a block in your Simulink model. You can then integrate BlackBox subsystems with other blocks in your Simulink model and then generate HDL code.

To make the BlackBox Subsystem compatible with other blocks for HDL code generation and to include this block in your model, create the block in Simulink:

- Name the block by using the same name as the VHDL entity or Verilog module.
- Define the same inputs and outputs, including the same types, sizes, and names.
- Define the same clock, reset, and clock enable signals. A single block can have not more than one clock, reset, and clock enable signal.
- Use a single sample rate for the block.
- Specify the **Architecture** of the block as `BlackBox` in the HDL Block Properties.

To learn more, see “Generate Black Box Interface for Subsystem” on page 32-4 .

- **DocBlock in BlackBox Subsystems**

To keep the HDL code with your model, instead of as a separate file, use a DocBlock to integrate custom HDL code. You can use your own handwritten VHDL or Verilog code as the text in the DocBlock.

You include each DocBlock that contains custom HDL code by placing it in a black box subsystem, and including the black box subsystem in your DUT. One HDL file is generated per black box subsystem. For more information, see “Integrate Custom HDL Code by Using DocBlock” on page 32-10.

- **HDL Cosimulation Blocks**

If you have a HDL simulator such as Mentor Graphics ModelSim or Cadence Incisive, you can use HDL Cosimulation blocks to simulate the HDL code for the DUT by using that HDL simulator.

You can simulate the HDL code for the DUT in Simulink and instantiate the HDL code in the generated code for the DUT.

Hierarchical Modeling Guidelines

Consider using these recommended settings when you build your model hierarchically and generate HDL code for your design. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Avoid Constant Block Connections to Subsystem Port Boundaries

Guideline ID

1.2.4

Severity

Mandatory

Description

It is recommended that you avoid directly connecting Constant blocks to the output ports of a Subsystem. Synthesis tools may optimize and remove the constants and create unconnected ports.

If you use floating-point data types with the **Native Floating Point** mode enabled, and input constant values to an arithmetic operator such as an Add block, HDL Coder™ replaces the Add block with a Constant block when generating code. This optimization can result in a Constant block directly connected to the output port. Therefore, it is recommended that you avoid such modeling constructs. See also “Simplify Constant Operations and Reduce Design Complexity in HDL Coder” on page 28-18.

For example, open the model `hdlcoder_constant_subsystem_boundary.slx`. The DUT contains two subsystems `Constant_subsys1` and `Constant_subsys2`, the outputs of which are inputs to a third Subsystem. `Constant_subsys1` contains Constant blocks directly connected to the output ports, and `Constant_subsys2` contains Constant blocks that have single data types as inputs to an Add block.

```
load_system('hdlcoder_constant_subsystem_boundary.slx')
set_param('hdlcoder_constant_subsystem_boundary','SimulationCommand','Update')
open_system('hdlcoder_constant_subsystem_boundary/DUT/Constant_subsys1')
```

```
open_system('hdlcoder_constant_subsystem_boundary/DUT/Constant_subsys2')
```

As `Constant_subsys2` uses single data types and the model has Native Floating Point mode enabled, when you generate HDL code for the DUT, the `Constant_subsys2` becomes a candidate for the optimization that simplifies constant operations. When you open the generated model, you see a Constant block directly connected to the output port.

```
open_system('gm_hdlcoder_constant_subsystem_boundary.slx')
set_param('gm_hdlcoder_constant_subsystem_boundary', 'SimulationCommand', 'Update')
open_system('gm_hdlcoder_constant_subsystem_boundary/DUT/Constant_subsys2')
```

Generate Parameterized HDL Code for Constant and Gain Blocks

Guideline ID

1.2.5

Severity

Recommended

Description

To generate parameterized HDL code for Gain and Constant blocks:

- The Subsystem that contains the Gain and Constant blocks must be a masked subsystem. The Gain and Constant blocks use these mask parameter values. You define mask parameters of the Subsystem in the Mask Editor dialog box.
- The Subsystem that contains the Gain and Constant blocks must be an Atomic Subsystem. To make a Subsystem an Atomic Subsystem, right-click that Subsystem and select **Treat as atomic unit**.
- Enable the **Generate parameterized HDL code from masked subsystem** setting in the Configuration Parameters dialog box or set `MaskParameterAsGeneric` to on at the command line using `makehdl` or `hdlset_param`. For more information, see “RTL Style Parameters” on page 21-58.

For an example, open the model `hdlcoder_masked_subsystems`. The Top Subsystem contains two atomic masked subsystems `MASKSUB` and `MASKSUB1` that are similar but for the masked parameter values.

```
load_system('hdlcoder_masked_subsystems')
set_param('hdlcoder_masked_subsystems', 'SimulationCommand', 'Update')
open_system('hdlcoder_masked_subsystems/TOP')
```

The model has the MaskParameterAsGeneric setting enabled. This setting corresponds to the **Generate parameterized HDL code from masked subsystem** setting that is enabled at the command line.

```
hdlsaveparams('hdlcoder_masked_subsystems')
```

```
%% Set Model 'hdlcoder_masked_subsystems' HDL parameters
hdlset_param('hdlcoder_masked_subsystems', 'HDLSubsystem', 'hdlcoder_masked_subsystems/TOP');
hdlset_param('hdlcoder_masked_subsystems', 'MaskParameterAsGeneric', 'on');
```

To generate VHDL® code for the Top Subsystem, run this command:

```
makehdl('hdlcoder_masked_subsystems/TOP')
```

In the generated code, you see that HDL Coder™ generates one HDL file MaskedSub with the different masked parameters mapped to generic ports.

SIGNAL MASKSUB1_out1         : std_logic_vector(16 DOWNT0 0); -- ufix17

BEGIN
  u_MASKSUB : MASKSUB
    GENERIC MAP( m => 5,
                 b => 2
               )
    PORT MAP( x => In1, -- uint8
              y => MASKSUB_out1 -- ufix17
            );

  u_MASKSUB1 : MASKSUB
    GENERIC MAP( m => 6,
                 b => 4
               )
    PORT MAP( x => In1, -- uint8
              y => MASKSUB1_out1 -- ufix17
            );

  Out1 <= MASKSUB_out1;

  Out2 <= MASKSUB1_out1;

END rtl;

```

Place Physical Signal Lines Inside a Subsystem

Guideline ID

1.2.6

Severity

Mandatory

Description

To avoid errors when generating HDL test bench, physical signal lines that are present at the same level as the DUT subsystem must be placed inside a Subsystem block. For example, consider this Simulink model that has physical signal lines outside the DUT subsystem, HDL_DUT.

Place the physical signal lines and the blocks connected to it that are highlighted inside a Subsystem block. You can then generate HDL code and test bench for the DUT subsystem.

Design Considerations for Matrices and Vectors

These guidelines recommend how you can use matrix and vector signals when modeling your design for HDL code generation. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Modeling Requirements for Matrices

Guideline ID

1.3.1

Severity

Mandatory

Description

HDL Coder™ support matrix data types at the DUT interfaces. You can use 2D or 3D matrices as a input to the DUT interface and generate HDL code for your model.

Example

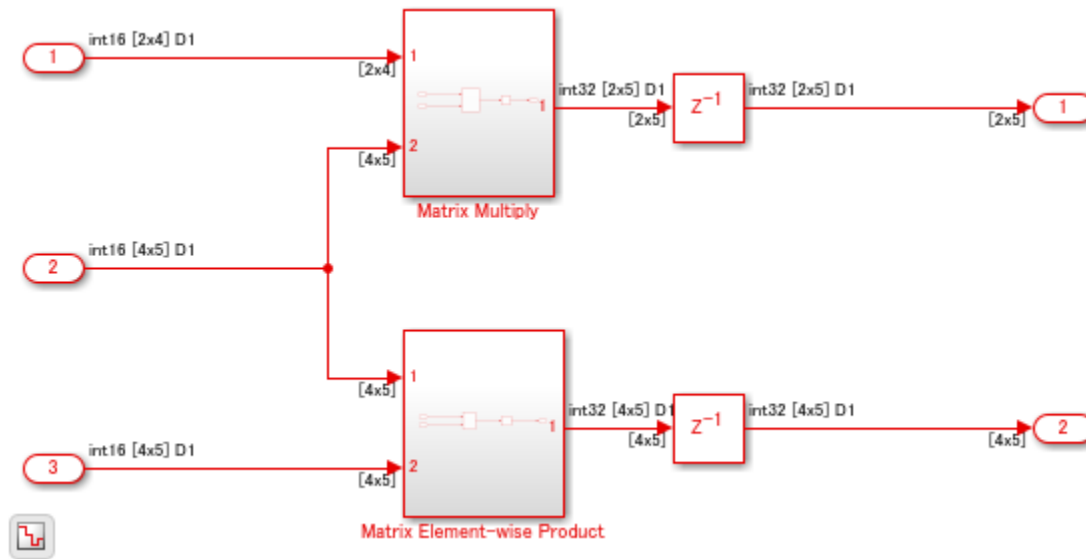

This example shows how to use matrix types in HDL Coder™. Open this model `hdlcoder_matrix_multiply`.

```
open_system('hdlcoder_matrix_multiply')
set_param('hdlcoder_matrix_multiply', 'SimulationCommand', 'update')
sim('hdlcoder_matrix_multiply')
```

If you open the DUT Subsystem, you see two subsystems. One subsystem uses a Matrix Multiply block and the other subsystem performs element-wise multiplication.

```
open_system('hdlcoder_matrix_multiply/DUT')
```

If you generate HDL code for the DUT Subsystem and open the generated model, you see how the multiplication operation is performed.

Modeling Considerations

- When you use the Product block, use the right **Multiplication** mode. By using this mode, you can perform either matrix multiplication or element-wise multiplication. The multiplied output can have different dimensions depending on the **Multiplication** mode.
- When you use the Product block to perform matrix multiplication, place the Matrix Multiply block inside a Subsystem block. When you generate code and open the generated model, you see that HDL Code expands the matrix multiplication to multiple Product and Add blocks. Placing the Matrix Multiply block inside a subsystem makes the generated model easier to understand. In addition, make sure that you do not provide more than two inputs to the Matrix Multiply block.

Limitations

HDL code generation does not support matrix inputs in these HDL workflows:

- Cosimulation model generation
- FPGA-in-the-Loop
- IP Core Generation

Avoid Generating Ascending Bit Order in HDL Code From Vector Signals

Guideline ID

1.3.2

Severity

Strongly Recommended

Description

In MATLAB, the default bit ordering for arrays is ascending. The generated VHDL code in such cases uses a declaration of `std_logic_vector (0 to n)`. This signal declaration generates warnings by violating certain HDL coding standard rules. These are some scenarios:

Ascending Bit Order Scenarios

Scenario	Problem Example	Workaround
<p>Delay block with a Delay length greater than 1.</p>	<p>This example illustrates the generated code for a Delay block with a Delay length of 5.</p> <pre> ENTITY Subsystem1 IS PORT(clk : IN std_logic; reset : IN std_logic; enb : IN std_logic; In1 : IN std_logic; -- ufix1 Out1 : OUT std_logic -- ufix1); END Subsystem1; ARCHITECTURE rtl OF Subsystem1 IS -- Signals SIGNAL Delay_reg : std_logic_vector(0 TO 4); SIGNAL Delay_out1 : std_logic; -- ufix1 </pre>	<p>Instead of using a Delay block with a Delay length of 5, you can connect five Delay blocks that have a Delay length of 1 in series.</p> <pre> ENTITY Subsystem1 IS PORT(clk : IN std_logic; reset : IN std_logic; enb : IN std_logic; In1 : IN std_logic; -- ufix1 Out1 : OUT std_logic -- ufix1); END Subsystem1; ARCHITECTURE rtl OF Subsystem1 IS -- Signals SIGNAL Delay_reg : std_logic_vector(0 TO 4); SIGNAL Delay_out1 : std_logic; -- ufix1 SIGNAL Delay1_out1 : std_logic; -- ufix1 SIGNAL Delay2_out1 : std_logic; -- ufix1 SIGNAL Delay3_out1 : std_logic; -- ufix1 SIGNAL Delay4_out1 : std_logic; -- ufix1 </pre>
<p>Combining multiple input signals to a vector signal using the Mux block.</p>	<p>This example illustrates the generated code when you use a Mux block to combine 4 input signals.</p> <pre> ENTITY Subsystem IS PORT(In1 : IN std_logic; -- ufix1 Out1 : OUT std_logic_vector(0 TO 3)); END Subsystem; ARCHITECTURE rtl OF Subsystem IS -- Signals SIGNAL Mux_out1 : std_logic_vector(0 TO 3); </pre>	<p>Use a Bit Concat block to combine the input signals. This example illustrates the generated code for this block by concatenating 4 input signals.</p> <pre> ENTITY Subsystem IS PORT(In1 : IN std_logic; -- ufix1 In2 : IN std_logic; -- ufix1 In3 : IN std_logic; -- ufix1 In4 : IN std_logic; -- ufix1 Out1 : OUT std_logic_vector(3 DOWNTO 0)); END Subsystem; ARCHITECTURE rtl OF Subsystem IS -- Signals SIGNAL Bit_Concat_out1 : unsigned(3 DOWNTO 0); -- u </pre>

Scenario	Problem Example	Workaround
<p>Using a Constant block to generate vector signals.</p>	<p>This example illustrates the generated code when you use a Constant block to generate a vector of 4 scalar boolean signals.</p> <pre> ENTITY Subsystem2 IS PORT(Out1 : OUT std_logic_vector(0 TO 3)); END Subsystem2; ARCHITECTURE rtl OF Subsystem2 IS -- Signals SIGNAL Constant_out1 : std_logic_vector(0 TO 3); </pre>	<p>Use a Demux block followed by a Bit Concat block after the Constant block. Use Bus Signals to Improve Readability of Model and Generate HDL Code

You can follow these guidelines to learn about bus signals, how to model your design by using these signals, and generate HDL code. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Guideline ID

1.3.3

Severity

Informative

Description

When to Use Buses?

If your DUT or other blocks in your model have many input or output signals, you can create bus signals to improve the readability of your model. A bus signal or bus is a composite signal that consists of other signals that are called elements. The bus signal can have a structure of different data types or a vector signal with the same data types. If all signals have the same data type, you generally use a Mux block. The constituent signals or elements of a bus can be:

- Mixed data type signals such as double, integer, and fixed-point
- Mixed scalar and vector elements
- Mixed real and complex signals
- Other buses nested to any level
- Multidimensional signals

HDL Coder Support for Buses

You can generate HDL code for designs that have:

- DUT subsystem ports connected to buses.
- Simulink® and Stateflow® blocks supported for HDL code generation.

HDL Coder™ supports code generation for bus-capable blocks in the **HDL Coder** block library. Bus-capable blocks are blocks that can accept bus signals as input and produce bus signals as outputs. For a list of bus-capable blocks that Simulink supports, see “Bus-Capable Blocks”.

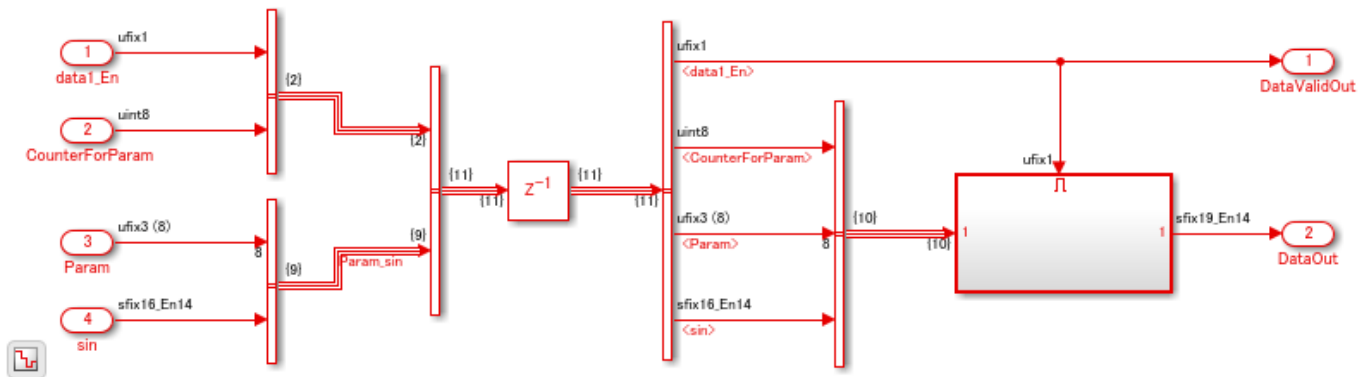

See “Signal and Data Type Support” on page 14-3 for blocks that support HDL code generation with buses.

Create Bus Signals

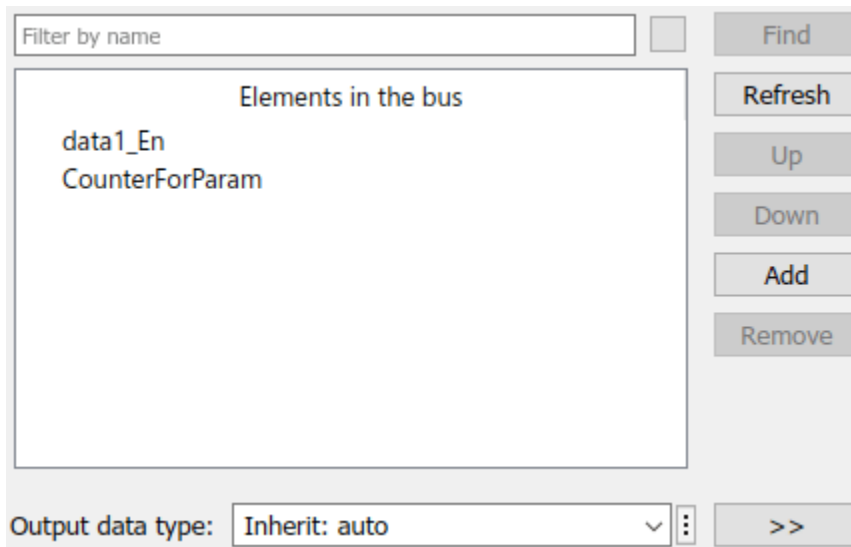

You can create bus signals by using Bus Creator blocks. A Bus Creator block assigns a name to each signal that it creates. You can then refer to signals by name when you search for their sources.

For an example that illustrates how to model with buses, open `hdlcoder_bus_nested.slx`. Double-click the HDL_DUT Subsystem.

```
open_system('hdlcoder_bus_nested')
set_param('hdlcoder_bus_nested', 'SimulationCommand', 'Update')
open_system('hdlcoder_bus_nested/HDL_DUT')
```

In this model, the Bus Creator blocks create two bus signals. One bus signal contains `data1_En` and `CounterForParam` signals. The other bus signal contains `Param` and `sin` signals. By default, each signal on the bus inherits the name of the signal connected to the bus. This figure shows the **Elements in the bus** block parameter for the Bus Creator block that takes inputs `data1_En` and `CounterForParam`.

Nest Buses

You see another Bus Creator block that combines these two bus signals. When one or more inputs to a Bus Creator block is a bus, the output is a nested bus.

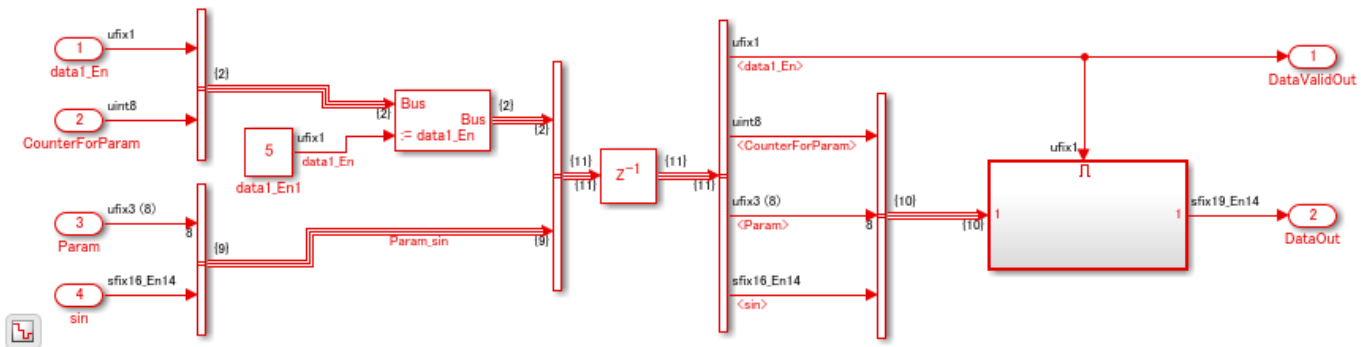

The Bus Creator block generates names for bus signals whose corresponding inputs do not have names. The names are in the form `signaln`, where `n` is the number of the port the input signal connects to. For example, if you open the Block Parameters dialog box for the second Bus Creator block, you see **Elements in the bus** as `signal1` and `Param_sin`.

Assign Signal Values to Bus

To change bus element values, use a Bus Assignment block. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus.

For example, open the model `hdlcoder_bus_nested_assignment`.

```
open_system('hdlcoder_bus_nested_assignment')
set_param('hdlcoder_bus_nested_assignment','SimulationCommand','Update')
open_system('hdlcoder_bus_nested_assignment/HDL_DUT')
```

In the model, you see a Bus Assignment block that assigns the value 5 to the `data1_En` signal in the bus.

Select Bus Outputs

To extract the signals from a bus that includes nested buses, use Bus Selector blocks. By default, the block outputs the specified bus elements as separate signals. You can also output the signals as another bus. You can use the `OutputSignals` block property to see the **Elements in the bus** that the block outputs. By using this property, you can track which signals are entering a Bus Selector block deep within your model hierarchy.

```
get_param('hdlcoder_bus_nested/HDL_DUT/Bus Selector5', 'OutputSignals')
```

ans =

```
'signal1.data1_En,signal1.CounterForParam,Param_sin.Param,Param_sin.sin'
```

Generate HDL Code

To generate HDL code for this model, run this command:

```
makehdl('hdlcoder_bus_nested/HDL_DUT')
```

You see that the code generator expands the bus signals to scalar signals in the generated code. For example, if you open the generated Verilog file for the `HDL_DUT` Subsystem, for the Delay block that takes the two nested bus signals `signal1` and `Param_sin`, you see four always blocks created for each signal in the bus. For example, you see an always block for the `data1_En` signal that is part of `signal1`. This figure displays the scalar signals created for each bus signal in the module definition.

```

`timescale 1 ns / 1 ns

module HDL_DUT
    (clk, reset, clk_enable,
     data1_En, alphaCounterForParam,
     Param_0, Param_1, Param_2, Param_3,
     Param_4, Param_5, Param_6, Param_7,
     sin, ce_out, DataValidOut, DataOut);

    .....

    assign ce_out = clk_enable;

endmodule // HDL_DUT

```

Simplify Subsystem Bus Interfaces

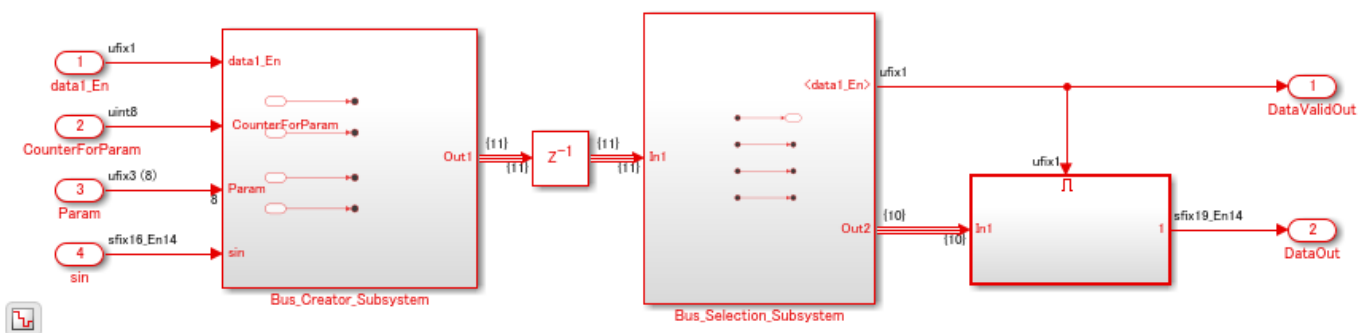

You can simplify the Subsystem bus interfaces by using Bus Element blocks. The In Bus Element and Out Bus Element blocks provide a simplified and flexible way to use bus signals as inputs and outputs to subsystems. The In Bus Element block is equivalent to an Inport block combined with a Bus Selector block. The Out Bus Element block is equivalent to an Outport block combined with a Bus Creator block. To refactor an existing model that uses Inport, Bus Selector, Bus Creator, and Outport blocks to use In Bus Element and Out Bus Element blocks, you can use Simulink Editor action bars.

For example, open the model `hdlcoder_bus_nested_simplified`. This model is functionally equivalent to the `hdlcoder_bus_nested` model but is a more simplified version.

```

open_system('hdlcoder_bus_nested_simplified')
set_param('hdlcoder_bus_nested_simplified','SimulationCommand','Update')
open_system('hdlcoder_bus_nested_simplified/HDL_DUT')

```

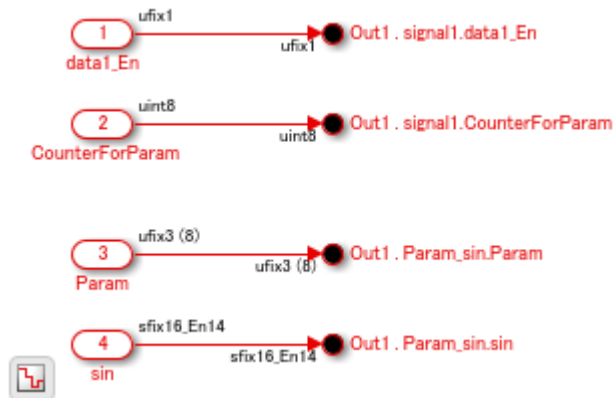

The model has two Subsystems that perform bus creation and bus selection by using Bus Element blocks. The `Bus_Creator_Subsystem` combines the Outport blocks with the Bus Creator blocks to create Out Bus Element blocks.

```

open_system('hdlcoder_bus_nested_simplified/HDL_DUT/Bus_Creator_Subsystem')

```

The Bus_Selection_Subsystem combines the Inport blocks with the Bus Selector blocks to create In Bus Element blocks.

```
open_system('hdlcoder_bus_nested_simplified/HDL_DUT/Bus_Selection_Subsystem')
```

To learn more, see “Simplify Subsystem and Model Interfaces with Bus Element Ports”.

Virtual and Nonvirtual Buses

The bus signals in the model `hdlcoder_bus_nested` created earlier by using Bus Creator and Bus Selector blocks are virtual buses. Each bus element signal is stored in memory, but the bus signal is not stored. The bus simplifies the graph but has no functional effect. In the generated HDL code, you see the constituent signals but not the bus signal.

To more easily track the correspondence between a bus signal in the model and the generated HDL code, use nonvirtual buses. Nonvirtual buses generate clean HDL code because it uses a structure to hold the bus signals. To convert a virtual bus to a nonvirtual bus, in the Block Parameters of the Bus Creator blocks, you specify the **Output data type** as `Bus: object_name` by replacing `object_name` with the name of the bus object and then select **Output as nonvirtual bus**.

See “Convert Virtual Bus to Nonvirtual Bus”.

Array of Buses

An array of buses is an array whose elements are buses. Each element in an array of buses must be nonvirtual and must have the same data type.

To learn more about modeling with array of buses, see “Generating HDL Code for Subsystems with Array of Buses” on page 14-22.

Guidelines for Clock and Reset Signals

In the Simulink modeling environment, You do not create global signals such as clock, reset, and clock enable. These signals are created when you generate HDL code for your model. You can specify the clock cycle by using the sample time in Simulink.

If your model is single rate, it means all blocks operate at the same sample time. The synthesis tools infer that the registers or Delay blocks you add to your model run at the clock rate. For the synthesis tools, data propagates from the source register to the destination register in one clock cycle.

You can follow these guidelines to learn about generating clock signals in the HDL code. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Use Global Oversampling to Create Frequency-Divided Clock

Guideline ID

1.4.1

Severity

Informative

Description

You can assign a frequency-divided clock rate for HDL code generation to be a multiple of the Simulink base sample rate. For example, if the Simulink base rate is 1 MHz and you want the clock frequency of your target hardware to run at 50 MHz, you can assign an **Oversampling factor** of 50. You specify the “Oversampling factor” on page 21-15 in the **HDL Code Generation > Global Settings** pane of the Configuration Parameters dialog box. To learn more, see “Generate a Global Oversampling Clock” on page 27-9.

Create Multirate Model with Integer Clock Multiples by Clock Division

Guideline ID

1.4.2

Severity

Mandatory

Description

You can generate a multirate model by using clock-rate division or by using clock multiples. For a multirate model, the fastest sample time in your Simulink® model corresponds to the primary clock rate. A timing controller entity is created to control the clocking for blocks operating at slower sample rates. Clock enable signals that have the necessary rate and phase information control the clocking for these blocks in your design.

Multirate models are created when you use certain blocks in your Simulink model, specify certain block architectures, or use operations such as resource sharing. For example, these block-architecture combinations generate a multirate model:

- Divide block with Newton-Raphson implementation.
- Reciprocal block with ReciprocalSqrtBasedNewton implementation.
- Sum of Elements and Product of Elements blocks with Cascade architecture.
- Sqrt with SqrtBasedNewton and Reciprocal Sqrt with ReciprocalSqrtBasedNewton implementation.

In addition, to model multirate designs in Simulink, use these blocks:

- In the **Simulink** > **Signal Attributes** Library, use the Rate Transition block.
- In the **DSP System Toolbox** > **Signal Operations** Library, you can use Upsample, Downsample, and Repeat blocks.
- In the **HDL Coder** > **HDL RAMs** Library, use the HDL FIFO block.

This model illustrates how to create a multirate design by using a Rate Transition block.

```
load_system('hdlcoder_multiclock')
set_param('hdlcoder_multiclock', 'SimulationCommand', 'Update')
open_system('hdlcoder_multiclock')
```

Copyright 2018-2021 The MathWorks, Inc.

The different colors in the model indicate that the model is multirate and has a faster rate D1 and a slower rate D2. To see the Rate Transition block that produces the different sample rates, double-click the DUT Subsystem.

```
open_system('hdlcoder_multiclock/DUT')
```

To see the sample times in your model, run this command:

```
ts = Simulink.BlockDiagram.getSampleTimes('hdlcoder_multiclock');
sampletime_D1 = ts(1)
sampletime_D2 = ts(2)
```

```
sampletime_D1 =
```

```
SampleTime with properties:
```

```
Value: [1.0000e-03 0]
Description: 'Discrete 1'
ColorRGBValue: [0.9000 0 0]
Annotation: 'D1'
OwnerBlock: []
ComponentSampleTimes: [0x0 Simulink.SampleTime]
```

```
sampletime_D2 =
```

```
SampleTime with properties:
```

```
Value: [0.0030 0]
Description: 'Discrete 2'
ColorRGBValue: [0 0.8200 0]
Annotation: 'D2'
OwnerBlock: []
ComponentSampleTimes: [0x0 Simulink.SampleTime]
```

When you use a Rate Transition block in your model for multirate design, select the block parameters **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)**. Make sure the output sample rate is an integer multiple of the input sample rate.

For a multirate design, you can generate a single clock signal or multiple clock signals to control the clocking to blocks that operate at various sample rates. To specify this setting, in the Configuration Parameters dialog box, on the **HDL Code Generation > Global Settings** pane, specify the **Clock inputs** setting.

By default, **Clock inputs** is specified as **single**. A single clock is generated to control the clocking for all registers or Delay blocks in your model. The timing controller enable signals control the

clocking to various blocks in your design. This mode can increase the power dissipation as a single, fastest clock is connected to all registers in your design.

If you specify **Clock inputs** as `multiple`, a clock signal is generated for each sample rate in your design. However, this mode requires you to connect each of the clock, clock enable, and reset ports externally. This mode reduces power as the HDL design contains registers connected to slower clock signals. For more information, see “Using Multiple Clocks in HDL Coder” on page 27-13.

Use Dual Rate Dual Port RAM for Noninteger Multiple Sample Times

Guideline ID

1.4.3

Severity

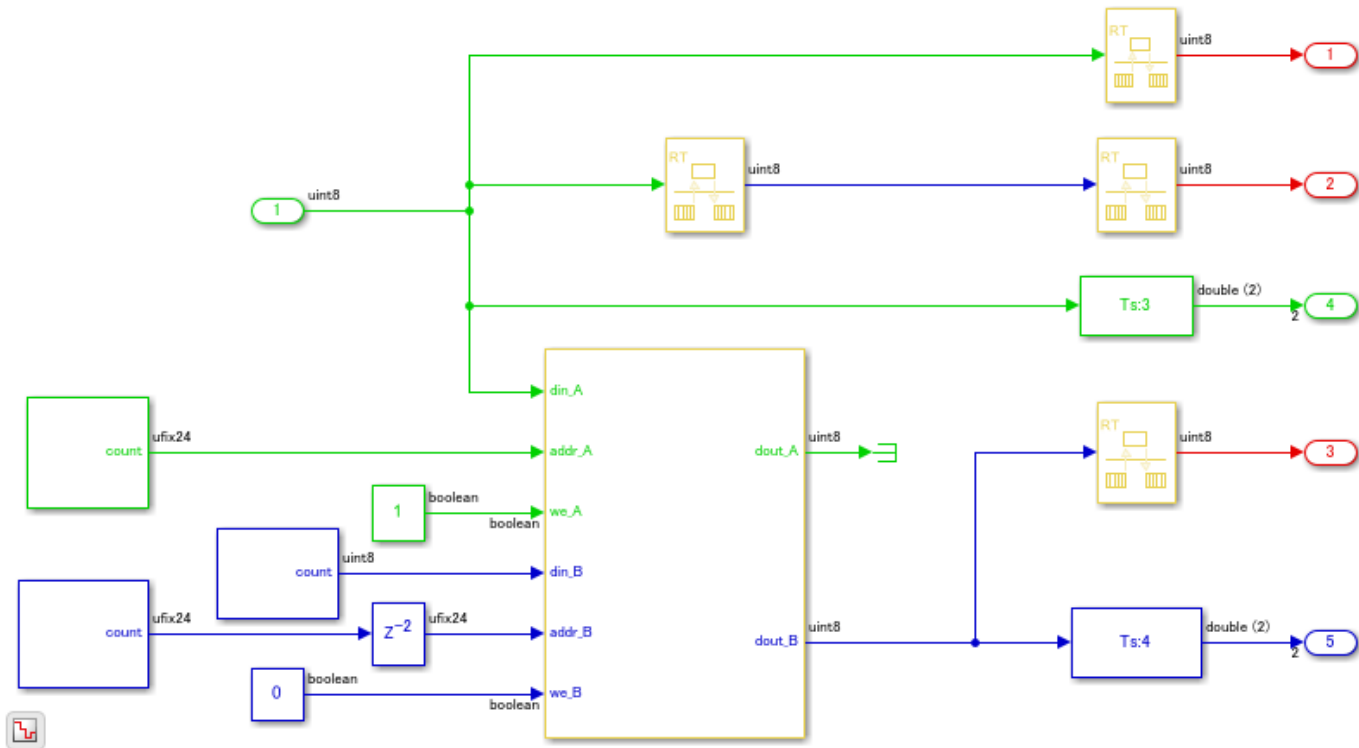

Mandatory

Description

When you use Rate Transition, Upsample, or Downsample blocks to create multirate models, the clock rates must be integer multiples of the base rate. To create a multirate model with clocks that are noninteger multiples, use a Dual Rate Dual Port RAM block. For integer clock multiplies, you can use the HDL FIFO or the Dual Rate Dual Port RAM block.

This model illustrates how you can create noninteger multiples of sample rates.

```
load_system('hdlcoder_dual_rate_dual_port_RAM')
set_param('hdlcoder_dual_rate_dual_port_RAM','SimulationCommand','Update')
open_system('hdlcoder_dual_rate_dual_port_RAM/DUT')
```

You cannot generate HDL code for this model because the Rate Transition blocks have the block parameter **Ensure data integrity during data transfer** cleared. To learn how you can manage address control when you use the RAM block, see “Design Considerations for RAM Blocks and Blocks in HDL Operations Library” on page 25-67.

Asynchronous Clock Modeling in HDL Coder

Guideline ID

1.4.4

Severity

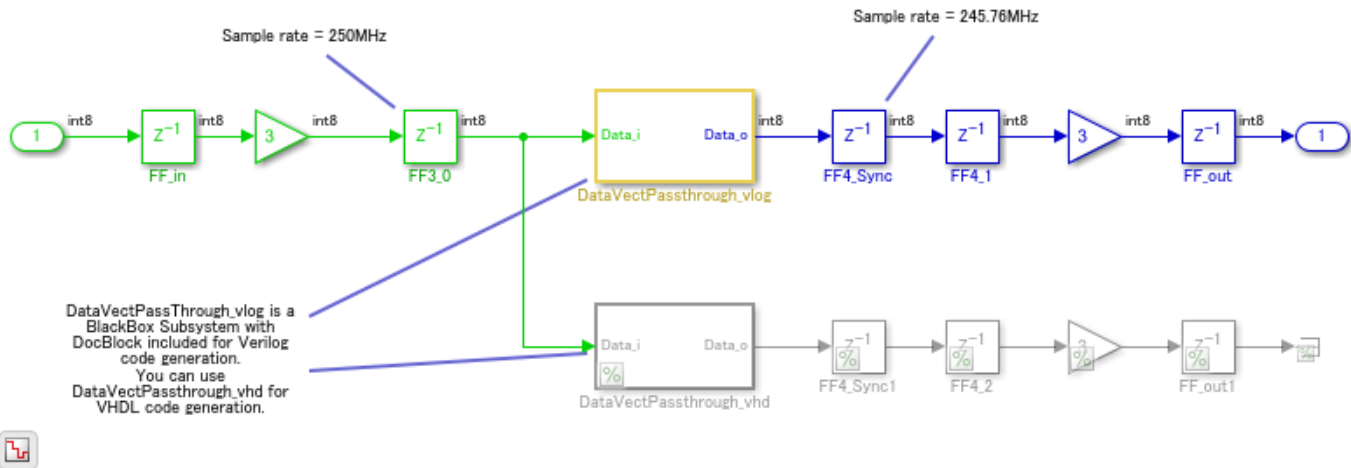

Recommended

Description

Most FPGA designs must have more than one clock domain with multiple parts of the design operating at various frequencies. You can model the various clock domains in Simulink® by using a pass-through implementation for transitioning between different sample rates. These sample rates correspond to the clock rates on the FPGA device.

For an example, open the model `hdlcoder_multi_clock_domain` and then open the DUT Subsystem.

```
load_system('hdlcoder_multi_clock_domain')
set_param('hdlcoder_multi_clock_domain', 'SimulationCommand', 'Update')
open_system('hdlcoder_multi_clock_domain/DUT')
```

You see a BlackBox Subsystem that contains a DocBlock, which is a text file that corresponds to the Verilog® code for a passthrough implementation. You can open the DocBlock to see the Verilog code. You see that the output of this Subsystem operates at a different sample rate or is in a clock domain that is different from the sample rate at the input of the Subsystem. The Subsystem also contains a commented out path that contains the VHDL® equivalent of the passthrough implementation. To generate VHDL code, uncomment this path and comment out the path that contains the Verilog BlackBox implementation.

To generate Verilog code for this model, run this command:

```
makehdl('hdlcoder_multi_clock_domain/DUT')
```

In the generated Verilog header file, you see the different clock domains in the model.

```

Use Global Reset Type Setting Based on Target Hardware

Guideline ID

1.4.5

Severity

Recommended

Description

Matching the reset type to the FPGA architecture can improve resource utilization and the speed at which your design runs on the target hardware. To control this setting, in the Configuration Parameters dialog box, on the **HDL Code Generation > Global Settings** settings, specify the **Reset type**.

When you target Xilinx devices, set **Reset type** to Synchronous. For Intel or Altera devices, set **Reset type** to Asynchronous.

To make sure that you use the correct reset type for the hardware that you are targeting, in the HDL Code Advisor, run the model check “Check for global reset setting for Xilinx and Altera devices” on page 44-7.

Note Some Intel devices recommend using synchronous reset. For recommended reset settings, see the Intel or Xilinx documentation for that device.

Modeling with Native Floating Point

HDL Coder native floating-point technology can generate HDL code from your floating-point design. These are some of the key features:

- Generation of target-independent HDL code that you can deploy on any FPGA or ASIC.
- Support for the full range of IEEE-754 features including denormal numbers, exceptions, and rounding modes.
- Extensive support for math and trigonometric blocks.

You can follow these guidelines as best practices when modeling your design for native floating-point code generation.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Guideline ID

1.5.1

Severity

Recommended

Description

Native floating-point support in HDL Coder generates code from your floating-point design. If your design has complex math and trigonometric operations or has data with a large dynamic range, use native floating-point. The generated HDL code is target-independent and complies with the IEEE-754 standard of floating-point arithmetic. To learn more, see “Getting Started with HDL Coder Native Floating-Point Support” on page 14-92.

You can use these modeling guidelines when using the native floating-point support in HDL Coder.

Use Blocks from HDL Floating Point Operations Library

The **HDL Floating Point Operations** block library consists of math and trigonometric functions and certain Simulink blocks that are configured for HDL code generation in native floating-point mode. For example, Discrete FIR Filter with **Architecture** set to **Fully Parallel**.

Use Floating-Point Types Based on Accuracy and Hardware Resource Usage Requirements

You can generate HDL code for models that contain floating-point and fixed-point data types in native floating-point mode. Floating point types have higher dynamic range but can potentially occupy more area on the target hardware. To design for these trade-offs, in your Simulink model, it is recommended to use floating-point data types to model the algorithm data path and fixed-point types to model the control logic. To switch between floating-point and fixed-point data types, use Data Type Conversion blocks.

See also “Data Type Considerations” on page 14-94.

Enable Optimizations such as Resource Sharing on Model

By enabling optimizations on the model, you can improve area and timing of your design on the target FPGA device. For example, to save area on the target FPGA device, use the resource sharing optimization. To share:

- Floating-point adders, set “Share Adders” on page 19-18 to on.
- Floating-point multipliers, make sure “Share Multipliers” on page 19-20 is set to on.
- Other floating-point resources, set “Share Floating-Point IPs” on page 19-29 to on.

See also “Resource Sharing” on page 28-45.

Simulate Latency of Blocks in Model

Floating-point designs have an inherent latency by default. This latency is added when generating HDL code for your model. It is recommended that you simulate latency in your model by adding this latency information to your original Simulink model. The code generator absorbs this latency during HDL code generation. To learn more, see “Latency Values of Floating-Point Operators” on page 14-103.

Customize Latency of Model or Blocks

You can customize the latency of an entire model, or selectively for certain blocks in your design. Using custom settings, you can specify a custom latency and design for trade-offs between latency and throughput.

To learn more, see “Latency Considerations with Native Floating Point” on page 14-109.

Use sincos Block Instead of Separate sin and cos Blocks

Certain modeling patterns that you use can optimize your model when you generate code with native floating-point technology. For example, if you are computing the trigonometric sine and cosine of the same input, in the HDL Floating Point Operations block library, use the Sincos block instead of separate Sin and Cos blocks. The Sincos block shares some of the logic that is used for computing the sine and cosine of the input. This implementation reduces the area footprint on the target FPGA device.

See also Trigonometric Function.

Use Tree as the HDL Architecture

To obtain a lower latency implementation, use Tree as the **HDL Architecture** for blocks such as the Sum of Elements and Product of Elements.

See also Sum of Elements and Product of Elements.

Design Considerations for RAM Blocks and Blocks in HDL Operations Library

Follow these guidelines to learn how you can use RAM blocks and blocks in the **HDL Operations** library when modeling your design.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

RAM Block Access Considerations

Guideline ID

2.1.1

Severity

Recommended

Description

In the **HDL RAMs** block library, there are seven different RAM blocks and a HDL FIFO block. If you see a RAM block that has the term **System** as part of the block name, such as Single Port RAM System, it is recommended that you use this block instead of the equivalent block that does not have **System** as part of the name, such as Single Port RAM. These blocks have **System** as part of the name because the block implementation is based on the `hdl.RAM System` object. The system blocks support vector inputs and yield much faster simulation results when used in your Simulink model.

When you use these blocks, make sure that the input sample time and output sample time are the same. This table illustrates the various RAM blocks that you can use and their purpose. Each row in the table describes a RAM block that is larger in circuit size than the RAM block in the previous row. The generated HDL code for these blocks maps to RAM in most FPGAs.

Block Name	Recommended Usage
Single Port RAM System	<p>Use this block to replace the Single Port RAM block in your model. You obtain faster simulation results when using this block in your model.</p> <p>The block implementation uses a MATLAB System block that uses the <code>hdl.RAM System</code> object. Use this block to perform sequential read and write operations. In the Block Parameters dialog box of the block, you can specify an initial value for the RAM. To perform simultaneous read and write operations to different addresses, use the Simple Dual Port RAM System or the Dual Port RAM System block instead.</p> <p>The block does not support boolean inputs. Cast boolean types to <code>ufix1</code> for input to the block.</p>

Block Name	Recommended Usage
Simple Dual Port RAM System	<p>Use this block to replace the Simple Dual Port RAM block in your model. You obtain faster simulation results when using this block in your model.</p> <p>The block implementation uses a MATLAB System block that uses the <code>hdl.RAM System</code> object. Use this block to perform simultaneous read and write operations. It has a single output port to read data. In the Block Parameters dialog box of the block, you can specify an initial value for the RAM.</p> <p>The block does not support boolean inputs. Cast <code>boolean</code> types to <code>ufix1</code> for input to the block.</p>
Dual Port RAM System	<p>Use this block to replace the Dual Port RAM block in your model. You obtain faster simulation results when using this block in your model.</p> <p>The block implementation uses a MATLAB System block that uses the <code>hdl.RAM System</code> object. Use this block to perform simultaneous read and write operations. It has a read data output port and a write data output port. In the Block Parameters dialog box of the block, you can specify an initial value for the RAM. If you do not want to use the write data output port, to achieve better RAM inference, use the Simple Dual Port RAM System block instead.</p> <p>The block does not support boolean inputs. Cast <code>boolean</code> types to <code>ufix1</code> for input to the block.</p>
Dual Rate Dual Port RAM	<p>This block does not have an equivalent System object-based implementation.</p> <p>Use this block to perform simultaneous read and write operations to two different addresses that operate at different clock rates. You cannot perform concurrent access to the same address of the RAM.</p> <p>To run the RAM ports at multiple clock rates, set Clock Inputs to Multiple. You can access this RAM twice in one clock cycle.</p>

Block Name	Recommended Usage
HDL FIFO	<p>The HDL FIFO block stores a sequence of samples in a first in, first out (FIFO) register.</p> <p>The inputs, <code>In</code> and <code>Push</code>, and the outputs, <code>Out</code> and <code>Pop</code> can run at different sample times. Specify the ratio of output to input sample time as a positive integer or $1/N$ such that N is a positive integer. For example:</p> <ul style="list-style-type: none"> • If you specify the ratio as 2, the output sample time is twice the input sample time. The outputs run slower than the input. • If you specify the ratio as $1/2$, the output sample time is half the input sample time. The outputs run faster than the input. <p>The signals <code>Full</code>, <code>Empty</code>, and <code>Num</code> run at the fastest rate in your model. When you use the control output of the FIFO in an input, you may have to perform a rate transition.</p> <p>The input and output rates of the FIFO block are synchronous to each other. For an example of asynchronous FIFO modeling by using the HDL FIFO block, open the model <code>hdlcoder_asynchronous_fifo</code>.</p> <pre>open_system('hdlcoder_asynchronous_fifo')</pre>

Serial to Parallel Conversion

Guideline ID

2.1.2

Severity

Informative

Description

You can use the `Serializer1D` and `Deserializer1D` blocks to perform serial to parallel and parallel to serial conversion.

Usage of Blocks in Logic and Bit Operations Library

These guidelines illustrate how to model your design for generating HDL-ready code from blocks in the **Logic and Bit Operations** Library. The Library contains blocks that perform logical and bitwise operations, bit reduction, and concatenation. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Logical and Arithmetic Bit Shift Operations

Guideline ID

2.2.1

Severity

Informative

Description

You can use Simulink blocks to perform bit shifting operations. The blocks can perform logical and arithmetic bit shift. Left logical and arithmetic bit shift produce the same results but right logical shift and arithmetic shift operate differently as illustrated in this table.

Block/Function Name	Parameter/Operation	Verilog Code Equivalent	VHDL code equivalent	Comments
Bit Shift	Shift Left Logical	<<<	sll (sll and SHIFT_LEFT are the same in VHDL).	This mode is the default mode for the block. The left shift operation does not preserve the sign bit. If the input uses a signed data type and has a positive value, the left shift operation shifts a 0 into the empty bit on the LSB (Least Significant Bit) side.
	Shift Right Logical	>>	srl	This mode does not preserve the sign bit. If the input uses a signed data type and has a positive value, the right shift operation shifts a 0 into the empty bit on the MSB (Most Significant Bit) side.
	Shift Right Arithmetic	>>>	SHIFT_RIGHT	When the input is a signed data type, the sign bit is preserved, and other bits shift to the right.
Shift Arithmetic block bitshift function	Positive value/shift right arithmetic	>>>	SHIFT_RIGHT	When the input is a signed data type, the sign bit is preserved, and other bits shift to the right.

Block/Function Name	Parameter/Operation	Verilog Code Equivalent	VHDL code equivalent	Comments
	Negative value/ shift left arithmetic	<<<	sll	This mode does not preserve the sign bit. If the input uses a signed data type and has a positive value, the left shift operation shifts a 0 into the empty bit on the LSB side. This mode does not check underflows and overflows.
bitsll function	None/logical left shift	<<<	sll	This mode does not preserve the sign bit. The generated HDL code is the same as that of the Shift Left Logical mode of the Bit Shift block.
bitsrl function	None/logical right shift	>>	srl	This mode does not preserve the sign bit. The generated HDL code is the same as that of the Shift Right Logical mode of the Bit Shift block.
bitsra function	None/arithmetic right shift	>>>	SHIFT_RIGHT	When the input is a signed data type, the sign bit is preserved, and other bits shift to the right. The generated HDL code is the same as that of the Shift Right Arithmetic mode of the Bit Shift block.

The difference between a logical shift and an arithmetic shift is whether the sign bit is preserved. For signed data types, this bit is the MSB. In a logical right shift, the sign bit is shifted to the right and zero goes into the MSB side. In an arithmetic right shift, the MSB (sign bit) is preserved during the shift operation. For example, this code illustrates the difference between the functions.

```
A = fi([], 1, 4, 0, 'bin', '1011');
B = bitsrl(A, 2)
```

```
B =
```

```
2
```

```
    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 4
    FractionLength: 0
```

```
B.bin
```

```
ans =
```

```
'0010'
```

```
C = bitsra(A, 2)
C =
    -2
    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 4
    FractionLength: 0
C.bin
ans =
    '1110'
```

Usage of Logical Operator, Bitwise Operator, and Bit Reduce Blocks

Guideline ID

2.2.2

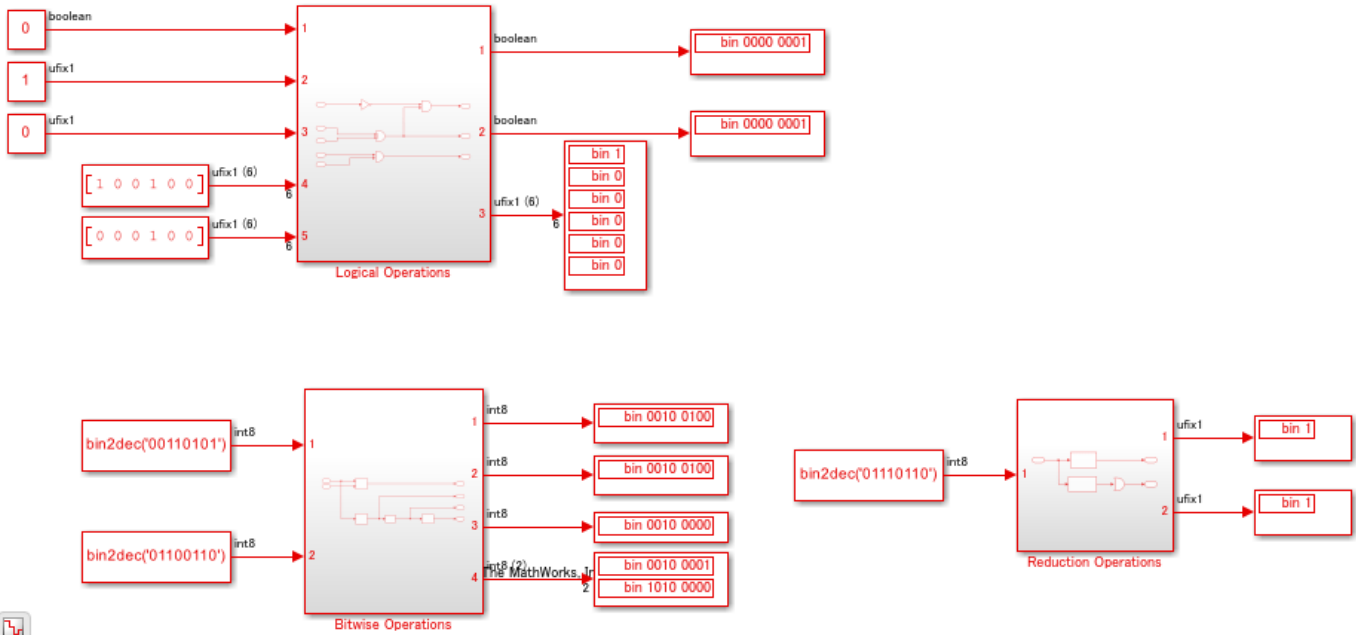

Severity

Informative

Description

For an example of logical and bitwise operations, open the model `hdlcoder_logical_bitwise_operations.slx`.

```
load_system('hdlcoder_logical_bitwise_operations')
sim('hdlcoder_logical_bitwise_operations')
open_system('hdlcoder_logical_bitwise_operations')
```

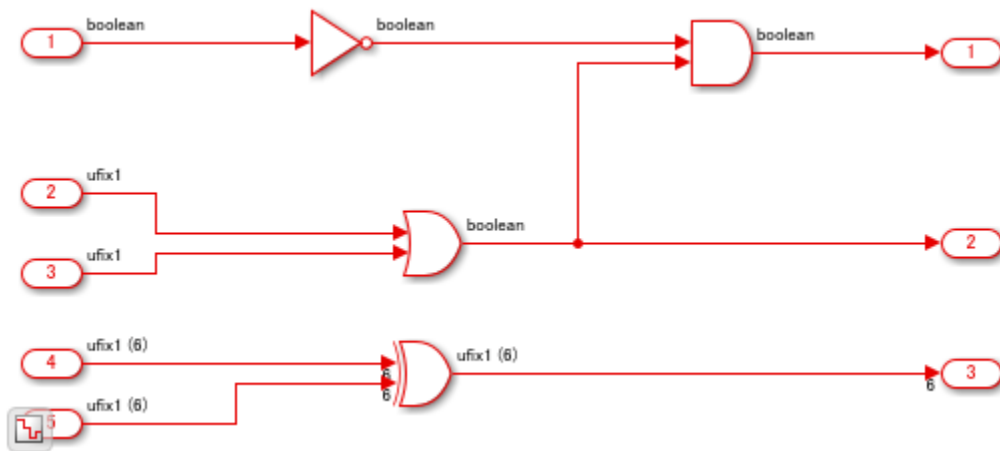

For single-bit operations that use Boolean or ufix1 data types, use a Logical Operator block. To view the operation as a logical circuit symbol, in the Block Parameters dialog box of the block, specify the **Icon shape** as Distinctive. You can also input vectors that have Boolean or ufix1 data types to the block.

Boolean and ufix1 are different data types. Avoid using both data types within the same model, or using them interchangeably. See “Simulink Data Type Considerations” on page 25-125.

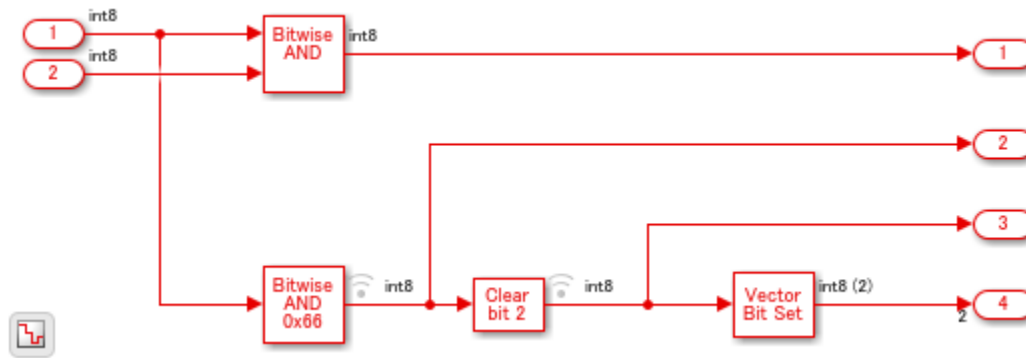

For an example of using the block, open the Logical Operations Subsystem.

```
open_system('hdlcoder_logical_bitwise_operations/Logical Operations')
```

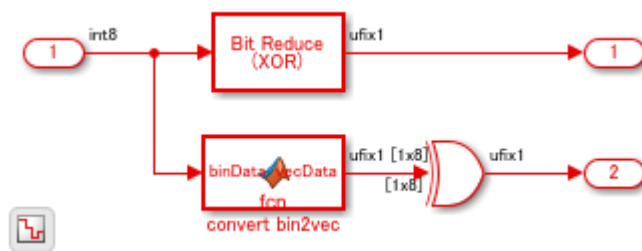

For bitwise operations on two or more bits that use integer or fixed-point data types, use the Bitwise Operator block. For an example, double-click the Bitwise Operations Subsystem.

```
open_system('hdlcoder_logical_bitwise_operations/Bitwise Operations')
```

To perform a bit-by-bit reduction operation on a vector that uses `Boolean` or `ufix1` and return a 1-bit value, use the Bit Reduce block. For an example, double-click the Reduction Operations Subsystem.

```
open_system('hdlcoder_logical_bitwise_operations/Reduction Operations')
```

The MATLAB Function block inside the Subsystem converts the 8-bit vector to a vector of 8 1-bit `ufix1` elements.

```
open_system('hdlcoder_logical_bitwise_operations/Reduction Operations/convert_bin2vec')
```

Use Boolean Output for Compare to Constant and Relational Operator Blocks

Guideline ID

2.2.3

Severity

Strongly Recommended

Description

For Compare To Constant, Compare To Zero, and Relational Operator blocks, you can specify `uint8` or `boolean` as the **Output data type**. To generate efficient HDL code for models that contain these blocks, specify `boolean` as the **Output data type**, because the HDL code has to connect only the LSB.

For a Relational Operator block, make sure that both inputs are of the same data type. Using different data types for the inputs can result in unintended truncation of bits such as the sign bit, which can lead to simulation mismatches after HDL code generation.

To verify whether Relational Operator blocks in your model use the same input data type, and use `boolean` as the output data type, run the HDL model check “Check for Relational Operator block usage” on page 44-30.

Generate FPGA Block RAM from Lookup Tables

To map the lookup table blocks to random-access memory (RAM) to save area on your target Field Programmable Gate Array (FPGA) device, follow these guidelines.

Each guideline has a severity level that indicates the level of compliance requirements. For more information, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Guideline ID

2.3.1

Severity

Strongly Recommended

Description

To map lookup tables to a block RAM, you can use the **Map lookup tables to RAM** parameter located in the **HDL Code Generation** tab > **Optimization** > **Pipelining** tab in the Model Configuration Parameters dialog box. This parameter is selected on by default. The optimization inserts a Delay block that has a **Delay length** of 1 and **ResetType** set to none immediately following the Lookup Table block. This modeling pattern efficiently maps your design to a Block RAM on the FPGA. To use the map lookup tables to RAM option, you must:

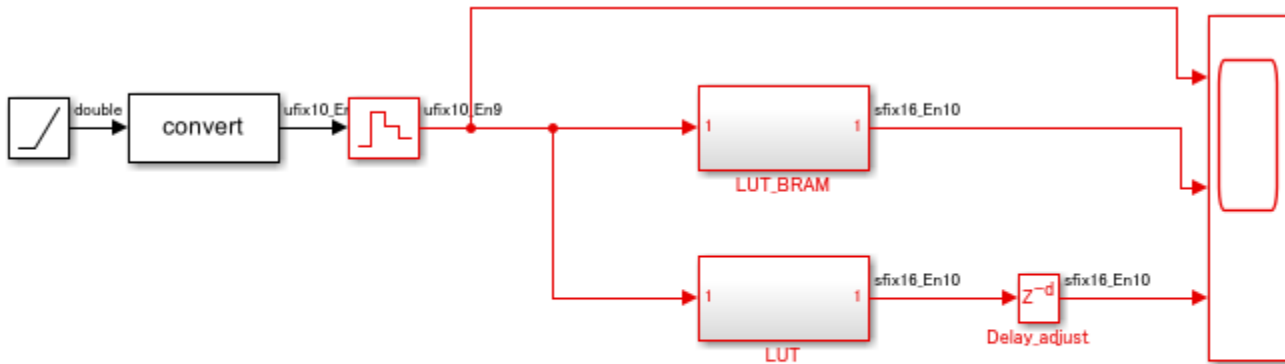

- Make sure that the **Map lookup tables to RAM** option is selected on for the model.
- Specify the synthesis tool.

See “Map lookup tables to RAM” on page 19-16.

Alternatively, you can selectively enable this optimization for certain subsystems in your design by using the MapToRAM HDL Block Property and disabling the **Map lookup tables to RAM** option for the model or create the modeling pattern in your design that is the same as the pattern otherwise generated by the optimization.

For an example, open the model `hdlcoder_LUT_BRAM_mapping.slx`.

```
open_system('hdlcoder_LUT_BRAM_mapping')
set_param('hdlcoder_LUT_BRAM_mapping','SimulationCommand','Update')
```

Copyright 2019 The MathWorks, Inc.

The **Map lookup tables to RAM** option is enabled on this model.

```
hdlget_param('hdlcoder_LUT_BRAM_mapping', 'LUTMapToRAM')
```

```
ans =
```

```
'on'
```

The LUT_BRAM Subsystem contains a 1-D Lookup Table block followed by a Delay block that has a **Delay length** of 1 and **ResetType** set to none.

```
open_system('hdlcoder_LUT_BRAM_mapping/LUT_BRAM')
```

When you generate HDL code and synthesize the design on an FPGA, this modeling pattern efficiently maps to Block RAM. This figure displays the synthesis results for the LUT_BRAM Subsystem.

Parsed resource report file: [LUT_OK_utilization_synth.rpt](#).

Resource summary	
Resource	Usage
Slice LUTs	0
Slice Registers	0
DSPs	0
Block RAM Tile	0.5

Parsed timing report file: [timing_post_map.rpt](#).

The LUT Subsystem in this model does not use this modeling pattern.

```
open_system('hdlcoder_LUT_BRAM_mapping/LUT')
```

Because the **Map lookup tables to RAM** option is enabled for this model, this subsystem still maps the logic to Block RAM. Click the MATLAB® script linked in the MATLAB command window to highlight lookup tables mapped to RAM in your model. You can generate this script by enabling the Diagnostic Parameter **Highlight lookup tables mapped to RAM** located in the **HDL Code Generation** tab > **Global Settings** > **Advanced** tab in the Model Configuration Parameters dialog box.

```
### Generating HDL for 'hdlcoder_LUT_BRAM_mapping/LUT'.
### Using the config set for model hdlcoder\_LUT\_BRAM\_mapping for HDL code generation parameters.
### Running HDL checks on the model 'hdlcoder_LUT_BRAM_mapping'.
### Begin compilation of the model 'hdlcoder_LUT_BRAM_mapping'...
### Applying HDL optimizations on the model 'hdlcoder_LUT_BRAM_mapping'...
### 'LUTMapToRAM' is set to 'On' for the model. This option is used to map lookup tables to a block RAM in hardware. To disable pipeline insertion for mapping
### The code generation and optimization options you have chosen have introduced additional pipeline delays.
### The delay balancing feature has automatically inserted matching delays for compensation.
### The DUT requires an initial pipeline setup latency. Each output port experiences these additional delays.
### Output port 1: 1 cycles.
### Begin model generation.
### Model generation complete.
### To highlight look up tables mapped to RAM, click the following MATLAB script: hdl\_prj\hdlsrc\hdlcoder\_LUT\_BRAM\_mapping\highlightLUTpipeliningDiagnostic.m
### To clear highlighting, click the following MATLAB script: hdl\_prj\hdlsrc\hdlcoder\_LUT\_BRAM\_mapping\clearhighlighting.m
```

In order to map the lookup table to Block RAM, the generated model for the LUT Subsystem inserts a Delay block that has a **Delay length** of 1 and **ResetType** set to none immediately following the Lookup Table block.

Recommended Block Parameter Settings of Multiport Switch Block for Numeric and Enumerated Types

Guideline ID

2.3.2

Severity

Recommended

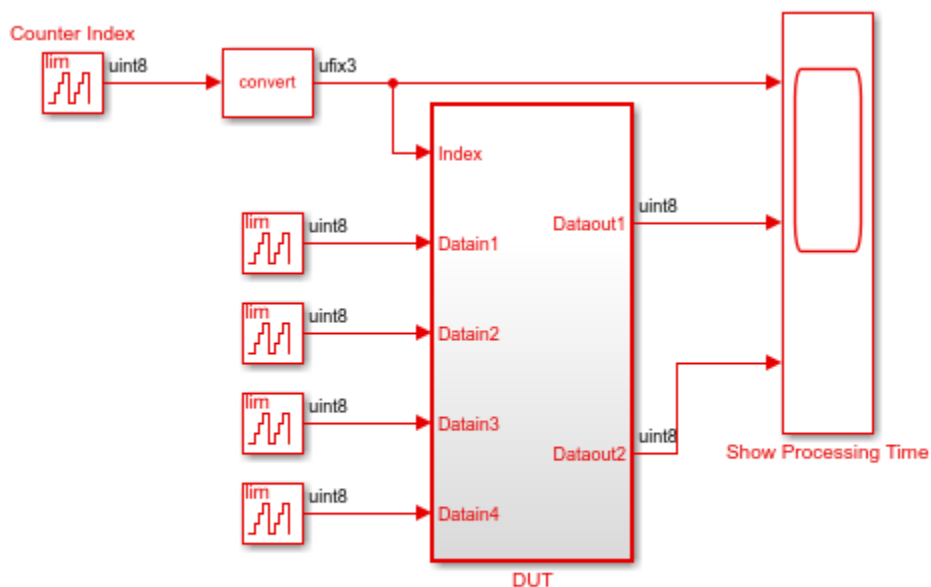

Description

To switch multiple input signals in your model for HDL code generation, you can use Switch, Multiport Switch, and Index Vector blocks. The Index Vector block is equivalent to the Multiport Switch block that has **Number of data terminals** set to 1.

You can use numeric and enumerated data types for the Multiport Switch block. When using numeric data types, in the Block Parameters dialog box of the Multiport Switch block, set **Data Port Order** to Zero-based contiguous and **Data port for default case** to Last data port. When number of input signals is a power of two, the Zero-based contiguous mode minimizes the number of bits of the control port.

For an example that uses Multiport Switch block with numeric types, open the model `hdlcoder_multiport_switch_numeric`.

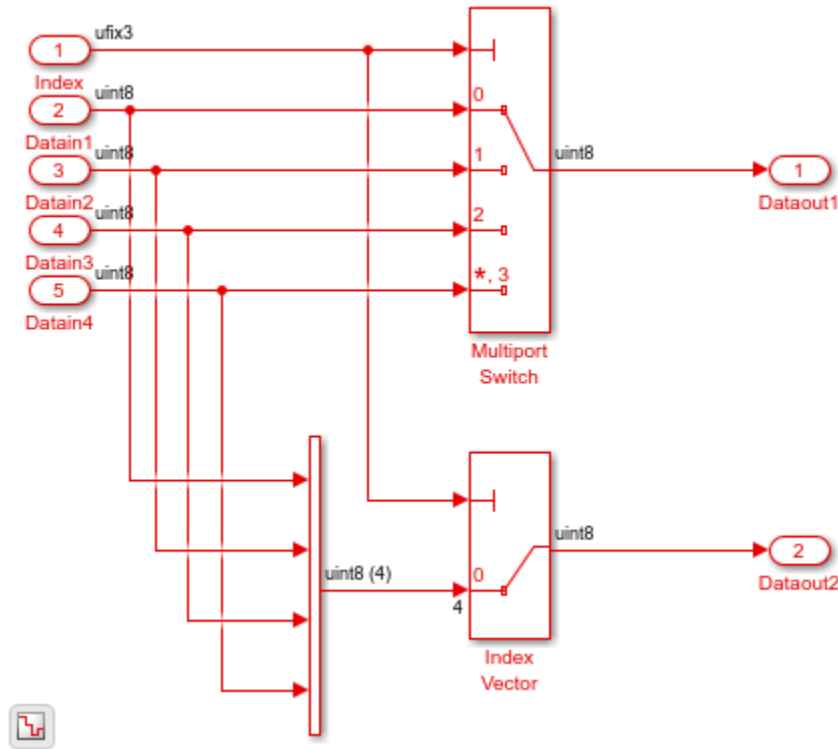

```
open_system('hdlcoder_multiport_switch_numeric')
set_param('hdlcoder_multiport_switch_numeric', 'SimulationCommand', 'Update')
```

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains a Multiport Switch block and an Index Vector block.

```
open_system('hdlcoder_multiport_switch_numeric/DUT')
```

To generate HDL code for the DUT, run the makehdl function.

```
makehdl('hdlcoder_multiport_switch_numeric/DUT')
```

```
### Generating HDL for 'hdlcoder_multiport_switch_numeric/DUT'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('hdlcoder_multiport_switch_numeric/DUT')">matlab:configset.showParameterGroup('hdlcoder_multiport_switch_numeric/DUT')</a>.
### Running HDL checks on the model 'hdlcoder_multiport_switch_numeric'.
### Begin compilation of the model 'hdlcoder_multiport_switch_numeric'...
### Working on the model 'hdlcoder_multiport_switch_numeric'...
### Working on... <a href="matlab:configset.internal.open('hdlcoder_multiport_switch_numeric','hdlcoder_multiport_switch_numeric')">matlab:configset.internal.open('hdlcoder_multiport_switch_numeric','hdlcoder_multiport_switch_numeric')</a>.
### Begin model generation 'gm_hdlcoder_multiport_switch_numeric' ....
### Copying DUT to the generated model....
### Model generation complete.
### Begin Verilog Code Generation for 'hdlcoder_multiport_switch_numeric'.
### Working on hdlcoder_multiport_switch_numeric/DUT as hdlsrc\hdlcoder_multiport_switch_numeric\hdlcoder_multiport_switch_numeric.v.
### Code Generation for 'hdlcoder_multiport_switch_numeric' completed.
### Creating HDL Code Generation Check Report file:///C:/TEMP/Bdoc23a_2213998_7084/ib967011/9/tp/hdlcoder_multiport_switch_numeric_codegen_report.html.
### HDL check for 'hdlcoder_multiport_switch_numeric' complete with 0 errors, 0 warnings, and 0 messages.
### HDL code generation complete.
```

When you use enumerated types as input to the Multiport Switch, set **Data Port Order** to Specify Indices. You define the enumeration class in a MATLAB® file. When you use the default case, set the **Default case diagnostic** to Warning or None.

For an example that uses Multiport Switch block with enumerated types, open the model hdlcoder_multiport_switch_enum. This code shows the enumerated class defined in MATLAB.

```

classdef BasicColors < Simulink.IntEnumType

    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end

    methods (Static)
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
    end

end

```

Open the model `hdlcoder_multiport_switch_enum`.

```

open_system('hdlcoder_multiport_switch_enum')
set_param('hdlcoder_multiport_switch_enum', 'SimulationCommand', 'Update')

```

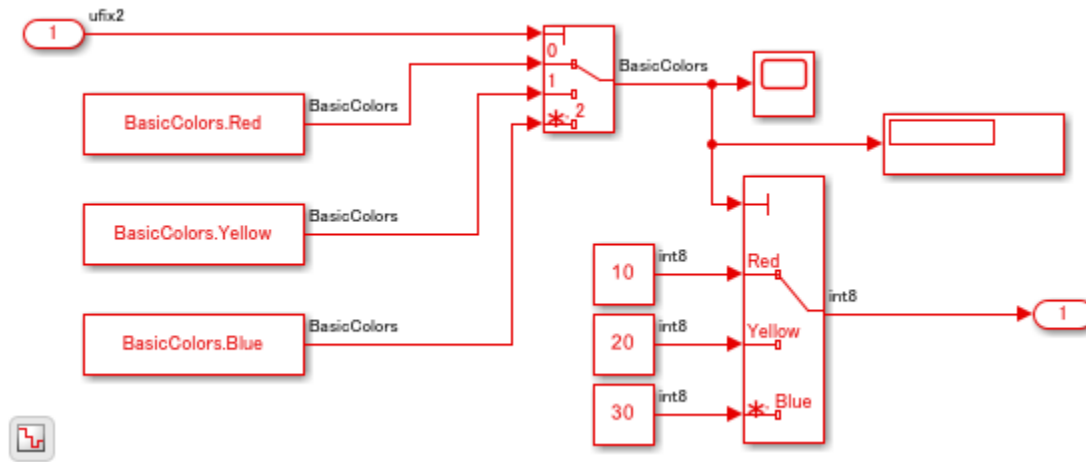

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains two Multiport Switch blocks. The second Multiport Switch block has **Data Port Order** set to **Specify Indices**.

```

open_system('hdlcoder_multiport_switch_enum/DUT')

```

To generate HDL code for the DUT, run the `makehdl` function.

```
makehdl('hdlcoder_multiport_switch_enum/DUT')
```

```
### Generating HDL for 'hdlcoder_multiport_switch_enum/DUT'.
### Using the config set for model <a href="matlab:configset.showParameterGroup('hdlcoder_multiport_switch_enum/DUT')">hdlcoder_multiport_switch_enum/DUT</a>.

Usage of Different Subsystem Types

To learn how to use different types of subsystems in your design and model your algorithm hierarchically, use these guidelines. Each guideline has a severity level that indicates the level of compliance requirements. For more information, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Virtual Subsystem: Use as DUT

Guideline ID

2.4.1

Severity

Strongly Recommended

Description

A virtual subsystem is a subsystem that is not a conditionally-executed subsystem or an Atomic Subsystem. By default, a regular Subsystem block that you add to your Simulink model is a virtual subsystem. Non-virtual subsystem types include Atomic Subsystem, model reference, Variant Subsystem, and a variant model.

To determine whether a subsystem is virtual, use the `get_param` function with the parameter `IsSubsystemVirtual`. For example:

```
get_param('sfir_fixed/symmetric_fir', 'IsSubsystemVirtual')
```

Atomic and Virtual Subsystems: Generate Reusable HDL Files

Guideline ID

2.4.2

Severity

Recommended

Description

To generate a single HDL file for identical instances of the subsystems that you use at lower levels of a hierarchy, see “Generate Reusable Code for Subsystems” on page 32-17 and “Code Reuse” on page 21-49.

To enable resource sharing on a subsystem unit, see “General Considerations for Sharing of Subsystems” on page 25-131.

You must turn off signal logging for generating reusable code from atomic and virtual subsystems. Generation of reusable code from atomic and virtual subsystem might not succeed if you log the signals inside the subsystems.

Variant Subsystem: Using Variant Subsystems for HDL Code Generation

Guideline ID

2.4.3

Severity

Mandatory

Description

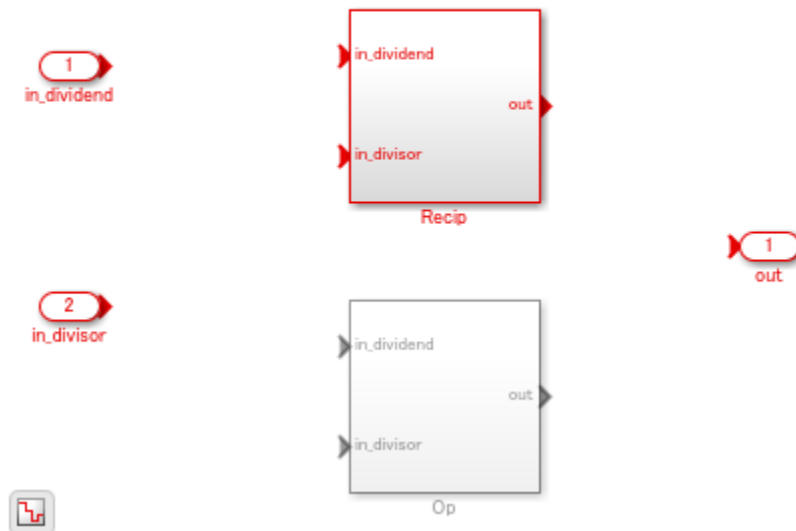

The Variant Subsystem, Variant Model, Variant Assembly Subsystem block is a template preconfigured to contain two Subsystem blocks to use as Variant Subsystem choices. During simulation, a variant control decides which of the two Subsystem blocks is active. Therefore, you can use the Variant Subsystem to create two different configurations or subsystem behaviors and then specify the active configuration at the model compile stage or simulation-loop stage of simulation.

- You cannot use a Variant Subsystem as the DUT. To generate code, place the Variant Subsystem inside the Subsystem that you want to use as the DUT. The file name and instance name of the generated code is created only for the active configuration or both active and inactive configurations.
- You cannot share multiple Variant Subsystem blocks by using the Variant Subsystem optimization.
- You must make sure that when verifying the functionality of the generated code, the active variant that you used when simulating the model is the same as the active variant that you used for generating HDL code.

For an example, open the model `hdlcoder_variant_subsystem_design.slx`. If you open the DUT Subsystem, you see a Variant Subsystem block, `Divide`. The Variant Subsystem has two different subsystems, `Recip` and `Op`. If you open the Block Parameters dialog box for the `Divide` Subsystem, you see the **Variant control expression** and the **Condition** that determines which Subsystem to enable during simulation. The **Variant activation time** determines at which stage of simulation to enable the Subsystem. In this case, `Rcp` is 1 and the activation time is `update` diagram. The `Recip` Subsystem becomes active during simulation.

```
load_system('hdlcoder_variant_subsystem_design')
set_param('hdlcoder_variant_subsystem_design','SimulationCommand','Update')
open_system('hdlcoder_variant_subsystem_design/DUT/Divide')
```

- 1) Only subsystems can be added as variant choices at this level
- 2) Blocks cannot be connected at this level as connectivity is automatically determined at simulation, based on the active variant

Generated Code

To generate HDL code, run this command:

```
makehdl('hdlcoder_variant_subsystem_design/DUT');
```

An HDL file with the name `Recip.vhd` is generated because the `Recip` Subsystem is active at code generation time and therefore has code generated for it.

To generate HDL code for both `Recip` and `Op`, change the settings of these parameters on the Block Parameters dialog box of the `Divide` Subsystem, then run the `makehdl` command.

1. Set **Variant activation time** to `startup`.

```
set_param('hdlcoder_variant_subsystem_design/DUT/Divide', 'VariantActivationTime', 'startup')
```

2. Set the variant control variable `Rcp` of type `Simulink.VariantControl`, normal MATLAB® variable, or `Simulink.Parameter` and set its value to an integer value. In this example, `Rcp` is a normal MATLAB variable with an `int16` value.

```
Rcp = int16(1);
```

3. Set **Allow zero active variant controls** to `on`.

```
set_param('hdlcoder_variant_subsystem_design/DUT/Divide', 'AllowZeroVariantControls', 'on')
```

4. Set **Propagate conditions outside of variant subsystem** to `off`.

```
set_param('hdlcoder_variant_subsystem_design/DUT/Divide', 'PropagateVariantConditions', 'off')
```

Note: Ensure that **Treat as atomic unit** of `Recip` and `Op` Subsystems is set to `on`.

```
set_param('hdlcoder_variant_subsystem_design/DUT/Divide/Recip', 'TreatAsAtomicUnit', 'on')
set_param('hdlcoder_variant_subsystem_design/DUT/Divide/Op', 'TreatAsAtomicUnit', 'on')
```

Generate the HDL code using the following command.

```
makehdl('hdlcoder_variant_subsystem_design/DUT');
```

HDL files with the name `Recip.vhd` and `Op.vhd` are generated because the code is generated for both the `Recip` and `Op` Subsystems.

HDL Coder generates the following VHDL® code for the Variant Subsystem `Divide`, which has its variant control variable set to a tunable parameter, `Rcp`. The code generator creates a DUT port and adds a comment to indicate that the port corresponds to a tunable parameter. You can change the value of `Rcp` by providing the value to the pin on the chip that is mapped to `Rcp`.

```
ENTITY Divide IS
  PORT( clk      : IN    std_logic;
        reset    : IN    std_logic;
        enb      : IN    std_logic;
        in_dividend : IN    std_logic_vector(15 DOWNTO 0); -- sfix16_En14
        in_divisor  : IN    std_logic_vector(15 DOWNTO 0); -- sfix16_En13
        Rcp       : IN    std_logic_vector(23 DOWNTO 0); -- sfix24_En9 Tunable port
        out_rsvd   : OUT   std_logic_vector(23 DOWNTO 0) -- sfix24_En9
  );
END Divide;
```

```
VariantMerge_For_Outport_out_out1 <= Op_out1_signed WHEN Selected_Index_floor = to_signed(16#000#
  Recip_out1_signed WHEN Selected_Index_floor = to_signed(16#0002#, 15) ELSE
  GroundForVM_out_out1;
```

Model References: Build Model Design Using Smaller Partitions

Guideline ID

2.4.4

Severity

Recommended

Description

Modeling a large design hierarchically can increase code generation time. If you specify generation of reports such as the traceability report, the code generation time can further increase significantly. To avoid such performance issues, it is recommended that you partition your design into smaller partitions. Use the Model block to unify a model that consists of smaller partitions. It also enables incremental code generation. You can generate HDL code for the parent model or the referenced model. To see the generated HDL code, in the `hdlsrc` folder, a folder is created for the parent model with a separate subfolder for the referenced model.

When generating the HDL test bench, if the test bench consists of blocks that operate with a continuous sample time, you can convert the DUT to a referenced model. This conversion enables the DUT to run at a fixed-step, discrete sample time. To learn more, see “Convert DUT Subsystem to Model Reference for Testbenches with Continuous Blocks” on page 25-36.

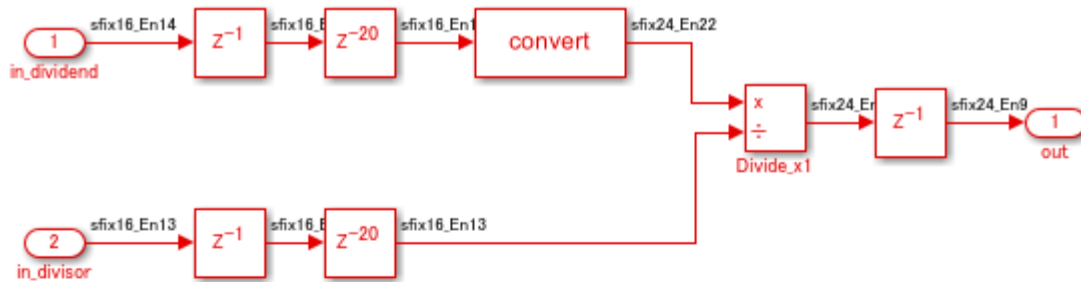

For an example, open the model `hdlcoder_divide_parentmodel.slx`. When you double-click the DUT Subsystem, you see a Model block that references the model `hdlcoder_divide_referencedmodel`.

```
load_system('hdlcoder_divide_parentmodel')
set_param('hdlcoder_divide_parentmodel', 'SimulationCommand', 'Update')
open_system('hdlcoder_divide_parentmodel/DUT')
```

To see the referenced model, double-click the Model block:

```
open_system('hdlcoder_divide_parentmodel/DUT/Model')
```

Copyright 2018–2021 The MathWorks, Inc.

To generate HDL code, enter this command:

```
makehdl('hdlcoder_divide_parentmodel/DUT')
```

For more information, see “Model Referencing for HDL Code Generation” on page 32-2.

Block Settings of Enabled and Triggered Subsystems

Guideline ID

2.4.5

Severity

Mandatory

Description

A Triggered Subsystem is a subsystem that receives a control signal via a Trigger block. The Triggered Subsystem executes for one cycle each time a trigger event occurs. When you generate HDL code for a triggered subsystem:

- Do not use the Triggered Subsystem block as the DUT. Place the Triggered Subsystem inside another Subsystem block, and use that Subsystem as the DUT.
- You can add unit delays to the output signals of the Triggered Subsystem, outside of the Triggered Subsystem block. The unit delays prevents HDL Coder from inserting additional bypass registers in the HDL code.
- Make sure that the **Use trigger signal as clock** setting does not result in timing mismatches when you simulate the testbench to verify the generated code. To learn more, see “Using Triggered Subsystems for HDL Code Generation” on page 27-18.

For other preferences when configuring the Triggered Subsystem block for HDL code generation, see “HDL Code Generation” on the Triggered Subsystem page.

An Enabled Subsystem is a subsystem that receives a control signal via an Enable block. The Enabled Subsystem executes at each simulation step where the control signal has a positive value. When you generate HDL code for an Enabled Subsystem:

- Do not use the Enabled Subsystem block as the DUT. Place the Enabled Subsystem inside another Subsystem block, and use that Subsystem as the DUT.
- You can add a State Control block in Synchronous mode inside the Enabled Subsystem to generate more efficient and hardware-friendly HDL code. The State Control block in Synchronous mode prevents HDL Coder from inserting additional bypass registers in the HDL code. The State Control block converts the Enabled Subsystem block to an Enabled Synchronous Subsystem block. To learn more, see “Synchronous Subsystem Behavior with the State Control Block” on page 32-72.
- If you want a State Control block in Classic mode or do not want a to add a State Control block, you can add unit delays to the output signals of the Enabled Subsystem, outside of the Enabled Subsystem block, to prevent HDL Coder from inserting additional bypass registers in the HDL code.

For other preferences when configuring the Enabled Subsystem block for HDL code generation, see “HDL Code Generation” on the Enabled Subsystem page.

Usage of Rate Change and Constant Blocks

You can follow these guidelines to learn how to use blocks that can perform rate conversions in your model and blocks from the Sources library such as Constant blocks in your design. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Usage of Rate Conversion Blocks

Guideline ID

2.5.1

Severity

Recommended

Description

There are various ways in which you can model rate transitions. How you model rate transitions determine the timing and resource requirements of your design. This guideline shows various approaches for modeling rate transitions.

Increasing the Sample Rate

This table illustrates the blocks that you can use to increase the sample rate of your design. When you use these blocks, leave the block parameters to the default settings.

Rate Conversion Approach

Block	Generates Bypass Register?	Generates Zero Padding?	Notes
Repeat	No	No	To use this block, you must have DSP System Toolbox installed.
Rate Transition	No	No	None
Upsample	Yes	Yes	To use this block, you must have DSP System Toolbox installed. When you use this block, consider the impact of the bypass register and the logic that inserts zero padding on hardware resource usage.

For the Rate Transition block, to upsample the input signal without incurring a unit delay, in the Block Parameters dialog box of the Rate Transition block:

- Clear the **Ensure data integrity during data transfer** check box.

Clearing this check box makes the **Ensure deterministic data transfer (maximum delay)** check box to disappear.

- Configure the output port sample time of the block to be an integer multiple of the input port sample time. Specify a fractional value of $1/n$ for **Sample time multiple** where n is an integer. You can choose any value for the block parameter **Output port sample time options** as long as **Sample time multiple** uses a value $1/n$.

When the input and output clocks are not synchronous to each other, to avoid insertion of a bypass register in the HDL code generated for the Repeat and Rate Transition blocks, insert one unit delay following the Repeat and Rate Transition blocks in your model.

You can use the **Initial Condition** parameter of the block when increasing the sample rate. This parameter is used for upsampling when you leave the **Ensure data integrity during data transfer** check box selected. The initial value is propagated to the generated HDL code for the state that is created from a Rate Transition block.

Decreasing the Sample Rate

To reduce the sample rate, you can use a Downsample or a Rate Transition block. To use the Downsample block, you must have DSP System Toolbox installed. When you use these blocks, leave the block parameters to the default settings.

When downsampling the input signal, use the Rate Transition block because you can leave the block parameters to the default settings for HDL code generation. The **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** check boxes must be left selected. This mode generates an additional bypass register in the HDL code.

You can use the **Initial Condition** parameter of the block when decreasing the sample rate. When downsampling, this parameter is implemented as a bypass register and is not seen because it passes from the input to the output at initial clock cycle. The initial value is propagated to the generated HDL code for the state that is created from a Rate Transition block.

Use Discrete and Finite Sample Time for Constant Block

Guideline ID

2.5.2

Severity

Recommended

Description

By default, the **Sample time** parameter of a Constant block is `inf`. When you use the Constant block, set the **Sample time** to `-1`. To identify Constant blocks that have infinite sample time in your design, in the Simulink model window, In the **Debug** tab, on the **Information Overlays > Sample Time** section, select **Colors**.

If you enable optimizations that add or handle latency in your design, such as streaming, sharing, clock-rate pipelining, or delay balancing, and then generate HDL code, HDL Coder resolves the sample times of Constant blocks with **Sample time** set to `inf`, if the sample times do not propagate to the device under test (DUT) output. For example, in this model DUT, you can generate HDL code with optimizations that add latency because the Product block merges the Constant and Ground blocks that have infinite sample times into a signal that has a fixed sample time, before to the DUT

output. The Sample Time Legend displays the infinite sample times in pink and the fixed sample times in red.

When the HDL block property **OutputPipeline** of the Product block is 3 and you generate HDL code and a generated model, the generated model shows the infinite sample times resolved to fixed sample times with the output pipeline delays applied and the balanced delays applied on the other signal path.

For blocks that have inf sample times propagate to the DUT output, you can identify and change the sample time of the blocks to -1 by using either of these approaches:

- Run a script that can programmatically change the sample time of the blocks to -1. For an example script, see “Identify and Programmatically Change and Display HDL Block Parameters” on page 25-30.
- Run the check “Check for infinite and continuous sample time sources” on page 44-15 in the HDL Code Advisor. If running the check fails, it displays sources such as Constant blocks that have infinite sample time. Select **Modify Settings** to update the sample time to -1 or to inherit via backpropagation.

Guidelines for Using Delays and Goto and From Blocks for HDL Code Generation

These guidelines illustrate the recommended settings for modeling delays in your model. You model delays by using blocks available in the **Discrete** Library. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Appropriate Usage of Delay Blocks as Registers

Guideline ID

2.6.1

Severity

Recommended

Description

For blocks in your model to be inferred as a flipflop on the target FPGA, use Delay blocks instead of memory blocks. You can specify a local reset and enable signal for each Delay block.

By default, the **Delay length** of the block is set to 2. In this case, the input to the block passes to the output after two time steps. If the **Delay length** is set to 0, the input passes to the output without any delay. The generated HDL code treats the block as a wire. To infer a flipflop or register on the target device, set the **Source** to dialog and specify a **Delay length** greater than zero.

When using a Delay block that has an external enable port or that is inside the Enabled Subsystem block, it is recommended to use the State Control block in synchronous mode. Similarly, when you use a Delay block that has an external reset port or that is inside the Resettable Subsystem block, it is recommended to use the State Control block in Synchronous mode. To learn more, see HDL Code Generation in Delay.

Do not use the Unit Delay Enabled, Unit Delay Resettable, and Unit Delay Enabled Resettable blocks for HDL code generation. These blocks have been removed. Instead, replace these blocks with the Unit Delay Enabled Synchronous, Unit Delay Resettable Synchronous, and Unit Delay Enabled Resettable Synchronous blocks. These blocks use the State Control block in synchronous hardware mode. To perform this block replacement in your model, run the model check “Check for obsolete Unit Delay Enabled/Resettable Blocks” on page 44-20.

Absorb Delays to Avoid Timing Difference

Guideline ID

2.6.2

Severity

Recommended

Description

Certain block implementations, floating-point operations, and optimization settings such as distributed pipelining introduce latency in the generated HDL code and the generated model. The additional latency results in a timing difference between the original model and the generated model. To avoid this timing difference, such as when you are using a control system with feedback loop, use a modeling pattern that can absorb delays. To absorb the delays:

- Place a Delay block after the block that is introducing latency.
- Set the Delay block **Delay length** value equal to the block latency.

By adding the Delay block to your original model, you can simulate your original model with latency.

These blocks can introduce latency:

- Divide, Sqrt, and Reciprocal blocks that have custom latency value greater than zero.
- Trigonometric Function blocks that have **Function** set to `sin`, `cos`, `sincos`, `cos+jsin`, or `atan2` and HDL architecture set to `CORDIC`
- Native floating-point operators that have **LatencyStrategy** set to `Max`, `Min`, or a custom value greater than zero.

For more information, see “Use Delay Absorption While Modeling with Latency” on page 28-87.

Map Large Delays to Block RAM

Guideline ID

2.6.3

Severity

Recommended

Description

To save area, when your design contains large design delays and pipeline delays, you can map the delays to block RAM and UltraRAM resources on the FPGA. Design delays are delays that you manually insert in your design by using Delay blocks, or other blocks that have state including Queue, HDL FIFO, or Buffer blocks. Pipeline delays are delays that are generated by optimization settings or block implementation settings such as Newton-Raphson implementation.

To map design delays to RAM:

- In the HDL Block Properties dialog box of Delay blocks, set **UseRAM** to on. To learn how you can set this option on Delay blocks in your design programmatically, see “Set HDL Block Parameters for Multiple Blocks Programmatically” on page 26-53.
- To map significantly large delays to UltraRAM resources, you can specify the `ram_style` attribute in the generated HDL code.

```
-- This VHDL code shows the ramstyle attribute set to ultra:
```

```
attribute ram_style: string;  
attribute ram_style of ram : signal is "ultra";
```

```
// This Verilog code shows the ramstyle attribute set to ultra:
```

```
(* ram_style = "ultra" *)
```

- As described in “Effects of Streaming and Distributed Pipelining” on page 26-28, even if **UseRAM** is off, you can map large delays that exceed a threshold value by using the “RAM mapping threshold” on page 19-7 parameter. You can change this threshold value depending on how large a delay you want to map to RAM.
- When you use MATLAB Function blocks, you can map persistent variables in your MATLAB code to RAM by setting HDL architecture to **MATLAB Datapath** and **MapPersistentVarsToRAM** HDL block property to on.

For pipeline delays that are inserted by optimizations, delay balancing automatically inserts matching delays in parallel paths. If the delay length at the critical path and the number of vector elements in the parallel path take large values, the pipeline delays can also become significantly large.

To map these large delays to Block RAM:

- Enable the “Map pipeline delays to RAM” on page 19-6 parameter.
- Adjust the **RAM mapping threshold (bits)** parameter to a value that is smaller than the required RAM size.

To calculate the total RAM size, use this formula:

$$\text{RAMSize} = \text{Delay length} * \text{Word length} * \text{Vector length} * \text{Complexity}$$

Complexity is 2 for a complex data type or 1 for a real datatype.

For more information, see “Apply RAM Mapping to Optimize Area” on page 28-122.

Required HDL Settings for Goto and From Blocks

Guideline ID

2.6.4

Severity

Mandatory

Description

When you generate HDL code for the DUT Subsystem that uses From and Goto blocks:

- Do not use From and Goto blocks across the boundary of the DUT subsystem. To connect the input and output ports of the DUT, use Inport and Outport blocks instead.
- Do not use From and Goto blocks across the boundary of an Atomic Subsystem. To connect the input and output ports of the DUT, use Inport and Outport blocks instead.

Using From and Goto blocks across a subsystem hierarchy can impact the readability of the model. Before generating HDL code, it is recommended that you use From and Goto blocks in the same subsystem and use `local` or `Scoped` visibility. When you generate HDL code, in the generated model, each Goto and From block becomes a pair of From and Goto subsystems connected back to back.

Modeling Efficient Multiplication and Division Operations for FPGA Targeting

These guidelines illustrate the recommended settings when using Divide and Product blocks in your model for improved area and timing on the target FPGA. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Designing Multipliers and Adders for Efficient Mapping to DSP Blocks on FPGA

Guideline ID

2.7.1

Severity

Strongly Recommended

Description

Digital signal processing (DSP) algorithms use several multipliers and accumulators. FPGA devices provided by vendors such as Xilinx® and Intel® contain dedicated DSP slices. These small size, high speed, DSP slices contain several multipliers and accumulators that make FPGA devices best suited for DSP applications.

The architecture of DSP slices varies widely across the different FPGA vendors and across different families of devices provided by the same vendor. To map your Simulink® model containing adders, multipliers, and delays to DSP slices, adapt your model to the DSP slice architecture by taking into consideration:

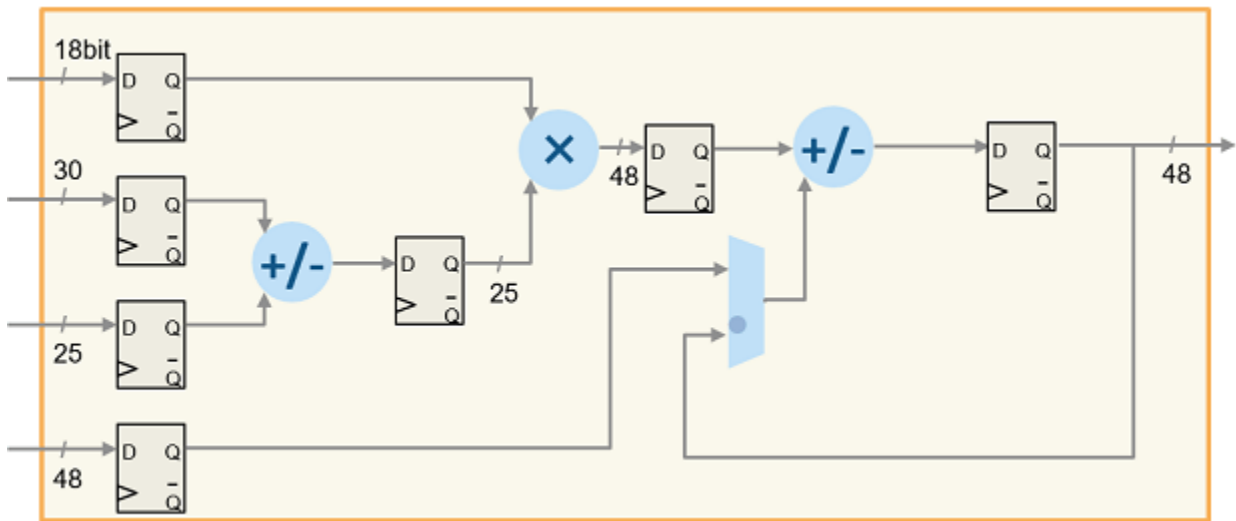

- Arrangement of flipflops, adders, and multipliers in the DSP slice.
- Rounding and saturation settings.
- Bit widths of the adders and multipliers. For efficient mapping, use bit widths in your model that are less than or equal to the bit widths of the DSP unit.

When the bit widths in your model become larger than the bit widths of the DSP, your design does not fit onto one DSP. In this case, multiple DSPs or additional logic is required.

You can map these blocks in your model to DSP blocks on an FPGA:

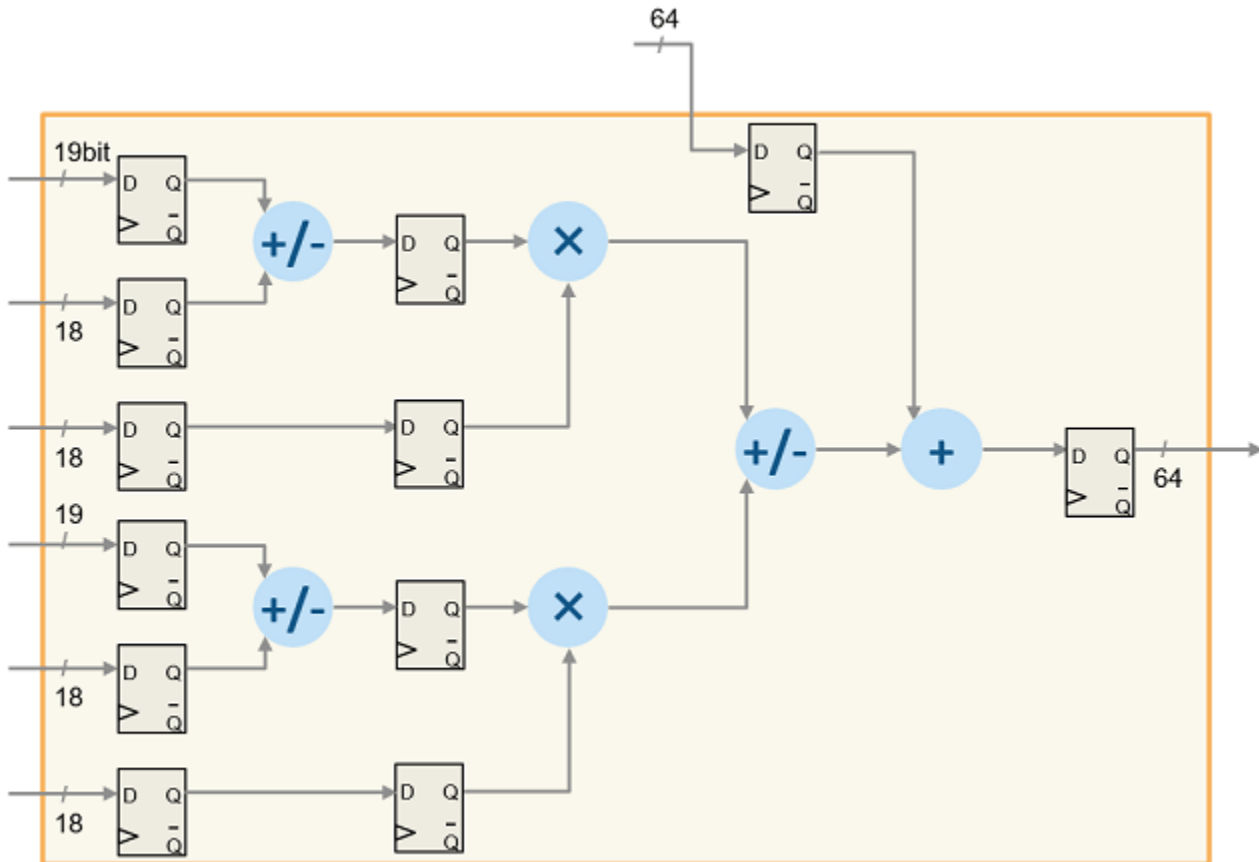

- Add and Sum
- Delay
- Product
- Multiply-Add
- Multiply-Accumulate

This figure illustrates the Xilinx DSP architecture. Xilinx 7 series FPGAs have dedicated DSP slices that use this architecture. The DSP architecture consists of input registers, pre-adder, 25x18 multiplier, intermediate registers, post-adder, and an output register.

For more information, see **DSP48E1 Slice Overview** in the Xilinx documentation.

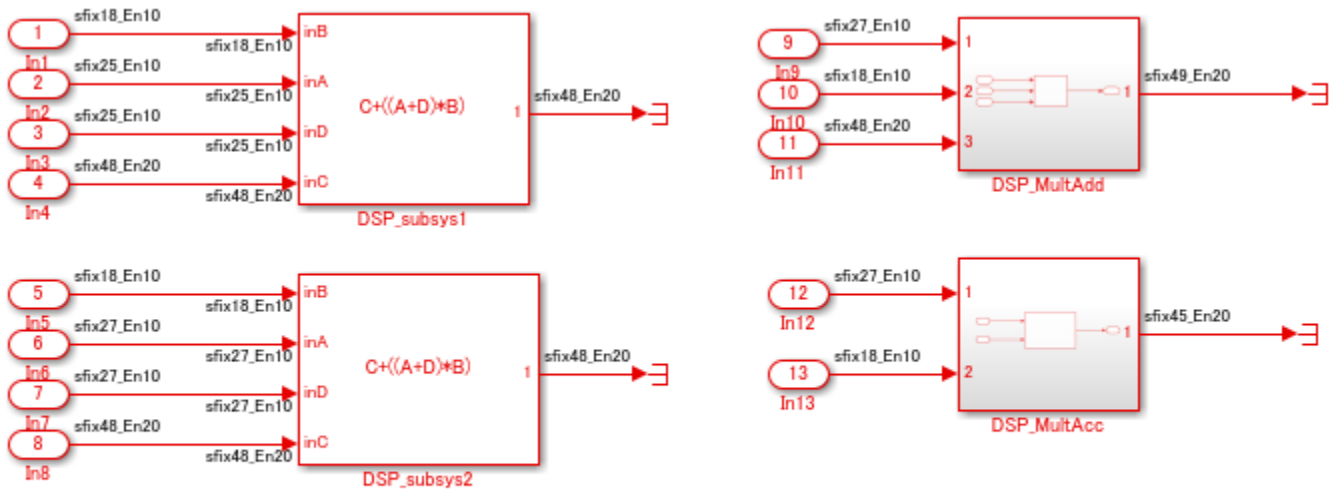

This figure illustrates the Intel DSP architecture. This DSP architecture for Stratix® V devices is a variable precision DSP architecture. The DSP blocks can have bit widths of 9, 18, 27, and 36 bits, and 18x25 complex multiplication for FFTs.

For more information, see DSP Block Architecture of Stratix V devices.

To learn how you can design your algorithm to map to this DSP unit, open the model `hdlcoder_multiplier_adder_dsp.slx`

```
open_system('hdlcoder_multiplier_adder_dsp')
set_param('hdlcoder_multiplier_adder_dsp', 'SimulationCommand', 'Update')
```

Copyright 2014–2019 The MathWorks, Inc.

The model consists of two subsystems `dsp_subsys1` and `dsp_subsys2` that implement the operation $C + ((A+D)*B)$. You can also implement this operation by using Multiply-Add or Multiply-Accumulate blocks as illustrated by subsystems `DSP_MultAdd` and `DSP_MultAcc`.

`dsp_subsys1` implements the operation $C + ((A+D)*B)$ by using bit widths that equal the DSP on a Xilinx 7 series FPGA. If you open the HDL Workflow Advisor and deploy this Subsystem onto a Xilinx Virtex® 7 FPGA, the entire design fits exactly onto one DSP slice.

Passed Synthesis

Parsed resource report file: [DSP_subsys1_utilization_synth.rpt](#).

Resource summary	
Resource	Usage
Slice LUTs	0
Slice Registers	0
DSPs	1
Block RAM Tile	0
URAM	0

`dsp_subsys2` implements the same operation by using bit widths that are larger than the DSP on a Xilinx FPGA. If you deploy this Subsystem onto a Xilinx Virtex 7 FPGA, you see that the entire design fits onto one DSP slice and uses additional slice logic.

Passed Synthesis

Parsed resource report file: [DSP_subsys2_utilization_synth.rpt](#).

Resource summary	
Resource	Usage
Slice LUTs	141
Slice Registers	210
DSPs	1

Set ConstMultiplierOptimization HDL Block Property to auto for Gain Block

Guideline ID

2.7.2

Severity

Strongly Recommended

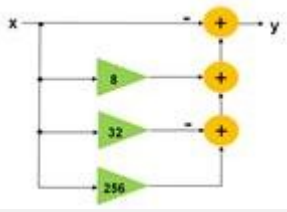

Description

When you use a Gain block in your design, to achieve the most area-efficient implementation, set the “ConstMultiplierOptimization” on page 26-7 HDL block property to `auto`. The code generator chooses between CSD and FCSD implementations that yields the smallest circuit size and generates HDL code without using the multiplication (*) operator.

You can use this setting to avoid targeting DSP resources and reduce the number of logic circuits on Intel Quartus Prime when synthesizing your design on the target FPGA. For example, this table shows the generated HDL code for the Gain block depending on the HDL block property settings for the **ConstMultiplierOptimization** block.

ConstMultiplierOptimization Settings and Impact on Generated HDL Code

ConstMultiplierOptimization Setting	Operations	Generated HDL Code
CSD	<p>Casts input data in parallel and adds or subtract the results.</p> 	<p>This code shows the generated VHDL code.</p> <pre>-- CSD Encoding(231): 1001'01001'; Cost (Adders) = 3 DOUT_mul_temp <= ((resize(DIN & '0' & '0' & '0' & '0' & '0', 21) - resize(DIN & '0' & '0' & '0' & '0', 21)) + resize(DIN & '0' & '0' & '0' & '0', 21)) - resize(DIN, 21); DOUT <= DOUT_mul_temp(19 DOWNTO 0);</pre> <p>This code shows the generated Verilog code.</p> <pre>// CSD Encoding (231) : 1001'01001'; Cost (Adders) = 3 assign Gain_1 = {DIN[11], {DIN, 8'b00000000}}; assign Gain_2 = {{4{DIN[11]}}, {DIN, 5'b000000}}; assign Gain_3 = {{6{DIN[11]}}, {DIN, 3'b000}}; assign Gain_4 = {{9{DIN[11]}}, DIN}; assign DOUT_mul_temp = ((Gain_1 - Gain_2) + Gain_3 - Gain_4); assign DOUT = DOUT_mul_temp[19:0];</pre>
FCSD	<p>Adds the input data and its cast data in each cascading.</p> 	<p>This code shows the generated VHDL code.</p> <pre>-- FCSD for 231 = 33 X 7; Total Cost = 2 -- CSD Encoding (33) : 0100001; Cost (Adders) = 1 Gain_factor <= resize(DIN & '0' & '0' & '0' & '0' & '0', 21) + resize(DIN, 21); -- CSD Encoding (7) : 1001'; Cost (Adders) = 1 DOUT_mul_temp <= resize(Gain_factor & '0' & '0' & '0', 21) - Gain_factor; DOUT <= DOUT_mul_temp(19 DOWNTO 0);</pre> <p>This code shows the generated Verilog code.</p> <pre>// FCSD for 231 = 33 X 7; Total Cost = 2 // CSD Encoding (33) : 0100001; Cost (Adders) = 1 assign Gain_3 = {{4{DIN[11]}}, {DIN, 5'b000000}}; assign Gain_4 = {{9{DIN[11]}}, DIN}; assign Gain_factor = Gain_3 + Gain_4; // CSD Encoding (7) : 1001'; Cost (Adders) = 1 assign Gain_1 = {Gain_factor, 3'b000}; assign Gain_2 = Gain_1[20:0]; assign DOUT_mul_temp = Gain_2 - Gain_factor; assign DOUT = DOUT_mul_temp[19:0];</pre>
auto	<p>Selects CSD or FCSD implementation that uses fewer adders.</p>	<p>Generated HDL code is same as CSD or FCSD implementation.</p>

ConstMultiplierOptimization Setting	Operations	Generated HDL Code
none	Uses multiplication operator (*).	<p>This code shows the generated VHDL code.</p> <pre>DOUT_mul_temp <= to_signed(2#011100111#, 9) * DIN; DOUT <= DOUT_mul_temp(19 DOWNTO 0);</pre> <p>This code shows the generated Verilog code.</p> <pre>assign DOUT_mul_temp = 231 * DIN; assign DOUT = DOUT_mul_temp[19:0];</pre>

Use ShiftAdd Architecture of Divide Block for Fixed-Point Types

Guideline ID

2.7.3

Severity

Recommended

Description

When you use fixed-point data types as inputs to the Divide block, specify the HDL Architecture of the block as `ShiftAdd` and then set the HDL block property “UsePipelines” on page 26-25 to on. In this architecture, the block computes the result by using multiple shift and add operations. The operations are pipelined to achieve higher clock frequencies on the target FPGA device.

When you use floating-point data types as inputs to the Divide block, leave the HDL Architecture to default value of `Linear` and select **Use Floating Point**.

More About

- “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116

Using Persistent Variables and fi Objects Inside MATLAB Function Blocks for HDL Code Generation

These guidelines illustrate the recommended settings when using persistent variables inside MATLAB Function blocks in your model. The MATLAB Function block is available in the **User-Defined Functions** block library. A persistent variable in a MATLAB Function block acts similar to a delay element in your Simulink model.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Update Persistent Variables at End of MATLAB Function

Guideline ID

2.8.1

Severity

Strongly Recommended

Description

To make sure that the persistent variables inside the MATLAB Function block map to a register on the target FPGA device, update the persistent variable at the end of the MATLAB code inside the MATLAB Function block. Do not update the persistent variable before its value is read or used by the function.

For example, this MATLAB code is not recommended because the function updates the persistent variable FF0 is updated before the value is read at the output.

```
function FF_out0 = fcn(FF_in)
%#codegen

persistent FF0

if isempty(FF0)
    FF0 = zeros(1, 'like', FF_in);
end

% Incorrect order of FF update
FF0 = FF_in

% Output FF0. FF_out0 is NOT delayed
FF_out0 = FF0;
```

This MATLAB code is recommended because the value is written to FF0 at the end of the code.

```
function FF_out0 = fcn(FF_in)
%#codegen

persistent FF0

if isempty(FF0)
    FF0 = zeros(1, 'like', FF_in);
```

```
end
```

```
% Output FF0
FF_out0 = FF0;
```

```
% Write FF update at the end of the code
FF0 = FF_in
```

Avoid Algebraic Loop Errors from Persistent Variables inside MATLAB Function Blocks

Guideline ID

2.8.2

Severity

Mandatory

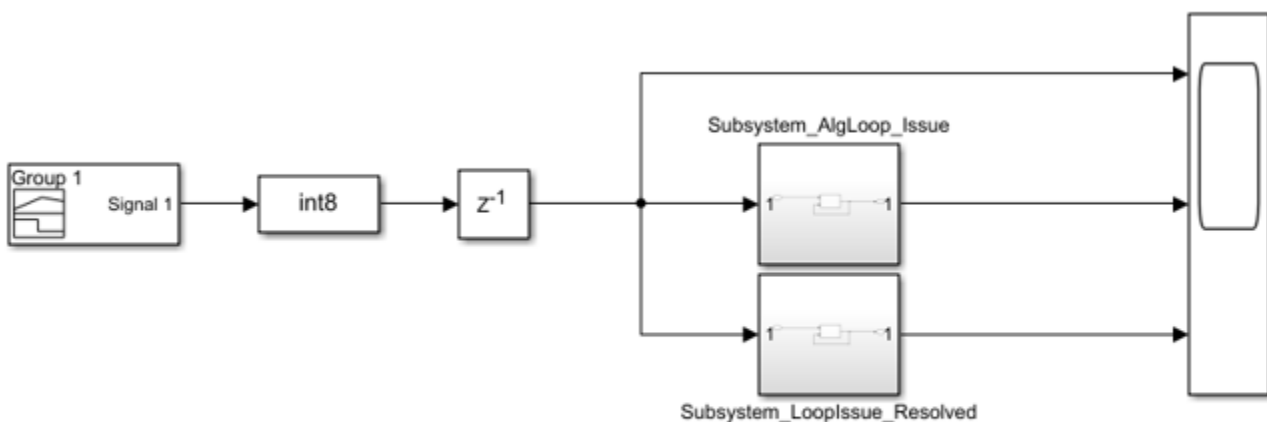

Description

When your Simulink® model contains MATLAB Function blocks inside a feedback loop and uses persistent variables, compiling or simulating the model might generate algebraic loop errors. To simulate the model and generate HDL code, use nondirect feedthrough.

In certain cases, the persistent delay in the MATLAB Function block inside a feedback loop causes an algebraic loop error. When you use direct feedthrough, the output of the block directly depends on the input. When **Allow direct feedthrough** is cleared, the output of the block depends on the internal state and properties and does not depend on the input. The nondirect feedthrough semantics prevents algebraic loops errors by making the outputs depend only on the state.

For an example, open the model `hdlcoder_MLFB_avoid_algebraic_loops`.

```
modelname = 'hdlcoder_MLFB_avoid_algebraic_loops';
blkname = 'hdlcoder_MLFB_avoid_algebraic_loops/Subsystem_AlgLoop_Issue/MATLAB Function1';
open_system(modelname)
```

When you simulate the model, the algebraic loop error message is displayed. The MATLAB Function block `hdlcoder_MLFB_avoid_algebraic_loops/Subsystem_AlgLoop_Issue/MATLAB Function` uses a persistent variable inside a MATLAB Function block.

```
open_system(blkname)
```

```
function y = fcn(u0, u1)
    %#codegen

    persistent tmp
    if isempty(tmp)
        tmp = int8(0);
    end

    % There is a delay but algebraic loop is detected
    y = tmp;

    if u0 ~= 0
        tmp = int8(u1 + u0);
    else
        tmp = int8(u1);
    end
end
```

To avoid this error, use nondirect feedthrough. To specify nondirect feedthrough at the command line, create a `MATLABFunctionConfiguration` object by using `get_param` function, and then change the property value `AllowDirectFeedthrough`:

```
MLFBConfig = get_param(blkname, 'MATLABFunctionConfiguration');
MLFBConfig.AllowDirectFeedthrough = 0;
```

See also `MATLABFunctionConfiguration`.

To specify nondirect feedthrough from the UI:

- 1 Open the MATLAB Function block `MATLAB Function1`.
- 2 Open the Property Inspector. In the **Modeling** tab, in the **Design** section, click **Property Inspector**.
- 3 In the **Property Inspector**, open the **Advanced** section and clear the **Allow direct feedthrough** check box.

See also “Prevent Algebraic Loop Errors in MATLAB Function, Chart, and Truth Table Blocks”.

The model now simulates without algebraic errors. You can now generate HDL code for the Subsystem block `Subsystem_AlgLoop_Issue`.

```
open_system(modelname)
set_param('hdlcoder_MLFB_avoid_algebraic_loops', 'SimulationCommand', 'Update')
makehdl('hdlcoder_MLFB_avoid_algebraic_loops/Subsystem_AlgLoop_Issue')
```

Use hdlfimath Setting and Specify fi Objects inside MATLAB Function Block

Guideline ID

2.8.3

Severity

Strongly Recommended

Description

`fimath` properties define the rules for performing arithmetic operations on `fi` objects. To specify `fimath` properties that govern arithmetic operations, use a `fimath` object. To see the default `fimath` property settings, run this command:

```
F = fimath
```

```
F =
```

```
    RoundingMethod: Nearest
    OverflowAction: Saturate
    ProductMode: FullPrecision
    SumMode: FullPrecision
```

The default `fimath` settings reduce rounding errors and overflows. However, HDL code generation for a MATLAB Function block that uses these settings can incur additional resource usage on the target FPGA device. To avoid the additional logic, use `hdlfimath`. The `hdlfimath` function is a utility that defines `fimath` properties optimized for HDL code generation. To see the default `hdlfimath` settings, run this command:

```
H = hdlfimath
```

```
H =
```

```
    RoundingMethod: Floor
    OverflowAction: Wrap
    ProductMode: FullPrecision
    SumMode: FullPrecision
```

HDL code generation for a MATLAB Function block that uses these settings avoids the additional resource usage and saves area on the target FPGA device.

To specify these settings for a MATLAB Function block:

- Double-click the MATLAB Function block.
- In the **Modeling** tab, in the **Design** section, click the **Property Inspector**.
- In the **Property Inspector**, open the **Fixed-point properties** section. For:

- **Treat these inherited Simulink signal types as fi objects**, select Fixed-point & Integer.

If you use the default Fixed-point setting, fixed-point data types specified by using fi objects and built-in integer types such as `int8` and `int16` are treated differently. When you use built-in integer types, the output data type for integer type calculations becomes the same as the input data type. The bit width is not expanded to perform numeric calculation.

- **MATLAB FUNCTION FIMATH**, select **Specify Other** and then enter `hdlfimath`.

To perform rounding operations that are different from the default `hdlfimath` settings, specify these settings explicitly by using the fi object as illustrated below.

```
A = fi(4.9, 1, 8)
```

```
A =
```

```
4.8750
```

```
      DataTypeMode: Fixed-point: binary point scaling  
      Signedness: Signed  
      WordLength: 8  
      FractionLength: 4
```

```
B = fi(2.3, 1, 10)
```

```
B =
```

```
2.2969
```

```
      DataTypeMode: Fixed-point: binary point scaling  
      Signedness: Signed  
      WordLength: 10  
      FractionLength: 7
```

```
C = fi(A+B, 'RoundingMethod', 'Nearest', 'OverflowAction', 'Saturate')
```

```
C =
```

```
7.1719
```

```
      DataTypeMode: Fixed-point: binary point scaling  
      Signedness: Signed  
      WordLength: 12  
      FractionLength: 7
```

```
      RoundingMethod: Nearest  
      OverflowAction: Saturate  
      ProductMode: FullPrecision  
      SumMode: FullPrecision
```

To make sure that the fimath settings are specified according to `hdlfimath` for the MATLAB Function block, you can run the check “Check for MATLAB Function block settings” on page 44-18.

Guidelines for HDL Code Generation Using Stateflow Charts

These guidelines illustrate the recommended settings when using Stateflow charts in your model. The Stateflow Chart block is available in the **Stateflow** block library. By using Stateflow charts, you can model delays in your Simulink model.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Choose State Machine Type based on HDL Implementation Requirements

Guideline ID

2.9.1

Severity

Strongly Recommended

Description

HDL Coder supports code generation for Mealy and Moore Stateflow charts. MATLAB Function block is also available to model Mealy or Moore state machines.

To specify whether you want a Mealy or Moore state machine, in the Chart (Stateflow) properties, specify the **State Machine Type**. Do not use **Classic** because it affects readability of the generated HDL code. Choose the **State Machine Type** depending on how you want the Stateflow semantics to map to a hardware implementation. See “Hardware Realization of Stateflow Semantics” on page 33-6.

When you use Mealy charts, the outputs depend on the current state and inputs. By using Mealy charts, you can more easily define state transitions which makes these charts more flexible to use. The generated HDL code from Mealy charts may be less readable.

For Moore charts, the outputs depend only on the current state. The generated HDL code from Moore charts is more readable. Moore charts restrict flexibility in defining state transitions.

Specify Block Configuration Settings of Stateflow Chart

Guideline ID

2.9.2

Severity

Strongly Recommended

Description

When you use Stateflow Chart (Stateflow) blocks in your model for HDL code generation, use these recommended settings:

- For **Action Language**, use MATLAB
- For **Update method**, use Discrete or Inherited. Do not use Continuous.

Moore Chart

- If you disable **Initialize Outputs Every Time Chart Wakes Up**, the generated HDL code includes additional registers for the state machine output values.
- Disable **Support Variable-Size Arrays**.

Mealy Chart

- If you disable **Initialize Outputs Every Time Chart Wakes Up**, the generated HDL code includes additional registers for the state machine output values.
- Disable **Enable Super Step Semantics**.
- Disable **Support Variable-Size Arrays**.
- Enable **Execute (enter) chart at initialization**.

To make sure that these settings are specified for the Stateflow Chart, you can run the check “Check for Stateflow chart settings” on page 44-19.

Insert Unconditional Transition State for Else Statement in HDL Code

Guideline ID

2.9.3

Severity

Recommended

Description

When you use Stateflow® charts for HDL code generation, insert unconditional states in the chart. The HDL code generated for such a chart contains an else branch with the if statement. The presence of an else branch prevents the third-party tool from inferring a latch when you deploy the HDL code. For example, open the model `hdlcoder_chart_ifnelsecond`.

```
open_system('hdlcoder_chart_ifnelsecond')
set_param('hdlcoder_chart_ifnelsecond', 'SimulationCommand', 'Update')
open_system('hdlcoder_chart_ifnelsecond/dut_chart')
```

The model contains two Stateflow Moore Charts. The chart `onlyif_chart` implements a simple condition that outputs `out1` based on `in1`.

```
open_system('hdlcoder_chart_ifnelsecond/dut_chart/onlyif_chart')
```

The Chart block `ifnelse_chart` is the same as `onlyif_chart` and has an unconditional transition state.

```
open_system('hdlcoder_chart_ifnelsecond/dut_chart/ifnelse_chart')
```

To generate HDL code for the DUT, run this command:

```
makehdl('hdlcoder_chart_ifnelsecond/dut_chart')
```

The HDL code generated for the `onlyif_chart` does not contain an else condition. Do not deploy this code to a target device because synthesis tools might infer a latch.

```
case (is_onlyif_chart)
  is_onlyif_chart_IN_Init :
    begin
      if (in < 4'sb0000) begin
        is_onlyif_chart_temp = is_onlyif_chart_IN_On1;
      end
    end
  default :
    begin
      //case IN_On1:
      if (in >= 4'sb0000) begin
        is_onlyif_chart_temp = is_onlyif_chart_IN_Init;
      end
    end
endcase
is_onlyif_chart <= is_onlyif_chart_temp;
```

The HDL code generated for the `ifnelse_chart` contains an else statement for the unconditional transition state. This code is recommended for deployment to the target FPGA device.

```
case (is_ifnelse_chart)
  is_ifnelse_chart_IN_Init :
    begin
      if (in < 4'sb0000) begin
        is_ifnelse_chart_temp = is_ifnelse_chart_IN_On1;
      end
      else begin
        is_ifnelse_chart_temp = is_ifnelse_chart_IN_Init;
      end
    end
  default :
    begin
      //case IN_On1:
      if (in >= 4'sb0000) begin
        is_ifnelse_chart_temp = is_ifnelse_chart_IN_Init;
      end
      else begin
        is_ifnelse_chart_temp = is_ifnelse_chart_IN_On1;
      end
    end
  endcase
is_ifnelse_chart <= is_ifnelse_chart_temp;
```

Data Type Settings and Casting in Stateflow Chart for HDL Code Generation

Guideline ID

2.9.4

Severity

Informative

Description

When you do not explicitly specify the data type of state and output variables in a Stateflow Chart that has MATLAB as the **Action Language**, the data type becomes double. If variables that have different data types are assigned to these Chart variables, a data type mismatch can occur, which can lead to simulation errors.

To avoid simulation errors, explicitly initialize the data type of the Chart variables by using fi objects, or specify their data type in Model Explorer. When performing assignments to variables of different types, you can perform data type conversion and initialization by using fi objects.

When you want to change the fi data type, you must specify the word lengths and fraction lengths for the types. For frequent data type conversions, you can instead cast the type to fi data types by using subscript(:). In this case, you can replace data type conversions with cast by subscript(:) in the Model

Explorer. The value of the substitution source is then type-converted to that of the substitution target variable.

Note: For assignments to intermediate variables, you do not have to cast the data type.

For an example that shows the different data type initialization methods, open the model `hdlcoder_chart_datatype_casting`.

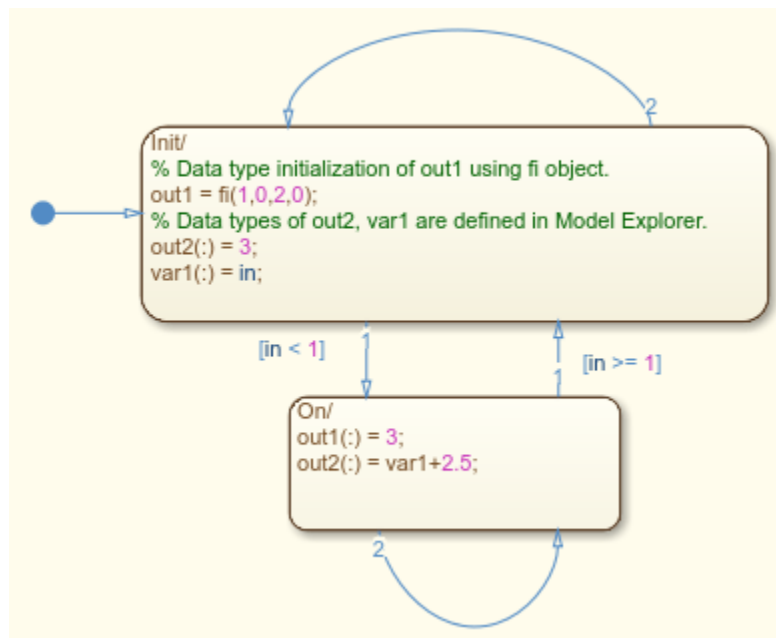

```
open_system('hdlcoder_chart_datatype_casting')
set_param('hdlcoder_chart_datatype_casting', 'SimulationCommand', 'Update')
```

Copyright 2020 The MathWorks, Inc.

The DUT subsystem contains a Moore chart that shows how the output variables `out1` and `out2` and an internal variable `var1` are defined. `out1` type is explicitly specified by using a `fi` object, and `out2` and `var1` types are defined in the Model Explorer.

```
open_system('hdlcoder_chart_datatype_casting/DUT/Chart')
```

To generate HDL code for the DUT subsystem, run the `makehdl` function.

```
makehdl('hdlcoder_chart_datatype_casting/DUT')
```

Using Absolute Time Temporal Logic in Stateflow Charts

Guideline ID

2.9.5

Severity

Mandatory

Description

When you use absolute time temporal logic in your Stateflow Chart blocks in your model for HDL code generation, use these settings.

For the sample rate of the chart:

- If you use seconds (sec), then the sample time must be an integer 65535 or lower, or a decimal between 65.535 and 0.001 having no more than three decimal places.
- If you use milliseconds (msec), the sample time must be a decimal between 65.535 and 0.001 having no more than three decimal places, or a decimal between 0.065535 and 0.000001 having no more than six decimal places.
- If you use microseconds (usec), the sample time must be a decimal between 0.065535 and 0.000001 having no more than six decimal places, or a decimal between 0.000065535 and 0.000000001 having no more than nine decimal places.
- If the sample time is an integer below 2^{16} , use 'sec'.
- If $1000 * \text{sample time}$ is an integer below 2^{16} , use 'sec' or 'msec'.
- If $1000000 * \text{sample time}$ is an integer below 2^{16} , use 'msec' or 'usec'.
- If $1000000000 * \text{sample time}$ is an integer below 2^{16} , use 'usec'.

Modeling Error (default) State in Stateflow Charts

Guideline ID

2.9.6

Severity

Informative

Description

When generating HDL code for Stateflow charts that have exclusive state decomposition, states are represented by case statements. For example, a chart with three states, A, B, and C, results in a switch case:

```
CASE is_Chart IS
    WHEN IN_A =>
        is_Chart_next <= IN_B;
```

```

    y_tmp <= to_signed(16#00000002#, 32);
  WHEN IN_B =>
    is_Chart_next <= IN_C;
    y_tmp <= to_signed(16#00000003#, 32);
  WHEN OTHERS =>
    --case IN_C:
    y_tmp <= to_signed(16#00000003#, 32);
  END CASE;

```

It is useful to control which of the states corresponds to the default case of the switch. For example, you can use the default state to model error behavior. The state whose name is alphabetically last occurs in the default branch. In the example code, the default branch is `WHEN OTHERS=>`.

If you are using variant transitions, an unreachable default state can be eliminated in the HDL code. To avoid this, the selected default state must be reachable. For example, you can connect the default state to another reachable state and provide a transition that is always false, such as `1 == 0`. For more information, see “Control Indicator Lamp Dimmer Using Variant Conditions” (Stateflow).

Enable Clock-Driven Outputs of Stateflow Charts (Moore Charts Only)

Guideline ID

2.9.7

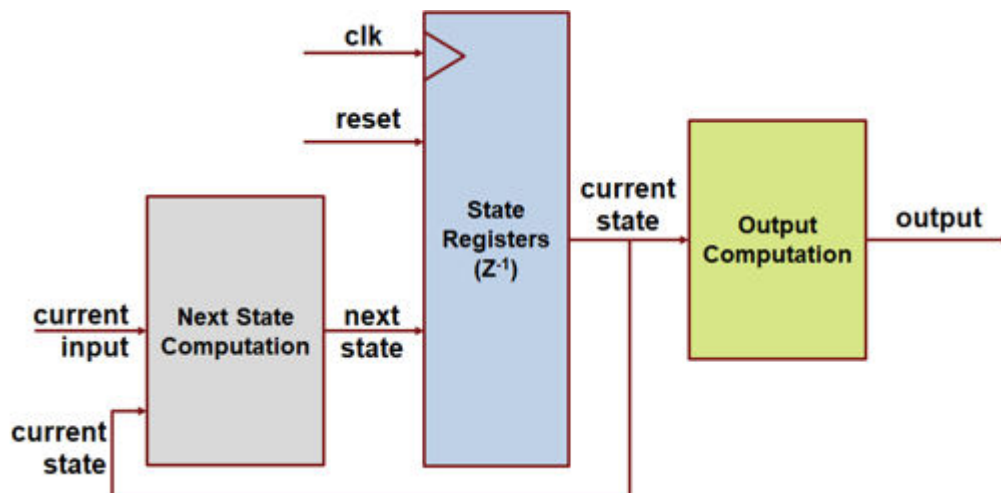

Severity

Informative

Description

You can generate HDL code that has clock-driven output signals for Moore charts in Stateflow. Clock-driven outputs prevent combinatorial logic from driving the output and allow an immediate output update when the clock signal and state change. You can enable clock-driven outputs for Stateflow charts by using the Stateflow chart HDL block property **ClockDrivenOutput**. This option is available only for Moore charts.

When **ClockDrivenOutput** is off, the HDL code generated from a Moore chart has this structure:

When you set **ClockDrivenOutput** to on, HDL Coder adds an output register that updates when the state updates. HDL Coder then assigns the final output variable a value from the clock-driven register. The generated HDL code has this structure:

The generated HDL code includes an additional output register for every output from the Moore chart.

Enumeration type for active state monitoring in a Stateflow chart with no default value

Guideline ID

2.9.8

Severity

Informative

Description

You can specify the enumeration type used to monitor state activity for a Stateflow chart that contains only literals that correspond to every state, without an extra literal for specifying the default **None** state, or any default state that does not represent a child state. The default value of the enumeration type can correspond to one of the states in the chart. Using an enumeration type that specifies only as many literals as there are states in the Stateflow chart allows you to generate HDL code that requires less area.

To monitor state activity for a Stateflow chart, enable active state data. See “Enable Active State Data” (Stateflow). To define the default value of the enumeration type as a state in your chart, select **Define enumerated type manually**. See “Define State Activity Enumeration Type” (Stateflow). If you use the option **Create enum definition from template** to create an enumeration definition template, the template creates the default state as **None**. Remove the **None** state.

For example, an enumerated type with the default state as **None** can have this definition:

```

classdef ChartModeType < Simulink.IntEnumType
    % MATLAB enumeration class definition generated from template
    %   to track the active child state of none_state_question2/Subsystem/Chart.

    enumeration
        A(0),
        B(1),
        None(3)
    end

    methods (Static)

        function defaultValue = getDefaultValue()
            % GETDEFAULTVALUE Returns the default enumerated value.
            %   If this method is not defined, the first enumeration is used.
            defaultValue = ChartModeType.None;
        end

        % Unchanged methods not shown
    end
end

```

The section of generated HDL code from the enumerated type looks like this:

```

reg [1:0] ChartMode_reg;           // enum type ChartModeType (3 enums)
reg [1:0] ChartMode_reg_next;     // enum type ChartModeType (3 enums)

```

The registers `ChartMode_reg` and `ChartMode_reg_next` in the generated HDL code use two bits each to store the enumerated type.

When you remove the default `None` state from the enumerated definition and the function `getDefaultValue()`, this is the enumerated type:

```

classdef ChartModeType < Simulink.IntEnumType
    % MATLAB enumeration class definition generated from template
    %   to track the active child state of none_state_question2/Subsystem/Chart.

    enumeration
        A(0),
        B(1),
    end

    methods (Static)
        % Unchanged methods not shown
    end
end

```

The registers `ChartMode_reg` and `ChartMode_reg_next` in the generated HDL code now use only one bit each to store the enumerated type:

```

reg ChartModeReg;                 // enum type ChartModeEnum (2 enums)
reg ChartModeReg_next;           // enum type ChartModeEnum (2 enums)

```

An enumerated type with no default `None` state for active state monitoring has these Stateflow limitations:

- You can only define an enumerated type with no `None` state to monitor the child activity of the top-most chart level.

- The Stateflow chart must have the property **Execute (enter) Chart At Initialization** enabled.
- You cannot use the `in` operator for the default child state.
- Local events are not allowed.
- You must set the configuration parameter **No unconditional default transitions** to error.

For more information on monitoring state activity in a Stateflow chart, see “Define State Activity Enumeration Type” (Stateflow).

Simulink Data Type Considerations

You can follow these guidelines to learn the recommended data type settings that you want to use in your Simulink model for HDL code generation. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Use Boolean for Logical Data and Ufix1 for Numerical Data

Guideline ID

2.10.1

Severity

Mandatory

Description

Boolean and the fixed-point type, `ufix1`, are both 1-bit data types in MATLAB and Simulink. These types are treated differently.

- Use **Boolean** for control logic signals such as enable and local reset signals. If you want to calculate a **Boolean** signal with a fixed-point data type, use a Data Type Conversion to convert the signal to a `fixdt (0,1,0)` type.
- To perform numeric calculations, use `fixdt (0,1,0)`. Sometimes, the output bit width can become larger than the bitwidth. To perform such operations, use the `Inherit: Inherit via internal rule` setting, because of the `numericType` property of `fixdt (0,1,0)`.

Specify Data Type of Gain Blocks

Guideline ID

2.10.2

Severity

Recommended

Description

Gain blocks have a **Gain** parameter and an **Output data type** setting. It is recommended that you use fixed-point data types for these settings. In the Block Parameters dialog box of the Gain block:

- Specify a `Simulink.NumericType` object, such as `fixdt (1, 16, 8)`.
- Make sure that the **Gain** parameter of the block does not use a round parameter value. To avoid rounding of the gain value, you can specify a `fi` object, such as `fi(3.44,0,8,4)`.
- Avoid using `Inherit:Inherit via internal rule`. This setting can result in an erroneous data type being assigned to the block, thereby resulting in an HDL code generation error.

Enumerated Data Type Restrictions

Guideline ID

2.10.3

Severity

Mandatory

Description

Certain optimizations such as pipelining and resource sharing do not work seamlessly in the presence of enumerated data types. It is recommended that you use enumerated types on an as needed basis. HDL code generation has certain restrictions when modeling with enumerated types.

- You cannot use an enumerated data type for the input or output port of the top-level DUT.
- You cannot perform arithmetic operations such as $*$, $/$, $-$, and $+$ with enumeration values.

- “Signal and Data Type Support” on page 14-3

Resource Sharing Settings for Various Blocks

Resource sharing is an area optimization in which HDL Coder identifies multiple functionally equivalent resources and replaces them with a single resource. The data is time-multiplexed over the shared resource to perform the same operations. To learn more about how resource sharing works, see “Resource Sharing” on page 28-45.

You can follow these guidelines to learn how to use the resource sharing optimization effectively with blocks such as Add and Product. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Resource Sharing of Add Blocks

Guideline ID

3.1.1

Severity

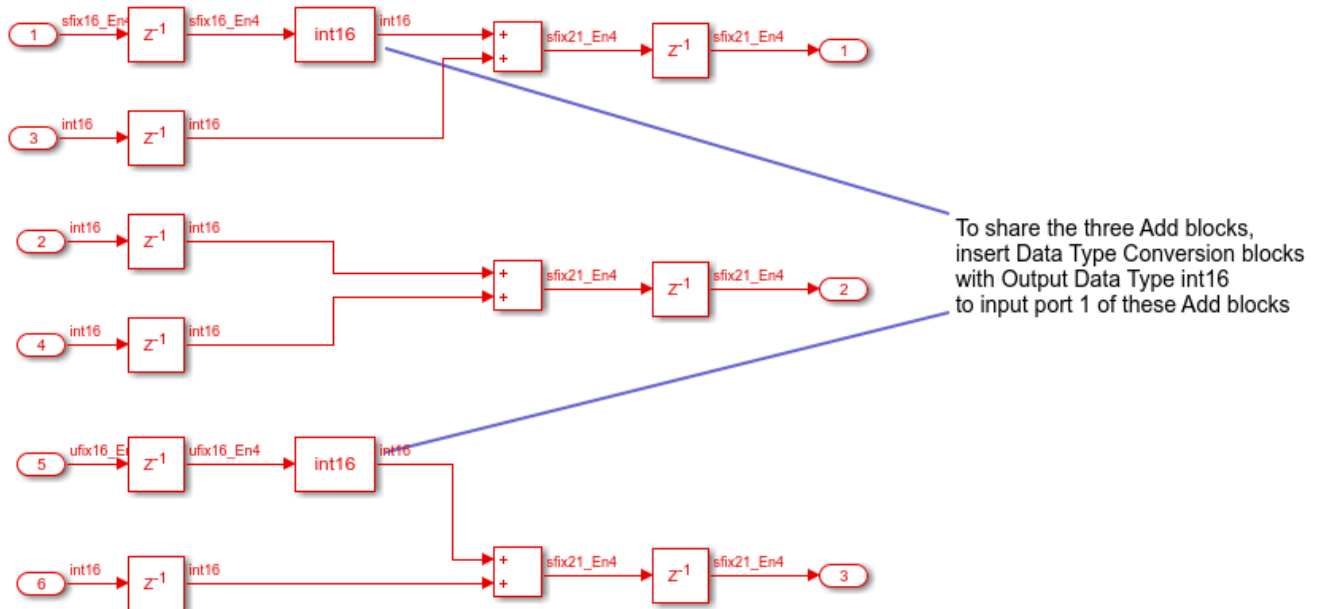

Recommended

Description

To share multiple Add blocks:

- Select the **Share Adders** setting.
- Leave the **Adder sharing minimum bitwidth** to 0.
- Determine whether to perform resource sharing at the existing clock rate or at a higher clock rate. To use a higher clock rate, specify an **Oversampling factor** greater than 1.
- Specify the “StreamingFactor” on page 26-25 for Add blocks with vector inputs or outputs.
- Specify the “SharingFactor” on page 26-23 for Add blocks with scalar inputs or outputs.
- Make sure that the input word-lengths of the Add blocks match.

For example, this figure illustrates a model containing three Add blocks placed inside a Subsystem with **SharingFactor** of 3. To share the Add blocks, you must insert Data Type Conversion blocks with **Output data type** set to `int16` so that the input word lengths match.

Resource Sharing of Gain Blocks

Guideline ID

3.1.2

Severity

Recommended

Description

When you share multiple Gain blocks in your design, the optimization inserts serialization and deserialization logic to share resources. This additional logic can become an area overhead if you are not sharing a large number of resources. Therefore, if your design does not contain a large number of Gain blocks to share, it is recommended that you disable the resource sharing optimization. To share multiple Gain blocks:

To share multiple Gain blocks:

- Determine how to implement the Gain block. HDL Coder does not share Gain blocks in either of these cases:
 - **ConstMultiplierOptimization** parameter set to `csd` or `fcasd`.
 - **Gain** parameter is a power of two.

In both these cases, the code generator uses a cast operation to replace the multiplier operations with shift and add or subtract operations, which causes sharing to be unsuccessful. In addition, if the **Gain** parameter is 0 or 1, then resource sharing requires no additional logic.

- Specify the “StreamingFactor” on page 26-25 for Gain blocks with vector inputs or outputs.

- Specify the “SharingFactor” on page 26-23 for Gain blocks with scalar inputs or outputs.
- Determine whether to perform resource sharing at the existing clock rate or at a higher clock rate. To use a higher clock rate, specify an **Oversampling factor** greater than 1.
- Use the same synthesis attribute settings if you specify the DSPStyle block property for the Gain blocks. HDL Coder does not share multipliers that have different synthesis attribute settings.

Resource Sharing of Product Blocks

Guideline ID

3.1.3

Severity

Recommended

Description

To share multiple Product blocks:

- Specify 18 as the **Multiplier partitioning threshold** when targeting Xilinx devices and 25 as the threshold when targeting Intel devices. This setting creates more resource sharing opportunities for multipliers with a wide bit width, which reduces the use of DSPs on the FPGA.
- Specify the **Multiplier promotion threshold** if you want to share Product blocks that have different word-lengths. The multiplier promotion threshold is the maximum word-length by which HDL Coder promotes a multiplier for sharing with other multipliers.
- Leave the **Share Multipliers** setting enabled and the **Multiplier sharing minimum bitwidth** to 0.
- Specify the “StreamingFactor” on page 26-25 for the subsystems that contain Product blocks with vector inputs or outputs.
- Specify the “SharingFactor” on page 26-23 for the subsystems that contain Product blocks with scalar inputs or outputs.
- Use a Gain block instead of a Product block when one of the inputs to the Product block is a constant. Use the constant value as the **Gain** parameter of the Gain block. If you use floating-point data types in the **Native Floating Point** mode, HDL Coder converts the Product block to a Gain block automatically during code generation. To learn more, see “Simplify Constant Operations and Reduce Design Complexity in HDL Coder” on page 28-18.
- Determine whether to perform resource sharing at the existing clock rate or at a higher clock rate. To use a higher clock rate, specify an **Oversampling factor** greater than 1.
- Use the same synthesis attribute settings if you specify the DSPStyle block property for the Product blocks. HDL Coder does not share multipliers that have different synthesis attribute settings.

Resource Sharing of Multiply-Add Blocks

Guideline ID

3.1.4

Severity

Recommended

Description

To share multiple Multiply-Add blocks:

- Leave the **Share Multiply-Add blocks** setting enabled and the **Multiply-Add block sharing minimum bitwidth** set to 0.
- Determine whether to perform resource sharing at the existing clock rate or at a higher clock rate. To use a higher clock rate, specify an **Oversampling factor** greater than 1.
- Specify the “SharingFactor” on page 26-23.

Resource Sharing of Subsystems and Floating-Point IPs

Resource sharing is an area optimization in which HDL Coder identifies multiple functionally equivalent resources and replaces them with a single resource. The data is time-multiplexed over the shared resource to perform the same operations. To learn more about how resource sharing works, see “Resource Sharing” on page 28-45.

You can follow these guidelines to learn how to use the resource sharing optimization effectively for subsystems such as atomic subsystems and MATLAB Function blocks, and with floating-point IPs. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

General Considerations for Sharing of Subsystems

Guideline ID

3.1.5

Severity

Recommended

Description

To share resources for identical subsystems, such as when grouping Product, Add, and Delay blocks to map to one DSP slice, the subsystems to be shared must be Atomic Subsystem blocks, Virtual Subsystem blocks, or MATLAB Function blocks.

- Determine whether you want to share resources at the existing clock rate or at a higher clock rate.
- Sharing of enabled subsystems is not supported. For sharing resources, use atomic or virtual subsystems without enable semantics.
- Specify a “SharingFactor” on page 26-23 that is greater than or equal to the number of subsystems that you want to share.

For example, if you have 10 subsystems, and you set the **SharingFactor** to 5, HDL Coder cannot implement the resource sharing to 2 instances of the subsystem. To share the subsystems, divide the subsystems, and then share the instances of the smaller subsystems.

- Check the **SharingFactor** that you specify for various subsystems. The resource sharing optimization overclocks the shared resources by the LCM (Least Common Multiple) of the **SharingFactor** of various subsystems.

For example, if you specify a **SharingFactor** of 5 for one Subsystem, and a **SharingFactor** of 7 for another Subsystem, the resource sharing optimization overclocks the shared resources by 35. In such cases, it is recommended that you use the same **SharingFactor** for both subsystems, such as 5 or 7. To learn more about this calculation, see “How Resource Sharing Works” on page 28-45.

Use MATLAB Datapath Architecture for Sharing with MATLAB Function Blocks

Guideline ID

3.1.6

Severity

Recommended

Description

HDL Coder shares MATLAB Function blocks that have:

- The same Simulink checksum. Use `Simulink.SubSystem.getChecksum` to determine the checksum.
- The same HDL block properties.

Make sure that the blocks do not use:

- Persistent variables
- Loop streaming
- Output pipelining

By using the MATLAB Datapath architecture, you can share resources inside the MATLAB Function block and across the MATLAB Function block with other blocks in your Simulink model. When you use this architecture, the code generator treats the MATLAB Function block like a regular Subsystem block. This capability enables you to more widely apply various speed and area optimizations with MATLAB Function blocks. See “HDL Optimizations Across MATLAB Function Block Boundary Using MATLAB Datapath Architecture” on page 28-203.

Sharing of Subsystems

Guideline ID

3.1.7

Severity

Recommended

Description

HDL Coder can share Subsystem blocks that have the same Simulink checksum and the same HDL block properties.

To share Subsystem blocks, the state elements that the blocks can contain are:

- Delay
- Unit Delay
- Unit Delay Enabled Synchronous

- Unit Delay Resettable Synchronous
- Unit Delay Enabled Resettable Synchronous

The state elements must have the **Initial condition** parameter set to 0.

Sharing of subsystems inside enabled subsystems with synchronous semantics is not supported. To share resources, use enabled subsystems with classic semantics.

You cannot share subsystems that contain the following blocks or block implementations:

- Detect Change
- Discrete Transfer Fcn
- HDL FFT
- HDL FIFO
- Math Function (conj, hermitian, transpose)
- MATLAB Function blocks that contain persistent variables
- Sqrt
- Cascade architecture (MinMax, Product, Sum)
- Reciprocal Newton architecture
- Filter blocks including Discrete FIR Filter
- Communications Toolbox blocks
- DSP System Toolbox blocks, except Discrete FIR Filter
- Stateflow blocks
- Blocks that are not supported for delay balancing. For details, see “Delay Balancing Limitations” on page 28-85.

Limitations

Resource sharing of atomic subsystems might cause a mismatch in the initialization cycles of the validation model if your model has:

- Logic in the subsystems shared that produce non-zero output when the input is zero.
- Subsystems shared that are in a serial configuration in your design under test (DUT) subsystem.

Resource Sharing of Floating-Point IPs

Guideline ID

3.1.8

Severity

Recommended

Description

To share multiple:

- Floating-point adders, set ShareAdders to on.

- Floating-point multipliers, make sure `ShareMultipliers` is set to on.
- Other floating-point resources, set `ShareFloatingPointIP` to on.

See also **Modeling with Native Floating Point**.

Resource Sharing Guidelines for Vector Processing and Matrix Multiplication

Resource sharing is an area optimization in which HDL Coder identifies multiple functionally equivalent resources and replaces them with a single resource. The data is time-multiplexed over the shared resource to perform the same operations. To learn more about how resource sharing works, see “Resource Sharing” on page 28-45.

You can follow these guidelines to learn how to use the resource sharing with streaming when processing 1-D vectors and 2-D matrices. Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Use StreamingFactor for Resource Sharing of Vector Signals

Guideline ID

3.1.9

Severity

Informative

Description

To reduce circuit area of a Subsystem block that performs the same computation on each element of a 1-D vector, use the Subsystem HDL block property **StreamingFactor**. For a vector signal that has N elements, set **StreamingFactor** to N. By using time-division multiplexing to process each element, you can process the result by using smaller number of operations. The clock frequency of the operators becomes N times faster than that of the original model.

When the subsystem containing resources to be shared uses multiple vector signals with different sizes, the clock frequency is multiplied by the least common multiple of the vector sizes, which can reduce the maximum achievable target frequency. To achieve the desired frequency:

- Add logic for demultiplexing the vector signal before it enters the subsystem and for multiplexing the signal that leaves the subsystem. You can then specify a **SharingFactor** on the subsystem instead of the **StreamingFactor**.
- Pad the different vector signals to make them the same size as the vector signal that has the maximum size, and then specify the **StreamingFactor**.

Open the model `hdlcoder_vector_stream_gain`.

```
open_system('hdlcoder_vector_stream_gain')
set_param('hdlcoder_vector_stream_gain', 'SimulationCommand', 'Update')
```

Copyright 2020 The MathWorks, Inc.

The model accepts a 10-element vector signal as input and multiplies each element by a gain value that is one more than the previous value.

```
open_system('hdlcoder_vector_stream_gain/Gain_Stream')
```

To see the simulation results, simulate the model and open the Scope block.

```
sim('hdlcoder_vector_stream_gain')
open_system('hdlcoder_vector_stream_gain/Show Processing Time')
```

The Gain_Stream subsystem has a **StreamingFactor** set to 10. To generate HDL code for this subsystem, run the `makehdl` function:

```
makehdl('hdlcoder_vector_stream_gain/Gain_Stream')
```

After generating HDL code, to see the effect of the streaming optimization, open the generated model and navigate inside the Gain_Stream subsystem.

The vector data is serialized on the input side and the output size parallelizes the serial data. This optimization increases the total circuit size conversely when the target circuit size to be shared is small. The Gain block inside the shared subsystem is running at a rate that is 10 times faster than the model base rate, which avoids an increase in the subsystem latency and balances the reduction in maximum achievable frequency by the increase in area savings on the target hardware.

Use SharingFactor and HDL Block Properties for Sharing Matrix Multiplication Operations

Guideline ID

3.1.10

Severity

Informative

Description

The Matrix Multiply block is a Product block that has **Multiplication** block parameter set to **Matrix(*)**. In the HDL Block Properties dialog box, the HDL architecture is set to **Matrix Multiply** and you can specify the “DotProductStrategy” on page 26-10.

DotProductStrategy Settings

DotProductStrategy	Description
'Fully Parallel' (default)	Performs multiplication and addition operations in parallel. $[M \times N] * [N \times M]$ matrix multiplication requires $N * M * M$ multipliers.
'Parallel Multiply-Accumulate'	Uses the Parallel architecture of the Multiply-Accumulate block to implement the matrix multiplication. This architecture performs multiple Multiply-Add blocks in parallel with accumulation.
'Serial Multiply-Accumulate'	Uses the Serial architecture of the Multiply-Accumulate block to implement the matrix multiplication. This mode performs N times oversampling and number of multipliers becomes $M * M$.

To share resources and reduce the number of multipliers further, when you have multiple Matrix Multiply blocks in the same subsystem, set **DotProductStrategy** to **Fully Parallel** and specify the **SharingFactor** on the upper subsystem.

For multiplications involving complex and real numbers, the number of multipliers become doubled.

Number of Multipliers Generated by Multiplication of $[M \times N] * [N \times M]$

Multiplication Type	Fully Parallel/Parallel Multiply-Accumulate	Serial Multiply-Accumulate
Real x Real	$N * M * M$	$M * M$
Complex x Real	$N * M * M * 2$	$M * M * 2$
Complex x Complex	$N * M * M * 4$	$M * M * 4$

For floating-point matrix multiplication, select **Use Floating Point**. In this case, you must use the **Fully Parallel DotProductStrategy**. As this mode does not use element-wise operations and performs parallel multiplication and addition operations, use the **SharingFactor** instead of the **StreamingFactor** to share resources and save circuit area.

For an example that shows how to perform streaming matrix multiplication using floating-point types, see “HDL Code Generation for Streaming Matrix Multiply System Object” on page 1-31.

Distributed Pipelining and Clock-Rate Pipelining Guidelines

The code generator introduces registers when you specify certain block implementations or use certain settings. You can follow these guidelines to learn more about these registers and how you can use them to optimize the timing of your design.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see “HDL Modeling Guidelines Severity Levels” on page 25-2.

Clock-Rate Pipelining Guidelines

Guideline ID

3.2.1

Severity

Informative

Description

In most cases, the code generator introduces the registers in regions that run slower than the clock rate. To avoid or minimize additional latency, you can run these registers at the fast clock rate by using clock-rate pipelining. You can use clock-rate pipelining with these optimizations:

- Input and output pipelining
- Multi-cycle block implementations, such as complex math operations like Sqrt and Reciprocal.
- Floating-point library mapping
- Delay balancing
- Resource sharing and streaming

For designs with multiple hierarchies, when you want to perform certain system-level optimizations, such as sharing or distributed pipelining, it is recommended that you have the HDL block property **FlattenHierarchy** enabled on the top-level Subsystem.

To learn more about clock-rate pipelining and blocks that act as barriers to this optimization, see “Clock-Rate Pipelining” on page 28-149.

Recommended Distributed Pipelining Settings

Guideline ID

3.2.2

Severity

Recommended

Description

Distributed pipelining is a speed optimization that reduces the critical path by moving existing delays in your design while preserving the functional behavior. This optimization moves the delays within a subsystem while preserving the hierarchy.

To use this optimization for a design, in the Configuration Parameters dialog box, on the **HDL Code Generation > Optimization** pane, navigate to the **Pipelining** tab and select the **Distributed pipelining** check box.

To more effectively use this optimization, in the Configuration Parameters dialog box, on the **HDL Code Generation > Optimization** pane, you can specify these additional settings.

- **ConstrainedOutputPipeline:** Make sure that the total number of delays that are inserted including any input and output pipelining that you specify is greater than or equal to the value that you specify for **ConstrainedOutputPipeline** on the Subsystem.
- **Use synthesis estimates for distributed pipelining:** Select this option if you want to use synthesis timing estimates to calculate the propagation delays of the components in your design for distributed pipelining. This option can more accurately reflect how components function on hardware to better distribute pipelines in your design and maximize the clock frequency for your target device. See “Distributed Pipelining Using Synthesis Timing Estimates” on page 28-137.
- **Clock-rate pipelining:** Select this option if you want the code generator to insert registers at the clock rate instead of the data rate.
- **Allow clock-rate pipelining of DUT output ports:** Select this option if you want the code generator to insert registers at the clock rate instead of the data rate at the DUT output ports.
- **Preserve design delays:** Select this option if you do not want the code generator to move the delays you added to your design. The optimization only moves pipeline registers.
- **Distributed pipelining priority:** Specify whether you want the priority to be `Numerical Integrity` or `Performance`. If you use `Performance`, make sure that the simulation results match. In some cases, this setting moves registers into blocks that have initial values such as constants, which can affect simulation results.

The subsystem to which you apply the optimization must meet these requirements:

- The subsystem that you apply this optimization on cannot contain any feedback loops.
- The subsystem must include only blocks that are supported for distributed pipelining. For a list of unsupported blocks, see “Limitations of Distributed Pipelining” on page 28-134. As a workaround:
 - Place some of the unsupported blocks, such as Dot Product blocks, inside another subsystem that does not have distributed pipelining enabled.
 - Change the **Distributed pipelining priority** parameter to `Performance` for blocks such as Enabled Subsystem blocks.
- The **Sample Time** parameter of the blocks must be discrete. If you have blocks with **Sample Time** set to `inf`, change them to `-1` if the infinite sample time propagates to the DUT output. To identify and change the sample time programmatically, see “Change Block Parameters by Using `find_system` and `set_param`” on page 25-35.

Insert Distributed Pipeline Registers for Blocks with Vector Data Type Inputs

Distributed pipelining is a speed optimization that reduces the critical path by moving existing delays in your design while preserving the functional behavior. This guidelines illustrates how you can use the optimization effectively for vector inputs.

Each guideline has a severity level that indicates the level of compliance requirements. To learn more, see "HDL Modeling Guidelines Severity Levels" on page 25-2.

Guideline ID

3.2.3

Severity

Informative

Description

Blocks that Participate in Distributed Pipelining with Vector Types

By specifying certain settings, you can apply the distributed pipelining optimization to insert pipeline registers for these blocks when you input vectors that are larger than 3 in size. For details, see the "HDL Code Generation" section of each block page.

- Adders: Add, Subtract, and Sum of Elements
- Multipliers: Gain, Product, and Product of Elements
- MinMax
- Dot Product

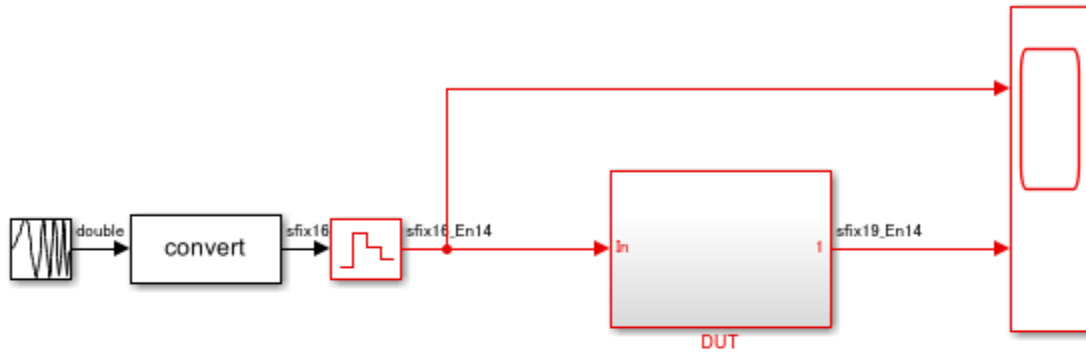

Block Settings and Requirements

- 1 In the HDL Block Properties for the blocks, set **Architecture** to :
 - **Tree** or **Linear** for adders, multipliers, and MinMax blocks. Distributed pipeline register insertion does not support **Cascade** architecture.
 - **Linear** for Dot Product. Distributed pipeline register insertion does not support **Tree** architecture for this block.
- 2 Specify the number of pipeline stages by using the **InputPipeline** and **OutputPipeline** properties in the HDL Block Properties dialog box, or by manually inserting Delay blocks.
- 3 Enable **DistributedPipelining** on the Subsystem for which you want to apply this optimization.
- 4 Open the Distributed Pipelining report.
- 5 Open and examine the generated model.

Distributed Pipelining Example for Vector Sum of Elements

This example shows how you can distribute pipeline registers at the output of a Sum of Elements block that accepts vector inputs.

```
open_system('hdlcoder_distributed_pipelining_soe')
set_param('hdlcoder_distributed_pipelining_soe','SimulationCommand','Update')
```

Copyright 2018–2021 The MathWorks, Inc.

If you navigate the model, you see three pipeline stages for the Sum of Elements block.

```
open_system('hdlcoder_distributed_pipelining_soe/DUT/Add')
```

You see a Delay block of three added at the output of the Sum of Elements block. You can use distributed pipelining to distribute the delays.

1. Set **Architecture** to **Tree** for the Sum of Elements block.

```
hdlset_param('hdlcoder_distributed_pipelining_soe/DUT/Add/Add', ...
             'Architecture','Tree')
```

2. Enable **DistributedPipelining** on the Add Subsystem

```
hdlset_param('hdlcoder_distributed_pipelining_soe/DUT/Add', ...
            'DistributedPipelining', 'On')
```

3. Generate HDL code for the DUT Subsystem.

```
makehdl('hdlcoder_distributed_pipelining_soe/DUT')
```

4. Open the Code Generation Report to see the effect of the distributed pipelining optimization.

Detailed Report

Subsystem: [Add](#)

Implementation Parameters: DistributedPipelining: 'on'; InputPipeline: 0; OutputPipeline: 0

Status: Distributed Pipelining successful.

Before Distributed Pipelining: 3 registers (57 flip-flops)

Registers	Count
19-bit	3

After Distributed Pipelining: 7 registers (123 flip-flops)

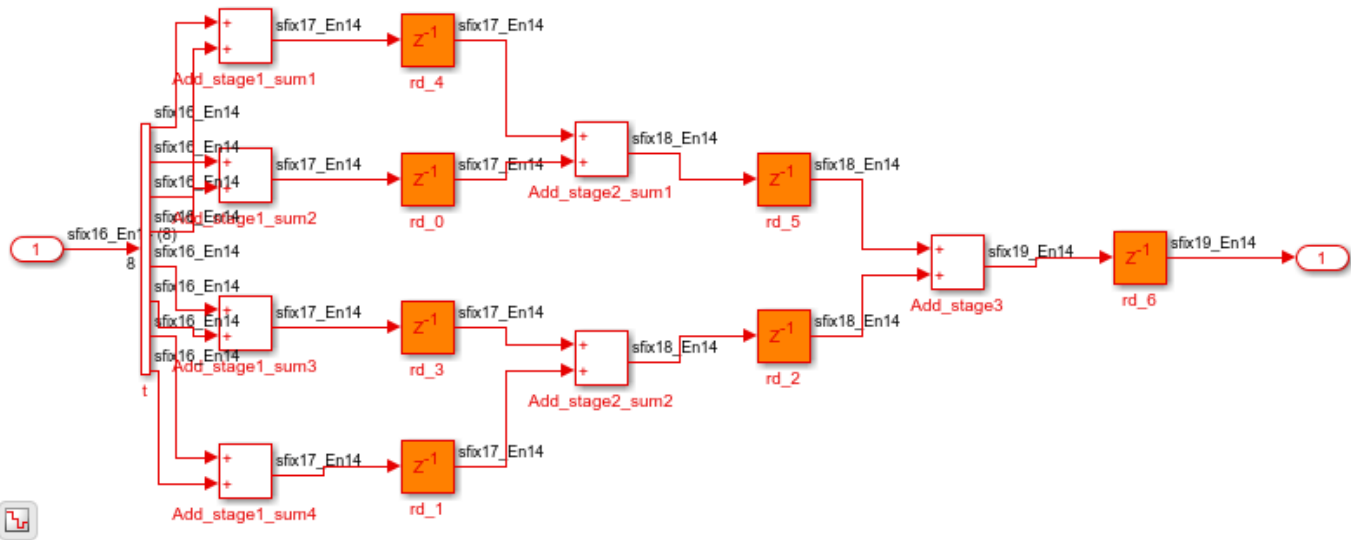

Registers	Count
17-bit	4
18-bit	2
19-bit	1

Generated Model

Generated model after the transformation: [gm_hdlcoder_distributed_pipelining_soe](#)

5. To see the effect of the transformation and how the pipeline registers are distributed, open the generated model and navigate to the Add Subsystem.

```
load_system('gm_hdlcoder_distributed_pipelining_soe')
set_param('gm_hdlcoder_distributed_pipelining_soe', 'SimulationCommand', 'Update')
open_system('gm_hdlcoder_distributed_pipelining_soe/DUT/Add')
```

View HDL-Supported Blocks and Documentation

You can generate efficient HDL code for a number of blocks in Simulink and other product libraries. To see the product libraries that support HDL code generation use the `hdlLib` function. This function filters the library browser to show blocks that are supported for HDL code generation. To learn more, see “Display Blocks for HDL Code Generation in Library Browser” on page 30-21.

This table shows blocks in various product libraries supported for HDL code generation. To view usage notes and limitations, in the corresponding reference page, scroll down to the **Extended Capabilities** section at the bottom and expand the **HDL Code Generation** section.

HDL code generation support for the blocks is summarized in the following tables.

- Blocks Supported for HDL Code Generation (Category List)
- Blocks Supported for HDL Code Generation (Alphabetical List)

View HDL-Specific Block Documentation

The HDL Block Properties dialog box contains HDL-specific properties for each block and subsystem in your model. On this dialog box, you can click the **Help** button to navigate to the documentation for that block. See also “HDL Block Properties: General” on page 26-3 and “HDL Block Properties: Native Floating Point” on page 26-30.

To view HDL-specific block documentation, either:

- In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select the block for which you want to see the help documentation and then select **HDL Block Properties**. To view the block documentation, click **Help**.
- Right-click the block and select **HDL Code > HDL Block Properties**. To view the block documentation, click **Help**.

You see the documentation in the **Extended Capabilities > HDL Code Generation** section of the block page in the product that owns the block.

Overview

Block implementation parameters enable you to control details of the code generated for specific block implementations. See “Set and View HDL Model and Block Parameters” on page 26-53 to learn how to select block implementations and parameters in the GUI or the command line.

Property names are specified as character vectors. The data type of a property value is specific to the property. This section describes the syntax of each block implementation parameter and how the parameter affects generated code.

HDL Block Properties of Library Blocks

HDL block properties of library blocks are treated similar to mask parameters. When you instantiate library blocks in your model, the current HDL block properties of that library block are copied to instances of that block in your model. The HDL block properties of these instances are not synchronized with the HDL block properties of the library block. That is, if you change the HDL block property of the library block, the change does not get propagated to instances of the library block that you already added to your Simulink model. If you want the HDL block properties of a library block to be synchronized with its instances in the model, create a Subsystem and then place this block inside that Subsystem. The HDL block properties of blocks that reside inside the library block are synchronized with the corresponding instances in your model.

Suppose a library contains a Subsystem block with HDL architecture set to `Module`. When you instantiate this block in your model, the block instance uses `Module` as the HDL architecture. If you change the HDL architecture of the Subsystem block in the library to `BlackBox`, existing instances of that Subsystem block in your model still use `Module` as the HDL architecture. If you now add instances of the Subsystem block from the library in your model, the new block instances get a copy of the current HDL block properties, and therefore use `BlackBox` as the HDL architecture. If you want the HDL architecture of the Subsystem block in the library to be synchronized with its instances in the model, create a wrapper subsystem with the HDL architecture that you want inside this Subsystem.

AdaptivePipelining

The `AdaptivePipelining` subsystem parameter enables you to set adaptive pipelining on a subsystem within a model.

Adaptive Pipelining Setting	Description
'inherit' (default)	Use the adaptive pipelining setting of the parent subsystem. If this subsystem is the highest-level subsystem, use the adaptive pipelining setting for the model.
'on'	Insert adaptive pipelines for this subsystem.
'off'	Do not insert adaptive pipelines for this subsystem, even if the parent subsystem has adaptive pipelining enabled.

To disable adaptive pipelining for a subsystem within a model, set the adaptive pipelining parameter, `AdaptivePipelining`, to 'off' for that subsystem.

To learn how to set model-level adaptive pipelining, see “Adaptive pipelining” on page 19-15.

Set Adaptive Pipelining For a Subsystem

To set adaptive pipelining for a subsystem from the HDL Block Properties dialog box:

- 1 Right-click the subsystem and select **HDL Code > HDL Block Properties**.

- For **AdaptivePipelining**, select **inherit**, **on**, or **off**.

To set adaptive pipelining for a subsystem from the command line, use `hdlset_param`. For example, to turn off adaptive pipelining for a subsystem, `my_dut`:

```
hdlset_param('my_dut', 'AdaptivePipelining', 'off')
```

See also `hdlset_param`.

BalanceDelays

The `BalanceDelays` subsystem parameter enables you to set delay balancing on a subsystem within a model.

BalanceDelays Setting	Description
'inherit' (default)	Use the delay balancing setting of the parent subsystem. If this subsystem is the highest-level subsystem, use the delay balancing setting for the model.
'on'	Balance delays for this subsystem.
'off'	Do not balance delays for this subsystem, even if the parent subsystem has delay balancing enabled.

To learn more about delay balancing, see “Delay Balancing” on page 28-81.

Set Delay Balancing For a Subsystem

To set delay balancing for a subsystem using the HDL Block Properties dialog box:

- Right-click the subsystem.
- Select **HDL Code > HDL Block Properties**.
- For **BalanceDelays**, select **inherit**, **on**, or **off**.

To set delay balancing for a subsystem from the command line, use `hdlset_param`. For example, to turn off delay balancing for a subsystem, `my_dut`:

```
hdlset_param('my_dut', 'BalanceDelays', 'off')
```

See also `hdlset_param`.

ClockRatePipelining

The `ClockRatePipelining` subsystem parameter enables you to set clock-rate pipelining on a subsystem within a model.

Clock-Rate Pipelining Setting	Description
'inherit' (default)	Use the clock-rate pipelining setting of the parent subsystem. If this subsystem is the highest-level subsystem, use the clock-rate pipelining setting for the model.
'on'	Insert clock-rate pipelines for this subsystem.
'off'	Do not insert clock-rate pipelines for this subsystem, even if the parent subsystem has clock-rate pipelining enabled.

To disable clock-rate pipelining for a subsystem within a model, set `ClockRatePipelining` to `off` for that subsystem.

To learn how to set model-level clock-rate pipelining, see “Clock-rate pipelining” on page 19-9.

Set Clock-Rate Pipelining For a Subsystem

To set clock-rate pipelining for a subsystem using the HDL Block Properties dialog box:

- 1 Right-click the subsystem.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 Set **ClockRatePipelining** to `inherit`, `on`, or `off`.

To set clock-rate pipelining for a subsystem from the command line, use `hdlset_param`. For example, to turn off clock-rate pipelining for a subsystem, `my_dut`:

```
hdlset_param('my_dut', 'ClockRatePipelining', 'off')
```

See Also

- “Clock-Rate Pipelining” on page 28-149
- “Increase Clock Frequency Using Clock-Rate Pipelining” on page 28-154

CodingStyle

When you use Multiport Switch blocks, use the `CodingStyle` parameter to specify whether you want to generate HDL code with if-else or case statements. By default, HDL Coder generates if-else statements. If you have several Multiport Switch blocks in your model, you can choose to specify a different `CodingStyle` for each block.

CodingStyle Setting	Description
'ifelse_stmt' (Default)	Generate if-else statements in the Verilog code or when-else statements in the VHDL code for a Multiport Switch block.
'case_stmt'	Generate case statements in the Verilog code or case-when statements in the VHDL code for a Multiport Switch block.

Set CodingStyle For Multiport Switch Block

To set `CodingStyle` for a Multiport Switch using the HDL Block Properties dialog box:

- 1 Right-click the Multiport Switch block.
- 2 Select **HDL Code > HDL Block Properties** .
- 3 For **CodingStyle**, select `ifelse_stmt` or `case_stmt`.

To see the `CodingStyle` specified for a subsystem from the command line, use `hdlget_param`. For example, to see the settings specified for a Multiport Switch block inside a subsystem, `my_dut`:

```
hdlget_param('my_dut/Multiport Switch', 'CodingStyle')
```

```
ans =
```

```
    'case_stmt'
```

See also `hdlset_param`.

ConstMultiplierOptimization

The `ConstMultiplierOptimization` implementation parameter lets you specify use of canonical signed digit (CSD) or factored CSD optimizations for processing coefficient multiplier operations in the generated code.

The following table shows the `ConstMultiplierOptimization` parameter values.

ConstMultiplierOptimization Setting	Description
'none' (Default)	By default, HDL Coder does not perform CSD or FCSD optimizations. Code generated for the Gain block retains multiplier operations.
'CSD'	When you specify this option, the generated code decreases the area used by the model while maintaining or increasing clock speed, using canonical signed digit (CSD) techniques. CSD replaces multiplier operations with add and subtract operations. CSD minimizes the number of addition operations required for constant multiplication by representing binary numbers with a minimum count of nonzero digits.
'FCSD'	This option uses factored CSD (FCSD) techniques, which replace multiplier operations with shift and add/subtract operations on certain factors of the operands. These factors are generally prime but can also be a number close to a power of 2, which favors area reduction. This option lets you achieve a greater area reduction than CSD, at the cost of decreasing clock speed.

ConstMultiplierOptimization Setting	Description
'auto'	When you specify this option, HDL Coder chooses between the CSD or FCSD optimizations. The coder chooses the optimization that yields the most area-efficient implementation, based on the number of adders required. When you specify 'auto', the coder does not use multipliers, unless conditions are such that CSD or FCSD optimizations are not possible (for example, if the design uses floating-point arithmetic).

The ConstMultiplierOptimization parameter is available for the following blocks:

- Gain
- Stateflow chart
- Truth Table
- MATLAB Function
- MATLAB System

ConstrainedOutputPipeline

Use the ConstrainedOutputPipeline parameter to specify a nonnegative number of registers to place at the block outputs.

HDL Coder moves existing delays within your design to try to meet your constraint. New registers are not added. If there are fewer registers than the coder needs to satisfy your constraint, the coder reports the difference between the number of desired and actual output registers. You can add delays to your design using input or output pipelining.

Distributed pipelining does not redistribute registers you specify with constrained output pipelining.

How to Specify Constrained Output Pipelining

To specify constrained output pipelining for a block using the GUI:

- 1 Right-click the block and select **HDL Code > HDL Block Properties**.
- 2 For **ConstrainedOutputPipeline**, enter the number of registers you want at the output ports.

To specify constrained output pipelining, at the command line, enter:

```
hdlset_param(path_to_block,
             'ConstrainedOutputPipeline', number_of_output_registers)
```

For example, to constrain 6 registers at the output ports of a subsystem, `subsys`, in your model, `mymodel`, enter:

```
hdlset_param('mymodel/subsys', 'ConstrainedOutputPipeline', 6)
```

See Also

- “Constrained Output Pipelining” on page 28-147

DistributedPipelining

The `DistributedPipelining` subsystem parameter enables pipeline register distribution, which is a speed optimization that increases your clock speed by reducing your critical path on a subsystem. This optimization moves the delays within a subsystem while preserving the hierarchy.

DistributedPipelining Setting	Description
'inherit' (default)	Use the distributed pipelining setting of the parent subsystem. If this subsystem is the highest-level subsystem, use the distributed pipelining setting for the model.
'off'	HDL Coder does not distribute the pipeline registers placed manually or by using the HDL block properties <code>InputPipeline</code> or <code>OutputPipeline</code> .
'on'	HDL Coder distributes registers inside the subsystem, MATLAB Function block, or Stateflow chart based on critical path analysis. This setting distributes the pipelines in the subsystem that are already placed manually or by using the HDL Block Properties <code>InputPipeline</code> or <code>OutputPipeline</code> .

Tip Output data might be in an invalid state initially if you insert pipeline registers. To avoid test bench errors resulting from initial invalid samples, disable output checking for those samples. For more information, see **Ignore output data checking (number of samples)**.

To enable distributed pipelining for a subsystem within a model, set `DistributedPipelining` to on for that subsystem.

To learn how to set model-level distributed pipelining, see “Distributed pipelining” on page 19-12.

Set Distributed Pipelining For a Subsystem

To set distributed pipelining for a subsystem using the HDL Block Properties dialog box:

- 1 Right-click the subsystem.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 Set **DistributedPipelining** to `inherit`, `on`, or `off`.

To set distributed pipelining for a subsystem from the command line, use the `hdlset_param` function. For example, enter:

```
hdlset_param('path/to/subsystem', 'DistributedPipelining', 'on')
```

- “Distributed Pipelining” on page 28-131
- “Distributed Pipelining: Speed Optimization” on page 28-140
- “Use Distributed Pipelining Optimization in Models with MATLAB Function Blocks” on page 34-32

DotProductStrategy

If you use the Product block for matrix multiplication in your design, use the DotProductStrategy to specify how you want to implement the matrix multiplication.

The DotProductStrategy options are listed in the following table.

DotProductStrategy Value	Description
'Fully Parallel' (default)	<p>Expands the matrix multiplication operation into multipliers and adders. For example, if you multiply two 2x2 matrices, the implementation uses four multipliers and two adders to compute the result.</p> <p>To share the multipliers to optimize area, use the HDL block property StreamingFactor.</p> <p>Note The DotProductStrategy must be set to 'Fully Parallel' when you use the Native Floating Point mode.</p>
'Fully Parallel Scalarized'	<p>Expands the matrix multiplication operation into multipliers and adders. For example, if you multiply two 2x2 matrices, the implementation uses eight multipliers and four adders to compute the result. Use this option for smaller sized matrices and when you want to enable sharing on both the multipliers and adders.</p> <p>To share the multipliers to optimize area, use the HDL block property SharingFactor.</p>
'Serial Multiply-Accumulate'	<p>Uses the Serial architecture of the Multiply-Accumulate block to implement the matrix multiplication.</p> <p>In this architecture, the clock rate must be faster than the clock rate that you specify with Parallel architecture. You can see the clock rate in the Clock Summary information of the Code Generation report.</p>
'Parallel Multiply-Accumulate'	<p>Uses the Parallel architecture of the Multiply-Accumulate block to implement the matrix multiplication.</p>

DSPStyle

DSPStyle enables you to generate code that includes synthesis attributes for multiplier mapping in your design. You can choose whether to map a particular block's multipliers to DSPs or logic in hardware.

For Xilinx targets, the generated code uses the use_dsp attribute. For Altera targets, the generated code uses the multstyle attribute.

The DSPStyle options are listed in the following table.

DSPStyle Value	Description
'none' (default)	Do not insert a DSP mapping synthesis attribute.
'on'	Insert synthesis attribute that directs the synthesis tool to map to DSPs in hardware.
'off'	Insert synthesis attribute that directs the synthesis tool to map to logic in hardware.

The DSPStyle parameter is available for the following blocks:

- Gain
- Product
- Product of Elements with Architecture set to Tree
- Subsystem
- Atomic Subsystem
- Variant Subsystem
- Enabled Subsystem
- Triggered Subsystem
- Model with Architecture set to ModelReference

Hierarchy Flattening Behavior

If you specify hierarchy flattening for a subsystem that also has a nondefault DSPStyle setting, HDL Coder propagates the DSPStyle setting to the parent subsystem.

If the flattened subsystem contains Gain, Product, or Product of Elements blocks, the coder keeps their nondefault DSPStyle settings, and replaces default DSPStyle settings with the flattened subsystem DSPStyle setting.

Synthesis Attributes in Generated Code

The generated code for synthesis attributes depends on:

- Target language
- DSPStyle value
- SynthesisTool value

The following table shows examples of synthesis attributes in generated code.

DSPStyle Value	TargetLanguage Value	SynthesisTool Value	
		'Altera Quartus II'	'Xilinx ISE' 'Xilinx Vivado'
'none'	'Verilog'	wire signed [32:0] m4_out1;	wire signed [32:0] m4_out1;
	'VHDL'	m4_out1 : signal;	m4_out1 : signal;

DSPStyle Value	TargetLanguage Value	SynthesisTool Value	
		'Altera Quartus II'	'Xilinx ISE' 'Xilinx Vivado'
'on'	'Verilog'	(* multstyle = "dsp" *) wire signed [32:0] m4_out1;	(* use_dsp = "yes" *) wire signed [32:0] m4_out1;
	'VHDL'	attribute multstyle : string ; attribute multstyle of m4_out1 : signal is "dsp" ;	attribute use_dsp : string ; attribute use_dsp of m4_out1 : signal is "yes" ;
'off'	'Verilog'	(* multstyle = "logic" *) wire signed [32:0] m4_out1;	(* use_dsp = "no" *) wire signed [32:0] m4_out1;
	'VHDL'	attribute multstyle : string ; attribute multstyle of m4_out1 : signal is "logic" ;	attribute use_dsp : string ; attribute use_dsp of m4_out1 : signal is "no" ;

Requirement For Synthesis Attribute Specification

You must specify a synthesis tool by using the SynthesisTool property.

How To Specify a Synthesis Attribute

To specify a synthesis attribute using the HDL Block Properties dialog box:

- 1 Right-click the block.
- 2 Select **HDL Code > HDL Block Properties** .
- 3 For **DSPStyle**, select **on**, **off**, or **none**.

To specify a synthesis attribute from the command line, use `hdlset_param`. For example, suppose you have a model, `my_model`, with a DUT subsystem, `my_dut`, that contains a . Gain block, `my_multiplier`. To insert a synthesis attribute to map `my_multiplier` to a DSP, enter:

```
hdlset_param('my_model/my_dut/my_multiplier', 'DSPStyle', 'on')
```

See also `hdlset_param`.

Limitations For Synthesis Attribute Specification

- When you specify a nondefault DSPStyle block property, the ConstMultiplierOptimization property must be set to 'none'.
- Inputs to multiplier components cannot use the double data type.
- Gain constant cannot be a power of 2.

FlattenHierarchy

FlattenHierarchy enables you to remove subsystem hierarchy from the HDL code generated from your design.

FlattenHierarchy Setting	Description
'inherit' (default)	Use the hierarchy flattening setting of the parent subsystem. If this subsystem is the highest-level subsystem, do not flatten.
'on'	Flatten this subsystem.
'off'	Do not flatten this subsystem, even if the parent subsystem is flattened.

To flatten hierarchy, you must also have the MaskParameterAsGeneric global property set to 'off'. For more information, see “Generate Parameterized HDL Code from Masked Subsystem” on page 21-61.

How To Flatten Hierarchy

To set hierarchy flattening using the HDL Block Properties dialog box:

- In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select the Subsystem and then click **HDL Block Properties**. For **FlattenHierarchy**, select **on**, **off**, or **inherit**.
- Right-click the Subsystem and select **HDL Code > HDL Block Properties**. For **FlattenHierarchy**, select **on**, **off**, or **inherit**.

To set hierarchy flattening from the command line, use `hdlset_param`. For example, to turn on hierarchy flattening for a subsystem, `my_dut`:

```
hdlset_param('my_dut', 'FlattenHierarchy', 'on')
```

See also `hdlset_param`.

Limitations For Hierarchy Flattening

A subsystem cannot be flattened if the subsystem is:

- A Synchronous Subsystem or uses the State Control block in Synchronous mode.
- A model reference implementation.
- A Triggered Subsystem when “Use trigger signal as clock” on page 21-41 is enabled.
- A masked subsystem that contains any of the following:
 - Bus.
 - Enumerated data type.
 - Lookup table blocks: 1-D Lookup Table, 2-D Lookup Table, Cosine HDL Optimized, Direct LookupTable (n-D), Prelookup, Sine HDL Optimized, n-D Lookup Table.
 - MATLAB System block.
 - Stateflow blocks: Chart, State Transition Table, Sequence Viewer.
 - Blocks with a pass-through or no-op implementation. See “Pass through, No HDL, and Cascade Implementations” on page 26-57.

Note This option removes subsystem boundaries before code generation. It does not necessarily generate HDL code with a completely flat hierarchy.

GuardIndexVariables

`GuardIndexVariables` enables you to specify whether to hoist array indices out of conditional statements or not. When you enable certain optimizations such as RAM Mapping, loop streaming, sharing, and so on, expressions are moved out of the array indices. A temporary variable is created for the expression that might result in an index out-of-bounds error during simulation. When you enable this option the generated code might be inefficient for your target hardware.

GuardIndexVariables Setting	Description
'off' (default)	Move the expression for array indices out of the conditional statement and create a temporary variable for the expression.
'on'	Do not move the expression for array indices out of the conditional statement and do not create a temporary variable for the expression.

This image shows the generated code with the option enabled and disabled. When the `GuardIndexVariable` option is `off`, the array index variable `i` is not decided by the conditional loop and might go out of bounds. When the `GuardIndexVariable` option is `on`, the array index variable `idx` is decided by the conditional loop preventing an array index out of bounds error during simulation.

If you get an index access violation error during simulation, use this option.

InputPipeline

`InputPipeline` lets you specify a implementation with input pipelining for selected blocks. The parameter value specifies the number of input pipeline stages (pipeline depth) in the generated code. Distributed pipelining can move input pipelines to optimize your design. To prevent distributed pipelining from moving input pipelines from a specified point in your design, use the `ConstrainedOutputPipeline` parameter.

The following code specifies an input pipeline depth of two stages for each Sum block in the model:

```

sblocks = find_system(gcb, 'BlockType', 'Sum');
for ii=1:length(sblocks),hdlset_param(sblocks{ii},'InputPipeline', 2), end;

```

Note The `InputPipeline` setting does not have any effect on blocks that do not have an input port.

When generating code for pipeline registers, HDL Coder appends a postfix string to names of input or output pipeline registers. The default postfix string is `_pipe`. To customize the postfix string, use the **Pipeline postfix** option in the **Global Settings / General** pane in the **HDL Code Generation** pane of the Configuration Parameters dialog box. Alternatively, you can pass the desired postfix as a character vector in the `makehdl` property `PipelinePostfix`. For an example, see “Pipeline postfix” on page 21-23.

InstantiateFunctions

For the MATLAB Function block, you can use the **InstantiateFunctions** parameter to generate a VHDL entity or Verilog module for each function. HDL Coder generates code for each entity or module in a separate file.

The **InstantiateFunctions** options for the MATLAB Function block are listed in the following table.

InstantiateFunctions Setting	Description
'off' (default)	Generate code for functions inline.
'on'	Generate a VHDL entity or Verilog module for each function, and save each module or entity in a separate file.

How To Generate Instantiable Code for Functions

To set the **InstantiateFunctions** parameter using the HDL Block Properties dialog box:

- 1 Right-click the MATLAB Function block.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 For **InstantiateFunctions**, select **on**.

To set the **InstantiateFunctions** parameter from the command line, use `hdlset_param`. For example, to generate instantiable code for functions in a MATLAB Function block, `myMatlabFcn`, in your DUT subsystem, `myDUT`, enter:

```
hdlset_param('my_DUT/my_MATLABFcnBlk', 'InstantiateFunctions', 'on')
```

Generate Code Inline for Specific Functions

If you want to generate instantiable code for some functions but not others, enable the option to generate instantiable code for functions, and use `coder.inline`. See `coder.inline` for details.

Limitations for Instantiable Code Generation for Functions

The software generates code inline when:

- Function calls are within conditional code or `for` loops.
- Any function is called with a nonconstant `struct` input.
- The function has state, such as a persistent variable, and is called multiple times.
- There is an enumeration anywhere in the design function.

InstantiateStages

For a Cascade architecture, you can use the **InstantiateStages** parameter to generate a VHDL entity or Verilog module for each computation stage. HDL Coder generates code for each entity or module in a separate file.

InstantiateStages Setting	Description
'off' (default)	Generate cascade stages in a single VHDL entity or Verilog module.
'on'	Generate a VHDL entity or Verilog module for each cascade stage, and save each module or entity in a separate file.

LoopOptimization

LoopOptimization enables you to stream or unroll loops in code generated from a MATLAB Function block. Loop streaming optimizes for area; loop unrolling optimizes for speed.

Note If you specify the MATLAB Datapath architecture of the MATLAB Function block, you can only unroll loops. To stream loops, you can use the streaming optimization by specifying a **StreamingFactor**. See “HDL Optimizations Across MATLAB Function Block Boundary Using MATLAB Datapath Architecture” on page 28-203.

LoopOptimization Setting	Description
'none' (default)	Do not optimize loops.
'Unrolling'	Unroll loops.
'Streaming'	Stream loops.

How to Optimize MATLAB Function Block For Loops

To select a loop optimization using the HDL Block Properties dialog box:

- 1 Right-click the MATLAB Function block.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 For **LoopOptimization**, select none, Unrolling, or Streaming.

To select a loop optimization from the command line, use `hdlset_param`. For example, to turn on loop streaming for a MATLAB Function block, `my_mlfm`:

```
hdlset_param('my_mlfm', 'LoopOptimization', 'Streaming')
```

See also `hdlset_param`.

Limitations for MATLAB Function Block Loop Optimization

HDL Coder cannot stream a loop if:

- The loop index counts down. The loop index must increase by 1 on each iteration.

- There are 2 or more nested loops at the same level of hierarchy within another loop.
- Any particular persistent variable is updated both inside and outside a loop.

HDL Coder can stream a loop when the persistent variable is:

- Updated inside the loop and read outside the loop.
- Read within the loop and updated outside the loop.

LUTRegisterResetType

Use the `LUTRegisterResetType` block parameter to control synthesis of a LUT into a ROM structure on an FPGA.

LUTRegisterResetType Value	Description
default	LUT output register has default reset logic. When you generate HDL, the LUT will be synthesized as registers.
none	LUT output register has no reset logic. When you generate HDL, the LUT will be synthesized as a ROM.

You can specify `LUTRegisterResetType` for the following blocks:

- Gamma Correction
- Lookup Table

MapPersistentVarsToRAM

With the `MapPersistentVarsToRAM` implementation parameter, you can use RAM-based mapping for persistent arrays of a MATLAB Function block instead of mapping to registers.

MapPersistentVarsToRAM Setting	Mapping Behavior
off	Persistent arrays map to registers in the generated HDL code.
on	Persistent array variables map to RAM. For restrictions, see “RAM Mapping Restrictions” on page 26-17.

RAM Mapping Restrictions

When you enable RAM mapping, a persistent array or user-defined System object private property maps to a block RAM when all of these conditions are true:

- Each read or write access is for a single element only. For example, submatrix access and array copies are not supported.
- Address computation logic is not read-dependent. For example, computation of a read or write address using the data read from the array is not supported.
- Persistent variables or user-defined System object private properties are initialized to 0 if they have a cyclic dependency. For example, if you have two persistent variables, A and B, you have a cyclic dependency if A depends on B, and B depends on A.

- If an access is within a conditional statement, the conditional statement uses only simple logic expressions (&&, ||, ~) or relational operators. For example, in this code, `r1` does not map to RAM:

```
if (mod(i,2) > 0)
    a = r1(u);
else
    r1(i) = u;
end
```

You can rewrite complex conditions, such as conditions that call functions, by assigning them to temporary variables, and using the temporary variables in the conditional statement. For example, to map `r1` to RAM, rewrite the previous code as:

```
temp = mod(i,2);
if (temp > 0)
    a = r1(u);
else
    r1(i) = u;
end
```

- The persistent array or user-defined System object private property value depends on external inputs.

For example, in the following code, `bigarray` does not map to RAM because it does not depend on `u`:

```
function z = foo(u)

persistent cnt bigarray
if isempty(cnt)
    cnt = fi(0,1,16,10,hdlfimath);
    bigarray = uint8(zeros(1024,1));
end
z = u + cnt;
idx = uint8(cnt);
temp = bigarray(idx+1);
cnt(:) = cnt + fi(1,1,16,0,hdlfimath) + temp;
bigarray(idx+1) = idx;
```

- The RAM size is greater than or equal to the `RAMMappingThreshold` value. The RAM size is the product of `Array Size * Word Length * Complexity`, where:
 - `Array Size` is the number of elements in the array.
 - `Word Length` is the number of bits that represent the data type of the array.
 - `Complexity` is 2 for a complex data type or 1 for a real datatype.
- Access to the persistent variable that you are mapping to RAM is not in a loop, such as a `for` loop, unless the loop is unrolled. For more information, see `coder.unroll`.
- Access to the persistent variable that you are mapping to RAM is not in a nested conditional statement, such as a nested `if` statement or nested `switch` statement.

If any of the above conditions is false, the persistent array or user-defined System object private property maps to a register in the HDL code.

RAMMappingThreshold

The default value of `RAMMappingThreshold` is 256. To change the threshold, use `hdlset_param`. For example, the following command changes the mapping threshold for the `sfir_fixed` model to 128 bits:

```
hdlset_param('sfir_fixed', 'RAMMappingThreshold', 128);
```

You can also change the RAM mapping threshold in the Configuration Parameters dialog box. For more information, see **RAM mapping threshold**.

Example

For an example that shows how to map persistent array variables to RAM in a MATLAB Function block, see “RAM Mapping With the MATLAB Function Block” on page 28-126.

MapToRAM

Use the `MapToRAM` property to map lookup tables (LUT) to RAM.

When **Simulate RAM Delay** is enabled, the `MapToRAM` property is disabled for the Sine HDL Optimized and Cosine HDL Optimized block.

MapToRAM Setting	Mapping Behavior
inherit (default)	The model setting Map lookup tables to RAM behavior is used.
off	The block lookup tables (LUTs) are mapped to logic slices on the FPGA.
on	The block lookup tables (LUTs) are mapped to RAM.

MapToRAM Considerations for Added Latency

When you enable either the block property `MapToRAM` or the global option `LUTMapToRAM` and the synthesis tool for the model is Xilinx or Altera, a unit delay without reset is added after the Lookup Table block. Because of the added unit delay, additional latency is inserted and delay balanced in the generated HDL Code and generated model. To avoid extra latency, you can add a Delay block with the HDL Block property **ResetType** set to **none** after the Lookup Table block in the original model.

OutputPipeline

`OutputPipeline` lets you specify a implementation with output pipelining for selected blocks. The parameter value specifies the number of output pipeline stages (pipeline depth) in the generated code. Distributed pipelining can move output pipelines to optimize your design. To prevent distributed pipelining from moving output pipelines from a specified point in your design, use the `ConstrainedOutputPipeline` parameter.

This code specifies an output pipeline depth of two stages for each Sum block in the model:

```
sblocks = find_system(gcb, 'BlockType', 'Sum');
for ii=1:length(sblocks),hdlset_param(sblocks{ii},'OutputPipeline', 2), end;
```

Note The `OutputPipeline` setting does not have any effect on blocks that do not have an output port.

When generating code for pipeline registers, HDL Coder appends a postfix string to names of input or output pipeline registers. The default postfix string is `_pipe`. To customize the postfix string, use the **Pipeline postfix** option in the Configuration Parameters dialog box, in the **HDL Code Generation > Global Settings > General** tab. Alternatively, you can use the `PipelinePostfix` property with `makehdl`. For an example, see “Pipeline postfix” on page 21-23.

See also “Use Distributed Pipelining Optimization in Models with MATLAB Function Blocks” on page 34-32.

PreserveUpstreamLogic

Control the removal of unconnected logic. Unconnected logic is logic that is connected upstream from a terminator block. This property is available for Terminator blocks only.

PreserveUpstreamLogic Options	PreserveUpstreamLogic Behavior
off (default)	Logic connected upstream from the Terminator block is not preserved in HDL code generation.
on	Logic connected upstream from the Terminator block is preserved in HDL code generation.

For an example, see the “Upstream Logic Preservation of Unused Port” section of “Optimize Unconnected Ports in HDL Code for Simulink Models” on page 28-246.

RAMDirective

Using `RAMDirective`, you can specify whether you want to map the Random Access Memory (RAM) blocks in your Simulink model to FPGA RAM memory blocks. You can map large memory blocks such as `ultra` from the Xilinx family and `M144k` from the Quartus family. Specify these `RAMDirective` values for the RAM blocks in your design based on the synthesis tool.

Synthesis Tool	RAM Style Attribute	RAMDirective Values
Quartus	<code>ramstyle</code>	<code>logic</code> <code>M9K</code> <code>M10K</code> <code>M20K</code> <code>M144K</code> <code>MLAB</code>
Xilinx	<code>ram_style</code>	<code>block</code> <code>distributed</code> <code>register</code> <code>ultra</code>
Microchip	<code>syn_ramstyle</code>	<code>block_ram</code> <code>registers</code> <code>lsram</code> <code>uram</code>

When you specify a value for this setting, HDL Coder generates a `ramstyle` attribute in the HDL code. This attribute specifies the type of RAM memory unit that you want the synthesis tool to use when inferring the RAM blocks in your design.

When you do not specify a value for this setting, HDL Coder does not generate the `ramstyle` attribute in the HDL code. The synthesis tool determines the type of inferred RAM for mapping the RAM blocks in your model.

Set RAMDirective for RAM Blocks

In the **HDL RAMs** library, except for the Dual Rate Dual Port RAM, you can specify the **RAMDirective** property for all other RAM blocks.

To set **RAMDirective** for a RAM block in the HDL Block Properties dialog box:

- 1 Right-click the RAM block.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 In **RAMDirective** property, specify the values as listed in the table.

You can also set the **RAMDirective** by using `hdlset_param` function.

```
hdlset_param(<ram_block_name>, 'RAMDirective', <attribute_value>);
```

To specify these attributes in the MATLAB HDL workflow, use the **RAMDirective** parameter value pair for `hdl.RAM` instantiation. Set this property by using this command:

```
hRam = hdl.RAM('RAMType', 'Single Port RAM', 'RAMDirective', 'ultra');
```

For example, generate an HDL attribute for mapping the RAM blocks in your model to `block RAM`. A `block RAM` is a dedicated memory unit on the FPGA. Sizes of `block RAMs` can be 4kb, 8kb, 16kb, and 32kb.

To map your RAM blocks to `block RAM`:

- Specify the synthesis tool. You must target a Xilinx device that contains `block RAM` resources. If the target device does not contain `block RAMs`, the synthesis tool ignores this attribute and might infer the RAM as distributed RAMs or Lookup Table (LUT) slices.
- Enter the **RAMDirective** value as `block` for your Simulink RAM blocks in HDL Block Properties.
- Generate the HDL code for your model.

This generated VHDL code shows the `ram_style` attribute is set to `block`:

```
attribute ram_style: string;
attribute ram_style of ram : signal is "block";
```

This generated Verilog code shows the `ram_style` attribute is set to `block`:

```
(* ram_style = "block" *)
```

Dependency

When using **RAMDirective** property, make sure to select the synthesis tool for your design.

ResetType

Use the **ResetType** block parameter to suppress reset logic generation.

ResetType Value	Description
default	Generate reset logic.

ResetType Value	Description
none	<p>Do not generate reset logic.</p> <p>Reset is not applied to generated registers. Therefore, mismatches between Simulink and the generated code occur for some number of samples during the initial phase, when registers are not fully loaded.</p> <p>To avoid test bench errors during the initial phase, determine the number of samples required to fully load the registers. Then, set the Ignore output data checking (number of samples) option accordingly. See also Ignore output data checking (number of samples) in “Test Bench Stimulus and Output Parameters” on page 23-20.</p>

You can specify **ResetType** for the following blocks:

- Chart
- Convolutional Deinterleaver
- Convolutional Interleaver
- Delay
- Delay (DSP System Toolbox)
- General Multiplexed Deinterleaver
- General Multiplexed Interleaver
- MATLAB Function
- MATLAB System
- Memory
- Tapped Delay
- Truth Table
- Unit Delay Enabled
- Unit Delay

Reset Logic for Optimizations in the MATLAB Function Block

When you set **ResetType** to none for a MATLAB Function block, HDL Coder does not generate reset logic for persistent variables in the MATLAB code.

However, if you specify other optimizations for the block, the coder may insert registers that use reset logic. The coder does not suppress reset logic generation for these registers. Therefore, if you set **ResetType** to none along with other block optimizations, your generated code may have a reset port at the top level.

How to Suppress Reset Logic Generation

To suppress reset logic generation for a block using the UI:

- 1 Right-click the block and select **HDL Code > HDL Block Properties**.

2 For **ResetType**, select none.

To suppress reset logic generation, on the command line, enter:

```
hdlset_param(path_to_block, 'ResetType', 'none')
```

For example, to suppress reset logic generation for a Unit Delay block, `UnitDelay1`, within a subsystem, `mySubsys`, on the command line, enter:

```
hdlset_param('mySubsys/UnitDelay1', 'ResetType', 'none');
```

Specify Synchronous or Asynchronous Reset

To specify a synchronous or asynchronous reset, use the `ResetType` model-level parameter. For details, see **Reset type** in “Reset Settings and Parameters” on page 21-8.

SerialPartition

Use this parameter on Min/Max blocks to specify partitions for a serial cascade architecture. The default setting uses the minimum number of partitions.

To Generate This Architecture...	Set SerialPartition to...
Cascade-serial with explicitly specified partitioning	[p1 p2 p3 . . . pN]: a vector of N integers, where N is the number of serial partitions. Each element of the vector specifies the length of the corresponding partition. The sum of the vector elements must be equal to the length of the input data vector. The values of the vector elements must be in descending order, except the last two elements can be equal. For example, for an input of 8 elements, partitions [5 3] or [4 2 2] are legal, but the partitions [2 2 2 2] or [3 2 3] raise an error at code generation time.
Cascade-serial with automatically optimized partitioning	0

This property is also used for serial filter architectures. For how to configure filter blocks, see “SerialPartition” on page 26-44.

SharingFactor

Use `SharingFactor` to specify the number of functionally equivalent resources to map to a single shared resource. The default is 0. See “Resource Sharing” on page 28-45.

SoftReset

Use the `SoftReset` block parameter to specify whether to generate hardware-friendly synchronous reset logic, or local reset logic that matches the Simulink simulation behavior. This property is available for the Unit Delay Resettable block or Unit Delay Enabled Resettable block.

SoftReset Value	Description
off (default)	Generate local reset logic that matches the Simulink simulation behavior.
on	Generate synchronous reset logic for the block. This option generates code that is more efficient for synthesis, but does not match the Simulink simulation behavior.

When SoftReset set to 'off', the following code is generated for a Unit Delay Resettable block :

```

always @(posedge clk or posedge reset)
  begin : Unit_Delay_Resettable_process
    if (reset == 1'b1) begin
      Unit_Delay_Resettable_zero_delay <= 1'b1;
      Unit_Delay_Resettable_switch_delay <= 2'b00;
    end
    else begin
      if (enb) begin
        Unit_Delay_Resettable_zero_delay <= 1'b0;
        if (UDR_reset == 1'b1) begin
          Unit_Delay_Resettable_switch_delay <= 2'b00;
        end
        else begin
          Unit_Delay_Resettable_switch_delay <= In1;
        end
      end
    end
  end
end

assign Unit_Delay_Resettable_1 =
  (UDR_reset ||
   Unit_Delay_Resettable_zero_delay ? 1'b1 : 1'b0);
assign out0 = (Unit_Delay_Resettable_1 == 1'b1 ? 2'b00 :
  Unit_Delay_Resettable_switch_delay);

```

When SoftReset set to 'on', the following code is generated for a Unit Delay Resettable block :

```

always @(posedge clk or posedge reset)
  begin : Unit_Delay_Resettable_process
    if (reset == 1'b1) begin
      Unit_Delay_Resettable_reg <= 2'b00;
    end
    else begin
      if (enb) begin
        if (UDR_reset != 1'b0) begin
          Unit_Delay_Resettable_reg <= 2'b00;
        end
        else begin
          Unit_Delay_Resettable_reg <= In1;
        end
      end
    end
  end
end

assign out0 = Unit_Delay_Resettable_reg;

```

StreamingFactor

Number of parallel data paths, or vectors, to transform into serial, scalar data paths by time-multiplexing serial data paths and sharing hardware resources. The default is 0, which implements fully parallel data paths. See also “Streaming” on page 28-42.

UsePipelines

You can use this mode with Product blocks in Divide and Reciprocal modes. This property becomes available when you set the HDL architecture for the blocks to `ShiftAdd`. This architecture uses a non-restoring division algorithm that performs multiple shift and add operations to compute the quotient. The `ShiftAdd` architecture provides improved accuracy compared to the Newton-Raphson approximation method.

When you use the `ShiftAdd` architecture, you can use the `UsePipelines` implementation parameter to specify whether to use a pipelined or non-pipelined implementation of the non-restoring division.

UsePipelines Setting	Mapping Behavior
on (default)	Use a pipelined implementation of the non-restoring shift and add operation for Divide and Reciprocal blocks. This setting adds more delays to your design but achieves a higher maximum clock frequency on the target FPGA device. The number of pipelines inserted matches the number of iterations that the algorithm requires to compute the quotient or reciprocal.
off	Use a non-pipelined implementation of the non-restoring shift and add operation for Divide and Reciprocal blocks. This setting does not add delays to your design. As division and reciprocal are resource-intensive operations, to achieve higher clock frequencies on the target FPGA, set UsePipelines to on.

Set UsePipelines for Divide and Reciprocal Blocks

To set `UsePipelines` for a subsystem from the HDL Block Properties dialog box:

- 1 Right-click the subsystem.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 For **UsePipelines**, select **on** or **off**.

To set `UsePipelines` for a block from the command line, use `hdlset_param`. For example, to turn off `UsePipelines` for a Divide block inside a subsystem, `my_dut`:

```
hdlset_param('my_dut/divide', 'UsePipelines', 'off');
```

See also `hdlset_param`.

UseRAM

The `UseRAM` implementation parameter enables using RAM-based mapping for a Delay block instead of mapping to a shift register.

UseRAM Setting	Mapping Behavior
off	The delay maps to a shift register in the generated HDL code, except in one case. For details, see “Effects of Streaming and Distributed Pipelining” on page 26-28.
on	<p>The delay maps to a dual-port RAM block when the following conditions are true:</p> <ul style="list-style-type: none"> • Initial value of the delay is zero. • The Delay block does not have an external reset or enable port. • Delay length greater than or equal to 4. • Delay has one of the following set of numeric and data type attributes: <ul style="list-style-type: none"> • (a) Real scalar with a non-floating-point data type (such as signed integer, unsigned integer, fixed point, or Boolean) • (b) Complex scalar with real and imaginary parts that use non-floating-point data type • (c) Vector where each element is either (a) or (b) • RAMSize is greater than or equal to the RAMMappingThreshold value. RAMSize is the product of DelayLength * WordLength * VectorLength * Complexity. <ul style="list-style-type: none"> • DelayLength is the number of delays that the Delay block specifies. • WordLength is the number of bits that represent the data type of the delay. • VectorLength is the vector length of the input to the Delay block. • Complexity is 2 for a complex data type or 1 for a real datatype. <p>For more information, see RAM mapping threshold.</p> <p>If any condition is false, the delay maps to a shift register in the HDL code unless it merges with other delays to map to a single RAM. For more information, see “Mapping Multiple Delays to RAM” on page 26-26.</p>

This implementation parameter is available for the Delay block in the Simulink Discrete library and the Delay block in the DSP System Toolbox Signal Operations library.

Mapping Multiple Delays to RAM

HDL Coder can also merge several delays of equal length into one delay and then map the merged delay to a single RAM. This optimization provides the following benefits:

- Increased occupancy on a single RAM
- Sharing of address generation logic, which minimizes duplication of identical HDL code
- Mapping of delays to a RAM when the *individual* delays do not satisfy the threshold

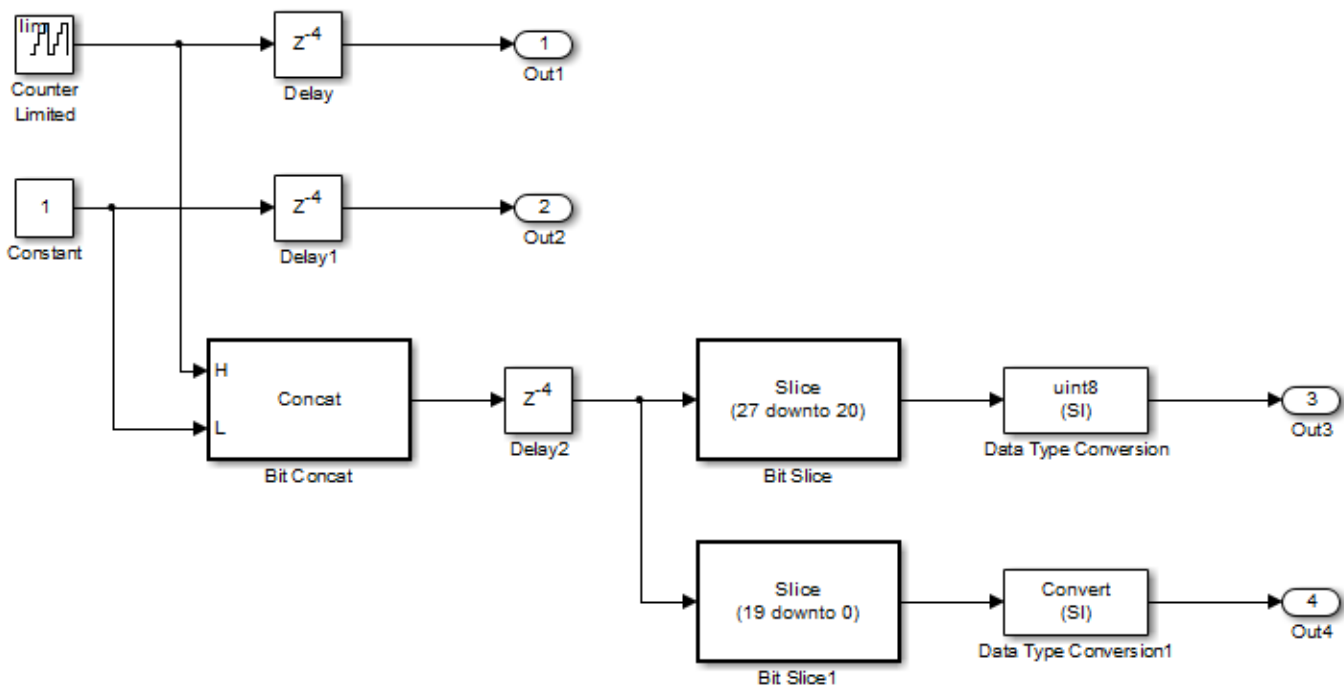

The following rules control whether or not multiple delays can merge into one delay:

- The delays must:

- Be at the same level of the subsystem hierarchy.
- Use the same compiled sample time.
- Have **UseRAM** set to on, or be generated by streaming or resource sharing.
- Have the same **ResetType** setting, which cannot be none.
- The total word length of the merged delay cannot exceed 128 bits.
- The **RAMSize** of the merged delay is greater than or equal to the **RAMMappingThreshold** value. **RAMSize** is the product of **DelayLength** * **WordLength** * **VectorLength** * **Complexity**.

Example of Multiple Delays Mapping to a Block RAM

RAMMappingThreshold for this model is 100 bits.

The Delay and Delay1 blocks merge and map to a dual-port RAM in the generated HDL code by satisfying the following conditions:

- Both delay blocks:
 - Are at the same level of the hierarchy.
 - Use the same compiled sample time.
 - Have **UseRAM** set to on in the HDL block properties dialog box.
 - Have the same **ResetType** setting of default.
- The total word length of the merged delay is 28 bits, which is below the 128-bit limit.
- The **RAMSize** of the merged delay is 112 bits (4 delays * 28-bit word length), which is greater than the mapping threshold of 100 bits.

When you generate HDL code for this model, HDL Coder generates additional files to specify RAM mapping. HDL Coder stores these files in the same source location as other generated HDL files, for example, the `hdlsrc` folder.

Effects of Streaming and Distributed Pipelining

When UseRAM is off for a Delay block, HDL Coder maps the delay to a shift register by default. However, the coder changes the UseRAM setting to on and tries to map the delay to a RAM under the following conditions:

- Streaming is *enabled* for the subsystem with the Delay block.
- Distributed pipelining is *disabled* for the subsystem with the Delay block.

Suppose that distributed pipelining is *enabled* for the subsystem with the Delay block.

- When UseRAM is off, the Delay block participates in retiming.
- When UseRAM is on, the Delay block does not participate in retiming. HDL Coder does not break up a delay marked for RAM mapping.

Consider a subsystem with two Delay blocks, three Constant blocks, and three Product blocks:

When UseRAM is on for the Delay block on the right, that delay does not participate in retiming.

The following summary describes whether or not HDL Coder tries to map a delay to a RAM instead of a shift register.

UseRAM Setting for the Delay Block	Optimizations Enabled for Subsystem with Delay Block		
	Distributed Pipelining Only	Streaming Only	Both Distributed Pipelining and Streaming
On	Yes	Yes	Yes
Off	No	Yes, because mapping to a RAM instead of a shift register can provide an area-efficient design.	No

VariablesToPipeline

Warning `VariablesToPipeline` is not recommended. Use `coder.hdl.pipeline` instead.

The `VariablesToPipeline` parameter enables you to insert a pipeline register at the output of one or more MATLAB variables. Specify a list of variables as a character vector, with spaces separating the variables.

See also “Pipeline MATLAB Expressions” on page 8-12.

HDL Block Properties: Native Floating Point

Overview

Block implementation parameters enable you to control details of the code generated for specific block implementations. See "Set and View HDL Model and Block Parameters" on page 26-53 to learn how to select block implementations and parameters in the GUI or the command line.

Property names are specified as character vectors. The data type of a property value is specific to the property. This section describes the syntax of each block implementation parameter that you can specify in the **Native Floating Point** tab of the HDL Block Properties. You can see how specifying the parameter affects the generated code.

HDL Block Properties of Library Blocks

HDL block properties of library blocks are treated similar to mask parameters. When you instantiate library blocks in your model, the current HDL block properties of that library block are copied to instances of that block in your model. The HDL block properties of these instances are not synchronized with the HDL block properties of the library block. That is, if you change the HDL block property of the library block, the change does not get propagated to instances of the library block that you already added to your Simulink model. If you want the HDL block properties of a library block to be synchronized with its instances in the model, create a Subsystem and then place this block inside that Subsystem. The HDL block properties of blocks that reside inside the library block are synchronized with the corresponding instances in your model.

Suppose a library contains a Subsystem block with HDL architecture set to `Module`. When you instantiate this block in your model, the block instance uses `Module` as the HDL architecture. If you change the HDL architecture of the Subsystem block in the library to `BlackBox`, existing instances of that Subsystem block in your model still use `Module` as the HDL architecture. If you now add instances of the Subsystem block from the library in your model, the new block instances get a copy of the current HDL block properties, and therefore use `BlackBox` as the HDL architecture. If you want the HDL architecture of the Subsystem block in the library to be synchronized with its instances in the model, create a wrapper subsystem with the HDL architecture that you want inside this Subsystem.

CheckResetToZero

You can use the **CheckResetToZero** property for the mod and rem functions of the Math Function block in native floating-point mode. If you have numbers a and b such that the quotient a/b is close to an integer, this setting treats a as an integral multiple of b , and $\text{rem}(a,b)=0$. This result is numerically accurate and matches the Simulink simulation result. However, computing this result uses additional resources and increases the area footprint on the target FPGA device.

For example, for these sets of numbers, you get different simulation results when you enable and disable the **CheckResetToZero** setting.

CheckResetToZero Setting	Description
'on' (default)	When you compute mod or rem of two numbers whose quotient is closer to an integer, and has a precision greater than that of the floating point data type you use, HDL Coder adds the required logic to output the result of mod or rem as zero when the quotient of the numbers is close to an integer.
'off'	HDL Coder does not insert the additional logic to calculate the quotient, which saves area on the target FPGA device.

Set CheckResetToZero For the Math Function Block

To set **CheckResetToZero** for a block from the HDL Block Properties dialog box:

- 1 Right-click the block.
- 2 Select **HDL Code HDL Block Properties**.
- 3 For **CheckResetToZero**, select **on** or **off**.

To set **CheckResetToZero** for the Math Function block inside a subsystem, `my_dut` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/Math', 'CheckResetToZero', 'on')
```

See also `hdlset_param`.

DivisionAlgorithm

You can use the **DivisionAlgorithm** property when you enable Native Floating Point mode for the Divide block and the Math Function block in Reciprocal mode.

DivisionAlgorithm Setting	Description
Radix-2 (default)	<p>The default Radix-2 mode performs repeated subtractions by computing one bit of the quotient in each iteration.</p> <p>To design for lower area usage while trading off for latency, use the Radix-2 mode.</p>

DivisionAlgorithm Setting	Description
Radix-4	The Radix-4 mode performs repeated subtractions by computing two bits of the quotient in each iteration. To compute the result, the Radix-4 mode uses half the number of iterations that is required by the Radix-2 mode. To design for lower latency while trading off for area, use the Radix-4 mode.

Single-Precision Division Resource Utilization and Maximum Clock Frequency on Xilinx Virtex-7

DivisionAlgorithm Mode	LatencyStrategy	Latency	Fmax	LUTs	Registers
Radix-2	MIN	17	334.4MHz	1248	1011
	MAX	32	454.5MHz	1294	1797
Radix-4	MIN	11	245.5MHz	1956	865
	MAX	20	453.1MHz	1854	1522

Specify DivisionAlgorithm For the Math Function or Division Block

To specify **DivisionAlgorithm** for a block from the HDL Block Properties dialog box:

- 1 Right-click the block.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 In the **Native Floating Point** tab, specify the **DivisionAlgorithm**.

To specify **DivisionAlgorithm** for the block at the command line, use `hdlset_param`. For example, this command specifies Radix-4 mode for a Divide block inside a subsystem, `my_dut` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/Divide', 'DivisionAlgorithm', 'Radix-4')
```

HandleDenormals

You can use the `HandleDenormals` property for certain blocks that support HDL code generation in **Native Floating Point** mode. Denormal numbers are numbers that have magnitudes less than the smallest floating-point number that can be represented without leading zeros in the mantissa. With this setting, you can specify whether you want HDL Coder to insert additional logic to handle the denormal numbers in your design. For more information, see “Denormal Numbers” on page 14-96.

HandleDenormals Setting	Description
'inherit' (default)	Use the handle denormals setting of the parent subsystem. If this subsystem is the highest-level subsystem, use the handle denormals setting for the model.

HandleDenormals Setting	Description
'on'	If you have denormal numbers at these block inputs, HDL Coder adds the logic to normalize the denormal numbers.
'off'	HDL Coder does not insert additional logic to handle denormal numbers in your design. The code generator treats the denormal value as zero before performing any computation.

To enable `HandleDenormals` for a block within a model, set the parameter, `HandleDenormals`, to 'on' for that block.

Set Handle Denormals For a Block

To set handle denormals for a block from the HDL Block Properties dialog box:

- 1 Right-click the block.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 For **HandleDenormals**, select **inherit**, **on**, or **off**.

To set handle denormals for a block from the command line, use `hdlset_param`. For example, to enable handle denormals for a Product block inside a subsystem, `my_dut` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/Product', 'HandleDenormals', 'on')
```

See also “Handle Denormals” on page 20-7.

InputRangeReduction

You can use the **InputRangeReduction** property for the `sin`, `cos`, `tan`, `sincos`, and `cos+jsin` functions of the Trigonometric Function block in **Native Floating Point** mode. By default, this setting is enabled for the block, and it assumes that your input range is unbounded. If your input to the block is bounded in the range $[-\pi, \pi]$, your design does not require the logic to reduce the input range. In that case, you can disable this setting, and the block implementation incurs a lower latency and uses fewer resources on the target hardware. When you disable the setting, the generated model contains a block that verifies whether the inputs are bounded in the range $[-\pi, \pi]$. If you have unbounded inputs, the generated model triggers an assertion during simulation.

InputRangeReduction Setting	Description
'on' (default)	Assumes that the input range is unbounded and inserts additional logic to reduce the input argument range to $[-\pi, \pi]$ before computing the algorithm.
'off'	Assumes that the input argument is bounded in the range $[-\pi, \pi]$ and does not insert the additional logic to reduce the input argument range. This implementation reduces the latency and saves area on the target platform.

Set InputRangeReduction For the Trigonometric Function Block

To set **InputRangeReduction** for a block from the HDL Block Properties dialog box:

- 1 Right-click the block.
- 2 Select **HDL Code HDL Block Properties**.
- 3 In the **Native Floating Point** tab, for **InputRangeReduction**, select **on** or **off**.

To disable **InputRangeReduction** for the Trigonometric Function block inside a subsystem, `my_trigonometric` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/my_trigonometric', ...
            'InputRangeReduction', 'off')
```

See also `hdlset_param`.

LatencyStrategy

You can use the `LatencyStrategy` property for certain blocks that support HDL code generation for fixed-point and floating-point types. When you use floating-point types, select the model configuration parameter **Use Floating Point**. For fixed-point types, the property specifies zero, maximum, or custom latency. For floating-point types, the property specifies whether the blocks map to minimum, maximum, or a custom latency for the operator.

LatencyStrategy Setting	Description
'inherit' (default)	Use the latency strategy setting of the parent subsystem. If this subsystem is the highest-level subsystem, use the latency strategy setting for the model.
'Max'	During code generation, HDL Coder uses the maximum latency value for the native floating point operator.
'Min'	During code generation, HDL Coder uses the minimum latency value for the native floating point operator.
'Zero'	During code generation, HDL Coder does not add any latency for the native floating point operator.
'Custom'	During code generation, HDL Coder adds latency equal to the value that you specify for CustomLatency or NFPCustomLatency settings of the native floating point operator. You can use this setting for certain blocks in the native floating-point mode. To see the blocks for which you can specify the setting, see “NFPCustomLatency” on page 26-36.

To specify the minimum latency option for a block within a model, set the parameter, `LatencyStrategy`, to 'MIN' for that block.

To learn how to set model-level latency strategy setting, see “Latency Considerations with Native Floating Point” on page 14-109.

Set Latency Strategy for Fixed-Point Blocks

When you use fixed-point types, you can specify the **LatencyStrategy** for these blocks.

- Divide and Reciprocal blocks that have `ShiftAdd` as the HDL architecture.
- Sqrt block that has `SqrtFunction` as the HDL architecture.
- Trigonometric Function block that has **Function** set to `sin`, `cos`, `sincos`, `cos+jsin`, or `atan2` and **Approximation method** as `CORDIC`.

To set latency strategy for a subsystem from the HDL Block Properties dialog box:

- 1 In the Simulink toolstrip, on the **Apps** tab, select **HDL Coder**.
- 2 Select the block, and on the **HDL Code** tab, click the **HDL Block Properties** button.
- 3 In the **General** tab, specify the **LatencyStrategy**. If you set **LatencyStrategy** to **Custom**, you must specify a value for the **CustomLatency**.

To specify the latency strategy for a block from the command line, use `hdlset_param`. For example, to specify the minimum latency for a Product block inside a subsystem `my_dut` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/Product', 'LatencyStrategy', 'MAX')
```

See also `hdlset_param`.

Set Latency Strategy for Floating-Point Block

To set latency strategy for a subsystem from the HDL Block Properties dialog box:

- 1 In the Simulink toolstrip, on the **Apps** tab, select **HDL Coder**.
- 2 Select the block, and on the **HDL Code** tab, click the **HDL Block Properties** button.
- 3 In the **Native Floating Point** tab, specify the **LatencyStrategy**. If you set **LatencyStrategy** to **Custom**, you must specify a value for the **NFPCustomLatency**.

For details, see the "HDL Code Generation" section of each block page. To learn about blocks for which you can specify a custom latency, see "NFPCustomLatency" on page 26-36.

To specify the latency strategy for a block from the command line, use `hdlset_param`. For example, to specify the minimum latency for a Product block inside a subsystem `my_dut` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/Product', 'LatencyStrategy', 'MIN')
```

See also `hdlset_param`.

CustomLatency

You can specify a custom latency for certain blocks for fixed-point types. By using the custom latency strategy, you can trade-off between clock frequency and power consumption. To specify a custom latency strategy, set **LatencyStrategy** to `CUSTOM` and specify a value for **CustomLatency**. For details, see the "HDL Code Generation" section of each block page.

You can specify the **CustomLatency** setting for these blocks with fixed-point types.

- Divide and Reciprocal blocks that have `ShiftAdd` as the HDL architecture.
- Sqrt block that has `SqrtFunction` as the HDL architecture.
- Trigonometric Function block that has **Function** set to `sin`, `cos`, `sincos`, `cos+jsin`, or `atan2` and **Approximation method** as `CORDIC`.

Set Custom Latency Value For a Block

To set custom latency value for a subsystem from the HDL Block Properties dialog box:

- 1 In the Simulink toolstrip, on the **Apps** tab, select **HDL Coder**.
- 2 Select the block, and on the **HDL Code** tab, click the **HDL Block Properties** button.
- 3 In the **General** tab, set **LatencyStrategy** to **Custom** and specify a value for **CustomLatency**.

To specify the latency strategy for a block from the command line, use `hdlset_param`. For example, to specify a custom latency of four for a Product block inside a subsystem `my_dut` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/Product', 'LatencyStrategy', 'Custom')
hdlset_param('my_design/my_dut/Product', 'CustomLatency', 4)
```

See also `hdlset_param`.

NFPCustomLatency

You can specify a custom latency for certain blocks in the native floating-point mode. By using the custom latency strategy, you can trade-off between clock frequency and power consumption. To specify a custom latency strategy, set **LatencyStrategy** to **Custom** and specify a value for **NFPCustomLatency**. You can specify the custom latency value from 1 to **Max** latency of the block. For more information on latency values of floating-point operators, see “Latency Values of Floating-Point Operators” on page 14-103.

You can specify the **NFPCustomLatency** setting for these blocks with both `single` and `double` data types.

- Add
- Subtract
- Product
- Math Function in Reciprocal mode
- Gain
- Divide
- Relational Operator
- Data Type Conversion
- Rounding Function

You can also specify a **NFPCustomLatency** setting for these blocks with `single` data types.

- Sqrt
- Reciprocal Sqrt
- Sum of Elements

- Product of Elements

Set Custom Latency Value For a Block

To set custom latency value for a subsystem from the HDL Block Properties dialog box:

- 1 Right-click the block.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 In the **Native Floating Point** tab, for **LatencyStrategy**, select **Custom**.
- 4 Specify a value for the **NFPCustomLatency**.

To specify the latency strategy for a block from the command line, use `hdlset_param`. For example, to specify a custom latency of four for a Product block inside a subsystem `my_dut` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/Product', 'LatencyStrategy', 'Custom')
hdlset_param('my_design/my_dut/Product', 'NFPCustomLatency', 4)
```

See also `hdlset_param`.

MantissaMultiplyStrategy

You can use the `MantissaMultiplyStrategy` property for multipliers that support HDL code generation in native floating-point mode. Blocks that have this setting include Product, Divide, Math Function (in Reciprocal mode), and so on. By using this setting, you can specify how you want HDL Coder to implement the mantissa multiplication operation for the blocks.

MantissaMultiplyStrategy Setting	Description
'inherit' (default)	Use the mantissa multiply strategy setting of the parent subsystem. If this subsystem is the highest-level subsystem, use the mantissa multiply strategy setting for the model.
'FullMultiplier'	HDL Coder uses multipliers to perform the mantissa multiplication operation for the native floating point operator. The multipliers can utilize DSP units on the target device.
'PartMultiplierPartAddShift'	HDL Coder splits the implementation into two parts. One part is implemented with multipliers. The other part is implemented with a combination of adders and shifters. The multipliers can utilize the DSP units on the target device. The combination of adders and shifters does not utilize the DSP.
'NoMultiplierFullAddShift'	HDL Coder uses adders and shifters to implement the mantissa multiplication. This option does not utilize DSP units on the target device. You can also use this option if your target device does not contain DSP units.

To implement the mantissa multiplication with adders and shifters, set `MantissaMultiplyStrategy`, to `'NoMultiplierFullAddShift'` for that block.

Set Mantissa Multiply Strategy For a Block

To set adaptive pipelining for a subsystem from the HDL Block Properties dialog box:

- 1 Right-click the block.
- 2 Select **HDL Code > HDL Block Properties**.
- 3 In the **Native Floating Point** tab, for **MantissaMultiplyStrategy**, select **inherit**, **FullMultiplier**, **PartMultiplierPartAddShift**, or **NoMultiplierFullAddShift**.

To specify the mantissa multiply strategy for a block from the command line, use `hdlset_param`. For example, to implement the mantissa multiplication using adders and shifters for a Product block inside a subsystem `my_dut` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/Product', ...
             'MantissaMultiplyStrategy', 'PartMultiplierPartAddShift')
```

See also `hdlset_param`.

MaxIterations

You can use the `MaxIterations` property for the `mod` and `rem` functions of the Math Function block in **Native Floating Point** mode. If you have numbers `a` and `b` that are significantly large integers, you can increase the **MaxIterations** setting to match the Simulink simulation result. However, computing this result uses additional resources and increases the area footprint on the target FPGA device.

MaxIterations Setting	Description
32 (default)	The default number of iterations to compute the result of <code>mod</code> and <code>rem</code> functions in Native Floating Point mode. This implementation can potentially result in a numerical mismatch with the Simulink simulation results for large integers.
64	Specify 64 as the number of iterations to compute the result of <code>mod</code> and <code>rem</code> functions in Native Floating Point mode. In this mode, the implementation has higher probability of matching the Simulink simulation result for significantly large integers but can use more hardware resources.
128	Specify 128 as the number of iterations to compute the result of <code>mod</code> and <code>rem</code> functions in Native Floating Point mode. In this mode, the implementation matches the Simulink simulation result for large integers but uses more hardware resources.

Set MaxIterations For the Math Function Block

To set **MaxIterations** for a block from the HDL Block Properties dialog box:

- 1 Right-click the block.
- 2 Select **HDL Code > HDL Block Properties** .
- 3 In the **Native Floating Point** tab, for **MaxIterations**, select **32**, **64**, or **128**.

To set handle denormals for a block from the command line, use `hdlset_param`. For example, to enable adaptive pipelining for a Product block inside a subsystem, `my_dut` in your Simulink model `my_design`:

```
hdlset_param('my_design/my_dut/Product', 'HandleDenormals', 'on')
```

See also `hdlset_param`.

AdderTreePipeline

This property applies to frame-based filters. It specifies how many pipeline registers the architecture includes between levels of the adder tree. These pipeline stages increase filter throughput while adding latency. The default value is 0. To improve the speed of this architecture, the recommended setting is 2.

Pipeline stages introduce delays along the path in the model that contains the affected filter. When you enable this pipeline option, the coder automatically adds balancing delays on parallel data paths.

For more information on the frame-based filter architecture, see “Frame-Based Architecture” on page 26-48.

AddPipelineRegisters

This property applies to scalar input filters. When you enable this property, the default linear adder of the filter is implemented as a pipelined tree adder instead. This architecture increases filter throughput while adding latency. The default value is off.

The following limitations apply to AddPipelineRegisters:

- If you use AddPipelineRegisters, the code generator forces full precision in the HDL and the generated filter model. This option implements a pipelined adder tree structure in the HDL code for which only full precision is supported. If you generate a validation model, you must use full precision in the original model to avoid validation mismatches.
- Pipeline stages introduce delays along the path in the model that contains the affected filter. When you enable this pipeline option, the coder automatically adds balancing delays on parallel data paths.

Note When you use this property with the CIC Interpolation block, delays in parallel paths are not automatically balanced. Manually add delays where required by your design.

For filter architecture diagrams that indicate where the pipeline stages are added, see “HDL Filter Architectures” on page 26-46.

ChannelSharing

You can use the `ChannelSharing` implementation parameter with a multichannel filter to enable sharing a single filter implementation among channels for a more area-efficient design. This parameter is either 'on' or 'off'. The default is 'off', and a separate filter will be implemented for each channel.

See “Multichannel FIR Filter for FPGA” (DSP System Toolbox).

CoeffMultipliers

The `CoeffMultipliers` implementation parameter lets you specify use of canonical signed digit (CSD) or factored CSD optimizations for processing coefficient multiplier operations in code generated for certain filter blocks. Specify the `CoeffMultipliers` parameter using one of the following options:

- 'csd': Use CSD techniques to replace multiplier operations with shift-and-add operations. CSD techniques minimize the number of addition operations required for constant multiplication by representing binary numbers with a minimum count of nonzero digits. This representation decreases the area used by the filter while maintaining or increasing clock speed.
- 'factored-csd': Use factored CSD techniques, which replace multiplier operations with shift-and-add operations on prime factors of the coefficients. This option lets you achieve a greater filter area reduction than CSD, at the cost of decreasing clock speed.
- 'multipliers' (default): Retain multiplier operations.

HDL Coder supports `CoeffMultipliers` for fully-parallel filter implementations. It is not supported for fully-serial and partly-serial architectures.

DALUTPartition

The size of the LUT grows exponentially with the order of the filter. For a filter with N coefficients, the LUT must have 2^N values. For higher order filters, LUT size must be reduced to reasonable levels. To reduce the size, you can subdivide the LUT into a number of LUTs, called LUT partitions. Each LUT partition operates on a different set of taps. The results obtained from the partitions are summed.

For example, for a 160-tap filter, the LUT size is $(2^{160}) * W$ bits, where W is the word size of the LUT data. Dividing this into 16 LUT partitions, each taking 10 inputs (taps), the total LUT size is reduced to $16 * (2^{10}) * W$ bits.

Although LUT partitioning reduces LUT size, more adders are required to sum the LUT data.

You can use `DALUTPartition` to enable DA code generation and specify the number and size of LUT partitions.

Specify LUT partitions as a vector of integers `[p1 p2 . . . pN]` where:

- N is the number of partitions.
- Each vector element specifies the size of a partition. The maximum size for an individual partition is 12.

- The sum of all vector elements equals the filter length FL. FL is calculated differently depending on the filter type. You can find how FL is calculated for different filter types in the next section.

See “Distributed Arithmetic for HDL Filters” on page 26-51.

Specifying DALUTPartition for Single-Rate Filters

To determine the LUT partition for one of the supported single-rate filter types, calculate FL as shown in the following table. Then, specify the partition as a vector whose elements sum to FL.

Filter Type	Filter Length (FL) Calculation
Direct-form FIR	$FL = \text{length}(\text{find}(\text{Hd.numerator} \sim= 0))$
Direct-form asymmetrical FIR, direct-form symmetrical FIR	$FL = \text{ceil}(\text{length}(\text{find}(\text{Hd.numerator} \sim= 0))/2)$

You can also specify generation of DA code for your filter design without LUT partitioning. To do so, specify a vector of one element, whose value is equal to the filter length.

Specifying DALUTPartition for Multirate Filters

For supported multirate filters (FIR Decimation and FIR Interpolation), you can specify the LUT partition as

- A vector defining a partition for LUTs for all polyphase subfilters.
- A matrix of LUT partitions, where each row vector specifies a LUT partition for a corresponding polyphase subfilter. In this case, the FL is uniform for all subfilters. This approach provides fine control for partitioning each subfilter.

The following table shows the FL calculations for each type of LUT partition.

LUT Partition	Filter Length (FL) Calculation
<i>Vector</i> : Determine FL as shown in the Filter Length (FL) Calculation column to the right. Specify the LUT partition as a vector of integers whose elements sum to FL.	$FL = \text{size}(\text{polyphase}(\text{Hm}), 2)$
<i>Matrix</i> : Determine the subfilter length FL_i based on the polyphase decomposition of the filter, as shown in the Filter Length (FL) Calculation column to the right. Specify the LUT partition for each subfilter as a row vector whose elements sum to FL_i .	$p = \text{polyphase}(\text{Hm});$ $FL_i = \text{length}(\text{find}(p(i, :)));$ where i is the index to the i th row of the polyphase matrix of the multirate filter. The i th row of the matrix p represents the i th subfilter.

DARadix

The inherently bit-serial nature of DA can limit throughput. To improve throughput, the basic DA algorithm can be modified to compute more than one bit sum at a time. The number of simultaneously computed bit sums is expressed as a power of two called the DA radix. For example, a DA radix of 2 (2^1) indicates that one bit sum is computed at a time. A DA radix of 4 (2^2) indicates that two bit sums are computed at a time, and so on.

To compute more than one bit sum at a time, the LUT is replicated. For example, to perform DA on 2 bits at a time (radix 4), the odd bits are fed to one LUT and the even bits are simultaneously fed to an

identical LUT. The LUT results corresponding to odd bits are left-shifted before they are added to the LUT results corresponding to even bits. This result is then fed into a scaling accumulator that shifts its feedback value by 2 places.

Processing more than one bit at a time introduces a degree of parallelism into the operation, improving speed at the expense of area.

You can use `DARadix` to specify the number of bits processed simultaneously in DA. The number of bits is expressed as `N`, which must be:

- A nonzero positive integer that is a power of two
- Such that $\text{mod}(W, \log_2(N)) = 0$, where `W` is the input word size of the filter

The default value for `N` is 2, specifying processing of one bit at a time, or fully serial DA, which is slow but low in area. The maximum value for `N` is 2^W , where `W` is the input word size of the filter. This maximum specifies fully parallel DA, which is fast but high in area. Values of `N` between these extrema specify partly serial DA.

Note When setting a `DARadix` value for symmetrical and asymmetrical filters, see “Considerations for Symmetrical and Asymmetrical Filters” on page 26-52.

See “Distributed Arithmetic for HDL Filters” on page 26-51.

FoldingFactor

`FoldingFactor` specifies the total number of clock cycles taken for the computation of filter output in an IIR SOS filter with serial architecture. It is complementary with “`NumMultipliers`” on page 26-44. You must select one property or the other; you cannot use both. If you do not specify either `FoldingFactor` or `NumMultipliers`, HDL code for the filter is generated with fully parallel architecture.

MultiplierInputPipeline

You can use this parameter to generate a specified number of pipeline stages at multiplier inputs for FIR filter structures. The default value is 0.

The following limitation applies to `MultiplierInputPipeline`:

- Pipeline stages introduce delays along the path in the model that contains the affected filter. When you enable this pipeline option, the coder automatically adds balancing delays on parallel data paths.

For diagrams of where these pipeline stages occur in the filter architecture, see “HDL Filter Architectures” on page 26-46.

MultiplierOutputPipeline

You can use this parameter to generate a specified number of pipeline stages at multiplier outputs for FIR filter structures. The default value is 0.

The following limitation applies to `MultiplierOutputPipeline`:

- Pipeline stages introduce delays along the path in the model that contains the affected filter. When you enable this pipeline option, the coder automatically adds balancing delays on parallel data paths.

For diagrams of where these pipeline stages occur in the filter architecture, see “HDL Filter Architectures” on page 26-46.

NumMultipliers

`NumMultipliers` specifies the total number of multipliers used for the filter implementation in an IIR SOS filter with serial architecture. It is complementary with “`FoldingFactor`” on page 26-43 property. You must select one property or the other; you cannot use both. If you do not specify either `FoldingFactor` or `NumMultipliers`, HDL code for the filter is generated with fully parallel architecture.

ReuseAccum

You can use this parameter to enable or disable accumulator reuse in a serial HDL architecture. The default is a fully parallel architecture.

To Generate This Architecture...	Set ReuseAccum to...
Fully parallel	Omit this property
Fully serial	Not specified, or 'off'
Partly serial	'off'
Cascade-serial with explicitly specified partitioning	'on'
Cascade-serial with automatically optimized partitioning	'on'

For more information on parallel and serial filter architectures, see “HDL Filter Architectures” on page 26-46

SerialPartition

Use this parameter to specify partitions for a serial filter architecture. The default is a fully parallel architecture.

To Generate This Architecture...	Set SerialPartition to...
Fully parallel	Omit this property
Fully serial	N, where N is the length of the filter

To Generate This Architecture...	Set SerialPartition to...
Partly serial	<p>[p1 p2 p3 . . . pN]: A vector of integers having N elements, where N is the number of serial partitions. Each element of the vector specifies the length of the corresponding partition. The sum of the vector elements must be equal to the length of the filter. When you define the partitioning for a partly serial architecture, consider the following:</p> <ul style="list-style-type: none"> • The filter length should be divided as uniformly as possible into a vector equal in length to the number of multipliers intended. For example, if your design requires a filter of length 9 with 2 multipliers, the recommended partition is [5 4]. If your design requires 3 multipliers, the recommended partition is [3 3 3] rather than some less uniform division such as [1 4 4] or [3 4 2]. • If your design is constrained by the need to compute each output value (corresponding to each input value) in an exact number N of clock cycles, use N as the largest partition size and partition the other elements as uniformly as possible. For example, if the filter length is 9 and your design requires exactly 4 cycles to compute the output, define the partition as [4 3 2]. This partition executes in 4 clock cycles, at the cost of 3 multipliers.
Cascade-serial with explicitly specified partitioning	<p>[p1 p2 p3 . . . pN]: A vector of N integers, where N is the number of serial partitions. Each element of the vector specifies the length of the corresponding partition. The sum of the vector elements must be equal to the length of the filter. The values of the vector elements must be in descending order, except the last two elements, which can be equal. For example, for a filter length of 8, partitions [5 3] or [4 2 2] are valid, but the partitions [2 2 2 2] and [3 2 3] raise an error at code generation time.</p>
Cascade-serial with automatically optimized partitioning	Omit this property.

For more information on parallel and serial filter architectures, see “HDL Filter Architectures” on page 26-46.

This property is also used for Min/Max blocks with cascade-serial architectures. For how to configure Min/Max cascades, see “SerialPartition” on page 26-23.

HDL Filter Architectures

The HDL Coder software provides architecture options that extend your control over speed vs. area tradeoffs in the realization of filter designs. To achieve the desired tradeoff for generated HDL code, you can either specify a fully parallel architecture, or choose one of several serial architectures. Configure a serial architecture using the “SerialPartition” on page 26-44 and “ReuseAccum” on page 26-44 parameters. You can also choose a frame-based filter for increased throughput.

Use pipelining parameters to improve speed performance of your filter designs. Add pipelines to the adder logic of your filter using AddPipelineRegisters on page 26-40 for scalar input filters, and “AdderTreePipeline” on page 26-40 for frame-based filters. Specify pipeline stages before and after each multiplier with MultiplierInputPipeline on page 26-43 and MultiplierOutputPipeline on page 26-43. Set the number of pipeline stages before and after the filter using “InputPipeline” on page 26-14 and “OutputPipeline” on page 26-19. The architecture diagrams show the locations of the various configurable pipeline stages.

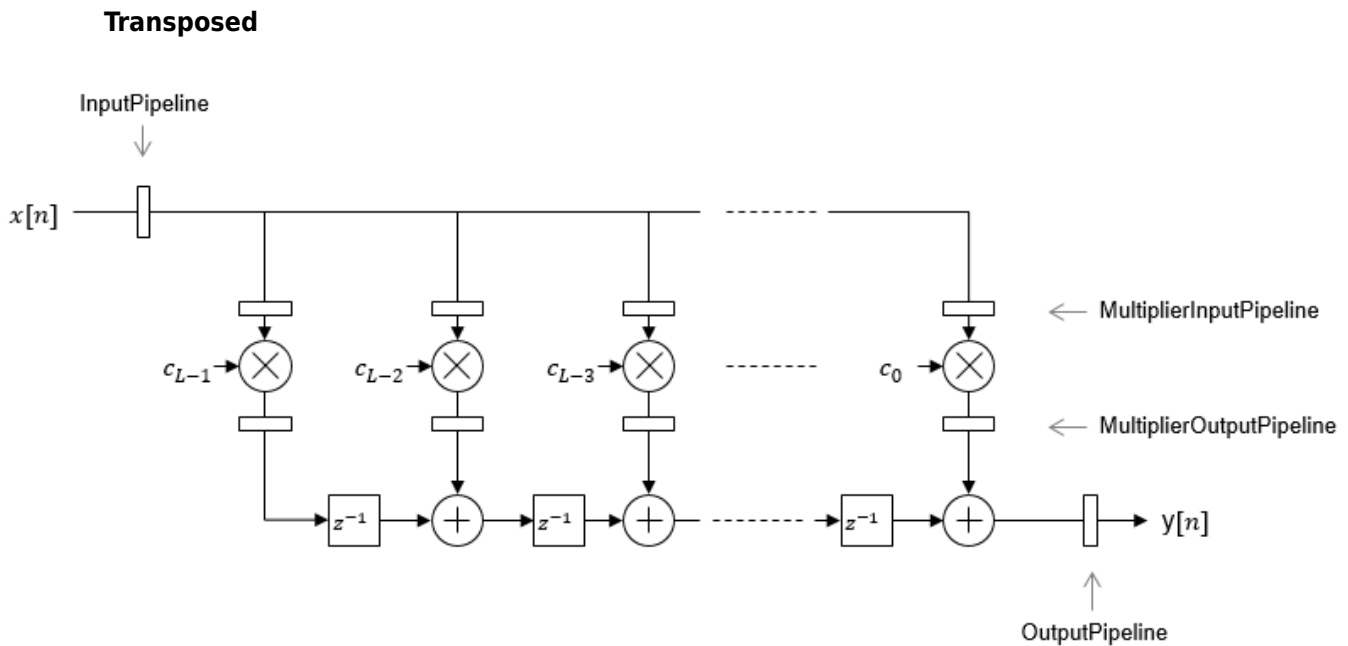

Fully Parallel Architecture

This option is the default architecture. A fully parallel architecture uses a dedicated multiplier and adder for each filter tap. The taps execute in parallel. A fully parallel architecture is optimal for speed. However, it requires more multipliers and adders than a serial architecture, and therefore consumes more chip area. The diagrams show the architectures for direct form and for transposed filter structures with fully parallel implementations, and the location of configurable pipeline stages.

Direct Form

By default, the block implements linear adder logic. When you enable AddPipelineRegisters, the adder logic is implemented as a pipelined adder tree. The adder tree uses full-precision data types. If you generate a validation model, you must use full precision in the original model to avoid validation mismatches.

The `AddPipelineRegisters` parameter has no effect on a transposed filter implementation.

Serial Architectures

Serial architectures reuse hardware resources in time, saving chip area. Configure a serial architecture using the “`SerialPartition`” on page 26-44 and “`ReuseAccum`” on page 26-44 parameters. The available serial architecture options are *fully serial*, *partly serial*, and *cascade serial*.

Fully Serial

A fully serial architecture conserves area by reusing multiplier and adder resources sequentially. For example, a four-tap filter design uses a single multiplier and adder, executing a multiply-accumulate operation once for each tap. The multiply-accumulate section of the design runs at four times the filter's input/output sample rate. This design saves area at the cost of some speed loss and higher power consumption.

In a fully serial architecture, the system clock runs at a much higher rate than the sample rate of the filter. Thus, for a given filter design, the maximum speed achievable by a fully serial architecture is less than that of a parallel architecture.

Partly Serial

Partly serial architectures cover the full range of speed vs. area tradeoffs that lie between fully parallel and fully serial architectures.

In a partly serial architecture, the filter taps are grouped into a number of serial partitions. The taps within each partition execute serially, but the partitions execute in parallel with respect to one another. The outputs of the partitions are summed at the final output.

When you select a partly serial architecture, you specify the number of partitions and the length (number of taps) of each partition. Suppose you specify a four-tap filter with two partitions, each having two taps. The system clock runs at twice the filter's sample rate.

Cascade Serial

A cascade-serial architecture closely resembles a partly serial architecture. As in a partly serial architecture, the filter taps are grouped into a number of serial partitions that execute in parallel with respect to one another. However, the accumulated output of each partition is cascaded to the accumulator of the previous partition. The output of all partitions is therefore computed at the accumulator of the first partition. This technique is termed *accumulator reuse*. A final adder is not required, which saves area.

The cascade-serial architecture requires an extra cycle of the system clock to complete the final summation to the output. Therefore, the frequency of the system clock must be increased slightly with respect to the clock used in a noncascade partly serial architecture.

To generate a cascade-serial architecture, specify a partly serial architecture with accumulator reuse enabled. If you do not specify the serial partitions, HDL Coder automatically selects an optimal partitioning.

Latency in Serial Architectures

Serialization of a filter increases the total latency of the design by one clock cycle. The serial architectures use an accumulator (an adder with a register) to add the products sequentially. An additional final register is used to store the summed result of all the serial partitions, requiring an extra clock cycle for the operation. To model this latency, HDL Coder inserts a Delay block into the generated model after the filter block.

Full-Precision for Serial Architectures

When you choose a serial architecture, the code generator uses full precision in the HDL code. HDL Coder therefore forces full precision in the generated model. If you generate a validation model, you must use full precision in the original model to avoid validation mismatches.

Frame-Based Architecture

When you select a frame-based architecture and provide an M -sample input frame, the coder implements a fully parallel filter architecture. The filter includes M parallel subfilters for each input sample.

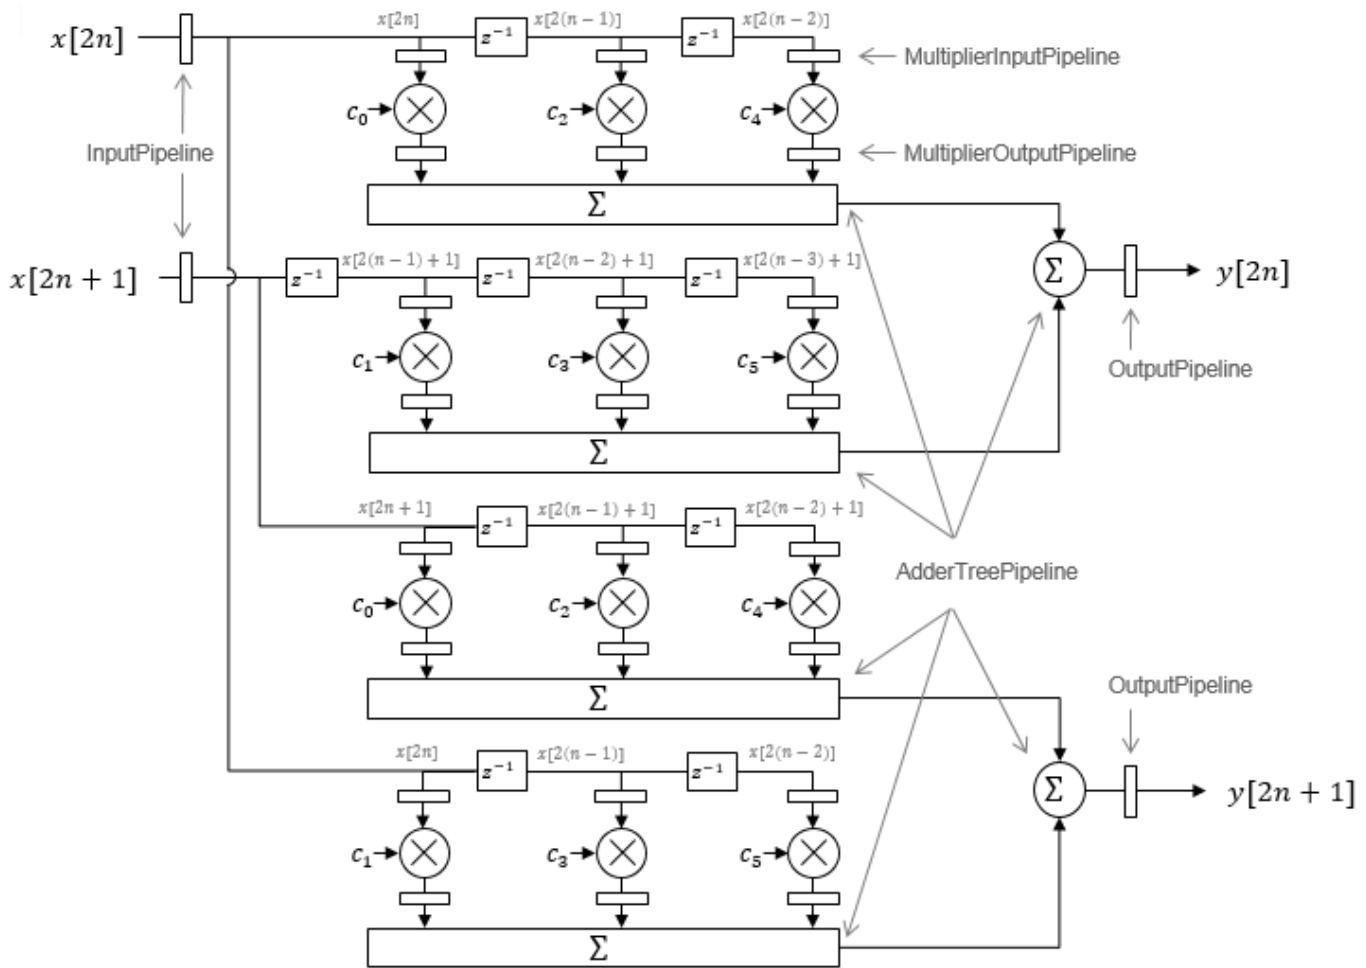

Each of the subfilters includes every M th coefficient. The subfilter results are added so that each output sample is the sum of each of the coefficients multiplied with one input sample.

Subfilter	Coefficients
0	c_0, c_M, \dots
1	c_1, c_{M+1}, \dots
$M-1$	c_{M-1}, c_{2M-1}, \dots

The diagram shows the filter architecture for a frame size of two samples ($M = 2$), and a filter length of six coefficients. The input is a vector with two values representing samples in time. The input samples, $x[2n]$ and $x[2n+1]$, represent the n th input pair. Every second sample from each stream is fed to two parallel subfilters. The four subfilter results are added together to create two output samples. In this way, each output sample is the sum of each of the coefficients multiplied with one of the input samples.

The sums are implemented as a pipelined adder tree. Set "AdderTreePipeline" on page 26-40 to specify the number of pipeline stages between levels of the adder tree. To improve clock speed, it is recommended that you set this parameter to 2. To fit the multipliers into DSP blocks on your FPGA, add pipeline stages before and after the multipliers using MultiplierInputPipeline on page 26-43 and MultiplierOutputPipeline on page 26-43.

For symmetric or antisymmetric coefficients, the filter architecture reuses the coefficient multipliers and adds design delay between the multiplier and summation stages as required.

Distributed Arithmetic for HDL Filters

Distributed Arithmetic (DA) is a widely used technique for implementing sum-of-products computations without the use of multipliers. Designers frequently use DA to build efficient Multiply-Accumulate Circuitry (MAC) for filters and other DSP applications. The main advantage of DA is its high computational efficiency. DA distributes multiply and accumulate operations across shifters, lookup tables (LUTs) and adders in such a way that conventional multipliers are not required.

In a DA realization of a FIR filter structure, a sequence of input data words of width W is fed through a parallel to serial shift register, producing a serialized stream of bits. The serialized data is then fed to a bit-wise shift register. This shift register serves as a delay line, storing the bit serial data samples.

The delay line is tapped (based on the input word size W), to form a W -bit address that indexes into a lookup table (LUT). The LUT stores all possible sums of partial products over the filter coefficients space. The LUT is followed by a shift and adder (scaling accumulator) that adds the values obtained from the LUT sequentially.

A table lookup is performed sequentially for each bit (in order of significance starting from the LSB). On each clock cycle, the LUT result is added to the accumulated and shifted result from the previous cycle. For the last bit (MSB), the table lookup result is subtracted, accounting for the sign of the operand.

This basic form of DA is fully serial, operating on one bit at a time. If the input data sequence is W bits wide, then a FIR structure takes W clock cycles to compute the output. Symmetric and asymmetric FIR structures are an exception, requiring $W+1$ cycles, because one additional clock cycle is needed to process the carry bit of the preadders.

You can control how DA code is generated by using the `DALUTPartition` and `DARadix` implementation parameters. The `DALUTPartition` and `DARadix` parameters have certain requirements and restrictions that are specific to different filter types. These requirements are included in the discussions of each parameter.

- Reduce LUT Size: “`DALUTPartition`” on page 26-41
- Improve Performance with Parallelism: “`DARadix`” on page 26-42

For information on the theoretical foundations of DA, see “Further References” on page 26-52.

Requirements and Considerations for Generating Distributed Arithmetic Code

Fixed-Point Quantization Required

Generation of DA code is supported only for fixed-point filter designs.

Specifying Filter Precision

The data path in HDL code generated for the DA architecture is carefully optimized for full precision computations. The filter result is cast to the output data size only at the final stage when it is presented to the output.

Distributed arithmetic merges the product and accumulator operations and does computations at full precision. This approach ignores the **Product output** and **Accumulator** properties of the Digital Filter block and sets these properties to full precision.

Coefficients with Zero Values

DA ignores taps that have zero-valued coefficients and reduces the size of the DA LUT accordingly.

Considerations for Symmetrical and Asymmetrical Filters

For symmetrical and asymmetrical filters:

- A bit-level preadder or presubtractor is required to add tap data values that have coefficients of equal value and/or opposite sign. One extra clock cycle is required to compute the result because of the additional carry bit.
- HDL Coder takes advantage of filter symmetry where possible. This reduces the DA LUT size substantially, because the effective filter length for these filter types is halved.

Set and View HDL Model and Block Parameters

In this section...

“Set HDL Block Parameters” on page 26-53

“Set HDL Block Parameters for Multiple Blocks Programmatically” on page 26-53

“View All HDL Block Parameters” on page 26-55

“View Non-Default HDL Block Parameters” on page 26-55

“View HDL Model Parameters” on page 26-55

You can view and set HDL-related block properties, such as implementation and implementation parameters, at the model level and at the individual block level.

Set HDL Block Parameters

To set the HDL Block parameters from the UI, open the HDL Block Properties dialog box, and modify the block properties. To open the HDL Properties dialog box, either:

- In the **Apps** tab, select **HDL Coder**. The **HDL Code** tab appears. Select the block for which you want to see the HDL parameters and then select **HDL Block Properties**.
- Right-click the block and select **HDL Code > HDL Block Properties**.

To set the HDL-related parameters at the command line, use `hdlset_param`.

`hdlset_param(path, Name, Value)` sets HDL-related parameters in the block or model referenced by *path*. One or more *Name, Value* pair arguments specify the parameters to be set, and their values. You can specify several name and value pair arguments in any order as *Name1, Value1, ..., NameN, ValueN*.

For example, to set the sharing factor to 2 and the architecture to Tree for a block in your model:

- 1 Open the model and select the block.
- 2 Enter the following at the command line:

```
hdlset_param(gcb, 'SharingFactor', 2, 'Architecture', 'Tree')
```

To view the HDL parameters specified for a block, use `hdlget_param`. For example, to see the HDL architecture setting for a block, at the command line, enter:

```
hdlget_param(gcb, 'Architecture')
```

You can also assign the returned HDL block parameters to a cell array. In the following example, `hdlget_param` returns all HDL block parameters and values to the cell array `p`.

```
p = hdlget_param(gcb, 'all')
```

```
p =
```

```
'Architecture' 'Linear' 'InputPipeline' [0] 'OutputPipeline' [0]
```

Set HDL Block Parameters for Multiple Blocks Programmatically

For models that contain a large number of blocks, using the **HDL Block Properties** dialog box to select block implementations or set implementation parameters for individual blocks may not be

practical. It is more efficient to set HDL-related model or block parameters for multiple blocks programmatically. You can use the `find_system` function to locate the blocks of interest. Then, use a loop to call `hdlset_param` to set the desired parameters for each block.

The following example uses the `sfir_fixed` model to demonstrate how to locate a group of blocks in a subsystem and specify the same output pipeline depth for all the blocks.

```
open_system('sfir_fixed')

% Find all Product blocks in the model
prodblocks = find_system('sfir_fixed/symmetric_fir', ...
                        'BlockType', 'Product')

% Set the output pipeline to 2 for the blocks
for ii=1:length(prodblocks)
    hdlset_param(prodblocks{ii}, 'OutputPipeline', 2)
end

prodblocks =

    4x1 cell array

    {'sfir_fixed/symmetric_fir/m1'}
    {'sfir_fixed/symmetric_fir/m2'}
    {'sfir_fixed/symmetric_fir/m3'}
    {'sfir_fixed/symmetric_fir/m4'}
```

To verify the settings, use `hdlget_param` to display the value of the `OutputPipeline` parameter for the blocks .

```
% Get the output pipeline to 2 for the blocks
for ii=1:length(prodblocks)
    hdlget_param(prodblocks{ii}, 'OutputPipeline')
end

ans =

    2

ans =

    2

ans =

    2

ans =

    2
```

View All HDL Block Parameters

`hdldispblkparams` displays the HDL block parameters available for a specified block.

The following example displays HDL block parameters and values for the currently selected block.

```
hdldispblkparams(gcb, 'all')
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
HDL Block Parameters ('simplevectorsum/vsum/Sum of
Elements')
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
```

```
Implementation
```

```
    Architecture : Linear
```

```
Implementation Parameters
```

```
    InputPipeline : 0
    OutputPipeline : 0
```

See also `hdldispblkparams`.

View Non-Default HDL Block Parameters

The following example displays only HDL block parameters that have non-default values for the currently selected block.

```
hdldispblkparams(gcb)
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
HDL Block Parameters ('simplevectorsum/vsum/Sum of
Elements')
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
```

```
Implementation
```

```
    Architecture : Linear
```

```
Implementation Parameters
```

```
    OutputPipeline : 3
```

View HDL Model Parameters

To display the names and values of HDL-related properties in a model, use the `hdldispmdlparams` function.

The following example displays HDL-related properties and values of the current model, in alphabetical order by property name.

```
hdldispmdlparams(bdroot, 'all')
```

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
```

HDL CodeGen Parameters

%%%

```
AddPipelineRegisters      : 'off'
Backannotation             : 'on'
BlockGenerateLabel        : '_gen'
CheckHDL                   : 'off'
ClockEnableInputPort      : 'clk_enable'
.
.
.
VerilogFileExtension      : '.v'
```

The following example displays only HDL-related properties that have non-default values.

hdldispmdlparams(bdroot)

%%%

HDL CodeGen Parameters (non-default)

%%%

```
CodeGenerationOutput      : 'GenerateHDLCodeAndDisplayGeneratedModel'
HDLSubsystem              : 'simplevectorsum/vsum'
ResetAssertedLevel        : 'Active-low'
Traceability               : 'on'
```

Pass through, No HDL, and Cascade Implementations

Pass-through and No HDL Implementations

Implementation	Description
Pass-through implementations	<p>Provides a pass-through implementation in which the block's inputs are passed directly to its outputs. HDL Coder supports the following blocks with a pass-through implementation:</p> <ul style="list-style-type: none"> • Convert 1-D to 2-D • Reshape • Signal Conversion • Signal Specification
No HDL	<p>The NoHDL implementation completely removes the block from the generated code. Thus, you can use the block in simulation but treat it as a “no-op” in the HDL code. This implementation is used for many blocks (such as Scopes and Assertions) that are significant in simulation but would be meaningless in HDL code.</p> <p>You can also use this implementation as an alternative implementation for subsystems.</p> <p>Logic driving a NoHDL subsystem might cause unconnected logic that is eliminated in the HDL code. For more information, see “Remove Redundant Logic and Unused Blocks in Generated HDL Code” on page 28-224.</p> <p>Output ports of NoHDL subsystems are not recommended. NoHDL subsystems appear in the generated model but are removed, along with any logic that only drives the subsystem, before code generation. To generate HDL for the surrounding logic of a NoHDL subsystem, comment through the subsystem in Simulink instead. For more information, see “Using Comment Out and Comment Through of Blocks” on page 25-27.</p>

For more information related to special-purpose implementations, see “External Component Interfaces”.

Cascade Architecture Best Practices

HDL Coder supports cascade implementations for the MinMax block. These implementations require multiple clock cycles to process their inputs; therefore, their inputs must be kept unchanged for their entire sample-time period. Generated test benches accomplish this by using a register to drive the inputs.

A recommended design practice, when integrating generated HDL code with other HDL code, is to provide registers at the inputs. While not strictly required, adding registers to the inputs improves timing and avoids problems with data stability for blocks that require multiple clock cycles to process their inputs.

Build a ROM Block with Simulink Blocks

HDL Coder does not provide a ROM block, but you can easily build one using basic Simulink blocks. The Getting Started with RAM and ROM example includes a ROM built using a 1-D Lookup Table block and a Unit Delay block. To open the example, type the following command at the MATLAB prompt:

```
hdlcoderramrom
```

Getting Started with RAM and ROM in Simulink

This example shows how to utilize RAM resources in your FPGA design using HDL Coder™.

Introduction

Dedicated RAM blocks in FPGA are valuable resources for digital designs. It is easy to design with RAM and ROM in Simulink®, and utilize the dedicated RAM blocks available in your FPGA using HDL Coder.

RAM Blocks in the HDL Example Library

HDL Coder provides following types of RAM blocks in the HDL RAMs block library. Use `hdllib` to display blocks that are compatible with HDL Coder™, and then select the HDL RAMs library under HDL Coder:

- Single Port RAM
- Single Port RAM System
- Simple Dual Port RAM
- Simple Dual Port RAM System
- Dual Port RAM
- Dual Port RAM System
- Dual Rate Dual Port RAM

Run this command navigate to RAM blocks in HDL library:

```
hdllib
```

The RAM blocks are masked subsystems built using Simulink blocks for behavioral simulation. For code generation, HDL Coder generates predefined templates that describe RAM structures in HDL. Most synthesis tools recognize the RAM structures in the templates, and map them to RAM resources on the FPGA.

Using Generic RAM Coding Style for RAM Blocks

By default, HDL Coder provides RAM template that uses clock enable for the RAM structures. As an alternative, HDL Coder also provides a style of generic template that does not use clock enable. The generic RAM style template implements clock enable with logic in a wrapper around the RAM. You can control this using **RAM Architecture** option in the HDL Coder global settings panel.

You may want to use the generic RAM style if your synthesis tool does not support RAM structures with a clock enable, and cannot map the HDL to FPGA RAM resources as a result.

The example `hdlcoderfirram` is an example of how to use the generic RAM style for your design.

```
open_system('hdlcoderfirram');  
open_system('hdlcoderfirram/FIR_RAM');
```

Selecting RAM Coding Style

The RAM Coding Style is selected by choosing the desired RAM Architecture on the **Coding Style** tab of the HDL Code Generation Global Settings configuration page.

Building a ROM Using Simulink Blocks

HDL Coder does not provide a ROM block, but you can easily build one using a Lookup Table block and a Unit Delay block from Simulink, as shown in the following example.

```
open_system('hdlcoderrrom');
open_system('hdlcoderrrom/ROM');
```

Follow these modeling guidelines when building a ROM from Simulink:

- For an n-bit address, specify all 2^n entries of the Lookup Table data. Otherwise, your synthesis tool may not map the generated code to RAM, and the code may not match your Simulink model.
- Place the Lookup Table and Unit Delay blocks in the same model hierarchy.
- Support of RAM reset logic varies among FPGA devices and synthesis tools. For best synthesis result, suppress the generation of reset logic for the Unit Delay block by setting its **ResetType** property to none, in the HDL Block Properties dialog box. Also set the **IgnoreDataChecking** property to 1 in the HDL Test Bench configuration parameters to ignore the initial simulation mismatch caused by suppressing the reset logic.

If you follow the preceding guidelines, most synthesis tools will implement the ROM using dedicated RAM blocks in an FPGA.

Minimum RAM Size Requirement

If the size of the RAM or ROM in your design is small, your synthesis tools may map the generated code to registers instead of dedicated RAM blocks for better speed performance. Check your synthesis tool for any minimum RAM size requirement, and if desired, how you may override that requirement.

Wireless Communications Design for ASICs, FPGAs, and SoCs

In this section...

“From Mathematical Algorithm to Hardware Implementation” on page 26-62

“HDL-Optimized Blocks” on page 26-64

“Reference Applications” on page 26-64

“Generate HDL Code and Prototype on FPGA” on page 26-64

Deploying algorithmic models to ASIC, FPGA, or SoC hardware makes it possible to do over-the-air testing and verification. However, designing wireless communications systems for hardware requires design tradeoffs between hardware resources and throughput. You can speed up hardware design and deployment by using HDL-optimized blocks that have hardware-suitable interfaces and architectures, reference applications that implement portions of the LTE, 5G NR, satellite communication, WLAN, and custom OFDM-based communications physical layer, and automatic HDL code generation. You can also use hardware support packages to assist with deploying and verifying your design on real hardware.

MathWorks® HDL products, such as Wireless HDL Toolbox, allow you to start with a mathematical model, such as MATLAB code from LTE Toolbox™, 5G Toolbox™, WLAN Toolbox™, or Satellite Communications Toolbox and design a hardware implementation of that algorithm that is suitable for ASICs, FPGAs, and SoCs.

From Mathematical Algorithm to Hardware Implementation

Wireless communications design often starts with algorithm development and testing using MATLAB functions. MATLAB code, which usually operates on matrices of floating-point data, is good for developing mathematical algorithms, manipulating large data sets, and visualizing data.

Hardware engineers typically receive a mathematical specification from an algorithm team, and reimplement the algorithm for hardware. Hardware designs require tradeoffs of resource usage for clock speed and overall throughput. Usually this tradeoff means operating on streaming data, and using some logic to control the storage and flow of data. Hardware engineers usually work in hardware description languages (HDLs), like VHDL and Verilog, that provide cycle-based modeling and parallelism.

To bridge this gap between mathematical algorithm and hardware implementation, use the MATLAB algorithm model as a starting point for hardware implementation. Make incremental changes to the design to make it suitable for hardware, and progress towards a Simulink model that you can use to automatically generate HDL code by using HDL Coder.

This diagram shows the design progression from mathematical algorithm in MATLAB, to hardware-compatible implementation in Simulink, and then the generated VHDL code.

While both MATLAB and Simulink support automatic generation of HDL code, you must construct your design with hardware requirements in mind, and Simulink is better-suited for cycle-based modeling for hardware. It can represent parallel data paths and streaming data with control signals to manage the timing of the data stream. To aid in fixed-point type choices, it clearly visualizes data type propagation in the design. It also allows for easy pipelining of mathematical operations to improve maximum clock frequency in hardware.

While you create your hardware-ready design, use the MATLAB algorithm as a "golden reference" to verify that each version of the design still meets the mathematical requirements. The workflow shown in the diagram uses MATLAB and Simulink as collaboration and communication tools between the algorithm and hardware design teams.

For instance, when designing for LTE, 5G, WLAN, and satellite communication wireless standards, you can use LTE Toolbox, 5G Toolbox, WLAN Toolbox, and Satellite Communications Toolbox functions to create a golden reference in MATLAB. Then transition to Simulink and create a hardware-compatible implementation by using library blocks from Wireless HDL Toolbox and DSP HDL Toolbox that support HDL code generation. You can reuse test and data generation infrastructure from MATLAB by importing data from MATLAB to your Simulink model and returning the output of the model to MATLAB to verify it against the "golden reference".

HDL-Optimized Blocks

Library blocks from Wireless HDL Toolbox implement encoders, decoders, modulators, demodulators, and sequence generators for use in an LTE, 5G, WLAN, satellite communications, or custom OFDM-based wireless communications system. These blocks use a standard streaming data interface for hardware. This interface makes it easy to connect parts of the algorithm together, and includes control signals that manage the flow of data and mark frame boundaries. These blocks support automatic HDL code generation with HDL Coder. You can also use blocks from DSP HDL Toolbox that support HDL code generation.

The blocks provide hardware-suitable architectures that optimize resource use, such as including adder and multiplier pipelining to fit well into FPGA DSP slices. They also support automatic and configurable fixed-point data types. Using predefined blocks also allows you to try different parameter configurations without changing the rest of the design.

For lists of blocks that support HDL code generation, see [Wireless HDL Toolbox Block List \(HDL Code Generation\)](#) and [DSP HDL Toolbox Block List \(HDL Code Generation\)](#).

Reference Applications

Wireless HDL Toolbox provides reference applications that contain hardware-ready implementations of large parts of the LTE, 5G NR, Satellite, WLAN, and custom OFDM-based communications physical layer. The subsystems in these reference applications have also been tested on hardware boards. These designs are verified against the "golden reference" functions provided by LTE Toolbox, 5G Toolbox, WLAN Toolbox, or Satellite Communications Toolbox. They are designed to be modular, scalable, and extensible so you can insert additional physical channels.

These reference applications can be used as-is to deliver packet information to your unique application and to generate synthesizable VHDL or Verilog with HDL Coder. They also serve as examples to illustrate recommended practices for implementing communications algorithms on FPGA or ASIC hardware.

Generate HDL Code and Prototype on FPGA

Wireless HDL Toolbox provides blocks that support HDL code generation. To generate HDL code from designs that use these blocks, you must have an HDL Coder license. HDL Coder produces device-independent code with signal names that correspond to the Simulink model. HDL Coder also provides

a tool to drive the FPGA synthesis and targeting process, and enables you to generate scripts and test benches for use with third-party HDL simulators.

To assist with the setup and targeting of programmable logic on a prototype board, and to verify your wireless communications system design on hardware, download required hardware support packages Communications Toolbox Support Package for Xilinx Zynq[®]-Based Radio or SoC Blockset[™] Support Package for Xilinx Devices.

Code Generation from Multirate Models

HDL Coder supports HDL code generation for single-clock and multiple clock multirate models. Your model can include blocks running at multiple sample rates:

- Within the device under test (DUT).
- In the test bench driving the DUT. In this case, the DUT inherits multiple sample rates from its inputs or outputs.
- In both the test bench and the DUT.

In general, generating HDL code for a multirate model does not differ greatly from generating HDL code for a single-rate model. However, there are a few requirements and restrictions on the configuration of the model and the use of specialized blocks (such as Rate Transitions) that apply to multirate models. For details, see “Multirate Model Requirements for HDL Code Generation” on page 27-7.

Clock Enable Generation for a Multirate DUT

The following block diagram shows the interior of a subsystem containing blocks that are explicitly configured with different sample times. The upper and lower Counter Free-Running blocks have sample times of 10 s and 20 s respectively. The counter output signals are routed to output ports ST10 and ST20, which inherit their sample times. The signal path terminating at ST10 runs at the base rate of the model; the signal path terminating at ST20 is a subrate signal, running at half the base rate of the model.

As shown in the next figure, the outputs of the multirate DUT drive To Workspace blocks in the test bench. These blocks inherit the sample times of the DUT outputs.

The following listing shows the VHDL entity declaration generated for the DUT.

```

ENTITY DUT IS
  PORT( clk
        : IN    std_logic;
        reset
        : IN    std_logic;
        clk_enable
        : IN    std_logic;
        ce_out_0
        : OUT   std_logic;
        ce_out_1
        : OUT   std_logic;
        ST10
        : OUT   std_logic_vector(7 DOWNTO 0); -- uint8
        ST20
        : OUT   std_logic_vector(5 DOWNTO 0) -- ufix6
  );
END DUT;

```

The entity has the standard clock, reset, and clock enable inputs and data outputs for the ST10 and ST20 signals. In addition, the entity has two clock enable outputs (ce_out_0 and ce_out_1). These clock enable outputs replicate internal clock enable signals maintained by the timing controller entity.

The following figure, showing a portion of a Mentor Graphics ModelSim simulation of the generated VHDL code, lets you observe the timing relationship of the base rate clock (clk), the clock enables, and the computed outputs of the model.

After the assertion of `clk_enable` (replicated by `ce_out_0`), a new value is computed and output to ST10 for every cycle of the base rate clock.

A new value is computed and output for subrate signal ST20 for every other cycle of the base rate clock. An internal signal, `enb_1_2_1` (replicated by `ce_out_1`) governs the timing of this computation.

Timing Controller for Multirate Models

A multirate model is model that contains blocks running at multiple sample rates. You can create a multirate model by adding blocks that run at different sample rates or by enabling an HDL optimization, such as streaming, sharing, or clock-rate pipelining, for a single rate model. In a multirate model, HDL Coder creates a timing controller entity to define timing signals for the model. These timing signals are signals such as a clock, reset, external clock enable inputs and a clock enable output. A timing controller generates the required rates from a single primary clock by using one or more counters to create multiple clock enables.

In single clock mode:

- HDL Coder generates a timing controller if you have a multirate model.
- The primary clock rate is the fastest rate in the model.
- HDL code generated from multirate models employs a single primary clock input that corresponds to the base rate of the DUT.

In multiple clock mode:

- HDL Coder generates a timing controller if the DUT contains downsampling operations that require a clock divider. The outputs of the timing controller are clock enable signals that run at rates that are an integer multiple slower than the timing controller primary clock.
- There is no primary clock rate in multiple clock mode.
- HDL code generated from multirate models employs one clock input for each rate in the DUT. The number of clock dividers generated in multiple clock mode depends on how many unique downsampling requests there are across various rates.

Timing Controller Naming

The timing controller generates a set of clock enables that contain the necessary rate and phase information to control the clocking for the design in the name of each clock enable. The naming of the clock enables shows the clock enable in relation to the model base rate. The model base rate might not be in the DUT. This naming convention keeps the naming consistent for mapping sample rate colors to the generated HDL code. For information on sample rate colors, see “View Sample Time Information”.

For example, if the model base rate is not used inside the DUT, the clock in a timing controller can be labeled as `enb_1_2_0` instead of `enb` because the model base rate is the fastest rate in the model. In this case, `enb_1_2_0` means the model base rate is twice as fast as the DUT base rate.

Each timing controller entity definition is written to a separate code file. The timing controller file and entity names are derived from the name of the DUT. To form the timing controller name, HDL Coder appends the value of the `TimingControllerPostfix` property to the DUT name. For example, if the name of your DUT is `my_test`, in the default case HDL Coder adds the `TimingControllerPostfix` value, `_tc`, to form the timing controller name `my_test_tc`.

Generate Reset for Timing Controller

In this section...
“Requirements for Timing Controller Reset Port Generation” on page 27-6
“How To Generate Reset for Timing Controller” on page 27-6
“Limitations for Timing Controller Reset Port Generation” on page 27-6

You can generate a reset port for the timing controller, which generates the clock, clock enable, and reset signals in a multirate DUT. In the generated code, the reset for the timing controller is a DUT input port.

Requirements for Timing Controller Reset Port Generation

Your design must use single-clock mode. That is, the `ClockInputs` property value must be `'Single'`.

How To Generate Reset for Timing Controller

To generate a reset port for the timing controller, set the `TimingControllerArch` property to `'resettable'` using `makehdl` or `hdlset_param`.

To disable reset port generation for the timing controller, set the `TimingControllerArch` property to `'default'`.

For example, for a model, `sfir_fixed`, specify a reset port for the timing controller by entering:

```
hdlset_param('sfir_fixed','TimingControllerArch','resettable')
```

Limitations for Timing Controller Reset Port Generation

The following workflows are not compatible with timing controller reset port generation:

- FPGA Turnkey
- FPGA-in-the-Loop
- Custom IP core generation

Multirate Model Requirements for HDL Code Generation

In this section...

“Model Configuration Parameters” on page 27-7

“Sample Rate” on page 27-7

“Blocks To Use For Rate Transitions” on page 27-7

Model Configuration Parameters

Before generating HDL code, configure the parameters of your model using the `hdlsetup` command. This sets up your multirate model for HDL code generation. This section summarizes settings applied to the model by `hdlsetup` that are relevant to multirate code generation. These include:

- **Solver** options that are recommended or required for HDL code generation:
 - **Type:** Fixed-step.
 - **Solver:** Discrete (no continuous states). Other fixed-step solvers could be selected, but this option is usually best for simulating discrete systems.
 - **Treat each discrete rate as a separate task:** Clear for single tasking mode.
- `hdlsetup` configures the following **Diagnostics / Sample time** options for all models:
 - **Multitask data transfer:** error
 - **Single task data transfer:** error

In multirate models intended for HDL code generation, Rate Transition blocks must be explicitly inserted when blocks running at different rates are connected. Set **Multitask data transfer** and **Single task data transfer** to error to detect illegal rate transitions before code is generated.

To learn more about the settings that `hdlsetup` configures, see “Check for model parameters suited for HDL code generation” on page 44-5.

Sample Rate

HDL Coder requires that at least one valid sample rate (sample time > 0) must exist in the model. If all rates are 0, -1, or -2, the code generator (`makehdl`) and compatibility checker (`checkhdl`) terminates with an error message.

Blocks To Use For Rate Transitions

Use Rate Transition blocks, rather than the following blocks, to create rate transitions in models intended for HDL code generation:

- Delay
- Tapped Delay
- Unit Delay
- Unit Delay Enabled
- Zero-Order Hold

The Delay blocks listed should be configured to have the same input and output sample rates. Zero-Order Hold blocks must be configured with inherited (-1) sample times.

Generate a Global Oversampling Clock

In this section...

“Why Use a Global Oversampling Clock?” on page 27-9
 “Requirements for the Oversampling Factor” on page 27-9
 “Specifying the Oversampling Factor From the GUI” on page 27-9
 “Specifying the Oversampling Factor From the Command Line” on page 27-10
 “Resolving Oversampling Rate Conflicts” on page 27-10

Why Use a Global Oversampling Clock?

In many designs, the DUT is not self-contained. For example, consider a DUT that is part of a larger system that supplies timing signals to its components under control of a global clock. The global clock typically runs at a higher rate than some of the components under its control. By specifying such a global oversampling clock, you can integrate your DUT into a larger system without using Upsample or Downsample blocks.

To generate global clock logic, you specify an oversampling factor. The oversampling factor expresses the desired rate of the global oversampling clock as a multiple of the base rate of your model.

When you specify an oversampling factor, HDL Coder generates the global oversampling clock and derives the required timing signals from clock signal. Generation of the global oversampling clock affects only generated HDL code. The clock does not affect the simulation behavior of your model.

Requirements for the Oversampling Factor

When you specify the oversampling factor for a global oversampling clock, note these requirements:

- The oversampling factor must be an integer greater than or equal to 1.
- The default value is 1. In the default case, HDL Coder does not generate a global oversampling clock.
- Some DUTs require multiple sampling rates for their internal operations. In such cases, the other rates in the DUT must divide evenly into the global oversampling rate. For more information, see “Resolving Oversampling Rate Conflicts” on page 27-10 .

Specifying the Oversampling Factor From the GUI

You can specify the oversampling factor for a global clock from the GUI as follows:

- 1 Select the **HDL Code Generation > Global Settings** pane in the Configuration Parameters dialog box.
- 2 For **Oversampling factor** in the **Clock settings** section, enter the desired oversampling factor. In the following figure, **Oversampling factor** specifies a global oversampling clock that runs at ten times the base rate of the model.
- 3 Click **Generate** on the **HDL Code Generation** pane to initiate code generation.

HDL Coder reports the oversampling clock rate:

```
### Begin VHDL Code Generation
### MESSAGE: The design requires 10 times faster clock with respect to the base rate = 1.
```

```

### Working on symmetric_fir_tc as hdlsrc\symmetric_fir_tc.vhd
### Working on sfir_fixed/symmetric_fir as hdlsrc\symmetric_fir.vhd
### HDL Code Generation Complete.

```

Specifying the Oversampling Factor From the Command Line

You can specify the oversampling factor for a global clock from the command line by setting the `Oversampling` property with `hdlset_param` or `makehdl`. The following example specifies an oversampling factor of 7:

```
makehdl(gcb, 'Oversampling', 7)
```

```

### Generating HDL for 'sfir_fixed/symmetric_fir'
### Starting HDL Check.
### HDL Check Complete with 0 errors, 0 warnings and 0 messages.

### Begin VHDL Code Generation
### MESSAGE: The design requires 7 times faster clock with respect to the base rate = 1.
### Working on symmetric_fir_tc as hdlsrc\symmetric_fir_tc.vhd
### Working on sfir_fixed/symmetric_fir as hdlsrc\symmetric_fir.vhd
### HDL Code Generation Complete.

```

Resolving Oversampling Rate Conflicts

The HDL realization of some designs is inherently multirate, even though the original Simulink model is single-rate. As an example, consider the `simplevectorsum_cascade` model.

This model consists of a subsystem, `vsum`, driven by a vector input of width 10, with a scalar output. The following figure shows the root level of the model.

The device under test is the `vsum` subsystem, shown in the following figure. The subsystem contains a `Sum` block, configured for vector summation.

The `simplevectorsum_cascade` model specifies a cascaded implementation (`SumCascadeHDL Emission`) for the Sum block. The generated HDL code for a cascaded vector Sum block implementation runs at two effective rates: a faster (oversampling) rate for internal computations and a slower rate for input/output. HDL Coder reports that the inherent oversampling rate for the DUT is five times the base rate:

```

dut = 'simplevectorsum_cascade/vsum';
makehdl(dut);

### Generating HDL for 'simplevectorsum_cascade/vsum'
### Starting HDL Check.
### HDL Check Complete with 0 errors, 0 warnings and 0 messages.

### The code generation and optimization options you have chosen have introduced
  additional pipeline delays.
### The delay balancing feature has automatically inserted matching delays for
  compensation.
### The DUT requires an initial pipeline setup latency. Each output port
  experiences these additional delays
### Output port 0: 1 cycles

### Begin VHDL Code Generation
### MESSAGE: The design requires 5 times faster clock with respect to the
  base rate = 1.
...
  
```

In some cases, the clock requirements for such a DUT conflict with the global oversampling rate. To avoid oversampling rate conflicts, verify that subrates in the model divide evenly into the global oversampling rate.

For example, if you request a global oversampling rate of 8 for the `simplevectorsum_cascade` model, the coder displays a warning and ignores the requested oversampling factor. The coder instead respects the oversampling factor that the DUT requests:

```

dut = 'simplevectorsum_cascade/vsum';
makehdl(dut,'Oversampling',8);

### Generating HDL for 'simplevectorsum/vsum'
### Starting HDL Check.
### HDL Check Complete with 0 errors, 0 warnings and 0 messages.

### The code generation and optimization options you have chosen have introduced
  additional pipeline delays.
  
```

```
### The delay balancing feature has automatically inserted matching delays for
compensation.
### The DUT requires an initial pipeline setup latency. Each output port
experiences these additional delays
### Output port 0: 1 cycles

### Begin VHDL Code Generation
### WARNING: The design requires 5 times faster clock with respect to
the base rate = 1, which is incompatible with the oversampling
value (8). Oversampling value is ignored.
...
```

An oversampling factor of 10 works in this case:

```
dut = 'simplevectorsum_cascade/vsum';
makehdl(dut, 'Oversampling', 10);
```

```
### Generating HDL for 'simplevectorsum_cascade/vsum'
### Starting HDL Check.
### HDL Check Complete with 0 errors, 0 warnings and 0 messages.

### The code generation and optimization options you have chosen have introduced
additional pipeline delays.
### The delay balancing feature has automatically inserted matching delays for
compensation.
### The DUT requires an initial pipeline setup latency. Each output port
experiences these additional delays
### Output port 0: 1 cycles

### Begin VHDL Code Generation
### MESSAGE: The design requires 10 times faster clock with respect to
the base rate = 1.
...
```

Using Multiple Clocks in HDL Coder

This example shows how to instantiate multiple top-level synchronous clock input ports in HDL Coder™.

Overview of Clocking Modes

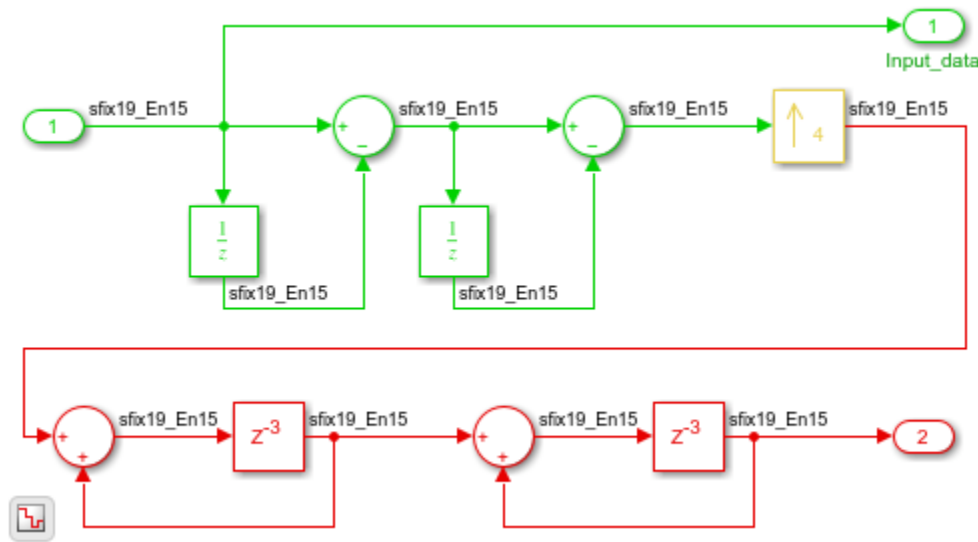

HDL Coder has two clocking modes. One mode generates a single clock input to the Device Under Test (DUT). The other mode generates a synchronous primary clock input for each Simulink® rate in the DUT. By default, HDL Coder creates an HDL design that uses a single clock port for the DUT. In single clock mode, if multiple rates exist in the Simulink model, a timing controller is created to control the clocking to the portions of the model that run at a slower rate. The timing controller generates a set of clock enables with the necessary rate and phase information to control the clocking for the design. Each generated clock enable is an integer multiple slower than the primary clock rate. Each output signal rate is associated with a clock enable output signal that indicates the correct timing to sample the output data.

In synchronous multiple clock mode, the generated code has a set of clock ports as primary inputs to the DUT. Each clock port corresponds to a separate rate in the model. Transitions between rates require clock enables at a given rate that are out of phase with that rate's clock. These out of phase signals are generated with a timing controller. A multiple clock model may require multiple timing controllers.

When using multiple clocks for multirate model, it is recommended to add sequential logic such as delay block at each Simulink rate. If the sequential logic is not present at a particular Simulink rate, HDL Coder does not generate separate clock port for that rate. For example, in a multirate model consisting of Downsample block, add a unit delay block after the Downsample block to generate the clock port of that downsampling rate.

The first example uses a multirate CIC Interpolation filter in single clock mode. The filter's input is also presented as an output for this example to present a model with output signals running at different rates.

```
load_system('hdlcoder_clockdemo');  
open_system('hdlcoder_clockdemo/DUT');  
set_param('hdlcoder_clockdemo', 'SimulationCommand', 'update');
```

Single Clock Mode DUT Timing Interface

In single clock mode, the HDL code for the DUT has a set of three signals that do not appear in the Simulink diagram added to it. Collectively, these are a clock bundle that contains signals for clock, primary clock enable, and reset. These signals appear in the VHDL Entity declaration and are used throughout the generated code.

```
hdlset_param('hdlcoder_clockdemo', 'Traceability', 'on');
makehdl('hdlcoder_clockdemo/DUT');
```

Clock Summary Reporting in Single Clock Mode

The file comment block in the HDL DUT code contains Clock Summary information. In single clock mode, this report contains a table detailing the sample rates for each clock enable output signal. The

report also contains a table listing each user output signal and its associated clock enable output signal. Any time a HTML report is generated, the Clock Summary Report is also generated.

Generating Synchronous Multiclock HDL Code

To generate multiple synchronous clocks for this design, the `ClockInputs` property must be set to `multiple`. Either change the `ClockInputs` property at the command line using `makehdl` or change the **Clock inputs** setting to `Multiple` on the **HDL Code Generation > Global Settings** tab of the Configuration Parameters dialog box.

```
makehdl('hdlcoder_clockdemo/DUT', 'ClockInputs', 'multiple');

### Generating HDL for 'hdlcoder_clockdemo/DUT'.

### HDL code generation complete.
```

Clock Summary Information in Multiclock Mode

The contents of the Clock Summary are different in multiple clock mode. The report now contains a clock table. This table has one entry for each primary DUT clock. It describes the relative clock ratio between each clock and the fastest clock in the model. As with single clock mode, this information is presented both in the HDL DUT file comment block and the HTML report.

Multiclock Mode and HDL Coder Optimizations

Multiple synchronous clocks can be useful even for a design with only a single Simulink rate. Various optimizations can require clock rates faster than indicated in the original model. The following example demonstrates an audio filtering model that applies the same filter on the left and right channels. By default, HDL Coder would generate two filter modules in hardware. With this configuration, multiple clock mode still only generates one clock, just as single clock mode does.

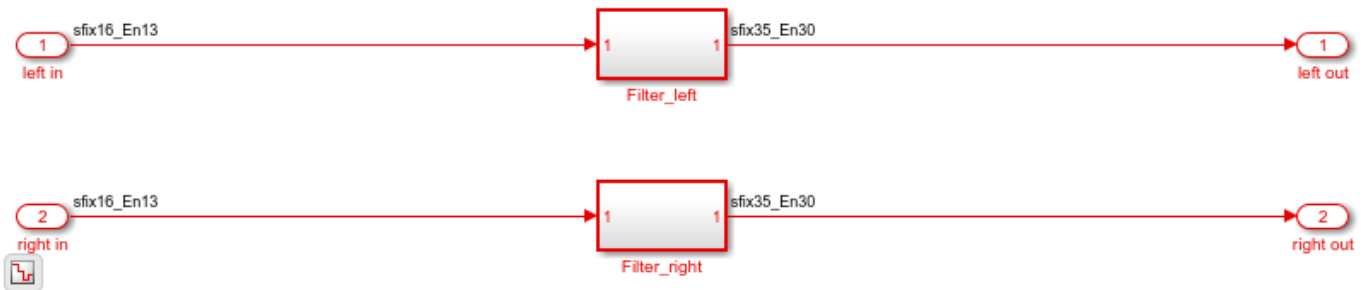

```
bdclose hdlcoder_clockdemo;
load_system('hdlcoder_audiofiltering');
open_system('hdlcoder_audiofiltering/Audio filter');
hdlset_param('hdlcoder_audiofiltering', 'ClockInputs', 'Multiple');
hdlset_param('hdlcoder_audiofiltering/Audio filter', 'SharingFactor', 0);
makehdl('hdlcoder_audiofiltering/Audio filter', 'Traceability', 'on');

### Generating HDL for 'hdlcoder_audiofiltering/Audio filter'.

### HDL code generation complete.

```

Using Multiple Clock Mode with Resource Sharing

With resource sharing applied to the identical left and right channel atomic subsystems, only one filter is generated. To meet the Simulink timing requirements, the single filter is run at twice the clock rate as the original Simulink model, as is shown below. Since the resource sharing optimization creates a second clock rate, the user can use synchronous multiple clock mode to provide external clocks for both rates. In this configuration, multiple clock mode still only generates one clock. You see the message:

The design requires 2 times faster clock with respect to the base rate = 0.00012207.

```

bdclose gm_hdlcoder_audiofiltering;
hdlset_param('hdlcoder_audiofiltering/Audio filter', 'SharingFactor', 2);

“Limitations” on page 27-22

The Triggered Subsystem block is a Subsystem block that executes each time the control signal has a trigger value. To learn more about the block, see Triggered Subsystem.

Best Practices

When using triggered subsystems in models targeted for HDL code generation, consider the following:

- For synthesis results to match Simulink results, drive the trigger port with registered logic (with a synchronous clock) on the FPGA.
- It is good practice to put unit delays on Triggered Subsystem output signals. Doing so prevents the code generator from inserting extra bypass registers in the HDL code.
- The use of triggered subsystems can affect synthesis results in the following ways:
 - In some cases, the system clock speed can drop by a small percentage.
 - Generated code uses more resources, scaling with the number of triggered subsystem instances and the number of output ports per subsystem.

Using the Signal Editor Block

When you connect outputs from a Signal Editor block to a triggered subsystem, you might need to use a Rate Transition block. To run all triggered subsystem ports at the same rate:

- If the trigger source is a Signal Editor block, but the other triggered subsystem inputs come from other sources, insert a Rate Transition block into the signal path before the trigger input.
- If all inputs (including the trigger) come from a Signal Editor block, they have the same rate, so special action is not required.

Using Trigger As Clock

Using the trigger as clock in triggered subsystems enables you to partition your design into different clock regions in the generated code. Make sure that the **Clock edge** setting in the Configuration Parameters dialog box matches the **Trigger type** of the Trigger block inside the triggered subsystem.

For example, you can model:

- A design with clocks that run at the same rate, but out of phase.
- Clock regions driven by an external or internal clock divider.
- Clock regions driven by clocks whose rates are not integer multiples of each other.
- Internally generated clocks.
- Clock gating for low-power design.

Note Using the trigger as clock for triggered subsystems can result in timing mismatches of one cycle during testbench simulation.

Specify Trigger As Clock

- In **HDL Code Generation > Global Settings > Ports** tab, select **Use trigger signal as clock**.
- Set the `TriggerAsClock` property using `makehdl` or `hdlset_param`. For example, to generate HDL code that uses the trigger signal as clock for triggered subsystems in a DUT subsystem, `myDUT`, in a model, `myModel`, enter:

```
makehdl ("myModel/myDUT",TriggerAsClock="on")
```

Trigger As Clock Without Synchronous Registers

When you use the trigger as clock in triggered subsystem, each triggered subsystem input or output requires synchronization delays immediately outside and immediately inside the subsystem. These delays act as a synchronization interface between the regions running at different rates. HDL Coder can allow you to generate HDL code without adding the synchronization delays by enabling the "trigger as clock without synchronous register" option. By default, this option is on.

You can enable or disable this option by using `makehdl` or `hdlset_param` function. For example, to generate an HDL code for a DUT subsystem, `myDUT` in a model, `myModel`, that uses trigger as a clock for triggered subsystem without having synchronization delays, enter:

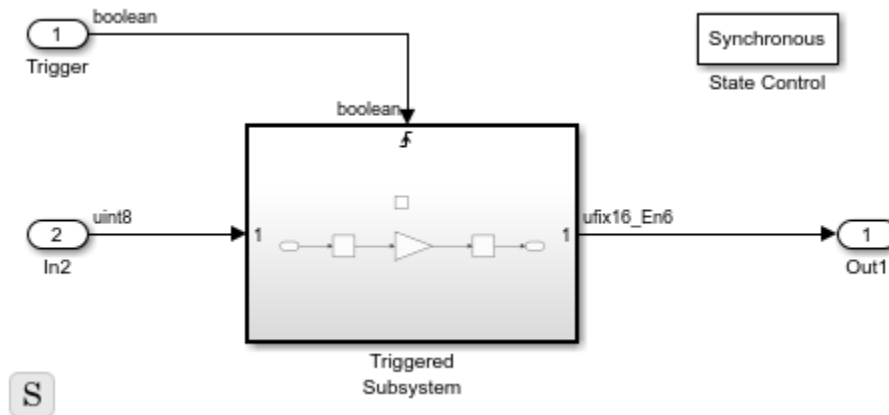

```
makehdl ("myModel/myDUT",TriggerAsClockWithoutSyncRegisters="on")
```

Model Trigger Signal As Clock in Triggered Subsystem

This example shows how to model trigger port of the Triggered Subsystem as a clock signal. Using trigger as clock functionality in the Triggered Subsystem enables you to use trigger signal as a clock in your generated HDL code.

The model `TriggerAsClockSingle` has a DUT subsystem which contains a Triggered Subsystem. Load and open the `TriggerAsClockSingle` model by running these commands:

```
load_system("TriggerAsClockSingle");
set_param("TriggerAsClockSingle",'SimulationCommand','Update')
open_system("TriggerAsClockSingle/DUT");
```

To use trigger signal as clock in your generated HDL code, enable **Use trigger signal as clock** option in the **HDL Code Generation > Global Settings > Ports** tab of the configuration settings. Then, generate the HDL code for a DUT subsystem using `makehdl` command or HDL Coder™ app:

```
makehdl("TriggerAsClockSingle/DUT")
```

In the generated HDL code, HDL Coder maps the trigger port of the Triggered Subsystem to the clock. This code snippet shows the HDL code of Triggered Subsystem which uses Trigger signal as a clock.

```
Delay1_process : PROCESS (Trigger, reset)
BEGIN
  IF reset = '1' THEN
    Delay1_out1 <= to_unsigned(16#0000#, 16);
  ELSIF Trigger'EVENT AND Trigger = '1' THEN
    Delay1_out1 <= Gain_out1;
  END IF;
END PROCESS Delay1_process;
```

Use Triggered and Resettable Subsystem to Model Clock and Reset Signals

You can model control signals, such as clock and reset, by using the triggered and resettable subsystem. You can use trigger as clock functionality to model trigger port from triggered subsystem as a clock and use resettable subsystem to model reset port from Simulink.

When you use triggered or resettable subsystem in your model targeted for HDL code generation, you can:

- Model a clock and reset signal from Simulink by including a resettable subsystem inside the triggered subsystem.
- Use a triggered subsystem with synchronous semantics.
- Generate a code with a single clock and reset for a nested resettable subsystem inside a triggered subsystem by using the **Use trigger signal as clock** and **Minimize global resets** parameters.
- Generate code that has multiple clock and reset signals for a model consisting of multiple triggered and resettable subsystem.
- Use Unit Delay Enabled Synchronous block inside the Triggered subsystem.

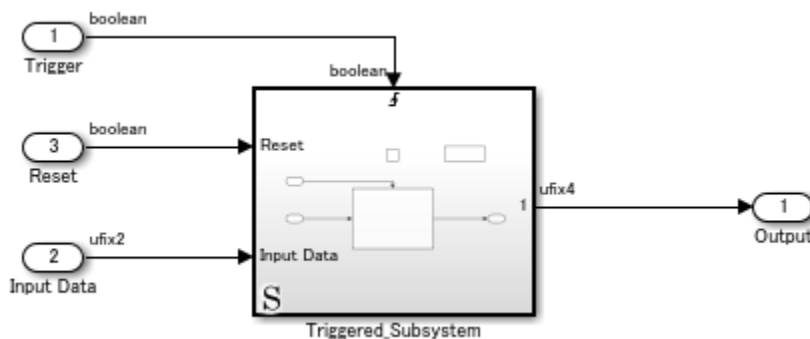

- Model a Unit Delay Resettable Synchronous block in the triggered subsystem by adding the Unit Delay block to a resettable subsystem with synchronous semantics and placing the resettable subsystem inside triggered subsystem.
- Model a Unit Delay Enabled Resettable Synchronous block in the triggered subsystem by adding the Unit Delay Enabled block to a resettable subsystem with synchronous semantics and placing the resettable subsystem inside triggered subsystem.

Model Single Clock and Reset Signal Using Triggered and Resettable Subsystems

This example shows how to model clock and reset signal using Triggered and Resettable subsystems. You can use trigger as clock functionality to model trigger port from triggered subsystem as a clock and use resettable subsystem to model reset port.

The model `ClockAndResetModellingUsingTriggerAsClock` has a DUT subsystem which contains a Triggered Subsystem. Load and open the `ClockAndResetModellingUsingTriggerAsClock` model by running these commands:

```
load_system("ClockAndResetModellingUsingTriggerAsClock");
set_param("ClockAndResetModellingUsingTriggerAsClock", 'SimulationCommand', 'Update')
open_system("ClockAndResetModellingUsingTriggerAsClock/DUT");
```

A resettable subsystem is placed within the triggered subsystem. Using resettable subsystem, you can model a reset port for your model. Minimize the global reset option so that model has single reset signal from resettable subsystem. To minimize global reset option, enable **Minimize global resets** in the **HDL Code Generation > Global Settings > Ports** tab of the configuration settings.

To use trigger signal as clock in your generated HDL code, enable **Use trigger signal as clock** option in the **HDL Code Generation > Global Settings > Ports** tab. Then, generate the HDL code for a DUT subsystem using `makehdl` command or HDL Coder™ app:

```
makehdl("ClockAndResetModellingUsingTriggerAsClock/DUT")
```

In the generated HDL code, HDL Coder maps the trigger port of the Triggered Subsystem to the clock. Also, the reset signal is generated from the Resettable subsystem. The HDL code of triggered subsystem shows mapping of trigger port to clock signal in the resettable subsystem.

```
module Triggered_Subsystem
    (Trigger,
```

```
        Reset_1,
        Input_Data,
        Output_rsvd);

input  Trigger;
input  Reset_1;
input  [1:0] Input_Data; // ufix2
output [3:0] Output_rsvd; // ufix4

wire [3:0] Resetable_Subsystem_out1; // ufix4

Resetable_Subsystem u_Resetable_Subsystem (.clk(Trigger),
                                           .Input_Data(Input_Data), // ufix2
                                           .Reset_1(Reset_1),
                                           .Output_rsvd(Resetable_Subsystem_out1) //
                                           );
assign Output_rsvd = Resetable_Subsystem_out1;
endmodule // Triggered_Subsystem
```

Limitations

HDL Coder supports HDL code generation for triggered subsystems that meet the following conditions:

- The triggered subsystem is not the DUT.
- The subsystem is not *both* triggered *and* enabled.
- The trigger signal is a scalar.
- If the output of the subsystem is a bus then initial value of the output must be 0.
- All inputs and outputs of the triggered subsystem (including the trigger signal) run at the same rate.
- The **Show output port** parameter of the Trigger block is set to Off.
- The **Latch input by delaying outside signal** check box is not selected on the Inport block inside the Triggered Subsystem.
- If the DUT contains the following blocks, RAMArchitecture is set to WithClockEnable:
 - Dual Port RAM
 - Simple Dual Port RAM
 - Single Port RAM
- The triggered subsystem does not contain the following blocks:
 - Discrete-Time Integrator
 - CIC Decimation
 - CIC Interpolation
 - FIR Decimation
 - FIR Interpolation
 - Downsample
 - Upsample
 - HDL Cosimulation blocks for HDL Verifier

- Rate Transition
- Pixel Stream FIFO (Vision HDL Toolbox)
- PN Sequence Generator, if the **Use trigger signal as clock** option is selected.

Use Triggered Subsystem for Asynchronous Clock Domain

You can design a model for an asynchronous clock domain using a triggered subsystem. An asynchronous clock domain design operates at different clock regions whose clock rates are not integer multiples of one another. You can model an asynchronous clock domain design in Simulink by using multiple triggered subsystems. You can use a trigger as a clock functionality to generate separate clock signals for each triggered subsystem.

Using a triggered subsystem and a trigger as a clock, you can design a model that has one of these characteristics:

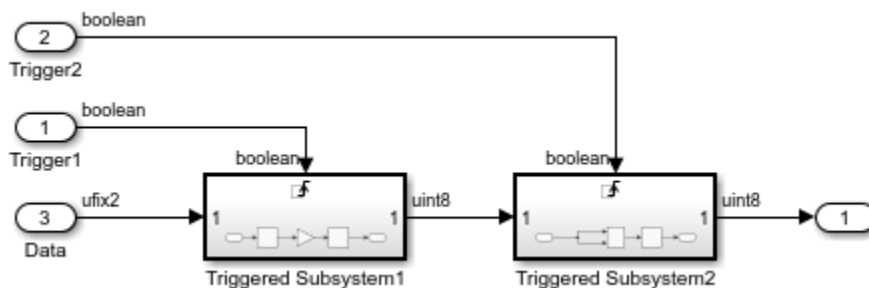

- Clock regions driven by clocks whose rates are not integer multiples of one another.
- Clocks that run at the same rate but out of phase.
- Multiple clocks that operate at different rates.
- Multiple clocks and resets modeled using nested resettable subsystems.

Generate Multiple Clocks Using Trigger As Clock

This example shows how to model multiple clock signals using triggered subsystems. Using trigger as clock functionality in the triggered subsystem enables you to use trigger signal as a clock in your generated HDL code. You can model an asynchronous clock domain design in Simulink® by using multiple triggered subsystem and use trigger as a clock functionality to generate separate clock signal for each triggered subsystem.

The model `AsynchronousClockUsingTriggerAsClock` has a DUT subsystem which contains a two Triggered Subsystem. Load and open the `AsynchronousClockUsingTriggerAsClock` model by running these commands:

```
load_system("AsynchronousClockUsingTriggerAsClock");
set_param("AsynchronousClockUsingTriggerAsClock", 'SimulationCommand', 'Update')
open_system("AsynchronousClockUsingTriggerAsClock/DUT");
```

To use trigger signal as clock in your generated HDL code, enable **Use trigger signal as clock** option in the **HDL Code Generation > Global Settings > Ports** tab of the configuration settings. Then, generate the HDL code for a DUT subsystem using `makehdl` command or HDL Coder™ app:

```
makehdl("AsynchronousClockUsingTriggerAsClock/DUT")
```

In the generated HDL code, HDL Coder generates two trigger ports for the DUT subsystem which are used as clock signal in the triggered subsystems.

```

module DUT
    (Trigger1,
     Trigger2,
     Data,
     Out1);

    input  Trigger1;
    input  Trigger2;
    input  [1:0] Data; // ufix2
    output [7:0] Out1; // uint8

    wire [7:0] Triggered_Subsystem1_out1; // uint8
    wire [7:0] Triggered_Subsystem2_out1; // uint8

    Triggered_Subsystem1 u_Triggered_Subsystem1 (.Trigger(Trigger1),
                                                .In1(Data), // ufix2
                                                .Out1(Triggered_Subsystem1_out1) // uint8
                                                );

    Triggered_Subsystem2 u_Triggered_Subsystem2 (.Trigger(Trigger2),
                                                .In1(Triggered_Subsystem1_out1), // uint8
                                                .Out1(Triggered_Subsystem2_out1) // uint8
                                                );

    assign Out1 = Triggered_Subsystem2_out1;

endmodule // DUT

```

Each triggered subsystem is driven by the separate clock connected to the trigger port of triggered subsystem. You can use these clock signals to operate the subsystems at different clock rates. In the HDL code for triggered subsystem, the trigger signals are used as clock as shown in code snippet below.

```

module Triggered_Subsystem1
    (Trigger,
     In1,
     Out1);

    input  Trigger;
    input  [1:0] In1; // ufix2
    output [7:0] Out1; // uint8

    ...
    ...
    always @(posedge Trigger)
    begin : Delay1_process
        Delay1_out1 <= Gain_out1;
    end

```

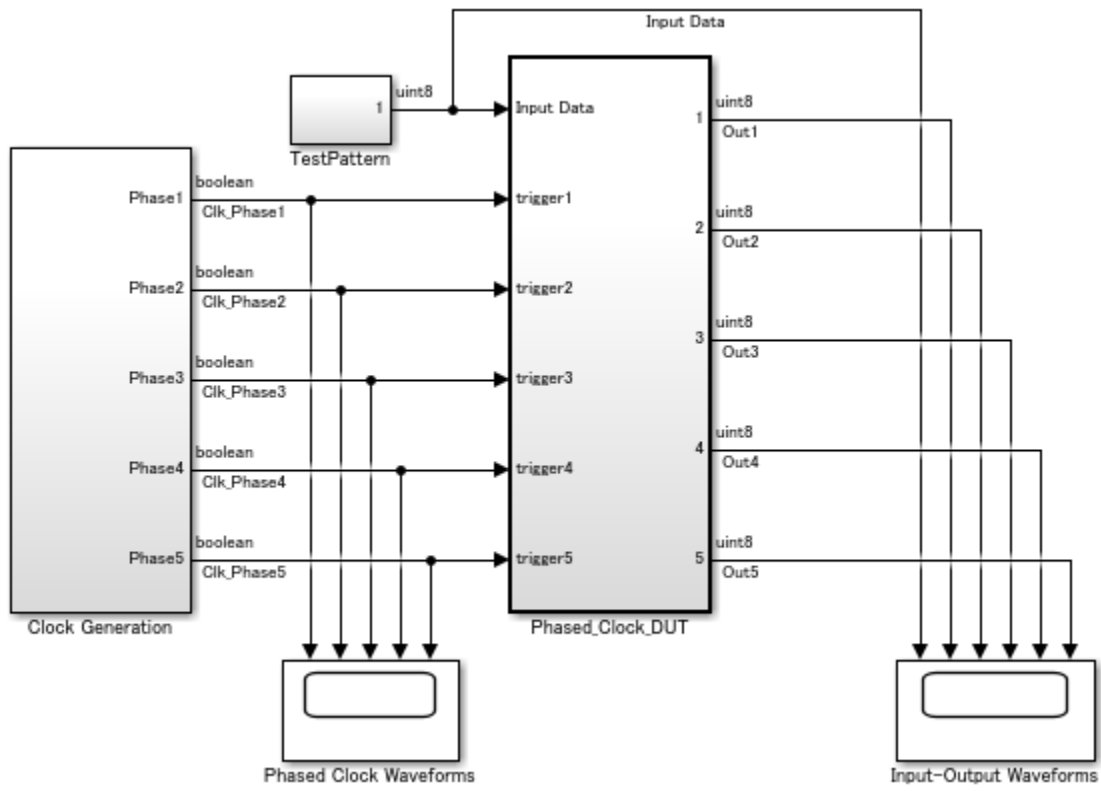

Design a Model With Clocks That Run at Same Rate, But Out of Phase

Using trigger as clock for triggered subsystem, you can model a design that has clocks which operate at same rate, but out of phase. For example, load and open the PhasedClocksUsingTriggeredSubsystem model.

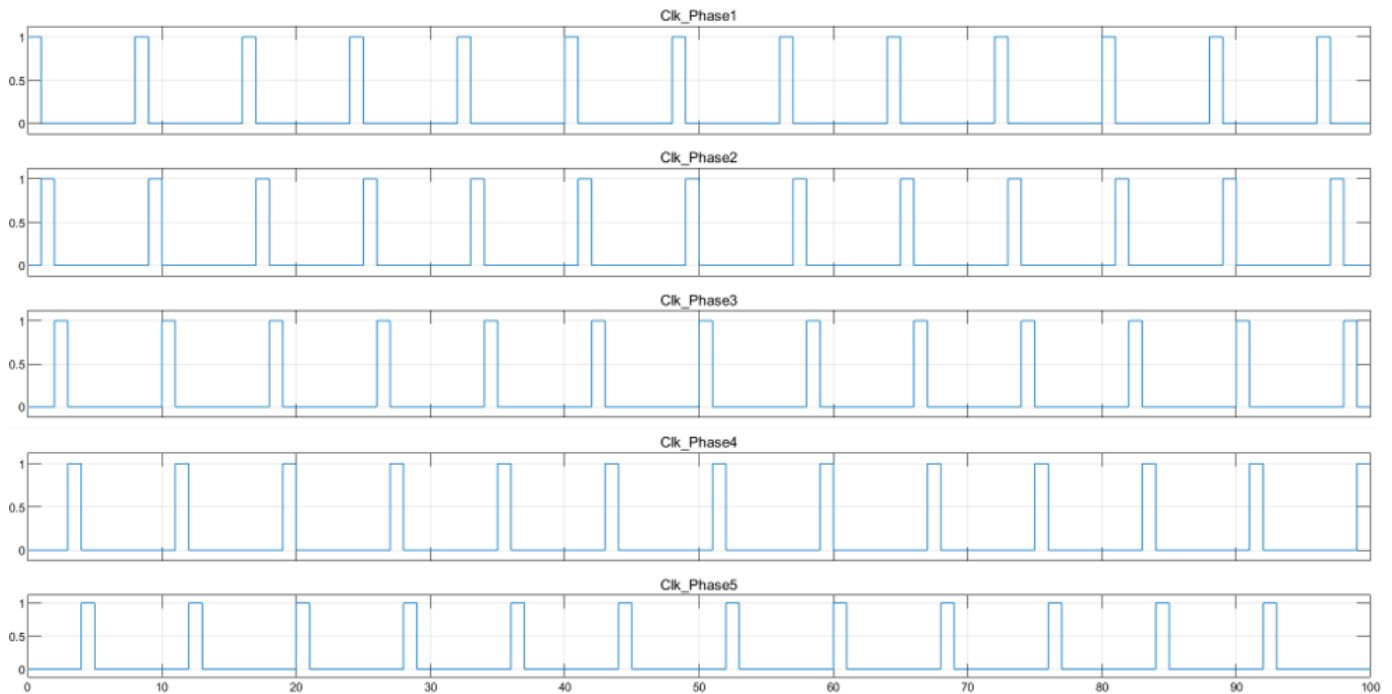

```

load_system("PhasedClocksUsingTriggeredSubsystem");
set_param("PhasedClocksUsingTriggeredSubsystem", 'SimulationCommand', 'Update')
open_system("PhasedClocksUsingTriggeredSubsystem");

```

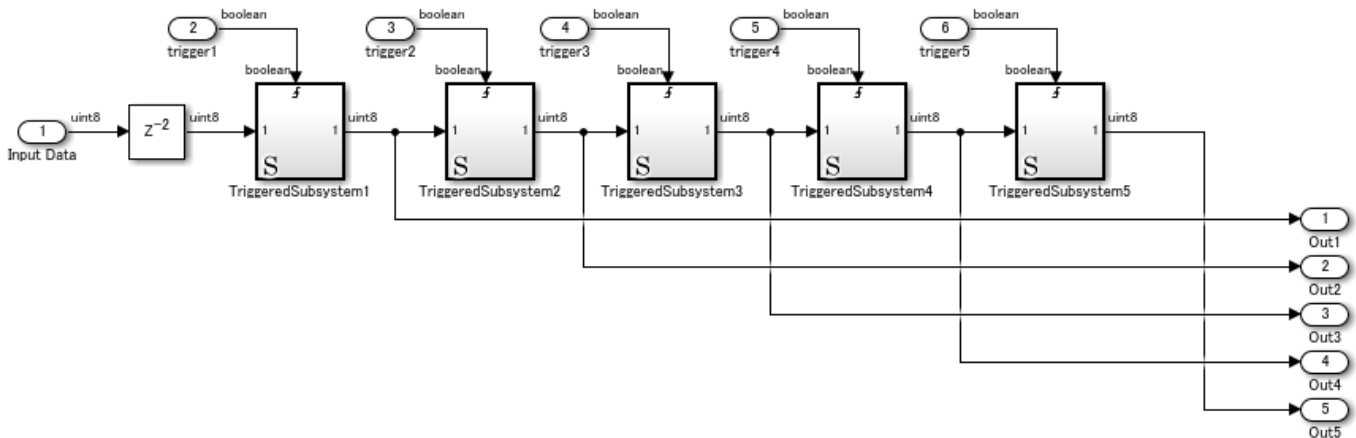

The model contains the Clock Generation subsystem which outputs five clock signals that run at same rate, but are out of phase. Run the simulation for the model and view waveforms of the phased clocks.

These clock signals are connected to trigger port of the triggered subsystems placed in the Phased_Clock_DUT subsystem. Open Phased_Clock_DUT subsystem.

```
open_system("PhasedClocksUsingTriggeredSubsystem/Phased_Clock_DUT");
```

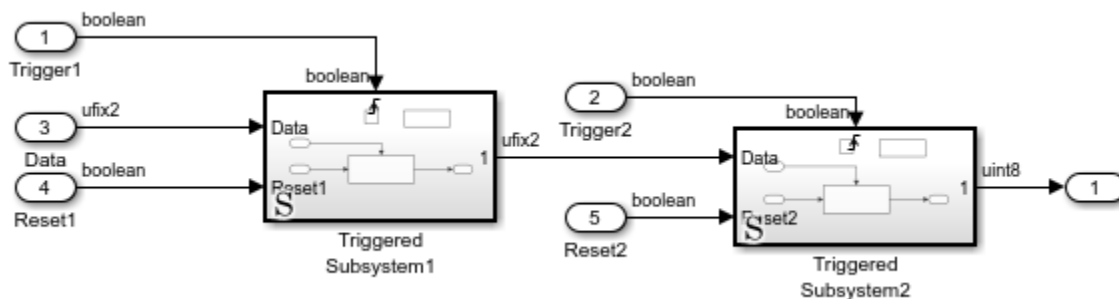

Enable **Use trigger signal as clock** option and generate HDL code for Phased_Clock_DUT subsystem. In the generated code, trigger port of the triggered subsystem acts as a clock which is driven by the corresponding clock signal.

Generate Multiple Clocks and Resets Using Triggered and Resettable Subsystems

This example shows how to model multiple clock and reset signals using triggered and resettable subsystems. Using trigger as clock functionality, you can model multiple clock signals from multiple triggered subsystems. By placing the resettable subsystem inside each triggered subsystem, you can model multiple reset signals in your Simulink model.

The model `AsynchronousClockandResetUsingTriggerAsClock` has a DUT subsystem which contains a two Triggered Subsystem. Load and open the `AsynchronousClockandResetUsingTriggerAsClock` model by running these commands:

```
load_system("AsynchronousClockandResetUsingTriggerAsClock");
set_param("AsynchronousClockandResetUsingTriggerAsClock", 'SimulationCommand', 'Update')
open_system("AsynchronousClockandResetUsingTriggerAsClock/DUT");
```

A resettable subsystem is placed within the triggered subsystem. Using resettable subsystem, you can model a reset port for your model. Minimize the global reset option so that model has reset ports from resettable subsystems. To minimize global reset option, enable **Minimize global resets** in the **HDL Code Generation > Global Settings > Ports** tab of the configuration settings.

To use trigger signal as clock in your generated HDL code, enable **Use trigger signal as clock** option in the **HDL Code Generation > Global Settings > Ports** tab of the configuration settings. Then, generate the HDL code for a DUT subsystem using `makehdl` command or HDL Coder™ app:

```
makehdl("AsynchronousClockandResetUsingTriggerAsClock/DUT")
```

The generated code for a DUT subsystem is shown in code snippet below. HDL Coder generates two trigger ports for the DUT subsystem which are used as clock signal in the triggered subsystems and two reset ports from the resettable subsystems.

```
ENTITY DUT IS
  PORT( Trigger1          : IN    std_logic;
        Trigger2        : IN    std_logic;
        Data             : IN    std_logic_vector(1 DOWNTO 0); -- ufix2
        Reset1          : IN    std_logic;
        Reset2          : IN    std_logic;
        Out2            : OUT   std_logic_vector(7 DOWNTO 0) -- uint8
        );
END DUT;

...
...

BEGIN
  u_Triggered_Subsystem1 : Triggered_Subsystem1
    PORT MAP( Trigger => Trigger1,
```

```
        Data => Data, -- ufix2
        Reset1 => Reset1,
        Out1 => Triggered_Subsystem1_out1 -- ufix2
    );

    u_Triggered_Subsystem2 : Triggered_Subsystem2
        PORT MAP( Trigger => Trigger2,
        Data => Triggered_Subsystem1_out1, -- ufix2
        Reset2 => Reset2,
        Out1 => Triggered_Subsystem2_out1 -- uint8
    );

    Out2 <= Triggered_Subsystem2_out1;

END rtl;
```

Overview

HDL Coder implements multirate systems in HDL by generating a primary clock running at the model base rate, and generating subrate timing signals from the primary clock (see also “Code Generation from Multirate Models” on page 27-2). The propagation time between two subrate registers can be more than one cycle of the primary clock. A multicycle path is a path between two such registers.

When synthesizing HDL code, it is often useful to provide an analysis of multicycle register-to-register paths to the synthesis tool. If the synthesis tool can identify multicycle paths, you may be able to:

- Realize higher clock rates from your multirate design.
- Reduce the area of your design.
- Reduce the execution time of the synthesis tool.

Using the **Generate multicycle path information** option (or the equivalent `MulticyclePathInfo` property for `makehdl`) you can instruct the coder to analyze multicycle paths in the generated code, and generate a multicycle path information file.

A multicycle path information file is a text file that describes one or more multicycle path constraints. A multicycle path constraint is a timing exception - it relaxes the default constraints on the system timing by allowing signals on a given path to have a longer propagation time. When using multiple clock mode, the file also contains clock definitions.

Typically a synthesis tool gives every signal a time budget of exactly 1 clock cycle to propagate from a source register to a destination register. A timing exception defines a *path multiplier*, N , that informs the synthesis tool that a signal has N clock cycles ($N > 1$) to propagate from the source to destination register. The path multiplier expresses some number of cycles of a *relative clock* at either the source or destination register. Where a timing exception is defined for a path, the synthesis tool has more flexibility in meeting the timing requirements for that path and for the system as a whole.

The generated multicycle path information file does not follow the native constraint file format of a particular synthesis tool. The file contains the multicycle path information required by popular synthesis tools. You can manually convert this information to multicycle path constraints in the format required by your synthesis tool, or write a script or tool to perform the conversion. The next section describes the format of a multicycle path constraint file in detail.

Format and Content of a Multicycle Path Information File

The following listing shows a simple multicycle path information file.

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Constraints Report
%   Module: Sbs
%   Model: mSbs.mdl
%
%   File Name:hdlsrc/Sbs_constraints.txt
%   Created: 2009-04-10 09:50:10
%   Generated by MATLAB 7.9 and HDL Coder 1.6
%
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Multicycle Paths
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
FROM : Sbs.boolireg; TO : Sbs.booloreg; PATH_MULT : 2; RELATIVE_CLK : source,
      Sbs.clk;
FROM : Sbs.boolireg_v<0>; TO : Sbs.booloreg_v<0>; PATH_MULT : 2;
      RELATIVE_CLK : source, Sbs.clk;
FROM : Sbs.doubireg; TO : Sbs.douboreg; PATH_MULT : 2; RELATIVE_CLK : source,
      Sbs.clk;
FROM : Sbs.doubireg_v<0>; TO : Sbs.douboreg_v<0>; PATH_MULT : 2;
      RELATIVE_CLK : source, Sbs.clk;
FROM : Sbs.intireg(7:0); TO : Sbs.intoreg(7:0); PATH_MULT : 2;
      RELATIVE_CLK : source, Sbs.clk;
FROM : Sbs.intireg_v<0>(7:0);TO : Sbs.intoreg_v<0>(7:0);PATH_MULT : 2
      RELATIVE_CLK : source,Sbs.clk;

```

The first section of the file is a header that identifies the source model and gives other information about how HDL Coder generated the file. this section terminates with the following comment lines:

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Multicycle Paths
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

```

Note For a single-rate model or a model without multicycle paths, the coder generates only the header section of the file.

The main body of the file follows. This section contains a flat table, each row of which defines a multicycle path constraint.

Each constraint consists of four fields. The format of each field is one of the following:

- KEYWORD : field;
- KEYWORD : subfield1,... subfield_N;

The keyword identifies the type of information contained in the field. The keyword string in each field terminates with a space followed by a colon.

The delimiter between fields is the semicolon. Within a field, the delimiter between subfields is the comma.

The following table defines the fields of a multicycle path constraint, in left-to-right order.

Keyword : field (or subfields)	Field Description
FROM : <i>src_reg_path</i> ;	The source (or FROM) register of a multicycle path in the system. The value of <i>src_reg_path</i> is the HDL path of the source register's output signal. See also "Register Path Syntax for FROM : and TO : Fields" on page 27-32.
TO : <i>dst_reg_path</i> ;	The destination (or TO) register of a multicycle path in the system. The FROM register drives the TO register in the HDL code. The value of <i>dst_reg_path</i> is the HDL path of the destination register's output signal. See also "Register Path Syntax for FROM : and TO : Fields" on page 27-32.
PATH_MULT : <i>N</i> ;	<p>The path multiplier defines the number of clock cycles that a signal has to propagate from the source to destination register. The RELATIVE_CLK field describes the clock associated with the path multiplier (the relative clock for the path).</p> <p>The path multiplier value <i>N</i> indicates that the signal has <i>N</i> clock cycles of its relative clock to propagate from source to destination register.</p> <p>The coder does not report register-to-register paths where <i>N</i> = 1, because this is the default path multiplier.</p>
RELATIVE_CLK : <i>relclock</i> , <i>sysclock</i> ;	<p>The RELATIVE_CLK field contains two comma-delimited subfields. Each subfield expresses the location of the relative clock in a different form, for the use of different synthesis tools. The subfields are:</p> <ul style="list-style-type: none"> • <i>relclock</i>: Since HDL Coder currently generates only single-clock systems, this subfield takes the value source. In a multi-clock system, the relative clock associated with a multicycle path could be either the source or destination register of the path, and this subfield could take on either of the values source or destination. This usage is reserved for future release of the coder. • <i>sysclock</i>: This subfield is intended for use with synthesis tools that require the actual propagation time for a multicycle path. <i>sysclock</i> provides the path to the system's top-level clock (e.g., <i>Sbs.clk</i>) You can use the period of this clock and the path multiplier to calculate the propagation time for a given path.

Register Path Syntax for FROM : and TO : Fields

The FROM : and TO : fields of a multipath constraint provide the path to a source or destination register and information about the signal data type, size, and other characteristics.

Fixed Point Signals

For fixed point signals, the register path has the form

```
reg_path<ps> (hb:lb)
```

where:

- *reg_path* is the HDL hierarchical path of the signal. The delimiter between hierarchical levels is the period, for example: *Sbs.u_H1.initreg*.
- *<ps>*: Part select (zero-origin integer index) for vector signals. Angle brackets *<>* delimit the part select field

- *(hb:lb)*: Bit select field, indicated from high-order bit to low-order bit. The signal width (*hb:lb*) is the same as the defined width of the signal in the HDL code. This representation does not necessarily imply that the bits of the FROM : register are connected to the corresponding bits of the TO : register. The actual bit-to-bit connections are determined during synthesis.

Boolean and Double Signals

For boolean and double signals, the register path has the form

```
reg_path<ps>
```

where:

- `reg_path` is the HDL hierarchical path of the signal. The delimiter between hierarchical levels is the period (`.`), for example: `Sbs.u_H1.intireg`.
- `<ps>`: Part select (zero-origin integer index) for vector signals. Angle brackets `<>` delimit the part select field

For boolean and double signals, no bit select field is present.

Note The format does not distinguish between boolean and double signals.

Examples

The following table gives several examples of register-to-register paths as represented in a multicycle path information file.

Path	Description
FROM : Sbs.intireg(7:0); TO : Sbs.intoreg(7:0);	Both signals are fixed point and eight bits wide.
FROM : Sbs.intireg; TO : Sbs.intoreg;	Both signals are either boolean or double.
FROM : Sbs.intireg<0>(7:0); TO : Sbs.intoreg<1>(7:0);	The FROM signal is the first element of a vector. The TO signal is the second element of a vector. Both signals are fixed point and eight bits wide.
FROM : Sbs.u_H1.intireg(7:0); TO : Sbs.intoreg(7:0);	The signal <code>intireg</code> is defined in the module <code>H1</code> , and <code>H1</code> is inside the module <code>Sbs.u_H1</code> . <code>u_H1</code> is the instance name of <code>H1</code> in <code>Sbs</code> . Both signals are fixed point and eight bits wide.

Ordering of Multicycle Path Constraints

For a given model or subsystem, the ordering of multicycle path constraints within a multicycle path information file may vary depending on whether the target language is VHDL or Verilog, and on other factors. The ordering of constraints may also change in future versions of the coder. When you design scripts or other tools that process multicycle path information file, do not build in any assumptions about the ordering of multicycle path constraints within a file.

Clock Definitions

When you use multiple clock mode, the multicycle path information file also contains a `Clock Definitions` section, as shown in the following listing. This section is located after the header and before the `Multicycle Paths` section.

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Clock Definitions
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
CLOCK: Sbs.clk PERIOD: 0.05
CLOCK: Sbs.clk_1_2 BASE_CLOCK: Sbs.clk MULTIPLIER: 2 PERIOD: 0.1

```

The following table defines the fields for the clock definitions.

Keyword : field (or subfields)	Field Description
CLOCK: clock_name	Each clock in the design has a CLOCK definition line.
PERIOD: float_value	The Simulink rate (floating point value) associated with this CLOCK.
BASE_CLOCK: base_clock_name	Names the primary clock. This field does not appear on the primary clock.
MULTIPLIER: int_value	Gives the ratio of the period of this clock to the primary clock. This field does not appear on the primary clock.

File Naming and Location Conventions

The file name for the multicycle path information file derives from the name of the DUT and the postfix string `'_constraints'`, as follows:

```
DUTname_constraints.txt
```

For example, if the DUT name is `symmetric_fir`, the name of the multicycle path information file is `symmetric_fir_constraints.txt`.

HDL Coder writes the multicycle path information file to the target .

Generating Multicycle Path Information Files Using the GUI

To enable generation of multicycle path information files, select **Register-to-register path info** in the **Multicycle Path Constraints** section of the **HDL Code Generation > Target and Optimizations** pane of the Configuration Parameters dialog box.

When you select this check box and generate code for your model, the code generator creates a multicycle path information file.

Generating Multicycle Path Information Files Using the Command Line

To generate a multicycle path information file from the command line, pass in the property/value pair `'MulticyclePathInfo', 'on'` to `makehdl`, as in the following example.

```

>> dut = 'hdlfirtdecim_multicycle/Subsystem';
>> makehdl(dut, 'MulticyclePathInfo', 'on');
### Generating HDL for 'hdlfirtdecim_multicycle/Subsystem'
### Starting HDL Check.
### HDL Check Complete with 0 errors, 0 warnings and 1 message.

### MESSAGE: For the block 'hdlfirtdecim_multicycle/Subsystem/downsamp0'
    The initial condition may not be used when the sample offset is 0.

### Begin VHDL Code Generation
### Working on Subsystem_tc as hdlsrc\Subsystem_tc.vhd
### Working on hdlfirtdecim_multicycle/Subsystem as hdlsrc\Subsystem.vhd
### Generating package file hdlsrc\Subsystem_pkg.vhd

```

```

### Finishing multicycle path connectivity analysis.
### Writing multicycle path information inhdlsrc\Subsystem_constraints.txt
### HDL Code Generation Complete.

```

Limitations

Unsupported Blocks and Implementations

The following table lists block implementations (and associated Simulink blocks) that will not contribute to multicycle path constraints information.

Implementation	Block(s)
SumCascadeHDLEmission	Add, Subtract, Sum, Sum of Elements
ProductCascadeHDLEmission	Product, Product of Elements
MinMaxCascadeHDLEmission	MinMax, Maximum, Minimum
ModelReferenceHDLInstantiation	Model
SubsystemBlackBoxHDLInstantiation	Subsystem
RamBlockDualHDLInstantiation	Dual Port RAM
RamBlockSimpDualHDLInstantiation	Simple Dual Port RAM
RamBlockSingleHDLInstantiation	Single Port RAM

Limitations on MATLAB Function Blocks and Stateflow Charts

Loop-Carried Dependencies

HDL Coder does not generate constraints for MATLAB Function blocks or Stateflow charts that contain a for loop with a loop-carried dependency.

Indexing Vector or Matrix Variables

In order to generate constraints for a vector or matrix index expression, the index expression must be one of the following:

- A constant
- A for loop induction variable

For example, in the following example of code for a MATLAB Function block, the index expression `reg(i)` does not generate constraints.

```

function y = fcn(u)
%#codegen

N=length(u);
persistent reg;
if isempty(reg)
    reg = zeros(1,N);
end

y = reg;

for i = 1:N-1
    reg(i) = u(i) + reg(i+1);
end
reg(N) = u(N);

```

File Generation Time

Tip Generation of constraint files for large models can be slow.

Meet Timing Requirements Using Enable-Based Multicycle Path Constraints

“Limitations” on page 27-42

If your Simulink model contains multiple sample rates or uses speed and area optimizations that insert pipeline registers, your design can have multicycle paths. Multicycle paths are data paths between two registers that operate at a sample rate slower than the FPGA clock rate and therefore take multiple clock cycles to complete their execution. To synchronize the clock rate to the sample rates of various paths in your design, you can use a single clock mode or a multiple clock mode. By default, HDL Coder uses a single clock mode that generates a single primary clock at the fastest sample rate and creates a timing controller entity to control the clock rate to the multicycle paths. The timing controller generates a set of clock enables with the required rate and phase information to control the sequential elements such as Delay blocks that operate at different sample rates.

When you synthesize the generated HDL code, synthesis tools can fail to meet the timing requirements of multicycle paths. The timing failure occurs because synthesis tools cannot infer the various sample rates in your design from the generated HDL code. The synthesis tools assume that the registers in your design run at the primary clock rate and requires data to travel between the registers within one clock cycle. However, the multicycle paths are not required to complete their execution within one clock cycle and therefore cannot meet the timing requirements. To meet the timing requirements, specify generation of enable-based multicycle path constraints.

How Enable-Based Multicycle Path Constraints Work

Synthesis tools require that data propagates from a source register to a destination register within one clock cycle. Multicycle path constraints relax this timing requirement by allowing multiple clock cycles for data to propagate between the registers. The code generator uses the timing controller enable signals to create enable-based register groups, with registers in each group driven by the same clock enable. When you apply the enable-based constraints and generate HDL code, the code generator outputs a constraints file with the naming convention `dutname_constraints`. The file defines the timing requirements of multicycle paths and contains information about the setup and hold constraints that needs to be met.

This figure shows a multicycle path that takes a certain number of clock cycles, say N , for the data to propagate from REGA to REGB. By default, the synthesis tools define the setup edge at the next active clock edge and the hold edge at the same active clock edge with respect to the destination clock signal. For a multicycle path that takes N clock cycles, the constraints redefine the setup and hold edge to allow for the longer data propagation time.

For example, consider a multicycle path takes two clock cycles for data to propagate from the source to the destination register. This waveform shows how applying enable-based constraints redefines the setup and hold edges. This code snippet shows this setup and hold requirement in the constraints file that gets generated when you enable multicycle path constraints.

```
set_multicycle_path 2 -setup -from $REGA -to $REGB
set_multicycle_path 1 -hold -from $REGA -to $REGB
```

Specify Enable-Based Constraints

Before you generate the enable-based constraints, you must:

- Preserve the multicycle paths in your design. Before you enable generation of multicycle path constraints, make sure that you disable optimizations such as clock rate pipelining and adaptive pipelining in those regions where you want to apply multicycle path constraints.

- Make sure that the region that operates at a slower clock rate is bounded by timing controller based clock enable signals operating at zero phase.
- Specify the **Synthesis tool**. The format of the multicycle path constraints file that gets generated depends on the **Synthesis tool** that you specify. If you do not specify the synthesis tool and the **Generate EDA Scripts** check box is selected, HDL Coder does not generate multicycle path constraints.
- Use the single clock mode. In the **HDL Code Generation > Global Settings** pane, set **Clock Inputs** to Single.

You can specify generation of multicycle constraints in the Configuration Parameters dialog box, or in the HDL Workflow Advisor UI, or at the command line.

- In the Configuration Parameters dialog box, on the **HDL Code Generation > Target and Optimizations** pane, select the **Enable based constraints** check box.
- In the HDL Workflow Advisor, on the **HDL Code Generation > Set Code Generation Options > Set Optimization Options** task, select the **Enable based constraints** check box.
- At the command line, use the `MulticyclePathConstraints` property with `hdlset_param` or `makehdl`.

Benefits of Using Enable-Based Constraints

If the synthesis tools identify the multicycle path constraints, you can:

- Realize higher clock rates and improve the timing of your design.
- Reduce the area footprint on the target FPGA device because multicycle path constraints do not introduce any pipeline registers.
- Reduce HDL code generation time because the code generator does not have to run many optimization settings.
- Reduce synthesis time since multicycle path constraints relax the timing requirements on the synthesis tool.
- Skip verification of your design after generating HDL code as the generated model with the constraints is identical to the original model.

When you specify the multicycle path information to the synthesis tool, it is not recommended to use the **Register-to-register path info** setting in the **Target and Optimizations** pane. If you use this setting, the code generator outputs a text file that describes the multicycle path information in a format that is not native to a particular synthesis tool. You must convert this information to the multicycle path constraints format required by your synthesis tool.

When you use the enable-based constraints setting:

- The generated constraints are more robust to name changes in synthesis tools.
- HDL code generation becomes faster.
- The **Target workflow** can be Generic ASIC/FPGA, FPGA Turnkey, IP Core Generation, and Simulink Real-Time FPGA I/O.
- The constraint file format is supported with Xilinx ISE, Xilinx Vivado, and Altera QUARTUS II.

Modeling Guidelines

When you specify generation of enable-based constraints, use these modeling patterns in your design. If your model contains slow-rate regions that are not bounded by registers, then add delays at the same slow rate to the input and output of the slow-rate regions. For example, if you enter `hdlcoder_clockdemo` at the command line in MATLAB, you see a multirate CIC Interpolation filter implemented in single clock mode. This figure shows how to bound the input and output of the slow-rate region annotated by the slow sample time D2 in the model with Unit Delay blocks so that the enable-based constraints can identify the slow-rate path.

Note You can use Rate Transition blocks to introduce the input and output registers but make sure that the registers are slow rate and have zero phase.

Multicycle Path Constraints for Various Synthesis Tools

Enable-based multicycle path constraints have various file formats that depend on the **Synthesis tool** that you specify.

Altera Quartus II

HDL Coder generates the constraints in the form of an SDC file. This code snippet shows the SDC file generated for Altera Quartus II.

```
# Multicycle constraints for clock enable: DUT_tc.u1_d4_o0
set enbreg [get_registers *u_DUT_tc|phase_0]
set_multicycle_path 4 -to [get_fanouts $enbreg -through [get_pins -hier *|ena]] -end -setup
set_multicycle_path 3 -to [get_fanouts $enbreg -through [get_pins -hier *|ena]] -end -hold
```

Xilinx Vivado

HDL Coder generates the constraints in the form of an XDC file. This code snippet shows the XDC file generated for Xilinx Vivado.

```
# Multicycle constraints for clock enable: DUT_tc.u1_d4_o0
set enbregcell [get_cells -hier -filter {mcp_info=="DUT_tc.u1_d4_o0"}]
set enbregnet [get_nets -of_objects [get_pins -of_objects $enbregcell -filter {DIRECTION == OUT}]
set reglist [get_cells -of [filter [all_fanout -flat -endpoints_only $enbregnet] IS_ENABLE]]
set_multicycle_path 4 -setup -from $reglist -to $reglist -quiet
set_multicycle_path 3 -hold -from $reglist -to $reglist -quiet
```

The multicycle path constraints form enable-based register groups by querying the synthesis netlist for the `ATTRIBUTE` keyword. When you run any of the supported target workflows, this code snippet shows this keyword in the synthesis netlist.

```

...
ATTRIBUTE mcp_info: string

ATTRIBUTE mcp_info OF phase_0 : SIGNAL IS "DUT_tc.u1_d4_o0";
...

```

The constraints file that is generated for Xilinx Vivado is more robust than pattern matching on module or signal names.

Xilinx ISE

HDL Coder generates the constraints in the form of a UCF file. This code snippet shows the UCF file generated for a model that has one slow-rate region controlled by a clock enable signal and has a target frequency of 300MHz. The multicycle path constraints depend on the **Target Frequency** that you specify.

```

# Multicycle constraints for clock enable: DUT_tc.u1_d4_o0
NET "*u_DUT_tc/phase_0" TNM_NET = FFS "TN_u_DUT_tc_phase_0";
TIMESPEC "TS_u_DUT_tc_phase_0" = FROM "TN_u_DUT_tc_phase_0" TO "TN_u_DUT_tc_phase_0" TS_FPGA_CLK;

```

The clock constraints that are generated when you run the Generic ASIC/FPGA, FPGA Turnkey, or the Simulink Real-Time FPGA I/O workflow with Xilinx ISE are shown in this code.

```

# Timing Specification Constraints

NET "clk" TNM_NET = "TN_clk";
TIMESPEC "TS_FPGA_CLK" = PERIOD "TN_clk" 300 MHz;

```

To use the multicycle path constraints when you generate HDL code by using the `makehdl` function, make sure that you add a `TS_FPGA_CLK` constraint to the UCF file.

Preserve Enable Signals in Timing Control Logic

When you apply enable-based multicycle path (MCP) constraints to relax the timing constraints on multicycle data paths, HDL Coder generates MCP with timing controller logic. If you source enable-based constraints to the synthesis tool, the synthesis tool optimizes this timing controller logic to convert it to the single clock domain design. The MCP constraints are not applied in the generated HDL code. To preserve this timing control logic in the synthesis tool, HDL Coder adds an attribute `direct_enable` to all of the enable signals in your generated timing controller HDL code.

This generated VHDL code shows the `direct_enable` attribute is added to the enable signal in timing controller logic:

```

...
ATTRIBUTE direct_enable OF enb_1_1_1: SIGNAL IS "yes";
...

```

This generated Verilog code shows the `direct_enable` attribute is added to the enable signal in timing controller logic:

```

...
(* direct_enable = "yes" *) output enb_1_1_1;
...

```

Due to the `direct_enable` attribute, the MCP constraints are applied to your design when you source MCP constraints in the synthesis tool.

Limitations

- The multicycle path constraints file is not supported with the FPGA-in-the-Loop workflow.
- If the slow-rate region is not bounded by registers, multicycle path constraints require that you to add two Delay blocks at the slow rate, which increases the latency of your design.
- The code generator does not add constraints on paths between registers that have a nonzero phase value for the timing controller-based enable signals. For the code generator to add constraints, use registers that derive from phase 0 clock enable signals, such as Delay blocks.
- The generated multicycle constraints can be less effective if you apply the constraints to regions that have optimizations such as clock-rate pipelining and adaptive pipelining enabled. With clock-rate pipelining, the registers operate at the faster clock rate and might not retain the slow-rate registers in your design.
- HDL Coder does not generate multicycle path constraints for single-rate models.
- If you use the multiple clock mode, the code generator does not output the multicycle path constraints file.

Use Multicycle Path Constraints to Meet Timing for Slow Paths

This example shows how to apply multicycle path constraints in your design to meet timing requirements. Using multicycle path constraints can save area and reduce synthesis run times. For more information, see “Meet Timing Requirements Using Enable-Based Multicycle Path Constraints” on page 27-37.

Introduction

Algorithms modeled in Simulink® for HDL code generation can have multiple sample rates. These multiple rates can be part of the Simulink model, or can be introduced with HDL Coder™ options such as oversampling. With oversampling specified, the generated HDL code will run on the FPGA at a faster clock rate. This faster rate allows additional optimizations to take effect.

When HDL Coder is configured to use a single clock, it generates a timing controller to control clocked elements, such as delays, at different sample rates with clock enables. These clock enables are synchronous to the single clock and toggle at rates that are multiple times slower than the base clock. The data paths between slow clocked element pairs are called multicycle paths, because they allow data to take multiple clock cycles to travel. However, synthesis tools cannot infer this acceptable delay directly from the HDL code. The tools assume that data changes every cycle and must travel from one register to the next within one clock cycle. Synthesis tools have to take more effort to meet the excessive timing requirement and therefore can fail timing. By declaring a set of data paths as multicycle paths and providing the actual timing of these paths to the downstream synthesis tool, HDL Coder can simplify and accelerate the process of meeting the desired timing constraints for a design.

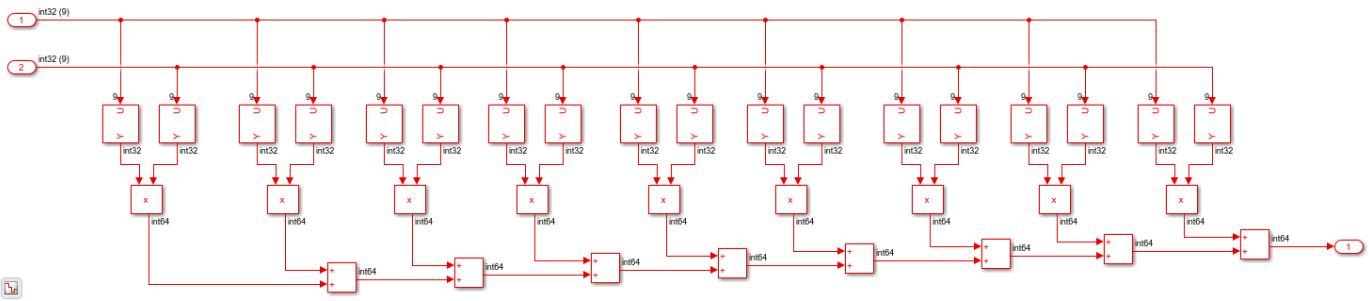

This example demonstrates how to generate multicycle path constraints in HDL Coder so that timing requirements may be specified, allowing efficient timing analysis in the synthesis tool.

Applying multicycle constraints using HDL Coder

In this example, we use Xilinx® Vivado® 2020.2 post place and routing static timing analysis results for a Zynq® UltraScale+(TM) device (xazu11eg-ffvf1517-1-i) to show the impact of enabled based multicycle path constraints. Other synthesis tools and devices have similar behavior. HDL Coder generates constraint files of XDC format for Xilinx Vivado, UCF format for Xilinx ISE, and SDC format for Altera Quartus II.

Consider the example, `hdlcoder_multi_cycle_path_constraints.slx`. The model contains a direct form FIR filter with an adder chain in the critical path. While the input data rate of this filter is specified to be 2MHz, we want this design to run as fast as possible so that it can be integrated with other IPs requiring high frequency. We start by choosing a 130MHz clock frequency without any timing optimization by setting the **Oversampling factor** to 65 and the **Target Frequency** to 130.

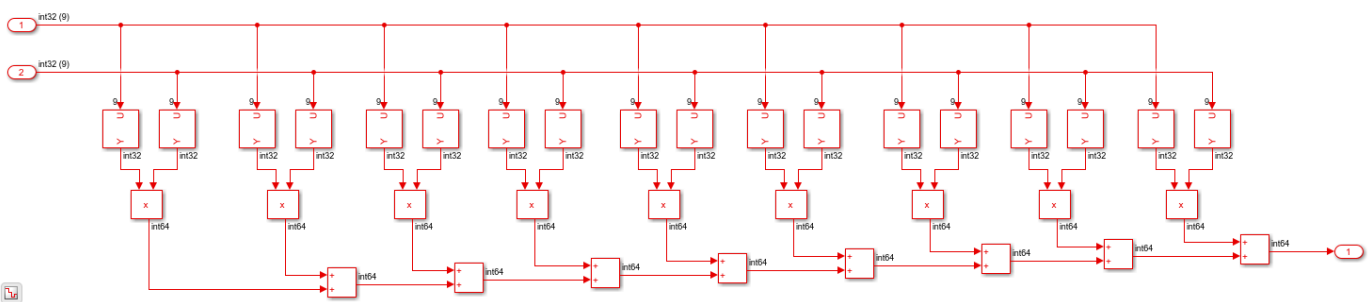

```
bdclose('all');
load_system('hdlcoder_multi_cycle_path_constraints');
open_system('hdlcoder_multi_cycle_path_constraints/Subsystem/Dot Product');
hdlset_param('hdlcoder_multi_cycle_path_constraints', 'Oversampling', 65);
hdlset_param('hdlcoder_multi_cycle_path_constraints', 'TargetFrequency', 130);
set_param('hdlcoder_multi_cycle_path_constraints', 'SimulationCommand', 'update');
```

Generate HDL with these settings and inspect the generated model. Notice that the generated model is actually identical to the original model.

```
makehdl('hdlcoder_multi_cycle_path_constraints/Subsystem');
load_system('gm_hdlcoder_multi_cycle_path_constraints');
set_param('gm_hdlcoder_multi_cycle_path_constraints', 'SimulationCommand', 'update');
open_system('gm_hdlcoder_multi_cycle_path_constraints/Subsystem/Dot Product');
```

### HDL code generation complete.
```

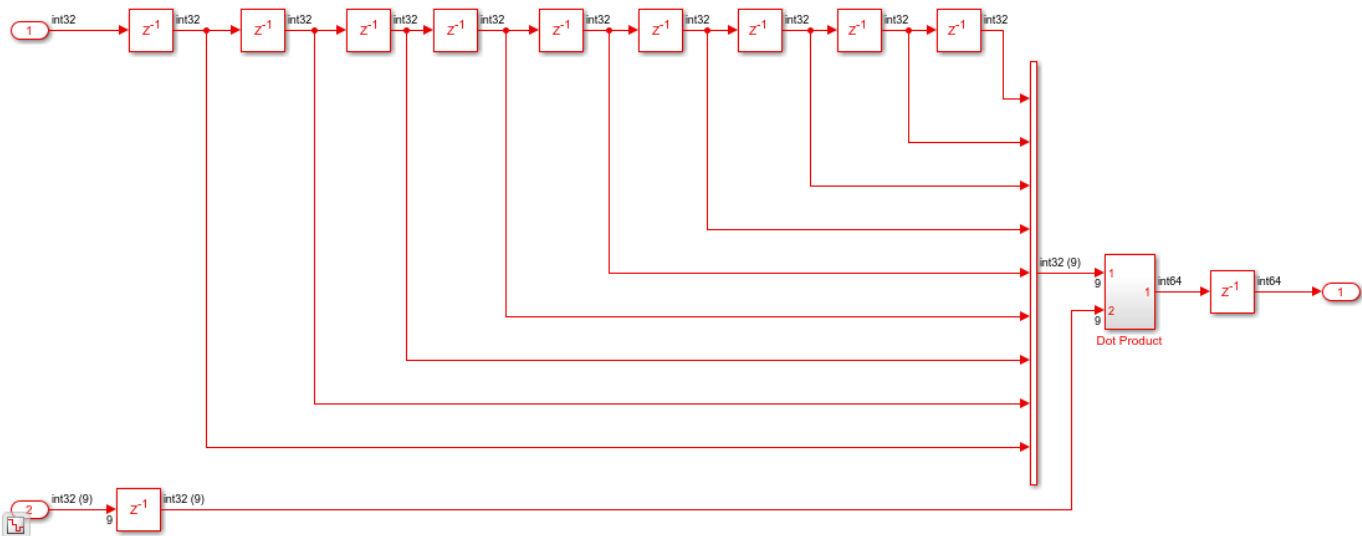

The generated HDL fails to meet the timing requirement for the clock at 130MHz. As shown in the timing report snippet below, the timing requirement is 7.692 ns (1/130MHz) and a negative slack indicates a timing violation of this requirement. Other synthesis tools' timing reports may look different, although the critical path from this example design will remain the same.

Max Delay Paths

```
-----
Slack (VIOLATED) : -1.979ns (required time - arrival time)
Source: Delay6_out1_reg[8]/C
(rising edge-triggered cell FDCE clocked by MWCLK {rise@0.000ns fall@3.846ns period=7.692ns});
Destination: Delay1_out1_reg[61]/D
(rising edge-triggered cell FDCE clocked by MWCLK {rise@0.000ns fall@3.846ns period=7.692ns});
Path Group: MWCLK
Path Type: Setup (Max at Slow Process Corner)
Requirement: 7.692ns (MWCLK rise@7.692ns - MWCLK rise@0.000ns)
Data Path Delay: 9.686ns (logic 7.297ns (75.333%) route 2.389ns (24.667%))
```

We are going to use multicycle path constraints to meet timing requirements. Check the original model.

```
open_system('hdlcoder_multi_cycle_path_constraints/Subsystem');
```

Notice that the Dot Product subsystem is surrounded by delays running at the desired 2MHz data rate. Due to the specified 65x oversampling, the design can tolerate multiple clock cycles for the data to propagate through it. HDL Coder requires multicycle regions to be surrounded by slow clocked elements, such as these delays, so that the constraints can define the paths among them as multicycle paths. Turn MulticyclePathConstraints on and HDL Coder will generate an additional file.

```
hdlset_param('hdlcoder_multi_cycle_path_constraints', 'MulticyclePathConstraints', 'on');
```

We can even increase the target frequency to 300MHz.

```
hdlset_param('hdlcoder_multi_cycle_path_constraints', 'Oversampling', 150);
hdlset_param('hdlcoder_multi_cycle_path_constraints', 'TargetFrequency', 300);
```

Generate HDL and multicycle path constraints.

```
makehdl('hdlcoder_multi_cycle_path_constraints/Subsystem');
```

6  set_multicycle_path 149 -hold -from $reglist1 -to $reglist1 -quiet
7
8  # Multicycle constraints for clock enable: Subsystem_tc.u1_d150_o1
9  set enbregcell [get_cells -hier -filter {mcp_info=="Subsystem_tc.u1_d150_o1"}]
10 set enbregnet [get_nets -of_objects [get_pins -of_objects $enbregcell -filter {DIRECTION ==
11 set reglist2 [get_cells -of [filter [all_fanout -flat -endpoints_only $enbregnet] IS_ENABL
12 set_multicycle_path 150 -setup -from $reglist2 -to $reglist2 -quiet
13 set_multicycle_path 149 -hold -from $reglist2 -to $reglist2 -quiet
14
15 # Multicycle constraints from clock enable: Subsystem_tc.u1_d150_o1 to clock enable: Subsys
16 set_multicycle_path 149 -setup -from $reglist2 -to $reglist1 -quiet
17 set_multicycle_path 149 -hold -from $reglist2 -to $reglist1 -quiet
18
19 # Multicycle constraints from clock enable: Subsystem_tc.u1_d150_o0 to clock enable: Subsys
20 set_multicycle_path 151 -setup -from $reglist1 -to $reglist2 -quiet
21 set_multicycle_path 149 -hold -from $reglist1 -to $reglist2 -quiet
22

```

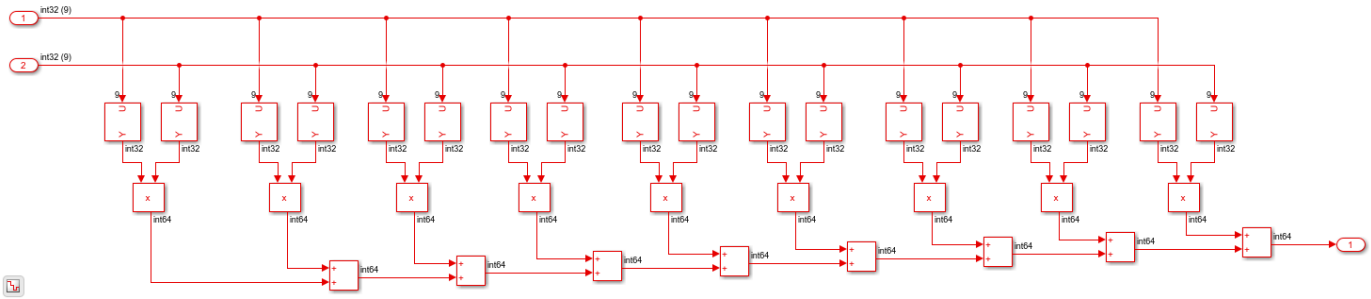

These constraints first find flip flops that are driven by the 2MHz clock enable signal. Then, they define the paths among these flip flops multicycle paths to allow up to 150 cycles for data to propagate.

Inspect the generated model.

```

open_system('gm_hdlcoder_multi_cycle_path_constraints/Subsystem/Dot Product');
set_param('gm_hdlcoder_multi_cycle_path_constraints', 'SimulationCommand', 'update');

```

The generated model and HDL code are identical to the previous results, because generating enabled based multicycle path constraints does not alter the HDL architecture. The design was previously unable to meet the desired timing at 130MHz. However, when you specify multicycle path constraints, this design can run at 300MHz on the FPGA.

Max Delay Paths

```
Slack (MET) : 0.612ns (required time - arrival time)
Source:      u_Subsystem_tc/phase_0_reg/C
              (rising edge-triggered cell FDCE clocked by MWCLK {rise@0.000ns fall@1.666ns period=3.333ns};
Destination: Delay6_out1_reg[4]/CE
              (rising edge-triggered cell FDCE clocked by MWCLK {rise@0.000ns fall@1.666ns period=3.333ns};
Path Group:  MWCLK
Path Type:   Setup (Max at Slow Process Corner)
Requirement: 3.333ns (MWCLK rise@3.333ns - MWCLK rise@0.000ns)
Data Path Delay: 2.408ns (logic 0.399ns (16.570%) route 2.009ns (83.430%))
```

Additional information about multicycle path constraints:

Multicycle path constraints are required for synthesis tools to understand timing requirements. This information is extracted from the Simulink model since it cannot be inferred from the generated HDL code. Multicycle path constraints identify paths between clocked elements driven by the same clock enable. It can fail to meet timing requirements in certain cases. For example, a data path is not recognized as a multicycle path, if it is not gated with both input and output delays or is between two delays of different rates. Therefore, if you want to use multicycle path constraints for certain parts in your design, it is important to retain the multicycle paths in that region from being altered by optimizations introducing pipelines, such as input and output pipelining, clock rate pipelining, adaptive pipelining resource sharing, streaming, pipelined math operations, e.g. Newton-Raphson method for sqrt or recip, Cordic algorithm for trigonometric functions, and floating-point IP mapping.

Speed and Area Optimizations in HDL Coder

Use area and speed optimizations in HDL Coder to save resources and improve the timing of your design on the target FPGA device. The optimizations do not change the functional behavior of your algorithm but can optimize certain resources in your design, introduce latency, or cause difference in sample rates.

You can initially generate HDL code and synthesize your design on your FPGA platform without enabling optimizations. If the design does not meet the timing requirements, you can enable the optimizations and rerun the workflow until your design meets the area and speed requirements. See “Basic HDL Code Generation Workflow”.

Optimizations in MATLAB HDL Code Generation

To enable optimizations on your MATLAB code, open the Workflow Advisor from MATLAB. In the Advisor, on the **HDL Code Generation** task, enable the settings in the **Optimization** tab.

Optimizations in Simulink HDL Code Generation

You can enable optimizations at the model level and at the block level. Specify model-level optimizations:

- In the Configuration Parameters dialog box, on the **HDL Code Generation > Optimization** pane. See “HDL Code Generation Pane: Optimization” on page 16-7.

- At the command line by using the `makehdl` or `hdlset_param` function to set the property value.
- In the Simulink HDL Workflow Advisor, on the **Set HDL Option** task, the **HDL Code Generation Settings** button opens the HDL code generation settings in the Configuration Parameters dialog box. You can then navigate to the **HDL Code Generation > Optimization** pane.

Subsystems in your model inherit the model-level optimization settings. You can change the subsystem level settings in the HDL Block Properties dialog box for the subsystems or by using the `hdlset_param` function. You can also specify certain additional settings for certain blocks in your model such as adding pipelines at the input and output. This table illustrates various optimizations that are available at the block level and model level.

Optimization	Model Level?	Subsystem Level?	Comments
Delay balancing	Yes	Yes	–
RAM mapping	Yes	No	–
Adaptive pipelining	Yes	Yes	–
Clock rate pipelining	Yes	Yes	–
Distributed pipelining	Yes	Yes	–
Resource sharing	Yes	Yes	At the model level, you specify the type of resources you want to share such as adders and multipliers. At the block level, you specify the SharingFactor .
Streaming	No	Yes	–

To see the effect of the optimizations:

- You can generate an optimization report with the HDL code. To learn how to enable this report, see “Create and Use Code Generation Reports” on page 30-2.
- Open the generated model or generate the validation model. The generated model is a behavioral model of the HDL code that shows the effect of block implementations and optimizations that you enabled. To verify the numerics of the generated model with the original model, you can generate a validation model. See “Generated Model and Validation Model” on page 28-10.

Tip To effectively use optimizations, change the sample time setting for Constant blocks from Inf to -1.

General Optimizations

Your model can have design delays and pipeline delays. Design delays are delays that you manually add to your model. Pipeline delays are delays that are introduced by pipelining settings specified on the blocks, block implementations such as Newton-Raphson method, native floating-point operators, or speed optimizations. You see these delays in the generated HDL code, generated model, and validation model.

General optimization parameters includes:

- RAM mapping: Use RAM mapping parameters to map large delays, persistent variables in MATLAB code, and pipeline delays to RAM based on a threshold bit width. See also “Apply RAM Mapping to Optimize Area” on page 28-122 and “RAM Mapping Parameters” on page 19-6.
- Delay balancing: Enabled by default, this optimization balances pipeline delays by inserting matching delays in parallel paths. The optimization matches numerics of the generated model with the original model. You see the effect of this optimization in the **Delay Balancing** section of the optimization report. See “Delay Balancing” on page 28-81.

Speed Optimizations

Speed optimizations improve the timing of your design on the target FPGA by optimizing the critical path. To identify the critical path, you can run the Generic ASIC/FPGA workflow for your FPGA device and then annotate the critical path or use the timing reports.

To identify the critical path more quickly and speed up the iterative process of finding and optimizing the critical path, use critical path estimation. You do not have to run synthesis or generate HDL code. Critical path estimation uses static timing analysis with timing data from target-specific timing databases. You see the effect of this optimization in the **Critical Path Estimation** section of the optimization report. See “Critical Path Estimation Without Running Synthesis” on page 28-192.

Speed optimizations include:

- Clock rate pipelining: A Simulink optimization that is enabled by default, and runs pipeline registers at a faster clock rate when you specify an **Oversampling factor** greater than one. Use clock-rate pipelining with hierarchy flattening to remove hierarchical boundaries in a subsystem, thereby improving retiming. See “Clock-Rate Pipelining” on page 28-149.
- Distributed pipelining: An optimization that retimes registers that are existing delays, or specified by using **InputPipeline** and **OutputPipeline** block settings. To preserve existing delays, enable the “Preserve design delays” on page 19-14 setting. To more accurately reflect how components function on hardware to better distribute pipelines and increase clock speed for your target device, use synthesis timing estimates for distributed pipelining. See “Use synthesis estimates for distributed pipelining” on page 19-14. Enable distributed pipelining on the model for retiming registers across hierarchies. You see the effect of this optimization in the **Distributed Pipelining** section of the optimization report. See “Distributed Pipelining” on page 28-131.
- Adaptive pipelining: A Simulink optimization that inserts pipeline registers at input or output or both ports of certain blocks to create patterns that efficiently map blocks to DSP units on the target FPGA device. The optimization considers the target device, target frequency, multiplier word lengths, and the HDL Block Property settings. You see the effect of this optimization in the **Adaptive Pipelining** section of the optimization report. See “Adaptive Pipelining” on page 28-181.
- Loop Unrolling: A MATLAB optimization that unrolls a loop by instantiating multiple instances of the loop body in the generated code. You can also partially unroll a loop. See “Optimize MATLAB Loops” on page 8-29

Area Optimizations

Area optimizations reduce resource usage of your design. Optimizing your design for area can reduce the speed at which your design runs on the FPGA.

Area optimizations include:

- **Resource Sharing:** An optimization that identifies multiple functionally equivalent resources and replaces them with a single resource. At the model level, you specify resources you want to share such as adders and multipliers. At the subsystem level, you specify a **SharingFactor** depending on the number of shareable resources in your design. By using the optimization with clock-rate pipelining, you can specify how to overclock the shared resources. See “Resource Sharing” on page 28-45
- **Streaming:** A Simulink optimization that splits a vector data path into multiple smaller vector data paths based on the **StreamingFactor** that you specify on the subsystems, thereby reducing hardware resource consumption. See “Streaming” on page 28-42.
- **Loop Streaming:** A MATLAB optimization that streams a loop by instantiating the loop body once and using that instance for each loop iteration. The code generator oversamples the loop body instance to keep the generated loop functionally equivalent to the original loop. See “Optimize MATLAB Loops” on page 8-29

Automatic Iterative Optimization

In this section...

“How Automatic Iterative Optimization Works” on page 28-7
 “Automatic Iterative Optimization Output” on page 28-8
 “Automatic Iterative Optimization Report” on page 28-8
 “Automatic Iterative Optimization Synthesis Tool and Hardware” on page 28-9
 “Limitations of Automatic Iterative Optimization” on page 28-9

Automatic iterative optimization enables you to optimize your clock frequency without specifying individual optimization options, such as input or output pipelining, distributed pipelining, or loop unrolling. Clock frequency is determined by the critical path of your design. Automatic iterative optimization improves clock frequency by inserting pipeline registers to break and shorten the critical path.

You can use `hdlcoder.optimizeDesign` to optimize your clock frequency in these ways:

- **Best clock frequency:** Specify the maximum number of iterations that you want HDL Coder to perform. HDL Coder iterates the optimization to minimize the critical path in your design.
- **Target clock frequency:** Specify a clock frequency target for your design and the maximum number of iterations you want HDL Coder to perform. HDL Coder iterates the optimization until it meets your target clock frequency or reaches the maximum number of iterations.

HDL Coder can determine that your target clock frequency is not achievable because your target clock period is less than the latency of the largest atomic combinational group of logic in your design.

How Automatic Iterative Optimization Works

You can specify your clock frequency goal, the maximum number of iterations, and the timing strategy for the iterative optimization by using the `hdlcoder.OptimizationConfig` object properties. Depending on the timing strategy that you choose, synthesis (the default) or critical path estimation, the steps that HDL Coder performs for each iteration vary.

Running the automatic iterative optimization with synthesis can take a long time, depending on the complexity of your design. For example, when running the `hdl.optimizeDesign` function that has synthesis as the timing strategy, synthesis can occupy nearly 94% of the run time of this function. To help mitigate the runtime and still use synthesis, the `hdlcoder.optimizeDesign` function can regenerate code from a previous run or resume from an interrupted run.

To help mitigate the runtime most effectively, you can choose critical path estimation as your timing strategy. Critical path estimation provides an estimated critical path rather than the actual critical path determined by synthesis. When using critical path estimation, automatic iterative optimization avoids model generation and HDL code generation to help increase the speed of every iteration. Critical path estimation as the timing strategy is most effective for placement of delays and reducing the critical path when you generate a timing database for your target device by first using the `genhdltdb` function. For an example that runs the `hdlcoder.optimizeDesign` function using both strategies, see “Use Critical Path Estimation for Faster Optimization”.

If you choose critical path estimation as your timing strategy, the automatic iterative optimization performs these steps:

- 1 Analyzes the logic in your design.
- 2 Estimates the critical path, and obtains timing analysis data by using a timing database. For more information, see “Critical Path Estimation Without Running Synthesis” on page 28-192.
- 3 Inserts pipeline registers to break the critical path.
- 4 Balances delays.
- 5 Saves iteration data in a new folder.

If you choose synthesis as your timing strategy, the automatic iterative optimization performs these steps:

- 1 Analyzes the logic in your design.
- 2 Generates code.
- 3 Uses the synthesis tool to analyze the generated code and obtains post-map timing analysis data.
- 4 Back-annotates the design by using the timing analysis data.
- 5 Inserts pipeline registers to break the critical path.
- 6 Balances delays.
- 7 Saves iteration data in a new folder.

When HDL Coder has met your clock frequency goal or it has reached the maximum number of iterations, it saves the generated code and iteration data in a new folder and generates a report that describes the final critical path.

Automatic Iterative Optimization Output

When HDL Coder exits the optimization loop, it saves the results of the final iteration in a folder, `hdlsrc/your_model_name/hdlexpl/Final-timestamp`.

The final iteration folder contains:

- The generated HDL code, in the `hdlsrc/your_model_name` folder.
- A data file, `cpGuidance.mat`, that you can use with your original model to regenerate code without rerunning the iterative optimization.
- The optimization report, `summary.html`.

Automatic Iterative Optimization Report

HDL Coder generates a report for the final optimization iteration and saves it in the final iteration folder, `hdlsrc/your_model_name/hdlexpl/Final-timestamp`.

The final optimization report, `summary.html`, contains:

- Summary Section containing:
 - Final critical path latency.
 - Critical path latency and elapsed time for each iteration.
- Diagnostic Section containing:
 - Reason for stopping at the final iteration.

- Model or block settings that can reduce the accuracy of the critical path analysis.

If your model has these settings, remove them where possible, and rerun the `hdlcoder.optimizeDesign` function. Some optimizations, such as distributed pipelining and constrained output pipeline, change the placement of pipeline registers after the coder analyzes the critical path.

- Critical path description, which shows signals and components in the original model and generated model that are part of the critical path.

You might see a message that a signal or component on the critical path cannot be traced back to the original model. HDL Coder might not be able to map its internal representation of your design back to the original design. Each optimization iteration changes the internal representation. The final representation can have a structure that is different from your original design.

Automatic Iterative Optimization Synthesis Tool and Hardware

If you are using synthesis as the timing strategy, your synthesis tool must be Xilinx ISE or Xilinx Vivado. Your target device must be a Xilinx FPGA.

Limitations of Automatic Iterative Optimization

- In the current release, automatic iterative optimization does not support Altera hardware if you are using synthesis as the timing strategy.
- Automatic iterative optimization is available from the command line only.
- When the timing strategy is set to synthesis, HDL Coder uses post-map timing information, which the synthesis tool generates before performing place and route. Post-map timing information is less accurate than timing information that the synthesis tool generates after place and route, but is faster to obtain.
- When the timing strategy is set to critical path estimation, HDL Coder uses a timing database to estimate the critical path. Critical path estimation yields a less accurate critical path result than synthesis does, but is the fastest option by a substantial amount (about 10x faster depending on your design) for iterative optimization.
- When using critical path estimation as the timing strategy, if there are blocks in the model that are not supported by critical path estimation, the results might be less optimal than using synthesis as the timing strategy. The blocks in the model that are not supported by critical path estimation appear as a message in the HDL Code Generation Check Report and the Resource Utilization Report, and as a link to a script to highlight the blocks in the MATLAB Command Window.
- You cannot compare the iterative optimization timing value for the critical path when using synthesis as the timing strategy to the result when using critical path estimation as the timing strategy. To compare the results, run synthesis on the final design after running `hdlcoder.optimizeDesign` with critical path estimation as the timing strategy .

Generated Model and Validation Model

In this section...
“Generated Model” on page 28-10
“Validation Model” on page 28-11

HDL Coder enables you to view the effect of HDL optimizations and block settings in your generated model.

Generated Model

Before generating code, HDL Coder creates a behavioral model of the HDL code called the generated model. The generated model is a model created during HDL code generation that captures cycle-accurate and bit-true behavior of the generated code in area and timing optimizations during code generation. It shows latency and numeric differences between your Simulink design under test (DUT) and the generated HDL code. Delays that HDL Coder inserts are highlighted in the generated model in various colors. Different delays in code generation, the corresponding highlight color, and how the delays are named in the generated model are listed in this table.

Delays	Highlight Color	Naming Convention
<ul style="list-style-type: none"> Block implementation RAM mapping 	Cyan	The block is highlighted in cyan. Delay blocks inside this block use the default name <code>Delay</code> and are not highlighted.
“Constrained Output Pipelining” on page 28-147	Green	Constrained output pipelining: <code>rd_n</code>
<ul style="list-style-type: none"> “Distributed Pipelining” on page 28-131 “InputPipeline” on page 26-14 and “OutputPipeline” on page 26-19 “Delay Balancing” on page 28-81 “Clock-Rate Pipelining” on page 28-149 “Adaptive Pipelining” on page 28-181 	Orange	<ul style="list-style-type: none"> Distributed pipelining: <code>rd_n</code> Input pipelining: <code>in_n_pipe_in_pipe</code> and output pipelining: <code>out_n_pipe_in_pipe</code> Delay balancing: <code>delayMatch</code> Clock-rate pipelining: <code>rd_n</code> Adaptive pipelining: <code>HwModeRegister</code> at block inputs and <code>PipelineRegister</code> at the block output.

With timing and area optimizations, the generated model is substantially different from the original model. For example, there are additional integer delays next to blocks if you request optimizations and additional balanced delays to maintain the accuracy of the algorithm. If you request resource sharing or streaming optimization where the same operator is time multiplexed across multiple operations, there are additional rates in your model. When the original model does not have any optimizations, the generated model is the same as the original model. The generated model simulates the generated HDL code. The generated model is useful for visualizing changes in latency, rates, and dataflow from the original model.

While the original model and generated model have the same simulation settings, these models are not required to have the same code generation settings. For example, if you set **ResetType** to `none` for a delay block in your model, this setting might not appear in the generated model equivalent delay

block because it does not affect simulation. To see the delay block with **ResetType** set to none mapped to the generated HDL code, see “Navigate Between Simulink Model and HDL Code by Using Traceability” on page 30-4.

The generated model is used in Register Transfer Level (RTL) test bench generation. The input stimulus and output response are captured from the generated model instead of the original model because the generated model reflects the algorithm timing changes required for optimizations. If you disable model generation, you cannot generate a test bench in HDL Coder.

After code generation, the generated model is saved in the target folder. By default, the generated model prefix is `gm_`. For example, if your model name is *myModel*, your generated model name is *gm_myModel*.

Customize the Generated Model

To customize the prefix of the generated model name, use the `GeneratedModelNamePrefix` property with the functions `makehdl` or `hdlset_param`. See “Prefix for generated model name” on page 21-96.

You can also specify various options for the naming and layout of the generated model. See “Naming and Layout Options for Model Generation” on page 21-96.

Validation Model

Because the generated model is often substantially different from the original model, the coder can also create a validation model to compare the original model to the generated model. The validation model inserts delays at the outputs of the original model to compensate for latency differences and compares the outputs of the two models. When you simulate the validation model, numeric differences in the output data trigger an assertion.

Using the validation model, you can verify that the output of the optimized DUT is bit-true to the results produced by the original DUT.

A validation model contains:

- A generated model.
- An original model that has compensating delays inserted.
- Original inputs, routed to the original model and the generated model.
- Scopes for comparing and viewing the outputs of the original model and generated model.

Latency Differences

Some block architectures and optimizations introduce latency. For example, for the Reciprocal block, you can specify HDL block architectures that implement the Newton-Raphson method. The Newton-Raphson method is iterative, so block architectures that use it are multicycle and introduce latency at the block rate.

Similarly, the resource sharing area optimization time-multiplexes data over a shared hardware resource, which introduces local multirate and latency at the upsampled rate.

Numeric Differences

HDL block architectures can introduce numeric differences between the original and generated model. For example:

- An HDL block property, such as “InputPipeline” on page 26-14 specified on the block, or certain HDL architectures or optimizations, such as distributed pipelining, that move delays to the input of the block.
- The Newton-Raphson method is an approximation. If you select a Newton-Raphson block implementation, the generated model shows a change in numerics.
- HDL implementations for signal processing blocks, such as filters, can change numerics.

See also “Locate Numeric Differences After Speed Optimization” on page 28-13.

Generate a Validation Model

- In the Configuration Parameters dialog box, in the **HDL Code Generation > Global Settings > Model Generation** pane, select **Validation Model**.
- In the HDL Workflow Advisor, in the **HDL Code Generation > Generate RTL Code and Testbench** pane, enable **Generate validation model**.
- Use the `GenerateValidationModel` property with the functions `makehdl` or `hdlset_param`.

Customize the Validation Model

To customize the suffix of the generated validation name, use the `ValidationModelNameSuffix` property with the functions `makehdl` or `hdlset_param`. See “Suffix for validation model name” on page 21-96.

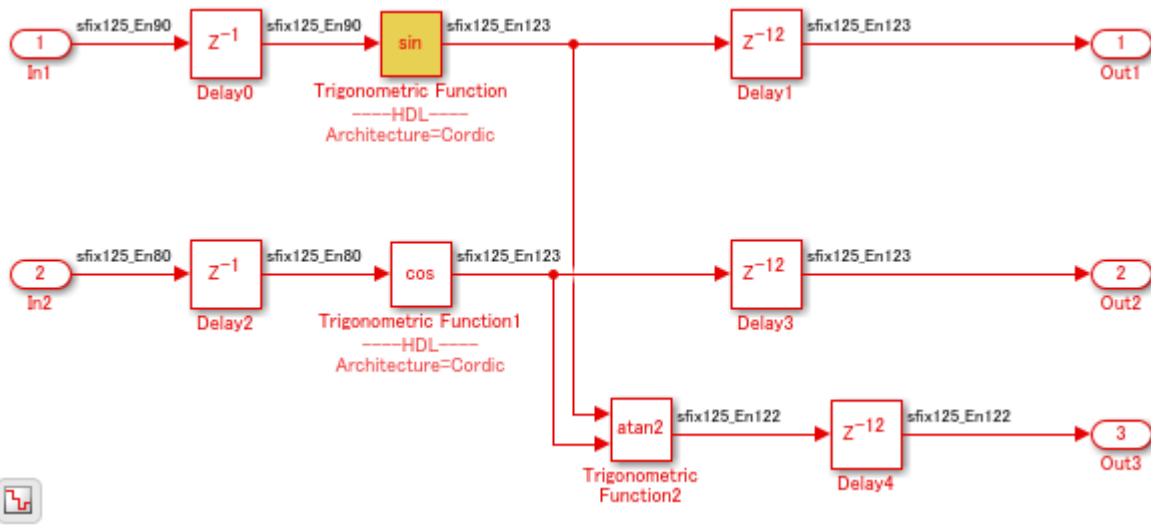

Restrictions

- To generate a validation model, you must generate HDL code for the DUT Subsystem. Model generation is not supported for generating code for the entire model instead of the DUT Subsystem.
- Make sure that the DUT subsystem has no unconnected output ports. See “Terminate Unconnected Block Outputs and Usage of Commenting Blocks” on page 25-26.

hdlset_param('hdlcoder_sincos_cordic_optimization', 'ResourceReport', 'on');
hdlset_param('hdlcoder_sincos_cordic_optimization', 'ShareAdders', 'on');
hdlset_param('hdlcoder_sincos_cordic_optimization', 'TargetLanguage', 'Verilog');
hdlset_param('hdlcoder_sincos_cordic_optimization', 'Traceability', 'on');

hdlset_param('hdlcoder_sincos_cordic_optimization/HDL_DUT/Trigonometric Function', 'Architecture', 'Cordic');
hdlset_param('hdlcoder_sincos_cordic_optimization/HDL_DUT/Trigonometric Function1', 'Architecture', 'Cordic');
```

Generate HDL Code and Validation Model

To see the effect of the optimization, generate HDL code and validation model for the HDL_DUT subsystem by using the `makehdl` function.

```
makehdl('hdlcoder_sincos_cordic_optimization')
```

When you open the HDL Check Report, you see a warning message displayed that indicates delays introduced at the inputs of the blocks, which might cause a numeric mismatch in the initial cycles when simulating the validation model.

After code generation, you see the model `gm_hdlcoder_sincos_cordic_optimization_vnl`. In this example, the model has been saved with the name `hdlcoder_sincos_cordic_optimization_validation`.

```
open_system('hdlcoder_sincos_cordic_optimization_validation')
set_param('hdlcoder_sincos_cordic_optimization_validation', 'SimulationCommand', 'Update')
```

Copyright 2020-2021 The MathWorks, Inc.

Observe Numeric Differences

The HDL_DUT subsystem highlighted in cyan indicates that this subsystem is different from the subsystem in the original model HDL_DUT_vnl. The HDL_DUT subsystem is part of the generated

model after HDL code generation, and shows the effect of optimizations. You also see the pipelines introduced by the Trigonometric Function blocks.

```
open_system('hdlcoder_sincos_cordic_optimization_validation/HDL_DUT')
```

When you simulate the model, you see assertions detected in the initial cycles of simulation, which indicates a numeric mismatch. The mismatch is caused by pipelines introduced at the input of the block. To fix the mismatch, avoid using block implementations, or HDL block properties such as **InputPipeline**, or optimizations that introduce pipelines at the input of the blocks.

Simplify Constant Operations and Reduce Design Complexity in HDL Coder

HDL Coder™ performs certain optimization techniques that improve the quality of the generated HDL code. When you use floating-point data types in **Native Floating Point** mode and generate code from your model, at compile-time, HDL Coder searches for a subset of blocks that fit a certain pattern. When the code generator recognizes the pattern, it automatically performs certain optimization techniques to replace the blocks in the subset with other, simpler blocks.

The optimization techniques:

- Remove redundant run-time computations
- Simplify your design
- Improve quality and efficiency of generated HDL code
- Reduce latency and area footprint
- Improve timing of your design on target hardware

Simplification of Constant Operations

HDL Coder removes redundant operations in your design by evaluating constant subexpressions in advance. This optimization technique identifies Simulink® blocks in your model that have constant values at all input ports, and then replaces the blocks with Constant blocks. The code generator propagates the input constants inside the blocks to compute the resulting Constant value.

For example, $c = 3 * 5$ becomes $c = 15$.

This optimization works with any Simulink block that supports HDL code generation. For example:

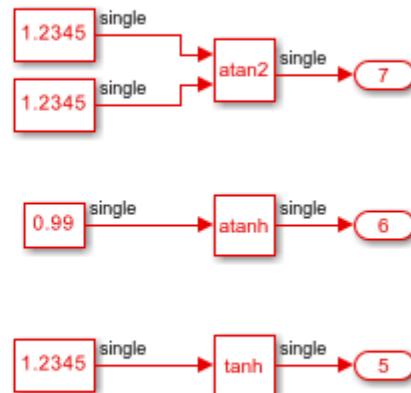

- Open the model `hdlcoder_constant_simplification`. Double-click the **Trigonometric Functions Subsystem**.

```
open_system('hdlcoder_constant_simplification')
open_system('hdlcoder_constant_simplification/Trigonometric Functions')
set_param('hdlcoder_constant_simplification', 'SimulationCommand', 'update');
```

Basic sin and cos functions

Arctangent and Hyperbolic functions

Trigonometric Functions

- To generate HDL code for the `hdlcoder_constant_simplification` model, enter this command.

```
makehdl('hdlcoder_constant_simplification')
```

- Open the generated model, and double-click the Trigonometric Functions subsystem.

HDL Coder recognized the modeling pattern and replaced the constant single-precision trigonometric operations with constants. This optimization results in significant area reduction and improvements to timing when you deploy the code onto the target platform.

Replacement of Slower Operations with Faster Equivalents

This optimization automatically replaces slower operations with faster equivalents.

For example, $r1 = r2 / 2$ becomes $r1 = r2 \gg 1$.

Examples of this optimization technique include replacement of a Product block or a Divide block by a Gain block. If one of the inputs to a Product block or a Divide block is a constant and a power of two, the code generator replaces that block by a Gain block. The code generator propagates the **Constant value** inside the Product block or the Divide block to compute the **Gain** parameter. This optimization works with single data types in the Native Floating Point mode.

For example:

- Open the model `hdlcoder_slow_operation_replacement`. Double-click the DUT Subsystem.

```
open_system('hdlcoder_slow_operation_replacement')
open_system('hdlcoder_slow_operation_replacement/DUT')
set_param('hdlcoder_slow_operation_replacement', 'SimulationCommand', 'update');
```

- To generate HDL code for the DUT Subsystem, enter this command:

```
makehdl('hdlcoder_slow_operation_replacement/DUT')
```

- Open the generated model, and double-click the DUT subsystem.

HDL Coder recognized the modeling pattern and replaced the Product block and the Divide block by a Gain block. This optimization significantly reduces the latency of your design, and improves area and timing on the target FPGA.

Combination of Multiple Operations

This optimization replaces several operations with one equivalent operation. Examples of this optimization technique include replacement of a Sin block and a Cos block by a Sincos block. If you provide the same input signal to a Sin block and a Cos block in your model, and when the HDL Block Properties of the Sin and Cos blocks match, the code generator replaces the blocks with a Sincos block. This optimization works with single data types in the Native Floating Point mode.

For example:

- Open the model `hdlcoder_combine_operations`. Double-click the DUT Subsystem.

```
open_system('hdlcoder_combine_operations')
open_system('hdlcoder_combine_operations/DUT')
set_param('hdlcoder_combine_operations', 'SimulationCommand', 'update');
```

- To generate HDL code for the DUT Subsystem, enter this command:

```
makehdl('hdlcoder_combine_operations/DUT')
```

- Open the generated model, and double-click the DUT Subsystem. The generated model appears as below.

HDL Coder recognized the modeling pattern and replaced the Sin block and the Cos block by a Sincos block. This optimization technique significantly improves the performance of your design on the target platform.

Considerations

- The optimizations work with floating-point data types. Fixed-point designs are not affected by this optimization. When you use single data types, enable the **Native Floating Point** mode. In the Configuration Parameters dialog box, in the **HDL Code Generation > Floating Point** pane, select **Use Floating Point**. To learn about native floating-point support in HDL Coder, see “Generate Target-Independent HDL Code with Native Floating-Point” on page 14-116.
- The optimizations preserve all comments from the blocks in the generated code. To learn about specifying comments to blocks, see “Generate Code with Annotations or Comments” on page 30-16.
- The optimizations do not optimize blocks that use tunable parameters or generic inputs because the tunable parameters are not treated as constant values. To make these blocks participate in the optimization, in the Mask Editor for the blocks, clear the Tunable check box. To learn about tunable parameters, see “Generate DUT Ports for Tunable Parameters” on page 14-18.
- The optimizations treat enumeration values and constants from the Workspace browser as constant values. The code generator therefore propagates these values inside various components and simplifies the constant operations.
